

## **Oracle® Fusion Middleware**

Fusion Developer's Guide for Oracle Application Development Framework

11g Release 1 (11.1.1.7.2)

**B31974-15**

March 2014

Documentation for Oracle Application Development Framework (Oracle ADF) developers that describes how to develop and deploy web-based applications using ADF Business Components, ADF task flows, and ADF Faces.

Oracle Fusion Middleware Fusion Developer's Guide for Oracle Application Development Framework 11g Release 1 (11.1.1.7.2)

This software and related documentation are provided under a license agreement containing restrictions on use and disclosure and are protected by intellectual property laws. Except as expressly permitted in your license agreement or allowed by law, you may not use, copy, reproduce, translate, broadcast, modify, license, transmit, distribute, exhibit, perform, publish, or display any part, in any form, or by any means. Reverse engineering, disassembly, or decompilation of this software, unless required by law for interoperability, is prohibited.

The information contained herein is subject to change without notice and is not warranted to be error-free. If you find any errors, please report them to us in writing.

If this is software or related documentation that is delivered to the U.S. Government or anyone licensing it on behalf of the U.S. Government, the following notice is applicable:

U.S. GOVERNMENT END USERS: Oracle programs, including any operating system, integrated software, any programs installed on the hardware, and/or documentation, delivered to U.S. Government end users are "commercial computer software" pursuant to the applicable Federal Acquisition Regulation and agency-specific supplemental regulations. As such, use, duplication, disclosure, modification, and adaptation of the programs, including any operating system, integrated software, any programs installed on the hardware, and/or documentation, shall be subject to license terms and license restrictions applicable to the programs. No other rights are granted to the U.S. Government.

This software or hardware is developed for general use in a variety of information management applications. It is not developed or intended for use in any inherently dangerous applications, including applications that may create a risk of personal injury. If you use this software or hardware in dangerous applications, then you shall be responsible to take all appropriate fail-safe, backup, redundancy, and other measures to ensure its safe use. Oracle Corporation and its affiliates disclaim any liability for any damages caused by use of this software or hardware in dangerous applications.

Oracle and Java are registered trademarks of Oracle and/or its affiliates. Other names may be trademarks of their respective owners.

Intel and Intel Xeon are trademarks or registered trademarks of Intel Corporation. All SPARC trademarks are used under license and are trademarks or registered trademarks of SPARC International, Inc. AMD, Opteron, the AMD logo, and the AMD Opteron logo are trademarks or registered trademarks of Advanced Micro Devices. UNIX is a registered trademark of The Open Group.

This software or hardware and documentation may provide access to or information on content, products, and services from third parties. Oracle Corporation and its affiliates are not responsible for and expressly disclaim all warranties of any kind with respect to third-party content, products, and services. Oracle Corporation and its affiliates will not be responsible for any loss, costs, or damages incurred due to your access to or use of third-party content, products, or services.

<b>What's New in This Guide for Release 11.1.1.7.2</b> .....	li
<b>Part I Getting Started with Fusion Web Applications</b>	
<b>1 Introduction to Building Fusion Web Applications with Oracle ADF</b>	
1.1 Introduction to Oracle ADF .....	1-1
1.2 Oracle ADF Architecture .....	1-2
1.2.1 ADF Business Components .....	1-3
1.2.2 ADF Model Layer .....	1-4
1.2.3 ADF Controller .....	1-5
1.2.4 ADF Faces Rich Client .....	1-5
1.3 Developing with Oracle ADF .....	1-6
1.3.1 Creating an Application Workspace .....	1-7
1.3.2 Modeling with Database Object Definitions .....	1-10
1.3.3 Creating Use Cases .....	1-12
1.3.4 Designing Application Control and Navigation Using ADF Task Flows .....	1-13
1.3.5 Identifying Shared Resources .....	1-14
1.3.6 Creating a Data Model to Access Data with ADF Business Components .....	1-15
1.3.6.1 Creating a Layer of Business Domain Objects for Tables .....	1-15
1.3.6.2 Building the Business Services .....	1-16
1.3.6.3 Testing and Debugging Business Services with the Business Component Browser .....	1-18
1.3.7 Implementing the User Interface with JSF .....	1-18
1.3.8 Data Binding with ADF Model Layer .....	1-20
1.3.9 Validation and Error Handling .....	1-23
1.3.10 Adding Security .....	1-24

1.3.11	Testing and Debugging the Web Client Application .....	1-24
1.3.12	Refactoring Application Artifacts .....	1-25
1.3.13	Deploying a Fusion Web Application .....	1-25
1.3.14	Integrating a Fusion Web Application .....	1-25
1.4	Working Productively in Teams .....	1-25
1.4.1	Enforcing Standards .....	1-27
1.4.2	Using a Source Control System .....	1-27
1.5	Learning Oracle ADF .....	1-29
1.6	Generation of Complete Web Tier Using Oracle JHeadstart .....	1-29

## 2 Introduction to the ADF Sample Application

2.1	Introduction to the Oracle Fusion Order Demo .....	2-1
2.2	Setting Up the Fusion Order Demo Application .....	2-2
2.2.1	How to Download the Application Resources .....	2-2
2.2.2	How to Install the Fusion Order Demo Schema .....	2-3
2.2.3	Overview of the Fusion Order Demo Schema .....	2-4
2.2.3.1	Translation Support in the Fusion Order Demo Schema .....	2-5
2.2.3.2	Lookup Tables in the Fusion Order Demo Schema .....	2-6
2.3	Running the Fusion Order Demo Application StoreFront Module .....	2-8
2.4	Running the Fusion Order Demo Standalone Applications .....	2-10
2.4.1	How to Run the Standalone Applications .....	2-11
2.4.2	Standalone Applications in the DevGuideExamples Application Workspace .....	2-13
2.4.3	Standalone Applications in the AdvancedExamples Application Workspace .....	2-15
2.4.4	Standalone Applications in the AdvancedEntityExamples Application Workspace .....	2-17
2.4.5	Standalone Applications in the AdvancedViewObjectExamples Application Workspace .....	2-19
2.5	Taking a Look at the Fusion Order Demo Application .....	2-21
2.5.1	Anonymous Browsing .....	2-22
2.5.1.1	Viewing Product Details .....	2-24
2.5.1.2	Browsing the Product Catalog .....	2-27
2.5.1.3	Searching for Products .....	2-28
2.5.2	The Login Process .....	2-31
2.5.3	The Ordering Process .....	2-32
2.5.4	The Customer Registration Process .....	2-36

## Part II Building Your Business Services

### 3 Getting Started with ADF Business Components

3.1	Introduction to ADF Business Components .....	3-1
3.1.1	ADF Business Components Features .....	3-2
3.1.2	ADF Business Components Core Objects .....	3-3
3.2	Comparison to Familiar 4GL Tools .....	3-3
3.2.1	Familiar Concepts for Oracle Forms Developers .....	3-3
3.2.1.1	Similarities Between the Application Module and a "Headless" Form Module ..	3-4
3.2.1.2	Similarities Between the Entity Object and a Forms Record Manager .....	3-5
3.2.1.3	Similarities Between the View Object and a Data Block .....	3-5
3.2.2	Familiar Concepts for PeopleTools Developers .....	3-5

3.2.2.1	Similarities Between the Application Module and a "Headless" Component .....	3-5
3.2.2.2	Similarities Between the Entity Object and a Record Definition .....	3-6
3.2.2.3	Similarities Between the View Object and a Row Set .....	3-6
3.2.3	Familiar Concepts for Siebel Tools Developers .....	3-6
3.2.3.1	Similarities Between the entity Object and a Table Object .....	3-7
3.2.3.2	Similarities Between the View Object and a Business Component .....	3-7
3.2.3.3	Similarities Between the Application Module and a Business Object .....	3-7
3.2.4	Familiar Functionality for ADO.NET Developers .....	3-7
3.2.4.1	Similarities Between the Application Module and a Data Set .....	3-7
3.2.4.2	Similarities Between the Entity Object and a Data Adapter .....	3-8
3.2.4.3	Similarities Between the View Object and a Data Table .....	3-8
3.3	Overview of Design Time Facilities .....	3-8
3.3.1	Choosing a Connection, SQL Flavor, and Type Map .....	3-8
3.3.2	What You May Need to Know About Displaying Numeric Values .....	3-10
3.3.3	Creating New Components Using Wizards .....	3-10
3.3.4	Creating New Components Using the Context Menu .....	3-10
3.3.5	Editing Components Using the Component Overview Editor .....	3-11
3.3.6	Visualizing, Creating, and Editing Components Using UML Diagrams .....	3-11
3.3.7	Testing Application Modules Using the Business Component Browser .....	3-12
3.3.8	Refactoring Components .....	3-12
3.4	Overview of the UI-Aware Data Model .....	3-12
3.4.1	A More Generic Business Service Solution .....	3-12
3.4.2	Typical Scenarios for a UI-Aware Data Model .....	3-13
3.4.3	UI-Aware Data Model Support for Custom Code .....	3-13
3.5	Overview of the Implementation Architecture .....	3-14
3.5.1	Standard Java and XML .....	3-14
3.5.2	Application Server or Database Independence .....	3-15
3.5.3	Java EE Design Pattern Support .....	3-15
3.5.4	Source Code Organization .....	3-15
3.5.5	Package Naming Conventions .....	3-16
3.5.6	Metadata with Optional Custom Java Code .....	3-17
3.5.6.1	Example of an XML-Only Component .....	3-18
3.5.6.2	Example of a Component with Custom Java Class .....	3-18
3.5.7	Basic Data Types .....	3-19
3.5.8	Generic Versus Strongly-Typed APIs .....	3-20
3.5.9	Custom Interface Support for Client-Accessible Components .....	3-21
3.5.9.1	Framework Client Interfaces for Components .....	3-21
3.5.9.2	Custom Client Interfaces for Components .....	3-21
3.6	Overview of Groovy Support .....	3-22
3.6.1	Referencing Business Components Objects in Groovy Expressions .....	3-23
3.6.2	Referencing Custom Business Components Methods and Attributes in Groovy Expressions .....	3-24
3.6.2.1	Referencing Members of the Same Business Component .....	3-24
3.6.2.2	Referencing Members of Other Business Components .....	3-25
3.6.3	Manipulating Business Component Attribute Values in Groovy Expressions .....	3-25

## 4 Creating a Business Domain Layer Using Entity Objects

4.1	Introduction to Entity Objects .....	4-1
4.2	Creating Entity Objects and Associations .....	4-2
4.2.1	How to Create Multiple Entity Objects and Associations from Existing Tables .....	4-2
4.2.2	How to Create Single Entity Objects Using the Create Entity Wizard .....	4-4
4.2.3	What Happens When You Create Entity Objects and Associations from Existing Tables .....	4-5
4.2.3.1	What Happens When Tables Have Foreign Key Relationships .....	4-5
4.2.3.2	What Happens When a Table Has No Primary Key .....	4-6
4.2.4	What Happens When You Create an Entity Object for a Synonym or View .....	4-6
4.2.5	How to Edit an Existing Entity Object or Association .....	4-6
4.2.6	How to Create Database Tables from Entity Objects .....	4-7
4.2.7	How to Synchronize an Entity with Changes to Its Database Table .....	4-7
4.2.7.1	Removing an Attribute Associated with a Dropped Column .....	4-7
4.2.7.2	Addressing a Data Type Change in the Underlying Table .....	4-8
4.2.8	How to Store Data Pertaining to a Specific Point in Time .....	4-8
4.2.9	What Happens When You Create Effective Dated Entity Objects .....	4-9
4.2.10	What You May Need to Know About Creating Entities from Tables .....	4-10
4.3	Creating and Configuring Associations .....	4-10
4.3.1	How to Create an Association .....	4-11
4.3.2	What Happens When You Create an Association .....	4-13
4.3.3	How to Change Entity Association Accessor Names .....	4-13
4.3.4	How to Rename and Move Associations to a Different Package .....	4-13
4.3.5	What You May Need to Know About Using a Custom View Object in an Association ..	4-14
4.3.6	What You May Need to Know About Composition Associations .....	4-15
4.4	Creating an Entity Diagram for Your Business Layer .....	4-16
4.4.1	How to Show Entity Objects in a Business Components Diagram .....	4-16
4.4.2	What Happens When You Create an Entity Diagram .....	4-17
4.4.3	What You May Need to Know About the XML Component Descriptors .....	4-18
4.4.4	What You May Need to Know About Changing the Names of Components .....	4-18
4.5	Defining Property Sets .....	4-18
4.5.1	How to Define a Property Set .....	4-19
4.5.2	How to Apply a Property Set .....	4-20
4.6	Defining Attribute Control Hints for Entity Objects .....	4-20
4.6.1	How to Add Attribute Control Hints .....	4-20
4.6.2	What Happens When You Add Attribute Control Hints .....	4-21
4.6.3	How to Define Formatters and Masks .....	4-21
4.7	Working with Resource Bundles .....	4-23
4.7.1	How to Set Message Bundle Options .....	4-24
4.7.2	How to Use Multiple Resource Bundles .....	4-25
4.7.3	How to Internationalize the Date Format .....	4-25
4.8	Defining Business Logic Groups .....	4-26
4.8.1	How to Create a Business Logic Group .....	4-26
4.8.2	How to Create a Business Logic Unit .....	4-27
4.8.3	How to Add Logic to a Business Logic Unit .....	4-28
4.8.4	How to Override Attributes in a Business Logic Unit .....	4-28

4.8.5	What Happens When You Create a Business Logic Group .....	4-28
4.8.6	What Happens at Runtime: Invoking a Business Logic Group .....	4-29
4.9	Configuring Runtime Behavior Declaratively .....	4-30
4.9.1	How to Configure Declarative Runtime Behavior .....	4-30
4.9.2	What Happens When You Configure Declarative Runtime Behavior .....	4-31
4.10	Setting Attribute Properties .....	4-31
4.10.1	How to Set Database and Java Data Types for an Entity Object Attribute .....	4-31
4.10.2	How to Indicate Data Type Length, Precision, and Scale .....	4-33
4.10.3	How to Control the Updatability of an Attribute .....	4-33
4.10.4	How to Make an Attribute Mandatory .....	4-33
4.10.5	How to Define the Primary Key for the Entity .....	4-33
4.10.6	How to Define a Static Default Value .....	4-34
4.10.7	How to Define a Default Value Using a Groovy Expression .....	4-34
4.10.8	What Happens When You Create a Default Value Using a Groovy expression .....	4-34
4.10.9	How to Synchronize with Trigger-Assigned Values .....	4-35
4.10.10	How to Get Trigger-Assigned Primary Key Values from a Database Sequence .....	4-35
4.10.11	How to Protect Against Losing Simultaneously Updated Data .....	4-36
4.10.12	How to Track Created and Modified Dates Using the History Column .....	4-37
4.10.13	How to Configure Composition Behavior .....	4-37
4.10.13.1	Orphan-Row Protection for New Composed Entities .....	4-38
4.10.13.2	Ordering of Changes Saved to the Database .....	4-38
4.10.13.3	Cascade Update of Composed Details from Refresh-On-Insert Primary Keys ..	4-38
4.10.13.4	Cascade Delete Support .....	4-38
4.10.13.5	Cascade Update of Foreign Key Attributes When Primary Key Changes .....	4-39
4.10.13.6	Locking of Composite Parent Entities .....	4-39
4.10.13.7	Updating of Composing Parent History Attributes .....	4-39
4.10.14	How to Set the Discriminator Attribute for Entity Object Inheritance Hierarchies ..	4-39
4.10.15	How to Define Alternate Key Values .....	4-39
4.10.16	What Happens When You Define Alternate Key Values .....	4-40
4.10.17	What You May Need to Know About Alternate Key Values .....	4-40
4.11	Creating Business Events .....	4-40
4.11.1	Introducing Event Definitions .....	4-41
4.11.2	Introducing Event Points .....	4-41
4.11.3	What You May Need to Know About Event Points .....	4-41
4.11.4	How to Create a Business Event .....	4-41
4.11.5	What Happens When You Create a Business Event .....	4-42
4.11.6	What You May Need to Know About Payload Size .....	4-44
4.11.7	How to Publish a Business Event .....	4-44
4.11.8	How to Subscribe to Business Events .....	4-44
4.12	Working Programmatically with Entity Objects and Associations .....	4-45
4.12.1	How to Find an Entity Object by Primary Key .....	4-46
4.12.2	How to Access an Associated Entity Using the Accessor Attribute .....	4-47
4.12.3	How to Update or Remove an Existing Entity Row .....	4-48
4.12.4	How to Create a New Entity Row .....	4-48
4.12.5	Assigning the Primary Key Value Using an Oracle Sequence .....	4-50
4.12.6	What You May Need to Know About Custom Entity Object Methods .....	4-51
4.13	Generating Custom Java Classes for an Entity Object .....	4-51

4.13.1	How to Generate Custom Classes .....	4-52
4.13.2	What Happens When You Generate Custom Classes .....	4-52
4.13.3	What Happens When You Generate Entity Attribute Accessors .....	4-52
4.13.4	How to Navigate to Custom Java Files .....	4-53
4.13.5	What You May Need to Know About Custom Java Classes .....	4-54
4.13.5.1	About the Framework Base Classes for an Entity Object .....	4-54
4.13.5.2	You Can Safely Add Code to the Custom Component File .....	4-54
4.13.5.3	Configuring Default Java Generation Preferences .....	4-54
4.13.5.4	Attribute Indexes and InvokeAccessor Generated Code .....	4-55
4.13.6	Programmatic Example for Comparison Using Custom Entity Classes .....	4-56
4.14	Adding Transient and Calculated Attributes to an Entity Object .....	4-59
4.14.1	How to Add a Transient Attribute .....	4-59
4.14.2	What Happens When You Add a Transient Attribute .....	4-60
4.14.3	How to Base a Transient Attribute On a Groovy Expression .....	4-60
4.14.4	What Happens When You Base a Transient Attribute on Groovy Expression .....	4-62
4.14.5	How to Add Java Code in the Entity Class to Perform Calculation .....	4-62

## 5 Defining SQL Queries Using View Objects

5.1	Introduction to View Objects .....	5-1
5.1.1	Overview of View Object Concepts .....	5-2
5.1.2	Runtime Features Unique to Entity-Based View Objects .....	5-3
5.2	Populating View Object Rows from a Single Database Table .....	5-4
5.2.1	How to Create an Entity-Based View Object .....	5-5
5.2.1.1	Creating a View Object with All the Attributes of an Entity Object .....	5-5
5.2.1.2	Creating an Entity-Based View Object from a Single Table .....	5-6
5.2.2	What Happens When You Create an Entity-Based View Object .....	5-9
5.2.3	How to Create an Expert Mode, Read-Only View Object .....	5-10
5.2.4	What Happens When You Create a Read-Only View Object .....	5-13
5.2.5	How to Edit a View Object .....	5-14
5.2.5.1	Overriding the Inherited Properties from Underlying Entity Object Attributes .....	5-14
5.2.5.2	Controlling the Length, Precision, and Scale of View Object Attributes .....	5-15
5.2.5.3	Converting a Read-Only View Object to Allow Attribute Updates .....	5-16
5.2.5.4	Customizing View Object Attribute Display in the Overview Editor .....	5-17
5.2.5.5	Modifying the Order of Attributes in the View Object Source File .....	5-18
5.2.6	How to Show View Objects in a Business Components Diagram .....	5-19
5.3	Populating View Object Rows with Static Data .....	5-19
5.3.1	How to Create Static View Objects with Data You Enter .....	5-20
5.3.2	How to Create Static View Objects with Data You Import .....	5-21
5.3.3	What Happens When You Create a Static List View Object .....	5-22
5.3.4	Editing Static List View Objects .....	5-23
5.3.5	What You May Need to Know About Static List View Objects .....	5-24
5.4	Limiting View Object Rows Using Effective Date Ranges .....	5-24
5.4.1	How to Create a Date-Effective View Object .....	5-24
5.4.2	How to Create New View Rows Using Date-Effective View Objects .....	5-25
5.4.3	How to Update Date-Effective View Rows .....	5-25
5.4.4	How to Delete Date-Effective View Rows .....	5-26
5.4.5	What Happens When You Create a Date-Effective View Object .....	5-27

5.4.6	What You May Need to Know About Date-Effective View Objects and View Links .....	5-28
5.5	Working with Multiple Tables in Join Query Results .....	5-28
5.5.1	How to Create Joins for Entity-Based View Objects .....	5-29
5.5.2	How to Select Additional Attributes from Reference Entity Usages .....	5-32
5.5.3	How to Remove Unnecessary Key Attributes from Reference Entity Usages .....	5-33
5.5.4	How to Hide the Primary Key Attributes from Reference Entity Usages .....	5-33
5.5.5	How to Modify a Default Join Clause to Be an Outer Join When Appropriate .....	5-33
5.5.6	What Happens When You Reference Entities in a View Object .....	5-35
5.5.7	How to Create Joins for Read-Only View Objects .....	5-36
5.5.8	How to Test the Join View .....	5-37
5.5.9	How to Use the SQL Statement Dialog with Read-Only View Objects .....	5-37
5.5.10	What You May Need to Know About Join View Objects .....	5-38
5.6	Working with Multiple Tables in a Master-Detail Hierarchy .....	5-38
5.6.1	How to Create a Master-Detail Hierarchy for Entity-Based View Objects .....	5-39
5.6.2	How to Create a Master-Detail Hierarchy Based on View Objects Alone .....	5-40
5.6.3	What Happens When You Create Master-Detail Hierarchies Using View Links .....	5-43
5.6.4	How to Enable Active Master-Detail Coordination in the Data Model .....	5-44
5.6.5	How to Test Master-Detail Coordination .....	5-45
5.6.6	How to Access the Detail Collection Using the View Link Accessor .....	5-46
5.6.6.1	Accessing Attributes of Row by Name .....	5-46
5.6.6.2	Programmatically Accessing a Detail Collection Using the View Link Accessor .....	5-46
5.7	Working with a Single Table in a Recursive Master-Detail Hierarchy .....	5-47
5.7.1	How to Create a Recursive Master-Detail Hierarchy for an Entity-Based View Object ..	5-47
5.7.2	What Happens When You Create a Recursive Master-Detail Hierarchy .....	5-52
5.8	Working with View Objects in Declarative SQL Mode .....	5-53
5.8.1	How to Create Declarative SQL View Objects .....	5-54
5.8.2	How to Filter Declarative SQL-Based View Objects When Table Joins Apply .....	5-57
5.8.3	How to Filter Master-Detail Related View Objects with Declarative SQL Mode .....	5-58
5.8.4	How to Force Attribute Queries for Declarative SQL Mode View Objects .....	5-59
5.8.5	What Happens When You Create a View Object in Declarative SQL Mode .....	5-61
5.8.6	What Happens at Runtime: When a Declarative SQL Mode Query is Generated .....	5-62
5.8.7	What You May Need to Know About Overriding Declarative SQL Mode Defaults .....	5-62
5.8.8	What You May Need to Know About Working Programmatically with Declarative SQL Mode View Objects .....	5-63
5.9	Working with View Objects in Expert Mode .....	5-64
5.9.1	How to Customize SQL Statements in Expert Mode .....	5-64
5.9.2	How to Name Attributes in Expert Mode .....	5-64
5.9.3	What Happens When You Enable Expert Mode .....	5-65
5.9.4	What You May Need to Know About Expert Mode .....	5-65
5.9.4.1	Expert Mode Provides Limited Attribute Mapping Assistance .....	5-65
5.9.4.2	Expert Mode Drops Custom Edits .....	5-66
5.9.4.3	Expert Mode Ignores Changes to SQL Expressions .....	5-66
5.9.4.4	Expert Mode Returns Error for SQL Calculations that Change Entity Attributes .....	5-67
5.9.4.5	Formatting of the SQL Statement in Expert Mode .....	5-68

5.9.4.6	Expert Mode Wraps Queries as Inline Views .....	5-68
5.9.4.7	Limitation of Inline View Wrapping at Runtime .....	5-69
5.9.4.8	Expert Mode Changes May Affect Dependent Objects .....	5-69
5.10	Working with Bind Variables .....	5-70
5.10.1	How to Add Bind Variables to a View Object Definition .....	5-70
5.10.2	How to Reference the Current User in a Named Bind Variable Using Groovy .....	5-72
5.10.3	What Happens When You Add Named Bind Variables .....	5-73
5.10.4	How to Test Named Bind Variables .....	5-73
5.10.5	How to Add a WHERE Clause with Named Bind Variables at Runtime .....	5-74
5.10.6	How to Set Existing Bind Variable Values at Runtime .....	5-76
5.10.7	What Happens at Runtime: When a Read-Only View Object WHERE Clause is Set .....	5-77
5.10.8	What You May Need to Know About Named Bind Variables .....	5-78
5.10.8.1	An Error Related to Clearing Bind Variables .....	5-78
5.10.8.2	Errors Related to the Names of Bind Variables .....	5-79
5.10.8.3	Default Value of NULL for Bind Variables .....	5-80
5.11	Working with Named View Criteria .....	5-80
5.11.1	How to Create Named View Criteria Declaratively .....	5-81
5.11.2	What Happens When You Create a Named View Criteria .....	5-86
5.11.3	What You May Need to Know About Bind Variable Options .....	5-87
5.11.4	What You May Need to Know About Nested Expressions .....	5-88
5.11.5	How to Set User Interface Hints on View Criteria .....	5-88
5.11.6	How to Use Master-Detail Related View Objects in View Criteria .....	5-91
5.11.7	How to Test View Criteria Using the Business Component Browser .....	5-95
5.11.8	How to Create View Criteria Programmatically .....	5-96
5.11.9	What Happens at Runtime: When the View Criteria Is Applied to a View Object ..	5-97
5.11.10	What You May Need to Know About the View Criteria API .....	5-98
5.11.10.1	Referencing Attribute Names in View Criteria .....	5-98
5.11.10.2	Referencing Bind Variables in View Criteria .....	5-98
5.11.10.3	Altering Compound Search Conditions Using Multiple View Criteria .....	5-99
5.11.10.4	Searching for a Row Whose Attribute Value Is NULL .....	5-100
5.11.10.5	Searching for Rows Using a Date Comparison .....	5-100
5.11.10.6	Searching for Rows Whose Attribute Value Matches a Value in a List .....	5-100
5.11.10.7	Searching Case-Insensitively .....	5-100
5.11.10.8	Clearing View Criteria in Effect .....	5-101
5.11.11	What You May Need to Know About Query-by-Example Criteria .....	5-101
5.12	Working with Row Finders .....	5-101
5.12.1	How to Add Row Finders to a View Object Definition .....	5-102
5.12.2	What Happens When You Define a Row Finder .....	5-104
5.12.3	What You May Need to Know About View Criteria and Row Finder Usage .....	5-106
5.12.4	How to Programmatically Invoke the Row Finder .....	5-106
5.12.5	How to Find Rows of a Master View Object .....	5-108
5.12.5.1	Defining a Row Finder on the Master View Object .....	5-108
5.12.5.2	What Happens When You Create a Row Finder for a Master View Object .....	5-110
5.13	Working with List of Values (LOV) in View Object Attributes .....	5-112
5.13.1	How to Define a Single LOV-Enabled View Object Attribute .....	5-114
5.13.2	How to Define Cascading Lists for LOV-Enabled View Object Attributes .....	5-115
5.13.2.1	Creating a Data Source View Object to Control the Cascading List .....	5-116

5.13.2.2	Creating a View Accessor to Filter the Cascading List .....	5-117
5.13.3	How to Specify Multiple LOVs for an LOV-Enabled View Object Attribute .....	5-119
5.13.4	How to Set User Interface Hints on a View Object LOV-Enabled Attribute .....	5-121
5.13.5	How to Handle Date Conversion for List Type UI Components .....	5-124
5.13.6	How to Automatically Refresh the View Object of the View Accessor .....	5-125
5.13.7	How to Test LOV-Enabled Attributes Using the Business Component Browser ...	5-126
5.13.8	What Happens When You Define an LOV for a View Object Attribute .....	5-127
5.13.9	What Happens at Runtime: When an LOV Queries the List Data Source .....	5-129
5.13.10	What You May Need to Know About Lists .....	5-130
5.13.10.1	Inheritance of AttributeDef Properties from Parent View Object Attributes ...	5-130
5.13.10.2	Using Validators to Validate Attribute Values .....	5-130
5.13.10.3	LOV Limitation When Exposing Application Module as EJB Session Bean ....	5-130
5.14	Defining Control Hints for View Objects .....	5-130
5.14.1	How to Add Attribute-Specific Control Hints .....	5-131
5.14.2	How to Add View Object Control Hints .....	5-131
5.14.3	How to Access Control Hints Using EL Expressions .....	5-132
5.14.4	What Happens When You Add Control Hints .....	5-132
5.14.5	What You May Need to Know About Resource Bundles .....	5-133
5.15	Adding Calculated and Transient Attributes to a View Object .....	5-134
5.15.1	How to Add a SQL-Calculated Attribute .....	5-134
5.15.2	What Happens When You Add a SQL-Calculated Attribute .....	5-135
5.15.3	How to Add a Transient Attribute .....	5-136
5.15.4	How to Add a Validation Rule to a Transient Attribute .....	5-138
5.15.5	What Happens When You Add a Transient Attribute .....	5-139
5.15.6	Adding Java Code in the View Row Class to Perform Calculation .....	5-139
5.15.7	What You May Need to Know About Transient Attributes .....	5-140

## 6 Working with View Object Query Results

6.1	Introduction to View Object Runtime Behavior .....	6-1
6.2	Creating an Application Module to Test View Instances .....	6-1
6.2.1	How to Create the Application Module with Individual View Object Instances .....	6-2
6.2.2	How to Create the Application Module with Master-Detail View Object Instances ..	6-2
6.3	Testing View Object Instances Using the Business Component Browser .....	6-5
6.3.1	How to Run the Business Component Browser .....	6-5
6.3.2	How to Test Entity-Based View Objects Interactively .....	6-7
6.3.3	How to Update the Business Component Browser to Display Project Changes .....	6-9
6.3.4	What Happens When You Use the Business Component Browser .....	6-9
6.3.5	How to Simulate End-User Interaction in the Business Component Browser .....	6-10
6.3.5.1	Testing Master-Detail Coordination .....	6-12
6.3.5.2	Testing UI Control Hints .....	6-12
6.3.5.3	Testing Business Domain Layer Validation .....	6-12
6.3.5.4	Testing Alternate Language Message Bundles and Control Hints .....	6-12
6.3.5.5	Testing View Objects That Reference Entity Usages .....	6-13
6.3.5.6	Testing Row Creation and Default Value Generation .....	6-13
6.3.5.7	Testing That New Detail Rows Have Correct Foreign Keys .....	6-13
6.3.6	How to Test Multiuser Scenarios in the Business Component Browser .....	6-13
6.3.7	How to Customize Configuration Options Before Running the Browser .....	6-14

6.3.8	How to Enable ADF Business Components Debug Diagnostics .....	6-14
6.3.9	What Happens at Runtime: When View Objects and Entity Objects Cooperate .....	6-15
6.3.9.1	What Happens When a View Object Executes Its Query .....	6-16
6.3.9.2	What Happens When a View Row Attribute Is Modified .....	6-17
6.3.9.3	What Happens When a Foreign Key Attribute is Changed .....	6-18
6.3.9.4	What Happens When a Transaction is Committed .....	6-19
6.3.9.5	What Happens When a View Object Requeries Data .....	6-20
6.3.10	What You May Need to Know About Optimizing View Object Runtime Performance .	6-22
6.4	Testing View Object Instances Programmatically .....	6-24
6.4.1	ViewObject Interface Methods for Working with the View Object's Default RowSet ....	6-24
6.4.1.1	The Role of the Key Object in a View Row or Entity Row .....	6-25
6.4.1.2	The Role of the Entity Cache in the Transaction .....	6-26
6.4.2	How to Create a Command-Line Java Test Client .....	6-27
6.4.2.1	Generating a Test Client with Skeleton Code .....	6-27
6.4.2.2	Modifying the Skeleton Code to Create the Test Client .....	6-28
6.4.3	What Happens When You Run a Test Client Program .....	6-30
6.4.4	What You May Need to Know About Running a Test Client .....	6-30
6.4.5	How to Count the Number of Rows in a Row Set .....	6-31
6.4.6	How to Access a Detail Collection Using the View Link Accessor .....	6-31
6.4.7	How to Iterate Over a Master-Detail-Detail Hierarchy .....	6-33
6.4.8	How to Find a Row and Update a Foreign Key Value .....	6-35
6.4.9	How to Create a New Row for a View Object Instance .....	6-36
6.4.10	How to Retrieve the Row Key Identifying a Row .....	6-37
6.4.11	How to Authenticate Test Users in the Test Client .....	6-39

## 7 Defining Validation and Business Rules Declaratively

7.1	Introduction to Declarative Validation .....	7-1
7.1.1	When to Use Business-Layer Validation or Model-Layer Validation .....	7-2
7.2	Understanding the Validation Cycle .....	7-2
7.2.1	Types of Entity Object Validation Rules .....	7-2
7.2.1.1	Attribute-Level Validation Rules .....	7-3
7.2.1.2	Entity-Level Validation Rules .....	7-3
7.2.2	Understanding Commit Processing and Validation .....	7-3
7.2.3	Understanding the Impact of Composition on Validation Order .....	7-4
7.2.4	Avoiding Infinite Validation Cycles .....	7-4
7.2.5	What Happens When Validations Fail .....	7-4
7.2.6	Understanding Entity Objects Row States .....	7-5
7.2.7	Understanding Bundled Exception Mode .....	7-6
7.3	Adding Validation Rules to Entity Objects and Attributes .....	7-6
7.3.1	How to Add a Validation Rule to an Entity or Attribute .....	7-6
7.3.2	How to View and Edit a Validation Rule On an Entity or Attribute .....	7-7
7.3.3	What Happens When You Add a Validation Rule .....	7-7
7.3.4	What You May Need to Know About Entity and Attribute Validation Rules .....	7-8
7.3.5	What You May Need to Know About List of Values and Attribute Validation Rules	7-8
7.4	Using the Built-in Declarative Validation Rules .....	7-9

7.4.1	How to Ensure That Key Values Are Unique .....	7-9
7.4.2	What Happens When You Use a Unique Key Validator .....	7-10
7.4.3	How to Validate Based on a Comparison .....	7-10
7.4.4	What Happens When You Validate Based on a Comparison .....	7-12
7.4.5	How to Validate Using a List of Values .....	7-12
7.4.6	What Happens When You Validate Using a List of Values .....	7-14
7.4.7	What You May Need to Know About the List Validator .....	7-14
7.4.8	How to Make Sure a Value Falls Within a Certain Range .....	7-15
7.4.9	What Happens When You Use a Range Validator .....	7-15
7.4.10	How to Validate Against a Number of Bytes or Characters .....	7-16
7.4.11	What Happens When You Validate Against a Number of Bytes or Characters .....	7-16
7.4.12	How to Validate Using a Regular Expression .....	7-17
7.4.13	What Happens When You Validate Using a Regular Expression .....	7-18
7.4.14	How to Use the Average, Count, or Sum to Validate a Collection .....	7-18
7.4.15	What Happens When You Use Collection Validation .....	7-19
7.4.16	How to Determine Whether a Key Exists .....	7-19
7.4.17	What Happens When You Use a Key Exists Validator .....	7-21
7.4.18	What You May Need to Know About Declarative Validators and View Accessors .....	7-21
7.5	Using Groovy Expressions For Validation and Business Rules .....	7-22
7.5.1	How to Reference Entity Object Methods in Groovy Validation Expressions .....	7-22
7.5.2	How to Validate Using a True/False Expression .....	7-24
7.5.3	What Happens When You Add a Groovy Expression .....	7-25
7.6	Triggering Validation Execution .....	7-26
7.6.1	How to Specify Which Attributes Fire Validation .....	7-26
7.6.2	What Happens When You Constrain Validation Execution with Triggering Attributes .....	7-28
7.6.3	How to Set Preconditions for Validation .....	7-28
7.6.4	How to Set Transaction-Level Validation .....	7-28
7.6.5	What You May Need to Know About the Order of Validation Execution .....	7-29
7.7	Creating Validation Error Messages .....	7-29
7.7.1	How to Create Validation Error Messages .....	7-29
7.7.2	How to Localize Validation Messages .....	7-30
7.7.3	How to Conditionally Raise Error Messages Using Groovy .....	7-30
7.7.4	How to Embed a Groovy Expression in an Error Message .....	7-30
7.8	Setting the Severity Level for Validation Exceptions .....	7-32
7.9	Bulk Validation in SQL .....	7-32

## 8 Implementing Validation and Business Rules Programmatically

8.1	Introduction to Programmatic Business Rules .....	8-1
8.2	Using Method Validators .....	8-2
8.2.1	How to Create an Attribute-Level Method Validator .....	8-3
8.2.2	What Happens When You Create an Attribute-Level Method Validator .....	8-4
8.2.3	How to Create an Entity-Level Method Validator .....	8-5
8.2.4	What Happens When You Create an Entity-Level Method Validator .....	8-6
8.2.5	What You May Need to Know About Translating Validation Rule Error Messages .....	8-6
8.3	Assigning Programmatically Derived Attribute Values .....	8-7
8.3.1	How to Provide Default Values for New Rows at Create Time .....	8-7

8.3.1.1	Choosing Between create() and initDefaultExpressionAttributes() Methods .....	8-7
8.3.1.2	Eagerly Defaulting an Attribute Value from a Database Sequence .....	8-7
8.3.2	How to Assign Derived Values Before Saving .....	8-8
8.3.3	How to Assign Derived Values When an Attribute Value Is Set .....	8-9
8.4	Undoing Pending Changes to an Entity Using the Refresh Method .....	8-9
8.4.1	How to Control What Happens to New Rows During a Refresh .....	8-10
8.4.2	How to Cascade Refresh to Composed Children Entity Rows .....	8-10
8.5	Using View Objects for Validation .....	8-10
8.5.1	How to Use View Accessors for Validation Against View Objects .....	8-10
8.5.2	How to Validate Conditions Related to All Entities of a Given Type .....	8-11
8.5.3	What You May Need to Know About Row Set Access with View Accessors .....	8-12
8.6	Accessing Related Entity Rows Using Association Accessors .....	8-12
8.6.1	How to Access Related Entity Rows .....	8-12
8.6.2	How to Access Related Entity Row Sets .....	8-13
8.7	Referencing Information About the Authenticated User .....	8-14
8.8	Accessing Original Attribute Values .....	8-14
8.9	Storing Information About the Current User Session .....	8-14
8.9.1	How to Store Information About the Current User Session .....	8-14
8.9.2	How to Use Groovy to Access Information About the Current User Session .....	8-16
8.10	Accessing the Current Date and Time .....	8-16
8.11	Sending Notifications Upon a Successful Commit .....	8-16
8.12	Conditionally Preventing an Entity Row from Being Removed .....	8-16
8.13	Determining Conditional Updatability for Attributes .....	8-17

## 9 Implementing Business Services with Application Modules

9.1	Introduction to Application Modules .....	9-1
9.2	Creating and Modifying an Application Module .....	9-3
9.2.1	How to Create an Application Module .....	9-3
9.2.2	What Happens When You Create an Application Module .....	9-4
9.2.3	How to Add a View Object Instance to an Application Module .....	9-5
9.2.3.1	Adding a View Object Instance to an Existing Application Module .....	9-5
9.2.3.2	Adding Master-Detail View Object Instances to an Application Module .....	9-6
9.2.3.3	Customizing a View Object Instance that You Add to an Application Module ..	9-9
9.2.4	What Happens When You Add a View Object Instance to an Application Module	9-10
9.2.5	How to Edit an Existing Application Module .....	9-11
9.2.6	How to Change the Data Control Name Before You Begin Building Pages .....	9-11
9.2.7	What You May Need to Know About Application Module Granularity .....	9-12
9.2.8	What You May Need to Know About View Object Components and View Object Instances .....	9-12
9.3	Configuring Your Application Module Database Connection .....	9-13
9.3.1	How to Use a JDBC URL Connection Type .....	9-13
9.3.2	How to Use a JDBC Data Source Connection Type .....	9-14
9.3.3	What Happens When You Create an Application Module Database Connection ...	9-15
9.3.4	How to Change Your Application Module's Runtime Configuration .....	9-16
9.3.5	How to Change the Database Connection for Your Project .....	9-17
9.4	Defining Nested Application Modules .....	9-17
9.4.1	How to Define a Nested Application Module .....	9-18

9.4.2	What You May Need to Know About Root Application Modules Versus Nested Application Module Usages .....	9-19
9.5	Creating an Application Module Diagram for Your Business Service .....	9-19
9.5.1	How to Create an Application Module Diagram .....	9-19
9.5.2	What Happens When You Create an Application Module Diagram .....	9-20
9.5.3	How to Use the Diagram to Edit the Application Module .....	9-20
9.5.4	How to Control Diagram Display Options .....	9-21
9.5.5	How to Filter Method Names Displayed in the Diagram .....	9-22
9.5.6	How to Show Related Objects and Implementation Files in the Diagram .....	9-22
9.5.7	How to Publish the Application Module Diagram .....	9-23
9.5.8	How to Test the Application Module from the Diagram .....	9-23
9.6	Supporting Multipage Units of Work .....	9-23
9.6.1	How to Simulate State Management in the Business Component Browser .....	9-24
9.6.2	What Happens When the Application Uses Application Module Pooling and State Management .....	9-24
9.7	Customizing an Application Module with Service Methods .....	9-25
9.7.1	How to Generate a Custom Class for an Application Module .....	9-26
9.7.2	What Happens When You Generate a Custom Class for an Application Module ...	9-27
9.7.3	What You May Need to Know About Default Code Generation .....	9-27
9.7.4	How to Add a Custom Service Method to an Application Module .....	9-28
9.7.5	How to Test the Custom Application Module Using a Static Main Method .....	9-29
9.7.6	What You May Need to Know About Programmatic Row Set Iteration .....	9-31
9.8	Customizing Application Module Message Strings .....	9-32
9.8.1	How to Add a Resource Bundle to an Application Module .....	9-32
9.8.2	What Happens When You Add a Resource Bundle to an Application Module .....	9-34
9.9	Publishing Custom Service Methods to UI Clients .....	9-34
9.9.1	How to Publish a Custom Method on the Application Module's Client Interface ...	9-34
9.9.2	What Happens When You Publish Custom Service Methods .....	9-35
9.9.3	How to Generate Client Interfaces for View Objects and View Rows .....	9-36
9.9.4	How to Test Custom Service Methods Using the Business Component Browser ....	9-37
9.9.5	What You May Need to Know About Method Signatures on the Client Interface ..	9-38
9.9.6	What You May Need to Know About Passing Information from the Data Model ..	9-39
9.10	Working Programmatically with an Application Module's Client Interface .....	9-39
9.10.1	How to Work Programmatically with an Application Module's Client Interface ....	9-39
9.10.2	What Happens When You Work with an Application Module's Client Interface ....	9-41
9.10.3	How to Access an Application Module Client Interface in a Fusion Web Application ...	9-41
9.11	Overriding Built-in Framework Methods .....	9-43
9.11.1	How to Override a Built-in Framework Method .....	9-44
9.11.2	What Happens When You Override a Built-in Framework Method .....	9-45
9.11.3	How to Override prepareSession() to Set Up an Application Module for a New User Session .....	9-45

## 10 Sharing Application Module View Instances

10.1	Introduction to Shared Application Modules .....	10-1
10.2	Sharing an Application Module Instance .....	10-1
10.2.1	How to Create a Shared Application Module Instance .....	10-3

10.2.2	What Happens When You Define a Shared Application Module .....	10-3
10.2.3	What You May Need to Know About Design Time Scope of the Shared Application Module .....	10-5
10.2.4	What You May Need to Know About the Design Time Scope of View Instances of the Shared Application Module .....	10-5
10.2.5	What You May Need to Know About Managing the Number of Shared Query Collections .....	10-6
10.2.6	What You May Need to Know About Shared Application Modules and Connection Pooling .....	10-6
10.3	Defining a Base View Object for Use with Lookup Tables .....	10-7
10.3.1	How to Create a Base View Object Definition for a Lookup Table .....	10-8
10.3.2	What Happens When You Create a Base View Object .....	10-10
10.3.3	How to Define the WHERE Clause of the Lookup View Object Using View Criteria ....	10-12
10.3.4	What Happens When You Create a View Criteria with the Editor .....	10-14
10.3.5	What Happens at Runtime: When a View Instance Accesses Lookup Data .....	10-15
10.4	Accessing View Instances of the Shared Service .....	10-15
10.4.1	How to Create a View Accessor for an Entity Object or View Object .....	10-16
10.4.2	How to Validate Against a View Accessor .....	10-18
10.4.3	What Happens When You Validate Against a View Accessor .....	10-20
10.4.4	How to Create an LOV Based on a Lookup Table .....	10-21
10.4.5	What Happens When You Define an LOV for a View Object Attribute .....	10-23
10.4.6	What Happens at Runtime: When the Attribute Displays the List of Values .....	10-24
10.4.7	What You May Need to Know About Displaying List of Values From a Lookup Table	10-24
10.4.8	What You May Need to Know About Inheritance of AttributeDef Properties .....	10-24
10.4.9	What You May Need to Know About Using Validators .....	10-24
10.5	Testing View Object Instances in a Shared Application Module .....	10-24
10.5.1	How to Test the Base View Object Using the Business Component Browser .....	10-25
10.5.2	How to Test LOV-Enabled Attributes Using the Business Component Browser ...	10-26
10.5.3	What Happens When You Use the Business Component Browser .....	10-26
10.5.4	What Happens at Runtime: When Another Service Accesses the Shared Application Module Cache .....	10-27

## 11 Integrating Service-Enabled Application Modules

11.1	Introduction to Service-Enabled Application Modules .....	11-1
11.2	Publishing Service-Enabled Application Modules .....	11-2
11.2.1	How to Enable the Application Module Service Interface .....	11-3
11.2.2	What Happens When You Create an Application Module Service Interface .....	11-10
11.2.2.1	Annotations Generated in the Web Service Interface .....	11-12
11.2.2.2	Web Service Schema Generated in the Web Service Schema File .....	11-13
11.2.2.3	WSDL Generated in the Web Service Definition File .....	11-13
11.2.2.4	Stateless Session Bean Specified by the Service Implementation Class .....	11-14
11.2.2.5	Lookup Defined in the connections.xml File .....	11-15
11.2.3	What You May Need to Know About Method Signatures on the ADF Web Service Interface .....	11-16
11.2.4	What You May Need to Know About Row Finders and the ADF Web Service Operations .....	11-17

11.2.5	How to Service-Enable Individual View Objects .....	11-17
11.2.6	How to Customize the SDO Properties of Service-Enabled View Objects .....	11-19
11.2.6.1	Excluding Individual SDO Properties in a Generated SDO Component .....	11-20
11.2.6.2	Associating Related SDO Properties Using Complex Data Types .....	11-20
11.2.7	How to Support Nested Processing in Service-Enabled Master-Detail View Objects .....	11-22
11.2.8	What Happens When You Create SDO Classes .....	11-23
11.2.8.1	Property Accessors Generated in the SDO Interface .....	11-23
11.2.8.2	View Object Interface Implemented by SDO Class .....	11-24
11.2.8.3	View Object Schema Generated in the SDO Schema File .....	11-24
11.2.8.4	Container Object Implemented by SDO Result Class and Interface .....	11-24
11.2.9	How to Expose a Declarative Find Operation Filtered By a Required Bind Variable .....	11-25
11.2.10	How to Expose a Custom Find Method Filtered By a Required Bind Variable .....	11-26
11.2.11	How to Generate Asynchronous ADF Web Service Methods .....	11-27
11.2.12	What Happens When You Generate Asynchronous ADF Web Service Methods ..	11-28
11.2.13	What Happens at Runtime: How the Asynchronous Call Is Made .....	11-29
11.2.14	How to Set Preferences for Generating the ADF Web Service Interface .....	11-30
11.2.15	How to Set Display Names for Service View Instances and Attributes .....	11-31
11.2.16	How to Secure the ADF Web Service for Access By SOAP Clients .....	11-32
11.2.17	How to Secure the ADF Web Service for Access By RMI Clients .....	11-35
11.2.17.1	Enabling Authentication for RMI Clients .....	11-35
11.2.17.2	Configuring Authorization for RMI Clients .....	11-38
11.2.18	How to Grant Test Users Access to the Service .....	11-39
11.2.19	How to Enable Support for Binary Attachments for SOAP Clients .....	11-42
11.2.20	How to Test the Web Service Using Integrated WebLogic Server .....	11-43
11.2.21	How to Prevent Custom Service Methods from Timing Out .....	11-43
11.2.22	How to Deploy Web Services to Oracle WebLogic Server .....	11-45
11.3	Accessing Remote Data Over the Service-Enabled Application Module .....	11-48
11.3.1	How to Use Service-Enabled Entity Objects and View Objects .....	11-49
11.3.1.1	Creating Entity Objects Backed by SDO Services .....	11-49
11.3.1.2	Using Complex Data Types with Service-Backed Entity Object Attributes .....	11-51
11.3.1.3	Creating View Objects Backed by SDO Services .....	11-52
11.3.2	What Happens When You Create Service-Backed Business Components .....	11-53
11.3.3	How to Update the Data Model for Service-Backed Business Components .....	11-54
11.3.4	How to Configure the Service-Backed Business Components Runtime .....	11-56
11.3.4.1	Adding the SDO Client Library to the Classpath .....	11-57
11.3.4.2	Registering the ADF Business Components Service in the Consuming Application's connections.xml for the EJB RMI Protocol .....	11-58
11.3.4.3	Registering the ADF Business Components Service in the Consuming Application's connections.xml for the SOAP Protocol .....	11-60
11.3.4.4	Registering the ADF Business Components Service in the Consuming Application's connections.xml for Fabric SDO Binding .....	11-63
11.3.5	How to Test the Service-Backed Components in the Business Component Browser .....	11-64
11.3.6	How to Invoke Operations of the Service-Backed Components in the Consuming Application .....	11-65

11.3.7	What You May Need to Know About Creating Service Data Objects in the Consuming Application .....	11-66
11.3.8	What You May Need to Know About Invoking Built-In Service Methods in the Consuming Application .....	11-66
11.3.9	What Happens at Runtime: How the Application Accesses the Published Application Module .....	11-66
11.3.10	What You May Need to Know About Service-Backed Entity Objects and View Objects .....	11-67

## 12 Using ADF Model in a Fusion Web Application

12.1	Introduction to ADF Data Binding .....	12-1
12.2	Exposing Application Modules with ADF Data Controls .....	12-3
12.2.1	How an Application Module Data Control Appears in the Data Controls Panel ....	12-4
12.2.1.1	How the Data Model and Service Methods Appear in the Data Controls Panel	12-5
12.2.1.2	How Transaction Control Operations Appear in the Data Controls Panel .....	12-6
12.2.1.3	How View Objects Appear in the Data Controls Panel .....	12-7
12.2.1.4	How Nested Application Modules Appear in the Data Controls Panel .....	12-9
12.2.2	How to Open the Data Controls Panel .....	12-10
12.2.3	How to Refresh the Data Controls Panel .....	12-10
12.2.4	Packaging a Data Control for Use in Another Project .....	12-11
12.3	Using the Data Controls Panel .....	12-11
12.3.1	How to Use the Data Controls Panel .....	12-14
12.3.2	What Happens When You Use the Data Controls Panel .....	12-15
12.3.3	What Happens at Runtime: How the Binding Context Works .....	12-17
12.4	Working with the DataBindings.cpx File .....	12-18
12.4.1	How JDeveloper Creates a DataBindings.cpx File .....	12-18
12.4.2	What Happens When JDeveloper Creates a DataBindings.cpx File .....	12-18
12.5	Configuring the ADF Binding Filter .....	12-20
12.5.1	How JDeveloper Configures the ADF Binding Filter .....	12-21
12.5.2	What Happens When JDeveloper Configures an ADF Binding Filter .....	12-21
12.5.3	What Happens at Runtime: How the ADF Binding Filter Works .....	12-21
12.6	Working with Page Definition Files .....	12-22
12.6.1	How JDeveloper Creates a Page Definition File .....	12-22
12.6.2	What Happens When JDeveloper Creates a Page Definition File .....	12-23
12.6.2.1	Bindings Binding Objects .....	12-26
12.6.2.2	Executable Binding Objects .....	12-28
12.7	Creating ADF Data Binding EL Expressions .....	12-30
12.7.1	How to Create an ADF Data Binding EL Expression .....	12-31
12.7.1.1	Opening the Expression Builder from the Property Inspector .....	12-31
12.7.1.2	Using the Expression Builder .....	12-32
12.7.2	What You May Need to Know About ADF Binding Properties .....	12-33
12.8	Using Simple UI First Development .....	12-33
12.8.1	How to Apply ADF Model Data Binding to Existing UI Components .....	12-35
12.8.2	What Happens When You Apply ADF Model Data Binding to UI Components ..	12-36

## 13 Integrating Web Services Into a Fusion Web Application

13.1	Introduction to Web Services in Fusion Web Applications .....	13-1
------	---	------

13.2	Calling a Web Service from an Application Module .....	13-2
13.2.1	How to Call an External Service Programmatically .....	13-2
13.2.1.1	Creating a Web Service Proxy Class to Programmatically Access the Service ..	13-3
13.2.1.2	Calling the Web Service Proxy Template to Invoke the Service .....	13-3
13.2.1.3	Calling a Web Service Method Using the Proxy Class in an Application Module ...	13-4
13.2.2	How to Create a New Web Service Connection .....	13-4
13.2.3	What Happens When You Create the Web Service Proxy .....	13-5
13.2.4	What Happens at Runtime: When You Call a Web Service Using a Web Service Proxy Class .....	13-6
13.2.5	What You May Need to Know About Web Service Proxies .....	13-6
13.2.5.1	Using a Try-Catch Block to Handle Web Service Exceptions .....	13-6
13.2.5.2	Separating Application Module and Web Services Transactions .....	13-7
13.2.5.3	Setting Browser Proxy Information .....	13-7
13.2.5.4	Invoking Application Modules with a Web Service Proxy Class .....	13-7
13.3	Creating Web Service Data Controls .....	13-7
13.3.1	How to Create a Web Service Data Control .....	13-8
13.3.2	How to Include a Header Parameter for a Web Service Data Control .....	13-8
13.3.3	How to Adjust the Endpoint for a Web Service Data Control .....	13-9
13.3.4	How to Refresh a Web Service Data Control .....	13-9
13.3.5	What You May Need to Know About Web Service Data Controls .....	13-9
13.4	Securing Web Service Data Controls .....	13-11
13.4.1	WS-Security Specification .....	13-12
13.4.2	Using Key Stores .....	13-12
13.4.3	How to Define Web Service Data Control Security .....	13-13

## Part III Creating ADF Task Flows

### 14 Getting Started with ADF Task Flows

14.1	Introduction to ADF Task Flows .....	14-1
14.1.1	Task Flow Advantages .....	14-2
14.1.2	Task Flow Types .....	14-2
14.1.2.1	Unbounded Task Flows .....	14-3
14.1.2.2	Bounded Task Flows .....	14-4
14.1.3	Control Flows .....	14-7
14.2	Creating a Task Flow .....	14-9
14.2.1	How to Create a Task Flow .....	14-9
14.2.2	What Happens When You Create a Task Flow .....	14-12
14.2.3	What You May Need to Know About the Default Activity in an ADF Bounded Task Flow .....	14-13
14.2.4	What You May Need to Know About Memory Scope for Task Flows .....	14-13
14.2.5	What Happens at Runtime: Using ADF Task Flows .....	14-16
14.3	Adding Activities to a Task Flow .....	14-16
14.3.1	How to Add Additional Activities to an ADF Task Flow .....	14-17
14.3.2	What Happens When You Add an Activity to an ADF Task Flow .....	14-18
14.3.3	How to Add Control Flows .....	14-18
14.3.4	How to Add a Wildcard Control Flow Rule .....	14-21

14.3.5	What Happens When You Create a Control Flow Rule .....	14-21
14.3.6	What Happens at Runtime: Evaluating Control Flow Rules .....	14-22
14.4	Testing ADF Task Flows .....	14-23
14.4.1	How to Run a Bounded Task Flow That Contains Pages .....	14-23
14.4.2	How to Run a Bounded Task Flow That Uses Page Fragments .....	14-23
14.4.3	How to Run a Bounded Task Flow That Has Parameters .....	14-24
14.4.4	How to Run a JSF Page .....	14-24
14.4.5	How to Run an ADF Unbounded Task Flow .....	14-25
14.4.6	How to Set a Run Configuration for a Project .....	14-25
14.5	Refactoring to Create New ADF Task Flows and Templates .....	14-26
14.5.1	How to Create an ADF Bounded Task Flow from Selected Activities .....	14-26
14.5.2	How to Create a Task Flow from JSF Pages .....	14-27
14.5.3	How to Convert ADF Bounded Task Flows .....	14-27
14.6	What You Should Know About Task Flow Constraints .....	14-28

## 15 Working with Task Flow Activities

15.1	Introduction to Activity Types .....	15-1
15.2	Using View Activities .....	15-3
15.2.1	Adding a View Activity .....	15-4
15.2.2	Transitioning Between View Activities .....	15-5
15.2.2.1	How to Transition to a View Activity .....	15-5
15.2.2.2	What Happens When You Transition Between Activities .....	15-6
15.2.3	Bookmarking View Activities .....	15-6
15.2.3.1	How to Create a Bookmarkable View Activity .....	15-8
15.2.3.2	How to Specify HTTP Redirect .....	15-8
15.2.3.3	What Happens When You Designate a View as Bookmarkable .....	15-9
15.3	Using URL View Activities .....	15-9
15.3.1	How to Add a URL View Activity to a Task Flow .....	15-10
15.3.2	Constructing a URL for Use Within a Portlet .....	15-11
15.4	Using Router Activities .....	15-11
15.5	Using Method Call Activities .....	15-13
15.5.1	How to Add a Method Call Activity .....	15-14
15.5.2	How to Specify Method Parameters and Return Values .....	15-17
15.5.3	What Happens When You Add a Method Call Activity .....	15-17
15.6	Using Task Flow Call Activities .....	15-18
15.6.1	How to Call a Bounded Task Flow Using a Task Flow Call Activity .....	15-18
15.6.2	What Happens When You Call a Bounded Task Flow Using a Task Flow Call Activity .....	15-20
15.6.3	How to Specify Input Parameters on a Task Flow Call Activity .....	15-20
15.6.4	How to Call a Bounded Task Flow Using a URL .....	15-21
15.6.5	What Happens When You Configure a Bounded Task Flow to be Invoked by a URL ...	15-22
15.6.6	What You May Need to Know About Calling a Bounded Task Flow Using a URL .....	15-23
15.6.7	How to Specify Before and After Listeners .....	15-24
15.6.8	What Happens When You Add a Task Flow Call Activity .....	15-25
15.6.9	What Happens at Runtime When a Task Flow Call Activity Invokes a Task Flow .....	15-26

15.7	Using Task Flow Return Activities .....	15-27
15.8	Using Save Point Restore Activities .....	15-29
15.9	Using Parent Action Activities .....	15-29
15.10	Using Task Flow Activities with Page Definition Files .....	15-30
15.10.1	How to Associate a Page Definition File with a Task Flow Activity .....	15-31
15.10.2	What Happens When You Associate a Page Definition File with a Task Flow Activity .	15-31

## 16 Using Parameters in Task Flows

16.1	Introduction to Parameters in Task Flows .....	16-1
16.2	Passing Parameters to a View Activity .....	16-1
16.3	How to Pass Parameters to an ADF Bounded Task Flow .....	16-2
16.4	Specifying Return Values .....	16-5
16.5	Specifying EL Binding Expressions .....	16-7

## 17 Using Task Flows as Regions

17.1	Introduction to Using Task Flows in ADF Regions .....	17-1
17.1.1	Benefits of Executing a Task Flow in an ADF Region .....	17-2
17.1.2	Task Flows and ADF Region Use Cases and Examples .....	17-2
17.1.3	Additional Functionality for Task Flows that Render in ADF Regions .....	17-4
17.1.3.1	Page Fragments and ADF Regions .....	17-4
17.1.3.2	View Ports and ADF Regions .....	17-5
17.1.3.3	Security and ADF Regions .....	17-5
17.1.3.4	Parent Page Determines the Capabilities of an ADF Region .....	17-5
17.2	Creating an ADF Region .....	17-6
17.2.1	How to Create an ADF Region .....	17-6
17.2.2	What Happens When You Create an ADF Region .....	17-7
17.3	Specifying Parameters for an ADF Region .....	17-8
17.3.1	How to Specify Parameters for an ADF Region .....	17-9
17.3.2	What Happens When You Specify Parameters for an ADF Region .....	17-9
17.4	Specifying Parameters for ADF Regions Using Parameter Maps .....	17-10
17.4.1	How to Create a Parameter Map to Specify Input Parameters for an ADF Region	17-10
17.4.2	What Happens When You Create a Parameter Map to Specify Input Parameters .	17-11
17.5	Refreshing an ADF Region .....	17-12
17.5.1	How to Configure the Refresh of an ADF Region .....	17-13
17.5.2	What You May Need to Know About Refreshing an ADF Region .....	17-14
17.6	Configuring Activation of an ADF Region .....	17-15
17.6.1	How to Configure Activation of an ADF Region .....	17-15
17.6.2	What Happens When You Configure Activation of an ADF Region .....	17-16
17.7	Navigating Outside an ADF Region's Task Flow .....	17-18
17.7.1	How to Trigger Navigation Outside of an ADF Region's Task Flow .....	17-18
17.7.2	What Happens When You Configure Navigation Outside a Task Flow .....	17-19
17.8	Configuring Transaction Management in an ADF Region .....	17-19
17.9	Creating ADF Dynamic Regions .....	17-21
17.9.1	How to Create an ADF Dynamic Region .....	17-22
17.9.2	What Happens When You Create an ADF Dynamic Region .....	17-23

17.10	Adding Additional Task Flows to an ADF Dynamic Region .....	17-24
17.10.1	How to Create an ADF Dynamic Region Link .....	17-25
17.10.2	What Happens When You Create an ADF Dynamic Region .....	17-25
17.11	Configuring a Page To Render an Unknown Number of Regions .....	17-26
17.11.1	How to Configure a Page to Render an Unknown Number of Regions .....	17-27
17.11.2	What Happens When You Configure a Page to Render an Unknown Number of Regions .....	17-28
17.11.3	What You May Need to Know About Configuring a Page to Render an Unknown Number of Regions .....	17-28

## 18 Creating Complex Task Flows

18.1	Introduction to Complex Task Flows .....	18-1
18.2	Using Initializers and Finalizers .....	18-2
18.3	Sharing Data Controls Between Task Flows .....	18-2
18.3.1	How to Share a Data Control Between Task Flows .....	18-3
18.3.2	What Happens When You Share a Data Control Between Task Flows .....	18-3
18.3.3	What Happens at Runtime: How Task Flows Share Data Controls .....	18-4
18.4	Managing Transactions .....	18-4
18.4.1	How to Enable Transactions in a Bounded Task Flow .....	18-6
18.4.2	What Happens When You Specify Transaction Options .....	18-8
18.4.3	What You May Need to Know About Sharing Data Controls and Managing Transactions .....	18-8
18.4.3.1	Creating Completely Separate Transactions .....	18-9
18.4.3.2	Guaranteeing a Called Bounded Task Joins an Existing Transaction .....	18-11
18.4.3.3	Using an Existing Transaction if Possible .....	18-12
18.4.4	What You May Need to Know About ADF Business Component Database Connections and Task Flow Transaction Options .....	18-13
18.5	Reentering a Bounded Task Flow .....	18-14
18.5.1	How to Set Reentry Behavior .....	18-14
18.5.2	How to Set Outcome-Dependent Options .....	18-15
18.5.3	What You Should Know About Managed Bean Values Upon Task Flow Reentry .....	18-16
18.6	Executing a Bounded Task Flow Directly From a JSF Page .....	18-16
18.7	Handling Exceptions in Task Flows .....	18-16
18.7.1	How to Designate an Activity as an Exception Handler .....	18-17
18.7.2	What Happens When You Designate an Activity as an Exception Handler .....	18-18
18.7.3	How to Designate Custom Code as an Exception Handler .....	18-18
18.7.4	What Happens When You Designate Custom Code as an Exception Handler .....	18-19
18.7.5	What You May Need to Know About Handling Exceptions During Transactions .....	18-19
18.7.6	What You May Need to Know About Handling Validation Errors .....	18-20
18.8	Configuring Your Application to Use Save Points .....	18-20
18.8.1	How to Configure Your Fusion Web Application to Use Save Points .....	18-20
18.8.2	What Happens When You Configure a Fusion Web Application to Use Save Points .....	18-21
18.8.3	What You May Need to Know About the Database Table for Save Points .....	18-21
18.9	Using Save Points in Task Flows .....	18-22
18.9.1	How to Add a Save Point to a Task Flow .....	18-23
18.9.2	What Happens When You Add Save Points to a Task Flow .....	18-24

18.9.3	How to Restore a Save Point .....	18-24
18.9.4	What Happens When You Restore a Save Point .....	18-24
18.9.5	How to Use the Save Point Restore Finalizer .....	18-25
18.9.6	What Happens When a Task Flow Invokes a Save Point Restore Finalizer .....	18-25
18.9.7	How to Enable Implicit Save Points .....	18-25
18.9.8	What You May Need to Know About Enabling Implicit Save Points .....	18-26
18.9.9	What You May Need to Know About the Time-to-Live Period for a Save Point ..	18-26
18.10	Minimizing the Number of Active Root View Ports in an Application .....	18-27
18.10.1	How to Minimize the Number of Active Root View Ports .....	18-27
18.10.2	What Happens When You Minimize the Number of Active Root View Ports .....	18-28
18.11	Creating a Train .....	18-28
18.11.1	Bounded Task Flows as Trains .....	18-29
18.11.2	Train Sequences .....	18-31
18.11.3	How to Create a Train .....	18-32
18.11.4	What You May Need to Know About Grouping Activities .....	18-33
18.11.5	What You May Need to Know About Grouping Activities in Child Task Flows ...	18-35
18.11.6	What You May Need To Know About Using Child Trains .....	18-36
18.11.7	What You May Need to Know About Branching .....	18-36
18.12	Running Multiple Task Flows .....	18-37
18.12.1	Understanding How the ViewPortInstance Works in ADF Regions .....	18-38
18.13	Creating a Task Flow Template .....	18-38
18.13.1	How to Copy and Reference a Task Flow Template .....	18-39
18.13.2	How to Create a Task Flow Template from Another Task Flow .....	18-41
18.13.3	How to Use a Task Flow Template .....	18-41
18.13.4	How to Create a Task Flow Template .....	18-42
18.13.5	What Happens When You Create a Task Flow Template .....	18-42
18.13.6	What You May Need to Know About Task Flow Templates That Use Bindings ..	18-43
18.14	Creating a Page Hierarchy .....	18-43
18.14.1	How to Create a Page Hierarchy .....	18-45
18.14.1.1	How to Create an XMLMenuModel Metadata File .....	18-46
18.14.1.2	How to Create a Submenu with a Hierarchy of Group and Child Nodes .....	18-47
18.14.1.3	How to Attach a Menu Hierarchy to Another Menu Hierarchy .....	18-48
18.14.2	What Happens When You Create a Page Hierarchy .....	18-48
18.15	Using BPEL with Task Flows .....	18-50
18.15.1	How to Invoke a BPEL Process from a Task Flow .....	18-50
18.15.2	How to Call a Bounded Task Flow from BPEL .....	18-50

## 19 Using Dialogs in Your Application

19.1	Introduction to Using Dialogs in Your Application .....	19-1
19.2	Running a Bounded Task Flow in a Modal Dialog .....	19-1
19.2.1	How to Run a Bounded Task Flow in a Modal Dialog .....	19-2
19.2.2	How to Return a Value From a Modal Dialog .....	19-2
19.2.3	What You May Need to Know About Running a Bounded Task Flow in a Modal Dialog .....	19-3
19.3	Using the ADF Faces Dialog Framework .....	19-4
19.3.1	How to Define a JSF Navigation Rule for Opening a Dialog .....	19-8
19.3.2	How to Create the JSF Page That Opens a Dialog .....	19-8

19.3.3	How to Create the Dialog Page and Return a Dialog Value .....	19-10
19.3.4	What Happens at Runtime: Raising the Return Event from the Dialog .....	19-11
19.3.5	How to Pass a Value into a Dialog .....	19-12
19.3.6	What Happens at Runtime: Handling the LaunchEvent .....	19-13
19.3.7	How to Handle the Return Value .....	19-13
19.3.8	What Happens at Runtime: Handling the ReturnEvent on the Launching Component .	19-14

## Part IV Creating a Databound Web User Interface

### 20 Getting Started with Your Web Interface

20.1	Introduction to Developing a Web Application with ADF Faces .....	20-1
20.2	Using Page Templates .....	20-1
20.2.1	How to Use ADF Data Binding in ADF Page Templates .....	20-3
20.2.2	What Happens When You Use ADF Model Layer Bindings on a Page Template ...	20-5
20.2.3	How to Add a Databound Page Template to a Page Dynamically .....	20-6
20.2.4	What Happens at Runtime: How Pages Use Templates .....	20-7
20.3	Creating a Web Page .....	20-7
20.4	Using a Managed Bean in a Fusion Web Application .....	20-8
20.4.1	How to Use a Managed Bean to Store Information .....	20-11
20.4.2	What Happens When You Create a Managed Bean .....	20-12
20.4.3	How to Set Managed Bean Memory Scopes in a Server-Cluster Environment .....	20-13

### 21 Understanding the Fusion Page Lifecycle

21.1	Introduction to the Fusion Page Lifecycle .....	21-1
21.2	The JSF and ADF Page Lifecycles .....	21-3
21.2.1	What You May Need to Know About Using the Refresh Property Correctly .....	21-7
21.2.2	What You May Need to Know About Task Flows and the Lifecycle .....	21-9
21.3	Object Scope Lifecycles .....	21-10
21.3.1	What You May Need to Know About Object Scopes and Task Flows .....	21-12
21.4	Customizing the ADF Page Lifecycle .....	21-13
21.4.1	How to Create a Custom Phase Listener .....	21-13
21.4.2	How to Register a Listener Globally .....	21-14
21.4.3	What You May Need to Know About Listener Order .....	21-14
21.4.4	How to Register a Lifecycle Listener for a Single Page .....	21-15

### 22 Creating a Basic Databound Page

22.1	Introduction to Creating a Basic Databound Page .....	22-1
22.2	Using Attributes to Create Text Fields .....	22-2
22.2.1	How to Create a Text Field .....	22-2
22.2.2	What Happens When You Create a Text Field .....	22-4
22.2.2.1	Creating and Using Iterator Bindings .....	22-4
22.2.2.2	Creating and Using Value Bindings .....	22-5
22.2.2.3	Using EL Expressions to Bind UI Components .....	22-5
22.3	Creating a Basic Form .....	22-7
22.3.1	How to Create a Form .....	22-7

22.3.2	What Happens When You Create a Form .....	22-8
22.4	Incorporating Range Navigation into Forms .....	22-9
22.4.1	How to Insert Navigation Controls into a Form .....	22-10
22.4.2	What Happens When You Create Command Buttons .....	22-10
22.4.2.1	Action Bindings for Built-in Navigation Operations .....	22-11
22.4.2.2	Iterator RangeSize Attribute .....	22-11
22.4.2.3	EL Expressions Used to Bind to Navigation Operations .....	22-12
22.4.3	What You May Need to Know About Automatic Partial Page Rendering .....	22-14
22.4.4	What Happens at Runtime: How Action Events and Action Listeners Work .....	22-14
22.4.5	What You May Need to Know About the Browser Back Button and Navigating Through Records .....	22-15
22.5	Creating a Form to Edit an Existing Record .....	22-15
22.5.1	How to Create Edit Forms .....	22-16
22.5.2	What Happens When You Use Built-in Operations to Change Data .....	22-17
22.6	Creating an Input Form .....	22-19
22.6.1	How to Create an Input Form Using a Task Flow .....	22-19
22.6.2	What Happens When You Create an Input Form Using a Task Flow .....	22-20
22.6.3	What Happens at Runtime: CreateInsert Action from the Method Activity .....	22-21
22.6.4	What You May Need to Know About Displaying Sequence Numbers .....	22-22
22.7	Using a Dynamic Form to Determine Data to Display at Runtime .....	22-22
22.7.1	How to Use Dynamic Forms .....	22-23
22.7.2	What Happens When You Use Dynamic Components .....	22-24
22.7.3	What Happens at Runtime: How Attribute Values Are Dynamically Determined .....	22-24
22.7.4	What You May Need to Know About Converters for Dynamic Forms .....	22-25
22.8	Modifying the UI Components and Bindings on a Form .....	22-25
22.8.1	How to Modify the UI Components and Bindings .....	22-25
22.8.2	What Happens When You Modify Attributes and Bindings .....	22-26

## 23 Creating ADF Databound Tables

23.1	Introduction to Adding Tables .....	23-1
23.2	Creating a Basic Table .....	23-2
23.2.1	How to Create a Basic Table .....	23-2
23.2.2	What Happens When You Create a Table .....	23-4
23.2.2.1	Iterator and Value Bindings for Tables .....	23-4
23.2.2.2	Code on the JSF Page for an ADF Faces Table .....	23-5
23.2.3	What You May Need to Know About Setting the Current Row in a Table .....	23-8
23.3	Creating an Editable Table .....	23-10
23.3.1	How to Create an Editable Table .....	23-11
23.3.2	What Happens When You Create an Editable Table .....	23-13
23.4	Creating an Input Table .....	23-13
23.4.1	How to Create an Input Table .....	23-13
23.4.2	What Happens When You Create an Input Table .....	23-14
23.4.3	What Happens at Runtime: How CreateInsert and Partial Page Refresh Work .....	23-15
23.4.4	What You May Need to Know About Creating a Row and Sorting Columns .....	23-15
23.4.5	What You May Need to Know About Create and CreateInsert .....	23-16
23.5	Creating a List View of a Collection .....	23-16
23.5.1	How to Create a Databound List View .....	23-17

23.5.2	What Happens When You Create a Databound List View .....	23-18
23.6	Providing Multiselect Capabilities .....	23-19
23.6.1	How to Add Multiselect Capabilities .....	23-20
23.6.2	What Happens at Runtime: How an Operation Executes Against Multiple Rows .....	23-22
23.7	Modifying the Attributes Displayed in the Table .....	23-22
23.7.1	How to Modify the Displayed Attributes .....	23-22
23.7.2	How to Change the Binding for a Table .....	23-23
23.7.3	What Happens When You Modify Bindings or Displayed Attributes .....	23-23

## 24 Displaying Master-Detail Data

24.1	Introduction to Displaying Master-Detail Data .....	24-1
24.2	Identifying Master-Detail Objects on the Data Controls Panel .....	24-3
24.3	Using Tables and Forms to Display Master-Detail Objects .....	24-5
24.3.1	How to Display Master-Detail Objects in Tables and Forms .....	24-6
24.3.2	What Happens When You Create Master-Detail Tables and Forms .....	24-7
24.3.2.1	Code Generated in the JSF Page .....	24-7
24.3.2.2	Binding Objects Defined in the Page Definition File .....	24-8
24.3.3	What Happens at Runtime: ADF Iterator for Master-Detail Tables and Forms .....	24-9
24.3.4	What You May Need to Know About Displaying Master-Detail Widgets on Separate Pages .....	24-10
24.4	Using Trees to Display Master-Detail Objects .....	24-10
24.4.1	How to Display Master-Detail Objects in Trees .....	24-11
24.4.2	What Happens When You Create an ADF Databound Tree .....	24-14
24.4.2.1	Code Generated in the JSF Page .....	24-14
24.4.2.2	Binding Objects Defined in the Page Definition File .....	24-15
24.4.3	What Happens at Runtime: Displaying an ADF Databound Tree .....	24-16
24.5	Using Tree Tables to Display Master-Detail Objects .....	24-16
24.5.1	How to Display Master-Detail Objects in Tree Tables .....	24-17
24.5.2	What Happens When You Create a Databound Tree Table .....	24-17
24.5.2.1	Code Generated in the JSF Page .....	24-17
24.5.2.2	Binding Objects Defined in the Page Definition File .....	24-18
24.5.3	What Happens at Runtime: Events .....	24-18
24.5.4	Using the TargetIterator Property .....	24-19
24.6	Using List Views to Display Master-Detail Objects .....	24-20
24.6.1	How to Display Master-Detail Objects in List Views .....	24-21
24.6.2	What Happens When You Create a Master-Detail List View .....	24-21
24.7	Using Selection Events with Trees and Tables .....	24-22
24.7.1	How to Use Selection Events with Trees and Tables .....	24-22
24.7.2	What Happens at Runtime: RowKeySet Objects and SelectionEvent Events .....	24-24

## 25 Creating Databound Selection Lists and Shuttles

25.1	Introduction to Selection Lists and Shuttles .....	25-1
25.2	Creating List of Values (LOV) .....	25-2
25.2.1	How to Create an LOV .....	25-7
25.2.2	What Happens When You Create an LOV .....	25-8
25.3	Creating a Selection List .....	25-9
25.3.1	How to Create a Single Selection List .....	25-10

25.3.2	How to Create a Model-Driven List .....	25-10
25.3.3	How to Create a Selection List Containing Fixed Values .....	25-12
25.3.4	How to Create a Selection List Containing Dynamically Generated Values .....	25-13
25.3.5	What Happens When You Create a Model-Driven Selection List .....	25-14
25.3.6	What Happens When You Create a Fixed Selection List .....	25-15
25.3.7	What You May Need to Know About Values in a Selection List .....	25-16
25.3.8	What Happens When You Create a Dynamic Selection List .....	25-16
25.4	Creating a List with Navigation List Binding .....	25-17
25.5	Creating a Databound Shuttle .....	25-17

## 26 Creating Databound ADF Data Visualization Components

26.1	Introduction to Creating ADF Data Visualization Components .....	26-1
26.2	Creating Databound Graphs .....	26-3
26.2.1	How to Create a Graph .....	26-6
26.2.2	What Happens When You Use the Data Controls Panel to Create a Graph .....	26-8
26.2.3	What You May Need to Know About Using a Graph's Row Selection Listener for Master-Detail Processing .....	26-9
26.2.4	How to Create a Databound Sparkchart .....	26-10
26.3	Creating Databound Gauges .....	26-12
26.3.1	How to Create a Databound Dial Gauge .....	26-13
26.3.2	What Happens When You Create a Dial Gauge from a Data Control .....	26-16
26.3.3	How to Create a Databound Status Meter Gauge Set .....	26-17
26.3.4	What Happens When You Create a Status Meter Gauge from a Data Control .....	26-19
26.4	Creating Databound Pivot Tables .....	26-20
26.4.1	How to Create a Pivot Table .....	26-21
26.4.2	What Happens When You Use the Data Controls Panel to Create a Pivot Table ...	26-32
26.4.2.1	Bindings for Pivot Tables .....	26-32
26.4.2.2	Code on the JSF Page for a Pivot Table and Pivot Filter Bar .....	26-33
26.4.3	What You May Need to Know About Aggregating Attributes in the Pivot Table ..	26-34
26.4.3.1	Default Aggregation of Duplicate Data Rows .....	26-34
26.4.3.2	Custom Aggregation of Duplicate Rows .....	26-34
26.4.4	What You May Need to Know About Specifying an Initial Sort for a Pivot Table	26-35
26.5	Creating Databound Geographic Maps .....	26-36
26.5.1	How to Create a Geographic Map with a Point Theme .....	26-37
26.5.2	How to Create Point Style Items for a Point Theme .....	26-40
26.5.3	What Happens When You Create a Geographic Map with a Point Theme .....	26-42
26.5.3.1	Binding XML for a Point Theme .....	26-42
26.5.3.2	XML Code on the JSF Page for a Geographic Map and Point Theme .....	26-42
26.5.4	What You May Need to Know About Adding Custom Point Style Items to a Map Point Theme .....	26-43
26.5.5	How to Add a Databound Color Theme to a Geographic Map .....	26-44
26.5.6	What Happens When You Add a Color Theme to a Geographic Map .....	26-46
26.5.6.1	Binding XML for a Color Theme .....	26-46
26.5.6.2	XML Code on the JSF Page for a Color Theme .....	26-46
26.5.7	What You May Need to Know About Customizing Colors in a Map Color Theme .....	26-47
26.5.8	How to Add a Databound Pie Graph Theme to a Geographic Map .....	26-47

26.5.9	What Happens When You Add a Pie Graph Theme to a Geographic Map .....	26-49
26.5.9.1	Binding XML for a Pie Graph Theme .....	26-49
26.5.9.2	Code on the JSF Page for a Pie Graph Theme .....	26-49
26.6	Creating Databound Thematic Maps .....	26-49
26.6.1	How to Create a Thematic Map Using ADF Data Controls .....	26-50
26.6.2	What Happens When You Use Data Controls to Create a Thematic Map .....	26-57
26.6.3	How to Add Data Layers to Thematic Maps .....	26-60
26.6.4	Styling Areas, Markers, and Images to Display Data .....	26-64
26.6.4.1	How to Style Areas to Display Data .....	26-64
26.6.4.2	How to Style Markers to Display Data .....	26-67
26.6.4.3	What You May Need to Know About Styling Markers .....	26-74
26.6.4.4	What You May Need to Know About Default Style Values for Attribute Groups ...	26-75
26.6.4.5	How to Use Images to Display Data .....	26-76
26.6.4.6	What You May Need to Know About SVG Files .....	26-79
26.6.5	What You May Need to Know About Base Map Location Ids .....	26-80
26.6.6	What You May Need to Know About Configuring Master-Detail Relationships ..	26-81
26.6.7	How to Define a Custom Map Layer .....	26-81
26.6.8	How to Configure Drilling in Thematic Maps .....	26-86
26.6.9	Creating Databound Legends .....	26-88
26.7	Creating Databound Gantt Charts .....	26-91
26.7.1	How to Create a Databound Project Gantt Chart .....	26-91
26.7.2	What Happens When You Create a Project Gantt Chart from a Data Control .....	26-95
26.7.3	What You May Need to Know About Summary Tasks in a Project Gantt Chart ...	26-97
26.7.4	What You May Need to Know About Percent Complete in a Project Gantt Chart	26-97
26.7.5	What You May Need to Know About Variance in a Project Gantt Chart .....	26-98
26.7.6	How to Create a Databound Resource Utilization Gantt Chart .....	26-98
26.7.7	What Happens When You Create a Resource Utilization Gantt Chart .....	26-100
26.7.8	How to Create a Databound Scheduling Gantt Chart .....	26-102
26.7.9	What Happens When You Create a Scheduling Gantt Chart .....	26-105
26.8	Creating Databound Timelines .....	26-106
26.8.1	How to Create a Timeline Using ADF Data Controls .....	26-108
26.8.2	What Happens When You Use Data Controls to Create a Timeline .....	26-113
26.8.3	What You May Need to Know About Using Data Controls to Create a Dual Timeline .	26-115
26.9	Creating Databound Hierarchy Viewers .....	26-116
26.9.1	How to Create a Databound Hierarchy Viewer .....	26-117
26.9.2	What Happens When You Create a Databound Hierarchy Viewer .....	26-126
26.9.3	How to Configure an Alternate View Object for a Databound Panel Card .....	26-128
26.9.3.1	What Happens When You Use an Alternate View Object for a Hierarchy Viewer	26-132
	Panel Card .....	
26.9.4	How to Create a Databound Search in a Hierarchy Viewer .....	26-134
26.10	Creating Databound Treemaps and Sunbursts .....	26-138
26.10.1	How to Create Treemaps and Sunbursts Using ADF Data Controls .....	26-140
26.10.2	What Happens When You Create a Databound Treemap or Sunburst .....	26-146
26.10.3	What Happens at Runtime: How Databound Sunbursts or Treemaps Are Initially	26-148
	Displayed .....	

## 27 Creating ADF Databound Search Forms

27.1	Introduction to Creating Search Forms .....	27-1
27.1.1	Query Search Forms .....	27-2
27.1.2	Quick Query Search Forms .....	27-11
27.1.3	Named Bind Variables in Query Search Forms .....	27-12
27.1.4	Filtered Table and Query-by-Example Searches .....	27-13
27.1.5	Implicit and Named View Criteria .....	27-15
27.1.6	List of Values (LOV) Input Fields .....	27-15
27.2	Creating Query Search Forms .....	27-16
27.2.1	How to Create a Query Search Form with a Results Table or Tree Table .....	27-16
27.2.2	How to Create a Query Search Form and Add a Results Component Later .....	27-17
27.2.3	How to Persist Saved Searches into MDS .....	27-18
27.2.4	How to Set Default Search Binding Behavior .....	27-18
27.2.5	What You May Need to Know About Dependent Criterion .....	27-20
27.2.6	What Happens When You Create a Query Form .....	27-21
27.2.7	What Happens at Runtime: Search Forms .....	27-22
27.3	Setting Up Search Form Properties .....	27-22
27.3.1	How to Set Search Form Properties on the View Criteria .....	27-23
27.3.2	How to Add Placeholder Text, Label, and Tooltip .....	27-24
27.3.3	How to Set Search Form Properties on the Query Component .....	27-24
27.3.4	How to Set Timezone Control Hint for Timestamp Attribute .....	27-25
27.3.5	How to Create Custom Operators or Remove Standard Operators .....	27-26
27.4	Creating Quick Query Search Forms .....	27-28
27.4.1	How to Create a Quick Query Search Form with a Results Table or Tree Table ....	27-29
27.4.2	How to Create a Quick Query Search Form and Add a Results Component Later	27-29
27.4.3	How to Set the Quick Query Layout Format .....	27-30
27.4.4	What Happens When You Create a Quick Query Search Form .....	27-30
27.4.5	What Happens at Runtime: Quick Query .....	27-30
27.5	Creating Standalone Filtered Search Tables from Named View Criteria .....	27-31

## 28 Creating More Complex Pages

28.1	Introduction to More Complex Pages .....	28-1
28.2	Creating Command Components to Execute Methods .....	28-2
28.2.1	How to Create a Command Component Bound to a Custom Method .....	28-2
28.2.2	What Happens When You Create Command Components Using a Method .....	28-3
28.2.2.1	Defining Method Action Binding .....	28-3
28.2.2.2	Using Parameters in a Method .....	28-3
28.2.2.3	Adding ADF Faces Component Code to JSF Page .....	28-4
28.2.2.4	Using EL Expressions to Bind to Methods .....	28-4
28.2.2.5	Using the Return Value from a Method Call .....	28-4
28.2.3	What Happens at Runtime: Command Button Method Bindings .....	28-5
28.3	Setting Parameter Values Using a Command Component .....	28-5
28.3.1	How to Set Parameters Using setPropertyListener Within a Command Component .....	28-6
28.3.2	What Happens When You Set Parameters .....	28-6
28.3.3	What Happens at Runtime: setPropertyListener for a Command Component .....	28-7

28.4	Overriding Declarative Methods .....	28-7
28.4.1	How to Override a Declarative Method .....	28-7
28.4.2	What Happens When You Override a Declarative Method .....	28-10
28.5	Using the ADF Faces Calendar Component .....	28-11
28.5.1	How to Use the ADF Faces Calendar .....	28-13
28.5.2	What Happens When You Create a Calendar .....	28-15
28.5.3	What Happens at Runtime: How the Calendar Binding Works .....	28-17
28.6	Using the ADF Faces Carousel Component .....	28-17
28.6.1	How to Create a Databound Carousel Component .....	28-18
28.6.2	What Happens When You Create a Carousel .....	28-20
28.7	Creating Contextual Events .....	28-21
28.7.1	How to Create Contextual Events Declaratively .....	28-24
28.7.1.1	Creating Contextual Events in the Publisher .....	28-25
28.7.1.2	Subscribing to and Consuming Events .....	28-26
28.7.2	How to Create Contextual Events Manually .....	28-28
28.7.3	How to Create Contextual Event Using Managed Beans .....	28-30
28.7.4	How to Create a Contextual Event from JavaScript .....	28-31
28.7.5	How to Manually Create the Event Map .....	28-32
28.7.6	How to Register a Custom Event Dispatcher .....	28-32
28.7.7	What Happens When You Create Contextual Events .....	28-33
28.7.8	How to Control Contextual Events Dispatch .....	28-34
28.7.9	What Happens at Runtime: Contextual Events .....	28-35
28.8	Adding ADF Model Layer Validation .....	28-35
28.8.1	How to Add Validation .....	28-35
28.8.2	What Happens at Runtime: Model Validation Rules .....	28-36
28.9	Displaying Error Messages .....	28-36
28.10	Customizing Error Handling .....	28-38
28.10.1	How to Customize the Detail Portion of a Message .....	28-39
28.10.2	How to Write an Error Handler to Deal with Multiple Threads .....	28-41

## 29 Designing a Page Using Placeholder Data Controls

29.1	Introduction to Placeholder Data Controls .....	29-1
29.2	Creating Placeholder Data Controls .....	29-2
29.2.1	How to Create a Placeholder Data Control .....	29-2
29.2.2	What Happens When You Create a Placeholder Data Control .....	29-3
29.3	Creating Placeholder Data Types .....	29-4
29.3.1	How to Create a Placeholder Data Type .....	29-5
29.3.2	What Happens When You Create a Placeholder Data Type .....	29-8
29.3.3	How to Configure a Placeholder Data Type Attribute to Be an LOV .....	29-9
29.3.3.1	Configuring an Attribute to Be a Fixed LOV .....	29-9
29.3.3.2	Configuring an Attribute to Be a Dynamic LOV .....	29-10
29.3.4	How to Create Master-Detail Data Types .....	29-11
29.3.5	What Happens When You Create a Master-Detail Data Type .....	29-13
29.3.6	How to Add Sample Data .....	29-13
29.3.6.1	Adding Sample Data Manually .....	29-14
29.3.6.2	Importing Sample Data .....	29-15
29.3.7	What Happens When You Add Sample Data .....	29-15

29.4	Using Placeholder Data Controls .....	29-16
29.4.1	Limitations of Placeholder Data Controls .....	29-16
29.4.2	Creating Layout .....	29-16
29.4.3	Creating a Search Form .....	29-17
29.4.4	Binding Components .....	29-17
29.4.5	Rebinding Components .....	29-17
29.4.6	Packaging Placeholder Data Controls to ADF Library JARs .....	29-17

## Part V Completing Your Application

### 30 Enabling ADF Security in a Fusion Web Application

30.1	Introduction to ADF Security .....	30-1
30.1.1	Integration of ADF Security and Java Security .....	30-3
30.1.2	Summary of ADF Security .....	30-4
30.2	ADF Security Process Overview .....	30-6
30.3	Enabling ADF Security .....	30-9
30.3.1	How to Enable ADF Security .....	30-9
30.3.2	What Happens When You Enable ADF Security .....	30-13
30.3.3	What Happens When You Generate a Default Form-Based Login Page .....	30-17
30.3.4	What You May Need to Know About the Configure ADF Security Wizard .....	30-18
30.3.5	What You May Need to Know About ADF Authentication .....	30-18
30.3.6	What You May Need to Know About the Built-In test-all Role .....	30-18
30.3.7	What You May Need to Know About the valid-users Role .....	30-19
30.4	Creating Application Roles .....	30-19
30.4.1	How to Create Application Roles .....	30-20
30.4.2	What Happens When You Create Application Roles .....	30-20
30.4.3	What You May Need to Know About Enterprise Roles and Application Roles .....	30-21
30.5	Defining ADF Security Policies .....	30-21
30.5.1	How to Make an ADF Resource Public .....	30-22
30.5.2	What Happens When You Make an ADF Resource Public .....	30-25
30.5.3	What Happens at Runtime: How the Built-in Roles Are Used .....	30-25
30.5.4	How to Define Policies for ADF Bounded Task Flows .....	30-26
30.5.5	How to Define Policies for Web Pages That Reference a Page Definition .....	30-29
30.5.6	How to Define Policies to Control User Access to ADF Methods .....	30-33
30.5.6.1	Creating a Resource Grant to Control Access to ADF Methods .....	30-33
30.5.6.2	Enforcing the Resource Grant in the User Interface .....	30-34
30.5.7	What Happens When You Define the Security Policy .....	30-35
30.5.8	What Happens at Runtime: How ADF Security Policies Are Enforced .....	30-36
30.5.9	What You May Need to Know About Defining Policies for Pages with No ADF Bindings .....	30-37
30.5.10	How to Use Regular Expressions to Define Policies on Groups of Resources .....	30-38
30.5.11	How to Define Policies for Data .....	30-39
30.5.11.1	Defining Permission Maps on ADF Entity Objects .....	30-40
30.5.11.2	Defining Permission Maps on ADF Entity Object Attributes .....	30-41
30.5.11.3	Granting Permissions on ADF Entity Objects and Entity Attributes .....	30-42
30.5.12	How to Aggregate Resource Grants as Entitlement Grants .....	30-43
30.5.13	What Happens After You Create an Entitlement Grant .....	30-45

30.6	Creating Test Users .....	30-47
30.6.1	How to Create Test Users in JDeveloper .....	30-47
30.6.2	What Happens When You Create Test Users .....	30-49
30.6.3	How to Associate Test Users with Application Roles .....	30-50
30.6.4	What Happens When You Configure Application Roles .....	30-51
30.7	Creating a Login Page .....	30-51
30.7.1	How to Create a Login Link Component and Add it to a Public Web Page for Explicit Authentication .....	30-52
30.7.2	How to Create a Login Page Specifically for Explicit Authentication .....	30-54
30.7.2.1	Creating Login Code for the Backing Bean .....	30-54
30.7.2.2	Creating an ADF Faces-Based Login Page Specifically for Explicit Authentication .	30-58
30.7.2.3	Ensuring That the Login Page Is Public .....	30-62
30.7.3	How to Ensure That the Custom Login Page's Resources Are Accessible for Explicit Authentication .....	30-62
30.7.4	How to Create a Public Welcome Page .....	30-63
30.7.4.1	Ensuring That the Welcome Page Is Public .....	30-63
30.7.4.2	Adding Login and Logout Links .....	30-63
30.7.4.3	Hiding Links to Secured Pages .....	30-64
30.7.5	How to Redirect a User After Authentication .....	30-64
30.7.6	How to Trigger a Custom Login Page Specifically for Implicit Authentication .....	30-66
30.7.7	What You May Need to Know About ADF Servlet Logout and Browser Caching .....	30-67
30.7.8	What You May Need to Know About IBM WebSphere Application Server .....	30-67
30.7.9	What You May Need to Know About Displaying Error Pages in Internet Explorer .....	30-67
30.8	Testing Security in JDeveloper .....	30-68
30.8.1	How to Configure, Deploy, and Run a Secure Application in JDeveloper .....	30-68
30.8.2	What Happens When You Configure Security Deployment Options .....	30-69
30.8.3	How to Use the Built-In test-all Application Role .....	30-70
30.8.4	What Happens at Runtime: How ADF Security Handles Authentication .....	30-71
30.8.5	What Happens at Runtime: How ADF Security Handles Authorization .....	30-73
30.9	Preparing the Secure Application for Deployment .....	30-75
30.9.1	How to Remove the test-all Role from the Application Policy Store .....	30-76
30.9.2	How to Remove Test Users from the Application Identity Store .....	30-77
30.9.3	How to Secure Resource Files Using a URL Constraint .....	30-77
30.10	Disabling ADF Security .....	30-78
30.10.1	How to Disable ADF Security .....	30-78
30.10.2	What Happens When You Disable ADF Security .....	30-79
30.11	Advanced Topics and Best Practices .....	30-80
30.11.1	Using Expression Language (EL) with ADF Security .....	30-80
30.11.1.1	How to Evaluate Policies Using EL .....	30-80
30.11.1.2	What Happens When You Use the Expression Builder Dialog .....	30-83
30.11.1.3	What You May Need to Know About Delayed Evaluation of EL .....	30-84
30.11.2	How to Protect UI Components Using OPSS Resource Permissions and EL .....	30-84
30.11.2.1	Creating the Custom Resource Type .....	30-85
30.11.2.2	Creating a Resource Grant for a Custom Resource Type .....	30-86
30.11.2.3	Associating the Rendering of a UI Component with a Resource Grant .....	30-87
30.11.3	How to Perform Authorization Checks for Entity Object Operations .....	30-89

30.11.4	Getting Information from the ADF Context .....	30-89
30.11.4.1	How to Determine Whether Security Is Enabled .....	30-90
30.11.4.2	How to Determine Whether the User Is Authenticated .....	30-90
30.11.4.3	How to Determine the Current User Name, Tenant Name, or Tenant ID .....	30-90
30.11.4.4	How to Determine Membership of a Java EE Security Role .....	30-91
30.11.4.5	How to Determine Permission Using Java .....	30-91
30.11.5	Best Practices for Working with ADF Security .....	30-92

## 31 Testing and Debugging ADF Components

31.1	Introduction to ADF Debugging .....	31-1
31.2	Correcting Simple Oracle ADF Compilation Errors .....	31-2
31.3	Correcting Simple Oracle ADF Runtime Errors .....	31-4
31.4	Validating ADF Controller Metadata .....	31-6
31.5	Using the ADF Logger .....	31-6
31.5.1	How to Set ADF Logging Levels .....	31-7
31.5.2	How to Create an Oracle ADF Debugging Configuration .....	31-9
31.5.3	How to Turn On Diagnostic Logging for Non-Oracle ADF Loggers .....	31-11
31.5.4	How to Use the Log Analyzer to View Log Messages .....	31-11
31.5.4.1	Viewing Diagnostic Messages in the Log Analyzer .....	31-12
31.5.4.2	Using the Log Analyzer to Analyze the ADF Request .....	31-14
31.5.4.3	Sorting Diagnostic Messages By ADF Events .....	31-18
31.5.5	What You May Need to Know About the Logging.xml File .....	31-21
31.5.6	What You May Need to Know About ADF Logging and Oracle WebLogic Server .....	31-22
31.6	Using the Business Component Browser for Testing and Debugging .....	31-23
31.6.1	How to Run in Debug Mode and Test with the Business Component Browser .....	31-23
31.6.2	How to Run the Business Component Browser and Test with a Specific Configuration .....	31-24
31.6.3	What Happens When You Run the Business Component Browser in Debug Mode .....	31-24
31.6.4	How to Verify Runtime Artifacts in the Business Component Browser .....	31-25
31.6.5	How to Refresh the Business Component Browser with Application Changes .....	31-25
31.7	Using the ADF Declarative Debugger .....	31-25
31.7.1	Using ADF Source Code with the Debugger .....	31-27
31.7.2	How to Set Up the ADF Source User Library .....	31-28
31.7.3	How to Add the ADF Source Library to a Project .....	31-28
31.7.4	How to Use the EL Expression Evaluator .....	31-29
31.7.5	How to View and Export Stack Trace Information .....	31-30
31.8	Setting ADF Declarative Breakpoints .....	31-31
31.8.1	How to Set and Use Task Flow Activity Breakpoints .....	31-39
31.8.2	How to Set and Use Page Definition Executable Breakpoints .....	31-41
31.8.3	How to Set and Use Page Definition Action Binding Breakpoints .....	31-42
31.8.4	How to Set and Use Page Definition Value Binding Breakpoints .....	31-43
31.8.5	How to Set and Use ADF Lifecycle Phase Breakpoints .....	31-44
31.8.6	How to Use the ADF Structure Window .....	31-47
31.8.7	How to Use the ADF Data Window .....	31-50
31.8.8	What Happens When You Set an ADF Declarative Breakpoint .....	31-61

31.9	Setting Java Code Breakpoints .....	31-61
31.9.1	How to Set Java Breakpoints on Classes and Methods .....	31-61
31.9.2	How to Optimize Use of the Source Editor .....	31-62
31.9.3	How to Set Breakpoints and Debug Using ADF Source Code .....	31-63
31.9.4	How to Use Debug Libraries for Symbolic Debugging .....	31-63
31.9.5	How to Use Different Kinds of Java Code Breakpoints .....	31-65
31.9.6	How to Edit Breakpoints for Improved Control .....	31-66
31.9.7	How to Filter Your View of Class Members .....	31-67
31.9.8	How to Use Common Oracle ADF Breakpoints .....	31-67
31.10	Regression Testing with JUnit .....	31-68
31.10.1	How to Obtain the JUnit Extension .....	31-69
31.10.2	How to Create a JUnit Test Case .....	31-70
31.10.3	How to Create a JUnit Test Fixture .....	31-72
31.10.4	How to Create a JUnit Test Suite .....	31-72
31.10.5	How to Create a Business Components Test Suite .....	31-73
31.10.6	How to a Create Business Components Test Fixture .....	31-75
31.10.7	How to Run a JUnit Test Suite as Part of an Ant Build Script .....	31-76

## 32 Refactoring a Fusion Web Application

32.1	Introduction to Refactoring a Fusion Web Application .....	32-1
32.2	Renaming Files .....	32-1
32.3	Moving JSF Pages .....	32-2
32.4	Refactoring pagedef.xml Bindings Objects .....	32-2
32.5	Refactoring ADF Business Components .....	32-3
32.6	Refactoring ADF Business Component Object Attributes .....	32-3
32.7	Refactoring Named Elements .....	32-4
32.8	Refactoring ADF Task Flows .....	32-5
32.9	Refactoring the DataBindings.cpx File .....	32-5
32.10	Refactoring Across Abstraction Layers .....	32-6
32.11	Refactoring Limitations .....	32-6
32.12	Refactoring the .jspx Project File .....	32-7

## 33 Reusing Application Components

33.1	Introduction to Reusable Components .....	33-1
33.1.1	Creating Reusable Components .....	33-3
33.1.1.1	Naming Conventions .....	33-3
33.1.1.2	The Naming Process for the ADF Library JAR Deployment Profile .....	33-5
33.1.1.3	Keeping the Relevant Project .....	33-6
33.1.1.4	Selecting the Relevant Technology Scope .....	33-6
33.1.1.5	Selecting Paths and Folders .....	33-6
33.1.1.6	Including Connections Within Reusable Components .....	33-6
33.1.2	Using the Resource Palette .....	33-7
33.1.3	Extension Libraries .....	33-8
33.2	Packaging a Reusable ADF Component into an ADF Library .....	33-11
33.2.1	How to Package a Component into an ADF Library JAR .....	33-12
33.2.2	What Happens When You Package a Project to an ADF Library JAR .....	33-16
33.2.2.1	Application Modules .....	33-16

33.2.2.2	Data Controls .....	33-17
33.2.2.3	Task Flows .....	33-17
33.2.2.4	Page Templates .....	33-17
33.2.2.5	Declarative Components .....	33-17
33.2.3	How to Place and Access JDeveloper JAR Files .....	33-17
33.3	Adding ADF Library Components into Projects .....	33-18
33.3.1	How to Add an ADF Library JAR into a Project using the Resource Palette .....	33-18
33.3.2	How to Add an ADF Library JAR into a Project Manually .....	33-20
33.3.3	What Happens When You Add an ADF Library JAR to a Project .....	33-21
33.3.4	What You May Need to Know About Using ADF Library Components .....	33-23
33.3.4.1	Using Data Controls .....	33-24
33.3.4.2	Using Application Modules .....	33-24
33.3.4.3	Using Business Components .....	33-24
33.3.4.4	Using Task Flows .....	33-25
33.3.4.5	Using Page Templates .....	33-25
33.3.4.6	Using Declarative Components .....	33-26
33.3.5	What You May Need to Know About Differentiating ADF Library Components .....	33-26
33.3.6	What Happens at Runtime: Adding ADF Libraries .....	33-26
33.4	Removing an ADF Library JAR from a Project .....	33-27
33.4.1	How to Remove an ADF Library JAR from a Project Using the Resource Palette .....	33-27
33.4.2	How to Remove an ADF Library JAR from a Project Manually .....	33-27

## 34 Customizing Applications with MDS

34.1	Introduction to Customization and MDS .....	34-1
34.1.1	Customizations and Layers .....	34-2
34.1.2	Static and Dynamic Customization Content .....	34-3
34.2	Developing a Customizable Application .....	34-4
34.2.1	How to Create Customization Classes .....	34-4
34.2.1.1	Customization Classes .....	34-4
34.2.1.2	Implementing the getValue() Method in Your Customization Class .....	34-6
34.2.1.3	Creating a Customization Class .....	34-8
34.2.2	What You May Need to Know About Customization Classes .....	34-9
34.2.3	How to Consume Customization Classes .....	34-10
34.2.3.1	Making Customization Classes Available to JDeveloper .....	34-10
34.2.3.2	Consuming Customization Classes from an Extension Project .....	34-11
34.2.4	How to Enable Seeded Customizations for View Projects .....	34-11
34.2.5	How to Enable Seeded Customizations in Existing Pages .....	34-12
34.2.6	How to Enable Customizations in Resource Bundles .....	34-13
34.2.7	How to Configure the adf-config.xml file .....	34-13
34.2.8	What Happens When You Create a Customizable Application .....	34-14
34.2.9	What You May Need to Know About Customizable Objects and Applications .....	34-15
34.3	Customizing an Application .....	34-15
34.3.1	Introducing the Customization Developer Role .....	34-15
34.3.2	How to Switch to the Customization Developer Role in JDeveloper .....	34-16
34.3.3	Introducing the Tip Layer .....	34-16
34.3.4	How to Configure Customization Layers .....	34-17
34.3.4.1	Configuring Layer Values Globally .....	34-18

34.3.4.2	Configuring Workspace-Level Layer Values from the adf-config Editor .....	34-18
34.3.4.3	Configuring Workspace-Level Layer Values from the Customization Context Window .....	34-19
34.3.5	How to Customize Metadata in JDeveloper .....	34-20
34.3.6	How to Fix Incongruencies Between the Tip Layer and Base Metadata .....	34-21
34.3.7	What Happens When You Customize an Application .....	34-22
34.3.8	How to Customize Business Logic using Groovy Triggers .....	34-22
34.3.9	How to Customize ADF Library Artifacts in JDeveloper .....	34-23
34.3.9.1	Specifying a Location for ADF Library Customizations .....	34-24
34.3.9.2	Viewing ADF Library Runtime Customizations from Exported JARs .....	34-24
34.3.10	What Happens When You Customize ADF Library Artifacts .....	34-25
34.3.11	How to Package and Deploy Customized Applications .....	34-26
34.3.11.1	Implicitly Creating a MAR .....	34-26
34.3.11.2	Explicitly Creating a MAR .....	34-27
34.3.12	What Happens at Runtime in a Customized Application .....	34-28
34.3.13	What You May Need to Know About Customized Applications .....	34-28
34.3.13.1	Customization and Integrated Source Control .....	34-28
34.3.13.2	Editing Resource Bundles in Customized Applications .....	34-28
34.4	Extended Metadata Properties .....	34-29
34.4.1	How to Edit Extended Metadata Properties .....	34-30
34.4.2	How to Enable Customization for Design Time at Runtime .....	34-30
34.5	Enabling Runtime Modification of Customization Configuration .....	34-32

## 35 Allowing User Customizations at Runtime

35.1	Introduction to Allowing User Customizations .....	35-1
35.2	Enabling Runtime User Customizations for a Fusion Web Application .....	35-6
35.2.1	How to Enable User Customizations .....	35-6
35.2.2	What Happens When You Enable User Customizations .....	35-7
35.3	Configuring User Customizations .....	35-8
35.3.1	How to Configure Change Persistence .....	35-9
35.3.2	What Happens When You Configure Change Persistence .....	35-10
35.4	Controlling User Customizations in Individual JSF Pages .....	35-10
35.4.1	How to Implement User Customizations on a JSF Page .....	35-11
35.4.2	What Happens at Runtime: How Changes Are Persisted and Restored .....	35-12
35.4.3	What You May Need to Know About Using Change Persistence on Templates, Regions, and Declarative Components .....	35-12
35.5	Implementing Custom User Customizations .....	35-13
35.5.1	Change Persistence Framework API .....	35-14
35.5.2	How to Create Code for Custom User Customizations .....	35-15
35.6	Creating Implicit Change Persistence in Custom Components .....	35-19
35.6.1	How to Set Implicit Change Persistence For Attribute Values that Use Events .....	35-19
35.6.2	How to Set Implicit Change Persistence For Other Attribute Values .....	35-20

## 36 Deploying Fusion Web Applications

36.1	Introduction to Deploying Fusion Web Applications .....	36-1
36.1.1	Developing Applications with Integrated WebLogic Server .....	36-3
36.1.2	Developing Applications to Deploy to Standalone Application Servers .....	36-3

36.2	Running an ADF Application in Integrated WebLogic Server .....	36-5
36.2.1	How to Run an Application in Integrated WebLogic Server .....	36-6
36.2.2	How to Run an Application with Metadata in Integrated WebLogic Server .....	36-6
36.3	Preparing the Application .....	36-8
36.3.1	How to Create a Connection to the Target Application Server .....	36-9
36.3.2	How to Create Deployment Profiles .....	36-11
36.3.2.1	Adding Customization Classes into a JAR .....	36-12
36.3.2.2	Creating a WAR Deployment Profile .....	36-13
36.3.2.3	Creating a MAR Deployment Profile .....	36-14
36.3.2.4	Creating an Application-Level EAR Deployment Profile .....	36-16
36.3.2.5	Delivering Customization Classes as a Shared Library .....	36-17
36.3.2.6	Viewing and Changing Deployment Profile Properties .....	36-18
36.3.3	How to Create and Edit Deployment Descriptors .....	36-18
36.3.3.1	Creating Deployment Descriptors .....	36-20
36.3.3.2	Viewing or Modifying Deployment Descriptor Properties .....	36-20
36.3.3.3	Configuring the application.xml File for Application Server Compatibility ...	36-21
36.3.3.4	Configuring the web.xml File for Application Server Compatibility .....	36-21
36.3.3.5	Enabling the Application for Real User Experience Insight .....	36-21
36.3.4	How to Deploy Applications with ADF Security Enabled .....	36-22
36.3.4.1	Applications That Will Run Using Oracle Single Sign-On (SSO) .....	36-22
36.3.4.2	Configuring Security for WebLogic Server .....	36-23
36.3.4.3	Configuring Security for WebSphere Server .....	36-25
36.3.5	How to Replicate Memory Scopes in a Clustered Environment .....	36-26
36.3.6	How to Enable the Application for ADF MBeans .....	36-26
36.3.7	What You May Need to Know About JDBC Data Source for Oracle WebLogic Server ..	36-27
36.4	Deploying the Application .....	36-29
36.4.1	How to Deploy to the Application Server from JDeveloper .....	36-32
36.4.2	How to Create an EAR File for Deployment .....	36-34
36.4.3	What You May Need to Know About EAR Files and Packaging .....	36-35
36.4.4	How to Deploy the Application Using Scripts and Ant .....	36-35
36.4.5	How to Deploy New Customizations Applied to ADF Library .....	36-35
36.4.5.1	Exporting Customization to a Deployed Application .....	36-36
36.4.5.2	Deploying Customizations to a JAR .....	36-36
36.4.6	What You May Need to Know About ADF Libraries .....	36-37
36.4.7	How to Deploy ADF Faces JARs with the Application .....	36-37
36.4.8	What You May Need to Know About JDeveloper Runtime Libraries .....	36-38
36.5	Postdeployment Configuration .....	36-38
36.5.1	How to Migrate an Application .....	36-38
36.5.2	How to Configure the Application Using ADF MBeans .....	36-38
36.6	Testing the Application and Verifying Deployment .....	36-38

## Part VI Advanced Topics

### 37 Advanced Business Components Techniques

37.1	Extending the ADF Business Components Framework .....	37-1
37.1.1	How To Create a Framework Extension Class .....	37-2

37.1.2	What Happens When You Create a Framework Extension Class .....	37-3
37.1.3	What You May Need to Know About Customizing Framework Extension Bases Classes .....	37-4
37.1.4	How to Base an ADF Component on a Framework Extension Class .....	37-4
37.1.5	How to Define Framework Extension Classes for All New Components .....	37-6
37.1.6	How to Define Framework Extension Classes for All New Projects .....	37-7
37.1.7	What Happens When You Base a Component on a Framework Extension Class ...	37-7
37.1.7.1	XML-Only Components .....	37-7
37.1.7.2	Components with Custom Java Classes .....	37-8
37.1.8	What You May Need to Know About Updating the Extends Clause in Custom Component Java Files .....	37-9
37.1.9	How to Package Your Framework Extension Layer in a JAR File .....	37-9
37.1.10	How to Create a Library Definition for Your Framework Extension JAR File .....	37-10
37.2	Customizing Framework Behavior with Extension Classes .....	37-11
37.2.1	How to Access Runtime Metadata For View Objects and Entity Objects .....	37-11
37.2.2	How to Implement Generic Functionality Using Runtime Metadata .....	37-12
37.2.3	How to Implement Generic Functionality Driven by Custom Properties .....	37-13
37.2.4	How to Configure Design Time Custom Property Names .....	37-14
37.2.5	What You May Need to Know About the Kinds of Attributes .....	37-14
37.2.6	What You May Need to Know About Custom Properties .....	37-14
37.3	Creating Generic Extension Interfaces .....	37-14
37.4	Invoking Stored Procedures and Functions .....	37-17
37.4.1	How to Invoke Stored Procedures with No Arguments .....	37-17
37.4.2	How to Invoke Stored Procedure with Only IN Arguments .....	37-17
37.4.3	How to Invoke Stored Function with Only IN Arguments .....	37-19
37.4.4	How to Call Other Types of Stored Procedures .....	37-20
37.5	Accessing the Current Database Transaction .....	37-22
37.6	Working with Libraries of Reusable Business Components .....	37-22
37.6.1	How To Create a Reusable Library of Business Components .....	37-22
37.6.2	How To Import a Package of Reusable Components from a Library .....	37-24
37.6.3	How to Remove an Imported Package from a Project .....	37-25
37.6.4	What Happens When You Import a Package of Reusable Components from a Library .	37-25
37.6.5	What You May Need to Know About Imported Projects .....	37-25
37.7	Customizing Business Components Error Messages .....	37-26
37.7.1	How to Customize Base ADF Business Components Error Messages .....	37-26
37.7.2	What Happens When You Customize Base ADF Business Components Error Messages .....	37-28
37.7.3	How to Display Customize Error Messages as Nested Exceptions .....	37-28
37.7.4	How to Customize Error Messages for Database Constraint Violations .....	37-30
37.7.5	How to Implement a Custom Constraint Error Handling Routine .....	37-30
37.7.5.1	Creating a Custom Database Transaction Framework Extension Class .....	37-30
37.7.5.2	Configuring an Application Module to Use a Custom Database Transaction Class 37-31	
37.8	Creating Extended Components Using Inheritance .....	37-32
37.8.1	How To Create a Component That Extends Another .....	37-33
37.8.2	How To Extend a Component After Creation .....	37-33
37.8.3	What Happens When You Create a Component That Extends Another .....	37-33

37.8.3.1	Attributes in an Extended Component Inherited from the Parent Component .....	37-33
37.8.3.2	Attributes Added to the Extended Component's XML Descriptor .....	37-34
37.8.3.3	Java Classes Generated for an Extended Component .....	37-35
37.8.4	What You May Need to Know About Extending Components .....	37-35
37.8.4.1	Parent Classes and Interfaces for Extended Components .....	37-35
37.8.4.2	Generated Classes for Extended Components .....	37-37
37.8.4.3	Business Component Types .....	37-37
37.8.4.4	New Attributes in an Extended Component .....	37-37
37.9	Substituting Extended Components in a Delivered Application .....	37-38
37.9.1	How To Substitute an Extended Component .....	37-39
37.9.2	What Happens When You Substitute .....	37-39
37.9.3	How to Enable the Substituted Components in the Base Application .....	37-40

## 38 Advanced Entity Object Techniques

38.1	Creating Custom, Validated Data Types Using Domains .....	38-1
38.1.1	How to Create a Domain .....	38-2
38.1.2	What Happens When You Create a Domain .....	38-2
38.1.3	What You May Need to Know About Domains .....	38-3
38.1.3.1	Using Domains for Entity and View Object Attributes .....	38-3
38.1.3.2	Validate Method Should Throw DataCreationException If Sanity Checks Fail .....	38-3
38.1.3.3	String Domains Aggregate a String Value .....	38-4
38.1.3.4	Other Domains Extend Existing Domain Type .....	38-4
38.1.3.5	Simple Domains Are Immutable Java Classes .....	38-5
38.1.3.6	Creating Domains for Oracle Object Types When Useful .....	38-5
38.1.3.7	Quickly Navigating to the Domain Class .....	38-6
38.1.3.8	Domains Get Packaged in the Common JAR .....	38-6
38.1.3.9	Entity and View Object Attributes Inherit Custom Domain Properties .....	38-6
38.1.3.10	Domain Settings Cannot Be Less Restrictive at Entity or View Level .....	38-7
38.2	Updating a Deleted Flag Instead of Deleting Rows .....	38-7
38.2.1	How to Update a Deleted Flag When a Row Is Removed .....	38-7
38.2.2	Forcing an Update DML Operation Instead of a Delete .....	38-7
38.3	Using Update Batching .....	38-8
38.4	Advanced Entity Association Techniques .....	38-9
38.4.1	Modifying Association SQL Clause to Implement Complex Associations .....	38-9
38.4.2	Exposing View Link Accessor Attributes at the Entity Level .....	38-10
38.5	Basing an Entity Object on a PL/SQL Package API .....	38-10
38.5.1	How to Create an Entity Object Based on a View .....	38-11
38.5.2	What Happens When You Create an Entity Object Based on a View .....	38-11
38.5.3	Centralizing Details for PL/SQL-Based Entities into a Base Class .....	38-12
38.5.4	Implementing the Stored Procedure Calls for DML Operations .....	38-13
38.5.5	Adding Select and Lock Handling .....	38-14
38.5.5.1	Updating PLSQLEntityImpl Base Class to Handle Lock and Select .....	38-14
38.5.5.2	Implementing Lock and Select for the Product Entity .....	38-15
38.5.5.3	Refreshing the Entity Object After RowInconsistentException .....	38-18
38.6	Basing an Entity Object on a Join View or Remote DBLink .....	38-18
38.7	Using Inheritance in Your Business Domain Layer .....	38-19

38.7.1	Understanding When Inheritance Can Be Useful .....	38-19
38.7.2	How to Create Entity Objects in an Inheritance Hierarchy .....	38-20
38.7.2.1	Start by Identifying the Discriminator Column and Distinct Values .....	38-20
38.7.2.2	Identify the Subset of Attributes Relevant to Each Kind of Entity .....	38-21
38.7.2.3	Creating the Base Entity Object in an Inheritance Hierarchy .....	38-21
38.7.2.4	Creating a Subtype Entity Object in an Inheritance Hierarchy .....	38-22
38.7.3	How to Add Methods to Entity Objects in an Inheritance Hierarchy .....	38-23
38.7.3.1	Adding Methods Common to All Entity Objects in the Hierarchy .....	38-23
38.7.3.2	Overriding Common Methods in a Subtype Entity .....	38-23
38.7.3.3	Adding Methods Specific to a Subtype Entity .....	38-24
38.7.4	What You May Need to Know About Using Inheritance .....	38-24
38.7.4.1	Sometimes You Need to Introduce a New Base Entity .....	38-24
38.7.4.2	Finding Subtype Entities by Primary Key .....	38-24
38.7.4.3	You Can Create View Objects with Polymorphic Entity Usages .....	38-25
38.8	Controlling Entity Posting Order to Avoid Constraint Violations .....	38-25
38.8.1	Understanding the Default Post Processing Order .....	38-25
38.8.2	How Compositions Change the Default Processing Ordering .....	38-25
38.8.3	Overriding postChanges() to Control Post Order .....	38-25
38.8.3.1	Observing the Post Ordering Problem First Hand .....	38-25
38.8.3.2	Forcing the Supplier to Post Before the Product .....	38-27
38.8.3.3	Understanding Associations Based on DBSequence-Valued Primary Keys ....	38-29
38.8.3.4	Refreshing References to DBSequence-Assigned Foreign Keys .....	38-29
38.9	Implementing Custom Validation Rules .....	38-30
38.9.1	How to Create a Custom Validation Rule .....	38-30
38.9.2	Adding a Design Time Bean Customizer for Your Rule .....	38-32
38.9.3	Registering and Using a Custom Rule in JDeveloper .....	38-33
38.10	Creating New History Types .....	38-33
38.10.1	How to Create New History Types .....	38-34
38.10.2	How to Remove a History Type .....	38-35

## 39 Advanced View Object Techniques

39.1	Advanced View Object Concepts and Features .....	39-1
39.1.1	Limiting the View Object Max Fetch Size to Fetch the First n Rows .....	39-1
39.1.2	Maintaining New Row Consistency in View Objects Based on the Same Entity .....	39-2
39.1.2.1	What Happens at Runtime When View Link Consistency is Enabled .....	39-3
39.1.2.2	How to Change the Default View Link Consistency Setting .....	39-3
39.1.2.3	How to Use a RowMatch to Qualify Which New, Unposted Rows Get Added to a Row Set .....	39-4
39.1.2.4	What You May Need to Know About the Dynamic WHERE Clause and View Link Consistency .....	39-5
39.1.3	Understanding View Link Accessors Versus Data Model View Link Instances .....	39-5
39.1.3.1	Enabling a Dynamic Detail Row Set with Active Master-Detail Coordination .	39-5
39.1.3.2	Accessing a Stable Detail Row Set Using View Link Accessor Attributes .....	39-6
39.1.3.3	Accessor Attributes Create Distinct Row Sets Based on an Internal View Object ....	39-6
39.1.4	Presenting and Scrolling Data a Page at a Time Using the Range .....	39-7
39.1.5	Efficiently Scrolling Through Large Result Sets Using Range Paging .....	39-8

39.1.5.1	Understanding How to Oracle Supports "TOP-N" Queries .....	39-9
39.1.5.2	How to Enable Range Paging for a View Object .....	39-10
39.1.5.3	What Happens When You Enable Range Paging .....	39-11
39.1.5.4	What Happens When View Rows are Cached When Using Range Paging .....	39-12
39.1.5.5	How to Scroll to a Given Page Number Using Range Paging .....	39-12
39.1.5.6	Estimating the Number of Pages in the Row Set Using Range Paging .....	39-12
39.1.5.7	Understanding the Tradeoffs of Using a Range Paging Mode .....	39-12
39.1.6	Setting Up a Data Model with Multiple Masters .....	39-13
39.1.7	Understanding When You Can Use Partial Keys with findByKey() .....	39-14
39.1.8	Creating Dynamic Attributes to Store UI State .....	39-15
39.1.9	Working with Multiple Row Sets and Row Set Iterators .....	39-15
39.1.10	Optimizing View Link Accessor Access By Retaining the Row Set .....	39-16
39.2	Tuning Your View Objects for Best Performance .....	39-17
39.2.1	Use Bind Variables for Parameterized Queries .....	39-17
39.2.1.1	Use Bind Variables to Avoid Re-parsing of Queries .....	39-17
39.2.1.2	Use Bind Variables to Prevent SQL-Injection Attacks .....	39-18
39.2.2	Consider Using Entity-Based View Objects for Read-Only Data .....	39-18
39.2.3	Use SQL Tracing to Identify Ill-Performing Queries .....	39-20
39.2.4	Consider the Appropriate Tuning Settings for Every View Object .....	39-21
39.2.4.1	Set the Database Retrieval Options Appropriately .....	39-22
39.2.4.2	Consider Whether Fetching One Row at a Time is Appropriate .....	39-22
39.2.4.3	Specify a Query Optimizer Hint if Necessary .....	39-22
39.2.5	Creating View Objects at Design Time .....	39-23
39.2.6	Use Forward Only Mode to Avoid Caching View Rows .....	39-23
39.3	Generating Custom Java Classes for a View Object .....	39-24
39.3.1	How To Generate Custom Classes .....	39-24
39.3.1.1	Generating Bind Variable Accessors .....	39-25
39.3.1.2	Generating View Row Attribute Accessors .....	39-25
39.3.1.3	Exposing View Row Accessors to Clients .....	39-26
39.3.1.4	Configuring Default Java Generation Preferences .....	39-27
39.3.2	What Happens When You Generate Custom Classes .....	39-27
39.3.2.1	Seeing and Navigating to Custom Java Files .....	39-28
39.3.3	What You May Need to Know About Custom Classes .....	39-28
39.3.3.1	About the Framework Base Classes for a View Object .....	39-28
39.3.3.2	You Can Safely Add Code to the Custom Component File .....	39-28
39.3.3.3	Attribute Indexes and InvokeAccessor Generated Code .....	39-29
39.3.3.4	Avoid Creating Dependencies on Parent Application Module Types .....	39-30
39.4	Working Programmatically with Multiple Named View Criteria .....	39-31
39.4.1	Applying One or More Named View Criteria .....	39-31
39.4.2	Removing All Applied Named View Criteria .....	39-32
39.4.3	Using the Named Criteria at Runtime .....	39-33
39.5	Performing In-Memory Sorting and Filtering of Row Sets .....	39-34
39.5.1	Understanding the View Object's SQL Mode .....	39-34
39.5.2	Sorting View Object Rows In Memory .....	39-35
39.5.2.1	Combining setSortBy and setQueryMode for In-Memory Sorting .....	39-35
39.5.2.2	Simplified In-Memory Sorting .....	39-37
39.5.2.3	Extensibility Points for In-Memory Sorting .....	39-37

39.5.3	Performing In-Memory Filtering with View Criteria .....	39-38
39.5.4	Performing In-Memory Filtering with RowMatch .....	39-40
39.5.4.1	Applying a RowMatch to a View Object .....	39-41
39.5.4.2	Using RowMatch to Test an Individual Row .....	39-42
39.5.4.3	How a RowMatch Affects Rows Fetched from the Database .....	39-42
39.6	Using View Objects to Work with Multiple Row Types .....	39-42
39.6.1	Working with Polymorphic Entity Usages .....	39-43
39.6.2	How To Create a View Object with a Polymorphic Entity Usage .....	39-43
39.6.3	What Happens When You Create a View Object with a Polymorphic Entity Usage .....	39-46
39.6.4	What You May Need to Know About Entity Usages .....	39-47
39.6.4.1	Your Query Must Limit Rows to Expected Entity Subtypes .....	39-47
39.6.4.2	Exposing Selected Entity Methods in View Rows Using Delegation .....	39-47
39.6.4.3	Creating New Rows With the Desired Entity Subtype .....	39-48
39.6.5	Working with Polymorphic View Rows .....	39-49
39.6.6	How to Create a View Object with Polymorphic View Rows .....	39-50
39.6.7	What You May Need to Know About Polymorphic View Rows .....	39-51
39.6.7.1	Selecting Subtype-Specific Attributes in Extended View Objects .....	39-51
39.6.7.2	Delegating to Subtype-Specific Methods After Overriding the Entity Usage .....	39-52
39.6.7.3	Working with Different View Row Interface Types in Client Code .....	39-52
39.6.7.4	Polymorphic Entity Usage and Polymorphic View Rows Usages .....	39-53
39.7	Reading and Writing XML .....	39-54
39.7.1	How to Produce XML for Queried Data .....	39-54
39.7.2	What Happens When You Produce XML .....	39-55
39.7.3	What You May Need to Know About Reading and Writing XML .....	39-57
39.7.3.1	Controlling XML Element Names .....	39-57
39.7.3.2	Controlling Element Suppression for Null-Valued Attributes .....	39-58
39.7.3.3	Printing or Searching the Generated XML Using XPath .....	39-58
39.7.3.4	Using the Attribute Map For Fine Control Over Generated XML .....	39-58
39.7.3.5	Use the Attribute Map Approach with Bi-Directional View Links .....	39-60
39.7.3.6	Transforming Generated XML Using an XSLT Stylesheet .....	39-60
39.7.3.7	Generating XML for a Single Row .....	39-62
39.7.4	How to Consume XML Documents to Apply Changes .....	39-62
39.7.5	What Happens When You Consume XML Documents .....	39-62
39.7.5.1	How ViewObject.readXML() Processes an XML Document .....	39-62
39.7.5.2	Using readXML() to Processes XML for a Single Row .....	39-63
39.8	Using Programmatic View Objects for Alternative Data Sources .....	39-66
39.8.1	How to Create a Read-Only Programmatic View Object .....	39-67
39.8.2	How to Create an Entity-Based Programmatic View Object .....	39-67
39.8.3	Key Framework Methods to Override for Programmatic View Objects .....	39-67
39.8.4	How to Create a View Object on a REF CURSOR .....	39-68
39.8.4.1	The Overridden create() Method .....	39-69
39.8.4.2	The Overridden executeQueryForCollection() Method .....	39-69
39.8.4.3	The Overridden createRowFromResultSet() Method .....	39-70
39.8.4.4	The Overridden hasNextForCollectionMethod() .....	39-70
39.8.4.5	The Overridden releaseUserDataForCollection() Method .....	39-71
39.8.4.6	The Overridden getQueryHitCount() Method .....	39-71
39.9	Creating a View Object with Multiple Updatable Entities .....	39-72

39.10	Programmatically Creating View Definitions and View Objects .....	39-74
39.11	Declaratively Preventing Insert, Update, and Delete .....	39-76

## 40 Application State Management

40.1	Understanding Why State Management is Necessary .....	40-1
40.1.1	Examples of Multi-Step Tasks .....	40-1
40.1.2	Stateless HTTP Protocol Complicates Stateful Applications .....	40-2
40.1.3	How Cookies Are Used to Track a User Session .....	40-2
40.1.4	Performance and Reliability Impact of Using HttpSession .....	40-3
40.2	Introduction to Fusion Web Application State Management .....	40-5
40.2.1	Basic Architecture of the Save for Later Facility .....	40-5
40.2.2	Basic Architecture of the Application Module State Management Facility .....	40-5
40.2.2.1	Understanding When Passivation and Activation Occurs .....	40-6
40.2.2.2	How Passivation Changes When Optional Failover Mode is Enabled .....	40-8
40.2.2.3	About State Management Release Levels .....	40-9
40.2.2.4	State Management and Subclassed Entity Objects .....	40-11
40.2.3	What You May Need to Know About Using Application Scoped Managed Beans in a Clustered Environment .....	40-11
40.3	Using Save For Later .....	40-11
40.4	Setting the Application Module Release Level at Runtime .....	40-12
40.4.1	How to Set Unmanaged Level .....	40-12
40.4.2	How to Set Reserved Level .....	40-12
40.4.3	How to Set Managed Level .....	40-12
40.4.4	How to Set Release Level in a JSF Backing Bean .....	40-12
40.4.5	How to Set Release Level in an ADF PagePhaseListener .....	40-13
40.4.6	How to Set Release Level in an ADF PageController .....	40-13
40.4.7	How to Set Release Level in a Custom ADF PageLifecycle .....	40-14
40.5	What Model State Is Saved and When It Is Cleaned Up .....	40-15
40.5.1	State Information Saved During Passivation .....	40-15
40.5.2	Where the Model State Is Saved .....	40-16
40.5.2.1	How Database-Backed Passivation Works .....	40-16
40.5.2.2	Controlling the Schema Where the State Management Table Resides .....	40-16
40.5.2.3	Configuring the Type of Passivation Store .....	40-17
40.5.3	Cleaning Up the Model State .....	40-17
40.5.3.1	Previous Snapshot Removed When Next One Taken .....	40-17
40.5.3.2	Passivation Snapshot Removed on Unmanaged Release .....	40-18
40.5.3.3	Passivation Snapshot Retained in Failover Mode .....	40-18
40.5.4	Cleaning Up Temporary Storage Tables .....	40-18
40.6	Timing Out the HttpSession .....	40-19
40.6.1	How to Configure the Implicit Timeout Due to User Inactivity .....	40-19
40.6.2	How to Code an Explicit HttpSession Timeout .....	40-19
40.7	Managing Custom User-Specific Information .....	40-20
40.7.1	How to Passivate Custom User-Specific Information .....	40-20
40.7.2	What Happens When You Passivate Custom Information .....	40-21
40.7.3	What You May Need to Know About Activating Custom Information .....	40-22
40.8	Managing the State of View Objects .....	40-22
40.8.1	How to Manage the State of View Objects .....	40-22

40.8.2	What You May Need to Know About Passivating View Objects .....	40-23
40.8.3	How to Manage the State of Transient View Objects and Attributes .....	40-23
40.8.4	What You May Need to Know About Passivating Transient View Objects .....	40-23
40.8.5	How to Use Transient View Objects to Store Session-level Global Variables .....	40-23
40.9	Using State Management for Middle-Tier Savepoints .....	40-25
40.9.1	How to Use State Management for Savepoints .....	40-25
40.10	Testing to Ensure Your Application Module is Activation-Safe .....	40-25
40.10.1	Understanding the jbo.ampool.doampooling Configuration Parameter .....	40-25
40.10.2	Disabling Application Module Pooling to Test Activation .....	40-26
40.11	Keeping Pending Changes in the Middle Tier .....	40-26
40.11.1	How to Set Applications to Use Optimistic Locking .....	40-27
40.11.2	How to Avoid Clashes Using the postChanges() Method .....	40-28
40.11.3	How to Use the Reserved Level For Pending Database States .....	40-28

## 41 Tuning Application Module Pools and Connection Pools

41.1	Introduction to Application Module Pooling .....	41-1
41.1.1	Types of Pools Created When Running the Fusion Web Application .....	41-2
41.1.1.1	Application Module Pools .....	41-2
41.1.1.2	Database Connection Pools .....	41-2
41.1.2	Understanding Application Module and Connection Pools .....	41-3
41.1.2.1	Single Oracle WebLogic Server Domain, Single Oracle WebLogic Server Instance, Single JVM .....	41-3
41.1.2.2	Multiple Oracle WebLogic Server Domains, Multiple Oracle WebLogic Server Instance, Multiple JVMs .....	41-4
41.2	Setting Pool Configuration Parameters .....	41-5
41.2.1	How to Set Configuration Properties Declaratively .....	41-5
41.2.2	What Happens When You Set Configuration Properties Declaratively .....	41-5
41.2.3	How to Set Configuration Properties as System Parameters .....	41-7
41.2.4	How to Programmatically Set Configuration Properties .....	41-7
41.2.5	What You May Need to Know About Configuration Property Scopes .....	41-8
41.2.6	What You May Need to Know About How Database and Application Module Pools Cooperate .....	41-10
41.2.7	What You May Need to Know About Application Module Pool Parameters .....	41-11
41.2.7.1	Pool Behavior Parameters .....	41-11
41.2.7.2	Pool Sizing Parameters .....	41-14
41.2.7.3	Pool Cleanup Parameters .....	41-15
41.2.8	What You May Need to Know About Data Source Configuration .....	41-18
41.2.9	What You May Need to Know About Database Connection Pool Parameters .....	41-19
41.3	Initializing Database State and Pooling Considerations .....	41-21
41.3.1	How to Set Database State Per User .....	41-21
41.3.2	What You May Need to Know About Optimizing Connection Pooling .....	41-22

## 42 Using the Active Data Service

42.1	Introduction to the Active Data Service .....	42-1
42.1.1	Limitations of the Active Data Service Framework .....	42-2
42.1.2	Active Data Service Framework .....	42-2
42.1.3	Data Transport Modes .....	42-4

42.2	Configuring the Active Data Service .....	42-5
42.2.1	How to Configure the Active Data Service .....	42-6
42.2.2	What You May Need to Know About Transport Modes .....	42-7
42.2.3	How to Configure Session Timeout for Active Data Service .....	42-9
42.3	Configuring Components to Use the Active Data Service .....	42-10
42.3.1	How to Configure Components to Use the Active Data Service Without the Active Data Proxy .....	42-11
42.3.2	How to Configure Components to Use the Active Data Service with the Active Data Proxy .....	42-11
42.3.3	What You May Need to Know About Displaying Active Data in ADF Trees .....	42-12
42.3.4	What Happens at Runtime: How Components Render When Bound to Active Data .....	42-12
42.3.5	What You May Need to Know About ADS and Google Chrome .....	42-12
42.4	Using the Active Data Proxy .....	42-13
42.4.1	What You May Need to Know About Read Consistency .....	42-18
42.5	Using the Active Data with a Scalar Model .....	42-18

## B Oracle ADF Binding Properties

## C Oracle ADF Permission Grants

## D ADF Equivalents of Common Oracle Forms Triggers

D.1	Validation and Defaulting (Business Logic)	D-1
D.2	Query Processing	D-2
D.3	Database Connection	D-3
D.4	Transaction "Post" Processing (Record Cache)	D-3
D.5	Error Handling	D-4

## E Most Commonly Used ADF Business Components Methods

E.1	Most Commonly Used Methods in the Client Tier	E-1
E.1.1	ApplicationModule Interface	E-1
E.1.2	Transaction Interface	E-3
E.1.3	ViewObject Interface	E-3
E.1.4	RowSet Interface	E-5
E.1.5	RowSetIterator Interface	E-6
E.1.6	Row Interface	E-7
E.1.7	StructureDef Interface	E-8
E.1.8	AttributeDef Interface	E-8
E.1.9	AttributeHints Interface	E-9
E.2	Most Commonly Used Methods in the Business Service Tier	E-10
E.2.1	Controlling Custom Java Files for Your Components	E-10
E.2.2	ApplicationModuleImpl Class	E-11
E.2.2.1	Methods You Typically Call on ApplicationModuleImpl	E-11
E.2.2.2	Methods You Typically Write in Your Custom ApplicationModuleImpl Subclass .. E-11	E-11
E.2.2.3	Methods You Typically Override in Your Custom ApplicationModuleImpl Subclass	E-12
E.2.3	DBTransactionImpl2 Class	E-13
E.2.3.1	Methods You Typically Call on DBTransaction	E-13
E.2.3.2	Methods You Typically Override in Your Custom DBTransactionImpl2 Subclass .. E-14	E-14
E.2.4	EntityImpl Class	E-15
E.2.4.1	Methods You Typically Call on EntityImpl	E-15
E.2.4.2	Methods You Typically Write in Your Custom EntityImpl Subclass	E-16
E.2.4.3	Methods You Typically Override in Your Custom EntityImpl Subclass	E-16
E.2.5	EntityDefImpl Class	E-17
E.2.5.1	Methods You Typically Call on EntityDefImpl	E-18
E.2.5.2	Methods You Typically Write in Your Custom EntityDefImpl Class	E-18
E.2.5.3	Methods You Typically Override in Your Custom EntityDefImpl	E-19
E.2.6	ViewObjectImpl Class	E-19
E.2.6.1	Methods You Typically Call on ViewObjectImpl	E-19
E.2.6.2	Methods You Typically Write in Your Custom ViewObjectImpl Subclass	E-20
E.2.6.3	Methods You Typically Override in Your Custom ViewObjectImpl Subclass ..	E-21
E.2.7	ViewRowImpl Class	E-22

E.2.7.1	Methods You Typically Call on ViewRowImpl .....	E-22
E.2.7.2	Methods You Typically Write in Your Custom ViewRowImpl Class .....	E-23
E.2.7.3	Methods You Typically Override in Your Custom ViewRowImpl Subclass .....	E-23
E.2.8	Setting Up Your Own Layer of Framework Base Classes .....	E-24

# Preface

Welcome to the *Oracle Fusion Middleware Fusion Developer's Guide for Oracle Application Development Framework*.

## Audience

This document is intended for enterprise developers who need to create and deploy database-centric Java EE applications with a service-oriented architecture using the Oracle Application Development Framework (Oracle ADF). This guide explains how to build Fusion web applications using ADF Business Components, ADF Controller, ADF Faces, and JavaServer Faces.

## Documentation Accessibility

For information about Oracle's commitment to accessibility, visit the Oracle Accessibility Program website at <http://www.oracle.com/pls/topic/lookup?ctx=acc&id=docacc>.

### Access to Oracle Support

Oracle customers have access to electronic support through My Oracle Support. For information, visit <http://www.oracle.com/pls/topic/lookup?ctx=acc&id=info> or visit <http://www.oracle.com/pls/topic/lookup?ctx=acc&id=trs> if you are hearing impaired.

## Conventions

The following text conventions are used in this document:

<b>Convention</b>	<b>Meaning</b>
<b>boldface</b>	Boldface type indicates graphical user interface elements (for example, menus and menu items, buttons, tabs, dialog controls), including options that you select.
<i>italic</i>	Italic type indicates book titles, emphasis, or placeholder variables for which you supply particular values.
monospace	Monospace type indicates language and syntax elements, directory and file names, URLs, text that appears on the screen, or text that you enter.

# What's New in This Guide for Release 11.1.1.7.2

For Release 11.1.1.7.2, this guide has been updated in several ways. The following table lists the sections that have been added or changed.

---

---

**Note:** This version of the guide may not contain the most recent content. To view the latest version, access the guide directly from the library on OTN. To see what has been added to this newer version, compare the What's New sections of each guide.

---

---

For changes made to Oracle JDeveloper and Oracle Application Development Framework (Oracle ADF) for this release, see the New Features page on the Oracle Technology Network at <http://www.oracle.com/technetwork/developer-tools/jdev/documentation/index.html>.

Sections	Changes Made
<b>Chapter 4, "Creating a Business Domain Layer Using Entity Objects"</b>	
<a href="#">Section 4.12.6, "What You May Need to Know About Custom Entity Object Methods"</a>	Section added to describe how to avoid dependencies on application modules and view objects in the methods that you implement in custom entity object classes.
<b>Chapter 5, "Defining SQL Queries Using View Objects"</b>	
<a href="#">Section 5.11.10.5, "Searching for Rows Using a Date Comparison"</a>	Section added to describe valid date comparison operators used in view criteria.
<a href="#">Section 5.12, "Working with Row Finders"</a>	Section added to describe row finder use cases and limitations.
<a href="#">Section 5.13.6, "How to Automatically Refresh the View Object of the View Accessor"</a>	Section revised to enhance the description of the restrictions that apply when enabling the <b>Auto Refresh</b> option for view objects.
<b>Chapter 11, "Integrating Service-Enabled Application Modules"</b>	
<a href="#">Section 11.2.1, "How to Enable the Application Module Service Interface"</a>	Section revised to describe the use of the built-in methods in the Create Service Interface wizard.

Sections	Changes Made
<a href="#">Section 11.2.15, "How to Set Display Names for Service View Instances and Attributes"</a>	Section added to describe how to set display name UI hints for view objects and view object attributes that have the <code>getDfltObjAttrHints()</code> built-in method configured on their service view instance.
<b>Chapter 18, "Creating Complex Task Flows"</b>	
<a href="#">Section 18.4, "Managing Transactions"</a>	Section revised to describe how choosing the <b>&lt;No Controller Transaction&gt;</b> option from a task flow's overview editor turns off the transaction management capabilities of the ADF task flow and delegates transaction management to the ADF Model layer.
<a href="#">Section 18.4.3.1, "Creating Completely Separate Transactions"</a>	Section added to describe the interactions that occur when you isolate two bounded task flow transactions completely so that they can be committed or rolled back separately.
<a href="#">Section 18.4.3.2, "Guaranteeing a Called Bounded Task Joins an Existing Transaction"</a>	Section added to describe the interactions that occur when you configure two bounded task flows to share a transaction to save connection resources and stop the transaction if the called bounded task flow cannot join the transaction of the calling bounded task flow.
<a href="#">Section 18.4.3.3, "Using an Existing Transaction if Possible"</a>	Section added to describe the interactions that occur when you call a bounded task flow that joins the transaction of the calling bounded task flow if one exists and, if not, creates its own transaction.
<a href="#">Section 18.4.4, "What You May Need to Know About ADF Business Component Database Connections and Task Flow Transaction Options"</a>	Section added that describes the configuration changes to make if you want to have separate root application modules connect to different data sources within the same ADF Model project
<a href="#">Section 18.10, "Minimizing the Number of Active Root View Ports in an Application"</a>	Section added to describe the new <code>&lt;max-root-view-ports&gt;</code> property that you can use to specify the maximum number of root view ports in an application.
<b>Chapter 23, "Creating ADF Databound Tables"</b>	
<a href="#">Section 23.5, "Creating a List View of a Collection"</a>	Section added to describe the new wizard available to create databound <code>listView</code> components.
<b>Chapter 24, "Displaying Master-Detail Data"</b>	
<a href="#">Section 24.6, "Using List Views to Display Master-Detail Objects"</a>	Section added to describe creating a databound master-detail view with the <code>listView</code> component.
<b>Chapter 26, Creating Databound ADF Data Visualization Components</b>	
<a href="#">Section 26.6, "Creating Databound Thematic Maps"</a>	Section added to describe how to create and configure thematic maps using ADF data controls.
<a href="#">Section 26.9.1, "How to Create a Databound Hierarchy Viewer"</a>	Section revised to reflect changes in the Create Hierarchy Viewer dialog.
<a href="#">Section 26.9.2, "What Happens When You Create a Databound Hierarchy Viewer"</a>	Section revised to better illustrate the rules for populating the nodes of the master-detail tree of a hierarchy viewer.
<a href="#">Section 26.9.3, "How to Configure an Alternate View Object for a Databound Panel Card"</a>	Section added to describe how to configure an alternate data source for the hierarchy viewer panel card.
<b>Chapter 27, "Creating ADF Databound Search Forms"</b>	
<a href="#">Section 27.1.1, "Query Search Forms"</a>	Section revised to describe support for organizing search fields into groups.

<b>Sections</b>	<b>Changes Made</b>
<a href="#">Section 27.3.2, "How to Add Placeholder Text, Label, and Tooltip"</a>	Section added to describe how to create watermark, label, and tooltip texts to a search field.
<b>Chapter 30, "Enabling ADF Security in a Fusion Web Application"</b>	
<a href="#">Section 30.5.6, "How to Define Policies to Control User Access to ADF Methods"</a>	Section added to describe how to control user access to command components in the user interface that execute ADF methods.
<a href="#">Section 30.5.12, "How to Aggregate Resource Grants as Entitlement Grants"</a>	Section added to describe how to control user access to multiple Oracle ADF artifacts, using a single ADF Security entitlement grant.
<a href="#">Section 30.9.3, "How to Secure Resource Files Using a URL Constraint"</a>	Section added to describe how to control user access to resource files, including images, style sheets, and JavaScript libraries, that support the Fusion web application.
<a href="#">Section 30.11.2, "How to Protect UI Components Using OPSS Resource Permissions and EL"</a>	Section revised to describe how to control user access to UI components in the user interface, using an ADF Security resource grant.
<a href="#">Section 30.11.3, "How to Perform Authorization Checks for Entity Object Operations"</a>	Section added to describe how to use entity row API and ADF Security EL methods to test permission for secured entity object operations.
<b>Chapter 36, "Deploying Fusion Web Applications"</b>	
<a href="#">Section 36.4, "Deploying the Application"</a>	Section revised to note the need to set the Serializing Access to the Session Data feature to prevent concurrent access when deploying to IBM WebSphere application server.
<b>Chapter 37, "Advanced Business Component Techniques"</b>	
<a href="#">Section 37.8.3.1, "Attributes in an Extended Component Inherited from the Parent Component"</a>	Section added to describe how overriding attributes in an extended component changes the behavior of inheritable attribute changes subsequently made in the parent component.
<b>Chapter 39, "Advanced View Object Techniques"</b>	
<a href="#">Section 39.3.3.4, "Avoid Creating Dependencies on Parent Application Module Types"</a>	Section added to describe how to avoid dependencies on application modules and view objects in the methods that you implement in custom view object and view row classes.
<b>Appendix A, "Oracle ADF XML Files"</b>	
<a href="#">Section A.11, "adf-config.xml"</a>	Section revised to describe the <code>allow-unbounded-task-flow-customizations</code> property that can be configured to disable support for user specific seeded customization or design time at runtime customization of unbounded task flow metadata in your application.

# Part I

## Getting Started with Fusion Web Applications

Part I contains the following chapters:

- [Chapter 1, "Introduction to Building Fusion Web Applications with Oracle ADF"](#)
- [Chapter 2, "Introduction to the ADF Sample Application"](#)

---

---

# Introduction to Building Fusion Web Applications with Oracle ADF

This chapter describes the architecture and key functionality of Oracle Application Development Framework (Oracle ADF) when used to build a Fusion web application that uses ADF Business Components, ADF Model, ADF Controller, and ADF Faces rich client, along with high-level development practices.

This chapter includes the following sections:

- [Section 1.1, "Introduction to Oracle ADF"](#)
- [Section 1.2, "Oracle ADF Architecture"](#)
- [Section 1.3, "Developing with Oracle ADF"](#)
- [Section 1.4, "Working Productively in Teams"](#)
- [Section 1.5, "Learning Oracle ADF"](#)
- [Section 1.6, "Generation of Complete Web Tier Using Oracle JHeadstart"](#)

## 1.1 Introduction to Oracle ADF

The Oracle Application Development Framework (Oracle ADF) is an end-to-end application framework that builds on Java Platform, Enterprise Edition (Java EE) standards and open-source technologies. You can use Oracle ADF to implement enterprise solutions that search, display, create, modify, and validate data using web, wireless, desktop, or web services interfaces. Because of its declarative nature, Oracle ADF simplifies and accelerates development by allowing users to focus on the logic of application creation rather than coding details. Used in tandem, Oracle JDeveloper 11g and Oracle ADF give you an environment that covers the full development lifecycle from design to deployment, with drag-and-drop data binding, visual UI design, and team development features built in.

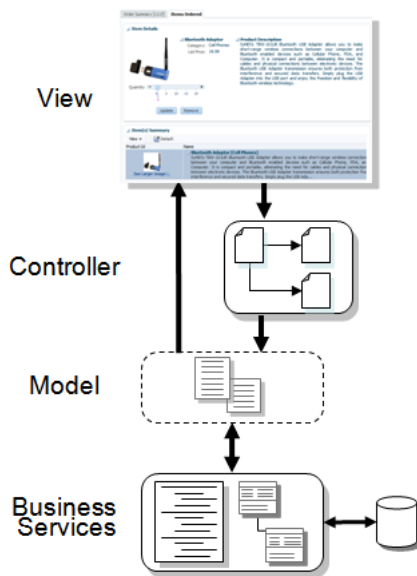

You can download and view the Fusion Order demo application, which helps to illustrate the concepts and procedures in this guide (and other Fusion Middleware developer guides). The StoreFront module of this application is built using the Fusion web application technology stack, which includes ADF Business Components, ADF Model, ADF Controller, and JavaServer Faces pages with ADF Faces rich client components. Screenshots and code samples from this module are used throughout this guide to provide you with real-world examples of using the Oracle ADF technologies in an application that uses the Fusion web technology stack. For more information about downloading and using the StoreFront module of the Fusion Order Demo application, see [Chapter 2, "Introduction to the ADF Sample Application."](#)

## 1.2 Oracle ADF Architecture

In line with community best practices, applications you build using the Fusion web technology stack achieve a clean separation of business logic, page navigation, and user interface by adhering to a model-view-controller architecture. As shown in [Figure 1-1](#), in an MVC architecture:

- The model layer represents the data values related to the current page
- The view layer contains the UI pages used to view or modify that data
- The controller layer processes user input and determines page navigation
- The business service layer handles data access and encapsulates business logic

**Figure 1-1 MVC Architecture Cleanly Separates UI, Business Logic and Page Navigation**

[Figure 1-2](#) illustrates where each ADF module fits in the Fusion web application architecture. The core module in the framework is ADF Model, a data binding facility. The ADF Model layer enables a unified approach to bind any user interface to any business service, without the need to write code. The other modules that make up a Fusion web application technology stack are:

- ADF Business Components, which simplifies building business services.
- ADF Faces rich client, which offers a rich library of AJAX-enabled UI components for web applications built with JavaServer Faces (JSF).
- ADF Controller, which integrates JSF with ADF Model. The ADF Controller extends the standard JSF controller by providing additional functionality, such as reusable task flows that pass control not only between JSF pages, but also between other activities, for instance method calls or other task flows.

---

**Note:** In addition to ADF Faces, Oracle ADF also supports using the Swing, JSP, and standard JSF view technologies. For more information about these technologies, refer to the JDeveloper online help. Oracle ADF also provides support for using Microsoft Excel as a view layer for your application. For more information, see the *Oracle Fusion Middleware Desktop Integration Developer's Guide for Oracle Application Development Framework*

---

**Figure 1–2 Simple Oracle ADF Architecture**

## 1.2.1 ADF Business Components

When building service-oriented Java EE applications, you implement your core business logic as one or more business services. These backend services provide clients with a way to query, insert, update, and delete business data as required while enforcing appropriate business rules. ADF Business Components are prebuilt application objects that accelerate the job of delivering and maintaining high-performance, richly functional, database-centric services. They provide you with a ready-to-use implementation of Java EE design patterns and best practices.

As illustrated in [Figure 1–3](#), Oracle ADF provides the following key components to simplify building database-centric business services:

- Entity object

An entity object represents a row in a database table and simplifies modifying its data by handling all data manipulation language (DML) operations for you. It can encapsulate business logic to ensure that your business rules are consistently enforced. You associate an entity object with others to reflect relationships in the underlying database schema to create a layer of business domain objects to reuse in multiple applications.

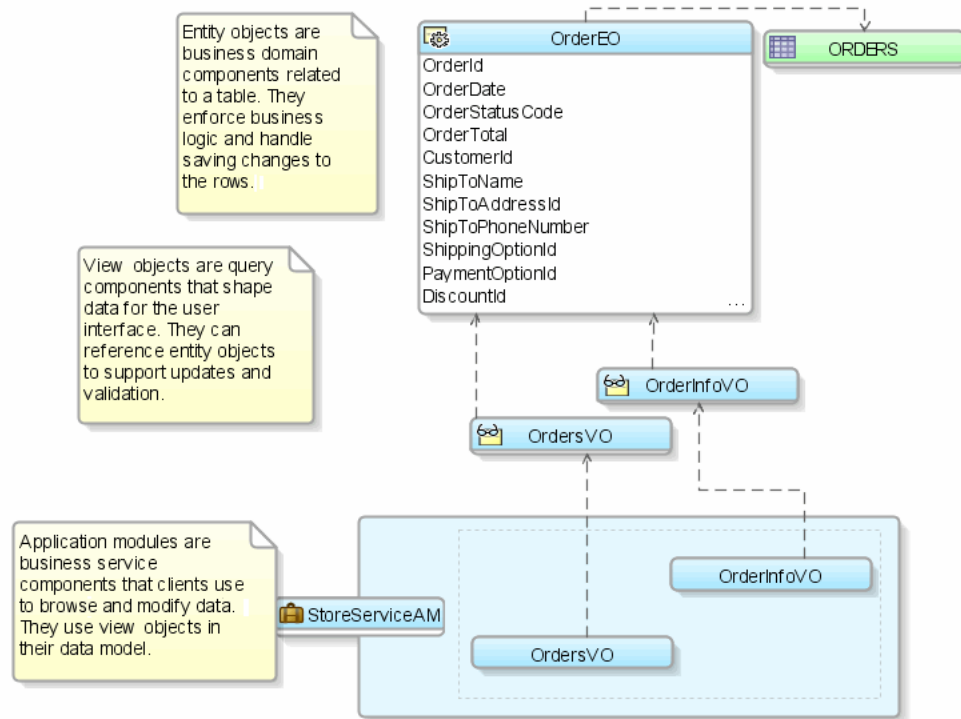

- View object

A view object represents a SQL query and simplifies working with its results. You use the SQL language to join, filter, sort, and aggregate data into the shape required by the end-user task being represented in the user interface. This includes the ability to link a view object with other entity objects to create master-detail hierarchies of any complexity. When end users modify data in the user interface, your view objects collaborate with entity objects to consistently validate and save the changes.

- Application module

An application module is the transactional component that UI clients use to work with application data. It defines an updateable data model along with top-level procedures and functions (called service methods) related to a logical unit of work related to an end-user task.

**Figure 1–3 ADF Business Components Simplify Data Access and Validation**

**Tip:** If you have previously worked with Oracle Forms, note that this combined functionality is the same set of data-centric features provided by the form, data blocks, record manager, and form-level procedures or functions. The key difference in Oracle ADF is that the user interface is cleanly separated from data access and validation functionality. For more information, see [Appendix G, "Performing Common Oracle Forms Tasks in Oracle ADF."](#)

## 1.2.2 ADF Model Layer

The ADF Model layer abstracts the business service implementation, providing a single programming interface for different types of services. *Data controls* provide this interface by using standard metadata interfaces to describe the service’s operations and data collections, including information about the properties, methods, and types involved. In JDeveloper, the functionality and attributes exposed by a business service are indicated by icons in the Data Controls panel. You can drag and drop onto a page to create UI components. JDeveloper automatically creates the bindings from the page and the UI components to the services. At runtime, the ADF Model layer reads the information describing your data controls and data bindings from appropriate XML files and implements the two-way connection between your user interface and your business service.

Oracle ADF provides out-of-the-box data control implementations for the most common business service technologies. Using JDeveloper and Oracle ADF together provides you with a drag-and-drop data binding experience as you build your user interfaces. Along with support for ADF application modules, ADF Model also provides support for the following service technologies:

- Enterprise JavaBeans (EJB) session beans and JPA entities
- JavaBeans
- Web services
- XML
- CSV files

### 1.2.3 ADF Controller

In the controller layer, where handling page flow of your web applications is a key concern, ADF Controller provides an enhanced navigation and state management model on top of JSF. JDeveloper allows you to declaratively create task flows where you can pass application control between different types of activities, such as pages, methods on managed beans, case statements, or calls to other task flows.

These task flows can be reused, and can also be nested, both within themselves and within pages. Task flows nested in pages become regions that contain their own set of navigatable pages, allowing users to view a number of different pages and functionality without leaving the main page.

### 1.2.4 ADF Faces Rich Client

ADF Faces rich client (ADF Faces for short), is a set of standard JSF components that include built-in AJAX functionality. AJAX is a combination of asynchronous JavaScript, dynamic HTML (DHTML), XML, and `XmlHttpRequest` communication channels. This combination allows requests to be made to the server without fully re-rendering the page. While AJAX allows rich client-like applications to use standard internet technologies, JSF provides server-side control, which reduces the dependency on an abundance of JavaScript often found in typical AJAX applications.

ADF Faces provides over 100 rich components, including hierarchical data tables, tree menus, in-page dialogs, accordions, dividers, and sortable tables. ADF Faces also provides ADF Data Visualization components, which are Flash- and SVG-enabled components capable of rendering dynamic charts, graphs, gauges, and other graphics that can provide a real-time view of underlying data. Each component also supports customization and skinning, along with internationalization and accessibility.

To achieve these front-end capabilities, ADF Faces components use a rendering kit that handles displaying the component and also provides the JavaScript objects needed for the rich functionality. This built-in support enables you to build rich applications without needing extensive knowledge of the individual technologies on the front or back end.

ADF Faces can also be used in an application that uses the Facelets library. Facelets is a JSF-centric XML view definition technology that provides an alternative to using the JSP engine. For more information about ADF Faces, including the architecture and detailed information about each of the components, see the *Oracle Fusion Middleware Web User Interface Developer's Guide for Oracle Application Development Framework*.

Along with ADF Faces, Oracle ADF also supports the following view technologies:

- Apache MyFaces Trinidad: This is the open source code donation from Oracle to the Apache Software Foundation. ADF Faces components are based on these Trinidad components.
- Java Swing and ADF Swing: ADF Swing is the development environment for building Java Swing applications that use the ADF Model layer.
- ADF Mobile: This is a framework that extends Oracle ADF to support mobile users, allowing the development of mobile browser-based or on-device applications that run on mobile devices.
- Microsoft Excel: You can create spreadsheets that are bound to data using the same binding principals as do other view technologies. For more information, see the *Oracle Fusion Middleware Desktop Integration Developer's Guide for Oracle Application Development Framework*.

## 1.3 Developing with Oracle ADF

Oracle ADF emphasizes the use of the declarative programming paradigm throughout the development process to allow users to focus on the logic of application creation without having to get into implementation details. Using JDeveloper 11g with Oracle ADF, you benefit from a high-productivity environment that automatically manages your application's declarative metadata for data access, validation, page control and navigation, user interface design, and data binding.

At a high level, the development process for a Fusion web application usually involves the following:

- Creating an application workspace: Using a wizard, JDeveloper automatically adds the libraries and configuration needed for the technologies you select, and structures your application into projects with packages and directories.
- Modeling the database objects: You can create an offline replica of any database, and use JDeveloper editors and diagrammers to edit definitions and update schemas.
- Creating use cases: Using the UML modeler, you can create use cases for your application.
- Designing application control and navigation: You use diagrammers to visually determine the flow of application control and navigation. JDeveloper creates the underlying XML for you.
- Identifying shared resources: You use a resource library that allows you to view and use imported libraries by simply dragging and dropping them into your application.
- Creating business components to access data: From your database tables, you create entity objects using wizards or dialogs. From those entity objects, you create the view objects used by the pages in your application. You can implement validation rules and other types of business logic using editors.
- Implementing the user interface with JSF: JDeveloper's Data Controls panel contains a representation of the view objects for your application. Creating a user interface is as simple as dragging an object onto a page and selecting the UI component you want to display the underlying data. For UI components that are not databound, you use the Component Palette to drag and drop components. JDeveloper creates all the page code for you.

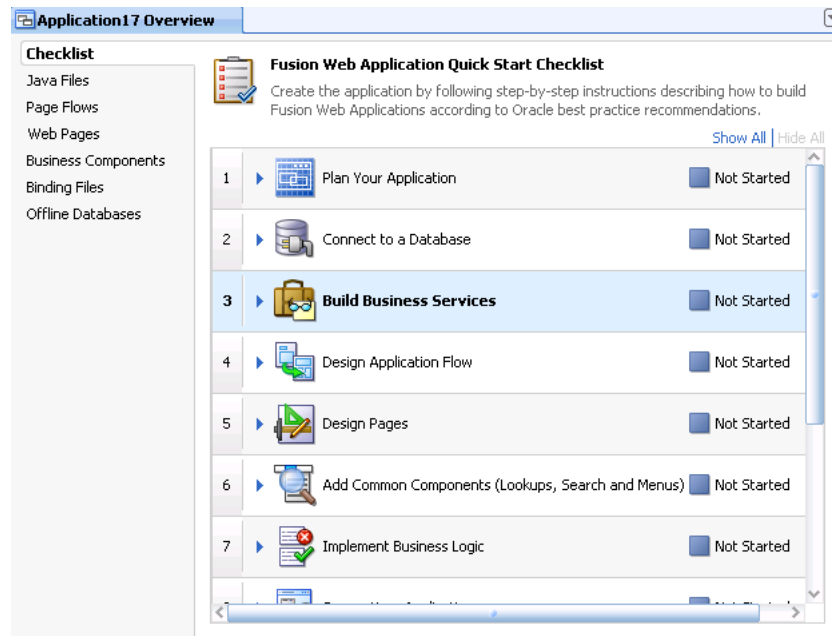

- Binding UI components to data using the ADF Model layer: When you drag an object from the Data Controls panel, JDeveloper automatically creates the bindings between the page and the data model.
- Incorporating validation and error handling: Once your application is created you use editors to add additional validation and to define error handling.
- Securing the application: You use editors to create roles and populate these with test users. You then use a flat file editor to define security policies for these roles and assign them to specific resources in your application.
- Testing and debugging: JDeveloper includes an integrated application server that allows you to fully test your application without needing to package it up and deploy it. JDeveloper also includes the ADF Declarative Debugger, a tool that allows you to set breakpoints and examine the data.
- Deploying the application: You use wizards and editors to create and edit deployment descriptors, JAR files, and application server connections.

### 1.3.1 Creating an Application Workspace

The first step in building a new application is to assign it a name and to specify the directory where its source files will be saved. When you create an application using the application templates provided by JDeveloper, it organizes your workspace into projects and creates and organizes many of the configuration files required by the type of application you are creating.

One of these templates is the Fusion Web Application (ADF) template, which provides the correctly configured set of projects you need to create a web application that uses ADF Faces for the view, ADF Page Flow for the controller, and ADF Business Components for business services. When you create an application workspace using this template, JDeveloper automatically creates the JSF and ADF configuration files needed for the application.

One part of the application overview is the Fusion Web Application Quick Start Checklist. This checklist provides you with the basic steps for creating a Fusion web application. Included are links to pertinent documentation, prerequisites, and the ability to keep track of status for each step in the checklist, as shown in [Figure 1-4](#).

**Figure 1–4 Fusion Web Application Quick Start Checklist**

JDeveloper also creates a project named `Model` that will contain all the source files related to the business services in your application, and a project named `ViewController` that will contain all the source files for your ADF Faces view layer, including files for the controller.

JDeveloper adds the following libraries to the data model project:

- ADF Model Runtime
- BC4J Oracle Domains
- BC4J Runtime
- BC4J Security
- BC4J Tester
- MDS Runtime
- MDS Runtime Dependencies
- Oracle JDBC

JDeveloper also adds the following libraries to the view project:

- JSP Runtime
- JSF 1.2
- JSTL 1.2
- ADF Page Flow Runtime
- ADF Controller Runtime
- ADF Controller Schema
- ADF Faces Runtime 11
- ADF Common Runtime
- ADF Web Runtime

- MDS Runtime
- MDS Runtime Dependencies
- Commons Beautils 1.6
- Commons Logging 1.0.4
- Commons Collections 3.1
- ADF DVT Faces Runtime
- ADF DVT Faces Databinding Runtime

Once you add a JSF page, JDeveloper adds the Oracle JEWTF library.

Once the projects are created for you, you can rename them as you need. You can then use JDeveloper to create additional projects, and add the packages and files needed for your application.

---

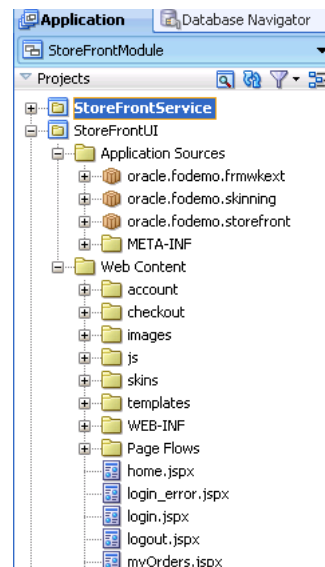

**Note:** If you plan to reuse artifacts in your application (for example, task flows), then you should follow the naming guidelines presented in [Chapter 33, "Reusing Application Components"](#) in order to prevent naming conflicts.

---

**Tip:** You can edit the default values used in application templates, as well as create your own templates. To do so, choose **Application > Manage Templates**.

[Figure 1–5](#) shows the different projects, packages, directories, and files for the `StoreFrontModule` application, as displayed in the Application Navigator.

**Figure 1–5** *StoreFrontModule Application Projects, Packages, and Directories*

For more information, see "Managing Applications and Projects" in the "JDeveloper Basics" section of the JDeveloper online help.

When you work with your files, you use mostly the editor window, the Structure window, and the Property Inspector, as shown in [Figure 1–6](#). The editor window allows you to view many of your files in a WYSIWYG environment, or you can view a

file in an overview editor where you can declaratively make changes, or you can view the source code for the file. The Structure window shows the structure of the currently selected file. You can select objects in this window and then edit the properties for the selection in the Property Inspector.

**Figure 1–6 The JDeveloper Workspace**

### 1.3.2 Modeling with Database Object Definitions

In JDeveloper, after you create your application workspace, you can copy database objects from a database schema to an offline database or project where they become available as offline database objects, saved as `.xml` files. You can then create and edit database object definitions within a project using the same editors that you use to create and edit database objects on live database connections. You can also compare your offline database objects with other offline or live database schemas and generate SQL statements (including `CREATE`, `REPLACE`, and `ALTER`).

For example, you can drag a table from a database connection that your application defines onto a database diagram and JDeveloper will give you the choice to model the database object live or offline (to create the `.xml` file representation of the object). Modeling database definitions, such as tables and foreign keys, visually captures the essential information about a schema. You can use the diagram to drag and drop columns and keys to duplicate, move, and create foreign key relationships. Working in offline mode, whenever you model a node on a diagram, JDeveloper creates the underlying offline object and lists it in the Application Navigator. Working with a live schema, JDeveloper updates the live database object as you amend the diagram. You can create multiple diagrams from the same offline database objects and spread your offline database across multiple projects.

Using a database diagram like the one shown in [Figure 1–7](#) you can visualize the following:

- Tables and their columns

- Foreign key relationships between tables
- Views
- Offline sequences and synonyms

In addition to using the diagram directly to create and edit database objects, you can work with specific database object editors. After you have finished working with the offline database objects, you can generate new and updated database definitions to online database schemas.

When you work with the database diagram you can customize the diagram to change the layout, change how objects are represented and grouped, add diagram annotations to specify dependencies or links (such as URLs), and change visual properties, such as color and font of diagram elements.

**Figure 1–7 Database Diagram for Payments Grouping**

Specifically, the following customizations were made to the database diagram shown in Figure 1–7:

- DISCOUNT\_TRANSLATIONS element show the table with constraints not displayed.

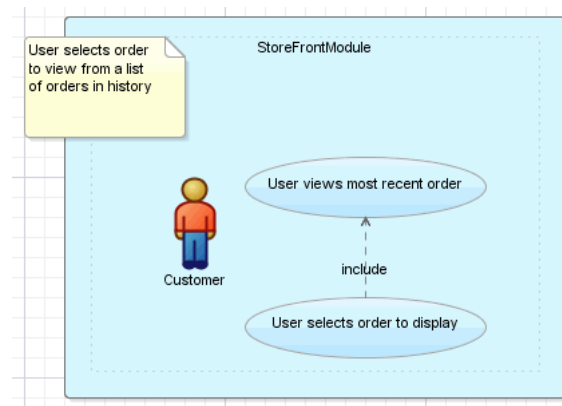

- DISCOUNTS\_BASE element shows the table with some column definitions hidden (such as CREATED\_BY, CREATION\_DATE, and LASTUPDATED\_BY) plus the diagram element has been sized to fit within the overall diagram (thus truncating some of the detail).
- DISCOUNT\_TRANSLATIONS\_SEQ element shows a sequence displayed in compact view in contrast to DISCOUNTS\_SEQ which shows the sequence properties.
- COUPON\_USAGES and ELIGIBLE\_DISCOUNTS elements use different colors both in compact view and each identifies their database schema (FODOffline).
- DISCOUNTS element is a view displayed. The element identifies the tables that comprise the view in compact mode and the JOIN type (INNER JOIN). It also identifies the usage relationships on tables with a dotted line.
- DISCOUNTS\_BASE and DISCOUNT\_TRANSLATIONS elements show a foreign key relationship.
- DISCOUNT\_SEQ element uses an annotation (dashed arrow) to represent the dependency with DISCOUNTS\_BASE table.
- Payments Grouping element uses HTML link annotations (for example, Customer Memberships) to display other diagrams from the project.
- Payments Grouping element nests elements with group shapes (Click to Access).

For more information about modeling database definitions with database diagrams, see "Creating, Editing, and Dropping Database Objects" in the "Designing Databases" section of the JDeveloper online help.

### 1.3.3 Creating Use Cases

After creating an application workspace, you may decide to begin the development process by doing use case modeling to capture and communicate end-user requirements for the application to be built. Figure 1-8 shows a simple diagram created using the UML modeler in JDeveloper. The diagram represents an end user viewing a list of his orders and then drilling down to view the details of an order. Using diagram annotations, you can capture particular requirements about what end users might need to see on the screens that will implement the use case. For example, in this use case, it is noted that the user will select order details for each order listed.

**Figure 1-8 Use Case Diagram for Viewing Order History**

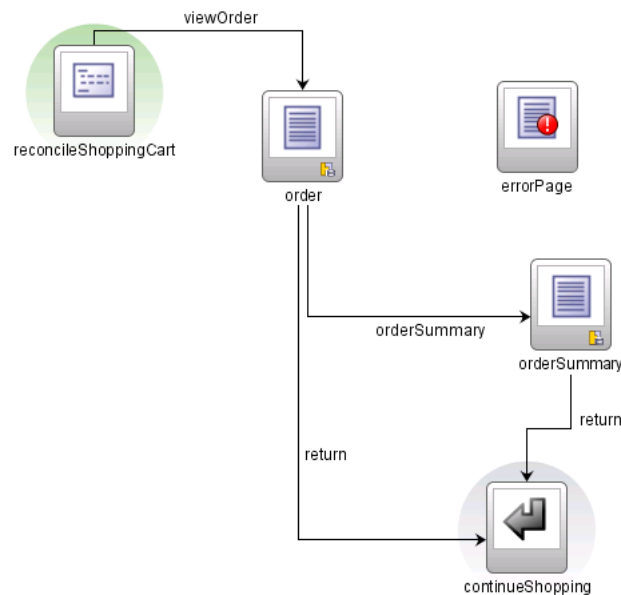

For more information about creating use case diagrams, see "Modeling With Diagrams" in the "Designing and Developing Applications" section of the JDeveloper online help.

### 1.3.4 Designing Application Control and Navigation Using ADF Task Flows

By modeling the use cases, you begin to understand the kinds of user interface pages that will be required to implement end-user requirements. At this point, you can begin to design the flow of your application. In a Fusion web application, you use ADF task flows instead of standard JSF navigation flows. Task flows provide a more modular and transaction-aware approach to navigation and application control. Like standard JSF navigation flows, task flows contain mostly viewable pages. However, instead of describing navigation between pages, task flows facilitate transitions between activities. Aside from navigation, task flows can also have nonvisual activities that can be chained together to affect the page flow and application behavior. For example, these nonvisual activities can call methods on managed beans, evaluate an EL expression, or call another task flow. This facilitates reuse, as business logic can be invoked independently of the page being displayed.

Figure 1-9 shows the checkout-task-flow task flow from the StoreFront module of the Fusion Order Demo application. In this task flow, `order` and `orderSummary` are view activities that represent pages, while `reconcileShoppingCart` is a method call activity. When the user enters this flow, the `reconcileShoppingCart` activity is invoked (because it is the entry point for the flow, as denoted by the green circle) and the corresponding method is called. From there, the flow continues to the `order` page. From the `order` page, control can be passed to the `orderSummary` page, or to the `continueShopping` return activity that is the exit point of the flow and passes control back to the home page.

**Figure 1-9 Task Flow in the StoreFrontModule Application**

The ADF Controller provides a mechanism to define navigation using control flow rules. The control flow rule information, along with other information regarding the flow, is saved in a configuration file. Figure 1-10 shows the Structure window for the checkout-task-flow task flow. This window shows each of the items configured in

the flow, such as the control flow rules. The Property Inspector (by default, located at the bottom right) allows you to set values for the different elements in the flow.

**Figure 1–10 Task Flow Elements in the Structure Window and Property Inspector**

Aside from pages, task flows can also coordinate page fragments. Page fragments are JSF JSP documents that are rendered as content in other JSF pages. You can create page fragments and the control between them in a bounded task flow as you would create pages, and then insert the entire task flow into another page as a region. Because it is simply another task flow, the region can independently execute methods, evaluate expressions, and display content, while the remaining content on the containing page remains the same. For example, before registering a new user, the application needs to determine what kind of user needs to be created. All the logic to do this is handled in the `user-registration-task-flow` task flow, which is used as a region in the `registerUser` page.

Regions also facilitate reuse. You can create a task flow as a region, determine the pieces of information required by a task and the pieces of information it might return, define those as parameters and return values of the region, then drop the region on any page in an application. Depending on the value of the parameter, a different view can display.

The chapters contained in [Part III, "Creating ADF Task Flows"](#) contain information about using task flows. For general information about task flows and creating them, see [Chapter 14, "Getting Started with ADF Task Flows."](#) For information about task flow activities, see [Chapter 15, "Working with Task Flow Activities."](#) If you need to pass parameters into or out of task flows, see [Chapter 16, "Using Parameters in Task Flows."](#) For more information about regions, see [Chapter 17, "Using Task Flows as Regions."](#) For information about advanced functionality that task flows can provide, such as transactional capabilities and creating mandatory sequences of pages (known as *trains*), see [Chapter 18, "Creating Complex Task Flows."](#) For information about using task flows to create dialogs, see [Chapter 19, "Using Dialogs in Your Application."](#)

### 1.3.5 Identifying Shared Resources

You may find that some aspects of your application can be reused throughout the application. For example, you may need the functionality of creating an address to appear both when a user registers and when a user creates an order. Or you may find throughout the development process that certain components of your application should be shared throughout the application. You can declaratively create ADF libraries that allow you to package artifacts and reuse them throughout the application. For example, you might create a task flow for the process of creating an address. You can then save this task flow and package it as a library. The library can be

sent to other developers who can add it to their a resource catalog, from which they can drag and drop it onto any page where it's needed. [Figure 1–11](#) shows the Resource Palette in JDeveloper.

**Figure 1–11 Resource Palette in JDeveloper**

When designing the application, be sure to note all the tasks that can possibly become candidates for reuse. [Chapter 33, "Reusing Application Components"](#) provides more information about the ADF artifacts that can be packaged and reused as an ADF library, along with procedures both for creating and using the libraries.

### 1.3.6 Creating a Data Model to Access Data with ADF Business Components

Typically, when you implement business logic as ADF Business Components, you do the following:

- Create entity objects to represent tables that you expect your application to perform a transaction against (if no transaction is to be performed, an entity object is not needed). Add validation and business rules as needed.
- Create view objects that work with the entity objects to query and update the database. These view objects will be used to make the data available for display at your view layer.
- Create the application module that the UI layer of your application will use. This application module contains view object instances in its data model along with any custom methods that users will interact with through the application's web pages.
- If needed, publish your services as web services for remote invocation.

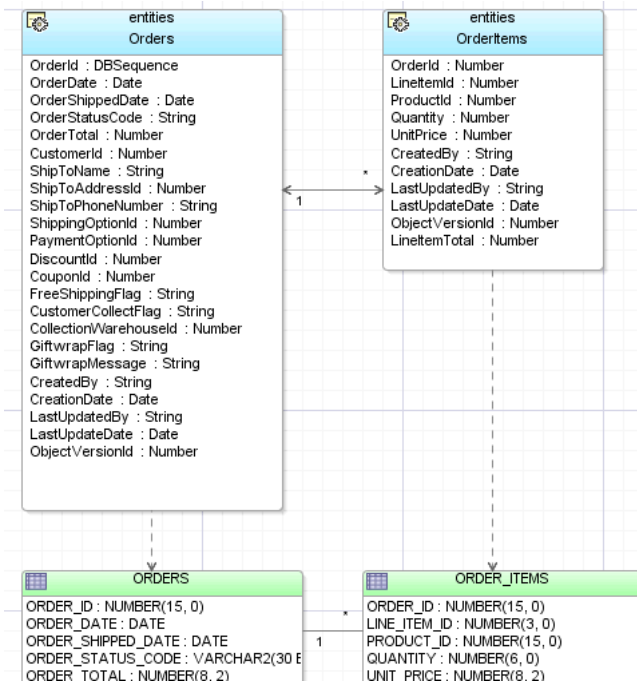

The chapters contained in [Part II, "Building Your Business Services"](#) provide information on creating each of these artifacts. The chapters in [Part VI, "Advanced Topics"](#) provide additional information, such as extending business objects, tuning, and state management.

#### 1.3.6.1 Creating a Layer of Business Domain Objects for Tables

Once you have an understanding of the data that will be presented and manipulated in your application, if you haven't already done so, you can build your database (for more information, see the "Designing Databases" topic in the "Designing and Developing Applications" section of the JDeveloper online help). Once the database tables are in place, you can create a set of entity objects that represents them and simplifies modifying the data they contain. When you use entity objects to encapsulate data access and validation related to the tables, any pages you build today or in the future that work with these tables are consistently validated. As you work, JDeveloper automatically configures your project to reference any necessary Oracle ADF runtime libraries your application will need at runtime.

For example, the `StoreFrontService` project of the `StoreFrontModule` application contains the business services needed by the application. [Figure 1–12](#) shows two of the entity objects that represent the database tables in that application.

**Figure 1–12 Business Components Diagram Showing Entity Objects and Related Tables**

To create the business layer, you first create the entity objects based on your database tables. Any relationships between the tables will be reflected as associations between the corresponding entity objects. Alternatively, you can first create the entity objects, and the associations, and then create database tables from those objects.

Once the entity objects are created, you can define control and attribute hints that simplify the display of the entities in the UI, and you can also add behaviors to the objects. For more information, see [Chapter 4, "Creating a Business Domain Layer Using Entity Objects."](#)

### 1.3.6.2 Building the Business Services

Once the reusable layer of business objects is created, you can implement the application module. An application module provides a data-model and service methods with which a UI client can work.

The application module's data model is composed of instances of the view object components you create that encapsulate the necessary queries. View objects can join, project, filter, sort, and aggregate data into the shape required by the end-user task being represented in the user interface. When the end user needs to update the data, your view objects reference entity objects in your reusable business domain layer. View objects are reusable and can be used in multiple application modules.

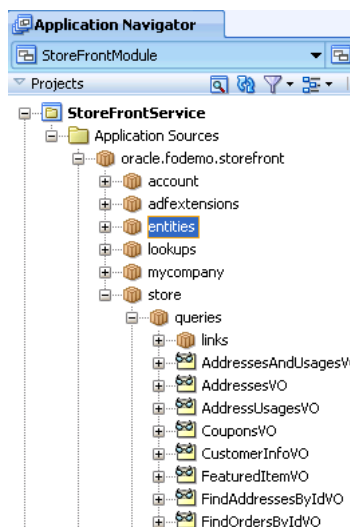

When you want the data to display in a consistent manner across all view pages that access that data, you can configure metadata on the view object to determine display properties. The metadata allows you to set display properties in one place and then change them as needed, so that you make the change only in one place instead of on all pages that display the data. Conversely, you can also have the query controlled by

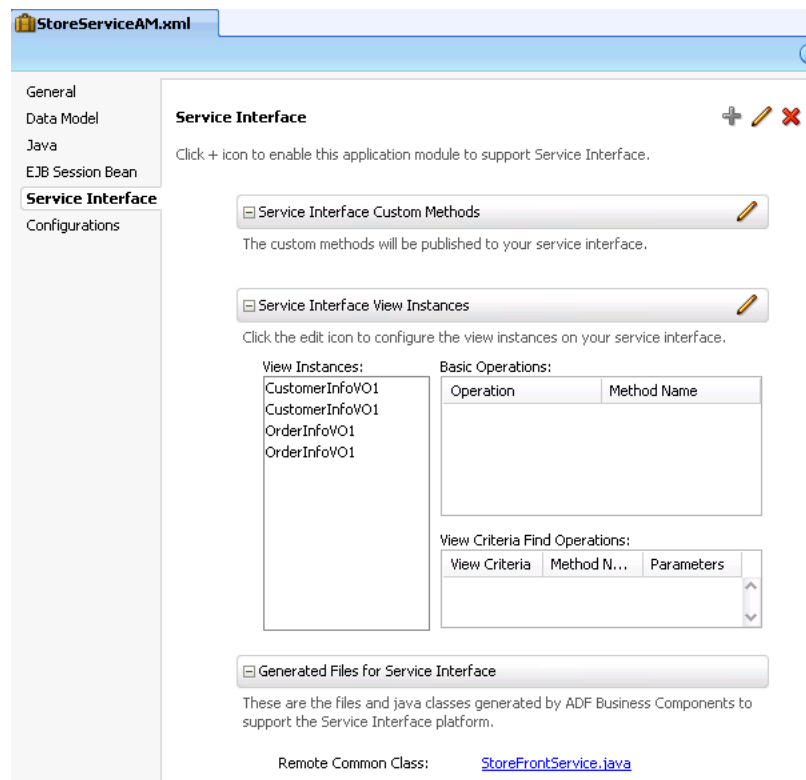

the data the page requires. All display functionality is handled by the page. For more information, see [Chapter 5, "Defining SQL Queries Using View Objects."](#)

For example, the `StoreFrontService` project contains the `oracle.fodemo.storefront.store.queries` package, which contains many of the queries needed by the `StoreFrontModule` application, as shown in [Figure 1-13](#).

**Figure 1-13 View Objects in the StoreFrontModule Application**

Additionally, you may find that you need to expose functionality to external applications. You can do this by exposing this functionality through a service interface. For example, the `StoreServiceAM` application module is exposed as a web service. This web service exposes the `CustomerInfo` and `OrderInfo` view instances, as shown in [Figure 1-14](#). For more information, see [Chapter 11, "Integrating Service-Enabled Application Modules."](#)

**Figure 1–14 StoreFrontModule Application in the Fusion Order Demo Application**

### 1.3.6.3 Testing and Debugging Business Services with the Business Component Browser

While you develop your application, you can iteratively test your business services using the Business Component Browser. The browser allows you to test the queries, business logic, and validation of your business services without having to use or create a user interface or other client to test your services. Using the browser allows you to test out the latest queries or business rules you've added, and can save you time when you're trying to diagnose problems. For more information about developing and testing application modules, see [Chapter 9, "Implementing Business Services with Application Modules."](#)

The browser also interacts with the ADF Declarative Debugger to allow debug your business services. You can set breakpoints on any custom methods you create. For more information, see [Section 31.6, "Using the Business Component Browser for Testing and Debugging."](#)

## 1.3.7 Implementing the User Interface with JSF

From the page flows you created during the planning stages, you can double-click the page icons to create the actual JSP files. When you create a JSP for an ADF Faces application, you can choose to create an XML-based JSP document (which uses the extension `*.jspx`) rather than a `*.jsp` file.

**Best Practice:** Using an XML-based document has the following advantages:

- Simplifies treating your page as a well-formed tree of UI component tags.
- Discourages you from mixing Java code and component tags.
- Allows you to easily parse the page to create documentation or audit reports.

If you want to use Facelets instead of JSP in your application, you can instead create XHTML files. Facelets is a JSF-centric XML view definition technology that provides an alternative to using the JSP engine.

**Tip:** While Facelet pages can use any well formed XML file, including `.jspx`, when you create a Facelet page in JDeveloper, it is created as an XHTML file.

**Best Practice:** Use Facelets to take advantage of the following:

- The Facelets layer was created specifically for JSF, which results in reduced overhead and improved performance during tag compilation and execution.
- Facelets is considered the primary view definition technology in JSF 2.0.
- Some future performance enhancements will only be available with Facelets

ADF Faces provides a number of components that you can use to define the overall layout of the page. JDeveloper contains predefined quick start layouts that use these components to provide you with an efficient way to correctly determine the layout of your pages. You can choose from one-, two-, or three-column layouts, and then determine how you want the columns to behave. You can also choose to apply themes to the layouts, which adds color to some of the components for you. For more information see the "Using Quick Start Layouts" section of the *Oracle Fusion Middleware Web User Interface Developer's Guide for Oracle Application Development Framework*.

Oracle ADF also allows you to create and use your own page templates. When creating templates, a developer can determine the layout of the page (either using one of the quick layout templates or creating the layout manually), provide static content that must appear on all pages, and create placeholder attributes that can be replaced with valid values for each page. Each time the template is changed, for example if the layout changes, any page that uses the template will reflect the update.

Most pages in the `StoreFrontModule` application use the `StoreFrontTemplate` template, which provides an area for branding and navigation, a main content area divided into three panes, and a footer area. If the template designer decides to switch the location of the branding and the navigation, all pages that use the template will automatically reflect that change at runtime.

The chapters in [Part IV, "Creating a Databound Web User Interface"](#) provide information on creating different types of UI functionality, from basic forms to more complex search capabilities.

### 1.3.8 Data Binding with ADF Model Layer

In JSF, you use a simple *expression language* (called EL) to bind to the information you want to present and/or modify (for more information, see <http://java.sun.com/products/jsp/reference/techart/unifiedEL.html>). Example expressions look like `#{userInfoBean.principalName}` to reference a particular user's name, or `#{userInfoBean.principalName eq 'SKING'}` to evaluate whether a user's name is SKING or not. At runtime, a generic expression evaluator returns the `String` and `boolean` value of these respective expressions, automating access to the individual objects and their properties without requiring code.

At runtime, the value of certain JSF UI components is determined by the `value` attribute. While a component can have static text as its value, typically the `value` attribute will contain a binding that is an EL expression that the runtime infrastructure evaluates to determine what data to display. For example, an `outputText` component that displays the name of the currently logged-in user might have its `value` attribute set to the expression `#{userInfoBean.principalName}`. Since any attribute of a component can be assigned a value using an EL expression, it's easy to build dynamic, data-driven user interfaces. For example, you could hide a component when a user is not logged in by using a boolean-valued expression like `#{userInfoBean.principalName != null}` in the UI component's `rendered` attribute. If there is no principal name in the current instantiation of the `userInfoBean`, the `rendered` attribute evaluates to `false` and the component disappears from the page.

In a typical JSF application, you would create objects like the `userInfoBean` object as a managed bean. The JSF runtime manages instantiating these beans on demand when any EL expression references them for the first time. However, in an application that uses the ADF Model layer, instead of binding the UI component attributes to properties or methods on managed beans, JDeveloper automatically binds the UI component attributes to the ADF Model layer, which uses XML configuration files that drive generic data binding features. It implements concepts that enable decoupling the user interface technology from the business service implementation: *data controls* and *declarative bindings*.

Data controls use XML configuration files to describe a service. At design time, visual tools like JDeveloper can leverage that metadata to allow you to declaratively bind UI components to any data control operation or data collection, creating bindings. For example, [Figure 1-15](#) shows the `StoreServiceAMDataControl` data control as it appears in the Data Controls panel of JDeveloper.

**Figure 1–15 StoreFrontServiceAMDataControl**

Note that the collections that display in the panel represent the set of rows returned by the query in each view object instance contained in the `StoreServiceAM` application module. For example, the `OrderPaymentOptions` data collection in the Data Controls panel represents the `OrderPaymentOptions` view object instance in the `StoreServiceAM`'s data model. The `OrderBillingAddress` data collection appears as a child, reflecting the master-detail relationship set up while building the business service. The attributes available in each row of the respective data collections appear as child nodes. The data collection level Operations node contains the built-in operations that the ADF Model layer supports on data collections, such as `previous`, `next`, `first`, `last`, and so on.

---

**Note:** If you create other kinds of data controls for working with web services, XML data retrieved from a URL, JavaBeans, or EJBs, these would also appear in the Data Controls panel with an appropriate display. When you create one of these data controls in a project, JDeveloper creates metadata files that contain configuration information. These additional files do not need to be explicitly created when you are working with Oracle ADF application modules, because application modules are already metadata-driven components, and so contain all the information necessary to be exposed automatically as data controls.

---

Using the Data Controls panel, you can drag and drop a data collection onto a page in the visual editor, and JDeveloper creates the necessary bindings for you. [Figure 1–16](#) shows the `CustomerRegistration` collection from the `StoreServiceAMDataControl` data control being dragged from the Data Controls panel, and dropped as a form onto a JSF page.

**Figure 1–16 Declaratively Creating a Form Using the Data Controls Panel**

The first time you drop a databound component from the Data Controls panel on a page, JDeveloper creates an associated page definition file. This XML file describes the group of bindings supporting the UI components on a page. The ADF Model uses this file at runtime to instantiate the page's bindings. These bindings are held in a request-scoped map called the *binding container*. Each time you add components to the page using the Data Controls panel, JDeveloper adds appropriate binding entries into this page definition file. Additionally, as you perform drag-and-drop data binding operations, JDeveloper creates the required tags representing the JSF UI components on the JSF page. For more information about using the Data Controls panel, see [Chapter 12, "Using ADF Model in a Fusion Web Application."](#)

---

**Note:** You can use dynamic UI components that create the bindings at runtime instead of design time. To use dynamic components, you set control hints on your view objects that determine how the data is to be displayed each time the view object is accessed by a page. This ensures that data is displayed consistently across pages, and also allows you to change in a single location, how the data is displayed instead of having to update each individual page. For more information, see [Section 22.7, "Using a Dynamic Form to Determine Data to Display at Runtime."](#)

---

[Figure 1–17](#) illustrates the architecture of a JSF application when you leverage ADF Model for declarative data binding. By combining ADF Model with JSF, you avoid having to write a lot of the typical managed bean code that would be required for real-world applications.

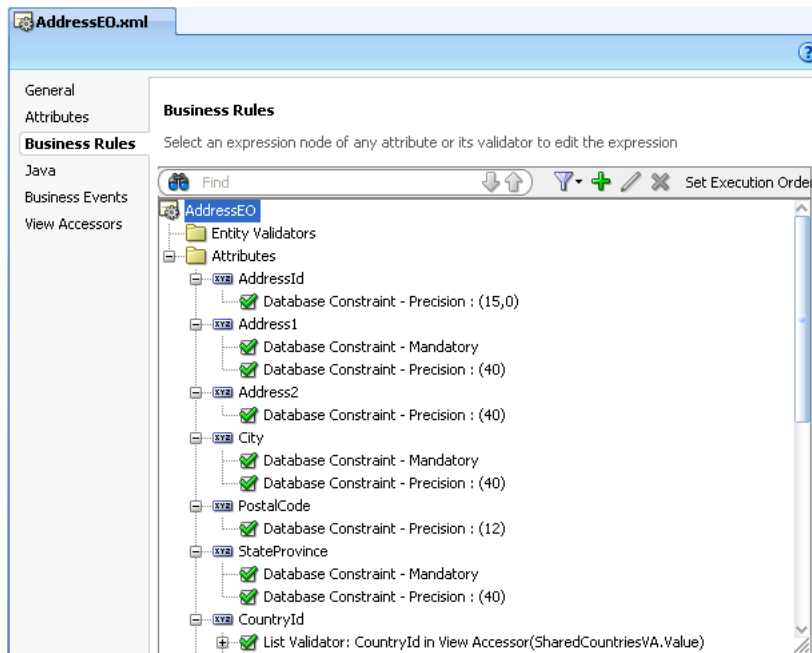

Figure 1–17 Architecture of a JSF Application Using ADF Model Data Binding

Aside from forms and tables that display or update data, you can also create search forms, and databound charts and graphs. For more information about using data controls to create different types of pages, see the chapters contained in [Part IV, "Creating a Databound Web User Interface"](#). For more information about the Data Controls panel and how to use it to create any UI data bound component, see [Chapter 12, "Using ADF Model in a Fusion Web Application."](#)

### 1.3.9 Validation and Error Handling

You can add validation to your business objects declaratively using the overview editors for entity and view objects. [Figure 1–18](#) shows the **Business Rules** tab of the overview editor for the `AddressEO` entity object.

**Figure 1–18 Setting Validation in the Overview Editor**

Along with providing the validation rules, you also set the error messages to display when validation fails. To supplement this declarative validation, you can also use Groovy-scripted expressions. For more information about creating validation at the service level, see [Chapter 7, "Defining Validation and Business Rules Declaratively."](#)

Additionally, ADF Faces input components have built-in validation capabilities. You set one or more validators on a component either by setting the `required` attribute or by using the prebuilt ADF Faces validators. You can also create your own custom validators to suit your business needs. For more information, see the "Validating and Converting Input" chapter of the *Oracle Fusion Middleware Web User Interface Developer's Guide for Oracle Application Development Framework*.

You can create a custom error handler to report errors that occur during execution of an ADF application. Once you create the error handler, you only need to register the handler in one of the application's configuration files. For more information, see [Section 28.10, "Customizing Error Handling."](#)

### 1.3.10 Adding Security

Oracle ADF provides a security implementation that is based on Java Authentication and Authorization Service (JAAS). JAAS is a standard security Application Programming Interface (API) that is added to the Java language through the Java Community Process. It enables applications to authenticate users and enforce authorization. The Oracle ADF implementation of JAAS is permission-based. You define these permissions and then grant them on application roles that you associate with users of the application. For more information about securing your application, see [Chapter 30, "Enabling ADF Security in a Fusion Web Application."](#)

### 1.3.11 Testing and Debugging the Web Client Application

Testing an Oracle ADF web application is similar to testing and debugging any other Java EE application. Most errors result from simple and easy-to-fix problems in the declarative information that the application defines or in the EL expressions that

access the runtime objects of the page's Oracle ADF binding container. In many cases, examination of the declarative files and EL expressions resolve most problems.

For errors not caused by the declarative files or EL expressions, JDeveloper includes the ADF Logger, which captures runtime trace messages from the ADF Model layer API. The trace includes runtime messages that may help you to quickly identify the origin of an application error. You can also search the log output for specific errors. JDeveloper also includes the ADF Declarative Debugger, a tool that allows you to set breakpoints. When a breakpoint is reached, the execution of the application is paused and you can examine the data that the Oracle ADF binding container has to work with, and compare it to what you expect the data to be. [Chapter 31, "Testing and Debugging ADF Components"](#) contains useful information and tips on how to successfully debug a Fusion web application.

For testing purposes, JDeveloper provides integration with JUnit. You use a wizard to generate regression test cases. For more information, see [Section 31.10, "Regression Testing with JUnit."](#)

### 1.3.12 Refactoring Application Artifacts

Using JDeveloper, you can easily rename or move the different components in your application. For example, you may find that you need to change the name of your view objects after you have already created them. JDeveloper allows you to easily do this and then propagates the change to all affected metadata XML files. For more information, see [Chapter 32, "Refactoring a Fusion Web Application."](#)

### 1.3.13 Deploying a Fusion Web Application

You can deploy a Fusion web application to either the integrated WebLogic server within JDeveloper or to a standalone instance. For more information about deployment, see [Chapter 36, "Deploying Fusion Web Applications."](#)

### 1.3.14 Integrating a Fusion Web Application

You can integrate your Fusion web application with any existing or new applications using service-oriented architecture (SOA) principals provided by Oracle SOA Suite. Oracle SOA Suite includes declarative development tools that allow you to easily integrate multiple applications using services, events, business rules, business process flows, and other SOA technologies.

You can build your Fusion web application so that it can easily integrate with other applications. You can publish your application modules as services. You can also create events that can be used for example, to initiate business processes. For more information, see [Chapter 11, "Integrating Service-Enabled Application Modules."](#) Your application modules can also call other web services directly. For more information, see [Section 13.2, "Calling a Web Service from an Application Module."](#) You can also integrate your application using task flows. For example, a task flow can be used to initiate a business process flow. For more information, see [Section 18.15, "Using BPEL with Task Flows."](#)

For more information about Oracle SOA Suite, see *Oracle Fusion Middleware Developer's Guide for Oracle SOA Suite*.

## 1.4 Working Productively in Teams

Often, applications are built in a team development environment. While a team-based development process follows the development cycle outlined in [Section 1.3,](#)

"Developing with Oracle ADF," many times developers are creating the different parts of the application simultaneously. Working productively means team members divide the work, understand how to enforce standards, and manage source files with a source control system, in order to ensure efficient application development.

Before beginning development on any large application, a design phase is typically required to assess use cases, plan task flows and screens, and identify resources that can be shared.

The following list shows how the work for a typical Fusion web application might be broken up once an initial design is in place:

- Infrastructure

A DBA creates Ant scripts (or other script files) for building and deploying the finished application. SQL scripts are developed to create the database schema used by the application.

- Entity objects

In a large development environment, a separate development group builds all entity objects for the application. Because the rest of the application depends on these objects, entity objects should be one of the first steps completed in development of the application.

Once the entity objects are finished, they can be shared with other teams using Oracle ADF libraries (see [Section 33.2, "Packaging a Reusable ADF Component into an ADF Library"](#) for more information). The other teams then access the objects by adding to them to a catalog in the Resource Palette. In your own application development process, you may choose not to divide the work this way. In many applications, entity objects and view objects might be developed by the same team (or even one person) and would be stored within one project.

- View objects

After the entity objects are created and provided either in a library or within the project itself, view objects can be created as needed to display data (in the case of building the UI) or supply service data objects (when data is needed by other applications in a SOA infrastructure).

When building the Fusion Order Demo application, each developer of a particular page or service was in charge of creating the view objects for that page or service. This was needed because of the tight integration between the view object and its use by a page in the Fusion Order demo; the team who built the UI also built the corresponding view objects.

During development, you may find that two or more view objects are providing the same functionality. In some cases, these view objects can be easily combined by altering the query in one of the objects so that it meets the needs of each developer's page or service.

Once the view objects are in place, you can create the application module, data controls, and add any needed custom methods. The process of creating view objects, reviewing for redundancy, and then adding them to the application module can be an iterative one.

- User interface (UI) creation

With a UI design in place, the view objects in place and the data controls created, the UI can be built either by the team that created the view objects (as described in the previous bullet point) or by a separate team. You can also develop using a UI-first strategy, which would allow UI designers to create pages before the data

controls are in place. Oracle ADF provides placeholder data controls that UI designers can use early in the development cycle. For more information, see [Chapter 29, "Designing a Page Using Placeholder Data Controls."](#)

## 1.4.1 Enforcing Standards

Because numerous individuals divided into separate teams will be developing the application, you should enforce a number of standards before development begins to ensure that all components of the application will work together efficiently. The following are areas within an application where it is important to have standardization in place when working in a team environment:

- Code layout style

So that more than one person can work efficiently in the code, it helps to follow specific code styles. JDeveloper allows you to choose how the built-in code editor behaves. While many of the settings affect how the user interacts with the code editor (such as display settings), others affect how the code is formatted. For example, you can select a code style that determines things like the placement of opening brackets and the size of indents. You can also import any existing code styles you may have, or you can create your own and export them for use by the team. For more information, see "Setting Preferences for the Source Editor" in the "JDeveloper Basics" section of the JDeveloper online help.

- Package naming conventions

You should determine not only how packages should be named, but also the granularity of how many and what kinds of objects will go into each package. For example, all managed beans in the StoreFront module are in the `view.managed` package. All beans that contain helper-type methods accessed by other beans are in `util` packages (one for Oracle ADF and one for JSF). All property files are in the `common` package.

- Pages

You can create templates to be used by all developers working on the UI, as described in [Section 1.3.7, "Implementing the User Interface with JSF."](#) This not only ensures that all pages will have the same look and feel, but also allows you to make a change in the template and have the change appear on all pages that use it. For more information, see [Section 20.2, "Using Page Templates."](#)

Aside from using templates, you should also devise a naming standard for pages. For example, you may want to have names reflect where the page is used in the application. To achieve this goal, you can create subdirectories to provide a further layer of organization.

- Connection names: Unlike most JDeveloper and Oracle ADF objects that are created only once per project and by definition have the same name regardless of who sees or uses them, database connection names might be created by individual team members, even though they map to the same connection details. Naming discrepancies may cause unnecessary conflicts. Team members should agree in advance on common, case-sensitive connection names that should be used by every member of the team.

## 1.4.2 Using a Source Control System

When working in a team environment, you will need to use a source control system. By default, Oracle JDeveloper provides integrated support for both the CVS and Subversion source control systems, though others may be available through

extensions. You can also create an extension that allows you to work with another system in JDeveloper. For information about using these systems within JDeveloper, see the "Using Versioning" topic in the "Designing and Developing Applications" section of the JDeveloper online help.

Following are suggestions for using source control with a Fusion web application:

- Checking out files

Using JDeveloper, you can create a connection to the source control server and use the source control window to check out the source. When you work locally in the files, the pending changes window notifies you of any changed files. You can create a script using Apache Ant (which is integrated into JDeveloper). You can then use the script to build all application workspaces locally. This can ensure that the source files compile before you check the changed files into the source control repository. To find out how to use Apache Ant to create scripts, see "Building With Apache Ant" in the "Designing and Developing Applications" section of the JDeveloper online help.

- Automating builds

Consider running a continuous integration tool. Once files are checked into the source server, the tool can be used to recognize either that files have changed or to check for changed files at determined intervals. At that point, the tool can run an Ant script on the server that copies the full source (note that this should be a copy, and not a checkout), compiles those files, and if the compilation is successful, creates a zip file for consumers (not developers) of the application to use. The script should then clean up the source directory. Running a continuous integration tool will improve confidence in the quality of the code in the repository, encourage developers to update more often, and lead to smaller updates and fewer conflicts. Examples of continuous integration tools include Apache Gump and Cruise Control.

- Updating and committing files

When working with Subversion, updates and commits should be done at the Working Copy level, not on individual files. If you attempt to commit and update an individual file, there is a chance you will miss a supporting metadata file and thereby corrupt the committed copy of the application.

- Resolving merge conflicts

When you add or remove business components in a JDeveloper ADF Business Components project, JDeveloper reflects it in the project file (.jpr). When you create (or refactor) a component into a new package, JDeveloper reflects that in the project file and in the ADF Business Components project file (.jpx). Although the XML format of these project control files has been optimized to reduce occurrences of merge conflicts, merge conflicts may still arise and you will need to resolve them using JDeveloper's **Resolve Conflicts** option on the context menu of each affected file.

After resolving merge conflicts in any ADF Business Components XML component descriptor files, the project file (.jpr) for an ADF Business Components project, or the corresponding business components project file (.jpx), close and reopen the project to ensure that you're working with latest version of the component definitions. To do this, select the project in the Application Navigator, choose **File > Close** from the JDeveloper main menu, and then expand the project again in the Application Navigator.

## 1.5 Learning Oracle ADF

In addition to this developers guide, Oracle also offers the following resources to help you learn how you can best use Oracle ADF in your applications:

- **Cue Cards in JDeveloper:** JDeveloper cue cards provide step-by-step support for the application development process using Oracle ADF. They are designed to be used either with the included examples and a sample schema, or with your own data. Cue cards also include topics that provide more detailed background information, viewlets that demonstrate how to complete the steps in the card, and code samples. Cue cards provide a fast, easy way to become familiar with the basic features of Oracle ADF, and to work through a simple end-to-end task.
- **Tutorials on Oracle Technology Network:** These short tutorials allow you to gain valuable hands-on experience, and then use the lessons as the foundation for your own implementation.
- *Oracle Fusion Middleware Web User Interface Developer's Guide for Oracle Application Development Framework:* Provides detailed information, procedures, and practices for using the ADF Faces components and architecture.

## 1.6 Generation of Complete Web Tier Using Oracle JHeadstart

As you'll learn throughout the rest of this guide, Oracle JDeveloper 11g and Oracle ADF give you a productive, visual environment for building richly functional, database-centric Java EE applications with a maximally declarative development experience. However, if you are used to working with tools like Oracle Designer that offer *complete* user interface generation based on a higher-level application structure definition, you may be looking for a similar facility for your Java EE development. If so, then the Oracle JHeadstart 11g application generator may be of interest to you. It is an additional extension for JDeveloper that uses Oracle ADF's built-in features to offer complete web-tier generation for your application modules. Starting with the data model you've designed for your ADF business service, you use the integrated editors that JHeadstart adds to the JDeveloper environment to iteratively refine a higher-level application structure definition. These editors controls the functionality and organization of the view objects' information in your generated web user interface. By checking boxes and choosing various options from dropdown lists, you describe a logical hierarchy of pages that can include multiple styles of search regions, list of values (LOVs) with validation, shuttle controls, nested tables, and other features. These declarative choices use terminology familiar to Oracle Forms and Designer users, further simplifying web development. Based on the application structure definition, you generate a complete web application that automatically implements the best practices described in this guide, easily leveraging the most sophisticated features that Oracle ADF and JSF have to offer.

Whenever you run the JHeadstart application generator, rather than generating *code*, it creates (or regenerates) all of the declarative view and controller layer artifacts of your Oracle ADF-based web application. These artifacts use the ADF Model layer and work with your ADF application module as their business service. The generated files are the same kinds you produce when using JDeveloper's built-in visual editors. The key difference is that JHeadstart creates them in bulk, based on a higher-level definition that you can iteratively refine until the generated pages match your end users' requirements as closely as possible. The generated files include:

- JSF Pages with databound ADF Faces UI components
- ADF Model page definition XML files describing each page's data bindings
- JSF navigation rules to handle page flow

- Resource files containing localizable UI strings

Once you've generated a maximal amount of your application's web user interface, you can spend your time using JDeveloper's productive environment to tailor the results or to concentrate your effort on additional showcase pages that need special attention. Once you've modified a generated page, you can adjust a setting to avoid regenerating that page on subsequent runs of the application generator. Of course, since both the generated pages and your custom designed ones leverage the same ADF Faces UI components, all of your pages automatically inherit a consistent look and feel. For more information on how to get a fully functional trial of JHeadstart for evaluation, including details on pricing, support, and additional services, see the JHeadstart page on the Oracle Technology Network at <http://www.oracle.com/technetwork/developer-tools/jheadstart/overview/index.html>.

---

## Introduction to the ADF Sample Application

This chapter describes how to run the StoreFront module of the Fusion Order Demo (FOD) application created as a sample to demonstrate the use of the Fusion web application technology stack to create transaction-based web applications as required for a web shopping storefront. Details about the schema and features that implement the Fusion Order Demo application are also provided. The demonstration application is used as an example throughout this guide to illustrate points and provide code samples.

Before examining the individual components and their source code in depth, you may find it helpful to install and become familiar with the functionality of the Fusion Order Demo application.

This chapter includes the following sections:

- [Section 2.1, "Introduction to the Oracle Fusion Order Demo"](#)
- [Section 2.2, "Setting Up the Fusion Order Demo Application"](#)
- [Section 2.3, "Running the Fusion Order Demo Application StoreFront Module"](#)
- [Section 2.4, "Running the Fusion Order Demo Standalone Applications"](#)
- [Section 2.5, "Taking a Look at the Fusion Order Demo Application"](#)

### 2.1 Introduction to the Oracle Fusion Order Demo

In this sample application, electronic devices are sold through a storefront-type web application. Customers can visit the web site, register, and place orders for the products. In order to register customers and fulfill orders, currently only a single application is in place. In a future release, several applications, will cooperate. For a detailed description of how the application works at runtime, see [Section 2.5, "Taking a Look at the Fusion Order Demo Application."](#)

In order to view and run the demo, you need to install Oracle JDeveloper 11g. You then need to download the application for this demonstration. Instructions to complete these tasks appear in this chapter. For complete details, see [Section 2.2, "Setting Up the Fusion Order Demo Application."](#)

Once the application is installed and running, you can view the code using Oracle JDeveloper. You can view the application at runtime by logging in as an existing customer and placing an order.

## 2.2 Setting Up the Fusion Order Demo Application

The Fusion Order Demo application runs using an Oracle database and Oracle JDeveloper 11g. The platforms supported are the same as those supported by JDeveloper.

To prepare the environment and run the Fusion Order Demo application, you must:

1. Install Oracle JDeveloper 11g and meet the installation prerequisites. The Fusion Order Demo application requires an existing Oracle database. For details, see [Section 2.2.1, "How to Download the Application Resources."](#)
2. Install the Fusion Order Demo application from the Oracle Technology Network. For details, see [Section 2.2.2, "How to Install the Fusion Order Demo Schema."](#)
3. Install Mozilla FireFox, version 2.0 or higher, or Internet Explorer, version 7.0 or higher.
4. Run the application on a monitor that supports a screen resolution of 1024 X 768 or higher. For details, see [Section 2.3, "Running the Fusion Order Demo Application StoreFront Module."](#)

### 2.2.1 How to Download the Application Resources

The Fusion Order Demo application requires an existing Oracle database. You run the Fusion Order Demo application using Oracle JDeveloper 11g.

Do the following before installing the Fusion Order Demo application:

- Install Oracle JDeveloper. You need Oracle JDeveloper 11g Studio Edition to view the application's projects and run the application using the JDeveloper integrated server. You can download Oracle JDeveloper from:

<http://www.oracle.com/technetwork/developer-tools/jdev/overview/index.html>

---

---

**Note:** Ensure that you download and install 11g and that it is the Studio Edition, not the Java Edition. You can verify these details in Oracle JDeveloper from the **Help > About** menu option.

---

---

- Download the Fusion Order Demo application ZIP file (FusionOrderDemo\_R1PSx.zip). You can download the ZIP file from:

[http://www.oracle.com/technetwork/developer-tools/jdev/learnmore/fo\\_d1111-407812.html](http://www.oracle.com/technetwork/developer-tools/jdev/learnmore/fo_d1111-407812.html)

- Install an Oracle database. The Fusion Order Demo application requires a database for its data.

The SQL scripts were written for an Oracle database, so you will need some version of an Oracle RDBMS, such as 11g, or XE. The scripts will not install into Oracle Lite. If you wish to use Oracle Lite or some other database, then you will need to modify the database scripts accordingly. You can download an Oracle database from:

<http://www.oracle.com/technetwork/index.html>

Specifically, the small footprint of the Oracle Express Edition (XE) is ideally suited for setting up the database on your local machine. You can download it from:

<http://www.oracle.com/technetwork/database/express-edition/overview/index.html>

## 2.2.2 How to Install the Fusion Order Demo Schema

You can download the Fusion Order Demo application from the Oracle Technology Network (OTN) web site.

### To download the demo and install the FOD schema to your database:

1. Navigate to <http://www.oracle.com/technetwork/developer-tools/jdev/learnmore/fod1111-407812.html> and download the ZIP file to a local directory.
2. Start Oracle JDeveloper 11g and from the main menu choose **File > Open**.
3. In the Open dialog, browse to the location where you extracted the ZIP file to in Step 1 and select **Infrastructure.jws** from the **infrastructure** directory. Click **Open**.
4. In the Application Navigator, expand **MasterBuildScript** and then **Resources**, and double-click **build.properties**.
5. In the editor, modify the properties shown in [Table 2-1](#) for your environment.

**Table 2-1 Properties Required to Install the Fusion Order Demo Application**

Property	Description
<code>jdeveloper.home</code>	The root directory where you have Oracle JDeveloper 11g installed. For example: <code>C:/JDeveloper/11/jdeveloper</code>
<code>jdbc.urlBase</code>	The base JDBC URL for your database in the format <code>jdbc:oracle:thin:@&lt;yourhostname&gt;</code> . For example: <code>jdbc:oracle:thin:@localhost</code>
<code>jdbc.port</code>	The port for your database. For example: 1521
<code>jdbc.sid</code>	The SID of your database. For example: ORCL or XE
<code>db.adminUser</code>	The administrative user for your database. For example: system
<code>db.demoUser.tablespace</code>	The table space name where FOD users will be installed. For example: USERS

6. From the JDeveloper main menu, choose **File > Save All**.
7. In the Application Navigator, under the **Resources** node, right-click **build.xml** and choose **Run Ant Target > buildAll**.
8. In the Enter Property dialog, enter the password for the database system user and click **Continue**.

Once you enter the password, the Ant build script creates the FOD users and populates the tables in the FOD schema. In the Apache Ant - Log window, you will see a series of SQL scripts and finally:

```
buildAll:
```

BUILD SUCCESSFUL

Total time: nn minutes nn seconds

For more information on the demo schema and scripts, see the README.txt file in the MasterBuildScript project.

## 2.2.3 Overview of the Fusion Order Demo Schema

Figure 2–1 shows a simplified representation of the schema for the Fusion Order Demo application. The blue shapes in the diagram represent the four core tables. The other tables and views are shown as yellow shapes that sometimes represent several tables to help simplify the diagram. Some of the tables use sequences, but only those used by the core tables are shown.

**Figure 2–1 Schema Diagram for the Fusion Order Demo Application**

The core tables represented by the blue diagram elements include:

- **PERSONS**: This table stores all the users who interact with the system, including customers, staff, and suppliers. The first and last name, email address, and person type code of each user is stored. A user is uniquely identified by an ID. Other IDs provide foreign keys to tables with address information and, in the case of customer's, membership information.
- **ORDERS**: This table represents activity by specific customers. When an order is created, the date of the order, the total amount of the order, the ID of the customer

who created it, and the status of the order are all recorded. After the order is fulfilled, the order status and order shipped date are updated. All orders are uniquely identified by a sequence-assigned ID.

- **ORDER\_ITEMS:** For each order, there may be many order items recorded. The unit price and quantity of each order item are recorded. The order line item and its order ID uniquely identify each order item.
- **PRODUCTS\_BASE:** This table stores all of the products available in the store. For each product, the name and cost are recorded. All products are uniquely identified by a sequence-assigned ID. The image of the product and its description are stored in separate tables, which each reference the product ID. The columns `ATTRIBUTEx` are reserved for future use with descriptive flexfields (commonly required by Oracle E-Business Suite schema).

The sequences that the core tables use include:

- **PERSON\_SEQ:** Populates the ID for for each new person.
- **ORDER\_SEQ:** Populates the ID for each new order.
- **ORDERS\_ITEMS\_SEQ:** Populates the ID for each new order item.
- **PRODUCTS\_SEQ:** Populates the ID for each product.

The PL/SQL package `USER_CONTEXT_PKG` contains a procedure `set_app_user_lang()` used to illustrate a simple example of how to set per-user database state from inside an application module.

Note the `SHIPPING_OPTIONS` view is reserved for future use and is not currently used in the Fusion Order Demo.

To support tracking of change history in the Fusion Order Demo, every table contains the history column `CREATED_BY`, `CREATION_DATE`, `LAST_UPDATED_BY`, `LAST_UPDATED_DATE`, and `OBJECT_VERSION_ID`, as shown in [Figure 2-2](#).

**Figure 2-2 History Columns for Tables in FOD Schema**

### 2.2.3.1 Translation Support in the Fusion Order Demo Schema

To support localization of the Fusion Order Demo, the `AVAILABLE_LANGUAGES` table lists all available languages. In this table, only one row will have the `DEFAULT_FLAG` set to Y corresponding to the current user's language.

Translations exist for the following base tables: `PRODUCTS_BASE` (`PRODUCT_TRANSLATIONS`), `PRODUCT_CATEGORIES_BASE` (`CATEGORY_TRANSLATIONS`), `SHIPPING_OPTIONS_BASE` (`SHIPPING_OPTION_TRANSLATIONS`),

MEMBERSHIPS\_BASE (MEMBERSHIP\_TRANSLATIONS) and DISCOUNTS\_BASE (DISCOUNT\_TRANSLATIONS).

Taking the Shipping Options group, as shown in Figure 2-3: SHIPPING\_OPTION\_TRANSLATIONS is fully populated so that each product has one row for each language. The column LANGUAGE holds the translation language identifier. The entry itself may not yet be translated, in which case the SOURCE\_LANGUAGE column holds the language that the entry is currently in. When a value has been translated, SOURCE\_LANGUAGE and LANGUAGE will hold the same value. The PL/SQL package USER\_CONTEXT\_PKG creates the custom USERENV ( ' CLIENT\_INFO ' ) variable that specifies the runtime locale used to pull the correct translations from SHIPPING\_OPTION\_TRANSLATIONS into the SHIPPING\_OPTIONS view along with the SHIPPING\_OPTIONS\_BASE table data. Each order has one set of Shipping Options associated with it.

Figure 2-3 Shipping Options Grouping for the Fusion Order Demo Schema

### 2.2.3.2 Lookup Tables in the Fusion Order Demo Schema

The code lookup table LOOKUP\_CODES table contains codes that are used throughout the Fusion Order Demo application. For example, the PERSONS table contains the columns person\_type\_code, marital\_status\_code, and gender. These codes have corresponding rows in the LOOKUP\_CODES table, discriminating on the lookup\_type column. Foreign keys are not defined for these rows, but instead are enforced in the user interface by populating user interface components with LOOKUP\_CODES values for a particular lookup type. For example, when creating a new registration (also known as a person) in the user interface, the values that can be used for the

person\_type\_code are populated in a dropdown list from the lookup\_code values with lookup\_type=person\_type\_code.

The LOOKUP\_CODES table also supports the localization of the user interface. The table uses a combined key of code and language (obtained from runtime locale or preference) to determine the code's meaning. Each code has an entry for each supported language, as described in [Section 2.2.3.1, "Translation Support in the Fusion Order Demo Schema."](#)

Using addresses as an example, as shown in [Figure 2-4](#): PERSONS uses an intersection ADDRESS\_USAGES to accommodate multiple address information. In addition ADDRESS\_USAGES uses LOOKUP\_CODES to store both OWNER\_TYPE\_CODE and USAGE\_TYPE\_CODE information, returning the MEANING (see table extract in [Figure 2-5](#)). ADDRESSES directly accesses COUNTRY\_CODES to look up and use the COUNTRY\_NAME associated with the COUNTRY\_ID stored in ADDRESSES. The PERSONS table also directly stores PRIMARY\_ADDRESS\_ID by a direct lookup to ADDRESSES.

**Figure 2-4 LOOKUP\_CODES Usage in the Fusion Order Demo Schema**

The correct translation is applied by using the LANGUAGE columns in both LOOKUP\_CODES and COUNTRY\_CODES with the runtime locale/preference.

**Figure 2-5 LOOKUP\_CODES Sample Data in the Fusion Order Demo Schema**

LOOKUP_TYPE	LOOKUP_CODE	MEANING
OWNER_TYPE_CODE	CUST	Customer
OWNER_TYPE_CODE	SUPP	Supplier
OWNER_TYPE_CODE	STAFF	Staff
USAGE_TYPE_CODE	IN	Invoice Address
USAGE_TYPE_CODE	SH	Shipping Address

The lookup table DEMO\_OPTIONS defines the various options within the Fusion Order Demo application that are switched on. It also caches general configuration information such as email addresses and phone numbers to use as overrides in this

demonstration scenario (for example, where email addresses are fictitious). This table is reserved for future use.

## 2.3 Running the Fusion Order Demo Application StoreFront Module

The Fusion Order Demo application consists of a web user interface and a business components layer. Specifically, the following projects are part of the Fusion Order Demo application:

- `StoreFrontService`: Provides access to the storefront data and provides transaction support to update data for customer information and orders.
- `StoreFrontUI`: Provides web pages that the customer uses to browse the storefront, place orders, register on the site, view order information, and update the user profile.

You run the StoreFront module of the Fusion Order Demo application in JDeveloper by running the `home.jspx` page in the `StoreFrontUI` project. The `StoreFrontUI` project uses JavaServer Faces (JSF) as the view technology, and relies on the ADF Model layer to interact with ADF Business Components in the `StoreFrontService` project. To learn more about the Fusion Order Demo application and to understand its implementation details, see [Section 2.5, "Taking a Look at the Fusion Order Demo Application."](#)

A second module of the Fusion Order Demo application is available to process the orders that you place using the StoreFront module. For example, the WebLogic Fusion Order Demo module uses various internal and external applications, including a customer service application, a credit validation system, and both an internal vendor and external vendor. These composite services are the subject of another developer's guide and are not addressed in the *Oracle Fusion Middleware Fusion Developer's Guide for Oracle Application Development Framework*. For details about the WebLogic Fusion Order Demo module used to demonstrate the capabilities of Oracle SOA Suite, see the *Oracle Fusion Middleware Developer's Guide for Oracle SOA Suite*.

You cannot run the WebLogic Fusion Order Demo module in JDeveloper. When you want to integrate the storefront portion with the composite services portion of the application, you must deploy the Fusion Order Demo application to a SOA-enabled Oracle WebLogic Server. Instructions to deploy any SOA web application to Oracle WebLogic Server, are addressed in the Fusion Order Demo home page on OTN at this link

<http://www.oracle.com/technetwork/developer-tools/jdev/index-095536.html>.

The easiest way to run the Fusion Order Demo application is to open only the StoreFront module in JDeveloper and run the `home.jspx` page in the `StoreFrontUI` project.

### To run the StoreFront module of the Fusion Order Demo application:

1. Open the application in Oracle JDeveloper:
  - a. From the JDeveloper main menu, choose **File > Open**.
  - b. Navigate to the location where you extracted the demo ZIP file to and select the **StoreFrontModule.jws** application workspace from the **StoreFrontModule** directory. Click **Open**.

[Figure 2–6](#) shows the Application Navigator after you open the file for the application workspace. For a description of each of the projects in the

workspace, see [Section 2.5, "Taking a Look at the Fusion Order Demo Application."](#)

**Figure 2–6** The Fusion Order Demo Projects in Oracle JDeveloper

2. In the Application Navigator, click the Application Resources accordion title to expand the panel.
3. In the Application Resources panel, expand the **Connections** and **Database** nodes.
4. Right-click **FOD** connection and choose **Properties**.
5. In the Edit Database Connection dialog, modify the connection information shown in [Table 2–2](#) for your environment.

**Table 2–2** Connection Properties Required to Run the Fusion Order Demo Application

Property	Description
Host Name	The host name for your database. For example: localhost
JDBC Port	The port for your database. For example: 1521
SID	The SID of your database. For example: ORCL or XE

Do not modify the user name and password **fod/fusion**. These must remain unchanged. Click **OK**.

6. In the Application Navigator, right-click **StoreFrontService** and choose **Rebuild**.
7. In the Application Navigator, right-click **StoreFrontUI** and choose **Run**.

The Configure Default Domain dialog displays the first time you run the application and start a new domain in Integrated WebLogic Server. Use the dialog to define an administrator password for the new domain. Passwords you enter can be eight characters or more and must have a numeric character.

The `home.jspx` page within the `StoreFrontUI` project is the default run target. When you run the default target, JDeveloper will launch the browser and display the Fusion Order Demo application home page.

Once the home page appears, you can browse the web site as an anonymous user, or you can choose to log in and place orders (may require registering as a customer first). Because the Fusion Order Demo application implements ADF Security to manage access to Oracle Application Development Framework (Oracle ADF) resources, only

the authenticated user will be able to view orders in their cart. [Table 2–3](#) shows the users who are authorized as members of the `fod-users` role to log into the Fusion Order Demo application.

---

**Note:** The Fusion Order Demo application ships with predefined user data. The schema for the application defines different types of users including customer, supplier, and staff types. All users are members of the `fod-users` role and are authorized to log in. However, only `ngreenbe` is the user type `CUST` (customer). When you log in as any other user, you will need to register as a customer before you can place an order. These additional users were created to support roles in other modules of the Fusion Order Demo application.

---

**Table 2–3** *Supplied Users in the Fusion Order Demo Application*

Username	Password	Application Role	Notes
<code>ngreenbe</code>	<code>welcome1</code>	<code>fod-users</code>	Can add items to cart, check out, and view order information. This is the only user who is preregistered as a customer in the StoreFront module of Fusion Order Demo.
<code>sking</code>	<code>welcome1</code>	<code>fod-users</code> , <code>fod-admin</code>	Can add items to cart, but must register as a customer to check out and view order information. This user also has administration privileges ( <code>fod-admin</code> ) in the MasterPriceList module of Fusion Order Demo.
<code>ahunold</code>	<code>welcome1</code>	<code>fod-users</code> , <code>fod-manager</code>	Can add items to cart, but must register as a customer to check out and view order information. This user also has read-only privileges ( <code>fod-manager</code> ) in the MasterPriceList module of Fusion Order Demo.
<code>pbrown / fdaviet</code>	<code>welcome1</code>	<code>fod-users</code>	Can add items to cart, but must register as a customer to check out and view order information. These users may be added to other roles in a future version of Fusion Order Demo.

## 2.4 Running the Fusion Order Demo Standalone Applications

The Fusion Order Demo application includes a set of sample applications that allow you to investigate Oracle ADF functionality that does not appear in the StoreFront module. Collectively, these sample applications are referred to as standalone applications. The standalone sample applications appear in five application workspaces, each consisting of several projects, located in the **StandaloneExamples** directory where you extracted the demo ZIP file.

In general, almost all of the standalone applications demonstrate concepts of ADF Business Components and data model projects. References to these standalone applications appear throughout the chapters contained in [Part II, "Building Your Business Services"](#) and [Part VI, "Advanced Topics"](#) of this developer's guide. As you read sections this guide, you may want to run the corresponding standalone application to investigate the concepts further. For a brief description of each

application workspace and links to the documentation, refer to the tables in [Section 2.4.2](#) through [Section 2.4.5](#).

## 2.4.1 How to Run the Standalone Applications

How you use JDeveloper to run a standalone application depends on the individual application. Some applications are set up to use the interactive testing tool JDeveloper provides for the ADF Business Components data model project (this tool is known as the Business Component Browser). Other applications provide Java test clients (with file names like `TestClientXxx.java`) that use the ADF Business Components API to execute queries and display results. In the case of the Business Component Browser, you work entirely in the tool, which essentially provides a convenient user interface for interacting with business components. In the case of the Java clients, the program files output their results and print statements to the JDeveloper Log window.

Familiarize yourself with the following general procedures about how to run the standalone applications. The first procedure describes how to run an application with its provided test client. The second describes how to launch the Business Component Browser on the data model project's ADF application module. Then read [Section 2.4.2](#) through [Section 2.4.5](#) for more details about the individual standalone applications.

### Before you begin:

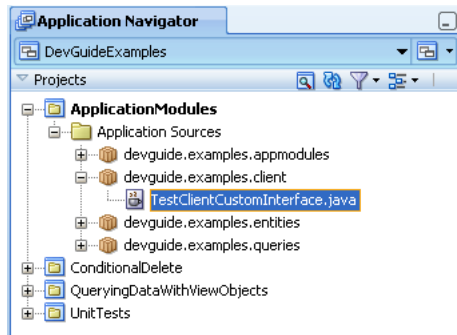

- In the Database Navigator, modify the connection information for the FOD database connection so it has the connection information for your environment, as described in [Section 2.3, "Running the Fusion Order Demo Application StoreFront Module."](#)
- Some of the standalone applications work with a modified version of the FOD schema. For standalone applications that require schema changes, the application's project will contain a SQL script that you must run within JDeveloper.

Once you are through investigating a standalone application, you can use the script to back out the schema changes.

### To run a standalone application from its provided test client:

1. Open the application in Oracle JDeveloper:
  - a. From the JDeveloper main menu, choose **File > Open**.
  - b. Navigate to the location where you extracted the demo ZIP file to, open the **StandaloneExamples** directory, then open the desired standalone application directory and select the application workspace (**.jws**) from the folder. Click **Open**.
2. In the Application Navigator, expand the project folder and locate the test client (`.java`) file. In some cases, the test client is added to a package located in the **Application Sources** folder. In other cases, the **Resources** folder contains the test client.

For example, [Figure 2-7](#) shows the expanded **ApplicationModules** project with the Java file node **TestClientCustomInterface.java** selected.

**Figure 2–7 Test Client Selected in Application Navigator**

3. Right-click the test client and choose **Run**.

For the names and location of the test clients provided with the standalone applications, see the tables in [Section 2.4.2](#) through [Section 2.4.5](#).

The Configure Default Domain dialog displays the first time you run the application and start a new domain in Integrated WebLogic Server. Use the dialog to define an administrator password for the new domain. Passwords you enter can be eight characters or more and must have a numeric character.

4. Examine the JDeveloper Log window for the test client's output.

Refer to the referenced documentation for details about the expected results.

When the standalone application does not provide a test client to programmatically exercise the ADF Business Components API, you will use the interactive testing tool, known as the Business Components Browser.

#### To run a standalone application in the Business Component Browser:

1. Open the application in Oracle JDeveloper:
  - a. From the JDeveloper main menu, choose **File > Open**.
  - b. Navigate to the location where you extracted the demo ZIP file to, open the **StandaloneExamples** directory, then open the desired standalone application directory and select the application workspace (.jws) from the folder. Click **Open**.
2. In the Application Navigator, expand the project folder and locate the application module in a package in the **Application Sources** folder.

For example, [Figure 2–8](#) shows the expanded **ConditionalDelete** project with the application module **AppModule** selected and a tooltip for the node displayed.

**Figure 2–8 Application Module Node Selected in Application Navigator**

3. Right-click the application module node and choose **Run**.

For the names of the runnable application modules, see the tables in [Section 2.4.2](#) through [Section 2.4.5](#).

The Configure Default Domain dialog displays the first time you run the application and start a new domain in Integrated WebLogic Server. Use the dialog to define an administrator password for the new domain. Passwords you enter can be eight characters or more and must have a numeric character.

4. Use the Business Component Browser to interact with the view instances of the standalone application.

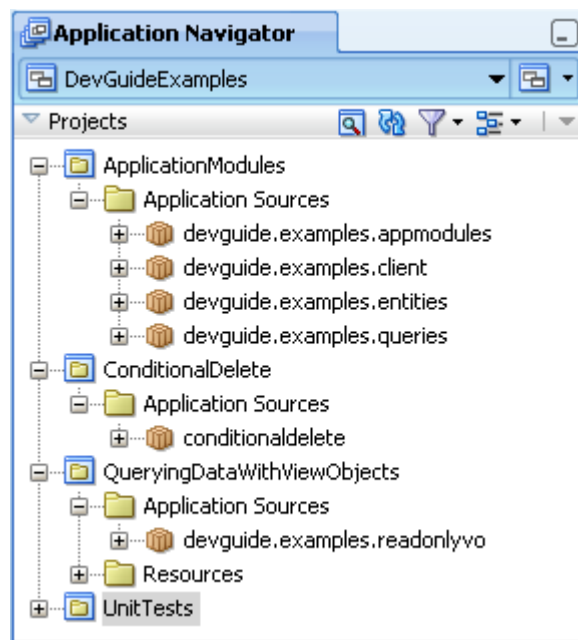

Refer to the referenced documentation for details about the application. For details about using the Browser to interact with the data model, see [Section 6.3, "Testing View Object Instances Using the Business Component Browser."](#)

## 2.4.2 Standalone Applications in the DevGuideExamples Application Workspace

Two of the standalone applications in the application workspace `DevGuideExamples` use programmatic test clients to demonstrate concepts related to the ADF Business Components framework. The third application demonstrates framework functionality when you run the application in the Business Component Browser.

[Figure 2-9](#) shows the Application Navigator after you open the `DevGuideExamples` application workspace.

**Figure 2-9** *Runnable Applications in the DevGuideExamples Application Workspace*

Note that the test clients for the `DevGuideExamples` standalone applications provide a good starting point for understanding how to exercise methods of the ADF Business Components API. They also make good samples for test clients that you may want to create to test business component queries in a data model project. For background on working with test clients, see [Section 6.4, "Testing View Object Instances Programmatically."](#)

---

**Note:** The ADF Business Components API is available when you need to generate custom classes to augment the default runtime behavior of the business components. For background about the ADF Business Components framework, see [Section 3.5, "Overview of the Implementation Architecture."](#)

---

[Table 2–4](#) describes the standalone applications in the `DevGuideExamples` application workspace. Examples from these applications appear throughout the chapters contained in [Part II, "Building Your Business Services"](#) of this guide.

**Table 2–4 Standalone Applications in the DevGuideExamples Application Workspace**

Project Name	Runnable Class or Project Target	Documentation
ApplicationModule	<p>Run <code>TestClientCustomInterface.java</code> in the <code>devguide.examples.client</code> package in the <b>Application Sources</b> folder.</p> <p>Exercises custom methods of <b>StoreFrontService</b> application module's client interface and prints to the JDeveloper Log window to indicate the results.</p>	<p>For details about the test client, see <a href="#">Section 9.10.1, "How to Work Programmatically with an Application Module's Client Interface."</a></p> <p>For details about the methods of the client interface, see the examples in <a href="#">Section 4.12, "Working Programmatically with Entity Objects and Associations."</a></p>
ConditionalDelete	<p>Launch the Business Component Browser on <b>AppModule</b> in the <b>Application Sources</b> folder.</p> <p>Overrides a method in the generated entity class that conditionally prevents deletion of entity rows. In the Business Component Browser, click <b>Delete the Current Row</b> and observe the exception statement. Then, click <b>Insert a New Row</b> and delete the new row.</p>	<p>For a description of overriding the <code>remove()</code> method that you generate in the entity implementation class file, see <a href="#">Section 8.12, "Conditionally Preventing an Entity Row from Being Removed."</a></p>

**Table 2–4 (Cont.) Standalone Applications in the DevGuideExamples Application Workspace**

Project Name	Runnable Class or Project Target	Documentation
QueryingDataWithView Objects	Run <b>TestClient.java</b> in the <b>Resources</b> folder.  Programmatically iterates over the <code>PersonList</code> view instance using methods of the Business Components API <code>RowIterator</code> interface and prints to the JDeveloper Log window.	For details about iterating over a collection, see <a href="#">Section 6.4.5, "How to Count the Number of Rows in a Row Set."</a>  For details about how to create test clients, see <a href="#">Section 6.4, "Testing View Object Instances Programmatically."</a>
	Run <b>TestClient2.java</b> in the <b>Resources</b> folder.  Programmatically iterates over the <code>PersonList</code> view instance, accesses the detail collection <code>OrdersToShipToCustomers</code> using a view link accessor attribute, and prints to the JDeveloper Log window.	For details about iterating over a detail collection, see <a href="#">Section 5.6.6, "How to Access the Detail Collection Using the View Link Accessor."</a>  For more details about the test client, see <a href="#">Section 6.4.6, "How to Access a Detail Collection Using the View Link Accessor."</a>
	Run <b>TestClient3.java</b> in the <b>Resources</b> folder.  Programmatically iterates over the <code>PersonList</code> view instance using a strongly-typed <code>PersonsRow</code> interface and prints to the JDeveloper Log window.	For details about iterating over a collection using the view row accessor attribute, see <a href="#">Section 39.3.1.3, "Exposing View Row Accessors to Clients."</a>
	Run <b>TestClientBindVars.java</b> in the <b>Resources</b> folder.  Programmatically sets the <code>WHERE</code> clause for the <code>PersonList</code> view instance using bind variables to filter the collection and prints to the JDeveloper Log window.	For details about setting bind variables, see <a href="#">Section 5.10.6, "How to Set Existing Bind Variable Values at Runtime."</a>  For more details about the test client, see <a href="#">Section 5.10.5, "How to Add a WHERE Clause with Named Bind Variables at Runtime."</a>
	Run <b>TestClientViewCriteria.java</b> in the <b>Resources</b> folder.  Programmatically sets a view criteria for the <code>PersonList</code> view instance to filter the collection and prints to the JDeveloper Log window.	For details about the ADF Business Component's view criteria API, see <a href="#">Section 5.11.10, "What You May Need to Know About the View Criteria API."</a>  For more details about the test client, see <a href="#">Section 5.11.8, "How to Create View Criteria Programmatically."</a>

### 2.4.3 Standalone Applications in the AdvancedExamples Application Workspace

The standalone applications assembled in the application workspace `AdvancedExamples` demonstrate advanced concepts that apply to the entire ADF Business Components framework.

[Figure 2–10](#) shows the Application Navigator after you open the `AdvancedExamples` application workspace.

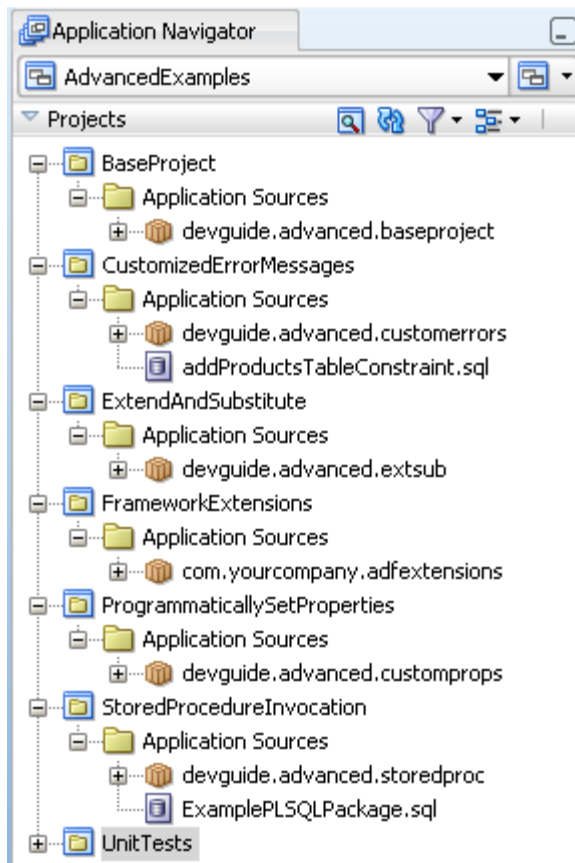

**Figure 2–10 Runnable Applications in the AdvancedExamples Application Workspace**

Table 2–5 describes the standalone applications in the AdvancedExamples application workspace. Examples from this application workspace are described in Chapter 37, "Advanced Business Components Techniques."

**Table 2–5 Standalone Applications in the AdvancedExamples Application Workspace**

Project Name	Runnable Class or Project Target	Documentation
BaseProject	Run <b>TestClient.java</b> in the <b>Application Sources</b> folder.	For details about how to extend business components to create a customized versions of the original, see <a href="#">Section 37.8, "Creating Extended Components Using Inheritance."</a>
CustomizedErrorMessages	Run the <code>addProductsTableConstraint.sql</code> scripts in the <b>Application Sources</b> folder against the FOD connection to set up the additional database objects required for the project.  Launch the Business Component Browser on <b>ProductModule</b> in the <b>Application Sources</b> folder.	For details about how to provide an alternative message string for the builtin error codes in a custom message bundle, see <a href="#">Section 37.7, "Customizing Business Components Error Messages."</a>
ExtendAndSubstitute	Not runnable.  Programmatically iterates over the <code>PersonList</code> view instance using methods of the Business Components API <code>RowIterator</code> interface and prints to the JDeveloper Log window.	For details about how to substitute business components, see <a href="#">Section 37.9, "Substituting Extended Components in a Delivered Application."</a>

**Table 2–5 (Cont.) Standalone Applications in the AdvancedExamples Application Workspace**

Project Name	Runnable Class or Project Target	Documentation
FrameworkExtensions	Not runnable. Provides template class files that you can use to modify your own generated ADF Business Components classes.	For details about framework extensions, see <a href="#">Section 37.2, "Customizing Framework Behavior with Extension Classes."</a>
ProgrammaticallySet Properties	Run <b>TestClient.java</b> in the <b>Application Sources</b> folder.	For details about how to communicate custom declarative information about business components to the generic code in framework extension classes, see <a href="#">Section 37.2, "Customizing Framework Behavior with Extension Classes."</a>
StoredProcedure Invocation	Run the <code>ExampleSQLPackage.sql</code> scripts in the <b>Application Sources</b> folder against the FOD connection to set up the additional database objects required for the project.  Run <b>TestClient.java</b> in the <b>Application Sources</b> folder.	For details about how to code custom Java classes for business components that invoke database stored procedures and functions, see <a href="#">Section 37.4, "Invoking Stored Procedures and Functions."</a>

## 2.4.4 Standalone Applications in the AdvancedEntityExamples Application Workspace

The standalone applications assembled in the application workspace `AdvancedEntityExamples` demonstrate advanced concepts that apply to ADF Business Components entity objects.

[Figure 2–11](#) shows the Application Navigator after you open the `AdvancedEntityExamples` application workspace.

**Figure 2–11 Runnable Applications in the AdvancedEntityExamples Application Workspace**

Table 2–6 describes the standalone applications in the `AdvancedEntityExamples` application workspace. Examples from this application workspace are described in Chapter 38, "Advanced Entity Object Techniques."

**Table 2–6 Standalone Applications in the AdvancedEntityExamples Application Workspace**

Project Name	Runnable Class or Project Target	Documentation
ControllingPostingOrder	Launch the Business Component Browser on <b>ProductsModule</b> in the <b>Application Sources</b> folder.	For details about controlling the posting order resulting from DML operations to save changes to a number of related entity objects, see <a href="#">Section 38.8, "Controlling Entity Posting Order to Avoid Constraint Violations."</a>
EntityWrappingPLSQLPackage	Run the <code>CreateProductsXXX.sql</code> scripts in the <b>Application Sources</b> folder against the FOD connection to set up the additional database objects required for the project.  Launch the Business Component Browser on <b>ProductsModule</b> in the <b>Application Sources</b> folder.	For details about overriding the default DML processing event for an entity object to invoke methods in a PL/SQL API PL/SQL package that encapsulates insert, update, and delete access to an underlying table, see <a href="#">Section 38.5, "Basing an Entity Object on a PL/SQL Package API."</a>
InheritanceAndPolymorphicQueries	Run the <code>AlterPersonsTable.sql</code> script in the <b>Application Sources</b> folder against the FOD connection to set up the additional database objects required for the project.  Run <code>TestEntityPolymorphism.java</code> in the <b>Resources</b> folder. Also, run <code>TestViewRowPolymorphism.java</code> in the <b>Resources</b> folder.	For details about creating an entity object inheritance hierarchy, see <a href="#">Section 38.7, "Using Inheritance in Your Business Domain Layer."</a>
SimpleDomains	Run the <code>CreateObjectType.sql</code> script in the <b>Application Sources</b> folder against the FOD connection to set up the additional database objects required for the project.  Launch the Business Component Browser on <b>PersonModule</b> in the <b>Application Sources</b> folder.	For details about creating custom data types, see <a href="#">Section 38.1, "Creating Custom, Validated Data Types Using Domains."</a>

## 2.4.5 Standalone Applications in the AdvancedViewObjectExamples Application Workspace

The standalone applications assembled in the application workspace `AdvancedViewObjectExamples` demonstrate advanced concepts that apply to ADF Business Components view objects.

[Figure 2–12](#) shows the Application Navigator after you open the `AdvancedViewObjectExamples` application workspace.

**Figure 2–12 Runnable Applications in the AdvancedViewObjectExamples Application Workspace**

Table 2–4 describes the standalone applications in the AdvancedViewObjectExamples application workspace. Examples from this application workspace are described in [Chapter 39, "Advanced View Object Techniques."](#)

**Table 2–7 Standalone Applications in the AdvancedViewObjectExamples Application Workspace**

Project Name	Runnable Class or Project Target	Documentation
DeclarativeBlockOperations	Launch the Business Component Browser on <b>AppModule</b> in the <b>Application Sources</b> folder.	For details about how to use custom metadata properties to control insert, update, or delete on a view object, see <a href="#">Section 39.11, "Declaratively Preventing Insert, Update, and Delete."</a>
InMemoryOperations	Launch the Business Component Browser on <b>AppModule</b> in the <b>Application Sources</b> folder.  Illustrates using the in-memory sorting and filtering functionality from the client side using methods on the interfaces in the <code>oracle.jbo</code> package.	For details about how to use view objects to perform in-memory searches and sorting to avoid unnecessary trips to the database, see <a href="#">Section 39.5, "Performing In-Memory Sorting and Filtering of Row Sets."</a>
MultipleMasters	Launch the Business Component Browser on <b>AppModule</b> in the <b>Application Sources</b> folder.	For details about creating a view object with multiple updatable entities to support creating new rows, see <a href="#">Section 39.9, "Creating a View Object with Multiple Updatable Entities."</a>

**Table 2–7 (Cont.) Standalone Applications in the AdvancedViewObjectExamples Application Workspace**

Project Name	Runnable Class or Project Target	Documentation
MultipleViewCriteria	Run <code>TestClientMultipleViewCriteria.java</code> in the <b>Application Sources</b> folder.	For details about how to programmatically filter query results, see <a href="#">Section 39.4, "Working Programmatically with Multiple Named View Criteria."</a>
ReadingAndWritingXML	Run <code>TestClientReadXML.java</code> in the <b>Resources</b> folder. Then run <code>TestClientWriteXML.java</code> in the <b>Resources</b> folder.	For details about how to produce XML from queried data, see <a href="#">Section 39.7, "Reading and Writing XML."</a>
ViewObjectOnRefCursor	Run the <code>CreateRefCursorPackage.sql</code> scripts in the <b>Application Sources</b> folder against the FOD connection to set up the additional database objects required for the project.  Launch the Business Component Browser on <b>OrdersModule</b> in the <b>Application Sources</b> folder.	For details about how to use PL/SQL to open a cursor to iterate through the results of a query, see <a href="#">Section 39.8.4, "How to Create a View Object on a REF CURSOR."</a>

## 2.5 Taking a Look at the Fusion Order Demo Application

Once you have opened the projects in Oracle JDeveloper, you can then begin to review the artifacts within each project. The development environment for the Fusion Order Demo application is divided into two projects: the `StoreFrontService` project and the `StoreFrontUI` project.

The `StoreFrontService` project contains the classes that allow the product data to be displayed in the web application. [Figure 2–13](#) shows the `StoreFrontService` project and its associated directories.

**Figure 2–13 The StoreFrontService Project**

The `StoreFrontService` project contains the following directories:

- `Application Sources`: Contains the files used to access the product data. Included are the metadata files used by Oracle Application Development Framework (Oracle ADF) to bind the data to the view.
- `META-INF`: Contains a file used in deployment.

The `StoreFrontUI` project contains the files for the web interface, including the backing beans, deployment files, and JSPX files. [Figure 2–14](#) shows the `StoreFrontUI` project and its associated directories.

**Figure 2–14** *The StoreFrontUI Project*

The `StoreFrontUI` project contains the following directories:

- `Application Sources`: Contains the code used by the web client, including the managed and backing beans, property files used for internationalization, and the metadata used by Oracle ADF to display bound data.
- `Web Content`: Contains the web files, including the JSP files, images, skin files, deployment descriptors, and libraries.

### 2.5.1 Anonymous Browsing

You start the Fusion Order Demo application by running the `home.jspx` page in the `StoreFrontUI` project. For details about running the application using the default target, `home.jspx` page, see [Section 2.3, "Running the Fusion Order Demo Application StoreFront Module."](#)

When you enter the storefront site, the site is available for anonymous browsing. You can use this page to browse the catalog of products without logging into an account.

The initial view shows the featured products that the site wishes to promote and gives you access to the full catalog of items. Products are presented as images along with the name of the product. Page regions divide the product catalog area from other features that the site offers.

Figure 2–15 shows the home page.

**Figure 2–15 Home Page with Multiple Regions**

### Where to Find Implementation Details

Following are the sections of the *Oracle Fusion Middleware Fusion Developer's Guide for Oracle Application Development Framework* that describe how to create a databound web page:

- Providing the structure for the web page

The home page separates features of the site into regions that are implemented using a combination of ADF Faces templates and JavaServer Faces (JSF) page fragments. ADF Faces templates and the fragments allow you to add ADF databound components. For information about the steps you perform before adding databound user interface components to a web page, see [Section 20.1, "Introduction to Developing a Web Application with ADF Faces."](#)

- Displaying information on a web page

To support data binding, the featured items on the tabbed region of the home page use EL (Expression Language) expressions to reference ADF data control usages in the declarative ADF page definition file. The page definition file, which JDeveloper creates for you when you work with the Data Controls panel to drag and drop databound ADF Faces components, is unique to each web page or page fragment. The ADF data control usages enable queries to the database and

ultimately work with the JSF runtime to render the databound ADF Faces components, such as the ADF Faces image component used to display images from the `PRODUCT_IMAGES` table. For information about creating a databound web page that references the ADF page definition file, see [Section 22.1, "Introduction to Creating a Basic Databound Page."](#)

- **Managing entry points to the application**

The home page is supported by an ADF unbounded task flow. In general, the Fusion web application relies on this ADF Controller feature to define entry points to the application. The unbounded task flow for the entire home page and its page fragments describes view activities for displaying the home page, displaying the orders page, displaying the register user page, and it defines a task flow reference to manage the checkout process. JDeveloper helps you to create the task flow with visual design elements that you drag and drop from the Component Palette. When you create an unbounded task flow, the elements allow you to identify how to pass control from one activity in the application to the next. Because a view activity must be associated with a web page or page fragment, JDeveloper allows you also to create the files for the web page or fragment directly from the task flow diagram. The process of creating a task flow adds declarative definitions to an ADF task flow configuration file. The resulting diagram lets you work with a visual control flow map of the pages and referenced task flows for your application. For more information about specifying the entry points to the application using an ADF unbounded task flows, see [Section 14.1, "Introduction to ADF Task Flows."](#)

### **2.5.1.1 Viewing Product Details**

To view detailed product information, you can click the product name link for any product in the home page. The product information is laid out with collapsing nodes organized by categories.

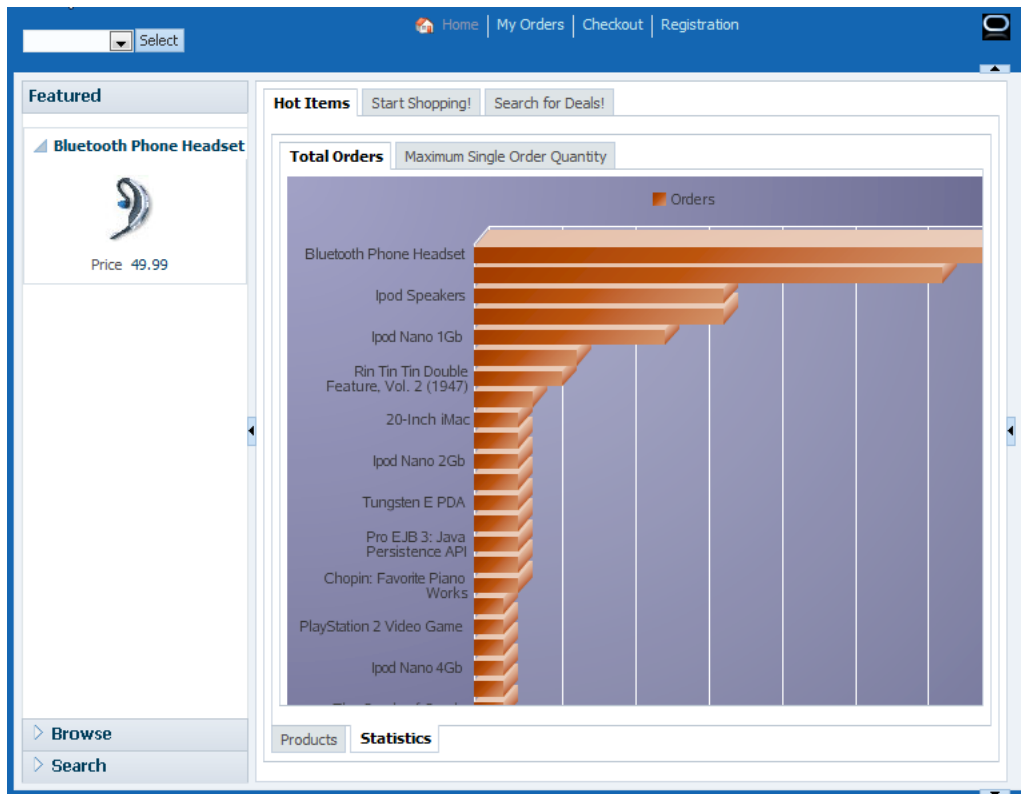

[Figure 2–16](#) shows the detail dialog that you can view for a product.

Figure 2–16 Home Page - Product Details Popup

You can also select the **Statistics** subtab on the home page to view a graphical representation of the number of orders that customers have placed for the featured items. To present the information so that quantities are easily compared, the graph sorts the products by the number of items ordered, in descending order.

Figure 2–17 shows the bar graph used to display the featured products' current order details.

**Figure 2–17 Home Page - Statistics for Featured Items**

### Where to Find Implementation Details

Following are the sections of the *Oracle Fusion Middleware Fusion Developer's Guide for Oracle Application Development Framework* that describe how to develop the components used to support browsing product details:

- Triggering an action to display data

To display data from the data model, user interface components in the web page are bound to ADF Model layer binding objects using JSF Expression Language (EL) expressions. For example, when the user clicks on a link to display an informational dialog, the JSF runtime evaluates the EL expression for the dialog's UI component and pulls the value from the ADF Model layer. At design time, when you work with the Data Controls panel to drag an attribute for an item of a data collection into your web page, and then choose an ADF Faces component to display the value, JDeveloper creates all the necessary JSF tag and binding code needed to display and update the associated data. For more information about the Data Controls panel and the declarative binding experience, see [Section 12.1, "Introduction to ADF Data Binding."](#)

- Displaying data in graphical format

JDeveloper allows you to create databound components declaratively for your JSF pages, meaning you can design most aspects of your pages without needing to look at the code. By dragging and dropping items from the Data Controls panel, JDeveloper declaratively binds ADF Faces UI components and ADF Data Visualization graph components to attributes on a data control using an ADF binding. For more information, see [Section 26.1, "Introduction to Creating ADF Data Visualization Components."](#)

### 2.5.1.2 Browsing the Product Catalog

To begin browsing, click the **Start Shopping** tab in the home page. This action changes the region of the page used to display details about featured products to a region that displays a product categories tree. You can collapse and expand the branch nodes of the tree to view the various product categories that make up the product catalog. The tree displays the product categories in alphabetical order, by category names. When you want to view all the products in a particular category, click its category node in the tree (for example, click **Electronics**, **Media**, or **Office**). The site refreshes the product information region to display the list of products organized as they appear in the database with an image and an accompanying description.

Figure 2–18 shows the home page with all the products in the **Electronics** category displayed.

Figure 2–18 Home Page - Product Categories View

#### Where to Find Implementation Details

Following are the sections of the *Oracle Fusion Middleware Fusion Developer's Guide for Oracle Application Development Framework* that describe how to use tables and forms to display master-detail related objects:

- Dragging and dropping master and detail components

You can create pages that display master-detail data using the Data Controls panel. The Data Controls panel displays master-detail related objects in a hierarchy that mirrors the one you defined in the ADF application module data model, where the detail objects are children of the master objects. All you have to do is drop the collections on the page and choose the type of component you want to use. For example, in the Fusion Order Demo application, the page `home.jspx` displays the master list of product categories in an `af:tree` component and displays the detail list of products in an `af:table` component. For more information about the data model, see [Section 3.4, "Overview of the UI-Aware](#)

**Data Model.** For more information about various types of pages that display master-detail related data, see [Section 24.1, "Introduction to Displaying Master-Detail Data."](#)

- Sorting data that displays in tables

When you create an ADF Faces table component you bind the table to the complete collection or to a range of data objects from the collection. The specific components that display the data in the columns are then bound to the attributes of the collection. The iterator binding handles displaying the correct data for each object, while the table component handles displaying each object in a row. You can set the **Sort** property for any column when you want the iterator to perform an order-by query to determine the order. You can also specify an `ORDER BY` clause for the query that the view object in the data model project defines. For more information about binding table components to a collection, see [Section 23.1, "Introduction to Adding Tables."](#) For more information about creating queries that sort data in the data model, see [Section 5.2, "Populating View Object Rows from a Single Database Table."](#)

### 2.5.1.3 Searching for Products

To search the product catalog, you have several choices. You can begin either by clicking the disclosure icon (a + symbol) on the **Search** tab on the panel accordion or by clicking the **Search for Deals** tab in the main region. When you click either of these, the home page displays both regions at once to allow you to enter a search criteria and view the search results. You use the **Search** tab on the accordion panel to perform a simple keyword search against the attributes common to all products, such as product names or product descriptions. When you select the attribute to search on from the dropdown list, the panel renders a search field using an appropriate input component to accept the search criteria. For example, in the case of the default searchable attribute **ProductId**, where a numeric value is expected, the search field uses a spinbox (the ADF Faces component `inputNumberSpinBox`) to return the product ID.

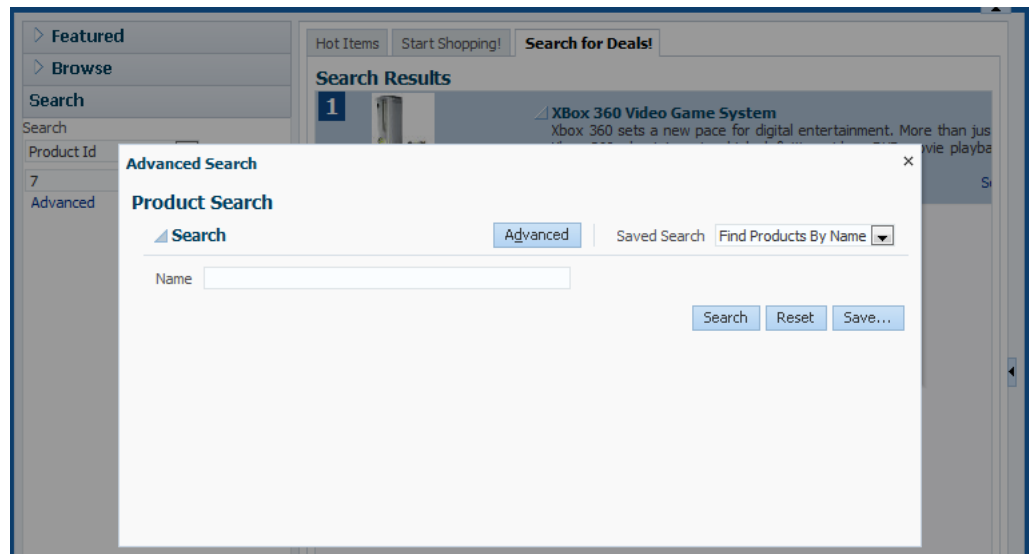

[Figure 2–19](#) shows the home page with the search results returned for the product with an ID equal to 7.

**Figure 2–19 Home Page - Search View**

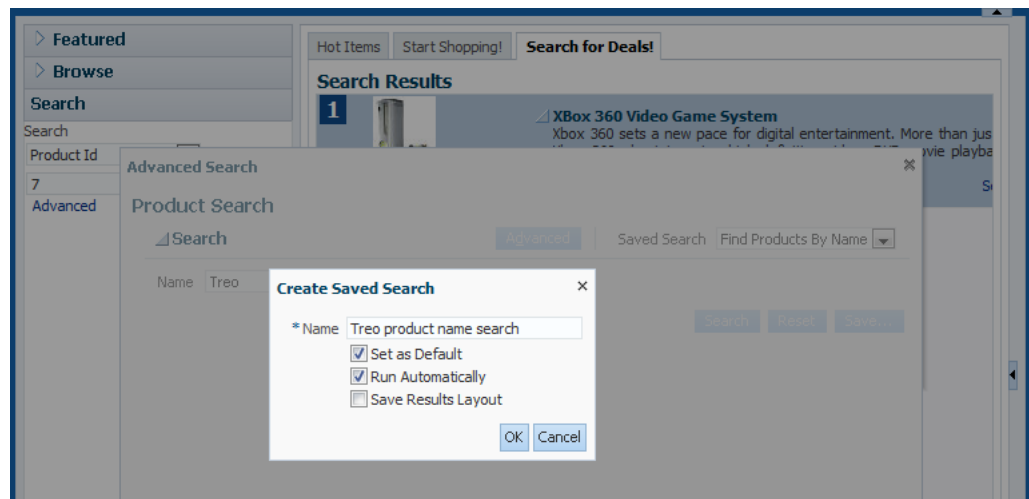

As an alternative to entering a simple search, you can use the advanced search feature to define and save search criteria based on any combination of searchable fields that you select for the product. Click the **Advanced** link to open the Advanced Search dialog. Developer-defined saved searches like **Find Products By Name** appear in the **Saved Search** dropdown list.

[Figure 2–20](#) shows the Advanced Search dialog with a single search criteria, **Name**, that the **Find Products By Name** saved search defines.

**Figure 2–20 Home Page - Advanced Search Dialog**

In addition to the developer-defined saved searches available in the Advanced Search dialog, the end user can create saved searches that will persist for the duration of their session. Enter the product search criteria in the Advanced Search dialog, then click the **Save** button to open the Create Saved Search dialog.

Figure 2–21 shows the Create Saved Search dialog that you use to specify how you want to save the search criteria you entered in the Advanced Search dialog. You can name the search, for example, **Treo product name search**, so that it will display in the **Saved Search** dropdown list of the Advanced Search dialog.

**Figure 2–21 Home Page - Advanced Search Dialog - Saved Searches Option**

You can also manage your saved searches by selecting the **Personalize** function in the **Saved Search** dropdown list of the Advanced Search dialog.

Figure 2–22 shows the Personalize Saved Search dialog for the **Find Products By Name** search, with **Show in Search List** enabled so that it will appear in the **Saved Search** dropdown list. Note that because this search is not a user-defined saved search, the personalization options appear disabled.

**Figure 2–22 Home Page - Advanced Search Dialog - Personalization Option**

### Where to Find Implementation Details

Following are the sections of the *Oracle Fusion Middleware Fusion Developer's Guide for Oracle Application Development Framework* that describe how to define queries and create query search forms:

- Defining the query for the search form to display
 

A query is associated with an ADF Business Components view object that you create for the data model project to define a particular query against the database. In particular, a query component is the visual representation of the view criteria defined on that view object. If there are multiple view criteria defined, each of the view criteria can be selected from the **Saved Search** dropdown list. These saved searches are created at design time by the developer. For example, in the Fusion Order Demo application, the `ProductsVO` view object defines two view criteria. When the query associated with that view object is run, both view criteria are available for selection. For more information, see [Section 27.1, "Introduction to Creating Search Forms."](#)
- Creating a quick search form
 

A quick query search form has one search criteria field with a dropdown list of the available searchable attributes from the associated data collection. By default, the searchable attributes are all the attributes in the associated view object. You can exclude attributes by setting the attribute's **Display** control hint to **Hide** in the view object. The user can search against the selected attribute or search against all the displayed attributes. The search criteria field type will automatically match the type of its corresponding attribute type. For more information, see [Section 27.1.2, "Quick Query Search Forms."](#)
- Creating a search form
 

You create a query search form by dropping a named view criteria item from the Data Controls panel onto a page. You have a choice of dropping only a search panel, dropping a search panel with a results table, or dropping a search panel with a tree table. For more information, see [Section 27.2, "Creating Query Search Forms."](#)
- Displaying the results of a query search

Normally, you would drop a query search panel with the results table or tree table. JDeveloper will automatically wire up the results table or tree table with the query panel. If you drop a query panel by itself and want a separate results component, you can set the query component's `resultComponentId` attribute to the relative expression of the results component. For example, in the Fusion Order Demo application, the page `home.jspx` displays an `af:table` with the ID `searchT` and the results ID of the advanced search dialog is assigned this ID. For more information, see [Section 27.2.2, "How to Create a Query Search Form and Add a Results Component Later."](#)

## 2.5.2 The Login Process

Until you attempt to access secure resources in the storefront site, you are free to browse the product catalog and update the shopping cart as an anonymous user. However, when you click the **My Orders** or **Checkout** links that appear at the top of the home page, you will be challenged by the web container running the site to supply login credentials. The site requires that you enter a valid user name and password before it completes your request to display the linked page.

---

**Note:** The Fusion Order Demo application supports the new customer registration process, but that user is not added to the security implementation. Thus, you must use a predefined customer's user name and password to log in, as shown in [Table 2-3](#).

---

[Figure 2-23](#) shows the login page fragment that displays before you can view order details or purchase items from the store. For demonstration purposes, log in as a customer by entering `ngreenbe` and `welcome1` for the **Username** and **Password**, respectively.

**Figure 2-23 Login Region**

The screenshot shows a login region with the following elements:

- A title "Log in" with a small upward-pointing triangle icon.
- A "Username" label followed by a text input field.
- A "Password" label followed by a text input field.
- A "Log In" button.
- A link: "Not a user? Create an account now!"
- A link: ">> Continue Shopping"

When you click the **Log In** button, the web container will compare your entries with the credential information stored in its identity store. If the web container is able to authenticate you (because you have entered the user name and password for a registered user), then the web container redirects to the web page specified by your link selection; otherwise, the site prompts you to create an account or to continue browsing as an unauthenticated user.

### Where to Find Implementation Details

Following are the sections of the *Oracle Fusion Middleware Fusion Developer's Guide for Oracle Application Development Framework* that describe how to secure Oracle ADF resources so that users are required to log in to access those resources:

- Enabling fine-grained security to secure Oracle ADF resources

ADF Security is a framework that provides a security implementation that is based on Java Authentication and Authorization Service (JAAS). The Oracle ADF implementation of JAAS is role-based. In JDeveloper, you define these roles and then make permission grants based on these roles to enable fine-grained security for Oracle ADF resources. JDeveloper supports declaratively defining the policy store for an ADF bounded task flow or individual web pages associated with their ADF page definition. For information about securing Oracle ADF resources, see [Section 30.5, "Defining ADF Security Policies."](#)

- Triggering dynamic user authentication

When you use ADF Security, authentication is triggered automatically if the user is not yet authenticated and tries to access a page that is not granted to the `anonymous-role` role. After successfully logging in, another check will be done to verify if the authenticated user has view access to the requested page. For more information, see [Section 30.3.5, "What You May Need to Know About ADF Authentication."](#)

- Performing permission checking within the web page

At runtime, the security policy you define for ADF resources is enforced using standard JAAS permission authorization to determine the user's access rights. If your application requires it, you can use Expression Language (EL) to perform runtime permission checks within the web page to hide components that should not be visible to the user. For example, in the Fusion Order Demo application, the page `myOrders.jsp` uses an expression with the value `userGrantedPermission` to test the user's authorization privileges before displaying their account number. For more information, see [Section 30.11.1, "Using Expression Language \(EL\) with ADF Security."](#)

### 2.5.3 The Ordering Process

You begin the order process by browsing the product catalog. When you click **Add** next to a product, the site updates the shopping cart region to display the item.

[Figure 2–24](#) shows the cart summary with a single item added. The summary shows a subtotal for the items that appear in the cart.

**Figure 2–24 Home Page - Shopping Cart Summary**

When you are satisfied with the items in the cart, you can complete the order by clicking the **Checkout** link at the top of the home page. To check out and complete the order, you must become an authenticated user, as described in [Section 2.5.2, "The Login Process."](#)

After you log in, the site displays the checkout page with order details, such as the name and address of the user you registered as. The order is identified by an **Order Information** number that is generated at runtime and assigned to the order. An Order Summary region displays the order items that comprise the new order. This region is similar to the cart summary on the home page, except that it adds the cost of shipping and deducts any discounts that apply to the order to calculate the total purchase amount.

[Figure 2–25](#) shows the checkout page with an order comprising four order items.

Figure 2–25 Checkout Page - Order Details Form

The screenshot displays the checkout page with the following sections:

- Shipping Details**
  - Customer Information**
    - General Information**: Customer Name: Nancy Greenberg, Member Since, Email Address: NGREENBE, Mobile Phone: 865.555.0102
    - Primary Address**: Address Line 1: 2549 Yonge Street, City: Toronto, Postal Code or ZIP: M4P 2H9, State / Province: ON, Country: CA
  - Order Information - #1120**
    - Shipping Information**: Ship to, Shipping Address: 100 N Peach St Philadelphia PA 19139 US, Phone Number
    - Payment Options**: Payment Option Code: 95317932161
    - Shipping Options**: Shipping Option Code: Standard Shipping (3-5 business days), Two-Day Shipping, One-Day Shipping, Pick-up
    - Discounts**: Coupon Code
    - Gift Options**: Gift Wrapping Message: None
- Order Summary**
  - Items: ×1,135.97
  - Shipping & Handling: ×35.94
  - Discounts: ×20.00
  - Your Total: ×1,151.91
  - Submit Order

You can use the checkout page to customize details of the order information. For example, click the **Edit** icon next to the **Payment Option Code** field to display and edit payment funding information for the order.

Figure 2–26 shows the detail dialog for the **Payment Option Code** field.

Figure 2–26 Checkout Page - Payment Option Detail Dialog

The screenshot shows the Payment Option Detail Dialog with the following fields and information:

- Payment Type**: Invoice
- Billing Address**: 100 N Peach St Philadelphia PA US 19139
- Account Number**: 5105105105105100
- Card Type**: MasterCard
- Expiration Date**: 01/15
- Check Digits**:
- Routing Identifier**:
- Institution Name**:
- Valid From Date**: 17-MAR-2011 09:22:43
- Valid To Date**:
- Valid sample credit card numbers include:**
  - Visa: 4012888888881881
  - MC: 5105105105105100
  - AMEX: 343434343434343
- Valid routing numbers include:** 9874321 and 789456124
- Buttons: OK, Cancel

Many of the fields of the payment options dialog offer user interface hints that guide you to enter specific information.

Figure 2–27 shows an example of a date entry (01/15) that the format mask (mm-yy) defines for the **Expiration Date** field.

**Figure 2–27 Checkout Page - Payment Options Detail Dialog - Date Format Mask**

The screenshot shows a dialog box with the following fields and values:

- \* Payment Type: Invoice
- \* Billing Address: 100 N Peach St Philadelphia PA US 19139
- \* Account Number: 5105105105100
- Card Type: MasterCard
- Expiration Date: 01/15 (with a tooltip example: 45/98)
- Check Digits: (empty)
- Routing Identifier: (empty)
- Institution Name: (empty)
- Valid From Date: 17-MAR-2011 09:22:43
- Valid To Date: (empty)

Valid sample credit card numbers include:  
 Visa: 401288888881881  
 MC: 5105105105100  
 AMEX: 343434343434343  
 Valid routing numbers include: 9874321 and 789456124

The **Card Type** field displays a dropdown that allows you to select from a valid list of credit card types.

Figure 2–28 displays the list of values for the **Card Type** field.

**Figure 2–28 Checkout Page - Payment Options Detail Dialog - List of Values (LOV) Choice List**

The screenshot shows the same dialog box as Figure 2–27, but with the **Card Type** dropdown menu open, displaying the following list of values:

- American Express
- Diners Club
- MasterCard
- Visa

The other fields and values remain the same as in Figure 2–27.

If you close the payment options dialog and click the **Submit Order** button in the checkout page, the purchase order is created and sent into a process flow.

After you place an order using the StoreFront module, a second module of the Fusion Order Demo application is available to process the order. For details about the WebLogic Fusion Order Demo module used to demonstrate the capabilities of Oracle SOA Suite, see *Oracle Fusion Middleware Developer's Guide for Oracle SOA Suite*. For

information about running this portion of the Fusion Order Demo application, see [Section 2.3, "Running the Fusion Order Demo Application StoreFront Module."](#)

### Where to Find Implementation Details

Following are the sections of the *Oracle Fusion Middleware Fusion Developer's Guide for Oracle Application Development Framework* that describe how to develop forms like the ones used in the order checkout process:

- **Creating a databound edit form**

When you want to create a basic form that collects values from the user, instead of having to drop individual attributes, JDeveloper allows you to drop all attributes for an object at once as an input form. You can create forms that display values, forms that allow users to edit values, and forms that collect values. For example, in the Fusion Order Demo application, the checkout page `orderSummary.jspx` displays one form to display user information and another form to collect shipping information for the user's order. For more information, see [Section 22.6, "Creating an Input Form."](#)
- **Defining format masks for input forms**

Format masks help ensure the user supplies attribute values in the required format. To facilitate this task, ADF Business Components provides declarative support known as control hints for attributes in the data model project. For example, in the Fusion Order Demo application, the attribute for the `CustomerPaymentOptionVO` view object used to assign the user's credit card expiration date is configured with a format mask hint and enforced in the Payment Options page fragment `paymentOptionsDetails.jsff`. For information on defining format masks for input form components, see [Section 5.14, "Defining Control Hints for View Objects."](#)
- **Defining a list of values for selection lists**

Input forms displayed in the user interface can utilize databound ADF Faces selection components to display a list of values (LOV) for individual attributes of the data collection. To facilitate this common design task, ADF Business Components provides declarative support to specify the LOV usage for attributes in the data model project. For example, in the Fusion Order Demo application, the three `af:selectOneChoice` components displayed in the Payment Options page fragment `paymentOptionsDetails.jsff` are bound to LOV-enabled attributes configured for the `CustomerPaymentOptionVO` view object. For more information about configuring attributes for LOV usage, see [Section 5.13, "Working with List of Values \(LOV\) in View Object Attributes."](#)
- **Keeping track of transient session information**

When you create a data model project that maps attributes to columns in an underlying table, your ADF view objects can include transient attributes that display calculated values (for example, using Java or Groovy expressions) or that are value holders. For example, in the Fusion Order Demo application, the order summary page `orderSummary.jspx` displays the value of the `InvoiceTotal` attribute calculated by the expression defined on the `OrderVO` view object. For more information about defining transient attributes in the data model project, see [Section 4.14, "Adding Transient and Calculated Attributes to an Entity Object."](#)

## 2.5.4 The Customer Registration Process

The site requires that you become an authenticated user before you can display the checkout page. To make it possible for new customers complete the order process, the

site needs to provide a way to guide users through customer registration. To begin, click the registration link on the home page and then click **Register as a customer**.

Customer registration progresses in steps, with one screen dedicated to each step. To represent the progression of these steps, the registration page displays a series of train stops labelled **Basic Information**, **Address**, **Payment Options**, and **Review**. To navigate the customer registration process, you can click certain train stops or you can click the **Next** button.

Figure 2–29 shows the first screen in the customer registration process. The **Basic Information** stop of the train is enabled and selected to identify it as the current stop. Notice that the next train stop icon, **Address**, is enabled but not highlighted, while the **Payment options** and **Review** train stop icons appear disabled and grayed out. Together, these train stops signify that you must complete the activity in a sequential flow.

**Figure 2–29 Customer Registration Page - Basic Information Form**

The screenshot shows a web form for customer registration. At the top, there is a progress indicator with four steps: 'Basic Information' (active), 'Address', 'Payment options', and 'Review'. The 'Basic Information' section contains the following fields:

- \* User Name (text input)
- Title (dropdown menu, currently '<No Selection>')
- First Name (text input)
- Last Name (text input)
- Person Type (dropdown menu, currently 'Customer')
- \* Email Address (text input)
- \* Confirmed Email Address (text input)
- Phone (text input)
- Mobile Phone (text input)
- \* Gender (dropdown menu, currently '<No Selection>')
- Date of Birth (text input with a calendar icon)
- Contact Method (dropdown menu, currently '<No Selection>')
- \* Marital Status (dropdown menu, currently '<No Selection>')
- Income (text input)

Below the form, there is a 'Categories of interest' section. It features a list of categories on the left and a 'Description' field on the right. The categories are: Audio and Video, Books, Camera and Photo, Cell Phones, DVDs, Electronics, Games, Hardware, Media, Music, and Office. The 'Electronics' category is currently selected, indicated by a blue double arrow icon pointing to the right. The 'Description' field is empty.

In the top right corner of the form, there are 'Cancel' and 'Next' buttons.

Before you enter any information into the Basic Information form, click the **Address** train stop. The page displays an error dialog to inform you that specific fields require a value before you can progress to the next step.

Figure 2–30 shows the error dialog with messages stating that the Basic Information form requires a user name and an email address.

**Figure 2–30 Customer Registration Page - Basic Information Form with Validation Error Popup**

Click **OK** to dismiss the error dialog. Then enter a user name and email address. Be sure to confirm the email address in the form.

Again, click **Next** to progress to the next task. This time, the site should display the Address screen with icon buttons that you can select to create a new address record in the database (or, in the case of an existing customer, to update an existing address record).

Figure 2–31 shows the Address screen with one column for **Address Label** and no row information. Because you are entering information as a new customer, no address record currently exists, so no rows are available to display below these columns.

**Figure 2–31 Customer Registration Page - Address Input Task**

Click **New**. The registration page changes to display an address input form and the current train stop remains on **Address**.

Figure 2–32 shows the empty address input form.

**Figure 2–32 Customer Registration Page - Address Input Form**

For the fields with an asterisk symbol (\*), enter the address information specified. The asterisk symbol indicates that the value is required. Note that you must also select a country from the dropdown list since this information is required by the database. Then click **Save & Return** to create the new address record in the database.

Figure 2–33 shows the Address screen with the row information for the new address record.

**Figure 2–33 Customer Registration Page - Address Record Complete**

This concludes the tour of the Fusion Order Demo application.

### Where to Find Implementation Details

Following are the sections of the *Oracle Fusion Middleware Fusion Developer's Guide for Oracle Application Development Framework* that describe how to use complex components like the ADF Faces Train component used in the registration process:

- Grouping activities using a bounded task flow

Every Fusion web application contains an unbounded task flow, which contains the entry points to the application. The application can then call bounded task flows from activities within the unbounded task flow. For example, in the Fusion Order Demo application, the bounded task flow `checkout-task-flow` controls the flow of the checkout process and calls another bounded task flow `customer-registration-task-flow` to control the flow of the registration process. For information about the bounded task flow, see [Section 14.1, "Introduction to ADF Task Flows."](#)

- Displaying a progression of related activities using a train component that you associate with a bounded task flow

You configure train stops based on activities that you select in an ADF bounded task flow and then you add the `af:train` component to your JSF pages. For example, in the Fusion Order Demo application, the bounded task flow `customer-registration-task-flow` defines four train stops for the page fragments `basicInformation.jsff`, `defineAddresses.jsff`, `paymentOptions.jsff`, and `reviewCustomerInfo.jsff`. The page `register.jspx` displays the fragments and each page fragment displays the train component bound to the activities that define the four stops. For information about the bounded task flow and how you can use it to define train stops, see [Section 18.11.3, "How to Create a Train."](#)

- Requiring values to complete an input form

The input form displays attributes of a data collection that you drop from the Data Controls panel. You can set the `required` property of individual components in the form to control whether an attribute value is mandatory. For details about how to customize the `required` property, see [Section 22.2, "Using Attributes to Create Text Fields."](#) Alternatively, you can set a display control hint property directly on the attribute where it is defined by an ADF Business Components entity object. The entity object is a data model component that represents a row from a specific

table in the database and that simplifies modifying its associated attributes. For details about using control hints to make an attribute mandatory, see [Section 4.10, "Setting Attribute Properties."](#)

## Getting Started with ADF Business Components

This chapter describes key features that you can use when you begin to work with the ADF Business Components layer of Oracle Application Development Framework (Oracle ADF). It also describes the implementation architecture of ADF Business Components and describes support for the Groovy scripting language with entity objects and view objects.

This chapter includes the following sections:

- [Section 3.1, "Introduction to ADF Business Components"](#)
- [Section 3.2, "Comparison to Familiar 4GL Tools"](#)
- [Section 3.3, "Overview of Design Time Facilities"](#)
- [Section 3.4, "Overview of the UI-Aware Data Model"](#)
- [Section 3.5, "Overview of the Implementation Architecture"](#)
- [Section 3.6, "Overview of Groovy Support"](#)

### 3.1 Introduction to ADF Business Components

ADF Business Components and JDeveloper simplify the development, delivery, and customization of business applications for the Java EE platform. With ADF Business Components, developers aren't required to write the application infrastructure code required by the typical Java EE application to:

- Connect to the database
- Retrieve data
- Lock database records
- Manage transactions

ADF Business Components addresses these tasks through its library of reusable software components and through the supporting design time facilities in JDeveloper. Most importantly, developers save time using ADF Business Components since the JDeveloper design time makes typical development tasks entirely declarative. In particular, JDeveloper supports declarative development with ADF Business Components to:

- Author and test business logic in components which automatically integrate with databases

- Reuse business logic through multiple SQL-based views of data, supporting different application tasks
- Access and update the views from browser, desktop, mobile, and web service clients
- Customize application functionality in layers without requiring modification of the delivered application

The goal of ADF Business Components is to make the business services developer more productive.

### 3.1.1 ADF Business Components Features

ADF Business Components provides a foundation of Java classes that allow your business-tier application components to leverage the functionality provided in the following areas:

#### **Simplifying Data Access**

- Design a data model for client displays, including only necessary data
- Include master-detail hierarchies of any complexity as part of the data model
- Implement end-user Query-by-Example data filtering without code
- Automatically coordinate data model changes with business domain object layer
- Automatically validate and save any changes to the database

#### **Enforcing Business Domain Validation and Business Logic**

- Declaratively enforce required fields, primary key uniqueness, data precision-scale, and foreign key references
- Easily capture and enforce both simple and complex business rules, programmatically or declaratively, with multilevel validation support
- Navigate relationships between business domain objects and enforce constraints related to compound components

#### **Supporting Sophisticated UIs with Multipage Units of Work**

- Automatically reflect changes made by business service application logic in the user interface
- Retrieve reference information from related tables, and automatically maintain the information when the user changes foreign-key values
- Simplify multistep web-based business transactions with automatic web-tier state management
- Handle images, video, sound, and documents without having to use code
- Synchronize pending data changes across multiple views of data
- Consistently apply prompts, tooltips, format masks, and error messages in any application
- Define custom metadata for any business components to support metadata-driven user interface or application functionality
- Add dynamic attributes at runtime to simplify per-row state management

#### **Implementing High-Performance Service-Oriented Architecture**

- Support highly functional web service interfaces for business integration without writing code

- Enforce best-practice interface-based programming style
- Simplify application security with automatic JAAS integration and audit maintenance
- "Write once, run anywhere": use the same business service as plain Java class or web service

#### **Streamlining Application Customization**

- Extend component functionality after delivery without modifying source code
- Globally substitute delivered components with extended ones without modifying the application
- Deliver application upgrades without losing or having to reapply downstream customizations manually

### **3.1.2 ADF Business Components Core Objects**

ADF Business Components implements the business service through the following set of cooperating components:

- Entity object

An *entity object* represents a row in a database table and simplifies modifying its data by handling all data manipulation language (DML) operations for you. It can encapsulate business logic for the row to ensure that your business rules are consistently enforced. You associate an entity object with others to reflect relationships in the underlying database schema to create a layer of business domain objects to reuse in multiple applications.

- View object

A *view object* represents a SQL query. You use the full power of the familiar SQL language to join, filter, sort, and aggregate data into exactly the shape required by the end-user task. This includes the ability to link a view object with others to create master-detail hierarchies of any complexity. When end users modify data in the user interface, your view objects collaborate with entity objects to consistently validate and save the changes.

- Application module

An *application module* is the transactional component that UI clients use to work with application data. It defines an updatable data model and top-level procedures and functions (called *service methods*) related to a logical unit of work related to an end-user task.

While the base components handle all the common cases through built-in behavior, customization is always possible and the default behavior provided by the base components can be easily overridden or augmented.

## **3.2 Comparison to Familiar 4GL Tools**

ADF Business Components provides components that implement functionality similar to that offered by enterprise 4GL tools. Several key components in ADF Business Components map to concepts that you may be familiar with in other 4GL tools.

### **3.2.1 Familiar Concepts for Oracle Forms Developers**

ADF Business Components implements all of the data-centric aspects of the familiar Oracle Forms runtime functionality, but in a way that is independent of the user

interface. In Oracle Forms, each *form* contains both visual objects (like canvases, windows, alerts, and LOVs), as well as nonvisual objects (like data blocks, relations, and record groups). Individual data block *items* have both visual properties like `Foreground Color` and `Bevel`, as well as nonvisual properties like `Data Type` and `Maximum Length`. Even the different event-handling triggers that Forms defines fall into visual and nonvisual categories. For example, it's clear that triggers like `WHEN-BUTTON-PRESSED` and `WHEN-MOUSE-CLICKED` are visual in nature, relating to the front-end UI, while triggers like `WHEN-VALIDATE-ITEM` and `ON-INSERT` are more related to the backend data processing. While merging visual and nonvisual aspects definitely simplifies the learning curve, the flip side is that it can complicate reuse. With a cleaner separation of UI-related and data-related elements, it would be easier to redesign the user interface without disturbing backend business logic and easier to repurpose back-end business logic in multiple different forms.

In order to imagine this separation of UI and data, consider reducing a form as you know it to only its nonvisual, data-related aspects. This reduces the form to a container of data blocks, relations, and record groups. This container would continue to provide a database connection for the data blocks to share and would be responsible for coordinating transaction commits or rollbacks. Of course, you could still use the *nonvisual* validation and transactional triggers to augment or change the default data-processing behavior as well. This nonvisual object you are considering is a kind of a "smart data model" or a generic application module, with data and business logic, but no user interface elements. The goal of separating this application module from anything visual is to allow any kind of user interface you need in the future to use it as a data service.

Focus a moment on the role the data blocks would play in this application module. They would query rows of data from the database using SQL, coordinate master/detail relationships with other data blocks, validate user data entry with `WHEN-VALIDATE-RECORD` and `WHEN-VALIDATE-ITEM` triggers, and communicate valid user changes back to the database with `INSERT`, `UPDATE`, and `DELETE` statements when you commit the data service's transaction.

Experience tells you that you need to filter, join, order, and group data for your end-users in a variety of ways to suit the many different tasks. On the other hand, the validation rules that you apply to your business domain data remain basically the same over time. Given these observations, it would be genuinely useful to write business entity validation exactly once, and leverage it consistently anywhere that data is manipulated by users in your applications.

Enabling this flexibility requires further "factoring" of your data block functionality. You need one kind of "SQL query" object to represent each of the many different views of data your application requires, and you need another kind of "business entity" object to enforce business rules and communicate changes to your base table in a consistent way. By splitting things like this, you can have multiple "view objects" with specific SQL queries that present the same business data yet each working with the same underlying "entity object."

Oracle ADF addresses the UI/data split by providing ready-to-use Java components that implement typical Forms functionality. Responsibilities between the querying and entity-related functions are cleanly separated, resulting in better reuse.

### **3.2.1.1 Similarities Between the Application Module and a "Headless" Form Module**

The application module component is the "data portion" of the form. The application module is a smart data service containing a data model of master-detail-related queries that your client interface needs to work with. It also provides a transaction and database connection used by the components it contains. It can contain form-level

procedures and functions, referred to as service methods, that are encapsulated within the service implementation. You can decide which of these procedures and functions should be private and which ones should be public.

### 3.2.1.2 Similarities Between the Entity Object and a Forms Record Manager

The entity object component implements the "validation and database changes" portion of the data block functionality. In the Forms runtime, this duty is performed by the record manager. The record manager is responsible for keeping track of which of the rows in the data block have changed, for firing the block-level and item-level validation triggers when appropriate, and for coordinating the saving of changes to the database. This is exactly what an entity object does for you. The entity object is a component that represents your business domain entity through an underlying database table. The entity object gives you a single place to encapsulate business logic related to validation, defaulting, and database modification behavior for that business object.

### 3.2.1.3 Similarities Between the View Object and a Data Block

The `ViewObject` component performs the "data retrieval" portion of the data block functionality. Each view object encapsulates a SQL query, and at runtime each one manages its own query result set. If you connect two or more view objects in master-detail relationships, that coordination is handled automatically. While defining a view object, you can link any of its query columns to underlying entity objects. By capturing this information, the view object and entity object can cooperate automatically for you at runtime to enforce your domain business logic, regardless of the "shape" of the business data required by the user's task.

## 3.2.2 Familiar Concepts for PeopleTools Developers

If you have developed solutions in the past with PeopleTools, you are familiar with the PeopleTools component structure. ADF Business Components implement the data access functionality you are familiar with from PeopleTools.

### 3.2.2.1 Similarities Between the Application Module and a "Headless" Component

Oracle ADF adheres to an MVC pattern and separates the model from the view. Pages, which you are familiar with in the PeopleTools Component, are defined in the view layer, using standard technologies like JSF and ADF Faces components for web-based applications or Swing for desktop-fidelity client displays.

The ADF application module defines the data structure, just like the PeopleTools Component Buffer does. By defining master-detail relationships between ADF query components that produce row sets of data, you ensure that any application module that works with the data can reuse the natural hierarchy as required, similar to the scroll levels in the Component Buffer.

Similar to the Component Interface you are familiar with, the application module is a service object that provides access to standard methods, as well as additional developer-defined business logic. In order to present a "headless" data service for a particular user interface, the Component Interface restricts a number of PeopleTools functions that are related to UI interaction. The application module is similar to the Component Interface in that it provides a "headless" data service, but in contrast it does not do this by wrapping a restricted view of an existing user interface. Instead, the application module is designed to deal exclusively with business logic and data access. Rather than building a Component Interface on top of the component, with ADF Business Components you first build the application module service that is

independent of user interface, and then build one or more pages on top of this service to accomplish some end-user task in your application.

The application module is associated with a transaction object in the same way that the PeopleTools Component Buffer is. The application module also provides a database connection for the components it contains. Any logic you associate today with the transaction as Component PeopleCode, in ADF Business Components you would define as logic on the application module.

Logic associated with records in the transaction, that today you write as Component Record PeopleCode or Component Record Field PeopleCode, should probably *not* be defined on the application module. ADF Business Components has view objects that allow for better re-use when the same record appears in different components.

In summary, PeopleTools uses the component for the container concept, whereas ADF Business Components uses the application module. That is where the similarity ends. Do not assume that all of your component code will migrate to an application module. First, understand the concept of the view object, which is the layer between the entity object and the application module. Then, decide which of your component code is suitable for an application module and which is suitable for view objects.

### **3.2.2.2 Similarities Between the Entity Object and a Record Definition**

The entity object is the mapping to the underlying data structure, just like the PeopleTools Record Definition maps to the underlying table or view. You'll often create one entity object for each of the tables that you need to manipulate your application.

Similar to how you declare a set of valid values for fields like "Customer Status" using PeopleTools' translate values, in ADF Business Components you can add declarative validations to the individual attributes of an entity object. Any logic you associate with the record that applies throughout your applications, which today you write as Record PeopleCode or Record Field PeopleCode, can be defined in ADF Business Components on the entity object.

### **3.2.2.3 Similarities Between the View Object and a Row Set**

Just like a PeopleTools row set, a view object can be populated by a SQL query. Unlike a row set, a view object definition can contain business logic.

Any logic which you would find in Component Record PeopleCode is a likely candidate to define on the view object. Component Record PeopleCode is directly tied to the component, but a view object can be associated with different application modules. Whereas you can use the same record definition in many PeopleTools components, Oracle ADF allows you to reuse the business logic across multiple applications.

The view object queries data in exactly the "shape" that is useful for the current application. Many view objects can be built on top of the same entity object.

You can define relationships between view objects to create master-detail structures, just as you find them in the scroll levels in the PeopleTools component.

## **3.2.3 Familiar Concepts for Siebel Tools Developers**

If you have developed solutions in the past with Siebel Tools version 7.0 or earlier, you will find that ADF Business Components implements all of the familiar data access functionality you are familiar with, with numerous enhancements.

### 3.2.3.1 Similarities Between the entity Object and a Table Object

Like the Siebel Table object, the ADF entity object describes the physical characteristics of a single table, including column names and physical data types. Both objects contain sufficient information to generate the DDL (data definition language) statements to create the physical tables in the database. In ADF Business Components you define associations between entity objects to reflect the foreign keys present in the underlying tables. These associations allow view object queries used by user interface pages to automatically join business information. ADF Business Components handles list of values (LOV) objects that you reference from data columns through a combination of declarative entity-level validation rules and view object attribute-level LOV definitions. You can also encapsulate other declarative or programmatic business logic with these entity object "table" handlers that is automatically reused in any view of the data you create.

### 3.2.3.2 Similarities Between the View Object and a Business Component

Like the Siebel Business Component, the ADF view object describes a logical mapping on top of the underlying physical table representation. Both the Siebel Business Component and the ADF view object allow you to provide logical field names, data, and calculated fields that match the needs of the user interface. As with the Siebel Business Component, with the ADF view object you can define view objects that join information from various underlying tables. The related ADF view link is similar to the Siebel Link object and allows you to define master-detail relationships. In ADF Business Components, your view object definitions can exploit the full power of the SQL language to shape the data as required by the user interface.

### 3.2.3.3 Similarities Between the Application Module and a Business Object

The Siebel Business Object lets you define a collection of business components. The ADF application module performs a similar task, allowing you to create a collection of master-detail view objects that act as a "data model" for a set of related user interface pages. In addition, the application module provides a transaction and database connection context for this group of data views. You can make multiple requests to objects obtained from the application module and these participate in the same transaction.

## 3.2.4 Familiar Functionality for ADO.NET Developers

If you have developed solutions in the past with Visual Studio 2003 or 2005, you are familiar with using the ADO.NET framework for data access. ADF Business Components implements all of the data access functionality you are familiar with from ADO.NET, with numerous enhancements.

### 3.2.4.1 Similarities Between the Application Module and a Data Set

The application module component plays the same role as the ADO.NET data set. It is a strongly typed service component that represents a collection of row sets called view object instances, which are similar to ADO.NET data tables. An application module exposes a service interface that surfaces the rows of data in a developer-configurable set of its view instances as an SDO-compatible service (accessible as a web service, or as an SCA composite). The application module works with a related transaction object to provide the context for the SQL queries that the view objects execute. The application module also provides the context for modifications saved to the database by the entity objects, which play the role of the ADO.NET data adapter.

### 3.2.4.2 Similarities Between the Entity Object and a Data Adapter

The entity object component is like a strongly-typed ADO.NET data adapter. It represents the rows in a particular table and handles the find-by-primary-key, insert, update, delete, and lock operations for those rows. In ADF Business Components, you don't have to specify these statements yourself, but you can override them if you need to. The entity object encapsulates validation or other business logic related to attributes or entire rows in the underlying table. This validation is enforced when data is modified and saved by the end user using any view object query that references the underlying entity object. One difference in ADF Business Components is that the arbitrary, flexible querying is performed by SQL statements at the view object instance level, but the view objects and entity objects coordinate automatically at runtime.

### 3.2.4.3 Similarities Between the View Object and a Data Table

The view object component encapsulates a SQL query and manages the set of resulting rows. It can be related to an underlying entity object to automatically coordinate validation and saving of modifications made by the user to those rows. This cooperation between a view object's queried data and an entity object's encapsulated business logic offers all of the benefits of the data table with the clean encapsulation of business logic into a layer of business domain objects. Like ADO.NET data tables, you can easily work with a view object's data as XML or have a view object read XML data to automatically insert, update, or delete rows based on the information it contains.

## 3.3 Overview of Design Time Facilities

JDeveloper includes comprehensive design time support for ADF Business Components. Collectively, these facilities let you create, edit, diagram, test, and refactor the business components.

### 3.3.1 Choosing a Connection, SQL Flavor, and Type Map

The first time you create a component, you'll see the Initialize Business Components Project dialog shown in [Figure 3-1](#). You use this dialog to select a design time application resource connection to use while working on your business components in this data model project or to create a new application resource connection by copying an existing IDE-level connection.

**Figure 3–1 Initialize Business Components Project Dialog**

Since this dialog appears before you create your first business component, you also use it to globally control the SQL platform that the view objects will use to formulate SQL statements. SQL platforms that you can choose include:

- Oracle SQL platform for an Oracle database connection (the default)
- OLite for the Oracle Lite database
- SQLServer for a Microsoft SQLServer database
- DB2 for an IBM DB2 database
- SQL92 for any other supported SQL92- compliant database

---

**Note:** If you plan to have your application run against both Oracle and non-Oracle databases, you should select the **SQL92** SQL platform when you begin building your application, not later. While this sacrifices some of the Oracle-specific optimizations that are inherent in using the Oracle SQL platform, it makes the application portable to both Oracle and non-Oracle databases.

---

Additionally, the dialog lets you determine which set of data types that you want the data model project to use. JDeveloper uses the data type selection to define the data types of attributes when you create entity object and view objects in the data model project. It is therefore important that you make the appropriate selection before you save the settings in the Initialize Business Components Project dialog. The dialog provides these options:

- **Java Extended for Oracle** type map is selected by default if JDeveloper detects you are using an Oracle database driver. The **Java Extended for Oracle** type map uses standard Java types and the optimized types in the `oracle.jbo.domain` package for common data types.

**Tip:** New Fusion web applications should use the default **Java Extended for Oracle** type.

- **Java** type map is provided to support applications that will run on a non-Oracle database and that you create using SQL92-compliance. In this case, you should set the data type map to **Java** to globally use only the basic Java data types.
- **Oracle Domains** type map is provided for backward compatibility and for ADF applications that do not use ADF Faces as the view layer technology, as explained in [Section 3.3.2, "What You May Need to Know About Displaying Numeric Values."](#) Please note that when you migrate an application developed with JDeveloper version 11.1.1.4.0 or earlier, your application will continue to use the **Oracle Domains** type map and will not change to the current default type map **Java Extended for Oracle**

Once you save project selections in the Initialize Business Components Project dialog, the project is considered initialized and you will not be able to change the data type map selection. After you initialize the project, you can override the SQL platform in the Business Components page of the overview editor for the `adf-config.xml` file, but you must do this before you add business components to the project. You can locate the `adf-config.xml` file in the Application Resources pane by expanding the **Descriptors** and **ADF META-INF** nodes. Specifying the database type in the `adf-config.xml` file supports generating SQL statements during runtime that can require the actual database type of the deployed Fusion web application.

### 3.3.2 What You May Need to Know About Displaying Numeric Values

The **Java Extended for Oracle** type map and the **Oracle Domains** type map handle numeric data differently. When you create a new application the default type map **Java Extended for Oracle** maps numeric data to the `java.math.BigDecimal` class, which inherits from `java.math.Number`. The `java.math.BigDecimal` default matches the way the Fusion web application view layer, consisting of ADF Faces components, preserves alignment of numeric data (such as numeric values displayed by ADF Faces input fields in a web page). Whereas the **Oracle Domains** type map, which maps numeric data to the `oracle.jbo.domain.Number` class, may not display the data with the alignment expected by certain ADF Faces components. Aside from this alignment issue, the **Oracle Domains** type map remains a valid choice and applications without ADF Faces components will function without issue.

### 3.3.3 Creating New Components Using Wizards

In the New Gallery in the **ADF Business Components** category, JDeveloper offers a wizard to create each kind of business component. Each wizard allows you to specify the component name for the new component and to select the package into which you'd like to organize the component. If the package does not yet exist, the new component becomes the first component in that new package.

The wizard presents a series of panels that capture the necessary information to create the component type. When you click **Finish**, JDeveloper creates the new component by saving its XML component definition file. If you have set your Java generation options to generate classes by default, JDeveloper also creates the initial custom Java class files.

### 3.3.4 Creating New Components Using the Context Menu

Once a package exists in the Application Navigator, you can quickly create additional business components of any type in the package by selecting it in the Application Navigator and using one of the options on the context menu shown in [Figure 3–2](#).

**Figure 3–2 Context Menu Options on a Package to Create Any Kind of Business Component**

### 3.3.5 Editing Components Using the Component Overview Editor

Once a business component exists, you can edit its properties using the respective overview editor that you access either by double-clicking the component in the Application Navigator or by selecting it and choosing the **Open** option from the context menu.

The overview editor presents the same editing options that you see in the wizard but it may arrange them differently. The overview editor allows you to change any aspect of the component. When you make a change in the component's editor, JDeveloper updates the component's XML component definition file and, if necessary, any of its related custom Java files. Because the overview editor is a JDeveloper editor window, rather than a modal dialog, you can open and view the overview editor for as many components as you require.

### 3.3.6 Visualizing, Creating, and Editing Components Using UML Diagrams

JDeveloper offers extensive UML diagramming support for ADF Business Components. You can drop components that you've already created onto a business components diagram to visualize them. You can also use the diagram to create and modify components. The diagrams are kept in sync with changes you make in the editors.

To create a new business components diagram, use the **Business Components Diagram** item in the **ADF Business Components** category of the JDeveloper New Gallery. This category is part of the **Business Tier** choices.

### 3.3.7 Testing Application Modules Using the Business Component Browser

Once you have created an application module component, you can test it interactively using the built-in Business Component Browser. To launch the Business Component Browser, select the application module in the Application Navigator or in the business components diagram and choose either **Run** or **Debug** from the context menu.

The Business Component Browser presents the view object instances in the application module's data model and allows you to interact with them using a dynamically generated user interface. The tool also provides a list of the application module's client interface methods that you can test interactively by double-clicking the application module node. This tool is invaluable for testing or debugging your business service both before and after you create the web page view layer.

### 3.3.8 Refactoring Components

At any time, you can select a component in the Application Navigator and choose **Refactor > Rename** from the context menu to rename the component. The Structure window also provides a **Rename** context menu option for details of components, such as view object attributes or view instances of the application module data model, that do not display in the Application Navigator. You can also select one or more components in the navigator by using Ctrl + click and then choosing **Refactor > Move** from the context menu to move the selected components to a new package. References to the old component names or packages in the current data model project are adjusted automatically.

## 3.4 Overview of the UI-Aware Data Model

One of the key simplifying benefits of using ADF Business Components for your business service implementation is the application module's support for a "UI-aware data model" of row sets. The data model defines the business objects specific to your application, while the row sets of each business object contain the data. In the UI portion of the application, the UI components interact with these business objects to perform retrieve, create, edit, and delete operations. When you use ADF Business Components in combination with the ADF Model layer and ADF Faces UI components, the data model is "UI aware" because your UI components will automatically update to reflect any changes to the row sets of these business objects

Thus, the UI-aware data model represents a solution that works across application technology layers to ensure that the UI and data model remain synchronized.

### 3.4.1 A More Generic Business Service Solution

Using a typical Java EE business service implementation makes the client developer responsible for:

- Invoking service methods to return data to present
- Tracking what data the client has created, deleted, or modified
- Passing the changes back to one or more different service methods to validate and save them

Retrieving, creating, editing, deleting, and saving is a typical sequence of tasks performed during application development. As a result, the ADF application module represents a smarter, more generic solution. Using the application module for your business service, you simply bind client UI components like fields, tables, and trees to the active view object instances in the application module's data model. Your UI

components in JSP or JSF pages for the web or mobile devices (as well as desktop-fidelity UIs comprising windows and panels that use Swing) automatically update to reflect any changes to the rows in the view object row sets of the data model. This active data notification also extends to custom business service methods that happen to produce changes to the data model.

Under the covers, the application module component implements a set of *generic* service methods that allow users to leverage its UI-aware data model in a service-oriented architecture (SOA). Both web service and UI clients can easily access an application module's data model using simple APIs. These APIs enable you to search for and modify any information that the application module makes available.

When you build UIs that take advantage of the ADF Model layer for declarative data binding, you generally won't need to write client-side code. Because the data model is UI-aware, your UI components will be bound declaratively to view objects in the data model and to custom business service methods.

### 3.4.2 Typical Scenarios for a UI-Aware Data Model

Without a UI-aware data model, you would need to write more code in the client to handle the straightforward, everyday CRUD-style operations. In addition, to keep pages up to date, you would need to manage "refresh flags" that clue the controller layer in to requesting a "repull" of data from the business service to reflect data that might have been modified. When using an ADF application module to implement your business service, you can focus on the business logic at hand, instead of the plumbing to make your business work as your end users expect.

Consider the following three simple, concrete examples of the UI-aware data model:

- New data appears in relevant displays without requerying

A customer logs into the Fusion Order Demo application and displays a list of items in their shopping cart. Then if the customer visits some product pages and creates a new order item, when they return back to display their shopping cart, the new item appears in their list without requiring the application to query the database.
- Changes caused by business domain logic automatically reflected

A back office application causes an update to the order status. Business logic encapsulated in the `Orders` entity object in the business domain layer contains a simple rule that updates the last update date whenever the order status attribute is changed. The user interface updates to automatically reflect the last update date that was changed by the logic in the business domain layer.
- Invocation of a business service method requeries data and sets current rows

In a tree display, the user clicks on a specific node in a tree. This action declaratively invokes a business service method on your application module that requeries master-detail information and sets the current rows to an appropriate row in the row set. The display updates to reflect the new master-detail data and current row displayed.

### 3.4.3 UI-Aware Data Model Support for Custom Code

Because the application module supports the UI-aware data model, your client user interface will remain up to date. This means you will not need to write code in the client that is related to setting up or manipulating the data model.

Another typical type of client-side code you no longer have to write using ADF Business Components is code that coordinates detail data collections when a row in the master changes. By linking the view objects, you can have the coordination performed automatically for you.

However, when you do need to write custom code, encapsulate that code inside custom methods of your application module component. For example, whenever the programmatic code that manipulates view objects is a logical aspect of implementing your complete business service functionality, you should encapsulate the details by writing a custom method in your application module's Java class. This includes, but is not limited to, code that:

- Configures view object properties to query the correct data to display
- Iterates over view object rows to return an aggregate calculation
- Performs any kind of multistep procedural logic with one or more view objects

By centralizing these implementation details in your application module, you gain the following benefits:

- You make the intent of your code more clear to clients.
- You allow multiple client pages to easily call the same code if needed.
- You simplify regression-testing of your complete business service functionality.
- You keep the option open to improve your implementation without affecting clients.
- You enable *declarative* invocation of logical business functionality in your pages.

## 3.5 Overview of the Implementation Architecture

Before you begin implementing specific ADF business components, it is a good idea to have some familiarity with the Oracle ADF business services layer's design and implementation.

### 3.5.1 Standard Java and XML

As is the case with all Oracle ADF technologies, ADF Business Components is implemented in Java. The working, tested components in the framework provide generic, metadata-driven functionality from a rich layer of robust code. ADF Business Components follows the Java EE community best practice of using cleanly separated XML files to store metadata that you define to configure each component's runtime behavior.

Since ADF Business Components is often used for business critical applications, it's important to understand that the full source for Oracle ADF, including the ADF Business Components layer, is available to supported customers through Oracle Worldwide Support. The full source code for Oracle ADF can be an important tool to assist you in diagnosing problems, as described in [Section 31.7, "Using the ADF Declarative Debugger."](#) Working with the full source code for Oracle ADF also helps you understand how to correctly extend the base framework functionality to suit your needs, as described in [Section 37.2, "Customizing Framework Behavior with Extension Classes."](#)

## 3.5.2 Application Server or Database Independence

Applications built using ADF Business Components can run on any Java-capable application server, including any Java EE-compliant application server. Because business components are implemented using plain Java classes and XML files, you can use them in any runtime environment where a Java Virtual Machine is present. This means that services built using ADF Business Components are easy to use both inside a Java EE server — known as the "container" of your application at runtime — and outside.

Customers routinely use application modules in such diverse configurations as command-line batch programs, web services, custom servlets, JSP pages, and desktop-fidelity clients built using Swing.

You can also build applications that work with non-Oracle databases, as described in [Section 3.3.1, "Choosing a Connection, SQL Flavor, and Type Map."](#) However, applications that target Oracle databases will find numerous optimizations built into ADF Business Components.

## 3.5.3 Java EE Design Pattern Support

The ADF Business Components layer implements all of the popular Java EE design patterns that you would normally need to understand, implement, and debug yourself to create a real-world enterprise Java EE application. If it is important to you to cross-reference the names of these design patterns from the Java EE specifications with their ADF Business Components counterparts, you can refer to [Appendix F, "ADF Business Components Java EE Design Pattern Catalog."](#)

## 3.5.4 Source Code Organization

Since ADF Business Components is implemented in Java, its classes and interfaces are organized into packages. Java packages are identified by dot-separated names that developers use to arrange code into a hierarchical naming structure.

The classes and interfaces that comprise the source code provided by ADF Business Components reside in the `oracle.jbo` package and numerous subpackages. However, in day to day work with ADF Business Components, you'll work typically with classes and interfaces in these two key packages:

- The `oracle.jbo` package, which contains all of the interfaces that are designed for the business service client to work with
- The `oracle.jbo.server` package, which contains the classes that implement these interfaces

---

---

**Note:** The term *client* here refers to any code in the model, view, or controller layers that accesses the application module component as a business service.

---

---

[Figure 3–3](#) shows a concrete example of the application module component. The client interface for the application module is the `ApplicationModule` interface in the `oracle.jbo` package. This interface defines the names and signatures of methods that clients can use while working with the application module, but it does not include any specifics about the implementation of that functionality. The class that implements the base functionality of the application module component resides in the `oracle.jbo.server` package and is named `ApplicationModuleImpl`.

**Figure 3–3 ADF Business Components Separate Interface and Implementation**

### 3.5.5 Package Naming Conventions

Since ADF Business Components is implemented in Java, the components of your application (including their classes, interfaces, and metadata files) will also be organized into packages.

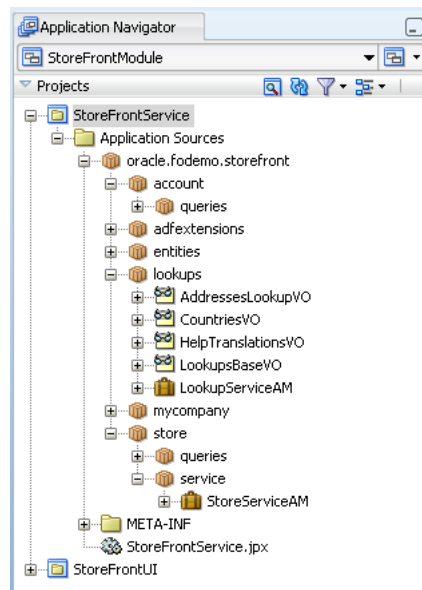

To ensure that your components won't clash with reusable components from other organizations, choose package names that begin with your organization's name or web domain name. So, for example, the Apache organization chose `org.apache.tomcat` for a package name related to its Tomcat web server, while Oracle picked `oracle.xml.parser` as a package name for its XML parser. Components you create for your own applications might reside in packages with names like `com.yourcompany.yourapp` and subpackages of these.

As a specific example, the ADF Business Components that make up the main business service for the Fusion Order Demo application are organized into the `oracle.fodemo.storefront` package and its subpackages. As shown in [Figure 3–4](#), these components reside in the `StoreFrontService` project in the `StoreFrontModule` application, and are organized broadly as follows:

- `oracle.fodemo.storefront.account.queries` contains the view objects used in the customer registration process
- `oracle.fodemo.storefront.client` contains test client `.java` files
- `oracle.fodemo.storefront.entities` contains the entity objects
- `oracle.fodemo.storefront.lookups` contains static data view objects and the `LookupServiceAM` shared application module
- `oracle.fodemo.storefront.store.queries` contains the view objects used to manage the storefront
- `oracle.fodemo.storefront.store.service` contains the `StoreServiceAM` application module

**Figure 3–4 Organization of ADF Business Components in the Fusion Order Demo Application**

In your own applications, you can choose any package organization that you believe best. In particular, keep in mind that you are not constrained to organize components of the same type into a single package.

Because JDeveloper supports component refactoring, you can easily rename components or move them to a different package at any time. This flexibility allows you to easily incorporate inevitable changes into the application as your application evolves.

There is no optimal number of components in a package. However, with experience, you'll realize that the best structure for your team falls somewhere between the two extremes of placing all components in a single package and placing each component in its own, separate package.

One thing to consider is that the package in ADF Business Components is the unit of granularity that JDeveloper supports for reuse in other data model projects. So, you might factor this consideration into how you choose to organize components. For more information, see [Section 37.6, "Working with Libraries of Reusable Business Components."](#)

### 3.5.6 Metadata with Optional Custom Java Code

Each kind of component in ADF Business Components comes with built-in runtime functionality that you control through declarative settings. These settings are stored in an XML component definition file with the same name as the component that it represents. When you need to write custom code for a component, for example to augment the component's behavior, you can enable an optional custom Java class for the component in question. [Figure 3–5](#) shows how the Application Navigator displays the XML component definition and optional custom Java class for an application module.

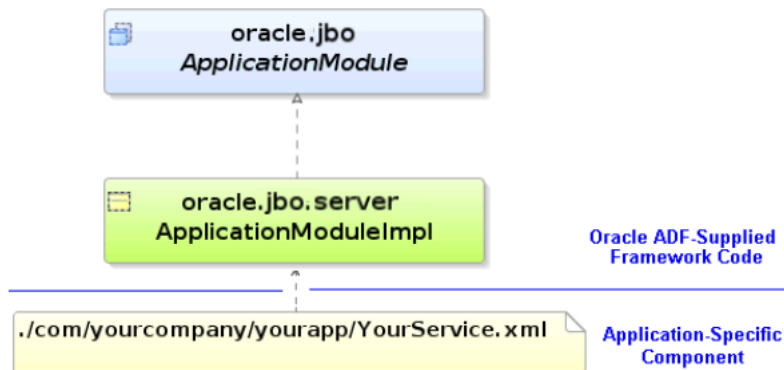

**Figure 3–5 Application Navigator Displays Component XML File and Optional Class Files**

### 3.5.6.1 Example of an XML-Only Component

Figure 3–6 illustrates the XML component definition file for an application-specific component like an application module named *YourService* that you create in a package named *com.yourcompany.yourapp*. The corresponding XML component definition resides in a *./com/yourcompany/yourapp* subdirectory of the data model project's source path root directory. That XML file records the name of the Java class it should use at runtime to provide the application module implementation. In this case, the XML records the name of the base `oracle.jbo.server.ApplicationModuleImpl` class provided by Oracle ADF.

**Figure 3–6 XML Component Definition File for an Application Module**

When used without customization, your component is completely defined by its XML component definition and it will be fully functional without custom Java code or even a Java class file for the component. If you have no need to extend the built-in functionality of a component in ADF Business Components, and no need to write any custom code to handle its built-in events, you can use the component in this XML-only fashion.

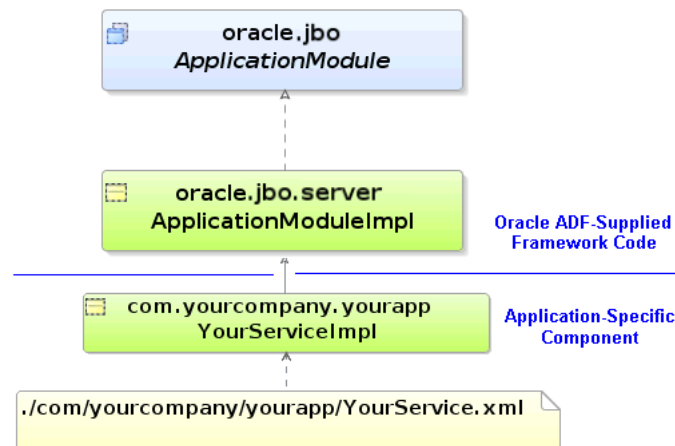

### 3.5.6.2 Example of a Component with Custom Java Class

When you need to add custom code to extend the base functionality of a component or to handle events, you can enable a custom Java class for any of the key types of ADF Business Components you create. You enable the generation of custom classes for a component on the Java page of its respective overview editor in JDeveloper. When you enable this option, JDeveloper creates a Java source file for a custom class related to the component whose name follows a configurable naming standard. This class, whose name is recorded in the component's XML component definition, provides a place where you can write the custom Java code required by that component. Once you've enabled a custom Java class for a component, you can navigate to it using a

corresponding **Go To *componentName* Class** option in the component's Application Navigator context menu.

Figure 3–7 illustrates what occurs when you enable a custom Java class for the *YourService* application module. A *YourServiceImpl.java* source code file is created in the same source path directory as your component's XML component definition file. The *YourServiceImpl.xml* file is updated to reflect the fact that at runtime the component should use the *com.yourcompany.yourapp.YourServiceImpl* class instead of the base *ApplicationModuleImpl* class.

**Figure 3–7 Component with Custom Java Class**

**Note:** The examples in this guide use default settings for generated names of custom component classes and interfaces. If you want to change these defaults for your own applications, use the Business Components: Class Naming page of the JDeveloper Preferences dialog. Changes you make only affect newly created components.

### 3.5.7 Basic Data Types

The Java language provides a number of built-in data types for working with strings, dates, numbers, and other data. When working with ADF Business Components, you can use these types, but by default you'll use an optimized set of types in the *oracle.jbo.domain* and *oracle.ord.im* packages. These types, shown in Table 3–1, allow data accessed from the Oracle database to remain in its native, internal format. You will achieve better performance using the optimized data types provided by ADF Business Components by avoiding costly type conversions when they are not necessary. To work with string-based data, by default ADF Business Components uses the regular *java.lang.String* type.

**Table 3–1 Basic Data Types in the *oracle.jbo.domain* and *oracle.ord.im* Packages**

Data Type	Package	Represents
Number	<i>oracle.jbo.domain</i>	Any numerical data
Date	<i>oracle.jbo.domain</i>	Date with optional time
DBSequence	<i>oracle.jbo.domain</i>	Sequential integer assigned by a database trigger
RowID	<i>oracle.jbo.domain</i>	Oracle database ROWID

**Table 3–1 (Cont.) Basic Data Types in the oracle.jbo.domain and oracle.ord.im Packages**

Data Type	Package	Represents
Timestamp	oracle.jbo.domain	Timestamp value
TimestampTZ	oracle.jbo.domain	Timestamp value with time zone information
TimestampLTZ	oracle.jbo.domain	Timestamp value with local time zone information retrieved from JavaVM or from the ADF Context when configured in the application's adf-config.xml with an EL expression: <pre>&lt;user-time-zone-config xmlns= "http://xmlns.oracle.com/adf/use rtimezone/config"&gt;   &lt;user-timezone expression= "EL exp" /&gt; &lt;/user-time-zone-config&gt;</pre> <p>The EL expression will be evaluated to determine the time zone of the current user; otherwise, the value defaults to the time zone of the JavaVM.</p>
BFileDomain	oracle.jbo.domain	Binary File (BFILE) object
BlobDomain	oracle.jbo.domain	Binary Large Object (BLOB)
ClobDomain	oracle.jbo.domain	Character Large Object (CLOB)
OrdImageDomain	oracle.ord.im	Oracle Intermedia Image (ORDIMAGE)
OrdAudioDomain	oracle.ord.im	Oracle Intermedia Audio (ORDAUDIO)
OrdVideoDomain	oracle.ord.im	Oracle Intermedia Video (ORDVIDEO)
OrdDocDomain	oracle.ord.im	Oracle Intermedia Document (ORDDOC)
Struct	oracle.jbo.domain	User-defined object type
Array	oracle.jbo.domain	User-defined collection type (e.g. VARRAY)

---

**Note:** The `oracle.jbo.domain.Number` class has the same class name as the built-in `java.lang.Number` type. Since the Java compiler *implicitly* imports `java.lang.*` into every class, you need to explicitly import the `oracle.jbo.domain.Number` class into any class that references it. Typically, JDeveloper will follow this practice for you, but when you begin to write more custom code of your own, you'll learn to recognize compiler or runtime errors related to "Number is an abstract class" as indicating that you are inadvertently using `java.lang.Number` instead of `oracle.jbo.domain.Number`. Adding the:

```
import oracle.jbo.domain.Number;
```

line at the top of your class, after the package line, prevents these kinds of errors.

---

### 3.5.8 Generic Versus Strongly-Typed APIs

When working with application modules, view objects, and entity objects, you can choose to use a set of generic APIs or you can have JDeveloper generate code into a custom Java class to enable a strongly-typed API for that component. For example,

when working with an view object, if you wanted to access the value of an attribute in any row of its result, the generic API would look like this:

```
Row row = ordersVO.getCurrentRow();
Date shippedDate = (Date)row.getAttribute("OrderShippedDate");
```

Notice that using the generic APIs, you pass string names for parameters to the accessor, and you have to cast the return type to the expected type, as with `Date` shown in the example.

Alternatively, when you enable the strongly typed style of working you can write code like this:

```
OrdersRow row = (OrdersRow)ordersVO.getCurrentRow();
Date shippedDate = row.getOrderShippedDate();
```

In this case, you work with generated method names whose return type is known at compile time, instead of passing string names and having to cast the results. Typically, it is necessary to use strongly typed accessors when you need to invoke the methods from the business logic code without sacrificing compile-time safety. This can also be useful when you are writing custom validation logic in setter methods, although in this case, you may want to consider using Groovy expressions instead of generating entity and view row implementation classes for Business Components. Subsequent chapters explain how to enable this strongly typed style of working by generating Java classes for business logic that you choose to implement using Java.

### 3.5.9 Custom Interface Support for Client-Accessible Components

Only these components of the business service as visible to the client:

- Application module, representing the service itself
- View objects, representing the query components
- View rows, representing each row in a given query component's results

The entity objects in the business service implementation is intentionally not designed to be referenced directly by clients. Instead, clients work with the data queried by view objects as part of an application module's data model. Behind the scenes, the view object cooperates automatically with entity objects in the business domain layer to coordinate validating and saving data that the user changes. For more information about this runtime interaction, see [Section 6.3.9, "What Happens at Runtime: When View Objects and Entity Objects Cooperate."](#)

#### 3.5.9.1 Framework Client Interfaces for Components

The Java interfaces of the `oracle.jbo` package provide a client-accessible API for your business service. This package intentionally does not contain an `Entity` interface, or any methods that would allow clients to directly work with entity objects. Instead, client code works with interfaces like:

- `ApplicationModule`, to work with the application module
- `ViewObject`, to work with the view objects
- `Row`, to work with the view rows

#### 3.5.9.2 Custom Client Interfaces for Components

When you begin adding custom code to your ADF Business Components that you want clients to be able to call, you can "publish" that functionality to clients for any client-visible component. For each of your components that publishes at least one

custom method to clients on its client interface, JDeveloper automatically maintains the related Java interface file. So, assuming you were working with an application module like `StoreServiceAM` in the Fusion Order Demo application, you could have custom interfaces like:

- Custom application module interface  
`StoreServiceAM` extends `ApplicationModule`
- Custom view object interface  
`OrderItemsInfo` extends `ViewObject`
- Custom view row interface  
`OrderItemsInfoRowClient` extends `Row`

Client code can then cast one of the generic client interfaces to the more specific one that includes the selected set of client-accessible methods you've selected for your particular component.

## 3.6 Overview of Groovy Support

Groovy is a scripting language with Java-like syntax for the Java platform. Groovy language expressions in ADF Business Components differs from the Java code that you might use in a Business Components custom Java class. The Groovy scripting language simplifies the authoring of code by employing dot-separated notation, yet still supporting syntax to manipulate collections, Strings, and JavaBeans. In Groovy expressions, type checking is done at runtime, whereas, in Java, type checking is done during compile time. Additionally, because Groovy expressions are dynamically compiled, they are stored in the XML definition files of the business components where you use it.

ADF Business Components supports the use of the Groovy scripting language in places where access to entity object and view object attributes is useful, including attribute validators (for entity objects), attribute default values (for either entity objects or view objects), transient attribute value calculations (for either entity objects or view objects), bind variable default values (in view object query statements and view criteria filters), and placeholders for error messages (in entity object validation rules). Additionally, ADF Business Components provides a limited set of built-in keywords that can be used in Groovy expressions.

Specifically, the ADF Business Components framework provides support for the use of Groovy to perform the following tasks:

- Define a Script Expression validator or Compare validator (see [Section 7.5, "Using Groovy Expressions For Validation and Business Rules"](#))
- Define error message tokens for handling validation failure (see [Section 7.7.4, "How to Embed a Groovy Expression in an Error Message"](#))
- Handle conditional execution of validators (see [Section 7.7.3, "How to Conditionally Raise Error Messages Using Groovy"](#))
- Set the default value of a bind variable in the view object query statement (see [Section 5.10, "Working with Bind Variables"](#))
- Set the default value of a bind variable that specifies a criteria item in the view criteria statement (see [Section 5.11, "Working with Named View Criteria"](#)).

- Define the default value for an entity object attribute (see [Section 4.10.6, "How to Define a Static Default Value"](#))
- Calculate the value of a transient attribute of an entity object or view object (see [Section 4.14, "Adding Transient and Calculated Attributes to an Entity Object"](#) and [Section 5.15, "Adding Calculated and Transient Attributes to a View Object"](#))

For more information about the Groovy language, refer to the following web site:

- <http://groovy.codehaus.org/>

### 3.6.1 Referencing Business Components Objects in Groovy Expressions

There is one top-level object named `adf` that allows you access to objects that the framework makes available to the Groovy script. The accessible Oracle ADF objects consist of the following:

- `adf.context` - to reference the `ADFContext` object
- `adf.object` - to reference the object on which the expression is being applied (which can also be referenced using the keyword `object`, without the `adf` prefix). Other accessible member names come from the context in which the Groovy script is applied.
  - Entity object attributes: The context is an instance of the entity implementation class. Through this object you can reference custom methods of the custom entity implementation class, any methods defined by the base implementation class as specified by the JavaDoc for `EntityImpl`, and you can reference the attributes of the entity instance.
  - Entity object script validation rules: The context is the validator object (`JboValidatorContext`) merged with the entity on which the validator is applied. For details about keywords that you can use in this context, see [Section 3.6.2.1, "Referencing Members of the Same Business Component."](#)
  - View object attributes: The context is an instance of the view row implementation class. Through this object, you can reference custom methods of the custom view row implementation class, any methods defined by the base implementation class as specified by the JavaDoc for `ViewRowImpl`, and you can reference the attributes of the view row instance as defined by the query row set.
  - Bind variable in view objects: The context is the variable object itself not the view row. You can reference the `structureDef` property to access other information as well as the `viewObject` property to access the view object in which the bind variable participates. However, access to view object attributes is not supported.
  - Bind variable in view accessors: The context is the current view row. The view accessor with bind variable is used to create a cascading List of Value (LOV). The view accessor can derive Groovy-driven values from the current view row in the view accessor view object used to formulate the list of valid choices.
  - Transient attributes: The context is the current entity or view row. You can reference attributes by name in the entity or view row in which the attribute appears, as well as public methods on that entity or view row. To access methods on the current object, you must use the `object` keyword to reference the current object (for example, `object.methodName( )`). The `object` keyword is equivalent to the `this` keyword in Java. Without it, in transient expressions, the method will be assumed to exist on the dynamically compiled Groovy script object itself.

- `adf.error` - in validation rules, to access the error handler that allows the validation expression to generate exceptions or warnings
- `adf.userSession` - returns a reference to the ADF Business Components user session (which you can use to reference values in the `userData` hashmap that is part of the session)

You can also reference the current date (time truncated) or current date and time using the following expressions:

- `adf.currentDate`
- `adf.currentDateTime`

## 3.6.2 Referencing Custom Business Components Methods and Attributes in Groovy Expressions

Groovy script language simplifies the authoring of code that you might write to access methods and attributes of your entity object and view objects.

### 3.6.2.1 Referencing Members of the Same Business Component

The simplest example of referencing business component members, including methods and attributes that the entity object and view object define, is to reference attributes that exist in the same entity object or view object as the attribute that you apply the expression.

For example, you could define a Groovy expression to calculate the value of a transient attribute `AnnualSalary` on an entity object with an attribute `Sal` that specifies the employee's monthly salary:

```
Sal * 12
```

Or, with Groovy you can write a simple validation rule to compare the attributes of a single view object using syntax like:

```
PromotionDate > HireDate
```

Using Java, this same comparison would look like:

```
((Date)getAttribute("PromotionDate")).compareTo((Date)getAttribute("HireDate")) > 0
```

Note that the current object is passed in to the script as the `this` object, so you can reference an attribute in the current object by simply using the attribute name. For example, in an attribute-level or entity-level Script Expression validator, to refer to an attribute named "HireDate", the script can simply reference `HireDate`.

Similar to referencing attributes, when you define custom methods in an entity implementation class, you can invoke those methods as part of your expression. For example, to define an attribute default value:

```
adf.object.getDefaultSalaryForGrade()
```

A method reference requires the prefix `adf.object` which allows you to reference the same entity that defines the attribute on which the expression is applied. This same prefix also allows you to reference the methods of the base class of the entity implementation class (`EntityImpl.java`) that your custom implementation class extends.

Note that when you want to reference the method of an entity implementation class in a validation rule, you use the `source` prefix:

```
source.getDefaultSalaryForGrade()
```

Use of the `source` prefix is necessary in validators because the `object` keyword implies the validation rule object instead of the entity object (where the method is defined).

To allow you to reference members of the validator object (`JobValidatorContext`), you can use these keywords in your validation rule expression:

- `newValue`: in an attribute-level validator, to access the attribute value being set
- `oldValue`: in an attribute-level validator, to access the current value of the attribute being set

For example, you might use the following expression to specify a dynamic validation rule check of the salary for a salesman.

```
if (Job == "SALESMAN")
{
return newValue < source.getMaxSalaryForGrade(Job)
}
else
return true
```

### 3.6.2.2 Referencing Members of Other Business Components

You can also reference the methods and attributes that entity objects and view objects defines in the expressions you apply to a different entity object attribute or validation rule. This is accomplished by referencing the accessor in the entity association.

For example, if you define an entity with a master-detail association for `Dept` and `Emp`, by default the accessor for the entity association will be named `Dept` and `Emp`, to identify the source and destination data source. Using that accessor in a Groovy expression to set the default value for a new employee's salary based on the location of their department:

```
adf.object.getDefaultSalaryForGrade(Dept.Loc)
```

This expression does not reference the entity even though it has the same name (`Dept`) as the accessor for the association. Instead, assuming a master-detail relationship between departments and employees, referencing the accessor allows the Groovy expression for the employee entity object to walk back to the master department entity and pass in the value of `Loc` from that master.

### 3.6.3 Manipulating Business Component Attribute Values in Groovy Expressions

You can use the following built-in aggregate functions on Oracle Business Components `RowSet` objects:

- `rowSetAttr.sum(GroovyExpr)`
- `rowSetAttr.count(GroovyExpr)`
- `rowSetAttr.avg(GroovyExpr)`
- `rowSetAttr.min(GroovyExpr)`
- `rowSetAttr.max(GroovyExpr)`

These aggregate functions accept a string-value argument that is interpreted as a Groovy expression that is evaluated in the context of each row in the row set as the aggregate is being computed. The Groovy expression must return a numeric value (or number domain).

For example, in a `Dept` entity object you could add a transient attribute that displays the sum of all employee salaries that is calculated by this expression:

```
EmployeesInDept.sum("Sal")
```

To reference the employees of a specific department, the expression supplies the name of the master-detail association's accessor for the destination `Emp` entity. In this case, the accessor is `EmployeesInDept` and salary is interpreted for each record of the `Emp` entity object.

Or, assume that you want the calculation of the salary total for specific departments to include each employee's benefits package, which varies with job role:

```
EmployeesInDept.sum("Sal + adf.object.getBenefitsValue(Job)")
```

---

# Creating a Business Domain Layer Using Entity Objects

This chapter describes how to use ADF entity objects to create a reusable business layer of Java objects that describe the business domain in an Oracle Application Development Framework (Oracle ADF) application.

This chapter includes the following sections:

- [Section 4.1, "Introduction to Entity Objects"](#)
- [Section 4.2, "Creating Entity Objects and Associations"](#)
- [Section 4.3, "Creating and Configuring Associations"](#)
- [Section 4.4, "Creating an Entity Diagram for Your Business Layer"](#)
- [Section 4.5, "Defining Property Sets"](#)
- [Section 4.6, "Defining Attribute Control Hints for Entity Objects"](#)
- [Section 4.7, "Working with Resource Bundles"](#)
- [Section 4.8, "Defining Business Logic Groups"](#)
- [Section 4.9, "Configuring Runtime Behavior Declaratively"](#)
- [Section 4.10, "Setting Attribute Properties"](#)
- [Section 4.11, "Creating Business Events"](#)
- [Section 4.12, "Working Programmatically with Entity Objects and Associations"](#)
- [Section 4.13, "Generating Custom Java Classes for an Entity Object"](#)
- [Section 4.14, "Adding Transient and Calculated Attributes to an Entity Object"](#)

## 4.1 Introduction to Entity Objects

An entity object is the ADF Business Components component that represents a row in the specified data source and simplifies modifying its associated attributes. Importantly, it allows you to encapsulate domain business logic to ensure that your business policies and rules are consistently validated.

Entity objects support numerous declarative business logic features to enforce the validity of your data. You will typically complement declarative validation with additional custom application logic and business rules to cleanly encapsulate a maximum amount of domain business logic into each entity object. Your associated set of entity objects forms a reusable business domain layer that you can exploit in multiple applications.

The key concepts of entity objects are the following:

- You define an entity object by specifying the database table whose rows it will represent.
- You can create associations to reflect relationships between entity objects.
- At runtime, entity rows are managed by a related entity definition object.
- Each entity row is identified by a related row key.
- You retrieve and modify entity rows in the context of an application module that provides the database transaction.

## 4.2 Creating Entity Objects and Associations

If you already have a database schema to work from, the simplest way to create entity objects and associations is to reverse-engineer them from existing tables. When needed, you can also create an entity object from scratch, and then generate a table for it later.

### 4.2.1 How to Create Multiple Entity Objects and Associations from Existing Tables

To create one or more entity objects, use the Business Components from Tables wizard, which is available from the New Gallery.

#### To create one or more entity objects and associations from existing tables:

1. In the Application Navigator, right-click the project in which you want to create the entity objects and choose **New**.
2. In the New Gallery, expand **Business Tier**, select **ADF Business Components** and then **Business Components from Tables**, and click **OK**.

If this is the first component you're creating in the project, the Initialize Business Components Project dialog appears to allow you to select a database connection.

3. In the Initialize Business Components Project dialog, select the database connection or choose **New** to create a connection. Click **OK**.
4. On the Entity Objects page, do the following to create the entity objects:
  - Enter the package name in which all of the entity objects will be created.
  - Select the tables from the **Available** list for which you want to create entity objects.

If the **Auto-Query** checkbox is selected, then the list of available tables appears immediately. In the **Name Filter** field, you can optionally enter a full or partial table name to filter the available tables list in real time. As an alternative to the auto-query feature, click the **Query** button to retrieve the list based on an optional table name filter. When no name filter is entered, JDeveloper retrieves all table objects for the chosen schema.

- Click **Filter Types** if you want to see only a subset of the database objects available. You can filter out tables, views, or synonyms.

Once you have selected a table from the **Available** list, the proposed entity object name for that table appears in the **Selected** list with the related table name in parenthesis.

- Select an entity object name in the **Selected** list and use the **Entity Name** field to change the default entity object name.

**Best Practice:** Since each entity object instance represents a *single* row in a particular table, name the entity objects with a singular noun (like Address, Order, and Person), instead of their plural counterparts. [Figure 4-1](#) shows what the wizard page looks like after selecting the ADDRESSES table in the FOD schema, setting a package name of oracle.fodemo.storefront.entities, and renaming the entity object in the singular.

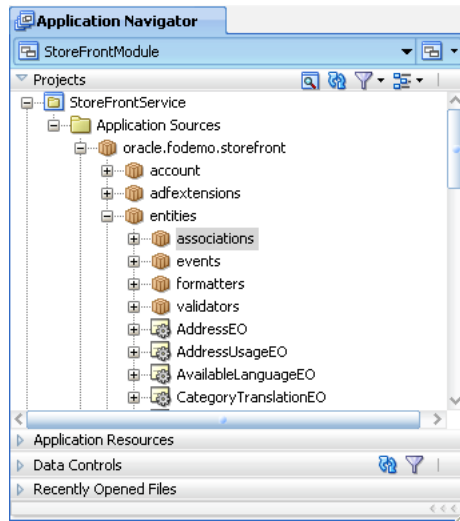

**Figure 4-1** Create Business Components from Tables Wizard, Entity Objects Page

5. When you are satisfied with the selected table objects and their corresponding entity object names, click **Finish**.

The Application Navigator displays the entity objects in the package you specified.

**Best Practice:** After you create associations, move all of your associations to a separate package so that you can view and manage them separately from the entity objects. In [Figure 4-2](#), the associations have been moved to a subpackage (associations) and do not appear in the entities package in the Application Navigator. For more information, see [Section 4.3.4, "How to Rename and Move Associations to a Different Package."](#)

**Figure 4–2 New Entity Objects in Application Navigator**

## 4.2.2 How to Create Single Entity Objects Using the Create Entity Wizard

To create a single entity object, you can use the Create Entity Object wizard, which is available in the New Gallery.

### To create a single entity object and association:

1. In the Application Navigator, right-click the project in which you want to create the entity object and choose **New**.
2. In the New Gallery, expand **Business Tier**, select **ADF Business Components** and then **Entity Object**, and click **OK**.

If this is the first component you're creating in the project, the Initialize Business Components Project dialog appears to allow you to select a database connection.

3. In the Initialize Business Components Project dialog, select the database connection or choose **New** to create a connection. Click **OK**.
4. On the Name page, do the following to create the entity object:
  - Enter the package name in which the entity object will be created.
  - Click **Browse** (next to the **Schema Object** field) to select the table for which you want to create the entity object.

Or, if you plan to create the table later, you can enter a name of a table that does not exist.

5. If you manually entered a table name in the **Schema Objects** field, you will need to define each attribute on the Attributes page of the wizard. Click **Next**.

You can create the table manually or generate it, as described in [Section 4.2.6, "How to Create Database Tables from Entity Objects."](#)

6. When you are satisfied with the table object and its corresponding entity object name, click **Finish**.

## 4.2.3 What Happens When You Create Entity Objects and Associations from Existing Tables

When you create an entity object from an existing table, first JDeveloper interrogates the data dictionary to infer the following information:

- The Java-friendly entity attribute names from the names of the table's columns (for example, `USER_ID` -> `UserId`)
- The SQL and Java data types of each attribute based on those of the underlying column
- The length and precision of each attribute
- The primary and unique key attributes
- The mandatory flag on attributes, based on `NOT NULL` constraints
- The relationships between the new entity object and other entities based on foreign key constraints

---

**Note:** Since an entity object represents a database row, it seems natural to call it an *entity row*. Alternatively, since at runtime the entity row is an instance of a Java object that encapsulates business logic for that database row, the more object-oriented term *entity instance* is also appropriate. Therefore, these two terms are interchangeable.

---

JDeveloper then creates the XML component definition file that represents its declarative settings and saves it in the directory that corresponds to the name of its package. For example, when an entity named `Order` appears in the `genericbcmodel.entities` package, JDeveloper will create the XML file `genericbcmodel/entities/Order.xml` under the project's source path. This XML file contains the name of the table, the names and data types of each entity attribute, and the column name for each attribute.

You can inspect the XML description for the entity object by opening the object in the overview editor and clicking the **Source** tab.

---

**Note:** If your IDE-level Business Components Java generation preferences so indicate, the wizard may also create an optional custom entity object class (for example, `OrderImpl.java`).

---

### 4.2.3.1 What Happens When Tables Have Foreign Key Relationships

In addition to the entity objects, the wizard also generates named association components that capture information about the relationships between entity objects. For example, the database diagram in [Figure 4-3](#) shows that JDeveloper derives default association names like `OrderItemsProductsFkAssoc` by converting the foreign key constraint names to a Java-friendly name and adding the `Assoc` suffix. For each association created, JDeveloper creates an appropriate XML component definition file and saves it in the directory that corresponds to the name of its package.

By default the associations reverse-engineered from foreign keys are created in the same package as the entities. For example, for the association `OrderItemsProductsFkAssoc` with entities in the `fodemo.storefront.entities` package, JDeveloper creates the association XML file named

```
./fodemo/storefront/entities/OrderItemsProductsFkAssoc.xml.
```

**Figure 4–3** *ORDER\_ITEMS* and *PRODUCTS\_BASE* Tables Related by Foreign Key

### 4.2.3.2 What Happens When a Table Has No Primary Key

If a table has no primary key constraint, then JDeveloper cannot infer the primary key for the entity object. Since every entity object must have at least one attribute marked as a primary key, the wizard will create an attribute named RowID and use the database ROWID value as the primary key for the entity. If appropriate, you can edit the entity object later to mark a different attribute as a primary key and remove the RowID attribute. When you use the Create Entity Object wizard and you have not set any other attribute as primary key, you will be prompted to use RowID as the primary key.

### 4.2.4 What Happens When You Create an Entity Object for a Synonym or View

When you create an entity object using the Business Components from Tables wizard or the Create Entity Object wizard, the object can represent an underlying table, synonym, or view. The framework can infer the primary key and related associations for a table or synonym by inspecting database primary and foreign key constraints in the data dictionary.

However, when your selected schema object is a database view, then neither the primary key nor associations can be inferred since database views do not have database constraints. In this case, if you use the Business Components from Tables wizard, the primary key defaults to RowID. If you use the Create Entity Object wizard, you'll need to specify the primary key manually by marking at least one of its attributes as a primary key. For more information, see [Section 4.2.3.2, "What Happens When a Table Has No Primary Key."](#)

When your selected schema object is a synonym, there are two possible outcomes. If the synonym is a synonym for a table, then the wizard and editor behave as if you had specified a table. If instead the synonym refers to a database view, then they behave as if you had specified a view.

### 4.2.5 How to Edit an Existing Entity Object or Association

After you've created a new entity object or association, you can edit any of its settings in the overview editor. To launch the editor, choose **Open** from the context menu for the entity object or association in the Application Navigator or double-click the object. By clicking the different tabs of the editor, you can adjust the settings that define the object and govern its runtime behavior.

## 4.2.6 How to Create Database Tables from Entity Objects

To create database tables based on entity objects, right-click the package in the Application Navigator that contains the entity objects and choose **Create Database Objects** from the context menu. A dialog appears to let you select the entities whose tables you'd like to create. This tool can be used to generate a table for an entity object you created from scratch, or to drop and re-create an existing table.

---

**Caution:** This feature does *not* generate a DDL script to run later. It performs its operations directly against the database and will drop existing tables. A dialog appears to confirm that you want to do this before proceeding. For entities based on existing tables, use with caution.

---

In the overview editor for an association, the **Use Database Key Constraints** checkbox on the Association Properties page controls whether the related foreign key constraint will be generated when creating the tables for entity objects. Selecting this option does not have any runtime implications.

## 4.2.7 How to Synchronize an Entity with Changes to Its Database Table

Inevitably you (or your DBA) might alter a table for which you've already created an entity object. Your existing entity will not be disturbed by the presence of additional attributes in its underlying table; however, if you want to access the new column in the table in your Java EE application, you'll need to synchronize the entity object with the database table.

For example, suppose you had done the following at the SQL\*Plus command prompt to add a new `SECURITY_QUESTION` column to the `PERSONS` table:

```
ALTER TABLE PERSONS ADD (security_question VARCHAR2(60));
```

Then you can use the synchronization feature to add the new column as an attribute on the entity object.

### To synchronize an entity with changes to its database table:

1. In the Application Navigator, right-click the desired entity object and choose **Synchronize with Database**.

The Synchronize with Database dialog shows the list of the actions that can be taken to synchronize the business logic tier with the database.

2. Select the action you want to take:
  - Select one or more actions from the list, and click **Synchronize** to synchronize the selected items.
  - Click **Synchronize All** to perform all actions in the list.
  - Click **Write to File** to save the action list to a text file. This feature helps you keep track of the changes you make.
3. When finished, click **OK** to close the dialog.

### 4.2.7.1 Removing an Attribute Associated with a Dropped Column

The synchronize feature does not handle dropped columns. When a column is dropped from the underlying database after an entity object has been created, you can

delete the corresponding attribute from the entity object. If the attribute is used in other parts of your application, you must remove those usages as well.

**To remove an entity attribute:**

1. In the Application Navigator, double-click the entity.
2. In the overview editor, click the **Attributes** navigation tab.
3. On the Attributes page, right-click the attribute, and choose **Delete Safely**.

If there are other usages, the Delete Attributes dialog displays the message "Usages were found."

4. If usages were found, click **View Usages**.

The Log window shows all usages of the attribute.

5. Work through the list in the Log window to delete all usages of the entity attribute.

#### 4.2.7.2 Addressing a Data Type Change in the Underlying Table

The synchronize feature does not handle changed data types. For a data type change in the underlying table (for example, precision increased), you must locate all usages of the attribute and manually make changes, as necessary.

**To locate all usages of an entity attribute:**

1. In the Application Navigator, double-click the entity.
2. In the overview editor, click the **Attributes** navigation tab.
3. On the Attributes page, right-click the attribute and choose **Find Usages**.

If there are other usages, they are displayed in the Log window.

## 4.2.8 How to Store Data Pertaining to a Specific Point in Time

Effective dated tables are used to provide a view into the data set pertaining to a specific point in time. Effective dated tables are widely used in applications like HRMS and Payroll to answer queries like:

- What was the tax rate for an employee on August 31st, 2005?
- What are the employee's benefits as of October 2004?

In either case, the employee's data may have changed to a different value since then.

The primary difference between the effective dated entity type and the dated entity type is that the dated entity does not cause row splits during update and delete.

---

---

**Note:** Take caution when using effective dating on a both ends of a master-detail relationship. Because child objects can raise events on parent objects, and effective dated entity objects cause row splits during update and delete operations, it is possible for the child object to raise an event on the wrong parent object if both the parent and child are updated during the same transaction. Do not configure a business event to be raised on an effective dated parent from an effective dated child. For more information about business events, see [Section 4.11, "Creating Business Events."](#)

---

---

When you create an effective dated entity object, you identify the entity as effective dated and specify the attributes of the entity that represent the start and end dates. The start date and end date attributes must be of the Date type.

Additionally, you can specify an attribute that represents the sequence for the effective dated entity and an attribute that represents a flag for the sequence. These attributes allow for tracking of multiple changes in a single day.

#### To create an effective dated entity object

1. In the Application Navigator, double-click the entity on which you want enable effective dating.
2. In the Property Inspector, expand the **Type** category.  
If necessary, choose **Property Inspector** from the **View** menu to display the Property Inspector.  
If the **Type** category is not displayed in the Property Inspector, click the **General** tab in the overview editor to set the proper focus.
3. From the context menu for the **Effective Date Type** property, choose **Edit**.  
To display the context menu, click the down arrow next to the property field.
4. In the Edit Property dialog, specify the following settings:
  - For **Effective Date Type**, select **EffectiveDated**.
  - For **Start Date Attribute**, select the attribute that corresponds to the start date.
  - For **End Date Attribute**, select the attribute that corresponds to the end date.
5. You can optionally specify attributes that allow for tracking of multiple changes in a single day.
  - For **Effective Date Sequence**, select the attribute that stores the sequence of changes.
  - For **Effective Date Sequence Flag**, select the attribute that stores a flag indicating the most recent change in the sequence.

Without specifying the **Effective Date Sequence** and **Effective Date Sequence Flag** attributes, the default granularity of effective dating is one day. For this reason, multiple changes in a single day are not allowed. An attempt to update the entity a second time in a single day will result in an exception being thrown. After these two attributes are specified, the framework inserts and updates their values as necessary to track multiple changes in a single day.

6. Click **OK**.

---

---

**Note:** You can also identify the start and end date attributes using the Property Inspector for the appropriate attributes. To do so, select the appropriate attribute in the overview editor and set the **IsEffectiveStartDate** or **IsEffectiveEndDate** property to **true** in the Property Inspector.

---

---

### 4.2.9 What Happens When You Create Effective Dated Entity Objects

When you create an effective dated entity object, JDeveloper creates a transient attribute called `sysEffectiveDate` to store the effective date for the row. Typically the Insert, Update, and Delete operations modify the transient attribute while the ADF

Business Components framework decides the appropriate values for the effective start date and the effective end date.

[Example 4-1](#) show some sample XML entries that are generated when you create an effective dated entity. For more information about working with effective dated objects, see [Section 5.4, "Limiting View Object Rows Using Effective Date Ranges."](#)

**Example 4-1 XML Entries for Effective Dated Entities**

```
// In the effective dated entity
<Entity
  ...
  EffectiveDateType="EffectiveDated">

// In the attribute identified as the start date
  <Attribute
    ...
    IsEffectiveStartDate="true">

// In the attribute identified as the end date
  <Attribute
    ...
    IsEffectiveEndDate="true">

// The SysEffectiveDate transient attribute
  <Attribute
    Name="SysEffectiveDate"
    IsQueryable="false"
    IsPersistent="false"
    ColumnName="$none$"
    Type="oracle.jbo.domain.Date"
    ColumnType="$none$"
    SQLType="DATE" />
```

#### 4.2.10 What You May Need to Know About Creating Entities from Tables

The Business Components from Tables wizard makes it easy to quickly generate many business components at the same time. In practice, this does not mean that you should use it to immediately create entity objects for every table in your database schema just because it is possible to do so. If your application requires all of the tables, then that strategy might be appropriate. But because you can use the wizard whenever needed, you should create the entity objects for the tables that you know will be involved in the application.

[Section 9.4, "Defining Nested Application Modules,"](#) describes a use case-driven design approach for your business services that can assist you in understanding which entity objects are required to support your application's business logic needs. You can always add more entity objects later as necessary.

### 4.3 Creating and Configuring Associations

If your database tables have no foreign key constraints defined, JDeveloper won't be able to infer the associations between the entity objects that you create. Since several ADF Business Components runtime features depend on the presence of entity associations, create them manually if the foreign key constraints don't exist.

### 4.3.1 How to Create an Association

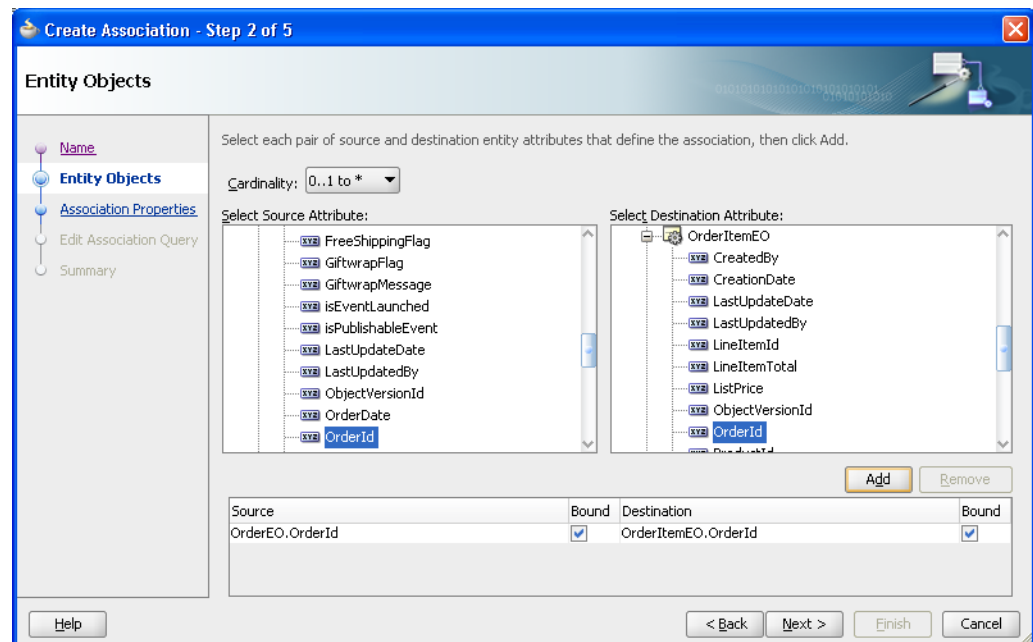

To create an association, use the Create New Association wizard, which is available in the New Gallery.

#### To create an association:

1. In the Application Navigator, right-click the project in which you want to create the association and choose **New**.
2. In the New Gallery, expand **Business Tier**, select **ADF Business Components** and then **Association**, and click **OK**.
3. On the Name page, do the following to create the association:
  - Enter the package name in which the association will be created.
  - Enter the name of the association component.
  - Click **Next**.
4. On the Entity Objects page, select the source and destination entity attributes:
  - Select a source attribute from one of the entity objects that is involved in the association to act as the master.
  - Select a corresponding destination attribute from the other entity object involved in the association.

For example, [Figure 4-4](#) shows the selected `OrderId` attribute from the `OrderEO` entity object as the source entity attribute. Because the `OrderItemEO` rows contain an order ID that relates them to a specific `OrderEO` row, you would select this `OrderId` foreign key attribute in the `OrderItemEO` entity object as the destination attribute.

**Figure 4-4** Create Association Wizard, Attribute Pairs That Relate Two Entity Objects Defined

5. Click **Add** to add the matching attribute pair to the table of source and destination attribute pairs below.

By default, the **Bound** checkbox is selected for both the source and destination attribute. This checkbox allows you to specify whether or not the value will be bound into the association SQL statement that is created internally when navigating from source entity to target entity or from target entity to source entity (depending on which side you select).

Typically, you would deselect the checkbox for an attribute in the relationship that is a transient entity attribute whose value is a constant and therefore should not participate in the association SQL statement to retrieve the entity.

6. If the association requires multiple attribute pairs to define it, you can repeat the preceding steps to add additional source/target attribute pairs.
7. Finally, ensure that the **Cardinality** dropdown correctly reflects the cardinality of the association. The default is a one-to-many relationship. Click **Next**.

For example, since the relationship between a `OrderEO` row and its related `OrderItemEO` rows is one-to-many, you can leave the default setting.

8. On the Association SQL page, you can preview the association SQL predicate that will be used at runtime to access the related destination entity objects for a given instance of the source entity object.
9. On the Association Properties page, disable the **Expose Accessor** checkbox on either the **Source** or the **Destination** entity object when you want to create an association that represents a one-way relationship. The default, bidirectional navigation is more convenient for writing business validation logic, so in practice, you typically leave these default checkbox settings.

For example, [Figure 4-5](#) shows an association that represents a bidirectional relationship, permitting either entity object to access the related entity row(s) on the other side when needed. In this example, this means that if you are working with an instance of an `OrderEO` entity object, you can easily access the collection of its related `OrderItemEO` rows. With any instance of a `OrderItemEO` entity object, you can also easily access the `Order` to which it belongs.

**Figure 4-5 Association Properties Control Runtime Behavior**

10. When you are satisfied with the association definition, click **Finish**.

### 4.3.2 What Happens When You Create an Association

When you create an association, JDeveloper creates an appropriate XML component definition file and saves it in the directory that corresponds to the name of its package. For example, if you created an association named `OrderItemsOrdersFkAssoc` in the `oracle.fodemo.storefront.entities.associations` subpackage, then the association XML file would be created in the `./oracle/fodemo/storefront/entities/associations` directory with the name `OrderItemsOrdersFkAssoc.xml`. At runtime, the entity object uses the association information to automate working with related sets of entities.

### 4.3.3 How to Change Entity Association Accessor Names

You should consider the default settings for the accessor names on the Association Properties page and decide whether changing the names to something more intuitive is appropriate. The default settings define the names of the accessor attributes you will use at runtime to programmatically access the entities on the other side of the relationship. By default, the accessor names will be the names of the entity object on the other side. Since the accessor names on an entity must be unique among entity object attributes and other accessors, if one entity is related to another entity in *multiple* ways, then the default accessor names are modified with a numeric suffix to make the name unique.

In an existing association, you can rename the accessor using the Association Properties dialog.

#### To rename the entity accessor in an association:

1. In the Application Navigator, double-click the association.
2. In the overview editor, click the **Relationships** navigation tab.
3. On the Relationships page, expand the **Accessors** category and click the **Edit** icon.  
The Association Properties dialog displays the current settings for the association's accessors.
4. Modify the name as necessary, and click **OK** to apply your changes and close the dialog.

### 4.3.4 How to Rename and Move Associations to a Different Package

Since associations are a component that you typically configure at the outset of your project and don't change frequently thereafter, you might want to move the associations to a different package so that your entity objects are easier to see. Both renaming components and moving them to a different package is straightforward using JDeveloper's refactoring functionality.

#### To move a set of business components to a different package:

1. In the Application Navigator, select the components you want to move.
2. Right-click one of the selected components, and choose **Refactor > Move**.
3. In the Move Business Components dialog, enter the name of the package to move the component(s) to, or click **Browse** to navigate to and select the package.
4. Click **OK** to apply your changes and close the dialog.

**To rename a component:**

1. In the Application Navigator, right-click the component you want to rename, and choose **Refactor > Rename**.
2. In the Rename dialog, enter the new name for the component and click **OK**.

When you refactor ADF Business Components, JDeveloper moves the XML and Java files related to the components, and updates any other components that might reference them.

Figure 4–6 shows what the Application Navigator would look like after renaming all of the associations and moving them to the `oracle.fodemo.storefront.associations` subpackage. While you can refactor the associations into any package name you choose, picking a subpackage keeps them logically related to the entities, and allows you to collapse the package of associations to better manage which files display in the Application Navigator.

**Figure 4–6 Application Navigator After Association Refactoring**

### 4.3.5 What You May Need to Know About Using a Custom View Object in an Association

You can associate a custom view object with the source end or destination end (or both) of an entity association.

When you traverse entity associations in your code, if the entities are not already in the cache, then the ADF Business Components framework performs a query to bring the entity (or entities) into the cache. By default, the query performed to bring an entity into the cache is the find-by-primary-key query that selects values for all persistent entity attributes from the underlying table. If the application performs a lot of programmatic entity association traversal, you could find that retrieving all of the attributes might be heavy-handed for your use cases.

Entity associations support the ability to associate a custom, entity-based view object with the source entity or destination entity in the association, or both. The primary entity usage of the entity-based view object you supply must match the entity type of the association end for which you use it.

Using a custom view object can be useful because the custom view object's query can include fewer columns and it can include an `ORDER BY` clause. This allows you to

control how much data is retrieved when an entity is brought into the cache due to association traversal, as well as the order in which any collections of related entities will appear.

For more information about creating a custom view object, see [Section 39.8.2, "How to Create an Entity-Based Programmatic View Object."](#)

### 4.3.6 What You May Need to Know About Composition Associations

An association represents a relationship between entities, such as `Person` referenced by an `Order` or an `OrderItem` contained in an `Order`. When you create associations, it is useful to know about the kinds of relationships you can represent, and the various options.

Associations between entity objects can represent two styles of relationships depending on whether the source entity:

- *References* the destination entity
- *Contains* the destination entity as a logical, nested part

[Figure 4-7](#) depicts an application business layer that represents both styles of relationships. For example, an `OrderEO` entry references a `PersonEO`. This relationship represents the first kind of association, reflecting that a `PersonEO` or an `OrderEO` entity object can exist independent from each other. In addition, the removal of an `Order` does not imply the cascade removal of the `Person` to which it was referring.

In contrast, the relationship between `OrderEO` and its collection of related `OrderItemEO` details is stronger than a simple reference. The `OrderItemEO` entries comprise a logical part of the overall `OrderEO`. In other words, an `OrderEO` is composed of `OrderItemEO` entries. It does not make sense for an `OrderItemEO` entity row to exist independently from an `OrderEO`, and when an `OrderEO` is removed — assuming the removal is allowed — all of its composed parts should be removed as well. This kind of logical containership represents the second kind of association, called a *composition*. The UML diagram in [Figure 4-7](#) illustrates the stronger composition relationship using the solid diamond shape on the side of the association which composes the other side of the association.

**Figure 4-7** *OrderEO Composed of OrderItemEO Entries and References Both PersonEO and AddressEO*

The Business Components from Tables Wizard creates composition associations by default for any foreign keys that have the `ON DELETE CASCADE` option. You can use the Create Association wizard or the overview editor for the association to indicate that an association is a composition association. Select the **Composition Association** checkbox on either the Association Properties page of the Create Association wizard or the Relationships page of the overview editor.

---

---

**Note:** A composition association cannot be based on a transient attribute.

---

---

An entity object offers additional runtime behavior in the presence of a composition. For the settings that control the behavior, see [Section 4.10.13, "How to Configure Composition Behavior."](#)

## 4.4 Creating an Entity Diagram for Your Business Layer

Since your layer of business domain objects represents a key reusable asset for your team, it is often convenient to visualize the business domain layer using a UML model. JDeveloper supports easily creating a diagram for your business domain layer that you and your colleagues can use for reference.

The UML diagram of business components is not just a static picture that reflects the point in time when you dropped the entity objects onto the diagram. Rather, it is a UML-based rendering of the current component definitions, that will always reflect the current state of affairs. What's more, the UML diagram is both a visualization aid and a visual navigation and editing tool. To open the overview editor for any entity object in a diagram, right-click the desired object and choose **Properties** from the context menu or double-click the desired object. You can also perform some entity object editing tasks directly on the diagram, like renaming entities and entity attributes, and adding or removing attributes.

### 4.4.1 How to Show Entity Objects in a Business Components Diagram

To create a diagram of your entity objects, you can use the Create Business Components Diagram dialog, which is available in the New Gallery.

**To create a business components diagram that models existing entity objects:**

1. In the Application Navigator, right-click the project in which you want to create the entity diagram and choose **New**.
2. In the New Gallery, expand **Business Tier**, select **ADF Business Components** and then **Business Components Diagram**, and click **OK**.
3. In the dialog, do the following to create the diagram:
  - Enter a name for the diagram, for example `Business Domain Objects`.
  - Enter the package name in which the diagram will be created. For example, you might create it in a subpackage like `myproject.model.design`.
4. Click **OK**.
5. To add existing entity objects to the diagram, select them in the Application Navigator and drop them onto the diagram surface.

After you have created the diagram you can use the Property Inspector to adjust visual properties of the diagram. For example you can:

- Hide or show the package name
- Change the font
- Toggle the grid and page breaks on or off
- Display association names that may otherwise be ambiguous

You can also create an image of the diagram in PNG, JPG, SVG, or compressed SVG format, by choosing **Publish Diagram** from the context menu on the diagram surface.

Figure 4–8 shows a sample diagram that models various entity objects from the business domain layer.

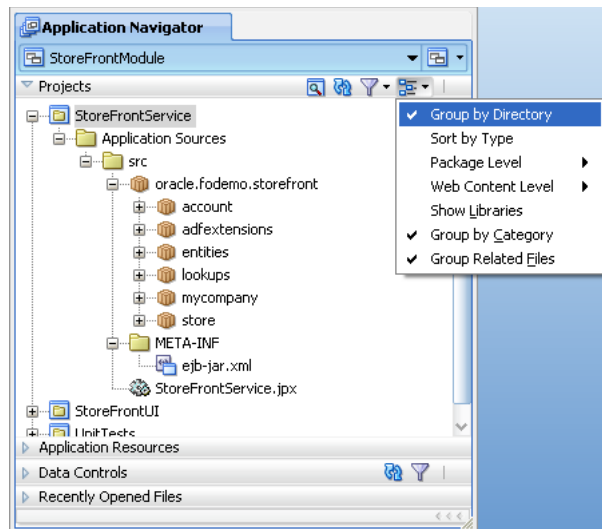

**Figure 4–8 UML Diagram of Business Domain Layer**

## 4.4.2 What Happens When You Create an Entity Diagram

When you create a business components diagram, JDeveloper creates an XML file `*.oxd_bc4j` representing the diagram in a subdirectory of the project's model path that matches the package name in which the diagram resides.

By default, the Application Navigator unifies the display of the project contents paths so that ADF components and Java files in the source path appear in the same package tree as the UML model artifacts in the project model path. However, as shown in Figure 4–9, using the **Navigator Display Options** toolbar button on the Application Navigator, you can see the distinct project content path root directories when you prefer.

**Figure 4–9** *Toggleing the Display of Separate Content Path Directories*

### 4.4.3 What You May Need to Know About the XML Component Descriptors

When you include a business component like an entity object to a UML diagram, JDeveloper adds extra metadata to a <Data> section of the component's XML component descriptor as shown in [Example 4–2](#). This additional information is used at design time only.

**Example 4–2** *Additional UML Metadata Added to an Entity Object XML Descriptor*

```
<Entity Name="OrderEO" ... >
  <Data>
    <Property Name ="COMPLETE_LIBRARY" Value ="FALSE" />
    <Property Name ="ID"
      Value ="ff16fca0-0109-1000-80f2-8d9081ce706f:::EntityObject" />
    <Property Name ="IS_ABSTRACT" Value ="FALSE" />
    <Property Name ="IS_ACTIVE" Value ="FALSE" />
    <Property Name ="IS_LEAF" Value ="FALSE" />
    <Property Name ="IS_ROOT" Value ="FALSE" />
    <Property Name ="VISIBILITY" Value ="PUBLIC" />
  </Data>
  :
</Entity>
```

### 4.4.4 What You May Need to Know About Changing the Names of Components

On an entity diagram, the names of entity objects, attributes, and associations can be changed for clarity. Changing names on a diagram does not affect the underlying data names. The name change persists for the diagram only. The new name may contain spaces and mixed case for readability. To change the actual entity object names, attribute names, or association names, open the entity object or association in the overview editor.

## 4.5 Defining Property Sets

A property set is a named collection of properties, where a property is defined as a name/value pair. Property sets are a convenience mechanism to group properties and then reference them from other ADF Business Components objects. Properties defined

in a property set can be configured to be translatable, in which case the translations are stored in a message bundle file owned by the property set.

Property sets can be used for a variety of functions, such as control hints and error messages. A property set may contain control hints and other custom properties, and you can associate them with multiple attributes of different objects.

---

**Note:** Take care when defining property sets that contain translatable content. Be sure not to "overload" common terms in different contexts. For example, the term "Name" might be applied to both an object and a person in one language, but then translated into two different terms in a target language. Even though a term in several contexts might be the same in the source language, a separate distinguishable term should be used for each context.

---

Property sets can be used with entity objects and their attributes, view objects and their attributes, and application modules.

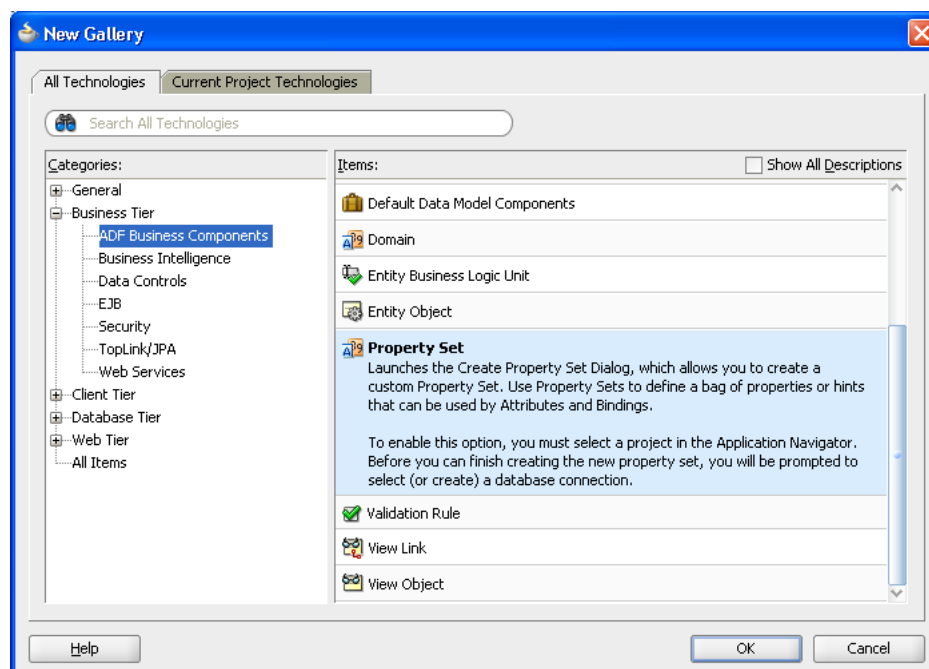

### 4.5.1 How to Define a Property Set

To define a property set, you create a new property set using a dialog and then specify properties using the Property Inspector.

#### To define a property set:

1. In the Application Navigator, right-click the project where you want to create the property set, and choose **New**.
2. In the New Gallery, expand **Business Tier**, select **ADF Business Components** and then **Property Set**, and click **OK**.

**Figure 4–10** Property Set in New Gallery

3. In the Create Property Set dialog, enter the name and location of the property set and click **OK**.
4. From the **View** menu, choose **Property Inspector**.
5. In the Property Inspector, define the properties for the property set.

## 4.5.2 How to Apply a Property Set

After you have created the property set, you can apply the property set to an entity object or attribute, and use the defined properties (or override them, if necessary).

### To apply a property set to an entity object or view object:

1. In the Application Navigator, double-click the desired object (entity object or view object).
2. In the overview editor, click the **General** navigation tab, and then click the **Edit** icon next to the **Property Set** line.
3. Select the appropriate property set, and click **OK**.

### To apply a property set to an attribute:

1. In the Application Navigator, double-click the desired object (entity object or view object).
2. In the overview editor, click the **Attributes** navigation tab, and double-click the attribute you want to edit.
3. In the Edit Attribute dialog, click the first node to view the general properties of the attribute.

For view objects, it is the **View Attribute** node. For entity objects, it is the **Entity Attribute** node.

4. In the **Property Set** dropdown list, select the appropriate property set, and click **OK**.

## 4.6 Defining Attribute Control Hints for Entity Objects

If you are familiar with previous versions of ADF business components, you may have used control hints. Control hints allow you to define label text, tooltip, and format mask hints for entity object attributes. The UI hints you define on your business domain layer are inherited by any entity-based view objects as well. You can also set additional control hints on view objects and application modules in a similar manner.

### 4.6.1 How to Add Attribute Control Hints

To add attribute control hints to an entity object, use the overview editor.

#### To add attribute control hints to an entity object:

1. In the Application Navigator, double-click the desired entity object.
2. In the overview editor, click the **Attributes** navigation tab, and double-click the attribute you want to edit.
3. In the Edit Attribute dialog, click the **Control Hints** node to view the attribute's control hints.
4. Specify control hints as necessary, and then click **OK**.

For example, [Figure 4–11](#) shows control hints defined for the attribute `expireDate` of the `PaymentOptionEO` entity object. The defined hints include the following:

- **Format Type** to `Simple Date`
- **Format** mask of `yyyy-MM-dd`

**Figure 4–11** *Edit Attribute Dialog, Control Hints Node*

---

**Note:** Java defines a standard set of format masks for numbers and dates that are different from those used by the Oracle database's SQL and PL/SQL languages. For reference, see the Javadoc for the `java.text.DecimalFormat` and `java.text.SimpleDateFormat` classes.

---

## 4.6.2 What Happens When You Add Attribute Control Hints

When you define attribute control hints for an entity object, JDeveloper creates a resource bundle file in which to store them. The hints that you define can be used by generated forms and tables in associated view clients. The type of file and its granularity are determined by Resource Bundle options in the Project Properties dialog. For more information, see [Section 4.7, "Working with Resource Bundles."](#)

## 4.6.3 How to Define Formatters and Masks

When you set the **Format Type** control hint (in the Edit Attribute dialog) for an attribute (for example, to **Simple Date**), you can also specify a format mask for the attribute to customize how the UI displays the value. If the mask you want to use is not listed in the **Format** dropdown list, you can simply type it into the field.

Not all formatters require format masks. Specifying a format mask is only needed if that formatter type requires it. For example, the date formatter requires a format mask,

but the currency formatter does not. In fact the currency formatter does not support format mask at all.

The mask elements that you can use are defined by the associated Java format class. For information about the mask elements for the Simple Date format type, see the Javadoc for `java.text.SimpleDateFormat`. For information about the mask elements for the Number format type, see the Javadoc for `java.text.DecimalFormat`.

If you have a format mask that you will continue to use on multiple occasions, you can add it to the `formatinfo.xml` file, so that it is available from the **Format** dropdown list in the Edit Attribute dialog. The entries in this file define the format masks and formatter classes for a domain class. [Example 4-3](#) shows the format definitions for the `java.util.Date` domain.

---

**Note:** You can find the `formatinfo.xml` file in the BC4J subdirectory of the JDeveloper system directory (for example, `C:\Documents and Settings\username\Application Data\JDeveloper\system##\o.BC4J\formatinfo.xml`).

---

**Example 4-3 Format Definitions for `java.util.Date` in `formatinfo.xml`**

```
<?xml version="1.0"?>
<FORMATTERS>
. . .
  <DOMAIN CLASS="java.util.Date">
    <FORMATTER name="Simple Date" class="oracle.jbo.format.DefaultDateFormatter">
      <FORMAT text="yyyy-MM-dd" />
      <FORMAT text="EEE, MMM d, ''yy" />
      <FORMAT text="dd-MM-yy" />
      <FORMAT text="dd-MMM-yyyy" />
      <FORMAT text="dd/MMM/yyyy" />
    </FORMATTER>
  </DOMAIN>
. . .
</FORMATTERS>
```

The definition of the format mask belongs to a formatter and a domain class, and includes the text specification of the mask as it appears in the Edit Attribute dialog. When you specify the **Format Type** (`FORMATTER name`) for an attribute of a given type (`DOMAIN CLASS`), the masks (`FORMAT text`) appear in the **Format** dropdown list.

To map a formatter to a domain for use with control hints, you can either amend one of the default formatters provided in the `oracle.jbo.format` package, or create a new formatter class by extending the `oracle.jbo.format.Formatter` class. The default formatters provided with JDeveloper aggregate the formatters provided in the `java.text` package.

It is not necessary to create new domain to map a formatter. You can use an existing domain when the business components project contains a domain of the same data type as the formatter.

**To define a new format mask:**

1. Open the `formatinfo.xml` file in a text editor.
2. Find the domain class and formatter name for which you want to add a format mask.

3. Insert a new `FORMAT` entry within the `FORMATTER` element.

After defining a format mask, you can select the new format mask from the **Format** dropdown list in the Edit Attribute dialog.

---

**Note:** If you create a new domain for the format mask, the XML definition of the formatter must include a `DOMAIN CLASS` (which can be a new or existing one), the `FORMATTER` (which includes the name and class), and the list of `FORMAT` definitions the formatter class specifies.

---

## 4.7 Working with Resource Bundles

When you define translatable strings (such as validator error messages, or attribute control hints for an entity object or view object), by default JDeveloper creates a project-level resource bundle file in which to store them. For example, when you define control hints for an entity object in the `StoreFront` project, JDeveloper creates the message bundle file named `StoreFrontBundle.xxx` for the package. The hints that you define can be used by generated forms and tables in associated view clients.

The resource bundle option that JDeveloper uses is determined by an option on the Resource Bundle page of the Project Properties dialog. By default JDeveloper sets the option to **Properties Bundle**, which produces a `.properties` file. For more information on this and other resource bundle options, see [Section 4.7.1, "How to Set Message Bundle Options."](#)

You can inspect the message bundle file for the entity object by selecting the object in the Application Navigator and looking in the corresponding **Sources** node in the Structure window. The Structure window shows the implementation files for the component you select in the Application Navigator.

[Example 4-4](#) shows a sample message bundle file where the control hint information appears. The first entry in each `String` array is a message key; the second entry is the locale-specific `String` value corresponding to that key.

### **Example 4-4 Project Message Bundle Stores Locale-Sensitive Control Hints**

```
AddressUsageEO_OwnerTypeCode_Error_0=Invalid OwnerTypeCode.
AddressUsageEO_UsageTypeCode_Error_0=Invalid UsageTypeCode.
OwnerTypeCode_CONTROLTYPE=105
PaymentOptionEO_RoutingIdentifier_Error_0=Please enter a valid routing identifier.
PaymentOptionsEO_PaymentTypeCode_Error_0=Invalid PaymentTypeCode.
PaymentTypeCode_CONTROLTYPE=105
PaymentOption_AccountNumber=Please enter a valid Account Number
MinPrice_FMT_FORMATTER=oracle.jbo.format.DefaultCurrencyFormatter
CostPrice_FMT_FORMATTER=oracle.jbo.format.DefaultCurrencyFormatter
UnitPrice_FMT_FORMATTER=oracle.jbo.format.DefaultCurrencyFormatter
OrderEO_GiftMessage=Please supply a message shorter than 200 characters
OrderEO=Please supply a gift message
DiscountBaseEO_DiscountAmount=Discount must be between 0 and 40%

oracle.fodemo.storefront.entities.PaymentOptionEO.ExpireDate_FMT_FORMAT=mm/yy
#Date range validation for ValidFrom and ValidTo dates
PaymentOptionEO_invalidDateRange_Error_0=Date range is invalid. {0} must be
greater than {1}.
PaymentOptionEO_DateRange_Error_0=Invalid date range.{0} should be greater than
{1}.
```

```

oracle.fodemo.storefront.entities.PaymentOptionEO.ValidFromDate_LABEL=Valid From
Date
oracle.fodemo.storefront.entities.PaymentOptionEO.ValidToDate_LABEL=Valid To Date
OrderItemsVO_ImageId_Rule_0=ImageId not found
oracle.fodemo.storefront.store.queries.AddressesVO.Address1_LABEL=Address
oracle.fodemo.storefront.store.queries.AddressesVO.PostalCode_LABEL=Post Code or
ZIP
. . .

```

## 4.7.1 How to Set Message Bundle Options

The resource bundle option JDeveloper uses to save control hints and other translatable strings is determined by an option on the Resource Bundle page of the Project Properties dialog. By default JDeveloper sets the option to **Properties Bundle** which produces a `.properties` file.

### To set resource bundle options for your project

1. In the Application Navigator, right-click the project and choose **Project Properties**.
2. Click **Resource Bundle**.
3. Select whether to use project or custom settings.

If you select **Use Custom Settings**, the settings apply only to your work with the current project. They are preserved between sessions, but are not recorded with the project and cannot be shared with other users. If you select **Use Project Settings**, your choices are recorded with the project and can be shared with others who use the project.

4. Specify your preference with the following options by selecting or deselecting the option:
  - **Automatically Synchronize Bundle**
  - **Warn About Hard-coded Translatable Strings**
  - **Always Prompt for Description**

For more information on these options, click **Help** to see the online help.
5. Select your choice of resource bundle granularity.
  - **One Bundle Per Project** (default)
  - **One Bundle Per File**
  - **Multiple Shared Bundles** (not available for ADF Business Components)
6. Select the type of file to use.

- **List Resource Bundle**

The `ListResourceBundle` class manages resources in a name/value array. Each `ListResourceBundle` class is contained within a Java class file. You can store any locale-specific object in a `ListResourceBundle` class.

- **Properties Bundle** (default)

A text file containing translatable text in name/value pairs. Property files (like the one shown in [Example 4-4](#)) can contain values only for String objects. If you need to store other types of objects, you must use a `ListResourceBundle` instead.

- **Xliff Resource Bundle**

The XML Localization Interchange File Format (XLIFF) is an XML-based format for exchanging localization data.

7. Click **OK** to apply your settings and close the dialog.

## 4.7.2 How to Use Multiple Resource Bundles

When you define translatable strings (for example, for attribute control hints), the Select Text Resource dialog allows you to enter a new string or select one that is already defined in the default resource bundle for the object. You can also use a different resource bundle if necessary. This is helpful when you use a common resource bundle that is shared between projects.

### To use strings in a nondefault resource bundle:

1. In the Select Text Resource dialog, select the bundle you want to use from the **Resource Bundle** dropdown list.

If the desired resource bundle is not included in the **Resource Bundle** dropdown list, click the **Browse** icon to locate and select the resource bundle you want to use.

The dialog displays the strings that are currently defined in the selected resource bundle.

2. Select an existing string and click **Select**, or enter a new string and click **Save and Select**.

If you entered a new string it is written to the selected resource bundle.

## 4.7.3 How to Internationalize the Date Format

Internationalizing the model layer of an application built using ADF Business Components entails producing translated versions of each component message bundle file. For example, the Italian version of the `OrdersImplMsgBundle` message bundle would be a class named `OrdersImplMsgBundle_it` and a more specific *Swiss* Italian version would have the name `OrdersImplMsgBundle_it_ch`. These classes typically extend the base message bundle class, and contain entries for the message keys that need to be localized, together with their localized translation.

[Example 4–5](#) shows the Italian version of an entity object message bundle. Notice that in the Italian translation, the format masks for `RequestDate` and `AssignedDate` have been changed to `dd/MM/yyyy HH:mm`. This ensures that an Italian user will see a date value like May 3rd, 2006, as `03/05/2006 15:55`, instead of `05/03/2006 15:55`, which the format mask in the default message bundle would produce. Notice the overridden `getContents()` method. It returns an array of messages with the more *specific* translated strings merged together with those that are not overridden from the superclass bundle. At runtime, the appropriate message bundles are used automatically, based on the current user's locale settings.

### Example 4–5 Localized Entity Object Component Message Bundle for Italian

```
package devguide.model.entities.common;
import oracle.jbo.common.JboResourceBundle;
public class ServiceRequestImplMsgBundle_it
    extends ServiceRequestImplMsgBundle {
    static final Object[][] sMessageStrings = {
        { "AssignedDate_FMT_FORMAT", "dd/MM/yyyy HH:mm" },
        { "AssignedDate_LABEL", "Assegnato il" },
        { "AssignedTo_LABEL", "Assegnato a" },
        { "CreatedBy_LABEL", "Aperto da" },
```

```

    { "ProblemDescription_LABEL", "Problema" },
    { "RequestDate_FMT_FORMAT", "dd/MM/yyyy HH:mm" },
    { "RequestDate_LABEL", "Aperto il" },
    { "RequestDate_TOOLTIP", "La data in cui il ticket è stato aperto" },
    { "Status_LABEL", "Stato" },
    { "SvrId_LABEL", "Ticket" }
};
public Object[][] getContents() {
    return super.getMergedArray(sMessageStrings, super.getContents());
}
}

```

## 4.8 Defining Business Logic Groups

Business logic groups allow you to encapsulate a set of related control hints, default values, and validation logic. A business logic group is maintained separate from the base entity in its own file, and can be enabled dynamically based on context values of the current row.

This is useful, for example, for an HR application that defines many locale-specific validations (like national identifier or tax law checks) that are maintained by a dedicated team for each locale. The business logic group eases maintenance by storing these validations in separate files, and optimizes performance by loading them only when they are needed.

Each business logic group contains a set of business logic units. Each unit identifies the set of business logic that is loaded for the entity, based on the value of the attribute associated with the business logic group.

For example, you can define a business logic group for an `Employee` entity object, specifying the `EmpRegion` attribute as the discriminator. Then define a business logic unit for each region, one that specifies a range validator for the employee's salary. When the application loads a row from the `Employee` entity, the appropriate validator for the `EmpSalary` attribute is loaded (based on the value of the `EmpRegion` attribute).

In another example, from the `StoreFront` module of the `Fusion Order Demo` application, the `PersonEO` entity object has a business logic group called `PersonTypeCodeGroup` that uses `PersonTypeCode` as the discriminator attribute. Because this attribute has three valid values (`CUST`, `STAFF`, and `SUPP`), there are three corresponding business logic units.

In this scenario, each business logic unit contains new or modified business logic that pertains only to that person type:

- The `CUST` business logic unit contains logic that pertains to customers. For example, it contains a validator that checks for a phone number because all customers must have a phone number.
- The `STAFF` business logic unit contains logic that pertains to staff members. For example, it contains a validator that constrains the credit limit.
- The `SUPP` business logic unit contains logic that pertains to suppliers. For example, it contains a validator that makes sure the `ContactByAffiliatesFlag` attribute is set to `N`, because suppliers cannot be contacted by affiliates.

### 4.8.1 How to Create a Business Logic Group

You create the business logic group for an entity object from the overview editor.

**To create a business logic group:**

1. In the Application Navigator, double-click the entity for which you want to create a business logic group.
2. In the overview editor, click the **General** navigation tab.
3. On the General page, expand the **Business Logic Groups** section, and click the **Add** icon.
4. In the creation dialog, select the appropriate group discriminator attribute and specify a name for the group.

**Tip:** To enhance the readability of your code, you can name the group to reflect the discriminator. For example, if the group discriminator attribute is `PersonTypeCode`, you can name the business logic group `PersonTypeCodeGroup`.

5. Click **OK**.

The new business logic group is added to the table in the overview editor. After you have created the group, you can add business logic units to it.

## 4.8.2 How to Create a Business Logic Unit

You can create a business logic unit from the New Gallery, or directly from the context menu of the entity that contains the business logic group.

**To create a business logic unit:**

1. In the Application Navigator, right-click the entity that contains the business logic group and choose **New Entity Business Logic Unit** from the context menu.
2. In the Create Business Logic Unit dialog, specify the name of the base entity and select the appropriate business logic group.
3. Enter a name for the business logic unit.

The name of each business logic unit must reflect a valid value of the group discriminator attribute with which this business logic unit will be associated. For example, if the group discriminator attribute is `PersonTypeCode`, the name of the business logic unit associated with the `PersonTypeCode` value of `STAFF` must be `STAFF`.

4. Specify the package for the business logic unit.

---

---

**Note:** The package for the business logic unit does not need to be the same as the package for the base entity or the business logic group. This allows you to develop and deliver business logic units separately from the core application.

---

---

5. Click **OK**.

JDeveloper creates the business logic unit and opens it in the overview editor. The name displayed for the business logic unit in the Application Navigator contains the name of the entity object and business logic group in the format `EntityName_BusLogicGroupName_BusLogicUnitName`. For example, when you create a business logic unit with the name `CUST` in the `PersonTypeCodeGroup` business logic group of the `PersonEO` entity object, the displayed name of the business logic unit is `PersonEO_PersonTypeCodeGroup_CUST`.

After you have created the unit, you can redefine the business logic for it.

### 4.8.3 How to Add Logic to a Business Logic Unit

After you have created a business logic unit, you can open it in the overview editor and add business logic (such as adding an entity-level validator) just as you would in the base entity.

**To add an entity validator to a business logic unit:**

1. In the Application Navigator, double-click the business logic unit.
2. In the overview editor, click the **Business Rules** navigation tab.
3. On the Business Rules page, select the Entity Validators folder and click the **Add** icon.
4. Define your validation rule, and click **OK**.

For example, the `PersonEO` entity object in the StoreFront module of the Fusion Order Demo application has a business logic unit called `PersonEO_PersonTypeCodeGroup_CUST`. This business logic unit has an entity validator that checks for the presence of a phone number to ensure that all persons who are customers have a phone number.

### 4.8.4 How to Override Attributes in a Business Logic Unit

When you view the Attributes page for the business logic unit (in the overview editor), you can see that the **Extends** column in the attributes table shows that the attributes are "extended" in the business logic unit. Extended attributes are editable only in the base entity, not in the business logic unit. To implement changes in the business logic unit rather than the base entity, you must define attributes as overridden in the business logic unit before you edit them.

**To override attributes in a business logic unit:**

1. In the Application Navigator, double-click the business logic unit.
2. In the overview editor, click the **Attributes** navigation tab.
3. On the Attributes page, select the desired attribute and click the **Override** button.

After you make an attribute overridden, you can edit the attribute as you normally would by double-clicking the attribute to open it in the Edit Attribute dialog. You will notice that in an overridden attribute, you are limited to making modifications to only control hints, validators, and default values.

### 4.8.5 What Happens When You Create a Business Logic Group

When you create a business logic group, JDeveloper adds a reference to the group in the base entity's XML file. [Example 4-6](#) shows the code added to the base entity's XML file for the business logic group.

**Example 4-6 XML Code in the Base Entity for a Business Logic Group**

```
<BusLogicGroup
  Name="PersonTypeCodeGroup"
  DiscrAttrName="PersonTypeCode"/>
```

When you create a business logic unit, JDeveloper generates an XML file similar to that of an entity object. [Example 4-7](#) shows XML code for a business logic unit.

---

---

**Note:** The package for the business logic unit does not need to be the same as the package for the base entity or the business logic group. This allows you to develop and deliver business logic units separately from the core application.

---

---

#### Example 4–7 XML Code for a Business Logic Unit

```
<Entity
  xmlns="http://xmlns.oracle.com/bc4j"
  Name="PersonEO_PersonTypeCodeGroup_CUST"
  Version="11.1.1.54.6"
  Extends="oracle.fodemo.storefront.entities.PersonEO"
  DBObjectType="table"
  DBObjectName="PERSONS"
  BindingStyle="OracleName"
  UseGlueCode="false"
  BusLogicGroupName="PersonTypeCodeGroup"
  BusLogicUnitName="CUST"
  xmlns:validation="http://xmlns.oracle.com/adfm/validation">
  <DesignTime>
    <Attr Name="_codegenFlag2" Value="Access"/>
    <AttrArray Name="_publishEvents"/>
  </DesignTime>
  <validation:ExpressionValidationBean
    Name="PersonEO_PersonTypeCodeGroup_CUST_Rule_0"
    OperandType="EXPR"
    Inverse="false">
    <validation:MsgIds>
      <validation:Item
        Value="CUST_PHONE_REQUIRED"/>
    </validation:MsgIds>
    <validation:TransientExpression>
      <![CDATA[if (PhoneNumber == null && MobilePhoneNumber == null)
        return false;
        else return true;]]>
    </validation:TransientExpression>
  </validation:ExpressionValidationBean>
  <ResourceBundle>
    <PropertiesBundle
      PropertiesFile="oracle.fodemo.storefront.entities.common.PersonEO_
PersonTypeCodeGroup_CUSTMsgBundle"/>
    </ResourceBundle>
  </Entity>
```

### 4.8.6 What Happens at Runtime: Invoking a Business Logic Group

When a row is loaded in the application at runtime, the entity object decides which business logic units to apply to it.

The base entity maintains a list of business logic groups. Each group references the value of an attribute on the entity, and this value determines which business logic unit to load for that group. This evaluation is performed for each row that is loaded.

If the logic for determining which business logic unit to load is more complex than just a simple attribute value, you can create a transient attribute on the entity object, and use a Groovy expression to determine the value of the transient attribute.

## 4.9 Configuring Runtime Behavior Declaratively

Entity objects offer numerous declarative features to simplify implementing typical enterprise business applications. Depending on the task, sometimes the declarative facilities *alone* may satisfy your needs. The declarative runtime features that describe the basic persistence features of an entity object are covered in this section, while declarative validation and business rules are covered in [Chapter 7, "Defining Validation and Business Rules Declaratively."](#)

---

---

**Note:** It is possible to go beyond the declarative behavior to implement more complex business logic or validation rules for your business domain layer when needed. In [Chapter 8, "Implementing Validation and Business Rules Programmatically,"](#) you'll see some of the most typical ways that you extend entity objects with custom code.

---

---

Also, it is important to note as you develop your application that the business logic you implement, either programmatically or declaratively, should not assume that the attributes of an entity object or view row will be set in a particular order. This will cause problems if the end user enters values for the attributes in an order other than the assumed one.

### 4.9.1 How to Configure Declarative Runtime Behavior

To configure the declarative runtime behavior of an entity object, use the overview editor.

**To configure the declarative runtime behavior of an entity object:**

1. In the Application Navigator, double-click an entity object.
2. In the overview editor, click the **General** navigation tab to view the name and package of the entity object, and configure aspects of the object at the entity level, such as its associated schema, alternative keys, custom properties, and security.
  - The **Alternate Keys** section allows you to select entity object attributes mapped to the database that can serve as an alternative primary key. For information on alternative keys, see [Section 4.10.15, "How to Define Alternate Key Values."](#)
  - The **Tuning** section allows you to set options to make database operations more efficient when you create, modify, or delete multiple entities of the same type in a single transaction. For more information, see [Section 38.3, "Using Update Batching."](#)
  - The **Custom Properties** section allows you to define custom metadata that you can access at runtime on the entity.
  - The **Security** section allows you to define role-based updatability permissions for the entity. For more information, see [Chapter 30, "Enabling ADF Security in a Fusion Web Application."](#)
  - The **Business Logic Groups** section allows you to add and edit business logic groups. For more information, see [Section 4.8, "Defining Business Logic Groups."](#)

3. Click the **Attributes** navigation tab to create or delete attributes that represent the data relevant to an entity object, and configure aspects of the attribute, such as validation rules, custom properties, and security.

Select an attribute and click the **Edit** icon to access the properties of the attribute. For information on how to set these properties, see [Section 4.10, "Setting Attribute Properties."](#)

---

**Tip:** If your entity has a long list of attribute names, there's a quick way to find the one you're looking for. In the Structure window with the **Attributes** node expanded, you can begin to type the letters of the attribute name and JDeveloper performs an incremental search to take you to its name in the tree.

---

4. Click the **Business Rules** navigation tab to define declarative validators for the entity object and its attributes. For more information, see [Chapter 7, "Defining Validation and Business Rules Declaratively."](#)
5. Click the **Java** navigation tab to select the classes you generate for custom Java implementation. You can use the Java classes for such things as defining programmatic business rules, as in [Chapter 8, "Implementing Validation and Business Rules Programmatically."](#)
6. Click the **Business Events** navigation tab to define events that your entity object can use to notify others of interesting changes in its state, optionally including some or all of the entity object's attributes in the delivered event. For more information about business events, see [Section 4.11, "Creating Business Events."](#)
7. Click the **View Accessors** navigation tab to create and manage view accessors. For more information, see [Section 10.4.1, "How to Create a View Accessor for an Entity Object or View Object."](#)

## 4.9.2 What Happens When You Configure Declarative Runtime Behavior

The declarative settings that describe and control an entity object's runtime behavior are stored in its XML component definition file. When you use the overview editor to modify settings of your entity, JDeveloper updates the component's XML definition file and optional custom Java files.

## 4.10 Setting Attribute Properties

The declarative framework helps you set attribute properties easily. In all cases, you set these properties in the Edit Attribute dialog, which you can access from the Attributes page of the overview editor.

### 4.10.1 How to Set Database and Java Data Types for an Entity Object Attribute

The **Persistent** property controls whether the attribute value corresponds to a column in the underlying table, or whether it is just a transient value. If the attribute is persistent, the **Database Column** area lets you change the name of the underlying column that corresponds to the attribute and indicate its column type with precision and scale information (e.g. `VARCHAR2 (40)` or `NUMBER (4, 2)`). Based on this information, at runtime the entity object enforces the maximum length and precision/scale of the attribute value, and throws an exception if a value does not meet the requirements.

Both the Business Components from Tables wizard and the Create Entity Object wizard infer the Java type of each entity object attribute from the SQL type of the database column type of the column to which it is related.

---

**Note:** The project's Type Map setting also plays a role in determining the Java data type. You specify the Type Map setting when you initialize your business components project, before any business components are created. For more information, see [Section 3.3.1, "Choosing a Connection, SQL Flavor, and Type Map."](#)

---

The **Attribute Type** field (in the Edit Attribute dialog) allows you to change the Java type of the entity attribute to any type you might need. The **Database Column Type** field reflects the SQL type of the underlying database column to which the attribute is mapped. The value of the **Database Column Name** field controls the column to which the attribute is mapped.

Your entity object can handle tables with various column types, as listed in [Table 4-1](#). With the exception of the `java.lang.String` class, the default Java attribute types are all in the `oracle.jbo.domain` and `oracle.ord.im` packages and support efficiently working with Oracle database data of the corresponding type. The dropdown list for the **Attribute Type** field includes a number of other common Java types that are also supported.

**Table 4-1 Default Entity Object Attribute Type Mappings**

Oracle Column Type	Entity Column Type	Entity Java Type
NVARCHAR2 (n), VARCHAR2 (n), NCHAR VARYING (n), VARCHAR (n)	VARCHAR2	<code>java.lang.String</code>
NUMBER	NUMBER	<code>oracle.jbo.domain.Number</code>
DATE	DATE	<code>oracle.jbo.domain.Date</code>
TIMESTAMP (n), TIMESTAMP (n) WITH TIME ZONE, TIMESTAMP (n) WITH LOCAL TIME ZONE	TIMESTAMP	<code>java.sql.Timestamp</code>
LONG	LONG	<code>java.lang.String</code>
RAW (n)	RAW	<code>oracle.jbo.domain.Raw</code>
LONG RAW	LONG RAW	<code>oracle.jbo.domain.Raw</code>
ROWID	ROWID	<code>oracle.jbo.domain.RowID</code>
NCHAR, CHAR	CHAR	<code>oracle.jbo.domain.Char</code>
CLOB	CLOB	<code>oracle.jbo.domain.ClobDomain</code>
NCLOB	NCLOB	<code>oracle.jbo.domain.NClobDomain</code>
BLOB	BLOB	<code>oracle.jbo.domain.BlobDomain</code>
BFILE	BFILE	<code>oracle.jbo.domain.BFileDomain</code>
ORDSYS.ORDIMAGE	ORDSYS.ORDIMAGE	<code>oracle.ord.im.OrdImageDomain</code>
ORDSYS.ORDVIDEO	ORDSYS.ORDVIDEO	<code>oracle.ord.im.OrdVideoDomain</code>
ORDSYS.ORDAUDIO	ORDSYS.ORDAUDIO	<code>oracle.ord.im.OrdAudioDomain</code>
ORDSYS.ORDDOC	ORDSYS.ORDDOC	<code>oracle.ord.im.OrdDocDomain</code>

---

---

**Note:** In addition to the types mentioned here, you can use any Java object type as an entity object attribute's type, provided it implements the `java.io.Serializable` interface.

---

---

#### 4.10.2 How to Indicate Data Type Length, Precision, and Scale

When working with types that support defining a maximum length like `VARCHAR2 (n)`, the **Database Column Type** field (in the Edit Attribute dialog) includes the maximum attribute length as part of the value. For example, an attribute based on a `VARCHAR2 (10)` column in the database will initially reflect the maximum length of 10 characters by showing `VARCHAR2 (10)` as the database column type. If for some reason you want to restrict the maximum length of the `String`-valued attribute to fewer characters than the underlying column will allow, just change the maximum length of the **Database Column Type** value.

For example, if the `EMAIL` column in the `PERSONS` table is `VARCHAR2 (50)`, then by default the `Email` attribute in the `Persons` entity object defaults to the same. But if you know that the actual email addresses are always 8 characters or fewer, you can update the database column type for the `Email` attribute to be `VARCHAR2 (8)` to enforce a maximum length of 8 characters at the entity object level.

The same holds for attributes related to database column types that support defining a precision and scale like `NUMBER (p [, s])`. For example, to restrict an attribute based on a `NUMBER (7, 2)` column in the database to instead have a precision of 5 and a scale of 1, just update the value of the **Database Column Type** field to be `NUMBER (5, 1)`.

#### 4.10.3 How to Control the Updatability of an Attribute

The `Updatable` property controls when the value of a given attribute can be updated. You can select the following values:

- **Always**, the attribute is always updatable
- **Never**, the attribute is read-only
- **While New**, the attribute can be set during the transaction that creates the entity row for the first time, but after being successfully committed to the database the attribute is read-only

---

---

**Note:** In addition to the static declaration of updatability, you can also add custom code in the `isAttributeUpdateable()` method of the entity to determine the updatability of an attribute at runtime.

---

---

#### 4.10.4 How to Make an Attribute Mandatory

Select the **Mandatory** checkbox if the field is required. The mandatory property is enforced during entity-level validation at runtime (and not when the attribute validators are run).

#### 4.10.5 How to Define the Primary Key for the Entity

The `Primary Key` property indicates whether the attribute is part of the key that uniquely identifies the entity. Typically, you use a single attribute for the primary key, but multiattribute primary keys are fully supported.

At runtime, when you access the related `Key` object for any entity row using the `getKey()` method, this `Key` object contains the value of the primary key attribute for the entity object. If your entity object has multiple primary key attributes, the `Key` object contains each of their values. It is important to understand that these values appear in the same *relative* sequential order as the corresponding primary key attributes in the entity object definition.

For example, if the `OrderItemEO` entity object has multiple primary key attributes `OrderId` and `LineItemId`. On the Entity Attribute page of the overview editor, `OrderId` is first, and `LineItemId` is second. An array of values encapsulated by the `Key` object for an entity row of type `OrderItemEO` will have these two attribute values in exactly this order.

It is crucial to be aware of the order in which multiple primary key attributes appear on the Entity Attributes page. If you try to use `findByPrimaryKey()` to find an entity with a multiattribute primary key, and the `Key` object you construct has these multiple primary key attributes in the wrong order, the entity row will not be found as expected.

#### 4.10.6 How to Define a Static Default Value

The **Value** field (in the Edit Attribute dialog) allows you to specify a static default value for the attribute when the **Value Type** is set to **Literal**. For example, you can set the default value of the `ServiceRequest` entity object's `Status` attribute to `Open`, or set the default value of the `User` entity object's `UserRole` attribute to `user`.

---

---

**Note:** When more than one attribute is defaulted for an entity object, the attributes are defaulted in the order in which they appear in the entity object's XML file.

---

---

#### 4.10.7 How to Define a Default Value Using a Groovy Expression

You can use a Groovy expression to define a default value for an attribute. This approach is useful if you want to be able to change default values at runtime, but if the default value is always the same, the value is easier to see and maintain using the **Default** field (in the Edit Attribute dialog). For general information about using Groovy, see [Section 3.6, "Overview of Groovy Support."](#)

**To define a default value using a Groovy expression:**

1. In the Application Navigator, double-click the entity to open the overview editor.
2. In the overview editor, click the **Attributes** navigation tab.
3. On the Attributes page, select the desired attribute and click the **Edit** icon.
4. In the Edit Attribute dialog, select **Expression** for the value type, and click **Edit** (next to the **Value** field).
5. Enter a Groovy expression in the field provided, and click **OK**.
6. Click **OK**.

#### 4.10.8 What Happens When You Create a Default Value Using a Groovy expression

When you define a default value using a Groovy expression, a `<TransientExpression>` tag is added to the entity object's XML file within the appropriate attribute. [Figure 4-8](#) shows sample XML code for an Groovy expression that gets the current date for a default value.

**Example 4–8 Default Date Value**

```
<TransientExpression>
  <![CDATA[
    newValue <= adf.currentDate
  ]]>
</TransientExpression>
```

**4.10.9 How to Synchronize with Trigger-Assigned Values**

If you know that the underlying column value will be updated by a database trigger during insert or update operations, you can enable the respective **Insert** or **Update** checkboxes in the **Refresh After** area (in the Edit Attribute dialog) to ensure the framework automatically retrieves the modified value and keeps the entity object and database row in sync. The entity object will use the Oracle SQL RETURNING INTO feature, while performing the INSERT or UPDATE to return the modified column back to your application in a single database roundtrip.

---

**Note:** If you create an entity object for a synonym that resolves to a remote table over a DBLINK, use of this feature will give an error at runtime like:

```
JBO-26041: Failed to post data to database during "Update"
## Detail 0 ##
ORA-22816: unsupported feature with RETURNING clause
```

[Section 38.6, "Basing an Entity Object on a Join View or Remote DBLink"](#) describes a technique to circumvent this database limitation.

---

**4.10.10 How to Get Trigger-Assigned Primary Key Values from a Database Sequence**

One common case for refreshing an attribute after insert occurs when a primary key attribute value is assigned by a BEFORE INSERT FOR EACH ROW trigger. Often the trigger assigns the primary key from a database sequence using PL/SQL logic. [Example 4–9](#) shows an example of this.

**Example 4–9 PL/SQL Code Assigning a Primary Key from a Database Sequence**

```
CREATE OR REPLACE TRIGGER ASSIGN_SVR_ID
BEFORE INSERT ON SERVICE_REQUESTS FOR EACH ROW
BEGIN
  IF :NEW.SVR_ID IS NULL OR :NEW.SVR_ID < 0 THEN
    SELECT SERVICE_REQUESTS_SEQ.NEXTVAL
    INTO :NEW.SVR_ID
    FROM DUAL;
  END IF;
END;
```

In the Edit Attribute dialog, you can set the value of the **Type** field to the built-in data type named DBSequence and the primary key will be assigned automatically by the database sequence. Setting this data type automatically selects the refresh after **Insert** checkbox.

---

---

**Note:** The sequence name shown on the **Sequence** tab is used only at design time when you use the **Create Database Tables** feature described in [Section 4.2.6, "How to Create Database Tables from Entity Objects."](#) The sequence indicated here will be created along with the table on which the entity object is based.

---

---

When you create a new entity row whose primary key is a DBSequence, a unique negative number is assigned as its temporary value. This value acts as the primary key for the duration of the transaction in which it is created. If you are creating a set of interrelated entities in the same transaction, you can assign this temporary value as a foreign key value on other new, related entity rows. At transaction commit time, the entity object issues its `INSERT` operation using the `RETURNING INTO` clause to retrieve the actual database trigger-assigned primary key value. In a composition relationship, any related new entities that previously used the temporary negative value as a foreign key will get that value updated to reflect the actual new primary key of the master.

You will typically also set the **Updatable** property of a DBSequence-valued primary key to **Never**. The entity object assigns the temporary ID, and then refreshes it with the actual ID value after the `INSERT` operation. The end user never needs to update this value.

For information on how to implement this functionality for an association that is not a composition, see [Section 38.8.3.3, "Understanding Associations Based on DBSequence-Valued Primary Keys."](#)

---

---

**Note:** For a metadata-driven alternative to the DBSequence approach, see [Section 4.12.5, "Assigning the Primary Key Value Using an Oracle Sequence."](#)

---

---

#### 4.10.11 How to Protect Against Losing Simultaneously Updated Data

At runtime, the framework provides automatic "lost update" detection for entity objects to ensure that a user cannot unknowingly modify data that another user has updated and committed in the meantime. Typically, this check is performed by comparing the original values of each persistent entity attribute against the corresponding current column values in the database at the time the underlying row is locked. Before updating a row, the entity object verifies that the row to be updated is still consistent with the current state of the database. If the row and database state are inconsistent, then the entity object raises the `RowInconsistentException`.

You can make the lost update detection more efficient by identifying any attributes of your entity whose values you know will be updated whenever the entity is modified. Typical candidates include a version number column or an updated date column in the row. The change-indicator attribute's value might be assigned by a database trigger you've written and refreshed in the entity object using the **Refresh After Insert** and **Refresh After Update** options (in the Edit Attribute dialog). Alternatively, you can indicate that the entity object should manage updating the change-indicator attribute's value using the history attribute feature described in [Section 4.10.12, "How to Track Created and Modified Dates Using the History Column."](#) To detect whether the row has been modified since the user queried it in the most efficient way, select the **Change Indicator** option to compare only the change-indicator attribute values.

#### 4.10.12 How to Track Created and Modified Dates Using the History Column

If you need to keep track of historical information in your entity object, such as when an entity was created or modified and by whom, or the number of times the entity has been modified, you specify an attribute with the **History Column** option selected (in the Edit Attribute dialog).

If an attribute's data type is `Number`, `String`, or `Date`, and if it is not part of the primary key, then you can enable this property to have your entity automatically maintain the attribute's value for historical auditing. How the framework handles the attribute depends which type of history attribute you indicate:

- **Created On:** This attribute is populated with the time stamp of when the row was created. The time stamp is obtained from the database.
- **Created By:** The attribute is populated with the name of the user who created the row. The user name is obtained using the `getUserPrincipalName()` method on the `Session` object.
- **Modified On:** This attribute is populated with the time stamp whenever the row is updated/created.
- **Modified By:** This attribute is populated with the name of the user who creates or updates the row.
- **Version Number:** This attribute is populated with a long value that is incremented whenever a row is created or updated.

#### 4.10.13 How to Configure Composition Behavior

An entity object exhibits composition behavior when it creates (or composes) other entities, such as an `OrderEO` entity creating a `OrderItemEO` entity. This additional runtime behavior determines its role as a logical container of other nested entity object parts. Because of this relationship, a composition association cannot be based on a transient attribute.

---

---

**Note:** Composition also affects the order in which entities are validated. For more information, see [Section 7.2.3, "Understanding the Impact of Composition on Validation Order."](#)

---

---

The features that are always enabled for composing entity objects are described in the following sections:

- [Section 4.10.13.1, "Orphan-Row Protection for New Composed Entities"](#)
- [Section 4.10.13.2, "Ordering of Changes Saved to the Database"](#)
- [Section 4.10.13.3, "Cascade Update of Composed Details from Refresh-On-Insert Primary Keys"](#)

The additional features, and the properties that affect their behavior, are described in the following sections:

- [Section 4.10.13.4, "Cascade Delete Support"](#)
- [Section 4.10.13.5, "Cascade Update of Foreign Key Attributes When Primary Key Changes"](#)
- [Section 4.10.13.6, "Locking of Composite Parent Entities"](#)
- [Section 4.10.13.7, "Updating of Composing Parent History Attributes"](#)

#### 4.10.13.1 Orphan-Row Protection for New Composed Entities

When a composed entity object is created, it performs an existence check on the value of its foreign key attribute to ensure that it identifies an existing entity as its owning parent entity. At create time, if no foreign key is found or else a value that does not identify an existing entity object is found, the entity object throws an `InvalidOwnerException` instead of allowing an orphaned child row to be created without a well-identified parent entity.

---

**Note:** The existence check finds new pending entities in the current transaction, as well as existing ones in the database if necessary.

---

#### 4.10.13.2 Ordering of Changes Saved to the Database

Composition behavior ensures that the sequence of data manipulation language (DML) operations performed in a transaction involving both composing and composed entity objects is performed in the correct order. For example, an `INSERT` statement for a new composing parent entity object will be performed before the DML operations related to any composed children.

#### 4.10.13.3 Cascade Update of Composed Details from Refresh-On-Insert Primary Keys

When a new entity row having a primary key configured to refresh on insert is saved, then after its trigger-assigned primary value is retrieved, any composed entities will have their foreign key attribute values updated to reflect the new primary key value.

There are a number of additional composition related features that you can control through settings on the Association Properties page of the Create Association wizard or the overview editor. [Figure 4–12](#) shows the Relationships page for the `OrderItemsOrdersFkAssoc` association between two entity objects: `OrderItemEO` and `OrderEO`.

#### 4.10.13.4 Cascade Delete Support

You can either enable or prevent the deletion of a composing parent while composed children entities exist. When the **Implement Cascade Delete** option (see [Figure 4–12](#)) is deselected, the removal of the composing entity object is prevented if it contains any composed children.

**Figure 4–12** Composition Settings on Relationship Page of Overview Editor for Associations

When selected, this option allows the composing entity object to be removed unconditionally together with any composed children entities. If the related **Optimize for Database Cascade Delete** option is deselected, then the composed entity objects perform their normal `DELETE` statement at transaction commit time to make the

changes permanent. If the option is selected, then the composed entities do not perform the `DELETE` statement on the assumption that the database `ON DELETE CASCADE` constraint will handle the deletion of the corresponding rows.

#### 4.10.13.5 Cascade Update of Foreign Key Attributes When Primary Key Changes

Select the **Cascade Update Key Attributes** option (see [Figure 4-12](#)) to enable the automatic update of the foreign key attribute values in composed entities when the primary key value of the composing entity is changed.

#### 4.10.13.6 Locking of Composite Parent Entities

Select the **Lock Top-Level Container** option (see [Figure 4-12](#)) to control whether adding, removing, or modifying a composed detail entity row should attempt to lock the composing entity before allowing the changes to be saved.

#### 4.10.13.7 Updating of Composing Parent History Attributes

Select the **Update Top-Level History Columns** option (see [Figure 4-12](#)) to control whether adding, removing, or modifying a composed detail entity object should update the **Modified By** and **Modified On** history attributes of the composing parent entity.

### 4.10.14 How to Set the Discriminator Attribute for Entity Object Inheritance Hierarchies

Sometimes a single database table stores information about several different kinds of logically related objects. For example, a payroll application might work with hourly, salaried, and contract employees all stored in a single `EMPLOYEES` table with an `EMPLOYEE_TYPE` column. In this case, the value of the `EMPLOYEE_TYPE` column contains values like `H`, `S`, or `C` to indicate respectively whether a given row represents an hourly, salaried, or contract employee. And while it is possible that many attributes and behavior are the same for all employees, certain properties and business logic may also depend on the type of employee.

In situations where common information exists across related objects, it may be convenient to represent these different types of entity objects using an inheritance hierarchy. For example, attributes and methods common to all employees can be part of a base `Employee` entity object, while subtype entity objects like `HourlyEmployee`, `SalariedEmployee`, and `ContractEmployee` extend the base `Employee` object and add additional properties and behavior. The **Discriminator** attribute setting is used to indicate which attribute's value distinguishes the type of row. [Section 38.7, "Using Inheritance in Your Business Domain Layer,"](#) explains how to set up and use inheritance.

### 4.10.15 How to Define Alternate Key Values

Database primary keys are often generated from a sequence and may not be data you want to expose to the user for a variety of reasons. For this reason, it's often helpful to have alternate key values that are unique. For example, you might want to enforce that every customer have a unique email address. Because a customer may change their email address, you won't want to use that value as a primary key, but you still want the user to have a unique field they can use for login or other purposes.

Alternate keys are useful for direct row lookups via the `findByKey` class of methods. Alternate keys are frequently used for efficient uniqueness checks in the middle tier. For information on how to find out if a value is unique, see [Section 7.4.1, "How to Ensure That Key Values Are Unique."](#)

To define an alternate key, you use the Create Entity Constraint wizard.

**To define alternate key values:**

1. In the Application Navigator, right-click an entity object and choose **New Entity Constraint**.
2. Follow the steps in the Create Entity Constraint wizard to name your constraint and select the attribute or attributes that participate in the key.
3. On the Properties page, select **Alternate Key** and choose the appropriate **Key Properties** options.

For more information about the **Key Properties** options, press the F1 key or click **Help**.

#### 4.10.16 What Happens When You Define Alternate Key Values

When you define alternate key values, a hashmap is created for fast access to entities that are already in memory.

#### 4.10.17 What You May Need to Know About Alternate Key Values

The Unique key constraint is used only for forward generation of **UNIQUE** constraints in the database, not for alternate key values.

### 4.11 Creating Business Events

Business events raised from the model layer are useful for launching business processes and triggering external systems synchronization by way of the Oracle Mediator.

Oracle Mediator supports declarative subscriptions which map business events to actions. In other words, you can define and publish a business event (such as a new customer being created) in one component, and then subscribe to that event in another component so that a business process is notified when it occurs. You can then, in the subscribing component, proceed with an action you assign to that event (such as sending a welcome new customer email).

You declaratively define business events at the entity level. You may also specify conditions under which those events should be raised. Business events that meet the specified criteria are raised upon successful commit of the changed data. A business event is raised to the Mediator on a successful create, update, or delete of an entity object.

To implement a business event, you first create an event definition, then map that event definition to an event point, then publish that definition. After the business event is published, you can subscribe to the event from another component.

---

---

**Note:** Do not configure a business event to be raised on an effective dated parent entity object from an effective dated child entity object in a master-detail relationship. Because child objects can raise events on parent objects, and effective dated entity objects cause row splits during update and delete operations, it is possible for the child object to raise an event on the wrong parent object if both the parent and child are updated during the same transaction. For more information about effective dated entity objects, see [Section 4.2.8, "How to Store Data Pertaining to a Specific Point in Time."](#)

---

---

### 4.11.1 Introducing Event Definitions

An event definition describes an event that will be published and raised with an event system Mediator. An event definition is stored in an entity object's XML file with the elements shown in [Table 4-2](#).

**Table 4-2 Event Definition Elements for Entity Objects**

Element	Description
Event Name	Name of the event, for example, OrderUpdated
Payload	A list of attributes sent to the subscriber. Attributes marked as optional appear on payload only if changed.

### 4.11.2 Introducing Event Points

An event point is a place from which an event can be raised. On a successful commit, one of the event points shown in [Table 4-3](#) can be raised to the Mediator for each entity in a transaction.

**Table 4-3 Example Event Points Raised to the Mediator**

DML Type	Event Name	Event Description
CREATE	<i>EntityCreated</i>	A new <i>Entity</i> has been created.
UPDATE	<i>EntityUpdated</i>	An existing <i>Entity</i> has been updated.
DELETE	<i>EntityDeleted</i>	An existing <i>Entity</i> has been deleted.

Note that no events are raised by default; all events are custom. When you create the event, you can specify the name and DML operation appropriately.

For each event point, you must specify which event definitions should be raised on a particular event point. In other words, you must declaratively map each event definition to an event point.

### 4.11.3 What You May Need to Know About Event Points

*Transactional event delivery*, where event delivery is part of the transaction, is not supported by the framework.

*Synchronous events*, where the publisher waits for further processing until the subscriber has confirmed event reception, is not supported by the framework.

### 4.11.4 How to Create a Business Event

To create a business event, use the Business Events page of the overview editor.

**To create a business event:**

1. In the Application Navigator, double-click an entity object.
2. In the overview editor, click the **Business Events** navigation tab.
3. On the Business Events page, expand the **Event Definitions** section and click the **New** icon.
4. In the Create Business Event Definition dialog, provide a name that describes this event, such as `EmployeeContactInfoChanged`.

- In the payload table, click **New** and **Delete** to select the appropriate attributes for this event.

Alternatively, you can double-click the cell and pick the attributes you want.

---

---

**Note:** Only attributes of supported types are displayed in the Entity Attribute column. While ClobDomain attributes are supported, very large clob data can impact performance.

---

---

- In the **Value Sent** field, choose whether the value should **Always** be sent, or **Only if changed**.

The **Only if changed** option provides the best performance because the attribute will be considered optional for the payload. If you leave the default **Always**, the payload will require the attribute whether or not the value has changed. For more details about payload efficiency, see [Section 4.11.6, "What You May Need to Know About Payload Size."](#)

- Use the arrow buttons to rearrange the order of attributes.

The order that the attributes appear in defines their order in the generated XSD. Since you'll be using the XSD to build your Fabric mediator and BPEL process, you might want the most frequently accessed attributes at the top.

- Click **OK**.

Repeat the procedure for each business event that you want to define. To publish an event, see [Section 4.11.7, "How to Publish a Business Event."](#)

### 4.11.5 What Happens When You Create a Business Event

When you create a business event, the entity object's XML file is updated with the event definition. [Example 4–10](#) shows an example of the XML code for a business event. JDeveloper also generates an associated XSD file for the event schema that allows specification of required attributes and optional attributes. Required attributes correspond to **Value Sent - Always** in the Create Business Event Definition dialog, whereas optional attributes are those for which you changed **Value Sent** to **Only if changed**.

#### **Example 4–10 XML Code for a Business Event**

```
<EventDef
  Name="CustBusEvent1">
  <Payload>
    <PayloadItem
      AttrName="Order.OrderId"/>
    <PayloadItem
      AttrName="LineItemId"/>
    <PayloadItem
      AttrName="ProductBase.ProductId"
      SendOnlyIfChanged="true"/>
  </Payload>
</EventDef>
```

[Example 4–11](#) shows an example of the XSD event schema for a business event.

#### **Example 4–11 XSD Event Schema for a Business Event**

```
<?xml version = '1.0' encoding = 'UTF-8'?>
```

```

<xs:schema
targetNamespace="/oracle/fodemo/storefront/entities/events/schema/OrderItemEO"
xmlns="/oracle/fodemo/storefront/entities/events/schema/OrderItemEO"
elementFormDefault="qualified" attributeFormDefault="unqualified"
xmlns:xs="http://www.w3.org/2001/XMLSchema">
  <xs:element name="CustBusEvent1Info">
    <xs:complexType>
      <xs:sequence>
        <xs:element name="Order.OrderId" type="DecimalValuePair" minOccurs="1"/>
        <xs:element name="LineItemId" type="DecimalValuePair" minOccurs="1"/>
        <xs:element name="ProductBase.ProductId" type="DecimalValuePair" minOccurs="0"/>
      </xs:sequence>
    </xs:complexType>
  </xs:element>
  <xs:complexType name="ValuePair" abstract="true"/>
  <xs:complexType name="DecimalValuePair">
    <xs:complexContent>
      <xs:extension base="ValuePair">
        <xs:sequence>
          <xs:element name="newValue" minOccurs="0">
            <xs:complexType>
              <xs:complexContent>
                <xs:extension base="xs:anyType">
                  <xs:attribute name="value" type="xs:decimal"/>
                </xs:extension>
              </xs:complexContent>
            </xs:complexType>
          </xs:element>

                <xs:extension base="xs:anyType">
                  <xs:attribute name="value" type="xs:decimal"/>
                </xs:extension>
              </xs:complexContent>
            </xs:complexType>
          </xs:element>
        </xs:sequence>
      </xs:extension>
    </xs:complexContent>
  </xs:complexType>
</xs:schema>

```

[Example 4-12](#) shows an example of the EDL event definition for the entity object.

#### **Example 4-12 EDL Event Definition for the Entity Object**

```

<definitions
targetNamespace="/oracle/fodemo/storefront/entities/events/edl/OrderItemEO"
xmlns:ns0="/oracle/fodemo/storefront/entities/events/schema/OrderItemEO"
xmlns="http://schemas.oracle.com/events/edl">
  <schema-import
namespace="/oracle/fodemo/storefront/entities/events/schema/OrderItemEO"
location="OrderItemEO.xsd"/>
  <event-definition name="CustBusEvent1">
    <content element="ns0:CustBusEvent1Info"/>
  </event-definition>
</definitions>

```

### 4.11.6 What You May Need to Know About Payload Size

The attributes of the associated entity object constitute the payload of a business event. The payload attributes for a business event are defined by the creator of the event. It isn't automatically optimized. When the event is defined, an attribute can be marked as sent **Always** or **Only if changed**. For events fired during creation, only new values are sent. For events fired during an update or delete, the new and old values are sent and only the attributes that should be based on the **Value Sent** setting. For best performance, you should include only the primary key attribute for delete events.

To support composition scenarios (such as a purchase order with line items), a child entity can raise events defined on the parent entity, and events defined on the child entity can include attributes from the parent entity. When a child entity raises an event on a parent entity, only a single event is raised for a particular top-level entity per transaction, regardless of how many times the child entity raises it.

In the case of entity subtypes (for example, a *Manager* entity object is a subtype of the *User* entity), ADF Business Components does not support overriding of business events. Because the subscriber to a business event listens to the event using the event name, overriding of events could cause the event subscriber to receive payload data unintended for that subscriber. Therefore, this capability is not supported.

When defining business events, remember that while *ClobDomain* attributes are supported, very large clob data can have performance implications.

### 4.11.7 How to Publish a Business Event

To publish a business event, use the Business Events page of the entity objects overview editor.

**To publish a business event:**

1. In the Application Navigator, double-click an entity object.
2. In the overview editor, click the **Business Events** navigation tab.
3. On the Business Events page, expand the **Event Publication** section and click the **Edit event publications** icon.
4. In the Edit Event Publications dialog, click **New** to create a new event.
5. Double-click the new cell in **Event** column, and select the appropriate event.
6. Double-click the corresponding cell in **Event Point** column, and select the appropriate event point action.
7. You can optionally define conditions for raising the event using the **Raise Conditions** table.
8. Click **OK**.

### 4.11.8 How to Subscribe to Business Events

After you have created a business event, you can subscribe and respond to the event.

**Before you begin:**

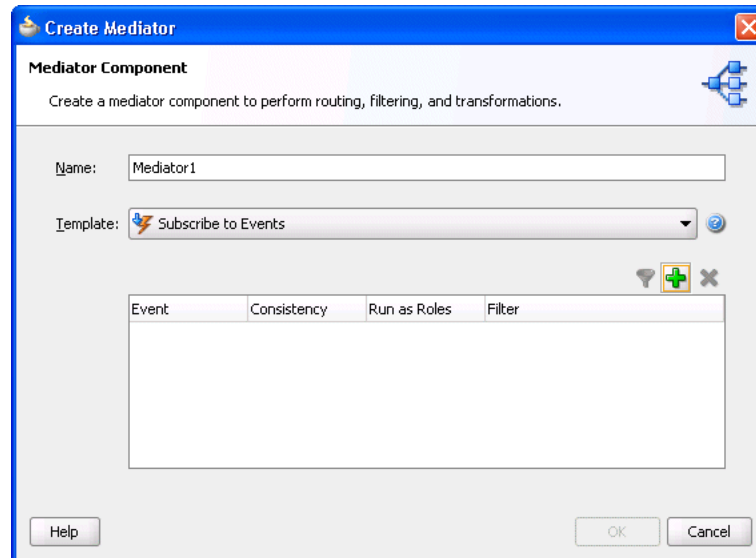

- Open (or create) the SCA project that will subscribe to the business event.

**To subscribe to a business event:**

1. Using the file system, copy the XSD and event definition files for the business event into your SCA project's source path.

2. In the Application Navigator, right-click the project, and choose **New**.
3. In the New Gallery, expand **SOA Tier**, select **Service Components** and then **Mediator**, and click **OK**.
4. In the Create Mediator dialog, select the **Subscribe to Events** template, as shown in [Figure 4–13](#).

**Figure 4–13 Create Mediator Dialog, Subscribe to Events**

5. Click the **Add** icon to add an event.
6. In the Event Chooser dialog, click the **Browse** icon to navigate to and select the event's definition file, and then click **OK**.
7. In the Create Mediator dialog, you can optionally change the **Consistency** option and specify a **Filter** for the event.
8. Click **OK** to generate the mediator.  
The resulting mediator (.mp1an file) is displayed in the overview editor.
9. You can now click the **Add** icon in the **Routing Rules** section to add a rule for how to respond to the event.

## 4.12 Working Programmatically with Entity Objects and Associations

You may not always need or want UI-based or programmatic clients to work directly with entity objects. Sometimes, you may just want to use an external client program to access an application module and work directly with the view objects in its data model. [Chapter 5, "Defining SQL Queries Using View Objects"](#) describes how to easily combine the flexible SQL-querying of view objects with the business logic enforcement and automatic database interaction of entity objects to build powerful applications. The combination enables a fully updatable application module data model, designed to meet the needs of the current end-user tasks at hand, that shares the centralized business logic in your reusable domain business object layer.

However, it is important first to understand how view objects and entity objects can be used on their own before learning to harness their combined power. By learning about

these objects in greater detail, you will have a better understanding of when you should use them alone and when to combine them in your own applications.

Since clients don't work *directly* with entity objects, any code you write that works programmatically with entity objects will typically be custom code in a custom application module class or in the custom class of another entity object.

### 4.12.1 How to Find an Entity Object by Primary Key

To access an entity row, you use a related object called the *entity definition*. At runtime, each entity object has a corresponding entity definition object that describes the structure of the entity and manages the instances of the entity object it describes. After creating an application module and enabling a custom Java class for it, imagine you wanted to write a method to return a specific order. It might look like the `retrieveOrderById()` method shown in [Example 4-13](#).

#### To find an entity object by primary key:

1. Find the entity definition.

You obtain the entity definition object for the `OrderEO` entity by passing its fully qualified name to the static `getDefinitionObject()` method imported from the `EntityDefImpl` class. The `EntityDefImpl` class in the `oracle.jbo.server` package implements the entity definition for each entity object.

2. Construct a key.

You build a `Key` object containing the primary key attribute that you want to look up. In this case, you're creating a key containing the single `orderId` value passed into the method as an argument.

3. Find the entity object using the key.

You use the entity definition's `findByPrimaryKey()` method to find the entity object by key, passing in the current transaction object, which you can obtain from the application module using its `getDBTransaction()` method. The concrete class that represents an entity object row is the `oracle.jbo.server.EntityImpl` class.

4. Return the object or some of its data to the caller.

[Example 4-13](#) show example code for a `retrieveOrderById()` method developed using this basic procedure.

#### **Example 4-13 Retrieving an OrderEO Entity Object by Key**

```
/* Helper method to return an Order by Id */
private OrderEOImpl retrieveOrderById(long orderId) {
    EntityDefImpl orderDef = OrderEOImpl.getDefinitionObject();
    Key orderKey = OrderEOImpl.createPrimaryKey(new DBSequence(orderId));
    return (OrderEOImpl) orderDef.findByPrimaryKey(getDBTransaction(), orderKey);
}
```

---

**Note:** The `oracle.jbo.Key` object constructor can also take an `Object` array to support creating multiattribute keys, in addition to the more typical single-attribute value keys.

---

## 4.12.2 How to Access an Associated Entity Using the Accessor Attribute

You can create a method to access an associated entity based on an accessor attribute that requires no SQL code. For example, the method `findOrderCustomer()` might find an order, then access the associated `PersonEO` entity object representing the customer assigned to the order. For an explanation of how associations enable easy access from one entity object to another, see [Section 4.3, "Creating and Configuring Associations."](#)

To avoid a conflict with an existing method in the application module that finds the same associated entity using the same accessor attribute, you can refactor this functionality into a helper method that you can then reuse anywhere in the application module it is required. For example, the `retrieveOrderById()` method (shown in [Example 4-13](#)) refactors the functionality that finds an order.

### To access an associated entity object using the accessor attribute:

1. Find the associated entity by the accessor attribute.

The `findOrderCustomer()` method uses the `retrieveOrderById()` helper method to retrieve the `OrderEO` entity object by ID.

2. Access the associated entity using the accessor attribute.

Using the attribute getter method, you can pass in the name of an association accessor and get back the entity object on the other side of the relationship. (Note that [Section 4.3.3, "How to Change Entity Association Accessor Names,"](#) explains that renaming the association accessor allows it to have a more intuitive name.)

3. Return some of its data to the caller.

The `findOrderCustomer()` method uses the getter methods on the returned `PersonEO` entity to return the assigned customer's name by concatenating their first and last names.

Notice that you did not need to write any SQL to access the related `PersonEO` entity. The relationship information captured in the ADF association between the `OrderEO` and `PersonEO` entity objects is enough to allow the common task of data navigation to be automated.

[Example 4-14](#) shows the code for `findOrderCustomer()` that uses the helper method.

### Example 4-14 Accessing an Associated Entity Using the Accessor Attribute

```
/* Access an associated Customer entity from the Order entity */
public String findOrderCustomer(long orderId) {
    //1. Find the OrderEO object
    OrderEOImpl order = retrieveOrderById(orderId);
    if (order != null) {
        //2. Access the PersonEO object using the association accessor attribute
        PersonEOImpl cust = (PersonEOImpl)order.getPerson();
        if (cust != null) {
            //3. Return attribute values from the associated entity object
            return cust.getFirstName() + " " + cust.getLastName();
        }
        else {
            return "Unassigned";
        }
    }
    else {
        return null;
    }
}
```

```

    }
}

```

### 4.12.3 How to Update or Remove an Existing Entity Row

Once you've got an entity row in hand, it's simple to update it or remove it. You could add a method like the `updateOrderStatus()` shown in [Example 4-15](#) to handle the job.

#### To update an entity row:

1. Find the Order by ID.

Using the `retrieveOrderById()` helper method, the `updateOrderStatus()` method retrieves the `OrderEO` entity object by ID.

2. Set one or more attributes to new values.

Using the `EntityImpl` class' `setAttribute()` method, the `updateOrderStatus()` method updates the value of the `Status` attribute to the new value passed in.

3. Commit the transaction.

Using the application module's `getDBTransaction()` method, the `updateOrderStatus()` method accesses the current transaction object and calls its `commit()` method to commit the transaction.

#### Example 4-15 Updating an Existing Entity Row

```

/* Update the status of an existing order */
public void updateOrderStatus(long orderId, String newStatus) {
    //1. Find the order
    OrderEOImpl order = retrieveOrderById(orderId);
    if (order != null) {
        //2. Set its Status attribute to a new value
        order.setOrderStatusCode(newStatus);
        //3. Commit the transaction
        try {
            getDBTransaction().commit();
        }
        catch (JboException ex) {
            getDBTransaction().rollback();
            throw ex;
        }
    }
}

```

The example for *removing* an entity row would be the same, except that after finding the existing entity, you would use the following line instead to remove the entity before committing the transaction:

```

// Remove the entity instead!
order.remove();

```

### 4.12.4 How to Create a New Entity Row

In addition to using the entity definition to find existing entity rows, you can also use it to create new ones. In the case of product entities, you could write a `createProduct()` method like the one shown in [Example 4-16](#) to accept the name and description of a new product, and return the new product ID assigned to it. This

example assumes that the `ProductId` attribute of the `ProductBaseEO` entity object has been updated to have the `DBSequence` type (see [Section 4.10.10, "How to Get Trigger-Assigned Primary Key Values from a Database Sequence"](#)). This setting ensures that the attribute value is refreshed to reflect the value of the trigger from the corresponding database table, assigned to it from the table's sequence in the application schema.

#### To create an entity row:

1. Find the entity definition.

Using the `getDefinitionObject()` method, the `createProduct()` method finds the entity definition for the `Product` entity.

2. Create a new instance.

Using the `createInstance2()` method on the entity definition, the `createProduct()` method creates a new instance of the entity object.

---

**Note:** The method name has a 2 at the end. The regular `createInstance()` method has protected access and is designed to be customized as described [Section E.2.4, "EntityImpl Class"](#) of [Appendix E, "Most Commonly Used ADF Business Components Methods."](#) The second argument of type `AttributeList` is used to supply attribute values that *must* be supplied at create time; it is *not* used to initialize the values of all attributes found in the list. For example, when creating a new instance of a composed child entity row using this API, you must supply the value of a composing parent entity's foreign key attribute in the `AttributeList` object passed as the second argument. Failure to do so results in an `InvalidOwnerException`.

---

3. Set attribute values.

Using the attribute setter methods on the entity object, the `createProduct()` method assigns values for the `Name`, `Status`, and other attributes in the new entity row.

4. Commit the transaction.

Calling `commit()` on the current transaction object, the `createProduct()` method commits the transaction.

5. Return the trigger-assigned product ID to the caller.

Using the attribute getter method to retrieve the value of the `ProductId` attribute as a `DBSequence`, and then calling `getSequenceNumber().longValue()`, the `createProduct()` method returns the sequence number as a long value to the caller.

#### Example 4-16 Creating a New Entity Row

```
/* Create a new Product and Return its new id */
public long createProduct(String name, String status, String shipCode) {
    //1. Find the entity definition for the Product entity
    EntityDefImpl productDef = ProductBaseEOImpl.getDefinitionObject();
    //2. Create a new instance of a Product entity
    ProductBaseEOImpl newProduct =
(ProductBaseEOImpl)productDef.createInstance2(getDBTransaction(), null);
    //3. Set attribute values
```

```

newProduct.setProductName(name);
newProduct.setProductStatus(status);
newProduct.setShippingClassCode(shipCode);
newProduct.setSupplierId(new Number(100));
newProduct.setListPrice(new Number(499));
newProduct.setMinPrice(new Number(479));
newProduct.setCreatedBy("Test Client");
newProduct.setLastUpdatedBy("Test Client");
newProduct.setCategoryId(new Number(5));
    //4. Commit the transaction
try {
    getDBTransaction().commit();
}
catch (JboException ex) {
    getDBTransaction().rollback();
    throw ex;
}
    //5. Access the database-trigger-assigned ProductId value and return it
DBSequence newIdAssigned = newProduct.getProductId();
return newIdAssigned.getSequenceNumber().longValue();
}

```

#### 4.12.5 Assigning the Primary Key Value Using an Oracle Sequence

As an alternative to using a trigger-assigned value (as described in [Section 4.10.10, "How to Get Trigger-Assigned Primary Key Values from a Database Sequence"](#)), you can assign the value to a primary key when creating a new row using an Oracle sequence. This metadata-driven approach allows you to centralize the code to retrieve the primary key into a single Java file that can be reused by multiple entity objects.

[Example 4-17](#) shows a simple `CustomEntityImpl` framework extension class on which the entity objects are based. Its overridden `create()` method tests for the presence of a custom attribute-level metadata property named `SequenceName` and if detected, populates the attribute's default value from the next number in that sequence.

##### **Example 4-17 CustomEntityImpl Framework Extension Class**

```

package sample;

import oracle.jbo.AttributeDef;
import oracle.jbo.AttributeList;
import oracle.jbo.server.EntityImpl;
import oracle.jbo.server.SequenceImpl;

public class CustomEntityImpl extends EntityImpl {
    protected void create(AttributeList attributeList) {
        super.create(attributeList);
        for (AttributeDef def : getEntityDef().getAttributeDefs()) {
            String sequenceName = (String)def.getProperty("SequenceName");
            if (sequenceName != null) {
                SequenceImpl s = new SequenceImpl(sequenceName, getDBTransaction());
                setAttribute(def.getIndex(), s.getSequenceNumber());
            }
        }
    }
}

```

**To assign the primary key value using an Oracle sequence:**

1. Create the `CustomEntityImpl.java` file in your project, and insert the code shown in [Example 4-17](#).
2. In the Application Navigator, double-click the entity you want to edit.
3. In the overview editor, click the **Attributes** navigation tab, and double-click the attribute you want to edit.
4. In the Edit Attribute dialog, set the attribute **Type** to **Number**, and then click the **Custom Properties** node.
5. Enter `SequenceName` for the name.
6. Enter the name of the database sequence for the value, click **Add**, and then click **OK** to create the custom property.

For example, a `Dept` entity could define the custom property `SequenceName` on its `Deptno` attribute with the value `DEPT_TABLE_SEQ`.

### 4.12.6 What You May Need to Know About Custom Entity Object Methods

Custom methods that you implement in the entity object class must not be dependent on the return type of an application module. At runtime, in specific cases, methods that execute with such a dependency may throw a `ClassCastException` because the returned application module does not match the expected type. It is therefore recommended that custom methods that you implement should not have code to get a specific application module implementation or view object implementation as shown below.

```
((MyAM) getTransaction().getRootApplicationModule()).getMyVO
```

Specifically, the above code fails with a `ClassCastException` in the following scenarios:

- When your code uses the entity object in the context of a different view object, other than the view object that you reference in the method. Because your application may map more than one view object definition to the same entity object, the ADF Business Components runtime does not guarantee that methods with dependencies on the view object will execute consistently.
- When you manually nest an application module under a root application module. In this case, the nested application modules share the same `Transaction` object and there is no guarantee that the expected application module type is returned with the above code.
- When the ADF Business Components framework implementation changes with releases. For example, in previous releases, the framework created an internal root application module in order to control declarative transactions that the application defined using ADF task flows.

## 4.13 Generating Custom Java Classes for an Entity Object

As described in this chapter, all of the database interaction and a large amount of declarative runtime functionality of an entity object can be achieved without using custom Java code. When you need to go beyond the declarative features to implement custom business logic for your entities, you'll need to enable custom Java generation for the entities that require custom code. [Appendix E, "Most Commonly Used ADF Business Components Methods,"](#) provides a quick reference to the most common code

that you will typically write, use, and override in your custom entity object and entity definition classes.

### 4.13.1 How to Generate Custom Classes

To enable the generation of custom Java classes for an entity object, use the Java page of the overview editor.

**To generate a custom Java class for an entity object:**

1. In the Application Navigator, double-click the entity.
2. In the overview editor, click the **Java** navigation tab, and then click the **Edit** icon.
3. In the Select Java Options dialog, select the types of Java classes you want to generate.
  - Entity Object Class — the most frequently customized, it represents each row in the underlying database table.
  - Entity Collection Class — rarely customized.
  - Entity Definition Class — less frequently customized, it represents the related class that manages entity rows and defines their structure.
4. Click **OK**.

### 4.13.2 What Happens When You Generate Custom Classes

When you select one or more custom Java classes to generate, JDeveloper creates the Java file(s) you've indicated. For example, assuming an entity object named `fodemo.storefront.entities.OrderEO`, the default names for its custom Java files will be `OrderEOImpl.java` for the entity object class and `OrderEODefImpl.java` for the entity definition class. Both files are created in the same `./fodemo/storefront/entities` directory as the component's XML component definition file.

The Java generation options for the entity object continue to be reflected on subsequent visits to the Java page of the overview editor. Just as with the XML definition file, JDeveloper keeps the generated code in your custom Java classes up to date with any changes you make in the editor. If later you decide you didn't require a custom Java file for any reason, disabling the relevant options on the Java page causes the custom Java files to be removed.

### 4.13.3 What Happens When You Generate Entity Attribute Accessors

When you enable the generation of a custom entity object class, if you also enable the **Accessors** option, then JDeveloper generates getter and setter methods for each attribute in the entity object. For example, an `OrderEO` entity object that has the corresponding custom `OrderEOImpl.java` class might have methods (like those shown in [Example 4–18](#)) generated in it.

**Example 4–18 Getter and Setter Methods from OrderEOImpl.java**

```
public DBSequence getOrderId() { ... }
public void setOrderId(DBSequence value) { ... }

public Date getOrderDate() { ... }
public void setOrderDate(Date value) { ... }
```

```

public String getOrderStatusCode() { ... }
public void setOrderStatusCode(String value) { ... }

public Number getCustomerId() { ... }
public void setCustomerId(Number value) { ... }

public String getShipToName() { ... }
public void setShipToName(String value) { ... }

```

These methods allow you to work with the row data with compile-time checking of the correct data type usage. That is, instead of writing a line like this to get the value of the `CustomerId` attribute:

```
Number customerId = (Number)order.getAttribute("CustomerId");
```

you can write the code like:

```
Number customerId = order.getCustomerId();
```

You can see that with the latter approach, the Java compiler would catch a typographical error had you accidentally typed `CustomerCode` instead of `CustomerId`:

```
// spelling name wrong gives compile error
Number customerId = order.getCustomerCode();
```

*Without* the generated entity object accessor methods, an incorrect line of code like the following cannot be caught by the compiler:

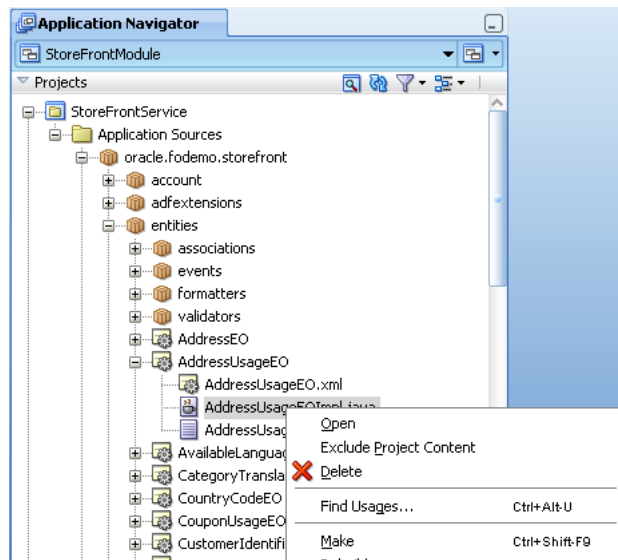

```
// Both attribute name and type cast are wrong, but compiler cannot catch it
String customerId = (String)order.getAttribute("CustomerCode");
```

It contains both an incorrectly spelled attribute name, as well as an incorrectly typed cast of the `getAttribute()` return value. When you use the generic APIs on the `Row` interface, which the base `EntityImpl` class implements, errors of this kind raise exceptions at runtime instead of being caught at compile time.

#### 4.13.4 How to Navigate to Custom Java Files

As shown in [Figure 4-14](#), when you've enabled generation of custom Java classes, they also appear as child nodes under the **Application Sources** node for the entity object. As with all ADF components, when you select an entity object in the Application Navigator, the Structure window provides a structural view of the entity. When you need to see or work with the source code for a custom Java file, there are two ways to open the file in the source editor:

- You can right-click the Java file, and choose **Open** from the context menu, as shown in [Figure 4-14](#).
- You can right-click an item in a node in the Structure window, and choose **Go To Source** from the context menu.

**Figure 4–14 Seeing and Navigating to Custom Java Classes for an Entity Object**

## 4.13.5 What You May Need to Know About Custom Java Classes

See the following sections for additional information about custom Java classes.

### 4.13.5.1 About the Framework Base Classes for an Entity Object

When you use an XML-only entity object, at runtime its functionality is provided by the default ADF Business Components implementation classes. Each custom Java class that is generated will automatically extend the appropriate ADF Business Components base class so that your code inherits the default behavior and you can easily add to or customize it. An entity object class will extend `EntityImpl`, while the entity definition class will extend `EntityDefImpl` (both in the `oracle.jbo.server` package).

### 4.13.5.2 You Can Safely Add Code to the Custom Component File

Some developers are hesitant to add their own code to generated Java source files. Each custom Java source code file that JDeveloper creates and maintains for you includes the following comment at the top of the file to clarify that it is safe for you to add your own custom code to this file.

```
// -----
// ---   File generated by Oracle ADF Business Components Design Time.
// ---   Custom code may be added to this class.
// ---   Warning: Do not modify method signatures of generated methods.
// -----
```

JDeveloper does not blindly regenerate the file when you click **OK** or **Apply** in an edit dialog. Instead, it performs a smart update to the methods that it needs to maintain, leaving your own custom code intact.

### 4.13.5.3 Configuring Default Java Generation Preferences

You can generate custom Java classes for your view objects when you need to customize their runtime behavior or when you simply prefer to have strongly typed access to bind variables or view row attributes.

To configure the default settings for ADF Business Components custom Java generation, you can choose **Preferences** from the **Tools** menu and open the Business Components page to set your preferences to be used for business components created in the future. Developers getting started with ADF Business Components should set their preference to generate no custom Java classes by default. As you run into a specific need for custom Java code, you can enable just the bit of custom Java you need for that one component. Over time, you'll discover which set of defaults works best for you.

#### 4.13.5.4 Attribute Indexes and InvokeAccessor Generated Code

The entity object is designed to function based on XML only or as an XML component definition combined with a custom Java class. To support this design choice, attribute values are not stored in private member fields of an entity's class (a file that is not present in the XML-only situation). Instead, in addition to a name, attributes are also assigned a numerical index in the entity's XML component definition based on the zero-based, sequential order of the `<Attribute>` and association-related `<AccessorAttribute>` tags in that file. At runtime, attribute values in an entity row are stored in a sparse array structure managed by the base `EntityImpl` class, indexed by the attribute's numerical position in the entity's attribute list.

For the most part, this private implementation detail is unimportant, since as a developer using entity objects, you are shielded from having to understand this. However, when you enable a custom Java class for your entity object, this implementation detail relates to some of the generated code that JDeveloper maintains in your entity object class. It is sensible to understand what that code is used for. For example, in the custom Java class for an `OrderEO` entity object, each attribute or accessor attribute has a corresponding generated integer enum. JDeveloper ensures that the values of these enums correctly reflect the ordering of the attributes in the XML component definition.

You'll also notice that the automatically maintained, strongly typed getter and setter methods in the entity object class use these attribute enums, as shown in [Example 4–19](#).

#### **Example 4–19** *Getter and Setter Methods Using Attribute Constants in the Custom Entity Java Class*

```
// In oracle.fodemo.storefront.entities.OrderEOImpl class
public Date getOrderDate() {
    return (Date)getAttributeInternal(ORDERDATE); // <-- Attribute enum
}
public void setOrderDate(Date value) {
    setAttributeInternal(ORDERDATE, value); // <-- Attribute enum
}
```

Another aspect of the automatically maintained code related to entity attribute enums are the `getAttrInvokeAccessor()` and `setAttrInvokeAccessor()` methods. These methods optimize the performance of attribute access by numerical index, which is how generic code in the `EntityImpl` base class typically accesses attribute values when performing generic processing. An example of the `getAttrInvokeAccessor()` method is shown in [Example 4–20](#). The companion `setAttrInvokeAccessor()` method looks similar.

#### **Example 4–20** *getAttrInvokeAccessor() Method in the Custom Entity Java Class*

```
// In oracle.fodemo.storefront.entities.OrderEOImpl class
/** getAttrInvokeAccessor: generated method. Do not modify. */
```

```

protected Object getAttrInvokeAccessor(int index, AttributeDefImpl attrDef)
    throws Exception {
    if ((index >= AttributesEnum.firstIndex()) && (index < AttributesEnum.count())) {
        return AttributesEnum.staticValues()[index - AttributesEnum.firstIndex()].get(this);
    }
    return super.getAttrInvokeAccessor(index, attrDef);
}

```

The rules of thumb to remember about this generated attribute-index related code are the following.

#### The Do's

- Add custom code if needed inside the strongly typed attribute getter and setter methods.
- Use the overview editor to change the order or type of entity object attributes.  
JDeveloper changes the Java signature of getter and setter methods, as well as the related XML component definition for you.

#### The Don'ts

- Don't modify the `getAttrInvokeAccessor()` and `setAttrInvokeAccessor()` methods.
- Don't change the values of the attribute index numbers manually.

---

**Note:** If you need to manually edit the generated attribute enums because of source control merge conflicts or other reasons, you must ensure that the zero-based ordering reflects the sequential ordering of the `<Attribute>` and `<AccessorAttribute>` tags in the corresponding entity object XML component definition.

---

### 4.13.6 Programmatic Example for Comparison Using Custom Entity Classes

To better evaluate the difference of using custom generated entity classes versus working with the generic `EntityImpl` class, [Example 4-21](#) shows a version of methods in a custom entity class (`StoreFrontServiceImpl.java`) from a custom application module class (`StoreFrontService2Impl.java`). Some important differences to notice are:

- Attribute access is performed using strongly typed attribute accessors.
- Association accessor attributes return the strongly typed entity class on the other side of the association.
- Using the `getDefinitionObject()` method in your custom entity class allows you to avoid working with fully qualified entity definition names as strings.
- The `createPrimaryKey()` method in your custom entity class simplifies creating the `Key` object for an entity.

#### **Example 4-21** Programmatic Entity Examples Using Strongly Typed Custom Entity Object Classes

```

package devguide.examples.appmodules;

import oracle.fodemo.storefront.entities.OrderEOImpl;

import oracle.fodemo.storefront.entities.PersonEOImpl;
import oracle.fodemo.storefront.entities.ProductBaseEOImpl;

```

```

import oracle.jbo.ApplicationModule;
import oracle.jbo.JboException;
import oracle.jbo.Key;
import oracle.jbo.client.Configuration;
import oracle.jbo.domain.DBSequence;
import oracle.jbo.domain.Number;
import oracle.jbo.server.ApplicationModuleImpl;
import oracle.jbo.server.EntityDefImpl;

// -----
// ---   File generated by Oracle ADF Business Components Design Time.
// ---   Custom code may be added to this class.
// ---   Warning: Do not modify method signatures of generated methods.
// -----
/**
 * This custom application module class illustrates the same
 * example methods as StoreFrontServiceImpl.java, except that here
 * we're using the strongly typed custom Entity Java classes
 * OrderEOImpl, PersonsEOImpl, and ProductsBaseEOImpl instead of working
 * with all the entity objects using the base EntityImpl class.
 */

public class StoreFrontService2Impl extends ApplicationModuleImpl {
    /**This is the default constructor (do not remove).
     */
    public StoreFrontService2Impl() {
    }
    /**
     * Helper method to return an Order by Id
     */
    private OrderEOImpl retrieveOrderById(long orderId) {
        EntityDefImpl orderDef = OrderEOImpl.getDefinitionObject();
        Key orderKey = OrderEOImpl.createPrimaryKey(new DBSequence(orderId));
        return (OrderEOImpl)orderDef.findByPrimaryKey(getDBTransaction(), orderKey);
    }

    /**
     * Find an Order by Id
     */
    public String findOrderTotal(long orderId) {
        OrderEOImpl order = retrieveOrderById(orderId);
        if (order != null) {
            return order.getOrderTotal().toString();
        }
        return null;
    }

    /**
     * Create a new Product and Return its new id
     */
    public long createProduct(String name, String status, String shipCode) {
        EntityDefImpl productDef = ProductBaseEOImpl.getDefinitionObject();
        ProductBaseEOImpl newProduct =
(ProductBaseEOImpl)productDef.createInstance2(getDBTransaction(), null);
        newProduct.setProductName(name);
        newProduct.setProductStatus(status);
        newProduct.setShippingClassCode(shipCode);
        newProduct.setSupplierId(new Number(100));
        newProduct.setListPrice(new Number(499));
    }
}

```

```

        newProduct.setMinPrice(new Number(479));
        newProduct.setCreatedBy("Test Client");
        newProduct.setLastUpdatedBy("Test Client");
        newProduct.setCategoryId(new Number(5));
    try {
        getDBTransaction().commit();
    }
    catch (JboException ex) {
        getDBTransaction().rollback();
        throw ex;
    }
    DBSequence newIdAssigned = newProduct.getProductId();
    return newIdAssigned.getSequenceNumber().longValue();
}
/*
 * Update the status of an existing order
 */
public void updateRequestStatus(long orderId, String newStatus) {
    OrderEOImpl order = retrieveOrderById(orderId);
    if (order != null) {
        order.setOrderStatusCode(newStatus);
        try {
            getDBTransaction().commit();
        }
        catch (JboException ex) {
            getDBTransaction().rollback();
            throw ex;
        }
    }
}

/*
 * Access an associated Customer entity from the Order entity
 */
public String findOrderCustomer(long orderId) {

    if (svcReq != null) {
        PersonEOImpl cust = (PersonEOImpl)svcReq.getPerson();
        if (cust != null) {
            return cust.getFirstName() + " " + cust.getLastName();
        }
        else {
            return "Unassigned";
        }
    }
    else {
        return null;
    }
}

/*
 * Testing method
 */
public static void main(String[] args) {
    String amDef = "devguide.model.StoreFrontService";
    String config = "StoreFrontServiceLocal";
    ApplicationModule am =
Configuration.createRootApplicationModule(amDef,config);
/*
 * NOTE: This cast to use the StoreFrontServiceImpl class is OK since

```

```

    * this code is inside a business tier *Impl.java file and not in a
    * client class that is accessing the business tier from "outside".
    */
StoreFrontServiceImpl service = (StoreFrontServiceImpl)am;
String total = service.findOrderTotal(1011);
System.out.println("Status of Order # 1011 = " + total);
String customerName = service.findOrderCustomer(1011);
System.out.println("Customer for Order # 1011 = " + customerName);
try {
    service.updateOrderStatus(1011, "CANCEL");
}
catch (JboException ex) {
    System.out.println("ERROR: "+ex.getMessage());
}
long id = 0;
try {
    id = service.createProduct(null, "NEW", "CLASS1");
}
catch (JboException ex) {
    System.out.println("ERROR: "+ex.getMessage());
}
id = service.createProduct("Canon PowerShot G9", "NEW", "CLASS1");
System.out.println("New product created successfully with id = "+id);
Configuration.releaseRootApplicationModule(am,true);
}
}

```

## 4.14 Adding Transient and Calculated Attributes to an Entity Object

In addition to having attributes that map to columns in an underlying table, your entity objects can include transient attributes that display values calculated (for example, using Java or Groovy) or that are value holders. For example, a transient attribute you create, such as `FullName`, could be calculated based on the concatenated values of `FirstName` and `LastName` attributes.

Once you create the transient attribute, you can perform a calculation in the entity object Java class, or use a Groovy expression in the attribute definition to specify a default value.

If you want to be able to change the value at runtime, you can use a Groovy expression. If the calculated value is not likely to change (for example, if it's a sum of the line items), you can perform the calculation directly in the entity object Java class.

### 4.14.1 How to Add a Transient Attribute

Use the Attributes page of the overview editor to create a transient attribute.

#### To add a transient attribute to an entity object:

1. In the Application Navigator, double-click the entity.
2. In the overview editor, click the **Attributes** navigation tab, and then click the **New** icon.
3. Enter a name for the attribute.
4. Set the Java attribute type.
5. Disable the **Persistent** option.
6. If the value will be calculated, set **Updatable** to **Never**.

7. Click OK.

## 4.14.2 What Happens When You Add a Transient Attribute

When you add a transient attribute, JDeveloper updates the XML component definition for the entity object to reflect the new attribute.

The `<Attribute>` tag of a transient attribute has no `TableName` and a `ColumnName` of `$none$`, as shown in [Example 4-22](#).

### **Example 4-22 XML Code for a Transient Attribute**

```
<Attribute
  Name="FullName"
  IsUpdateable="false"
  IsQueryable="false"
  IsPersistent="false"
  ColumnName="$none$"
  Type="java.lang.String"
  ColumnType="$none$"
  SQLType="VARCHAR" >
</Attribute>
```

In contrast, a persistent entity attribute has both a `TableName` and a `ColumnName`, as shown in [Example 4-23](#).

### **Example 4-23 XML Code for a Persistent**

```
<Attribute
  Name="FirstName"
  IsNotNull="true"
  Precision="30"
  ColumnName="FIRST_NAME"
  Type="java.lang.String"
  ColumnType="VARCHAR2"
  SQLType="VARCHAR"
  TableName="USERS" >
</Attribute>
```

## 4.14.3 How to Base a Transient Attribute On a Groovy Expression

When creating a transient attribute, you can use a Groovy expression to provide the default value.

### **To create a transient attribute based on a Groovy expression:**

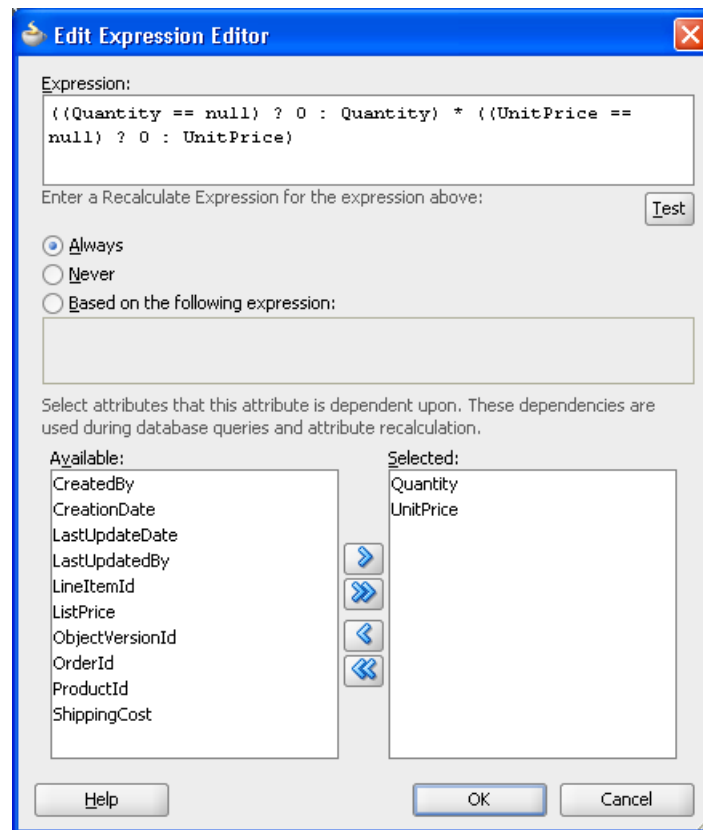

1. Create a new attribute, as described in the first four steps of [Section 4.14.1, "How to Add a Transient Attribute."](#)
2. In the Application Navigator, double-click the entity.
3. In the overview editor, click the **Attributes** navigation tab, and then click the **New** icon.
4. In the New Entity Attribute dialog box, enter a name for the attribute.
5. Set the Java attribute type.
6. Click the **Edit** button next to the **Value** field.

Expressions that you define are evaluated using the Groovy scripting language, as described in [Section 3.6, "Overview of Groovy Support."](#) Groovy lets you insert expressions and variables into strings. The expression is saved as part of the entity object definition.

7. In the Edit Expression dialog, enter an expression in the field provided, as shown in [Figure 4–15](#).

Attributes that you reference can include any attribute that the entity object defines. Do not reference attributes in the expression that are not defined by the entity object.

**Figure 4–15** *Edit Expression Dialog*

8. Select the appropriate recalculate setting.

If you select **Always** (default), the expression is evaluated each time any attribute in the row changes. If you select **Never**, the expression is evaluated only when the row is created.

9. You can optionally provide a condition for when to recalculate the expression.

For example, the following expression in the **Based on the following expression** field causes the attribute to be recalculated when either the `Quantity` attribute or the `UnitPrice` attribute are changed:

```
return (adf.object.isAttributeChanged("Quantity") ||
adf.object.isAttributeChanged("UnitPrice"));
```

10. You can also list attributes on which this attribute is dependent.

In [Figure 4–15](#), the `Quantity` and `UnitPrice` attributes are selected, which causes the attribute to be recalculated when either attribute is changed.

11. Click **OK** to save the expression.
12. Then click **OK** to create the attribute.

---

**Note:** If either the value expression or the optional recalculate expression that you define references an attribute from the base entity object, you must define this as a dependency on the `Dependencies` page of the `Edit Attribute` dialog. In the `Dependency` page, locate the attributes in the **Available** list and shuttle each to the **Selected** list.

---

#### 4.14.4 What Happens When You Base a Transient Attribute on Groovy Expression

When you base a transient attribute on a Groovy expression, a `<TransientExpression>` tag is added to the entity object's XML file within the appropriate attribute, as shown in [Example 4–24](#).

**Example 4–24 Calculating a Transient Attribute Using a Groovy Expression**

```
<TransientExpression>
  <![CDATA[
    ((Quantity == null) ? 0 : Quantity) * ((UnitPrice == null) ? 0 : UnitPrice)
  ]]>
</TransientExpression>
```

#### 4.14.5 How to Add Java Code in the Entity Class to Perform Calculation

A transient attribute is a placeholder for a data value. If you change the **Updatable** property of the transient attribute to **While New** or **Always**, then the end user can enter a value for the attribute. If you want the transient attribute to display a calculated value, then you'll typically leave the **Updatable** property set to **Never** and write custom Java code that calculates the value.

After adding a transient attribute to the entity object, to make it a *calculated* attribute you need to:

- Enable a custom entity object class on the Java page of the overview editor, choosing to generate accessor methods
- Write Java code inside the accessor method for the transient attribute to return the calculated value
- Specify each dependent attribute for the transient attribute on the `Dependencies` page of the `Edit Attribute` dialog

For example, after generating the view row class, the Java code to return the transient attribute's calculated value would reside in the getter method for the attribute (such as `FullName`), as shown in [Example 4–25](#).

**Example 4–25 Getter Method for a Transient Attribute**

```
// Getter method for FullName calculated attribute in UserImpl.java
public String getFullName() {
    // Commented out original line since we'll always calculate the value
    // return (String)getAttributeInternal(FULLNAME);
    return getFirstName()+" "+getLastName();
}
```

To ensure that the transient attribute is reevaluated whenever the attributes to be concatenated (such as `LastName` and `FirstName`) might be changed by the end user, specify the dependent attributes for the transient attribute. On the Dependencies page of the Edit Attribute dialog, locate the attributes in the **Available** list and shuttle each to the **Selected** list.

---

## Defining SQL Queries Using View Objects

This chapter describes how to create ADF view objects to create SQL queries that join, filter, sort, and aggregate data for use in an Oracle Application Development Framework (Oracle ADF) application. It describes how view objects map their SQL-derived attributes to database table columns and static data source, such as flat files.

This chapter includes the following sections:

- [Section 5.1, "Introduction to View Objects"](#)
- [Section 5.2, "Populating View Object Rows from a Single Database Table"](#)
- [Section 5.3, "Populating View Object Rows with Static Data"](#)
- [Section 5.4, "Limiting View Object Rows Using Effective Date Ranges"](#)
- [Section 5.5, "Working with Multiple Tables in Join Query Results"](#)
- [Section 5.6, "Working with Multiple Tables in a Master-Detail Hierarchy"](#)
- [Section 5.7, "Working with a Single Table in a Recursive Master-Detail Hierarchy"](#)
- [Section 5.8, "Working with View Objects in Declarative SQL Mode"](#)
- [Section 5.9, "Working with View Objects in Expert Mode"](#)
- [Section 5.10, "Working with Bind Variables"](#)
- [Section 5.11, "Working with Named View Criteria"](#)
- [Section 5.12, "Working with Row Finders"](#)
- [Section 5.13, "Working with List of Values \(LOV\) in View Object Attributes"](#)
- [Section 5.14, "Defining Control Hints for View Objects"](#)
- [Section 5.15, "Adding Calculated and Transient Attributes to a View Object"](#)

### 5.1 Introduction to View Objects

A *view object* is an Oracle Application Development Framework (Oracle ADF) component that encapsulates a SQL query and simplifies working with its results. There are several types of view objects that you can create in your ADF Business Components project:

- Entity-based view objects when data updates will be performed
- Read-only view objects when updates to data are not necessary (can also be entity-based)
- Static data view objects for data defined by the view object itself

- Programmatically populated view objects (for more information, see [Chapter 39, "Advanced View Object Techniques"](#))

An *entity-based view object* can be configured to support updatable rows when you create view objects that map their attributes to the attributes of one or more existing entity objects. The mapped entity object is saved as an entity usage in the view object definition. In this way, entity-based view objects cooperate automatically with entity objects to enable a fully updatable data model. The entity-based view object queries just the data needed for the client-facing task and relies on its mapped entity objects to automatically validate and save changes made to its view rows. An entity-based view object encapsulates a SQL query, it can be linked into master-detail hierarchies, and it can be used in the data model of your application modules.

### 5.1.1 Overview of View Object Concepts

View objects with no entity usage definition are always read-only. They do not pick up entity-derived default values, they do not reflect pending changes, and they do not reflect updated reference information. In contrast to entity-based view objects, *read-only view objects* require you to write the query using the SQL query language. The Create View Object wizard and overview editor for entity-based view objects, on the other hand, simplify this task by helping you to construct the SQL query declaratively. For this reason, it is almost always preferable to create a non-updatable, entity-mapped view object, even when you want to create a view object just to read data. Additionally, as an alternative to creating view objects that specify a SQL statement at design time, you can create entity-mapped view objects that dynamically generate SQL statements at runtime.

There remain a few situations where it is still preferable to create a non-entity-mapped view object to read data, including SQL-based validation, Unions, and Group By queries.

This chapter helps you understand these view object concepts as illustrated in [Figure 5-1](#):

- You define a view object by providing a SQL query (either defined explicitly or declaratively).
- You use view object instances in the context of an application module that provides the database transaction for their queries.
- You can link a view object to one or more others to create master-detail hierarchies.
- At runtime, the view object executes your query and produces a set of rows (represented by a `RowSet` object).
- Each row is identified by a corresponding row key.
- You iterate through the rows in a row set using a row set iterator.
- You can filter the row set a view object produces by applying a set of Query-by-Example criteria rows.

**Figure 5–1 A View Object Defines a Query and Produces a Row Set of Rows**

### 5.1.2 Runtime Features Unique to Entity-Based View Objects

When a view object has one or more underlying entity usages, you can create new rows, and modify or remove queried rows. The entity-based view object coordinates with underlying entity objects to enforce business rules and to permanently save the changes to the database. In addition, entity-based view objects provide these capabilities that do not exist with read-only view objects:

- Changes in cache (updates, inserts, deletes) managed by entities survive the view object's execution boundary.
- Changes made to relevant entity object attributes through other view objects in the same transaction are immediately reflected.
- Attribute values of new rows are initialized to the values from the underlying entity object attributes.
- Changes to foreign key attribute values cause reference information to get updated.
- Validation for row (entity) level is supported.
- Composition features, including validation, locking, ordered-updates are supported.
- Support for effective dating, change indicator, and business events.

This chapter explains how instances of entity-based view objects contained in the data model of your application module enable clients to search for, update, insert, and delete business domain layer information in a way that combines the full data shaping power of SQL with the clean, object-oriented encapsulation of reusable domain business objects. And all without requiring a line of code.

This chapter helps you to understand these entity-based view object concepts as illustrated in [Figure 5–2](#):

- You define an updatable view object by referencing attributes from one or more entity objects.
- You can use multiple, associated entity objects to simplify working with reference information.
- You can define view links based on underlying entity associations.

- You use your entity-based view objects in the context of an application module that provides the transaction.
- At runtime, the view row delegates the storage and validation of its attributes to underlying entity objects.

**Figure 5–2 View Objects and Entity Objects Collaborate to Enable an Updatable Data Model**

## 5.2 Populating View Object Rows from a Single Database Table

View objects provide the means to retrieve data from a data source. In the majority of cases, the data source will be a database and the mechanism to retrieve data is the SQL query. ADF Business Components can work with JDBC to pass this query to the database and retrieve the result.

When view objects use a SQL query, query columns map to view object attributes in the view object. The definition of these attributes, saved in the view object’s XML definition file, reflect the properties of these columns, including data types and precision and scale specifications.

**Performance Tip:** If the query associated with the view object contains values that may change from execution to execution, use bind variables. Using bind variables in the query allows the query to reexecute without needing to reparse the query on the database. You can add bind variables to the view object in the Query page of the overview editor for the view object. For more information, see [Section 5.10, "Working with Bind Variables."](#)

Using the same Create View Object wizard, you can create view objects that either map to the attributes of existing entity objects or not. Only entity-based view objects automatically coordinate with mapped entity objects to enforce business rules and to permanently save data model changes. Additionally, you can disable the Updatable feature for entity-based view objects and work entirely declaratively to query read-only data. Alternatively, you can use the wizard or editor’s expert mode to work directly with the SQL query language, but the view object you create will not support the transaction features of the entity-based view object.

While there is a small amount of runtime overhead associated with the coordination between view object rows and entity object rows, weigh this against the ability to keep the view object definition entirely declarative and maintain a customizable view object. Queries that cannot be expressed in entity objects, and that therefore require

expert-mode query editing, include Unions and Group By queries. Expert mode-based view objects are also useful in SQL-based validation queries used by the view object-based Key Exists validator. Again, it is worth repeating that, by definition, using expert mode to define a SQL query means the view object must be read-only.

For more information about the differences between entity-based view objects and read-only view objects, see [Section 5.1.2, "Runtime Features Unique to Entity-Based View Objects."](#)

## 5.2.1 How to Create an Entity-Based View Object

Creating an entity-based view object is the simplest way to create a view object. It is even easier than creating an expert-mode, read-only view object, since you don't have to type in the SQL statement yourself. An entity-based view object also offers significantly more runtime functionality than its expert-mode counterpart.

In an entity-based view object, the view object and entity object play cleanly separated roles:

- The view object is the data *source*: it retrieves the data using SQL.
- The entity object is the data *sink*: it handles validating and saving data changes.

Because view objects and entity objects have cleanly separated roles, you can build a hundred different view objects — projecting, filtering, joining, sorting the data in whatever way your user interfaces require, application after application — without any changes to the reusable entity object. In fact, it is possible that the development team responsible for the core business domain layer of entity objects might be completely separate from another team responsible for the specific application modules and view objects needed to support the end-user environment. This relationship is enabled by metadata that the entity-based view object encapsulates. The metadata specifies how the `SELECT` list columns are related to the attributes of one or more underlying entity objects.

Your entity-based view object may be based on more than one database table. To use database joins to add multiple tables to the view object, see [Section 5.5, "Working with Multiple Tables in Join Query Results."](#)

### 5.2.1.1 Creating a View Object with All the Attributes of an Entity Object

When you want to allow the client to work with *all* of the attributes of an underlying entity object, you can use the Create View Object wizard as described in [Section 5.2.1.2, "Creating an Entity-Based View Object from a Single Table."](#) After selecting the entity object, simply select *all* of its attributes on the Attributes page. However, for this frequent operation, there is an even quicker way to perform the same task in the Application Navigator.

#### Before you begin:

Create the desired entity objects as described in [Section 4.2.1, "How to Create Multiple Entity Objects and Associations from Existing Tables."](#)

#### To create a default entity-based view object:

1. In the Application Navigator, right-click the entity object and choose **New Default View Object**.

This context menu option lets you create a view object based on a single entity object that you select. If you need to add additional entity objects to the view object definition, you can use the Entity Objects page of the view object overview editor after you create the view object.

2. Provide a package and component name for the new view object in the Create Default View Object dialog.

In the Create Default View Object dialog you can click **Browse** to select the package name from the list of existing packages. For example, in [Figure 5-3](#), clicking Browse locates `oracle.fodemo.storefront.entities` package on the classpath for the `StoreFrontService` project in the `StoreFrontModule` application.

**Figure 5-3** *Shortcut to Creating a Default View Object for an Entity Object*

The new entity-based view object created will be identical to one you could have created with the Create View Object wizard. By default, it will have a single entity usage referencing the entity object you selected in the Application Navigator, and will include all of its attributes. It will initially have neither a `WHERE` nor `ORDER BY` clause, and you may want to use the overview editor for the view object to:

- Remove unneeded attributes
- Refine its selection with a `WHERE` clause
- Order its results with an `ORDER BY` clause
- Customize any of the view object properties

### 5.2.1.2 Creating an Entity-Based View Object from a Single Table

To create an entity-based view object, use the Create View Object wizard, which is available from the New Gallery.

#### Before you begin:

Create the desired entity objects as described in [Section 4.2.1, "How to Create Multiple Entity Objects and Associations from Existing Tables."](#)

#### To create an entity-based view object from a single table:

1. In the Application Navigator, right-click the project in which you want to create the view object and choose **New**.
2. In the New Gallery, expand **Business Tier**, select **ADF Business Components** and then **View Object**, and click **OK**.

If this is the first component you're creating in the project, the Initialize Business Components Project dialog appears to allow you to select a database connection.

3. In the Initialize Business Components Project dialog, select the database connection or choose **New** to create a connection. Click **OK**.
4. In the Create View Object wizard, on the Name page, enter a package name and a view object name. Keep the default setting **Updatable access through entity objects** enabled to indicate that you want this view object to manage data with its base entity object. Click **Next**.
5. On the Entity Objects page, select an entity object whose data you want to use in the view object. Click **Next**.

An entry in this list is known as an *entity usage*, since it records the entity objects that the view object will be using. Each entry could also be thought of as an *entity reference*, since the view object references attributes from that entity. For information about working table joins to create additional entity usages, see [Section 5.5, "Working with Multiple Tables in Join Query Results."](#)

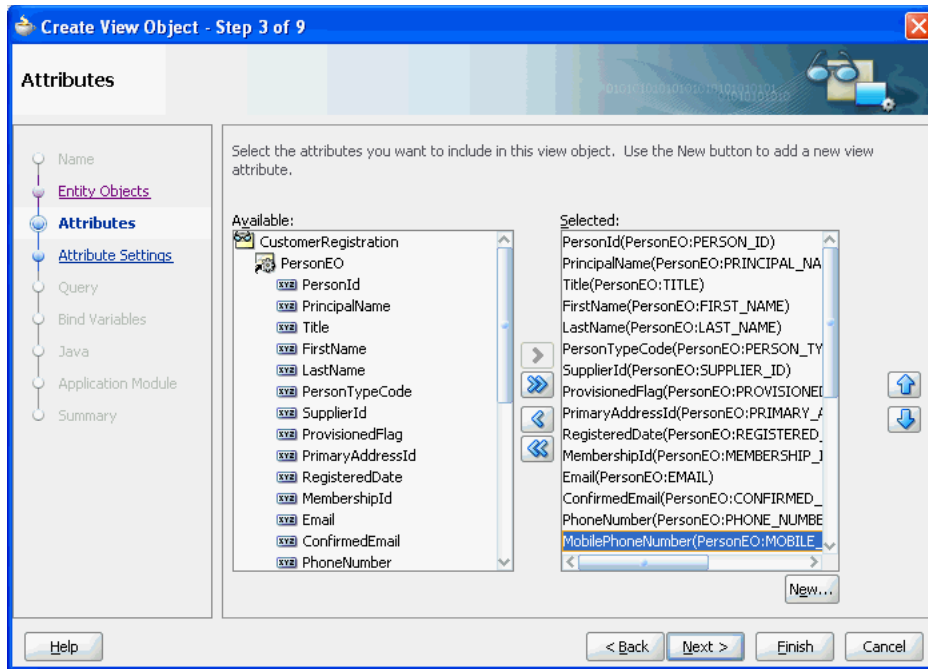

For example, [Figure 5–4](#) shows the result after shuttling the PersonEO entity object into the **Selected** list.

**Figure 5–4** Create View Object Wizard, Entity Objects Page

6. On the Attributes page, select the attributes you want to include from each entity usage in the **Available** list and shuttle them to the **Selected** list. Click **Next**.

For example, [Figure 5–5](#) shows the attributes have been selected from the PersonEO.

**Figure 5–5 Create View Object Wizard, Attributes Page**

7. On the Attribute Settings page, optionally, use the **Select Attribute** dropdown list to switch between the view object attributes in order to change their names or any of their initial settings.

For more information about any of the attribute settings, press F1 or click **Help**.

8. On the Query page, optionally, add a `WHERE` and `ORDER BY` clause to the query to filter and order the data as required. JDeveloper automatically generates the `SELECT` statement based on the entity attributes you've selected.

Do not include the `WHERE` or `ORDER BY` keywords in the **Where** and **Order By** field values. The view object adds those keywords at runtime when it executes the query.

For example, [Figure 5–6](#) shows the `ORDER BY` clause is specified to order the data by first name, last name, and email.

Figure 5–6 Create View Object Wizard, Query Page

9. When you are satisfied with the view object, click **Finish**.

## 5.2.2 What Happens When You Create an Entity-Based View Object

When you create a view object, JDeveloper creates the XML document file that represents the view object's declarative settings and saves it in the directory that corresponds to the name of its package. For example, the view object `Orders`, added to the `queries` package, will have the XML file `./queries/Orders.xml` created in the project's source path.

To view the view object settings, select the desired view object in the Application Navigator and open the Structure window. The Structure window displays the list of XML definitions, including the SQL query, the name of the entity usage, and the properties of each attribute. To open an XML definition in the editor, right-click the corresponding node and choose **Go to Source**.

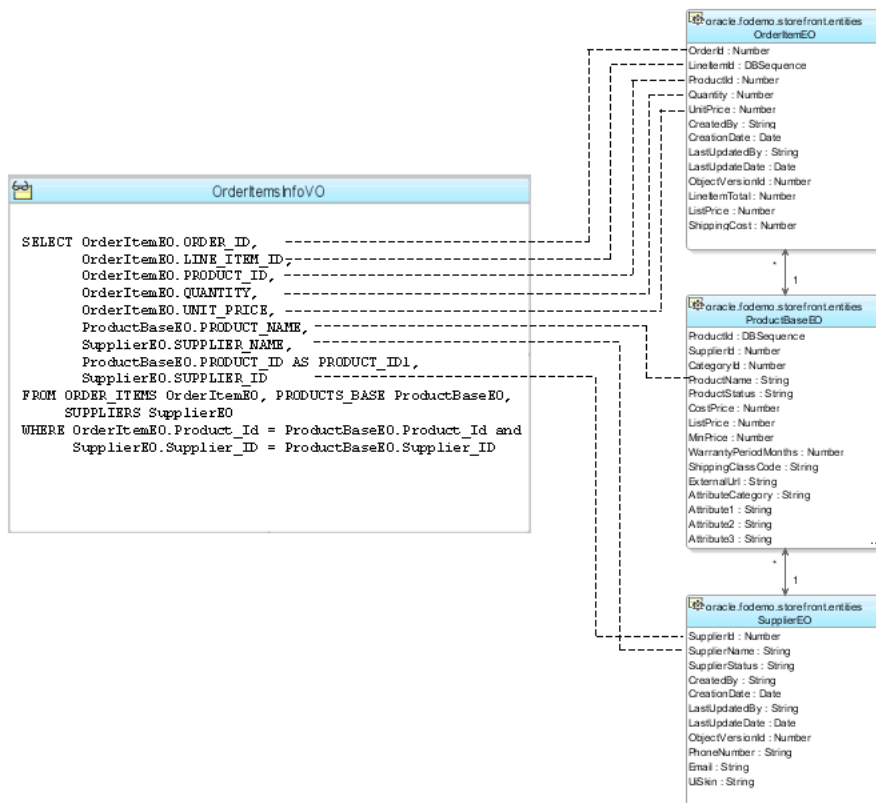

---

**Note:** If you configure JDeveloper preferences to generate default Java classes for ADF Business Components, the wizard will also create an optional custom view object class (for example, `OrdersImpl.java`) and/or a custom view row class (for example, `OrdersRowImpl.java`). For details about setting preferences, see [Section 39.3.1.4, "Configuring Default Java Generation Preferences."](#)

---

Figure 5–7 depicts the entity-based view object `OrderItemsInfoVO` and the three entity usages referenced in its query statement. The dotted lines represent the metadata captured in the entity-based view object's XML document that map `SELECT` list columns in the query to attributes of the entity objects used in the view object. The query of the entity-based view object joins data from a primary entity usage (`OrderItemEO`) with that from secondary reference entity usages (`ProductBaseEO` and `SupplierEO`).

**Figure 5–7 View Object Encapsulates a SQL Query and Entity Attribute Mapping Metadata**

### 5.2.3 How to Create an Expert Mode, Read-Only View Object

When you need full control over the SQL statement, the Create View Object wizard lets you specify that you want a view object to be read-only. In this case, you will not benefit from the declarative capabilities to define a non-updatable entity-based view object. However, there are a few situations where it is desirable to create read-only view objects using expert mode. Primarily, the read-only view object that you create will be useful when you need to write Unions or Group By queries. Additionally, you can use a read-only view object if you need to create SQL-based validation queries used by the view object-based Key Exists validator, provided that you have marked a key attribute.

**Best Practice:** Unlike entity-based view objects, read-only view objects that you create in expert mode, will not define a key attribute by default. While it is possible to create a read-only view object without defining its key attribute, in expert mode it is a best practice to select the attribute that corresponds to the queried table’s primary key and mark it as the key attribute. The presence of a key attribute ensures the correct runtime behavior for row set navigation. For example, the user interface developer may create an LOV component based on the read-only view object collection. Without a key attribute to specify the row key value, the LOV may not behave properly and a runtime error can result.

For more information about the tradeoffs between working with entity-based view objects that you define as non-updatable and strictly read-only view objects, see [Section 39.2.2, "Consider Using Entity-Based View Objects for Read-Only Data."](#)

To create a read-only view object, use the Create View Object wizard, which is available from the New Gallery.

**To create a read-only view object:**

1. In the Application Navigator, right-click the project in which you want to create the view object and choose **New**.
2. In the New Gallery, expand **Business Tier**, select **ADF Business Components** and then **View Object**, and click **OK**.

If this is the first component you're creating in the project, the Initialize Business Components Project dialog appears to allow you to select a database connection.

3. In the Initialize Business Components Project dialog, select the database connection or choose **New** to create a connection. Click **OK**.
4. In the Create View Object wizard, on the Name page, enter a package name and a view object name. Select **Read-only access through SQL query** to indicate that you want this view object to manage data with read-only access. Click **Next**.
5. On the Query page, use one of the following techniques:
  - Type or paste any valid SQL statement into the **Query Statement** box. The query statement can use a **WHERE** clause and an **Order By** clause. For example, [Figure 5–8](#) shows a query statement that uses a **WHERE** clause and an **Order By** clause to query a list of country codes in the language used by the application.
  - Click **Query Builder** to open the SQL Statement dialog and use the interactive query builder.

**Figure 5–8** Create View Object Wizard, Query Page

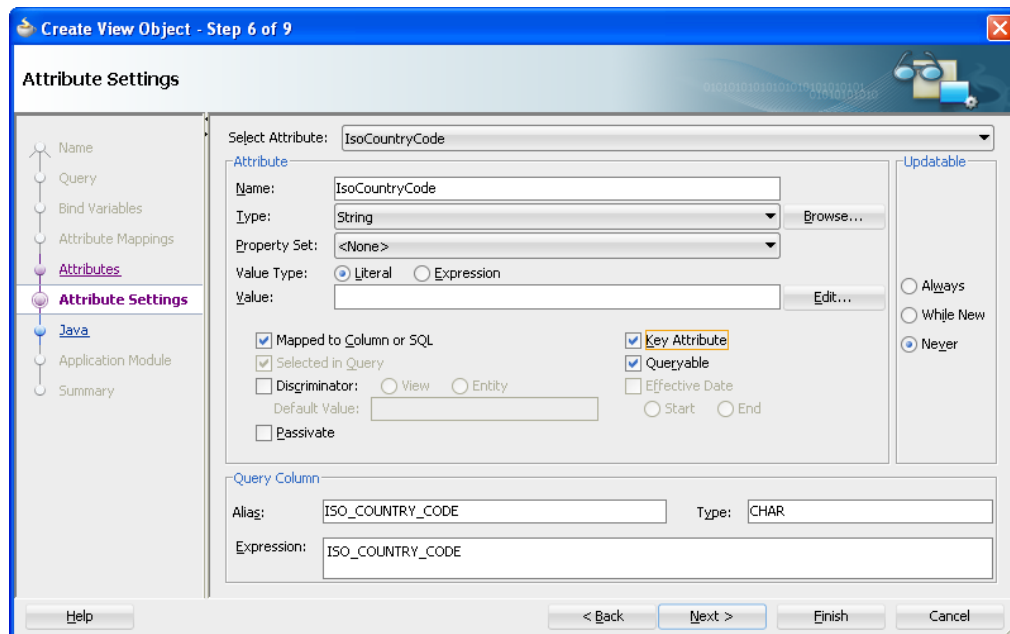

**Note:** If the Entity Objects page displays instead of the Query page, go back to Step 1 of the wizard and ensure that you've selected **Read-only Access**.

6. After entering or building the query statement, click **Next**.
7. On the Bind Variables page, do one of the following:
  - If the query does not reference any bind variables, click **Next** to skip Step 6.
  - To add a bind variable and work with it in the query, see [Section 5.10.1, "How to Add Bind Variables to a View Object Definition."](#)
8. On the Attribute Settings page, from the **Select Attribute** dropdown, select the attribute that corresponds to the primary key of the queried table and then enable the **Key Attribute** checkbox.

The Create View Object wizard auto-detects key attributes from the database and enables the **Key Attribute** checkbox, as shown in [Figure 5–9](#). Failure to define the key attribute can result in unexpected runtime behavior for ADF Faces components with a data control based on the view object collection.

**Figure 5–9** Create View Object Wizard, Attribute Settings Page

9. On the Attribute Mappings page, click **Finish**.

**Note:** In the ADF Business Components wizards and editors, the default convention is to use camel-capped attribute names, beginning with a capital letter and using uppercase letters in the middle of the name to improve readability when the name comprises multiple words.

## 5.2.4 What Happens When You Create a Read-Only View Object

When you create a view object, JDeveloper first parses the query to infer the following from the columns in the SELECT list:

- The Java-friendly view attribute names (for example, `CountryName` instead of `COUNTRY_NAME`)

By default, the wizard creates Java-friendly view object attribute names that correspond to the SELECT list column names, as shown in [Figure 5–10](#).

For information about using view object attribute names to access the data from any row in the view object's result set by name, see [Section 6.4, "Testing View Object Instances Programmatically."](#)

- The SQL and Java data types of each attribute

**Figure 5–10** Create View Object Wizard, Attribute Mappings Page

Each part of an underscore-separated column name like `SOME_COLUMN_NAME` is turned into a camel-capped word (like `SomeColumnName`) in the attribute name. While the view object attribute names correspond to the underlying query columns in the SELECT list, the attribute names at the view object level need not match necessarily.

**Tip:** You can rename the view object attributes to any names that might be more appropriate without changing the underlying query.

JDeveloper then creates the XML document file that represents the view object's declarative settings and saves it in the directory that corresponds to the name of its package. For example, the XML file created for a view object named `CountriesVO` in the `lookups` package is `./lookups/CountriesVO.xml` under the project's source path.

To view the view object settings, select the desired view object in the Application Navigator and open the Structure window. The Structure window displays the list of XML definitions, including the SQL query and the list of attributes. To open an XML definition in the editor, right-click the corresponding node and choose **Go to Source**.

## 5.2.5 How to Edit a View Object

After you've created a view object, you can edit any of its settings in the overview editor for the view object.

**Performance Tip:** How you configure the view object to fetch data plays a large role in the runtime performance of the view object. For information about the tuning parameters that you can edit to optimize performance, see [Section 6.3.10, "What You May Need to Know About Optimizing View Object Runtime Performance."](#)

### To edit a view object definition:

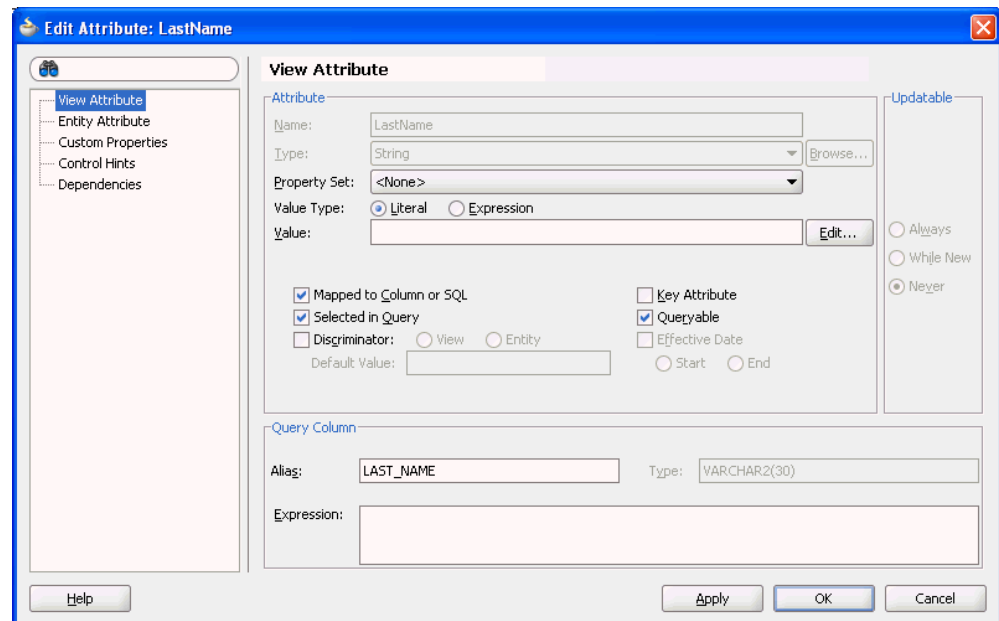

1. In the Application Navigator, double-click the view object to open the overview editor.
2. Select a navigation tab to open any editor page where you can adjust the SQL query, change the attribute names, add named bind variables, add UI controls hints, control Java generation options, and edit other settings.

### 5.2.5.1 Overriding the Inherited Properties from Underlying Entity Object Attributes

One interesting aspect of entity-based view objects is that each attribute that relates to an underlying entity object attribute inherits that attribute's properties. [Figure 5–11](#) shows the Edit Attribute dialog with the inherited attribute selected. You can see that fields like the Java attribute type and the query column type are disabled and their values are inherited from the related attribute of the underlying entity object to which this view object is related. Some properties like the attribute's data type are inherited and cannot be changed at the view object level.

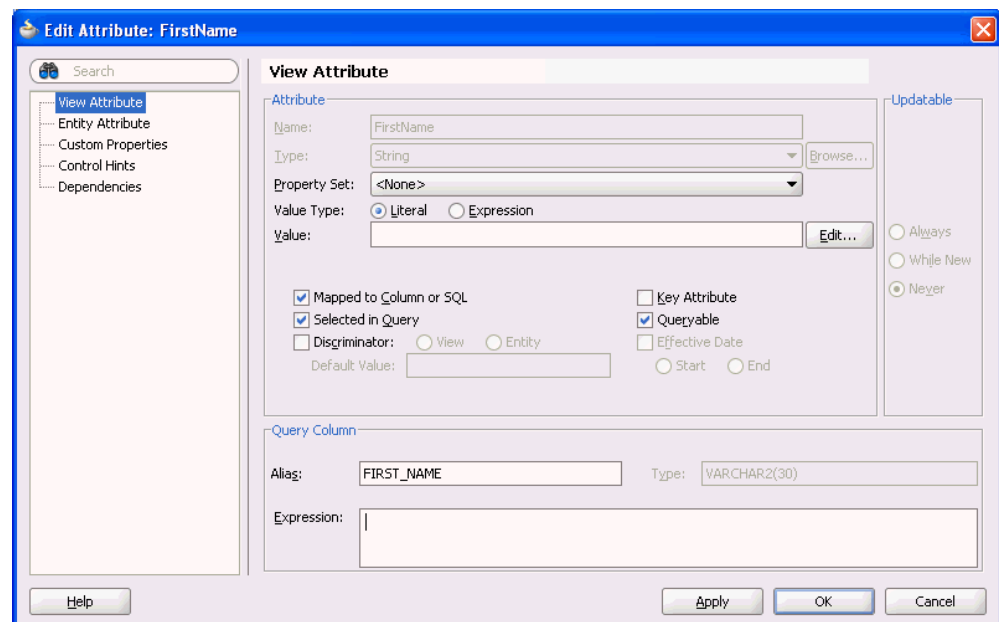

Other properties like `Queryable` and `Updatable` are inherited but can be overridden as long as their overridden settings are more restrictive than the inherited settings. For example, the attribute from underlying entity object might have an **Updatable** setting of **Always**. As shown [Figure 5–11](#), the Edit Attribute dialog allows you to set the corresponding view object attribute to a more restrictive setting like **While New** or **Never**. However, if the attribute in the underlying entity object had instead an **Updatable** setting of **Never**, then the editor would not allow the view object's related attribute to have a less restrictive setting like **Always**.

**Figure 5–11 View Object Attribute Properties Inherited from Underlying Entity Object**

### 5.2.5.2 Controlling the Length, Precision, and Scale of View Object Attributes

When you display a particular attribute of the view object in the Edit Attribute dialog, you can see and change the values of the declarative settings that control its runtime behavior. One important property is the **Type** in the **Query Column** section, shown in [Figure 5–11](#). This property records the SQL type of the column, including the length information for VARCHAR2 columns and the precision and scale information for NUMBER columns.

**Figure 5–12 Custom Attribute Settings in the Edit Attribute Dialog**

JDeveloper tries to infer the type of the column automatically, but for some SQL expressions the inferred value might default to VARCHAR2 (255). You can update the

**Type** value for this type of attribute to reflect the correct length if you know it. In the case of read-only view objects, this property is editable in the Edit Attribute dialog you display from the overview editor for the view object. In the case of entity-based view objects, you must edit the **Type** property in the Edit Attribute dialog that you display for the entity object, as described in [Section 4.10.2, "How to Indicate Data Type Length, Precision, and Scale."](#)

For example, `VARCHAR2 (30)` which shows as the **Type** for the `FirstName` attribute in [Figure 5–12](#) means that it has a maximum length of 30 characters. For a `NUMBER` column, you would indicate a **Type** of `NUMBER (7, 2)` for an attribute that you want to have a precision of 7 digits and a scale of 2 digits after the decimal.

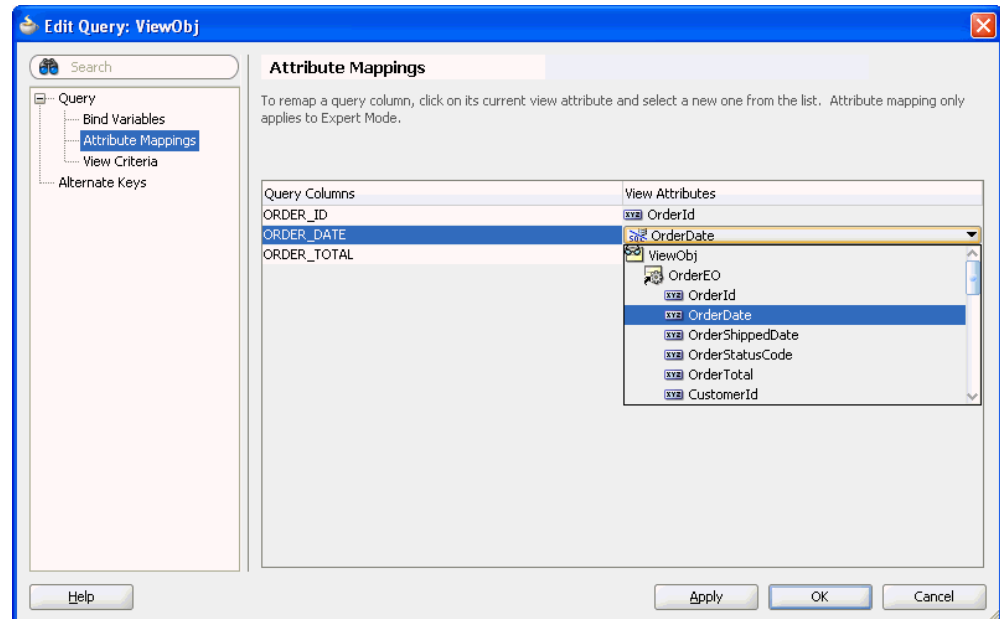

**Performance Tip:** Your SQL expression can control how long the describe from the database says the column is. Use the `SUBSTR ()` function around the existing expression. For example, if you specify `SUBSTR(yourexpession, 1, 15)`, then the describe from the database will inform JDeveloper that the column has a maximum length of 15 characters.

### 5.2.5.3 Converting a Read-Only View Object to Allow Attribute Updates

When you use the Create View Object wizard to create a read-only view object, by default the attributes of the view object will not be updateable. Later you may decide to convert the view object to one that permits updates to its SQL-mapped table columns. However, this cannot be accomplished by merely changing the attribute's **Updateable** property. To convert a read-only view object to one that is updateable, you must add an entity usage that maps to the same table as the one used to create the read-only view object. Choosing an entity usage that defines the same table ensures that you can then remap the SQL-derived view attributes to entity usage attributes corresponding to the same table columns.

#### To modify a read-only view object to allow updates:

1. In the Application Navigator, double-click the read-only view object.
2. In the overview editor, click the **Entity Objects** navigation tab.
3. In the Entity Objects page, expand the **Available** list and double-click the entity object that describes the attributes of the read-only view object.  
The entity object that you double-click will appear in the **Selected** list as an entity usage. You will need to remap the SQL-derived attributes to corresponding attributes defined by the entity usage.
4. Click the **Query** navigation tab, and in the Query page, click the **Edit SQL Query** button.
5. In the Edit Query dialog, click **Query** and then click **Attribute Mappings**.
6. In the Attribute Mappings page, perform the following steps to convert all SQL-derived attributes to their corresponding entity usage mapped attribute.
  - a. Click an attribute field in the **View Attributes** column and scroll to the top of the dropdown list to locate the entity usage attributes.
  - b. In the entity usage attribute list, select the attribute corresponding to the read-only attribute that you want to remap, as shown in [Figure 5–11](#).

**Figure 5–13 Specifying an Entity-Derived Attribute in the Edit Query Dialog**

7. Click **OK**.

#### 5.2.5.4 Customizing View Object Attribute Display in the Overview Editor

When you edit view objects in the overview editor, you can customize the Attributes page of the overview editor to make better use of the attributes table displayed for the view object.

Customization choices that you make for the attributes table include the list of attribute properties to display as columns in the attributes table, the order that the columns appear (from left to right) in the attributes table, the sorting order of the columns, and the width of the columns. The full list of columns that you can choose to display correspond to the attribute properties that you might edit in the view object's Edit Attributes dialog.

For example, you can add the **Updatable** property as a column to display in the attributes table when you want to quickly determine which attributes of your view object are updatable. Or, you can add the attributes' **Label** property as a column and see the same description as the end user. Or, you might want to view the list of attributes based on their entity usages. In this case, you can display the **Entity Usage** column and sort the entire attributes table on this column.

When you have set up the attributes table with the list of columns that you find most useful, you can apply the same set of columns to the attributes table displayed for other view objects by right-clicking the attributes table and choose **Apply to All View Objects**.

#### To customize the attributes table display:

1. In the Application Navigator, double-click the view object.
2. In the overview editor, click the **Attributes** navigation tab.
3. In the Attributes page, click the dropdown menu to the right of the attribute column headers (just below the attributes table's button bar) and choose **Select Columns**.

4. In the Select Columns dialog, perform any of the following actions.
  - a. Click the left/right shuttle buttons to change the list of visible columns in the attributes table of the overview editor. The overview editor displays only those columns corresponding to the attribute properties that appear the **Selected** list.
  - b. Click one of the **Move Selection** buttons to change the position of the columns in the attributes table of the overview editor. The overview editor displays the attribute properties arranged from left to right starting with the property at the top of the **Selected** list.
5. Click **OK**.
6. On the Attributes page of the overview editor, perform any of the following actions.
  - a. Select any column header and drag to change the position of the column in the attributes table of the overview editor.
  - b. Click any column header to sort all columns in the attributes table by the selected column.

This feature is particularly useful when you want to focus on a particular column. For example, in the case of an entity-based view object, you can click the **Entity Usage** column header to group attributes in the attributes table by their underlying entity objects. To save this setting across all view objects that you display in the overview editor, click the dropdown menu to the right of the column headers and choose **Apply to All View Objects**.

- c. Click any column header border and drag to adjust the width of the attributes table's column.
  - d. Click the dropdown icon to the right of the column headers and select among the list of displayed columns to change the visibility of a column in the current attributes table display.

This feature lets you easily hide columns when you want to simplify the attributes table display in the current view object overview editor.

7. To extend the changes in the columns (including column list, column order, column sorting, and column width) to all other view object overview editors, click the dropdown menu to the right of the column headers and choose **Apply to All View Objects**.

This feature allows you to easily compare the same attributes across view objects. The overview editor will apply the column selections (and order) that you make in the Select Columns dialog and the current attributes table's column sorting and column widths to all view objects that you edit. View objects that are currently displayed in an open overview editor are not updated with these settings; you must close the open view object overview editor and then reopen the view object to see these settings applied.

#### 5.2.5.5 Modifying the Order of Attributes in the View Object Source File

After you create a view object definition, you may decide to change the order of the attributes queried by the view object. This view object editing feature allows you to easily change the order that the attributes will appear in the attributes table displayed on the Attributes page of the view object overview editor. Because this feature acts on specific attributes and alters the XML definition of the current view object, it does not apply to other view objects that you may edit. Alternatively, you can sort the display

of attributes on the Attribute page of the view object overview editor without affecting the source file by clicking any column header in the overview editor's attributes table.

**To modify the order of attributes in the view object source file:**

1. In the Application Navigator, double-click the view object.
2. In the overview editor, click the **Attributes** navigation tab and click **Set Source Order**.
3. In the Set Source Order dialog, select the attribute you want to reposition and click one of the **Move Selection** buttons.
4. Click **OK**.

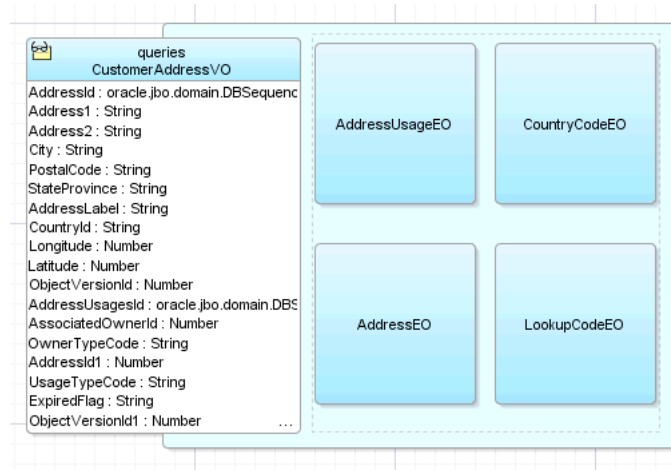

This feature has no affect on other view objects that you may edit; it only affects the current view object.

## 5.2.6 How to Show View Objects in a Business Components Diagram

JDeveloper's UML diagramming lets you create a Business Components diagram to visualize your business domain layer. In addition to supporting entity objects, JDeveloper's UML diagramming allows you to drop view objects onto diagrams as well to visualize their structure and entity usages. For example, if you create a new Business Components Diagram named `StoreFrontService Data Model` in the `oracle.fodemo.storefront` package, and drag the `CustomerAddressVO` view object from the Application Navigator onto the diagram, its entity usages would display, as shown in [Figure 5–14](#). When viewed as an expanded node, the diagram shows a compartment containing the view objects entity usages.

For information about creating the diagram, see [Section 4.4, "Creating an Entity Diagram for Your Business Layer."](#)

**Figure 5–14** View Object and Its Entity Usages in a Business Components Diagram

## 5.3 Populating View Object Rows with Static Data

ADF Business Components lets you create view objects in your data model project with rows that you populate at design time. Typically, you create view objects with static data when you have a small amount of data to maintain and you do not expect that data to change frequently. The decision whether to use a lookup table from the database or whether to use a static view object based on a list of hardcoded values

depends on the size and nature of the data. The static view object is useful when you have no more than 100 entries to list. Any larger number of rows should be read from the database with a conventional table-based view object. The static view object has the advantage of being easily translatable because attribute values are stored in a resource bundle. However, all of the rows of a static view object will be retrieved at once and therefore, using no more than 100 entries yields the best performance.

**Best Practice:** When you need to create a view object to access a small list of static data, you should use the static view object rather than query the database. The static view object is ideal for lists not exceeding 100 rows of data. Because the Create View Object wizard saves the data in a resource message file, these data are easily translatable.

Static list view objects are useful as an LOV data source when it is not desirable to query the database to supply the list of values. Suppose your order has the following statuses: open, closed, pending. You can create a static view object with these values and define an LOV on the static view object's status attribute. Because the wizard stores the values of the status view object in a translatable resource file, the UI will display the status values using the resource file corresponding to the application's current locale.

### 5.3.1 How to Create Static View Objects with Data You Enter

You use the Create View Object wizard to create static view objects. The wizard lets you define the desired attributes (columns) and enter as many rows of data as necessary. The wizard displays the static data table as you create it.

---

---

**Note:** Because the data in a static view object does not originate in database tables, the view object will be read-only.

---

---

You can also use the Create View Object wizard to create the attributes based on data from a comma-separated value (CSV) file format like a spreadsheet file.

#### To manually create attributes for a static view object:

1. In the Application Navigator, right-click the project in which you want to create the static list view object and choose **New**.
2. In the New Gallery, expand **Business Tier**, select **ADF Business Components** and then **View Object**, and click **OK**.

If this is the first component you're creating in the project, the Initialize Business Components Project dialog appears to allow you to select a database connection.

3. In the Initialize Business Components Project dialog, select the database connection or choose **New** to create a connection. Click **OK**.
4. In the Create View Object wizard, on the Name page, enter a package name and a view object name. Select **Rows populated at design time (Static List)** to indicate that you want to supply static list data for this view object. Click **Next**.
5. On the Attributes page, click **New** to add an attribute that corresponds to the columns in the static data table. In the New View Object Attribute dialog, enter a name and select the attribute type. Click **OK** to return to the wizard, and click **Next**.
6. On the Attribute Settings page, do nothing and click **Next**.

7. On the Static List page, click the **Add** icon to enter the data directly into the wizard page. The attributes you defined will appear as the columns for the static data table.
8. On the Application Module pages, do nothing and click **Next**.
9. On the Summary page, click **Finish**.

### 5.3.2 How to Create Static View Objects with Data You Import

Using the Import feature of the Create View Object wizard, you can create a static data view object with attributes based on data from a comma-separated value (CSV) file format like a spreadsheet file. The wizard will use the first row of a CSV flat file to identify the attributes and will use the subsequent rows of the CSV file for the data for each attribute. For example, if your application needs to display choices for international currency, you might define the columns Symbol, Country, and Description in the first row and then add rows to define the data for each currency type, as shown in [Figure 5–15](#).

**Figure 5–15 Sample Data Ready to Import from CSV Flat File**

	A	B	C
1	Symbol	Country	Description
2	USD	United States of America	Dollars
3	CNY	P. R. China	Yuan Renminbi
4	EUR	Europe	Euro
5	JPY	Japan	Yen

#### To create attributes of a static view object based on a flat file:

1. In the Application Navigator, right-click the project in which you want to create the static list view object and choose **New**.
2. In the New Gallery, expand **Business Tier**, select **ADF Business Components** and then **View Object**, and click **OK**.

If this is the first component you're creating in the project, the Initialize Business Components Project dialog appears to allow you to select a database connection.

3. In the Initialize Business Components Project dialog, select the database connection or choose **New** to create a connection. Click **OK**.
4. In the Create View Object wizard, on the Name page, enter a package name and a view object name. Select **Rows populated at design time (Static List)** to indicate that you want to supply static list data for this view object. Click **Next**.
5. On the Attributes page, optionally, click **New** to add an attribute that corresponds to the columns in the static data table. In the New View Object Attribute dialog, enter a name and select the attribute type. Click **OK** to return to the wizard, and click **Next**.

When the static data will be loaded from a CSV flat file, you can optionally skip this step. If you do not create the attributes yourself, the wizard will attempt to use the first row of the CSV file to create the attributes. However, if you create the attributes in the wizard, then the attributes you create must match the order of the columns defined by the flat file. If you have created fewer attributes than columns, the wizard will ignore extra columns during import. Conversely, if you create more attributes than columns, the wizard will define extra attributes with the value `NULL`.

6. On the Attribute Settings page, do nothing and click **Next**.

7. On the Static List page, click **Import** to locate the CSV file and display the data in the wizard. Verify the data and edit the values as needed.  
To edit an attribute value, double-click in the value field.
8. Optionally, click the **Add** icon or **Remove** icon to change the number of rows of data. Click **Next**.  
To enter values for the attributes of a new row, double-click in the value field.
9. On the Application Module page, do nothing and click **Next**.
10. On the Summary page, click **Finish**.

### 5.3.3 What Happens When You Create a Static List View Object

When you create a static view object, the overview editor for the view object displays the rows of data that you defined in the wizard. You can use the editor to define additional data, as shown in [Figure 5–16](#).

**Figure 5–16** Static Values Page Displays Data

Symbol	Country	Description
USD	United States of America	Dollars
CNY	P.R. China	Yuan Renminbi
EUR	Europe	Euro
JPY	Japan	Yen

The generated XML definition for the static view object contains one transient attribute for each column of data. For example, if you import a CSV file with data that describes international currency, your static view object might contain a transient attribute for Symbol, Country, and Description, as shown in [Example 5–1](#).

#### **Example 5–1** XML Definition for Static View Object

```
<ViewObject
...
<!-- Transient attribute for first column -->
  <ViewAttribute
    Name="Symbol"
    IsUpdateable="false"
    IsSelected="false"
    IsPersistent="false"
    PrecisionRule="true"
    Precision="255"
    Type="java.lang.String"
    ColumnType="VARCHAR2"
    AliasName="Symbol"
    SQLType="VARCHAR" />
<!-- Transient attribute for second column -->
  <ViewAttribute
    Name="Country"
    IsUpdateable="false"
    IsPersistent="false"
    PrecisionRule="true"
    Precision="255"
    Type="java.lang.String"
```

```

        ColumnType="VARCHAR"
        AliasName="Country"
        SQLType="VARCHAR"/>
<!-- Transient attribute for third column -->
<ViewAttribute
  Name="Description"
  IsUpdateable="false"
  IsPersistent="false"
  PrecisionRule="true"
  Precision="255"
  Type="java.lang.String"
  ColumnType="VARCHAR"
  AliasName="Description"
  SQLType="VARCHAR"/>
<StaticList
  Rows="4"
  Columns="3"/>
<!-- Reference to file that contains static data -->
<ResourceBundle>
  <PropertiesBundle
    PropertiesFile="model.ModelBundle"/>
  </ResourceBundle>
</ViewObject>

```

Because the data is static, the overview editor displays no Query page and the generated XML definition for the static view object contains no query statement. Instead, the `<ResourceBundle>` element in the XML definition references a resource bundle file. [Example 5-1](#) shows the reference to the file as `PropertiesFile="model.ModelBundle"`. The resource bundle file describes the rows of data and also lets you localize the data. When the default resource bundle type is used, the file `ModelBundle.properties` appears in the data model project, as shown in [Example 5-2](#).

**Example 5-2 Default Resource Bundle File for Static View Object**

```

model.ViewObj.SL_0_0=USD
model.ViewObj.SL_0_1=United States of America
model.ViewObj.SL_0_2=Dollars
model.ViewObj.SL_1_0=CNY
model.ViewObj.SL_1_1=P.R. China
model.ViewObj.SL_1_2=Yuan Renminbi
model.ViewObj.SL_2_0=EUR
model.ViewObj.SL_2_1=Europe
model.ViewObj.SL_2_2=Euro
model.ViewObj.SL_3_0=JPY
model.ViewObj.SL_3_1=Japan
model.ViewObj.SL_3_2=Yen

```

### 5.3.4 Editing Static List View Objects

When you need to make changes to the static list table, double-click the view object in the Application Navigator to open the overview editor for the view object. You can add and delete attributes (columns in the static list table), add or delete rows (data in the static list table), sort individual rows, and modify individual attribute values. The editor will update the view object definition file and save the modified attribute values in the message bundle file.

### 5.3.5 What You May Need to Know About Static List View Objects

The static list view object has a limited purpose in the application module's data model. Unlike entity-based view objects, static list view objects will not be updatable. You use the static list view object when you want to display read-only data to the end user and you do not want to create a database table for the small amount of data the static list table contains.

## 5.4 Limiting View Object Rows Using Effective Date Ranges

Applications that need to query data over a specific date range can generate *date-effective row sets*. To define a date-effective view object you must create an entity-based view object that is based on a date-effective entity object. User control over the view object's effective date usage is supported by metadata on the view object at design time. At runtime, ADF Business Components generates the query filter that will limit the view rows to an effective date.

### 5.4.1 How to Create a Date-Effective View Object

Whether or not the query filter for an effective date will be generated depends on the value of the **Effective Dated** property displayed in the Property Inspector for the view object (to view the property, select any tab in the overview editor for the view object other than **Attributes**).

---

---

**Note:** Because the date-effective view object must be based on a date-effective entity object, setting a view object's **Effective Dated** property to **True** without an underlying date-effective entity object, will result in a runtime exception.

---

---

The overview editor for the view object does not display the date-effective query clause in the `WHERE` clause. You can use the Explain Plan dialog or Test Query dialog to view the clause. A typical query filter for effective dates looks like this:

```
(:Bind_SysEffectiveDate BETWEEN Person.EFFECTIVE_START_DATE AND  
Person.EFFECTIVE_END_DATE)
```

At runtime, the bind value for the query can be obtained from a property of the root application module or can be assigned directly to the view object. To set the effective date for a transaction, use code similar to the following snippet:

```
am.setProperty(ApplicationModule.EFF_DT_PROPERTY_STR, new  
Date("2008-10-01"));
```

If you do not set `EFF_DT_PROPERTY_STR` on the application module, the current date is used in the query filter, and the view object returns the effective rows filtered by the current date.

The view object has its own transient attribute, `SysEffectiveDate`, that you can use to set the effective date for view rows. Otherwise, the `SysEffectiveDate` attribute value for new rows and defaulted rows is derived from the application module. ADF Business Components propagates the effective date from the view row to the entity object during DML operations only.

**Before you begin:**

1. Create an effective dated entity object as described in [Section 4.2.8, "How to Store Data Pertaining to a Specific Point in Time."](#)

2. Use the Create View Object wizard to create the entity-based view object as described in [Section 5.2.1, "How to Create an Entity-Based View Object."](#)

The view object you create should be based on the effective dated entity object you created. In the Attributes page of the wizard, be sure to add the date-effective attributes that specify the start date and end date on the entity object to the **Selected** list for the view object.

**To enable effective dates for a view object using the SysEffectiveDate attribute:**

1. In the Application Navigator, double-click the view object you created based on the effective dated entity object.

2. In the overview editor, click the **General** navigation tab.

3. In the Property Inspector, expand the **Name** category.

If the **Name** category is not displayed in the Property Inspector, click the **General** navigation tab in the overview editor to set the proper focus.

4. Verify that the context menu for the **Effective Dated** property displays **True**.

5. In the overview editor, click the **Attributes** navigation tab and double-click the attribute for the start date.

6. In the Edit Attribute dialog, verify that **Effective Date** is enabled and that **Start** is selected, as shown in [Figure 5-17](#). Verify that the attribute for the end date is also enabled correctly, as shown in the figure. Note that these fields appear grayed out to indicate that they cannot be edited for the view object.

**Figure 5-17 Edit Attribute Dialog Displays Effective Date Settings**

7. Click **OK**.

No additional steps are required once you have confirmed that the view object has inherited the desired attributes from the date-effective entity object.

## 5.4.2 How to Create New View Rows Using Date-Effective View Objects

Creating (inserting) date-effective rows is similar to creating or inserting ordinary view rows. The start date and end date can be specified as follows:

- The user specifies the effective date on the application module. The start date is set to the effective date, and the end date is set to end of time.
- The user specifies values for the start date and the end date (advanced).

In either case, during entity validation, the new row is checked to ensure that it does not introduce any gaps or overlaps. During post time, ADF Business Components will acquire a lock on the previous row to ensure that the gap or overlaps are not created upon the row insert.

## 5.4.3 How to Update Date-Effective View Rows

Date-effective rows are updated just as non date-effective rows are updated, using a `Row.setAttribute()` call. However, for the desired operation to take effect, an effective date mode must be set on the row before the update. ADF Business Components supports various modes to initiate the row update.

To set the update mode, invoke the `Row.setEffectiveDateMode(int mode)` method with one of the following mode constants.

- **CORRECTION (Correction Mode)**  
The effective start date and effective end dates remain unchanged. The values of the other attributes may change. This is the standard row update behavior.
- **UPDATE (Update Mode)**  
The effective end date of the row will be set to the effective date. All user modifications to the row values are reverted on this row. A new row with the modified values is created. The effective start date of the new row is set to the effective date plus one day, and the effective end date is set to end of time. The new row will appear after the transaction is posted to the database.
- **OVERRIDE (Update Override Mode)**  
The effective end date of the modified row will be set to the effective date. The effective start date of the next row is set to effective date plus one day, and the effective end date of the next row is set to end of time.
- **CHANGE\_INSERT (Change Insert Mode)**  
The effective end date of the modified row should be set to the effective date. All user modifications to the row values are reverted on this row. A new row with the modified values will be created. The effective start date of the new row is set to effective date plus one day, and the effective end date is set to effective start date of the next row minus one day. The new row will appear after the transaction is posted to the database.

#### 5.4.4 How to Delete Date-Effective View Rows

ADF Business Components supports various modes to initiate the row deletion. You can mark view rows for deletion by using API calls like `RowSet.removeCurrentRow()` or `Row.remove()`.

To set the deletion mode, invoke the `Row.setEffectiveDateMode(int mode)` method with one of the following mode constants.

- **DELETE (Delete Mode)**  
The effective date of the row is set to the effective date. The operation for this row is changed from delete to update. All rows with the same noneffective date key values and with an effective start date greater than the effective date are deleted.
- **NEXT\_CHANGE (Delete Next Change Mode)**  
The effective end date of the row is set to the effective end date of the next row with the same noneffective date key values. The operation for this row is changed from delete to update. The next row is deleted.
- **FUTURE\_CHANGE (Delete Future Change Mode)**  
The effective end date of the row is set to the end of time. The operation for this row is changed from delete to update. All future rows with the same noneffective date key values are deleted.
- **ZAP (Zap Mode)**  
All rows with the same non-effective date key values are deleted.

The effective date mode constants are defined on the row interface as well.

## 5.4.5 What Happens When You Create a Date-Effective View Object

When you create a date-effective view object, the view object inherits the transient attribute `SysEffectiveDate` from the entity object to store the effective date for the row. Typically, the insert/update/delete operations modify the transient attribute while Oracle ADF decides the appropriate values for effective start date and effective end date.

The query displayed in the overview editor for the date-effective view object does not display the `WHERE` clause needed to filter the effective date range. To view the full query for the date-effective view object, including the `WHERE` clause, edit the query and click **Explain Plan** in the Edit Query dialog. The following sample shows a typical query and query filter for effective dates:

```
SELECT OrdersVO.ORDER_ID,
       OrdersVO.CREATION_DATE,
       OrdersVO.LAST_UPDATE_DATE
FROM ORDERS OrdersVO
WHERE (:Bind_SysEffectiveDate BETWEEN OrdersVO.CREATION_DATE AND
      OrdersVO.LAST_UPDATE_DATE)
```

[Example 5-3](#) shows sample XML entries that are generated when you create an date-effective view object.

### **Example 5-3 XML Definition for Date-Effective View Object**

```
<ViewObject
...
<!-- Property that enables date-effective view object. -->
  IsEffectiveDated="true">
  <EntityUsage
    Name="Orders1"
    Entity="model.OrdersDatedEO"
    JoinType="INNER JOIN"/>
  <!-- Attribute identified as the start date -->
  <ViewAttribute
    Name="CreationDate"
    IsNotNull="true"
    PrecisionRule="true"
    IsEffectiveStartDate="true"
    EntityAttrName="CreationDate"
    EntityUsage="Orders1"
    AliasName="CREATION_DATE"/>
  <!-- Attribute identified as the end date -->
  <ViewAttribute
    Name="LastUpdateDate"
    IsNotNull="true"
    PrecisionRule="true"
    IsEffectiveEndDate="true"
    EntityAttrName="LastUpdateDate"
    EntityUsage="Orders1"
    AliasName="LAST_UPDATE_DATE"/>
  <!-- The SysEffectiveDate transient attribute -->
  <ViewAttribute
    Name="SysEffectiveDate"
    IsPersistent="false"
    PrecisionRule="true"
    Type="oracle.jbo.domain.Date"
    ColumnType="VARCHAR2"
    AliasName="SysEffectiveDate"
    Passivate="true"
```

```

        SQLType="DATE" />
    </ViewObject>

```

## 5.4.6 What You May Need to Know About Date-Effective View Objects and View Links

Effective dated associations and view links allow queries to be generated that take the effective date into account. The effective date of the driving row is passed in as a bind parameter during the query execution.

While it is possible to create a noneffective dated association between two entities when using the Create Association wizard or Create View Link wizard, JDeveloper will by default make the association or link effective dated if one of the ends is effective dated. However, when the association or view link exists between an effective dated and a noneffective dated object, then at runtime ADF Business Components will inspect the effective dated nature of the view object or entity object before generating the query clause and binding the effective date. The effective date is first obtained from the driving row. If it is not available, then it is obtained from the property `EFF_DT_PROPERTY_STR` of the root application module. If you do not set `EFF_DT_PROPERTY_STR` for the application module, the current date is used in the query filter on the driving row and applied to the other side of the association or view link.

## 5.5 Working with Multiple Tables in Join Query Results

Many queries you will work with will involve multiple tables that are related by foreign keys. In this scenario, you join the tables in a single view object query to show additional descriptive information in each row of the main query result. You use the Create View Object wizard to define the query using declarative options. Whether your view object is read-only or entity-based determines how you can define the join:

- When you work with entity-based view objects, the Create View Object wizard uses an existing association defined between the entities to automatically build the view object's join `WHERE` clause. You can declaratively specify the type of join you want to result from the entity objects. Inner join (equijoin) and outer joins are both supported.
- When you work with read-only view objects, you can use the SQL Builder dialog to build the view object's join `WHERE` clause. In this case, you must select the columns from the tables that you want to join.

Figure 5–18 illustrates the rows resulting from two tables queried by a view object that defines a join query. The join is a single flattened result.

**Figure 5–18** Join Query Result

Join Query	101	Order	322	Pat	Fay
	212	Order	322	Pat	Fay
	222	Order	310	John	Chen
	123	Order	300	Steven	King

Persons  
 Orders

## 5.5.1 How to Create Joins for Entity-Based View Objects

It is extremely common in business applications to supplement information from a *primary* business domain object with secondary reference information to help the end user understand what foreign key attributes represent. Take the example of the `OrderItems` entity object. It contains foreign key attribute of type `Number` like:

- `ProductId`, representing the product to which the order item pertains

From experience, you know that showing an end user exclusively these "raw" numerical values won't be very helpful. Ideally, reference information from the view object's related entity objects should be displayed to improve the application's usability. One typical solution involves performing a join query that retrieves the combination of the primary and reference information. This is equivalent to populating "dummy" fields in each queried row with reference information based on extra queries against the lookup tables.

When the end user can *change* the foreign key values by editing the data, this presents an additional challenge. Luckily, entity-based view objects support easily including reference information that's always up to date. The key requirement to leverage this feature is the presence of associations between the entity object that act as the view object's primary entity usage and the entity objects that contribute reference information.

To include reference entities in a join view object, use the Create View Object wizard. The Create View Object wizard lets you specify the type of join:

- **Inner Join**

Select when you want the view object to return all rows between two or more entity objects, where each entity defines the same primary key column. The inner join view object will not return rows when a primary key value is missing from the joined entities.

- **Outer Join**

Select when you want the view object to return all rows that exist in one entity object, even though corresponding rows do not exist in the joined entity object. Both left and right outer join types are supported. The left and right designation refers to the source (left) and destination (right) entity object named in an association. For details about changing the default inner join to an outer join, see [Section 5.5.5, "How to Modify a Default Join Clause to Be an Outer Join When Appropriate."](#)

Both inner joins and outer joins are supported with the following options:

- **Reference**

Select when you want the data from the entity object to be treated as reference information for the view object. Automatic lookup of the data is supported and attribute values will be dynamically fetched from the entity cache when a controlling key attribute changes.

- **Updatable**

Deselect when you want to prevent the view object from modifying any entity attributes in the entity object. By default, the first entity object (primary) in the **Selected** list is updatable and subsequent entity objects (secondary) are not updatable. To understand how to create a join view object with *multiple* updatable entity usages, see [Section 39.9, "Creating a View Object with Multiple Updatable Entities."](#)

- **Participate in row delete**

Select when you have defined the entity as updatable and you want the action of removing rows in the UI to delete the participating reference entity object. This option is disabled for the primary entity. For example, while it may be possible to delete an order item, it should not be possible to delete the order when a remove row is called from the join view object.

**Before you begin:**

Create the desired entity objects as described in [Section 4.2.1, "How to Create Multiple Entity Objects and Associations from Existing Tables."](#)

**To create a view object that joins entity objects:**

1. In the Application Navigator, right-click the project in which you want to create the view object and choose **New**.

When you want to modify an existing view object that you created to include reference information from its related entity objects, double-click the view object and open the Entity Objects page in the overview editor for the view object.

2. In the New Gallery, expand **Business Tier**, select **ADF Business Components** and then **View Object**, and click **OK**.
3. In the Create View Object wizard, on the Name page, enter a package name and a view object name. Keep the default setting **Updatable Access Through Entity Objects** enabled to indicate that you want this view object to manage data with its base entity object. Click **Next**.
4. In the Entity Objects page, the first entity usage in the **Selected** list is known as the *primary* entity usage for the view object. Select the primary entity object from the **Available** list and shuttle it to the **Selected** list.

The list is not limited to a single, primary entity usage.

5. To add additional, secondary entity objects to the view object, select them in the **Available** list and shuttle them to the **Selected** list.

The **Association** dropdown list shows you the name of the association that relates the selected secondary entity usage to the primary one. For example, [Figure 5–19](#) shows the result of adding one secondary reference entity usage, `ShippingOptionTranslationEO`, in addition to the primary `ShippingOptionBaseEO` entity usage. The association that relates to this secondary entity usage is `ShippingOptionTranslationFkAssociation`.

Figure 5–19 Create View Object Wizard, Entity Objects Page

6. Optionally, use the **Alias** field to give a more meaningful name to the entity usage when the default name is not clear.
7. If you add multiple entity usages for the same entity, use the **Association** dropdown list to select which association represents that usage's relationship to the primary entity usage. Click **Next**.

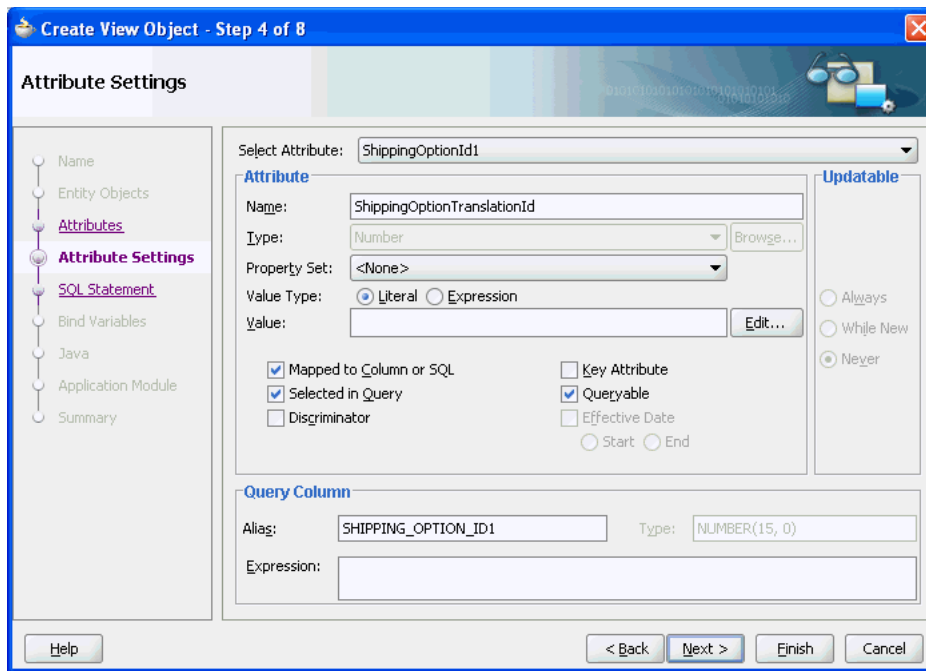

For each secondary entity usage, the **Reference** option is enabled to indicate that the entity provides reference information and that it is not the primary entity. The **Updatable** option is disabled. This combination represents the typical usage. However, when you want to create a join view object with multiple, updatable entity usages, see [Section 39.9, "Creating a View Object with Multiple Updatable Entities."](#)

Secondary entity usages that are updatable can also have the **Participate in row delete** option enabled. This will allow secondary entity attributes to appear `NULL` when the primary entity is displayed.

8. On the **Attributes** page, select the attributes you want each entity object usage to contribute to the view object. Click **Next**.
9. On the **Attribute Settings** page, you can rename an attribute when the names are not as clear as they ought to be.

The same attribute name often results when the reference and secondary entity objects derive from the same table. [Figure 5–20](#) shows the attribute `ShippingOptionId1` in the **Select Attribute** dropdown list, which has been renamed to `ShippingOptionTranslationId` in the **Name** field.

Figure 5–20 Create View Object Wizard, Attribute Settings Page

10. Click **Finish**.

## 5.5.2 How to Select Additional Attributes from Reference Entity Usages

After adding secondary entity usages, you can use the overview editor for the view object to select the specific, additional *attributes* from these new usages that you want to include in the view object.

**Tip:** The overview editor lets you sort attributes displayed in the Attributes page by their entity usages. By default, the attributes table displays attributes in the order they appear in the underlying entity object. To sort the attributes by entity usage, click the header for the **Entity Usage** column of the attributes table. If the **Entity Usage** column does not appear in the attributes table, click the dropdown menu icon on the top-right corner of the table (below the button bar) and choose **Select Columns** to add the column to the **Selected** list.

### To select attributes from a secondary entity usage:

1. In the Application Navigator, double-click the view object.
2. In the overview editor, click the **Attributes** navigation tab and click the **Add from Entity** button to view the list of available entity-derived attributes.
3. In the Attributes dialog, select the desired attribute and add it to the **Selected** list.

Note that even if you didn't intend to include them, JDeveloper automatically verifies that the primary key attribute from each entity usage is part of the **Selected** list. If it's not already present in the list, JDeveloper adds it for you. When you are finished, the overview editor Query page shows that JDeveloper has included the new columns in the `SELECT` statement.

4. Click **OK**.

### 5.5.3 How to Remove Unnecessary Key Attributes from Reference Entity Usages

The view object attribute corresponding to the primary key attribute of the primary entity usage acts as the primary key for identifying the view row. When you add secondary entity usages, JDeveloper marks the view object attributes corresponding to their primary key attributes as part of the view row key as well. When your view object consists of a single updatable primary entity usage and a number of reference entity usages, the primary key attribute from the primary entity usage is enough to uniquely identify the view row. Further key attributes contributed by secondary entity usages are not necessary and you should disable their **Key Attribute** settings.

For example, based on the view object with primary entity usage `ShippingOptionEO`, you could disable the **Key Attribute** property for the `ShippingOptionTranslationEO` entity usage so that this property is no longer selected for this additional key attribute: `ShippingTranslationsId`.

#### To remove unnecessary key attributes:

1. In the Application Navigator, double-click the view object.
2. In the overview editor, click the **Attributes** navigation tab.
3. In the Attributes page, in the attributes table, select the key attribute (identified by the key icon in the **Name** column), and click the **Edit selected attribute(s)** button.
4. In the View Attribute page of the Edit Attribute dialog, deselect the **Key Attribute** property.
5. Click **OK**.

### 5.5.4 How to Hide the Primary Key Attributes from Reference Entity Usages

Since you generally won't want to display the primary key attributes that were automatically added to the view object, you can set the attribute's **Display Hint** property in the Control Hints page of the Edit Attribute dialog to **Hide**.

#### To hide the primary key attribute:

1. In the Application Navigator, double-click the view object.
2. In the overview editor, click the **Attributes** navigation tab.
3. In the Attributes page, in the attributes table, select the primary key attribute (identified by the key icon in the **Name** column), and click the **Edit selected attribute(s)** button.
4. In the Control Hints page of the Edit Attribute dialog, select **Hide** in the **Display Hint** dropdown list.
5. Click **OK**.

### 5.5.5 How to Modify a Default Join Clause to Be an Outer Join When Appropriate

When you add a secondary entity usage to a view object, the entity usage is related to an entity usage that precedes it in the list of selected entities. This relationship is established by an entity association displayed in the **Association** dropdown list in the Entity Objects page of the overview editor for the view object. You use the **Association** dropdown list in the editor to select the entity association that relates the secondary entity usage to the desired preceding entity usage in the **Selected** list. The name of the preceding entity usage is identified in the **Source Usage** dropdown list.

When JDeveloper creates the WHERE clause for the join between the table for the primary entity usage and the tables for related secondary entity usages, by default it always creates inner joins. You can modify the default inner join clause to be a left or right outer join when appropriate. The left designation refers to the source entity object named in the selected association. This is the entity identified in the **Source Usage** dropdown list. The right designation refers to the current secondary entity usage that you have selected in the **Selected** list.

In the left outer join, you will include all rows from the left table (related to the entity object named in the **Source Usage** list) in the join, even if there is no matching row from the right table (related to the current secondary entity object selection). The right outer join specifies the reverse scenario: you will include all rows from the right table (related to the entity object named in the **Selected** list) in the join, even if there is no matching row from the left table (related to the current secondary entity object selection).

For example, assume that a person is not yet assigned a membership status. In this case, the `MembershipId` attribute will be NULL. The default inner join condition will not retrieve these persons from the `MEMBERSHIPS_BASE` table. Assuming that you want persons without membership status to be viewable and updatable through the `MembershipDiscountsVO` view object, you can use the Entity Objects page in the overview editor for the view object to change the query into an left outer join to the `MEMBERSHIPS_BASE` table for the possibly null `MEMBERSHIP_ID` column value. When you add the person entity to the view object, you would select the **left outer join** as the join type. As shown in [Figure 5–21](#), the association `PersonsMembershipsBaseFkAssoc` identifies a source usage `MembershipBaseEO` on the left side of the join and the selected `PersonEO` entity usage on the right side. The view object `MembershipDiscountsVO` joins the rows related to both of these entity objects and defines a left outer join for `PersonEO` to allow the view object to return rows from the table related to `MembershipBaseEO` even if they do not have a match in the table related to `PersonEO`.

**Figure 5–21** Setting an Outer Join to Return NULL Rows from Joined Entities

The view object's updated WHERE clause includes the addition (+) operator on the right side of the equals sign for the related table whose data is allowed to be missing in the left outer join:

```
PersonEO.MEMBERSHIP_ID = MembershipBaseEO.MEMBERSHIP_ID(+)
```

**Before you begin:**

Create the desired entity objects and associations as described in [Section 4.2.1, "How to Create Multiple Entity Objects and Associations from Existing Tables."](#)

**To change an inner join type to an outer join:**

1. In the Application Navigator, double-click the view object.
2. In the overview editor, click the **Entity Objects** navigation tab.  
The entity object you select represents the table on the right side of the join.
3. In the Entity Objects page, in the **Selected** list, select the entity object that you want to change the join type for.  
The entity object you select represents the table on the right side of the join.
4. In the **Association** dropdown list, if only one association is defined, leave it selected; otherwise, select among the list of entity object associations that relate the secondary entity object to the desired entity object. The entity usage that represents the joined table will be displayed in the **Source Usage** dropdown list.  
The entity object in the **Source Usage** dropdown list that you choose through the association selection represents the table on the left side of the join.
5. In the **Join Type** dropdown list, decide how you want the view object to return rows from the joined entity objects:
  - **left outer join** will include rows from the left table in the join, even if there is no matching row from the right table.
  - **right outer join** will include rows from the right table in the join, even if there is no matching row from the left table.

The **Source Usage** dropdown list is the left side of the join and the current entity usage in the **Selected** list is the right side.

## 5.5.6 What Happens When You Reference Entities in a View Object

When you create a join view object to include secondary entity usages by reference, JDeveloper updates the view object's XML document to include information about the additional entity usages. For example, the `ShippingOptionsVO.xml` file for the view object includes an additional reference entity usage. You will see this information recorded in the multiple `<EntityUsage>` elements. For example, [Example 5-5](#) shows an entity usage entry that defines the primary entity usage.

### Example 5-4 Primary Entity Usage

```
<EntityUsage
  Name="ShippingOptionBaseEO"
  Entity="oracle.fodemo.storefront.entities.ShippingOptionBaseEO"/>
```

The secondary reference entity usages will have a slightly different entry, including information about the association that relates it to the primary entity usage, like the entity usage shown in [Example 5-5](#).

### Example 5-5 Secondary Reference Entity Usage

```
<EntityUsage
  Name="ShippingOptionTranslationEO"
  Entity="oracle.fodemo.storefront.entities.ShippingOptionTranslationEO"
  Association="oracle.fodemo.storefront.entities.associations."/>
```

```

        ShippingOptionTranslationFkAssoc"
    AssociationEnd="oracle.fodemo.storefront.entities.associations.
        ShippingOptionTranslationFkAssoc.ShippingOptionTranslation"
    SourceUsage="oracle.fodemo.storefront.store.queries.ShippingOptionsVO.
        ShippingOptionBaseEO"
    ReadOnly="true"
    Reference="true" />

```

Each attribute entry in the XML file indicates which entity usage it references. For example, the entry for the `ShippingOptionId` attribute in [Example 5–6](#) shows that it's related to the `ShippingOptionBaseEO` entity usage, while the `ShippingMethod` attribute is related to the `ShippingOptionTranslationEO` entity usage.

#### **Example 5–6 Entity Usage Reference of View Object Attribute**

```

<ViewAttribute
  Name="ShippingOptionId"
  IsNotNull="true"
  EntityAttrName="ShippingOptionId"
  EntityUsage="ShippingOptionBaseEO"
  AliasName="SHIPPING_OPTION_ID" >
</ViewAttribute>
...
<ViewAttribute
  Name="ShippingMethod"
  IsUpdatable="true"
  IsNotNull="true"
  EntityAttrName="ShippingMethod"
  EntityUsage="ShippingOptionTranslationEO"
  AliasName="SHIPPING_METHOD" >
</ViewAttribute>

```

The Create View Object wizard uses this association information at design time to automatically build the view object's join `WHERE` clause. It uses the information at runtime to enable keeping the reference information up to date when the end user changes foreign key attribute values.

### **5.5.7 How to Create Joins for Read-Only View Objects**

To create a read-only view object joining two tables, use the Create View Object wizard.

#### **To create a read-only view object joining two tables:**

1. In the Application Navigator, right-click the project in which you want to create the view object and choose **New**.
2. In the New Gallery, expand **Business Tier**, select **ADF Business Components** and then **View Object**, and click **OK**.
3. In the Initialize Business Components Project dialog, select the database connection or choose **New** to create a connection. Click **OK**.
4. In the Create View Object wizard, on the Name page, enter a package name and a view object name. Select **Read-only access through SQL query** to indicate that you want this view object to manage data with read-only access. Click **Next**.
5. On the Query page, use one of the following techniques to create the SQL query statement that joins the desired tables:

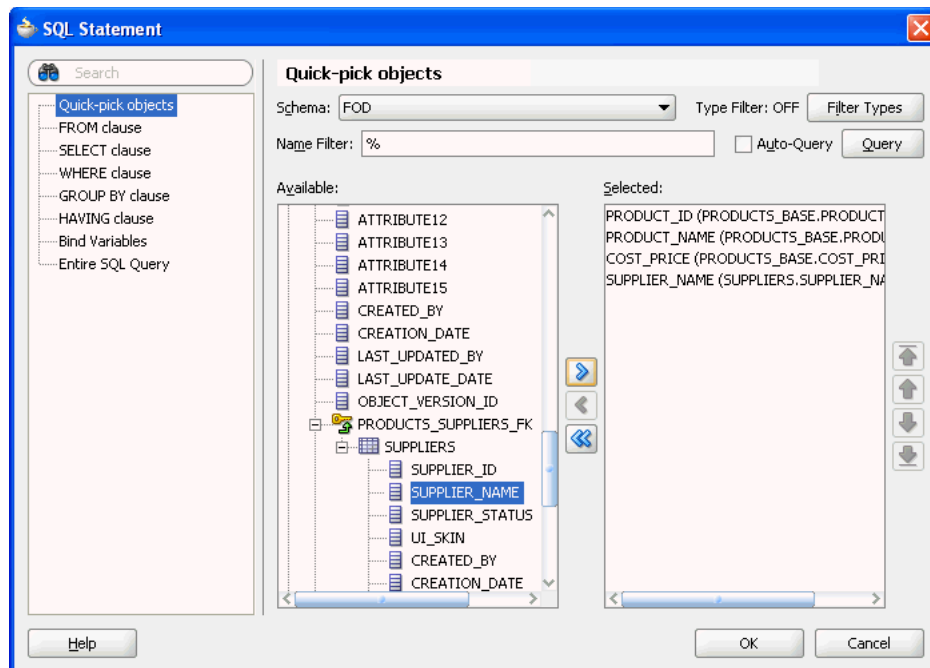

- Type or paste any valid SQL statement into the **Query Statement** box.
  - Click **Query Builder** to open the SQL Statement dialog and use the interactive query builder, as described in [Section 5.5.9, "How to Use the SQL Statement Dialog with Read-Only View Objects."](#)
6. After entering or building the query statement, click **Next**.
  7. On the Bind Variables page, do one of the following:
    - If the query does not reference any bind variables, click **Next** to skip Step 3.
    - To add a bind variable and work with it in the query, see [Section 5.10.1, "How to Add Bind Variables to a View Object Definition."](#)
  8. On the Attribute Mappings page, click **Finish**.

### 5.5.8 How to Test the Join View

To test the new view object, edit the application module and on the Data Model page add an instance of the new view object to the data model. Then, use the Business Component Browser to verify that the join query is working as expected. For details about editing the data model and running the Business Component Browser, see [Section 6.3, "Testing View Object Instances Using the Business Component Browser."](#)

### 5.5.9 How to Use the SQL Statement Dialog with Read-Only View Objects

The Quick-pick objects page of the SQL Statement dialog lets you view the tables in your schema, including the foreign keys that relate them to other tables. To include columns in the select list of the query, shuttle the desired columns from the **Available** list to the **Selected** list. For example, [Figure 5-22](#) shows the result of selecting the `PRODUCT_ID`, `PRODUCT_NAME`, and `COST_PRICE` columns from the `PRODUCTS` table, along with the `SUPPLIER_NAME` column from the `SUPPLIERS` table. The column from the second table appears, beneath the `PRODUCTS_SUPPLIERS_FK` foreign key in the **Available** list. When you select columns from tables joined by a foreign key, the SQL Statement dialog automatically determines the required join clause for you.

**Figure 5–22 View Object Query Builder to Define a Join**

Optionally, use the WHERE clause page of the SQL Statement dialog to define the expression. To finish creating the query, click **OK** in the SQL Statement dialog. The Edit Query dialog will show a query like the one shown in [Example 5–7](#).

#### **Example 5–7 Creating a Query Using SQL Builder**

```
SELECT
    PRODUCTS_BASE.PRODUCT_ID PRODUCT_ID,
    PRODUCTS_BASE.PRODUCT_NAME PRODUCT_NAME,
    PRODUCTS_BASE.COST_PRICE COST_PRICE,
    SUPPLIERS.SUPPLIER_NAME SUPPLIER_NAME
FROM
    PRODUCTS_BASE JOIN SUPPLIERS USING (SUPPLIER_ID)
```

You can use the Attributes page of the Create View Object wizard to rename the view object attribute directly as part of the creation process. Renaming the view object here saves you from having to edit the view object again, when you already know the attribute names that you'd like to use. As an alternative, you can also alter the default Java-friendly name of the view object attributes by assigning a column alias, as described in [Section 5.9.2, "How to Name Attributes in Expert Mode."](#)

### **5.5.10 What You May Need to Know About Join View Objects**

If your view objects reference multiple entity objects, they are displayed as separate entity usages on a business components diagram.

## **5.6 Working with Multiple Tables in a Master-Detail Hierarchy**

Many queries you will work with will involve multiple tables that are related by foreign keys. In this scenario, you can create separate view objects that query the related information and then link a "source" view object to one or more "target" view objects to form a master-detail hierarchy.

There are two ways you might handle this situation. You can either:

- Create a view link based on an association between entity objects when the source and target view objects are based on the underlying entity objects' association.
- Create a view link that defines how the source and target view objects relate.

Whether or not an association exists is determined when entity objects are created. By default, the entity object associations model the hierarchical relationships of the data source. For example, entity objects based on database tables related by foreign keys will capture these relationships in entity associations. If you do base the view link on an existing entity association, there is no performance penalty over defining the view link on the view objects alone. In either case, you use the Create View Link wizard to define the master-detail relationship.

---

**Note:** A view link defines a basic master-detail relationship between two view objects. However, by creating more view links you can achieve master-detail hierarchies of any complexity, including:

- Multilevel master-detail-detail
- Master with multiple (peer) details
- Detail with multiple masters

The steps to define these more complex hierarchies are the same whether you create the relationships based on view objects alone or view objects with entity associations. In either case, you just need to create each additional hierarchy, one view link at time.

---

Figure 5–23 illustrates the multilevel result that master-detail linked queries produce.

**Figure 5–23** *Linked Master-Detail Queries*

### 5.6.1 How to Create a Master-Detail Hierarchy for Entity-Based View Objects

Just as with read-only view objects, you can link entity-based view objects to other view objects to form master-detail hierarchies of any complexity. The only difference in the creation steps involves the case when both the master and detail view objects are entity-based view objects and their respective entity usages are related by an association. In this situation, since the association captures the set of source and destination attribute pairs that relate them, you create the view link just by indicating which association it should be based on.

To create an association-based view link, you use the Create View Link wizard.

**Before you begin:**

Create the desired entity-based view objects as described in [Section 5.2.1, "How to Create an Entity-Based View Object."](#)

**To create an association-based view link**

1. In the Application Navigator, right-click the project in which you want to create the view object and choose **New**.

To avoid having to type in the package name in the Create View Link wizard, you can choose **New View Link** on the context menu of the **links** package node in the Application Navigator.

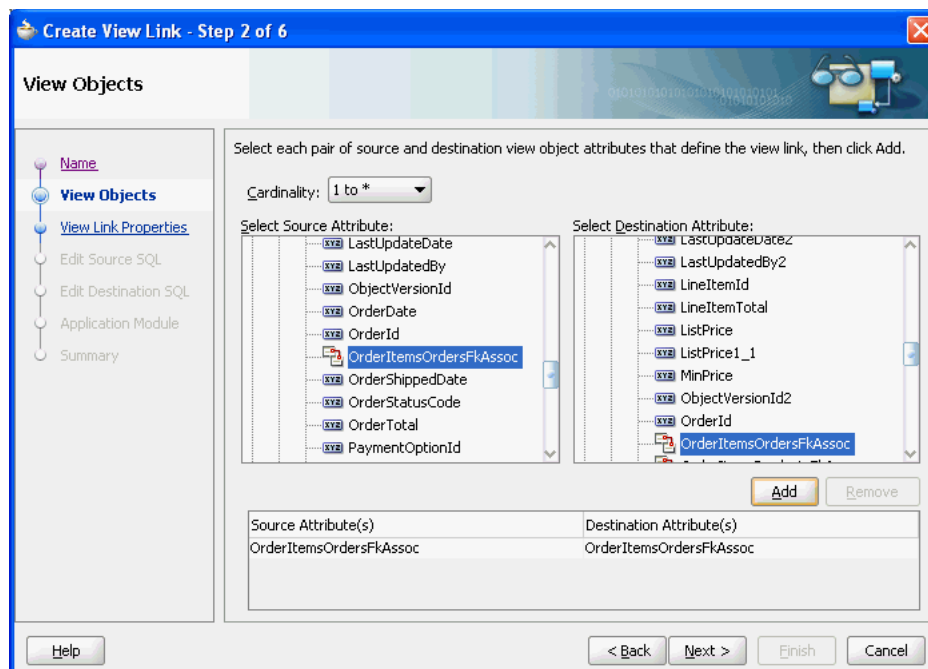

2. In the New Gallery, expand **Business Tier**, select **ADF Business Components** and then **View Link**, and click **OK**.
3. In the Create View Link wizard, on the Name page, supply a package and a component name.
4. On the View Objects page, in the **Select Source Attribute** tree expand the source view object in the desired package. In the **Select Destination Attribute** tree expand the destination view object.

For entity-based view objects, notice that in addition to the view object attributes, relevant associations also appear in the list.

5. Select the same association in both **Source** and **Destination** trees. Then click **Add** to add the association to the table below.

For example, [Figure 5–24](#) shows the same `OrderItemsOrdersFkAssoc` association in both **Source** and **Destination** trees selected.

**Figure 5–24 Master and Detail Related by an Association Selection**

6. Click **Finish**.

## 5.6.2 How to Create a Master-Detail Hierarchy Based on View Objects Alone

When you want to show the user a set of master rows, and for each master row a set of coordinated detail rows, then you can create view links to define how you want the master and detail view objects to relate. For example, you could link the `Persons`

view object to the `Orders` view object to create a master-detail hierarchy of customers and the related set of orders they have placed.

To create the view link, use the Create View Link wizard.

**Before you begin:**

Create the desired read-only view objects as described in [Section 5.2.3, "How to Create an Expert Mode, Read-Only View Object."](#)

**To create a view link between read-only view objects:**

1. In the Application Navigator, right-click the project in which you want to create the view object and choose **New**.
2. In the New Gallery, expand **Business Tier**, select **ADF Business Components** and then **View Link**, and click **OK**.
3. In the Create View Link wizard, on the Name page, enter a package name and a view link name. For example, given the purpose of the view link, a name like `OrdersPlacedBy` is a valid name. Click **Next**.
4. On the View Objects page, select a "source" attribute from the view object that will act as the master.

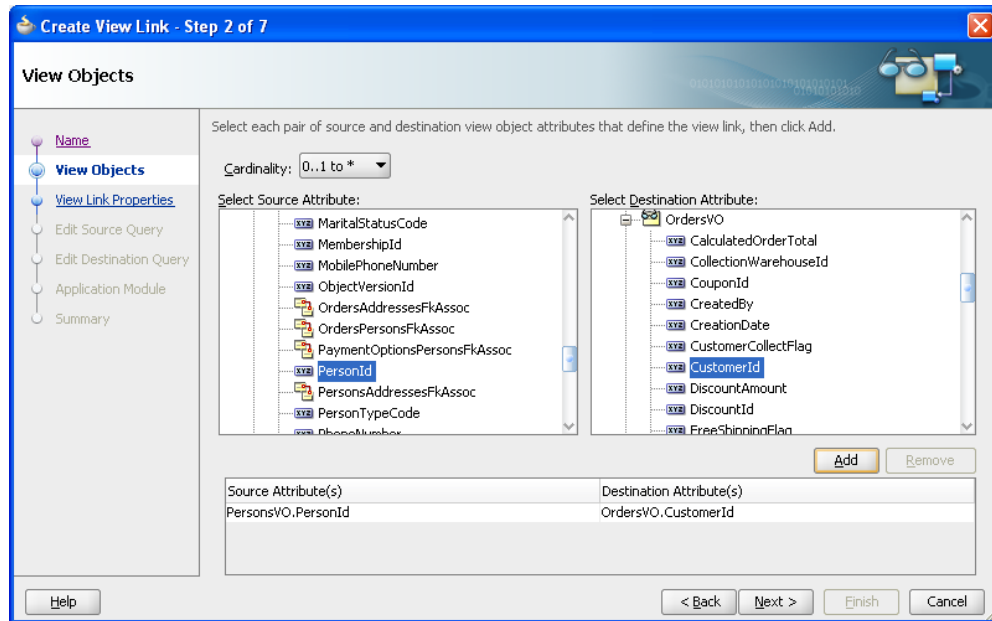

For example, [Figure 5–25](#) shows the `PersonId` attribute selected from the `PersonsVO` view object to perform this role. Click **Next**.

5. On the View Objects page, select a corresponding destination attribute from the view object that will act as the detail.

For example, if you want the detail query to show orders that were placed by the currently selected customer, select the `CustomerId` attribute in the `OrdersVO` to perform this role.

6. Click **Add** to add the matching attribute pair to the table of source and destination attribute pairs below. When you are finished defining master and detail link, click **Next**.

[Figure 5–25](#) shows just one (`PersonId,CustomerId`) pair. However, if you require multiple attribute pairs to define the link between master and detail, repeat the steps for the View Objects page to add additional source-target attribute pairs.

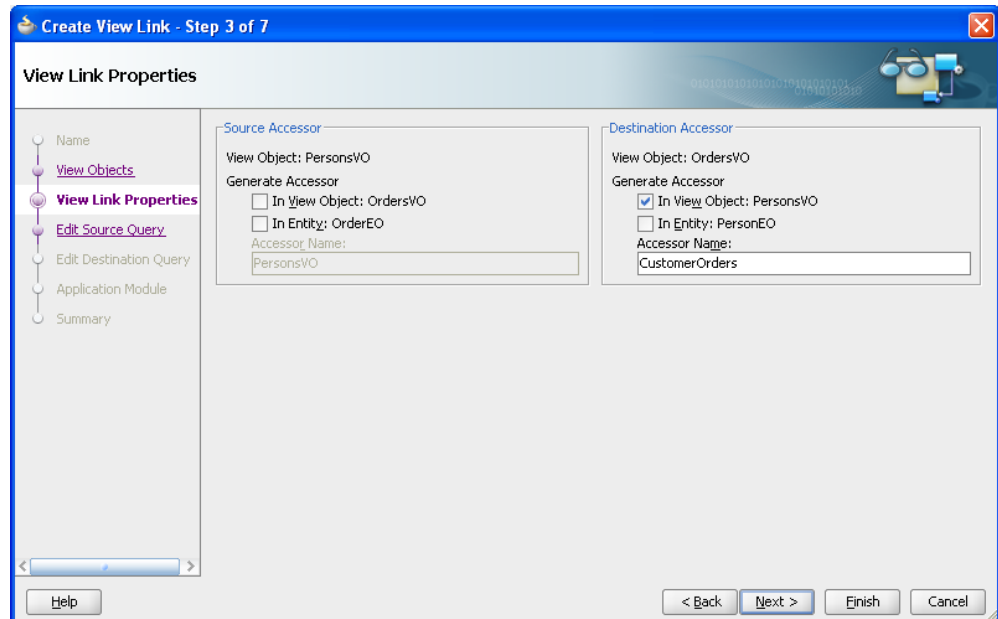

**Figure 5–25 Defining Source/Target Attribute Pairs While Creating a View Link**

7. On the View Link Properties page, you can use the **Accessor Name** field to change the default name of the accessor that lets you programmatically access the destination view object.

By default, the accessor name will match the name of the destination view object. For example, you might change the default accessor name `OrdersVO` to `CustomerOrders` to better describe the master-detail relationship that the accessor defines.

8. Also on the View Link Properties page, you control whether the view link represents a one-way relationship or a bidirectional one.

By default, a view link is a one-way relationship that allows the current row of the source (master) to access a set of related rows in the destination (detail) view object. For example, in Figure 5–26, the checkbox settings indicate that you'll be able to access a detail collection of rows from `OrdersVO` for the current row in `PersonsVO`, but not vice versa. In this case, this behavior is specified by the checkbox setting in the **Destination Accessor** group box for the `OrdersVO` (the **Generate Accessor In View Object: PersonsVO** box is selected) and checkbox setting in the **Source Accessor** group box for `PersonsVO` (the **Generate Accessor In View Object: OrdersVO** box is not selected).

**Figure 5–26 View Link Properties Control Name and Direction of Accessors**

9. On the Edit Source Query page, preview the view link SQL predicate that will be used at runtime to access the master row in the source view object and click **Next**.
10. On the Edit Destination Query page, preview the view link SQL predicate that will be used at runtime to access the correlated detail rows from the destination view object for the current row in the source view object and click **Next**.
11. On the Application Module page, add the view link to the data model for the desired application module and click **Finish**.

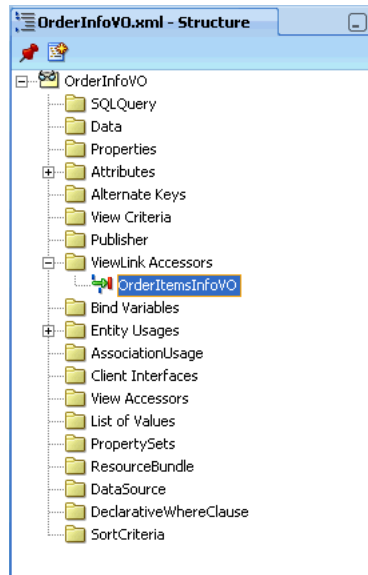

By default the view link will not be added to the application module's data model. Later you can add the view link to the data model using the overview editor for the application module.

### 5.6.3 What Happens When You Create Master-Detail Hierarchies Using View Links

When you create a view link or an association-based view link, JDeveloper creates the XML document file that represents its declarative settings and saves it in the directory that corresponds to the name of its package. For example, if the view link is named `OrderInfoToOrderItemsInfo` and it appears in the `queries.links` package, then the XML file created will be

`./queries/link/OrderInfoToOrderItemsInfo.xml` under the project's source path. This XML file contains the declarative information about the source and target attribute pairs you've specified and, in the case of an association-based view link, contains the declarative information about the association that relates the source and target view objects you've specified.

In addition to saving the view link component definition itself, JDeveloper also updates the XML definition of the *source* view object in the view link relationship to add information about the view link accessor you've defined. As a confirmation of this, you can select the source view object in the Application Navigator and inspect its details in the Structure window. As shown in [Figure 5–27](#), you can see the defined accessor in the **ViewLink Accessors** node for the `OrderItemsInfoVO` source view object of the `OrderInfoToOrderItemsInfo` view link.

**Figure 5–27 View Object with View Link Accessor in the Structure Window**

## 5.6.4 How to Enable Active Master-Detail Coordination in the Data Model

When you enable programmatic navigation to a row set of correlated details by defining a view link as described in [Section 5.6.1, "How to Create a Master-Detail Hierarchy for Entity-Based View Objects,"](#) the view link plays a *passive* role, simply defining the information necessary to retrieve the coordinated detail row set when your code requests it. The view link accessor attribute is present and programmatically accessible in any result rows from any instance of the view link's source view object. In other words, programmatic access does not require modifying the application module's data model.

However, since master-detail user interfaces are such a frequent occurrence in enterprise applications, the view link can be also used in a more *active* fashion so you can avoid needing to coordinate master-detail screen programmatically. You opt to have this active master-detail coordination performed by *explicitly* adding an instance of a view-linked view object to your application module's data model.

To enable active master-detail coordination, open the application module in the overview editor and select the Data Model page.

### Before you begin:

Create the desired view objects as described in [Section 5.2.1, "How to Create an Entity-Based View Object"](#) and [Section 5.2.3, "How to Create an Expert Mode, Read-Only View Object."](#)

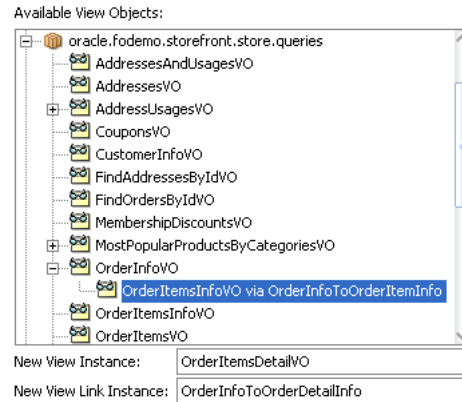

### To add a detail instance of a view object:

1. In the Application Navigator, double-click the application module.
2. In the overview editor, click the **Data Model** navigation tab.
3. In the Data Model page, expand the **View Object Instances** section and, in the **Available View Objects** list, select the detail view object node that is indented beneath the master view object.

Note that the list shows the detail view object *twice*: once on its own, and once as a detail view object via the view link. For example, in [Figure 5–28](#) you would select

the detail view object `OrderItemsInfoVO` via `OrderInfoToOrderItemInfo` instead of the view object labeled as `OrderItemsInfoVO` (which, in this case, appears beneath the highlighted view object).

**Figure 5–28** *Detail View Object Selection from Available View Objects*

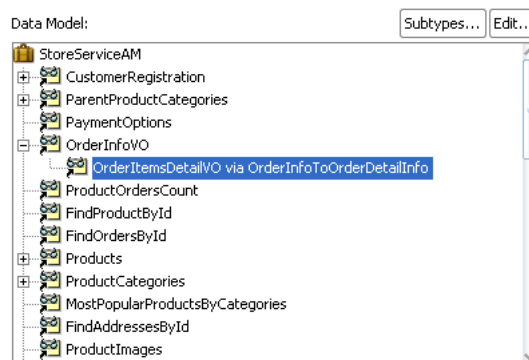

4. Enter a name for the detail instance you're about to create in the **Name View Instance** field below the **Available View Objects** list.

For example, [Figure 5–28](#) shows the name `OrderItemsDetailVO` for the instance of the `OrderItemsInfoVO` view object that is a detail view.

5. In the **Data Model** list, select the instance of the view object that you want to be the actively-coordinating master.
6. Click **Add Instance** to add the detail instance to the currently selected master instance in the data model, with the name you've chosen.

For example, in [Figure 5–29](#), the **Data Model** list shows a master-detail hierarchy of view object instances with `OrderItemsDetailVO` as the detail view object.

**Figure 5–29** *Data Model with View Linked View Object*

## 5.6.5 How to Test Master-Detail Coordination

To test active master-detail coordination, launch the Business Component Browser on the application module by choosing **Run** from its context menu in the Application Navigator. The Business Component Browser data model tree shows the view link instance that is actively coordinating the detail view object instance with the master view object instance. You can double-click the view link instance node in the tree to

open a master-detail data view page in the Business Component Browser. Then, when you use the toolbar buttons to navigate in the master view object — changing the view object's current row as a result — the coordinated set of details is automatically refreshed and the user interface stays in sync.

If you double-click another view object that is not defined as a master and detail, a second tab will open to show its data; in that case, since it is not actively coordinated by a view link, its query is not constrained by the current row in the master view object.

For information about editing the data model and running the Business Component Browser, see [Section 6.3, "Testing View Object Instances Using the Business Component Browser."](#)

## 5.6.6 How to Access the Detail Collection Using the View Link Accessor

To work with view links effectively, you should also understand that view link accessor attributes return a `RowSet` object and that you can access a detail collection using the view link accessor programmatically.

### 5.6.6.1 Accessing Attributes of Row by Name

At runtime, the `getAttribute()` method on a `Row` object allows you to access the value of any attribute of that row in the view object's result set by name. The view link accessor behaves like an additional attribute in the current row of the source view object, so you can use the same `getAttribute()` method to retrieve its value. The only practical difference between a regular view attribute and a view link accessor attribute is its data type. Whereas a regular view attribute typically has a scalar data type with a value like `303` or `ngreenbe`, the value of a view link accessor attribute is a row set of zero or more correlated detail rows. Assuming that `curUser` is a `Row` object from some instance of the `Orders` view object, you can write a line of code to retrieve the detail row set of order items:

```
RowSet items = (RowSet)curUser.getAttribute("OrderItems");
```

---

**Note:** If you generate the custom Java class for your view row, the type of the view link accessor will be `RowIterator`. Since at runtime the return value will always be a `RowSet` object, it is safe to cast the view link attribute value to `RowSet`.

---

### 5.6.6.2 Programmatically Accessing a Detail Collection Using the View Link Accessor

Once you've retrieved the `RowSet` object of detail rows using a view link accessor, you can loop over the rows it contains just as you would loop over a view object's row set of results, as shown in [Example 5-8](#).

#### **Example 5-8 Programmatically Accessing a Detail Collection**

```
while (items.hasNext()) {
    Row curItem = items.next();
    System.out.println("--> (" + curItem.getAttribute("LineItemId") + ") " +
        curItem.getAttribute("LineItemTotal"));
}
```

For information about creating a test client, see [Section 6.4.6, "How to Access a Detail Collection Using the View Link Accessor."](#)

## 5.7 Working with a Single Table in a Recursive Master-Detail Hierarchy

A recursive data model is one that utilizes a query that names source and destination attributes in a master-detail relationship based on a single table. In a typical master-detail relationship, the source attribute is supplied by the primary key attribute of the master view object and the destination attribute is supplied by foreign key attribute in the detail view object. For example, a typical master-detail relationship might relate the `DepartmentId` attribute on the `DEPARTMENT` table and the corresponding `DepartmentId` attribute on the `EMPLOYEE` table. However, in a recursive data model, the source attribute `EmployeeId` and the target attribute `ManagerId` both exist in the `EMPLOYEE` table. The query for this relationship therefore involves only a single view object. In this scenario, you create the view object for a single base entity object that specifies both attributes and then you define a self-referential view link to configure this view object as both the "source" and the "target" view object to form a master-detail hierarchy.

After you create the view link, there are two ways you can handle the recursive master-detail hierarchy in the data model project. You can either:

- Create a data model that exposes two instances of the same view object, one playing the role as master and the other playing the role as detail, actively coordinated by a view link instance. This can be useful when you anticipate needing to show a single level of master rows and detail rows at a time in two separate tables.
- Create a data model that exposes only a single instance of the view object, and use the view link accessor attribute in each row to access a row set of details. This is the more typical use case of the two because it allows you to display (or programmatically work with) the recursive master-detail hierarchy to any number of levels that exist in the data. For example, to show the recursive hierarchy in a `tree` or `treeTable` component, you would use this approach, as described in [Section 24.4.1, "How to Display Master-Detail Objects in Trees."](#)

### 5.7.1 How to Create a Recursive Master-Detail Hierarchy for an Entity-Based View Object

In a recursive master-detail hierarchy, the attributes of the view object that you select for the source and destination in the view link will typically be the same pair of attributes that define the self-referential association between the underlying entity object, if this association exists. While this underlying association is not required to create the view link, it does simplify the creation of the view link, so you will first create a foreign key association for the base entity object of the view object.

To create an association, you use the Create Association wizard. Then the association will appear as a selection choice when you use the Create View Link wizard. The view link will be self-referential because the association you select for the source and the destination view object names the *same* entity object, which is derived from a single database table.

#### Before you begin:

- When you create the view link JDeveloper won't be able to infer the association between the source and destination attributes of the entity object. To support the recursive hierarchy, you can use the Create Association wizard to create an association between the source attribute and the destination attribute. On the Entity Objects page, select the same entity object to specify the source and destination attributes and leave all other default selections unchanged in the

wizard. For details about creating an association, see [Section 4.3, "Creating and Configuring Associations."](#)

For example, assume the recursive master-detail hierarchy displays a list of employees based on their management hierarchy. In this scenario, you would create the association based on the `Employees` entity object. On the Entity Objects page of the Create Association wizard, you would select `Employees.EmployeeId` as the source attribute and `Employee.ManagerId` as the destination attribute. The entity object `Employees` supplies both attributes to ensure the association is self-referential.

- Create the entity-based view object and create a view criteria that will filter the view instance's results to include only those rows you want to see at the "root" of the hierarchy. To create a view criteria that uses a bind variable to filter the view object, see [Section 5.11, "Working with Named View Criteria."](#)

For example, in a recursive hierarchy of managers and employees, you would create the entity-based view object `EmployeesView`. After you create the view object in the Create View Object wizard, you can use the Query page of the overview editor to create a bind variable and view criteria which allow you to identify the employee or employees that will be seen at the top of the hierarchy. If only a single employee should appear at the root of the hierarchy, then the view criteria in this scenario will filter the employees using a bind variable for the employee ID (corresponding to the source attribute) and the `WHERE` clause shown in the Create View Criteria dialog would look like `( (Employees.EMPLOYEE_ID = :TheEmployeeId ) )`, where `TheEmployeeId` is the bind variable name. For more information on creating a view criteria that uses a bind variable to filter the view object, see [Section 5.13.2.1, "Creating a Data Source View Object to Control the Cascading List."](#)

When you are ready to expose the employees view object in your project's data model, you will configure the view instance in the data model to use this view criteria to filter the initial employee in the root of the tree. You'll configure the bind variable to specify the employee ID of the employee that you want to be the root value of the entire hierarchy. For example, the root value of the recursive hierarchy of managers and employees would be the employee ID of the highest level manager in the organization.

#### To create an association-based, self-referential view link:

1. In the Application Navigator, right-click the project in which you want to create the view object and choose **New**.

To avoid having to type in the package name in the Create View Link wizard, you can choose **New View Link** on the context menu of the `links` package node in the Application Navigator.

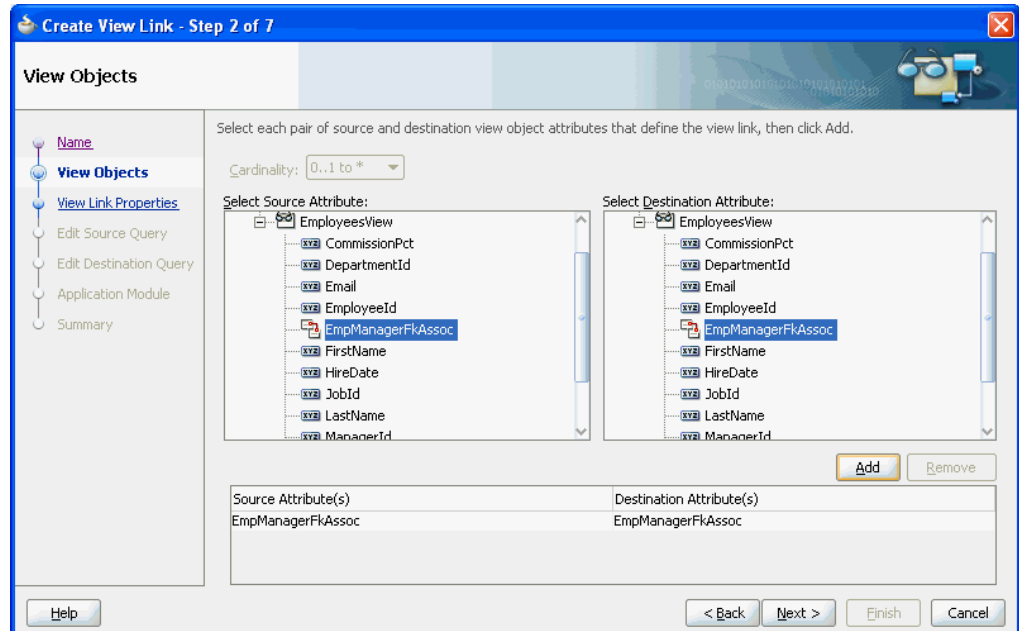

2. In the New Gallery, expand **Business Tier**, select **ADF Business Components** and then **View Link**, and click **OK**.
3. In the Create View Link wizard, on the Name page, supply a package and a component name.
4. On the View Objects page, in the **Select Source Attribute** tree expand the source view object in the desired package. In the **Select Destination Attribute** tree expand the destination view object.

For entity-based view objects, notice that in addition to the view object attributes, relevant associations also appear in the list.

5. Select the same association in both **Source** and **Destination** trees. Then click **Add** to add the association to the table below.

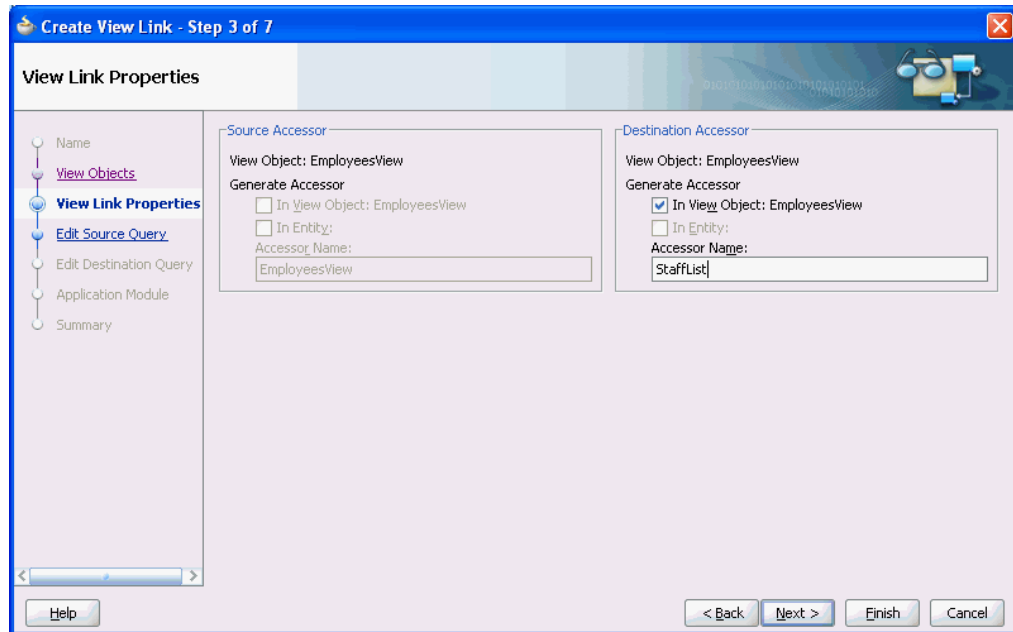

For example, [Figure 5–30](#) shows the same `EmpManagersFkAssoc` association in both **Source** and **Destination** trees selected. The view link is self-referential because the definition of the association names the source and destination attribute on the *same* entity object (in this case, `Employees`).

**Figure 5–30 Master and Detail Related by a Self-Referential Association Selection**

6. On the View Link Properties page, leave the default selections unchanged, but edit the accessor name of the destination accessor to provide a meaningful name.

For example, [Figure 5–31](#) shows the destination accessor has been renamed from `EmployeesView` to `StaffList`. This name will be exposed in the binding editor when the user interface developer populates the ADF Faces tree component by selecting this accessor. The name you provide will make clear to the UI developer the purpose of the accessor; in this case, to generate a list of employees associated with each manager.

**Figure 5–31 Renamed Destination Accessor in View Link**

7. Click **Finish**.

**To define the view object instance in an existing application module:**

1. In the Application Navigator, double-click the application module.
2. In the overview editor, click the **Data Model** navigation tab.
3. In the Data Model page, expand the **View Object Instances** section and, in the **Available View Objects** list, select the view object definition that you defined the view criteria to filter.

The **New View Instance** field below the list shows the name that will be used to identify the next instance of that view object that you add to the data model.

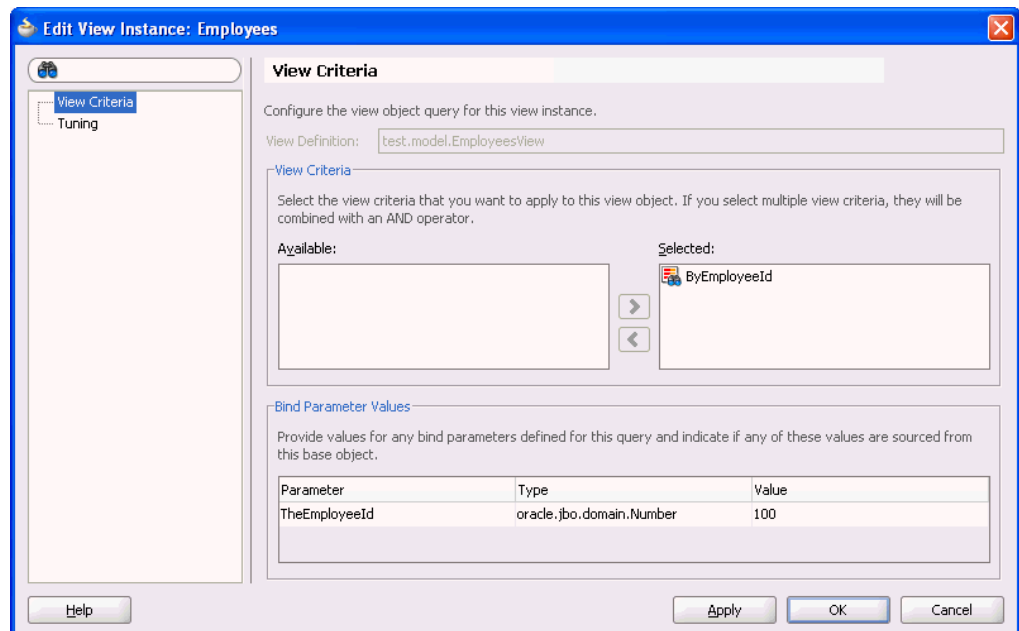

4. To change the name before adding it, enter a different name in the **New View Instance** field.
5. With the desired view object selected, shuttle the view object to the **Data Model** list.

Figure 5–32 shows the view object `EmployeesView` has been renamed to `Employees` before it was shuttled to the **Data Model** list.

**Figure 5–32 Data Model Displays Added View Object Instance**

6. To filter the view object instance so that you specify the root value of the hierarchy, select the view object instance you added and click **Edit**.
7. In the Edit View Instance dialog, shuttle the view criteria you created to the **Selected** list and enter the bind parameter value that corresponds to the root of the hierarchy.

Figure 5–33 shows the view object `ByEmployeeId` view criteria with the bind parameter `TheEmployeeId` set to the value 100 corresponding to the employee that is at the highest level of the hierarchy.

**Figure 5–33 View Criteria Filters View Instance**

8. Click **OK**.

## 5.7.2 What Happens When You Create a Recursive Master-Detail Hierarchy

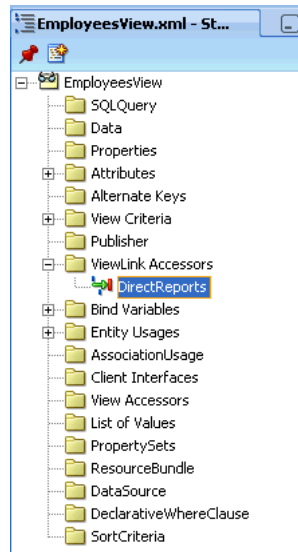

When you create a self-referential view link, JDeveloper creates the XML document file that represents its declarative settings and saves it in the directory that corresponds to the name of its package. This XML file contains the declarative information about the source and target attribute pairs that the association you selected specifies and contains the declarative information about the association that relates the source and target view object you selected.

[Example 5–9](#) shows how the `EmpManagerFkLink` defines the same view object `EmployeesView` for the source and destination in its XML document file.

### **Example 5–9 Self-Referential View Link Defined in XML**

```
<ViewLink
  xmlns="http://xmlns.oracle.com/bc4j"
  Name="EmpManagerFkLink"
  Version="11.1.1.53.5"
  EntityAssociation="test.model.EmpManagerFkAssoc">
  <ViewLinkDefEnd
    Name="EmployeesView1"
    Cardinality="1"
    Owner="test.model.EmployeesView"
    Source="true">
    <DesignTime>
      <Attr Name="_finderName" Value="ManagerIdEmployeesView"/>
      <Attr Name="_isUpdateable" Value="true"/>
    </DesignTime>
    <AttrArray Name="Attributes">
      <Item Value="test.model.EmployeesView.EmployeeId"/>
    </AttrArray>
  </ViewLinkDefEnd>
  <ViewLinkDefEnd
    Name="EmployeesView2"
    Cardinality="-1"
    Owner="test.model.EmployeesView">
    <DesignTime>
      <Attr Name="_finderName" Value="DirectReports"/>
      <Attr Name="_isUpdateable" Value="true"/>
    </DesignTime>
    <AttrArray Name="Attributes">
      <Item Value="test.model.EmployeesView.ManagerId"/>
    </AttrArray>
  </ViewLinkDefEnd>
</ViewLink>
```

In addition to saving the view link component definition itself, JDeveloper also updates the XML definition of the view object to add information about the view link accessor you've defined. As a confirmation of this, you can select the view object in the Application Navigator and inspect its details in the Structure window. As shown in [Figure 5–34](#), you can see the defined accessor in the **ViewLink Accessors** node for the `EmployeesView` view object of the `EmpManagerFkLink` view link.

**Figure 5–34 View Object with View Link Accessor in the Structure Window**

## 5.8 Working with View Objects in Declarative SQL Mode

At runtime, when ADF Business Components works with JDBC to pass a query to the database and retrieve the result, the mechanism to retrieve the data is the SQL query. As an alternative to creating view objects that specify a SQL statement at design time, you can create entity-based view objects that contain no SQL statements. This capability of the ADF Business Components design time and runtime is known as *declarative SQL mode*. When the data model developer works with the wizard or editor for a view object in declarative SQL mode, they require no knowledge of SQL. In declarative SQL mode, the view object's metadata causes the ADF Business Components runtime to generate the SQL query statements as follows:

- Optionally, generates `SELECT` and `FROM` lists based on the rendered web page's databound UI components' usage of one or more entity objects' attributes

Specifying the runtime query statement based solely on databound UI component attribute usage is an optimization that you control at the level of each view object attribute by changing the attribute's `IsSelected` property setting. By default, the property setting is `IsSelected=true` for each attribute that you add to the view object in declarative SQL mode. The default setting specifies the added attribute will be selected in the SQL statement regardless of whether or not the attribute is exposed in the UI by a databound component. For details about changing the property setting to optimize the runtime query statement, see [Section 5.8.1, "How to Create Declarative SQL View Objects."](#)

- Optionally, generates a `WHERE` clause based on a view criteria that you add to the view object definition
- Optionally, generates an `ORDERBY` clause based on a sort criteria that you add to the view object definition.
- Optionally, augments the `WHERE` clause to support table joins based on named view criteria that you add to the view object definition
- Optionally, augments the `WHERE` clause to support master-detail view filtering based on a view criteria that you add to either the source or destination of a view link definition

Additionally, the SQL statement that a declarative SQL mode view object generates at runtime will be determined by the SQL flavor specified in the Business Components page of the Project Properties dialog.

---

---

**Note:** Currently, the supported flavors for runtime SQL generation are SQL92 (ANSI) style and Oracle style. For information about setting the SQL flavor for your project, see [Section 3.3.1, "Choosing a Connection, SQL Flavor, and Type Map."](#)

---

---

Declarative SQL mode selection is supported in JDeveloper as a setting that you can apply either to the entire data model project or to individual view objects that you create. The ADF Business Components design time also allows you to override the declarative SQL mode project-level setting for any view object you create.

The alternatives to declarative SQL mode are normal mode and expert mode. When you work in either of those modes, the view object definitions you create at design time always contain the entire SQL statement based on the SQL flavor required by your application module's defined database connection. Thus the capability of SQL independence does not apply to view objects that you create in normal or expert mode. For information about using the wizard and editor to customize view objects when SQL is desired at design time, see [Section 5.2, "Populating View Object Rows from a Single Database Table."](#)

### 5.8.1 How to Create Declarative SQL View Objects

All view objects that you create in JDeveloper rely on the same design time wizard and editor. However, when you enable declarative SQL mode, the wizard and editor change to support customizing the view object definition without requiring you to display or enter any SQL. For example, the Query page of the Create View Object wizard with declarative SQL mode enabled lacks the **Generated SQL** field present in normal mode.

Additionally, in declarative SQL mode, since the wizard and editor do not allow you to enter `WHERE` and `ORDERBY` clauses, you provide equivalent functionality by defining a view criteria and sort criteria respectively. In declarative SQL mode, these criteria appear in the view object metadata definition and will be converted at runtime to their corresponding SQL clause. When the databound UI component has no need to display filtered or sorted data, you may omit the view criteria or sort criteria from the view object definition.

Otherwise, after you enable declarative SQL mode, the basic procedure to create a view object with ensured SQL independence is the same as you would follow to create any entity-based view object. For example, you must still ensure that your view object encapsulates the desired entity object metadata to support the intended runtime query. As with any entity-based view object, the columns of the runtime-generated `FROM` list must relate to the attributes of one or more of the view object's underlying entity objects. In declarative SQL mode, you automatically fulfill this requirement when working with the wizard or editor when you add or remove the attributes of the entity objects on the view object definition.

If you prefer to optimize the declarative SQL query so that the `SELECT` and `FROM` clauses of the SQL query statement are based solely on whether or not the attributes you add to the view object are rendered at runtime by a databound UI component, then you must disable the **Selected in Query** checkbox (sets `IsSelected=false` for the view object definition) for all added attributes. By default, the `IsSelected` property is `true` for any attribute that you add to the view object in declarative SQL

mode. The default setting means the added attribute will be selected in the SQL statement regardless of whether or not the attribute is exposed by a databound UI component. When you create a new view object in declarative SQL mode, you can use the Attribute Settings page of the Create View Object wizard to change the setting for each attribute. If you need to alter this setting after you generate the view object, you can use the Property Inspector to change the **Selected in Query** property setting for one or more attributes that you select in the Attributes page of the view object editor.

**Performance Tip:** A view object instance configured to generate SQL statements dynamically will requery the database during page navigation if a subset of all attributes with the same list of key entity objects is used in the subsequent page navigation. Thus performance can be improved by activating a superset of all the required attributes to eliminate a subsequent query execution.

Thus there are no unique requirements for creating entity-based view objects in declarative SQL mode, nor does declarative SQL mode sacrifice any of the runtime functionality of the normal mode counterpart. You can enable declarative SQL mode as a global preference so that it is the Create View Object wizard's default mode, or you can leave the setting disabled and select the desired mode directly in the wizard. The editor for a view object also lets you select and change the mode for an existing view object definition.

#### To enable declarative SQL mode for all new view objects:

1. From the main menu, choose **Tools > Preferences**.
2. In the Preferences dialog, expand the **Business Components** node and choose **View Objects**.
3. On the Business Components: View Object page, select **Enable Declarative SQL mode for new objects** and click **OK**.

To predetermine how the FROM list will be generated at runtime you can select **Include all attributes in runtime-generated query**, as described in [Section 5.8.4, "How to Force Attribute Queries for Declarative SQL Mode View Objects."](#)

To create an entity-based view object in declarative SQL mode, use the Create View Object wizard, which is available from the New Gallery.

#### Before you begin:

Create the desired entity objects as described in [Section 4.2.1, "How to Create Multiple Entity Objects and Associations from Existing Tables."](#)

#### To create declarative SQL-based view objects:

1. In the Application Navigator, right-click the project in which you want to create the view objects and choose **New**.
2. In the New Gallery, expand **Business Tier**, select **ADF Business Components** and then **View Object**, and click **OK**.
3. On the Name page, enter a package name and a view object name. Keep the default setting **Updatable access through entity objects** enabled to indicate that you want this view object to manage data with its base entity object. Click **Next**.

Any other choice for the data selection will disable declarative SQL mode in the Create View Object wizard.

4. On the Entity Objects page, select the entity object whose data you want to use in the view object. Click **Next**.

When you want to create a view object that joins entity objects, you can add secondary entity objects to the list. To create more complex entity-based view objects, see [Section 5.5.1, "How to Create Joins for Entity-Based View Objects."](#)

5. On the Attributes page, select at least one attribute from the entity usage in the **Available** list and shuttle it to the **Selected** list. Attributes you do not select will not be eligible for use in view criteria and sort criteria. Click **Next**.

You should select any attribute that you intend to customize (in the Attribute Settings page) or any attributes that you intend to use in a view criteria or sort criteria (in the Query page). Additionally, the tables that appear in the FROM list of the runtime-generated query will be limited to the tables corresponding to the attributes of the entity objects you select.

6. On the Attribute Settings page, optionally, use the **Select Attribute** dropdown list to switch between the view object attributes in order to change their names or any of their initial settings.
7. Use the **Select Attribute** dropdown list to switch between the previously selected view object attributes and deselect **Selected in Query** for each attribute that you want to be selected in the SQL statement based solely on whether or not the attribute is rendered by a databound UI component. Click **Next**.

By default, the **Selected in Query** checkbox is enabled for all view object attributes that you add in declarative SQL mode. This default setting will generate a SQL statement with all added attributes selected. When you deselect the checkbox for an attribute, the `isSelected` property is set to `false` and whether or not the attribute is selected will be determined at runtime by the databound UI component's usage of the attribute.

8. On the Query page, select **Declarative** in the **Query Mode** dropdown list if it is not already displayed. The wizard changes to declarative SQL mode.

Changing the mode to **Declarative** in the wizard allows you to override the default mode for this single view object. If you did not select **Enable declarative SQL mode for new objects** in the Preferences dialog, the wizard displays the default query mode, **Normal**.

9. Optionally, define **Where** and **Order By** criteria to filter and order the data as required. At runtime, ADF Business Components automatically generates the corresponding SQL statements based on the criteria you create.

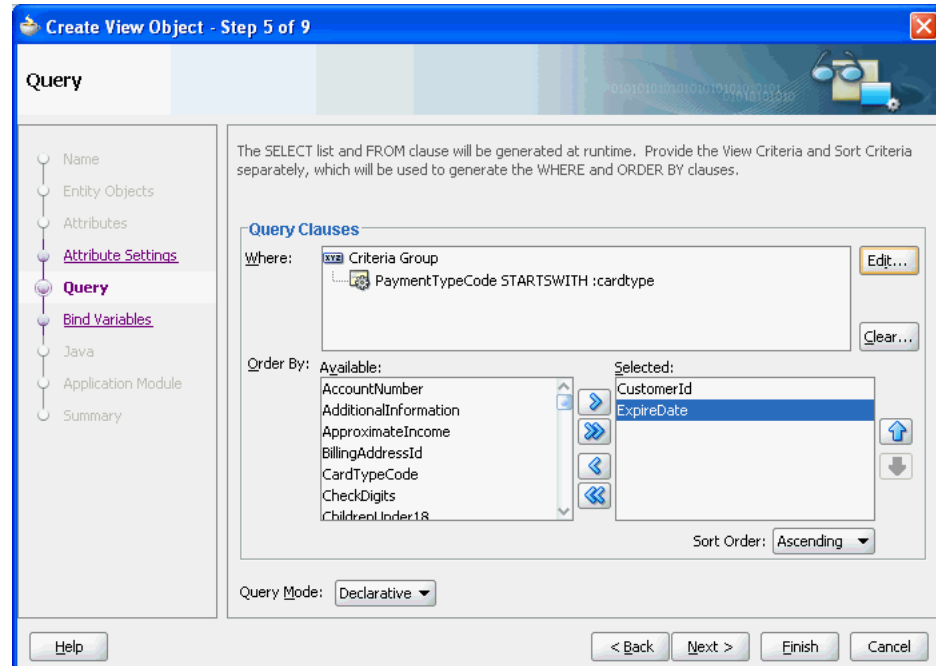

Click **Edit** next to the **Where** field to define the view criteria you will use to filter the data. The view criteria you enter will be converted at runtime to a WHERE clause that will be enforced on the query statement. For information about specifying view criteria, see [Section 5.11, "Working with Named View Criteria."](#)

In the **Order By** field select the desired attribute in the **Available** list and shuttle it to the **Selected** list. Attributes you do not select will not appear in the SQL ORDERBY clause generated at runtime. Add additional attributes to the **Selected** list when you want the results to be sorted by more than one column. Arrange the selected attributes in the list according to their sort precedence. Then for each sort attribute, assign whether the sort should be performed in ascending or descending order. Assigning the sort order to each attribute ensures that attributes ignored by the UI component still follow the intended sort order.

For example, as shown in [Figure 5-35](#), to limit the `CustomerCardStatus` view object to display only the rows in the `CUSTOMERS` table for customers with a

specific credit card code, the view criteria in the **Where** field limits the `CardTypeCode` attribute to a runtime-determined value. To order the data by customer ID and the customer's card expiration date, the **Order By** field identifies those attributes in the **Selected** list.

**Figure 5–35** *Creating View Object Wizard, Query Page with Declarative Mode Selected*

10. Click **Finish**.

## 5.8.2 How to Filter Declarative SQL-Based View Objects When Table Joins Apply

When you create an entity-based view object you can reference more than one entity object in the view object definition. In the case of view objects you create in declarative SQL mode, whether the base entity objects are activated from the view object definition will depend on the requirements of the databound UI component at runtime. If the UI component displays attribute values from multiple entity objects, then the SQL generated at runtime will contain a `JOIN` operation to query the appropriate tables.

Just as with any view object that you create, it is possible to filter the results from table joins by applying named view criteria. In the case of normal mode view objects, all entity objects and their attributes will be referenced by the view object definition and therefore will be automatically included in the view object's SQL statement. However, by delaying the SQL generation until runtime with declarative SQL mode, there is no way to know whether the view criteria should be applied.

---

**Note:** In declarative SQL mode, you can define a view criteria to specify the `WHERE` clause (optional) when you create the view object definition. This type of view criteria when it exists will always be applied at runtime. For a description of this usage of the view criteria, see [Section 5.8.1, "How to Create Declarative SQL View Objects."](#)

---

Because a SQL `JOIN` may not always result from a view object defined in declarative SQL mode with multiple entity objects, named view criteria that you define to filter query results should be applied conditionally at runtime. In other words, named view criteria that you create for declarative SQL-based view objects need not be applied as required, automatic filters. To support declarative SQL mode, named view criteria that you apply to a view object created in declarative SQL mode can be set to apply only on the condition that the UI component is bound to the attributes referenced by the view criteria. The named view criteria once applied will, however, support the UI component's need to display a filtered result set.

You use the Edit View Criteria dialog to create the named view criteria and enable its conditional usage by setting the `appliedIfJoinSatisfied` property in the Property Inspector.

**To define a view criteria to filter only when the join is satisfied:**

1. Create the view object with declarative SQL mode enabled as described in [Section 5.8.1, "How to Create Declarative SQL View Objects."](#)
2. In the Application Navigator, double-click the view object.
3. In the overview editor, click the **Query** navigation tab.
4. In Query page, expand the **View Criteria** section, and click the **Create new view criteria** button.
5. In the Create View Criteria dialog, create the view criteria as described in [Section 5.11.1, "How to Create Named View Criteria Declaratively."](#)
6. After creating the view criteria, select it in the **View Criteria** section of Query page of the overview editor.
7. With the view criteria selected, open the Property Inspector and set the `AppliedIfJoinSatisfied` property to **true**.

The property value **true** means you want the view criteria to be applied only on the condition that the UI component requires the attributes referenced by the view criteria. The default value **false** means that the view criteria will automatically be applied at runtime. In the case of declarative SQL mode-based view objects, the value **true** ensures that the query filter will be appropriate to needs of the view object's databound UI component.

### 5.8.3 How to Filter Master-Detail Related View Objects with Declarative SQL Mode

Just as with normal mode view objects, you can link view objects that you create in declarative SQL mode to other view objects to form master-detail hierarchies of any complexity. The steps to create the view links are the same as with any other entity-based view object, as described in [Section 5.6.1, "How to Create a Master-Detail Hierarchy for Entity-Based View Objects."](#) However, in the case of view objects that you create in declarative SQL mode, you can further refine the view object results in the Source SQL or Destination SQL dialog for the view link by selecting a previously defined view criteria in the Create View Link wizard or the overview editor for the view link.

**To define a view criteria for view link source or view link destination:**

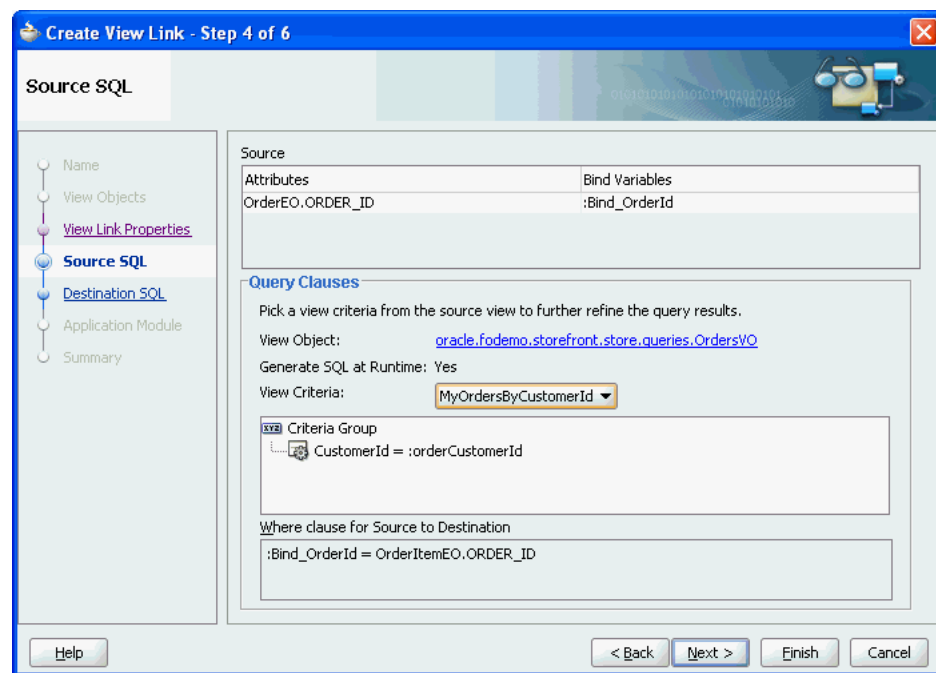

1. Create the view objects in declarative SQL mode as described in [Section 5.8.1, "How to Create Declarative SQL View Objects."](#)
2. In the overview editor for the view objects, define the desired view criteria for either the source (master) view object or the destination (detail) view object as

described in [Section 5.8.2, "How to Filter Declarative SQL-Based View Objects When Table Joins Apply."](#)

3. Create the view link as described in [Section 5.6.1, "How to Create a Master-Detail Hierarchy for Entity-Based View Objects"](#) and perform one of these additional steps:
  - On the SQL Source page, select a previously defined view criteria to filter the master view object. Click **Next**.
  - On the Destination SQL page, select a previously defined view criteria to filter the detail view object.

[Figure 5–35](#) shows a view criteria that filters the master view object based on customer IDs.

**Figure 5–36 Filtering a View Link in Declarative SQL Mode**

4. After you create the view link, you can also select a previously defined view criteria. In the overview editor navigation list, select **Query** and expand the **Source** or **Destination** sections. In the **View Criteria** dropdown list, select the desired view criteria. The dropdown list will be empty if no view criteria exist for the view object.

If the overview editor does not display a dropdown list for view criteria selection, then the view objects you selected for the view link were not created in declarative SQL mode. For view objects created in normal or expert mode, you must edit the WHERE clause to filter the data as required.

## 5.8.4 How to Force Attribute Queries for Declarative SQL Mode View Objects

Typically, when you define a declarative SQL mode view object, the attributes that get queried at runtime will be determined by the requirements of the databound UI component as it is rendered in the web page. This is the runtime-generation capability that makes view objects independent of the design time database's SQL flavor. However, you may also need to execute the view object programmatically without

exposing it to an ADF data binding in the UI. In this case, you can enable the **Include all attributes in runtime-generated query** option to ensure that a programmatically executed view object has access to all of the entity attributes.

---

---

**Note:** Be careful to limit the use of the **Include all attributes in runtime-generated query** option to programmatically executed view objects. If you expose the view object with this setting enabled to a databound UI component, the runtime query will include all attributes.

---

---

The **Include all attributes in runtime-generated query** option can be specified as a global preference setting or as a setting on individual view objects. Both settings may be used in these combinations:

- Enable the global preference so that every view object you create includes all attributes in the runtime query statement.
- Enable the global preference, but disable the setting on view objects that will not be executed programmatically and therefore should not include all attributes in the runtime query statement.
- Disable the global preference (default), but enable the setting on view objects that will be executed programmatically and therefore should include all attributes in the runtime query statement.

**To set the global preference to include all attributes in the query:**

1. From the main menu, choose **Tools > Preferences**.
2. In the Preferences dialog, expand **Business Components** and select **View Objects**.
3. On the Business Components: View Object page, select **Enable Declarative SQL mode for new objects**.
4. Select **Include all attributes in runtime-generated query** to force all attributes of the view object's underlying entity objects to participate in the query and click **OK**.

Enabling this option sets a flag in the view object definition but you will still need to add entity object selections and entity object attribute selections to the view object definition.

You can change the view object setting in the **Tuning** section of the overview editor's General page. The overview editor only displays the **Include all attributes in runtime-generated query** option if you have created the view object in declarative SQL mode.

**To set the view object-specific preference to include all attributes in the query:**

1. When you want to force all attributes for specific view objects, create the view object in the Create View Object wizard and be sure that you have enabled declarative SQL mode.

You can verify this in the overview editor. In the overview editor, click the **Query** navigation tab and click the **Edit SQL Query** button along the top of the page. In the Edit Query dialog, verify that the **SQL Mode** dropdown list shows the selection **Declarative**.

2. In the overview editor, click the **General** navigation tab.

3. In the General page, expand the **Tuning** section and select **Include all attributes in runtime-generated query**.

Enabling this option forces all attributes of the view object's underlying entity objects to participate in the query. When enabled, it sets a flag in the view object definition but you will still need to add entity object selections and entity object attribute selections to the view object definition.

### 5.8.5 What Happens When You Create a View Object in Declarative SQL Mode

When you create the view object in declarative SQL mode, three properties get added to the view object's metadata: `SelectListFlags`, `FromListFlags`, and `WhereFlags`. Properties that are absent in declarative SQL mode are the normal mode view object's `SelectList`, `FromList`, and `Where` properties, which contain the actual SQL statement (or, for expert mode, the `SQLQuery` element). [Example 5-10](#) shows the three view object metadata flags that get enabled in declarative SQL mode to ensure that SQL will be generated at runtime instead of specified as metadata in the view object's definition.

#### **Example 5-10 View Object Metadata with Declarative SQL Mode Enabled**

```
<ViewObject
  xmlns="http://xmlns.oracle.com/bc4j"
  Name="CustomerCardStatus"
  SelectListFlags="1"
  FromListFlags="1"
  WhereFlags="1"
  ...
```

Similar to view objects that you create in either normal or expert mode, the view object metadata also includes a `ViewAttribute` element for each attribute that you select in the Attribute page of the Create View Object wizard. However, in declarative SQL mode, when you "select" attributes in the wizard (or add an attribute in the overview editor), you are not creating a `FROM` or `SELECT` list in the design time. The attribute definitions that appear in the view object metadata only determine the list of potential entities and attributes that will appear in the runtime-generated statements. For information about how ADF Business Components generates these SQL lists, see [Section 5.8.6, "What Happens at Runtime: When a Declarative SQL Mode Query is Generated."](#)

[Example 5-11](#) shows the additional features of declarative SQL mode view objects, including the optional declarative `WHERE` clause (`DeclarativeWhereClause` element) and the optional declarative `ORDERBY` clause (`SortCriteria` element).

#### **Example 5-11 View Object Metadata: Declarative View Criteria and Sort Criteria**

```
<DeclarativeWhereClause>
  <ViewCriteria
    Name="CustomerStatusWhereCriteria"
    ViewObjectName="oracle.fodemo.storefront.store.queries.CustomerCardStatus"
    Conjunction="AND"
    Mode="3"
    AppliedIfJoinSatisfied="false">
    <ViewCriteriaRow
      Name="vcrow60">
      <ViewCriteriaItem
        Name="CardTypeCode"
        ViewAttribute="CardTypeCode"
        Operator="STARTSWITH"
```

```

        Conjunction="AND"
        Required="Optional">
    <ViewCriteriaItemValue
        Value=":cardtype"
        IsBindVarValue="true" />
    </ViewCriteriaItem>
</ViewCriteriaRow>
</ViewCriteria>
</DeclarativeWhereClause>
<SortCriteria>
    <Sort
        Attribute="CustomerId" />
<Sort
        Attribute="CardTypeCode" />
</SortCriteria>

```

### 5.8.6 What Happens at Runtime: When a Declarative SQL Mode Query is Generated

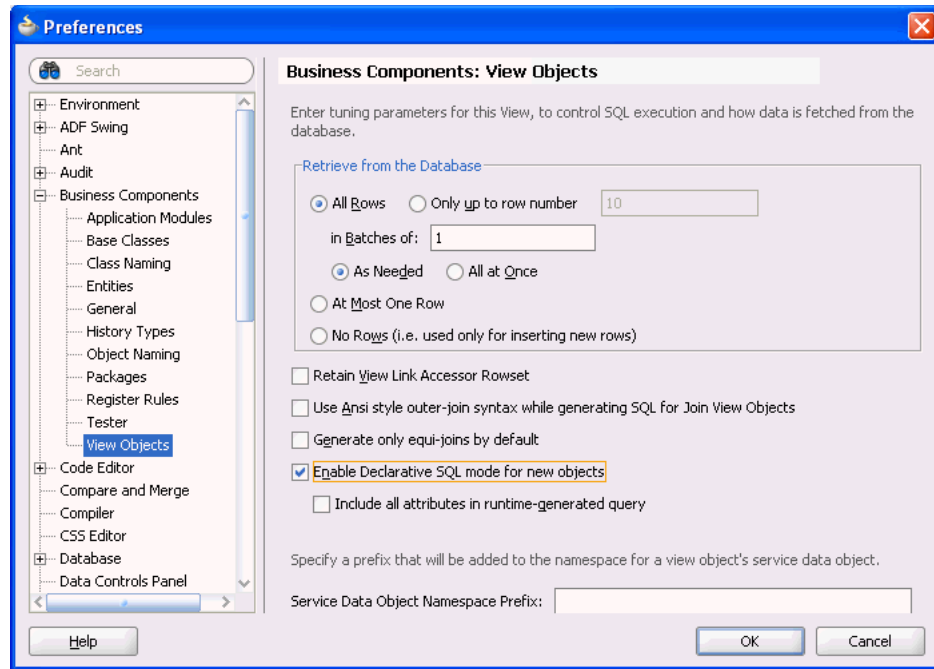

At runtime, when a declarative SQL mode query is generated, ADF Business Components determines which attributes were defined from the metadata `ViewCriteria` element and `SortCriteria` element. It then uses these attributes to generate the `WHERE` and `ORDERBY` clauses. Next, the runtime generates the `FROM` list based on the tables corresponding to the entity usages defined by the metadata `ViewAttribute` elements. Finally, the runtime builds the `SELECT` statement based on the attribute selection choices the end user makes in the UI. As a result, the view object in declarative SQL mode generates all SQL clauses entirely at runtime. The runtime-generated SQL statements will be based on the flavor that appears in the project properties setting. Currently, the runtime supports SQL92 (ANSI) style and Oracle style flavors.

### 5.8.7 What You May Need to Know About Overriding Declarative SQL Mode Defaults

JDeveloper lets you control declarative SQL mode for all new view objects you add to your data model project or for individual view objects you create or edit. These settings may be used in these combinations:

- Enable the global preference in the Preferences dialog (select **Tools > Preferences**). Every view object you create will delay SQL generation until runtime. [Figure 5-37](#) shows the global preference **Enable declarative SQL for new objects** set to enabled.
- Enable the global preference in the Preferences dialog, but change the SQL mode for individual view objects. In this case, unless you change the SQL mode, the view objects you create will delay SQL generation until runtime.
- Disable the global preference (default) in the Preferences dialog, but select declarative SQL mode for individual view objects. In this case, unless you change the SQL mode, view objects you create will contain SQL statements.

**Figure 5–37 Preferences Dialog with Declarative SQL Mode Enabled**

To edit the SQL mode for a view object you have already created, open the Query page in the Edit Query dialog and select **Declarative** from the **SQL Mode** dropdown list. To display the Edit Query dialog, open the view object in the overview editor, select **Query** from the navigation list and click the **Edit SQL Query** button. The same option appears in the Query page of the Create View Object wizard.

## 5.8.8 What You May Need to Know About Working Programmatically with Declarative SQL Mode View Objects

As a convenience to developers, the view object implementation API allows individual attributes to be selected and deselected programmatically. This API may be useful in combination with the view objects you create in declarative SQL mode and intend to execute programmatically. [Example 5–12](#) shows how to call `selectAttributeDefs()` on the view object when you want to add a subset of attributes to those already configured with SQL mode enabled.

### **Example 5–12 ViewObjectImpl API with SQL Mode View Objects**

```
ApplicationModule am = Configuration.createRootApplicationModule(amDef, config);
ViewObjectImpl vo = (ViewObjectImpl) am.findViewObject("CustomerVO");
vo.resetSelectedAttributeDefs(false);
vo.selectAttributeDefs(new String[] {"FirstName", "LastName"});
vo.executeQuery();
```

The call to `selectAttributeDefs()` adds the attributes in the array to a private member variable of `ViewObjectImpl`. A call to `executeQuery()` transfers the attributes in the private member variable to the actual select list. It is important to understand that these `ViewObjectImpl` attribute calls are not applicable to the client layer and are only accessible inside the `Impl` class of the view object on the middle tier.

Additionally, you might call `unselectAttributeDefs()` on the view object when you want to deselect a small subset of attributes after *enabling* the **Include all**

**attributes in runtime-generated query** option. Alternatively, you can call `selectAttributeDefs()` on the view object to select a small subset of attributes after *disabling* the **Include all attributes in runtime-generated query** option.

---

**Caution:** Be careful not to expose a declarative SQL mode view object executed with this API to the UI since only the value of the **Include all attributes in runtime-generated query** option will be honored.

---

## 5.9 Working with View Objects in Expert Mode

When defining entity-based view objects in Normal mode, you can fully specify the `WHERE` and `ORDER BY` clauses, whereas, by default, the `FROM` clause and `SELECT` list are automatically derived. The names of the tables related to the participating entity usages determine the `FROM` clause, while the `SELECT` list is based on the:

- Underlying column names of participating entity-mapped attributes
- SQL expressions of SQL-calculated attributes

When you require full control over the `SELECT` or `FROM` clause in a query, you can enable expert mode.

**Tip:** The view object editors and wizard in the JDeveloper provide full support for generating SQL from choices that you make. For example, two such options allow you to declaratively define outer joins and work in declarative SQL mode (where no SQL is generated until runtime).

### 5.9.1 How to Customize SQL Statements in Expert Mode

To enable expert mode, select **Expert Mode** from the **SQL Mode** dropdown list on the Query panel of the Create View Object wizard. You can also modify the SQL statement of an existing entity-based view object in the view object overview editor. In the overview editor, navigate to the Query page and click the **Edit SQL Query** button. In the Edit Query dialog, select **Expert Mode** from the **SQL Mode** dropdown list.

### 5.9.2 How to Name Attributes in Expert Mode

If your SQL query includes a calculated expression, use a SQL alias to assist the Create View Object wizard in naming the column with a Java-friendly name. [Example 5-13](#) shows a SQL query that includes a calculated expression.

**Example 5-13 SQL Query with Calculated Expression**

```
select PERSON_ID, EMAIL,
       SUBSTR(FIRST_NAME,1,1) || '.' || LAST_NAME
from PERSONS
order by EMAIL
```

[Example 5-14](#) uses a SQL alias `USER_SHORT_NAME` to assist the Create View Object wizard in naming the column with a Java-friendly name. The wizard will display `UserShortName` as the name of the attribute derived from this calculated expression.

**Example 5-14 SQL Query with SQL Alias**

```
select PERSON_ID, EMAIL,
```

```

SUBSTR(FIRST_NAME,1,1) || '. ' || LAST_NAME AS USER_SHORT_NAME
from PERSONS
order by EMAIL

```

### 5.9.3 What Happens When You Enable Expert Mode

When you enable expert mode, the read-only **Generated Statement** section of the Query page becomes a fully editable **Query Statement** text box, displaying the full SQL statement. Using this text box, you can change every aspect of the SQL query.

For example, [Figure 5–38](#) shows the Query page of the Edit Query dialog for the OrderItems view object. It's an expert mode, entity-based view object that references a PL/SQL function `decode` that obtains its input values from an expression set on the `ShippingCost` attribute.

**Figure 5–38** OrderItems Expert Mode View Object

### 5.9.4 What You May Need to Know About Expert Mode

When you define a SQL query using expert mode in the Edit Query dialog, you type a SQL language statement directly into the editor. Using this mode places some responsibility on the Business Components developer to understand how the view object handles the metadata resulting from the query definition. Review the following information to familiarize yourself with the behavior of the Edit Query dialog that you use in expert mode.

#### 5.9.4.1 Expert Mode Provides Limited Attribute Mapping Assistance

The automatic cooperation of a view object with its underlying entity objects depends on correct attribute-mapping metadata saved in the XML document. This information relates the view object attributes to corresponding attributes from participating entity usages. JDeveloper maintains this attribute mapping information in a fully automatic way for normal entity-based view objects. However, when you decide to use expert mode with a view object, you need to pay attention to the changes you make to the

`SELECT` list. That is the part of the SQL query that directly relates to the attribute mapping. Even in expert mode, JDeveloper continues to offer some assistance in maintaining the attribute mapping metadata when you do the following to the `SELECT` list:

- Reorder an expression without changing its column alias  
JDeveloper reorders the corresponding view object attribute and maintains the attribute mapping.
- Add a new expression  
JDeveloper adds a new SQL-calculated view object attribute with a corresponding camel-capped name based on the column alias of the new expression.
- Remove an expression  
JDeveloper converts the corresponding SQL-calculated or entity-mapped attribute related to that expression to a transient attribute.

However, if you rename a column alias in the `SELECT` list, JDeveloper has no way to detect this, so it is treated as if you removed the old column expression and added a new one of a different name.

After making any changes to the `SELECT` list of the query, visit the Attribute Mappings page to ensure that the attribute-mapping metadata is correct. The table on this page, which is disabled for view objects in normal mode, becomes enabled for expert mode view objects. For each view object attribute, you will see its corresponding SQL column alias in the table. By clicking into a cell in the **View Attributes** column, you can use the dropdown list that appears to select the appropriate entity object attribute to which any entity-mapped view attributes should correspond.

---

---

**Note:** If the view attribute is SQL-calculated or transient, a corresponding attribute with a "SQL" icon appears in the **View Attributes** column to represent it. Since neither of these type of attributes are related to underlying entity objects, there is no entity attribute related information required for them.

---

---

#### 5.9.4.2 Expert Mode Drops Custom Edits

When you disable expert mode for a view object, it will return to having its `SELECT` and `FROM` clause be derived again. JDeveloper warns you that doing this might cause your custom edits to the SQL statement to be lost. If this is what you want, after acknowledging the alert, your view object's SQL query reverts back to the default.

#### 5.9.4.3 Expert Mode Ignores Changes to SQL Expressions

Consider a `Products` view object with a SQL-calculated attribute named `Shortens` whose SQL expression you defined as `SUBSTR(NAME, 1, 10)`. If you switch this view object to expert mode, the **Query Statement** box will show a SQL query similar to the one shown in [Example 5-15](#).

##### **Example 5-15 SQL-Calculated Attribute Expression in Expert Mode**

```
SELECT Products.PROD_ID,
       Products.NAME,
       Products.IMAGE,
       Products.DESCRPTION,
       SUBSTR(NAME,1,10) AS SHORT_NAME
```

```
FROM PRODUCTS Products
```

If you go back to the attribute definition for the `Shortens` attribute and change the **SQL Expression** field from `SUBSTR (NAME, 1, 10)` to `SUBSTR (NAME, 1, 15)`, then the change will be saved in the view object's XML document. Note, however, that the SQL query in the **Query Statement** box will remain as the original expression. This occurs because JDeveloper never tries to *modify* the text of an expert mode query. In expert mode, the developer is in full control. JDeveloper attempts to adjust metadata as a result of some kinds of changes you make yourself to the expert mode SQL statement, but it does not perform the reverse. Therefore, if you change view object metadata, the expert mode SQL statement is not updated to reflect it.

Therefore, you need to update the expression in the expert mode SQL statement itself. To be completely thorough, you should make the change *both* in the attribute metadata *and* in the expert mode SQL statement. This would ensure — if you (or another developer on your team) ever decides to toggle expert mode *off* at a later point in time — that the automatically derived `SELECT` list would contain the correct SQL-derived expression.

---

**Note:** If you find you had to make numerous changes to the view object metadata of an expert mode view object, you can avoid having to manually translate any effects to the SQL statement by copying the text of your customized query to a temporary backup file. Then, you can disable expert mode for the view object and acknowledge the warning that you will lose your changes. At this point JDeveloper will rederive the correct generated SQL statement based on all the new metadata changes you've made. Finally, you can enable expert mode once again and reapply your SQL customizations.

---

#### 5.9.4.4 Expert Mode Returns Error for SQL Calculations that Change Entity Attributes

When changing the `SELECT` list expression that corresponds to *entity-mapped* attributes, don't introduce SQL calculations into SQL statements that change the value of the attribute when retrieving the data. To illustrate the problem that will occur if you do this, consider the query for a simple entity-based view object named `Products` shown in [Example 5-16](#).

##### **Example 5-16 Query Statement Without SQL-Calculated Expression**

```
SELECT Products.PROD_ID,
       Products.NAME,
       Products.IMAGE,
       Products.DESCRPTION
FROM PRODUCTS Products
```

Imagine that you wanted to limit the name column to display only the first ten characters of the name of a product query. The correct way to do that would be to introduce a new SQL-calculated field, such as `ShortName` with an expression like `SUBSTR (Products . NAME, 1, 10)`. One way you should *avoid* doing this is to switch the view object to expert mode and change the `SELECT` list expression for the entity-mapped `NAME` column to include the SQL-calculate expression, as shown in [Example 5-17](#).

##### **Example 5-17 Query Statement With SQL-Calculated Expression**

```
SELECT Products.PROD_ID,
```

```

        SUBSTR(Products.NAME,1,10) AS NAME,
        Products.IMAGE,
        Products.DESCRPTION
FROM PRODUCTS Products

```

This alternative strategy would initially appear to work. At runtime, you see the truncated value of the name as you are expecting. However, if you modify the row, when the underlying entity object attempts to lock the row it does the following:

- Issues a `SELECT FOR UPDATE` statement, retrieving all columns as it tries to lock the row.
- If the entity object successfully locks the row, it compares the original values of all the persistent attributes in the entity cache as they were last retrieved from the database with the values of those attributes just retrieved from the database during the lock operation.
- If any of the values differs, then the following error is thrown:

```

(oracle.jbo.RowInconsistentException)
JBO-25014: Another user has changed the row with primary key [...]

```

If you see an error like this at runtime even though you are the *only* user testing the system, it is most likely due to your inadvertently introducing a SQL function in your expert mode view object that changed the selected value of an entity-mapped attribute. In [Example 5-17](#), the `SUBSTR(Products.NAME,1,10)` function introduced causes the original selected value of the `Name` attribute to be truncated. When the row-lock SQL statement selects the value of the `NAME` column, it will select the entire value. This will cause the comparison shown in [Example 5-17](#) to fail, producing the "phantom" error that another user has changed the row.

The same thing would happen with `NUMBER`-valued or `DATE`-valued attributes if you inadvertently apply SQL functions in expert mode to truncate or alter their retrieved values for entity-mapped attributes.

Therefore, if you need to present altered versions of entity-mapped attribute data, introduce a new SQL-calculated attribute with the appropriate expression to handle the task.

#### 5.9.4.5 Formatting of the SQL Statement in Expert Mode

When you change a view object to expert mode, its XML document changes from storing parts of the query in separate XML attributes, to saving the entire query in a single `<SQLQuery>` element. The query is wrapped in an XML `CDATA` section to preserve the line formatting you may have done to make a complex query be easier to understand.

#### 5.9.4.6 Expert Mode Wraps Queries as Inline Views

If your expert-mode view object:

- Contains a `ORDERBY` clause specified in the **Order By** field of the Query Clauses page at design time, or
- Has a dynamic `WHERE` clause or `ORDERBY` clause applied at runtime using `setWhereClause()` or `setOrderByClause()`

then its query gets nested into an inline view before applying these clauses. For example, suppose your expert mode query was defined like the one shown in [Example 5-18](#).

**Example 5–18 Expert Mode Query Specified At Design Time**

```
select PERSON_ID, EMAIL, FIRST_NAME, LAST_NAME
from PERSONS
union all
select PERSON_ID, EMAIL, FIRST_NAME, LAST_NAME
from INACTIVE_PERSONS
```

Then, at runtime, when you set an additional `WHERE` clause like `email = :TheUserEmail`, the view object nests its original query into an inline view like the one shown in [Example 5–19](#).

**Example 5–19 Runtime-Generated Query With Inline Nested Query**

```
SELECT * FROM(
select PERSON_ID, EMAIL, FIRST_NAME, LAST_NAME
from PERSONS
union all
select PERSON_ID, EMAIL, FIRST_NAME, LAST_NAME
from INACTIVE_PERSONS) QRSLT
```

And, the view object adds the dynamic `WHERE` clause predicate at the end, so that the final query the database sees looks like the one shown in [Example 5–20](#).

**Example 5–20 Runtime-Generated Query With Dynamic WHERE Clause**

```
SELECT * FROM(
select PERSON_ID, EMAIL, FIRST_NAME, LAST_NAME
from PERSONS
union all
select PERSON_ID, EMAIL, FIRST_NAME, LAST_NAME
from INACTIVE_PERSONS) QRSLT
WHERE email = :TheUserEmail
```

This query "wrapping" is necessary in general for expert mode queries, because the original query could be arbitrarily complex, including SQL UNION, INTERSECT, MINUS, or other operators that combine multiple queries into a single result. In those cases, simply "gluing" the additional runtime `WHERE` clause onto the end of the query text could produce unexpected results. For example, the clause might apply only to the *last* of several UNION'ed statements. By nesting the original query verbatim into an inline view, the view object guarantees that your additional `WHERE` clause is correctly used to filter the results of the original query, regardless of how complex it is.

**5.9.4.7 Limitation of Inline View Wrapping at Runtime**

Inline view wrapping of expert mode view objects, limits a dynamically added `WHERE` clause to refer only to columns in the `SELECT` list of the original query. To avoid this limitation, when necessary you can disable the use of the inline view wrapping by calling `setNestedSelectForFullSql(false)`.

**5.9.4.8 Expert Mode Changes May Affect Dependent Objects**

When you modify a view object query to be in expert mode after you have already created the view links that involve that view object or after you created other view objects that extend the view object, JDeveloper will warn you with the alert shown in [Figure 5–39](#). The alert reminds you that you should revisit these dependent components to ensure their SQL statements still reflect the correct query.

**Figure 5–39 Proactive Reminder to Revisit Dependent Components**

For example, if you were to modify the `OrdersVO` view object to use expert mode, because the `OrdersByStatusVO` view object extends it, you need to revisit the extended component to ensure that its query still logically reflects an extension of the modified parent component.

## 5.10 Working with Bind Variables

Bind variables provide you with the means to supply attribute values at runtime to the view object or view criteria. All bind variables are defined at the level of the view object and used in one of the following ways:

- You can type the bind variable directly into the `WHERE` clause of your view object's query to include values that might change from execution to execution. In this case, bind variables serve as placeholders in the SQL string whose value you can easily change at runtime without altering the text of the SQL string itself. Since the query doesn't change, the database can efficiently reuse the same parsed representation of the query across multiple executions, which leads to higher runtime performance of your application.
- You can select the bind variable from a selection list to define the attribute value for a view criteria in the Edit View Criteria dialog you open on the view object. In this case, the bind variables allow you to change the values for attributes you will use to filter the view object row set. For more information about filtering view object row sets, see [Section 5.11, "Working with Named View Criteria."](#)

If the view criteria is to be used in a seeded search, you have the option of making the bind variable updatable by the end user. With this updatable option, end users will be expected to enter the value in a search form corresponding to the view object query.

Bind variables that you add to a `WHERE` clause require a valid value at runtime, or a runtime exception error will be thrown. In contrast, view criteria execution need not require the bind variable value if the view criteria item for which the bind variable is assigned is not required. To enforce this desired behavior, the Bind Variable dialog lets you can specify whether a bind variable is required or not.

You can define a default value for the bind variable or write scripting expressions for the bind variable that includes dot notation access to attribute property values. Expressions are based on the Groovy scripting language, as described in [Section 3.6, "Overview of Groovy Support."](#)

### 5.10.1 How to Add Bind Variables to a View Object Definition

To add a named bind variable to a view object, use the Query page of the overview editor for the view object. You can define as many bind variables as you need.

**Before you begin:**

Create the desired view objects as described in [Section 5.2.1, "How to Create an Entity-Based View Object,"](#) and [Section 5.2.3, "How to Create an Expert Mode, Read-Only View Object."](#)

**To define a named bind variable:**

1. In the Application Navigator, double-click the view object.
2. In the overview editor, click the **Query** navigation tab.
3. In the Query page, expand the **Bind Variables** section and click the **Create new bind variable** button.
4. In the Bind Variable dialog, enter the name and data type for the new bind variable.

Because the bind variables share the same namespace as view object attributes, specify names that don't conflict with existing view object attribute names. As with view objects attributes, by convention bind variable names are created with an initial capital letter, but you can rename it as desired.

5. Optionally, specify a default value for the bind variable:
  - When you want the value to be determined at runtime using an expression, enter a Groovy scripting language expression, select the **Expression** value type and enter the expression in the **Value** field. Optionally, click **Edit** to open the Expression dialog. The Expression dialog gives you a larger text area to write the expression. For example, you might want to define a bind variable to filter view instances based on the current user, as described in [Section 5.10.2, "How to Reference the Current User in a Named Bind Variable Using Groovy."](#)
  - When you want to define a default value, select the **Literal** value type and enter the literal value in the **Value** field.
6. Decide on one of the following runtime usages for the bind variable:
  - When you want the value to be supplied to a SQL `WHERE` clause using a bind variable in the clause, select the **Required** checkbox. This ensures that a runtime exception will be thrown if the value is not supplied. For more information, see [Section 5.10.8.2, "Errors Related to the Names of Bind Variables."](#)
  - When you want the value to be supplied to a view criteria using a bind variable in the view criteria, only select the **Required** checkbox when you need to reference the same bind variable in a SQL `WHERE` clause or when you want to use the bind variable as the assigned value of a view criteria item that is specifically defined as required by a view criteria that is applied to a view object. When **Required** is unselected this ensures that the value is optional and that no runtime exception will be thrown if the bind variable is not resolved. For example, view criteria with bind variables defined can be used to create Query-by-Example search forms in the user interface. For more information, see [Section 5.11, "Working with Named View Criteria."](#)
7. Select the **Control Hints** tab and specify control hints like **Label Text**, **Format Type**, **Format** mask, and others.

The view layer will use bind variable control hints when you build user interfaces like search pages that allow the user to enter values for the named bind variables. The **Updatable** checkbox controls whether the end user will be allowed to change the bind variable value through the user interface. If a bind variable is not updatable, then its value can only be changed programmatically by the developer.

8. Click **OK**.

After defining the bind variables, the next step is to reference them in the SQL statement. While SQL syntax allows bind variables to appear both in the `SELECT` list and in the `WHERE` clause, you'll typically use them in the latter context, as part of your `WHERE` clause. For example, [Example 5–21](#) shows the bind variables `LowUserId` and `HighUserId` introduced into a SQL statement created using the Query page in the overview editor for the view object.

**Example 5–21 Bind Variables in the WHERE Clause of View Object SQL Statement**

```
select PERSON_ID, EMAIL, FIRST_NAME, LAST_NAME
from PERSONS
where (upper(FIRST_NAME) like upper(:TheName) || '%'
      or upper(LAST_NAME) like upper(:TheName) || '%')
      and PERSON_ID between :LowUserId and :HighUserId
order by EMAIL
```

Notice that you reference the bind variables in the SQL statement by prefixing their name with a colon like `:TheName` or `:LowUserId`. You can reference the bind variables in any order and repeat them as many times as needed within the SQL statement.

## 5.10.2 How to Reference the Current User in a Named Bind Variable Using Groovy

You can use the Groovy expression `adf.context.securityContext.userName` to set the default value for the named bind variable that you use to provide the current user in a view instance filter. Specifically, you can use the bind variable in a named view criteria that you define to filter a view object instance in the data model for the project. For example, in the `StoreFront` module of the Fusion Order Demo application, the named bind variable `userPrincipal` is defined for the `PersonsVO` view object, as shown in [Figure 5–40](#).

**Figure 5–40 Groovy Expression Used to Set userPrincipal Bind Variable**

The `PersonsVO` view object also defines the `AuthenticatedUserByPrincipalCriteria` view criteria. This view criteria defines a filter for the `PrincipalName` attribute of the `PersonsVO` with the bind variable `userPrincipal` providing the value. In this example, the bind variable

`userPrincipal` is defined with **Updatable** enabled. This ensures that the view criteria is able to set the value obtained at runtime from the ADF security context. Since the bind variable is not used in the SQL `WHERE` clause for the `PersonsVO` view object, the **Required** field is unselected. This ensures that the value is optional and that no runtime exception will be thrown if the bind variable is not resolved.

Then in the data model for the `StoreFrontService` project, where the `PersonsVO` specifies the view definition for the usage `AuthenticatedUser`, the view criteria `AuthenticatedUserByPrincipalCriteria` with the named bind variable is defined as the view usage's runtime filter. For details about creating view instances for your project's data model, see [Section 9.2.3.3, "Customizing a View Object Instance that You Add to an Application Module."](#)

### 5.10.3 What Happens When You Add Named Bind Variables

Once you've added one or more named bind variables to a view object, you gain the ability to easily see and set the values of these variables at runtime. Information about the name, type, and default value of each bind variable is saved in the view object's XML document. If you have defined UI control hints for the bind variables, this information is saved in the view object's component message bundle file along with other control hints for the view object.

### 5.10.4 How to Test Named Bind Variables

The Business Component Browser allows you to interactively inspect and change the values of the named bind variables for any view object, which can really simplify experimenting with your application module's data model when named bind parameters are involved. For more information about editing the data model and running the Business Component Browser, see [Section 6.3, "Testing View Object Instances Using the Business Component Browser."](#)

The first time you execute a view object in the Business Component Browser to display the results in the data view page, a Bind Variables dialog will appear, as shown in [Figure 5-41](#).

The Bind Variables dialog lets you:

- View the name, as well as the default and current values, of the particular bind variable you select from the list
- Change the value of any bind variable by updating its corresponding **Value** field before clicking **OK** to set the bind variable values and execute the query
- Inspect and set the bind variables for the view object in the current data view page, using the **Edit Bind Parameters** button in the toolbar — whose icon looks like `:id`
- Verify control hints are correctly set up by showing the label text hint in the **Bind Variables** list and by formatting the **Value** attribute using the respective format mask

**Figure 5–41** Setting Bind Variables in the Business Component Browser

If you defined the bind variable in the Bind Variables dialog with the **Reference** checkbox deselected (the default), you will be able to test view criteria and supply the bind variable with values as needed. Otherwise, if you selected the **Reference** checkbox, then you must supply a value for the bind variable in the Business Component Browser. The Business Component Browser will throw the same exception seen at runtime for any view object whose SQL statement use bind variables that do not resolve with a supplied value.

### 5.10.5 How to Add a WHERE Clause with Named Bind Variables at Runtime

Using the view object's `setWhereClause()` method, you can add an additional filtering clause at runtime. This runtime-added WHERE clause predicate does *not* replace the design-time generated predicate, but rather further narrows the query result by adding to the existing design time WHERE clause. Whenever the dynamically added clause refers to a value that might change during the life of the application, you should use a named bind variable instead of concatenating the literal value into the WHERE clause predicate.

For example, assume you want to further filter the `PersonList` view object at runtime based on the value of the `PERSON_TYPE_CODE` column in the table. Also assume that you plan to search sometimes for rows where `PERSON_TYPE_CODE = 'CUST'` and other times for rows where `PERSON_TYPE_CODE = 'SUPP'`. While it contains slightly fewer lines of code, [Example 5–22](#) is not desirable because it changes the WHERE clause twice just to query two different *values* of the same `PERSON_TYPE_CODE` column.

#### **Example 5–22** Incorrect Use of `setWhereClause()` Method

```
// Don't use literal strings if you plan to change the value!
vo.setWhereClause("person_type_code = 'CUST'");
// execute the query and process the results, and then later...
vo.setWhereClause("person_type_code = 'SUPP'");
```

Instead, you should add a WHERE clause predicate that references named bind variables that you define at runtime as shown in [Example 5–23](#).

#### **Example 5–23** Correct Use of `setWhereClause()` Method and Bind Variable

```
vo.setWhereClause("person_type_code = :ThePersonType");
vo.defineNamedWhereClauseParam("ThePersonType", null, null);
vo.setNamedWhereClauseParam("ThePersonType", "CUST");
// execute the query and process the results, and then later...
```

```
vo.setNamedWhereClauseParam("ThePersonType", "SUPP");
```

This allows the text of the SQL statement to stay the same, regardless of the value of `PERSON_TYPE_CODE` you need to query on. When the query text stays the same across multiple executions, the database will return the results without having to reparse the query.

If you later need to remove the dynamically added `WHERE` clause and bind variable, you should do so the next time you need them to be different, just before executing the query. This will prevent the type of SQL execution error as described in [Section 5.10.8.1, "An Error Related to Clearing Bind Variables."](#) Avoid calling `removeNamedWhereClauseParam()` in your code immediately after setting the `WHERE` clause.

An updated test client class illustrating these techniques would look like what you see in [Example 5–24](#). In this case, the functionality that loops over the results several times has been refactored into a separate `executeAndShowResults()` method. The program first adds an additional `WHERE` clause of `person_id = :ThePersonId` and then later replaces it with a second clause of `person_type_code = :ThePersonType`.

**Example 5–24 TestClient Program Exercising Named Bind Variable Techniques**

```
package devguide.examples.readonlyvo.client;

import oracle.jbo.ApplicationModule;
import oracle.jbo.Row;
import oracle.jbo.ViewObject;
import oracle.jbo.client.Configuration;
import oracle.jbo.domain.Number;

public class TestClientBindVars {
    public static void main(String[] args) {
        String      amDef = "devguide.examples.readonlyvo.PersonService";
        String      config = "PersonServiceLocal";
        ApplicationModule am =
            Configuration.createRootApplicationModule(amDef, config);
        ViewObject vo = am.findViewObject("PersonList");
        // Set the two design time named bind variables
        vo.setNamedWhereClauseParam("TheName", "shelli%");
        vo.setNamedWhereClauseParam("HighUserId", new Number(215));
        executeAndShowResults(vo);
        // Add an extra where clause with a new named bind variable
        vo.setWhereClause("person_type_code = :ThePersonId");
        vo.defineNamedWhereClauseParam("ThePersonId", null, null);
        vo.setNamedWhereClauseParam("ThePersonId", new Number(116));
        executeAndShowResults(vo);
        vo.removeNamedWhereClauseParam("ThePersonId");
        // Add an extra where clause with a new named bind variable
        vo.setWhereClause("person_type_code = :ThePersonType");
        vo.defineNamedWhereClauseParam("ThePersonType", null, null);
        vo.setNamedWhereClauseParam("ThePersonType", "SUPP");
        // Show results when :ThePersonType = 'SUPP'
        executeAndShowResults(vo);
        vo.setNamedWhereClauseParam("ThePersonType", "CUST");
        // Show results when :ThePersonType = 'CUST'
        executeAndShowResults(vo);
        Configuration.releaseRootApplicationModule(am, true);
    }
    private static void executeAndShowResults(ViewObject vo) {
```

```

System.out.println("---");
vo.executeQuery();
while (vo.hasNext()) {
    Row curUser = vo.next();
    System.out.println(curUser.getAttribute("PersonId")+ " "+
        curUser.getAttribute("ShortName"));
}
}
}
}

```

However, if you run this test program, you may actually get a runtime error like the one shown in [Example 5–25](#).

**Example 5–25 Runtime Error Resulting From a SQL Parsing Error**

```

oracle.jbo.SQLStmtException: JBO-27122: SQL error during statement preparation.
Statement:
SELECT * FROM (select PERSON_ID, EMAIL, FIRST_NAME, LAST_NAME
from PERSONS
where (upper(FIRST_NAME) like upper(:TheName)||'%'
    or upper(LAST_NAME) like upper(:TheName)||'%'
    and PERSON_ID between :LowUserId and :HighUserId
order by EMAIL) QRSLT WHERE (person_type_code = :ThePersonType)
## Detail 0 ##
java.sql.SQLException: ORA-00904: "PERSON_TYPE": invalid identifier

```

The root cause, which appears after the `## Detail 0 ##` in the stack trace, is a SQL parsing error from the database reporting that `PERSON_TYPE_CODE` column does not exist even though the `PERSONS` table definitely has a `PERSON_TYPE_CODE` column. The problem occurs due to the mechanism that view objects use by default to apply additional runtime `WHERE` clauses on top of read-only queries. [Section 5.10.7, "What Happens at Runtime: When a Read-Only View Object WHERE Clause is Set,"](#) explains a resolution for this issue.

## 5.10.6 How to Set Existing Bind Variable Values at Runtime

To set named bind variables at runtime, use the `setNamedWhereClauseParam()` method on the `ViewObject` interface. In JDeveloper, you can choose **Refactor > Duplicate** to create a new `TestClientBindVars` class based on the existing `TestClient.java` class as shown in [Section 6.4.2, "How to Create a Command-Line Java Test Client."](#) In the test client class, you can set the values of the bind variables using a few additional lines of code. For example, the `setNamedWhereClauseParam()` might take as arguments the bind variables `HighUserId` and `TheName` as shown in [Example 5–26](#).

**Example 5–26 Setting the Value of Named Bind Variables Programmatically**

```

// changed lines in TestClient class
ViewObject vo = am.findViewObject("PersonList");
vo.setNamedWhereClauseParam("TheName", "alex%");
vo.setNamedWhereClauseParam("HighUserId", new Number(315));
vo.executeQuery();
// etc.

```

Running the test client class shows that your bind variables are filtering the data. For example, the resulting rows for the `setNamedWhereClauseParam()` method shown in [Example 5–26](#) may show only two matches based on the name `alex` as shown in [Example 5–27](#).

**Example 5–27 Result of Bind Variables Filtering the Data in TestClient Class**

```
303 ahunold
315 akhoo
```

Whenever a view object's query is executed, you can view the actual bind variable values in the runtime debug diagnostics like the sample shown in [Example 5–28](#).

**Example 5–28 Debug Diagnostic Sample With Bind Variable Values**

```
[256] Bind params for ViewObject: PersonList
[257] Binding param "LowUserId": 0
[258] Binding param "HighUserId": 315
[259] Binding param "TheName": alex%
```

This information that can be invaluable when debugging your applications. Notice that since the code did not set the value of the `LowUserId` bind variable, it took on the default value of 0 (zero) specified at design time. Also notice that the use of the `UPPER()` function in the `WHERE` clause and around the bind variable ensured that the match using the bind variable value for `TheName` was performed case-insensitively. The sample code set the bind variable value to "alex%" with a lowercase "a", and the results show that it matched Alexander.

## 5.10.7 What Happens at Runtime: When a Read-Only View Object WHERE Clause is Set

If you dynamically add an additional `WHERE` clause at runtime to a read-only view object, its query gets nested into an inline view before applying the additional `WHERE` clause.

For example, suppose your query was defined as shown in [Example 5–29](#).

**Example 5–29 Query Specified At Design Time**

```
select PERSON_ID, EMAIL, FIRST_NAME, LAST_NAME
from PERSONS
where (upper(FIRST_NAME) like upper(:TheName) || '%'
      or upper(LAST_NAME) like upper(:TheName) || '%')
      and PERSON_ID between :LowUserId and :HighUserId
order by EMAIL
```

At runtime, when you set an additional `WHERE` clause like `person_type_code = :ThePersonType` as the test program did in [Example 5–24](#), the framework nests the original query into an inline view like the sample shown in [Example 5–30](#).

**Example 5–30 Runtime-Generated Query With Inline Nested Query**

```
SELECT * FROM(
select PERSON_ID, EMAIL, FIRST_NAME, LAST_NAME
from PERSONS
where (upper(FIRST_NAME) like upper(:TheName) || '%'
      or upper(LAST_NAME) like upper(:TheName) || '%')
      and PERSON_ID between :LowUserId and :HighUserId
order by EMAIL) QRSLT
```

Then the framework adds the dynamic `WHERE` clause predicate at the end, so that the final query the database sees is like the sample shown in [Example 5–31](#).

**Example 5–31 Runtime-Generated Query With Dynamic WHERE Clause**

```
SELECT * FROM(
```

```

select PERSON_ID, EMAIL, FIRST_NAME, LAST_NAME
from PERSONS
where (upper(FIRST_NAME) like upper(:TheName) || '%'
      or upper(LAST_NAME) like upper(:TheName) || '%')
      and PERSON_ID between :LowUserId and :HighUserId
order by EMAIL) QRSLT
WHERE person_type_code = :ThePersonType

```

This query "wrapping" is necessary in the general case since the original query could be arbitrarily complex, including SQL UNION, INTERSECT, MINUS, or other operators that combine multiple queries into a single result. In those cases, simply "gluing" the additional runtime WHERE clause onto the end of the query text could produce unexpected results because, for example, it might apply only to the *last* of several UNION'ed statements. By nesting the original query verbatim into an inline view, the view object guarantees that your additional WHERE clause is correctly used to filter the results of the original query, regardless of how complex it is. The consequence (that results in an ORA-00904 error) is that the dynamically added WHERE clause can refer only to columns that have been selected in the original query.

The simplest solution is to add the dynamic query column names to the end of the query's SELECT list on the Edit Query dialog (click the **Edit SQL Query** button on the Query page of the overview editor for the view object). Just adding the new column name at the end of the existing SELECT list — of course, preceded by a comma — is enough to prevent the ORA-00904 error: JDeveloper will automatically keep your view object's attribute list synchronized with the query statement. Alternatively, [Section 5.9.4.7, "Limitation of Inline View Wrapping at Runtime"](#) explains how to disable this query nesting when you don't require it.

The test client program in [Example 5-24](#) now produces the results shown in [Example 5-32](#).

**Example 5-32 Named Bind Variables Resulting From Corrected TestClient**

```

---
116 S. Baida
---
116 S. Baida
---
---
116 S. Baida

```

## 5.10.8 What You May Need to Know About Named Bind Variables

There are several things you may need to know about named bind variables, including the runtime errors that are displayed when bind variables have mismatched names and the default value for bind variables.

### 5.10.8.1 An Error Related to Clearing Bind Variables

You need to ensure that your application handles changing the value of bind variables properly for use with activation and passivation of the view object instance settings at runtime. For example, before you deploy the application, you will want to stress-test your application in JDeveloper by disabling application module pooling, as described in [Section 40.10, "Testing to Ensure Your Application Module is Activation-Safe."](#) Following the instructions in that section effectively simulates the way your application will manage the passivation store when you eventually deploy the application.

When the application reactivates the pending state from the passivation store upon subsequent requests during the same user session, the application will attempt to set the values of any dynamically added named `WHERE` clause bind variables. Changing the values to null before passivation takes place will prevent the bind variable values from matching the last time the view object was executed and the following error will occur during activation:

```
(oracle.jbo.SQLStmtException) JBO-27122: SQL error during statement preparation.
(java.sql.SQLException) Attempt to set a parameter name that does not occur in
SQL: 1
```

Do not change the value of the bind variables (or other view object instance settings) just after executing the view object. Rather, if you will not be re-executing the view object again during the same block of code (and therefore during the same HTTP request), you should defer changing the bind variable values for the view object instance until the next time you need them to change, just before executing the query. To accomplish this, use the following pattern:

1. (Request begins and application module is acquired)
2. Call `setWhereClause(null)` to clear `WHERE` clause
3. Call `setWhereClauseParams(null)` to clear the `WHERE` clause bind variables
4. Call `setWhereClause()` that references  $n$  bind variables
5. Call `setWhereClauseParams()` to set the  $n$  values for those  $n$  bind variables
6. Call `executeQuery()`
7. (Application module is released)

### 5.10.8.2 Errors Related to the Names of Bind Variables

You need to ensure that the list of named bind variables that you reference in your SQL statement matches the list of named bind variables that you've defined in the **Bind Variables** section of the overview editor's Query page for the view object. Failure to have these two agree correctly can result in one of the following two errors at runtime.

If you use a named bind variable in your SQL statement but have not defined it, you'll receive an error like this:

```
(oracle.jbo.SQLStmtException) JBO-27122: SQL error during statement preparation.
## Detail 0 ##
(java.sql.SQLException) Missing IN or OUT parameter at index:: 1
```

On the other hand, if you have defined a named bind variable, but then forgotten to reference it or mistyped its name in the SQL, then you will see an error like this:

```
oracle.jbo.SQLStmtException: JBO-27122: SQL error during statement preparation.
## Detail 0 ##
java.sql.SQLException: Attempt to set a parameter name that does not occur in the
SQL: LowUserId
```

To resolve either of these errors, double-check that the list of named bind variables in the SQL matches the list of named bind variables in the **Bind Variables** section of the overview editor's Query page for the view object. Additionally, open the Bind Variables dialog for the bind variable and verify that the **Reference** checkbox is not still deselected (the default). To use the bind variable in a SQL statement, you must select the **Reference** checkbox.

### 5.10.8.3 Default Value of NULL for Bind Variables

If you do not supply a default value for your named bind variable, it defaults to the NULL value at runtime. This means that if you have a WHERE clause like:

```
PERSON_ID = :ThePersonId
```

and you do not provide a default value for the `ThePersonId` bind variable, it will default to having a NULL value and cause the query to return no rows. Where it makes sense for your application, you can leverage SQL functions like `NVL()`, `CASE`, `DECODE()`, or others to handle the situation as you require. For example, the following WHERE clause fragment allows the view object query to match any name if the value of `:TheName` is null.

```
upper(FIRST_NAME) like upper(:TheName) || '%'
```

## 5.11 Working with Named View Criteria

AA view criteria you define lets you specify filter information for the rows of a view object collection. The view criteria object is a row set of one or more view criteria groups, whose attributes mirror those in the view object. The view criteria definition comprises query conditions that augment the WHERE clause of the target view object. However, unlike the WHERE clause defined by the view object query statement, which applies to all instances of the view object, the view criteria query condition is added to specific view object instances. This allows you to create specific usages of the target view object definition using query conditions that apply to the individual attributes of the target view object.

View criteria definitions support Query-by-Example operators and therefore allows the user to enter conditions such as "OrderId > 304", for example.

The Edit View Criteria dialog lets you create view criteria and save them as part of the view object's definition, where they appear as named view criteria. You use the View Criteria page of the overview editor to define view criteria for specific view objects. View criteria that you define at design time can participate in these scenarios where filtering results is desired at runtime.

- Supporting Query-by-Example search forms that allow the end user to supply values for attributes of the target view object.
 

For example, the end user might input the value of a customer name and the date to filter the results in a web page that displays the rows of the `CustomerOrders` view object. The web page designer will see the named view criteria in the JDeveloper Data Controls panel and, from them, easily create a search form. For more information about the utilizing the named view criteria in the Data Controls panel, see [Section 27.2, "Creating Query Search Forms."](#)
- Supporting row finder operations that the application may use to perform row look ups using any non-key attribute.
 

For example, it is usually preferable to allow the end user to make row updates without the need to know the row key value (often an ID). In this case, a row finder that you apply to a view criteria supports locating a row using easily identifiable attribute values, such as by user name and user email address. For more information, see [Section 5.12, "Working with Row Finders."](#)
- Filtering the list of values (LOV) components that allow the end user may select from one attribute list (displayed in the UI as an LOV component).

The web page designer will see the attributes of the view object in the JDeveloper Data Controls panel and, from them, easily create LOV controls. For more information about utilizing LOV-enabled attributes in the Data Controls panel, see [Section 25.3, "Creating a Selection List."](#)

- Validating attribute values using a view accessor with a view criteria applied to filter the view accessor results.

For more information about create view accessor validators, see [Section 10.4.2, "How to Validate Against a View Accessor."](#)

- Creating the application module's data model from a single view object definition with a unique view criteria applied for each view instance.

The single view object query modified by view criteria is useful with look up data that must be shared across the application. In this case, a base view object definition queries the lookup table in the database and the view criteria set the lookup table's `TYPE` column to define application-specific views. To define view instances in the data model using the view criteria you create for a base view object definition, see [Section 10.3.3, "How to Define the WHERE Clause of the Lookup View Object Using View Criteria."](#)

Additionally, view criteria have full API support, and it is therefore possible to create and apply view criteria to view objects programmatically.

### 5.11.1 How to Create Named View Criteria Declaratively

View criteria have a number of uses in addition to applying them to declarative queries at runtime. In all usages, the named view criteria definition consists of a set of attribute requirements that you specify to filter individual view object results. The features of the view criteria definition that you can use will depend on its intended usage.

To define view criteria for the view object you wish to filter, you open the view object in the overview editor and use the **View Criteria** section of the Query page. A dedicated editor (the Create View Criteria dialog) that you open from the **View Criteria** section helps you to build a `WHERE` clause using attribute names instead of the target view object's corresponding SQL column names. You may define multiple named view criteria for each view object.

Before you work with the Create View Criteria dialog to create named view criteria, familiarize yourself with the usages described in [Section 5.11, "Working with Named View Criteria."](#) The chapter references provide additional details that will help you to anticipate using the appropriate features of the Create View Criteria dialog. For example, when you create a view criteria to specify the searchable attributes of a search form, the view criteria condition defines a simple list of attributes (a subset of the view object's attributes) to be presented to the user, but then the view criteria definition requires that you specify UI hints (model-level properties) to control the behavior of those attributes in the search form. The Create View Criteria dialog displays all the UI hints in a separate tabbed page that you select for the view criteria you are defining. Whereas, when your view criteria is intended to specify view instances in the data model, you can define arbitrarily complex query filter conditions, but you can ignore the UI hints features displayed by the Create View Criteria dialog.

Each view criteria definition consists of the following elements:

- One or more view criteria rows consisting of an arbitrary number of view criteria groups or an arbitrary number of references to another named view criteria already defined for the current view object.

- Optional view criteria groups consisting of an arbitrary number of view criteria items.
- View criteria items consisting of an attribute name, an attribute-appropriate operator, and an operand. Operands can be a literal value when the filter value is defined or a bind variable that can optionally utilize a scripting expression that includes dot notation access to attribute property values.

Expressions are based on the Groovy scripting language, as described in [Section 3.6, "Overview of Groovy Support."](#)

When you define a view criteria, you control the source of the filtered results. You can limit the results of the filtered view object to:

- Just the database table specified by the view object
- Just the in-memory results of the view object query
- Both the database and the in-memory results of the view object query.

Filtering on both database tables and the view object's in-memory results allows you to filter rows that were created in the transaction but not yet committed to the database.

View criteria expressions you construct in the Edit View Criteria dialog use logical conjunctions to specify how to join the selected criteria item or criteria group with the previous item or group in the expression:

- AND conjunctions specify that the query results meet both joined conditions. This is the default for each view criteria item you add.
- OR conjunctions specify that the query results meet either or both joined conditions. This is the default for view criteria groups.

Additionally, you may create nested view criteria when you want to filter rows in the current view object based on criteria applied to view-linked detail views. A nested view criteria group consists of an arbitrary number of nested view criteria items. You can use nested view criteria when you want to have more controls over the logical conjunctions among the various view criteria items. The nested criteria place restrictions on the rows that satisfy the criteria under the nested criteria's parent view criteria group. For example, you might want to query both a list of employees with (`Salary > 3000`) and belonging to (`DeptNo = 10` or `DeptNo = 20`). You can define a view criteria with the first group with one item for (`Salary > 3000`) and a nested view criteria with the second group with two items `DeptNo = 10` and `DeptNo = 20`.

#### **Before you begin:**

- Create the desired view objects as described in [Section 5.2.1, "How to Create an Entity-Based View Object,"](#) and [Section 5.2.3, "How to Create an Expert Mode, Read-Only View Object."](#)
- If the view criteria will use a bind variable in the operand, create the bind variable as described in [Section 5.10.1, "How to Add Bind Variables to a View Object Definition."](#)

#### **To define a named view criteria:**

1. In the Application Navigator, double-click the view object for which you want to create the named view criteria.
2. In the overview editor, click the **Query** navigation tab.

3. In the Query page, expand the **View Criteria** section and click the **Create new view criteria** button.
4. In the Create View Criteria dialog, enter the name of the view criteria to identify its usage in your application.
5. In the **Query Execution Mode** dropdown list, decide how you want the view criteria to filter the view object query results.

You can limit the view criteria to filter the database table specified by the view object query, the in memory row set produced by the query, or both the database table and the in-memory results.

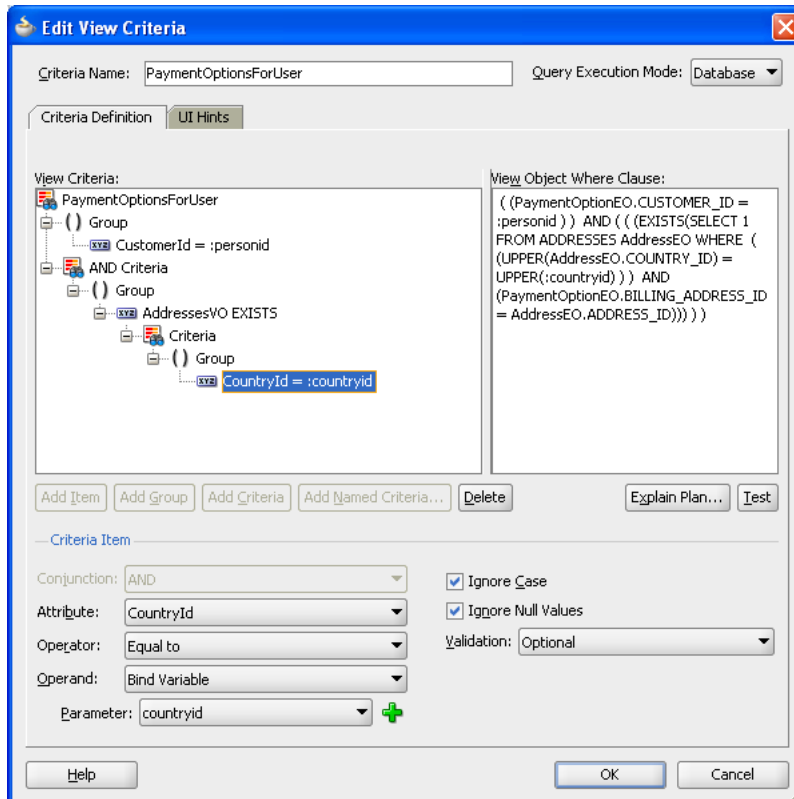

Choosing **Both** may be appropriate for situations where you want to include rows created as a result of enforced association consistency. In this case, in-memory filtering is performed after the initial fetch.

6. Click one of these **Add** buttons to define the view criteria.
  - **Add Item** to add a single criteria item. The editor will add the item to the hierarchy beneath the current group or view criteria selection. By default each time you add an item, the editor will choose the next attribute to define the criteria item. You can change the attribute to any attribute that the view object query defines.
  - **Add Group** to add a new group that will compose criteria items that you intend to add to it. When you add a new group, the editor inserts the **OR** conjunction into the hierarchy. You can change the conjunction as desired.
  - **Add Criteria** to add a view criteria that you intend to define. This selection is an alternative to adding a named criteria that already exists in the view object definition. When you add a new view criteria, the editor inserts the **AND** conjunction into the hierarchy. You can change the conjunction as desired. Each time you add another view criteria, the editor nests the new view criteria beneath the current view criteria selection in the hierarchy. The root node of the hierarchy defines the named view criteria that you are currently editing.
 

Search forms that the UI designer will create from view criteria are not able to use directly nested view criteria. For more information about defining nested expressions for use with search forms, see [Section 5.11.4, "What You May Need to Know About Nested Expressions."](#)
  - **Add Named Criteria** to add a view criteria that the view object defines. The named criteria must appear in the overview editor for the view object you are defining the view criteria.
7. Select a view criteria item node in the view criteria hierarchy and define the added node in the **Criteria Item** section.
  - Choose the desired **Attribute** for the criteria item. By default the editor adds the first one in the list.

Optionally, you can add a nested view criteria inline when a view link exists for the current view object you are editing. The destination view object name will appear in the **Attribute** dropdown list. Selecting a view object lets you filter the view criteria based on view criteria items for the nested view criteria based on a view link relationship. For example, `AddressVO` is linked to the `PaymentOptionsVO` and a view criteria definition for `PaymentOptionsVO` will display the destination view object `AddressVO`. You could define the nested view criteria to filter payment options based on the `CountryId` attribute of the current customer, as specified by the `CustomerId` criteria item, as shown in [Figure 5-42](#).

Figure 5–42 Edit View Criteria Dialog with Nested View Criteria Specified

- Choose the desired **Operator**.

The list displays only the operators that are appropriate for the selected attribute or view object. In the case of a view object selection, the **exists** operator applies to a view criteria that you will define (or reference) as an operand. In the case of Strings and Date type attributes, the **Between** and **Not between** operators require you to supply two operand values to define the range. In the case of Date type attributes, you can select operators that test for a date or date range (with date values entered in the format YYYY-MM-DD). For example, for December 16th, 2010, enter 2010-12-16.

JDeveloper does not support the **IN** operator. However, you can create a view criteria with the **IN** operator using the API, as described in [Section 5.11.8, "How to Create View Criteria Programmatically."](#)

8. Choose the desired **Operand** for the view criteria item selection.
  - Select **Literal** when you want to supply a value for the attribute or when you want to define a default value for a user-specified search field for a Query-by-Example search form. When the view criteria defines a query search form for the user interface, you may leave the **Value** field empty. In this case, the user will supply the value. You may also provide a value that will act as a search field default value that the user will be able to override. The value you supply in the **Value** field can include wildcard characters \* or %.
  - Select **Bind Variable** when you want the value to be determined at runtime using a bind variable. If the variable was already defined for the view object, select it from the **Parameters** dropdown list. Otherwise, click **New** to display the Bind Variable dialog that lets you create a new bind variable on the view

object. For more information about creating bind variables, see [Section 5.10.1, "How to Add Bind Variables to a View Object Definition."](#)

When you define bind variables on the view object for use by the view criteria, you must specify that the variable is not required by the SQL query that the view object defines. To do this, deselect the **Required** checkbox in the Bind Variables dialog, as explained in [Section 5.10.1, "How to Add Bind Variables to a View Object Definition."](#)

For further discussion about view criteria use cases for bind variables and literals, see [Section 5.11.3, "What You May Need to Know About Bind Variable Options."](#)

9. For each item, group, or nested view criteria that you define, optionally change the default conjunction to specify how the selection should be joined.
  - **AND** conjunction specifies that the query results meet both joined conditions. This is the default for each view criteria item or view nested view criteria that you add.
  - **OR** conjunction specifies that the query results meet either or both joined conditions. This is the default for view criteria groups.
10. Verify that the view criteria definition is valid by doing one of the following:
  - Click **Explain Plan** to visually inspect the view criteria's generated `WHERE` clause.
  - Click **Test** to allow JDeveloper to verify that the `WHERE` clause is valid.
11. To prevent the attribute to be filtered based on the case of the runtime-supplied value, leave **Ignore Case** selected.
 

The criteria item can be a literal value that you define or a runtime parameter that the end user supplies. This option is supported for attributes of type String only. The default disables case sensitive searches.
12. In the **Validation** dropdown list, decide whether the view criteria item is a required or an optional part of the attribute value comparison in the generated `WHERE` clause.
  - **Selectively Required** means that the `WHERE` clause will ignore the view criteria item at runtime if no value is supplied and there exists at least one criteria item at the same level that has a criteria value. Otherwise, an exception is thrown.
  - **Optional** means the view criteria is added to the `WHERE` clause only if the value is non-NULL. The default **Optional** for each new view criteria item means no exception will be generated for null values.
  - **Required** means that the `WHERE` clause will fail to execute and an exception will be thrown when no value is supplied for the criteria item.
13. If the view criteria uses a bind variable as the operand, decide whether the `IS NULL` condition is the generated in the `WHERE` clause. This field is enabled only if you have selected **Optional** for the validation of the bind variable.
  - Leave **Ignore Null Values** selected (default) when you want to permit the view criteria to return a result even when the bind variable value is not supplied at runtime. For example, suppose you define a view criteria to allow users to display a cascading list of countries and states (or provinces) through a bind variable that takes the `countryID` as the child list's controlling attribute. In this case, the default behavior for the view criteria execution

returns the list of *all* states if the user makes no selection in the parent LOV (an empty `countryId` field). The generated `WHERE` clause would look similar to `((CountryEO.COUNTRY_ID=:bvCountryId) OR (:bvCountryId IS NULL))`, where the test for a null value guarantees that the child list displays a result even when the bind variable is not set. When validation is set to **Required** or **Optionally Required**, the view criteria expects to receive a value and thus this option to ignore null values is disabled.

- **Deselect Ignore Null Values** when you expect the view criteria to return a null result when the bind variable value is not supplied at runtime. In the example of the cascading lists, the view criteria execution returns *no* states if the user makes no selection with an empty `countryID` field. In this case, the generated `WHERE` clause would look similar to `(CountryEO.COUNTRY_ID=:bvCountryId)`, where the test for null is not performed, which means the query is expected to function correctly with a null value bind variable.

Note that the validation settings **Required** or **Optionally Required** also remove the null value condition but support a different use case. They should be used in combination with **Ignore Null Values** feature to achieve the desired runtime behavior. For more details about the interaction of these features, see [Section 5.11.3, "What You May Need to Know About Bind Variable Options."](#)

14. Click OK.

## 5.11.2 What Happens When You Create a Named View Criteria

The Create View Criteria dialog in JDeveloper lets you easily create view criteria and save them as named definitions. These named view criteria definitions add metadata to the XML document file that represents the target view object's declarative settings. Once defined, named view criteria appear by name in the Query page of the overview editor for the view object.

To view the view criteria, expand the desired view object in the Application Navigator, select the XML file under the expanded view object, open the Structure window, and expand the View Criteria node. Each view criteria definition for a view object contains one or more `<ViewCriteriaRow>` elements corresponding to the number of groups that you define in the Create View Criteria dialog. [Example 5–33](#) shows the `ProductsVO.xml` file with the `<ViewCriteria>` definition `FindByProductNameCriteria` and a single `<ViewCriteriaRow>` that defines a developer-seeded search for products using the bind variable `:bvProductName`. Any control hints that you selected to customize the behavior of a developer-seeded search will appear in the `<ViewCriteria>` definition as attributes of the `<CustomProperties>` element. For details about specific control hints for view criteria, see [Section 5.11.5, "How to Set User Interface Hints on View Criteria."](#)

### **Example 5–33** *FindByProductNameCriteria View Criteria in the ProductsVO View Object Definition*

```
<ViewObject
  xmlns="http://xmlns.oracle.com/bc4j"
  Name="ProductsVO"
  ... >
<SQLQuery>
  ...
</SQLQuery>
...
<ViewCriteria
  Name="FindByProductNameCriteria"
```

```

ViewObjectName="oracle.fodemo.storefront.store.queries.ProductsVO"
Conjunction="AND">
<Properties>
  <CustomProperties>
    <Property
      Name="mode"
      Value="Basic"/>
    <Property
      Name="autoExecute"
      Value="false"/>
    <Property
      Name="showInList"
      Value="true"/>
    <Property
      Name="displayName"
      Value="Find Products By Name"/>
    <Property
      Name="displayOperators"
      Value="InAdvancedMode"/>
    <Property
      Name="allowConjunctionOverride"
      Value="true"/>
  </CustomProperties>
</Properties>
<ViewCriteriaRow
  Name="vcrow87">
  <ViewCriteriaItem
    Name="ProductName"
    ViewAttribute="ProductName"
    Operator="CONTAINS"
    Conjunction="AND"
    Value=":bvProductName"
    UpperColumns="1"
    IsBindVarValue="true"
    Required="Optional"/>
  </ViewCriteriaItem>
</ViewCriteriaRow>
...
</ViewObject>

```

Additionally, when you create view objects and specify them as instances in an application module, JDeveloper automatically creates a data control to encapsulate the collections (view instances) that the application module contains. JDeveloper then populates the Data Controls panel with these collections and any view criteria that you have defined, as shown in [Section 12.2.1.3, "How View Objects Appear in the Data Controls Panel."](#)

### 5.11.3 What You May Need to Know About Bind Variable Options

The view criteria filter that you define using a bind variable expects to obtain its value at runtime. This can be helpful in a variety of user interface scenarios. To support a particular use case, familiarize yourself with the combination of the **Validation** and **Ignore Null Values** settings shown in [Table 5–1](#).

**Table 5–1 Use Cases for Bind Variable Options in View Criteria**

Validation	Ignore Null Values	Use Cases	Notes
Optional	True (Default)	Configure cascading List of Values (LOV) where the parent LOV value is optional.  Generate an optional search field in a search form.	This combination generates the SQL query <code>(ProductName = :bind) OR (:bind IS NULL)</code> .  When used for cascading LOVs, no selection in the parent LOV returns all rows in the child LOV.  Note that the preferred implementation for an optional search field is a view criteria item with a literal operand type.
Optional	False	Configure cascading LOVs where the parent LOV value is required.	This combination generates the SQL query <code>(ProductName = :bind)</code> .  When used for cascading LOVs, no selection in the parent LOV returns no rows in the child LOV.  Avoid this combination for search forms, because when the user leaves the search field blank the search will attempt to find rows where this field is explicitly NULL. A better way to achieve this is for the user to explicitly select the "IS NULL" operator in advanced search mode.
Required	False (default)	Generate a required search field in a search form.	This combination generates the SQL query <code>ProductName = :bind</code> .  Avoid this setting for cascading LOVs, because no selection in the parent LOV will cause a validation error.  Note that the preferred implementation for a required search field is a view criteria item with a literal operand (not a bind variable) type.

#### 5.11.4 What You May Need to Know About Nested Expressions

Search forms that the UI designer will create from view criteria are not able to work with all types of nested expressions. Specifically, search forms do not support expressions with directly nested view criteria. This type of nested expression defines one view criteria as a direct child of another view criteria. Query search forms do support nested expressions where you nest the view criteria as a child of a criteria item which is itself a child of a view criteria. For more information about using view criteria to create search forms, see [Section 27.1.5, "Implicit and Named View Criteria."](#)

#### 5.11.5 How to Set User Interface Hints on View Criteria

Named view criteria that you create for view object collections can be used by the web page designer to create Query-by-Example search forms. Web page designers select your named view criteria from the JDeveloper Data Controls panel to create search forms for the Fusion web application. In the web page, the search form utilizes an ADF Faces query search component that will be bound initially to the named view criteria selected in the Data Controls panel. At runtime, the end user may select among all other named view criteria that appear in the Data Controls panel. Named view criteria that the end user can select in a search form are known as *developer-seeded searches*. The

query component automatically displays these seeded searches in its **Saved Search** dropdown list. For more information about creating search forms and using the ADF query search component, see [Section 27.2, "Creating Query Search Forms."](#)

---

---

**Note:** By default, any named view criteria you create in the Edit View Criteria dialog will appear in the Data Controls panel. As long as the **Show In List** option appears selected in the UI Hints page of the Edit View Criteria dialog, JDeveloper assumes that the named view criteria should be available as a developer-seeded search. When you want to create a named view criteria that you do not want the end user to see in search forms, deselect the **Show In List** option in the dialog. For example, you might create a named view criteria only for an LOV-enabled attribute and so you would need to deselect **Show In List**.

---

---

Because developer-seeded searches are created in the data model project, the UI Hints page of the Edit View Criteria dialog lets you specify the default properties for the query component's runtime usage of individual named view criteria. At runtime, the query component's behavior will conform to the selections you make for the following seeded search properties:

**Search Region Mode:** Select the mode that you want the query component to display the seeded search as. The **Basic** mode has all features of **Advanced** mode, except that it does not allow the end user to dynamically modify the displayed search criteria fields. The default is **Basic** mode for a view criteria you define in the Edit View Criteria dialog.

**Query Automatically:** Select when you want the query associated with the named view criteria to be executed and the results displayed in the web page. Any developer-seeded search with this option enabled will automatically be executed when the end user selects it from the query component's **Saved Search** list. Deselect when the web page designer prefers not to update the previously displayed results until the end user submits the search criteria values on the form. Additionally, when a search form is invoked from a task flow, the search form will appear empty when this option is deselected and populated when enabled. By default, this option is disabled for a view criteria you define in the Edit View Criteria dialog.

**Show Operators:** Determine how you want the query component to display the operator selection field for the view criteria items to the end user. For example, select **Always** when you want to allow the end user to customize the operators for criteria items (in either basic or advanced modes) or select **Never** when you want the view criteria to be executed using the operators it defines. Note that the end user cannot change the operator for criteria items that you specify with a bind variable because bind variables may be used in more than one criteria item.

**Show Match All and Match Any:** Select to allow the query component to display the **Match All** and **Match Any** radio selection buttons to the end user. When these buttons are present, the end user can use them to modify the search to return matches for all criteria or any one criteria. This is equivalent to enforcing **AND** (match all) or **OR** (match any) conjunctions between view criteria items. Deselect when you want the view criteria to be executed using the conjunctions it defines. In this case, the query component will not display the radio selection buttons.

**Rendered Mode:** Select individual view criteria items from the view criteria tree component and choose whether you want the selected item to appear in the search form when the end user toggles the query component between basic mode and

advanced mode. The default for every view criteria item is **All**. The default mode permits the query component to render an item in either basic or advanced mode. By changing the **Rendered Mode** setting for individual view criteria items, you can customize the search form's appearance at runtime. For example, you may want basic mode to display a simplified search form to the end user, reserving advanced mode for displaying a search form with the full set of view criteria items. In this case, you would select **Advanced** for the view criteria item that you do not want displayed in the query component's basic mode. In contrast, when you want the selected view criteria item to be rendered only in basic mode, select **Basic**. Set any item that you do not want the search form to render in either basic or advanced mode to **Never**.

---

---

**Note:** When your view criteria includes an item that should not be exposed to the user, use the **Rendered Mode** setting **Never** to prevent it from appearing in the search form. For example, a view criteria may be created to search for products in the logged-in customer's cart; however, you may want to prevent the user from changing the customer ID to display another customer's cart contents. In this scenario, the view criteria item corresponding to the customer ID would be set to the current customer ID using a named bind variable. Although the bind variable definition might specify the variable as not required and not updatable, with the control hint property **Display** set to **Hide**, only the **Rendered Mode** setting determines whether or not the search form displays the value.

---

---

**Support Multiple Value Selection:** Select when you want to allow the end user to make multiple selections for an individual criteria item that the query component displays. This option is only enabled when the view object attribute specified by the view criteria item has a List of Values (LOV) defined. Additionally, multiple selections will only be supported by the query component when the end user selects the operator **equal to** or **not equal to**. For example, if the criteria item names an attribute `CountryId` and this attribute derives its values from a list of country IDs accessed by the attribute's associated LOV, then selecting this option would allow the end user to submit the query with multiple country selections. At runtime, the query component will generate the appropriate query clause based on the end user's operator selection.

**Show In List:** Select to ensure that the view criteria is defined as a developer-seeded query. Deselect when the named view criteria you are defining is not to be used by the query search component to display a search form. Your selection determines whether the named view criteria will appear in the query search component's **Saved Search** dropdown list of available seeded searches. By default, this option is enabled for a view criteria you define in the Edit View Criteria dialog.

**Display Name:** Enter the name of the seeded search that you want to appear in the query component's **Saved Search** dropdown list or click the ... button (to the right of the edit field) to select a message string from the resource bundle associated with the view object. The display name will be the name by which the end user identifies the seeded search. When you select a message string from the resource bundle, JDeveloper saves the string's corresponding message key in the view object definition file. At runtime, the UI locates the string to display based on the end user's locale setting and the message key in the localized resource bundle. When you do not specify a display name, the view criteria name displayed in the Edit View Criteria dialog will be used by default.

To create a seeded search for use by the ADF query search component, you select **Show In List** in the UI Hints page of the Edit View Criteria dialog. You deselect **Show In List** when you do not want the end user to see the view criteria in their search form.

**Before you begin:**

- Create the desired view objects as described in [Section 5.2.1, "How to Create an Entity-Based View Object,"](#) and [Section 5.2.3, "How to Create an Expert Mode, Read-Only View Object."](#)
- Create the view criteria as described in [Section 5.11.1, "How to Create Named View Criteria Declaratively."](#)

**To customize a named view criteria for the user interface:**

1. In the Application Navigator, double-click the view object that defines the named view criteria you want to use as a seeded search.
2. In the overview editor, click the **Query** navigation tab.
3. In the Query page, expand the **View Criteria** section and double-click the named view criteria that you want to allow in seeded searches.
4. On the UI Hints page of the Edit View Criteria dialog, ensure that **Show In List** is selected.

This selection determines whether or not the query component will display the seeded search in its **Saved Search** dropdown list.

5. Enter a user-friendly display name for the seeded search to be added to the query component **Saved Search** dropdown list.

When left empty, the view criteria name displayed in the Edit View Criteria dialog will be used by the query component.

6. Optionally, enable **Query Automatically** when you want the query component to automatically display the search results whenever the end user selects the seeded search from the **Saved Search** dropdown list.

By default, no search results will be displayed.

7. Optionally, apply **Criteria Item UI Hints** to customize whether the query component renders individual criteria items when the end user toggles the search from between basic and advanced mode.

By default, all view criteria items defined by the seeded search will be displayed in either mode.

If a rendered criteria item is of type `Date`, you must also define UI hints for the corresponding view object attribute. Set the view object attribute's Format Type hint to **Simple Date** and set the Format Mask to an appropriate value, as described in [Section 5.14.1, "How to Add Attribute-Specific Control Hints."](#) This will allow the search form to accept date values.

8. Click OK.

## 5.11.6 How to Use Master-Detail Related View Objects in View Criteria

View criteria provide a declarative way to define view object query filters that apply to the view object's own query. In certain cases you may need to filter the master view object using attributes of the detail view object. View criteria that involve master and detail view objects rely on the `EXISTS` operator and an inline view criteria to define the query filter. The `EXISTS` operator allows the inline view criteria to reference a

detail view object and apply attributes that you select as criteria items. For example, a view criteria used in combination with a row finder can filter the master row set and locate specific rows in the row set using view criteria items from the detail view object.

You use the View Criteria page of the view object overview editor to define the view criteria on the master view object. For example, a view criteria `findPersonByEmail` that filters the rows in the master `PersonsVO` using the `EmailAddress` attribute of the detail `AddressVO` might look similar to the one shown in [Example 5-34](#). In this example, the view criteria statement uses a bind variable `EmailBindVar` to obtain the value of the email attribute on the detail view object `AddressVO` at runtime.

**Example 5-34 EXISTS View Criteria Statement**

```
( ( EXISTS(SELECT 1 FROM ADDRESS AdresseEO WHERE
      (UPPER(AdresseEO.EMAIL_ADDRESS LIKE UPPER (:EmailBindVar || '%' ) ) )
      AND
      (PersonEO.PERSON_ID = AdresseEO.PERSON_ID) ) ) )
```

**Before you begin:**

It may be helpful to have an understanding of the row finder that operates on a master view object. For more information, see [Section 5.12, "Working with Row Finders."](#)

It may be helpful to have an understanding of view criteria. For more information, see [Section 5.11, "Working with Named View Criteria."](#)

You will need to complete this task:

Create the desired master-detail view objects, as described in [Section 5.6.1, "How to Create a Master-Detail Hierarchy for Entity-Based View Objects"](#) or [Section 5.6.2, "How to Create a Master-Detail Hierarchy Based on View Objects Alone."](#)

**To create an inline view criteria:**

1. In the Application Navigator, double-click the view object for which you want to create the inline view criteria.
 

The view object that you create the inline view criteria on must be a master view object in a master-detail hierarchy.
2. In the overview editor, click the **View Criteria** navigation tab and click the **Create New View Criteria** button.
3. In the Create View Criteria dialog, enter the name of the view criteria to identify its usage in your application.

For example, to filter the person row set by an employee's email, you might specify a view criteria name like `findPersonByEmail`.

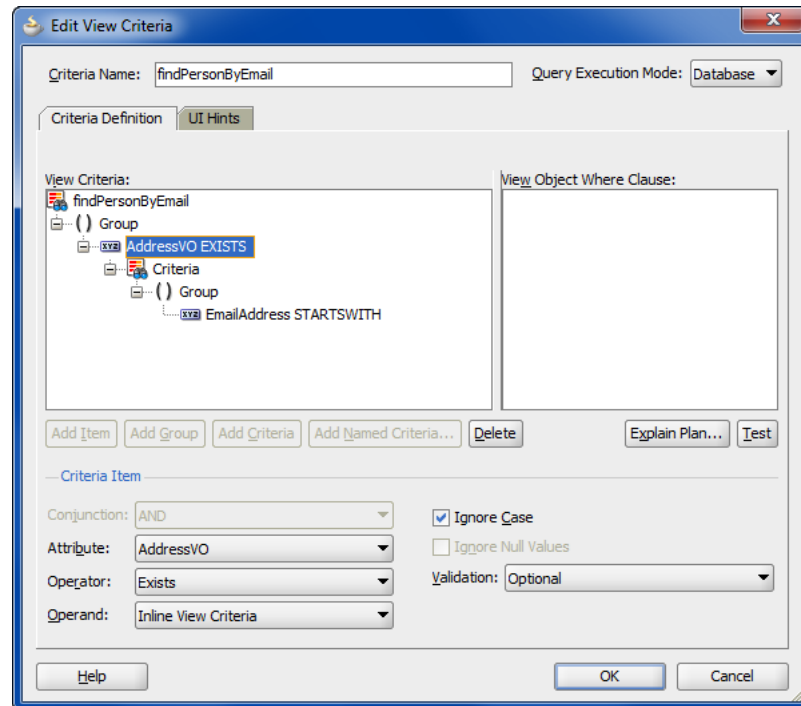

4. In the **Query Execution Mode** dropdown list, leave the default **Database** selected.
 

The default mode allows the view criteria to filter the database table specified by the view object query.
5. In the Criteria Definition tab, click **Add Item** to define the view criteria.
6. In the view criteria hierarchy, select the unassigned view criteria item node beneath **Group** and, in the **Criteria Item** section, select the **Attribute** dropdown and select the detail view object from the list.

When a view link exists for the current view object you are editing, you may select a detail view object to create a view criteria with a nested view criteria inline. The

detail view object name will appear in the **Attribute** dropdown list. For example, PersonsVO is linked to the AddressVO and a view criteria definition for findPersonByEmail filters the master view object PersonsVO by attributes of the detail view object AddressVO, as shown in [Example 5-43](#).

**Figure 5-43** Edit View Criteria Dialog with Inline View Criteria Specified

7. Leave the default **Operator** and **Operand** selections unchanged.

When you create an inline view criteria with a view object criteria item, the editor specifies the **Exists** operator and **Inline View Criteria** operand as the default choices. At runtime, the EXISTS operator tests for the presence of the attribute value in the detail view object and filter the rows in the master view object, as shown in [Example 5-34](#).

8. In the view criteria hierarchy, select the new view criteria item node beneath **Group** and, in the **Criteria Item** section, enter the following:
  - In the **Attribute** dropdown, select the attribute from the detail view object that you want to filter by.  
The detail attribute is the attribute that will be used to filter the master view object. The value of this attribute can be supplied by the end user when a bind variable is defined for the criteria item.
  - In the **Operator** dropdown, select the desired filter operator.
  - In the **Operand** dropdown, select **Bind Variable** to specify the name of the bind variable for the detail attribute. If the variable was already defined for the view criteria, select it from the **Parameter** dropdown list. Otherwise, click **New** to display the New Variable dialog that lets you name a new bind variable on the view criteria.

**Note:** When you select an existing bind variable from the dropdown list for use by the view criteria, do not select a bind variable that has been defined for the view object query (these will appear on the Query page of the overview

editor). Select only bind variables that you define in the View Criteria page of the overview editor.

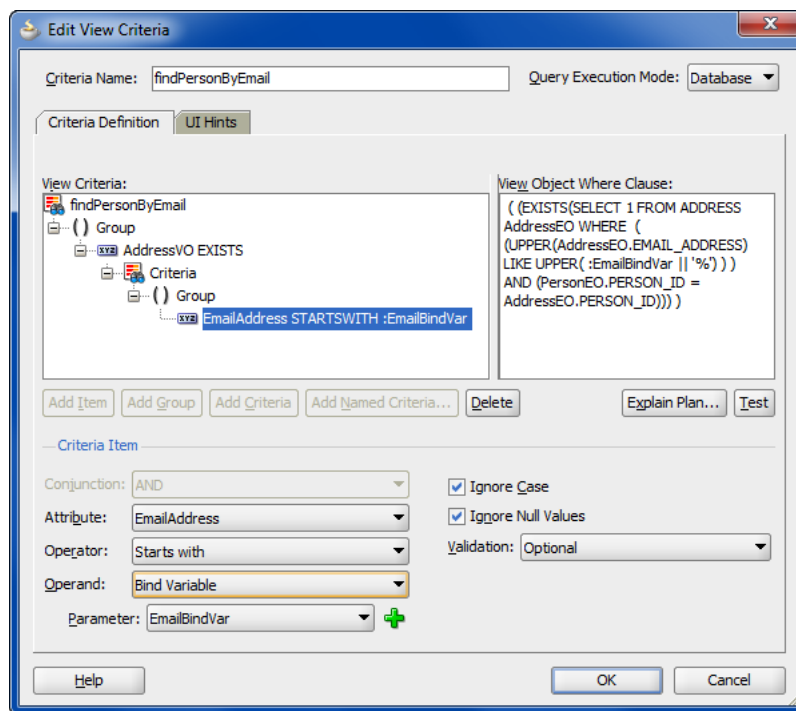

9. To disable case-sensitive filtering of the attribute based on the case of the runtime-supplied value, leave **Ignore Case** selected.

This option is supported for attributes of type String only. The default disables case sensitive searches.

10. In the **Validation** dropdown list, leave the default **Optional** selected.

**Optional** means the view criteria (or search field) is added to the WHERE clause only if the value is non-NULL. The default **Optional** for each new view criteria item means no exception will be generated for null values. For example, a `findPersonByEmail` view criteria definition filters the master view object `PersonsVO` by the `Email` attribute of the detail view object `AddressVO`, and the value may be null, as shown in [Figure 5-44](#).

**Figure 5-44** Edit View Criteria Dialog with Bind Variable Criteria Item Specified

11. Click **OK**.
12. In the View Criteria page of the overview editor, select the bind variable and in the **Details** section, leave the default settings unchanged:
  - Leave **Literal** selected but do not supply a default value. The value will be obtained from the end user at runtime.
  - Leave **Updatable** selected to allow the bind variable value to be defined through the user interface.
13. In the View Criteria page, click the **UI Hints** tab and specify hints like **Label**, **Format Type**, **Format** mask, and others.

The view layer will use bind variable UI hints when you build user interfaces like search pages that allow the user to enter values for the named bind variables. Note

that formats are only supported for bind variables defined by the `Date` type or any numeric data type.

### 5.11.7 How to Test View Criteria Using the Business Component Browser

To test the view criteria you added to a view object, use the Business Component Browser, which is accessible from the Application Navigator.

The Business Component Browser, for any view object instance that you browse, lets you bring up the Business Components View Criteria dialog, as shown in [Figure 5-45](#). The dialog allows you to create a view criteria comprising one or more view criteria rows.

To apply criteria attributes from a single view criteria row, click the **Specify View Criteria** toolbar button in the browser and enter Query-by-Example criteria in the desired fields, then click **Find**.

#### To test view criteria using the Business Component Browser:

1. In the Application Navigator, expand the project containing the desired application module and view objects.
2. Right-click the application module and choose **Run**.
3. In the Business Component Browser, right-click the view instance you want to filter and choose **Find**.

Alternatively, after you double-click a view instance, you can click the **Specify View Criteria** toolbar button to test the view criteria.

4. In the Business Components View Criteria dialog, perform one of the following tasks:
  - To test a view criteria that you added to the view object in your project, select from the list and click **Find**. Any additional criteria that you enter in the ad hoc Criteria panel will be added to the filter.
  - To test ad hoc criteria attributes from a single view criteria row, enter the desired values for the view criteria and click **Find**. For example, [Figure 5-45](#) shows the filter to return all customers who possess a customer ID that begins with the letter "d" and placed an order in the amount greater than 100.
  - To test additional ad hoc view criteria rows, click the **OR** tab and use the additional tabs that appear to switch between pages, each representing a distinct view criteria row. When you click **Find**, the Business Component Browser will create and apply the view criteria to filter the result.

**Figure 5–45 Business Components View Criteria Dialog**

### 5.11.8 How to Create View Criteria Programmatically

[Example 5–35](#) shows the `main()` method finds the `PersonList` view object instance to be filtered, creates a view criteria for the attributes of this view object, and applies the view criteria to the view object.

To create a view criteria programmatically, follow these basic steps (as illustrated in [Example 5–35](#)):

1. Find the view object instance to be filtered.
2. Create a view criteria row set for the view object.
3. Use the view criteria to create one or more empty view criteria rows
4. Set attribute values to filter on the appropriate view criteria rows.

You can use the single method `setAttribute()` on the view criteria rows to set attribute name, comparison operator, and value to filter on. Alternatively, use `ensureCriteriaItem()`, `setOperator()`, and `setValue()` on the view criteria rows to set attribute name, comparison operator, and value to filter on individually.

5. Add the view criteria rows to the view criteria row set.
6. Apply the view criteria to the view object.
7. Execute the query.

The last step to execute the query is important, since a newly applied view criteria is applied to the view object's SQL query only at its next execution.

#### **Example 5–35 Creating and Applying a View Criteria**

```
package devguide.examples.readonlyvo.client;

import oracle.jbo.ApplicationModule;
import oracle.jbo.Row;
```

```

import oracle.jbo.ViewCriteria;
import oracle.jbo.ViewCriteriaRow;
import oracle.jbo.ViewObject;
import oracle.jbo.client.Configuration;

public class TestClientViewCriteria {
    public static void main(String[] args) {
        String amDef = "devguide.examples.readonlyvo.PersonService";
        String config = "PersonServiceLocal";
        ApplicationModule am =
            Configuration.createRootApplicationModule(amDef, config);
        // 1. Find the view object to filter
        ViewObject vo = am.findViewObject("PersonList");
        // Work with your appmodule and view object here
        Configuration.releaseRootApplicationModule(am, true);
        // 2. Create a view criteria row set for this view object
        ViewCriteria vc = vo.createViewCriteria();
        // 3. Use the view criteria to create one or more view criteria rows
        ViewCriteriaRow vcr1 = vc.createViewCriteriaRow();
        ViewCriteriaRow vcr2 = vc.createViewCriteriaRow();
        // 4. Set attribute values to filter on in appropriate view criteria rows
        vcr1.setAttribute("PersonId", "> 200");
        vcr1.setAttribute("Email", "d%");
        vcr1.setAttribute("PersonTypeCode", "STAFF");
        // Note the IN operator must be followed by a space after the operator.
        vcr2.setAttribute("PersonId", "IN (204,206)");
        vcr2.setAttribute("LastName", "Hemant");
        // 5. Add the view criteria rows to the view criteria row set
        vc.add(vcr1);
        vc.add(vcr2);
        // 6. Apply the view criteria to the view object
        vo.applyViewCriteria(vc);
        // 7. Execute the query
        vo.executeQuery();
        while (vo.hasNext()) {
            Row curPerson = vo.next();
            System.out.println(curPerson.getAttribute("PersonId") + " " +
                curPerson.getAttribute("Email"));
        }
    }
}

```

Running the `TestClientViewCriteria` example produces the results shown in [Example 5-35](#):

206 SHEMANT

### 5.11.9 What Happens at Runtime: When the View Criteria Is Applied to a View Object

When you apply a view criteria containing one or more view criteria rows to a view object, the next time it is executed it augments its SQL query with an additional `WHERE` clause predicate corresponding to the Query-by-Example criteria that you've populated in the view criteria rows. As shown in [Figure 5-46](#), when you apply a view criteria containing multiple view criteria rows, the view object augments its design time `WHERE` clause by adding an additional runtime `WHERE` clause based on the non-null example criteria attributes in each view criteria row.

A corollary of the view criteria feature is that each time you apply a new view criteria (or remove an existing one), the text of the view object's SQL query is effectively changed. Changing the SQL query causes the database to reparse the statement the

next time it is executed. You can eliminate the reparsing and improve the performance of a view criteria as described in [Section 5.11.11, "What You May Need to Know About Query-by-Example Criteria."](#)

**Figure 5–46 View Object Automatically Translates View Criteria Rows into Additional Runtime WHERE Filter**

### 5.11.10 What You May Need to Know About the View Criteria API

When you need to perform tasks that the Edit View Criteria dialog does not support, review the View Criteria API. For example, programmatically, you can alter compound search conditions using multiple view criteria rows, search for a row whose attribute value is NULL, search case insensitively, and clear view criteria in effect.

#### 5.11.10.1 Referencing Attribute Names in View Criteria

The `setWhereClause()` method allows you to add a dynamic WHERE clause to a view object, as described in [Section 6.4.1, "ViewObject Interface Methods for Working with the View Object's Default RowSet."](#) You can also use `setWhereClause()` to pass a string that contains literal database column names like this:

```
vo.setWhereClause("LAST_NAME LIKE UPPER(:NameToFind)");
```

In contrast, when you use the view criteria mechanism, shown in [Example 5–35](#), you must reference the view object attribute name instead, like this:

```
ViewCriteriaItem vc_item1 = vc_row1.ensureCriteriaItem("UserId");
vc_item1.setOperator(">");
vc_item1.setValue("304");
```

The view criteria rows are then translated by the view object into corresponding WHERE clause predicates that reference the corresponding column names.

#### 5.11.10.2 Referencing Bind Variables in View Criteria

When you want to set the value of a view criteria item to a bind variable, use `setIsBindVarValue(true)`, like this:

```
ViewCriteriaItem vc_item1 = vc_row1.ensureCriteriaItem("UserId");
```

```
vc_item1.setIsBindVarValue(true);
vc_item1.setValue(":VariableName");
```

### 5.11.10.3 Altering Compound Search Conditions Using Multiple View Criteria

When you add multiple view criteria, you can call the `setConjunction()` method on a view criteria to alter the conjunction used between the predicate corresponding to that view criteria and the one for the previous view criteria. The legal constants to pass as an argument are:

- `ViewCriteriaComponent.VC_CONJ_AND`
- `ViewCriteriaComponent.VC_CONJ_NOT`
- `ViewCriteriaComponent.VC_CONJ_UNION`
- `ViewCriteriaComponent.VC_CONJ_OR` (*default*)

The NOT value can be combined with AND or OR to create filter criteria like:

```
( PredicateForViewCriteria1 ) AND ( NOT ( PredicateForViewCriteria2 ) )
```

or

```
( PredicateForViewCriteria1 ) OR ( NOT ( PredicateForViewCriteria2 ) )
```

The syntax to achieve compound search conditions requires using Java's bitwise OR operator like this:

```
vc2.setConjunction(ViewCriteriaComponent.VC_CONJ_AND | ViewCriteriaComponent.VC_CONJ_NOT);
```

**Performance Tip:** Use the UNION value instead of an OR clause when the UNION query can make use of indices. For example, if the view criteria searches for `sal > 2000 or job = 'CLERK'` this query may turn into a full table scan. Whereas if you specify the query as the union of two inner view criteria, and the database table has an index on `sal` and an index on `job`, then the query can take advantage of these indices and the query performance will be significantly better for a large data set.

The limitation for the UNION clause is that it must be defined over one view object. This means that the SELECT and the FROM list will be the same for inner queries of the UNION clause. To specify a UNION query, call `setConjunction()` on the outer view criteria like this:

```
vc.setConjunction(ViewCriteriaComponent.VC_CONJ_UNION);
```

The outer view criteria should contain inner queries whose results will be the union. For example, suppose you want to specify the union of these two view criteria:

- A view criteria named `MyEmpJob`, which searches for `Job = 'SALESMAN'`.
- A view criteria named `MyEmpSalary`, which searches for `Sal = 1500`.

To create the UNION query for these two view criteria, you would make the calls shown in [Example 5-36](#).

#### **Example 5-36 Applying the Union of Two View Criteria**

```
vcu = voEmp.createViewCriteria();
```

```

vcm = voEmp.getViewCriteriaManager();

vcu.setConjunction(ViewCriteria.VC_CONJ_UNION);
vcu.add(vcm.getViewCriteria("MyEmpJob"));
vcu.add(vcm.getViewCriteria("MyEmpSal"));

voEmp.applyViewCriteria(vcu);

```

When this view criteria is applied, it will return rows where Job is SALESMAN or Sal is greater than 1500.

When you use a UNION view criteria, be sure that only one of the applied view criteria has the UNION conjunction. Other view criteria that you apply will be applied to each inner query of the UNION query.

#### 5.11.10.4 Searching for a Row Whose Attribute Value Is NULL

To search for a row containing a NULL value in a column, populate a corresponding view criteria row attribute with the value "IS NULL" or use `ViewCriteriaItem.setOperator("ISBLANK")`.

#### 5.11.10.5 Searching for Rows Using a Date Comparison

When you want to perform a comparison of date values in a view criteria item, use the following predefined operators:

- BEFORE
- AFTER
- ONORBEFORE
- ONORAFTER

For example, to search for rows that contain a DATE type attribute whose value is after a given date, you would use `ViewCriteriaItem.setOperator("AFTER")`.

Do not use operators like `<`, `>`, `<=`, and `>=` because these operators perform string comparisons that yield inaccurate results for date values.

#### 5.11.10.6 Searching for Rows Whose Attribute Value Matches a Value in a List

To search for all rows with a value in a column that matches any value in a list of values that you specify, populate a corresponding view criteria row attribute with the comma-separated list of values and use the IN operator. For example, to filter the list of persons by IDs that match 204 and 206, set:

```
vcr.setAttribute("PersonId", "IN (204,206)");
```

Note that there must be a space between the IN operator and the brace:

- `IN (204,206)` is correct.
- `IN(204,206)` throws a `SQLException` error.

#### 5.11.10.7 Searching Case-Insensitively

To search case-insensitively, call `setUpperColumns(true)` on the view criteria row to which you want the case-insensitivity to apply. This affects the WHERE clause predicate generated for String-valued attributes in the view object to use `UPPER(COLUMN_NAME)` instead of `COLUMN_NAME` in the predicate. Note that the value of the supplied view criteria row attributes for these String-valued attributes must be uppercase or the predicate won't match. In addition to the predicate, it also possible

to use `UPPER()` on the value. For example, you can set `UPPER(ename) = UPPER('scott')`.

#### 5.11.10.8 Clearing View Criteria in Effect

To clear any view criteria in effect, you can call `getViewCriteria()` on a view object and then delete all the view criteria rows from it using the `remove()` method, passing the zero-based index of the criteria row you want to remove. If you don't plan to add back other view criteria rows, you can also clear all the view criteria in effect by simply calling `applyViewCriteria(null)` on the view object.

### 5.11.11 What You May Need to Know About Query-by-Example Criteria

For performance reasons, you want to avoid setting a bind variable as the value of a view criteria item in these two cases:

- In the specialized case where the value of a view criteria item is defined as selectively required and the value changes from non-NULL to NULL.  
In this case, the SQL statement for the view criteria will be regenerated each time the value changes from non-NULL to NULL.
- In the case where the value of the view criteria item is optional and that item references an attribute for an indexed column.  
In the case of optional view criteria items, an additional SQL clause `OR (:Variable IS NULL)` is generated, and the clause does not support using column indices.

In either of the following cases, you will get better performance by using a view object whose `WHERE` clause contains the named bind variables, as described in [Section 5.10.1, "How to Add Bind Variables to a View Object Definition."](#) In contrast to the view criteria filtering feature, when you use named bind variables, you can change the *values* of the search criteria without changing the *text* of the view object's SQL statement each time those values change.

## 5.12 Working with Row Finders

Row finders are objects that the application may use to locate specific rows within a row set using a view criteria. You can define a row finder when you need to perform row lookup operations on the row set and you do not want the application to use row key attributes to specify the row lookup.

Currently, row finders that you define at design time can participate in these scenarios where non-row key attribute lookup is desired at runtime:

- When you expose the row finder in an ADF Business Components web service, the end user may initiate row updates on the specific rows of the service view instance that match one or more row-finder mapped, non-key attribute values. For more information about this use case, see [Section 5.12.3, "What You May Need to Know About View Criteria and Row Finder Usage."](#)
- Programmatically in the application when you want to obtain a set of rows that match one or more row-finder mapped, non-key attribute values. For more information about this use case, see [Section 5.12.4, "How to Programmatically Invoke the Row Finder."](#)

---

---

**Note:** Row finders that you define on a view object are not currently supported by the ADF Business Components data control for use in a view project. Therefore the row-finder mapped attributes of a view object that the application exposes as a collection in the Data Controls panel will not participate in row finder lookup operations

---

---

When the application programmatically invokes the row finder on the view object instance, or when the end user supplies a value for a row-finder mapped attribute in the web service payload, the row finder locates the rows that match the values supplied to bind variables of the view criteria. The row finder does not alter the row set when locating matching rows.

You can specify the row finder to locate all row matches or a specified number of row matches. If the row finder locates more rows than the fetch limit you specify, you can enable the row finder to throw an exception.

The view object definition with row finder includes the following elements.

1. A specified view criteria that applies one or more view criteria items to filter the view object. View criteria items are defined on the view object attributes that determine the row match and must be defined by bind variables to allow the row finder to supply the values at runtime.
2. A mapping between view criteria bind variables and the source of the value: either a transient attribute of the view object or an attribute value expression.

For example, where `EmpVO` has an attribute `email`, an `EmpVO` row finder may locate a specific employee row using a view criteria defined on the `EmpVO` and the email address of the employee. The view criteria for the `EmpVO` might look similar to the one shown in [Example 5–37](#). In this example, the view criteria statement uses a bind variable `EmailBindVar` to set the value of the email attribute on the view object `EmpVO`.

**Example 5–37 View Criteria Statement Uses Bind Variables**

```
( (UPPER(EmpVO.EMAIL) = UPPER(:EmailBindVar) ) )
```

The application may invoke the row finder by applying values to the mapped view criteria bind variables in a variety of ways:

- An ADF Business Components web service with an enabled update operation may display a form with input fields that are bound to view object transient attributes that the row finder maps to view criteria bind variables.

For details about enabling operations of Business Components web services, see [Section 11.2.1, "How to Enable the Application Module Service Interface."](#)

- The application may invoke the row finder on the view object and programmatically set the value of the mapped view object attributes to the view criteria bind variables.

For more information, see [Section 5.12.4, "How to Programmatically Invoke the Row Finder."](#)

## 5.12.1 How to Add Row Finders to a View Object Definition

You use the Row Finders page of the view object's overview editor to define the row finder. In the editor, you define a value source for each bind variable of the view

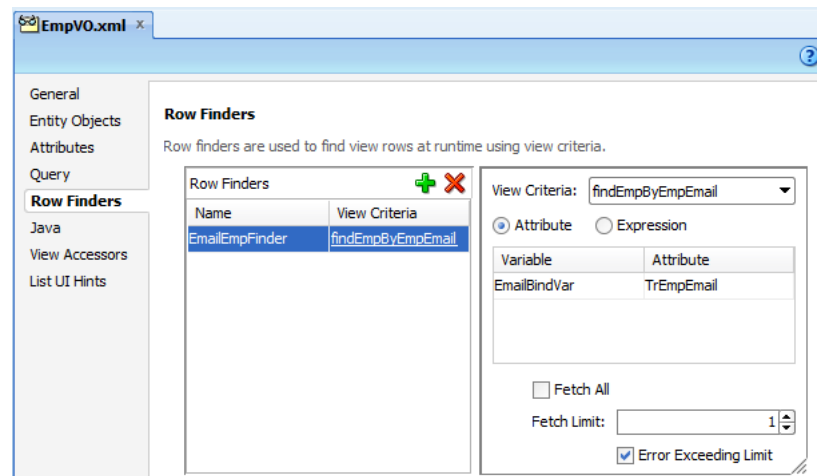

criteria that you select. Attributes of the view object or attribute value expressions are both valid sources for bind variables defined by the row finder.

The row finder that you define can map any number of view criteria bind variables to a valid value source. Mapping additional variables in the row finder definition will result in more restrictive row matches. In this regard, row finders are similar to query search operations that do not alter the row set. Using an appropriately defined row finder, the application can locate a single, specific row and allow the end user to perform row updates on the row.

Figure 5–47 shows the overview editor with a row finder that maps the view criteria bind variable `EmailBindVar` specified in the `findEmpByEmpEmail` view criteria to the transient attribute `TrEmpEmail` defined by the view object `EmpVO` as its value source.

**Figure 5–47** View Object Overview Editor with Row Finder

---

**Note:** You can define row finders on master view objects in a master-detail hierarchy when you want to filter the master by attributes of the detail view object. In this scenario, the view criteria uses an inline view criteria, as described in [Section 5.12.5, "How to Find Rows of a Master View Object."](#)

---

#### Before you begin:

It may be helpful to have an understanding of the row finder. For more information, see [Section 5.12, "Working with Row Finders."](#)

It may be helpful to have an understanding of view criteria. For more information, see [Section 5.11, "Working with Named View Criteria."](#)

You will need to complete these tasks:

- Create the desired view objects, as described in [Section 5.2, "Populating View Object Rows from a Single Database Table"](#) or [Section 5.5, "Working with Multiple Tables in Join Query Results."](#)
- Define a view criteria on the view object, as described in [Section 5.11.1, "How to Create Named View Criteria Declaratively."](#)
- Optionally, add transient attributes to the view object, as described in [Section 5.15.3, "How to Add a Transient Attribute."](#) The transient attribute is an

alternative to an attribute value expression that is evaluated at runtime. The transient attribute may be set programmatically by the application or exposed in an ADF Business Components web service payload to solicit the value from an end user. The transient attributes must be defined as updatable to receive the criteria lookup value.

**To create a row finder for a view object:**

1. In the Application Navigator, double-click the view object for which you want to create the row finder.
2. In the overview editor, click the **Row Finders** navigation tab and then click the **Add Row Finder** button.
3. In the **Name** field, rename the row finder.

For example, a row finder that you define to locate an employee by their email address, might be named `EmpByEmailRowFinder`.

4. Select the new row finder in the **Row Finders** list and then, in the **View Criteria** dropdown, select the view criteria that filters the view object row set.

The desired row finder should appear highlighted, as shown in [Figure 5-47](#). The view criteria list will be empty unless you have created a view criteria for the row finder to use.

5. When you want the end user of an ADF Business Components web service to supply a value, leave **Attribute** selected, select the bind variable from the list, and then, in the **Attribute** dropdown, select the transient attribute from the view object that supplies the bind variable value at runtime.

The transient attribute that you select will be the one that the end user updates to supply the criteria attribute value. For example, a row finder that matches the employee record by their email address, might include a transient attribute named `TrEmpEmail` that you define on the `EmpVO` view object.

**Note:** When you create the transient attribute in the overview editor for the view object, be sure to define the transient attribute as **Updatable** so it can receive the criteria lookup value.

6. Deselect **FetchAll** when you want to specify the number of rows that the row finder is allowed to match.

When you enter a number of rows for **Fetch Limit**, you can also select **Error Exceeding Limit** to enable Oracle ADF to throw an exception when more matching rows exist in the database than the number you specify for **Fetch Limit**.

## 5.12.2 What Happens When You Define a Row Finder

When you create a view object row finder, the view object definition contains all the metadata required by the row finder, including the row finder definition itself. As [Example 5-38](#) shows, the metadata for a row finder `RowFinder` includes a bind variable `EmailBindVar` in the `<Variable>` element, a transient attribute `TrEmpEmail` in the `<ViewAttribute>` element, a view criteria `findEmpByEmpEmail` and a view criteria row `EmpVOCriteria_Row0` in the `<ViewCriteria>` element, and finally the row finder `EmpByEmailRowFinder` in the `<RowFinders>` element of the view object definition.

The row finder `<VarAttributeMapping>` subelement maps the view criteria bind variable `EmailBindVar` to the transient attribute `TrEmpEmail` of the view object, which allows the end user to supply a value at runtime and allows the application to

invoke the row finder with the required criteria attribute. The `<ViewCriteriaItem>` subelement sets the criteria attribute `Email` to the value of the bind variable `EmailBindVar`.

At runtime, when the row finder is invoked on the view object, the transient attribute values passed to one or more criteria attributes identify the matching rows in the row set. In this example, the email of the employee is used to match the employee record from the `S_EMP` table. The row finder locates the record for the employee without the need to pass a row key value.

### **Example 5–38 Row Finder Defined on a View Object**

```
<ViewObject
  xmlns="http://xmlns.oracle.com/bc4j"
  Name="EmpVO"
  SelectList="EmpEO.ID,
             EmpEO.LAST_NAME,
             EmpEO.FIRST_NAME"
             EmpEO.USERID"
             EmpEO.DEPT_ID"
             EmpEO.EMAIL"
  FromList="S_EMP EmpEO"
  ...
<Variable
  Name="EmailBindVar"
  Kind="viewcriteria"
  Type="java.lang.String" />
<EntityUsage
  Name="EmpEO"
  Entity="model.entities.EmpEO" />
  ...
<ViewAttribute
  Name="TrEmpEmail"
  IsUpdateable="false"
  IsSelected="false"
  IsPersistent="false"

</ViewObject>

```

### 5.12.3 What You May Need to Know About View Criteria and Row Finder Usage

Row finders and view criteria can both be used either programmatically or declaratively to filter a view object row set. The row finder differs from the view criteria because it defines a map between transient attributes that you define on the view object and view criteria attribute bind variables. Ultimately, the row finder matches one or more rows on the view object by applying the view criteria to the view object with the bind variable defined by a transient attribute value that is resolved at runtime.

The transient attribute mapped by the row finder allows the row finder to be used in application use cases that would not be suitable for view criteria alone. In particular, row finders are most useful when ADF Business Components web services enable CRUD operations. In this case, the row finder gives the ADF Business Components web services developer the ability to expose CRUD operations without needing obscure row key values.

Fusion web application developers can create a web service data control to expose the view objects of an ADF Business Components web service in the JDeveloper Data Controls panel. The exposed row-finder mapped transient attributes of the view object can then be used to design an input form that allows the end user to make the desired updates. For example, an end user may supply the value of a familiar attribute, such as a person's email address, to match a particular person row and then initiate an update operation on any attribute of that row, such as the one that would allow a name change.

For details about support for row finder in ADF web services, see [Section 11.2.4, "What You May Need to Know About Row Finders and the ADF Web Service Operations."](#) For details about creating data controls based on ADF web services, see [Chapter 13, "Integrating Web Services Into a Fusion Web Application."](#)

Note that the capability of row finders to match rows using non-key attributes extends to master-detail related view objects, as described [Section 5.12.5, "How to Find Rows of a Master View Object."](#)

### 5.12.4 How to Programmatically Invoke the Row Finder

When you define a row finder you invoke the row finder on the view object. If the row finder definition specifies a row limit, the executed row finder will throw a `RowFinderFetchLimitExceededException` exception.

To invoke a row finder that you define on a view object, follow these basic steps (as illustrated in [Example 5–39](#)):

1. Find the view object that defines the row finder.
2. Find the row finder from the view object.
3. Create a name value pair for each row finder bind variable mapping.
4. Set each bind variable using a row-finder mapped transient attribute.
5. Invoke the row finder on the desired view object.
6. Throw an exception when the number of matching rows exceeds the row finder fetch limit.

At runtime, when the row finder is invoked on the view object, row-finder mapped transient attribute values populated by `setAttribute()` are set on criteria attributes to identify the matching rows in the row set. In the following example, the email address of the employee is used to match the employee record on the `EmpView` view object. The row finder `EmpByEmailRowFinder` locates the record for the employee using the transient attribute `TrEmpEmail` to specify the criteria attribute without the need to pass a row key value.

**Example 5–39 Invoking a Row Finder on a View Object**

```
package model;

import oracle.jbo.*;
import oracle.jbo.client.Configuration;
import oracle.jbo.server.RowFinder;
import oracle.jbo.server.ViewObjectImpl;

public class TestClient
{
    public TestClient()
    {
        super();
    }

    public static void main(String[] args)
    {
        TestClient testClient = new TestClient();
        String amDef = "model.AppModule";
        String config = "AppModuleLocal";
        ApplicationModule am =
            Configuration.createRootApplicationModule(amDef, config);

        // 1. Find the view object with the row finder
        ViewObjectImpl vo = (ViewObjectImpl)am.findViewObject("EmpView1");
        Row r;
        RowIterator ri;

        // 2. Find the row finder
        RowFinder finder = vo.lookupRowFinder("EmpByEmailRowFinder");
        // 3. Create name value pairs for the row finder
        NameValuePairs nvp = new NameValuePairs();
        // 4. Set the row-finder mapped transient attribute
        nvp.setAttribute("TrEmpEmail", "cee.mague@company.com");
        // 5. Invoke the row finder
        try
        {
```

```

        ri = finder.execute(nvp, vo);
    }
    // 6. Throw an exception when row match exceeds specified limit
    catch(RowFinderFetchLimitExceededException e)
    {
        System.out.println("Warning: more than one row match exists.");
    }

    while (ri.hasNext())
    {
        r = ri.next();
        System.out.println("Find emp row by email finder: " +
            r.getAttribute("FirstName") + "/" + r.getAttribute("LastName"));
    }

    Configuration.releaseRootApplicationModule(am, true);
}
}

```

### 5.12.5 How to Find Rows of a Master View Object

Row finders are objects that the application may use to locate specific rows within a row set using a view criteria. The row finder may be invoked on the master row set to match one or more criteria attributes supplied by the detail row set.

The view criteria attributes defined by the view criteria can be any attribute that the detail view object defines and specifically need not be a row key attribute. For example, in a master-detail relationship, where `PersonsVO` is the master view object and `AddressVO` is the detail view object, the attribute `EmailAddress` will locate the person row that matches the email address of the person in the `AddressVO` row set.

To create a row finder to locate rows of the master view object using criteria attributes supplied by the detail view object, perform the following steps:

1. Define an inline view criteria on the master view object to reference the detail view object and specify the criteria attributes as a view criteria items defined by bind variables.
2. Define a transient attribute on the master view object to receive the value of each criteria attribute. At runtime, the transient attribute may be set programmatically or exposed in a web service payload to allow an end user to supply the criteria attribute value (for example, an email address).
3. Define the row finder on the master view object by selecting the view criteria and setting each criteria attribute's bind variable to a corresponding transient attribute from the master view object.

#### 5.12.5.1 Defining a Row Finder on the Master View Object

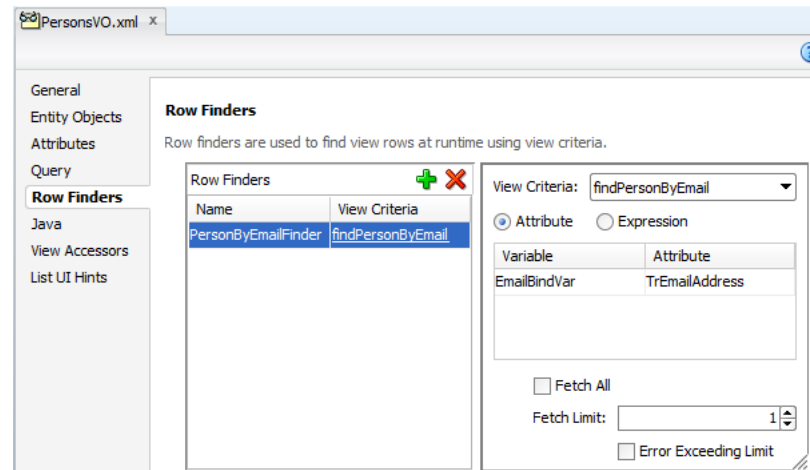

Row finders that you define to filter the row set of a master view object are defined entirely on the master view object. The row finder matches the criteria attributes that you specified in the inline view criteria with values obtained at runtime. In order to receive the criteria attribute values, the master view object may define transient attributes that are programmatically set by the application using row finder methods on the view object or that a web service payload may expose to receive end user-supplied values.

You use the Row Finders page of the master view object's overview editor to define the row finder. In the editor, you define a value source for each bind variable of the

view criteria that you select. Attributes of the view object or attribute value expressions are both valid sources for bind variables defined by the row finder.

Figure 5–48 shows the overview editor with a row finder that maps the view criteria bind variable `EmailBindVar` specified in the `findPersonByEmail` view criteria to the transient attribute `TrEmailAddress` defined by the master view object `PersonsVO` as its value source.

**Figure 5–48** View Object Overview Editor with Row Finder

---

**Note:** You can also define row finders on view objects that do not participate in a master-detail hierarchy, as described in [Section 5.12.1, "How to Add Row Finders to a View Object Definition."](#)

---

#### Before you begin:

It may be helpful to have an understanding of the row finder for master-detail view objects. For more information, see [Section 5.12.5, "How to Find Rows of a Master View Object."](#)

It may be helpful to have an understanding of master-detail view objects. For more information, see [Section 5.6, "Working with Multiple Tables in a Master-Detail Hierarchy."](#)

You will need to complete these tasks:

- Create the desired master-detail view objects, as described in [Section 5.6.1, "How to Create a Master-Detail Hierarchy for Entity-Based View Objects"](#) or [Section 5.6.2, "How to Create a Master-Detail Hierarchy Based on View Objects Alone."](#)
- Define an inline view criteria on the master view object, as described in [Section 5.11.6, "How to Use Master-Detail Related View Objects in View Criteria."](#) The inline view criteria references the detail view object and specifies one or more detail attributes as view criteria items.
- Optionally, add transient attributes to the master view object, as described in [Section 5.15.3, "How to Add a Transient Attribute."](#) For example, the transient attribute allows end users of an ADF Business Components web service to enter the criteria attribute value (for example, an email address). The transient attributes must be defined as updatable to receive the criteria lookup value.

**To create a row finder for a master view object:**

1. In the Application Navigator, double-click the master view object that you want to customize with a new row finder.
2. In the overview editor, click the **Row Finders** navigation tab and then click the **Add Row Finder** button.
3. In the **Name** field, rename the row finder.

For example, a row finder that you define to locate a person record by their email address, might be named `PersonByEmailFinder`.

4. Select the new row finder in the **Row Finders** list and then, in the **View Criteria** dropdown, select the view criteria that filters the view object row set.

The desired row finder should appear highlighted, as shown in [Figure 5–48](#). The view criteria list will be empty unless you have created a view criteria for the row finder to use.

5. When you want the end user of an ADF Business Components web service to supply a value, leave **Attribute** selected, select the bind variable from the list, and then, in the **Attribute** dropdown, select the transient attribute from the master view object that supplies the bind variable value at runtime.

The transient attribute that you select will be used by the row finder to supply the criteria attribute value. For example, a `PersonsVO` master view object that matches rows based on the email address in the `AddressVO`, might include a transient attribute that you define named `TrEmailAddress`.

**Note:** When you create the transient attribute in the overview editor for the view object, be sure to define the transient attribute as **Updatable** so it can receive the criteria lookup value.

6. Deselect **FetchAll** when you want to specify the number of rows that the row finder is allowed to match.

When you enter a number of rows for **Fetch Limit**, you can also select **Error Exceeding Limit** to enable Oracle ADF to throw an exception when more matching rows exist in the database than the number you specify for **Fetch Limit**.

**5.12.5.2 What Happens When You Create a Row Finder for a Master View Object**

When you create a master view object row finder, the view object definition contains all the metadata required by the row finder, including the row finder definition itself. As [Example 5–40](#) shows, the metadata for a row finder `PersonByEmailFinder` includes a bind variable `EmailBindVar` in the `<Variable>` element, a transient attribute `TrEmailAddress` in the `<ViewAttribute>` element, a view criteria `findPersonByEmail` and an inline view criteria `AddressVONestedCriteria` in the `<ViewCriteria>` element, and finally the row finder `PersonByEmailFinder` in the `<RowFinders>` element of the view object definition.

The row finder `<VarAttributeMapping>` subelement maps the view criteria bind variable `EmailBindVar` to the transient attribute `TrEmailAddress` of the master view object, which allows the end user to supply a value at runtime and allows the application to invoke the row finder with the required criteria attribute. The inline `<ViewCriteriaItem>` subelement sets the criteria attribute `EmailAddress` on the detail view object to the value of the bind variable.

At runtime, when the row finder is invoked on the master view object, the transient attribute values passed to one or more criteria attributes identify the matching rows in the master row set. In this example, the email address is used to match the person to

which the email address belongs. The row finder locates the person record without the need to pass a row key value.

**Example 5–40 Row Finder Defined on a Master View Object**

```
<ViewObject
  xmlns="http://xmlns.oracle.com/bc4j"
  Name="PersonsVO"
  SelectList="PersonEO.ID,
             PersonEO.FIRST_NAME
             PersonEO.LAST_NAME"
  FromList="PERSON PersonEO"
  ...
  <Variable
    Name="EmailBindVar"
    Kind="viewcriteria"
    Type="java.lang.String"/>
  <EntityUsage
    Name="PersonEO"
    Entity="model.entities.PersonEO"/>
  ...
  <ViewAttribute
    Name="TrEmailAddress"
    IsUpdateable="false"
    IsSelected="false"
    IsPersistent="false"
    PrecisionRule="true"
    Type="java.lang.String"
    ColumnType="CHAR"
    AliasName="VIEW_ATTR"
    SQLType="VARCHAR"/>
  <ViewCriteria
    Name="findPersonByEmail"
    ViewObjectName="model.views.PersonsVO"
    Conjunction="AND">
    ...
    <ViewCriteriaRow
      Name="PersonsVOCriteria_row_0"
      UpperColumns="1">
      <ViewCriteriaItem
        Name="PersonsVOCriteria_PersonsVOCriteria_row_0_AddressVO"
        ViewAttribute="AddressVO"
        Operator="EXISTS"
        Conjunction="AND"
        IsNestedCriteria="true"
        Required="Optional">
      <ViewCriteria
        Name="AddressVONestedCriteria"
        ViewObjectName="model.views.AddressVO"
        Conjunction="AND">
      <ViewCriteriaRow
        Name="AddressVONestedCriteria_row_0"
        UpperColumns="1">
      <ViewCriteriaItem
        Name="AddressVONestedCriteria_row_0_EmailAddress"
        ViewAttribute="EmailAddress"
        Operator="="
        Conjunction="AND"
        Value=":EmailBindVar"
        IsBindVarValue="true"
```

```

        Required="Optional" />
    </ViewCriteriaRow>
</ViewCriteria>
</ViewCriteriaItem>
</ViewCriteriaRow>
</ViewCriteria>
...
<RowFinders>
<AttrValueRowFinder
    Name="PersonByEmailFinder"
    FetchLimit="1">
    <ViewCriteriaUsage
        Name="findPersonByEmail"
        FullName="model.views.PersonsVO.findPersonByEmail" />
    <VarAttributeMap>
        <VariableAttributeMapping
            Variable="EmailBindVar"
            Attribute="TrEmailAddress" />
    </VarAttributeMap>
    </AttrValueRowFinder>
</RowFinders>
</ViewObject>

```

## 5.13 Working with List of Values (LOV) in View Object Attributes

Edit forms displayed in the user interface portion of your application can utilize LOV-enabled attributes that you define in the data model project to predetermine a list of values for individual input fields. When the user submits the form with their selected values, ADF data bindings in the ADF Model layer update the value on the view object attributes corresponding to the databound fields. To facilitate this common design task, ADF Business Components provides declarative support to specify the LOV usage in the user interface.

Defining an LOV for attributes of a view object in the data model project greatly simplifies the task of working with list controls in the user interface. Because you define the LOV on the individual attributes of the view object, you can customize the LOV usage for an attribute once and expect to see the list component in the form wherever the attribute appears.

---

**Note:** In order for the LOV to appear in the UI, the LOV usage must exist before the user interface designer creates the databound form. Defining an LOV usage for an attribute referenced by an existing form will not change the component that the form displays to an LOV.

---

You can define an LOV for any view object attribute that you anticipate the user interface will display as a selection list. The characteristics of the attribute's LOV definition depend on the requirements of the user interface. The information you gather from the user interface designer will determine the best solution. For example, you might define LOV attributes in the following cases:

- When you need to display attribute values resulting from a view object query against a business domain object.

For example, define LOV attributes to display the list of suppliers in a purchase order form.

- When you want to display attribute values resulting from a view object query that you wish to filter using a parameter value from any attribute of the LOV attribute's current row.

For example, define LOV attributes to display the list of supplier addresses in a purchase order form but limit the addresses list based on the current supplier.

If you wish, you can enable a second LOV to drive the value of the parameter based on a user selection. For example, you can let the user select the current supplier to drive the supplier addresses list. In this case, the two LOVs are known as a *cascading list*.

Before you can define the LOV attribute, you must create a data source view object in your data model project that queries the eligible rows for the attribute value you want the LOV to display. After this, you work entirely on the base view object to define the LOV. The base view object is the one that contains the primary data for display in the user interface. The LOV usage will define the following additional view object metadata:

- A view accessor to access the data source for the LOV attribute. The view accessor is the ADF Business Components mechanism that lets you obtain the full list of possible values from the row set of the data source view object.
- Optionally, supplemental values that the data source may return to attributes of the base view object other than the data source attribute for which the list is defined.
- User interface hints, including the type of list component to display, attributes to display from the current row when multiple display attributes are desirable, and a few options specific to the choice list component.

---

**Note:** The LOV feature does not support the use of attribute validation to validate the display list. Any validation rules that may have been defined on data source attributes (including supplemental ones) will be suppressed when the list is displayed and will therefore not limit the LOV list. Developers must ensure that the list of values returned from the data source view object contains only desired, valid values.

---

The general process for defining the LOV-enabled attribute relies on the Edit Attribute dialog that you display for the base view object attribute.

**To define the LOV-enabled attribute, follow this general process:**

1. Select the **Enable List of Values** option.
2. Create a new view accessor definition to point to the data source view object or select an existing view accessor that the base view object already defines.  
  
Always create a new view accessor for each use case that your wish to support. Oracle recommends that you do not reuse a view accessor to define multiple LOV lists that happen to rely on the same data source. Reusing a view accessor can produce unintended results at runtime.
3. Optionally, you can filter the view accessor by creating a view criteria using a bind variable that obtains its value from any attribute of the base view object's current row.

If you create a view criteria to filter the data source view object, you may also set a prerequisite LOV on the attribute of the base view object that you use to supply

the value for the view criteria bind variable. LOV lists that cooperate in this manner, are known as cascading LOV lists. You set cascading LOV lists when you want the user's selection of one attribute to drive the options displayed in a second attribute's list.

4. Optionally, select list return values to map any supplemental values that your list returns to the base view object.
5. Select user interface hints to specify the list's display features.
6. Save the attribute changes.

Once you create the LOV-enabled attribute, the user interface designer can create the list component in the web page by dragging the LOV-enabled attribute's collection from the Data Controls panel. For further information about creating a web page that display the list, see [Chapter 25, "Creating Databound Selection Lists and Shuttles."](#) Specifically, for more information about working with LOV-enabled attributes in the web page, see [Section 25.3.2, "How to Create a Model-Driven List."](#)

### 5.13.1 How to Define a Single LOV-Enabled View Object Attribute

When an edit form needs to display a list values that is not dependent on another selection in the edit form, you can define a view accessor to point to the list data source. For example, assume that a purchase order form contains a field that requires the user to select the order item's supplier. In this example, you would first create a view accessor that points to the data source view object (`SuppliersView`). You would then set the LOV on the `SupplierDesc` attribute of the base view object (`PurchaseOrdersView`). Finally, you would reference that view accessor from the LOV-enabled attribute (`SupplierDesc`) of the base view object and select the data source attribute (`SupplierDesc`).

You will use the Create List of Values dialog to define an LOV-enabled attribute for the base view object. The dialog lets you select an existing view accessor or create a new one to save with the LOV-attribute definition.

#### Before you begin:

Create the desired view objects as described in [Section 5.2.1, "How to Create an Entity-Based View Object,"](#) and [Section 5.2.3, "How to Create an Expert Mode, Read-Only View Object."](#)

#### To define an LOV that displays values from a view object attribute:

1. In the Application Navigator, double-click the view object that contains the attribute you wish to enable as an LOV.
2. In the overview editor, click the **Attributes** navigation tab.
3. In the Attributes page, select the attribute that is to display the LOV, and then expand the **List of Values** section and click the **Add list of values** button.

Use the Create List of Values dialog to create the LOV on the attribute you have currently selected in the attribute list of the overview editor. JDeveloper assigns a unique name to identify the LOV usage. For example, the metadata for the attribute `SupplierDesc` will specify the name `SupplierDescLOV` to indicate that the attribute is LOV enabled.

4. In the Create List of Values dialog, click the **Create new view accessor** button to add a view accessor to the view object you are currently editing.

Alternatively, you can expand **List Data Source** and select among the existing view accessors. The dropdown list displays all view accessors that you have added to the view object you are editing.

5. In the View Accessors dialog, select the view object definition or shared view instance that defines the data source for the attribute and shuttle it to the view accessors list.

By default, the view accessor you create will display the same name as the view object. You can edit the accessor name to supply a unique name. For example, assign the name `SuppliersViewAccessor` for the `SuppliersView` view object.

The view instance is a view object usage that you have defined in the data model of a shared application module. For more information about using shared view instances in an LOV, see [Section 10.4.4, "How to Create an LOV Based on a Lookup Table."](#)

6. Click **OK** to save the view accessor definition for the view object.
7. In the Create List of Values dialog, expand **List Data Source** and select the view accessor you created for the base view object to use as the data source. Then select the same attribute from this view accessor that will provide the list data for the LOV-enabled attribute.

The editor creates a default mapping between the list data source attribute and the LOV-enabled attribute. For example, the attribute `SuppliersDesc` from the `PurchaseOrdersView` view object would map to the attribute `SuppliersDesc` from the `SuppliersViewAccessor` view accessor.

The editor does not allow you to remove the default attribute mapping for the attribute for which the list is defined.

8. Optionally, when you want to specify supplemental values that your list returns to the base view object, click the **Create return attribute map** button in the **List Return Values** section and map the desired base view object attributes with attributes accessed by the view accessor.

Supplemental attribute return values are useful when you do not require the user to make a list selection for the attributes, yet you want those values, as determined by the current row, to participate in the update. For example, to map the attribute `SupplierAddress` from the `PurchaseOrdersView` view object, you would choose the attribute `SupplierAddress` from the `SuppliersViewAccessor` view accessor.

9. Click **OK**.

### 5.13.2 How to Define Cascading Lists for LOV-Enabled View Object Attributes

When the application user interface requires a list of values in one input field to be dependent on the user's entry in another field, you can create attributes that will display as cascading lists in the user interface. In this case, the list of possible values for the LOV-enabled attributes might be different for each row. As the user changes the current row, the LOV values vary based on the value of one or more controlling attribute values in the LOV-enabled attribute's view row. To apply the controlling attribute to the LOV-enabled attribute, you will create a view accessor to access the data source view object with the additional requirement that the accessor filters the list of possible values based on the current value of the controlling attribute. To filter the LOV-enabled attribute, you can edit the view accessor to add a named view criteria with a bind variable to obtain the user's selection.

For example, assume that a purchase order form contains a field that requires the user to select the supplier's specific site and that the available sites will depend on the order's already specified supplier. To implement this requirement, you would first create a view accessor that points to the data source view object. The data source view object will be specific to the LOV usage, because it must perform a query that filters the available supplier sites based on the user's supplier selection. You might name this data source view object definition `SupplierIdsForCurrentSupplierSite` to help distinguish it from the `SupplierSitesView` view object that the data model already contains. The data source view object will use a named view criteria (`SupplierCriteria`) with a single view criteria item set by a bind variable (`TheSupplierId`) to obtain the user's selection for the controlling attribute (`SupplierId`).

You would then set the LOV on the `SupplierSiteId` attribute of the base view object (`PurchaseOrdersView`). You can then reference the view accessor that points to the data source view object from the LOV-enabled attribute (`PurchaseOrdersView.SupplierSiteId`) of the base view object. Finally, you must edit the LOV-enabled attribute's view accessor definition to specify the corresponding attribute (`SupplierIdsForCurrentSupplierSite.SupplierSiteId`) from the view object as the data source and, importantly, source the value of the bind variable from the view row's result using the attribute `SupplierId`.

### 5.13.2.1 Creating a Data Source View Object to Control the Cascading List

The data source view object defines the controlling attribute for the LOV-enabled attribute. To make the controlling attribute accessible to the LOV-enabled attribute of the base view object, you must define a named view criteria to filter the data source attribute based on the value of another attribute. Because the value of the controlling attribute is expected to change at runtime, the view criteria uses a bind variable to set the controlling attribute.

#### To define the view criteria for the data source to be referenced by the LOV-enabled attribute:

1. In the Application Navigator, double-click the view object that you created to query the list of all possible values for the controlling attribute.

For example, if the LOV-enabled attribute `SupplierSiteId` depends on the controlling attribute `SupplierId` value, you might have created the data source view object `SupplierIdsForCurrentSupplierSite` to query the list of all supplier sites.

2. In the overview editor, click the **Query** navigation tab.
3. In the Query page, expand the **Bind Variables** section and click the **Create new bind variable** button to add a bind variable to the data source view object.

For example, for a data source view object `SupplierIdsForCurrentSupplierSite` used to query the list of all supplier sites, you would create the bind variable `TheSupplierId`, since it will be the controlling attribute for the LOV-enabled attribute.

4. In the Bind Variable dialog, enter the name and type of the bind variable. Leave all other options unchanged and click **OK**.

By default, the view accessor you create will display the same name as the view object instance. You can edit the accessor name to supply a unique name. For example, assign the name `CurrencyLookupViewAccessor` for the `CurrencyLookupView` view object instance.

5. In Query page of the overview editor, expand the **View Criteria** section and click the **Create new view criteria** button to add the view criteria to the data source view object you are currently editing.
6. In the Create View Criteria dialog, click **Add Group** and define a single **Criteria Item** for the group as follows:
  - Enter a **Criteria Name** to identify the view criteria. For example, you might enter the name `SupplierCriteria` for the `SupplierIdsForCurrentSupplierSite`.
  - Select the controlling attribute from the **Attributes** list. For example, you would select the `SupplierSiteId` attribute from the `SupplierIdsForCurrentSupplierSite`.
  - Select **equal to** from the view criteria **Operator** list.
  - Select **Bind Variable** from the view criteria **Operand** list.
  - Select the name of the previously defined bind variable from the **Parameter** list.
  - Select among the following bind variable configuration options to determine whether or not the value is required by the parent LOV:
    - Optional** from the **Validation** menu and deselect **Ignore Null Values** when you want to configure cascading LOVs where the parent LOV value is required. This combination supports the cascading LOV use case where no selection in the parent LOV returns *no* rows in the child LOV. The `WHERE` clause shown in the Edit View Criteria dialog should look similar to `((SupplierIdsForCurrentSupplierSite.SUPPLIER_ID = :TheSupplierId))`.
    - Optional** from the **Validation** menu and leave **Ignore Null Values** selected (default) when you want to configure cascading LOVs where the parent LOV value is optional. This combination supports the cascading LOV use case where no selection in the parent LOV returns *all* rows in the child LOV. The `WHERE` clause shown in the Edit View Criteria dialog should look similar to `((SupplierIdsForCurrentSupplierSite.SUPPLIER_ID = :TheSupplierId) OR (:TheSupplierId IS NULL))`.
7. Click **OK**.

### 5.13.2.2 Creating a View Accessor to Filter the Cascading List

To populate the cascading LOV-enabled attribute, you must first set up a named view criteria on a data source view object. To make the LOV-enabled attribute of the base view object dependent on the controlling attribute of the data source view object, you then add a view accessor to the LOV-enabled attribute of the base view object and reference the previously defined data source view object's named view criteria.

#### Before you begin:

Create the data source view object and named view criteria as described in [Section 5.13.2.1, "Creating a Data Source View Object to Control the Cascading List."](#)

**To create a view accessor that filters display values for an LOV-enabled attribute based on the value of another attribute in the same view row:**

1. In the Application Navigator, double-click the base view object that contains the attribute you want to use the filtered view accessor as the list data source.

For example, the base view object `PurchaseOrdersView` might contain the attribute `SupplierSiteId` that will depend on the value of the controlling attribute `SupplierId`.

2. In the overview editor, click the **Attributes** navigation tab.
3. In the Attributes page, select the attribute that is to filter the cascading LOV, and then expand the **List of Values** section and click the **Add list of values** button.
4. In the Create List of Values dialog, click the **Create new view accessor** button to add a view accessor to the view object you are currently editing.

Alternatively, you can expand **List Data Source** and select among the existing view accessors. The dropdown list displays all view accessors that you have added to the view object you are editing.

5. In the View Accessors dialog, select the view object instance name you created for data source view object and shuttle it to the view accessors list.
6. With the new view accessor selected in the dialog, click **Edit**.
7. In the Edit View Accessor dialog, apply the previously defined view criteria to the view accessor and provide a value for the bind variable as follows:
  - Click the data source view object's view criteria in the **Available** list and add it to the Selected list. For example, you would select `SupplierCriteria` from the `SupplierIdsForCurrentSupplierSite` view object definition.
  - Set the value for the bind variable to the name of the controlling attribute. The attribute name must be identical to the base view object's controlling attribute. For example, if the base view object `PurchaseOrdersView` contains the LOV-enabled attribute `SupplierSiteId` that depends on the value of the controlling attribute `SupplierId`, you would enter `SupplierId` for the bind variable value.
  - Select the name of the previously defined bind variable from the **Parameter** list.
  - Select **Required** from the **Usage** dropdown list.

8. Click **OK** to save the view accessor definition for the base view object.
9. In the Attributes page of the overview editor, select the attribute that is to display the LOV, and then expand the **List of Values** section and click the **Add list of values** button.
10. In the Create List of Values dialog, expand **List Data Source** and select the view accessor you created for the data source view object instance to use as the data source. Then select the controlling attribute from this view accessor that will serve to filter the attribute you are currently editing.

The editor creates a default mapping between the view object attribute and the LOV-enabled attribute. You use separate attributes in order to allow the bind variable (set by the user's controlling attribute selection) to filter the LOV-enabled attribute. For example, the LOV-enabled attribute `SupplierId` from the `PurchaseOrdersView` view object would map to the controlling attribute `SupplierSiteId` for the `SupplierIdsForCurrentSupplierSiteViewAccessor`. The runtime

automatically supports these two cascading LOVs where the row set and the base row attribute differ.

11. Click OK.

### 5.13.3 How to Specify Multiple LOVs for an LOV-Enabled View Object Attribute

Another way to vary the list of values that your application user interface can display is to define multiple list of values for a single LOV-enabled view object attribute. In contrast to a cascading list, which varies the list contents based on a dependent LOV list selection, an LOV-enabled switcher attribute with multiple LOVs lets you vary the entire LOV itself. The LOV choice to display is controlled at runtime by the value of an attribute that you have defined specifically to resolve to the name of the LOV to apply.

For example, you might want to define one LOV to apply in a create or edit form and another LOV to apply for a search component. In the first case, the LOV-enabled attribute that the form can use is likely to be an entity-based view accessor that is shared across all the view objects that reference the entity. The entity-based view accessor is useful for user interface forms because a single accessor definition can apply to each instance of the LOV in the forms. However, in the case of the search component, LOV definitions based on view accessors derived from an underlying entity will not work. The LOV definitions for search components must be based on view accessors defined in the view object. Note that when the user initiates a search, the values in the criteria row will be converted into WHERE clause parameters. Unlike a regular view row displayed in create or edit type forms, the criteria row is not backed by an entity. In this scenario, one LOV uses the entity-based accessor as a data source and a second LOV uses the view object-based accessor as a data source.

To address this requirement to define multiple LOV lists that access the same attribute, you add a switcher attribute to the base view object. For example, you might add a `ShipperLOVSwitcher` attribute for the `Orders` view object that resolves through an expression to the name of the LOV to display. Such an expression can specify two LOVs that may apply to the `ShipperID` attribute:

```
(adf.isCriteriaRow) ? "LOV_ShipperID_ForSearch" : "LOV_ShipperID"
```

This expression would appear in the **Value** field of the switcher attribute. At runtime, in the case of the search component, the expression resolves to the value that identifies the view object-based accessor LOV. In the case of the create or edit form, the expression resolves to the value that identifies the entity-based accessor LOV.

You will use the Create List of Values dialog to add multiple LOV lists to an attribute of the base view object. You will also use the List of Values section in the Attributes page of the overview editor for the base view object to define the default LOV to display and the switcher attribute to apply.

#### Before you begin:

Create the first LOV list for the attribute as described in [Section 5.13.1, "How to Define a Single LOV-Enabled View Object Attribute."](#)

Note that the switcher attribute scenario requires that you create unique view accessors. You must not reuse a view accessor to define multiple LOV lists. Reusing a view accessor various use cases can produce unintended results at runtime.

#### To specify additional LOV lists for a view object attribute with an existing LOV:

1. In the Application Navigator, double-click the view object that contains the attribute for which you want to specify multiple LOV lists.

2. In the overview editor, click the **Attributes** navigation tab.
3. In the Attributes page, select the desired attribute, and then expand the **List of Values** section and click the **Add list of values** button.
4. In the Create List of Values dialog, define the first LOV as described in [Section 5.13.1, "How to Define a Single LOV-Enabled View Object Attribute."](#)

When you define the LOV, change the name of the LOV to match the value returned by the attribute that you will use to determine which LOV your application applies to the LOV-enabled attribute.

5. After you define the first LOV, return to the **List of Values** section of the Attributes page of the overview editor and, with the original attribute selected, click the **Add List of Values** button.

If you have selected the correct attribute from the Attributes page of the overview editor, the **List of Values** section should display your previously defined LOV.

6. In the Create List of Values dialog, repeat the procedure described in [Section 5.13.1, "How to Define a Single LOV-Enabled View Object Attribute"](#) to define each subsequent LOV.

The name of each LOV must correspond to a unique value returned by the attribute that determines which LOV to apply to the LOV-enabled attribute.

You must define the second LOV using a unique view accessor, but you may use any attribute. There are no restrictions on the type of LOV lists that you can add to an attribute with multiple LOV lists specified.

After you finish defining the second LOV, the **List of Values** section changes to display additional features that you will use to control the selection of the LOV.

7. In the Attributes page of the overview editor, expand the **List of Values** section and use the **List of Values Switcher** dropdown list to select the attribute that will return the name of the List of Value to use.

The dropdown list displays the attributes of the base view object. If you want your application to dynamically apply the LOV from the LOVs you have defined, your view object must define an attribute whose values resolve to the names of the LOVs you defined. If you have not added this attribute to the view object, be sure that the dropdown list displays **<None Specified>**. In this case, at runtime your application will display the LOV-enabled attribute with the default LOV and it will not be possible to apply a different LOV.

8. To change the default LOV to apply at runtime, choose the **Default** radio button corresponding to the desired LOV definition.

The default LOV selection determines which list of values your application will display when the **List of Values Switcher** dropdown list displays **<None Specified>**. Initially, the first LOV in the overview editor **List of Values** section is the default.

9. To change the component that your application will use to display the various LOV lists, select from desired component from the **List Type UI Hint** dropdown list.

The component you select will apply to all LOV lists. For a description of the available components, see [Table 5-2](#).

### 5.13.4 How to Set User Interface Hints on a View Object LOV-Enabled Attribute

When you know how the view object attribute that you define as an LOV should appear in the user interface, you can specify additional properties of the LOV to determine its display characteristics. These properties, or *UI hints*, augment the attribute hint properties that ADF Business Components lets you set on any view object attribute. Among the LOV UI hints for the LOV-enabled attribute is the type of component the user interface will use to display the list. For a description of the available components, see [Table 5-2](#). (Not all ADF Faces components support the default list types, as noted in the [Table 5-2](#).)

**Table 5-2 List Component Types for List Type Control Hint**

LOV List Component Type	Usage
<p><b>Choice List</b></p> 	<p>This component does not allow the user to type in text, only select from the dropdown list.</p>
<p><b>Combo Box</b></p> 	<p>This component allows the user to type text or select from the dropdown list. This component sometimes supports auto-complete as the user types.</p> <p>This component is <i>not</i> supported for ADF Faces.</p>
<p><b>Combo Box with List of Values</b></p> 	<p>This component is the same as the combo box, except that the last entry (More...) opens a List of Values lookup dialog that supports query with filtering when enabled for the LOV attribute in its UI hints. The default UI hint enables queries on all attributes.</p> <p>This component is <i>not</i> supported for ADF Faces.</p> <p>Note that when the LOV attribute appears in a table component, the list type changes to an <b>Input Text with List of Values</b> component.</p>
<p><b>Input Text with List of Values</b></p> 	<p>This component displays an input text field with an LOV button next to it. The List of Values lookup dialog opens when the user clicks the button or enters an invalid value into the text field. The List of Values lookup dialog for this component supports query with filtering when enabled in the UI hints for the LOV attribute. The default UI hint enables queries on all attributes.</p> <p>This component may also support auto-complete when a unique match exists.</p>

**Table 5–2 (Cont.) List Component Types for List Type Control Hint**

LOV List Component Type	Usage
<p><b>List Box</b></p> 	<p>This component takes up a fixed amount of real estate on the screen and is scrollable (as opposed to the choice list, which takes up a single line until the user clicks on it).</p>
<p><b>Radio Group</b></p> 	<p>This component displays a radio button group with the selection choices determined by the LOV attribute values. This component is most useful for very short, fixed lists.</p>

**Before you begin:**

Create the LOV list for the attribute as described in [Section 5.13.1, "How to Define a Single LOV-Enabled View Object Attribute."](#)

**To set view object attribute UI hints for an LOV-enabled attribute:**

1. In the Application Navigator, double-click the view object that contains the attribute that you want to customize.
2. In the overview editor, click the **Attributes** navigation tab.
3. In the Attributes page, and select the desired attribute and then expand the **List of Values** section.
4. In the List of Values section, select the LOV list that you want to customize and click the **Edit list of values** button.
5. In the Edit List of Values dialog, select the **UI Hints** tab.
6. In the UI Hints page, select a default list type as the type of component to display the list.

For a description of the available components, see [Table 5–2](#).

The list component displayed by the web page and the view object's default list type must match at runtime or a method-not-found runtime exception results. To avoid this error, confirm the desired list component with the user interface designer. You can also edit the default list type to match, so that, should the user interface designer subsequently change the component used in the web page, the two stay in sync.

7. Optionally, select additional display attributes to add values to the display.

The list of additional attributes is derived from the LOV-enabled attribute's view row. The additional attribute values can help the end user select an item from the list.

8. If you selected the **Combo Box with List of Values** type component, by default, the dropdown list for the component will display the first 10 records from the data source. This limit also serves to keep the view object fetch size small. To change the number of records the dropdown list of a Combo Box with List of Values component can display, enter the number of records for **Query Limit**.

Because **Query Limit** also controls the number of rows the view object will fetch (its sets the view object definition `ListRangeSize` property), specifying a large value for **Query Limit** is not recommended. The end user can open the component's LOV lookup dialog to access the full set of records (by clicking the component's lookup icon). **Query Limit** is disabled for all other component types and those components place no restriction on the number of rows that the LOV will access.

For details about the `ListRangeSize` property, see [Section 5.13.9, "What Happens at Runtime: When an LOV Queries the List Data Source."](#)

9. If you selected a component type that allows the user to open a List of Values lookup dialog to select a list value (this includes either the **Combo Box with List of Values** type component or **Input Text with List of Values** type component), by default, the lookup dialog will display a search form that will allow the user to search on all queryable attributes of the data source view object (the one defined by the LOV-enabled attribute's view accessor). Decide how you want to customize these components.
  - a. When you select the **Combo Box with List of Values** type component and you have added a large number of attributes to the **Selected** list, use **Show in Combo Box** to improve the readability of the dropdown list portion of the component. To limit the attribute columns to display in the dropdown list that the Combo Box with List of Values component displays, choose **First** from **Show in Combo Box** and enter a number corresponding to the number of attributes from the top of the **Selected** list that you want the dropdown menu to display (this combination means you are specifying the "first"  $x$  number of attributes to display from the Create List of Values dialog's **Selected** list). Limiting the number of attribute columns to display in the dropdown list ensures that the user does not have to horizontally scroll to view the full list, but it does not limit the number of attribute columns to display in the List of Values lookup dialog. This option is disabled for all list component types except Combo Box with List of Values.
  - b. You can limit the attributes to display in the List of Values lookup dialog by selecting a view criteria from the **Include Search Region** dropdown list. To appear in the dropdown list, the view criteria must already have been defined on the data source view object (the one that the LOV-enabled attribute's view accessor defines). Click the **Edit View Criteria** button to set search form properties for the selected view criteria. For more information about customizing view criteria for search forms, see [Section 5.11.5, "How to Set User Interface Hints on View Criteria."](#)
  - c. You can prepopulate the results table of the List of Values lookup dialog by selecting **Query List Automatically**. The List of Values lookup dialog will display the results of the query when the user opens the dialog. If you leave this option deselected, no results will be displayed until the user submits the search form.
10. Alternatively, if you prefer not to display a search region in the List of Values lookup dialog, select **<No Search>** from the **Include Search Region** dropdown list. In this case, the List of Values lookup dialog will display only attributes you add to the **Display Attributes** list.

11. If you selected a choice type component to display the list, you can specify a **Most Recently Used Count** as an alternative to displaying all possible values.

For example, your form might display a choice list of `SupplierId` values to drive a purchase order form. In this case, you can allow the user to select from a list of their most recently viewed suppliers, where the number of supplier choices is determined by the count you enter. The default count 0 (zero) for the choice list displays all values for the attribute.

12. If you selected a **Combo Box with List of Values** type component to display the list, you can select a view criteria from the **Filter Combo Box Using** dropdown list to limit the list of valid values the LOV will display.

When you enable **Filter Combo Box Using**, the dropdown list displays the existing view criteria from the view object definition related to the LOV's view accessor. If the dropdown list displays no view criteria, then the data source view object defines no view criteria. When you do not enable this feature, the Combo Box with List of Values component derives its values from the full row set returned by the view accessor. The filtered Combo Box with List of Values is a useful feature when you want to support the use of an LOV with popup search dialog or LOV with a dropdown list that has a limited set of valid choices. For details about using the Combo Box with List of Values component in user interfaces, see [Section 27.1.6, "List of Values \(LOV\) Input Fields."](#)

13. Decide how you want the list component to handle a `NULL` value choice to display in the list component. This option is not enabled for every list component type that you can select.

If you enable **Include "No Selection" Item**, you can also determine how the `NULL` value selection should appear in the list by making a selection from the dropdown list. For example, when you select **Labeled Item**, you can enter the desired label in the edit field to the right of the dropdown list or you can click the ... button (to the right of the edit field) to select a message string from the resource bundle associated with the view object. When you select a message string from the resource bundle, JDeveloper saves the string's corresponding message key in the view object definition file. At runtime, the UI locates the string to display based on the current user's locale setting and the message key in the localized resource bundle.

14. Click OK.

### 5.13.5 How to Handle Date Conversion for List Type UI Components

When the LOV-enabled attribute of the view object is bound to date information (such as the attribute `OrderShippedDate`), by default Oracle ADF assumes a format for the field like `yyyy-MM-dd hh:mm:ss`, which combines date and time. This combined date-time format is specified by the ADF Business Components Date domain class (`jbo.domain.Date`) and creates a conversion issue for the ADF Faces component when the user selects a date supplied by the LOV-enabled attribute. When the ADF Faces component is unable to convert the domain type to the Date type, the user interface invalidates the input field and displays the message `Error: The date is not in the correct format.`

To avoid this potential conversion error, configure a UI hint setting for the date value attribute of the view object that you want to enable for an LOV. The UI hint you specify will define a date-only mask, such as `yyyy-MM-dd`. Subsequently, any ADF Faces component that references the attribute will perform the conversion based on a pattern specified by its EL value-binding expression (such as `#{bindings.Hiredate.format}`) and will reference the UI hint format instead of

the ADF Business Components domain date-time. The conversion error happens when the EL expression evaluates to null because no format mask has been specified. For more information about control hints, see [Section 5.14, "Defining Control Hints for View Objects."](#)

**To set a control hint to match the date format for the LOV-enable attribute:**

1. In the Application Navigator, double-click the view object.
2. In the overview editor, click the **Attributes** navigation tab and double-click the date-value attribute that you want to customize with control hints.

Alternatively, display the Property Inspector for the selected attribute and select the **UI Hints** navigation tab. The Property Inspector provides a way to customize the attribute's control hints without using the Edit Attribute dialog.

3. In the Edit Attribute dialog, select **Control Hints**, and in the Control Hints page, select **Simple Date** for the **Format Type** and choose the format with the date only mask.

Mapping of the ADF Business Components domain type to its available formatters is provided in the `formatinfo.xml` file in the BC4J subdirectory of the JDeveloper system directory (for example, `C:\Documents and Settings\\Application Data\JDeveloper\system<version#>\o.BC4J.\formatinfo.xml`).

4. Click **OK**.

### 5.13.6 How to Automatically Refresh the View Object of the View Accessor

If you need to ensure that your view accessor always queries the latest data from the database table, you can set the **Auto Refresh** property on the data source view object. This property allows the view object instance to refresh itself after a change in the database. You can enable this feature for any read-only view instance that your application modules define. Once you enable this property on a view object, it ensures that the changes a user commits to a database table will become available to any other user working with the same database table. A typical use case is to enable auto refresh for the data source view object when you define a view accessor for an LOV-enabled view object attribute.

Because the auto-refresh feature relies on the database change notification feature, observe these restrictions when enabling auto-refresh for your view object:

- Ensure the view objects query only read-only tables, and as few tables as possible. This will ensure the best performance and prevent the database invalidation queue from becoming too large.
- Configure the application module that contains updatable, auto-refresh view instances to be shared and to lock rows during updates.
- Ensure the database user has database notification privileges. For example, to accomplish this with a SQL\*Plus command use `grant change notification to <user name>`.
- Ensure the query is compatibility with query result change notification before you enable auto refresh on the view object. Not all query definitions satisfy the requirements for query result change notification. For information, see the "Using Continuous Query Notification" chapter in the *Oracle Database Advanced Application Developer's Guide*.

When you enable auto refresh for the view object and observe these restrictions, the refresh is accomplished through the Oracle database change notification feature. At runtime, prior to executing the view object query, the framework will use the JDBC API to register the view object query to receive database change notifications for underlying data changes. When the view object receives a notification (because its underlying data has changed), the row sets of the view object are marked as dirty and the framework will refresh the row set on the next server trip from the client to the middle tier. At that point, the dirty collections will be discarded and the request for the updated data will trigger a new query execution by the view object. Because the application module waits until the next checkout, the row set currency of the current transaction is maintained and the end user is not hampered by the update

For example, assume that a user can create or edit a calendar entry but cannot edit calendar entries added by other users. When the user creates and commits a new entry, then in the same server trip the calendar entries that other users modified or entered will be updated. But when another user creates a calendar entry, the view object receives a notification and waits for the next server trip before it refreshes itself; the delay to perform the update prevents contention among various users to read the same data.

---

---

**Best Practice:** Use optimistic row locking for web applications. Optimistic locking, the default configuration setting, assumes that multiple transactions can complete without affecting each other. Optimistic locking therefore allows auto-refresh to proceed without locking the rows being refreshed. Pessimistic row locking prevents the row set refresh and causes the framework to throw an exception anytime the row set has a transaction pending (for example, a user may be in the process of adding a new row). To ensure that the application module configuration uses optimistic row locking, open the **Properties** tab of the Business Components Configuration dialog and confirm the `jbo.locking.mode` property is set to `optimistic`.

---

---

**To register a view object to receive data change notifications:**

1. In the Application Navigator, double-click the view object that you want to receive database change notifications.
2. In the Property Inspector expand the **Tuning Database Retrieve** section, and select **True** for the **Auto Refresh** property.

### 5.13.7 How to Test LOV-Enabled Attributes Using the Business Component Browser

To test the LOV you created for a view object attribute, use the Business Component Browser, which is accessible from the Application Navigator.

The Business Component Browser, for any view object instance that you browse, will display any LOV-enabled attributes using one of two component types you can select in the UI Hints page of the List of Values dialog. Currently, only a Choice List component type and Input Text with List of Values component type are supported. Otherwise, the Business Component Browser uses the default choice list type to display the LOV-enabled attribute.

**To test an LOV using the Business Component Browser:**

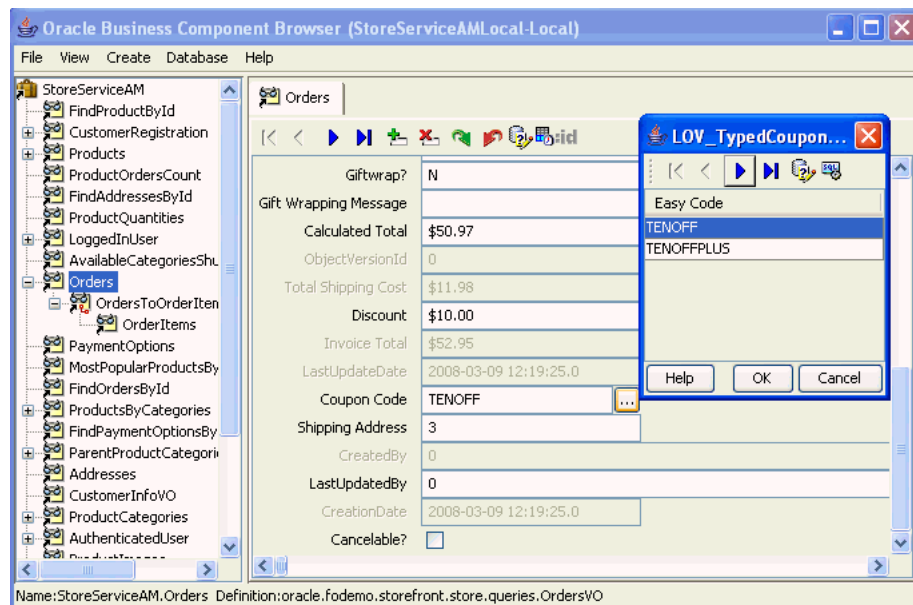

1. In the Application Navigator, expand the project containing the desired application module and view objects.

2. Right-click the application module and choose **Run**.
3. In the Select Business Components Configuration dialog, select the desired application module configuration from the **Configuration Name** list to run the Business Component Browser.
4. Click **Connect** to start the application module using the selected configuration.
5. In the Business Component Browser, select the desired view object from the section on the left. The Business Component Browser displays the LOV-enabled attribute as a dropdown choice list unless you specified the component type as an Input Text with List of Value, UI hint.

Figure 5–49 shows an LOV-enabled attribute, `TypeCouponCode` for the `OrdersVO`, that specifies an input text field and List of Values dialog as the UI hint. The Input Text with List of Values component is useful when you want to display the choices in a separate LOV dialog. Other list types are not supported by the Business Component Browser.

**Figure 5–49** *Displaying LOV-Enabled Attributes in the Business Component Browser*

### 5.13.8 What Happens When You Define an LOV for a View Object Attribute

When you define an LOV for a view object attribute, the view object metadata defines the following additional information, as shown in Example 5–41 for the `OrdersVO.TypeCouponCode` attribute in the Fusion Order Demo application.

- The `<ViewAttribute>` element names the attribute, points to the list binding element that defines the LOV behavior, and specifies the component type to display in the web page. For example, the LOV-enabled attribute `TypeCouponCode` points to the list binding named `LOV_TypeCouponCode` and defines the `CONTROLTYPE` input text field with list (`input_text_lov`) to display the LOV data.

When the user interface designer creates the web page using the Data Controls panel, the `<CONTROLTYPE Value="namedType" />` definition determines the component that JDeveloper will add to the web page. When the component type definition in the data model project does not match the component type displayed

in the web page, a runtime exception will result. For more information, see [Section 5.13.9, "What Happens at Runtime: When an LOV Queries the List Data Source."](#)

- The `<ListBinding>` element defines the behavior of the LOV. It also identifies a view accessor to access the data source for the LOV-enabled attribute. The view accessor is the ADF Business Components mechanism that lets you obtain the full list of possible values from the row set of the data source view object. For example, `ListVOName="Coupon"` points to the Coupons view accessor, which accesses the view object CouponsVO.
- The `<ListBinding>` element maps the list data source attribute to the LOV-enabled attribute. For example, the `ListAttrNames` item `EasyCode` is mapped to the LOV-enabled attribute `TypedCouponCode`.
- Optionally, the `<ListBinding>` element defines supplemental values that the data source may return to attributes of the base view object other than the data source attribute for which the list is defined. For example, `DerivedAttrNames` item `CouponId` is a supplemental value set by the `ListAttrNames` item `DiscountId`.
- The `<ListBinding>` element also identifies one or more attributes to display from the current row and provides a few options that are specific to the choice list type component. For example, the `ListDisplayAttrNames` item `EasyCode` is the only attribute displayed by the LOV-enabled attribute `TypedCouponCode`. In this example, the value `none` for `NullValueFlag` means the user cannot select a blank item from the list.

**Example 5–41 View Object MetaData For LOV-Attribute Usage**

```
<ViewAttribute
  Name="TypedCouponCode"
  LOVName="LOV_TypedCouponCode"
  . . .
  <Properties>
    <SchemaBasedProperties>
      <CONTROLTYPE Value="input_text_lov" />
    </SchemaBasedProperties>
  </Properties>
</ViewAttribute>
. . .
<ListBinding
  Name="LOV_TypedCouponCode"
  ListVOName="Coupons"
  ListRangeSize="-1"
  NullValueFlag="none"
  NullValueId="LOV_TypedCouponCode_NullValueId"
  MRUCount="0">
  <AttrArray Name="AttrNames">
    <Item Value="TypedCouponCode" />
  </AttrArray>
  <AttrArray Name="DerivedAttrNames">
    <Item Value="CouponId" />
  </AttrArray>
  <AttrArray Name="ListAttrNames">
    <Item Value="EasyCode" />
    <Item Value="DiscountId" />
  </AttrArray>
  <AttrArray Name="ListDisplayAttrNames">
    <Item Value="EasyCode" />
  </AttrArray>
```

```

    </AttrArray>
</ListBinding>

. . .
<ViewAccessor
  Name="Coupons"
  ViewObjectName="oracle.fodemo.storefront.store.queries.CouponsVO" />

```

### 5.13.9 What Happens at Runtime: When an LOV Queries the List Data Source

The ADF Business Components runtime adds view accessors in the attribute setters of the view row and entity object to facilitate the LOV-enabled attribute behavior. In order to display the LOV-enabled attribute values in the user interface, the LOV facility fetches the data source, and finds the relevant row attributes and mapped target attributes.

The number of data objects that the LOV facility fetches is determined in part by the `ListRangeSize` setting in the LOV-enabled attribute's list binding definition, which is specified in the Edit List of Values dialog that you display on the attribute from the view object overview editor. If the number of records fetched is very large, the default value for `ListRangeSize` may truncate the values available to the dropdown list component used to display the records. The default number of fetched records for LOV queries depends on the type of list component used to display the records. In the case of the Combo Box with List of Values component and the Input Text with List of Values component, the default value for `ListRangeSize` is 10. In the case of all other types of list components that you can select (including choice list, combo box, list box, and radio button group), the default value for `ListRangeSize` is set to -1. The value -1 means that the user will be able to view all the data objects from the data source. The `ListRangeSize` value has no effect on the records that the end user can search on in the lookup dialog displayed for the two List of Values type components. For more information about how each list component displays values, see [Section 5.13.4, "How to Set User Interface Hints on a View Object LOV-Enabled Attribute."](#)

Note that although you can alter the `ListRangeSize` value in the metadata definition for the `<ListBinding>` element, setting the value to a discrete number of records (for example, `ListRangeSize="5"`) most likely will not provide the user with the desired selection choices. Instead, if the value is -1 (default for simple list components without a LOV dialog), then no restrictions are made to the number of records the list component will display, and the user will have access to the full set of values.

**Performance Tip:** To limit the set of values a LOV displays, use a view accessor to filter the LOV binding, as described in [Section 5.13.1, "How to Define a Single LOV-Enabled View Object Attribute."](#) Additionally, in the case of component types that display a choice list, you can change the **Most Recently Used Count** setting to limit the list to display the user's previous selections, as described in [Section 5.13.4, "How to Set User Interface Hints on a View Object LOV-Enabled Attribute."](#)

Note, a runtime exception will occur when a web page displays a UI component for an LOV-enabled attribute that does not match the view object's `CONTROLTYPE` definition. When the user interface designer creates the page in JDeveloper using the Data Controls panel, JDeveloper automatically inserts the list component identified by the **Default List Type** selection you made for the view object's LOV-enabled attribute in the List UI Hint dialog. However, if the user interface designer changes the list type

subsequent to creating the web page, you will need to edit the selection in the List UI Hint dialog to match.

### 5.13.10 What You May Need to Know About Lists

There are several things you may need to know about LOVs that you define for attributes of view objects, including how to propagate LOV-enabled attributes from parent view objects to child view objects (by extending an existing view object) and when to use validators instead of an LOV to manage a list of values.

#### 5.13.10.1 Inheritance of AttributeDef Properties from Parent View Object Attributes

When a view object extends another view object, you can create the LOV-enabled attribute on the base object. Then when you define the child view object in the overview editor, the LOV definition will be visible on the corresponding view object attribute. This inheritance mechanism allows you to define an LOV-enabled attribute once and later apply it across multiple view objects instances for the same attribute.

You can also use the overview editor to extend the inherited LOV definition. For example, you may add extra attributes already defined by the base view object's query to display in selection list. Alternatively, you can define a view object that uses a custom WHERE clause to query the supplemental attributes not already queried by the based view object. For information about customizing entity-based view objects, see [Section 5.10, "Working with Bind Variables."](#)

#### 5.13.10.2 Using Validators to Validate Attribute Values

If you have created an LOV-enabled attribute for a view object, there is no need to validate the attribute using a List Validator. You only use an attribute validator when you do not want the list to display in the user interface, but still need to restrict the list of valid values. List validation may be a simple static list or it may be a list of possible values obtained through a view accessor you define. Alternatively, you might prefer to use Key Exists validation when the attribute displayed in the UI is one that references a key value (such as a primary, foreign, or alternate key). For information about declarative validation in ADF Business Components, see [Chapter 7, "Defining Validation and Business Rules Declaratively."](#)

#### 5.13.10.3 LOV Limitation When Exposing Application Module as EJB Session Bean

A limitation exists related to LOV-enabled attributes when your application uses an EJB Session Bean to expose application module services. The Data Controls panel exposes these services in the user interface project, using data binding functionality, and you will be able to create a databound LOV list component. However, at runtime, the LOV list will appear empty. Additionally, if the LOV dialog includes search capabilities, clicking the search link will result in a `FacesCtrlSearchBinding` exception error. This is a known limitation of deploying the business services, as supported by an EJB Session Bean, and the user interface in separate tiers.

## 5.14 Defining Control Hints for View Objects

One of the built-in features of ADF Business Components is the ability to define control hints on view objects and attributes of view objects. Control hints are settings that the view layer can use to automatically display the queried information to the user in a consistent, locale-sensitive way. For example, in web pages, a UI developer may access control hint values by entering EL expressions utility methods defined on the `bindings` name space and specified for ADF binding instance names.

JDeveloper stores the hints in resource bundle files that you can easily localize for multilingual applications.

### 5.14.1 How to Add Attribute-Specific Control Hints

To create control hints for attributes of a view object, use the overview editor for the view object, which is accessible from the Application Navigator. You can also display and edit control hints using the Property Inspector that you display for an attribute.

#### Before you begin:

Create the desired view objects as described in [Section 5.2.1, "How to Create an Entity-Based View Object,"](#) and [Section 5.2.3, "How to Create an Expert Mode, Read-Only View Object."](#)

#### To customize view object attribute with control hints:

1. In the Application Navigator, double-click the view object.
2. In the overview editor, click the **Attributes** navigation tab and double-click the attribute that you want to customize with control hints.

Alternatively, display the Property Inspector for the selected attribute and select the **UI Hints** navigation tab. The Property Inspector provides a way to customize the attribute's control hints without using the Edit Attribute dialog.

3. In the Edit Attribute dialog, select **Control Hints** and define the desired hints.

For example, for an attribute `userId`, you might enter a value for its **Label Text** hint like "Id" or set the **Format Type** to Number, and enter a **Format** mask of 00000.

4. Click OK.

---

**Note:** Java defines a standard set of format masks for numbers and dates that are different from those used by the Oracle database's SQL and PL/SQL languages. For reference, see the Javadoc for the `java.text.DecimalFormat` and `java.text.SimpleDateFormat` classes.

---

### 5.14.2 How to Add View Object Control Hints

To create control hints for attributes of a view object, use the overview editor for the view object, which is accessible from the Application Navigator. You can also display and edit several additional control hints using the Property Inspector that you display for the view object.

#### Before you begin:

It may be helpful to have an understanding of control hints. For more information, see [Section 5.14, "Defining Control Hints for View Objects."](#)

You will need to complete this task:

Create the desired view objects as described in [Section 5.2.1, "How to Create an Entity-Based View Object,"](#) and [Section 5.2.3, "How to Create an Expert Mode, Read-Only View Object."](#)

#### To customize view objects with control hints:

1. In the Application Navigator, double-click the view object.

2. In the overview editor, click the **General** navigation tab.
3. In the General page, enter a **Display Name** to define an EL accessible hint for the view object name.  
For example, for a view object `OrdersVO`, you might enter a value for its **Display Name** hint like `"Order"`.
4. With the General page displayed in the overview editor, open the Property Inspector for the view object and expand the **UI Hints** section, and then enter additional hints as needed.  
For example, for a view object `OrdersVO`, you might enter a value for the **Display Name (Plural)** hint like `"Orders"` and, for the **Description** hint, you might enter a value like `"customer orders"`.

### 5.14.3 How to Access Control Hints Using EL Expressions

A UI developer can access control hints using EL expressions and display the hint values as data in a web page. The UI developer may access control hints through the ADF binding instances that they create after dropping databound components into their web pages.

In the case of the view object hints, the UI developer accesses the view object hints through the iterator binding defined for the view object. For example, assume that you have configured the view object control hints as follows.

- `OrdersVO` view object **Display Name** hint = `Order`
- `OrdersVO` view object **Display Name (Plural)** hint = `Orders`
- `OrdersVO` view object **Description** hint = `customer orders`

The UI developer might display a header that makes use of these hints like this:

Showing *customer orders* number 10 of 51 *Orders*.

[Example 5-42](#) shows that the EL expression that produces the above text. In this EL expression the iterator binding `OrdersVO1Iterator` provides access to the view object hints. The names of the EL expression utility methods match the property names defined in the view object XML definition file for the control hints. For example, the view object property name `labelPlural`, which defines the **Display Name (Plural)** hint, corresponds to the utility method name used in the expression `bindings.OrdersVO1Iterator.hints.labelPlural`.

#### **Example 5-42 EL to Access View Object Control Hints**

```
<af:panelHeader id="ph1"
    text="Showing #{bindings.OrdersVO1Iterator.hints.description} number
        #{bindings.Orderno.inputValue} of
        #{bindings.OrdersVO1.estimatedRowCount}
        #{bindings.OrdersVO1Iterator.hints.labelPlural}.">
```

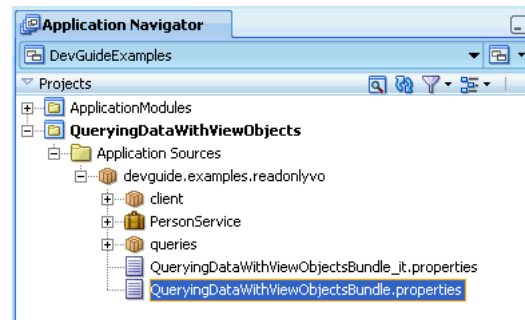

### 5.14.4 What Happens When You Add Control Hints

When you define control hints for a view object or view object attributes, by default JDeveloper creates a project-level resource bundle file in which to store them. For example, when you define control hints for a view object in the `StoreFront` project, JDeveloper creates the message bundle file named `StoreFrontBundle.xxx` for the package. The hints that you define can be used by generated forms and tables in associated view clients.

The type of resource bundle file that JDeveloper uses and the granularity of the file are determined by settings on the Resource Bundle page of the Project Properties dialog. By default, JDeveloper sets the option to **Properties Bundle** and generates one `.properties` file for the entire data model project.

Alternatively, if you select the option in the Project Properties dialog to generate one resource bundle per file, you can inspect the message bundle file for any view object by selecting the object in the Application Navigator and looking in the corresponding **Sources** node in the Structure window. The Structure window shows the implementation files for the component you select in the Application Navigator. You can inspect the resource bundle file for the view object by expanding the parent package of the view object in the Application Navigator, as shown in [Figure 5–50](#).

**Figure 5–50 Resource Bundle File in Application Navigator**

For more information on the resource bundle options you can select, see [Section 4.7.1, "How to Set Message Bundle Options."](#)

[Example 5–43](#) shows a sample message bundle file where the control hint information appears. The first entry in each `String` array is a message key; the second entry is the locale-specific `String` value corresponding to that key.

**Example 5–43 Resource File With Locale-Sensitive Control Hints**

```
devguide.examples.readonlyvo.queries.Persons.PersonId_FMT_FORMATTER=
    oracle.jbo.format.DefaultNumberFormatter
devguide.examples.readonlyvo.queries.Persons.PersonId_FMT_FORMAT=00000
devguide.examples.readonlyvo.queries.Persons.PersonId_LABEL=Id
devguide.examples.readonlyvo.queries.Persons.Email_LABEL=Email Address
devguide.examples.readonlyvo.queries.Persons.LastName_LABEL=Surname
devguide.examples.readonlyvo.queries.Persons.FirstName_LABEL=Given Name
```

## 5.14.5 What You May Need to Know About Resource Bundles

Internationalizing the model layer of an application built using ADF Business Components entails producing translated versions of each component's resource bundle file. For example, the Italian version of the `QueryDataWithViewObjectsBundle.properties` file would be a file named `QueryDataWithViewObjectsBundle_it.properties`, and a more specific *Swiss* Italian version would have the name `QueryDataWithViewObjectsBundle_it_ch.properties`.

Resource bundle files contain entries for the message keys that need to be localized, together with their localized translation. For example, assuming you didn't want to translate the number format mask for the Italian locale, the Italian version of the `QueryDataWithViewObjects` view object message keys would look like what you

see in [Example 5–44](#). At runtime, the resource bundles are used automatically, based on the current user's locale settings.

**Example 5–44 Localized View Object Component Resource Bundle for Italian**

```
devguide.examples.readonlyvo.queries.Persons.PersonId_FMT_FORMATTER=
    oracle.jbo.format.DefaultNumberFormatter
devguide.examples.readonlyvo.queries.Persons.PersonId_FMT_FORMAT=00000
devguide.examples.readonlyvo.queries.Persons.PersonId_LABEL=Codice Utente
devguide.examples.readonlyvo.queries.Persons.Email_LABEL=Indirizzo Email
devguide.examples.readonlyvo.queries.Persons.LastName_LABEL=Cognome
devguide.examples.readonlyvo.queries.Persons.FirstName_LABEL=Nome
```

## 5.15 Adding Calculated and Transient Attributes to a View Object

In addition to having attributes that map to underlying entity objects, your view objects can include calculated attributes that don't map to any entity object attribute value. The two kinds of calculated attributes are known as:

- *SQL-calculated attributes*, when their value is retrieved as an expression in the SQL query's SELECT list
- *Transient attributes*, when their value is not retrieved as part of the query

A view object can include an entity-mapped attribute which itself is a transient attribute at the entity object level.

### 5.15.1 How to Add a SQL-Calculated Attribute

You use the overview editor for the view object to add a SQL-calculated attribute.

**Before you begin:**

Create the desired view objects as described in [Section 5.2.1, "How to Create an Entity-Based View Object,"](#) and [Section 5.2.3, "How to Create an Expert Mode, Read-Only View Object."](#)

**To add a SQL-calculated attribute to a view object:**

1. In the Application Navigator, double-click the view object for which you want to define a SQL-calculated attribute.
2. In the overview editor, click the **Attributes** navigation tab and click the **Create new attribute** button.
3. In the New View Object Attribute dialog, enter a name for the attribute.
4. Set the Java attribute type to an appropriate value.
5. Select the **Mapped to Column or SQL** checkbox.
6. Provide a SQL expression in the **Expression** field.

For example, to change the order of first name and last name, you could write the expression `LAST_NAME || ' , ' || FIRST_NAME`, as shown in [Figure 5–51](#).

**Figure 5–51 New SQL-Calculated Attribute**

7. Consider changing the SQL column alias to match the name of the attribute.
8. Verify the database query column type and adjust the length (or precision/scale) as appropriate.
9. Click OK.

### 5.15.2 What Happens When You Add a SQL-Calculated Attribute

When you add a SQL-calculated attribute in the overview editor for the view object, JDeveloper updates the XML document for the view object to reflect the new attribute. The entity-mapped attribute's `<ViewAttribute>` tag looks like the sample shown in [Example 5–45](#). The entity-mapped attribute inherits most of its properties from the underlying entity attribute to which it is mapped.

#### **Example 5–45 Metadata For Entity-Mapped Attribute**

```
<ViewAttribute
  Name="LastName"
  IsNotNull="true"
  EntityAttrName="LastName"
  EntityUsage="User1"
  AliasName="LAST_NAME" >
</ViewAttribute>
```

Whereas, in contrast, a SQL-calculated attribute's `<ViewAttribute>` tag looks like sample shown in [Example 5–46](#). As expected, the tag has no `EntityUsage` or `EntityAttrName` property, and includes datatype information along with the SQL expression.

#### **Example 5–46 Metadata For SQL-Calculated Attribute**

```
<ViewAttribute
  Name="LastCommaFirst"
  IsUpdatable="false"
  IsPersistent="false"
  Precision="62"
```

```
Type="java.lang.String"
ColumnType="VARCHAR2"
AliasName="FULL_NAME"
Expression="LAST_NAME||' , '&#39;||FIRST_NAME"
SQLType="VARCHAR" >
</ViewAttribute>
```

---

---

**Note:** The `&#39;` is the XML character reference for the apostrophe. You reference it by its numerical ASCII code of 39 (decimal). Other characters in literal text that require similar construction in XML are the less-than, greater-than, and ampersand characters.

---

---

### 5.15.3 How to Add a Transient Attribute

Transient attributes are often used to provide subtotals or other calculated expressions that are not stored in the database.

**Before you begin:**

Create the desired view objects as described in [Section 5.2.1, "How to Create an Entity-Based View Object,"](#) and [Section 5.2.3, "How to Create an Expert Mode, Read-Only View Object."](#)

**To add a transient attribute to a view object:**

1. In the Application Navigator, double-click the view object for which you want to define a transient attribute.
2. In the overview editor, click the **Attributes** navigation tab and click the **Create new attribute** button.
3. In the New View Object Attribute dialog, enter a name for the attribute.
4. Set the Java attribute type to an appropriate value.

For example, a calculated attribute that concatenates a first name and a last name would have the type `String`, as shown in [Figure 5-52](#).

Figure 5–52 New Transient Attribute

The screenshot shows the 'New View Object Attribute' dialog box. It is divided into several sections:

- Attribute:**
  - Name: FirstDotLast
  - Type: String (with a 'Browse...' button)
  - Property Set: <None>
  - Value Type:  Literal,  Expression
  - Value: (empty field with an 'Edit...' button)
  - Mapped to Column or SQL
  - Selected in Query
  - Discriminator:  View,  Entity
  - Default Value: (empty field)
  - Passivate
  - Key Attribute
  - Queryable
  - Effective Date
  - Start,  End
- Updatable:**
  - Always
  - While New
  - Never
- Query Column:**
  - Alias: VIEW\_ATTR
  - Type: VARCHAR2
  - Expression: (empty text area)

Buttons at the bottom: Help, OK, Cancel.

5. Leave the **Mapped to Column or SQL** checkbox unselected.
6. Click **OK**.

#### To create a transient attribute based on an expression:

1. In the Application Navigator, double-click the view object for which you want to define a transient attribute.
2. In the overview editor, click the **Attributes** navigation tab and click the **Create new attribute** button.
3. In the New View Object Attribute dialog, enter a name for the attribute.
4. Set the Java attribute type to an appropriate value.
5. Leave the **Mapped to Column or SQL** checkbox unselected.

A transient attribute does not include a SQL expression.

6. Next to the **Value** field, click **Edit** to define an expression that calculates the value of the attribute.

Expressions you define will be evaluated using the Groovy Expression Language. Groovy lets you insert expressions and variables into strings. The expression will be saved as part of the view object definition. For more information about Groovy, see [Section 3.6, "Overview of Groovy Support."](#)

7. In the Edit Expression dialog, enter an expression in the field provided.

Attributes that you reference can include any attribute that the base entity objects define. Do not reference attributes in the expression that are not defined by the view object's underlying entity objects.

8. Select the appropriate recalculate setting.

If you select **Always** (default), the expression is evaluated each time any attribute in the row changes. If you select **Never**, the expression is evaluated only when the row is created.

9. You can optionally provide a condition for when to recalculate the expression.

For example, the following expression in the **Based on the following expression** field causes the attribute to be recalculated when either the Quantity attribute or the UnitPrice attribute are changed:

```
return (adf.object.isAttributeChanged("Quantity") ||
adf.object.isAttributeChanged("UnitPrice"));
```

10. When either the value expression or the optional recalculate expression that you define references an attribute from the base entity object, you must define this as a dependency in the Edit Expression dialog. Locate each attribute in the **Available** list and shuttle it to the **Selected** list.
11. Click **OK** to save the expression and return to the New View Object Attribute dialog.
12. Click **OK**.

A view object can include an entity-mapped attribute which itself is a transient attribute at the entity object level.

**To add a transient attribute from an entity object to an entity-based view object:**

1. In the Application Navigator, double-click the view object for which you want to add a transient attribute based on an entity usage.
2. In the overview editor, click the **Attributes** navigation tab and click the **Add From Entity** button.
3. In the Attributes dialog, move the desired transient attribute from the **Available** list into the **Selected** list.
4. Click **OK**.

If you use the Business Component Browser to test the data model, you can see the usage of your transient attributes. [Figure 5-53](#) shows three attributes that were created using a SQL-calculated attribute (`LastCommaFirst`), a transient attribute (`FirstDotLast`) and an entity-derived transient attribute (`FullName`).

**Figure 5-53 View Object with Three Kinds of Calculated Attributes**

#### 5.15.4 How to Add a Validation Rule to a Transient Attribute

Attribute-level validation rules are triggered for a particular view object transient attribute when either the end user or the program code attempts to modify the attribute's value. Since you cannot determine the order in which attributes will be set, attribute-level validation rules should be used only when the success or failure of the rule depends exclusively on the candidate value of that single attribute.

The process for adding a validation rule to a view object transient attribute is similar to create declarative validation rules, and is done using the Add Validation Rule dialog.

You can open this dialog from the overview editor for the view object by clicking the **Add Validation Rule** icon on the Attributes page. You must first select the transient attribute from the attributes list.

**To add a validation rule for a transient attribute:**

1. In the Application Navigator, double-click the desired view object.
2. Click the **Attributes** navigation tab on the overview editor.
3. Select the transient attribute for which you want to add a validation rule, expand the **Validation Rules** section, and then click the **Add Validation Rule** icon.

When you add a new validation rule, the Add Validation Rule dialog appears.

4. Select the type of validation rule desired from the **Rule Type** dropdown list.
5. Use the dialog settings to configure the new rule.

The controls will change depending on the kind of validation rule you select. For more information about the different validation rules, see [Section 7.4, "Using the Built-in Declarative Validation Rules."](#)

6. You can optionally click the **Validation Execution** tab and enter criteria for the execution of the rule, such as dependent attributes and a precondition expression. For more information, see [Section 7.6, "Triggering Validation Execution."](#)
7. Click the **Failure Handling** tab and enter or select the error message that will be shown to the user if the validation rule fails. For more information, see [Section 7.7, "Creating Validation Error Messages."](#)
8. Click **OK**.

### 5.15.5 What Happens When You Add a Transient Attribute

When you add a transient attribute in the overview editor for a view object, JDeveloper updates the XML document for the view object to reflect the new attribute. A transient attribute's `<ViewAttribute>` tag in the XML is similar to the SQL-calculated one, but it lacks an `Expression` property.

When you base a transient attribute on a Groovy expression, a `<TransientExpression>` tag is created within the appropriate attribute, as shown in [Example 5-47](#).

**Example 5-47 Calculating a Transient Attribute Using a Groovy Expression**

```
<TransientExpression>
  <![CDATA[
    ((Quantity == null) ? 0 : Quantity) * ((UnitPrice == null) ? 0 : UnitPrice)
  ]]>
</TransientExpression>
```

### 5.15.6 Adding Java Code in the View Row Class to Perform Calculation

A transient attribute is a placeholder for a data value. If you change the **Updatable** property of the transient attribute to **While New** or **Always**, the end user can enter a value for the attribute. If you want the transient attribute to display a calculated value, then you'll typically leave the **Updatable** property set to **Never** and write custom Java code that calculates the value.

After adding a transient attribute to the view object, to make it a *calculated* transient attribute you need to enable a custom view row class and choose to generate accessor

methods, in the Java dialog that you open clicking the **Edit** icon on the Java page of the overview editor for the view object. Then you would write Java code inside the accessor method for the transient attribute to return the calculated value.

[Example 5-47](#) shows the `StaffListRowImpl.java` view row class contains the Java code to return a calculated value in the `getLastNameCommaFirst()` method.

```
// In StaffListRowImpl.java
public String getFirstDotLast() {
    // Commented out this original line since we're not storing the value
    // return (String) getAttributeInternal(FIRSTDOTLAST);
    return getFirstName().substring(0,1)+" ". +getLastName();
}
```

### 5.15.7 What You May Need to Know About Transient Attributes

The view object includes the SQL expression for your SQL-calculated attribute in the `SELECT` list of its query at runtime. The database is the one that evaluates the expression, and it returns the result as the value of that column in the query. The value is reevaluated each time you execute the query.

---

---

## Working with View Object Query Results

This chapter describes how to interactively test ADF view objects query results using the Business Component Browser provided in JDeveloper. This chapter also explains how to use the Business Components API to access view object instances in a test client outside of JDeveloper.

This chapter includes the following sections:

- [Section 6.1, "Introduction to View Object Runtime Behavior"](#)
- [Section 6.2, "Creating an Application Module to Test View Instances"](#)
- [Section 6.3, "Testing View Object Instances Using the Business Component Browser"](#)
- [Section 6.4, "Testing View Object Instances Programmatically"](#)

### 6.1 Introduction to View Object Runtime Behavior

JDeveloper includes an interactive application module testing tool that you can use to test all aspects of its data model without having to use your application user interface or write a test client program. Running the Business Component Browser can often be the quickest way of exercising the data functionality of your business service during development.

---

---

**Note:** When you want to test an application module programmatically, you can write a test client. For more information, see [Section 6.4.2, "How to Create a Command-Line Java Test Client."](#) When you want to log query execution, use the ADF Logger. For more information, see [Section 31.5, "Using the ADF Logger."](#)

---

---

Using the Business Component Browser, you can simulate an end user interacting with your application module data model before you have started to build any custom user interface of your own. Even *after* you have your UI pages constructed, you will come to appreciate using the Business Component Browser to assist in diagnosing problems when they arise. You can reproduce the issues in the Business Component Browser to discover if the issue lies in the view or controller layers of the application, or is instead a problem in the business service layer application module itself.

### 6.2 Creating an Application Module to Test View Instances

Before you can test view objects that you create in your data model project, you must create an application module where you will define instances of the view objects you

want to test. The application module is the transactional component that the Business Component Browser (or UI client) will use to work with application data. The set of view objects used by an application module defines its *data model*, in other words, the set of data that a client can display and manipulate through a user interface.

To test the view objects you added to an application module, use the Business Component Browser, which is accessible from the Application Navigator. For details about using the Business Component Browser, see [Section 6.3, "Testing View Object Instances Using the Business Component Browser."](#)

## 6.2.1 How to Create the Application Module with Individual View Object Instances

To create an application module that will define instances of individual view objects, use the Create Application Module wizard, which is available in the New Gallery.

### Before you begin:

Create the desired view objects, as described in [Section 5.2.1, "How to Create an Entity-Based View Object"](#) and [Section 5.2.3, "How to Create an Expert Mode, Read-Only View Object."](#)

### To create an application module to test individual view object instances:

1. In the Application Navigator, right-click the project in which you want to create the application module and choose **New**.
2. In the New Gallery, expand **Business Tier**, select **ADF Business Components** and then **Application Module**, and click **OK**.
3. In the Items list, select **Application Module** to launch the Create Application Module wizard.
4. In the Create Application Module wizard, in the Name page, provide a package name and an application module name. Click **Next**.
5. On the Data Model page, include instances of the view objects you have previously defined and edit the view object instance names to be exactly what you want clients to see. Then click **Finish**.

Instead of accepting the default instance name shown in the Data Model page, you can change the instance name to something more meaningful (for example, instead of the default name `OrderItems1` you can rename it to `AllOrderItems`).

## 6.2.2 How to Create the Application Module with Master-Detail View Object Instances

You can also use the Create Application Module wizard to create a hierarchy of view objects for an application module, based on master-detail relationships that the view objects represent.

### Before you begin:

Create hierarchical relationships between view objects, as described in [Section 5.6, "Working with Multiple Tables in a Master-Detail Hierarchy."](#)

### To create an application module based on view object relationships:

1. In the Application Navigator, right-click the project in which you want to create the application module and choose **New**.

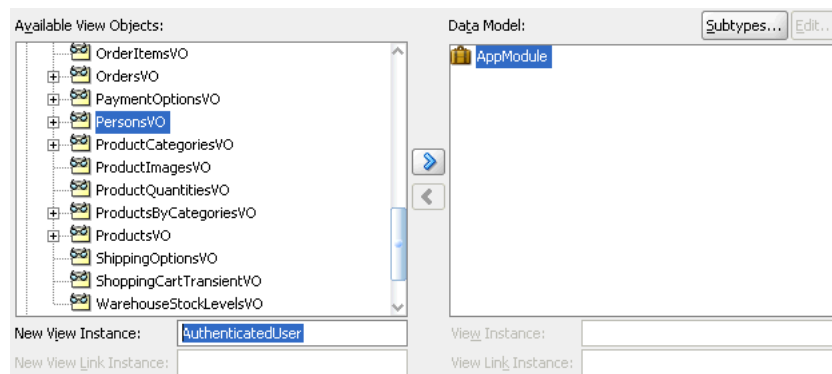

2. In the New Gallery, expand **Business Tier**, select **ADF Business Components** and then **Application Module**, and click **OK**.
3. In the Items list, select **Application Module** to launch the Create Application Module wizard.
4. In the Create Application Module wizard, select the **Data Model** node.
5. In the **Available View Objects** list on the left, select the instance of the view object that you want to be the actively coordinating master.

The master view object will appear with a plus sign in the list indicating the available view links for this view object. The view link must exist to define a master-detail hierarchy.

For example, [Figure 6–1](#) shows `PersonsVO` selected and renamed `AuthenticatedUser` in the **New View Instance** field.

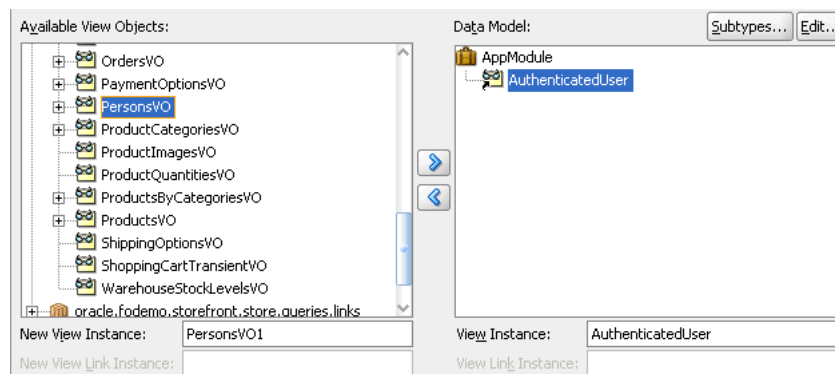

**Figure 6–1 Master View Object Selected**

6. Shuttle the selected master view object to the **Data Model** list

For example, [Figure 6–2](#) shows the newly created master view instance `AuthenticatedUser` in the **Data Model** list after you add it to the list.

**Figure 6–2 Master View Instance Created**

7. In the **Data Model** list, leave the newly created master view instance selected, so that it appears highlighted. This will be the target of the detail view instance you will add. Then locate and select the detail view object beneath the master view object in the **Available View Objects** list.

For example, [Figure 6–3](#) shows the detail `OrdersVO` indented beneath master `PersonsVO` with the name `OrdersVO` via `PersonsToOrders`. The name identifies the view link `PersonsToOrders`, which defines the master-detail hierarchy between `PersonsVO` and `OrdersVO`. The detail view instance is renamed to `MyOrders`.

**Figure 6–3** *Detail View Object Selected*

8. To add the detail instance to the previously added master instance, shuttle the detail view object to the **Data Model** list below the selected master view instance.

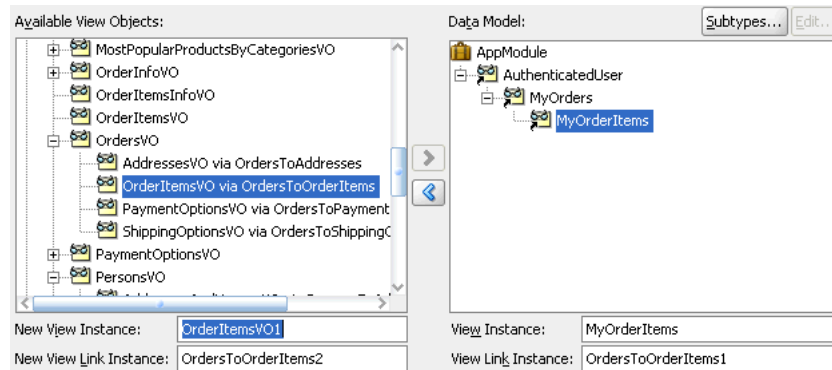

[Figure 6–4](#) shows the newly created detail view instance `MyOrders` is a detail of the `AuthenticatedUser` in the data model.

**Figure 6–4** *Master View Instance Created*

9. To add another level of hierarchy, select the newly added detail in the **Data Model** list, then shuttle over the new detail which itself has a master-detail relationship with the previously added detail instance.

Your data model can contain as many levels of hierarchy as your view object relationships support. For example, [Figure 6–5](#) shows the **Data Model** list with instance `AuthenticatedUser` (renamed for `PersonsVO`) as the master of `MyOrders` (renamed for `OrdersVO` via `PersonsToOrders`), which in turn is a master for `MyOrderItems` (renamed from `OrderItemsVO` via `OrdersToOrderItems`). The detail view object `MyOrderItems` is the last level of the hierarchy possible because this view object is itself not a master for another view object.

**Figure 6–5 Master-Detail-Detail Hierarchy Created**

## 6.3 Testing View Object Instances Using the Business Component Browser

Using the Business Component Browser, you can simulate an end user interacting with your application module data model before you have started to build any custom user interface of your own. Even *after* you have your UI pages constructed, you will come to appreciate using the Business Component Browser to assist in diagnosing problems when they arise. You can reproduce the issues in the Business Component Browser to discover whether the problem lies in the view or controller layers of the application, or whether there is instead a problem in the business service layer application module itself.

### 6.3.1 How to Run the Business Component Browser

To test the view objects you added to an application module, use the Business Component Browser, which is accessible from the Application Navigator.

#### To test view objects in an application module configuration:

1. In the Application Navigator, expand the project containing the desired application module and view objects.
2. Right-click the application module and choose **Run**.

Alternatively, choose **Debug** when you want to run the application in the Business Component Browser with debugging enabled. JDeveloper opens the debugger process panel in the Log window and the various debugger windows. For example, when debugging using the Business Component Browser, you can view status message and exceptions, step in and out of source code, and manage breakpoints.

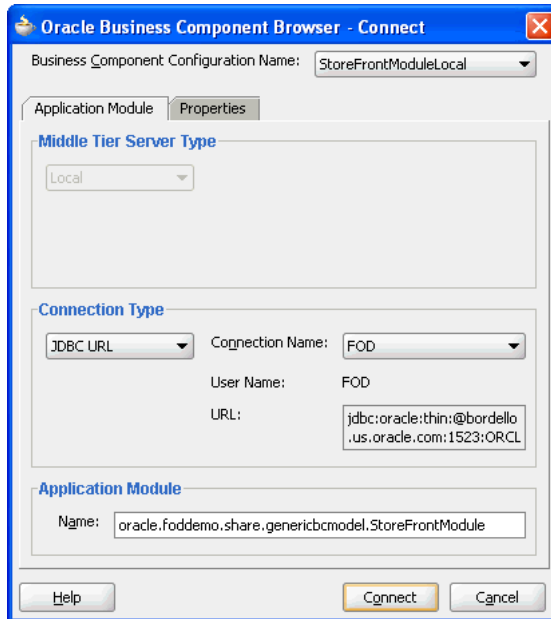

For information about receiving diagnostic messages specific to ADF Business Component debugging, see [Section 6.3.8, "How to Enable ADF Business Components Debug Diagnostics"](#).

3. In the Select Business Components Configuration dialog, choose the desired application module configuration from the **Business Component Configuration Name** list to run the Business Component Browser.

By default, an application module has only its default configurations, named *AppModuleNameLocal* and *AppModuleNameShared*. For example, [Figure 6–6](#) shows the *StoreFrontModuleLocal* configuration used by the application module to connect to the database.

If you have created additional configurations for your application module and want to test it using one of those instead, just select the desired configuration from the **Business Component Configuration Name** dropdown list on the Configuration dialog before clicking **Connect**.

**Figure 6–6 Configuration Selection in Configuration Dialog**

4. Click **Connect** to start the application module using the selected configuration.
5. To execute a view object in the Business Component Browser, expand the data model tree and double-click the desired view object node.

Note that the view object instance may already appear executed in the testing session. In this case, the Business Component Browser data view page on the right already displays query results for the view object instance. The fields in the Business Component Browser data view page of a read-only view object will always appear disabled since the data it represents is not editable. For example, in [Figure 6–7](#), data for the view instance `Products` appears in the Browser. Fields like **Product Id**, **Language**, and **Category** appear disabled because the attributes themselves are not editable.

**Figure 6–7 Testing the Data Model in the Business Component Browser**

6. Right-click a node in the data model tree at the left of the Business Component Browser to display the context menu for that node. For example, on a view object node you can reexecute the query if needed, to remove the view object from the data model tree, and perform other tasks.
7. Right-click the tab of an open data viewer to display the context menu for that tab, as shown in Figure 6–8. For example, you can close the data viewer or open it in a separate window.

**Figure 6–8 Context Menu for Data Viewer Tabs in the Business Component Browser**

### 6.3.2 How to Test Entity-Based View Objects Interactively

You test entity-based view objects interactively in the same way as read-only ones. Just add instances of the desired view objects to the data model of some application module, and then test that application module using the Business Component Browser.

You'll find the Business Component Browser invaluable for quickly testing and debugging your application modules. Table 6–1 gives an overview of the operations that the Business Component Browser toolbar buttons perform when you display an entity-based view object.

**Table 6–1 Business Component Browser Toolbar Buttons**

Button	Operation	Usage
	Move to ... row	Changes the current row displayed by the Business Component Browser. Moves to the first, previous, next, or last row.

**Table 6–1 (Cont.) Business Component Browser Toolbar Buttons**

Button	Operation	Usage
	Insert a new row	Creates and inserts a new row.
	Delete the current row	Deletes the current row.
	Save changes to the database	Posts and commits changes that you made in the ADF Business Components cache.
	Discard all changes since last save	Discards changes that you made in the ADF Business Components cache and restores the original values, rolling back any changes posted to the database.
	Specify view criteria	Displays the Business Component View Criteria dialog that you can use to create and apply view criteria to the master view object instance.
	Validate row	Validates the current row by applying validation rules defined for all entity object instances. Disabled unless at least one field is editable.
	Edit bind variables	Displays the Bind Variable dialog that you can use to enter values for bind parameters used in the view object query. Disabled unless the view object query uses bind parameters in the query statement.

To test the entity-based view objects you added to an application module, use the Business Component Browser, which is accessible from the Application Navigator.

**To test entity-based view objects using an application module configuration:**

1. Select the application module in the Application Navigator and choose **Run** from the context menu.
2. Click **Connect** on the Select Business Component Browser Configuration dialog and use the desired configuration for testing.
3. To execute an entity-based view object in the Business Component Browser, expand the data model tree and double-click the desired view object node.

Unlike the fields of a read-only view object, the fields displayed in the data view page will appear enabled, because the data it represents is editable.

4. You can use the editable fields to update individual values and perform validation checks on the entered data.

In the case of a view instance with referenced entities, you can change the foreign key value and observe that the referenced part changes.

5. You can use the toolbar buttons to perform row-level operations, such as navigate rows, create row, remove row, and validate the current row.

For further discussion about simulating end-user interaction in the data view page, see [Section 6.3.5, "How to Simulate End-User Interaction in the Business Component Browser"](#).

### 6.3.3 How to Update the Business Component Browser to Display Project Changes

Normally, changes that you make to the data model project will not be picked up automatically by running the Business Component Browser. You can, however, force the Business Component Browser to reload metadata from the data model project any time you want to synchronize the displayed data model and the data model project. This option is an alternative to quitting the Business Component Browser, editing your project, and rerunning the Business Component Browser to view the latest changes.

Using the **Reload Application** option saves time, especially as you work iteratively between the Business Component Browser and JDeveloper. For example, while running the Business Component Browser you might determine the need to modify the data model with a new view instance or you might find that a view instance is missing an LOV attribute definition. You can return to JDeveloper and use the Business Components overview editors to make the changes that alter the data model metadata. Then, after you recompile the project (a necessary step), you can return to the Business Component Browser to reload the updated metadata from the project's class path.

#### To reload the data model metadata in the running Business Component Browser:

1. In the Application Navigator, right-click the application module and choose **Run**.
2. Test the data model and determine any changes you want to make. Do not exit the Business Component Browser.
3. In JDeveloper, make the desired changes and recompile the data model project. (For example, you can right-click the data model project in the Application Navigator and choose **Make** to complete the recompile step.)

Although the metadata changes that you make are not involved in compiling the project, the compile step is necessary to copy the metadata to the class path and to allow the Business Component Browser to reload it.

4. Return to the Business Component Browser and click the **Reload the Application Metadata** button above the data model tree. The Business Component Browser closes all open windows.

Alternatively, you can choose **Reload Application** from the **File** menu of the Business Component Browser.

5. Reopen the desired windows and view your changes.

### 6.3.4 What Happens When You Use the Business Component Browser

When you launch the Business Component Browser, JDeveloper starts the tool in a separate process and the Business Component Browser appears. The tree at the left of the dialog displays all of the view object instances in your application module's data model. After you double-click the desired view object instance, the Business Component Browser will display a data view page to inspect the query results. For example, [Figure 6-7](#) shows the view instance `Products` that has been double-clicked in the expanded tree to display the data for this view instance in the data view page on the right.

The data view page will appear disabled for any read-only view objects you display because the data is not editable. But even for a read-only view object, the tool affords some useful features:

- You can validate that the UI hints based on the Label Text control hint and format masks are defined correctly.

- You can also scroll through the data using the toolbar buttons.
- You can enter Query-by-Example criteria to find a particular row whose data you want to inspect. By clicking the **Specify View Criteria** button in the toolbar, the View Criteria dialog displays the list of available Query-by-Example criteria.

For example, as shown in [Figure 6–9](#), you can select a view criteria like `CustomerInfoVOCriteria` and enter a query criteria like "H%" for a `LastName` attribute and click **Find** to narrow the search to only those users with a last name that begins with the letter H.

The Business Component Browser becomes even more useful when you create entity-based view objects that allow you to simulate inserting, updating, and deleting rows, as described in [Section 6.3.2, "How to Test Entity-Based View Objects Interactively."](#)

**Figure 6–9 Built-in Query-by-Example Functionality**

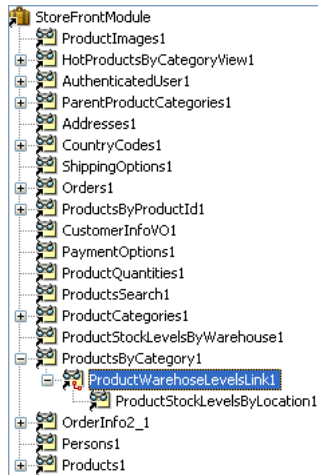

### 6.3.5 How to Simulate End-User Interaction in the Business Component Browser

When you launch the Business Component Browser, the tree at the left of the display shows the hierarchy of the view object instances that the data model of your application module defines. If the data model defines master-detail view instance relationships, the tree will display them as parent and child nodes. A node between the master-detail view instances represents the view link instance that performs the active master-detail coordination as the current row changes in the master. For example, in [Figure 6–10](#) the tree is expanded to show the master-detail relationship between the master `ProductByCategory1` view instance and the detail `ProductStockLevelsByLocation1` view instance. The selected node, `ProductWarehousesLevelsLink1`, is the view link instance that defines the master-detail relationship.

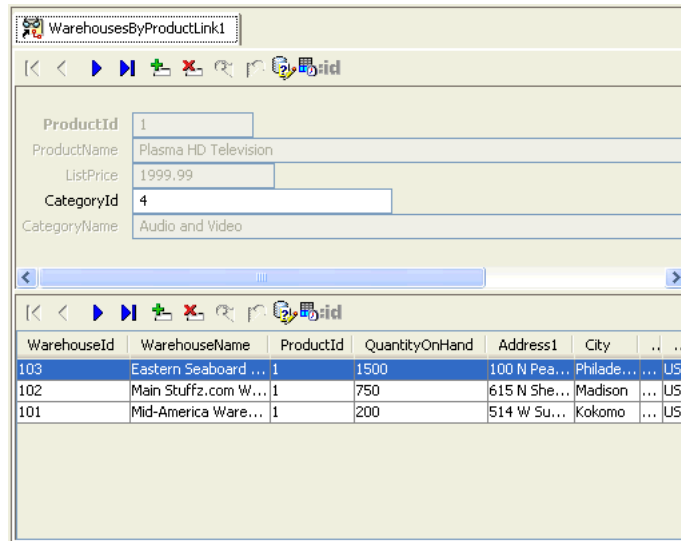

**Figure 6–10 Application Module Data Model in the Business Component Browser**

Double-clicking the view link instance executes the master object and displays the master-detail data in the data view page. For example, in [Figure 6–11](#), double-clicking the `ProductWarehousesLevelsLink1` view link instance in the tree executes the `ProductsByCategory` master view instance in the top portion of the data view page and the `ProductStockLevelsByLocation1` view instance in the bottom portion of the data view page. Additional context menu items on the view object node allow you to reexecute the query if needed, remove the view object from the data model panel, and perform other tasks.

In the master-detail data view page, you can scroll through the query results. Additionally, because instance of entity-based view objects are fully editable, Instead of displaying *disabled* UI controls showing read-only data for a read-only view object, the data view page displays editable fields. You are free to experiment with creating, inserting, updating, validating, committing, and rolling back.

**Figure 6–11 Master-Detail Data View Page in the Business Component Browser**

For example, you can view multiple levels of master-detail hierarchies, opening multiple data view pages at the same time. Use the **Detach** context menu item to open

any tab into a separate window and visualize multiple view object's data at the same time.

Using just the master-detail data view page, you can test several functional areas of your application.

### 6.3.5.1 Testing Master-Detail Coordination

When you click the navigation buttons on the Business Component Browser toolbar, you can see that the rows for the current master view object are correctly coordinated. For example, [Figure 6–11](#) shows a master-detail hierarchy with products and warehouses. If you click the **Next Row** button in the master panel, the master panel will display the next product (identified by a product ID) and the detail panel will update to display the list of warehouses and quantities available for the product.

### 6.3.5.2 Testing UI Control Hints

The entity-based view object attributes inherit their control hints from those on the underlying entity object attribute. The prompts displayed in the data view page help you see whether you have correctly defined a user-friendly label text control hint for each attribute. For details on setting up the hint on your entity object, see [Section 5.14, "Defining Control Hints for View Objects."](#)

### 6.3.5.3 Testing Business Domain Layer Validation

Depending on the validation rules you have defined, you can try entering invalid values to trigger and verify validation exceptions. For example, when you have defined a range validation rule, enter a value outside the range and see an error similar to:

```
(oracle.jbo.AttrSetValException) Valid product codes are between 100 and 999
```

Click the rollback button in the toolbar to revert data to the previous state.

### 6.3.5.4 Testing Alternate Language Message Bundles and Control Hints

When your application defines alternative languages in your resource message bundles, you can configure the Business Component Browser to recognize these languages. In the Business Component Browser, you can then display the **Locale** menu and select among the available language choices.

#### To specify a default language for the Business Component Browser:

1. Choose **Preferences** from the **JDeveloper Tools** menu.
2. Expand **Business Components** in the selection panel, and select **Tester**.
3. To execute an entity-based view object in the Business Component Browser, expand the data model tree and double-click the desired view object node.
4. In the Business Component Browser page, add any locale for which you have created a resource message bundle to the **Selected** list.

Alternatively, you can configure the default language choice by setting ADF Business Components runtime configuration properties for a specific application module configuration. These runtime properties also determine which language the Business Component Browser will display as the default. In the Edit Configuration dialog for the configuration, select the **Properties** tab and enter the desired country code for the country and language. For example, to specify the Italian language, you would enter `IT` and `it` for these two properties:

- `jbo.default.country = IT`
- `jbo.default.language = it`

Testing the language message bundles in the Business Component Browser lets you verify that the translations of the control hints are correctly located. Or, if the message bundle defines date formats for specific attributes, the tool lets you verify that date formats change (like 04/12/2013 to 12/04/2013).

### 6.3.5.5 Testing View Objects That Reference Entity Usages

By scrolling through the data — or using the **Specify View Criteria** button in the Business Component Browser toolbar to search — you can verify whether you have correctly altered the `WHERE` clause in an entity-based view object's query to use an outer join. The rows should appear as expected.

You also can try changing a primary key attribute of a master view object. This will allow you to verify that the corresponding reference information is automatically updated to reflect the new primary key value.

Use the Business Component Browser to verify that control hints defined at the view object level override the ones it would normally inherit from the underlying entity object. If you notice that several attributes share the same label text, you can edit the control hint for the desired attributes at the view object level. For example, you can set the **Label Text** hint to **Member Since** for the `RegisteredDate` attribute and **Provisioned?** for the `ProvisionedFlag` attribute.

### 6.3.5.6 Testing Row Creation and Default Value Generation

When displaying an entity-based view object, click the **Create Row** button in the Business Component Browser toolbar for the view object instance to create a new blank row. Any fields that have a declarative default value will appear with that value in the blank row. If the a `DBSequence`-valued attribute is used, a temporary value will appear in the new row. After entering all the required fields, click the **Commit** button to commit the transaction. The actual, trigger-assigned primary key should appear in the field after successful commit.

### 6.3.5.7 Testing That New Detail Rows Have Correct Foreign Keys

If you click **Create Row** in the Business Component Browser toolbar to try adding a new row to an existing detail entity-based view object instance, you'll notice that the view link automatically ensures that the foreign key attribute value in the new row is set to the value of the current master view instance row.

## 6.3.6 How to Test Multiuser Scenarios in the Business Component Browser

When view objects and entity objects cooperate at runtime, two exceptions can occur when you run the application in a multiuser environment. To anticipate these exceptions, you can simulate a multiuser environment for testing purposes using the Business Component Browser. For example, when the application displays edit forms for view object queries, what is the expected behavior when two users attempt to modify the same attribute in their forms?

To understand the expected behavior, open two instances of the Business Component Browser on the application module to simulate two users editing the same view object attribute. Keep both instances open and perform the following two tests to demonstrate how multiuser exceptions can arise:

- In one instance of the Business Component Browser, modify an attribute of an existing view object and tab out of the field. Then, in the other browser instance,

try to modify the same view object attribute in some way and commit the change. You'll see that the second user gets the `oracle.jbo.AlreadyLockedException`.

You can then change the value of `jbo.locking.mode` to be `pessimistic` on the Properties page of the Business Component Browser Connect dialog and try repeating the test (the default mode is set to `optimistic`). You'll see the error occurs for the second user immediately after changing the value instead of after committing the change.

- In one instance of the Business Component Browser, modify an attribute of an existing view object and tab out of the field. Then, in the other browser instance, retrieve (but don't modify) the same view object attribute. Back in the first window, commit the change. If the second user then tries to modify that same attribute, you'll see that the second user gets the `oracle.jbo.RowInconsistentException`. The row has been modified and committed by another user since the second user retrieved the row into the entity cache.

### 6.3.7 How to Customize Configuration Options Before Running the Browser

Using the Select Business Components Configuration dialog, you can select a predefined configuration to run the tool using that named set of runtime configuration properties. The Select Configuration dialog also features a **Properties** tab that allows you to see the selected configurations settings and to override any of the configuration's settings for the current run of the browser. For example, you could alter the default language for the UI control hints for a single instance of the Business Component Browser by opening the **Properties** tab and setting the following two properties with the desired country code (in this case, `IT` for Italy):

- `jbo.default.country = IT`
- `jbo.default.language = it`

**Tip:** If you wanted to make the changes to your configuration permanent, you could use the Configuration Manager to copy the current configuration and create a new configuration in which you set the desired properties set. For example, anytime you wanted to test in Italian you could simply choose to use the `UserServiceLocalItalian` configuration, instead of the default `UserServiceLocal`.

### 6.3.8 How to Enable ADF Business Components Debug Diagnostics

When launching the Business Component Browser, if your data model project's current run configuration is set to include the Java System parameter `jbo.debugoutput=console`, you can enable ADF Business Components debug diagnostics with messages directed to the JDeveloper Log window.

---

---

**Note:** Despite the similar name, the JDeveloper project's run configurations are different from the ADF application module's configurations. The former are part of the project properties, the latter are defined along with your application module component in its `bc4j.xcfg` file and edited using the Edit Business Components Configuration dialog.

---

---

To set the system debug output property, open the Run/Debug/Profile page in the Project Properties dialog for your data model project. Click **Edit** to edit the chosen run configuration, and add following string to the **Java Options** field in the page.

```
-Djbo.debugoutput=console
```

The next time you run the Business Component Browser and double-click the view object, you'll see detailed diagnostic output in the console, as shown in [Example 6-1](#). Using the diagnostics will allow you to visualize everything the framework components are doing for your application.

#### **Example 6-1 Diagnostic Output of Business Component Browser**

```
:
[355] Oracle SQLBuilder: Registered driver: oracle.jdbc.OracleDriver
[356] Creating a new pool resource
[357] **** DBTransactionImpl establishNewConnection
[358] Successfully logged in
[359] JDBCVersion: 11.1.0.7.0-Production
[360] DatabaseProductName: Oracle
[361] DBTransactionImpl initTransaction
[362] Replacing: null with: StoreServiceAM_AddressesPageDef
[363] Replacing: null with: StoreServiceAM_MostPopularProductsByCategoriesPageDef
...
[537] Orders ViewRowSetImpl.execute caused params to be "un"changed
[538] Column count: 41
[539] ViewObject: Orders Created new QUERY statement
[540] Orders>#q computed SQLStmtBufLen: 952, actual=865, storing=895
[541] SELECT OrderEO.ORDER_ID, OrderEO.ORDER_DATE, OrderEO.ORDER_SHIPPED_DATE,
      FROM ORDERS OrderEO ORDER BY OrderEO.ORDER_DATE desc
[542] Bind params for ViewObject: Orders
```

Other legal values for this property are `silent` (the default, if not specified) and `file`. If you choose the file option, diagnostics are written to the system temp directory.

**Tip:** You can create separate JDeveloper run configurations, one with the ADF Business Components debug diagnostics enabled, and another without it. By choosing the appropriate project run configuration, you can easily run JDeveloper with or without debug diagnostics.

### **6.3.9 What Happens at Runtime: When View Objects and Entity Objects Cooperate**

On their own, view objects and entity objects simplify two important jobs that every enterprise application developer needs to do:

- Work with SQL query results
- Modify and validate rows in database tables

Entity-based view objects can query any selection of data that you want the end user to be able to view and modify. Any data the end user is allowed to change will be validated and saved by your reusable business domain layer. The key ingredients you provide as the developer are the ones that only *you* can know:

- You decide what business logic should be enforced in your business domain layer
- You decide what queries describe the data you need to put on the screen

These are the things that make *your* application unique. The built-in functionality of your entity-based view objects handles the rest of the implementation details.

---

---

**Note:** Understanding row keys and what role the entity cache plays in the transaction are important concepts that help to clarify the nature of the entity-based view objects. These two concepts are addressed in [Section 6.4.1, "ViewObject Interface Methods for Working with the View Object's Default RowSet."](#)

---

---

### 6.3.9.1 What Happens When a View Object Executes Its Query

After adding an instance of an entity-based view object to the application module's data model, you can see what happens at runtime when you execute the query. Like a read-only view object, an entity-based view object sends its SQL query straight to the database using the standard Java Database Connectivity (JDBC) API, and the database produces a result set. In contrast to its read-only counterpart, however, as the entity-based view object retrieves each row of the database result set, it partitions the row attributes based on which entity usage they relate to. This partitioning occurs by creating an entity object row of the appropriate type for each of the view object's entity usages, populating them with the relevant attributes retrieved by the query, and storing each of these entity rows in its respective entity cache. Then, rather than storing duplicate copies of the data, the view row simply *points* at the entity row parts that comprise it.

[Figure 6-12](#) illustrates how the entity cache partitions the result set attributes of two entity-based view objects. In this example, the highlighted row in the database result set is partitioned into an `Order` entity row with primary key 112 and a `CustomerInfo` entity row with primary key 301.

As described in [Section 6.4.1.2, "The Role of the Entity Cache in the Transaction,"](#) the entity row that is brought into the cache using `findByPrimaryKey()` contains *all* attributes of the entity object. In contrast, an entity row created by partitioning rows from the entity-based view object's query result contains values only for attributes that appear in the query. It does *not* include the complete set of attributes. This partially populated entity row represents an important runtime performance optimization.

Since the ratio of rows retrieved to rows modified in a typical enterprise application is very high, you can save memory by bringing only the attributes into memory that you need to display instead of bringing all attributes into memory all the time.

**Figure 6–12 Entity Cache Partitions View Rows into Entity Rows**

By partitioning queried data this way into its underlying entity row constituent parts, the first benefit you gain is that all of the rows that include some data queried will display a consistent result when changes are made in the current transaction. In other words, if one view object allows the `PaymentType` attribute of customer 301 to be modified, then all rows in any entity-based view object showing the `PaymentType` attribute for customer 301 will update instantly to reflect the change. Since the data related to customer 301 is stored exactly once in the `CustomerInfo` entity cache in the entity row with primary key 301, any view row that has queried the order's `PaymentType` attribute is just pointing at this single entity row.

Luckily, these implementation details are completely hidden from a client working with the rows in a view object's row set. The client works with a view row, getting and setting the attributes, and is unaware of how those attributes might be related to entity rows behind the scenes.

### 6.3.9.2 What Happens When a View Row Attribute Is Modified

When a user attempts to update the attribute of a view row, a series of steps occur to automatically coordinate this view row attribute modification with the underlying entity row. These steps ensure that a validation rule defined on the entity-mapped attribute will be triggered before the value is changed.

Figure 6–13 illustrates the basic steps that occur at runtime when the user attempts to update an entity-mapped attribute. In this example, the modified attribute `Status` is mapped to an entity usage where a validation rule is defined.

1. The user attempts to set the `Status` attribute to the value `Ship`.
2. Since `Status` is an entity-mapped attribute from the `Order` entity usage, the view row delegates the attribute set to the appropriate underlying entity row in the `Order` entity cache having primary key 112.
3. Any attribute-level validation rules on the `Status` attribute of the `Order` entity object are evaluated and the modification attempt will fail if any rule does not succeed.

Assume that some validation rule for the `Status` attribute programmatically references the `ShipDate` attribute (for example, to enforce a business rule that an `Order` cannot be shipped the same day it is placed). The `ShipDate` was not one of the `Order` attributes retrieved by the query, so it is not present in the partially populated entity row in the `Order` entity cache.

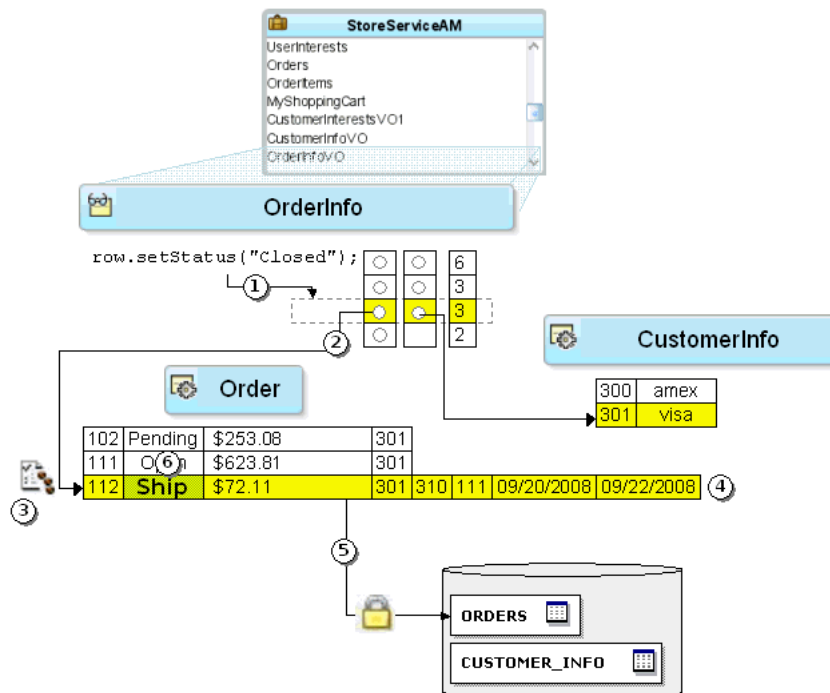

4. To ensure that business rules can always reference all attributes of the entity object, the entity object detects this situation and "faults-in" the entire set of `Order` entity object attributes for the entity row being modified using the primary key (which must be present for each entity usage that participates in the view object).
5. After the attribute-level validations all succeed, the entity object attempts to acquire a lock on the row in the `ORDERS` table before allowing the first attribute to be modified.
6. If the row can be locked, the attempt to set the `Status` attribute in the row succeeds and the value is changed in the entity row.

---

**Note:** The `jbo.locking.mode` configuration property controls how rows are locked. The default value is `optimistic`. Typically, Fusion web applications will use the default setting `optimistic`, so that rows aren't locked until transaction commit time. In `pessimistic` locking mode, the row must be lockable before any change is allowed to it in the entity cache.

---

**Figure 6–13 View Row Attribute Updates Delegate to the Entity**

### 6.3.9.3 What Happens When a Foreign Key Attribute is Changed

When a user attempts to update a foreign key attribute, a series of steps occur to automatically coordinate this view row attribute modification with the underlying entity row. These steps ensure that a validation rule defined on the foreign key, entity-mapped attribute will be triggered before the value is changed. They also

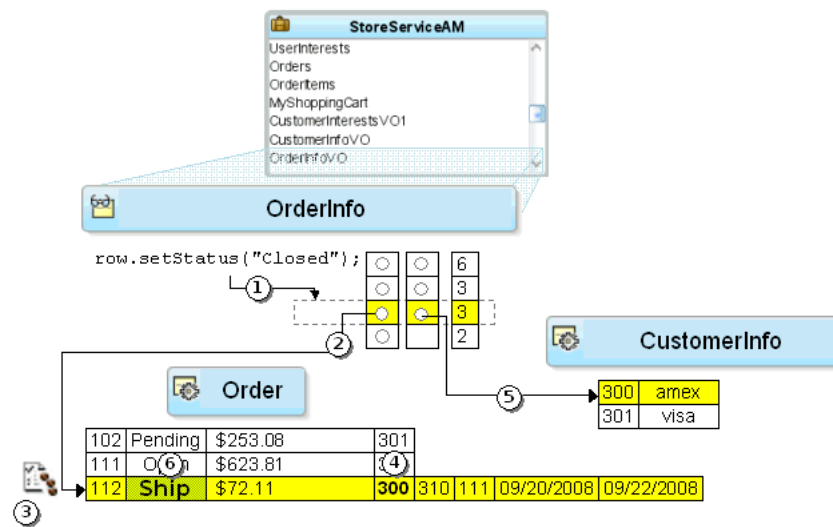

ensure that the view row for the changed foreign key attribute reflects the correct attributes of all referenced entity objects.

Figure 6–14 illustrates the basic steps that occur at runtime when the user attempts to update a foreign key, entity-mapped attribute. In this example, the modified attribute `CustomerInfoId` is mapped to an entity usage `Order` where the attribute is associated with another entity object `CustomerInfo`.

1. The user attempts to set the `CustomerInfoId` attribute to the value 300.
2. Since `CustomerInfoId` is an entity-mapped attribute from the `Order` entity usage, the view row delegates the attribute set to the appropriate underlying entity row in the `Order` entity cache, which has primary key 112.
3. Any attribute-level validation rules on the `CustomerInfoId` attribute of the `Order` entity object are evaluated and the modification attempt will fail if any rule does not succeed.
4. The row is already locked, so the attempt to set the `CustomerInfoId` attribute in the row succeeds and the value is changed in the entity row.
5. Since the `CustomerInfoId` attribute on the `Order` entity usage is associated with the `CustomerInfo` entity object, this change of foreign key value causes the view row to replace its current entity row part for customer 301 with the entity row corresponding to the new `CustomerInfoId` = 300. This effectively makes the view row for order 112 point to the entity row for 300, so the value of the `PaymentType` in the view row updates to reflect the correct reference information for this newly assigned customer.

Figure 6–14 After Updating a Foreign Key, View Row Points to a New Entity

#### 6.3.9.4 What Happens When a Transaction is Committed

Suppose the user is satisfied with the changes, and commits the transaction. As shown in Figure 6–15, there are two basic steps:

1. The `Transaction` object validates any invalid entity rows in its pending changes list.
2. The entity rows in the pending changes list are saved to the database.

The figure depicts a loop in Step 1 before the act of validating one modified entity object might programmatically affect changes to other entity objects. Once the transaction has processed its list of invalid entities on the pending changes list, if the list has entities, the transaction will complete another pass. It will attempt up to ten passes through the list. If by that point there are still invalid entity rows, it will throw an exception because this typically means you have an error in your business logic that needs to be investigated.

**Figure 6–15** Committing the Transaction Validates Invalid Entities, Then Saves Them

### 6.3.9.5 What Happens When a View Object Queries Data

When you reexecute a view object's query, by default the view rows in its current row set are "forgotten" in preparation for reading in a fresh result set. This view object operation does not directly affect the entity cache, however. The view object then sends the SQL to the database and the process begins again to retrieve the database result set rows and partition them into entity row parts.

---

**Note:** Typically when the view object queries data, you expect it to retrieve the latest database information. If instead you want to avoid a database roundtrip by restricting your view object to querying only over existing entity rows in the cache, or over existing rows already in the view object's row set, see [Section 39.5, "Performing In-Memory Sorting and Filtering of Row Sets."](#)

---

**6.3.9.5.1 How Unmodified Attributes are Handled During Query** As part of the entity row partitioning process during a query, if an attribute on the entity row is unmodified, then its value in the entity cache is updated to reflect the newly queried value.

**6.3.9.5.2 How Modified Attributes are Handled During Query** However, if the value of an entity row attribute has been *modified* in the current transaction, then during a query the entity row partitioning process does not refresh its value. Uncommitted changes in the current transaction are left intact so the end-user's logical unit of work is preserved. As with any entity attribute value, these pending modifications continue to

be consistently displayed in any entity-based view object rows that reference the modified entity rows.

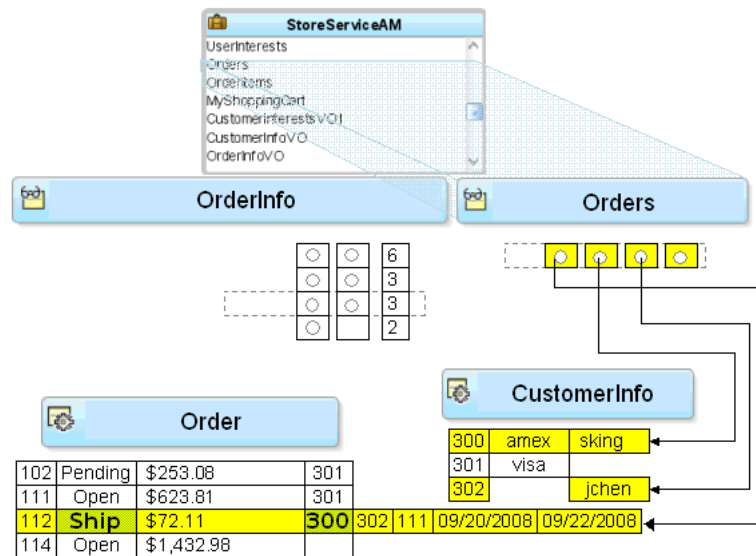

---

**Note:** End-user row inserts and deletes are also managed by the entity cache, which permits new rows to appear and deleted rows to be skipped during requerying. For more information about new row behavior, see [Section 39.1.2, "Maintaining New Row Consistency in View Objects Based on the Same Entity."](#)

---

For example, [Figure 6–16](#) illustrates the scenario where a user "drills down" to a different page that uses the `Orders` view object instance to retrieve all details about order 112 and that this happens in the context of the current transaction's pending changes. That view object has two entity usages: a primary `Orders` usage and a reference usage for `CustomerInfo`. When its query result is partitioned into entity rows, it ends up pointing at the same `Order` entity row that the previous `OrderInfo` view row had modified. This means the end user will correctly see the pending change, that the order is assigned to `sking` in this transaction.

**Figure 6–16 Entity Cache Merges Sets of Entity Attributes from Different View Objects**

**6.3.9.5.3 How Overlapping Subsets of Attributes are Handled During Requery** Two different view objects can retrieve two *different* subsets of reference information and the results are merged whether or not they have matching sets of attributes. For example, [Figure 6–16](#) also illustrates the situation, where the `Orders` view object queries the user's `Email`, while the `OrderInfo` view object queried the user's `PaymentOption`. The figure shows what happens at runtime: if while partitioning the retrieved row, the entity row part contains a different set of attributes than does the partially populated entity row that is already in the cache, the attributes get "merged". The result is a partially populated entity row in the cache with the *union* of the overlapping subsets of user attributes. In contrast, for `jchen` (user 302), who wasn't in the cache already, the resulting new entity row contains only the `Email` attribute, but not the `PaymentOption`.

### 6.3.10 What You May Need to Know About Optimizing View Object Runtime Performance

The view object provides tuning parameters that let you control how SQL is executed and how data is fetched from the database. These tuning parameters play a significant role in the runtime performance of the view object. If the fetch options are not tuned correctly for the application, then your view object may fetch an excessive amount of data and may make too many roundtrips to the database.

You can use the **Tuning** section of the General page of the overview editor to configure the fetch options shown in [Table 6–2](#).

**Table 6–2 Parameters to Tune View Object Performance**

Fetch Tuning Parameters	Usage
Fetch Mode	The default fetch option is the <b>All Rows</b> option, which will be retrieved <b>As Needed</b> ( <code>FetchMode="FETCH_AS_NEEDED"</code> ) or <b>All at Once</b> ( <code>FetchMode="FETCH_ALL"</code> ), depending on which option is desired. The <b>As Needed</b> option ensures that an <code>executeQuery()</code> operation on the view object initially retrieves only as many rows as necessary to fill the first page of a display, whose number of rows is set based on the view object's range size.
Fetch Size	In conjunction with the <b>Fetch Mode</b> option, the <b>in Batches of</b> field controls the number of records fetched at one time from the database ( <code>FetchSize</code> in the view object XML). The default value is 1, which will give poor performance unless only one row will be fetched. The suggested configuration is to set this value to $n+1$ where $n$ is the number of rows to be displayed in the user interface.

**Table 6–2 (Cont.) Parameters to Tune View Object Performance**

Fetch Tuning Parameters	Usage
Max Fetch Size	<p>The default max fetch size for a view object is -1, which means that there is no limit to the number of rows the view object can fetch. In cases where the result set should contain only <i>n</i> rows of data, the option <b>Only up to row number</b> should be selected and set to <i>n</i>. The developer can alternatively call <code>setMaxFetchSize(<i>n</i>)</code> to set this programmatically or manually add the parameter <code>MaxFetchSize</code> to the view object XML.</p> <p>For view objects whose <code>WHERE</code> clause expects to retrieve a single row, set the option <b>At Most One Row</b>. This way the view object knows you don't expect any more rows and it will skip its normal test for that situation.</p> <p>As mentioned earlier, setting a maximum fetch size of 0 (zero) makes the view object insert-only. In this case, no select query will be issued, so no rows will be fetched.</p> <p>When you want to specify a global threshold for all view object queries in the application, you can configure the <b>Row Fetch Limit</b> property in the <code>adf-config.xml</code> file. Setting this property means you can avoid changing the <b>Max Fetch Size</b> for individual query operations. If you do specify a fetch limit for individual view objects, the <b>Row Fetch Limit</b> setting will be ignored in those cases. For more details about <b>Row Fetch Limit</b>, see <a href="#">Section 39.1.1, "Limiting the View Object Max Fetch Size to Fetch the First <i>n</i> Rows."</a></p>
Forward-only Mode	<p>If a data set will only be traversed going forward, then forward-only mode can help performance when iterating through the data set. This can be configured by programmatically calling <code>setForwardOnly(true)</code> on the view object. Setting forward-only will also prevent caching previous sets of rows as the data set is traversed.</p>

When you tune view objects, you should also consider these issues:

- **Large data sets:** View objects provide a mechanism to page through large data sets such that a user can jump to a specific page in the results. This is configured by calling `setRangeSize(n)` followed by `setAccessMode(RowSet.RANGE_PAGING)` on the view object where *n* is the number of rows contained within one page. When the user navigates to a specific page in the data set, the application can call `scrollToRangePage(P)` on the view object to navigate to page *P*. Range paging fetches and caches only the current page of rows in the view object row cache at the cost of another query execution to retrieve each page of data. Range paging is not appropriate where it is beneficial to have all fetched rows in the view object row cache (for example, when the application needs to read all rows in a dataset for an LOV or page back and forth in records of a small data set).
- **Spillover:** There is a facility to use the data source as "virtual memory" when the JVM container runs out of memory. By default, this is disabled and can be turned

on as a last resort by setting `jbo.use.pers.coll=true`. Enabling spillover can have a large performance impact.

- **SQL style:** If the generic SQL92 SQL style is used to connect to generic SQL92-compliant databases, then some view object tuning options will not function correctly. The parameter that choosing the generic SQL92 SQL style affects the most is the fetch size. When SQL92 SQL style is used, the fetch size defaults to 10 rows regardless of what is configured for the view object. You can set the SQL style when you define the database connection. By default, the SQL style will be Oracle. To manually override the SQL style, you can also pass the parameter `-Djbo.SQLBuilder="SQL92"` to the JVM upon startup.

Additionally, you have some options to tune the view objects' associated SQL for better database performance:

- **Bind variables:** If the query associated with the view object contains values that may change from execution to execution, use bind variables. Using bind variables in the query allows the query to reexecute without needing to reparse the query on the database. You can add bind variables to the view object in the Query page of the overview editor for the view object. For more information, see [Section 5.10, "Working with Bind Variables."](#)
- **Query optimizer hints:** The view object can pass hints to the database to influence which execution plan to use for the associated query. The optimizer hints can be specified in the **Retrieve from the Database** group box in the Tuning section of the overview editor for the view object. For information about optimizer hints, see [Section 39.2.4.3, "Specify a Query Optimizer Hint if Necessary."](#)

## 6.4 Testing View Object Instances Programmatically

When you are ready to test a working application module containing at least one view object instance, you can build a simple test client program to illustrate the basics of working programmatically with the data in the contained view object instances.

From the point of view of a client accessing your application module's data model, the API's to work with a read-only view object and an entity-based view object are identical. The key functional difference is that entity-based view objects allow the data in a view object to be fully updatable. The application module that contains the entity-based view objects defines the unit of work and manages the transaction. This section presents four simple test client programs that work with the `StoreFrontAM` application module in the Fusion Order Demo to illustrate:

- Iterating master-detail-detail hierarchy
- Finding a row and updating a foreign key value
- Creating a new order
- Retrieving the row key identifying a row

### 6.4.1 ViewObject Interface Methods for Working with the View Object's Default RowSet

The `ViewObject` interface in the `oracle.jbo` package provides the methods to easily perform any data-retrieval task. Some of these methods used in the example include:

- `executeQuery()`, to execute the view object's query and populate its row set of results
- `setWhereClause()`, to add a dynamic predicate at runtime to narrow a search

- `setNamedWhereClauseParam()`, to set the value of a named bind variable
- `hasNext()`, to test whether the row set iterator has reached the last row of results
- `next()`, to advance the row set iterator to the next row in the row set
- `getEstimatedRowCount()`, to count the number of rows a view object's query would return

Typically, when you work with a view object, you will work with only a single row set of results at a time. To simplify this overwhelmingly common use case, as shown in [Figure 6–17](#), the view object contains a default `RowSet`, which, in turn, contains a default `RowSetIterator`. The default `RowSetIterator` allows you to call all of the data-retrieval methods directly on the `ViewObject` component itself, knowing that they will apply automatically to its default row set.

**Figure 6–17** *ViewObject Contains a Default RowSet and RowSetIterator*

---

**Note:** [Chapter 39, "Advanced View Object Techniques"](#) presents situations when you might want a single view object to produce *multiple* distinct row sets of results. You can also find scenarios for creating *multiple* distinct row set iterators for a row set. Most of the time, however, you'll need only a single iterator.

---

The phrase "working with the rows in a view object," when used in this guide more precisely means working with the rows in the view object's default row set. Similarly, the phrase "iterate over the rows in a view object," more precisely means you will use the default row set iterator of the view object's default row set to loop over its rows.

#### 6.4.1.1 The Role of the Key Object in a View Row or Entity Row

When you work with view rows you use the `Row` interface in the `oracle.jbo` package. As shown in [Figure 6–18](#), the interface contains a method called `getKey()` that you can use to access the `Key` object that identifies any row. Notice that the `Entity` interface in the `oracle.jbo.server` package extends the `Row` interface. This relationship provides a concrete explanation of why the term *entity row* is so appropriate. Even though an entity row supports additional features for encapsulating business logic and handling database access, you can still treat any entity row as a `Row`.

An entity-based view object delegates the task of finding rows by key to its underlying entity row parts.

Recall that both view rows and entity rows support either single-attribute or multiattribute keys, so the `Key` object related to any given `Row` will encapsulate all of the attributes that comprise its key. Once you have a `Key` object, you can use the `findByKey()` method on any row set to find a row based on its `Key` object. When you use the `findByKey()` method to find a view row by key, the view row proceeds to use the entity definition's `findByPrimaryKey()` method to find each entity row contributing attributes to the view row key.

In the case of a read-only view object with no underlying entity row to which to delegate this task, the view object implementation automatically enables the `manageRowsByKey` flag when at least one primary key attribute is detected. This ensures that the `findByKey()` method is successful in the case of read-only view objects. If the `manageRowsByKey` flag is not enabled, then UI operations like setting the current row with the key, which depend on the `findByKey()` method, would not work.

**Figure 6–18 Any View Row or Entity Row Supports Retrieving Its Identifying Key**

**Note:** When you define an entity-based view object, by default the primary key attributes for all of its entity usages are marked with their **Key Attribute** property set to `true`. In any *nonupdatable* reference entity usages, you should disable the **Key Attribute** property for the key attributes. Since view object attributes related to the primary keys of *updatable* entity usages must be part of the composite view row key, their **Key Attribute** property cannot be disabled.

#### 6.4.1.2 The Role of the Entity Cache in the Transaction

An application module is a transactional container for a logical unit of work. At runtime, it acquires a database connection using information from the named configuration you supply, and it delegates transaction management to a companion `Transaction` object. Since a logical unit of work may involve finding and modifying multiple entity rows of different types, the `Transaction` object provides an entity cache as a "work area" to hold entity rows involved in the current user's transaction. Each entity cache contains rows of a single entity type, so a transaction involving two or more entity objects holds the working copies of those entity rows in separate caches.

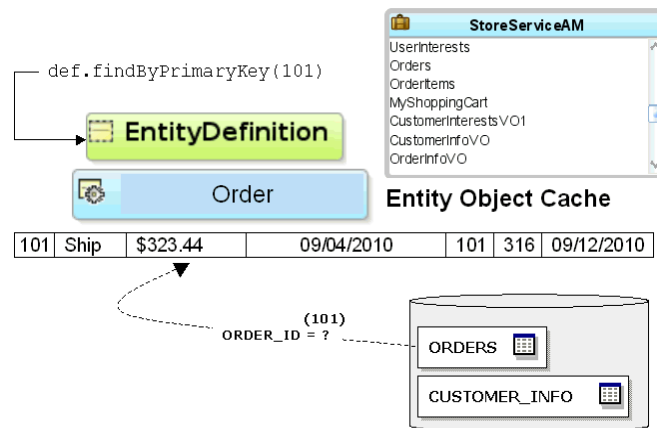

By using an entity object's related entity definition, you can write code in an application module to find and modify existing entity rows. As shown in [Figure 6–19](#), by calling `findByPrimaryKey()` on the entity definition for the `Order` entity object, you can retrieve the row with that key. If it is not already in the entity cache, the entity object executes a query to retrieve it from the database. This query selects all of the entity object's persistent attributes from its underlying table, and finds the row using an appropriate `WHERE` clause against the column corresponding to the entity object's primary key attribute. Subsequent attempts to find the same entity row by key during the same transaction will find it in the cache, preventing the need for a trip to the database. In a given entity cache, entity rows are indexed by their primary key. This makes finding an entity row in the cache a fast operation.

When you access related entity rows using association accessor methods, they are also retrieved from the entity cache. If related entity rows are not in the cache, then they are retrieved from the database. Finally, the entity cache is also the place where new entity rows wait to be saved. In other words, when you use the `createInstance2()`

method on the entity definition to create a new entity row, it is added to the entity cache.

**Figure 6–19 Entity Cache Stores Entity Rows During the Transaction**

When an entity row is created, modified, or removed, it is automatically enrolled in the transaction's list of pending changes. When you call `commit()` on the `Transaction` object, it processes its pending changes list, validating new or modified entity rows that might still be invalid. When the entity rows in the pending list are all valid, the `Transaction` issues a database `SAVEPOINT` and coordinates saving the entity rows to the database. If all goes successfully, it issues the final database `COMMIT` statement. If anything fails, the `Transaction` performs a `ROLLBACK TO SAVEPOINT` to allow the user to fix the error and try again.

The `Transaction` object used by an application module represents the working set of entity rows for a single end-user transaction. By design, it is *not* a shared, global cache. The database engine itself is an extremely efficient shared, global cache for multiple, simultaneous users. Rather than attempting to duplicate all the work of fine-tuning that has gone into the database's shared, global cache functionality, ADF Business Components consciously embraces it. To refresh a single entity object's data from the database at any time, you can call its `refresh()` method. You can `setClearCacheOnCommit()` or `setClearCacheOnRollback()` on the `Transaction` object to control whether entity caches are cleared at commit or rollback. The defaults are `false` and `true`, respectively. The `Transaction` object also provides a `clearEntityCache()` method you can use to programmatically clear entity rows of a given entity type (or all types). When you clear an entity cache, you allow entity rows of that type to be retrieved from the database fresh the next time they are either found by primary key or retrieved by an entity-based view object.

## 6.4.2 How to Create a Command-Line Java Test Client

To create a test client program, use the Create Java Class wizard, which is accessible from the New Gallery.

### 6.4.2.1 Generating a Test Client with Skeleton Code

When you use the Create Java Class wizard to create the test client program, JDeveloper will open your program file in the source editor and allow you to add code from a predefined code template to complete the test client.

**To generate a skeleton Java test client:**

1. In the Application Navigator, right-click the project in which you want to create the test client and choose **New**.
2. In the New Gallery, expand **General**, select **Java** and then **Java Class**, and click **OK**.
3. In the Create Java Class dialog, enter a class name, like `TestClient`, a package name, like `oracle.fodemo.storefront.client`, and ensure that the **Extends** field shows `java.lang.Object`.
4. In **Optional Attributes**, deselect **Constructors from Superclass** and select **Main Method**.
5. Click **OK**.

The `.java` file opens in the source editor to show the skeleton code, as shown in [Example 6-2](#).

**Example 6-2 Skeleton Code for TestClient.java**

```
package oracle.fodemo.storefront.client;
public class TestClient {
    public static void main(String[] args) {

    }
}
```

**6.4.2.2 Modifying the Skeleton Code to Create the Test Client**

After you generate skeleton code for the test client, you can proceed to edit the file using the predefined `bc4jclient` code template available from JDeveloper.

**To insert the bc4jclient code template:**

1. Place the cursor on a blank line inside the body of the `main()` method and use the `bc4jclient` code template to create the few lines of necessary code.
2. Type the characters `bc4jclient` followed `Ctrl + Enter`.  
JDeveloper will expand the class file with the template as shown in [Example 6-3](#).
3. Adjust the values of the `amDef` and `config` variables to reflect the names of the application module definition and the configuration that you want to use, respectively.

For the [Example 6-3](#), the changed lines look like this:

```
String amDef = "oracle.fodemo.storefront.store.service.StoreServiceAM";
String config = "StoreServiceAMLocal";
```

4. Finally, change the view object instance name in the call to `findViewObject()` to the one you want to work with. Specify the name exactly as it appears in the **Data Model** tree on the Data Model page of the overview editor for the application module.

For the [Example 6-3](#), the changed line looks like this:

```
ViewObject vo = am.findViewObject("Persons");
```

**Example 6-3 Expanded Skeleton Code for TestClient.java**

```
package oracle.fodemo.storefront.client;
```

```

import oracle.jbo.client.Configuration;
import oracle.jbo.*;
import oracle.jbo.domain.Number;
import oracle.jbo.domain.*;
public class TestClient {
    public static void main(String[] args) {
        String      amDef = "test.TestModule";
        String      config = "TestModuleLocal";
        ApplicationModule am =
            Configuration.createRootApplicationModule(amDef,config);
        ViewObject vo = am.findViewObject("TestView");
        // Work with your appmodule and view object here
        Configuration.releaseRootApplicationModule(am,true);
    }
}

```

Your skeleton test client for your application module should contain source code like what you see in [Example 6-4](#).

---

**Note:** The examples throughout [Section 9.10, "Working Programmatically with an Application Module's Client Interface"](#) expand this test client sample code to illustrate calling custom application module service methods, too.

---

#### **Example 6-4 Working Skeleton Code for an Application Module Test Client Program**

```

package oracle.fodemo.storefront.client;
import oracle.jbo.ApplicationModule;
import oracle.jbo.Row;
import oracle.jbo.RowSet;
import oracle.jbo.ViewObject;
import oracle.jbo.client.Configuration;

public class TestClient {

    public static void main(String[] args) {
        String amDef = "oracle.fodemo.storefront.store.service.StoreServiceAM";
        String config = "StoreServiceAMLocal";
        ApplicationModule am =
            Configuration.createRootApplicationModule(amDef,config);
        // 1. Find the Persons view object instance.
        ViewObject personList = am.findViewObject("Persons");
        // Work with your appmodule and view object here
        Configuration.releaseRootApplicationModule(am,true);
    }
}

```

Replace `// Work with your appmodule and view object here`, with code that will execute the view objects you want to test. For example, to execute the view object's query, display the number of rows it will return, and loop over the result to fetch the data and print it out to the console, you can adapt the code shown in [Example 6-5](#) for your model project components.

#### **Example 6-5 Looping Over Master-Detail View Objects and Printing the Results to the Console**

```

// 2. Execute the query
personList.executeQuery();
// 3. Iterate over the resulting rows

```

```

while (personList.hasNext()) {
    Row person = personList.next();
    // 4. Print the person's email
    System.out.println("Person: " + person.getAttribute("Email"));
    // 5. Get related rowset of Orders using view link accessor attribute
    RowSet orders = (RowSet)person.getAttribute("Orders");
    // 6. Iterate over the Orders rows
    while (orders.hasNext()) {
        Row order = orders.next();
        // 7. Print out some order attribute values
        System.out.println(" ["+order.getAttribute("OrderStatusCode")+"] "+
            order.getAttribute("OrderId")+": "+
            order.getAttribute("OrderTotal"));
        if(!order.getAttribute("OrderStatusCode").equals("COMPLETE")) {
            // 8. Get related rowset of OrderItems
            RowSet items = (RowSet)order.getAttribute("OrderItems");
            // 9. Iterate over the OrderItems rows
            while (items.hasNext()) {
                Row item = items.next();
                // 10. Print out some order items attributes
                System.out.println(" "+item.getAttribute("LineItemId")+": "+
                    item.getAttribute("LineItemTotal"));
            }
        }
    }
}
}

```

The first line calls the `executeQuery()` method to execute the view object's query. This produces a row set of zero or more rows that you can loop over using a `while` statement that iterates until the view object's `hasNext()` method returns `false`. Inside the loop, the code puts the current `Row` in a variable named `person`, then invokes the `getAttribute()` method twice on that current `Row` object to get the value of the `Email` and `Orders` attributes to print order information to the console. A second `while` statement performs the same task for the line items of the order.

### 6.4.3 What Happens When You Run a Test Client Program

The call to `createRootApplicationModule()` on the `Configuration` object returns an instance of the application module to work with. As you might have noticed in the debug diagnostic output, the ADF Business Components runtime classes load XML component definitions as necessary to instantiate the application module and the instance of the view object component that you've defined in its data model at design time. The `findViewObject()` method on the application module finds a view object instance by name from the application module's data model. After the loop shown in [Example 6-5](#), the test client executes `releaseRootApplicationModule()` on the `Configuration` object. This signals that you're done using the application module and it allows the framework to clean up resources, like the database connection that was used by the application module.

### 6.4.4 What You May Need to Know About Running a Test Client

The `createRootApplicationModule()` and `releaseRootApplicationModule()` methods are very useful for command-line access to application module components. However, you typically won't need to write these two lines of code in the context of an ADF-based web or Swing application. The ADF Model data binding layer cooperates automatically with the ADF Business Components layer to acquire and release application module components for you in those scenarios.

## 6.4.5 How to Count the Number of Rows in a Row Set

The `getEstimatedRowCount()` method is used on a `RowSet` to determine how many rows it contains:

```
long numReqs = reqs.getEstimatedRowCount();
```

The implementation of the `getEstimatedRowCount()` initially issues a `SELECT COUNT(*)` query to calculate the number of rows that the query will return. The query is formulated by "wrapping" your view object's entire query in a statement like:

```
SELECT COUNT(*) FROM ( ... your view object's SQL query here ... )
```

The `SELECT COUNT(*)` query allows you to access the count of rows for a view object without necessarily retrieving all the rows themselves. This approach permits an important optimization for working with queries that return a large number of rows, or for testing how many rows a query *would* return before proceeding to work with the results of the query.

Once the estimated row count is calculated, subsequent calls to the method do not reexecute the `COUNT(*)` query. The value is cached until the next time the view object's query is executed, since the fresh query result set returned from the database could potentially contain more, fewer, or different rows compared with the last time the query was run. The estimated row count is automatically adjusted to account for pending changes in the current transaction, adding the number of relevant new rows and subtracting the number of removed rows from the count returned.

You can also override `getEstimatedRowCount()` to perform a custom count query that suits your application's needs.

## 6.4.6 How to Access a Detail Collection Using the View Link Accessor

Once you've retrieved the `RowSet` of detail rows using a view link accessor, as described in [Section 5.6.6.2, "Programmatically Accessing a Detail Collection Using the View Link Accessor"](#), you can loop over the rows it contains using the same pattern used by the view object's row set of results, as shown in [Example 6-6](#).

### **Example 6-6** Pattern Used to Access a Detail Collection

```
while (reqs.hasNext()) {
    Row curReq = reqs.next();
    System.out.println("--> (" + curReq.getAttribute("OrderId") + ") " +
        curReq.getAttribute("OrderTotal"));
}
```

[Example 6-7](#) shows the `main()` method sets a dynamic `WHERE` clause to restrict the `PersonList` view object instance to show only persons whose `person_type_code` has the value `CUST`. Additionally, the `executeAndShowResults()` method accesses the view link accessor attribute and prints out the request number (`PersonId`) and `Email` attribute for each one.

To access the a detail collection using a view link accessor, follow these basic steps (as illustrated in [Example 6-7](#)):

1. Find the master view object instance.
2. Execute the query.
3. Iterate over the master view object rows.

4. Get the related row set of the detail view object using the view link accessor attribute.
5. Iterate over the detail view object rows.
6. Optionally, do something with the detail row set attributes.

**Performance Tip:** If the code you write to loop over the rows does not need to display them, then you can call the `closeRowSet()` method on the row set when you're done. This technique will make memory use more efficient. The next time you access the row set, its query will be reexecuted.

**Example 6–7 Programmatically Accessing Detail Rows Using the View Link Accessor**

```
package devguide.examples.readonlyvo.client;

import oracle.jbo.ApplicationModule;
import oracle.jbo.Row;
import oracle.jbo.RowSet;
import oracle.jbo.ViewObject;
import oracle.jbo.client.Configuration;

public class TestClient2 {
    public static void main(String[] args) {
        String amDef = "devguide.examples.readonlyvo.PersonService";
        String config = "PersonServiceLocal";
        ApplicationModule am =
            Configuration.createRootApplicationModule(amDef, config);
        // 1. Find the Persons view object instance.
        ViewObject vo = am.findViewObject("PersonList");
        // Add an extra where clause with a new named bind variable
        vo.setWhereClause("person_type_code = :ThePersonType");
        vo.defineNamedWhereClauseParam("ThePersonType", null, null);
        vo.setNamedWhereClauseParam("ThePersonType", "CUST");
        // Show results when :ThePersonType = 'CUST'
        executeAndShowResults(vo);
        Configuration.releaseRootApplicationModule(am, true);
    }
    private static void executeAndShowResults(ViewObject vo) {
        System.out.println("---");
        // 2. Execute the query
        vo.executeQuery();
        // 3. Iterate over the resulting rows of the Persons view object
        while (vo.hasNext()) {
            Row curPerson = vo.next();
            // 4. Access the row set of Orders using the view link accessor attribute
            RowSet orders = (RowSet)curPerson.getAttribute("OrdersShippedToPurchaser");
            long numOrders = orders.getEstimatedRowCount();
            System.out.println(curPerson.getAttribute("PersonId") + " " +
                curPerson.getAttribute("Email")+" ["+
                numOrders+" orders]");
            // 5. Iterate over the resulting detail rows
            while (orders.hasNext()) {
                Row curOrder = orders.next();
                // 6. Print out some Order attribute values
                System.out.println("--> (" + curOrder.getAttribute("OrderId") + ") " +
                    curOrder.getAttribute("OrderTotal"));
            }
        }
    }
}
```

```
}

```

Running `TestClient2.java` produces output in the Log window, as shown in [Example 6-8](#). Each customer is listed, and for each customer that has some orders, the order total appears beneath their name.

**Example 6-8 Results of Running `TestClient.java`**

```
---
121 AFRIPP [0 orders]
115 AKHOO [0 orders]
109 DFAVIET [0 orders]
114 DRAPHEAL [0 orders]
118 GHIMURO [0 orders]
126 IMIKKILI [0 orders]
111 ISCIARRA [0 orders]
110 JCHEN [0 orders]
127 JLANDRY [0 orders]
112 JMURMAN [0 orders]
125 JNAYER [0 orders]
119 KCOLMENA [0 orders]
124 KMOURGOS [0 orders]
129 LBISSOT [0 orders]
113 LPOPP [1 orders]
--> (1013) 89.99
120 MWEISS [1 orders]
--> (1003) 5000
108 NGREENBE [1 orders]
--> (1002) 1249.91
122 PKAUFLIN [0 orders]
116 SBAIDA [0 orders]
128 SMARKLE [0 orders]
117 STOBIAS [0 orders]
123 SVOLLMAN [0 orders]
```

If you run `TestClient2.java` with debug diagnostics enabled, you will see the SQL queries that the view object performed. The view link `WHERE` clause predicate is used to automatically perform the filtering of the detail service request rows for the current row in the `PersonList` view object.

### 6.4.7 How to Iterate Over a Master-Detail-Detail Hierarchy

To iterate over a master-detail with an additional level of nesting, follow these basic steps (as illustrated in [Example 6-9](#)):

1. Find the master view object instance.
2. Executes the query.
3. Iterate over the resulting rows.
4. Optionally, do something with the attributes of the master row set.
5. Get the related row set of the detail view object using the view link accessor attribute.
6. Iterate over the detail row set rows.
7. Optionally, do something with the attributes of the detail row set.
8. Get the related row set of the second detail view object using the view link accessor attribute.

9. Iterates over the second detail row set rows.
10. Optionally, do something with the second detail row set attributes.

Other than having one additional level of nesting, [Example 6–9](#) uses the same APT's used in the `TestClient` program that was iterating over master-detail read-only view objects in [Section 6.4.6, "How to Access a Detail Collection Using the View Link Accessor."](#)

If you use JDeveloper's **Refactor > Duplicate** functionality on an existing `TestClient.java` class, you can quickly "clone" it to create a `TestClient2.java` class. For example, the `TestClient.java` class in [Example 6–8](#) is suited to this technique.

### **Example 6–9 Iterating Master/Detail/Detail Hierarchy**

```
package oracle.fodemo.storefront.client;
import oracle.jbo.ApplicationModule;
import oracle.jbo.Row;
import oracle.jbo.RowSet;
import oracle.jbo.ViewObject;
import oracle.jbo.client.Configuration;

public class TestClient2 {

    public static void main(String[] args) {
        String    amDef =
            "oracle.fodemo.storefront.store.service.StoreServiceAM";
        String    config = "StoreServiceAMLocal";
        ApplicationModule am =
            Configuration.createRootApplicationModule(amDef, config);
        // 1. Find the Persons view object instance.
        ViewObject personList = am.findViewObject("Persons");
        // 2. Execute the query
        personList.executeQuery();
        // 3. Iterate over the resulting rows
        while (personList.hasNext()) {
            Row person = personList.next();
            // 4. Print the person's email
            System.out.println("Person: " + person.getAttribute("Email"));
            // 5. Get related rowset of Orders using view link accessor attribute
            RowSet orders = (RowSet)person.getAttribute("Orders");
            // 6. Iterate over the Orders rows
            while (orders.hasNext()) {
                Row order = orders.next();
                // 7. Print out some order attribute values
                System.out.println(" ["+order.getAttribute("OrderStatusCode")+"] "+
                    order.getAttribute("OrderId")+": "+
                    order.getAttribute("OrderTotal"));
                if(!order.getAttribute("OrderStatusCode").equals("COMPLETE")) {
                    // 8. Get related rowset of OrderItems using view link accessor attribute
                    RowSet items = (RowSet)order.getAttribute("OrderItems");
                    // 9. Iterate over the OrderItems rows
                    while (items.hasNext()) {
                        Row item = items.next();
                        // 10. Print out some order items attributes
                        System.out.println("   "+item.getAttribute("LineItemId")+": "+
                            item.getAttribute("LineItemTotal"));
                    }
                }
            }
        }
    }
}
```

```

    }
    Configuration.releaseRootApplicationModule(am, true);
}
}

```

Running the program produces the output shown in [Example 6–10](#).

**Example 6–10 Results of Running TestClient2.java**

## 6.4.8 How to Find a Row and Update a Foreign Key Value

To find a row and update a foreign key value, follow these basic steps (as illustrated in [Example 6–11](#)):

1. Find the view object instance.
2. Construct a Key object to look up the row for the view instance.
3. Use `findByKey()` to find the row.
4. Optionally, do something with the row's attribute.

[Example 6–11](#) shows the `main()` method finds and updates a foreign key value to find a row of the `Orders` view object instance. The sample then prints out the existing value of the `OrderStatusCode` attribute before changing the value on the row.

**Example 6–11 Finding and Updating a Foreign Key Value**

```

package oracle.fodemo.storefront.client;

import oracle.jbo.ApplicationModule;
import oracle.jbo.JboException;
import oracle.jbo.Key;
import oracle.jbo.Row;
import oracle.jbo.ViewObject;
import oracle.jbo.client.Configuration;

public class TestFindAndUpdate {
    public static void main(String[] args) {
        String amDef =
            "oracle.fodemo.storefront.store.service.StoreServiceAM";
        String config = "StoreServiceAMLocal";
        ApplicationModule am =
            Configuration.createRootApplicationModule(amDef, config);
        // 1. Find the Orders view object instance
        ViewObject vo = am.findViewObject("Orders");
        // 2. Construct a new Key to find Order # 1011
    }
}

```

```

Key orderKey = new Key(new Object[]{1011});
// 3. Find the row matching this key
Row[] ordersFound = vo.findByKey(orderKey,1);
if (ordersFound != null && ordersFound.length > 0) {
    Row order = ordersFound[0];
    // 4. Print some order information
    String orderStatus = (String)order.getAttribute("OrderStatusCode");
    System.out.println("Current status is: "+ orderStatus);
    try {
        // 5. Try setting the status to an illegal value
        order.setAttribute("OrderStatusCode", "REOPENED");
    }
    catch (JboException ex) {
        System.out.println("ERROR: "+ex.getMessage());
    }
    // 6. Set the status to a legal value
    order.setAttribute("OrderStatusCode", "PENDING");
    // 7. Show the value of the status was updated successfully
    System.out.println("Current status is: " +
        order.getAttribute("OrderStatusCode"));
    // 8. Show the current value of the customer for this order
    System.out.println("Customer: " + order.getAttribute("CustomerId"));
    // 9. Reassign the order to customer # 113
    order.setAttribute("CustomerId",113); // Luis Popp
    // 10. Show the value of the reference information now
    System.out.println("Customer: "+order.getAttribute("CustomerId"));
    // 11. Rollback the transaction
    am.getTransaction().rollback();
    System.out.println("Transaction canceled");
}
Configuration.releaseRootApplicationModule(am,true);
}
}

```

Running this example produces the output shown in [Example 6–12](#).

**Example 6–12 Results of Running TestFindAndUpdate.java**

```

Current status is: Closed
ERROR: The status must be Open, Pending, or Closed
Current status is: Open
Assigned: bernst
Assigned: Luis Popp
Transaction canceled

```

## 6.4.9 How to Create a New Row for a View Object Instance

To create a new view row instance, follow these basic steps (as illustrated in [Example 6–13](#)):

1. Find the view object instance.
2. Create a new row and insert it into the row set.
3. Set the values of the required attributes in the new row.
4. Commit the transaction.

[Example 6–13](#) shows the `main()` method finds the `Orders` view object instance and inserts a new row into the row set. Because the `Orders` view object is entity-based, the

CreatedBy attribute derives its value from the mapped entity object attribute. The sample then sets values for the remaining attributes before committing the transaction.

**Example 6–13 Creating a New Order**

```
package oracle.fodemo.storefront.client;
import oracle.jbo.ApplicationModule;
import oracle.jbo.Row;
import oracle.jbo.ViewObject;
import oracle.jbo.client.Configuration;
import oracle.jbo.domain.DBSequence;
import oracle.jbo.domain.Date;
import oracle.jbo.domain.Timestamp;

public class TestCreateOrder {
    public static void main(String[] args) throws Throwable {
        String amDef = "oracle.fodemo.storefront.store.service.StoreServiceAM";
        String config = "StoreServiceAMLocal";
        ApplicationModule am =
            Configuration.createRootApplicationModule(amDef, config);
        // 1. Find the Orders view object instance.
        ViewObject orders = am.findViewObject("Orders");
        // 2. Create a new row and insert it into the row set
        Row newOrder = orders.createRow();
        orders.insertRow(newOrder);
        // Show the entity object-related defaulting for CreatedBy attribute
        System.out.println("CreatedBy defaults to: " +
            newOrder.getAttribute("CreatedBy"));
        // 3. Set values for some of the required attributes
        Date now = new Date(new Timestamp(System.currentTimeMillis()));
        newOrder.setAttribute("OrderDate", now);
        newOrder.setAttribute("OrderStatusCode", "PENDING");
        newOrder.setAttribute("OrderTotal", 500);
        newOrder.setAttribute("CustomerId", 110);
        newOrder.setAttribute("ShipToAddressId", 2);
        newOrder.setAttribute("ShippingOptionId", 2);
        newOrder.setAttribute("FreeShippingFlag", "N");
        newOrder.setAttribute("GiftwrapFlag", "N");
        // 4. Commit the transaction
        am.getTransaction().commit();
        // 5. Retrieve and display the trigger-assigned order id
        DBSequence id = (DBSequence)newOrder.getAttribute("OrderId");
        System.out.println("Thanks, reference number is " +
            id.getSequenceNumber());
        Configuration.releaseRootApplicationModule(am, true);
    }
}
```

Running this example produces the results shown in [Example 6–14](#).

**Example 6–14 Results of Running TestCreateOrder.java**

```
CreatedBy defaults to: Luis Popp
Thanks, reference number is 200
```

## 6.4.10 How to Retrieve the Row Key Identifying a Row

To retrieve a row key to identify a row, follow these basic steps (as illustrated in [Example 6–15](#)):

1. Find the view object instance.
2. Construct a key using a supplied value.
3. Find the row with this key.
4. Optionally, do something with the key of the row.

**Example 6–15** shows the `main()` method finds the `Orders` view object instance and constructs a row key to find an order number. The `findByKey()` method find the `Orders` rows with the specified key. The sample then displays the key of the row, accesses the row set using the `OrderItems` view link accessor, and iterates over the rows to display the key of each `OrderItems` row.

**Example 6–15 Retrieving the Row Key Identifying a Row**

```
package oracle.fodemo.storefront.client;
import oracle.jbo.ApplicationModule;
import oracle.jbo.Key;
import oracle.jbo.Row;
import oracle.jbo.RowSet;
import oracle.jbo.ViewObject;
import oracle.jbo.client.Configuration;

public class TestFindAndShowKeys {
    public static void main(String[] args) {
        String amDef = "oracle.fodemo.storefront.store.service.StoreServiceAM";
        String config = "StoreServiceAMLocal";
        ApplicationModule am =
            Configuration.createRootApplicationModule(amDef, config);
        // 1. Find the Orders view object instance
        ViewObject vo = am.findViewObject("Orders");
        // 2. Construct a key to find order number 1011
        Key orderKey = new Key(new Object[] { 1011 });
        // 3. Find the Orders row with the key
        Row[] ordersFound = vo.findByKey(orderKey, 1);
        if (ordersFound != null && ordersFound.length > 0) {
            Row order = ordersFound[0];
            // 4. Displays the key of the Orders row
            showKeyFor(order);
            // 5. Accesses row set of Orders using OrderItems view link accessor
            RowSet items = (RowSet)order.getAttribute("OrderItems");
            // 6. Iterates over the OrderItems row
            while (items.hasNext()) {
                Row itemRow = items.next();
                // 4. Displays the key of each OrderItems row
                showKeyFor(itemRow);
            }
        }
        Configuration.releaseRootApplicationModule(am, true);
    }

    private static void showKeyFor(Row r) {
        // get the key for the row passed in
        Key k = r.getKey();
        // format the key as "(val1,val2)"
        String keyAttrs = formatKeyAttributeNamesAndValues(k);
        // get the serialized string format of the key, too
        String keyStringFmt = r.getKey().toStringFormat(false);
        System.out.println("Key " + keyAttrs + " has string format " +
            keyStringFmt);
    }
}
```

```

    }
    // Build up "(val1,val2)" string for key attributes

    private static String formatKeyAttributeNamesAndValues(Key k) {
        StringBuffer sb = new StringBuffer("(");
        int attrsInKey = k.getAttributeCount();
        for (int i = 0; i < attrsInKey; i++) {
            if (i > 0)
                sb.append(", ");
            sb.append(k.getAttributeValues()[i]);
        }
        sb.append(")");
        return sb.toString();
    }
}

```

Running the example produces the results shown in [Example 6–16](#). Notice that the serialized string format of a key is a hexadecimal number that includes information in a single string that represents all the attributes in a key.

**Example 6–16 Results of Running TestFindAndShowKeys.java**

```

Key (1011) has string format 000100000003313031
Key (1011,1) has string format 000200000003C2020200000002C102
Key (1011,2) has string format 000200000003C2020200000002C103

```

## 6.4.11 How to Authenticate Test Users in the Test Client

If you have enabled ADF Security for your application and provisioned the `jazn-data.xml` file with test users, you will need to include method calls to authenticate a user before you run the test client. To authenticate a user in the test client, follow these basic steps (as illustrated in [Example 6–17](#)):

1. Create the authentication service.
2. Pass in the login credentials for a test user defined in the `jazn-data.xml` file.
3. If authentication succeeds, then test the application module.
4. Log the user out.

For details about how to run the Configure ADF Security wizard to enable ADF Security and how to create test users in JDeveloper’s identity store, see [Section 30.2, "ADF Security Process Overview."](#)

**Example 6–17 Passing Login Credentials in the Test Client**

```

package oracle.demo.model.test;

import oracle.jbo.ApplicationModule;
import oracle.jbo.Key;
import oracle.jbo.Row;
import oracle.jbo.RowSet;
import oracle.jbo.ViewObject;
import oracle.jbo.client.Configuration;

import oracle.adf.share.security.AuthenticationService;
import oracle.adf.share.security.authentication.AuthenticationServiceUtil;
import oracle.adf.share.ADFContext;
import oracle.adf.share.security.SecurityContext;
import oracle.adf.share.security.SecurityEnv;

```

```
import javax.security.auth.Subject;

public class TestAuthenticationClient {
    public static void main(String[] args) {
        String amDef = "test.TestAuthModule";
        String config = "TestAuthModuleLocal";

        // 1. Create authentication service.
        AuthenticationService authService =
            AuthenticationServiceUtil.getAuthenticationService();

        try
        {
            // 2. Pass in user id and password defined in local identity store.
            authService.login("tester1", "welcome1");
        }
        catch (Exception e)
        {
        }

        // Uncomment to output authentication status
        // String userName =
            ADFContext.getCurrent().getSecurityContext().getUserName();

        // System.out.println("*** userName : " + userName);
        // Subject subject =
            ADFContext.getCurrent().getSecurityContext().getSubject();
        // System.out.println("Subject : " + subject);

        // 3. Test application module if authentication succeeds.
        if (ADFContext.getCurrent().getSecurityContext().isAuthenticated()) {
            ApplicationModule am =
                Configuration.createRootApplicationModule(amDef, config);
            ViewObject vo = am.findViewObject("TestView");
            // Work with your appmodule and view object here
            Configuration.releaseRootApplicationModule(am, true);

            // 4. Log out test user.
            authService.logout();

            // Uncomment to report logout success
            // boolean isAuthenticated =
                ADFContext.getCurrent().getSecurityContext().isAuthenticated();
            // System.out.println("*** isAuthenticated : " + isAuthenticated);
        }
    }
}
```

---

## Defining Validation and Business Rules Declaratively

This chapter explains how to use ADF entity objects to write typical business rules that implement declarative validation in an Oracle Application Development Framework (Oracle ADF) application.

This chapter includes the following sections:

- [Section 7.1, "Introduction to Declarative Validation"](#)
- [Section 7.2, "Understanding the Validation Cycle"](#)
- [Section 7.3, "Adding Validation Rules to Entity Objects and Attributes"](#)
- [Section 7.4, "Using the Built-in Declarative Validation Rules"](#)
- [Section 7.5, "Using Groovy Expressions For Validation and Business Rules"](#)
- [Section 7.6, "Triggering Validation Execution"](#)
- [Section 7.7, "Creating Validation Error Messages"](#)
- [Section 7.8, "Setting the Severity Level for Validation Exceptions"](#)
- [Section 7.9, "Bulk Validation in SQL"](#)

### 7.1 Introduction to Declarative Validation

The easiest way to create and manage validation rules is through *declarative validation rules*. Declarative validation rules are defined using the overview editor, and once created, are stored in the entity object's XML file. Declarative validation is different from programmatic validation (covered in [Chapter 8, "Implementing Validation and Business Rules Programmatically"](#)), which is stored in an entity object's Java file.

Oracle ADF provides built-in declarative validation rules that satisfy many of your business needs. If you have custom validation rules you want to reuse, you can code them and add them to the IDE, so that the rules are available directly from JDeveloper. Custom validation rules are an advanced topic and covered in [Section 38.9, "Implementing Custom Validation Rules."](#) You can also base validation on a Groovy expression, as described in [Section 7.5, "Using Groovy Expressions For Validation and Business Rules."](#)

When you add a validation rule, you supply an appropriate error message and can later translate it easily into other languages if needed. You can also define how validation is triggered and set the severity level.

One benefit of using declarative validation (versus writing your own validation) is that the validation framework takes care of the complexities of batching validation

exceptions, which frees you to concentrate on your application's specific validation rule logic.

---

---

**Note:** It is possible to go beyond the declarative behavior to implement more complex validation rules for your business domain layer when needed. [Section 8.2, "Using Method Validators"](#) explains how to use the Method validator to invoke custom validation code and [Section 38.9, "Implementing Custom Validation Rules"](#) details how to extend the basic set of declarative rules with custom rules of your own.

---

---

### 7.1.1 When to Use Business-Layer Validation or Model-Layer Validation

In an ADF Business Components application, most of your validation code is defined in your entity objects. Encapsulating the business logic in these shared, reusable components ensures that your business information is validated consistently in every view object or client that accesses it, and it simplifies maintenance by centralizing where the validation is stored.

In the model layer, ADF Model validation rules can be set for the attributes of a collection. Many of the declarative validation features available for entity objects are also available at the model layer, should your application warrant the use of model-layer validation in addition to business-layer validation.

When you use the ADF Business Components application module data control, you do not need to use model-layer validation. Consider defining all or most of your validation rules in the centralized, reusable, and easier to maintain entity objects of your business layer. With other types of data controls, model-layer validation can be more useful.

## 7.2 Understanding the Validation Cycle

Each entity row tracks whether or not its data is valid. When an existing entity row is retrieved from the database, the entity is assumed to be valid. When the first persistent attribute of an existing entity row is modified, or when a new entity row is created, the entity is marked invalid.

When an entity is in an invalid state, the declarative validation you have configured and the programmatic validation rules you have implemented are evaluated again before the entity can be considered valid again. You can determine whether a given entity row is valid at runtime by calling the `isValid()` method on it.

---

---

**Note:** Because attributes can (by default) be left blank, validations are not triggered if the attribute contains no value. For example, if a user creates a new entity row and does not enter a value for a given attribute, the validation on that attribute is not run. To force the validation to execute in this situation, set the Mandatory flag on the attribute.

---

---

### 7.2.1 Types of Entity Object Validation Rules

Entity object validation rules fall into two basic categories: *attribute-level* and *entity-level*.

### 7.2.1.1 Attribute-Level Validation Rules

Attribute-level validation rules are triggered for a particular entity object attribute when either the end user or the program code attempts to modify the attribute's value. Since you cannot determine the order in which attributes will be set, attribute-level validation rules should be used only when the success or failure of the rule depends exclusively on the candidate value of that single attribute.

The following examples are attribute-level validations:

- The value of the `OrderDate` of an order should not be a date in the past.
- The `ProductId` attribute of a product should represent an existing product.

### 7.2.1.2 Entity-Level Validation Rules

All other kinds of validation rules are entity-level validation rules. These are rules whose implementation requires considering two or more entity attributes, or possibly composed children entity rows, in order to determine the success or failure of the rule.

The following examples are entity-level validations:

- The value of the `OrderShippedDate` should be a date that comes after the `OrderDate`.
- The `ProductId` attribute of an order should represent an existing product.

Entity-level validation rules are triggered by calling the `validate()` method on a `Row`. This occurs when:

- You call the method explicitly on the entity object
- You call the method explicitly on a view row with an entity row part that is invalid
- A view object's iterator calls the method on the current row in the view object before allowing the current row to change
- During transaction commit, processing validates an invalid entity (in the list of pending changes) before proceeding with posting the changes to the database

As part of transaction commit processing, entity-level validation rules can fire multiple times (up to a specified limit). For more information, see [Section 7.2.4, "Avoiding Infinite Validation Cycles."](#)

## 7.2.2 Understanding Commit Processing and Validation

Transaction commit processing happens in three basic phases:

1. Ensure that any invalid entity rows on the pending changes list are valid.
2. Post the pending changes to the database by performing appropriate DML operations.
3. Commit the transaction.

If you have business validation logic in your entity objects that executes queries or stored procedures that depend on seeing the posted changes in the `SELECT` statements they execute, they should be coded in the `beforeCommit()` method described in [Section 8.5.3, "What You May Need to Know About Row Set Access with View Accessors."](#) This method fires after all DML statements have been applied so queries or stored procedures invoked from that method can "see" all of the pending changes that have been saved, but not yet committed.

---

---

**Caution:** don't use the transaction-level `postChanges()` method in web applications unless you can guarantee that the transaction will definitely be committed or rolled-back during the same HTTP request. This method exists to force the transaction to post unvalidated changes without committing them. Failure to heed this advice can lead to strange results in an environment where both application modules and database connections can be pooled and shared serially by multiple different clients.

---

---

### 7.2.3 Understanding the Impact of Composition on Validation Order

Because a composed child entity row is considered an integral part of its composing parent entity object, any change to composed child entity rows causes the parent entity to be marked invalid. For example, if a line item on an order were to change, the entire order would now be considered to be changed, or invalid.

Therefore, when the composing entity is validated, it causes any currently invalid composed children entities to be validated first. This behavior is recursive, drilling into deeper levels of invalid composed children if they exist.

### 7.2.4 Avoiding Infinite Validation Cycles

If your validation rules contain code that updates attributes of the current entity or other entities, then the act of validating the entity can cause that or other entities to become invalid. As part of the transaction commit processing phase that attempts to validate all invalid entities in the pending changes list, the transaction performs multiple passes (up to a specified limit) on the pending changes list in an attempt to reach a state where all pending entity rows are valid.

The maximum number of validation passes is specified by the transaction-level validation threshold setting. The default value of this setting is 10. You can increase the threshold count to greater than one if the entities involved contain the appropriate logic to validate themselves in the subsequent passes.

If after 10 passes, there are still invalid entities in the list, you will see the following exception:

```
JBO-28200: Validation threshold limit reached. Invalid Entities still in cache
```

This is a sign that you need to debug your validation rule code to avoid inadvertently invalidating entities in a cyclic fashion.

To change the validation threshold, use the `SetValidationThreshold()` method as shown in [Example 7-1](#). In this example, the new threshold is 12.

**Example 7-1 Changing the Validation Threshold**

```
oracle.jbo.server.DBTransaction::setValidationThreshold(12)
```

### 7.2.5 What Happens When Validations Fail

When an entity object's validation rules throw exceptions, the exceptions are bundled and returned to the client. If the validation failures are thrown by methods you've overridden to handle events during the transaction `postChanges` processing, then the validation failures cause the transaction to roll back any database `INSERT`,

UPDATE, or DELETE statements that might have been performed already during the current `postChanges` cycle.

---

**Note:** The bundling of exceptions is the default behavior for ADF Model-based web applications, but not for Business Component Browser or Swing bindings. Additional configuration is required to bundle exceptions for the Business Component Browser or Swing clients.

---

## 7.2.6 Understanding Entity Objects Row States

When an entity row is in memory, it has an entity state that reflects the logical state of the row. [Figure 7-1](#) illustrates the different entity row states and how an entity row can transition from one state to another. When an entity row is first created, its status is `New`. You can use the `setNewRowState()` method to mark the entity as being `Initialized`, which removes it from the transaction's list of pending changes until the user sets at least one of its attributes, at which time it returns to the `New` state. This allows you to create more than one initialized row and post only those that the user modifies.

The `Unmodified` state reflects an entity that has been retrieved from the database and has not yet been modified. It is also the state that a `New` or `Modified` entity transitions to after the transaction successfully commits. During the transaction in which it is pending to be deleted, an `Unmodified` entity row transitions to the `Deleted` state. Finally, if a row that was `New` and then was removed before the transaction commits, or `Unmodified` and then successfully deleted, the row transitions to the `Dead` state.

**Figure 7-1** Diagram of Entity Row States and Transitions

You can use the `getEntityState()` and `getPostState()` methods to access the current state of an entity row in your business logic code. The `getEntityState()` method returns the current state of an entity row with regard to the transaction, while the `getPostState()` method returns the current state of an entity row with regard to the database after using the `postChanges()` method to post pending changes without committing the transaction.

For example, if you start with a new row, both `getEntityState()` and `getPostState()` return `STATUS_NEW`. Then when you post the row (before commit or rollback), the row will have entity state of `STATUS_NEW` and a post state of `STATUS_UNMODIFIED`. If you subsequently remove that row, the entity state will remain `STATUS_NEW` because for the transaction the row is still new. But the post state will be `STATUS_DEAD`.

## 7.2.7 Understanding Bundled Exception Mode

An application module provides a feature called bundled exception mode which allows web applications to easily present a maximal set of failed validation exceptions to the end user, instead of presenting only the *first* error that gets raised. By default, the ADF Business Components application module pool enables bundled exception mode for web applications.

You typically will not need to change this default setting. However it is important to understand that it is enabled by default since it effects how validation exceptions are thrown. Since the Java language and runtime only support throwing a single exception object, the way that bundled validation exceptions are implemented is by wrapping a set of exceptions as details of a new "parent" exception that contains them. For example, if multiple attributes in a single entity object fail attribute-level validation, then these multiple `ValidationException` objects will be wrapped in a `RowValException`. This wrapping exception contains the row key of the row that has failed validation. At transaction commit time, if multiple rows do not successfully pass the validation performed during commit, then all of the `RowValException` objects will get wrapped in an enclosing `TxnValException` object.

When writing custom error processing code, you can use the `getDetails()` method of the `JboException` base exception class to recursively process the bundled exceptions contained inside it.

---

---

**Note:** All the exception classes mentioned here are in the `oracle.jbo` package.

---

---

## 7.3 Adding Validation Rules to Entity Objects and Attributes

The process for adding a validation rule to an entity object is similar for most of the validation rules, and is done using the Add Validation Rule dialog. You can open this dialog from the overview editor by clicking the **Add** icon on the Business Rules page.

It is important to note that when you define a rule declaratively using the Add Validation Rule dialog, the rule definition you provide specifies the *valid* condition for the attribute or entity object. At runtime, the entry provided by the user is evaluated against the rule definition and an error or warning is raised if the entry fails to satisfy the specified criteria. For example, if you specify a Length validator on an attribute that requires it to be `Less Than or Equal To 12`, the validation fails if the entry is more than 12 characters, and the error or warning is raised.

### 7.3.1 How to Add a Validation Rule to an Entity or Attribute

To add a declarative validation rule to an entity object, use the Business Rules page of the overview editor.

**To add a validation rule:**

1. In the Application Navigator, double-click the desired entity object.
2. Click the **Business Rules** navigation tab on the overview editor.
3. Select the object for which you want to add a validation rule, and then click the **Add** icon.
  - To add a validation rule at the entity object level, select **Entity**.
  - To add a validation rule for an attribute, expand **Attributes** and select the desired attribute.

When you add a new validation rule, the Add Validation Rule dialog appears.

4. Select the type of validation rule desired from the **Rule Type** dropdown list.
5. Use the dialog settings to configure the new rule.

The controls will change depending on the kind of validation rule you select. For more information about the different validation rules, see [Section 7.4, "Using the Built-in Declarative Validation Rules."](#)

6. You can optionally click the **Validation Execution** tab and enter criteria for the execution of the rule, such as dependent attributes and a precondition expression. For more information, see [Section 7.6, "Triggering Validation Execution."](#)

---

**Note:** For Key Exists and Method entity validators, you can also use the **Validation Execution** tab to specify the validation level.

---

7. Click the **Failure Handling** tab and enter or select the error message that will be shown to the user if the validation rule fails. For more information, see [Section 7.7, "Creating Validation Error Messages."](#)
8. Click **OK**.

### 7.3.2 How to View and Edit a Validation Rule On an Entity or Attribute

The Business Rules page of the overview editor for entity objects displays the validation rules for an entity and its attributes in a tree control. To see the validation rules that apply to the entity as a whole, expand in the **Entity** node. To see the validation rules that apply to an attribute, expand the **Attributes** node and then expand the attribute.

The validation rules that are shown on the Business Rules page of the overview editor include those that you have defined as well as database constraints, such as mandatory or precision. To open a validation rule for editing, double-click the rule or select the rule and click the **Edit** icon.

### 7.3.3 What Happens When You Add a Validation Rule

When you add a validation rule to an entity object, JDeveloper updates its XML component definition to include an entry describing what rule you've used and what rule properties you've entered. For example, if you add a range validation rule to the `DiscountAmount` attribute, this results in a `RangeValidationBean` entry in the XML file, as shown in [Example 7-2](#).

#### **Example 7-2 Range Validation Bean**

```
<Attribute
  Name="DiscountAmount "
  IsNotNull="true"
  ColumnName="DISCOUNT_AMOUNT"
  . . .
  <validation:RangeValidationBean
    xmlns="http://xmlns.oracle.com/adfm/validation"
    Name="DiscountAmount_Rule_0"
    ResId="DiscountAmount_RangeError_0"
    OnAttribute="DiscountAmount "
    OperandType="LITERAL"
    Inverse="false"
    MinValue="0"
```

```
        MaxValue="40" />  
        . . .  
    </Attribute>
```

At runtime, the rule is enforced by the entity object based on this declarative information.

### 7.3.4 What You May Need to Know About Entity and Attribute Validation Rules

Declarative validation enforces both entity-level and attribute-level validation, depending on where you place the rules. Entity-level validation rules are enforced when a user tries to commit pending changes or navigates between rows. Attribute-level validation rules are enforced when the user changes the value of the related attribute.

The Unique Key validator (described in [Section 7.4.1, "How to Ensure That Key Values Are Unique"](#)) can be used only at the entity level. Internally the Unique Key validator behaves like an attribute-level validator. This means that users see the validation error when they tab out of the key attribute for the key that the validator is validating. This is done because the internal cache of entities can never contain a duplicate, so it is not allowed for an attribute value to be set that would violate that. This check needs to be performed when the attribute value is being set because the cache consistency check is done during the setting of the attribute value.

**Best Practice:** If the validity of one attribute is dependent on one or more other attributes, enforce this rule using entity validation, not attribute validation. Examples of when you would want to do this include the following:

- You have a Compare validator that compares one attribute to another.
- You have an attribute with an expression validator that examines the value in another attribute to control branching in the expression to validate the attribute differently depending on the value in this other attribute.
- You make use of conditional execution, and your precondition expression involves an attribute other than the one that you are validating.

Entity object validators are triggered whenever the entity, as a whole, is dirty. To improve performance, you can indicate which attributes play a role in your rule and thus the rule should be triggered only if one or more of these attributes are dirty. For more information on triggering attributes, see, [Section 7.6, "Triggering Validation Execution."](#)

### 7.3.5 What You May Need to Know About List of Values and Attribute Validation Rules

Developers may define a List of Values (LOV) attribute on a view object to support displaying choice lists in the user interface. The view object's LOV attribute in turn relies on a data source view object to provide the values for display. Because the LOV feature assumes that the queried data source contains only valid values, any validation rules defined on data source view object attributes will be suppressed before the choice list displays in the user interface. Therefore, the developer who defines the LOV must ensure that the list of values returned by the data source view object contains only valid values, as describe in [Section 5.13, "Working with List of Values \(LOV\) in View Object Attributes."](#)

## 7.4 Using the Built-in Declarative Validation Rules

The built-in declarative validation rules can satisfy many, if not all, of your business needs. These rules are easy to implement because you don't write any code. You use the user-interface tools to choose the type of validation and how it is used.

Built-in declarative validation rules can be used to:

- Ensure that key values are unique (primary key or other unique keys)
- Determine the existence of a key value
- Make a comparison between an attribute and anything from a literal value to a SQL query
- Validate against a list of values that might be a literal list, a SQL query, or a view attribute
- Make sure that a value falls within a certain range, or that it is limited by a certain number of bytes or characters
- Validate using a regular expression or evaluate a Groovy expression
- Make sure that a value satisfies a relationship defined by an aggregate on a child entity available through an accessor
- Validate using a validation condition defined in a Java method on the entity

### 7.4.1 How to Ensure That Key Values Are Unique

The Unique Key validator ensures that primary key values for an entity object are always unique. The Unique Key validator can also be used for a non-primary-key attribute, as long as the attribute is defined as an alternate key. For information on how to define alternate keys, see [Section 4.10.15, "How to Define Alternate Key Values."](#)

Whenever any of the key attribute values change, this rule validates that the new key does not belong to any other entity object instance of this entity object class. (It is the business-logic tier equivalent of a unique constraint in the database.) If the key is found in one of the entity objects, a `TooManyObjectsException` is thrown. The validation check is done both in the entity cache and in the database.

There is a slight possibility that unique key validation might not be sufficient to prevent duplicate rows in the database. It is possible for two application module sessions to simultaneously attempt to create records with the same key. To prevent this from happening, create a unique index in the database for any unique constraint that you want to enforce.

#### To ensure that a key value is unique:

1. In the Application Navigator, double-click the desired entity object.
2. On the Business Rules page of the overview editor, select the **Entity** folder, and click the **Add** icon.
3. In the Add Validation Rule dialog, in the **Rule Type** dropdown list, select **UniqueKey**.
4. In the **Keys** box, select the primary or alternate key.
5. You can optionally click the **Validation Execution** tab and enter criteria for the execution of the rule, such as dependent attributes and a precondition expression. For more information, see [Section 7.6, "Triggering Validation Execution."](#)

**Best Practice:** While it is possible to add a precondition for a Unique Key validator, it is not a best practice. If a Unique Key validator fails to fire, for whatever reason, the cache consistency check is still performed and an error will be returned. It is generally better to add the validator and a meaningful error message.

6. Click the **Failure Handling** tab and enter or select the error message that will be shown to the user if the validation rule fails. For more information, see [Section 7.7, "Creating Validation Error Messages."](#)
7. Click **OK**.

## 7.4.2 What Happens When You Use a Unique Key Validator

When you use a Unique Key validator, a `<UniqueKeyValidationBean>` tag is added to the entity object's XML file. [Example 7-3](#) shows the XML for a Unique Key validator.

### Example 7-3 Unique Key Validator XML Code

```
<validation:UniqueKeyValidationBean
  Name="PersonEO_Rule_1"
  KeyName="AltKey"
  ResId="PersonEO_Rule_1">
  <validation:OnAttributes>
    <validation:Item
      Value="Email"/>
  </validation:OnAttributes>
</validation:UniqueKeyValidationBean>
```

## 7.4.3 How to Validate Based on a Comparison

The Compare validator performs a logical comparison between an entity attribute and a value. When you add a Compare validator, you specify an operator and something to compare with. You can compare the following:

- Literal value

When you use a Compare validator with a literal value, the value in the attribute is compared against the specified literal value. When using this kind of comparison, it is important to consider data types and formats. The literal value must conform to the format specified by the data type of the entity attribute to which you are applying the rule. In all cases, the type corresponds to the type mapping for the entity attribute.

For example, an attribute of column type DATE maps to the `oracle.jbo.domain.Date` class, which accepts dates and times in the same format accepted by `java.sql.Timestamp` and `java.sql.Date`. You can use format masks to ensure that the format of the value in the attribute matches that of the specified literal. For information about entity object attribute type mappings, see [Section 4.10.1, "How to Set Database and Java Data Types for an Entity Object Attribute."](#) For information about the expected format for a particular type, refer to the Javadoc for the type class.

- Query result

When you use this type of validator, the SQL query is executed each time the validator is executed. The validator retrieves the first row from the query result, and it uses the value of the first column in the query (of that first row) as the value

to compare. Because this query cannot have any bind variables in it, this feature should be used only when selecting one column of one row of data that does not depend on the values in the current row.

- View object attribute

When you use this type of validator, the view object's SQL query is executed each time the validator is executed. The validator retrieves the first row from the query result, and it uses the value of the selected view object attribute from that row as the value to compare. Because you cannot associate values with the view object's named bind variables, those variables can only take on their default values. Therefore this feature should be used only for selecting an attribute of one row of data that does not depend on the values in the current row.

- View accessor attribute

When defining the view accessor, you can assign row-specific values to the validation view object's bind variables.

- Expression

For information on the expression option, see [Section 7.5, "Using Groovy Expressions For Validation and Business Rules."](#)

- Entity attribute

The entity attribute option is available only for entity-level Compare validators.

#### To validate based on a comparison:

1. In the Application Navigator, double-click the desired entity object.
2. On the Business Rules page of the overview editor, select where you want to add the validator.
  - To add an entity-level validator, select the **Entity** folder.
  - To add an attribute-level validator, expand the **Attributes** folder and select the appropriate attribute.
3. Click the **Add** icon.
4. In the Add Validation Rule dialog, in the **Rule Type** dropdown list, select **Compare**. Note that the subordinate fields change depending on your choices.
5. Select the appropriate operator.
6. Select an item in the **Compare With** list, and based on your selection provide the appropriate comparison value.
7. You can optionally click the **Validation Execution** tab and enter criteria for the execution of the rule, such as dependent attributes and a precondition expression. For more information, see [Section 7.6, "Triggering Validation Execution."](#)
8. Click the **Failure Handling** tab and enter or select the error message that will be shown to the user if the validation rule fails. For more information, see [Section 7.7, "Creating Validation Error Messages."](#)
9. Click **OK**.

[Figure 7-2](#) shows what the dialog looks like when you use an entity-level Compare validator with a entity attribute.

**Figure 7–2 Compare Validator Using an Entity Object Attribute**

#### 7.4.4 What Happens When You Validate Based on a Comparison

When you use a Compare validator, a `<CompareValidationBean>` tag is added to an entity object's XML file. [Example 7–4](#) shows the XML code for the Email attribute in the PersonEO entity object.

##### **Example 7–4 Compare Validator XML Code**

```
<validation:CompareValidationBean
  xmlns="http://xmlns.oracle.com/adfm/validation"
  Name="PersonEO_Rule_0"
  ResId="PersonEO_Rule_0"
  OnAttribute="Email"
  OperandType="ATTR"
  Inverse="false"
  CompareType="EQUALTO"
  CompareValue="ConfirmedEmail"/>
```

#### 7.4.5 How to Validate Using a List of Values

The List validator compares an attribute against a list of values (LOV). When you add a List validator, you specify the type of list to choose from:

- Literal values - The validator ensures that the entity attribute is in (or not in, if specified) the list of values.
- Query result - The validator ensures that the entity attribute is in (or not in, if specified) the first column of the query's result set. The SQL query validator

cannot use a bind variable, so it should be used only on a fixed, small list that you have to query from a table. All rows of the query are retrieved into memory.

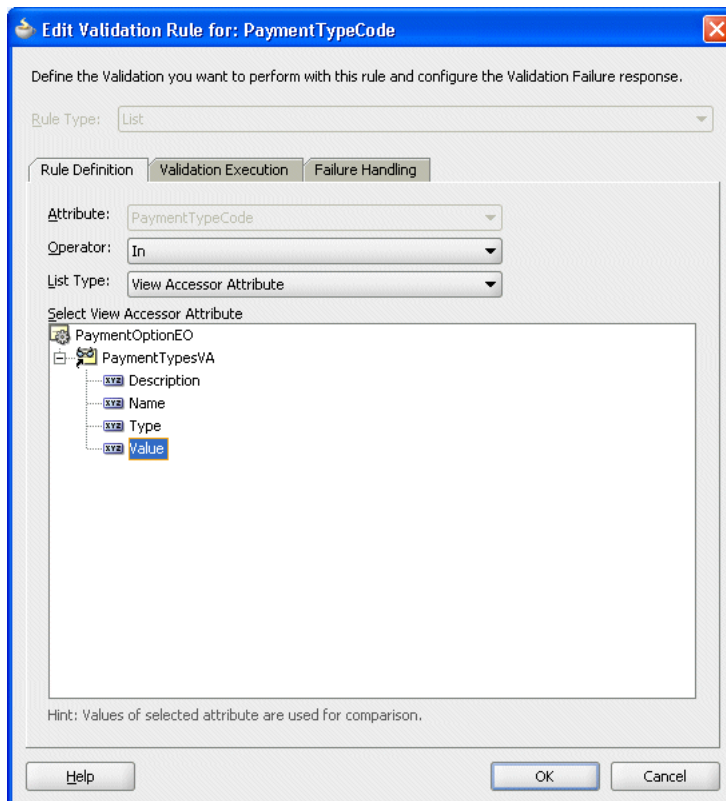

- View object attribute - The validator ensures that the entity attribute is in (or not in, if specified) the view attribute. The View attribute validator cannot use a bind variable, so it should be used only on a fixed, small list that you have to query from a table. All rows of the query are retrieved into memory.
- View accessor attribute - The validator ensures that the entity attribute is in (or not in) the view accessor attribute. The view accessor is probably the most useful option, because it can take bind variables and after you've created the LOV on the user interface, a view accessor is required.

**Best Practice:** When using a List validator, the view accessor is typically the most useful choice because you can define a view criteria on the view accessor to filter the view data when applicable; and when defining an LOV on a view attribute, you typically use a view accessor with a view criteria.

#### To validate using a list of values:

1. In the Application Navigator, double-click the desired entity object.
2. On the Business Rules page of the overview editor, select where you want to add the validator.
  - To add an entity-level validator, select the **Entity** folder.
  - To add an attribute-level validator, expand the **Attributes** folder and select the appropriate attribute.
3. Click the **Add** icon.
4. In the Add Validation Rule dialog, in the **Rule Type** dropdown list, select **List**.
5. In the **Attribute** list, choose the appropriate attribute.
6. In the **Operator** field, select **In** or **NotIn**, depending on whether you want an inclusive list or exclusive.
7. In the **List Type** field, select the appropriate type of list.
8. Depending on the type of list you selected, you can either enter a list of values (each value on a new line) or an SQL query, or select a view object attribute or view accessor attribute.
9. You can optionally click the **Validation Execution** tab and enter criteria for the execution of the rule, such as dependent attributes and a precondition expression. For more information, see [Section 7.6, "Triggering Validation Execution."](#)
10. Click the **Failure Handling** tab and enter or select the error message that will be shown to the user if the validation rule fails. For more information, see [Section 7.7, "Creating Validation Error Messages."](#)
11. Click **OK**.

[Figure 7-3](#) shows what the dialog looks like when you use a List validator with a view accessor attribute.

**Figure 7-3 List Validator Using a View Accessor Attribute**

## 7.4.6 What Happens When You Validate Using a List of Values

When you validate using a list of values, a `<ListValidationBean>` tag is added to an entity object's XML file. [Example 7-5](#) shows the `PaymentOptionEO.PaymentTypeCode` attribute, which uses a view accessor attribute for the List validator.

### Example 7-5 List Validator XML Code

```
<validation:ListValidationBean
  xmlns="http://xmlns.oracle.com/adfm/validation"
  Name="PaymentTypeCode_Rule_0"
  ResId="PaymentTypeCode_Rule_0"
  OnAttribute="PaymentTypeCode"
  OperandType="VO_USAGE"
  Inverse="false"
  ViewAccAttrName="Value"
  ViewAccName="PaymentTypesVA"/>
```

## 7.4.7 What You May Need to Know About the List Validator

The List validator is designed for validating an attribute against a relatively small set of values. If you select the **Query Result** or **View Object Attribute** type of list validation, keep in mind that the validator retrieves all of the rows from the query before performing an in-memory scan to validate whether the attribute value in question matches an attribute in the list. The query performed by the validator's SQL or view object query does not reference the value being validated in the `WHERE` clause of the query.

It is inefficient to use a validation rule when you need to determine whether a user-entered product code exists in a table of a large number of products. Instead, [Section 8.5, "Using View Objects for Validation"](#) explains the technique you can use to efficiently perform SQL-based validations by using a view object to perform a targeted validation query against the database. See also [Section 5.13.10.2, "Using Validators to Validate Attribute Values."](#)

Also, if the attribute you're comparing to is a key, the Key Exists validator is more efficient than validating a list of values; and if these choices need to be translatable, you should use a static view object instead of the literal choice.

## 7.4.8 How to Make Sure a Value Falls Within a Certain Range

The Range validator performs a logical comparison between an entity attribute and a range of values. When you add a Range validator, you specify minimum and maximum literal values. The Range validator verifies that the value of the entity attribute falls within the range (or outside the range, if specified).

If you need to dynamically calculate the minimum and maximum values, or need to reference other attributes on the entity, use the Script Expression validator and provide a Groovy expression. For more information, see [Section 3.6.1, "Referencing Business Components Objects in Groovy Expressions"](#) and [Section 3.6.3, "Manipulating Business Component Attribute Values in Groovy Expressions."](#)

### To validate within a certain range:

1. In the Application Navigator, double-click the desired entity object.
2. On the Business Rules page of the overview editor, select where you want to add the validator.
  - To add an entity-level validator, select the **Entity** folder.
  - To add an attribute-level validator, expand the **Attributes** folder and select the appropriate attribute.
3. Click the **Add** icon.
4. In the Add Validation Rule dialog, in the **Rule Type** dropdown list, select **Range**.
5. In the **Attribute** list, select the appropriate attribute.
6. In the **Operator** field, select **Between** or **NotBetween**.
7. In the **Minimum** and **Maximum** fields, enter appropriate values.
8. You can optionally click the **Validation Execution** tab and enter criteria for the execution of the rule, such as dependent attributes and a precondition expression. For more information, see [Section 7.6, "Triggering Validation Execution."](#)
9. Click the **Failure Handling** tab and enter or select the error message that will be shown to the user if the validation rule fails. For more information, see [Section 7.7, "Creating Validation Error Messages."](#)
10. Click **OK**.

## 7.4.9 What Happens When You Use a Range Validator

When you validate against a range, a `<RangeValidationBean>` tag is added to the entity object's XML file. [Example 7-6](#) shows the `PersonEO.CreditLimit` attribute with a minimum credit limit of zero and a maximum of 10,000.

**Example 7–6 Range Validator XML Code**

```
<validation:RangeValidationBean
  Name="CreditLimit_Rule_0"
  ResId="CreditLimit_Rule_0"
  OnAttribute="CreditLimit"
  OperandType="LITERAL"
  Inverse="false"
  MinValue="0"
  MaxValue="10000"/>
```

**7.4.10 How to Validate Against a Number of Bytes or Characters**

The Length validator validates whether the string length (in characters or bytes) of an attribute's value is less than, equal to, or greater than a specified number, or whether it lies between a pair of numbers.

**To validate against a number of bytes or characters:**

1. In the Application Navigator, double-click the desired entity object.
2. On the Business Rules page of the overview editor, select where you want to add the validator.
  - To add an entity-level validator, select the **Entity** folder.
  - To add an attribute-level validator, expand the **Attributes** folder and select the appropriate attribute.
3. Click the **Add** icon.
4. In the Add Validation Rule dialog, in the **Rule Type** dropdown list, select **Length**.
5. In the **Attribute** list, select the appropriate attribute.
6. In the **Operator** field, select how to evaluate the value.
7. In the **Comparison Type** field, select **Byte** or **Character** and enter a length.
8. You can optionally click the **Validation Execution** tab and enter criteria for the execution of the rule, such as dependent attributes and a precondition expression. For more information, see [Section 7.6, "Triggering Validation Execution."](#)
9. Click the **Failure Handling** tab and enter or select the error message that will be shown to the user if the validation rule fails. For more information, see [Section 7.7, "Creating Validation Error Messages."](#)
10. Click **OK**.

**7.4.11 What Happens When You Validate Against a Number of Bytes or Characters**

When you validate using length, a `<LengthValidationBean>` tag is added to the entity object's XML file, as shown in [Example 7–7](#). For example, you might have a field where the user enters a password or PIN and the application wants to validate that it is at least 6 characters long, but not longer than 10. You would use the Length validator with the Between operator and set the minimum and maximum values accordingly.

**Example 7–7 Validating the Length Between Two Values**

```
<validation:LengthValidationBean
  OnAttribute="pin"
  CompareType="BETWEEN"
  DataType="CHARACTER"
```

```

MinValue="6"
MaxValue="10"
Inverse="false"/>

```

## 7.4.12 How to Validate Using a Regular Expression

The Regular Expression validator compares attribute values against a mask specified by a Java regular expression.

If you want to create expressions that can be personalized in metadata, you can use the Script Expression validator. For more information, see [Section 7.5, "Using Groovy Expressions For Validation and Business Rules."](#)

### To validate using a regular expression

1. In the Application Navigator, double-click the desired entity object.
2. On the Business Rules page of the overview editor, select where you want to add the validator.
  - To add an entity-level validator, select the **Entity** folder.
  - To add an attribute-level validator, expand the **Attributes** folder and select the appropriate attribute.
3. Click the **Add** icon.
4. In the Add Validation Rule dialog, in the **Rule Type** dropdown list, select **Regular Expression**.
5. In the **Operator** field, you can select **Matches** or **Not Matches**.
6. To use a predefined expression (if available), you can select one from the dropdown list and click **Use Pattern**. Otherwise, write your own regular expression in the field provided.

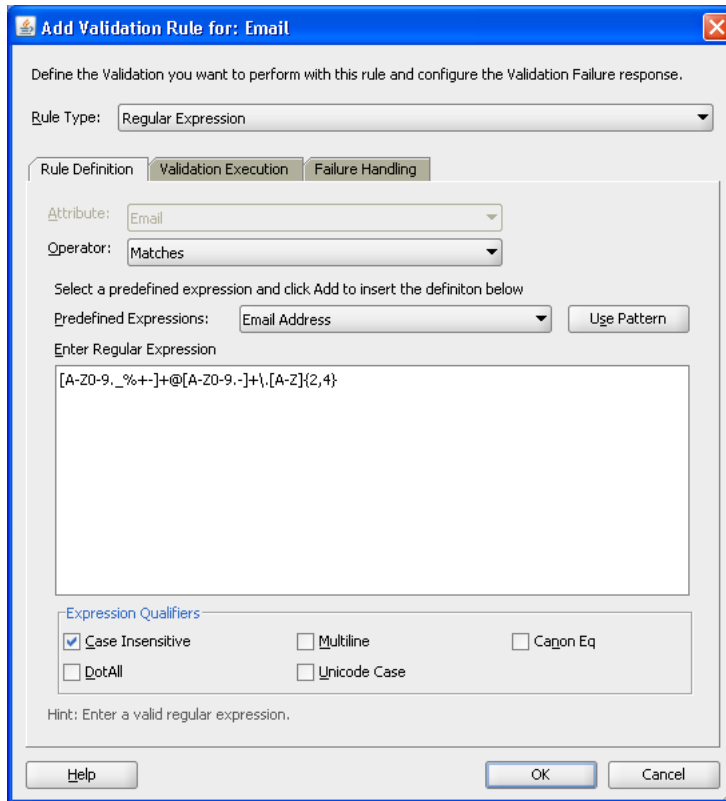

---

**Note:** You can add your own expressions to the list of predefined expressions. To add a predefined expression, add an entry in the `PredefinedRegExp.properties` file in the BC4J subdirectory of the JDeveloper system directory (for example, `C:\Documents and Settings\username\Application Data\JDeveloper\system##\o.BC4J\PredefinedRegExp.properties`).

---

7. You can optionally click the **Validation Execution** tab and enter criteria for the execution of the rule, such as dependent attributes and a precondition expression. For more information, see [Section 7.6, "Triggering Validation Execution."](#)
8. Click the **Failure Handling** tab and enter or select the error message that will be shown to the user if the validation rule fails. For more information, see [Section 7.7, "Creating Validation Error Messages."](#)
9. Click **OK**.

Figure 7-4 shows what the dialog looks like when you select a Regular Expression validator and validate that the `Email` attribute matches a predefined **Email Address** expression.

**Figure 7-4 Regular Expression Validator Matching Email Address**

### 7.4.13 What Happens When You Validate Using a Regular Expression

When you validate using a regular expression, a `<RegExpValidationBean>` tag is added to the entity object's XML file. [Example 7-8](#) shows an `Email` attribute that must match a regular expression.

#### **Example 7-8 Regular Expression Validator XML Code**

```
<validation:RegExpValidationBean
  Name="Email_Rule_0"
  OnAttribute="Email"
  Pattern="[A-Z0-9._%+-]+@[A-Z0-9.-]+\.[A-Z]{2,4}"
  Flags="CaseInsensitive"
  Inverse="false"/>
```

### 7.4.14 How to Use the Average, Count, or Sum to Validate a Collection

You can use collection validation on the average, count, sum, min, or max of a collection. This validator is available only at the entity level. It is useful for validating the aggregate calculation over a collection of associated entities by way of an entity accessor to a child entity (on the many end of the association). You must select the association accessor to define the Collection validator.

#### **To validate using an aggregate calculation:**

1. In the Application Navigator, double-click the desired entity object.
2. On the Business Rules page of the overview editor, select the **Entity** folder and click the **Add** icon.

3. In the Add Validation Rule dialog, in the **Rule Type** dropdown list, select **Collection**.
4. In the **Operation** field, specify the operation (sum, average, count, min, or max) to perform on the collection for comparison.
5. Select the appropriate accessor and attribute for the validation.  
The accessor you choose must be a composition association accessor. Only accessors of this type are displayed in the dropdown list.
6. Specify the operator and the comparison type and value.
7. You can optionally click the **Validation Execution** tab and enter criteria for the execution of the rule, such as dependent attributes and a precondition expression. For more information, see [Section 7.6, "Triggering Validation Execution."](#)
8. Click the **Failure Handling** tab and enter or select the error message that will be shown to the user if the validation rule fails. For more information, see [Section 7.7, "Creating Validation Error Messages."](#)
9. Click OK.

### 7.4.15 What Happens When You Use Collection Validation

When you validate using a Collection validator, a `<CollectionValidationBean>` tag is added to the entity object's XML file, as in [Example 7-9](#).

#### **Example 7-9 Collection Validator XML Code**

```
<validation:CollectionValidationBean
  Name="OrderEO_Rule_0"
  OnAttribute="OrderTotal"
  OperandType="LITERAL"
  Inverse="false"
  CompareType="LESSTHAN"
  CompareValue="5"
  Operation="sum" />
```

### 7.4.16 How to Determine Whether a Key Exists

The Key Exists validator is used to determine whether a key value (primary, foreign, or alternate key) exists.

There are a couple of benefits to using the Key Exists validator:

- The Key Exists validator has better performance because it first checks the cache and only goes to the database if necessary.
- Since the Key Exists validator uses the cache, it will find a key value that has been added in the current transaction, but not yet committed to the database. For example, you add a new `Department` and then you want to link an `Employee` to that new department.

#### **To determine whether a value exists:**

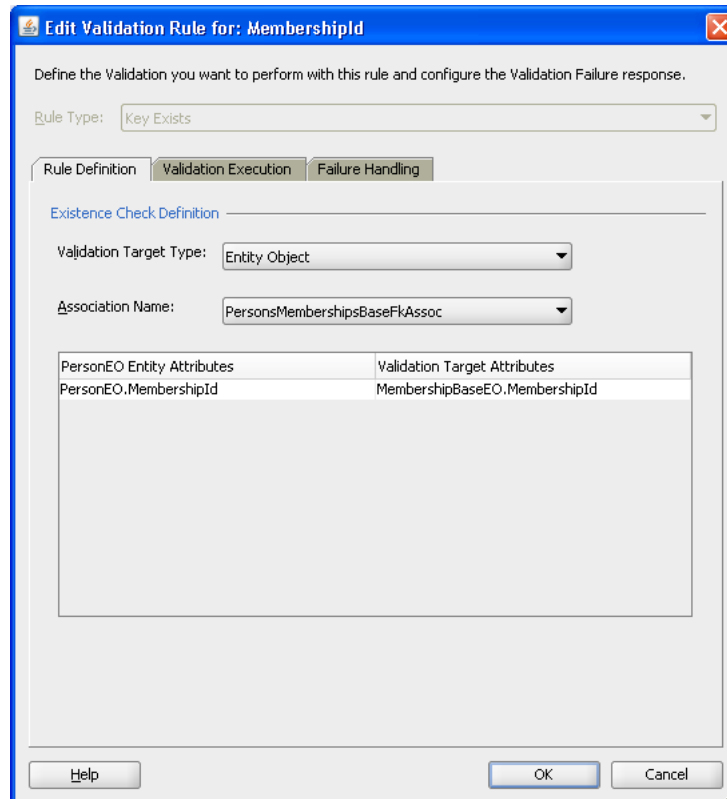

1. In the Application Navigator, double-click the desired entity object.
2. On the Business Rules page of the overview editor, select where you want to add the validator.
  - To add an entity-level validator, select the **Entity** folder.

- To add an attribute-level validator, expand the **Attributes** folder and select the appropriate attribute.
3. Click the **Add** icon.
4. In the Add Validation Rule dialog, select **Key Exists** from the **Rule Type** list.
5. Select the type of validation target (**Entity Object**, **View Object**, or **View Accessor**).

If you want the Key Exists validator to be used for all view objects that use this entity attribute, select **Entity Object**.
6. Depending on the validation target, you can choose either an association or a key value.

If you are searching for an attribute that does not exist in the **Validation Target Attributes** list, it is probably not defined as a key value. To create alternate keys, see [Section 4.10.15, "How to Define Alternate Key Values."](#)
7. You can optionally click the **Validation Execution** tab and enter criteria for the execution of the rule, such as dependent attributes and the validation level (entity or transaction). For more information, see [Section 7.6, "Triggering Validation Execution."](#)
8. Click the **Failure Handling** tab and enter or select the error message that will be shown to the user if the validation rule fails. For more information, see [Section 7.7, "Creating Validation Error Messages."](#)
9. Click **OK**.

[Figure 7-5](#) shows a Key Exists validator that validates whether the `MembershipId` entered in the `PersonEO` entity object exists in the `MembershipBaseEO` entity object.

**Figure 7-5** Key Exists Validator on an Entity Attribute

### 7.4.17 What Happens When You Use a Key Exists Validator

When you use a Key Exists validator, an `<ExistsValidationBean>` tag is created in the XML file for the entity object, as in [Example 7-10](#).

#### **Example 7-10** Using the Key Exists Validator With an Association

```
<validation:ExistsValidationBean
  Name="MembershipId_Rule_0"
  ResId="MembershipId_Rule_0"
  OperandType="EO"
  AssocName=
    "oracle.fodemo.storefront.entities.associations.PersonsMembershipsBaseFkAssoc"/>
```

### 7.4.18 What You May Need to Know About Declarative Validators and View Accessors

When using declarative validators you must consider how your validation will interact with expected input. The combination of declarative validators and view accessors provides a simple yet powerful alternative to coding. But, as powerful as the combination is, you still need to consider how data composition can impact performance.

Consider a scenario where you have the following:

- A `ServiceRequestEO` entity object with `Product` and `RequestType` attributes, and a view accessor that allows it to access the `RequestTypeVO` view object
- A `RequestTypeVO` view object with a query specifying the `Product` attribute as a bind parameter

The valid list of `RequestTypes` varies by `Product`. So, to validate the `RequestType` attribute, you use a `List` validator using the view accessor.

Now lets add a set of new service requests. For the first service request (row), the `List` validator binds the value of the `Product` attribute to the view accessor and executes it. For each subsequent service request the `List` validator compares the new value of the `Product` attribute to the currently bound value.

- If the value of `Product` matches, the current `RowSet` object is retained.
- If the value of `Product` has changed, the new value is bound and the view accessor re-executed.

Now consider the expected composition of input data. For example, the same products could appear in the input multiple times. If you simply validate the data in the order received, you might end up with the following:

1. Dryer (initial query)
2. Washing Machine (re-execute view accessor)
3. Dish Washer (re-execute view accessor)
4. Washing Machine (re-execute view accessor)
5. Dryer (re-execute view accessor)

In this case, the validator will execute 5 queries to get 3 distinct row sets. As an alternative, you can add an `ORDER BY` clause to the `RequestTypeVO` to sort it by `Product`. In this case, the validator would execute the query only once each for `Washing Machine` and `Dryer`.

1. Dish Washer (initial query)
2. Dryer (re-execute view accessor)
3. Dryer
4. Washing Machine (re-execute view accessor)
5. Washing Machine

A small difference on a data set this size, but multiplied over larger data sets and many users this could easily become an issue. An `ORDER BY` clause is not a solution to every issue, but this example illustrates how data composition can impact performance.

## 7.5 Using Groovy Expressions For Validation and Business Rules

Groovy expressions are Java-like scripting code stored in the XML definition of an entity object. Because Groovy expressions are stored in XML, you can change the expression values even if you don't have access to the entity object's Java file. You can even change or specify values at runtime.

For more information about using Groovy script in your entity object business logic, see [Section 3.6, "Overview of Groovy Support."](#)

### 7.5.1 How to Reference Entity Object Methods in Groovy Validation Expressions

You can call methods on the current entity instance using the `source` property of the current object. The `source` property allows you to access to the entity instance being validated.

If the method is a non-boolean type and the method name is `getXYZabc()` with no arguments, then you access its value as if it were a property named `XYZabc`. For a boolean-valued property, the same holds true but the JavaBean naming pattern for the getter method changes to recognize `isXYZabc()` instead of `getXYZabc()`. If the method on your entity object does not match the JavaBean getter method naming pattern, or if it takes one or more arguments, then you must call it like a method using its complete name.

For example, say you have an entity object with the four methods shown in [Example 7–11](#).

#### **Example 7–11 Sample Entity Object Methods**

```
public boolean isNewRow() {
    System.out.println("## isNewRow() accessed ##");
    return true;
}

public boolean isNewRow(int n) {
    System.out.println("## isNewRow(int n) accessed ##");
    return true;
}

public boolean testWhetherRowIsNew() {
    System.out.println("## testWhetherRowIsNew() accessed ##");
    return true;
}

public boolean testWhetherRowIsNew(int n) {
    System.out.println("## testWhetherRowIsNew(int n) accessed ##");
    return true;
}
```

Then the following Groovy validation condition would trigger them all, one of them being triggered twice, as shown in [Example 7–12](#).

#### **Example 7–12 Groovy Script Calling Sample Methods**

```
newRow && source.newRow && source.isNewRow(5) && source.testWhetherRowIsNew() &&
source.testWhetherRowIsNew(5)
```

By running this example and forcing entity validation to occur, you would see the diagnostic output shown in [Example 7–13](#) in the log window:

#### **Example 7–13 Output From Sample Groovy Script**

```
## isNewRow() accessed ##
## isNewRow() accessed ##
## isNewRow(int n) accessed ##
## testWhetherRowIsNew() accessed ##
## testWhetherRowIsNew(int n) accessed ##
```

Notice the slightly different syntax for the reference to a method whose name matches the JavaBeans property getter method naming pattern. Both `newRow` and `source.newRow` work to access the boolean-valued, JavaBeans getter-style method that has no arguments. But because the `testWhetherRowIsNew` method does not match the JavaBeans getter method naming pattern, and the second `isRowNew` method takes an argument, then you must call them like methods using their complete name.

## 7.5.2 How to Validate Using a True/False Expression

You can use a Groovy expression to return a true/false statement. The Script Expression validator *requires* that the expression either return `true` or `false`, or that it calls the `adf.error.raise/warn()` method. A common use of this feature would be to validate an attribute value, for example, to make sure that an account number is valid.

---

---

**Note:** Using the `adf.error.raise/warn()` method (rather than simply returning `true` or `false`) allows you to define the message text to show to the user, and to associate an entity-level validator with a specific attribute. For more information, see [Section 7.7.3, "How to Conditionally Raise Error Messages Using Groovy."](#)

---

---

### To validate using a true/false expression:

1. In the Application Navigator, double-click the desired entity object.
2. On the Business Rules page of the overview editor, select where you want to add the validator.
  - To add an entity-level validator, select the **Entity** folder.
  - To add an attribute-level validator, expand the **Attributes** folder and select the appropriate attribute.
3. Click the **Add** icon.
4. In the Add Validation Rule dialog, in the **Rule Type** dropdown list, select **Script Expression**.
5. Enter a validation expression in the field provided.
6. You can optionally click the **Validation Execution** tab and enter criteria for the execution of the rule, such as dependent attributes and a precondition expression. For more information, see [Section 7.6, "Triggering Validation Execution."](#)
7. Click the **Failure Handling** tab and enter or select the error message that will be shown to the user if the validation rule fails. For more information, see [Section 7.7, "Creating Validation Error Messages."](#)
8. Click **OK**.

The sample code in [Example 7–14](#) comes from the `PaymentOptionEO` entity object. The code validates account numbers based on the Luhn algorithm, a checksum formula in widespread use.

#### **Example 7–14 Validating an Account Number Using an Expression**

```
<validation:ExpressionValidationBean
  Name="AccountNumber_Rule_0"
  OperandType="EXPR"
  Inverse="false">
  <OnCondition>
    <![CDATA[PaymentTypeCode=='CC']]>
  </OnCondition>
  <MsgIds>
    <Item
      Value="PaymentOption_AccountNumber"/>
    </Item>
  </MsgIds>
  <TransientExpression>
    <![CDATA[
```

```

String acctnumber = newValue;
sumofdigits = 0;
digit = 0;
addend = 0;
timesTwo = false;
range = acctnumber.length()-1..0
range.each {i ->
digit = Integer.parseInt (acctnumber.substring (i, i + 1));
if (timesTwo) {
addend = digit * 2;
if (addend > 9) {
addend -= 9;
}
}
else {
addend = digit;
}
sumofdigits += addend;
timesTwo = !timesTwo;
}
modulus = sumofdigits % 10;
return modulus == 0;
]]>
</TransientExpression>
</ExpressionValidationBean>

```

### 7.5.3 What Happens When You Add a Groovy Expression

When you create a Groovy expression, it is saved in the entity object's XML component. [Example 7-15](#) shows the `RegisteredDate` attribute in the `PersonEO.xml` file. The Groovy expression is wrapped by a `<TransientExpression>` tag.

#### **Example 7-15 XML Code for RegisteredDate Attribute on the PersonEO Entity Object**

```

<Attribute
  Name="RegisteredDate"
  IsUpdateable="true"
  ColumnName="REGISTERED_DATE"
  Type="oracle.jbo.domain.Date"
  ColumnType="DATE"
  SQLType="DATE"
  TableName="PERSONS">
  <DesignTime>
    <Attr Name="_DisplaySize" Value="7"/>
  </DesignTime>
  <validation:ExpressionValidationBean
    Name="RegisteredDate_Rule_0"
    OperandType="EXPR"
    Inverse="false">
    <MsgIds>
      <Item
        Value="RegisteredDate_Rule_0"/>
    </MsgIds>
    <TransientExpression>
      <![CDATA[
newValue <= (new java.sql.Timestamp(System.currentTimeMillis()))
      ]]>
    </TransientExpression>

```

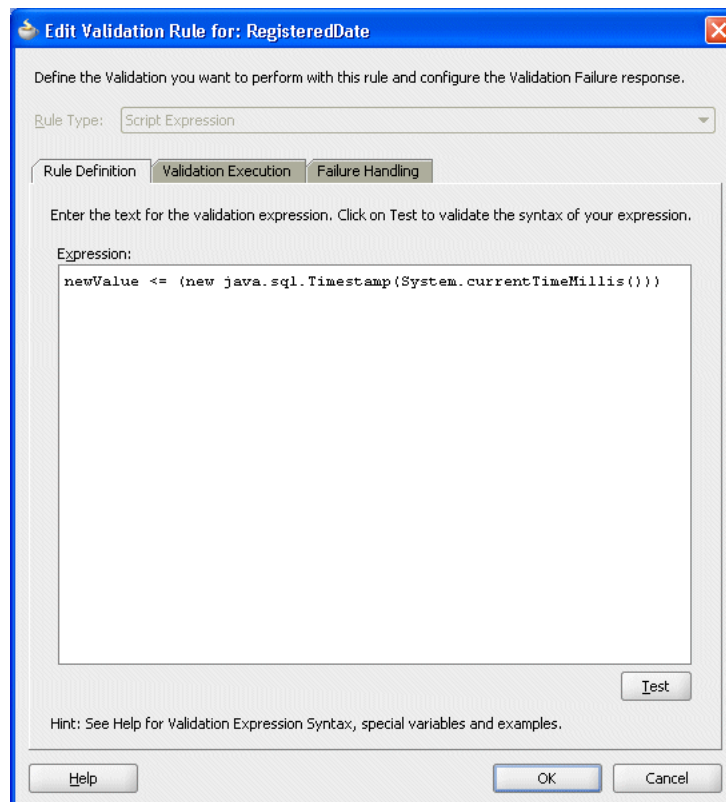

```

    </ExpressionValidationBean>
  </Attribute>

```

This tag can take one of several forms. For some Groovy expressions, the `<TransientExpression>` tag is wrapped by an `<ExpressionValidationBean>` tag as well. [Figure 7–6](#) shows the validation expression in the Edit Validation Rule dialog.

**Figure 7–6** Validation Expression for RegisteredDate Attribute on the PersonEO Entity Object

## 7.6 Triggering Validation Execution

JDeveloper allows you to select the attributes that trigger validation, so that validation execution happens only when one of the triggering attributes is dirty. In previous releases of JDeveloper, an entity-level validator would fire on an attribute whenever the entity as a whole was dirty. This feature is described in [Section 7.6.1, "How to Specify Which Attributes Fire Validation."](#)

JDeveloper also allows you to specify a precondition for the execution of a validator (as described in [Section 7.6.3, "How to Set Preconditions for Validation"](#)) and set transaction-level validation (described in [Section 7.6.4, "How to Set Transaction-Level Validation"](#)).

### 7.6.1 How to Specify Which Attributes Fire Validation

When defining a validator at the entity level, you have the option of selecting one or more attributes of the entity object that, when changed, trigger execution of the validator.

---

**Note:** When the validity of one attribute is dependent on the value in another attribute, the validation should be performed as entity validation, not attribute validation. You can set validation execution order on the entity level or attribute level.

---

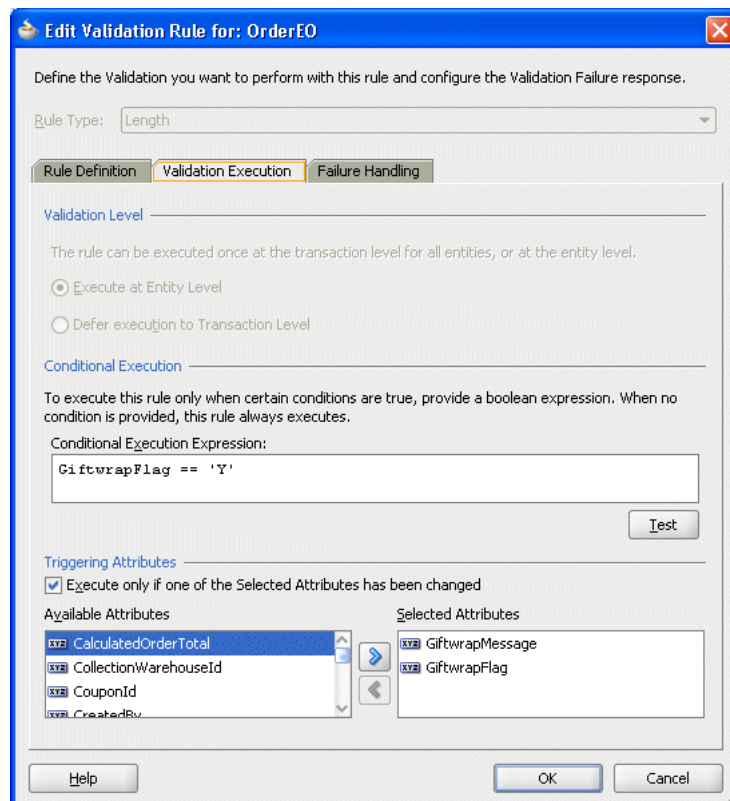

If you do not specify one or more dependent attributes, the validator will fire whenever the entity is dirty. Firing execution only when required makes your application more performant.

**To specify which attributes fire validation:**

1. In the Application Navigator, double-click the desired entity object.
2. On the Business Rules page of the overview editor, select a validation rule and click the **Edit** icon.
3. In the Edit Validation Rule dialog, click the **Validation Execution** tab.
4. Select the attributes that will fire validation.
5. Click **OK**.

For example, in the StoreFront module of the Fusion Order Demo application, the OrderEO entity object has an entity-level validator that constrains the length of the GiftwrapMessage attribute. As shown in [Figure 7-7](#), this validator is set to be executed on the entity object only when either the GiftwrapMessage attribute or the GiftwrapFlag attribute has been changed.

**Figure 7-7** Triggering attributes on the Validation Execution tab of the Edit Validation Rule dialog

## 7.6.2 What Happens When You Constrain Validation Execution with Triggering Attributes

When you specify triggering attributes on the **Validation Execution** tab of the Edit Validation Rule dialog, JDeveloper adds an `<OnAttributes>` tag to the validator definition in the entity object's XML file. [Example 7-16](#) shows the XML code for the entity-level validator for the `OrderEO` entity object in the StoreFront module of the Fusion Order Demo application.

### Example 7-16 `OnAttributes` element in XML validation code

```
<LengthValidationBean
  xmlns="http://xmlns.oracle.com/adfm/validation"
  Name="OrderEO_Rule_0"
  OnAttribute="GiftwrapMessage"
  CompareType="GREATERTHANEQUALTO"
  DataType="CHARACTER"
  CompareLength="1"
  Inverse="false"
  ResId="GiftMessage_Required_Error_0">
  <OnAttributes>
    <Item Value="GiftwrapMessage"/>
    <Item Value="GiftwrapFlag"/>
  </OnAttributes>
  <OnCondition>
    <![CDATA[GiftwrapFlag == 'Y']]>
  </OnCondition>
</LengthValidationBean>
```

## 7.6.3 How to Set Preconditions for Validation

The **Validation Execution** tab (on the Add/Edit Validation Rule dialog) allows you to add a Groovy expression that serves as a precondition. If you enter an expression in the **Conditional Execution Expression** box, the validator is executed only if the condition evaluates `True`.

**Best Practice:** While it is possible to add a precondition for a Unique Key validator, it is not a best practice. If a Unique Key validator fails to fire, for whatever reason, the cache consistency check is still performed and an error will be returned. It is generally better to add the validator and a meaningful error message.

## 7.6.4 How to Set Transaction-Level Validation

Performing a validation during the transaction level (rather than entity level) means that the validation will be performed after all entity-level validation is performed. For this reason, it may be useful if you want to ensure that a validator is performed at the end of the process.

In addition, the Key Exists validator is more performant with bulk transactions if it is run as a transaction level validator since it will be run only once for all entities in the transaction (of the same type), rather than once per entity. This will result in improved performance if the validator has to go to the database.

---

**Note:** Transaction-level validation is only applicable to Key Exists and Method entity validators.

---

**To specify entity-level or transaction-level validation:**

1. In the Application Navigator, double-click the desired entity object.
2. On the Business Rules page of the overview editor, select an entity-level validation rule and click the **Edit** icon.
3. In the Edit Validation Rule dialog, click the **Validation Execution** tab.
4. Select **Execute at Entity Level** or **Defer Execution to Transaction Level**.
5. Click **OK**.

### 7.6.5 What You May Need to Know About the Order of Validation Execution

You cannot control the order in which attributes are validated – they are always validated in the order they appear in the entity definition. You can order validations for a given attribute (or for the entity), but you cannot reorder the attributes themselves.

## 7.7 Creating Validation Error Messages

Validation error messages provide important information for the user: the message should convey what went wrong and how to fix it.

### 7.7.1 How to Create Validation Error Messages

When you create or edit a validation rule, enter text to help the user determine what caused the error.

**To create validation error messages:**

1. In the Application Navigator, double-click the desired entity object.
2. On the Business Rules page of the overview editor, select a validation rule and click the **Edit** icon.
3. In the Edit Validation Rule dialog, click the **Failure Handling** tab.
4. In the **Message Text** field, enter your error message.

You can also define error messages in a message bundle file. To select a previously defined error message or to define a new one in a message bundle file, click the **Select Message** icon.

---

**Note:** The Script Expression validator allows you to enter more than one error message. This is useful if the validation script conditionally returns different error or warning messages. For more information, see [Section 7.7.3, "How to Conditionally Raise Error Messages Using Groovy."](#)

---

5. You can optionally include message tokens in the body of the message, and define them in the **Token Message Expressions** list.

[Figure 7–8](#) shows the failure message for a validation rule in the `PaymentOptionEO` entity object that contains message tokens. For more information on this feature, see [Section 7.7.4, "How to Embed a Groovy Expression in an Error Message."](#)

6. Click **OK**.

## 7.7.2 How to Localize Validation Messages

The error message is a translatable string and is managed in the same way as translatable UI control hints in an entity object message bundle class. To view the error message for the defined rule in the message bundle class, locate the `String` key in the message bundle that corresponds to the `ResId` property in the XML component definition entry for the validator. For example, [Example 7–17](#) shows a message bundle where the `NAME_CANNOT_BEGIN_WITH_U` key appears with the error message for the default locale.

### **Example 7–17 Message Bundle Contains Validation Error Messages**

```
package devguide.advanced.customerrors;
import java.util.ListResourceBundle;

public class CustomMessageBundle extends ListResourceBundle {
    private static final Object[][] sMessageStrings = new String[][] {
        // other strings here
        {"NAME_CANNOT_BEGIN_WITH_U", "The name cannot begin with the letter u!"},
        // other strings here
    };
    // etc.
}
```

Resource bundles can be created for your applications as a list resource bundle (as shown in [Example 7–17](#)), as a properties bundle, or as an XLIFF resource bundle. For more information about using translatable strings in a resource bundle, see [Section 4.7, "Working with Resource Bundles."](#)

## 7.7.3 How to Conditionally Raise Error Messages Using Groovy

You can use the `adf.error.raise()` and `adf.error.warn()` methods to conditionally raise one error message or another depending upon branching in the Groovy expression. For example, if an attribute value is *x*, then validate as follows, and if the validation fails, raise error messageA; whereas if the attribute value is *y*, then instead validate a different way and if validation fails, raise error messageB.

If the expression returns `false` (versus raising a specific error message using the `raise()` method), the validator calls the first error message associated with the validator.

The syntax of the `raise()` method takes one required parameter (the `msgId` to use from the message bundle), and optionally can take the `attrName` parameter. If you pass in the `AttrName`, the error is associated with that attribute even if the validation is assigned to the entity.

You can use either `adf.error.raise()` or `adf.error.warn()` methods, depending on whether you want to throw an exception, or whether you want processing to continue, as described in [Section 7.8, "Setting the Severity Level for Validation Exceptions."](#)

## 7.7.4 How to Embed a Groovy Expression in an Error Message

A validator's error message can contain embedded expressions that are resolved by the server at runtime. To access this feature, simply enter a named token delimited by curly braces (for example, `{2}` or `{errorParam}`) in the error message text where you want the result of the Groovy expression to appear.

After entering the token into the text of the error message (on the **Failure Handling** tab of the Edit Validation Rule dialog), the **Token Message Expressions** table at the bottom of the dialog displays a row that allows you to enter a Groovy expression for the token. [Figure 7-8](#) shows the failure message for a validation rule in the `PaymentOptionEO` entity object that contains message tokens.

**Figure 7-8 Using Message Tokens in a Failure Message**

The expressions shown in [Figure 7-8](#) are Groovy expressions that return the labels of the specified fields. You can also use Groovy expressions to access attribute values and other business components objects. You can use the Groovy expression `newValue` to return the entered value, as shown in the Rule validator for the `RoutingIdentifier` attribute of the `PaymentOptionEO` entity object in the `StoreFront` module of the Fusion Order Demo application.

The Groovy syntax to retrieve a value from a view accessor is `accessorName.currentRow.AttributeName`. For example, the Groovy expression `MyEmpAccessor.currentRow.Job` returns the value of the `Job` attribute in the current row of the `MyEmpAccessor` view accessor.

The Groovy expression can also be more complex, as in [Example 7-18](#), which shows an expression in the error message for the `List` validation rule for the `OwnerTypeCode` attribute in the `AddressUsageEO` entity object.

**Example 7-18 Groovy Script in the OwnerTypeCode Validation Error Message**

```
def ownertypevalue = []
while ( AddressOwnerTypesVA.hasNext() ) {
AddressOwnerTypesVA.next ()
    ownertypevalue.add(AddressOwnerTypesVA.currentRow.Value)
}
}
```

```
return ownertypevalue
```

For more information about accessing business components objects using Groovy, see [Section 3.6, "Overview of Groovy Support."](#)

## 7.8 Setting the Severity Level for Validation Exceptions

You can set the severity level for validation exceptions to two levels, Informational Warning and Error. If you set the severity level to Informational Warning, an error message will display, but processing will continue. If you set the validation level to Error, the user will not be able to proceed until you have fixed the error.

Under most circumstances you will use the Error level for validation exceptions, so this is the default setting. However, you might want to implement a Informational Warning message if the user has a certain security clearance. For example, a store manager may want to be able to make changes that would surface as an error if a clerk tried to do the same thing.

To set the severity level for validation exceptions, use the **Failure Handling** tab of the Add Validation Rule dialog.

### To set the severity level of a validation exception:

1. In the Application Navigator, double-click the desired entity object.
2. On the Business Rules page, select an existing validation rule and click the **Edit** icon, or click the **Add** icon to create a new rule.
3. In the Edit/Add Validation Rule dialog, click the **Failure Handling** tab and select the option for either **Error** or **Informational Warning**.
4. Click **OK**.

## 7.9 Bulk Validation in SQL

To improve the performance of batch-load applications, such as data synchronization programs, the ADF framework employs bulk validation for primary keys (including alternate keys) and foreign keys.

When the Key Exists validator is configured to defer validation until the transaction commits, or when the rows are being updated or inserted through the `processXXX` methods of the ADF business components service layer, the validation cache is preloaded. This behavior uses the normal row-by-row derivation and validation logic, but uses validation logic that checks a memory cache before making queries to the database. Performance is improved by preloading the memory cache using bulk SQL operations based on the inbound data.

---

# Implementing Validation and Business Rules Programmatically

This chapter explains how to use ADF entity object events and features to programmatically implement the most common kinds of business rules in an Oracle Application Development Framework (Oracle ADF) application. It also describes how to invoke custom validation code, for example, using setter methods to populate entity rows.

This chapter includes the following sections:

- [Section 8.1, "Introduction to Programmatic Business Rules"](#)
- [Section 8.2, "Using Method Validators"](#)
- [Section 8.3, "Assigning Programmatically Derived Attribute Values"](#)
- [Section 8.4, "Undoing Pending Changes to an Entity Using the Refresh Method"](#)
- [Section 8.5, "Using View Objects for Validation"](#)
- [Section 8.6, "Accessing Related Entity Rows Using Association Accessors"](#)
- [Section 8.7, "Referencing Information About the Authenticated User"](#)
- [Section 8.8, "Accessing Original Attribute Values"](#)
- [Section 8.9, "Storing Information About the Current User Session"](#)
- [Section 8.10, "Accessing the Current Date and Time"](#)
- [Section 8.11, "Sending Notifications Upon a Successful Commit"](#)
- [Section 8.12, "Conditionally Preventing an Entity Row from Being Removed"](#)
- [Section 8.13, "Determining Conditional Updatability for Attributes"](#)

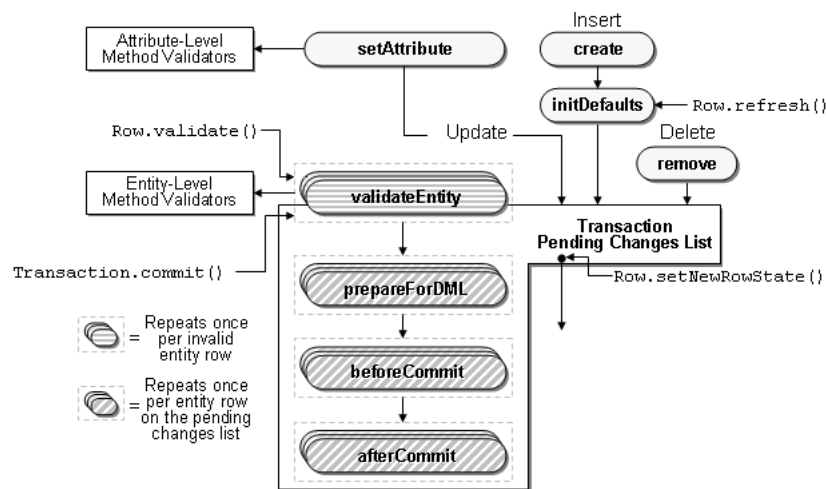

## 8.1 Introduction to Programmatic Business Rules

Complementing the built-in *declarative* validation features, entity objects and view objects have method validators and several events you can handle to *programmatically* implement encapsulated business logic using Java code. These concepts are illustrated in [Figure 8-1](#).

- Attribute-level method validators trigger validation code when an attribute value changes.
- Entity-level method validators trigger validation code when an entity row is validated.
- You can override the following key methods in a custom Java class for an entity:

- `create()`, to assign default values when a row is created
- `initDefaultExpressionAttributes()`, to assign defaults either when a row is created or when a new row is refreshed
- `remove()`, to conditionally disallow deleting
- `isAttributeUpdateable()`, to make attributes conditionally updatable
- `setAttribute()`, to trigger attribute-level method validators
- `validateEntity()`, to trigger entity-level method validators
- `prepareForDML()`, to assign attribute values before an entity row is saved
- `beforeCommit()`, to enforce rules that must consider all entity rows of a given type
- `afterCommit()`, to send notifications about a change to an entity object's state

**Figure 8–1 Key Entity Objects Features and Events for Programmatic Business Logic**

**Note:** When coding programmatic business rules, it's important to have a firm grasp of the validation cycle. For more information, see [Section 7.2, "Understanding the Validation Cycle."](#)

## 8.2 Using Method Validators

Method validators are the primary way of supplementing declarative validation rules and Groovy-scripted expressions using your own Java code. Method validators trigger Java code that you write in your own validation methods at the appropriate time during the entity object validation cycle. There are many types of validation you can code with a method validator, either on an attribute or on an entity as a whole.

You can add any number of attribute-level or entity-level method validators, provided they each trigger a distinct method name in your code. All validation method names must begin with the word `validate`; however, following that rule you are free to name them in any way that most clearly identifies the functionality. For an attribute-level validator, the method must take a single argument of the same type as the entity attribute. For an entity-level validator, the method takes no arguments. The

method must also be public, and must return a boolean value. Validation will fail if the method returns `false`.

---

**Note:** Although it is important to be aware of these rules, when you use JDeveloper to create method validators, JDeveloper creates the correct interface for the class.

---

At runtime, the Method validator passes an entity attribute to a method implemented in your entity object class.

In [Example 8-1](#), the method accepts strings that start with a capital letter and throws an exception on null values, empty strings, and strings that do not start with a capital letter.

**Example 8-1 Method That Validates If the First Letter Is a Capital**

```
public boolean validateIsCapped(String text)
{
    if (text != null &&
        text.length() != 0 &&
        text[0] >= 'A' &&
        text[0] <= 'Z')
    {
        return true;
    }
}
```

## 8.2.1 How to Create an Attribute-Level Method Validator

**To create an attribute-level Method validator:**

1. In the Application Navigator, double-click the desired entity object.
2. In the overview editor, click the **Java** navigation tab.

The Java page shows the Java generation options that are currently enabled for the entity object. If your entity object does not yet have a custom entity object class, then you must generate one before you can add a Method validator. To generate the custom Java class, click the **Edit** icon, then select **Generate Entity Object Class**, and click **OK** to generate the `*.java` file.

3. Click the **Business Rules** navigation tab, and then expand the **Attributes** node, and select the attribute that you want to validate.
4. Click the **New** icon to add a validation rule.
5. Select **Method** from the **Rule Type** dropdown list.

The Add Validation Rule dialog displays the expected method signature for an attribute-level validation method. You have two choices:

- If you already have a method in your entity object's custom Java class of the appropriate signature, it will appear in the list and you can select it after deselecting the **Create and Select Method** checkbox.
- If you leave the **Create and Select Method** checkbox selected (see [Figure 8-2](#)), you can enter any method name in the **Method Name** box that begins with the word `validate`. When you click **OK**, JDeveloper adds the method to your entity object's custom Java class with the appropriate signature.

- Finally, supply the text of the error message for the default locale that the end user should see if this validation rule fails.

**Figure 8–2 Adding an Attribute-Level Method Validator**

## 8.2.2 What Happens When You Create an Attribute-Level Method Validator

When you add a new method validator, JDeveloper updates the XML component definition to reflect the new validation rule. If you asked to have the method created, the method is added to the entity object's custom Java class. [Example 8–2](#) illustrates a simple attribute-level validation rule that ensures that the `OrderShippedDate` of an order is a date in the current month. Notice that the method accepts an argument of the same type as the corresponding attribute, and that its conditional logic is based on the value of this incoming parameter. When the attribute validator fires, the attribute value has not yet been set to the new value in question, so calling the `getOrderShippedDate()` method inside the attribute validator for the `OrderShippedDate` attribute would return the attribute's *current* value, rather than the *candidate* value that the client is attempting to set.

### **Example 8–2 Simple Attribute-Level Method Validator**

```
public boolean validateOrderShippedDate(Date data) {
    if (data != null && data.compareTo(getFirstDayOfCurrentMonth()) <= 0) {
        return false;
    }
    return true;
}
```

---

---

**Note:** The return value of the `compareTo()` method is zero (0) if the two dates are equal, negative one (-1) if the first date is less than the second, or positive one (1) if the first date is greater than the second.

---

---

### 8.2.3 How to Create an Entity-Level Method Validator

**To create an entity-level method validator:**

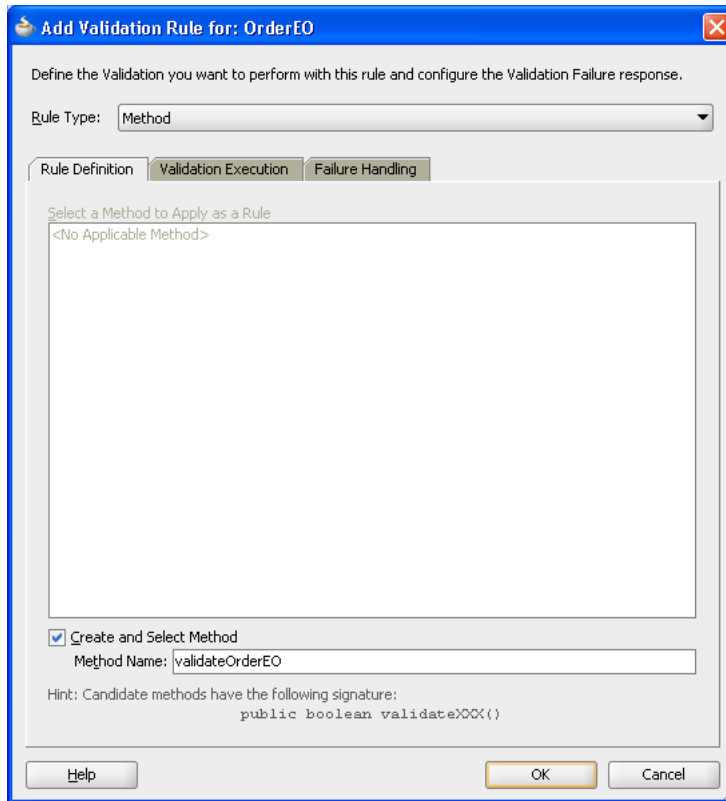

1. In the Application Navigator, double-click the desired entity object.
2. In the overview editor, click the **Java** navigation tab.

The Java page shows the Java generation options that are currently enabled for the entity object. If your entity object does not yet have a custom entity object class, then you must generate one before you can add a Method validator. To generate the custom Java class, click the **Edit** icon, then select **Generate Entity Object Class**, and click **OK** to generate the `*.java` file.

3. Click the **Business Rules** navigation tab, and then select the **Entity** node.
4. Click the **New** icon to add a validation rule.
5. Select **Method** from the **Rule Type** dropdown list.

The Add Validation Rule dialog displays the expected method signature for an entity-level validation method. You have two choices:

- If you already have a method in your entity object's custom Java class of the appropriate signature, it will appear in the list and you can select it after deselecting the **Create and Select Method** checkbox.
  - If you leave the **Create and Select Method** checkbox selected (see [Figure 8-3](#)), you can enter any method name in the **Method Name** box that begins with the word `validate`. When you click **OK**, JDeveloper adds the method to your entity object's custom Java class with the appropriate signature.
6. Finally, supply the text of the error message for the default locale that the end user should see if this validation rule fails.

**Figure 8–3 Adding an Entity-Level Method Validator**

## 8.2.4 What Happens When You Create an Entity-Level Method Validator

When you add a new method validator, JDeveloper updates the XML component definition to reflect the new validation rule. If you asked to have the method created, the method is added to the entity object's custom Java class. [Example 8–3](#) illustrates a simple entity-level validation rule that ensures that the `OrderShippedDate` of an order comes after the `OrderDate`.

### **Example 8–3 Simple Entity-Level Method Validator**

```
public boolean validateOrderShippedDateAfterOrderDate() {
    Date orderShippedDate = getOrderShippedDate();
    Date orderDate = getOrderDate();
    if (orderShippedDate != null && orderShippedDate.compareTo(orderDate) < 0) {
        return false;
    }
    return true;
}
```

## 8.2.5 What You May Need to Know About Translating Validation Rule Error Messages

Like the locale-specific UI control hints for entity object attributes, the validation rule error messages are added to the entity object's component message bundle file. These entries in the message bundle represent the strings for the default locale for your application. To provide translated versions of the validation error messages, follow the same steps as for translating the UI control hints, as described in [Section 4.7, "Working with Resource Bundles."](#)

## 8.3 Assigning Programmatically Derived Attribute Values

When declarative defaulting falls short of your needs, you can perform programmatic defaulting in your entity object:

- When an entity row is first created
- When the entity row is first created or when refreshed to null values
- When the entity row is saved to the database
- When an entity attribute value is set

### 8.3.1 How to Provide Default Values for New Rows at Create Time

The `create()` method provides the entity object event you can handle to initialize default values the first time an entity row is created. [Example 8-4](#) shows the overridden create method of the `OrderEO` entity object in the `StoreFront` module of the Fusion Order Demo. It calls an attribute setter methods to populate the `OrderDate` attribute in a new order entity row.

You can also define default values using a Groovy expression. For more information, see [Section 4.10.6, "How to Define a Static Default Value."](#)

#### **Example 8-4 Programmatically Defaulting Attribute Values for New Rows**

```
// In OrderEOImpl.java in Fusion Order Demo
protected void create(AttributeList nameValuePair) {
    super.create(nameValuePair);
    this.setOrderDate(new Date());
}
```

---

**Note:** Calling the `setAttribute()` method inside the overridden `create()` method does not mark the new row as being changed by the user. These programmatically assigned defaults behave like declaratively assigned defaults.

---

#### 8.3.1.1 Choosing Between `create()` and `initDefaultExpressionAttributes()` Methods

You should override the `initDefaultExpressionAttributes()` method for programmatic defaulting logic that you want to fire both when the row is first created, and when it might be refreshed back to initialized status.

If an entity row has `New` status and you call the `refresh()` method on it, then the entity row is returned to an `Initialized` status if you do not supply either the `REFRESH_REMOVE_NEW_ROWS` or `REFRESH_FORGET_NEW_ROWS` flag. As part of this process, the entity object's `initDefaultExpressionAttributes()` method is invoked, but not its `create()` method again.

#### 8.3.1.2 Eagerly Defaulting an Attribute Value from a Database Sequence

[Section 4.10.9, "How to Synchronize with Trigger-Assigned Values,"](#) explains how to use the `DBSequence` type for primary key attributes whose values need to be populated by a database sequence at `commit` time. Sometimes you may want to eagerly allocate a sequence number at entity row creation time so that the user can see its value and so that this value does not change when the data is saved. To accomplish this, use the `SequenceImpl` helper class in the `oracle.jbo.server` package in an overridden `create()` method as shown in [Example 8-5](#). It shows code from the

custom Java class of the WarehouseEO entity object in the StoreFront module of the Fusion Order Demo. After calling `super.create()`, it creates a new instance of the `SequenceImpl` object, passing the sequence name and the current transaction object. Then it calls the `setWarehouseId()` attribute setter method with the return value from `SequenceImpl`'s `getSequenceNumber()` method.

---

**Note:** For a metadata-driven alternative to this approach, see [Section 4.12.5, "Assigning the Primary Key Value Using an Oracle Sequence."](#)

---

**Example 8-5 Eagerly Defaulting an Attribute's Value from a Sequence at Create Time**

```
// In WarehouseEOImpl.java
import oracle.jbo.server.SequenceImpl;
// Default WarehouseId value from WAREHOUSE_SEQ sequence at entity row create time
protected void create(AttributeList attributeList) {
    super.create(attributeList);
    SequenceImpl sequence = new SequenceImpl("WAREHOUSE_SEQ",getDBTransaction());
    setWarehouseId(sequence.getSequenceNumber());
}
```

### 8.3.2 How to Assign Derived Values Before Saving

If you want to assign programmatic defaults for entity object attribute values before a row is saved, override the `prepareForDML()` method and call the appropriate attribute setter methods to populate the derived attribute values. To perform the assignment only during INSERT, UPDATE, or DELETE, you can compare the value of the `operation` parameter passed to this method against the integer constants `DML_INSERT`, `DML_UPDATE`, `DML_DELETE` respectively.

[Example 8-6](#) shows an overridden `prepareForDML()` method that assigns derived values.

**Example 8-6 Assigning Derived Values Before Saving Using PrepareForDML**

```
protected void prepareForDML(int operation, TransactionEvent e) {
    super.prepareForDML(operation, e);
    //Populate GL Date
    if (operation == DML_INSERT) {
        if (this.getGlDate() == null) {
            String glDateDefaultOption =
                (String)this.getInvoiceOption().getAttribute("DefaultGlDateBasis");
            if ("I".equals(glDateDefaultOption)) {
                setAttribute(GLDATE, this.getInvoiceDate());
            } else {
                setAttribute(GLDATE, this.getCurrentDBDate());
            }
        }
    }
}

//Populate Exchange Rate and Base Amount if null
if ((operation == DML_INSERT) || (operation == DML_UPDATE)) {
    BigDecimal defaultExchangeRate = new BigDecimal(1.5);
    if ("Y".equals(this.getInvoiceOption().getAttribute("UseForeignCurTrx"))) {
        if (!(this.getInvoiceCurrencyCode().equals(
            this.getLedger().getAttribute("CurrencyCode")))) {
            if (this.getExchangeDate() == null) {
```

```

        setAttribute(EXCHANGEDATE, this.getInvoiceDate());
    }
    if (this.getExchangeRateType() == null) {
        String defaultConvRateType =
            (String)this.getInvoiceOption().getAttribute("DefaultConvRateType");
        if (defaultConvRateType != null) {
            setAttribute(EXCHANGERATEATYPE, defaultConvRateType);
        } else {
            setAttribute(EXCHANGERATEATYPE, "User");
        }
    }
    if (this.getExchangeRate() == null) {
        setAttribute(EXCHANGERATE, defaultExchangeRate);
    }
    if ((this.getExchangeRate() != null) &&
        (this.getInvoiceAmount() != null)) {
        setAttribute(INVAMOUNTFUNCCURR,
            (this.getExchangeRate().multiply(this.getInvoiceAmount())));
    }
} else {
    setAttribute(EXCHANGEDATE, null);
    setAttribute(EXCHANGERATEATYPE, null);
    setAttribute(EXCHANGERATE, null);
    setAttribute(INVAMOUNTFUNCCURR, null);
}
}
}
}
}

```

### 8.3.3 How to Assign Derived Values When an Attribute Value Is Set

To assign derived attribute values whenever another attribute's value is set, add code to the latter attribute's setter method. [Example 8-7](#) shows the setter method for an `AssignedTo` attribute in an entity object.

#### **Example 8-7** Setting the Assigned Date Whenever the AssignedTo Attribute Changes

```

public void setAssignedTo(Number value) {
    setAttributeInternal(ASSIGNEDTO, value);
    setAssignedDate(getCurrentDateWithTime());
}

```

After the call to `setAttributeInternal()` to set the value of the `AssignedTo` attribute, it uses the setter method for the `AssignedDate` attribute to set its value to the current date and time.

---

**Note:** It is safe to add custom code to the generated attribute getter and setter methods as shown here. When JDeveloper modifies code in your class, it intelligently leaves your custom code in place.

---

## 8.4 Undoing Pending Changes to an Entity Using the Refresh Method

You can use the `refresh(int flag)` method on a row to refresh any pending changes it might have. The behavior of the `refresh()` method depends on the flag that you pass as a parameter. The three key flag values that control its behavior are the following constants in the `Row` interface:

- `REFRESH_WITH_DB_FORGET_CHANGES` forgets modifications made to the row in the current transaction, and the row's data is refreshed from the database. The latest data from the database replaces data in the row regardless of whether the row was modified or not.
- `REFRESH_WITH_DB_ONLY_IF_UNCHANGED` works just like `REFRESH_WITH_DB_FORGET_CHANGES`, but for *unmodified* rows. If a row was already modified by this transaction, the row is not refreshed.
- `REFRESH_UNDO_CHANGES` works the same as `REFRESH_WITH_DB_FORGET_CHANGES` for *unmodified* rows. For a modified row, this mode refreshes the row with attribute values at the beginning of this transaction. The row remains in a modified state if it had been previously posted but not committed in the current transaction prior to performing the refresh operation.

### 8.4.1 How to Control What Happens to New Rows During a Refresh

By default, any entity rows with `New` status that you `refresh()` are reverted back to blank rows in the `Initialized` state. Declarative defaults are reset, as well as programmatic defaults coded in the `initDefaultExpressionAttributes()` method, but the entity object's `create()` method is not invoked during this blanking-out process.

You can change this default behavior by combining one of the flags in [Section 8.4](#) with one of the following two flags (using the bitwise-OR operator):

- `REFRESH_REMOVE_NEW_ROWS`, new rows are removed during refresh.
- `REFRESH_FORGET_NEW_ROWS`, new rows are marked `Dead`.

### 8.4.2 How to Cascade Refresh to Composed Children Entity Rows

You can cause a `refresh()` operation to cascade to composed child entity rows by combining the `REFRESH_CONTAINEES` flag (using the bitwise-OR operator) with any of the valid flag combinations described in [Section 8.4](#) and [Section 8.4.1](#). This causes the entity to invoke `refresh()` using the same mode on any composed child entities it contains.

## 8.5 Using View Objects for Validation

When your business logic requires performing SQL queries, the natural choice is to use a view object to perform that task. Keep in mind that the SQL statements you execute for validation will "see" pending changes in the entity cache only if they are entity-based view objects. Read-only view objects will only retrieve data that has been posted to the database.

### 8.5.1 How to Use View Accessors for Validation Against View Objects

Since entity objects are designed to be reused in any application scenario, they should not depend *directly* on a view object instance in any specific application module's data model. Doing so would prevent them from being reused in other application modules, which is highly undesirable.

Instead, you should use a view accessor to validate against a view object. For more information, see [Section 10.4.1, "How to Create a View Accessor for an Entity Object or View Object."](#)

Using a view accessor, your validation code can access the view object and set bind variables, as shown in [Example 8–8](#).

**Example 8–8 Using a Validation View Object in a Method Validator**

```
// Sample entity-level validation method
public boolean validateSomethingUsingViewAccessor() {
    RowSet rs = getMyValidationVO();
    rs.setNamedBindParameter("Name1", value1);
    rs.setNamedBindParameter("Name2", value2);
    rs.executeQuery();
    if ( /* some condition */ ) {
        /*
         * code here returns true if the validation succeeds
         */
    }
    return false;
}
```

**Best Practice:** Any time you access a row set programmatically, you should consider creating a secondary iterator for the row set. This ensures that you will not disturb the current row set of the default row set iterator that may be utilized when you expose your view objects as data controls to the user interface project. You can call `createRowSetIterator()` on the row set you are working with to create a secondary named row set iterator. When you are through with programmatic iteration, your code should call `closeRowSetIterator()` on the row set to remove the secondary iterator from memory.

As the sample code suggests, view objects used for validation typically have one or more named bind variables in them. In this example, the bind variables are set using the `setNamedBindParameter()` method. However, you can also set these variables declaratively in JDeveloper using Groovy expressions in the view accessor definition page.

Depending on the kind of data your view object retrieves, the `/* some condition */` expression in the example will look different. For example, if your view object's SQL query is selecting a `COUNT()` or some other aggregate, the condition will typically use the `rs.first()` method to access the first row, then use the `getAttribute()` method to access the attribute value to see what the database returned for the count.

If the validation succeeds or fails based on whether the query has returned zero or one row, the condition might simply test whether `rs.first()` returns `null` or not. If `rs.first()` returns `null`, there is no "first" row. In other words, the query retrieved no rows. In other cases, you may be iterating over one or more query results retrieved by the view object to determine whether the validation succeeds or fails.

## 8.5.2 How to Validate Conditions Related to All Entities of a Given Type

The `beforeCommit()` method is invoked on *each* entity row in the pending changes list after the changes have been posted to the database, but before they are committed. This can be a useful method in which to execute view object based validations that must assert some rule over all entity rows of a given type.

---

---

**Note:** You can also do this declaratively using a transaction-level validator (see [Section 7.6.4, "How to Set Transaction-Level Validation"](#)).

---

---

If your `beforeCommit()` logic can throw a `ValidationException`, you must set the `job.txn.handleafterpostexc` property to `true` in your configuration to have the framework automatically handle rolling back the in-memory state of the other entity objects that may have already successfully posted to the database (but not yet been committed) during the current commit cycle.

### 8.5.3 What You May Need to Know About Row Set Access with View Accessors

If your entity object or view object business logic iterates over its own view accessor row set, and that view accessor is not also used by a model-defined List of Values, then there is no need to use a secondary row set iterator. For example, if an entity object has a view accessor named `AirportValidationVA` for a view object that takes one named bind parameter, it can iterate its own view accessor row set using either Groovy script or Java. [Example 8-9](#) show a Groovy script that iterates over a view accessor row set.

#### **Example 8-9 Using a View Accessor in Groovy Script**

```
AirportValidationVA.setNamedWhereClauseParam("VarTla", newValue)
AirportValidationVA.executeQuery();
return AirportValidationVA.first() != null;
```

[Example 8-10](#) shows a Java method validator that iterates over a view accessor row set.

#### **Example 8-10 Using a View Accessor in a Method Validator**

```
public boolean validateJob(String job) {
    getAirportValidationVA().setNamedWhereClauseParam("VarTla", job);
    getAirportValidationVA().executeQuery();
    return getAirportValidationVA().first() != null;
}
```

## 8.6 Accessing Related Entity Rows Using Association Accessors

To access information from related entity objects, you use an association accessor method in your entity object's custom Java class. By calling the accessor method, you can easily access any related entity row — or set of entity rows — depending on the cardinality of the association.

### 8.6.1 How to Access Related Entity Rows

You can use an association accessor to access related entity rows. [Example 8-11](#) shows code from the `ControllingPostingOrder` project in the `AdvancedEntityExamples` module of the Fusion Order Demo that shows the overridden `postChanges()` method in the `ProductsBase` entity object's custom Java class. It uses the `getSupplier()` association accessor to retrieve the related supplier for the product.

**Example 8–11 Accessing a Parent Entity Row In a Create Method**

```
// In ProductBaseImpl.java in the ControllingPostingOrder project
// of the Fusion Order Demo Advanced Entity Examples
@Override
public void postChanges(TransactionEvent transactionEvent) {
    /* If current entity is new or modified */
    if (getPostState() == STATUS_NEW || getPostState() == STATUS_MODIFIED) {
        /* Get the associated supplier for the product */
        SuppliersImpl supplier = getSupplier();
        /* If there is an associated product */
        if (supplier != null) {
            /* And if it's post-status is NEW */
            if (supplier.getPostState() == STATUS_NEW) {
                /* Post the supplier first, before posting this entity */
                supplier.postChanges(transactionEvent);
            }
        }
    }
    super.postChanges(transactionEvent);
}
```

**8.6.2 How to Access Related Entity Row Sets**

If the cardinality of the association is such that multiple rows are returned, you can use the association accessor to return sets of entity rows.

[Example 8–12](#) illustrates the code for the overridden `postChanges()` method in the `Suppliers` entity object's custom Java class. It shows the use of the `getProductsBase()` association accessor to retrieve the `RowSet` object of `ProductsBase` rows in order to update the `SupplierId` attribute in each row using the `setSupplierId()` association accessor.

**Example 8–12 Accessing a Related Entity Row Set Using an Association Accessor**

```
// In SuppliersImpl.java in the ControllingPostingOrder project
// of the Fusion Order Demo Advanced Entity Examples
RowSet newProductsBeforePost = null;
@Override
public void postChanges(TransactionEvent transactionEvent) {
    /* Only update references if Supplier is new */
    if (getPostState() == STATUS_NEW) {
        /*
         * Get a rowset of products related to this new supplier before calling super
         */
        newProductsBeforePost = (RowSet)getProductsBase();
    }
    super.postChanges(transactionEvent);
}

...

protected void refreshFKInNewContainees() {
    if (newProductsBeforePost != null) {
        Number newSupplierId = getSupplierId().getSequenceNumber();
        /*
         * Process the rowset of suppliers that referenced the new product prior
         * to posting, and update their ProdId attribute to reflect the refreshed
         * ProdId value that was assigned by a database sequence during posting.
         */
    }
}
```

```
while (newProductsBeforePost.hasNext()){
    ProductsBaseImpl product = (ProductsBaseImpl)newProductsBeforePost.next();
    product.setSupplierId(newSupplierId);
}
closeNewProductRowSet();
}
```

## 8.7 Referencing Information About the Authenticated User

If you have run the Configure ADF Security wizard on your application to enable the ADF authentication servlet to support user login and logout, the `oracle.jbo.server.SessionImpl` object provides methods you can use to get information about the name of the authenticated user and about the roles of which they are a member. This is the implementation class for the `oracle.jbo.Session` interface that clients can access.

For information about how to access information about the authenticated user, see [Section 30.11.4.3, "How to Determine the Current User Name, Tenant Name, or Tenant ID"](#) and [Section 30.11.4.4, "How to Determine Membership of a Java EE Security Role"](#).

For more information about security features in Oracle Fusion Web Applications, read [Chapter 30, "Enabling ADF Security in a Fusion Web Application."](#)

## 8.8 Accessing Original Attribute Values

If an entity attribute's value has been changed in the current transaction, when you call the attribute getter method for it you will get the pending changed value. Sometimes you want to get the original value before it was changed. Using the `getPostedAttribute()` method, your entity object business logic can consult the original value for any attribute as it was read from the database before the entity row was modified. This method takes the attribute *index* as an argument, so pass the appropriate generated attribute index enums that JDeveloper maintains for you.

## 8.9 Storing Information About the Current User Session

If you need to store information related to the current user session in a way that entity object business logic can reference, you can use the user data hash table provided by the `Session` object.

### 8.9.1 How to Store Information About the Current User Session

When a new user accesses an application module for the first time, the `prepareSession()` method is called. As shown in [Example 8-13](#), the application module overrides `prepareSession()` to retrieve information about the authenticated user by calling a `retrieveUserInfoForAuthenticatedUser()` method on the view object instance. Then, it calls the `setUserIdIntoUserDataHashtable()` helper method to save the user's numerical ID into the user data hash table.

**Example 8-13** *Overriding `prepareSession()` to Query User Information*

```
// In the application module
protected void prepareSession(Session session) {
    super.prepareSession(session);
    /*
```

```

    * Query the correct row in the VO based on the currently logged-in
    * user, using a custom method on the view object component
    */
    getLoggedInUser().retrieveUserInfoForAuthenticatedUser();
    setUserIdIntoUserDataHashtable();
}

```

[Example 8-14](#) shows the code for the view object's `retrieveUserInfoForAuthenticatedUser()` method. It sets its own `EmailAddress` bind variable to the name of the authenticated user from the session and then calls `executeQuery()` to retrieve the additional user information from the `USERS` table.

**Example 8-14 Accessing Authenticated User Name to Retrieve Additional User Details**

```

// In the view object's custom Java class
public void retrieveUserInfoForAuthenticatedUser() {
    SessionImpl session = (SessionImpl) getDBTransaction().getSession();
    setEmailAddress(session.getUserPrincipalName());
    executeQuery();
    first();
}

```

One of the pieces of information about the authenticated user that the view object retrieves is the user's numerical ID number, which that method returns as its result. For example, the user `sking` has the numeric `UserId` of 300.

[Example 8-15](#) shows the `setUserIdIntoUserDataHashtable()` helper method — used by the `prepareSession()` code in [Example 8-13](#) — that stores this numerical user ID in the user data hash table, using the key provided by the string constant `CURRENT_USER_ID`.

**Example 8-15 Setting Information into the UserData Hashtable for Access By Entity Objects**

```

// In the application module
private void setUserIdIntoUserDataHashtable() {
    Integer userid = getUserIdForLoggedInUser();
    Hashtable userdata = getDBTransaction().getSession().getUserData();
    userdata.put(CURRENT_USER_ID, userid);
}

```

The corresponding entity objects in this example can have an overridden `create()` method that references this numerical user ID using a helper method like the one in [Example 8-16](#) to set the `CreatedBy` attribute programmatically to the value of the currently authenticated user's numerical user ID.

**Example 8-16 Referencing the Current User ID in a Helper Method**

```

protected Number getCurrentUserId() {
    Hashtable userdata = getDBTransaction().getSession().getUserData();
    Integer userId = (Integer) userdata.get(CURRENT_USER_ID);
    return userdata != null ? Utils.intToNumber(userId) : null;
}

```

## 8.9.2 How to Use Groovy to Access Information About the Current User Session

The top-level `adf` object allows you access to objects that the framework makes available to Groovy script. The `adf.userSession` object returns a reference to the ADF Business Components user session, which you can use to reference values in the `userData` hash map that is part of the session.

[Example 8-17](#) shows the Groovy script you would use to reference a `userData` hash map key named `MyKey`.

### **Example 8-17 Accessing the Current User Session Using Groovy Script**

```
adf.userSession.userData.MyKey
```

## 8.10 Accessing the Current Date and Time

You might find it useful to reference the current date and time in your entity object business logic. You can reference the current date or current date and time using the following Groovy script expressions:

- `adf.currentDate` — returns the current date (time truncated)
- `adf.currentDateTime` — returns the current date and time

For more information about using Groovy script in your entity object business logic, see [Section 3.6, "Overview of Groovy Support."](#)

## 8.11 Sending Notifications Upon a Successful Commit

The `afterCommit()` method is invoked on *each* entity row that was in the pending changes list and got successfully saved to the database. You can use this method to send a notification on a commit.

A better way to send notifications upon a successful commit is by declaring a business event. For more information on how to create a business event, see [Section 4.11, "Creating Business Events."](#)

## 8.12 Conditionally Preventing an Entity Row from Being Removed

Before an entity row is removed, the `remove()` method is invoked on an entity row. You can throw a `JboException` in the `remove()` method to prevent a row from being removed if the appropriate conditions are not met.

For example, you can add a test in the `remove()` method that determines the state of the entity object and allows the removal only if it is a new record. [Example 8-18](#) demonstrates this technique.

---

---

**Note:** This example is in the `AddressesImpl.java` file in the `ConditionalDelete` project of the `DevGuideExamples` workspace in the `StandaloneExamples` module of the Fusion Order Demo application.

---

---

### **Example 8-18 Overriding the remove() Method to Verify Entity Status Before Removal**

```
// In the Addresses entity object custom Java class
private boolean isDeleteAllowed() {
    byte s = this.getEntityState();
```

```

    return s==STATUS_NEW;
}

/**
 * Add entity remove logic in this method.
 */
public void remove() {
    if (isDeleteAllowed())
        super.remove();
    else
        throw new JboException("Delete not allowed in this view");
}

```

---

---

**Note:** The entity object offers declarative prevention of deleting a master entity row that has existing, composed children rows. You configure this option on the Relationship page of the overview editor for the association.

---

---

## 8.13 Determining Conditional Updatability for Attributes

You can override the `isAttributeUpdateable()` method in your entity object class to programmatically determine whether a given attribute is updatable or not at runtime based on appropriate conditions.

[Example 8–19](#) shows how an entity object can override the `isAttributeUpdateable()` method to enforce that its `PersonTypeCode` attribute is updatable only if the current authenticated user is a staff member. Notice that when the entity object fires this method, it passes in the integer attribute index whose updatability is being considered.

You can implement conditional updatability logic for a particular attribute inside an `if` or `switch` statement based on the attribute index. Here `PERSONTYPECODE` is referencing the integer attribute index enums that `JDeveloper` maintains in your entity object custom Java class.

### **Example 8–19** Conditionally Determining an Attribute's Updatability at Runtime

```

// In the entity object custom Java class
public boolean isAttributeUpdateable(int index) {
    if (index == PERSONTYPECODE) {
        if (!currentUserIsStaffMember()) {
            return super.isAttributeUpdateable(index);
        }
        return CUSTOMER_TYPE.equals(getPersonTypeCode()) ? false : true;
    }
    return super.isAttributeUpdateable(index);
}

```

---

---

**Note:** Entity-based view objects inherit this conditional updatability as they do everything else encapsulated in your entity objects. Should you need to implement this type of conditional updatability logic in a way that is specific to a transient view object attribute, or to enforce some condition that involves data from multiple entity objects participating in the view object, you can override this same method in a view object's view row class to achieve the desired result.

# Implementing Business Services with Application Modules

This chapter describes how to create ADF application modules that encapsulate the data model of an Oracle ADF application derived from a JDBC data source. This chapter also describes how to combine business service methods with that data model to implement a complete business service.

This chapter includes the following sections:

- Section 9.1, "Introduction to Application Modules"
- Section 9.2, "Creating and Modifying an Application Module"
- Section 9.3, "Configuring Your Application Module Database Connection"
- Section 9.4, "Defining Nested Application Modules"
- Section 9.5, "Creating an Application Module Diagram for Your Business Service"
- Section 9.6, "Supporting Multipage Units of Work"
- Section 9.7, "Customizing an Application Module with Service Methods"
- Section 9.8, "Customizing Application Module Message Strings"
- Section 9.9, "Publishing Custom Service Methods to UI Clients"
- Section 9.10, "Working Programmatically with an Application Module's Client Interface"
- Section 9.11, "Overriding Built-in Framework Methods"

## 9.1 Introduction to Application Modules

An *application module* is an ADF Business Components component that encapsulates the business service methods and UI-aware data model for a logical unit of work related to an end-user task.

In the early phases of application development, architects and designers often use UML use case techniques, as well as ADF task flows, to create a high-level description of the application's planned end-user functionalities. Each high-level, end-user use case identified during the design phase typically depends on:

- The domain business objects involved. To answer the question, "What core business data is relevant to the use case?"
- The user-oriented view of business data required. To answer the questions, "What subset of columns, what filtered set of rows, sorted in what way, grouped in what way, is needed to support the use case?"

The identified domain objects involved in each use case help you identify the required entity objects from your business domain layer. The user-oriented view of the required business data helps to define the right SQL queries captured as view objects and to retrieve the data in the exact way needed by the end user. For best performance, this includes retrieving the minimum required details necessary to support the use case. In addition to leveraging view object queries and view criteria to shape the data, you've learned how to use view links to set up natural master-detail hierarchies in your data model to match exactly the kind of end-user experience you want to offer the user to accomplish the use case.

The application module is the "work unit" container that includes instances of the reusable view objects required for the use case in question. These view object instances are related through metadata to the underlying entity objects in your reusable business domain layer where the end-user use cases determine the information being presented or modified.

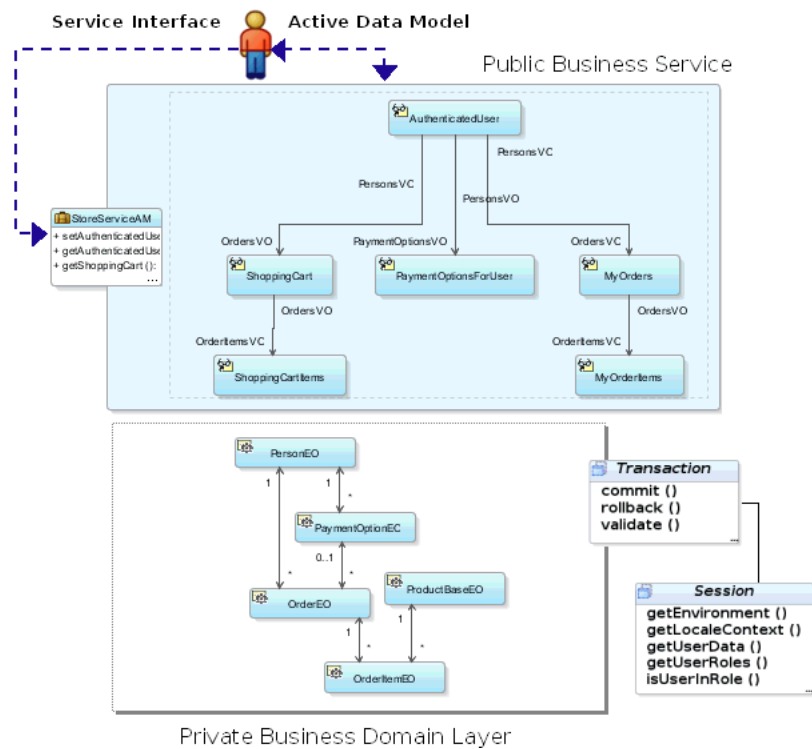

This chapter illustrates the following concepts illustrated in [Figure 9-1](#), and more:

- You expose instances of view objects in an application module to define its data model.
- You write service methods to encapsulate task-level business logic.
- You expose selected methods on the client interface for UI clients to call.
- You expose selected methods on the service interface for programmatic use in application integration scenarios.

Starting in release 11.1.1.7.0, the best practice for exposing service methods for use by other applications is to create web services, as described in [Chapter 11, "Integrating Service-Enabled Application Modules."](#) In previous releases, JDeveloper supported exposing service methods using an EJB Session Bean through the overview editor for application modules. This design time support for creating EJB Session Beans from ADF Business Component application modules has been retained for backward compatibility only and is a configurable option that you must enable in the ADF Business Components-Application Modules page of the Preferences dialog.

- You use application module instances from a pool during a logical transaction that can span multiple web pages or views.
- Your application module works with a `Transaction` object that acquires a database connection and coordinates saving or rolling back changes made to entity objects.
- The related `Session` object provides runtime information about the current application user.

**Figure 9–1 Application Module Is a Business Service Component Encapsulating a Unit of Work**

## 9.2 Creating and Modifying an Application Module

In a large application, you typically create one application module to support each coarse-grained end-user task. In a smaller-sized application, you may decide that creating a single application module is adequate to handle the needs of the complete set of application functionality. [Section 9.4, "Defining Nested Application Modules"](#) provides additional guidance on this subject.

### 9.2.1 How to Create an Application Module

Any view object you create is a reusable component that can be used in the context of one or more application modules. Each view object performs the query it encapsulates in the context of that application module's transaction. The set of view object instances used by an application module defines its *data model*, in other words, the set of data that a client can display and manipulate through a user interface.

To add an application module to your existing ADF Business Components project, use the Create Application Module wizard, which is available in the New Gallery.

#### Before you begin:

Create the desired view objects as described in [Section 5.2.1, "How to Create an Entity-Based View Object,"](#) and [Section 5.2.3, "How to Create an Expert Mode, Read-Only View Object."](#)

#### To manually create an application module:

1. In the Application Navigator, right-click the project in which you want to create the application module and choose **New**.

2. In the New Gallery, expand **Business Tier**, select **ADF Business Components** and then **Application Module**, and click **OK**.
3. In the Create Application Module wizard, on the Name page, provide a package name and an application module name. Click **Next**.

---

**Note:** In Fusion web applications, the reserved words `data`, `bindings`, `security`, and `adfContext` must not be used to name your application module. Also, avoid using the "\_" (underscore) at the beginning of the name. For more information, see [Section 9.2.5, "How to Edit an Existing Application Module."](#)

---

4. On the Data Model page, include instances of the view objects you have previously defined and edit the view object instance names to be exactly what you want clients to see in the Data Controls panel. Then click **Next**.
5. On the Java page, you can optionally generate the Java files that allow you to programmatically customize the behavior of the application module or to expose methods on the application module's client interface that can be called by clients. To generate an XML-only application module component, leave the fields unselected and click **Finish**.

Initially, you may want to generate only the application module XML definition component. After you complete the wizard, you can subsequently use the overview editor to generate the application module class files when you require programmatic access. For details about the programmatic use of the application module, see [Section 9.7, "Customizing an Application Module with Service Methods."](#)

For more step by step details, see [Section 9.2.3.2, "Adding Master-Detail View Object Instances to an Application Module."](#)

## 9.2.2 What Happens When You Create an Application Module

When you create an application module, JDeveloper creates the XML component definition file that represents its declarative settings and saves it in the directory that corresponds to the name of its package. For example, given an application module named `StoreServiceAM` in the `storefront.model` package, the XML file created will be `./storefront/model/StoreServiceAM.xml` under the project's source path. This XML file contains the information needed at runtime to re-create the view object instances in the application module's data model.

If you are curious to view its contents, you can see the XML file for the application module by double-clicking the application module node in the Application Navigator to open the overview editor. In the editor window, click the **Source** tab to view the XML so that you can inspect it. The Structure window shows the structure of the XML file.

When you create business components, JDeveloper automatically creates a data control that contains all the functionality of the application module. Data controls are an ADF Model abstraction layer that provides supplemental metadata to describe the application module's operations and data collections (row sets of view object instances), including information about the attributes, methods, and types involved. Developers can then use the representation of the data control displayed in JDeveloper's Data Controls panel to create UI components that are automatically bound to the application module. At runtime, the ADF Model layer reads the metadata describing the data controls and bindings from appropriate XML files and

implements the two-way connection between the user interface and the business service.

For example, the `StoreServiceAMDataControl` application module implements the business service layer of the `StoreFront` module application. Its data model contains numerous view object instances, including several master-detail hierarchies. The view layer of the Fusion Order Demo application consists of JSF pages whose UI components are bound to data from the view object instances in the `StoreServiceAMDataControl`'s data model, and to built-in operations and service methods on its client interface. For details about how the Data Controls panel exposes the application module to UI developers, see [Section 12.2, "Exposing Application Modules with ADF Data Controls."](#)

## 9.2.3 How to Add a View Object Instance to an Application Module

You can add a view object instance to an application module as you create the application module with the Create Application Module wizard, or you can add it later to an already created application module.

For information about using the Create Application Module wizard, see [Section 9.2.1, "How to Create an Application Module."](#)

### 9.2.3.1 Adding a View Object Instance to an Existing Application Module

You can add a view object instance to an application module that you have already created. To add a view object instance to an existing application module, and optionally, customize the view object instance, use the Data Model page of the overview editor for the application module.

#### Before you begin:

Create the desired view objects as described in [Section 5.2.1, "How to Create an Entity-Based View Object,"](#) and [Section 5.2.3, "How to Create an Expert Mode, Read-Only View Object."](#)

#### To add a view object instance to an existing application module:

1. In the Application Navigator, double-click the application module.
2. In the overview editor, click the **Data Model** navigation tab.
3. On the Data Model Components page, expand the **View Object Instances** section and, in the **Available View Objects** list, select the view instance you want to add.

The **New View Instance** field below the list shows the name that will be used to identify the next instance of that view object that you add to the data model.

4. To change the name before adding it, enter a different name in the **New View Instance** field.
5. With the desired view object selected, shuttle the view object to the **Data Model** list.

[Figure 9–2](#) shows the view object `AddressVO` has been renamed to `Address` before it was shuttled to the **Data Model** list.

**Figure 9–2 Data Model Displays Added View Object Instances**

**Data Model Components**

Select a view object from the tree of available view objects, select the instance or application module to be its parent in the data model tree, and click '>' to create a named instance of the view object in the data model.

**View Object Instances**

The data model contains a list of view object and view link instances, displaying master-detail relationships.

**9.2.3.2 Adding Master-Detail View Object Instances to an Application Module**

You can use the data model that the application module overview editor displays to create a hierarchy of view instances, based on existing view links that your project defines. If you have defined view links that establish more than one level of master-detail hierarchy, then you can proceed to create as many levels of master-detail view instances as your application supports.

**Before you begin:**

Create hierarchical relationships between view objects as described in [Section 5.6, "Working with Multiple Tables in a Master-Detail Hierarchy."](#)

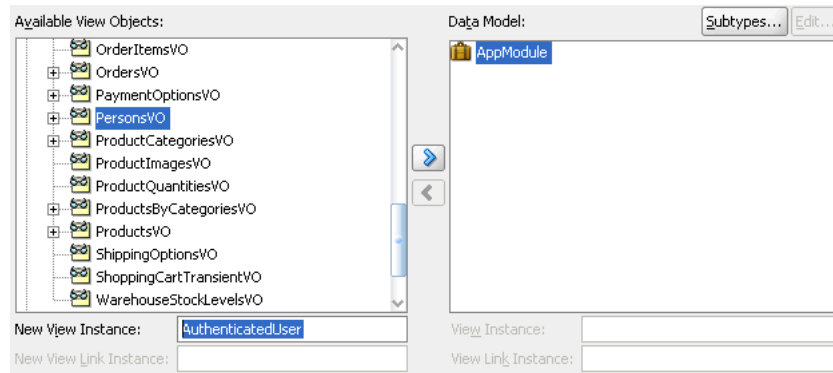

**To add master-detail view object instances to a data model:**

1. In the Application Navigator, double-click the application module.
2. In the overview editor, click the **Data Model** navigation tab.
3. On the Data Model Components page, expand the **View Object Instances** section and, in the **Data Model** list, select the instance of the view object that you want to be the actively coordinating master.

The master view object will appear with a plus sign in the list indicating the available view links for this view object. The view link must exist to define a master-detail hierarchy.

[Figure 9–3](#) shows `PersonsVO` selected and renamed `AuthenticatedUser` in the **New View Instance** field.

**Figure 9–3 Master View Object Selected**

4. Shuttle the selected master view object to the **Data Model** list.

Figure 9–4 shows the newly created master view instance `AuthenticatedUser` in the **Data Model** list.

**Figure 9–4 Master View Instance Created**

5. In the **Data Model** list, leave the newly created master view instance selected so that it appears highlighted. This will be the target of the detail view instance you will add. Then locate and select the detail view object beneath the master view object in the **Available View Objects** list.

Figure 9–5 shows the detail `OrdersVO` indented beneath master `PersonsVO` with the name `OrdersVO` via `PersonsToOrders`. The name identifies the view link `PersonsToOrders`, which defines the master-detail hierarchy between `PersonsVO` and `OrdersVO`. Notice also that the `OrdersVO` will have the view instance name `MyOrders` when added to the data model.

**Figure 9–5 Detail View Object Selected**

- To add the detail instance to the previously added master instance, shuttle the detail view object to the **Data Model** list below the selected master view instance.

Figure 9–6 shows the newly created detail view instance `MyOrders` as a detail of the `AuthenticatedUser` in the data model.

**Figure 9–6 Master View Instance Created**

- To add another level of hierarchy, repeat Step 3 through Step 6, but select the newly added detail in the **Data Model** list, then shuttle over the new detail, which itself has a master-detail relationship with the previously added detail instance.

Figure 9–7 shows the **Data Model** list with instance `AuthenticatedUser` (renamed from `PersonsVO`) as the master of `MyOrders` (renamed from `OrdersVO via PersonsToOrders`), which is, in turn, a master for `MyOrderItems` (renamed from `OrderItemsVO via OrdersToOrderItems`).

**Figure 9–7 Master-Detail-Detail Hierarchy Created**

### 9.2.3.3 Customizing a View Object Instance that You Add to an Application Module

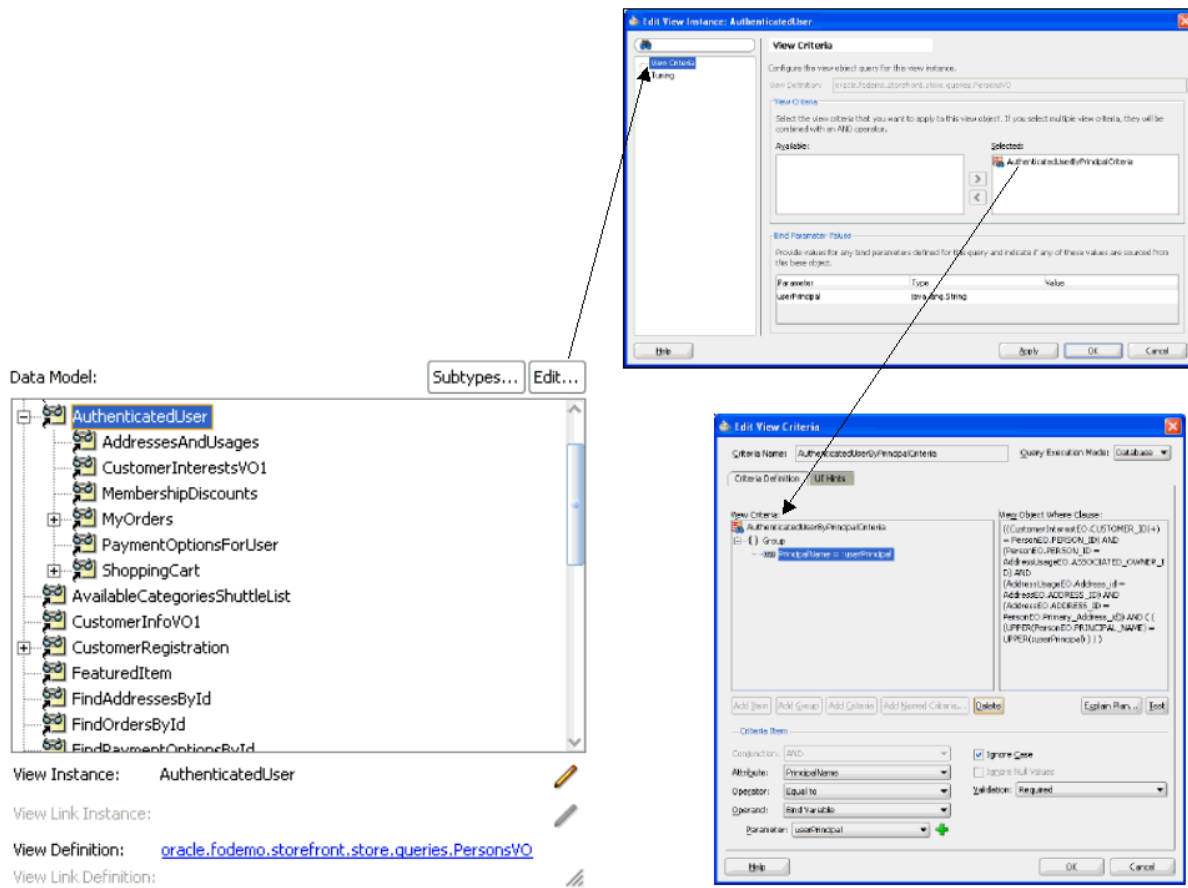

You can optionally customize the view object instance by using the Data Model Components page of the overview editor for the application module. For example, you might want to apply a filter to set the controlling attribute for a master-detail view object relationship.

#### To customize a view object instance that you add to an existing application module:

1. In the Application Navigator, double-click the application module.
2. In the overview editor, click the **Data Model** navigation tab.
3. On the Data Model Components page, expand the **View Object Instances** section and, in the **Data Model** list, select the view object instance you want to customize and click the **Edit** button.
4. In the Edit View Instance dialog, perform any of the following steps, and then click **OK**.
  - In the **View Criteria** group box, select one or more view criteria that you want to apply to the view object instance. The view criteria will be appended as a **WHERE** clause to the instance query. For details about defining view criteria, see [Section 5.11, "Working with Named View Criteria."](#)
  - In the **Bind Parameters Values** group box, enter any values that you wish the instance to use when applying the defined view criteria. For more information about defining bind variables, see [Section 5.10, "Working with Bind Variables."](#)

[Figure 9–8](#) shows the Edit View Instance dialog opened for the `AuthenticatedUser` view usage with the `AuthenticatedUserByPrincipalCriteria` selected. No default value is supplied for the bind variable `userPrincipal` since the value will be provided at runtime through the evaluation of a Groovy expression that obtains the current user from the ADF security context. The data model for the project defines a master-detail relationship with the `PrincipalName` attribute as the controlling attribute for `AuthenticatedUser` view usage. The controlling attribute, when set by the view criteria filter, provides a way to retrieve only the view rows for the current user.

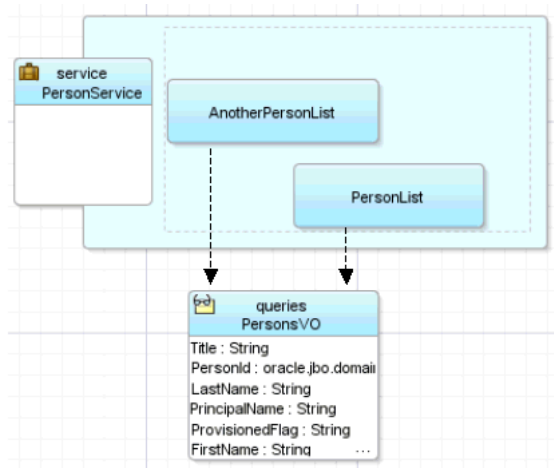

**Figure 9–8 Customized View Object Instance Using a View Criteria Filter**

**9.2.4 What Happens When You Add a View Object Instance to an Application Module**

You add instances of view object components to define the data model of an application module. Figure 9–9 shows a JDeveloper business components diagram of a `PersonService` application module.

**Figure 9–9 Application Module Containing Two Instances of a View Object Component**

The sample application module contains two instances of the `Persons` view object component, with member names of `PersonList` and `AnotherPersonList` to distinguish them. At runtime, both instances share the same `PersonsVO` view object component definition—this ensures that they have the same attribute structure and view object behavior—however, each might be used independently to retrieve data about different users. For example, some of the runtime properties, like an additional filtering `WHERE` clause or the value of a bind variable, might be different on the two distinct instances.

[Example 9–1](#) shows how the `PersonService` application module defines its member view object instances in its XML component definition file.

**Example 9–1 Member View Object Instances Defined in XML**

```
<AppModule Name="PersonService">
  <ViewUsage
    Name="PersonList"
    ViewObjectName="oracle.fodemo.storefront.store.queries.PersonsVO"/>
  <ViewUsage
    Name="AnotherPersonList"
    ViewObjectName="oracle.fodemo.storefront.store.queries.PersonsVO"/>
</AppModule>
```

## 9.2.5 How to Edit an Existing Application Module

After you've created a new application module, you can edit any of its settings by using the Edit Application Module dialog. To launch the editor, choose **Open** from the context menu in the Application Navigator, or double-click the application module. By visiting the different pages of the editor, you can adjust the data model to determine whether or not to reference nested application modules, specify Java generation settings, client interface methods, runtime instantiation behavior, and custom properties.

If you edit the name of your application module, choose a name that is not among the reserved words that Oracle Application Development Framework (Oracle ADF) defines. In particular, reserved words are not valid for a data control usage name which JDeveloper automatically assigns based on your application module's name. In Fusion web applications, these reserved words consist of `data`, `bindings`, `security`, and `adfContext`. For example, you should not name an application module `data`. If JDeveloper creates a data control usage with an ID that collides with a reserved word, your application may not reliably access your data control objects at runtime and may fail with a runtime `ClassCastException`.

Do not name the application module with an initial underscore (`_`) character to prevent a potential name collision with a wider list of reserved words that begin with the underscore.

Application module names that incorporate a reserved word into their name (or that change the case of the reserved word) will not conflict. For example, `Product_Data`, `Product_data`, or just `Data` are all valid application module names since the whole name does not match the reserved word `data`.

## 9.2.6 How to Change the Data Control Name Before You Begin Building Pages

By default, an application module will appear in the Data Controls panel as a data control named `AppModuleNameDataControl`. The user interface designer uses the Data Controls panel to bind data from the application module to the application's web

pages. For example, if the application module is named `StoreServiceAM`, the Data Controls panel will display the data control with the name `StoreServiceAMDataControl`. You can change the default data control name to make it shorter or to supply a more preferable name.

When the user interface designer works with the data control, they will see the data control name for your application module in the `DataBindings.cpx` file in the user interface project and in each data binding page definition XML file. In addition, you might refer to the data control name in code when needing to work programmatically with the application module service interface. For this reason, if you plan to change the name of your application module, do this change before you begin building your view layer.

For complete information about the application module data control, see [Chapter 12, "Using ADF Model in a Fusion Web Application."](#)

---

---

**Note:** If you decide to change the application module's data control name after you have already referenced it in one or more pages, you will need to open the page definition files and `DataBindings.cpx` file where it is referenced and update the old name to the new name manually.

---

---

**To change the application module data control name:**

1. In the Application Navigator, double-click the application module.
2. Open the Property Inspector and expand the **Other** section.
3. Enter your preferred data control name in the **Data Control Name** field.

## 9.2.7 What You May Need to Know About Application Module Granularity

A common question related to application modules is, "How big should my application module be?" In other words, "Should I build one big application module to contain the entire data model for my enterprise application, or many smaller application modules?" The answer depends on your situation.

In general, application modules should be as big as necessary to support the specific use case you have in mind for them to accomplish. They can be assembled from finer-grained application module components using a nesting feature, as described in [Section 9.4, "Defining Nested Application Modules."](#) Since a complex business application is not really a single use case, a complex business application implemented using Oracle ADF will typically not be just a single application module.

In actual practice, you may choose any granularity you wish. For example, in a small application with one main use case and a "backend" supporting use case, you could create two application modules. However, for the sake of simplicity you can combine both use cases, rather than create a second application module that contains just a couple of view objects.

## 9.2.8 What You May Need to Know About View Object Components and View Object Instances

While designing an application module, you use instances of a view object component to define its data model. Just as the user interface may contain two instances of a `Button` component with member names of `myButton` and `anotherButton` to distinguish them, your application module contains two instances of the `Persons`

view object component, with member names of `PersonList` and `AnotherPersonList` to distinguish them.

## 9.3 Configuring Your Application Module Database Connection

You configure your application module to use a database connection by identifying either a Java Database Connectivity (JDBC) URL or a JDBC data source name in the **Connection Type** section of the Edit Business Components Configuration dialog. A data source is a vendor-independent encapsulation of a database server connection.

You can use either the JDBC URL and the JDBC data source connection type to run the application module in any context where Java can run. Your application is not restricted to running inside a Java Enterprise Edition (Java EE) application server. For example, although the Business Component Browser is a standalone Java tool and does not run within the context of a Java EE application server, you can use either connection type to test your business components in the Business Component Browser.

The JDBC data source offers advantages that the JDBC URL connection type does not. When you define a connection type based on a data source, you reconfigure the data source without changing the deployed application. The data source is also centrally defined at the application server level, whereas JDBC URL connections are not. Although the default connection type for the application module is the JDBC URL, the Edit Business Components Configuration dialog lets you select among the existing application resources connections that appears in the Database Navigator.

### 9.3.1 How to Use a JDBC URL Connection Type

The default `YourAppModuleNameLocal` configuration uses a JDBC URL connection. It is based on the named connection definition set on the Business Components page of the Project Properties dialog for the project containing your application module. [Figure 9–10](#) shows what this section would look like in a configuration using a JDBC URL connection.

---

**Note:** If you are using a non-Oracle JDBC driver, make sure that you set the appropriate properties for the driver on the **Properties** page of the Edit Business Components Configuration dialog to avoid runtime exceptions.

For example, if you are using a Sybase JDBC driver, you must set the `jbo.sql92.LockTrailer` property (which is set to `FOR UPDATE` by default) to a value appropriate for the Sybase database. Not setting this property would generate a `SybSQLException` runtime exception.

---

**Figure 9–10 JDBC URL Connection Type Setting in Edit Business Components Configuration Dialog**

---

**Note:** See [Section 41.1.1.2, "Database Connection Pools,"](#) and [Section 41.2.9, "What You May Need to Know About Database Connection Pool Parameters"](#) for more information on how database connection pools are used and how you can tune them.

---

### 9.3.2 How to Use a JDBC Data Source Connection Type

The other type of connection you can use is a JDBC data source. You define a JDBC data source as part of your application server configuration information, and then the application module looks up the resource at runtime using a logical name. [Figure 9–11](#) shows what this section would look like in a configuration using a JDBC data source connection

**Figure 9–11** *JDBC DataSource Connection Type Setting in Edit Business Components Configuration Dialog*

[Example 9–2](#) shows the `<resource-ref>` tags in the `web.xml` file of a Fusion web application. These define two logical data sources named `jdbc/FODemoDS` and `jdbc/FODemoCoreDS`. The Edit Business Components Configuration dialog references this logical connection name after the prefix `java:comp/env` in the **JDBC Datasource Name** field. For example, the JDBC data source connection name for the same Fusion web application would display the value `java:comp/env/jdbc/FODemoDS` that you can select. Therefore the **JDBC Datasource Name** field is prepopulated with the JNDI name for all available application resources connection names.

**Example 9–2** *Logical Data Source Resource Names Defined in web.xml*

```
<!-- In web.xml -->
<resource-ref>
  <res-ref-name>jdbc/FODemoDS</res-ref-name>
  <res-type>javax.sql.DataSource</res-type>
  <res-auth>Container</res-auth>
</resource-ref>
<resource-ref>
  <res-ref-name>jdbc/FODemoCoreDS</res-ref-name>
  <res-type>javax.sql.DataSource</res-type>
  <res-auth>Container</res-auth>
</resource-ref>
```

You can directly edit the **JDBC Datasource Name** field when you want to specify a connection name for a global data source that is required to run the application on a target standalone application server. When you deploy to Oracle WebLogic Server, by default, the application-specific data source is not packaged with the application and Oracle WebLogic Server is configured to find a global data source named `jdbc/applicationConnectNameDS` using the look up `java:comp/env/jdbc/applicationConnectNameDS`. Therefore, by following this naming convention, you enable a single data source connection name to work correctly when running the application in JDeveloper using an application-specific data source or when running on the deployed standalone server using a global data source.

---

**Note:** When configuring the ADF application module to access a highly available database system, such as redundant databases or Oracle Real Application Clusters (Oracle RAC) as the backend, the data source must be container-defined. In this scenario, the application module will use a multi data source; however, from the standpoint of the application module configuration, the naming convention for the multi data source is the same as it is for a non-multi data source. This ensures that the correct data source will be used at runtime. For details about configuring multi data sources for high availability applications, see the *Oracle Fusion Middleware High Availability Guide*.

---

### 9.3.3 What Happens When You Create an Application Module Database Connection

When you select the database connection in the Edit Business Components Configuration dialog, JDeveloper updates the application module configuration file, `bc4j.xcfg` in the `./common` subdirectory relative to the application module's XML component definition. The file defines configurations for all of the application modules in a single Java package. For example, if you look at the `bc4j.xcfg` file in the `./classes/oracle/fodemo/storefront/store/service/common` directory of the Fusion Order Demo application's `StoreFront` project, you will see the three named configurations for its `StoreServiceAM` application module.

The configurations defined by the `bc4j.xcfg` file allow the Fusion web application to interact with specific, deployed application modules. In addition to the database connection details for the application module, the `bc4j.xcf` file contains metadata information about application module names and it contains the runtime parameters that are configured for the application module.

[Example 9-3](#) displays a sample `bc4j.xcfg` file from the Fusion Order Demo application. The configurations `StoreServiceAMLocal` and `StoreServiceAMLocalWeb` both reference a JDBC connection (named `FOD`) in the `JDBCName` attribute. The JDBC connection string for the JDBC connection is defined in the `Connections` folder of the Application Navigator and saved in the application's `connections.xml` file. The configuration `StoreFrontService` references a data source that will eventually be defined on the target application server. The `JDBCDataSource` attribute in the `StoreFrontService` configuration specifies the JNDI name for the application resources connection name in the form of `java:comp/env/jdbc/applicationConnectNameDS`, where `applicationConnectName` is the name of the application resources database connection defined in JDeveloper (in this case, `FOD`). This JNDI naming convention (with the application-specific name space `java:comp/env/jdbc/` and `DS` appended to the application resources database connection name) ensures that a deployed Fusion web application will run on Oracle WebLogic Server using the application's global data source and no changes will be required. The global data source is typically defined by the application server administrator using the Oracle WebLogic Server Administration Console.

#### **Example 9-3 Application Module Database Configurations in the `bc4j.xcfg` File**

```
<BC4JConfig version="11.1" xmlns="http://xmlns.oracle.com/bc4j/configuration">
  <AppModuleConfigBag ApplicationName="oracle.fodemo.storefront.store.service.StoreServiceAM">
    <AppModuleConfig
      DeployPlatform="LOCAL"
      JDBCName="FOD"
      jbo.project="StoreFrontService"
```

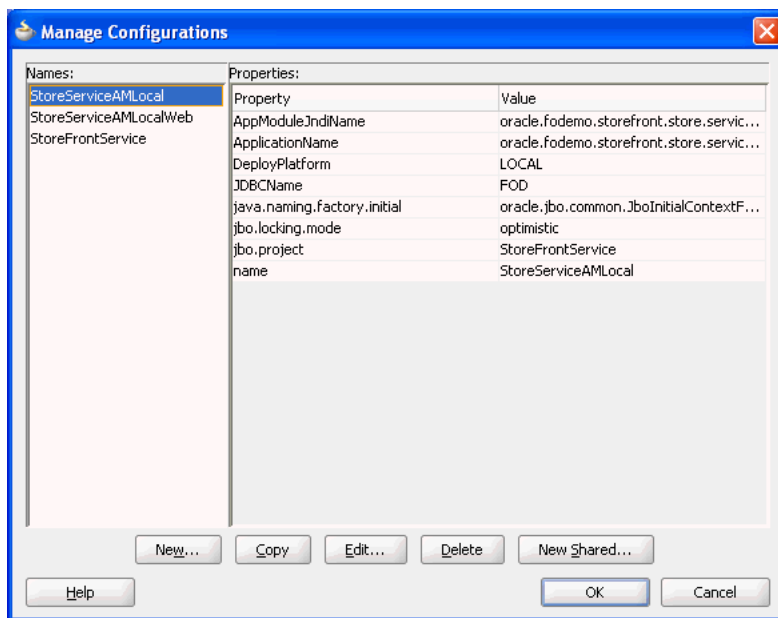

```

        name="StoreServiceAMLocal"
        ApplicationName="oracle.fodemo.storefront.store.service.StoreServiceAM">
        ...
    </AppModuleConfig>
    <AppModuleConfig
        DeployPlatform="LOCAL"
        JDBCName="FOD"
        jbo.project="StoreFrontService"
        name="StoreServiceAMLocalWeb"
        ApplicationName="oracle.fodemo.storefront.store.service.StoreServiceAM">
        ...
    </AppModuleConfig>
    <AppModuleConfig
        name="StoreFrontService"
        ApplicationName="oracle.fodemo.storefront.store.service.StoreServiceAM"
        jbo.project="StoreFrontService"
        ...
        <Custom JDBCDataSource="java:comp/env/jdbc/FODDS"/>
    </AppModuleConfig>
</AppModuleConfigBag>
</BC4JConfig>
    
```

### 9.3.4 How to Change Your Application Module's Runtime Configuration

In addition to creating the application module XML component definition, JDeveloper also adds a default configuration named `appModuleNameLocal` to the `bc4j.xcfg` file in the subdirectory named `common`, relative to the directory containing the application module XML component definition file. The `bc4j.xcfg` file does not appear in the Application Navigator. To view the default settings or to change the application module's runtime configuration settings, you can double-click a configuration in the overview editor to open the Manage Configurations dialog shown in Figure 9-12.

**Figure 9-12** *bc4j.xcfg File Configurations Displayed by Manage Configurations Dialog*

**To manage your application module's configuration:**

1. To display the Edit Business Components Configuration dialog, do one of the following:
  - In the Application Navigator, right-click the application module and choose **Configurations**. In the Manage Configurations dialog, select the default configuration named `appModuleNameLocal` and click **Edit**.
  - In the overview editor for the application module, click the **Configurations** navigation tab and double-click the default configuration named `appModuleNameLocal` in the displayed list.
2. In the Edit Business Components Configuration dialog, edit the desired runtime properties and click **OK** to save the changes for your configuration.

### 9.3.5 How to Change the Database Connection for Your Project

When you are developing applications, you may have a number of different users or schemas that you want to switch between. You can do this by changing the connection properties of the project that contains the business components. The selection you make will automatically update the connection name for each configuration that your project's `bc4j.xcfg` file defines.

**To change the connection used by your application module's configuration:**

1. In the Application Navigator, right-click the project that contains the application module and choose **Project Properties**.
2. In the Project Properties dialog, select **Business Components** to display the Business Components page, which shows details of the current database connection.
3. Click **Edit**, and in the Edit Database Connection dialog, make the appropriate changes.
4. Click **OK**.

## 9.4 Defining Nested Application Modules

Application modules support the ability to create software components that mimic the modularity of your use cases, for which your higher-level functions might reuse a "subfunction" that is common to several business work flows. You can implement this modularity by defining composite application modules that you assemble using instances of other application modules. This task is referred to as *application module nesting*. That is, an application module can contain (logically) one or more other application module instances, as well as view object instances. The outermost containing application module is referred to as the *root application module*.

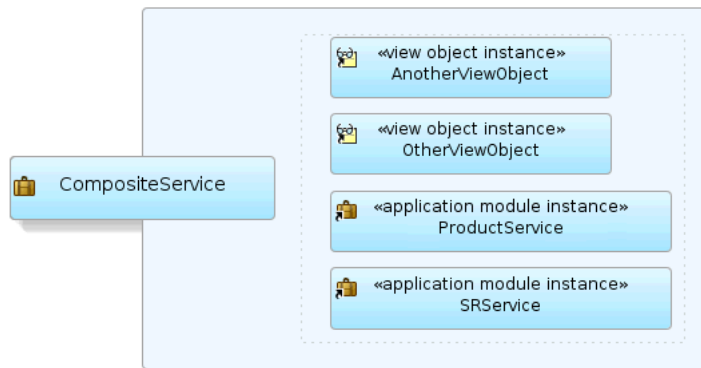

Declarative support for defining nested application modules is available through the overview editor for the application module, as shown in [Figure 9-14](#). The API for application modules also supports nesting of application modules at runtime.

When you nest an instance of one application module inside another, you aggregate not only the view object instances in its data model, but also any custom service methods it defines. This feature of "nesting," or reusing, an instance of one application module inside of another is an important design aspect of ADF Business Components for implementing larger-scale, real-world application systems.

Considering that an application module represents an end-user use case or work flow, you can build application modules that cater to the data required by some shared,

modular use case, and then reuse those application modules inside of other more complicated application modules that are designed to support a more complex use case. For example, imagine that after creating the application modules `StoreServiceAM` and `ProductService`, you later need to build an application that uses both of these services as an integral part of a new composite service application module. [Figure 9–13](#) illustrates what this composite service would look like in a JDeveloper business components diagram. Notice that an application module like `CompositeService` can contain a combination of view object instances and application module instances.

**Figure 9–13 Application Module Instances Can Be Reused to Assemble Composite Services**

### 9.4.1 How to Define a Nested Application Module

To specify a composite root application module that nests an instance of an existing application module, use the overview editor for the application module. All of the nested component instances (contained by the application module instance) share the same transaction and entity object caches as the root application module that reuses an instance of them.

**Tip:** If you leverage nested application modules in your application, be sure to read [Section 12.2.1.4, "How Nested Application Modules Appear in the Data Controls Panel"](#) to avoid common pitfalls when performing data binding involving them.

#### Before you begin:

Create the desired application modules as described in [Section 9.2.1, "How to Create an Application Module."](#)

#### To define a nested application module:

1. In the Application Navigator, double-click the root application module.
2. In overview editor, click the **Data Model** navigation tab.
3. In the Data Model Components page, expand the **Application Module Instances** section and, in the **Available** list, select the application module that you want to add to the data model.

The **New App Module Instance** field below the list shows the name that will be used to identify the nested application module that you add to the data model.

4. To change the name before adding it, type a different name in the **New App Module Instance** field.

5. With the desired application module selected, shuttle the application module to the **Selected** list.

Figure 9–14 shows the application module `LookupServiceAM` has been renamed to `NestedLookupServiceAM` before it was shuttled to the **Selected** list.

**Figure 9–14 Data Model Displays Added Application Module Instances**

## 9.4.2 What You May Need to Know About Root Application Modules Versus Nested Application Module Usages

At runtime, your application works with a *main* — or what's known as a *root* — application module. Any application module can be used as a root application module; however, in practice the application modules that are used as root application modules are the ones that map to more complex end-user use cases, assuming you're not just building a straightforward CRUD application. When a root application module contains other nested application modules, they all participate in the root application module's transaction and share the same database connection and a single set of entity caches. This sharing is handled for you automatically by the root application module and its `Transaction` object.

Additionally, when you construct an application using an ADF bounded task flow, to declaratively manage the transactional boundaries, Oracle ADF will automatically nest application modules used by the task flow at runtime. For details about bounded task flows and transactions, see [Section 18.4, "Managing Transactions."](#)

## 9.5 Creating an Application Module Diagram for Your Business Service

As you develop the business service's data model, it is often convenient to be able to visualize it using a UML model. JDeveloper supports easily creating a diagram for your application module that other developers can use for reference.

You can perform a number of tasks directly on the diagram, such as editing the application module, controlling display options, filtering methods names, showing related objects and files, publishing the application, and launching the Business Component Browser.

### 9.5.1 How to Create an Application Module Diagram

To create an application module diagram, use the Create Business Components Diagram dialog, which is available in the New Gallery.

**To create a diagram of your application module:**

1. In the Application Navigator, right-click the project in which you want to create the diagram and choose **New**.
2. In the New Gallery, expand **Business Tier**, select **ADF Business Components** and then **Business Components Diagram**, and click **OK**.
3. In the Create Business Components dialog, enter a diagram name and a package name in which the diagram will be created.
4. Click **OK** to create the empty diagram and open the diagrammer.
5. To add your existing application module to the open diagram, select the desired application module in the Application Navigator and drop it onto the diagram surface.
6. Use the Property Inspector to:
  - Hide the package name
  - Change the font
  - Turn off the grid and page breaks
  - Turn off the display of the end names on the view link connectors ("Master"/"Detail")

After completing these steps, the diagram looks similar to the diagram shown in [Figure 9–15](#).

**Figure 9–15 Partial UML Diagram of Application Module**

## 9.5.2 What Happens When You Create an Application Module Diagram

When you create a business components diagram, JDeveloper creates a `.adfbcdiagram` file to represent the diagram in a subdirectory of the project's model path that matches the package name in which the diagram resides.

By default, the Application Navigator unifies the display of the project content's paths so that ADF components and Java files in the source path appear in the same package tree as the UML model artifacts in the project model path. You can use the **Navigator Display Options > Show Directories** toolbar option in the Application Navigator to switch between the unified directory view and a more distinct directory path view of the project content.

## 9.5.3 How to Use the Diagram to Edit the Application Module

The UML diagram of business components is not just a static picture that reflects the point in time when you dropped the application module onto the diagram. Rather, it is a UML-based rendering of the current component definitions, so it will always reflect the current state of affairs. The UML diagram is both a visualization aid and a visual navigation and editing tool.

You can bring up the overview editor for any application module in a diagram by choosing **Properties** from the context menu (or by double-clicking the application module).

You can also perform some application module editing tasks directly on the diagram, tasks such as renaming view object instances, dropping view object definitions from the Application Navigator onto the data model to create a new view object instance, and removing view object instances by pressing the Delete key.

---

---

**Note:** Deleting components from the diagram only removes their visual representation on the diagram surface. The components and classes remain on the file system and in the Application Navigator.

---

---

## 9.5.4 How to Control Diagram Display Options

After you display the application module in the diagram, you can use the Property Inspector to control its display options.

In the **Display Options** category, toggle properties like the following:

- **Show Methods** — to display service methods
- **Show Package** — to display the package name
- **Show Stereotype** — to display the type of object (for example "<<application module>>")

---

---

**Note:** The term *operation* is a more generic, UML name for methods.

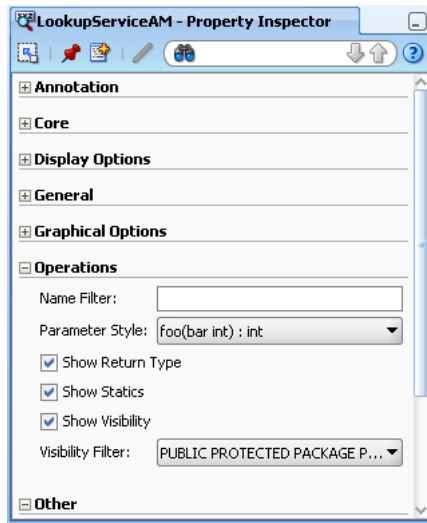

---

---

In the **Operations** category, consider changing the following properties depending on the amount of detail you want to provide in the diagram:

- **Parameter Style**
- **Show Return Type**
- **Show Visibility** (public, private, etc.)

By default, all operations of the application module are fully displayed, as shown by the Property Inspector settings in [Figure 9-16](#).

**Figure 9–16 Property Inspector with Default Diagrammer Options**

On the context menu of the diagram, you can also select to **View As**:

- **Compact** — to show only the icon and the name
- **Symbolic** — to show service operations
- **Expanded** — to show operations and data model (*default*)

### 9.5.5 How to Filter Method Names Displayed in the Diagram

Initially, if you show the operations for the application module, the diagram displays all the methods. Any method it recognizes as an overridden framework method displays in the **<<Framework>>** operations category. The rest display in the **<<Business>>** methods category.

The **Name Filter** property in the **Operations** category of the Property Inspector is a regular expression that you can use to filter out methods you don't want to display on the diagram. For example, by setting the **Name Filter** property to:

```
findLoggedInUser.*|retrieveOrder.*|get.*
```

you can filter out all of the following application module methods:

- `findLoggedInUserByEmail`
- `retrieveOrderById`
- All the generated view object getter methods

### 9.5.6 How to Show Related Objects and Implementation Files in the Diagram

After selecting the application module on the diagram — or any set of individual view object instances in its data model — you can choose **Show > Related Elements** from the context menu to display related component definitions on the diagram. In a similar fashion, choosing **Show > Implementation Files** will include the files that implement the application module on the diagram. You can repeat these options on the additional diagram elements that appear until the diagram includes the level of detail you want to convey.

[Figure 9–17](#) illustrates how the diagram displays the implementation files for an application module. You will see the related elements for the application module's

implementation class (`StoreServiceAMImpl`). The diagram also draws an additional dependency line between the application module and the implementation class. If you have cast the application module instance to a specific custom interface, the diagram will also show that.

**Figure 9–17 Adding Detail to a Diagram Using Show Related Elements and Show Implementation Files**

## 9.5.7 How to Publish the Application Module Diagram

To publish the diagram to PNG, JPG, SVG, or compressed SVG format, choose **Publish Diagram** from the context menu on the diagram surface.

## 9.5.8 How to Test the Application Module from the Diagram

To launch the Business Component Browser for an application module in the diagram, choose **Run** from the context menu.

## 9.6 Supporting Multipage Units of Work

While interacting with your Fusion web application, end users might:

- Visit the same pages multiple times, expecting fast response times
- Perform a logical unit of work that requires visiting many different pages to complete
- Need to perform a partial "rollback" of a pending set of changes they've made but haven't saved yet.
- Unwittingly be the victim of an application server failure in a server farm before saving pending changes

The application module pooling and state management features simplify implementing scalable, well-performing applications to address these requirements.

---

---

**Note:** ADF bounded task flows can represent a transactional unit of work. You can specify options on the task flow to determine how to handle the transaction. For details about the declarative capabilities of ADF bounded task flows, see [Section 18.4, "Managing Transactions."](#)

---

---

## 9.6.1 How to Simulate State Management in the Business Component Browser

To simulate what the state management functionality does, you can launch two instances of Business Component Browser on an application module.

### To simulate transaction state passivation using the Business Component Browser:

1. Run the Business Component Browser and double-click a view object instance to query its data.
2. Make a note of the current values of a several attributes for a few rows.
3. Update those rows to have a different value for those attributes, but do not commit the changes.
4. Choose **File > Save Transaction State** from the Business Component Browser main menu.

A Passivated Transaction State dialog appears, indicating a numerical transaction ID number. Make a note of this number.

5. Exit out of the Business Component Browser completely.
6. Restart the Business Component Browser and double-click the same view object instance to query its data.
7. Notice that the data is *not* changed. The queried data from the data reflects the current state of the database without your changes.
8. Choose **File > Restore Transaction State** from the Business Component Browser main menu, and enter the transaction ID you noted in Step 4.

At this point, you'll see that your pending changes are reflected again in the rows you modified. If you commit the transaction now, your changes are permanently saved to the database.

## 9.6.2 What Happens When the Application Uses Application Module Pooling and State Management

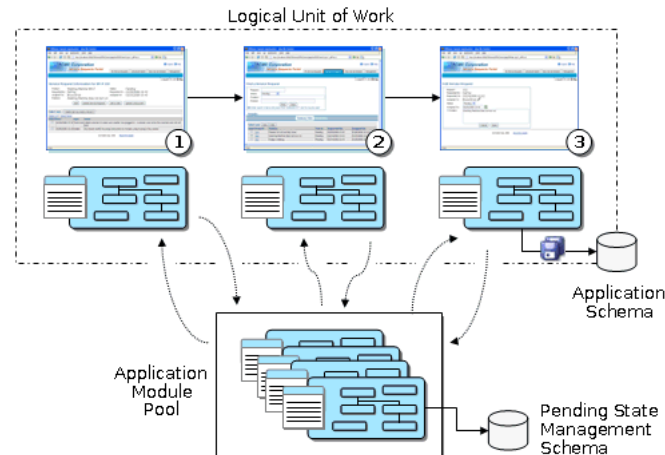

Applications you build that leverage an application module as their business service take advantage of an automatic application module pooling feature. This facility manages a configurable set of application module instances that grows and shrinks as the end-user load on your application changes during the day. Due to the natural "think time" inherent in the end user's interaction with your application user interface, the number of application module instances in the pool can be smaller than the overall number of active users using the system.

As shown in [Figure 9–18](#), as a given end user visits multiple pages in your application to accomplish a logical task, with each page request an application module instance in the pool is acquired automatically from the pool for the lifetime of that one request. At the end of the request, the instance is automatically returned to the pool for use by another user session. In order to protect the end user's work against application server failure, the application module supports the ability to freeze the set of pending

changes in its entity caches to a persistent store by saving an XML snapshot describing the change set. For scalability reasons, this state snapshot is typically saved in a state management schema that is a different database schema than the one containing the application data.

**Figure 9–18 Using Pooled Application Modules Throughout a Multipage, Logical Unit of Work**

The pooling algorithm affords a tunable optimization whereby a certain number of application module instances will attempt to stay "sticky" to the last user session that returned them to the pool. The optimization is not a guarantee, but when a user can benefit from the optimization, they continue to work with the same application module instance from the pool as long as system load allows. When load is too high, the pooling algorithm uses any available instance in the pool to service the user's request and the frozen snapshot of their logical unit of work is reconstituted from the persistent store to allow the new instance of the application module to continue where the last one left off. The end user continues to work in this way until they commit or roll back their changes.

Using these facilities, the application module delivers the productivity of a stateful paradigm that can easily handle multipage work flows, in an architecture that delivers the runtime performance near that of a completely stateless application. You will learn more about these application module features in [Chapter 40, "Application State Management"](#) and about how to tune them in [Chapter 41, "Tuning Application Module Pools and Connection Pools."](#)

## 9.7 Customizing an Application Module with Service Methods

An application module can expose its data model of view object instances to clients without requiring any custom Java code. This allows client code to use the `ApplicationModule`, `ViewObject`, `RowSet`, and `Row` interfaces in the `oracle.jbo` package to work directly with any view object in the data model. However, just because you *can* programmatically manipulate view objects any way you want to in client code doesn't mean that doing so is always a best practice.

Whenever the programmatic code that manipulates view objects is a logical aspect of implementing your complete business service functionality, you should encapsulate the details by writing a custom method in your application module's Java class. This includes code that:

- Configures view object properties to query the correct data to display

- Iterates over view object rows to return an aggregate calculation
- Performs any kind of multistep procedural logic with one or more view objects

By centralizing these implementation details in your application module, you gain the following benefits:

- You make the intent of your code more clear to clients.
- You allow multiple client pages to easily call the same code if needed.
- You simplify regression-testing of your complete business service functionality.
- You keep the option open to improve your implementation without affecting clients.
- You enable *declarative* invocation of logical business functionality in your pages.

### 9.7.1 How to Generate a Custom Class for an Application Module

To add a custom service method to your application module, you must first enable a custom Java class for it. If you have configured your IDE-level Business Components Java generation preferences to automatically generate an application module class, a custom class will be present. If you're not sure whether your application module has a custom Java class, open the overview editor for the application module node in the Application Navigator. The Java Classes page of the editor displays the complete list of classes generated for the application module in the project. If the file exists because someone created it already, then the Java Classes page will display a linked file name identified as the **Application Module Class**. To open an existing file in the source editor, click the corresponding file name link.

You can also check the application module node's context menu for the **Go to Application Module Class** option, as shown in [Figure 9–19](#). When this option is present in the menu, you can use it to quickly navigate to your application module's custom class. If you don't see the option in the menu, then your application module is currently an XML-only component.

**Figure 9–19** Quickly Navigating to an Application Module's Custom Java Class

If no Java class exists in your project, you can generate one using the Java Classes page of the overview editor for the application module.

#### Before you begin:

Create the desired application module as described in [Section 9.2.1, "How to Create an Application Module."](#)

**To generate a Java file for your application module class:**

1. In the Application Navigator, double-click the application module.
2. In the overview editor, click the **Java** navigation tab and click the **Edit java options** button.
3. In the Select Java Options dialog, select **Generate Application Module Class**.
4. Click **OK**.

The new `.java` file will appear in the Java Classes page.

## 9.7.2 What Happens When You Generate a Custom Class for an Application Module

When you generate a custom class for an application module, JDeveloper creates the file in the same directory as the component's XML component definition file. The default name for its custom Java file will be `AppModuleNameImpl.java`.

The Java generation option choices you made for the application module persist on the Java Classes page on subsequent visits to the overview editor for the application module. Just as with the XML definition file, JDeveloper keeps the generated code in your custom Java classes up to date with any changes you make in the editor. If later you decide you do not require a custom Java file, from the Java Classes page open the Select Java Options dialog and deselect **Generate Application Module Class** to remove the custom Java file from the project.

## 9.7.3 What You May Need to Know About Default Code Generation

By default, the application module Java class will look similar to what you see in [Example 9-4](#) when you've first enabled it. Of interest, it contains:

- Getter methods for each view object instance in the data model
- A `main()` method allowing you to debug the application module using the Business Component Browser

### **Example 9-4 Default Application Module Generated Code**

```
package devguide.model;
import devguide.model.common.StoreServiceAM;
import oracle.jbo.server.ApplicationModuleImpl;
import oracle.jbo.server.ViewLinkImpl;
import oracle.jbo.server.ViewObjectImpl;
// -----
// ---   File generated by Oracle ADF Business Components Design Time.
// ---   Custom code may be added to this class.
// ---   Warning: Do not modify method signatures of generated methods.
// -----
public class StoreServiceAMImpl extends ApplicationModuleImpl {
    /** This is the default constructor (do not remove) */
    public StoreServiceAMImpl() { }

    /** Container's getter for YourViewObjectInstance1 */
    public ViewObjectImpl getYourViewObjectInstance1() {
        return (ViewObjectImpl)findViewObject("YourViewObjectInstance1");
    }

    // ... Additional ViewObjectImpl getters for each view object instance

    // ... ViewLink getters for view link instances here
}
```

As shown in [Figure 9–20](#), your application module class extends the base ADF `ApplicationModuleImpl` class to inherit all the default behavior before adding your custom code.

**Figure 9–20** Your Custom Application Module Class Extends `ApplicationModuleImpl`

### 9.7.4 How to Add a Custom Service Method to an Application Module

To add a custom service method to an application module, simply navigate to the application module's custom class and enter the Java code for a new method into the application module's Java implementation class. Use the following guidelines to decide on the appropriate visibility for the method:

- If you will use the method only inside this component's implementation as a helper method, make the method `private`.
- If you want to allow eventual subclasses of your application module to be able to invoke or override the method, make it `protected`.
- If you need clients to be able to invoke it, it must be `public`.

---

**Note:** The `StoreServiceAM` application module examples in this chapter use the strongly typed, custom entity object classes that you saw illustrated in the `StoreServiceAMImpl2.java` example at the end of [Chapter 4, "Creating a Business Domain Layer Using Entity Objects."](#)

---

[Example 9–5](#) shows a private `retrieveOrderById()` helper method in the `StoreServiceAMImpl.java` class for the `StoreServiceAM` application module. It uses the static `getDefinition()` method of the `OrdersEOImpl` entity object class to access its related entity definition, it uses the `createPrimaryKey()` method on the entity object class to create an appropriate `Key` object to look up the order, and then it uses the `findByPrimaryKey()` method on the entity definition to find the entity row in the entity cache. It returns an instance of the strongly typed `OrdersEOImpl` class, the custom Java class for the `OrderEO` entity object.

**Example 9–5** Private Helper Method in Custom Application Module Class

```

// In devguide.model.StoreServiceAMImpl class
/*
 * Helper method to return a Order by Id
 */
private OrdersEOImpl retrieveOrderById(long orderId) {
    EntityDefImpl orderDef = OrdersEOImpl.getDefinitionObject();
    Key orderKey =
        OrdersEOImpl.createPrimaryKey(new DBSequence(orderId));
    return (OrdersEOImpl)orderDef.findByPrimaryKey(getDBTransaction(),

```

```

                                orderKey);
}

```

[Example 9–6](#) shows a public `createProduct()` method that allows the caller to pass in a name and description of a product to be created. It uses the `getDefinition()` method of the `ProductImpl` entity object class to access its related entity definition, and it uses the `createInstance2()` method to create a new `ProductImpl` entity row, whose `Name` and `Description` attributes it populates with the parameter values passed in before committing the transaction.

**Example 9–6 Public Method in Custom Application Module Class**

```

/*
 * Create a new Product and Return its new id
 */
public long createProduct(String name, String description) {
    EntityDefImpl productDef = ProductImpl.getDefinitionObject();
    ProductImpl newProduct =
        (ProductImpl)productDef.createInstance2(getDBTransaction(), null);
    newProduct.setName(name);
    newProduct.setDescription(description);
    try {
        getDBTransaction().commit();
    }
    catch (JboException ex) {
        getDBTransaction().rollback();
        throw ex;
    }
    DBSequence newIdAssigned = newProduct.getProdId();
    return newIdAssigned.getSequenceNumber().longValue();
}

```

## 9.7.5 How to Test the Custom Application Module Using a Static Main Method

When you are ready to test the methods of your custom application module, you can use JDeveloper to generate JUnit test cases. With JUnit, you can use any of the programmatic APIs available in the `oracle.jbo` package to work with the application module and invoke the custom methods. For details about using JUnit with ADF Business Components, see [Section 31.10, "Regression Testing with JUnit."](#)

As an alternative to JUnit test cases, a common technique to test your custom application module methods is to write a simple test case. For example, you could build the testing code into an object and include that code in the `static main()` method. [Example 9–7](#) shows a sample `main()` method you could add to your custom application module class to test the sample methods you will write. You'll make use of a Configuration object (see [Section 6.4.2, "How to Create a Command-Line Java Test Client"](#)) to instantiate and work with the application module for testing.

---

---

**Note:** The fact that this `Configuration` object resides in the `oracle.jbo.client` package suggests that it is used for accessing an application module as an application *client*. Because a `main()` method is a kind of programmatic, command-line client, so this is an acceptable practice. Furthermore, even though you typically would not cast the return value of `createRootApplicationModule()` directly to an application module's implementation class, it is legal to do so in this one situation since despite being a client to the application module, the `main()` method's code resides right inside the application module implementation class itself.

---

---

A glance through the code in [Example 9–7](#) shows that it exercises the four methods created in the previous examples to:

1. Retrieve the total for order 1011.
2. Retrieve the name of the customer for order 1011.
3. Set the status of order 1011 to the value "CANCEL".
4. Create a new product supplying a null product name.
5. Create a new product with a product name and display its newly assigned product ID.

**Example 9–7 Sample Main Method to Test a Custom Application Module from the Inside**

```
// Main method in StoreServiceAMImpl.java
public static void main(String[] args) {
    String      amDef = "devguide.model.StoreFrontService";
    String      config = "StoreServiceLocal";
    /*
     * This is the correct way to use application custom methods
     * from the client, by using the application module's automatically-
     * maintained custom service interface.
     */
    // 1. Acquire instance of application module, cast to client interface
    ApplicationModule am =
        Configuration.createRootApplicationModule(amDef,config);
    /*
     * NOTE: This cast to use the StoreFrontServiceImpl class is OK since this
     * code is inside a business tier *Impl.java file and not in a
     * client class that is accessing the business tier from "outside".
     */
    StoreFrontServiceImpl service = (StoreFrontServiceImpl)am;
    String total = service.findOrderTotal(1011);
    System.out.println("Total for Order # 1011 = " + total);
    String customerName = service.findOrderCustomer(1011);
    System.out.println("Customer for Order # 1011 = " + customerName);
    try {
        service.updateOrderStatus(1011,"CANCEL");
    }
    catch (JboException ex) {
        System.out.println("ERROR: "+ex.getMessage());
    }
    long id = 0;
    try {
        id = service.createProduct(null, "NEW", "CLASS1");
    }
}
```

```

catch (JboException ex) {
    System.out.println("ERROR: "+ex.getMessage());
}
id = service.createProduct("Canon PowerShot G9", "NEW", "CLASS1");
System.out.println("New product created successfully with id = "+id);
Configuration.releaseRootApplicationModule(am,true);
}

```

Running the custom application module class calls the `main()` method in [Example 9-7](#), and shows the following output:

```

Total for Order # 1011 = 99.99
Customer for Order # 1011 = John Chen
ERROR: JBO-27014: Attribute ProductName in ProductsBaseEO is required.
New product created successfully with id = 133

```

Notice that the first attempt to call `createProduct()` with a null for the product name raises an exception due to the built-in mandatory validation on the `Name` attribute of the `Product` entity object.

---

---

**Note:** For an explanation of how you can use the client application to invoke the custom service methods that you create in your custom application module, see [Section 9.9, "Publishing Custom Service Methods to UI Clients."](#)

---

---

## 9.7.6 What You May Need to Know About Programmatic Row Set Iteration

Any time your application logic accesses a row set to perform programmatic iteration, you should use a secondary row set iterator when working with view object instances in an application module's data model, or view link accessor row sets of these view object instances, since they may be bound to user interface components. To create a secondary iterator, use the `createRowSetIterator()` method on the row set you are working with. When you are done using it, call the `closeRowSetIterator()` method on the row set to remove the secondary iterator from memory. [Example 9-8](#) shows a typical application module custom method that correctly uses a secondary row set iterator for programmatic iteration, because the `EmpView1` view object instance in its data model may be bound to a user interface (either now or at a later time).

### **Example 9-8 Using a Secondary Row Set Iterator in an Application Module Custom Method**

```

// Custom method in an application module implementation class
public void doSomeCustomProcessing() {
    ViewObject vo = getEmpView1();
    // create secondary row set iterator with system-assigned name
    RowSetIterator iter = vo.createRowSetIterator(null);
    while (iter.hasNext()) {
        Row r = iter.next();
        // Do something with the current row.
    }
    // close secondary row set iterator
    iter.closeRowSetIterator();
}

```

---

---

**Note:** The same recommendation holds for custom code in a view object's implementation class that iterates its own default row set using that row set's default row set iterator.

---

---

There are two important reasons to follow this recommendation. Failing to do so can lead to confusion for the end user when the current row unexpectedly changes or it can introduce subtle business logic errors because the first or last row, or both rows get skipped.

- Confusing the end user by changing the current row unexpectedly

The iterator bindings determine what row the end-user sees as the current row in the row set. If your own programmatic logic iterates through the row set using the same default row set iterator that the iterator binding uses, you may inadvertently change the current row the user has selected, leaving the user confused.

- Introducing subtle business logic errors by inadvertently skipping the first or last row

Iterator bindings force their row set iterator to be on a valid row to guarantee that UI components display data when the row set is not empty. This has the side-effect of preventing your custom logic from navigating to the slot either before the first row or to the slot after the last row (when it is using the same row set iterator as an iterator binding). In concrete terms, this means that a typical `while (rowset.hasNext())` iteration loop will either be skipped or start by processing the second row instead of the first as shown in [Example 9-9](#).

**Example 9-9 Consequences of Using the Default Row Set Iterator**

```
// Reset the default row set iterator to the slot before the first row
rowset.reset();
// If an iterator binding is bound to the same default row set iterator,
// then it has already forced it to navigate to the first row here instead
// of being on the slot before the first row.
//
// If the row set has only one row, the following will then return false
while (rowset.hasNext()) {
    // If the row set has more than one row, the first time through the loop
    // this call to next() will return the second row rather than the first
    // row as expected.
    Row curRow = rowset.next();
    // Do something with current row
}
```

## 9.8 Customizing Application Module Message Strings

The ADF application module does not have a resource bundle of its own and there is no design time in JDeveloper to associate one with the application module. However, if you do want to register a `.properties` file that contains your custom message strings, you can set a resource bundle definition in the definition class file that you generate for the application module.

### 9.8.1 How to Add a Resource Bundle to an Application Module

To generate the custom definition class file for the application module, use the Select Java Options dialog, which you open for the application module on the Java Classes

page of the application module overview editor. You can use this file to override the built-in framework method `finishedLoading()`.

#### Before you begin:

1. Create the desired application module, as described in [Section 9.2.1, "How to Create an Application Module."](#)
2. Create the `.properties` file and add the message key and message, as described in [Section 4.7, "Working with Resource Bundles."](#)

The `.properties` file you create can reference attribute properties by their fully-qualified package name and custom method exception messages. For example, you might define message keys and strings as follows:

```
test.Order.Orderno_LABEL=Order Number
INVALID=You have called the method foo in an invalid way.
```

3. If your resource bundle defines a message for a method exception message, the custom method should appear in the application module client interface, as described in [Section 9.9.1, "How to Publish a Custom Method on the Application Module's Client Interface."](#)

For example, if you defined a message for the method `foo()` that to replace the exception message `INVALID`, your interface might define this method to invoke the message from the resource bundle as:

```
public void foo() {
    ResourceBundleDef r = getResourceBundleDef();
    throw new JboException(r, "INVALID", null);
}
```

#### To generate the definition class and override the finishedLoading method:

1. In the Application Navigator, double-click the application module.
2. In the overview editor, click the **Java** navigation tab.
3. On the Java Classes page, click the **Edit java options** button.
4. In the Select Java Options dialog, select **Generate Application Module Definition Class** and click **OK**.
5. In the overview editor, on the Java Classes page, click the linked file name of the application module definition class that you want to customize. JDeveloper opens the class file in the source editor.
6. From the JDeveloper toolbar, choose **Source > Override Methods**.  
If the Source menu is not displayed in the JDeveloper toolbar, be sure the definition class file is open and the source editor is visible.
7. In the Override Methods dialog, scroll the list to locate the `finishedLoading()` methods, select it, and click **OK**.
8. In the source editor for the definition class file, add the code to invoke your message bundle `.properties` file.

For example, if your file is `MyAMBundLe` in the `test` package, your code would look like:

```
@Override
protected void finishedLoading() {
    super.finishedLoading();
    PropertiesBundleDef pbd = new PropertiesBundleDef(this);
```

```
        pbd.setPropertiesFile("test.MyAMBundle");
        setResourceBundleDef(pbd);
    }
```

In this example, the `finishedLoading()` method creates a message bundle definition and then sets the custom message bundle on the definition.

9. Save the file.

## 9.8.2 What Happens When You Add a Resource Bundle to an Application Module

When you generate a custom definition class for an application module, JDeveloper creates the file in the same directory as the component's XML component definition file. The default name for its custom Java file will be `AppModuleNameDefImpl.java`.

Because you override the built-in `finishedLoading()` method in the definition class file, after the application is loaded at runtime, the framework will invoke the method and automatically load the named `.properties` file.

## 9.9 Publishing Custom Service Methods to UI Clients

When you add a `public` custom method to your application module class, if you want your application's UI to be able to invoke it, you need to include the method on the application module's UI client interface.

### 9.9.1 How to Publish a Custom Method on the Application Module's Client Interface

To include a public method from your application module's custom Java class on the client interface, use the Java Classes page of the overview editor for the application module, and then click the **Edit** icon in the **Client Interface** section of the page to display the Edit Client Interface dialog. Select one or more desired methods from the **Available** list and click the **Add** button to shuttle them into the **Selected** list. Then click **OK** to close the editor. [Figure 9-21](#) shows multiple public methods added to the client interface.

**Figure 9–21 Public Methods Added to an Application Module's Client Interface**

## 9.9.2 What Happens When You Publish Custom Service Methods

When you publish custom service methods on the client interface, as shown in [Figure 9–22](#), JDeveloper creates a Java interface with the same name as the application module in the common subpackage of the package in which your application module resides. For an application module named `StoreServiceAM` in the `fodemo.model` package, this interface will be named `StoreServiceAM` and reside in the `fodemo.model.common` package. The interface extends the base `ApplicationModule` interface in the `oracle.jbo` package, reflecting that a client can access all of the base functionality that your application module inherits from the `ApplicationModuleImpl` class.

**Figure 9–22 Custom Client Interface Extends the Base ApplicationModule Interface**

As shown in [Example 9–10](#), the `StoreServiceAM` interface includes the method signatures of all of the methods you've selected to be on the client interface of your application module.

**Example 9–10 Custom Client Interface Based on Methods Selected in the Client Interface Panel**

```
package fodemo.model.common;
import oracle.jbo.ApplicationModule;
// -----
// ---   File generated by Oracle ADF Business Components Design Time.
// -----
public interface StoreServiceAM extends ApplicationModule {
```

```

void deleteCurrentMyOrderItem();
void executeMyOrdersForCustomerVO();
void userRegistrationCreate(String userType);
void updateUserInterests(List pCategoryIds);
void userRegistrationCreateAddress();
}

```

---

**Note:** After adding new custom methods to the client interface, if your new custom methods do not appear to be available when you use JDeveloper's code insight context-sensitive statement completion, try recompiling the generated client interface. To do this, select the application module in the Application Navigator, select the source file for the interface of the same name in the Structure window, and choose **Rebuild** from the context menu. Consider this tip for new custom methods added to view objects and view rows as well.

---

### 9.9.3 How to Generate Client Interfaces for View Objects and View Rows

In addition to generating a client interface for your application module, it is also possible to generate strongly typed client interfaces for working with the other key client objects that you can customize. For example, you can open Java page in the overview editor for a view object, you can then expand the **Client Interface** section and the **Client Row Interface** section and add custom methods to the view object client interface and the view row client interface, respectively.

If for the `Products` view object in the `devguide.model.queries` package you were to enable the generation of a custom view object Java class and add one or more custom methods to the view object client interface, JDeveloper would generate the `ProductsImpl` class and `Products` interface, as shown in [Figure 9–23](#). As with the application module custom interface, notice that it gets generated in the `common` subpackage.

**Figure 9–23 Custom View Object Interface Extends the Base ViewObject Interface**

Likewise, if for the same view object you were to enable the generation of a custom view row Java class and add one or more custom methods to the view row client interface, JDeveloper would generate the `ProductsRowImpl` class and `ProductsRow` interface, as shown in [Figure 9–24](#).

Figure 9–24 Custom View Row Interface Extends the Base Row Interface

### 9.9.4 How to Test Custom Service Methods Using the Business Component Browser

You can test the methods of your custom application module in the Business Component Browser after you have published them on the client interface, as described in [Section 9.9, "Publishing Custom Service Methods to UI Clients."](#)

#### To test the service methods that you have published:

1. In the Application Navigator, expand the project containing the desired application module and view objects.
2. Right-click the application module and choose **Run**.

Alternatively, choose **Debug** when you want to run the application in the Business Component Browser with debugging enabled. JDeveloper opens the debugger process panel in the Log window and the various debugger windows. When debugging using the Business Component Browser, you can use these windows to view status message and exceptions, step in and out of source code, and manage breakpoints.

For information about receiving diagnostic messages specific to ADF Business Component debugging, see [Section 6.3.8, "How to Enable ADF Business Components Debug Diagnostics."](#)

3. To open the method testing panel for a method defined by a client interface, do one of the following:
  - In the data model tree, select the application module node and from the main menu choose **View - Operations** when you want to execute a method you published for the application module client interface. You can also double-click the application module node to display the method testing panel.
  - In the data model tree, select the desired view object node and from the main menu choose **View - Operations** when you want to execute a method you published on the client interface for a view object. You can also right-click the view object node and choose **Operations**.
4. To open the method testing panel for a method defined by a client row interface for a view object row, expand the data model tree, right-click the desired view object node and choose **Show Table**. Then in the overview panel for the view instance, select the desired row, and from the main menu, choose **View - Operations**.

Do not select a master view instance in the data model tree since view row operations are not permitted on master view objects. Always select a detail view instance or a view instance that is not specified in a master-detail hierarchy, as shown in [Figure 9–25](#).

**Tip:** In the case of a detail view instance, you can open the master view instance to navigate to the detail with the desired row. The Business Component Browser automatically synchronizes the data displayed in the open overview panel with the master view instance that you navigate to.

**Figure 9–25 Menu Selection for View Row Operations in the Business Component Browser**

- In the method panel, select the desired service method from the dropdown list, enter values to pass as method parameters, and click **Execute**.

Notice that the method testing panel displays the parameter names to help you identify where to enter the values to pass. This is particularly useful when the method signature defines multiple parameters of the same data type.

You can view the return value (if any) and test result. The result displayed in the Business Component Browser will indicate whether or not the method executed successfully.

### 9.9.5 What You May Need to Know About Method Signatures on the Client Interface

You can include any custom method in the client interface that obeys these implementation rules:

- If the method has a non-void return type, the type must be serializable.
- If the method accepts any parameters, all their types must be serializable.
- If the method signature includes a throws clause, the exception must be an instance of `JboException` in the `oracle.jbo` package.

In other words, all the types in its method signature must implement the `java.io.Serializable` interface, and any checked exceptions must be `JboException` or its subclass. Your method can throw any unchecked exception — `java.lang.RuntimeException` or a subclass of it — without disqualifying the method from appearing on the application module's client interface.

Note that method signatures of type `java.util.List` are allowed as long as the implementing class for the interface is serializable. For example, `java.util.ArrayList` and `java.util.LinkedList` are both serializable implementing classes. The same requirement applies to element types within the collection. The ADF Business Components runtime will produce an error if you

instantiate a class that implements the interface yet does not implement the `java.io.Serializable` interface.

---

**Note:** If the method you've added to the application module class doesn't appear in the **Available** list, first verify that it doesn't violate any of the method implementation rules. If it seems like it should be a legal method, try recompiling the application module class before visiting the overview editor for the application module again.

---

## 9.9.6 What You May Need to Know About Passing Information from the Data Model

The private implementation of an application module custom method can easily refer to any view object instance in the data model using the generated accessor methods. By calling the `getCurrentRow()` method on any view object, it can access the same current row for any view object that the client user interface sees as the current row. As a result, while writing application module business service methods, you may not need to pass in parameters from the client. This is true if you would be passing in values only from the current rows of other view object instances in the same application module's data model.

For example, the custom application module method in [Example 9–11](#) accepts no parameters. Internally, the `createOrderItem()` method calls `getGlobals().getCurrentRow()` to access the current row of the `Globals` view object instance. Then it uses the strongly typed accessor methods on the row to access the values of the `Description` and `LineItemId` attributes to set them as the values of corresponding attributes in a newly created `OrderItem` entity object row.

### **Example 9–11 Using View Object Accessor Methods to Access a Current Row**

```
// In StoreServiceAMImpl.java, createOrderItem() method
GlobalsRowImpl globalsRow = (GlobalsRowImpl)getGlobals().getCurrentRow();
newReq.setDescription(globalsRow.getDescription());
newReq.setLineItemId(globalsRow.getLineItemId());
```

## 9.10 Working Programmatically with an Application Module's Client Interface

After publishing methods on your application module's client interface, you can invoke those methods from a client.

### 9.10.1 How to Work Programmatically with an Application Module's Client Interface

To work programmatically with an application module's client interface, do the following:

- Cast `ApplicationModule` to the more specific client interface.
- Call any method on the interface.

---

**Note:** For simplicity, this section focuses on working only with the custom application module interface; however, the same downcasting approach works on the client to use a `ViewObject` interface as a view object interface like `Orders` or a `Row` interface as a custom view row interface like `OrdersRow`.

---

**Example 9–12** illustrates a `TestClientCustomInterface` class that puts these two steps into practice. You could also use the `main()` method of this class to test application module methods, as described in [Section 9.7.5, "How to Test the Custom Application Module Using a Static Main Method."](#) Here you use it to call all of the same methods from the client using the `StoreFrontService` client interface.

---

**Note:** If you work with your application module using the default `ApplicationModule` interface in the `oracle.jbo` package, you won't have access to your custom methods. Make sure to cast the application module instance to your more specific custom interface like the `StoreFrontService` interface in this example.

---

The basic logic of [Example 9–12](#) follows these steps:

1. Retrieve the total for order 1011.
2. Retrieve the name of the customer for order 1011.
3. Set the status of order 1011 to the value "CANCEL".
4. Create a new product supplying a null product name.
5. Create a new product with a product name and display its newly assigned product ID.

**Example 9–12 Using the Custom Interface of an Application Module from the Client**

```
package devguide.examples.appmodules;

import devguide.examples.appmodules.common.StoreFrontService;
import devguide.examples.entities.PersonsEOImpl;
import devguide.examples.entities.ProductsBaseEOImpl;

import oracle.jbo.ApplicationModule;
import oracle.jbo.JboException;
import oracle.jbo.Key;
import oracle.jbo.client.Configuration;
import oracle.jbo.domain.DBSequence;
import oracle.jbo.domain.Number;
import oracle.jbo.server.ApplicationModuleImpl;
import oracle.jbo.server.EntityDefImpl;

public class TestClientCustomInterface {
    public static void main(String[] args) {
        String      amDef = "devguide.model.StoreFrontService";
        String      config = "StoreFrontServiceLocal";
        /*
         * This is the correct way to use application custom methods
         * from the client, by using the application module's automatically-
         * maintained custom service interface.
         */
        // Acquire instance of application module, cast to client interface
        StoreFrontService service =
            (StoreFrontService)Configuration.createRootApplicationModule(amDef, config);
        String total = service.findOrderTotal(1011);
        System.out.println("Status of Order # 1011 = " + total);
        String customerName = service.findOrderCustomer(1011);
        System.out.println("Customer for Order # 1011 = " + customerName);
        try {
            service.updateOrderStatus(1011, "CANCEL");
        }
    }
}
```

```

    }
    catch (JboException ex) {
        System.out.println("ERROR: "+ex.getMessage());
    }
    long id = 0;
    try {
        id = service.createProduct(null, "NEW", "CLASS1");
    }
    catch (JboException ex) {
        System.out.println("ERROR: "+ex.getMessage());
    }
    id = service.createProduct("Canon PowerShot G9", "NEW", "CLASS1");
    System.out.println("New product created successfully with id = "+id);
    Configuration.releaseRootApplicationModule(am, true);
}
}

```

Running the test client in [Example 9–12](#) calls the custom methods of the client interface, and shows the following output:

```

Total for Order # 1011 = 99.99
Customer for Order # 1011 = John Chen
ERROR: JBO-27014: Attribute ProductName in ProductsBaseEO is required.
New product created successfully with id = 133

```

Notice that the first attempt to call `createProduct()` with a null for the product name raises an exception due to the built-in mandatory validation on the `Name` attribute of the `Product` entity object

### 9.10.2 What Happens When You Work with an Application Module's Client Interface

Because the client layer accessing your application module will be located in the same tier of the Java EE architecture, the application module is deployed in what is known as *local mode*. In local mode, the client interface is implemented directly by your custom application module Java class. You access an application module in local mode whenever you access the application module in the web tier of a JavaServer Faces application.

### 9.10.3 How to Access an Application Module Client Interface in a Fusion Web Application

The `Configuration` class in the `oracle.jbo.client` package makes it very easy to get an instance of an application module for *testing*. This eases writing test client programs like the test client program described in [Section 31.10, "Regression Testing with JUnit"](#) as part of the JUnit regression testing fixture.

**Best Practice:** For Fusion web applications you should always work through the binding layer to access the application module. While developers may be tempted to use the class `createRootApplicationModule()` and `releaseApplicationModule()` methods *anywhere* to access an application module, the best approach is to use the declarative features of the ADF Model layer.

When working with Fusion web applications using the ADF Model layer for data binding, `JDeveloper` configures a servlet filter in your user interface project called the `ADFBindingFilter`. It orchestrates the automatic acquisition and release of an appropriate application module instance based on declarative binding metadata, and

ensures that the service is available to be looked up as a data control using a known action binding or iterator binding, specified by any page definition file in the user interface project. You may eventually want to read about the ADF binding container, data controls, page definition files, and bindings, as described in [Chapter 12, "Using ADF Model in a Fusion Web Application."](#) For now, it is enough to realize that you can access the application module's client interface from this `DCBindingContainer` by naming an ADF action binding or an ADF iterator binding. You can reference the binding context and call methods on the custom client interface in a JSF managed bean, as shown in [Example 9–13](#) for an action binding and [Example 9–14](#) for an iterator binding.

To access the custom interface of your application module using an action binding, follow these basic steps (as illustrated in [Example 9–13](#)):

1. Access the ADF binding container.
2. Find a named action binding. (Use the name of any available action binding in the page definition files of the user interface project.)
3. Get the data control by name from the action binding.
4. Access the application module data provider from the data control.
5. Cast the application module to its client interface.
6. Call any method on the client interface.

**Example 9–13 Accessing the Application Module Client Interface in a JSF Backing Bean Using a Named Action Binding**

```
package demo.view;
import oracle.fodemo.storefront.store.service.common.StoreServiceAM;
import oracle.adf.model.binding.DCBindingContainer;
import oracle.adf.model.binding.DCDataControl;
import oracle.jbo.ApplicationModule;
import oracle.jbo.uicli.binding.JUCtrlActionBinding;
public class YourBackingBean {
    public String commandButton_action() {
        // Example using an action binding to get the data control
        public String commandButton_action() {
            // 1. Access the binding container
            DCBindingContainer bc = (DCBindingContainer)getBindings();
            // 2. Find a named action binding
            JUCtrlActionBinding action =
                (JUCtrlActionBinding)bc.findCtrlBinding("SomeActionBinding");
            // 3. Get the data control from the iterator binding (or method binding)
            DCDataControl dc = action.getDataControl();
            // 4. Access the data control's application module data provider
            ApplicationModule am = (ApplicationModule)dc.getDataProvider();
            // 5. Cast the AM to call methods on the custom client interface
            StoreServiceAM service = (StoreServiceAM)am;
            // 6. Call a method on the client interface
            service.doSomethingInteresting();
            return "SomeNavigationRule";
        }
    }
}
```

To access the custom interface of your application module using an iterator binding, follow these basic steps (as illustrated in [Example 9–14](#)):

1. Access the ADF binding container.

2. Find a named iterator binding. (Use the name of any iterator binding in the page definition files of the user interface project.)
3. Get the data control by name from the iterator binding.
4. Access the application module data provider from the data control.
5. Cast the application module to its client interface.
6. Call any method on the client interface.

**Example 9–14 Accessing the Application Module Client Interface in a JSF Backing Bean Using a Named Iterator Binding**

```
package demo.view;
import oracle.fodemo.storefront.store.service.common.StoreServiceAM;
import oracle.adf.model.binding.DCBindingContainer;
import oracle.adf.model.binding.DCDataControl;
import oracle.adf.model.binding.DCIteratorBinding;
import oracle.jbo.ApplicationModule;
public class YourBackingBean {
    public String commandButton_action() {
        // Example using an iterator binding to get the data control
        public String commandButton_action() {
            // 1. Access the binding container
            DCBindingContainer bc = (DCBindingContainer)getBindings();
            // 2. Find a named iterator binding
            DCIteratorBinding iter = bc.findIteratorBinding("SomeIteratorBinding");
            // 3. Get the data control from the iterator binding
            DCDataControl dc = iter.getDataControl();
            // 4. Access the data control's application module data provider
            ApplicationModule am = (ApplicationModule)dc.getDataProvider();
            // 5. Cast the AM to call methods on the custom client interface
            StoreServiceAM service = (StoreServiceAM)am;
            // 6. Call a method on the client interface
            service.doSomethingInteresting();
            return "SomeNavigationRule";
        }
    }
}
```

These backing bean examples depend on the helper method shown in [Example 9–15](#).

**Example 9–15 Helper Method for Backing Bean Class**

```
public BindingContainer getBindings() {
    {
        return BindingContext.getCurrent().getCurrentBindingsEntry();
    }
}
```

If you create the backing bean class by overriding a button that is declaratively bound to an ADF action, then JDeveloper will automatically generate this method in your class. Otherwise, you will need to add the helper method to your class yourself.

## 9.11 Overriding Built-in Framework Methods

The `ApplicationModuleImpl` base class provides a number of built-in methods that implement its functionality. While [Appendix E, "Most Commonly Used ADF Business Components Methods"](#) provides a quick reference to the most common code that you will typically write, use, and override in your custom application module classes, this section focuses on helping you understand the basic steps to override one of these built-in framework methods to augment the default behavior.

### 9.11.1 How to Override a Built-in Framework Method

To override a built-in framework method for an application module, use the Override Methods dialog, which you select for the application module Java class from the main menu.

#### Before you begin:

Create the desired application module as described in [Section 9.2.1, "How to Create an Application Module."](#)

#### To override an application module framework method:

1. In the Application Navigator, double-click the application module.
2. In the overview editor, click the **Java** navigation tab.
3. On the Java Classes page, click the linked file name of the application module Java class that you want to customize.

JDeveloper opens the class file in the source editor.

4. From the main menu, choose **Source > Override Methods**.

If the **Source** menu is not displayed, be sure that the desired Java class file is open and that the source editor is visible.

5. In the Override Methods dialog, scroll the list to locate the desired methods or type the first few letters of the method name to perform an incremental search.
6. Select one or more methods.

The Override Methods dialog allows you to select any number of methods to override simultaneously.

For example, if you wanted to override the application module's `prepareSession()` method to augment the default functionality when a new user session begins working with an application module service component for the first time, you would select the checkbox next to the `prepareSession(Session)` method, as shown in [Figure 9–26](#).

**Figure 9–26** Overriding a Built-in Framework Method

7. Click OK.

### 9.11.2 What Happens When You Override a Built-in Framework Method

When you dismiss the Override Methods dialog, you return to the source editor with the cursor focus on the overridden method, as shown in [Figure 9–27](#). Notice that the method appears with a single line that calls `super.prepareSession()`. This is the syntax in Java for invoking the default behavior that the base class would have normally performed for this method. By adding code before or after this line in the custom application module class, you can augment the default behavior before or after the default functionality.

**Figure 9–27 Source Editor Margin Gives Visual Feedback About Overridden Methods**

```

316     @Override
317     protected void prepareSession(Session session) {
318         super.prepareSession(session);
319     }

```

Also notice that when you override a method using the Override Methods dialog, the source editor inserts the JDK `@Override` annotation just before the overridden method. This causes the compiler to generate a compile-time error if the method in the application module class does not match the signature of any method in the superclass.

Be careful when you add method names to your class to override a method in the superclass; you must have the signature *exactly* the same as the base class method you want to override. Be sure to add the `@Override` annotation just before the method. This way, if your method does not match the signature of any method in the superclass, the compiler will generate a compile-time error. Also, when you write code for a method instead of calling the superclass implementation, you should have a thorough understanding of what built-in code you are suppressing or replacing.

### 9.11.3 How to Override `prepareSession()` to Set Up an Application Module for a New User Session

Since the `prepareSession()` method is invoked by the application module when it is used for the first time by a new user session, it's a useful method to override in your custom application module class to perform setup tasks that are specific to each new user that uses your application module. [Example 9–16](#) illustrates an overridden `prepareSession()` method in the `oracle.fodemo.storefront.adfextensions.FODApplicationModuleImpl` class that invokes a `setCurrentUserLanguage()` helper method to initialize the language used by the application.

**Example 9–16 Initializing the Language to Use for Current User Session**

```

public class FODApplicationModuleImpl extends ApplicationModuleImpl {

    public static String preferredLanguage;
    public static boolean isWebUser=false;
    private String[] supportedLanguages = {"EN", "JA", "EL", "FR", "DE"};

    /**
     * @param session
     */
    @Override
    protected void prepareSession(Session session) {

```

```

        super.prepareSession(session);
        setCurrentUserLanguage();
    }

    private void setCurrentUserLanguage() {
        DBTransactionImpl dbti = (DBTransactionImpl) getDBTransaction();
        CallableStatement statement =
            dbti.createCallableStatement(("BEGIN " +
                                         "user_context_pkg.set_app_user_lang(?); " +
                                         "END;"), 0);

        try {
            statement.setString(1, getApplicationLanguage());
            statement.execute();
        } catch (SQLException sqlerr) {
            throw new JboException(sqlerr);
        } finally {
            try {
                if (statement != null) {
                    statement.close();
                }
            } catch (SQLException closeerr) {
                throw new JboException(closeerr);
            }
        }
    }

    /**
     * @return
     */
    public String getApplicationLanguage(){
        String appLanguage = "EN";
        if (isWebUser){
            for (int index=0; index<supportedLanguages.length; index++){
                if (preferredLanguage.equals(supportedLanguages[index])){
                    appLanguage = preferredLanguage;
                    break;
                }
            }
        } else{
            appLanguage = getAMLanguage();
        }
        return appLanguage;
    }

    /**
     * @return
     */
    public String getAMLanguage(){
        PropertyMetadata langProperty =
            PropertyMetadata.findProperty("jbo.default.language");
        String amLanguage = langProperty.getProperty();
        return amLanguage.toUpperCase();
    }
}

```

---

---

## Sharing Application Module View Instances

This chapter describes how to organize your ADF Business Components data model project to most efficiently share read-only data accessed from lookup tables or other static data source, such as a flat file. It describes the differences between ADF application modules that you may share at the application level and those that you may share at the session level.

This chapter includes the following sections:

- [Section 10.1, "Introduction to Shared Application Modules"](#)
- [Section 10.2, "Sharing an Application Module Instance"](#)
- [Section 10.3, "Defining a Base View Object for Use with Lookup Tables"](#)
- [Section 10.4, "Accessing View Instances of the Shared Service"](#)
- [Section 10.5, "Testing View Object Instances in a Shared Application Module"](#)

### 10.1 Introduction to Shared Application Modules

Web applications often utilize data that is required across sessions and does not change very frequently. An example of this type of *static data* might be displayed in the application user interface in a lookup list. Each time your application accesses the static data, you could incur an unnecessary overhead when the static data caches are repopulated from the database for each application session on every request. In order to optimize performance, a common practice when working with ADF Business Components is to cache the shared static data for reuse across sessions and requests.

### 10.2 Sharing an Application Module Instance

Declarative support for shared data caches is available in JDeveloper through the Project Properties dialog. Creating a shared application module allows requests from multiple sessions to share a single application module instance which is managed by an application pool for the lifetime of the web server virtual machine.

**Best Practice:** Use a shared application module to group view instances when you want to reuse lists of static data across the application. The shared application module can be configured to allow any user session to access the data or it can be configured to restrict access to just the UI components of a single user session. For example, you can use a shared application module to group view instances that access lookup data, such as a list of countries. The use of a shared application module allows all shared resources to be managed in a single place and does not require a scoped managed bean for this purpose.

As shown in [Figure 10–1](#), the Project Properties dialog lets you specify application-level or session-level sharing of the application module’s data model. In the case of *application-level sharing*, any HTTP user session will be able to access the same view instances contained in the shared application module. In contrast, the lifecycle of the *session-level shared* application module extends to an application module session (`SessionImpl`) that is in use by a single HTTP user session and applies to a single root application module. In this case, each distinct *root* application module used by a given HTTP user session will get its own distinct instance of a session-scoped shared application module. In other words, distinct root application modules used by the same HTTP session do not share data in a session-scoped shared application module.

**Figure 10–1** Project Properties Dialog Defines Shared Application Module Instance

When you create the data model for the application module that you intend to share, be sure that the data in cached row sets will not need to be changed either at the application level or session level. For example, in the application-level shared application module, view instances should query only static data such as state codes or currency types. If a view object instance queries data that depends on the current user, then the query can be cached at the session level and shared by all components that reference the row-set cache. For example, the session-level shared application module might contain a view instance with data security that takes a manager as the

current user to return the list of direct reports. In this case, the cache of direct reports would exist for the duration of the manager's HTTP user session. The ADF Business Components application module pool will recreate the session-scoped application module should an HTTP user session be assigned a recycled application module from the pool. This ensures that the duration of the session-scoped application module is tied to the HTTP session for as long as the HTTP session is able to continue to use the same root application module instance. Note that the cache of direct reports of the session-level shared application module cannot be accessed across distinct root application modules.

## 10.2.1 How to Create a Shared Application Module Instance

To create a shared application module instance, use the Project Properties dialog. You define a logical name for a distinct, separate root application module that will hold your application's read-only data.

### Before you begin:

Create the application module that you will share as described in [Section 9.2.1, "How to Create an Application Module."](#)

### To create a shared application module instance:

1. In the Application Navigator, right-click the project in which you want to create the shared application module and choose **Project Properties**.
2. In the Project Properties dialog, expand **Business Components** and select **Application Module Instances**.
3. In the **Available Application Modules** list, select the desired application module and shuttle it to the **Application Module Instances** list.
4. Assign the application module a unique instance name.

The shared application module instance (of either scope) must have a unique instance name. Supplying a meaningful name will also help to clarify which shared application module instance a given usage is referencing.

5. Select the **Cache level** of the shared application module:
  - When you want to define the shared application module for the context of the application, select **Application**.
  - When you want to define the shared application module for the context of the current user session, select **Session**.
6. Click **OK**.

## 10.2.2 What Happens When You Define a Shared Application Module

JDeveloper automatically creates the `AppModuleNameShared` configuration when you create an application module. The presence of this configuration in the `bc4j.xcfg` file informs JDeveloper that the application module is a candidate to be shared, and allows JDeveloper to display the application module in the **Available Application Modules** list of the Project Properties dialog's Application Module Usage page.

The `AppModuleNameShared` configuration sets these properties on the application module to enable sharing and help to maintain efficient use of the shared resource at runtime:

- `jbo.ampool.isuseexclusive` is set to `false` to specify that requests from multiple sessions can share a single instance of the application module, which is managed by the application pool for the lifetime of the web server virtual machine. When you do not enable application module sharing, JDeveloper sets the value `true` to repopulate the data caches from the database for each application session on every request.
- `jbo.ampool.maxpoolsize` is set to `1` (one) to specify that only a single application module instance will be created for the ADF Business Components application module pool. This setting enforces the efficient use of the shared application module resource and prevents unneeded multiple instances of the shared application module from being created at runtime.

You can view the shared application module's configuration by choosing **Configurations** from the context menu on the application module in the Application Navigator. JDeveloper saves the `bc4j.xcfg` file in the `./common` subdirectory relative to the application module's XML component definition. If you remove the configuration or modify the values of the `jbo.ampool` runtime properties (`isuseexclusive`, `maxpoolsize`), the application module will not be available to use as a shared application module instance.

For example, if you look at the `bc4j.xcfg` file in the `./src/oracle/fodemo/storefront/lookups/common` directory of the Fusion Order Demo application's `StoreFrontService` project, you will see the two named configurations for the `LookupServiceAM` application module, as shown in [Example 10–1](#). Specifically, the `LookupServiceAMShared` configuration sets the `jbo.ampool` runtime properties on the shared application module instance. For more information about the ADF Business Components application module pooling and runtime configuration of application modules, see [Chapter 41, "Tuning Application Module Pools and Connection Pools."](#)

#### **Example 10–1** *LookupServiceAMShared Configuration in the `bc4j.xcfg` File*

```
<BC4JConfig version="11.1" xmlns="http://xmlns.oracle.com/bc4j/configuration">
  <AppModuleConfigBag
    ApplicationName="oracle.fodemo.storefront.lookups.LookupServiceAM">
    <AppModuleConfig DeployPlatform="LOCAL"
      JDBCName="FOD"
      jbo.project="StoreFrontService"
      name="LookupServiceAMLocal"
      ApplicationName="oracle.fodemo.storefront.lookups.LookupServiceAM">
      <Database jbo.locking.mode="optimistic"/>
      <Security
        AppModuleJndiName="oracle.fodemo.storefront.lookups.LookupServiceAM"/>
    </AppModuleConfig>
    <AppModuleConfig DeployPlatform="LOCAL"
      JDBCName="FOD"
      jbo.project="StoreFrontService"
      name="LookupServiceAMShared"
      ApplicationName="oracle.fodemo.storefront.lookups.LookupServiceAM">
      <AM-Pooling jbo.ampool.dynamicjdbccredentials="false"
        jbo.ampool.isuseexclusive="false"
        jbo.ampool.maxpoolsize="1"
        jbo.ampool.resetnontransactionalstate="false"/>
      <Database jbo.locking.mode="optimistic"/>
      <Security
        AppModuleJndiName="oracle.fodemo.storefront.lookups.LookupServiceAM"/>
    </AppModuleConfig>
  </AppModuleConfigBag>
```

```
</BC4JConfig>
```

Because the shared application module can be accessed by any Business Components project in the same application workspace, JDeveloper maintains the scope of the shared application module in the Business Components project configuration file (.jspx). This file is saved in the `src` directory of the project. For example, if you look at the `StoreFrontService.jsx` file in the `./src` directory of the Fusion Order Demo application's `StoreFrontService` project, you will see that the `SharedLookupService` application module's usage definition specifies `SharedScope = 2`, corresponding to application-level sharing, as shown in [Example 10–2](#). An application module that you set to session-level sharing will show `SharedScope = 1`.

**Example 10–2 Application Module Usage Configuration in the .jspx File**

```
<JboProject
  xmlns="http://xmlns.oracle.com/bc4j"
  Name="StoreFrontService"
  SeparateXMLFiles="true"
  PackageName="" >
  . . .
  <AppModuleUsage
    Name="SharedLookupService"
    FullName="oracle.fodemo.storefront.lookups.LookupServiceAM"
    ConfigurationName="oracle.fodemo.storefront.lookups.LookupServiceAMShared"
    SharedScope="2" />
</JboProject>
```

### 10.2.3 What You May Need to Know About Design Time Scope of the Shared Application Module

Defining the shared application module in the Project Properties dialog makes the application module's data model available to other Business Components projects of the same application workspace only. When you want to make the data model available beyond the application workspace, you can publish the data model as an ADF Library, as described in [Chapter 33, "Reusing Application Components."](#)

When viewing a data control usage from the `DataBindings.cpx` file in the Structure window, do not set the **Configuration** property to a shared application module configuration. By default, for an application module named `AppModuleName`, the Property Inspector will list the configurations named `AppModuleNameShared` and `AppModuleNameLocal`. At runtime, Oracle Application Development Framework (Oracle ADF) uses the shared configuration automatically when you configure an application as a shared application module, but the configuration is not designed to be used by an application module data control usage. For more information about data control usage, see [Section 12.4, "Working with the DataBindings.cpx File."](#)

### 10.2.4 What You May Need to Know About the Design Time Scope of View Instances of the Shared Application Module

In JDeveloper, you must define view accessors on the business component definition for the project that will permit access to view instances of the shared application module. The view accessor lets you point from an entity object or view object definition in one Business Components project to a view object definition or view instance in a shared application module. For details about creating view accessors for this purpose, see [Section 10.4, "Accessing View Instances of the Shared Service."](#)

## 10.2.5 What You May Need to Know About Managing the Number of Shared Query Collections

Similar to the way application module pooling works in ADF Business Components, shared query collections are stored in a query collection pool. To manage the query collection pool, the ADF Business Components framework removes query collections based on a maximum idle time setting. This behavior limits the growth of the cache and prevents rarely-used query collections from occupying memory space.

As in application module and connection pooling, a query collection pool monitor wakes up after a user-specified sleep interval and then initiates the cleanup operation. Any query collection that exceeds the maximum idle time (length of time since it was last used), will be removed from the pool.

You can change the default values for the maximum idle time for the shared query collection (default is 900000 ms/15 min) and the sleep period for its pool monitor (default is 1800000 ms/30 min). To configure these values, open the Edit Business Components Configuration dialog, select the *AppModuleNameShared* configuration, and set these properties in the Properties page of the editor:

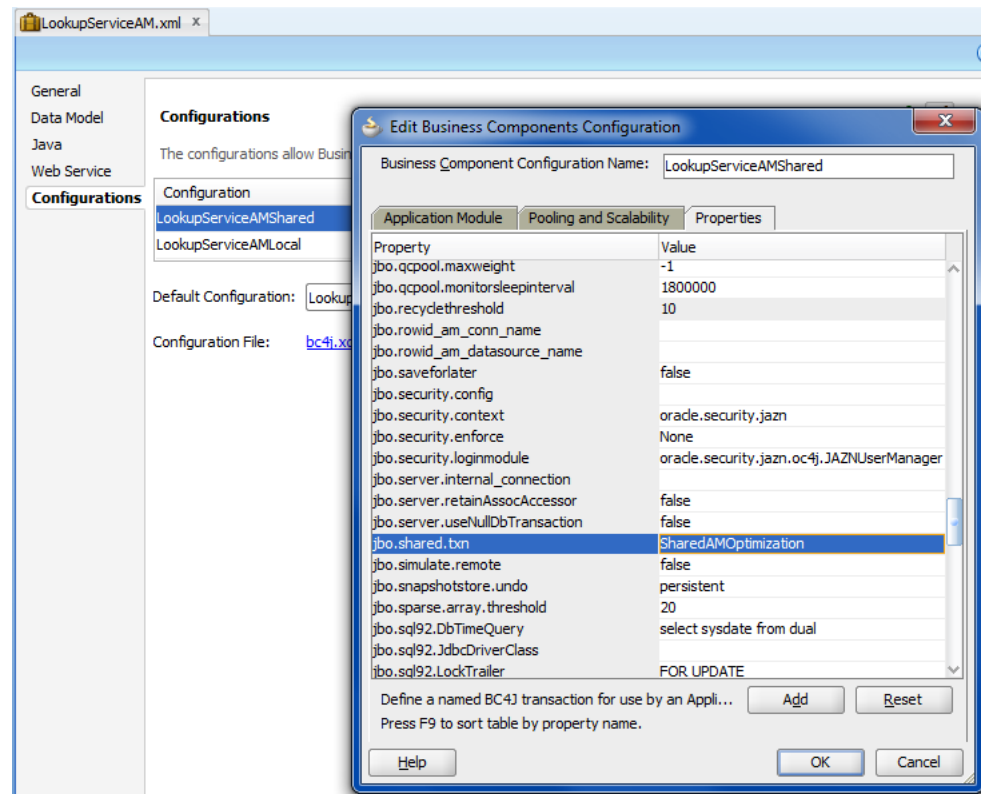

- `jbo.qcpool.monitorsleepinterval` the time (ms) that the shared query collection pool monitor should sleep between pool checks.
- `jbo.qcpool.maxinactiveage` the maximum amount of time (ms) that a shared query collection may remain unused before it is removed from the pool.

## 10.2.6 What You May Need to Know About Shared Application Modules and Connection Pooling

The default connection behavior for all application modules is to allow each root application module to have its own database connection. When your application defines more than one shared application module, you can configure the application to nest them under the same transaction in order to use a single database connection. This optimization allows the shared application module instances to share the same connection and entity cache and reduces the database resources that the application uses. This is particularly useful for shared application modules cases because they are read only and have longer life than transactional application modules.

**Best Practice:** Oracle recommends nesting shared application module instances under a single transaction to reduce the database resources required by the application. You can make this shared application module optimization by setting the `jbo.shared.txn` property to use the same transaction name (an arbitrary identifier you supply) for each shared application module configuration the application defines.

Set the `jbo.shared.txn` property using the Edit Configuration dialog that you open from the Configurations page of the overview editor for the shared application module, as shown in [Figure 10-2](#). Repeat the `jbo.shared.txn` property setting using the same transaction name for each shared application module configuration that your application defines.

**Figure 10–2 Supplying a Common Transaction Name for Shared Application Modules**

Currently, the application module configuration parameter `jbo.doconnectionpooling=true` is not supported for use with shared application modules. This feature is available to configure non-shared application modules when it is desirable to release JDBC connection objects to the database connection pool.

This feature is intentionally not supported for shared application modules to prevent decreases in performance that would result from managing state for shared access. Instead, the default use of `jbo.doconnectionpooling=false` is enforced.

The default connection pooling configuration ensures that each shared application module instance holds onto the JDBC connection object that it acquires from the pool until the application module instance is removed from the application module pool. For more information about the `jbo.doconnectionpooling` parameter and connection pool behavior, see [Section 41.2.6, "What You May Need to Know About How Database and Application Module Pools Cooperate."](#)

## 10.3 Defining a Base View Object for Use with Lookup Tables

When your application needs to display static data, you can define a shared application module with view instances that most likely will access lookup tables. A lookup table is a static, translated list of data to which the application refers. Lookup table data can be organized in the database in various ways. While it is possible to store related lookup data in separate tables, it is often convenient to combine all of the lookup information for your application within a single table. For example, a column `LOOKUP_TYPE` created for the `ORDERS_LOOKUPS` table would serve to partition one table that might contain diverse codes such as `FWK_TBX_YES_NO` for the values yes and no, `FWK_TBX_COUNTRY` for country names, and `FWK_TBK_CURRENCY` for the names of national currencies.

When your database schema organizes lookup data in a single database table, you want to avoid creating individual queries for each set of data. Instead, you will use the overview editor to define a single, base view object that maps the desired columns of the lookup table to the view object attributes you define. Since only the value of the `LOOKUP_TYPE` column will need to change in the query statement, you can add view criteria on the view object definition to specify a `WHERE` clause that will set the `LOOKUP_TYPE` value. In this way, your application encapsulates access to the lookup table data in a single view object definition that will be easy to maintain when a `LOOKUP_TYPE` value changes or your application needs to query additional lookup types.

### 10.3.1 How to Create a Base View Object Definition for a Lookup Table

The base view object that queries columns of the lookup table will be a read-only view object, since you do not need to handle updating data or require any of the benefits provided by entity-based view objects. (For a description of those benefits, see [Section 5.1.2, "Runtime Features Unique to Entity-Based View Objects."](#))

---

---

**Note:** While read-only view objects you create to access lookup tables are ideal for inclusion in a shared application module, if you intend to share the view object in a shared application module instance, you must create the view object in the same package as the shared application module.

---

---

To create a read-only view object, use the Create View Object wizard, which is available from the New Gallery.

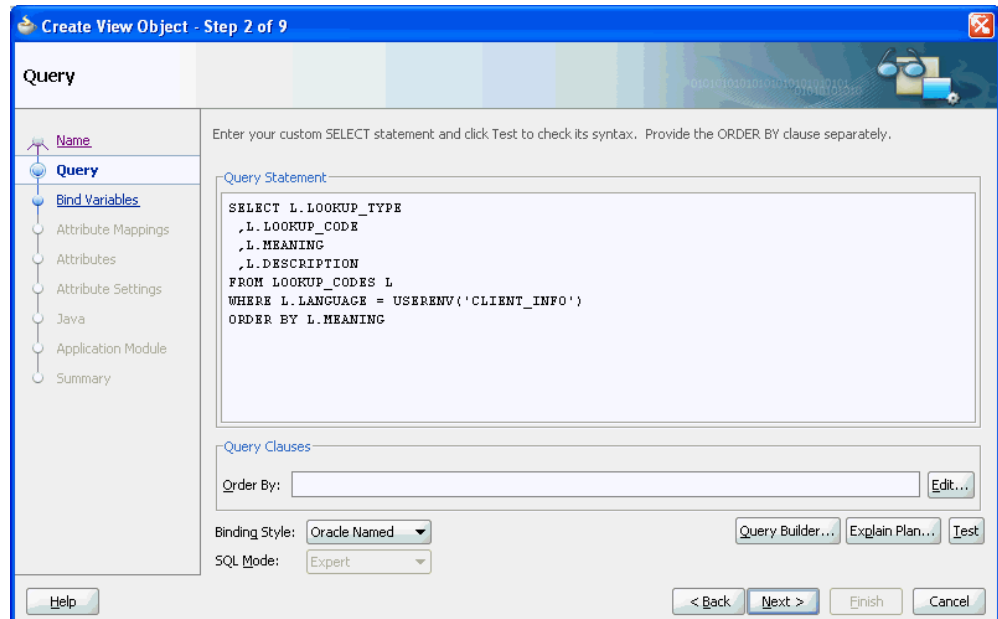

**To create a base view object for a lookup table:**

1. In the Application Navigator, locate the shared application module you created in which you want to create the view object, right-click its package node, and choose **New**.
2. In the New Gallery, expand **Business Tier**, select **ADF Business Components** and then select **View Object**, and click **OK**.
3. In the Create View Object wizard, on the Name page, enter a package name and a view object name.

When naming the package, consider creating a separate package for the lookup.

4. Select **Read-only access through SQL query** to indicate that you want this view object to manage data with read-only access and click **Next**.
5. On the Query page, enter your SQL statement directly into the **Query Statement** box.

Your query names the columns of the lookup table, similar to the SQL statement shown in [Figure 10-3](#) to query the `LOOKUP_CODE`, `MEANING`, and `DESCRIPTION` columns in the `LOOKUP_CODES` table.

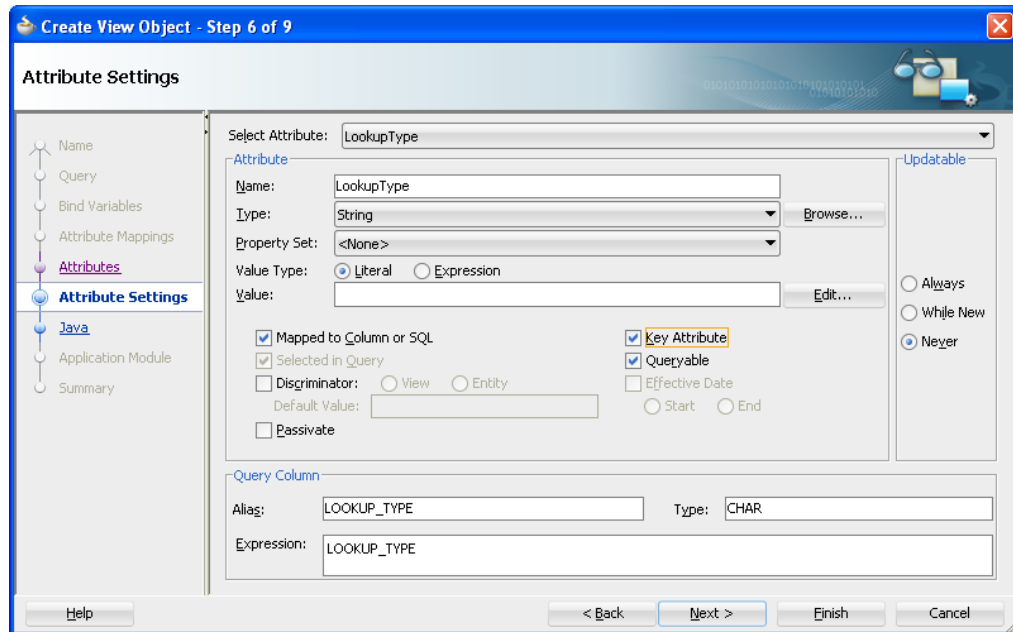

**Figure 10–3 Create View Object Wizard, SQL Query for Lookup Table**

6. After entering the query statement, no other changes are required. Click **Next**.
7. On the **Bind Variables** page, click **Next**.
8. On the **Attribute Mappings** page, note the mapped view object attribute names displayed and click **Next**.

By default, the wizard creates Java-friendly view object attribute names that correspond to the `SELECT` list column names.

9. On the **Attribute Settings** page, from the **Select Attribute** dropdown, select the attribute that corresponds to the primary key of the queried table and then enable the **Key Attribute** checkbox.

Because the read-only view object is not based on an entity object, the Create View Object wizard does not define a key attribute by default. Failure to define the key attribute can result in unexpected runtime behavior for ADF Faces components with a data control based on the read-only view object collection. In the case of read-only view objects, define the key attribute, as shown in [Figure 10–4](#).

**Figure 10–4 Create View Object Wizard, Attribute Settings Page**

10. If you want to rename individual attributes to use names that might be more appropriate, from the **Select Attributes** dropdown, choose the attribute and enter the desired name in the **Name** field. When you are finished, click **Next**.

For example, the Fusion Order Demo application renames the default attributes `LookupType` and `LookupCode` to `Type` and `Value` respectively. Changes you make to the view object definition will not change the underlying query.

11. On the Java page, click **Next**.
12. On the Application Module page, do not add an instance of the view object to the application module data model. Click **Finish**.

The shared application module data model will include view instances based on view criteria that you add to the base view object definition. In this way, you do not need to create an individual view object to query each `LOOKUP_TYPE` value. For details about adding the view object instances to the data model, see [Section 9.2.3.2, "Adding Master-Detail View Object Instances to an Application Module."](#)

### 10.3.2 What Happens When You Create a Base View Object

When you create the view object definition for the lookup table, JDeveloper first describes the query to infer the following from the columns in the `SELECT` list:

- The Java-friendly view attribute names (for example, `LookupType` instead of `LOOKUP_TYPE`)

By default, the wizard creates Java-friendly view object attribute names that correspond to the `SELECT` list column names.

- The SQL and Java data types of each attribute

JDeveloper then creates the XML component definition file that represents the view objects's declarative settings and saves it in the directory that corresponds to the name of its package. For example, the XML file created for a view object named

LookupsBaseVO in the lookups package is `./lookups/LookupsBaseVO.xml` under the project's source path.

To view the view object settings, expand the desired view object in the Application Navigator, select the XML file under the expanded view object, and open the Structure Window. The Structure window displays the list of definitions, including the SQL query and the properties of each attribute. To open the file in the editor, double-click the corresponding `.xml` node. As shown in [Example 10-3](#), the `LookupsBaseVO.xml` file defines one `<SQLQuery>` definition and one `<ViewAttribute>` definition for each mapped column. Without a view criteria to filter the query results, the view object query returns the `LOOKUP_CODE`, `LOOKUP_MEANING`, and `LOOKUP_DESCRIPTION` and maps them to view instance attribute values for `Value`, `Name`, and `Description` respectively. Key attributes are defined to ensure proper row set navigation when the base view object collection is bound to an ADF Faces component.

### Example 10-3 LookupsBaseVO SQL Query and Attribute Mapping Definition

```
<ViewObject
  xmlns="http://xmlns.oracle.com/bc4j"
  Name="LookupsBaseVO"
  BindingStyle="OracleName"
  CustomQuery="true"
  PageIterMode="Full"
  UseGlueCode="false"
  FetchMode="FETCH_AS_NEEDED"
  FetchSize="500">
  <SQLQuery>
    <![CDATA[SELECT L.LOOKUP_TYPE
      ,L.LOOKUP_CODE
      ,L.MEANING
      ,L.DESCRPTION
    FROM LOOKUP_CODES L
    WHERE L.LANGUAGE = USERENV('CLIENT_INFO')
    ORDER BY L.MEANING]]>
  </SQLQuery>
  <DesignTime>
    <Attr Name="_codeGenFlag2" Value="Access|VarAccess"/>
    <Attr Name="_isExpertMode" Value="true"/>
  </DesignTime>
  <ViewAttribute
    Name="Type"
    IsUpdateable="false"
    IsPersistent="false"
    IsNotNull="true"
    PrecisionRule="true"
    Precision="255"
    Type="java.lang.String"
    ColumnType="VARCHAR2"
    AliasName="LOOKUP_TYPE"
    Expression="LOOKUP_TYPE"
    SQLType="VARCHAR">
    <DesignTime>
      <Attr Name="_DisplaySize" Value="30"/>
    </DesignTime>
    ...
  </ViewAttribute>
  <ViewAttribute
    Name="Value"
    IsUpdateable="false"
    IsPersistent="false"
```

```

        IsNotNull="true"

        IsUpdateable="false"
        IsPersistent="false"
        PrecisionRule="true"
        Precision="240"
        Type="java.lang.String"
        ColumnType="VARCHAR2"
        AliasName="DESCRIPTION"
        Passivate="true"
        Expression="DESCRIPTION"
        SQLType="VARCHAR">
        <DesignTime>
            <Attr Name="_DisplaySize" Value="240"/>
        </DesignTime>
        ...
    </ViewAttribute>
    <AttrArray Name="KeyAttributes">
        <Item Value="Type"/>
        <Item Value="Value"/>
    </AttrArray>
    . . .
</ViewObject>

```

### 10.3.3 How to Define the WHERE Clause of the Lookup View Object Using View Criteria

You create named view criteria definitions in the data model project when you need to filter view object results. View criteria that you define at design time can participate in UI scenarios that require filtering of data.

Use the Edit View Criteria dialog to create the view criteria definition for the lookup base view object you defined to query the lookup table. The editor lets you build a `WHERE` clause using attribute name instead of the target view object's corresponding SQL column names. The resulting definition will include:

- One view criteria row consisting of one view criteria group, with a single view criteria item used to define the lookup view object's `Type` attribute.
- The view criteria item will consist of an `Type` attribute name, the Equal operator, and the value of the `LOOKUP_TYPE` that will filter the query results.

Because a single view criteria is defined, no logical conjunctions are needed to bracket the `WHERE` clause conditions.

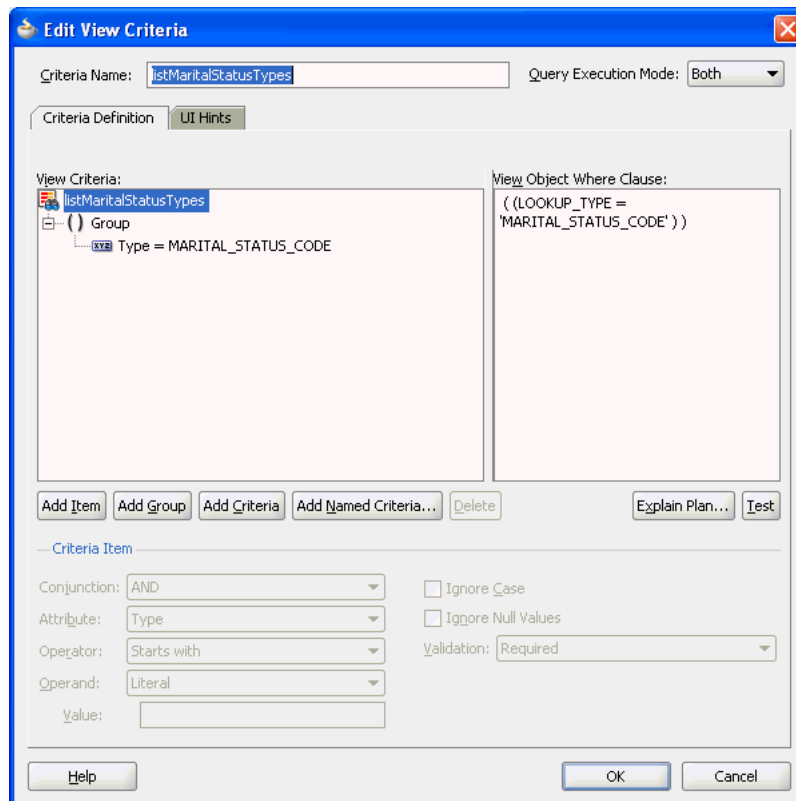

**To create `LOOKUP_TYPE` view criteria for the lookup view object:**

1. In the Application Navigator, double-click the lookup base view object you defined.
2. In the overview editor, click the **Query** navigation tab.
3. In the Query page, expand the **View Criteria** section, and click the **Create new view criteria** button.
4. In the Create View Criteria dialog, on the View Criteria page, click the **Add Item** button to add a single criteria item to the view criteria group.
5. In the **Criteria Item** panel, define the criteria item as follows:
  - Choose **Type** as the attribute (or other name that you defined for the attribute the view object maps to the `LOOKUP_TYPE` column).
  - Choose **equal to** as the operator.
  - Keep **Literal** as the operand choice and enter the value name that defines the desired type. For example, to query the marital status codes, you might enter the value `MARITAL_STATUS_CODE` corresponding to the `LOOKUP_TYPE` column.

Leave all other settings unchanged.

The view object `WHERE` clause shown in the editor should display a simple criteria similar to the one shown in [Figure 10-5](#), where the value `MARITAL_STATUS_CODE` is set to filter the `LOOKUP_TYPE` column.

6. Click **OK**.
7. Repeat this procedure to define one view criteria for each `LOOKUP_TYPE` that you wish to query.

**Figure 10–5 Edit View Criteria Dialog with Lookup View Object View Criteria Specified**

### 10.3.4 What Happens When You Create a View Criteria with the Editor

The Create View Criteria dialog in JDeveloper lets you easily create view criteria and save them as named definitions. These named view criteria definitions add metadata to the target view object's own definition. Once defined, named view criteria appear by name in the Query page of the overview editor for the view object.

JDeveloper then creates the XML component definition file that represents the view objects's declarative settings and saves it in the directory that corresponds to the name of its package. For example, the XML file created for a view object named LookupsBaseVO in the lookups package is `./lookups/LookupsBaseVO.xml` under the project's source path.

To view the view criteria, expand the desired view object in the Application Navigator, select the XML file under the expanded view object, open the Structure window, and expand the View Criteria node. As shown in [Example 10–4](#), the `LookupsBaseVO.xml` file specifies the `<ViewCriteria>` definition that allows the `LookupsBaseVO` to return only the marital types. Other view criteria added to the `LookupsBaseVO` are omitted from this example for brevity.

#### **Example 10–4 listMaritalStatusTypes View Criteria in the Lookup View Object Definition**

```
<ViewObject
  xmlns="http://xmlns.oracle.com/bc4j"
  Name="LookupsBaseVO"
  BindingStyle="OracleName"
  CustomQuery="true"
  PageIterMode="Full"
  UseGlueCode="false">
```

```

<SQLQuery>
  <![CDATA[SELECT L.LOOKUP_TYPE
    ,L.LOOKUP_CODE
    ,L.MEANING
    ,L.DESCRPTION
  FROM LOOKUP_CODES L
  WHERE L.LANGUAGE = SYS_CONTEXT('USERENV','LANG')
  ORDER BY L.MEANING]]>
</SQLQuery>
...
<ViewCriteria
  Name="listMaritalStatusTypes"
  ViewObjectName="oracle.fodemo.storefront.lookups.LookupsBaseVO"
  Conjunction="AND"
  Mode="3"
  <Properties>
    <CustomProperties>
      <Property
        Name="autoExecute"
        Value="false"/>
      <Property
        Name="showInList"
        Value="true"/>
      <Property
        Name="mode"
        Value="Basic"/>
    </CustomProperties>
  </Properties>
  <ViewCriteriaRow
    Name="vcrow24">
    <ViewCriteriaItem
      Name="Type"
      ViewAttribute="Type"
      Operator="="
      Conjunction="AND"
      Value="MARITAL_STATUS_CODE"
      Required="Optional"/>
    </ViewCriteriaRow>
  </ViewCriteria>

```

### 10.3.5 What Happens at Runtime: When a View Instance Accesses Lookup Data

When you create a view instance based on a view criteria, the next time the view instance is executed it augments its SQL query with an additional `WHERE` clause predicate corresponding to the view criteria that you've populated in the view criteria rows.

## 10.4 Accessing View Instances of the Shared Service

*View accessors* in ADF Business Components are value accessor objects that point from an entity object attribute (or view object) to a destination view object or shared view instance in the same application workspace. The view accessor returns a row set that by default contains all rows from the destination view object. You can optionally filter this row set by applying view criteria to the view accessor. The base entity object or view object on which you create the view accessor and the destination view object need not be in the same project or application module, but they must be in the same application workspace.

Because view accessors give you the flexibility to reach across application modules to access the queried data, they are ideally suited for accessing view instances of shared application modules. For details about creating a data model of view instances for a shared application module, see [Section 10.2.1, "How to Create a Shared Application Module Instance."](#)

This ability to access view objects in different application modules makes view accessors particularly useful for:

- Validation rules that you set on the attributes of an entity object. In this case, the view accessor derives the validation rule's values from lookup data corresponding to a view instance attribute in the shared application module.
- List of Value (LOV) that you enable for the attribute of any view object. In this case, the view accessor derives the list of values from lookup data corresponding to a view instance attribute in the shared application module.

Validation rules with accessors are useful when you do not want the UI to display a list of values to the user, but you still need to restrict the list of valid values. Alternatively, consider defining an LOV for view object attributes to simplify the task of working with list controls in the user interface. Because you define the LOV on the individual attributes of business components, you can customize the LOV usage for an attribute once and expect to see the list control in the form wherever the attribute appears.

### 10.4.1 How to Create a View Accessor for an Entity Object or View Object

View accessors provide the means to access a data source independent of the application module. View accessors can be defined at the level of the entity object or individual view objects. However, because at runtime view accessor results are often filtered depending on the usage involved, it is recommended that you create unique view accessors for each usage in your application.

**Best Practice:** Oracle recommends creating unique view accessors whenever your application needs to expose an LOV-enabled attribute. Reusing view accessors to create multiple list of values is discouraged because LOV results are often filtered at runtime. For example, the results of a saved search will filter the row set of the target view object until the end user unapplies the search criteria. Consequently, view accessors that get applied to this same destination view object will have their results filter too. To ensure the view accessor always returns the intended row set at runtime, create unique view accessors for each usage.

Defining view accessors on the entity object should be used carefully since view objects that you create based on the entity object will inherit the view accessors of their base entity objects. While defining the view accessor once on the entity object itself allows you to reuse the same view accessor, the view accessor must not be used in different application scenarios. If you intend to define validation rules for the entity object attributes and create LOV-enabled attributes for that entity object's view object, it is recommended that you create separate view accessors.

For example, in the `StoreFrontModule` package of the Fusion Order Demo application, the `AddressEO` entity object defines the `Shared_CountriesVA` view accessor and the `AddressesVO` view object inherits this view accessor. In this case, defining the view accessor on the entity object is useful: the accessor for `AddressEO` defines a validation rule on the `CountryId` attribute. But a different view accessor for `AddressesVO` should be used to enable an LOV on its `CountryId` attribute.

When you create a view accessor that accesses a view instance from a shared application module, you may want to use a prefix like `Shared_` to name the view accessor. This naming convention will help you identify the view accessor when you need to select it for the entity object or view object.

You can further refine the list returned by a view accessor by applying view criteria that you define on the view object. To create view criteria for use with a view accessor, see [Section 10.3.3, "How to Define the WHERE Clause of the Lookup View Object Using View Criteria."](#)

**To create the view accessor:**

1. In the Application Navigator, double-click the entity object or view object on which you want to define the view accessor.

Whether you create the view accessor on the entity object or on the view object will depend on the view accessor's intended usage. Generally, creating view accessors on the entity object ensures the widest possible usage.

2. In the overview editor, click the **View Accessors** navigation tab and click the **Create new view accessors** button to add the accessor to the entity object or view object definition you are currently editing.
3. In the View Accessors dialog, select the view instance name you created for your lookup table from the shared application module node and shuttle it to the view accessors list.

For example, the View Accessors dialog in the Fusion Order Demo application shows the shared application module `LookupServiceAM` with the list of view instances, as shown in [Figure 10–6](#).

The dialog will display all view objects and view instances from your application. If you have not yet enabled application module sharing, you must do so before selecting the view instance. For details, see [Section 10.2.1, "How to Create a Shared Application Module Instance."](#)

By default, the view accessor you create will display the same name as the view object instance (or will have an integer appended when it is necessary to distinguish it from a child view object of the same name). You can edit **Accessor Name** to give it a unique name.

For example, the View Accessors dialog in [Figure 10–6](#) shows the view accessor `SharedLookupService_AddressUsageTypesVA` for the `AddressUsageTypes` view instance selection in the shared application module `LookupServiceAM`. This view accessor is created on the base entity object `AddressUsagesEO` and accesses the row set of the `AddressUsageTypes` view instance.

**Figure 10–6 Defining a View Accessor on an Entity Object**

4. Optionally, if you want to apply an existing view criteria to filter the accessor, with the view accessor selected in the overview editor, click the **Edit** icon.

In the Edit View Accessor dialog, click **Edit** and perform the following steps to apply the view criteria:

- a. Select the view criteria that you want to apply and shuttle it to the **Selected** list.

You can add additional view criteria to apply multiple filters (a logical AND operation will be performed at runtime).

- b. Enter the attribute name for the bind variable that defines the controlling attribute for the view accessor row set.

Unlike view criteria that you set directly on a view object (to create a view instance, for example), the controlling attribute of the view accessor's view criteria derives the value from the view accessor's base view object.

- c. Click **OK** to return to the View Accessors dialog.

5. Click **OK**.

## 10.4.2 How to Validate Against a View Accessor

View accessors that you create to access the view rows of a destination view object may be used to verify data that your application solicits from the end user at runtime. For example, when the end user fills out a registration form, individual validation rules can verify the title, marital status, and contact code against lookup table data queried by view instances of the shared application module.

You can apply view accessors you have defined on the entity object to these built-in declarative validation rules:

- The Compare validator performs a logical comparison between an entity attribute and a value. When you specify a view accessor to determine the possible values, the compare validator applies the `Equals`, `NotEquals`, `GreaterThan`, `LessThan`, `LessOrEqualTo`, `GreaterOrEqualTo` operator you select to compare against the values returned by the view accessor.

- The List validator compares an entity attribute against a list of values. When you specify a view accessor to determine the valid list values, the List validator applies an `In` or `Not.In` operator you select against the values returned by the view accessor.
- The Collection validator performs a logical comparison between an operation performed on a collection attribute and a value. When you specify a view accessor to determine the possible values, the Collection validator applies the Sum, Average, Count, Min, Max operation on the selected collection attribute to compare against the values returned by the view accessor.

Validation rules that you define to allow runtime validation of data for entity-based view objects are always defined on the attributes of the entity object. You use the editor for the entity object to define the validation rule on individual attributes. Any view object that you later define that derives from an entity object with validation rules defined will automatically receive attribute value validation.

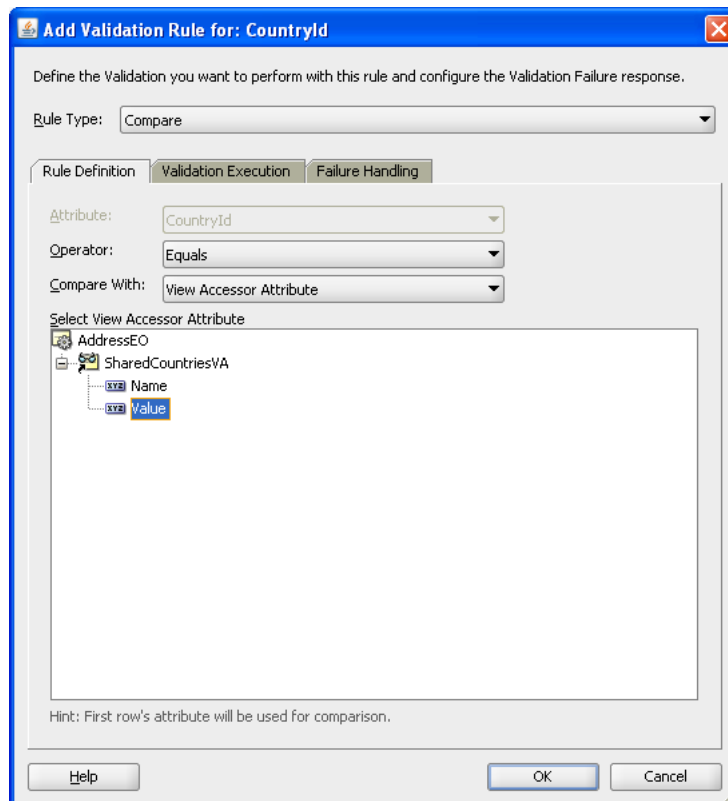

**Before you begin:**

Create the desired entity objects as described in [Section 4.2.1, "How to Create Multiple Entity Objects and Associations from Existing Tables."](#)

**To validate against a view accessor comparison, list, or collection type:**

1. In the Application Navigator, double-click the desired entity object.
2. In the overview editor, click the **Business Rules** navigation tab.
3. In the Business Rules page, expand the entity object, select the attribute to be validated and then click the **Create new validator** button to add the validation rule to the entity object attribute.
4. In the Add Validation Rule dialog, in the **Rule Type** dropdown list, select **Compare, List, or Collection**.
5. Make the selections required by the validator selection.
6. In the **Compare With** or **List Type** dropdown list, select **View Accessor Attribute**.
7. In the **Select View Accessor Attribute** group box, expand the desired view accessor from the shared service and select the attribute you want to provide as validation.

[Figure 10–7](#) shows what the dialog looks like when you use a List validator to select a view accessor attribute.

**Figure 10–7 List Validator Using a View Accessor**

8. Click the **Failure Handling** tab and enter a message that will be shown to the user if the validation rule fails.
9. Click **OK**.

### 10.4.3 What Happens When You Validate Against a View Accessor

When you use a List validator, a `<ListValidationBean>` tag is added to an entity object's XML file. [Example 10–5](#) shows the XML code for the `CountryId` attribute in the `Address` entity object. A List validator has been used to validate the user's entry against the list of country ID values as retrieved by the view accessor from the `Countries` view instance.

#### **Example 10–5 List Validator with View Accessor List Type XML Code**

```
<Attribute
  Name="CountryId"
  IsNotNull="true"
  Precision="2"
  ColumnName="COUNTRY_ID"
  Type="java.lang.String"
  ColumnType="CHAR"
  SQLType="VARCHAR"
  TableName="ADDRESSES">
  RetrievedOnUpdate="true"
  RetrievedOnInsert="true">
  <DesignTime>
    <Attr Name="_DisplaySize" Value="2"/>
  </DesignTime>
  <ListValidationBean
```

```

xmlns="http://xmlns.oracle.com/adfm/validation"
Name="CountryId_Rule_1"
ResId="CountryId_Rule_0"
OnAttribute="CountryId"
OperandType="VO_USAGE"
Inverse="false"
ViewAccAttrName="Value"
ViewAccName="SharedCountriesVA">
<ResExpressions>
  <Expression
    Name="0"><![CDATA[SharedCountriesVA.Value]]>
  </Expression>
</ResExpressions>
</ListValidationBean>
<Properties>
  <SchemaBasedProperties>
    <LABEL
      ResId="CountryId_LABEL" />
    </SchemaBasedProperties>
  </Properties>
</Attribute>

```

## 10.4.4 How to Create an LOV Based on a Lookup Table

View accessors that you create to access the view rows of a destination view object may be used to display a list of values to the end user at runtime. You first create a view accessor with the desired view instance as its data source, and then you can add the view accessor to an LOV-enabled attribute of the displaying view object. You will edit the view accessor definition for the LOV-enabled attribute so that it points to the specific lookup attribute of the view instance. Because you want to populate the row set cache for the query with static data, you would locate the destination view instance in a shared application module.

While the list usage is defined on the attribute of a view object bound to a UI list control, the view accessor definition exists on either the view object or the view object's base entity object. If you choose to create the view accessor on the view object's entity object, the View Accessors page of the overview editor for the view object will display the inherited view accessor, as shown in [Figure 10–8](#). Alternatively, if you choose to create the view accessor on the attribute's view object, you can accomplish this from either the editor for the LOV definition or from the View Accessors page of the overview editor.

To ensure that the view accessor for the LOV always queries the latest data from the database table, you can enable the auto-refresh feature on the view accessor's destination view object.

**Figure 10–8** View Accessors Page of the Overview Editor

For additional examples of how to work with LOV-enabled attributes, see [Section 5.13, "Working with List of Values \(LOV\) in View Object Attributes."](#)

**Before you begin:**

You will need to complete these tasks:

- Create the desired view objects as described in [Section 5.2.1, "How to Create an Entity-Based View Object,"](#) and [Section 5.2.3, "How to Create an Expert Mode, Read-Only View Object."](#)
- Optionally, enable auto refresh for the read-only view object that you will define as a view instance of a shared application module, as described in [Chapter 5.13.6, "How to Automatically Refresh the View Object of the View Accessor."](#)

If you need to ensure that your view accessor always queries the latest data from the lookup table, you can set the **Auto Refresh** property on the destination view object. This property allows the view object instance to refresh itself after a change in the database. The typical use case is when you define a view accessor for the destination view object.

**To create an LOV that displays values from a lookup table:**

1. In the Application Navigator, right-click the view object that contains the desired attribute and choose **Open ViewObjectName**.
2. In the overview editor, click the **View Accessors** navigation tab.
3. In the View Accessors page, check to see whether the view object inherited the desired view accessor from its base entity object. If no view accessor is present, either create the view accessor on the desired entity object or click the **Create new view accessors** button to add the accessor to the view object you are currently editing.

Validation rules that you define are always defined on the attributes of the view object's base entity object. It may therefore be convenient to define view accessors at the level of the base entity objects when you know that you will also validate entity object attributes using a view accessor list.

For details about creating a view accessor, see [Section 10.4.1, "How to Create a View Accessor for an Entity Object or View Object."](#)

4. In the overview editor, click the **Attributes** navigation tab.
5. In the Attributes page, select the attribute that is to display the LOV, and then expand the **List of Values** section and click the **Add list of values** button.
6. In the List of Values dialog, select the view accessor from the **List Data Source** dropdown list.

The view accessor you select, will be the one created for the lookup table view object instances to use as the data source.

7. Select the attribute from this view accessor from the **List Attribute** dropdown list that will return the list of values for the attribute you are currently editing.

The editor creates a default mapping between the view object attribute and the LOV-enabled attribute. In this use case, the attributes are the same. For example, the attribute `OrderId` from the `OrdersView` view object would map to the attribute `OrderId` from the `Shared_OrdersVA` view accessor.

8. Optionally, when you want to specify supplemental values that your list returns to the base view object, click **Add** icon in **List Return Values** and map the desired view object attributes to the same attributes accessed by the view accessor.

Supplemental attribute return values are useful when you do not require the user to make a list selection for the attributes, yet you want those attributes values, as determined by the current row, to participate in the update.

For example, to map the attribute `StartDate` from the `OrdersView` view object, you would choose the attribute `StartDate` from the `Shared_OrdersVA` view accessor. Do not remove the default attribute mapping for the attribute for which the list is defined.

9. Click OK.

## 10.4.5 What Happens When You Define an LOV for a View Object Attribute

When you add an LOV to a view object attribute, JDeveloper updates the view object's XML file with an `LOVName` property in the `<ViewAttribute>` element. The definition of the LOV appears in a new `<ListBinding>` element. The metadata in [Example 10–6](#) shows that the `MaritalStatusCode` attribute refers to the `MaritalStatusLOV` LOV and sets the choice control type to display the LOV. The LOV definition for `MaritalStatusLOV` appears in the `<ListBinding>` element.

### Example 10–6 View Object with LOV List Binding XML Code

```
<ViewObject
  xmlns="http://xmlns.oracle.com/bc4j"
  Name="CustomerRegistrationVO"
  ...
  <ViewAttribute Name="MaritalStatusCode" IsNotNull="true" PrecisionRule="true"
    EntityAttrName="MaritalStatusCode" EntityUsage="PersonEO"
    AliasName="MARITAL_STATUS_CODE"
    LOVName="MaritalStatusCodeLOV">
    <Properties>
      <SchemaBasedProperties>
        <CONTROLTYPE Value="choice"/>
      </SchemaBasedProperties>
    </Properties>
  </ViewAttribute>
  ...
  <ListBinding
    Name="MaritalStatusLOV"
    ListVOName="PersonEO.MaritalStatusVA"
    ListRangeSize="-1"
    NullValueFlag="start"
    NullValueId="LOVUIHints_NullValueId"
    MRUCount="0">
    <AttrArray Name="AttrNames">
      <Item Value="MaritalStatusCode"/>
    </AttrArray>
    <AttrArray Name="ListAttrNames">
      <Item Value="Value"/>
    </AttrArray>
    <AttrArray Name="ListDisplayAttrNames">
      <Item Value="Name"/>
    </AttrArray>
    <DisplayCriteria/>
    <AttrArray Name="DerivedAttrNames"/>
  </ListBinding>
  ...
</ViewObject>
```

### 10.4.6 What Happens at Runtime: When the Attribute Displays the List of Values

The ADF Business Components runtime adds functionality in the attribute setters of the view row and entity object to facilitate the LOV-enabled attribute behavior. In order to display the LOV-enabled attribute values in the user interface, the LOV facility fetches the data source, and finds the relevant row attributes and mapped target attributes.

### 10.4.7 What You May Need to Know About Displaying List of Values From a Lookup Table

Unlike entity-based view objects, read-only view objects that you create in expert mode, will not define a key attribute by default. While it is possible to create a read-only view object without defining its key attribute, in expert mode it is a best practice to select the attribute that corresponds to the queried table's primary key and mark it as the key attribute. The presence of a key attribute ensure the correct runtime behavior for row set navigation. For example, the user interface developer may create a LOV component based on the read-only view object collection. Without a key attribute to specify the row key value, the LOV may not behave properly and a runtime error can result.

### 10.4.8 What You May Need to Know About Inheritance of AttributeDef Properties

When one view object extends another, you can create the LOV-enabled attribute on the base object. Then when you define the child view object in the overview editor, the LOV definition will be visible on the corresponding view object attribute. This inheritance mechanism allows you to define an LOV-enabled attribute once and apply it later across multiple view objects instances for the same attribute. For details about extending a view object from another view object definition, see [Section 37.8.2, "How To Extend a Component After Creation."](#)

You can also use the overview editor to extend the inherited LOV definition. For example, you may add extra attributes already defined by the base view object's query to display in selection list. Alternatively, you can create a view object instance that uses a custom `WHERE` clause to query the supplemental attributes not already queried by the base view object. For information about customizing entity-based view objects, see [Section 5.10, "Working with Bind Variables."](#)

### 10.4.9 What You May Need to Know About Using Validators

If you have created an LOV-enabled attribute for a view object, there is no need to validate the attribute using a List validator. You use an attribute validator only when you do not want the list to display in the user interface but still need to restrict the list of valid values. A List validator may be a simple static list or it may be a list of possible values obtained through a view accessor you define. Alternatively, you might prefer to use a Key Exists validator when the attribute displayed in the UI is one that references a key value (such as a primary, foreign, or alternate key). For information about declarative validation in ADF Business Components, see [Chapter 7, "Defining Validation and Business Rules Declaratively."](#)

## 10.5 Testing View Object Instances in a Shared Application Module

JDeveloper includes an interactive application module testing tool that you can use to test all aspects of its data model without having to use your application user interface or write a test client program. Running the Business Component Browser can often be

the quickest way of exercising the data functionality of your business service during development.

### 10.5.1 How to Test the Base View Object Using the Business Component Browser

The application module is the transactional component that the Business Component Browser (or UI client) will use to work with application data. The set of view objects used by an application module defines its data model, in other words, the set of data that a client can display and manipulate through a user interface. You can use the Business Component Browser to test that the accessors you defined yield the expected validation result and that they display the correct LOV attribute values.

To create an application module, use the Create Application Module wizard, which is available in the New Gallery. For more information, see [Section 9.2, "Creating and Modifying an Application Module."](#)

To test the view objects you added to an application module, use the Business Component Browser, which is accessible from the Application Navigator.

#### To test view objects in an application module configuration:

1. In the Application Navigator, expand the project containing the desired application module and view objects.
2. Right-click the application module and choose **Run**.

Alternatively, choose **Debug** when you want to run the application in the Business Component Browser with debugging enabled. For example, when debugging using the Business Component Browser, you can view status message and exceptions, step in and out of source code, and manage breakpoints. JDeveloper opens the debugger process panel in the Log window and the various debugger windows.

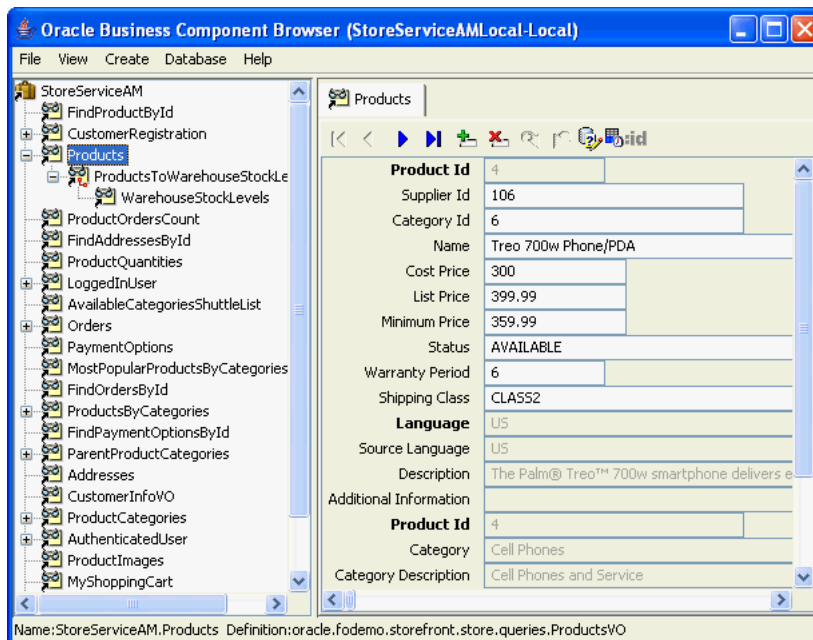

For details about receiving diagnostic messages specific to ADF Business Components debugging, see [Section 6.3.8, "How to Enable ADF Business Components Debug Diagnostics."](#)

3. In the Select Business Components Configuration dialog, choose the desired application module configuration from the **Business Component Configuration Name** list to run the Business Component Browser.

By default, an application module has only its default configurations, named *AppModuleNameLocal* and *AppModuleNameShared*. If you have created additional configurations for your application module and want to test it using one of those instead, just select the desired configuration from the **Business Components Configuration** dropdown list on the Connect dialog before clicking **Connect**.

4. Click **Connect** to start the application module using the selected configuration.
5. To execute a view object in the Business Component Browser, expand the tree list and double-click the desired view object node.

Note that the view object instance may already appear executed in the testing session. In this case, the tester panel on the right already displays query results for the view object instance, as shown in [Figure 10-9](#). The fields in the tester panel of a read-only view object will always appear disabled since the data it represents is not editable.

**Figure 10–9 Testing the Data Model in the Business Component Browser**

## 10.5.2 How to Test LOV-Enabled Attributes Using the Business Component Browser

To test the LOV you created for a view object attribute, use the Business Component Browser, which is accessible from the Application Navigator. For details about displaying the Browser and the supported control types, see [Section 5.13.7, "How to Test LOV-Enabled Attributes Using the Business Component Browser."](#)

## 10.5.3 What Happens When You Use the Business Component Browser

When you launch the Business Component Browser, JDeveloper starts the tester tool in a separate process and the Business Component Browser appears. The tree at the left of the dialog displays all of the view object instances in your application module's data model. [Figure 10–9](#) shows just one instance in the expanded tree, called `ProductImages`. After you double-click the desired view object instance, the Business Component Browser will display a panel to inspect the query results, as shown in [Figure 10–9](#).

The test panel will appear disabled for any read-only view objects you display because the data is not editable. But even for the read-only view objects, the tool affords some useful features:

- You can validate that the UI hints based on the Label Text control hint and format masks are defined correctly.
- You can also scroll through the data using the toolbar buttons.

The Business Component Browser becomes even more useful when you create entity-based view objects that allow you to simulate inserting, updating, and deleting rows, as described in [Section 6.3.2, "How to Test Entity-Based View Objects Interactively."](#)

## 10.5.4 What Happens at Runtime: When Another Service Accesses the Shared Application Module Cache

When a shared application module with application scope is requested by an LOV, then the ADF Business Components runtime will create an `ApplicationPool` object for that usage. There is only one `ApplicationPool` created for each shared usage that has been defined in the Business Components project file (`.jspx`). The runtime will then use that `ApplicationPool` to acquire an application module instance that will be used like a user application module instance, to acquire data. The reference to the shared application module instance will be released once the application-scoped application module is reset. The module reference is released whenever you perform an unmanaged release or upon session timeout.

Since multiple threads will be accessing the data caches of the shared application module, it is necessary to partition the iterator space to prevent race conditions between the iterators of different sessions. This will help ensure that the next request from one session does not change the state of the iterator that is being used by another session. The runtime uses ADF Business Components support for multiple iterators on top of a single `RowSet` to prevent these race conditions. So, the runtime will instantiate as many iterators as there are active sessions for each `RowSet`.

An application-scoped shared application module lifecycle is similar to the lifecycle of any application module that is managed by the `ApplicationPool` object. For example, once all active sessions have released their shared application module, then the application module may be garbage-collected by the `ApplicationPool` object. The shared pool may be tuned to meet specific application requirements.

Session-scoped shared application modules are simply created as nested application module instances within the data model of the root, user application module. For details about nested application modules, [Section 9.4, "Defining Nested Application Modules."](#)

---

---

# Integrating Service-Enabled Application Modules

This chapter describes how to publish ADF application modules and how to define a service interface connection to make them available as external web services in a Fusion web application. It also describes how to incorporate the published application module as an external service in a Fusion web application.

This chapter includes the following sections:

- [Section 11.1, "Introduction to Service-Enabled Application Modules"](#)
- [Section 11.2, "Publishing Service-Enabled Application Modules"](#)
- [Section 11.3, "Accessing Remote Data Over the Service-Enabled Application Module"](#)

## 11.1 Introduction to Service-Enabled Application Modules

*Service-enabled application modules* are ADF application modules that you advertise through a service interface to service consumers. There are three scenarios for service consumers to consume a published service-enabled application module: web service access, Service Component Architecture (SCA) composite access, and access by another ADF application module.

---

---

**Note:** For background about web services and Oracle WebLogic Server support for web services, see *Oracle Fusion Middleware Introducing Web Services*.

---

---

Service Component Architecture (SCA) provides an open, technology-neutral model for implementing remotable services that are defined in terms of business functionality and that make middleware functions more accessible to application developers. ADF Business Components supports an SCA-compliant solution through application modules you can publish with a service interface.

When you service-enable your application module, JDeveloper generates the necessary artifacts comprising: 1) The Java interface defining the service, 2) an EJB 3.0 session bean that implements this Java interface, 3) a WSDL file that describes the service's operations, and (4) XML schema documents (XSD) that defines the service's data structures. The service interface is described for Fusion web application clients in a language-neutral way by the combination of WSDL and XSD.

SCA defines two kinds of service:

- Remotable services, typically coarse-grained and designed to be published remotely in a loosely coupled SOA architecture
- Local services, typically fine-grained and designed to be used locally by other implementations that are deployed concurrently in a tightly coupled architecture

ADF Business Components services fall into the first category, and should only be used as remotable services.

ADF Business Components services, including data access and method calls, defined by the remote application modules are interoperable with any other application module. This means the same application module can support interactive web user interfaces using ADF data controls and web service clients.

Any development team can publish a service-enabled application module to contribute to the Fusion web application. The Fusion web application assembled from remote web services also does not require the participating services to run on a single application server.

Although the web applications may run on separate application servers, the appearance that SCA provides is one of a unified application. Consuming client projects use the ADF service factory lookup mechanism to access the data and any business methods encapsulated by the service-enabled application module. At runtime, the calling client and the ADF web service may or may not participate in the same transaction, depending on the protocol used to invoke the service (either SOAP or RMI). Only the RMI protocol and a Java Transaction API (JTA) managed transaction support the option to call the service in the same transaction as the calling client. By default, to support the RMI protocol, the ADF web service is configured to participate in the same transaction.

For information about the SCA service data object (SDO) standards, see the Specifications section of the website for the Organization for the Advancement of Structured Information Standards (OASIS) through the Open Composite Services Architecture (CSA) at <http://www.oasis-open.org>.

## 11.2 Publishing Service-Enabled Application Modules

The application module is ADF Business Components framework component that encapsulates business logic as a set of related business functions. Application modules are mapped to services. You use the overview editor for your application module to enable a web service interface and publish rows of view object data as service data object (SDO) components.

The SDO framework upon which the SDO components are based abstracts the data of the view object and standardizes the way that data structures are passed between Java and XML. This data abstraction simplifies working with heterogeneous data sources in a service-oriented architecture (SOA) and lets you selectively service-enable view objects using the same view object to support interactive web user interfaces and web service clients.

JDeveloper allows you to expose application modules as web services which use SDO components based on view instance that your application module defines to standardize the way that data structures are passed between Java and XML. JDeveloper also generates the WSDL service description that is used by the web service client in the consuming application.

---

---

**Note:** JDeveloper only supports generating SDO components for view objects of a service-enabled application module. Currently, no other ADF Business Components may be defined as SDO components.

---

---

The service-enabled application module exposes the view objects, custom methods, built-in data manipulation operations, and specialized find methods based on named view criteria to be used by the client. Once you have enabled the application module service interface, you will need to create an ADF Business Components Service Interface deployment profile and deploy it to the target application server.

You can also expose the view instance data manipulation operations for use with a Business Process Execution Language (BPEL) process service component. BPEL is a language for composing multiple services into an end-to-end business process. For details about how to delegate data operations to the SDO data provider through the use of the BPEL entity variable, see the "Delegating XML Data Operations to Data Provider Services" section in the "Manipulating XML Data in a BPEL Process" chapter of the *Oracle Fusion Middleware Developer's Guide for Oracle SOA Suite*.

---

---

**Note:** It is important to note that you don't implement methods with SDO parameters directly. The SDO framework is used to wrap the view row types during runtime only.

---

---

## 11.2.1 How to Enable the Application Module Service Interface

You edit the application module in JDeveloper to create a web service interface that exposes the top-level view objects and defines the available service operations it supports. The top-level view objects that you select are service-enabled automatically and will be accessible by the service client.

The primary purpose of the standard service operations is to expose data manipulation operations on the view objects. Any business logic that you have defined on the underlying framework objects (for example, business rule validation) will be applied when you invoke a standard service operation. [Table 11-1](#) shows the list of standard operations that service view instances support.

**Table 11-1 Standard View Instance Data Manipulation Operations**

Operation	Method Name	Operation Description
Create	create<VOName>	Creates an ADF Business Components view row.
Update	update<VOName>	Updates an ADF Business Components view row.
Delete	delete<VOName>	Deletes an ADF Business Components view row.
Merge	merge<VOName>	Updates an ADF Business Components view row if one exists; otherwise, creates a new one.
GetByKey	get<VOName>	Gets a single ADF Business Components view row by primary key.

**Table 11–1 (Cont.) Standard View Instance Data Manipulation Operations**

Operation	Method Name	Operation Description
Find (by view criteria applied to view object query statement)	<code>find&lt;VOName&gt;</code>	<p>Finds and returns a list of ADF Business Components view rows using an SDO-based view criteria that is applied to the selected view object's query statement.</p> <p>Note that the query must not specify a bind variable defined as required for the query to execute. The service interface does not expose required bind variables at runtime. For details about creating a find method for this scenario, see <a href="#">Section 11.2.9, "How to Expose a Declarative Find Operation Filtered By a Required Bind Variable."</a></p>
Find (by view criteria)	<code>find&lt;VOName&gt;&lt;VCName&gt;</code>	Finds and returns a list of single ADF Business Components view rows by named view criteria and values for the required bind variables. This is the preferred way to filter the ADF Business Components view rows that rely on a required bind variable.
Process	<code>process&lt;VOName&gt;</code>	Performs a Create, Update, Delete, or Merge operation on a list of ADF Business Components view rows. The specified operation is applied to all objects in the given list.
ProcessChangeSummary	<code>processCS&lt;VOName&gt;</code>	Performs a Create, Update, or Delete operation on a list of ADF Business Components view rows. Different operations may be applied to different objects, depending on what is specified in the <code>ChangeSummary</code> object.

Additionally, several built-in methods can be optionally added to the client service interface of the application module (`AppModuleService.java`). [Table 11–2](#) shows the list of built-in methods that provide runtime support for service view instances that you enable.

**Table 11–2 Built-In Service Interface Methods**

Operation	Method Name and Async Method Name	Method Description
Generate Object and Attribute Control Hint Operations	getDfltObjAttrHints() getDfltObjAttrHintsAsync()	Returns the base UI hints, including object and attribute display name labels, for an object based on a specific locale. The method takes the name of the object, at the service, to get the hints and the locale name (in ISO 639-1 format) to drive localization of base hints.  This method may be used by the web service consuming application to generate a user interface with the correct labels for the service view instance and its attributes. For details about specifying display name UI hints, see <a href="#">Section 11.2.15, "How to Set Display Names for Service View Instances and Attributes."</a>
Generate Last Update Time Operations	getServiceLastUpdateTime() getServiceLastUpdateTimeAsyncResponse()	Returns the last modified time for the service schema files at the SOAP service endpoint.  This method may be used by the web service consuming application that caches the service view instance schema files (XSD) to determine when the object has been updated.
Generate Entity List Operation	getEntityList() getEntityListAsync()	Returns the list of service view instance names and flags that indicate whether each service view object at the SOAP service endpoint supports Create, Update, Merge, and Delete operations.  This method may be used by the web service consuming application that uses custom object services to determine the available operations. Custom object services are not created using the ADF Business Components web service design time and are not described in this documentation.

---

**Note:** When you enable the service interface on a parent view object, JDeveloper automatically enables the service interface for view instances that extend the parent in a polymorphic collection. For details about polymorphic view objects, see [Section 39.6.5, "Working with Polymorphic View Rows."](#)

---

For information on how to create SDO classes to selectively service-enable child view objects, see [Section 11.2.5, "How to Service-Enable Individual View Objects."](#)

**Before you begin:**

Create the desired application module as described in [Section 9.2.1, "How to Create an Application Module."](#)

When you create the service-enabled application module, do not create it in a project that already contains a standard web service (a Java class or interface with the `@WebService` annotation). JDeveloper deployment profiles do not support deploying a standard web service and an ADF Business Service web service from the same project. If you attempt to deploy the ADF Business Service web service from the same project as a standard web service, the deployment will fail with an Oracle WebLogic Server exception error.

You will need to complete these tasks:

- Create the desired view objects, as described in [Section 5.2.1, "How to Create an Entity-Based View Object."](#)
- Create the desired application module, as described in [Section 9.2.1, "How to Create an Application Module."](#)
- Optionally, set JDeveloper preferences to specify a default suffix for the names of generated SDO classes, modify the default subpackage where the service interface and classes reside, and set the default namespace prefix for the generated SDO schema and web service, as described in [Section 11.2.14, "How to Set Preferences for Generating the ADF Web Service Interface."](#)
- Optionally, specify view object UI hints to define display name labels when you want to support a web service consuming application that programmatically creates the user interface with the display name labels, as described in [Section 11.2.15, "How to Set Display Names for Service View Instances and Attributes."](#)
- If you want to expose custom find operations on the service, create declarative view criteria to specify the custom query, as described in [Section 5.11.1, "How to Create Named View Criteria Declaratively."](#)

**To create the web service interface:**

1. In the Application Navigator, double-click the application module.
2. In the overview editor, click the **Service Interface** navigation tab and then click the **Enable support for Service Interface** button.

Use the Create Service Interface wizard to configure the desired options.

3. In Create Service Interface wizard, on the Service Interface page, enter the name and target namespace for the web service.

The target namespace is a URI for the service that you can assign to group similar services together by entering the same URI. The default target namespace is the package name of the application module combined with package names that you specify in the Preferences dialog.

**Tip:** You can define JDeveloper preferences that will shape the URI and allow you to define a unique target namespace for your service. For details about namespace URI shaping preferences, see [Section 11.2.14, "How to Set Preferences for Generating the ADF Web Service Interface."](#)

4. To expose the methods of the application module as asynchronous service methods and enable both synchronous and asynchronous operations on the web service, select **Generate Asynchronous Web Service Methods**.

By default, the web service supports synchronous service methods. This forces the invoking client application to wait for the response to return before it can continue

with its work. In cases where the response returns immediately, this method of invoking the web service is common. However, because request processing can be delayed, it is often useful for the client application to continue its work and to handle the response later on.

5. The **Service Categories** list will appear empty unless role shaping has been defined based on previously defined customization roles. Leave the Selected list empty unless your organization is classifying services.

This feature has no impact on the service WSDL file and has no relevance to the operation of web services.

6. On the Service Built-in Methods page, optionally, select **Generate Object and Attribute Control Hints Operation** to generate a method that will return the static control hints (UI hints) defined on a view instance and its attributes.

When you enable this option, the wizard adds the `getDfltObjAttrHints()` method to the client service interface (`AppModuleService.java`). The web service consuming application can invoke this method to resolve UI hints on the server without requiring a database roundtrip. The method takes a service view object name and a locale name and returns the base UI hints, including object and attribute display name labels, for an object based on a specific locale. If the locale name is not specified, the method uses the default locale.

7. Optionally, select **Generate Last Update Time Operation** to generate a method that will return the last modified time for the service schema files.

When you enable this option, the wizard adds the `getServiceLastUpdateTime()` method to the client service interface (`AppModuleService.java`). Before any customization occurs, this method returns the file timestamp of the last updated schema file. When a schema is customized at runtime, the last-update timestamp is updated, and this latest timestamp will be returned. This feature is primarily useful in web service consuming applications that cache the service XSD.

8. Optionally, select **Generate Entity List Operation** to generate a method that will return the list of service view instances.

When you enable this option, the wizard adds the `getEntityList()` method to the client service interface (`AppModuleService.java`). The method returns the list of service view instance names, XSD type, and flags that indicate whether the service view supports Create, Update, Merge, and Delete operations. This feature is primarily useful in web service consuming applications that require customization.

9. On the Service Custom Methods page, add the custom methods you want to expose in the service interface and define the data types of each method's parameters and return value.

The parameters and non-void return value of the custom service methods you enable must be one of the service-interface supported data types, such as a Java primitive type, or a list of the service-interface supported data types (including `oracle.jbo.server.ViewRowImpl`, `java.util.List<ViewRowImpl>`, `oracle.jbo.AttributeList`, `java.util.List<AttributeList>`, or `java.util.List<PrimitiveType>`).

Note that although both `ViewRowImpl` and `AttributeList` data types expose the identical row structure to the web service client, at runtime there will be a fundamental difference. For a description of the supported data types, see [Section 11.2.3, "What You May Need to Know About Method Signatures on the ADF Web Service Interface."](#)

After selecting a qualifying custom method to appear in the service interface, for each parameter and return value using the `ViewRowImpl` or `AttributeList` data type, you must in turn select the name of the view object instance corresponding to the row structure:

- a. In the Selected list, expand **return** or **parameters** and select the item.
- b. Enter the Java element data type in **Element Java Type**.
- c. In the case where the Java element type is `ViewRowImpl` or `AttributeList`, enter the view object instance name to identify the row structure in **Element View Object**.

For example, if you define a custom method to return a single row of the `CustomerInfo` view object instance, you would need a custom method signature like this:

```
public ViewRowImpl findCustomerInfo(int id)
```

Then, after selecting the `findCustomerInfo()` custom method to appear in the service interface, you would select its return value in the tree and configure its **View Object** property to be `CustomerInfo`, the view instance name whose row structure should be used at runtime.

10. To expose service information messages for a custom method or warnings for process operation methods, select **Include Warnings in Return Service Data Object**.

For example, you might want to display an informational message when a method returns the total employee compensation and the total is outside of the desired range.

If **Include Warnings** is not selected, no informational messages will be returned with the service response.

This option is only enabled when the method does not return a view row or a list of view rows. When the method returns view rows, the underlying view object determines whether the method supports warnings, as described [Section 11.2.5, "How to Service-Enable Individual View Objects."](#)

The informational messages (and warnings) are reported as part of the return object. JDeveloper generates appropriate wrappers as the return objects, and the wrappers contain the actual method return and the informational messages.

11. On the Service View Instances page, select the top-level view instances in the application module that you want to expose in the service interface.

View object subtypes of the top-level view instance will automatically be service-enabled.

Also, on this page, you can enable the available data manipulation operations supported on the exposed methods, as shown in [Figure 11-1](#).

Figure 11–1 View Instances and CRUD Operation Selection

12. In the Basic Operations tab, select the data manipulation operations for the currently selected view instance and in the **Method Name** field, change the names of the selected service operations to the names that you prefer to expose in the service interface.

The primary purpose of the standard service operations is to expose data manipulation operations on the view objects. Any business logic that you have defined on the underlying framework objects (for example, business rule validation) will be applied when you invoke the service operations. For a description of the operations that service view instances support, see [Table 11–1](#).

In the case of the find method operation that you can select, the find method must not reference a required bind variable in the view object's query statement. A required bind variable is one that makes the query execution dependent on the availability of a valid value for the bind variable. The service interface does not expose required bind variables at runtime. For details about defining a find operation for this scenario, see [Section 11.2.9, "How to Expose a Declarative Find Operation Filtered By a Required Bind Variable."](#)

13. To expose declarative find operations, select the **View Criteria Find Operations** tab and click the **Add View Criteria** icon.

You can define custom find operations when you want the service to support executing a predefined query. For information about defining a named view criteria, see [Section 5.11, "Working with Named View Criteria."](#)

---

**Caution:** The service interface find operations are based on specific view criteria that your project defines. This means that the bind variables of the view criteria must match the parameters of the corresponding find operation method. If you change the number or order of the bind variables after the find operation is defined and service interface generated, the corresponding method will not execute at runtime. Therefore, after changing the underlying view criteria, you must regenerate the service interface.

---

- a. In the Configure View Criteria Find Operation dialog, choose the named view criteria for the find operation.

The dialog displays the list of view criteria exposed by the referenced view object. For example, `OrderInfoVO` defines `OrderInfoVOCriteria` with a bind variable `OrdId` that specifies the order ID, as shown in [Figure 11–2](#).

**Figure 11–2 Specialized Find Methods Based on Named View Criteria**

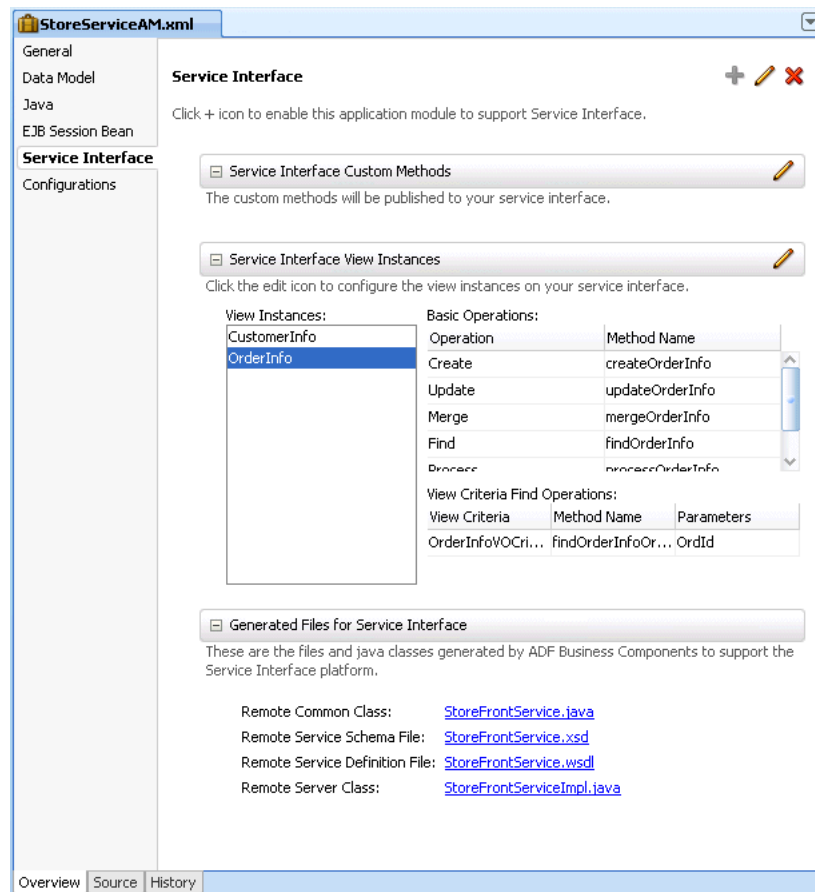

- b. If the view criteria uses a bind variable, you can double-click the XML name to customize the name as it will appear in the XML definition for the service.
14. Click **Next** to review the custom methods that your service view instances will expose.
  15. Click **Finish**.

## 11.2.2 What Happens When You Create an Application Module Service Interface

JDeveloper generates the service interface class and enables any view instance options you have chosen, as shown in [Figure 11–3](#).

Do not modify the generated files for the service-enabled application module. The generated files implement required methods of the service interface. An exception to this are use cases that require adding Java annotations to the service implementation class. For example, annotations that you add in the service implementation class let you attach security policies, as described in [Section 11.2.16, "How to Secure the ADF Web Service for Access By SOAP Clients."](#)

**Figure 11–3 Service Interface Page of the Overview Editor for an Application Module**

The following types of files are generated and are listed in the Application Navigator in the Projects panel, under the application module's **serviceinterface** node, as shown in Figure 11–4.

- Web service interface, for example, `StoreFrontService.java`
- Web service schema file, for example, `StoreFrontService.xsd`
- Web service definition file, for example, `StoreFrontService.wsdl`
- Web service implementation class, for example, `StoreFrontServiceImpl.java`

**Figure 11–4 Service Interface Files Appear Below Application Module**

In addition, the `connections.xml` file is created when you first create an ADF Business Components service. Although this file is only used by the web service client (the consuming application), it is generated with the service-enabled application module as a convenience. This file appears in the Application Navigator in the Application Resources panel, under the **Descriptors** and **ADF META-INF** nodes.

### 11.2.2.1 Annotations Generated in the Web Service Interface

The web service interface uses metadata annotations specified by the web service specification (JSR-181) to indicate how the interface should be exposed as a web service. This example shows part of `StoreFrontService.java`, which is the web service interface for the `StoreServiceAM` application module in the `StoreFront` module of the Fusion Order Demo.

#### Example 11–1 Web Service Interface in Fusion Order Demo

```
package oracle.fodemo.storefront.store.service.common.serviceinterface;
...
import javax.jws.WebMethod;
import javax.jws.WebParam;
import javax.jws.WebResult;
import javax.jws.soap.SOAPBinding;
...
import oracle.fodemo.storefront.store.queries.common.CustomerInfoVOSDO;
import oracle.fodemo.storefront.store.queries.common.OrderInfoVOSDO;
...
import oracle.webservices.annotations.PortableWebService;
import oracle.webservices.annotations.SDODatabinding;
...
@SOAPBinding(parameterStyle = SOAPBinding.ParameterStyle.WRAPPED, style=SOAPBinding.Style.DOCUMENT)
@PortableWebService(targetNamespace="http://www.globalcompany.com/StoreFrontService",
    name="StoreFrontService",
    wsdlLocation=
```

```

        "oracle/fodemo/storefront/store/service/common/serviceinteface/StoreFrontService.wsdl")
@SDODataBinding(schemaLocation=
        "oracle/fodemo/storefront/store/service/common/serviceinteface/StoreFrontService.xsd")
public interface StoreFrontService
{
    public static final String NAME = ("http://www.globalcompany.com/StoreFrontService")

    /**
     * @param orderId
     * @return
     * @throws ServiceException
     */
    @WebMethod(action="www.globalcompany.example.com/getOrderInfoVOSDO",
        operationName="getOrderInfoVOSDO")
    @RequestWrapper(targetNamespace="www.globalcompany.example.com/types/",
        localName="getOrderInfoVOSDO")
    @ResponseWrapper(targetNamespace="www.globalcompany.example.com/types/",
        localName="getOrderInfoVOSDOResponse")
    @WebResult(name="result")
    OrderInfoVOSDO getOrderInfoVOSDO(@WebParam(mode = WebParam.Mode.IN, name="orderId")
        BigInteger orderId) throws ServiceException;
    ...
}

```

### 11.2.2.2 Web Service Schema Generated in the Web Service Schema File

The web service schema file is an XML schema file which represents the web service schema, as shown in [Figure 11-5](#).

**Figure 11-5 Web Service Schema File**

### 11.2.2.3 WSDL Generated in the Web Service Definition File

The web service definition file is a XML-structured document file that conforms to the Web Service Definition Language (WSDL) specification that describes the generated web service as a collection of endpoints, or ports. A port is defined by associating a

network address with a reusable binding. The client application that connects to the web service reads the WSDL to determine what functions are available on the server. The WSDL also specifies the endpoint for the service itself, which you can use to locate and test your deployed service.

Figure 11–6 shows the WSDL for the web service generated for the `StoreServiceAM` application module in the WSDL visual editor. You can see the WSDL as an XML document by selecting the **Source** tab.

**Figure 11–6 WSDL Document**

#### 11.2.2.4 Stateless Session Bean Specified by the Service Implementation Class

The service implementation class is an EJB 3.0 stateless session bean that implements the web service interface and extends the `oracle.jbo.server.svc.ServiceImpl` class, the generic service implementation for ADF Business Components.

Example 11–2 shows part of `StoreFrontServiceImpl.java`, which is the service implementation class for the `StoreServiceAM` application module in the `StoreFront` module of the Fusion Order Demo.

#### Example 11–2 Web Service Implementation Class Implements the Web Service Interface

```
package oracle.fodemo.storefront.store.service.server.serviceinterface;
...
import oracle.fodemo.storefront.store.queries.common.CustomerInfoVOSDO;
import oracle.fodemo.storefront.store.queries.common.OrderInfoVOSDO;
import oracle.fodemo.storefront.store.service.common.serviceinterface.StoreFrontService;
...
import oracle.webservices.annotations.PortableWebService;
import weblogic.javaee.CallByReference;
...
@Stateless(name="oracle.fodemo.storefront.store.service.common.StoreFrontServiceBean")
@Remote(StoreFrontService.class)
@PortableWebService(targetNamespace="http://www.globalcompany.com/StoreFrontService",
    serviceName="StoreFrontService", portName="StoreFrontServiceSoapHttpPort",
    endpointInterface="oracle.fodemo.storefront.store.service.common.serviceinterface.StoreFrontService")
```

```

@CallByReference
public class StoreFrontServiceImpl extends ServiceImpl implements StoreFrontService
{
    ...
    /**
     * findCustomerInfoV01: generated method. Do not modify.
     * @param findCriteria
     * @param findControl
     * @return
     * @throws ServiceException
     */
    public List<CustomerInfoVOSDO> findCustomerInfoV01(FindCriteria findCriteria,
                                                       FindControl findControl) throws ServiceException {
        return (List<CustomerInfoVOSDO>)find(findCriteria, findControl,
                                             "CustomerInfoV01",
                                             CustomerInfoVOSDO.class);
    }
    ...
}

```

### 11.2.2.5 Lookup Defined in the connections.xml File

The `connections.xml` file allows the web service client to look up the service with the factory class `oracle.jbo.client.svc.ServiceFactory`. The ADF Business Components service factory provides the mechanism that allows the service client to look up the service. The service factory relies on ADF connection architecture and the `connections.xml` file to manage service endpoint locations. The `connections.xml` file is created when you first create an ADF Business Components service. This file appears in the Application Navigator in the Application Resources panel, under the **Descriptors** and **ADF META-INF** nodes.

[Example 11-3](#) shows the initial `connections.xml` entry created by JDeveloper when you first create an ADF Business Components service.

#### **Example 11-3** *connections.xml* File Generated by JDeveloper

```

<Reference name="{http://www.globalcompany.com}StoreFrontService"
           className="oracle.jbo.client.svc.Service" xmlns="">
  <Factory className="oracle.jbo.client.svc.ServiceFactory"/>
  <RefAddresses>
    <StringRefAddr addrType="serviceName">
      <Contents>oracle.fodemo.storefront.store.service.common.serviceinterface.
        StoreFrontService</Contents>
    </StringRefAddr>
    <StringRefAddr addrType="serviceEndpointProvider">
      <Contents>ADFBC</Contents>
    </StringRefAddr>
    <StringRefAddr addrType="jndiName">
      <Contents>oracle.fodemo.storefront.store.service.common.
        StoreFrontServiceBean</Contents>
    </StringRefAddr>
    <StringRefAddr addrType="serviceSchemaName">
      <Contents>StoreFrontService.xsd</Contents>
    </StringRefAddr>
    <StringRefAddr addrType="serviceSchemaLocation">
      <Contents>oracle/fodemo/storefront/store/service/common/
        serviceinterface/</Contents>
    </StringRefAddr>
  </RefAddresses>
</Reference>

```

### 11.2.3 What You May Need to Know About Method Signatures on the ADF Web Service Interface

You can define two different kinds of interfaces for an application module: the client interface and the service interface. The client interface is used by the ADF Model layer for UI clients. The service interface is for application integration and is used by external web services or other application services (either programmatically or automatically using the service-enabled entity feature).

An application module can support no interface at all, only client interfaces, only service interfaces, or both client interfaces and service interfaces combined. However, be aware that the two kinds of interfaces differ in the data types that are supported for the parameters and/or return values of your custom methods that you define for the respective interfaces. The types supported on the client interface are described in [Section 9.9.5, "What You May Need to Know About Method Signatures on the Client Interface."](#)

The service interface, in contrast to the client interface, supports a more narrow set of data types for custom method parameters and return values and is limited to:

- Java primitive types and their object wrapper types (for example, `int`, `Integer`, and `Long`)
- `java.lang.String`
- `java.math.BigDecimal`
- `java.math.BigInteger`
- `java.sql.Date`
- `java.sql.Time`
- `java.sql.Timestamp`
- `java.util.Date`
- `oracle.jbo.AttributeList`
- `oracle.jbo.domain.BlobDomain`
- `oracle.jbo.domain.Char`
- `oracle.jbo.domain.ClobDomain`
- `oracle.jbo.domain.DBSequence`
- `oracle.jbo.domain.Date`
- `oracle.jbo.domain.NClobDomain`
- `oracle.jbo.domain.Number`
- `oracle.jbo.domain.Timestamp`
- `oracle.jbo.domain.TimestampLTZ`
- `oracle.jbo.domain.TimestampTZ`
- `oracle.jbo.server.ViewRowImpl` or any subtype
- `java.util.List<aType>`, where *aType* is any of the service-interface supported data types, including Java primitive type

**Note:** The service interface specifically does not support Java Map collection. This means it is not possible to return a collection of objects that are of different types. However, a collection is not limited to view row attributes, a return type can be defined as a list of any service-interface supported data type. For example, `List<DataObject>`, `List<AttributeList>`, and `List<String>` are all valid types.

You can define a custom method that returns a type of `AttributeList` when you want to allow the client developer to work with the list of attributes and perform custom operations without the need to involve framework behavior before the custom method executes. As an alternative, when the client developer wants the framework to manage rows (create, find, and populate), define custom methods that return `ViewRowImpl` or `List<ViewRowImpl>` instead. In summary, if your method signature defines `ViewRowImpl` or `List<ViewRowImpl>` as the data type, then the application automatically:

1. Looks up the row in the corresponding view object instance by primary key and/or alternate key
2. If the row is not found, then creates a new row
3. Applies the attribute changes in the found or new row

Whereas, if your method signature defines the `AttributeList` data type, then no automatic behavior is provided, and the actions performed and data modified by the custom method will be limited to your custom method's code.

## 11.2.4 What You May Need to Know About Row Finders and the ADF Web Service Operations

When you create a row finder for a view object, the service operations of the exposed service view instance support row lookup using non-key attributes defined by the row finder. For example, the service can invoke the row finder to locate the employee by their email address instead of the employee ID (a row key attribute). When the row finder is defined on a non-key attribute of the view object and the end user supplies a value for this attribute in the web service payload, the service will automatically invoke the row finder to identify the matching rows. Where the email address is the row finder's only required value, the service update operation would allow the end user to update the record of an employee who is identified only by their email address. For details about defining a row finder for use with the service view instance, see [Section 5.12, "Working with Row Finders."](#)

## 11.2.5 How to Service-Enable Individual View Objects

As a result of enabling the web service interface using the overview editor for the application module, JDeveloper automatically enables your parent view instance selections as Service Data Object (SDO) components. The generated SDO components for each view instance will reference the same namespace and will be configured with the same settings for options such as whether or not warnings are supported. You can use the Java page of the overview editor to customize the SDO definition of these existing service-enabled view objects. You can also use the Java page to service-enable view objects that were not added already to the service interface. For example, if you selected a parent view object that represents the master in a master-detail relationship, the child view object will not be automatically service-enabled. You can use the Java page of the overview editor for the child view object to individually add it to the service interface.

You use the Java page of the overview editor for the view object to configure the SDO name and namespace for a view object, or to selectively service-enable child view objects.

**Before you begin:**

You will need to complete these tasks:

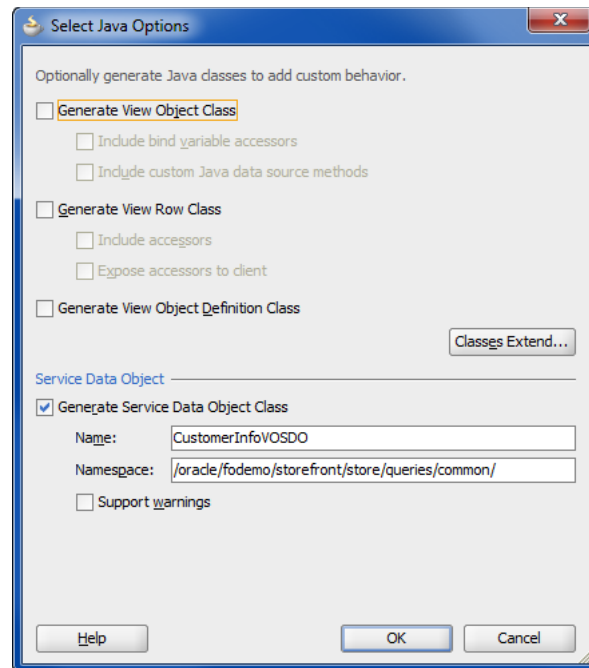

1. Create the desired view objects, as described in [Section 5.2.1, "How to Create an Entity-Based View Object."](#)
2. Enable the service interface for the application module, as described in [Section 11.2.1, "How to Enable the Application Module Service Interface."](#)
3. Optionally, set JDeveloper preferences to specify a default suffix for the names of generated SDO classes, modify the default subpackage where the service interface and classes reside, and set the default namespace prefix for the generated SDO schema and web service, as described in [Section 11.2.14, "How to Set Preferences for Generating the ADF Web Service Interface."](#)
4. If you want to expose custom find operations on the service, create declarative view criteria to specify the custom query, as described in [Section 5.11.1, "How to Create Named View Criteria Declaratively."](#)

**To set the SDO name and namespace for a view object:**

1. In the Application Navigator, double-click the view object.
2. In the overview editor, click the **Java** navigation tab and then click the **Edit java options** button.
3. In the Select Java Options dialog, in the **Service Data Object** section, select **Generate Service Data Object Class**. Enter a value for the service data object name and the service data object's target namespace.

The target namespace is a URI for the SDO component that you can assign to group similar SDO components together by entering the same URI.

A default SDO namespace is created for you based on the SDO component's package name with periods replaced by "/". If you have defined a prefix for the namespace in the Service page of the Preferences dialog, the prefix will be added at runtime to the beginning of the namespace. For example, [Figure 11-7](#) shows the default namespace based on the package name.

**Figure 11-7 Service Data Object Name and Namespace Options**

4. When you want to be able to extract warnings associated with the view rows of the service interface object, select **Support Warnings**.

For example, your view object might have a range validator defined on the `Salary` attribute and failure handling for the validator is specified as `Informational Warning`.

If **Support Warnings** is not selected, no informational messages will be returned with the service response.

When enabled and a warning is generated from the underlying ADF business component object for one of the standard service operations or custom operations, the warning information will be captured by the response object. You can use the methods generated for the service object result class to extract the messages from the view rows, as described in [Section 11.2.8.4, "Container Object Implemented by SDO Result Class and Interface."](#)

5. Click **OK**.

## 11.2.6 How to Customize the SDO Properties of Service-Enabled View Objects

You can use the overview editor for the view object to customize the SDO component definition of the service-enabled view object. By default, all attributes of the service-enabled view object will be exposed as SDO properties. By customizing the view object definition, you can exclude individual SDO properties from participating in the service interface. In the case of SDO properties that define numeric values, you can associate two properties so they appear as a single complex type in the service interface. For example, you can associate one property that defines a currency code or unit of measure with another property that displays the numeric value. Currently, only the complex service types `AmountType` (a currency code) and `MeasureType` (a unit of measure) are supported.

### 11.2.6.1 Excluding Individual SDO Properties in a Generated SDO Component

As a result of enabling the web service interface using the overview editor for the application module, JDeveloper automatically enables your parent view instance selections as SDO components. Additionally, you can selectively service-enable individual child view objects and generate SDO components. By default, generated SDO components expose all attributes of their base view object definition as SDO properties. You can hide any attribute that you do not want the service interface to return as an SDO property.

You use the Attributes page of the overview editor to select the view object attribute that you want to exclude from the service interface. You then use the Edit Attribute dialog that you display from the Attributes page of the overview editor for the view object to hide the selected attribute from the SDO component.

#### Before you begin:

It may be helpful to have an understanding of how the SDO framework supports service-enabled ADF view objects and enables web service clients to access rows of data and perform service operations. For more information, see [Section 11.2, "Publishing Service-Enabled Application Modules."](#)

You will need to complete these tasks:

1. Create the desired view objects, as described in [Section 5.2.1, "How to Create an Entity-Based View Object,"](#) and [Section 5.2.3, "How to Create an Expert Mode, Read-Only View Object."](#)
2. Service-enable the desired view object, as described in [Section 11.2.5, "How to Service-Enable Individual View Objects."](#)

#### To exclude an SDO property from a service-enabled view object:

1. In the Application Navigator, double-click the view object.
2. In the overview editor, click the **Attributes** navigation tab.
3. In the Attributes page, select the attribute corresponding to the property that you want to exclude and then click the **Edit selected attribute** button.
4. In the Edit Attribute dialog, in the View Attribute page, deselect **SDO Property**.
5. Click **OK**.

### 11.2.6.2 Associating Related SDO Properties Using Complex Data Types

As a result of service-enabling the view object, JDeveloper automatically exposes SDO properties as XSD-defined service types that correspond to the data types of the underlying view object's attributes. In the case of attributes that define numeric values, you can change the SDO property's service type to associate a related property using one of these predefined service types:

- `AmountType` service type, for use with any property that defines a currency code
- `MeasureType` service type, for use with any property that defines a unit of measure

When you change the service type of an SDO property to either of these complex types, the service interface associates the two properties together and returns them as a single XML element. Both properties of the SDO component must be defined by attributes in the base service-enabled view object.

For example, suppose that your view object defines the `OrderTotal` attribute and a `CurrencyCode` attribute to specify the currency code of allowed countries. By

default, the service interface exposes these attributes as SDO properties and returns each property as a separate XML element:

```
<OrderTotal>100.00</Price>
<CurrencyCode>USD</CurrencyCode>
```

If you change the type of the `OrderTotal` property (assume that the XSD file defines this property as a decimal type) to the complex type `AmountType` and then associate the `CurrencyCode` property, the service interface will return them as one XML element:

```
<OrderTotal CurrencyCode="USD">123.00</OrderTotal>
```

Also, when you generate a web service proxy, as described in [Section 13.2.5.4, "Invoking Application Modules with a Web Service Proxy Class,"](#) the class treats the two values as one object:

```
AmountType price;
...
price.setValue(123.00);
price.setCurrencyCode("USD");
```

You use the **Attributes** page of the overview editor to select the view object attribute whose service type you want to customize. You use the **Edit Attribute** dialog that you display from the **Attributes** page of the overview editor to associate SDO properties for the selected attribute and select the predefined complex service type.

#### Before you begin:

It may be helpful to have an understanding of how the SDO framework supports service-enabled ADF view objects and enables web service clients to access rows of data and perform service operations. For more information, see [Section 11.2, "Publishing Service-Enabled Application Modules."](#)

Complete these tasks:

1. Create the desired view objects, as described in [Section 5.2.1, "How to Create an Entity-Based View Object,"](#) and [Section 5.2.3, "How to Create an Expert Mode, Read-Only View Object."](#)
2. Service-enable the desired view object, as described in [Section 11.2.5, "How to Service-Enable Individual View Objects."](#)

#### To associate SDO properties in a service-enabled view object:

1. In the Application Navigator, double-click the view object.
2. In the overview editor, click the **Attributes** navigation tab.
3. In the **Attributes** page, select the attribute corresponding to the property that you will associate with another SDO property, and then click the **Edit selected attribute** button.

The attribute you select must define a numeric type. For example, to associate a currency code with the attribute that displays the amount paid by a customer, you might select the `OrderTotal` attribute in the `Orders` service-enabled view object.

4. In the **Edit Attribute** dialog, in the **View Attribute** page, choose the desired XSD Type.

If the **XSD Type** dropdown is not enabled, return to the attribute list and select an attribute of type numeric. Attributes whose values are not a numeric type cannot be associated with the available complex service types.

The SDO framework supports the complex service types `AmountType` and `MeasureType`. Choose **AmountType** when the property you want to associate specifies currency information. Choose **MeasureType** when the property you want to associate specifies a unit of measure.

5. In the **currencyCode** or **unitCode** dropdown list, select the view object attribute to define the complex type.

The dialog changes to display the dropdown list appropriate to the XSD type selection. Choose the attribute that is used to determine the currency code or unit of measure.

6. Click OK.

## 11.2.7 How to Support Nested Processing in Service-Enabled Master-Detail View Objects

When your data model defines master-detail relationships between parent and child view objects, the service operations that you enable for the master view object may not automatically be executed on the detail view object. Post operations on the detail view object are supported by default when the primary source entity object of the master view object is composed with the primary destination entity object of the detail view object. This master-detail relationship is known as a composition association and is created in JDeveloper when the source entity object contains the destination entity object as a logical, nested part, as described in [Section 4.3.6, "What You May Need to Know About Composition Associations."](#)

To support create/merge/update/process methods that post child details along with the parent, you will need to create a view link to define the master-detail relationship according to one of these scenarios:

- The view link uses the composition association, then post operations on the detail view object are supported by default.
- The view link is based on an association, and the association has the destination accessor generated, and the association has a custom property `SERVICE_PROCESS_CHILDREN=true` defined.
- The view link is not based on an association but has a custom property `SERVICE_PROCESS_CHILDREN=true` defined.

The custom property provides an alternative to using a composition association that makes it convenient to support nested processing for any view objects with a view link defined. You can define `SERVICE_PROCESS_CHILDREN` as a custom property in the overview editor for either the view link or the view link's association (when present).

To support get and find methods that retrieve child details along with the parent, the view link between the master and detail view objects must have the destination accessor generated. The destination accessor permits traversal of the hierarchy from the master to the detail view object.

### Before you begin:

1. Create the desired view objects and service-enable the child view object in the master-detail hierarchy, as described in [Section 11.2.5, "How to Service-Enable Individual View Objects."](#)
2. If the view link is not based on an association, confirm that a destination accessor exists for the view link by opening the view link in the overview editor and viewing the Relationship page. To generate the accessor so it appears in the Relationship page, click the **Edit Accessors** button, and then, in the View Link

Properties dialog, select **Generate Accessor in View Object** for the destination accessor. For more information about view links, see [Section 5.6, "Working with Multiple Tables in a Master-Detail Hierarchy."](#)

If the view link is based on an association, then the destination accessor must exist for the association's destination entity object. To generate one, use the Relationship page of the overview editor for the association. For more information about associations, see [Section 4.3, "Creating and Configuring Associations."](#)

#### To support nested processing in a master-detail hierarchy:

1. If the view link for the master-detail hierarchy is not based on an association, then in the Application Navigator, double-click the view link; otherwise, if the view is based on an association, then in the Application Navigator, double-click the association.

You can confirm how the view link was created in the Relationship page of the overview editor. The Attributes section names the source and destination attributes. When the view link is based on an association, the attribute hyperlinks will contain the names of the association. Otherwise, the hyperlinks will contain the names of the base entity objects.

2. In the overview editor, click the **General** navigation tab.

The overview editor for the view link and the association display similar selections.

3. In the General page, expand the Custom Properties section, and then click the **Add Custom Property** icon and enter `SERVICE_PROCESS_CHILDREN` for the property and enter `true` for the property value, as shown in [Figure 11-8](#).

**Figure 11-8 Custom Property to Support Nested Processing**

## 11.2.8 What Happens When You Create SDO Classes

When you create SDO classes, the following files are generated and appear in the Application Navigator under the owning view object:

- Service data object interface
- Service data object class
- Service data object schema file
- Service data object result class and Interface, generated when **Support Warnings** is enabled in the Select Java Options dialog

Do not modify the files generated for service-enabled view objects. The generated files implement required methods of the view object SDO interface.

### 11.2.8.1 Property Accessors Generated in the SDO Interface

The view object SDO interface contains strongly typed accessors for the SDO properties, as shown in [Example 11-4](#).

**Example 11–4 SDO Interface Contains Strongly Typed Accessors for SDO Properties**

```
package oracle.fodemo.storefront.store.queries.common;
public interface AddressesVOSDO {
    public java.math.BigInteger getAddressId();
    public void setAddressId(java.math.BigInteger value);
    ...}

```

**11.2.8.2 View Object Interface Implemented by SDO Class**

The view object SDO class implements the view object SDO interface and extends the `SDODataObject` class, which is Oracle's implementation of the SDO specification.

At runtime an instance of an SDO object represents a row in memory.

The SDO class is similar to the view row class, as shown in [Example 11–5](#).

**Example 11–5 SDO Class Implements View Object SDO Interface**

```
package oracle.fodemo.storefront.store.queries.common;
import commonj.sdo.Type;
import oracle.sdo.SDODataObject;
public class AddressesVOSDOImpl extends SDODataObject implements AddressesVOSDO
{
    ...
}

```

**11.2.8.3 View Object Schema Generated in the SDO Schema File**

The view object SDO schema file, as shown in [Figure 11–15](#), is an XML Schema file which represents the SDO schema.

**Figure 11–9 Generated SDO Schema****11.2.8.4 Container Object Implemented by SDO Result Class and Interface**

The view object SDO result class is a container object that allows a service operation to return a list of view rows (wrapped in service data objects) and a list of warnings associated with these view rows. Specifically, the service get operation returns the

original object, while the create/update/merge/find/process operations return a wrapper object that contains a list of the original object and a list of information messages, and the delete operation returns only the informational message. If you have enabled the **Support Warnings** option for the service-enabled view object, you can use the generated method result interface to extract warnings.

The view object SDO result class, as shown in [Example 11–6](#), is similar to the view row class.

**Example 11–6 SDO Result Class Defines Methods to Get Warnings from List**

```
package oracle.fodemo.storefront.store.queries.common;
import oracle.sdo.SDODataObject;
public class OrderInfoVOSDOResultImpl extends
    oracle.jbo.common.service.types.MethodResultImpl implements OrderInfoVOResult {

    public static final int START_PROPERTY_INDEX =
        oracle.jbo.common.service.types.MethodResultImpl.END_PROPERTY_INDEX + 1;
    public static final int END_PROPERTY_INDEX = START_PROPERTY_INDEX + 0;
    public OrderInfoVOResultImpl() {}
    public java.util.List getValue() {
        return getList(START_PROPERTY_INDEX + 0);
    }

    public void setValue(java.util.List value) {
        set(START_PROPERTY_INDEX + 0 , value);
    }
}
```

## 11.2.9 How to Expose a Declarative Find Operation Filtered By a Required Bind Variable

The ADF service interface framework allows you to expose declarative find operations to execute the query define by a view object you select. However, when that query uses a bind variable to filter the query results, the bind variable must not be specified as **Required** and **Updatable**. Because the service interface does not expose required, updatable bind variables, a find operation that you execute for such a view object would fail to return any result.

When you want to filter a query result using bind parameters, use the view criteria and expose it as a find operation on the service interface. A service interface find operation based on a view criteria that you create can specify required bind variables.

**Before you begin:**

1. Create the desired application module, as described in [Section 9.2.1, "How to Create an Application Module."](#)
2. Create the view criteria, as described in [Section 5.11.1, "How to Create Named View Criteria Declaratively."](#) In the Edit View Criteria dialog, set the criteria item as a bind variable and set the **Validation** field to **Required**. This selection ensures that the query will not execute without a valid value.

**To expose a find operation for a view criteria with required bind variable:**

1. In the Application Navigator, double-click the application module.
2. In the overview editor, click the **Service Interface** navigation tab and then click the **Edit attributes of Service Interface** icon.

Alternatively, you can select **Edit Service Custom Methods** if you have already defined the service interface.

3. In the Edit Service Interface dialog, select **Service View Instances** from the navigation list and add the view object that you want to filter with its named view criteria to the **Selected** list.
4. To expose the find operation, select the view instance, click the **View Criteria Find Operations** tab and then click the **Add View Criteria** button.
5. In the Configure View Criteria Find Operation dialog, choose the named view criteria for the find operation.

The dialog displays the bind variable for the selected view criteria.

6. you want to customize the bind variable name shown in the XML definition for the service, in the **Find Operations Parameters** section, double-click the XML name and edit the name.
7. Click **OK**.

### 11.2.10 How to Expose a Custom Find Method Filtered By a Required Bind Variable

As an alternative to exposing a declarative find operation that relies on a view criteria, you can define a service method in your data model project's application module implementation class. The class you create for this purpose allows you to encapsulate business service functionality into a single method that you implement. For details about the purpose of the custom application module implementation class, see [Section 9.7, "Customizing an Application Module with Service Methods."](#)

[Example 11-7](#) shows a custom find method implemented in the `AppModuleImpl.java` file to set the bind variable and execute the view object instance query. It uses `setNamedWhereClauseParam()` on the view object instance to set the bind variable. Before executing the query, the find method sets the view object in forward-only mode to prevent caching the view rows that the find method iterates over. For more information about programmatically filtering a query result, see [Section 5.10.5, "How to Add a WHERE Clause with Named Bind Variables at Runtime."](#)

#### **Example 11-7 Find Method Added to Application Module Implementation Class**

```
public class AppModuleImpl extends ApplicationModuleImpl
{
    public List<ViewRowImpl> findProducts(String location)
    {
        List<ViewRowImpl> result = new ArrayList<ViewRowImpl>();
        ViewObjectImpl vo = getProductsView1();
        vo.setNamedWhereClauseParam("TheLocation", location);
        vo.setForwardOnly(true);
        vo.executeQuery();
        while (vo.hasNext()) {
            result.add((ViewRowImpl)vo.next());
        }
        return result;
    }
}
```

#### **Before you begin:**

You will need to complete these tasks:

1. Create the custom application module class, as described in [Section 9.7.1, "How to Generate a Custom Class for an Application Module."](#)
2. Create the custom find method to programmatically filter a query result and set the required bind variable, as described in [Section 5.10.5, "How to Add a WHERE Clause with Named Bind Variables at Runtime."](#)

**To expose a find method that sets a required bind variable:**

1. In the Application Navigator, double-click the application module.
2. In the overview editor, click the **Service Interface** navigation tab and then click the **Edit attributes of Service Interface** icon.

Alternatively, you can click the **Edit Service Custom Methods** icon if you have already defined the service interface.

3. In the Edit Service Interface dialog, select **Service View Instances** from the navigation list and add the find method that you defined to the **Selected** list.
4. Click **OK**.

### 11.2.11 How to Generate Asynchronous ADF Web Service Methods

By default, the web service supports synchronous service methods. This forces the invoking client application to wait for the response to return before it can continue with its work. In cases where the response returns immediately, this method of invoking the web service is common. However, because request processing can be delayed, it is often useful for the client application to continue its work and to handle the response later on.

For more information about invoking the web service using asynchronous request-response, see the "Overview of Asynchronous Web Services" section in the "Developing Asynchronous Web Services" chapter of the *Oracle Fusion Middleware Developer's Guide for Oracle Infrastructure Web Services*.

Before you can deploy an asynchronous web service, you must configure the queues used to store the request and response. For information about configuring the request and response queues, see the "Creating Custom Request and Response Queues" section in the "Developing Asynchronous Web Services" chapter of the *Oracle Fusion Middleware Developer's Guide for Oracle Infrastructure Web Services*.

**Before you begin:**

Create the desired application module as described in [Section 9.2.1, "How to Create an Application Module."](#)

**To expose asynchronous web service methods:**

1. In the Application Navigator, double-click the application module.
2. In the overview editor, click the **Service Interface** navigation tab and then click the **Edit attributes of Service Interface** icon.
3. In the Edit Service Interface dialog, in the Service Interface page, select **Generate Asynchronous Web Service Methods**.
4. Click **OK**.

## 11.2.12 What Happens When You Generate Asynchronous ADF Web Service Methods

JDeveloper generates the service interface for the web service and enables the asynchronous service operation. As shown in [Example 11–8](#), the class annotation `@AsyncWebService` declares the `EmpService` service interface asynchronous and for each synchronous method in the interface, the service exposes an asynchronous method with the same method name and "Async" appended.

Exposing both synchronous and asynchronous methods in the same interface allows the web service client developer to decide how to invoke the operation through a web service proxy: by calling the appropriately named method. Note that developers must not invoke asynchronous methods through the ADF Business Components service proxy that is returned from

```
oracle.jbo.client.svc.ServiceFactory.getServiceProxy() method.
```

In this example, because the `EmpService` service is enabled for asynchronous operation, the interface exposes the `getEmployeeAsync()` method and declares the `getEmployee()` method synchronous using the method annotation `@CallbackMethod(exclude=true)` to override the default operation (it is the `exclude=true` part that declares a method in the asynchronous service as synchronous). No annotation is required to declare the asynchronous service methods when the class annotation `@AsyncWebService` is present.

### Example 11–8 Web Service Interface with Asynchronous Service Methods

```
import javax.xml.ws.Action;
...
import oracle.webservices.annotations.async.AsyncWebService;
import oracle.webservices.annotations.async.CallbackMethod;

@SOAPBinding(parameterStyle=SOAPBinding.ParameterStyle.WRAPPED, style=SOAPBinding.Style.DOCUMENT)
@PortableWebService(targetNamespace="http://xmlns.example.com/apps/service/", name="EmpService",
    wsdlLocation="oracle/apps/service/EmpService.wsdl")
@SDODatabinding(schemaLocation="oracle/apps/service/EmpService.xsd")
@AsyncWebService
public interface EmpService
{
    ...

    @WebMethod(action="http://xmlns.example.com/apps/service/getEmployee",
        operationName="getEmployee")
    @RequestWrapper(targetNamespace="http://xmlns.example.com/apps/service/types/",
        localName="getEmployee")
    @ResponseWrapper(targetNamespace="http://xmlns.example.com/apps/service/types/",
        localName="getEmployeeResponse")
    @WebResult(name="result")
    @CallbackMethod(exclude=true)
    Emp getEmployee(@WebParam(mode = WebParam.Mode.IN, name="empno") Integer empno)
        throws ServiceException;

    @WebMethod(action="http://xmlns.example.com/apps/service/getEmployeeAsync",
        operationName="getEmployeeAsync")
    @RequestWrapper(targetNamespace="http://xmlns.example.com/apps/service/types/",
        localName="getEmployeeAsync")
    @ResponseWrapper(targetNamespace="http://xmlns.example.com/apps/service/types/",
        localName="getEmployeeAsyncResponse")
    @WebResult(name="result")
    @Action(input="http://xmlns.example.com/apps/service/getEmployeeAsync",
        output="http://xmlns.example.com/apps/service/getEmployeeAsyncResponse")
    Emp getEmployeeAsync(@WebParam(mode = WebParam.Mode.IN, name="empno") Integer empno);
```

```
}

```

The duplicate asynchronous methods delegate to the synchronous methods in the service implementation, as shown in [Example 11–9](#). This ensures that the underlying business logic is the same for operations declared as either synchronous or asynchronous.

**Example 11–9 Web Service Implementation Class Implements Asynchronous Service Methods**

```
...
import oracle.webservices.annotations.async.AsyncWebService;

@Stateless(name="oracle.apps.service.EmpServiceBean", mappedName="EmpServiceBean")
@Remote(EmpService.class)
@PortableWebService(targetNamespace="http://xmlns.oracle.com/apps/service/",
                    serviceName="EmpService", portName="EmpServiceSoapHttpPort",
                    endpointInterface="oracle.apps.service.EmpService")
@Interceptors(ServiceContextInterceptor.class)
@AsyncWebService
public class EmpServiceImpl extends ServiceImpl implements EmpService
{
    ...

    /**
     * getEmployee: generated method. Do not modify.
     */
    public Emp getEmployee(Integer empno)
        throws ServiceException
    {
        return (Emp) get(new Object[] { empno }, "Employee", Emp.class);
    }

    /**
     * getEmployeeAsync: generated method. Do not modify.
     */
    public Emp getEmployeeAsync(Integer empno)
        throws ServiceException
    {
        return getEmployee(empno);
    }
}

```

### 11.2.13 What Happens at Runtime: How the Asynchronous Call Is Made

From the client’s point of view, an asynchronous call consists of two one-way message exchanges. The sequence diagram in [Figure 11–10](#) depicts the following flow:

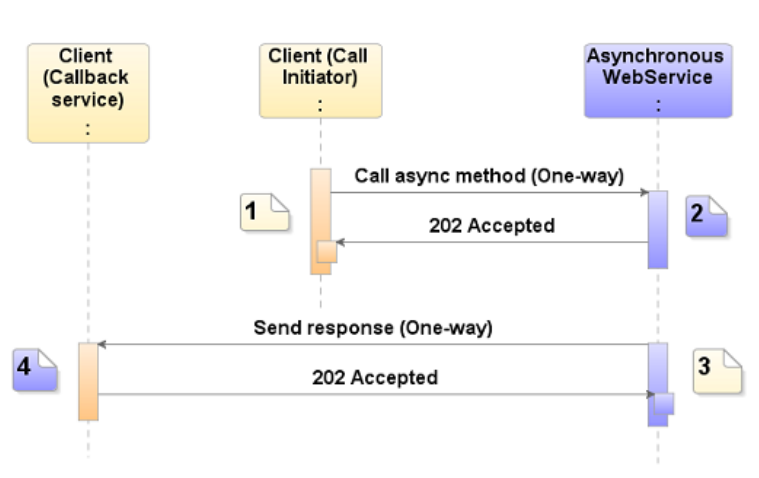

1. The client calls for the asynchronous operation. (In the figure, Step 1.)
2. The asynchronous service receives the request and returns the HTTP acknowledgement back to the client without actually processing the request. (In the figure, Step 2)
3. Eventually the asynchronous operation will complete and the module on the server side will send the response to the client side. (In the figure, Step 3.)

To receive the response at the client side, the client must have some kind of HTTP listener, for example, a servlet or a web service.

4. The client side-generated web service (the Callback Service) receives the asynchronous responses. (In the figure, Step 4.)

The module in Step 3 on the server side acts like a client to the callback service and so is referred as the callback client.

**Figure 11–10 Asynchronous Call Sequence**

### 11.2.14 How to Set Preferences for Generating the ADF Web Service Interface

You have additional control of the service generated by JDeveloper. You can set JDeveloper preferences to perform the following tasks:

- Specify a default suffix for the names of generated SDO classes
- Modify the default subpackage where the service interface and classes reside
- Shape the URI of the generated SDO schema and web service target namespace by setting a default namespace prefix and by specifying the names of packages that you want to exclude from the URI.

#### To set the SDO class name suffix:

1. In the main menu, choose **Tools** and then **Preferences**.
2. In the Preferences dialog, expand **ADF Business Components** and choose **Class Naming**.
3. In the **View Object** suffix list, enter a suffix for **SDO**, for example, `SDO`.

#### To set the default subpackage for the generated service interface:

1. In the main menu, choose **Tools** and then **Preferences**.
2. In the Preferences dialog, expand **ADF Business Components** and choose **Packages**.
3. In the **Relative Package Specification for Classes** list, specify the default package names:
  - To set the Service Interface package name, enter a value for the **Client Interface**. (The **Service Interface** displays the same package name you specify for the client interface). The default package name is `common`.
  - Enter a value for the **Service Interface Subpackage** of the **Service Interface**. The default subpackage name is `serviceinterface`.

For example, if you enter `common` for **Service Interface** and `serviceinterface` for **Service Interface Subpackage** (the defaults), service interfaces for data model components in the data model package `oracle.storefront.store.service` will be placed in the subpackage `oracle.storefront.store.service.common.serviceinterface`.

### To shape the URI of the generated SDO schema and service interface target namespace:

1. In the main menu, choose **Tools** and then **Preferences**.
2. In the Preferences dialog, expand **ADF Business Components** and choose **Service**.
3. Enter a value for the **Default Namespace Prefix** to be added to the beginning of the target namespace of the generated SDO schema and web service.

For example, when you enable **Generate Service Data Object Class** in the Java page of the Create View Object wizard, a namespace prefix `www.globalcompany.example.com` would be added to the package name for the SDO to create the target namespace `www.globalcompany.example.com/oracle/storefront/model/amservice/common/`.

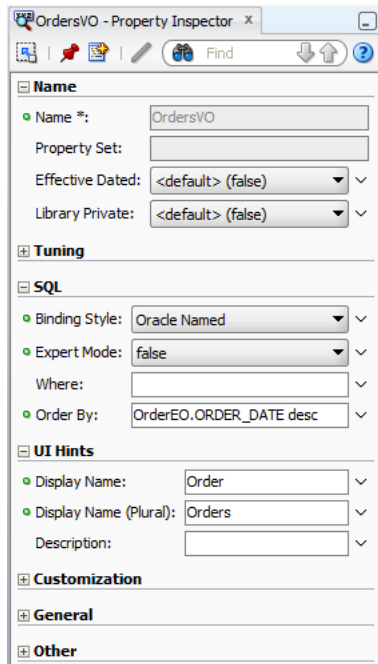

4. Enter a semi-colon separated list of package names for the **Packages to Exclude** to shape the URI of the default target namespace.

For example, when you enter a namespace prefix `www.globalcompany.example.com` and the package name of the SDO is `globalcompany.storefront.model.amservice/` the generated target namespace would incorrectly duplicate the package name `globalcompany`. In this situation, you can exclude the package name `globalcompany` to shape the URI for the target namespace as `www.globalcompany.example.com/storefront/model/amservice/comm`.

More than one package name can be excluded in a semi-colon separated list, as `a;a.b` to yield `<namespace-prefix>/c/d`. In the case of subpackage names, be sure to specify fully-qualified package names. For example to exclude package `c` in the package name `a.b.c.d`, enter `a.b.c`. In this case, the default target namespace yields `<namespace-prefix>/a/b/d/`.

## 11.2.15 How to Set Display Names for Service View Instances and Attributes

Display names are labels that support the web service consuming application to programmatically generate a user interface and to display the service view instance and its attributes with the correct identifying labels. To enable access to these display names at runtime by the consuming application, you use the Create Service Interface wizard to add the built-in method `getDefaultObjAttrHints()` to the remote client service interface. This method lets the consuming application developer programmatically retrieve the **Display Name** UI hint associated with the service view instance and its attributes. You define the UI hints in the Property Inspector for the view object, where you can define a singular label and a plural label for each view instance name and attribute name. For example, as [Figure 11-11](#) shows, you may define UI hints for the `OrdersVO` view object with the labels `Order` and `Orders`.

**Figure 11–11 Display Name UI Hints for View Objects****Before you begin:**

You will need to complete this task:

- Define the built-in method `getDefaultObjAttrHints()` in the remote client service interface, as described in [Section 11.2.1, "How to Enable the Application Module Service Interface."](#)

**To set UI Hint labels for the view instance and its attributes:**

- In the Application Navigator, double-click the application module that defines the view instance for the SDO.
- In the Data Model list, select the view instance name and, below the list, click the **View Definition** link.
- In the overview editor for the view object, click the **General** navigation tab.
- In the main menu, choose **View** and then **Property Inspector**.
- In the Property Inspector, to set the label for the view object instance, expand **UI Hints** and enter the labels for the **Display Name** and **Display Name (Plural)**.
- In the overview editor for the view object, click the **Attributes** navigation tab and select the attribute that you want to label.
- In the Property Inspector, to set the label for the view object attribute, expand **UI Hints** and enter the labels for the **Label** and **Display Name (Plural)**.

**11.2.16 How to Secure the ADF Web Service for Access By SOAP Clients**

At runtime, the web service client will invoke the service-enable methods of the application module through the SOAP protocol. You can configure an Oracle Web Service Manager (OWSM) security policy to enable authentication and authorization on the service. The security policy that you select will require the SOAP client call to provide credential information (or SAML token) as part of the SOAP header. You can

also configure other policies to enable message protection (integrity and confidentiality) for inbound SOAP requests, for instance.

To secure the web service for SOAP clients:

1. Configure an OWSM authentication policy.
2. Configure an OWSM authorization policy.

You can enable authentication to require users to supply credentials before they have access to the service methods on the service interface. The type of authentication required is configured on the service implementation class using an OWSM authentication policy annotation.

You can enable permission checking to enable only users with sufficient privileges to invoke a service method on the service interface. Permission checking is configured on the service implementation class using this OWSM authorization annotation:

- `binding_permission_authorization_policy`

This policy provides simple permission-based authorization for the request based on the authenticated Subject at the SOAP binding level. This policy ensures that the Subject has permission to perform the operation. This policy should follow an authentication policy where the Subject is established and can be attached to any SOAP-based endpoint.

As an alternative to the permission checking policy, you can configure one of these role-based OWSM security policies:

- `binding_authorization_denyall_policy`

This policy provides simple role-based authorization for the request based on the authenticated Subject at the SOAP binding level. This policy denies all users with any roles. It should follow an authentication policy where the Subject is established and can be attached to any SOAP-based endpoint.

- `binding_authorization_permitall_policy`

This policy provides a simple role-based authorization for the request based on the authenticated Subject at the SOAP binding level. This policy permits all users with any roles. It should follow an authentication policy where the Subject is established and can be attached to any SOAP-based endpoint.

For further details about the authorization policies, see the "Authorization Only Policies" section in the "Predefined Policies" appendix of the *Oracle Fusion Middleware Security and Administrator's Guide for Web Services*.

ADF service interface framework also provides an EJB interceptor `ServicePermissionCheckInterceptor` which does the same permission check as `oracle/binding_permission_authorization_policy`, and additionally covers RMI invocation to services. If your services will always be invoked through SOAP, you should attach the OWSM `oracle/binding_permission_authorization_policy` authorization policy. If your services will also be invoked through RMI, you should attach the EJB interceptor `ServicePermissionCheckInterceptor`.

#### **Before you begin:**

You will need to complete this task:

- Grant users access to the service, as described in [Section 11.2.18, "How to Grant Test Users Access to the Service."](#)

**To configure an authentication and authorization:**

1. In the Application Navigator, expand the application module, expand the **serviceinterface** node, and then double-click the service implementation class (*AppModuleServiceImpl.java*) node.

In the web service generated from the *StoreFrontService* application module in the *StoreFrontModule* workspace, the service implementation class is *StoreFrontServiceImpl.java*.

2. If your services will always be invoked exclusively through SOAP (and not RMI), you should use an OWSM authorization policy as follows:

- a. In the source for the service implementation class, place your cursor on the `@PortableWebService` annotation.

For example, *StoreFrontServiceImpl.java* shows the annotation for the service as follows:

```
...
@PortableWebService(
    targetNamespace="www.globalcompany.example.com",
    serviceName="StoreFrontService",
    portName="StoreFrontServiceSoapHttpPort",
    endpointInterface=
        "oracle.fodemo.storefront...common.serviceinterface.StoreFrontService")
```

- b. In the Property Inspector, expand the **Policies** section, and click the button next to the **Multiple Policies** field.
- c. In the Edit Property: Multiple Policies dialog, select the desired security policy and click **OK**.

For details about the security policies supported by OWSM, see the "Authorization Only Policies" section in the "Predefined Policies" appendix of the *Oracle Fusion Middleware Security and Administrator's Guide for Web Services*.

- d. Return to the source file and note that annotation `@PolicySet` is configured.

The `@PolicySet` annotation that you define for the service implementation class specifies the security requirements to potential clients. In this example, the annotation shows both the permission-checking authorization policy (*oracle/binding\_permission\_authorization\_policy*) and an authentication policy:

```
...
@PortableWebService(
    targetNamespace="www.globalcompany.example.com",
    serviceName="StoreFrontService",
    portName="StoreFrontServiceSoapHttpPort",
    endpointInterface=

"oracle.fodemo.storefront.store.service.common.serviceinterface.StoreFrontS
ervice")
@PolicySet(references = {
    @PolicyReference(value =
        "oracle/wss_username_token_service_policy"),
    @PolicyReference(value =
        "oracle/binding_permission_authorization_policy")
})
```

3. If your services will be invoked through SOAP and RMI, you should use `ServicePermissionCheckInterceptor` only (there is no need to use an OWSM authorization policy) as follows.

In the source editor, place your cursor in the `@Interceptors` annotation and add `ServicePermissionCheckInterceptor.class` to enable permission checking at runtime.

```
...
@Interceptors({ ServiceContextInterceptor.class,
                ServicePermissionCheckInterceptor.class })
@Stateless(name=

"oracle.fodemo.storefront.store.service.common.serviceinterface.StoreFrontServiceBean",
           mappedName="ServiceFrontServiceBean")
```

4. Save the service implementation class file.

## 11.2.17 How to Secure the ADF Web Service for Access By RMI Clients

Because the ADF web service is implemented as an EJB and deployed on Oracle WebLogic Server as Oracle Web Service's `PortableWebService`, the client application can invoke the service-enable methods of the application module through the RMI protocol.

To secure the web service for RMI clients:

1. Configure JNDI context properties to enable authentication.
2. Enable permission checking to configure an authorization policy.

### Before you begin:

It may be helpful to have an understanding of the predefined authorization policies supported by OWSM. For more information, see the "Authorization Only Policies" section in the "Predefined Policies" appendix of the *Oracle Fusion Middleware Security and Administrator's Guide for Web Services*.

### 11.2.17.1 Enabling Authentication for RMI Clients

When the ADF web service is invoked through RMI, authentication is handled with the common JAAS login module. The login module can be passed the principal and credential as part of the JNDI initial context for the EJB in the calling application. If you do not define the JNDI context properties, the login module will attempt to obtain the caller's current security context.

When you choose to define remote JNDI context information, then these four JNDI context properties need to be added to the `connections.xml` file.

---

**Note:** When you intend to test the service in JDeveloper using Integrated WebLogic Server, before deploying the service you can edit the JNDI context properties in the `connections.xml` file directly. However, when you deploy the service to standalone Oracle WebLogic Server, you will use Oracle Enterprise Manager to configure the JNDI context properties.

---

- `jndiFactoryInitial` should be set to `weblogic.jndi.WLInitialContextFactory`.

- `jndiProviderURL` is the JNDI provider URL that indicates the location of the JNDI server. The URL should be composed as `t3://<hostname>:<server port>`.

When you test the service in JDeveloper, and your service is deployed to Integrated WebLogic Server, specify the JNDI provider URL of Integrated WebLogic Server: `t3://<hostname>:7101`.

When you deploy the service to remote Oracle WebLogic Server, specify a URL like: `t3://localhost:8888`, where `t3` is the Oracle WebLogic protocol, `localhost` is the host name that the remote Oracle WebLogic Server instance runs in, `8888` is the port number.

- `jndiSecurityPrincipal` specifies the principal (user name) with permission to access the remote JNDI.

As [Example 11-10](#) shows, when you test the service in JDeveloper Integrated WebLogic Server, you should omit this context property since no security is configured for the JNDI server on Integrated WebLogic Server.

As [Example 11-11](#) and [Example 11-12](#) show, when you deploy the service to standalone Oracle WebLogic Server, the user name can be read from the file.

- `jndiSecurityCredentials` specifies the credentials (password) to be used for the security principal.

As [Example 11-10](#) shows, when you test the service in JDeveloper Integrated WebLogic Server, you should omit this context property since no security is configured for the JNDI server on Integrated WebLogic Server.

As [Example 11-11](#) shows, when you deploy the service to standalone Oracle WebLogic Server in a test environment, you can specify credentials in plain text for the JNDI provider. For example, you can specify `weblogic/weblogic1` which are the default administrator user name/password credentials with sufficient privileges to access JNDI provider for Oracle WebLogic Server.

When you deploy the service to a production environment, you must remove the plain text password to avoid creating a security vulnerability. As [Example 11-12](#) shows, the `connections.xml` file must contain `<SecureRefAddr addrType="jndiSecurityCredentials"/>` with no password. To configure the service password for standalone Oracle WebLogic Server, you must use Oracle Enterprise Manager, which will store the encrypted password in Oracle's credential store.

#### To configure JNDI context properties to handle authentication:

1. In the Application Resources panel, expand the **Descriptors** and **ADF META-INF** nodes, and then double-click `connections.xml`.
2. If the source editor, use the JNDI context properties to specify the principal and credentials.

If you are testing the service in JDeveloper's Integrated WebLogic Server, you only need to specify the `jndiProviderURL` property, as shown in [Example 11-10](#).

#### **Example 11-10 JNDI Properties for JDeveloper Integrated WebLogic Server**

```
<References xmlns="http://xmlns.oracle.com/adf/jndi">
  <Reference name="{www.globalcompany.com}StoreFrontService"
    className="oracle.jbo.client.svc.Service" xmlns="">
    <Factory className="oracle.jbo.client.svc.ServiceFactory"/>
  </RefAddresses>
```

```

...
<StringRefAddr addrType="jndiFactoryInitial">
  <Contents>weblogic.jndi.WLInitialContextFactory</Contents>
</StringRefAddr>
<StringRefAddr addrType="jndiProviderURL">
  <Contents>t3://a_hostname:7101</Contents>
</StringRefAddr>
...
</RefAddresses>
</Reference>
...
</References>

```

If you are deploying the service for testing purposes to standalone Oracle WebLogic Server, you can use the `connections.xml` file to specify credentials for the JNDI provider. For example, as shown in [Example 11-11](#), you can specify `weblogic/weblogic1` which are the default administrator user name/password credentials with sufficient privileges to access JNDI provider for Oracle WebLogic Server.

#### **Example 11-11 JNDI Properties for a Test Environment**

```

<References xmlns="http://xmlns.oracle.com/adf/jndi">
  <Reference name="{www.globalcompany.com}StoreFrontService"
    className="oracle.jbo.client.svc.Service" xmlns="">
    <Factory className="oracle.jbo.client.svc.ServiceFactory"/>
  <RefAddresses>
    ...
    <StringRefAddr addrType="jndiFactoryInitial">
      <Contents>weblogic.jndi.WLInitialContextFactory</Contents>
    </StringRefAddr>
    <StringRefAddr addrType="jndiProviderURL">
      <Contents>t3://localhost:8888</Contents>
    </StringRefAddr>
    <StringRefAddr addrType="jndiSecurityPrincipal">
      <Contents>weblogic</Contents>
    </StringRefAddr>
    <SecureRefAddr addrType="jndiSecurityCredentials">
      <Contents>weblogic1</Contents>
    </SecureRefAddr>
    ...
  </RefAddresses>
</Reference>
...
</References>

```

If you are deploying the service to production Oracle WebLogic Server, you can use the `connections.xml` file to specify the user name. As shown in [Example 11-12](#), you must not specify the password.

#### **Example 11-12 JNDI Properties for a Production Environment**

```

<References xmlns="http://xmlns.oracle.com/adf/jndi">
  <Reference name="{www.globalcompany.com}StoreFrontService"
    className="oracle.jbo.client.svc.Service" xmlns="">
    <Factory className="oracle.jbo.client.svc.ServiceFactory"/>
  <RefAddresses>
    ...
    <StringRefAddr addrType="jndiFactoryInitial">
      <Contents>weblogic.jndi.WLInitialContextFactory</Contents>

```

```

    </StringRefAddr>
    <StringRefAddr addrType="jndiProviderURL">
        <Contents>t3://localhost:8888</Contents>
    </StringRefAddr>
    <StringRefAddr addrType="jndiSecurityPrincipal">
        <Contents>a_username</Contents>
    </StringRefAddr>
    <SecureRefAddr addrType="jndiSecurityCredentials/">
        ...
    </RefAddresses>
</Reference>
...
</References>

```

3. Save the file.

### 11.2.17.2 Configuring Authorization for RMI Clients

You can enable permission checking to allow only users with sufficient privileges to invoke a service method on the service interface. In order to enable permission checking, the ADF service interface framework provides an EJB interceptor named `ServicePermissionCheckInterceptor`. This EJB interceptor ensures permission checking is enforced at runtime. Currently, the interceptor is coded with the same logic that OWSM implements for the authorization policy `binding_permission_authorization_policy`. For further details about this authorization policy, see the "Authorization Only Policies" section in the "Predefined Policies" appendix of the *Oracle Fusion Middleware Security and Administrator's Guide for Web Services*.

#### Before you begin:

1. Configure the authentication policy for the service in the `connections.xml` file of the client application (the one invoking the service), as described in [Section 11.2.17.1, "Enabling Authentication for RMI Clients."](#)
2. Grant users access to the service, as described in [Section 11.2.18, "How to Grant Test Users Access to the Service."](#)

#### To configure a permission-based authorization policy:

1. In the Application Navigator, expand the **META-INF** node of the web service project and double-click the `ejb-jar.xml` node.
2. In the source editor, add the following `JpsInterceptor` definition required by the EJB for application roles evaluation.

```

<?xml version = '1.0' encoding = 'windows-1252'?>
<ejb-jar xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="http://java.sun.com/xml/ns/javaee
    http://java.sun.com/xml/ns/j2ee/ejb-jar_3_0.xsd" version="3.0"
    xmlns="http://java.sun.com/xml/ns/javaee">
    <enterprise-beans>
        ...
    </enterprise-beans>
    <interceptors>
        <interceptor>
            <interceptor-class>
                oracle.security.jps.ee.ejb.JpsInterceptor
            </interceptor-class>
            <env-entry>
                <env-entry-name>application.name</env-entry-name>
                <env-entry-type>java.lang.String</env-entry-type>
            </env-entry>
        </interceptor>
    </interceptors>

```

```

        <env-entry-value>ApplicationName</env-entry-value>
        <injection-target>
            <injection-target-class>
                oracle.security.jps.ee.ejb.JpsInterceptor
            </injection-target-class>
            <injection-target-name>
                application_name
            </injection-target-name>
        </injection-target>
    </env-entry>
</interceptor>
...
<interceptors>
<assembly-descriptor>
    <interceptor-binding>
        <ejb-name>*</ejb-name>
        <interceptor-class>
            oracle.security.jps.ee.ejb.JpsInterceptor
        </interceptor-class>
    </interceptor-binding>
</assembly-descriptor>
</ejb-jar>

```

3. In the Application Navigator, expand the application module, expand the **serviceinterface** node, and then double-click the service implementation class (*AppModuleServiceImpl.java*) node.
4. In the source editor, place your cursor at the end of your annotations section and add the annotation named `ServicePermissionCheckInterceptor` to enable permission checking at runtime.

```

...
@Stateless(name="oracle.fodemo.storefront.store.service.common.
                StoreFrontServiceBean")

@Remote(StoreFrontService.class)
@PortableWebService(targetNamespace="http://www.globalcompany.com/
                StoreFrontService", serviceName="StoreFrontService",
                portName="StoreFrontServiceSoapHttpPort",
                endpointInterface="oracle.fodemo.storefront.
                service.common.serviceinteface.StoreFrontService")

@CallByReference
@Interceptors({ServiceContextInterceptor.class,
                ServicePermissionCheckInterceptor.class})

```

5. Save the files.

## 11.2.18 How to Grant Test Users Access to the Service

After you have configured the authorization policy for the service, you must configure the Oracle Platform Security Services (OPSS) security provider to specify which users can invoke method on the service. At design time, you perform this task by editing the `jazn-data.xml` configuration file to create application roles and make an invoke permission grant to the desired application roles. Then when you deploy the service, the administrator for the target Oracle WebLogic Server will associate enterprise users with the application roles you specify. This allows you to confer the right to invoke a service method to any user who is a member of that application role. Users who are members of a role that has not been granted the invoke permission, will be denied access to the service method. For more information about the OPSS security

provider and application roles, see the "Introduction to Oracle Platform Security Services" chapter of the *Oracle Fusion Middleware Application Security Guide*.

To configure the `jazn-data.xml` file with test users that you can use to run the application in Integrated WebLogic Server, see [Section 30.6, "Creating Test Users."](#)

The `invoke` permission for Oracle Web Services is defined by the `oracle.wsm.security.WSFunctionPermission` class. You can grant the `invoke` permission to the application roles you define for all the methods of the service or just to individual methods.

#### **Before you begin:**

1. Configure authentication and authorization policies for your service, as described in [Section 11.2.16, "How to Secure the ADF Web Service for Access By SOAP Clients,"](#) or [Section 11.2.17, "How to Secure the ADF Web Service for Access By RMI Clients."](#)
2. Add the OPSS security provider configuration file to your project by creating a `jazn-data.xml` deployment descriptor. For more information about deployment descriptors, see "Creating and Editing a Deployment Descriptor" in the Deploying Applications section of the JDeveloper online help.

Note that in JDeveloper you open the New Gallery, expand **General**, select **Deployment Descriptors** and then **Oracle Deployment Descriptors**, and click **OK**.

3. Create the desired application roles that you want to make grants to, as described in [Section 30.4, "Creating Application Roles."](#)
4. For the purpose of testing your web service in JDeveloper using Integrated WebLogic Server, you can populate the application roles with test users, as described in [Section 30.6, "Creating Test Users."](#)

#### **To grant the web service permission to application roles in the jazn-data.xml file:**

1. In the main menu, choose either **Application > Secure > Resource Grants** or **Application > Secure > Entitlement Grants**.

You can grant multiple privileges to an application role as an entitlement set or you can grant individual privileges to a resource. Create an entitlement grant to aggregate privileges that together secure a specific end user duty. For details about entitlement grants, see [Section 30.5.12, "How to Aggregate Resource Grants as Entitlement Grants."](#)

2. In the editor window for the `jazn-data.xml` file, click the **Source** tab.
3. In the source for the `jazn-data.xml` file, expand the `<policy-store>` element to view all ADF security policies that you already defined for your application.

Currently, this release does not provide an editor to create an application security policy; you will need to manually create the policy in the source for the `jazn-data.xml` file.

4. Inside the `<jazn-policy>` element, create a `<grant>` element that defines the `<grantee>` with the desired application role and the `<permission>` with the fully qualified class name of the OWSM permission class (`oracle.wsm.security.WSFunctionPermission`), the permission target name that uniquely identifies the service method, and the `invoke` method action that you want to grant to the application role principal.

Your finished source should look similar to this:

```

<grant>
  <grantee>
    <principals>
      <principal>
        <class>oracle.security.jps.service.policystore.ApplicationRole</class>
        <name>customers</name>
      </principal>
    </principals>
  </grantee>
  <permissions>
    <permission>
      <class>oracle.wsm.security.WSFunctionPermission</class>
      <name>www.globalcompany.example.com/
          StoreFrontService#CreateAccount</name>
      <actions>invoke</actions>
    </permission>
  </permissions>
</grant>

```

The `<principal>` element is defined by the application role class name `oracle.security.jps.service.policystore.ApplicationRole` and an application role name that you already created. For example, if you created an application role `customers` and you want to grant `invoke` service method permission to the members of that role, then enter `customers`.

The `<permission>` element is defined by the OWSM class name `oracle.wsm.security.WSFunctionPermission` and the permission target name. The permission target name is formed by appending `/serviceInterfaceName` and `#serviceName` (or wildcard character) to the service target namespace.

**Tip:** You can find the target namespace and service name from the WSDL definition file for the service. In the Application Navigator, double-click the WSDL file in the **serviceinterface** folder to view the name and `targetNamespace` definitions.

For example, in the Fusion Order Demo, the WSDL definition file might define the following name and namespace:

```

<wsdl:definitions
  name="StoreFrontService"
  targetNamespace="www.globalcompany.example.com"

```

Assume that you want to grant a permission to allow authorized users to invoke a `CreateAccount` service method on the service interface with these Fusion Order Demo name and namespace, you would enter the target name like this:

```
www.globalcompany.example.com/StoreFrontService#CreateAccount
```

Alternatively, you can enter the target name using the wildcard character `*` to grant all operations of the service interface in a single permission:

```
www.globalcompany.example.com/StoreFrontService#*
```

The actions that you can enter are defined by the permission class. In this case, `oracle.wsm.security.WSFunctionPermission` defines the single action `invoke`.

5. Save the changes to the `jazn-data.xml` file.

## 11.2.19 How to Enable Support for Binary Attachments for SOAP Clients

The ADF service interface framework supports using Message Transmission Optimization Mechanism (MTOM) to handle sending binary data in any service method that operates on a `ViewRow` with a `BlobDomain/ClobDomain` attribute. This permits binary data to accompany XML messages, for example when images are required to document an insurance claim. The SDO data objects of the service-enabled application module maps `BlobDomain/ClobDomain` to `javax.activation.DataHandler`. These `DataHandler` properties could be passed as attachments during SDO data object marshalling/unmarshalling when the web service is called using the SOAP protocol.

To enable MTOM support for your SOAP protocol, you must add the `@MTOM` annotation to the service implementation class (for example, `StoreFrontServiceImpl.java`) and your method must operate on a `ViewRow` with `BlobDomain/ClobDomain` attribute.

### To enable support for sending binary data attachments:

1. In the Application Navigator, expand the application module, expand the **serviceinterface** node, and then double-click the service implementation class (`AppModuleServiceImpl.java`) file.

In the web service generated from the `StoreServiceAM` application module in the `StoreFrontModule` application of the Fusion Order Demo, the service implementation class is `StoreFrontServiceImpl.java`.

2. In the source for the service implementation class, place your cursor anywhere in the annotation section.

For example, in the `StoreFrontServiceImpl.java` the annotation section for the service is:

```
...
@Stateless(name="oracle.fodemo.storefront...common.StoreFrontServiceBean",
    mappedName="StoreFrontServiceBean")
@Remote(StoreFrontService.class)
@PortableWebService(targetNamespace="www.globalcompany.example.com",
    serviceName="StoreFrontService", portName="StoreFrontServiceSoapHttpPort",
    endpointInterface=
        "oracle.fodemo.storefront...common.serviceinterface.StoreFrontService")
...
```

3. In the Property Inspector, expand the **Web Services** section and select **Enable MTOM**.

JDeveloper adds the `@MTOM` annotation to the annotations section of the file.

```
...
@Stateless(name="oracle.fodemo.storefront...common.StoreFrontServiceBean",
    mappedName="StoreFrontServiceBean")
@Remote(StoreFrontService.class)
@PortableWebService(targetNamespace="www.globalcompany.example.com",
    serviceName="StoreFrontService", portName="StoreFrontServiceSoapHttpPort",
    endpointInterface=
        "oracle.fodemo.storefront...common.serviceinterface.StoreFrontService")
@MTOM
...
```

## 11.2.20 How to Test the Web Service Using Integrated WebLogic Server

You can run the web service in JDeveloper using Integrated WebLogic Server. You can also deploy the web service to Oracle WebLogic Server to test the service.

### To run and test using Integrated WebLogic Server:

1. In the Application Navigator, expand the application module, expand the **serviceinterface** node, and then select the service implementation class (`AppModuleServiceImpl.java`) file.

In the web service generated from the `StoreServiceAM` application module in the `StoreFrontModule` application of the Fusion Order Demo, the service implementation class is `StoreFrontServiceImpl.java`.

2. Right-click the service implementation class file, and choose **Run** or **Debug**.

The Configure Default Domain dialog appears the first time you run the application and start a new domain in Integrated WebLogic Server. Use the dialog to define an administrator password for the new domain. Passwords you enter can be eight characters or more and must have a numeric character.

JDeveloper initializes the server instance, and then deploys the application and starts the web service. During this time, the output from these processes is displayed in the **Running** tab of the Log window. After the web service has started, the target URL is also displayed in the Log window.

3. Copy the target URL (beginning with `http://`) from the Log window.

For example, if the Log window displays:

```
http://<ipaddress>/ADFServiceDemo-ADFModel-context-root
```

Integrated WebLogic Server will display the service endpoint URL. So there is no need to append the service name.

4. Launch a web browser, paste the target URL you copied from the Log window into the browser address field, and submit the HTTP request.
5. In the test page, choose the operation you want to invoke from the **Operations** dropdown list and enter sample data in its parameter fields.
6. When you are ready, press **Invoke** to submit the operation and view the results for the operation in the Test Results page.

The Test Results page displays the XML Soap format of the information returned by the operation.

## 11.2.21 How to Prevent Custom Service Methods from Timing Out

When you test the web service you may find that some of your custom methods exceed the established timeout limitation established by the Java Transaction API (JTA). The JTA timeout setting establishes an execution boundary for service methods that by default may not exceed 30 seconds. You can use the Administration Console for Oracle WebLogic Server to increase the JTA timeout setting. If you still receive a timeout exception or you anticipate that the custom methods of the service interface may be long running, you can specify an EJB transaction attribute for the stateless session bean to prevent the EJB from executing those methods in a JTA transaction.

To make a custom method exempt from timing out, you set `TransactionAttributeType.NOT_SUPPORTED` in the Property Inspector specifically for that method. As [Example 11-13](#) shows, JDeveloper updates the method

by adding the annotation

```
@TransactionAttribute(TransactionAttributeType.NOT_SUPPORTED).
```

**Example 11–13 NOT\_SUPPORTED Annotation in Custom Service Method**

```
@TransactionAttribute(TransactionAttributeType.NOT_SUPPORTED)
public void updateCustomerInterests(List<String> pCategoryIds) throws
    ServiceException {
    invokeCustom((Method) _map.get("updateCustomerInterests"),
        new Object[] { pCategoryIds }, new String[] { null }, false);
}
```

Because a method with this transaction attribute setting will not be executed in the JTA transaction, it is your responsibility to enforce control over the transaction using the ADF Business Components methods of the `oracle.jbo.ApplicationModule` and `oracle.jbo.Transaction` interfaces. For instance, as [Example 11–14](#) shows, the methods of the implementation class of the application module that you service-enabled, will need to call `am.getDBTransaction().commit()` or `rollback()` in order to complete the transaction.

**Example 11–14 Custom Code to Handle Transaction Execution in Implementation Method**

```
public void updateCustomerInterests(List pCategoryIds) {
    try
    {
        if (pCategoryIds != null && pCategoryIds.size() > 0) {
            List<Integer> copyOfCategoryIds = (List<Integer>)
                this.cloneList(pCategoryIds);
            ViewObject selectedCategories =
                this.getSelectedCategoriesShuttleList();
            RowSetIterator rsi = selectedCategories.createRowSetIterator(null);
            // remove rows for the current user not in the list of product keys
            while (rsi.hasNext()) {
                Row r = rsi.next();
                Number interestId = (Number)r.getAttribute("CategoryId");
                // existing row is in the list, we're ok, so remove from list.
                if (copyOfCategoryIds.contains(interestId)) {
                    copyOfCategoryIds.remove(interestId);
                }
                // if the existing row is in not list, remove it.
                else {
                    r.remove();
                }
            }
            rsi.closeRowSetIterator();
            // at this point, add new rows for the keys that are left
            for (int i =0 ;i < copyOfCategoryIds.size(); i++ ) {
                Row newRow = selectedCategories.createRow();
                selectedCategories.insertRow(newRow);
                newRow.setAttribute("CategoryId", (String)
                    copyOfCategoryIds.get(i).toString());
            }
            this.getTransaction().commit();
        }
    }
    catch (JboException e)
    {
        this.getTransaction().rollback();
        throw e;
    }
}
```

```
    }
}
```

You should not change the default transaction attribute setting for the standard service methods generated for the service interface (see [Table 11-1](#)). The standard methods will execute within the default execution boundary set for the JTA transaction.

#### To prevent custom methods from executing in a JTA transaction:

1. In the Application Navigator, expand the application module, expand the **serviceinterface** node, then double-click the service implementation class (*AppModuleServiceImpl.java*) file.

In the web service generated from the *StoreServiceAM* application module in the *StoreFrontModule* workspace, the service implementation class is *StoreServiceAMServiceImpl.java*.

2. In the source editor, locate the custom method that you want to prevent from timing out and place your cursor on the method.
3. In the Property Inspector, expand **Stateless Session Bean**, and then select **TransactionAttributeType.NOT\_SUPPORTED** from the **TransactionAttribute** dropdown list.

As shown in *updateCustomerInterests()* in [Example 11-13](#), JDeveloper updates the custom service method with the annotation.

4. Save the service implementation class.
5. In the Application Navigator, double-click the application module implementation class (*AppModuleImpl.java*) file.

The implementation class defines the custom methods that you exposed through the service interface. In the *StoreServiceAM* workspace, the application module implementation class is *StoreServiceAMImpl.java*.

6. In the source editor, in the custom method that implements the service method that you previously set the **TransactionAttribute** property on, add the custom code that will commit and roll back the transaction.

As [Example 11-14](#) shows, if you configured the **TransactionAttribute** property on the service method named *updateCustomerInterests()*, then you would open the implementation class for the application module, locate the custom method *updateCustomerInterests()*, and add *am.getDBTransaction().commit()* and *rollback()* as part of the method's try and catch statements.

7. Save the application module implementation class.

## 11.2.22 How to Deploy Web Services to Oracle WebLogic Server

You can deploy the web service to Oracle WebLogic Server, for example to perform a second stage of testing the service.

---

---

**Caution:** Follow the procedure outlined in this section to modify the `web.xml` of the packaged EAR file for a web service with authorization enabled, but do not use JDeveloper to deploy the EAR file since this will overwrite the `web.xml` file on the target server. Instead, use a tool like the Administration Console for Oracle WebLogic Server to manually deploy the packaged application's EAR file. For details about deploying secure web service applications outside of JDeveloper, see the "Deploying Web Services Applications" chapter of the *Oracle Fusion Middleware Security and Administrator's Guide for Web Services*.

---

---

**Before you begin:**

1. If your project contains a standard web service (a Java class or interface with the `@WebService` annotation), you must remove the `@WebService` annotation from the Java class before you can deploy the Business Components web service. If you attempt to deploy the Business Components web service from the same project as the standard web service, deployment will fail with an Oracle WebLogic Server exception error. It is therefore necessary to create standard web services in a separate project from your ADF Business Components service.
2. If you created an asynchronous web service, before you can deploy the service you must configure the queues used to store the request and response. For information about configuring the request and response queues, see the "Creating Custom Request and Response Queues" section in the "Developing Asynchronous Web Services" chapter of the *Oracle Fusion Middleware Developer's Guide for Oracle Infrastructure Web Services*.
3. If you configured authorization for the web service, as described in [Section 11.2.16, "How to Secure the ADF Web Service for Access By SOAP Clients,"](#) edit the `weblogic-application.xml` file to define application ID parameters. This file appears in the Application Navigator in the Application Resources panel, under the **Descriptors** and **META-INF** nodes.

Add the following `<application-param>` definition as the first element:

```
<weblogic-application
xmlns="http://www.bea.com/ns/weblogic/weblogic-application"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation=

"http://www.bea.com/ns/weblogic/weblogic-application.xsd">
  <application-param>
    <param-name>jps.policystore.applicationid</param-name>
    <param-value>ApplicationName</param-value>
  </application-param>
  ...
</weblogic-application>
```

Note that the `ApplicationName` that you enter must match the name identified in the `jazn-data.xml` policy store definition:

```
<jazn-data>
  <policy-store>
    <applications>
      <application>
        <name>ApplicationName</name>
        <app-roles>
          ...
```

```

        </app-roles>
        <jazn-policy>
            ...
        </jazn-policy>
    </application>
</applications>
</policy-store>
</jazn-data>

```

4. Edit the `ejb-jar.xml` file to add the following `JpsInterceptor` definition required by the EJB for application roles evaluation. This file appears in the Application Navigator under the **META-INF** node of the web service project.

```

<?xml version = '1.0' encoding = 'windows-1252'?>
<ejb-jar xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
        xsi:schemaLocation="http://java.sun.com/xml/ns/javaee
        http://java.sun.com/xml/ns/j2ee/ejb-jar_3_0.xsd" version="3.0"
        xmlns="http://java.sun.com/xml/ns/javaee">
    <enterprise-beans>
        ...
    </enterprise-beans>
    <interceptors>
        <interceptor>
            <interceptor-class>
                oracle.security.jps.ee.ejb.JpsInterceptor
            </interceptor-class>
            <env-entry>
                <env-entry-name>application.name</env-entry-name>
                <env-entry-type>java.lang.String</env-entry-type>
                <env-entry-value>ApplicationName</env-entry-value>
                <injection-target>
                    <injection-target-class>
                        oracle.security.jps.ee.ejb.JpsInterceptor
                    </injection-target-class>
                    <injection-target-name>
                        application_name
                    </injection-target-name>
                </injection-target>
            </env-entry>
        </interceptor>
        ...
    </interceptors>
    <assembly-descriptor>
        <interceptor-binding>
            <ejb-name>*</ejb-name>
            <interceptor-class>
                oracle.security.jps.ee.ejb.JpsInterceptor
            </interceptor-class>
        </interceptor-binding>
    </assembly-descriptor>
</ejb-jar>

```

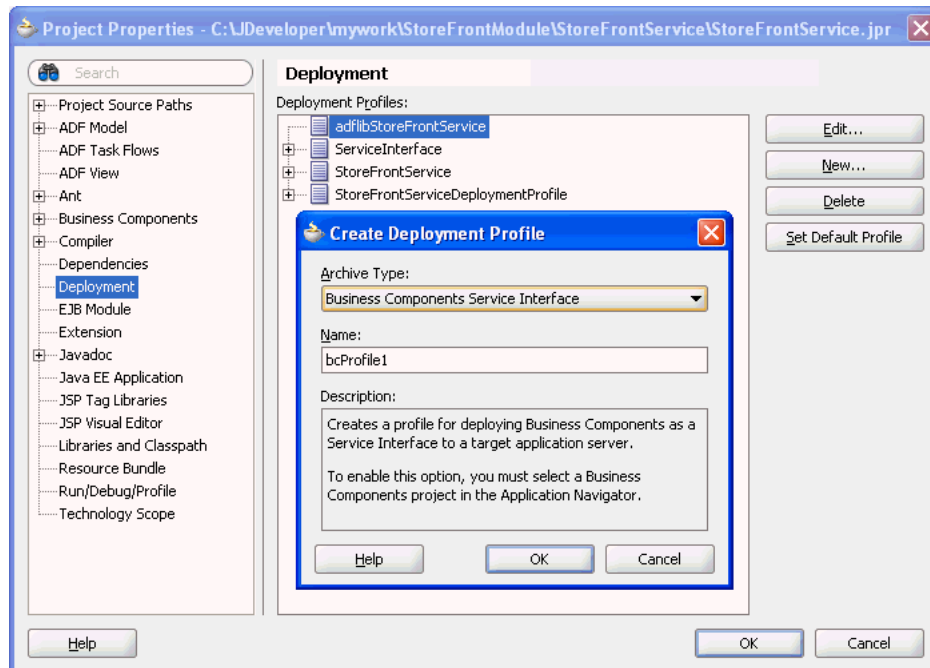

Note that *ApplicationName* must also match the application name identified in the `jazn-data.xml` policy store definition.

#### To deploy to Oracle WebLogic Server:

1. Create an application server connection to Oracle WebLogic Server:
  - a. In the main menu, choose **View** and then **Application Server Navigator**.

- b. In the Application Server Navigator, right-click the **Application Servers** node and choose **New Application Server**, and complete the Create Application Server Connection wizard.
2. Create a service deployment profile:
    - a. In the Application Navigator, right-click the project that contains the web service and choose **Project Properties**.
    - b. In the Project Properties dialog, open the Deployment page and click **New**.
    - c. In the Create Deployment Profile dialog, choose **Business Components Service Interface** as the archive type, as shown in [Figure 11–12](#).

**Figure 11–12** Dialog for Creating a Business Components Service Deployment Profile

3. In the main menu, choose **Application > Deploy > deployment profile** for the deployment profile you created.
4. In the Deploy wizard, on the Deployment Action page, select **Deploy to Application Server** and click **Next**.
5. On the Select Server page, select the application server connection.
6. Click **OK**.

## 11.3 Accessing Remote Data Over the Service-Enabled Application Module

ADF Business Components application modules offer built-in support for web services and for publishing rows of view object data as service data objects (SDOs). Entity objects that you create in your local data model project can utilize the SDO services that the service-enabled application module exposes on its service interface. By creating service-backed entity objects in your local project, you avoid having to work directly with the service proxy and SDOs programmatically for all common web service data access tasks.

The Create Entity Object wizard makes it easy for you to choose between a local database and the ADF Business Components web service when you create the entity object, as described in [Section 11.3.1, "How to Use Service-Enabled Entity Objects and View Objects."](#) In this way, service-enabled application modules provide an alternative way to access data that is not available locally in the database.

Once you create the service-backed entity object, you will be able to create view objects, view links, and view criteria to filter the data at runtime. You will also be able to utilize these view objects in your data model as though you were working with locally available data accessed from database tables.

The following sections describe how to augment your data model project using a service-enabled ADF application module.

### 11.3.1 How to Use Service-Enabled Entity Objects and View Objects

You will want to use the service-backed components as part of your application design strategy when one of the following conditions is true:

- The client data model project needs to work with data from a service-enabled application that is part of a separate business process.
- The client data model project needs to work with data from a pluggable, external service.

In the first case, you provide both sides of the service. In the second case, you may not know what the external service looks like and you may need to perform the following:

1. Even though you might not need a Fusion implementation of the service, since the service-enabled application module's service interface is the supported unit of pluggability and the supported way of creating service-backed entity objects and view objects, you create an application module with a service interface that describes the shape you want your "canonical" pluggable service to have.
2. After generating the service-enabled application module, as described in [Section 11.2.1, "How to Enable the Application Module Service Interface,"](#) you then build service-back entity objects and view objects.
3. Finally, you can create an EJB session bean (or an SCA composite) that supports the same service interface as the "canonical" service-enabled application module that you created in Step 2 and configure the `connections.xml` file of the client project containing the service-enabled business components based on this service interface to use this "plugged" version instead.

For details about how to expose an application module as a web service, see [Section 11.2, "Publishing Service-Enabled Application Modules."](#)

#### 11.3.1.1 Creating Entity Objects Backed by SDO Services

You create the service-backed entity object using the Create Entity Object wizard by supplying the URL for the WSDL document that describes the deployed service already running on an application server. You may locate the WSDL either from a UDDI registry or, when the URL endpoint is not accessible, from the WSDL document file that you have downloaded. The wizard uses the WSDL service description to display the list of available service view instances. In the wizard, you select among the displayed view instances to specify the entity object's data source. At the time you run the wizard, the service endpoint must be accessible in order to locate the WSDL document.

Only unsecured (HTTP) service endpoints may be used to create the service-backed entity object; the Create Entity Object wizard displays an error message when you attempt to access a secured (HTTPS) service endpoint.

**Before you begin:**

You will need to complete these tasks:

1. Obtain the URL for the WSDL document that describes the deployed service. If the unsecured HTTP URL is not accessible, download the WSDL file for the service and use the downloaded WSDL to obtain the service from the local file system.
2. Expose an application module as a web service, as described in [Section 11.2.1, "How to Enable the Application Module Service Interface."](#)
3. Service-enable specific view object as needed, as described in [Section 11.2.5, "How to Service-Enable Individual View Objects."](#)
4. Define a complex type (one that includes currency codes or a unit of measure) for attributes of the service-enabled view object as needed, as described in [Section 11.2.6.2, "Associating Related SDO Properties Using Complex Data Types."](#)

**To create the entity object that uses a service view instance as its data source:**

1. In the Application Navigator, right-click the project in which you want to create the entity object and choose **New**.
2. In the New Gallery, expand the **Business Tier** node, select **ADF Business Components** and then **Entity Object**, and click **OK**.
3. On the Name page of the Create Entity Object wizard, do the following to create the entity object:
  - a. Enter the package name in which the entity object will be created and enter the entity object name.
  - b. Select **Service Interface** as the data source for which you want to create the entity object.
  - c. Enter the WSDL document URL for the published web service, or click **Browse** and choose **UDDI Registry** to use the Find Web Services wizard to locate the web service from a UDDI registry. If the URL endpoint is not accessible, copy the WSDL file to the local file system and then click **Browse** and choose **File System** to navigate to the file.

JDeveloper will attempt to connect with the service endpoint and populate the list of service view instances from the WSDL service description. If the endpoint is unavailable, the list will remain empty.

- d. From the **Service View Instance** dropdown, choose the appropriate service view instance as the data source, as shown in [Figure 11–13](#).

**Figure 11–13 Service Interface as Data Source in the Create Entity Object Wizard**

4. Click **Next** and modify the attributes settings of the entity object before you complete the wizard.

For example, on the Attributes Settings page, you can enable the **Refresh After Insert** and **Refresh After Update** options for attributes that you anticipate will be modified whenever the entity is modified. Typical candidates include a version number column or an updated date column in the row.

5. Click **Finish**.

### 11.3.1.2 Using Complex Data Types with Service-Backed Entity Object Attributes

As a result of creating a service-backed entity object, JDeveloper automatically exposes attributes that were defined by the SDO properties of the base service-enabled view object. When your entity object contains attributes with complex types, you will need to select the complex type's related attribute from the entity object. For example, suppose that your service-backed entity object defines the `OrderTotal` attribute and a `CurrencyCode` attribute to specify the currency code of allowed countries. You will need to map the related attribute `CurrencyCode` to the SDO property type specified by the service-enabled view object. Complex types support these service types:

- `AmountType` service type, for use with any property that defines a currency code
- `MeasureType` service type, for use with any property that defines a unit of measure

For more information about complex types and SDO properties, see [Section 11.2.6.2, "Associating Related SDO Properties Using Complex Data Types."](#)

You use the Attributes page of the overview editor to select the entity object attribute defined as a complex type. You use the Edit Attribute dialog that you display from the Attributes page of the overview editor to map the complex type of the selected attribute to a related attribute of the appropriate type.

**Before you begin:**

You will need to complete these tasks:

1. Expose an application module as a web service, as described in [Section 11.2.1, "How to Enable the Application Module Service Interface."](#)
2. Service-enable the desired view object, as described in [Section 11.2.5, "How to Service-Enable Individual View Objects."](#)
3. Specify a complex type for individual attributes of the service-enabled view object, as described in [Section 11.2.6.2, "Associating Related SDO Properties Using Complex Data Types."](#)
4. Create the service-backed entity object from the service-enabled view object, as described in [Section 11.3.1.1, "Creating Entity Objects Backed by SDO Services."](#)

**To associate attributes using a complex type in the service-backed entity object:**

1. In the Application Navigator, double-click the service-backed entity object.
2. In the overview editor, click the **Attributes** navigation tab.
3. In the Attributes page, select the attribute backed by an attribute defined as a complex type in the service-enabled view object.

The attribute you select will be defined as a numeric type by the SDO property of the service-enabled view object.

4. With the attribute selected, click the **Edit Attribute** button.
5. In the Edit Attribute dialog, in the **Service** section, in the **currencyCode** or **unitCode** dropdown list, select the entity object attribute that you want to associate with the complex type.

The dropdown list displays all `String` attributes that the entity object defines. Select the attribute that is appropriate to map as the related attribute in the complex type definition. For example, to associate a currency code with the `OrderTotal` attribute that displays the amount paid by a customer, you might select the `CurrencyCode` attribute in the `Orders` service-backed entity object.

The SDO framework supports related service attribute values **currencyCode** and **unitCode**. When the editor displays **currencyCode**, the attribute you associate must specify currency information. When the editor displays **unitCode**, the attribute you associate must specify a unit of measure.

6. Click **OK**.

**11.3.1.3 Creating View Objects Backed by SDO Services**

After you add the service-backed entity object to your project, you can create service-backed view objects to query and optionally filter the data from the web service for use in the user interface. A service-backed view object is a view object whose single entity usage references an entity object that is backed an SDO service. You cannot make existing view objects service-backed. Instead, when you create the view object, the new view object will automatically be service-backed if its entity usage is a service-backed entity object.

**Before you begin:**

Create the service-backed entity object, as described in [Section 11.3.1.1, "Creating Entity Objects Backed by SDO Services."](#)

**To create a view object from the service-backed entity object:**

1. In the Application Navigator, right-click the service-backed entity object and choose **New Default View Object**.
2. In the Create Default View Object dialog, enter the package name in which the view object will be created and enter the view object name, as shown in [Figure 11-14](#).

The generated view object will contain the same attributes as the entity object. You can optionally edit the view object in the overview editor to customize the query. You can also define view criteria for the view object when you want to filter the data from the web service. For details about filtering query results, see [Section 5.11, "Working with Named View Criteria."](#)

**Figure 11-14** View Object Can Be Created from Service-Backed Entity Object

### 11.3.2 What Happens When You Create Service-Backed Business Components

The service-backed entity object is an entity object that encapsulates the details of accessing and, if necessary, modifying a row of data from an ADF Business Components web service. After you use the Create Entity Object wizard to create the service-backed entity object, JDeveloper saves additional service-related metadata in the `<DataSource>` element of the entity component definition. The entity component definition includes all the attributes that you selected from the service-enabled view object instance, including attributes with a complex type definition, as shown in [Example 11-15](#).

The service-backed view object references the single, service-backed entity object in its metadata just as any entity-based view object does. You can use the service-backed view object just as you would use any other view object. For details about working with view objects, see [Chapter 5, "Defining SQL Queries Using View Objects."](#) The ADF runtime handles the interaction with the ADF Business Components web service.

**Example 11-15** Entity Object Metadata Shows Service View as Data Source

```
<Entity
  xmlns="http://xmlns.example.com/bc4j"
  Name="Customer_ServiceBasedEO"
  InheritPersonalization="true"
  AliasName="CustomerSEO"
  BindingStyle="OracleName"
  UseGlueCode="false">
  <DataSource
    DataSourceClass="oracle.jbo.datasource.svc.SIEODDataSourceImpl"
    Type="ServiceInterface">
    <ServiceInterface
      ServiceName="{http://www.globalcompany.com/oesvc/}OrderEntryService"
      SDOName="{http://www.globalcompany.com/oesvc/}CustomersSVO"
      SVIName="{http://www.globalcompany.com/oesvc/}CustomersSVO"
      CreateOpName="createCustomer"
      UpdateOpName="updateCustomer"
      DeleteOpName="deleteCustomer"
```

```

        GetOpName="getCustomer"
        FindOpName="findCustomers"
        ProcessOpName="processCustomers"/>
</DataSource>
<Attribute
    Name="CustomerId"
    ColumnName="CustomerId"
    SQLType="NUMERIC"
    Type="oracle.jbo.domain.Number"
    ColumnType="NUMBER"
    PrimaryKey="true"/>
<!-- ... Attribute that is associated with complex type attribute ... -->
<Attribute
    Name="CurrencyCode"
    Precision="255"
    ColumnName="CurrencyCode"
    SQLType="VARCHAR"
    Type="java.lang.String"
    ColumnType="VARCHAR2"/>
<!-- ... Attribute with complex type mapping ... -->
<Attribute
    Name="OrderTotal"
    ColumnName="OrdTotal"
    SQLType="NUMERIC"
    Type="java.math.BigDecimal"
    ColumnType="NUMBER"
    <Properties>
        <SchemaBasedProperties>
            <DomainAttrMappings>
                <DomainAttrMapping
                    MappedAttrName="CurrencyCode"
                    Name="currencyCode"/>
            </DomainAttrMappings>
        </SchemaBasedProperties>
    </Properties>
</Attribute>
<!-- ... Other Attribute elements here ... -->
</Entity>

```

### 11.3.3 How to Update the Data Model for Service-Backed Business Components

Because the service interface exposes individual view instances, you are responsible for defining hierarchical relationships between service-backed entity objects (through associations) and service-backed view objects (through view links) in your consuming project. View links and associations are not automatically created when you create the service-backed business component. For example, if the application module of the published ADF Business Components service defines a master-detail relationship that you want to utilize, then you must define a view link for the corresponding view objects in your own project to preserve this hierarchy.

Furthermore, while you can create view links between view objects that query their data locally and service-backed view objects (and the other way around), once you define the view link, you will not be able to create entity-based view objects with the following entity object usages:

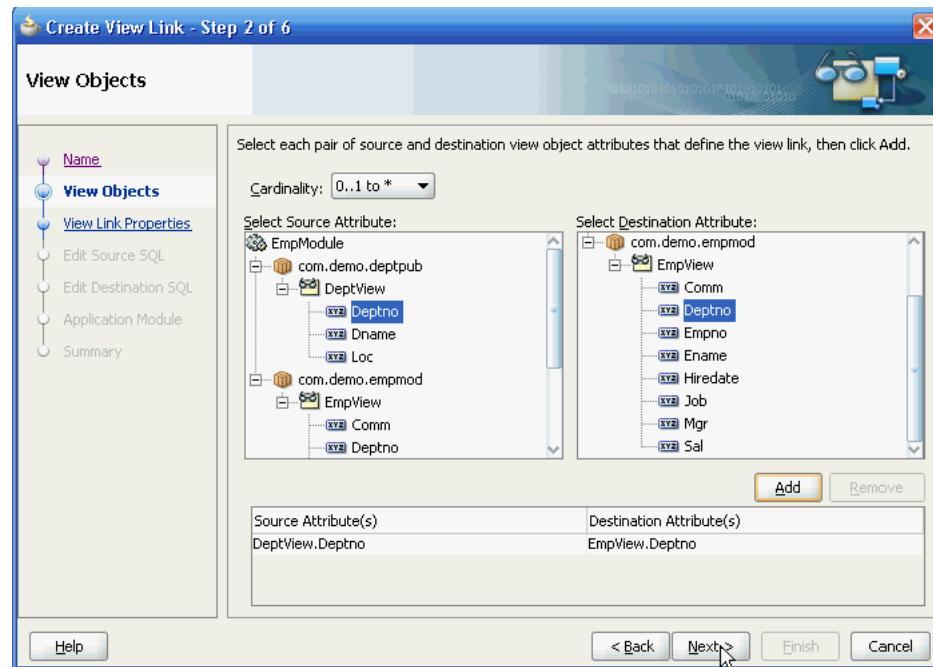

- The view object will not be able to reference a secondary entity usage that is a service-backed entity object.
- The view object will not be able to reference a primary entity usage that is a service-backed entity object with secondary entity usages.

The same restrictions apply to associations in the client project between regular entity objects and service-backed entity objects: while you can create the associations, you will not be able to create view objects.

You use the Create View Link wizard to specify relationships between the view objects that your project defines, as shown in Figure 11–15. For details about creating view links, see Section 5.6.1, "How to Create a Master-Detail Hierarchy for Entity-Based View Objects."

**Figure 11–15 One to Many Relationship Defined in Create View Link Wizard**

View links you create may define relationships between service-backed view objects and view objects that query locally accessed database tables. For example, you might choose to drive a database-derived detail view object with a service-backed master view object. You can create view links with the combinations shown in Table 11–3.

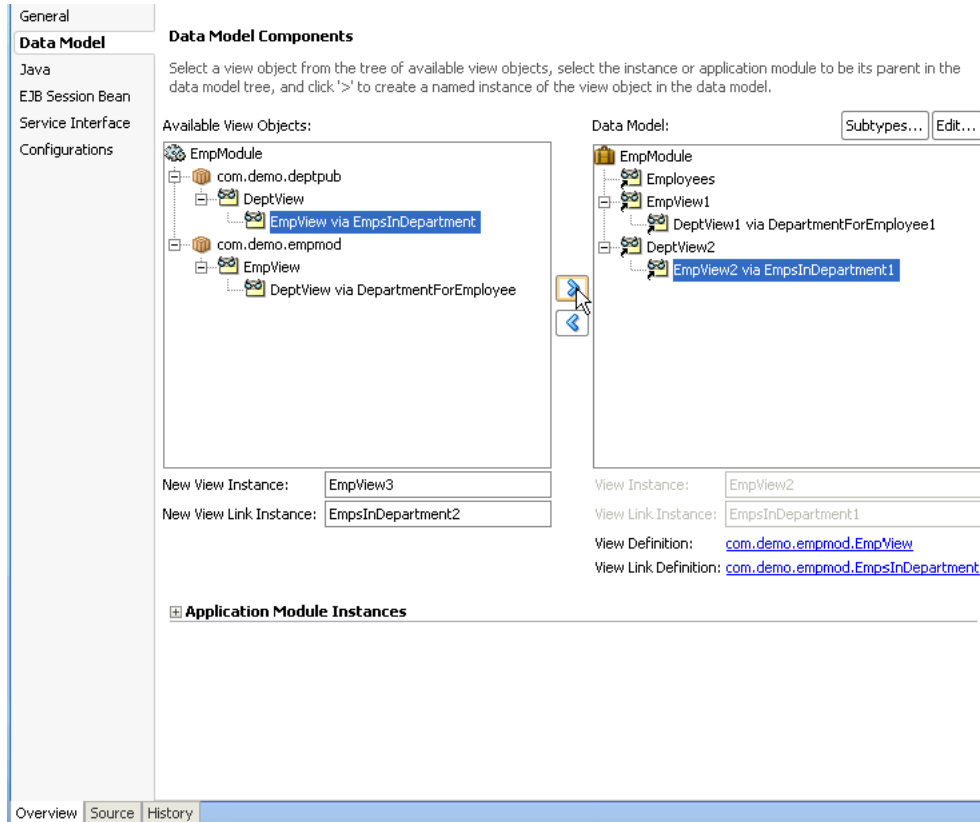

**Table 11–3 Supported View Link Combinations Involving Service-Backed View Objects**

Use Case	Master View Object Type	View Linked Detail View Object Type	View Link Cardinality
Local master rows with remote details	Query-based	Service-backed	One-to-many
Remote master rows with local details	Service-backed	Query-based	One-to-many
Local master rows with remote reference information	Query-based	Service-backed	Many-to-one
Remote master rows with local reference information	Service-backed	Query-based	Many-to-one

Once you have defined the desired view hierarchy, using the Create View Link wizard, you use the overview editor for your project’s application module to define new view instances on the data model, as shown in Figure 11–16. The updated data model

allows you to expose the view objects as ADF data controls that enable databinding with the user interface components of the Fusion web application. For details about updating the data model, see [Section 9.2.3.2, "Adding Master-Detail View Object Instances to an Application Module."](#)

**Figure 11–16 Data Model Contains Service View Instances**

### 11.3.4 How to Configure the Service-Backed Business Components Runtime

Before you can run your application and interact with the published service-enabled ADF application module to invoke service operations, you need to describe the published service, including the service’s endpoint provider type and other configuration information. The ADF Business Components `ServiceFactory` class (`oracle.jbo.client.svc.ServiceFactory`) returns a proxy for the service, then uses the service proxy to invoke the service operations. The service factory can return proxies for three different service endpoint providers, to support these transport protocols:

- When the service endpoint provider is ADF Business Component, the transport protocol is EJB RMI.
- When the service endpoint provider is SOA Fabric, the transport protocol is SOA Fabric SDO binding.
- When the service endpoint provider is SOAP (for JAX-WS clients), the transport protocol is SOAP.

To configure the consuming application to invoke published service operations:

1. Add the `bcProfileName_Common.jar` file for the SDO’s generated classes to the client project’s classpath.

2. Update the `connections.xml` file in the client project's `.adf/META-INF` folder to describe the published ADF Business Components service.

The updates you make to the file will depend on the transport protocol your application uses: EJB RMI protocol, SOA Fabric SDO binding, or SOAP protocol (for JAX-WS clients).

#### 11.3.4.1 Adding the SDO Client Library to the Classpath

Before your application can access the published service, the service consuming project must have access to the generated SDO classes and their schema definitions. These files are packaged in the `bcProfileName_Common.jar` file generated by the development team responsible for publishing the service.

To make the SDO classes and their schema definitions available to your application, obtain the `bcProfileName_Common.jar` file from the service-provider team and place this JAR file in a folder of your local project. For example, you may copy the JAR file into your project's deploy folder. You can then use JDeveloper to add the JAR file to your project's classpath with a SDO client library you create. For steps to generate the SDO classes JAR file, see [Section 11.2.22, "How to Deploy Web Services to Oracle WebLogic Server."](#)

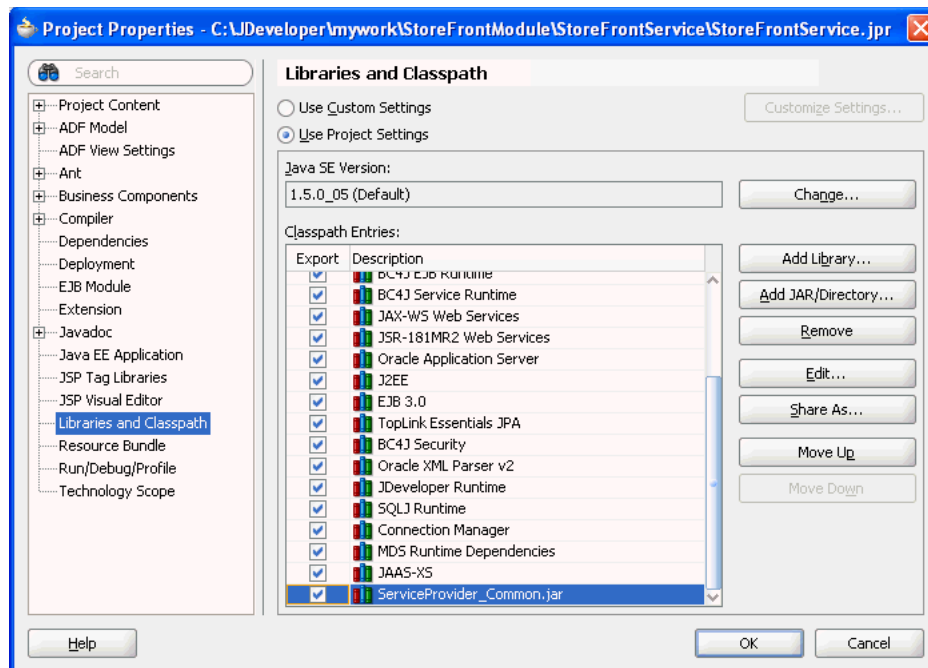

##### To add the SDO client library to the classpath:

1. In the Application Navigator, right-click the project that contains the SDO classes and choose **Project Properties**.
2. In the Project Properties dialog, select **Libraries and Classpath** and click **Add Libraries**.
3. In the Add Library dialog, click **New** to create the SDO client library.
4. In the Create Library dialog, click **Add Entry** to add a classpath entry.
5. In the Select Path Entry dialog, browse to the folder that contains the `bcProfileName_Common.jar` file and select the file to view it in the Create Library dialog.

The Select Path Entry dialog lets you browse the file system or local area network to locate the JAR file. If you cannot browse the deploy folder of the service-provider's application workspace to obtain the JAR file, you must obtain the file and copy it into your own project's folder. For example, you may have copied the JAR file into your project's deploy folder.

6. Click **OK** in the dialogs to display the Project Properties dialog with the SDO client library selected. Click **OK** to add the library to the classpath.

[Figure 11-17](#) shows the SDO client library with the name `ServiceProvider_Common.jar` selected. In this case, the library name is the same as the JAR file name. Optionally, you can edit the library name in the Create Library dialog.

**Figure 11–17 SDO Client Library Classpath Entry**

### 11.3.4.2 Registering the ADF Business Components Service in the Consuming Application's connections.xml for the EJB RMI Protocol

When the service endpoint provider is ADF Business Components, the service factory will return an EJB object proxy bound to a stateless session bean running in the EJB container. You must provide the JNDI context information to allow the consuming application to look up the published service.

Lookup information that you provide to register the published ADF Business Components service appears in the consuming Fusion web application's `connections.xml` file, located in the `.adf/META-INF` folder relative to the application. The ADF connection architecture uses this file to encapsulate the details of the service endpoint provider.

The JNDI lookup information you provide will depend on whether the published service runs locally (in the same JVM) with the consuming application or runs remotely on a separate server from the consuming application. Typically, the ADF Business Components service is in a different application from the consuming application and is therefore run remotely.

To register the published service with your client application, update the `connections.xml` file following the example in [Example 11–16](#). When the ADF Business Components service runs local to the consuming application (as occurs when you run within JDeveloper), the service factory needs only the JNDI name to look up the service.

---

**Note:** When you deploy the calling application to standalone Oracle WebLogic Server, you will use Oracle Enterprise Manager to configure the JNDI context properties instead of editing the `connections.xml` file. For instructions, refer to the online documentation in Oracle Enterprise Manager.

---

**Example 11–16 Client connections.xml File Registers the Local EJB ADF Business Components Service**

```

<References xmlns="http://xmlns.oracle.com/adf/jndi">
  <Reference name="{www.globalcompany.com}StoreFrontService"
    className="oracle.jbo.client.svc.Service" xmlns="">
    <Factory className="oracle.jbo.client.svc.ServiceFactory"/>
    <RefAddresses>
      <StringRefAddr addrType="serviceInterfaceName">
        <Contents>oracle.foddemo.storefront.store.service.common.
          serviceinterface.StoreFrontService</Contents>
      </StringRefAddr>
      <StringRefAddr addrType="serviceEndpointProvider">
        <Contents>ADFBC</Contents>
      </StringRefAddr>
      <StringRefAddr addrType="jndiName">
        <Contents>StoreFrontServiceBean#oracle.fodemo.storefront.store.service.common.
          serviceinterface.StoreFrontService</Contents>
      </StringRefAddr>
      <StringRefAddr addrType="serviceSchemaName">
        <Contents>StoreFrontAMService.xsd</Contents>
      </StringRefAddr>
      <StringRefAddr addrType="serviceSchemaLocation">
        <Contents>oracle/fodemo/storefront/store/service/common/serviceinterface/</Contents>
      </StringRefAddr>
    </RefAddresses>
  </Reference>
  ...
</References>

```

When the ADF Business Components service runs remotely to the calling client, then remote JNDI context information needs to be added to the `connections.xml` file. You can edit these JNDI context properties in the `connections.xml` file, as shown in [Example 11–17](#):

- `jndiFactoryInitial` should be set to `weblogic.jndi.WLInitialContextFactory`.
- `jndiProviderURL` is the JNDI provider URL that indicates the location of the JNDI server. The URL should be composed as `t3://<hostname>:<server port>`.  
For example, specify a URL like: `t3://localhost:8888`, where `t3` is the Oracle WebLogic protocol, `localhost` is the host name that the remote Oracle WebLogic Server instance runs in, `8888` is the port number.
- `jndiSecurityPrincipal` specifies the principal (user name) with permission to access the remote JNDI.  
When you deploy the service to standalone Oracle WebLogic Server, the user name can be read from the file.
- `jndiSecurityCredentials` specifies the credentials (password) to be used for the security principal.

As [Example 11–11](#) shows, when you deploy the service to standalone Oracle WebLogic Server in a test environment, you can specify credentials in plain text for the JNDI provider. For example, you can specify `weblogic/weblogic1` which are the default administrator user name/password credentials with sufficient privileges to access JNDI provider for Oracle WebLogic Server.

When you deploy the service to a production environment, you must remove the plain text password to avoid creating a security vulnerability. As [Example 11–17](#) shows, the `connections.xml` file must contain `<SecureRefAddr`

addrType="jndiSecurityCredentials"/> with no password. To configure the service password for standalone Oracle WebLogic Server, you must use Oracle Enterprise Manager, which will store the encrypted password in Oracle's credential store.

**Example 11–17 Client connections.xml File Registers the Remote EJB ADF Business Components Service**

```
<References xmlns="http://xmlns.oracle.com/adf/jndi">
  <Reference name="{www.globalcompany.com}StoreFrontService"
    className="oracle.jbo.client.svc.Service" xmlns="">
    <Factory className="oracle.jbo.client.svc.ServiceFactory"/>
    <RefAddresses>
      <StringRefAddr addrType="serviceInterfaceName">
        <Contents>oracle.foddemo.storefront.store.service.common.
          serviceinterface.StoreFrontService</Contents>
      </StringRefAddr>
      <StringRefAddr addrType="serviceEndpointProvider">
        <Contents>ADFBC</Contents>
      </StringRefAddr>
      <StringRefAddr addrType="jndiName">
        <Contents>StoreFrontServiceBean#oracle.fodemo.storefront.store.service.common.
          serviceinterface.StoreFrontService</Contents>
      </StringRefAddr>
      <StringRefAddr addrType="jndiFactoryInitial">
        <Contents>weblogic.jndi.WLInitialContextFactory</Contents>
      </StringRefAddr>
      <StringRefAddr addrType="jndiProviderURL">
        <Contents>t3://localhost:8888</Contents>
      </StringRefAddr>
      <StringRefAddr addrType="jndiSecurityPrincipal">
        <Contents>a_username</Contents>
      </StringRefAddr>
      <SecureRefAddr addrType="jndiSecurityCredentials"/>
      <StringRefAddr addrType="serviceSchemaName">
        <Contents>StoreFrontAMService.xsd</Contents>
      </StringRefAddr>
      <StringRefAddr addrType="serviceSchemaLocation">
        <Contents>oracle/fodemo/storefront/store/service/common/serviceinterface/</Contents>
      </StringRefAddr>
    </RefAddresses>
  </Reference>
  ...
</References>
```

### 11.3.4.3 Registering the ADF Business Components Service in the Consuming Application's connections.xml for the SOAP Protocol

When the service endpoint provider is SOAP, the service factory will create a dynamic JAX-WS client proxy. You must provide the WSDL URL and port name to allow the consuming application to look up the published service. Additionally, for the SOAP client, OWSM client security policy can be attached as part of the SOAP header.

Lookup information that you provide to register the published ADF Business Components service appears in the consuming Fusion web application's `connections.xml` file, located in the `.adf/META-INF` folder relative to the application. The ADF connection architecture uses this file to encapsulate the details of the service endpoint provider.

---

---

**Note:** When you deploy the calling application to standalone Oracle WebLogic Server, you will use Oracle Enterprise Manager to configure the JNDI context properties instead of editing the `connections.xml` file. For instructions, refer to the online documentation in Oracle Enterprise Manager.

---

---

To register the published service with your client application for the SOAP protocol, depending on whether your application uses identity propagation or identity switching, update the `connections.xml` file following the example in either [Example 11-18](#) or [Example 11-19](#). Identity propagation and switching are similar in that each process involves propagating an identity. In Fusion web applications, identity propagation involves propagating the identity that is currently executing code. Identity switching, on the other hand, involves propagating an application identity that is different from that currently executing code.

To register the published service with your client application so the user identity will be switched based on the credential key, specify the clientside policy `oracle/wss11_username_token_with_message_protection_client_policy` in the `connections.xml` file following the example in [Example 11-18](#).

---

---

**Note:** The `connections.xml` file supports Oracle WSM security policy client overrides. When the security policy is `oracle/wss11_username_token_with_message_protection_client_policy`, the `csf-key` property can be overridden to specify the consuming application's credentials.

---

---

**Example 11-18 Client connections.xml File Registers the Remote Business Components Service for the SOAP Protocol Using Identity Switching**

```
<Reference name="{http://xmlns.oracle.com/apps/sample/hrService/HrService}"
className="oracle.jbo.client.svc.Service" xmlns="">
  <Factory className="oracle.jbo.client.svc.ServiceFactory"/>
  <RefAddresses>
    <StringRefAddr addrType="serviceInterfaceName">

  <RefAddresses>
```

```

<XmlRefAddr addrType="WebServiceConnection">
  <Contents>
    <wsconnection
      description="http://rws65094fwks:7202/MySampleSvc/HrService?WSDL"
      service="{http://xmlns.oracle.com/apps/sample/hrService/}HrService">
      <model
        name="{http://xmlns.oracle.com/apps/sample/hrService/}HrService"
        xmlns="http://oracle.com/ws/model">
        <service name="{http://xmlns.oracle.com/apps/sample/hrService/}HrService">
          <port name="HrServiceSoapHttpPort"
            binding="{http://xmlns.oracle.com/apps/sample/hrService/}HrServiceSoapHttp"
            portType="http://xmlns.oracle.com/apps/sample/hrService/}HrService">
            <call-properties xmlns="http://oracle.com/adf">
              <call-property id="csf-key" xmlns="">
                <name>csf-key</name>
                <value>meuser.credentials</value>
              </call-property>
            </call-properties>
            <policy-references xmlns="http://oracle.com/adf">
              <policy-reference category="security"
                uri="oracle/wss11_username_token_with_message_protection_client_policy"
                enabled="true"
                id="oracle/wss11_username_token_with_message_protection_client_policy"
                xmlns="" />
            </policy-references>
            <soapaddressUrl="http://rws65094fwks:7202/MySampleSvc/HrService"
              xmlns="http://schemas.xmlsoap.org/wsdl/soap/" />
          </port>
        </service>
      </model>
    </wsconnection>
  </Contents>
</XmlRefAddr>
</RefAddresses>
</Reference>
    
```

To register the published service with your client application so the user identity will be propagated to the caller, specify the clientside policy `oracle/wss11_saml_token_with_message_protection_client_policy` in the `connections.xml` file following the example in [Example 11-19](#).

**Example 11-19 Client connections.xml File Registers the Remote Business Components Service for the SOAP Protocol Using Identify Propagation**

```

<Reference name="{http://xmlns.oracle.com/apps/sample/hrService/}HrService"
  className="oracle.jbo.client.svc.Service" xmlns="">

#### 11.3.4.4 Registering the ADF Business Components Service in the Consuming Application's connections.xml for Fabric SDO Binding

When the service endpoint provider is Fabric, the service factory will return a SOA Fabric composite proxy and call the service running inside a Fabric composite through Fabric's SDO binding. You must provide the name of the Fabric composite to allow the consuming application to look up the published service.

Lookup information that you provide to register the published ADF Business Components service appears in the consuming Fusion web application's `connections.xml` file, located in the `.adf/META-INF` folder relative to the application. The ADF connection architecture uses this file to encapsulate the details of the service endpoint provider.

---

---

**Note:** When you deploy the calling application to standalone Oracle WebLogic Server, you will use Oracle Enterprise Manager to configure the JNDI context properties instead of editing the `connections.xml` file. For instructions, refer to the online documentation in Oracle Enterprise Manager.

---

---

To register the published service with your client application for the Fabric protocol, update the `connections.xml` file following the example in [Example 11–20](#), where `fabricAddress` is the name of the Fabric composite for the published service.

**Example 11–20 Client connections.xml File Registers the Remote Business Components Service for the Fabric SDO Binding**

```

```

### 11.3.5 How to Test the Service-Backed Components in the Business Component Browser

Before you can launch the Business Component Browser, your project must meet the runtime requirements, as described in [Section 11.3.4, "How to Configure the Service-Backed Business Components Runtime."](#) The Business Component Browser will display the view objects you create from the remote web service and allow you to interact with the service to perform standard CRUD operations.

Because the application module that you run can access locally queried data and remotely queried data together, service-backed view objects and database-derived view objects will display in the same Browser. If the endpoint is unavailable at the time you select the service-backed view object in the Business Component Browser, you will get a runtime exception.

For details about running the Business Component Browser, see [Section 6.3.1, "How to Run the Business Component Browser."](#)

## 11.3.6 How to Invoke Operations of the Service-Backed Components in the Consuming Application

The ADF Business Components service interface requires that you return a service proxy to ensure that operations you invoke use the transport protocol specified by the published service.

### Before you begin:

Ensure that the consuming application has the correct libraries on the classpath. In the Application Navigator, double-click the project and in the Project Properties dialog, select **Libraries and Classpath** and confirm the following libraries appear:

- **Java EE 1.5**
- **Oracle XML Parser v2**
- **BC4J Service Client**
- **JAX-WS Client**
- The service's common JAR file

As [Example 11–21](#) shows, when you invoke the operation, you perform the following tasks:

1. Import the `oracle.jbo.client.svc.ServiceFactory` class and published service class.
2. Call `getServiceProxy()` on the service factory object and pass in the service name in the form `<serviceName>.NAME`. The ADF service factory embeds a `SDOHelperContext` ID in the service proxy object returned by this method to ensure delivery of the latest ADF Business Component service schema metadata to the SDO.

The schema (`.xsd` files) for the service object may be stored in MDS and may have been extended for example to add more business component attributes, extend existing types, or define new types. The local helper context allows customization of individual service's schema definitions without affecting other service's SDO metadata or requiring restarting the application.

3. Call `create()` on a data factory object, where the proxy object is obtained from the `getServiceProxy()` call.
4. Invoke the operation on the proxy object and return a data object.
5. Save the data object return as XML.

### Example 11–21 Obtaining and Invoking a Service Proxy in the Consuming Application

```
import commonj.sdo.DataObject;
import commonj.sdo.helper.DataFactory;
import commonj.sdo.helper.XMLHelper;
import hr.common.Dept;
import hr.common.serviceinterface.HRAppService;
import oracle.jbo.client.svc.ServiceFactory;
...
{
    HRAppService proxy = (HRAppService) ServiceFactory.getServiceProxy(HRAppService.NAME);

    Dept dept = (Dept)
        ServiceFactory.getDataFactory(proxy).create("http://example.com/hr/common/" + "Dept");
    dept.setDname("ENGINEERING");
    ...
}
```

```

dept = proxy.createDept(dept);
String xml = ServiceFactory.getXMLHelper(proxy).save((DataObject) dept,
                                                    "http://example.com/hr/common/", "dept");
out.print(xml);
}

```

### 11.3.7 What You May Need to Know About Creating Service Data Objects in the Consuming Application

The ADF service interface framework defines a set of common data objects, such as `oracle.jbo.common.service.types.FindCriteria`, `oracle.jbo.common.service.types.FindControl`, `oracle.jbo.common.service.types.ProcessControl`, and so on. Those data objects are used in standard `findXxx()` method and `processXxx()` method calls. You can create these data objects in the consuming application and pass them to the standard service methods. As [Example 11-22](#) shows, you can need to call the data factory class' `create()` method to construct those data objects before passing them into the `findXxx()` or `processXxx()` methods.

#### **Example 11-22** *Creating Data Objects in the Consuming Application*

```

FindCriteria fc = (FindCriteria) ServiceFactory.getDataFactory(proxy).create
                  ("http://xmlns.oracle.com/adf/svc/types/", "FindCriteria");

```

### 11.3.8 What You May Need to Know About Invoking Built-In Service Methods in the Consuming Application

The ADF service interface framework defines several built-in SOAP service methods that may be optionally enabled for the service view instances, including `getDftlObjAttrHints()`, `getServiceLastUpdateTime()`, and `getEntityList()`, as described in [Table 11-2](#). These methods primarily support programmatic interaction with the service endpoint by the consuming application and are not supported at design time by data controls.

### 11.3.9 What Happens at Runtime: How the Application Accesses the Published Application Module

The ADF runtime obtains the data source information from the service-backed entity object XML definition to automate interactions with the service interface methods as needed. By using the service-backed entity object, you avoid having to work directly with the service proxy and service data objects programmatically for all common web service data access tasks. The ADF service factory looks up the service and then uses the service interface you specified in the `connections.xml` to invoke the service methods.

When your application accesses an ADF Business Components web service, each remote call is stateless, and the remote service will not participate in the same transaction as the business component that uses a service-enabled application module's service interface.

In the majority of the cases, calls to remote services will be informational in nature and will not make changes to remote objects. However, if you must use a remote service to make changes, then keep these points in mind:

- An exception thrown by the remote service will cause the local transaction to fail.

- If you successfully call a remote service that results in modifying data, and then subsequently your local transaction fails for any reason, then it is the responsibility of your error handling code to perform a compensating transaction against the remote service to "undo" the previous change made.

### 11.3.10 What You May Need to Know About Service-Backed Entity Objects and View Objects

You will use some web services to access reference information. However, other services you call may modify data. This data modification might be in your own company's database if the service was written by a member of your own or another team in your company. If the web service is outside your firewall, of course the database being modified will be managed by another company. In either of these situations, it is important to understand that any data modifications performed by a web service you invoke will occur in its own distinct transaction unrelated to the service-enabled application module's current unit of work. For example, if you have invoked a web service that modifies data and then you later call `rollback()` to cancel the pending changes in the application module's current unit of work, rolling back the changes has no effect on the changes performed by the web service you called in the process. You may need to invoke a corresponding web service method to perform a compensating change to account for your rollback of the application module's transaction.

At runtime, ADF handles the interaction with the ADF Business Components web service. However, you should be aware that service-backed business components have the following design time restrictions that may restrict your application's runtime behavior. For more details about how these restrictions apply at design time, see [Section 11.3.3, "How to Update the Data Model for Service-Backed Business Components."](#)

- View objects that you create cannot reference a service-backed entity object as a secondary entity object usage.
- View objects that you create cannot produce a flattened join from two or more related entity objects when at least one of those entity objects is a service-backed entity object.
- Service-backed view objects that you create from service-backed entity objects will not reference secondary entity usages.

For more details about how these restrictions apply at design time, see [Section 11.3.3, "How to Update the Data Model for Service-Backed Business Components."](#)

---

---

## Using ADF Model in a Fusion Web Application

This chapter describes how an ADF application module's data model and business service interface methods appear at design time for drag and drop data binding, how they are accessible at runtime by the ADF Model data binding layer using the application module data control, and how developers can use the Data Controls panel to create databound pages.

This chapter includes the following sections:

- [Section 12.1, "Introduction to ADF Data Binding"](#)
- [Section 12.2, "Exposing Application Modules with ADF Data Controls"](#)
- [Section 12.3, "Using the Data Controls Panel"](#)
- [Section 12.4, "Working with the DataBindings.cpx File"](#)
- [Section 12.5, "Configuring the ADF Binding Filter"](#)
- [Section 12.6, "Working with Page Definition Files"](#)
- [Section 12.7, "Creating ADF Data Binding EL Expressions"](#)
- [Section 12.8, "Using Simple UI First Development"](#)

### 12.1 Introduction to ADF Data Binding

ADF Model implements concepts that enable decoupling the user interface technology from the business service implementation: *data controls* and *declarative bindings*.

Data controls abstract the implementation technology of a business service by using standard metadata interfaces to describe the service's operations and data collections, including information about the properties, methods, and types involved. In an application that uses business components, a data control is automatically created when you create an application module, and it contains all the functionality of the application module. Developers can then use the representation of the data control displayed in JDeveloper's Data Controls panel to create UI components that are automatically bound to the application module. At runtime, the ADF Model layer reads the information describing the data controls and bindings from appropriate XML files and implements the two-way connection between the user interface and the business service.

Declarative bindings abstract the details of accessing data from data collections in a data control and of invoking its operations. There are three basic kinds of declarative binding objects:

- Iterator bindings: Simplify the building of user interfaces that allow scrolling and paging through collections of data and drilling-down from summary to detail information.
- Value bindings: Used by UI components that display data. Value bindings range from the most basic variety that work with a simple text field to more sophisticated list and tree bindings that support the additional needs of list, table, and tree UI controls.
- Action bindings: Used by UI components like hyperlinks or buttons to invoke built-in or custom operations on data collections or a data control without writing code.

Figure 12–1 shows how bindings connect UI components to data control collections and methods.

**Figure 12–1 Bindings Connect UI Components to Data Controls**

The group of bindings supporting the UI components on a page are described in a page-specific XML file called the *page definition file*. The ADF Model layer uses this file at runtime to instantiate the page's bindings. These bindings are held in a request-scoped map called the *binding container*, accessible during each page request

using the EL expression `#{bindings}`. This expression always evaluates to the binding container for the current page.

You can design a databound user interface by dragging an item from the Data Controls panel and dropping it on a page as a specific UI component. When you use data controls to create a UI component, JDeveloper automatically creates the various code and objects needed to bind the component to the data control you selected.

---

---

**Note:** Using the ADF Model layer to perform business service access ensures that the view and the business service stay in sync. For example, while you could call a method on an application module by class-casting the data control reference to the application module instance and then calling the method directly, doing so would bypass the model layer and it would then become unaware of any changes.

---

---

## 12.2 Exposing Application Modules with ADF Data Controls

The application module data control is a thin adapter over an application module pool that automatically acquires an available application module instance at the beginning of the request. During the current request, the application module data control holds a reference to the application module instance on behalf of the current user session. At the end of the request, the data control releases the instance back to the pool. Importantly, the application module component directly implements the interfaces that the binding objects expect for data collections, built-in operations, and service methods. This optimized interaction allows the bindings to work *directly* with the application module instances in its data model in the following ways:

- Iterator bindings directly bind to the default row set iterator of the default row set of any view object instance. The row set iterator manages the current object and current range information.

**Tip:** You can also use the iterator binding to bind to a secondary named row set that you have created. To bind to a secondary row set, you need to use the `RSName` attribute on the binding. For more information about the difference between the default row set and secondary row sets and how to create them, see [Section 39.1.9, "Working with Multiple Row Sets and Row Set Iterators."](#)

- Action bindings directly bind to either:
  - Custom methods on the data control client interface
  - Built-in operations of the application module and view objects

[Figure 12-2](#) illustrates the pool management role the application module data control plays and highlights the direct link between the bindings and the application module instance.

**Figure 12–2 Bindings Connect Directly to View Objects and Methods of an Application Module from a Pool**

### 12.2.1 How an Application Module Data Control Appears in the Data Controls Panel

You use the Data Controls panel to create databound HTML elements (for JSP pages), and databound UI components (for JSF JSP pages) by dragging and dropping icons from the panel onto the visual editor for a page. [Figure 12–3](#) shows the Data Controls panel displaying the data controls for the StoreFront module.

**Figure 12–3 Data Controls Panel in JDeveloper**

The Data Controls panel lists all the data controls that have been created for the application's business services and exposes all the collections (row sets of data objects), methods, and built-in operations that are available for binding to UI components.

---

**Note:** If you've configured JDeveloper to expose them, any view link accessor returns are also displayed. For more information, see [Section 5.6, "Working with Multiple Tables in a Master-Detail Hierarchy."](#) To view the accessor methods:

1. From the JDeveloper main menu, choose **Tools > Preferences**.
  2. Select the **Data Controls Panel** node.
  3. Select **Show Underlying Accessor Nodes** to activate the checkbox.
- 

For example, in an application that uses ADF Business Components to define the business services, each data control on the Data Controls panel represents a specific application module, and exposes the view object instances in that application's data model. The hierarchy of objects in the data control is defined by the view links between view objects that have specifically been added to the application module data model. For information about creating view objects and view links, see [Chapter 5, "Defining SQL Queries Using View Objects."](#) For information about adding view links to the data model, see [Section 5.6.4, "How to Enable Active Master-Detail Coordination in the Data Model."](#)

**Tip:** You can open the overview editor for a view object by right-clicking the associated data control object and choosing **Edit Definition**.

For example, the `StoreServiceAMDataControl` application module implements the business service layer of the `StoreFront` module application. Its data model contains numerous view object instances, including several master-detail hierarchies. The view layer of the ADF sample application consists of JSF pages whose UI components are bound to data from the view object instances in the `StoreServiceAMDataControl`'s data model, and to built-in operations and service methods on its client interface.

### 12.2.1.1 How the Data Model and Service Methods Appear in the Data Controls Panel

Each view object instance appears as a named data collection whose name matches the view object instance name. [Figure 12-4](#) illustrates how the Data Controls panel displays the view object instances in the `StoreServiceAMDataControl`'s data model (note that for viewing simplicity, the figure omits some details in the tree that appear for each view object). The Data Controls panel reflects the master-detail hierarchies in your application module data model by displaying detail data collections nested under their master data collection.

The Data Controls panel also displays each custom method on the application module's client interface as a named data control custom operation whose name matches the method name. If a method accepts arguments, they appear in a `Parameters` node as operation parameters nested inside the operation's node.

**Figure 12-4 How the Data Model Appears in the Data Controls Panel**

### 12.2.1.2 How Transaction Control Operations Appear in the Data Controls Panel

The application module data control exposes two data control built-in operations named Commit and Rollback, as shown in Figure 12-5 (note that the Operations node in the data controls tree omits all of the data collections and custom operations for a more streamlined view). At runtime, when these operations are invoked by the data binding layer, they delegate to the `commit()` and `rollback()` methods of the Transaction object associated with the current application module instance.

---

**Note:** In an application module with many view object instances and custom methods, you may need to scroll the Data Controls panel display to find the Operations node that is the direct child node of the data control. This node is the one that contains these built-in operations.

---

**Figure 12-5 How Transaction Control Operations Appear in the Data Controls panel**

### 12.2.1.3 How View Objects Appear in the Data Controls Panel

The view object attributes are displayed as immediate child nodes of the corresponding data collection, as are any custom methods you've created. [Figure 12-6](#) shows how each view object instance in the application module's data model appears in the Data Controls panel. If you have selected any custom methods to appear on the view object's client interface, they appear as custom methods immediately following the view object attributes at the same level. If the method accepts arguments, these appear in a nested Parameters node as operation parameters.

By default, implicit view criteria are created for each attribute that is able to be queried on a view object. They appear as the All Queriable Attributes node under the Named Criteria node, as shown in [Figure 12-6](#). If any named view criteria were created for the view object, they appear under the Named Criteria node. The View Criteria expressions (both implicit and named) appear as method returns. The conjunction used in the query, along with the criteria items and if applicable, any nested criteria, are shown as children. These items are used to create quick search forms, as detailed in [Chapter 27, "Creating ADF Databound Search Forms."](#)

**Figure 12-6 How View Objects Appear in the Data Controls Panel**

As shown in [Figure 12-6](#), the Operations node under the data collection displays all its available built-in operations. If an operation accepts one or more parameters, then those parameters appear in a nested Parameters node. At runtime, when one of these data collection operations is invoked by name by the data binding layer, the application module data control delegates the call to an appropriate method on the

ViewObject interface to handle the built-in functionality. The built-in operations fall into three categories: operations that affect the current row, operations that refresh the data collection, and all other operations.

Operations that affect the current row:

- **Create:** Creates a new row that becomes the current row, but does not insert it.
- **CreateInsert:** Creates a new row that becomes the current row, and inserts the new blank row into the data source.
- **Create with Parameters:** Creates a new row taking parameter values. The passed parameters can supply the create-time value of the discriminator or composing parent's foreign key attributes that are required at create time for polymorphic view object and for a composed child view object row when not created in the context of a current view linked parent row, respectively. For more information about polymorphic view objects, see [Section 39.6, "Using View Objects to Work with Multiple Row Types."](#)
- **Delete:** Deletes the current row.
- **First:** Sets the current row to be the first row in the row set.
- **Last:** Sets the current row to be the last row in the row set.
- **Next:** Sets the row to be the next row in the row set.
- **Next Set:** Navigates forward one full set of rows.
- **Previous:** Sets the current row to be the previous row in the row set.
- **Previous Set:** Navigates backward one full set of rows.
- **setCurrentRowWithKey:** Tries to find a row using the serialized string representation of row key passed as a parameter. If found, that row becomes the current row.
- **setCurrentRowWithKeyValue:** Tries to find a row using the primary key attribute value passed as a parameter. If found, that row becomes the current row.

Operations that refresh the data collection:

- **Execute:** Refreshes the data collection by executing or reexecuting the view object's query, leaving any bind parameters at their current values.
- **ExecuteWithParams:** Refreshes the data collection by first assigning new values to the named bind variables passed as parameters, then executing or reexecuting the view object's query.

---

---

**Note:** The `executeWithParams` operation appears only for view objects that have defined one or more named bind variables at design time.

---

---

All other operations:

- **removeRowWithKey:** Tries to find a row using the serialized string representation of row key passed as a parameter. If found, the row is removed.
- **Find:** Toggles "Find Mode" on and off for the data collection.

### 12.2.1.4 How Nested Application Modules Appear in the Data Controls Panel

If you build composite application modules by including nested instances of other application modules, the Data Controls panel reflects this component assembly in the tree hierarchy. For example, assume that, in addition to the `StoreServiceAMDataControl` application module, you have also created the following application modules in the same package:

- An application module named `ProductService`, and renamed its data control to `ProductService`
- An application module named `CompositeService`, and renamed its data control to `CompositeService`

Then assume that you've added two view object instances named `OtherViewObject` and `AnotherViewObject` to the data model of `CompositeService` and that on the Application Modules page of the Edit Application Module dialog you have added an instance of the `StoreServiceAMDataControl` application module and an instance of the `ProductService` application module to reuse them as part of `CompositeService`. [Figure 12-7](#) illustrates how your `CompositeService` would appear in the Data Controls panel (note that much of the structure of the nested `StoreServiceAMDataControl` has been omitted for clarity). The nested instances of `StoreServiceAMDataControl` and `ProductService` appear in the panel tree display nested inside of the `CompositeService` data control. The entire data model and set of client methods that the nested application module instances expose to clients are automatically available as part of the `CompositeService` that reuses them.

**Figure 12-7 How Nested Application Modules Appear in the Data Controls Panel**

One possibly confusing point is that even though you have reused nested instances of `StoreServiceAMDataControl` and `ProductService` inside of `CompositeService`, the `StoreServiceAMDataControl` and `ProductService` application modules also appear themselves as top-level data control nodes in the panel tree. JDeveloper assumes that you might want to sometimes use `StoreServiceAMDataControl` or `ProductService` on their own as separate data controls from `CompositeService`, so it displays all three of them. You need to be careful to perform your drag-and-drop data binding from the correct data control. If you want your page to use a view object instance from the nested `StoreServiceAMDataControl` instance's data model that is an aggregated part of the `CompositeService` data control, then ensure that you select the data collection that appears as part of the `CompositeService` data control node in the panel.

It is important to do the drag-and-drop operation that corresponds to your intended usage. When you drop a data collection from the *top-level* `StoreServiceAMDataControl` data control node in the panel, at runtime your page will use an instance of the `StoreServiceAMDataControl` application module

acquired from a pool of `StoreServiceAMDataControl` components. When you drop a data collection from the *nested* instance of `StoreServiceAMDataControl` that is part of `CompositeService`, at runtime your page will use an instance of the `CompositeService` application module acquired from a pool of `CompositeService` components. Since different types of application module data controls will have distinct transactions and database connections, inadvertently mixing and matching data collections from both a nested application module and a top-level data control will lead to unexpected runtime behavior.

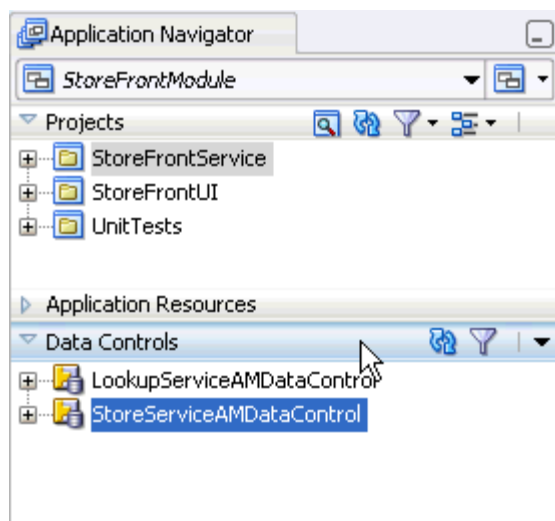

## 12.2.2 How to Open the Data Controls Panel

The Data Controls panel is a panel within the Application Navigator, located at the top left of JDeveloper. To view its contents, click the panel header to expand the panel. If you do not see the panel header, then the Application Navigator may not be displaying.

**To open the Application Navigator and Data Controls panel:**

1. From the main menu, choose **View > Application Navigator**.
2. To open the Data Controls accordion panel, click the expand icon in the Data Controls header, as shown in [Figure 12-8](#).

**Figure 12-8** Data Controls Panel in the Application Navigator

## 12.2.3 How to Refresh the Data Controls Panel

Any time changes are made to the application module or underlying services, you need to manually refresh the data control in order to view the changes. To refresh the application module data control, click the **Refresh** icon in the header of the Data Controls panel, as shown in [Figure 12-9](#).

**Figure 12–9 Refresh Icon on Data Controls Panel**

When you click **Refresh**, the Data Controls panel looks for all available data controls, and therefore will now reflect any structural changes made to the data control.

### 12.2.4 Packaging a Data Control for Use in Another Project

You can package up data controls so that they can be used in another project. For example, one development group might be tasked with creating the services and data controls, while another development group might be tasked with creating the UI. The first group would create the services and data controls, and then package them up as an Oracle ADF Library and send it to the second group. The second group can then add the data controls to their project using the Resource Palette. For more information, see [Chapter 33, "Reusing Application Components."](#)

## 12.3 Using the Data Controls Panel

You can design a databound user interface by dragging an item from the Data Controls panel and dropping it on a page as a specific UI component. When you use data controls to create a UI component, JDeveloper automatically creates the various code and objects needed to bind the component to the data control you selected.

In the Data Controls panel, each data control object is represented by a specific icon. [Table 12–1](#) describes what each icon represents, where it appears in the Data Controls panel hierarchy, and what components it can be used to create.

**Table 12–1 Data Controls Panel Icons and Object Hierarchy**

Icon	Name	Description	Used to Create...
	Data Control	<p>Represents a data control. You cannot use the data control itself to create UI components, but you can use any of the child objects listed under it. Depending on how your business services were defined, there may be more than one data control.</p> <p>Usually, there is one data control for each application module. However, you may have additional data controls that were created for other types of business services (for example, for web services). For information about creating data controls for web services, see <a href="#">Chapter 13, "Integrating Web Services Into a Fusion Web Application."</a></p>	Serves as a container for the other object and is not used to create anything.
	Collection	<p>Represents a named data collection. A <i>data collection</i> represents a set of data objects (also known as a <i>row set</i>) in the data model. Each object in a data collection represents a specific structured data item (also known as a <i>row</i>) in the data model. Throughout this guide, <i>data collection</i> and <i>collection</i> are used interchangeably.</p> <p>For application modules, the data collection is the default row set contained in a view object instance. The name of the collection matches the view object instance name.</p> <p>A view link creates a master-detail relationship between two view objects. If you explicitly add an instance of a detail view object (resulting from a view link) to the application module data model, the collection contained in that detail view object appears as a child of the collection contained in the master view object. For information about adding detail view objects to the data model, see <a href="#">Section 5.6.4, "How to Enable Active Master-Detail Coordination in the Data Model."</a></p> <p>The children under a collection may be attributes of the collection, other collections that are related by a view link, custom methods that return a value from the collection, or built-in operations that can be performed on the collection.</p> <p>If you've configured JDeveloper to display viewlink accessor returns, then those are displayed as well.</p>	<p>Forms, tables, graphs, trees, range navigation components, and master-detail components.</p> <p>For more information about using collections on a data control to create forms, see <a href="#">Chapter 22, "Creating a Basic Databound Page."</a></p> <p>For more information about using collections to create tables, see <a href="#">Chapter 23, "Creating ADF Databound Tables."</a></p> <p>For more information about using master-detail relationships to create UI components, see <a href="#">Chapter 24, "Displaying Master-Detail Data."</a></p> <p>For information about creating graphs, charts, and other visualization UI components, see <a href="#">Chapter 26, "Creating Databound ADF Data Visualization Components."</a></p>
	Attribute	<p>Represents a discrete data element in an object (for example, an attribute in a row). Attributes appear as children under the collections or method returns to which they belong.</p> <p>Only the attributes that were included in the view object are shown under a collection. If a view object joins one or more entity objects, that view object's collection will contain selected attributes from all of the underlying entity objects.</p>	<p>Label, text field, date, list of values, and selection list components.</p> <p>For information about using attributes to create fields on a page, see <a href="#">Section 22.2, "Using Attributes to Create Text Fields."</a></p> <p>For information about creating lists, see <a href="#">Chapter 25, "Creating Databound Selection Lists and Shuttles."</a></p>

**Table 12–1 (Cont.) Data Controls Panel Icons and Object Hierarchy**

Icon	Name	Description	Used to Create...
	Structured Attribute	Represents a returned object that is neither a Java primitive type (represented as an attribute) nor a collection of any type. An example of a structured attribute would be a domain, which is a developer-created data type used to simplify application maintenance.  For more information about domains, see <a href="#">Section 38.1, "Creating Custom, Validated Data Types Using Domains."</a>	Label, text field, date, list of values, and selection list components.
	Method	Represents an operation in the data control or one of its exposed structures that may accept parameters, perform some business logic and optionally return single value, a structure, or a collection.  In application module data controls, custom methods are defined in the application module itself and usually return either nothing or a single scalar value. For more information about creating custom methods, see <a href="#">Chapter 9, "Implementing Business Services with Application Modules."</a>	Command components  For methods that accept parameters: command components and parameterized forms.  For more information about using methods that accept parameters, see <a href="#">Section 28.2.2.2, "Using Parameters in a Method."</a>
	Method Return	Represents an object that is returned by a custom method. The returned object can be a single value or a collection.  If a custom method defined in the application module returns anything at all, it is usually a single scalar value. Application module methods do not need to return a set of data to the view layer, because displaying the latest changes to the data is handled by the view objects in the data model (for more information, see <a href="#">Section 3.4, "Overview of the UI-Aware Data Model"</a> ). However, custom methods in non-application module data controls (for example, a data control for a CSV file) can return collections to the view layer.  A method return appears as a child under the method that returns it. The objects that appear as children under a method return can be attributes of the collection, other methods that perform actions related to the parent collection, or operations that can be performed on the parent collection.	The same components as for collections and attributes.  For named criteria: query or quick query forms. For more information, see <a href="#">Chapter 27, "Creating ADF Databound Search Forms."</a>  When a single-value method return is dropped, the method is not invoked automatically by the framework. You need either to create an invoke action as an executable, or to drop the corresponding method as a button to invoke the method. For more information about executables, see <a href="#">Section 12.6.2.2, "Executable Binding Objects."</a>
	Operation	Represents a built-in data control operation that performs actions on the parent object. Data control operations are located in an Operations node under collections or method returns, and also under the root data control node. The operations that are children of a particular collection or method return operate on those objects only, while operations under the data control node operate on all the objects in the data control.  If an operation requires one or more parameters, they are listed in a Parameters node under the operation.	UI command components, such as buttons, links, and menus.  For more information, see <a href="#">Section 22.4, "Incorporating Range Navigation into Forms,"</a> and <a href="#">Section 22.5, "Creating a Form to Edit an Existing Record."</a>
	Parameter	Represents a parameter value that is declared by the method or operation under which it appears. Parameters appear in the Parameters node under a method or operation.	Label, text, and selection list components.

## 12.3.1 How to Use the Data Controls Panel

JDeveloper provides you with a predefined set of UI components from which to choose for each data control item you can drop.

### To use the Data Controls panel to create UI components:

1. Select an item in the Data Controls panel and drag it onto the visual editor for your page. For a definition of each item in the panel, see [Table 12-1](#).

**Tip:** If you need to drop an operation or method onto a method activity in a task flow, you can simply drag and drop it onto the activity in the diagram.

**Tip:** You can use the Filter icon in the Data Controls Panel header to search for a specific item, as shown in [Figure 12-10](#).

**Figure 12-10** Filtering the Data Controls Panel

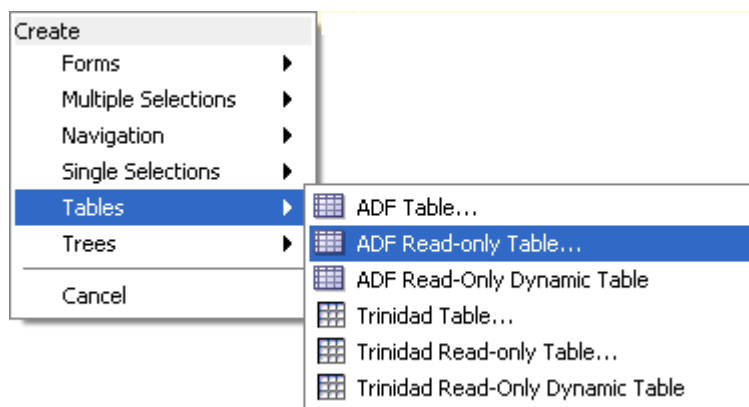

2. From the ensuing context menu, select a UI component.

When you drag an item from the Data Controls panel and drop it on a page, JDeveloper displays a context menu of all the default UI components available for the item you dropped. The components displayed are based on the libraries in your project.

[Figure 12-11](#) shows the context menu displayed when a data collection from the Data Controls panel is dropped on a page.

**Figure 12-11** Data Controls Panel Context Menu

Depending on the component you select from the context menu, JDeveloper may display a dialog that enables you to define how you want the component to look.

For example, if you select **ADF Read-only Table** from the context menu, the Edit Table Columns dialog launches. This dialog enables you to define which attributes you want to display in the table columns, what the column labels are, what types of text fields you want use for each column, and what functionality you want to include, such as row selection or column sorting. For more information about creating tables, see [Chapter 23, "Creating ADF Databound Tables."](#)

The UI components selected by default are determined first by any UI control hints set on the corresponding business object. If no control hints have been set, then JDeveloper uses input components for standard forms and tables, and output components for read-only forms and tables. Components for lists are determined based on the type of list you chose when dropping the data control object.

Once you select a component, JDeveloper inserts the UI component on the page in the visual editor. For example, if you drag a collection from the Data Controls panel and choose **ADF Read-only Table** from the context menu, a read-only table appears in the visual editor, as shown in [Figure 12–12](#).

**Figure 12–12 Databound UI Component: ADF Read-Only Table**

Product Id	Supplier Id	Category Id	Name
#{...ProductId}	#{...SupplierId}	#{...CategoryId}	#{...ProductName}
#{...ProductId}	#{...SupplierId}	#{...CategoryId}	#{...ProductName}
#{...ProductId}	#{...SupplierId}	#{...CategoryId}	#{...ProductName}

By default, the UI components created when you use the Data Controls panel use ADF Faces components, are bound to attributes in the ADF data control, and may have one or more built-in features, including:

- Databound labels
- Tooltips
- Formatting
- Basic navigation buttons
- Validation, if validation rules are attached to a particular attribute. For more information, see [Chapter 7, "Defining Validation and Business Rules Declaratively."](#)

The default components are fully functional without any further modifications. However, you can modify them to suit your particular needs. Each component and its various features are discussed further in [Section IV, "Creating a Databound Web User Interface."](#)

**Tip:** If you want to change the type of ADF databound component used on a page, the easiest method is to delete the component and drag and drop a new one from the Data Controls panel. When you delete a databound component from a page, if the related binding objects in the page definition file are not referenced by any other component, JDeveloper automatically deletes those binding objects for you.

## 12.3.2 What Happens When You Use the Data Controls Panel

When an Oracle ADF web application is built using the JSF framework, it requires a few additional application object definitions to render and process a page containing

ADF databound UI components. If you do not use the Data Controls panel, you will have to manually configure these various files yourself. However, when you use the Data Controls panel, JDeveloper does all of the following required steps:

- Creates a `DataBindings.cpx` file in the default package for the project (if one does not already exist), and adds an entry for the page.

`DataBindings.cpx` files define the *binding context* for the application. The binding context is a container object that holds a list of available data controls and data binding objects. For more information, see [Section 12.3.3, "What Happens at Runtime: How the Binding Context Works."](#) Each `DataBindings.cpx` file maps individual pages to the binding definitions in the page definition file and registers the data controls used by those pages. For more information, see [Section 12.4, "Working with the DataBindings.cpx File."](#)
- Creates the `adfm.xml` file in the META-INF directory. This file creates a registry for the `DataBindings.cpx` file, which allows the application to locate it at runtime so that the binding context can be created.
- Registers the ADF binding filter in the `web.xml` file.

The ADF binding filter preprocesses any HTTP requests that may require access to the binding context. For more information about the binding filter configuration, see [Section 12.5, "Configuring the ADF Binding Filter."](#)
- Creates the `orion-application.xml` file and adds a reference to the Oracle ADF shared libraries needed by the application
- Adds the following libraries to the view project:
  - ADF Faces Databinding Runtime
  - Oracle XML Parser v2
  - JDeveloper Runtime
  - SQLJ Runtime
  - ADF Model Runtime
  - BC4J Runtime
  - Oracle JDBC
  - Connection Manager
  - BC4J Oracle Domains
- Adds a page definition file (if one does not already exist for the page) to the page definition subpackage, the name of which is defined in the ADF Model settings of the project properties. The default subpackage is `view.pageDefs` in the `adfmsrc` directory.

The page definition file (`pageNamePageDef.xml`) defines the ADF binding container for each page in an application's view layer. The binding container provides runtime access to all the ADF binding objects for a page. In later chapters, you will see how the page definition files are used to define and edit the binding object definitions for specific UI components. For more information about the page definition file, see [Section 12.6, "Working with Page Definition Files."](#)
- Configures the page definition file, which includes adding definitions of the binding objects referenced by the page.
- Adds ADF Faces components to the JSF page.

These prebuilt components include ADF data binding expression language (EL) expressions that reference the binding objects in the page definition file. For more information, see [Section 12.7, "Creating ADF Data Binding EL Expressions."](#)

- Adds all the libraries, files, and configuration elements required by ADF Faces components. For more information, see the "ADF Faces Configuration" appendix in the *Oracle Fusion Middleware Web User Interface Developer's Guide for Oracle Application Development Framework*.

### 12.3.3 What Happens at Runtime: How the Binding Context Works

When a page contains ADF bindings, at runtime the interaction with the business services initiated from the client or controller is managed by the application through a single object known as the *binding context*. The binding context is a runtime map (named *data* and accessible through the EL expression `# {data}`) of all data controls and page definitions within the application.

The ADF lifecycle creates the Oracle ADF binding context from the application module, `DataBindings.cpx`, and page definition files, as shown in [Figure 12-13](#). The union of all the `DataControls.dcx` files and any application modules in the workspace define the available data controls at design time, but the `DataBindings.cpx` files define what data controls are available to the application at runtime. A `DataBindings.cpx` file lists all the data controls that are being used by pages in the application and maps the binding containers, which contain the binding objects defined in the page definition files, to web page URLs. The page definition files define the binding objects used by the application pages. There is one page definition file for each page.

The binding context does not contain real live instances of these objects. Instead, the map contains references that become data control or binding container objects on demand. When the object (such as a page definition) is released from the application, for example when a task flow ends or when the binding container or data control is released at the end of the request, data controls and binding containers turn back into reference objects. For information about the ADF lifecycle, see [Chapter 21, "Understanding the Fusion Page Lifecycle."](#)

**Figure 12–13 ADF File Binding Runtime Usage**

## 12.4 Working with the DataBindings.cpx File

The `DataBindings.cpx` files define the binding context for the entire application and provide the metadata from which the Oracle ADF binding objects are created at runtime. An application may have more than one `DataBindings.cpx` file if a component, for example a region, was created outside of the project and then imported. These files map individual pages to page definition files and declare which data controls are being used by the application. At runtime, only the data controls listed in the `DataBindings.cpx` files are available to the current application.

### 12.4.1 How JDeveloper Creates a DataBindings.cpx File

The first time you use the Data Controls panel to add a component to a page or an operation to an activity, JDeveloper automatically creates a `DataBindings.cpx` file in the default package of the view project. It resides in the `adfmsrc` directory for the project. Once the `DataBindings.cpx` file is created, JDeveloper adds an entry for the first page or task flow activity. Each subsequent time you use the Data Controls panel, JDeveloper adds an entry to the `DataBindings.cpx` for that page or activity, if one does not already exist.

**Tip:** JDeveloper supports refactoring. That is, you can safely rename or move many of the objects referenced in the `DataBindings.cpx` file, and the references will be updated. For more information, see [Chapter 32, "Refactoring a Fusion Web Application."](#)

### 12.4.2 What Happens When JDeveloper Creates a DataBindings.cpx File

Once JDeveloper creates a `DataBindings.cpx` file, you can open it in the overview editor. [Figure 12–14](#) shows the `DataBindings.cpx` file from the StoreFront module application, as viewed in the overview editor (note that it's been truncated).

**Figure 12–14** DataBindings.cpx File in the Overview Editor**Data Binding Registry**

This file defines the Oracle ADF binding context for your application. JDeveloper creates this file the first time you data bind a UI component.

</dataControlUsages>
</Application>

```

The **Page Mappings** section of the editor maps each JSF page or task flow activity to its corresponding page definition file using an ID. The **Page Definition Usages** section maps the page definition ID to the absolute path for page definition file in the application. The **Data Control Usages** section identifies the data controls being used by the binding objects defined in the page definition files. These mappings allow the binding container to be initialized when the page is invoked.

You can use the overview editor to change the ID name for page definition files or data controls by double-clicking the current ID name and editing inline. Doing so will update all references in the application. Note, however, that JDeveloper updates only the ID name, it does not update the file name. Be sure that you do not change a data control name to a reserved word. For more information, see [Section 9.2.5, "How to Edit an Existing Application Module."](#)

You can also click an element in the Structure window and then use the Property Inspector to change property values. For more information about the elements and attributes in the `DataBindings.cpx` file, see [Section A.7, "DataBindings.cpx."](#)

## 12.5 Configuring the ADF Binding Filter

The ADF binding filter is a servlet filter that is an instance of the `oracle.adf.model.servlet.ADFBindingFilter` class. ADF web applications use the ADF binding filter to preprocess any HTTP requests that may require access to the binding context. To do this, the ADF binding filter must be aware of all `DataBindings.cpx` files that exist for an application.

## 12.5.1 How JDeveloper Configures the ADF Binding Filter

The first time you add a databound component to a page using the Data Controls panel, JDeveloper automatically configures the filter for you in the application's `web.xml` file.

## 12.5.2 What Happens When JDeveloper Configures an ADF Binding Filter

To configure the binding filter, JDeveloper adds the following elements to the `web.xml` file:

- An ADF binding filter class: Specifies the name of the binding filter object, which implements the `javax.servlet.Filter` interface.

The ADF binding filter is defined in the `web.xml` file, as shown in [Example 12-2](#). The `filter-name` element must contain the value `adfBindings`, and the `filter-class` element must contain the fully qualified name of the binding filter class, which is `oracle.adf.model.servlet.ADFBindingFilter`.

### Example 12-2 Binding Filter Class Defined in the `web.xml` File

```
<filter>
  <filter-name>adfBindings</filter-name>
  <filter-class>oracle.adf.model.servlet.ADFBindingFilter</filter-class>
</filter>
```

- Filter mappings: Link filters to static resources or servlets in the web application.

At runtime, when a mapped resource is requested, a filter is invoked. Filter mappings are defined in the `web.xml` file, as shown in [Example 12-3](#). The `filter-name` element must contain the value `adfBindings`.

### Example 12-3 Filter Mapping Defined in the `web.xml` File

```
<filter-mapping>
  <filter-name>adfBindings</filter-name>
  <servlet-name>Faces Servlet</servlet-name>
  <dispatcher>FORWARD</dispatcher>
  <dispatcher>REQUEST</dispatcher>
</filter-mapping>
```

**Tip:** If you have multiple filters defined in the `web.xml` file, be sure to list them in the order in which you want them to run. At runtime, the filters are executed in the sequence in which they appear in the `web.xml` file. The `adfBindings` filter should appear before any filters that depend on the ADF context to be initialized.

## 12.5.3 What Happens at Runtime: How the ADF Binding Filter Works

At runtime, the ADF binding filter performs the following functions:

- Overrides the character encoding when the filter is initialized with the name specified as a filter parameter in the `web.xml` file. The parameter name of the filter `init-param` element is `encoding`.
- Instantiates the `ADFContext` object, which is the execution context for a Fusion web application and contains context information about ADF, including the security context and the environment class that contains the request and response object.

- Initializes the binding context for a user's HTTP session. To do this, it first loads the bindings as defined in the `DataBindings.cpx` file in the current project's `adfmsrc` directory. If the application contains `DataBindings.cpx` files that were imported from another project, those files are present in the application's class path. The filter additively loads any auxiliary `.cpx` files found in the class path of the application.
- Serializes incoming HTTP requests from the same browser (for example, from frame sets) to prevent multithreading problems.
- Notifies data control instances that they are about to receive a request, allowing them to do any necessary per-request setup.
- Notifies data control instances after the response has been sent to the client, allowing them to do any necessary per-request cleanup.

## 12.6 Working with Page Definition Files

Page definition files define the binding objects that populate the data in UI components at runtime. For every page that has ADF bindings, there must be a corresponding page definition file that defines the binding objects used by that page. Page definition files provide design time access to all the ADF bindings. At runtime, the binding objects defined by a page definition file are instantiated in a binding container, which is the runtime instance of the page definition file.

---

---

**Note:** When multiple windows are open to the same page, the ADF Controller assigns each window its own `DataControlFrame`. This ensures that each window has its own binding container.

---

---

### 12.6.1 How JDeveloper Creates a Page Definition File

The first time you use the Data Controls panel, JDeveloper automatically creates a page definition file for that page and adds definitions for each binding object referenced by the component. For each subsequent databound component you add to the page, JDeveloper automatically adds the necessary binding object definitions to the page definition file.

By default, the page definition files are located in the `view.PageDefs` package in the Application Sources directory of the view project. If the corresponding JSF page is saved to a directory other than the default (`public_html`), or to a subdirectory of the default, then the page definition will also be saved to a package of the same name. For example, if you save your JSF file to the `public_html/myDirectory` directory, the page definition will be saved to the `myDirectory` package. You can change the location of the page definition files using the ADF Model Settings page of the Project Properties dialog.

JDeveloper names the page definition files using the following convention:

`pageNamePageDef.xml`

where `pageName` is the name of the JSF page. For example, if the JSF page is named `home.jsp`, the default page definition file name is `homePageDef.xml`. If you organize your pages into subdirectories, JDeveloper prefixes the directory name to the page definition file name using the following convention:

`directoryName_pageNamePageDef.xml`

For example, in the StoreFront module, the name of the page definition file for the `updateUserInfo` page, which is in the `account` subdirectory of the Web Content node is `account_updateUserInfoPageDef.xml`.

**Tip:** Page definitions for task flows follow the same naming convention.

To open a page definition file, you can right-click directly on the page or activity in the visual editor, and choose **Go to Page Definition**, or for a JSF page, you can click the **Bindings** tab of the editor and click the Page Definition File link.

**Tip:** While JDeveloper automatically creates a page definition for a JSF page when you create components using the Data Controls panel, or for a task flow when you drop an item onto an activity, it does not delete the page definition when you delete the associated JSF page or task flow activity (this is to allow bindings to remain when they are needed without a JSF page, for example when using desktop integration). If you no longer want the page definition, you need to delete the page definition and all references to it manually. Note however, that as long as a corresponding page or activity is never called, the page definition will never be used to create a binding context. It is therefore not imperative to remove any unused page definition files from your application.

## 12.6.2 What Happens When JDeveloper Creates a Page Definition File

When JDeveloper creates a page definition file, it is displayed in the overview editor. [Figure 12–15](#) shows the page definition file in the overview editor that was created for the `myOrders.jspx` page in the StoreFront module application.

**Figure 12–15** Page Definition File in the Overview Editor

The overview editor contains the following tabs, which allow you to view and configure bindings, contextual events, and parameters for a page:

- Bindings and Executables:** The Bindings and Executables tab of the page definition overview editor shows three different types of objects: bindings, executables, and the associated data controls (note that the data controls do not display unless you select a binding or executable). For example, in [Figure 12–15](#), you can see that the binding for the `OrderDate1` attribute uses the `MyOrdersIterator` iterator to get its value. The iterator accesses the `MyOrders` collection on the `StoreServiceAMDataControl` data control. For more information, see [Section 12.6.2.2, "Executable Binding Objects."](#)

By default, the model binding objects are named after the data control object that was used to create them. If a data control object is used more than once on a page, JDeveloper adds a number to the default binding object names to keep them unique. In [Section 12.7, "Creating ADF Data Binding EL Expressions,"](#) you will see how the ADF data binding EL expressions reference the binding object names.

[Table 12–2](#) shows the icons for each of the binding objects, as displayed in the overview editor (note that while parameter objects are shown in the **Parameter** section of the editor, they are also considered binding objects).

**Table 12–2 Binding Object Icons**

Binding Object Type	Icon	Description
Parameter		Represents a parameter binding object.
Bindings		Represents an attribute value binding object.
		Represents a list value binding object.
		Represents a tree value binding object.
		Represents a method action binding object.
Bindings/ Executables		Represents an action binding object. Also represents an invoke action executable binding object and an event.
Executables		Represents an iterator binding object.
		Represents a task flow executable binding object.

- **Contextual Events:** You can create contextual events that artifacts in an application can subscribe to. For example, in the StoreFront module, contextual events are used in the customer registration page to display the appropriate informational topic. The `register.jspx` page contains two regions. One region contains the customer registration task flow, and the other contains the informational topic task flow. A contextual event is passed from the customer registration region to the informational topic region so that the informational topic task flow can display the correct information topic. At design time, the event name, producer region, consumer region, consumer handler, and other information is stored in the event map section of the page definition file. For more information about contextual events, see [Section 28.7, "Creating Contextual Events."](#)
- **Parameters:** Parameter binding objects declare the parameters that the page evaluates at the beginning of a request. (For more information about the ADF lifecycle, see [Chapter 21, "Understanding the Fusion Page Lifecycle."](#)) You can define the value of a parameter in the page definition file using static values, or EL expressions that assign a static value.

[Example 12–4](#) shows how parameter binding objects can be defined in a page definition file.

**Example 12–4 parameters Element of a Page Definition File**

```
<parameters>
  <parameter id="filedBy"
    value="{bindings.userId}"/>
  <parameter id="status"
    value="{param.status != null ? param.status : 'Open'}/>
</parameters>
```

The value of the `filedBy` parameter is defined by a binding on the `userId` data attribute, which would be an attribute binding defined later in the `bindings` element. The value of the `status` parameter is defined by an EL expression, which assigns a static value.

**Tip:** By default, JDeveloper uses the dollar sign (`$`), which is a JSP EL syntax standard, as the prefix for EL expressions that appear in the page definition file. However, you can use the hash sign (`#`) prefix, which is a JSF EL syntax standard, as well.

For more information about passing parameters to methods, see [Section 28.3, "Setting Parameter Values Using a Command Component."](#)

When you click an item in the overview editor (or the associated node in the Structure window), you can use the Property Inspector to view and edit the attribute values for the item, or you can edit the XML source directly by clicking the **Source** tab. [Example 12–5](#) shows abbreviated XML code for the page definition file shown in [Figure 12–15](#).

**Example 12–5 Page Definition File**

```
<pageDefinition xmlns="http://xmlns.oracle.com/adfm/uimodel"
  version="11.1.1.44.61" id="myOrdersPageDef"
  Package="oracle.fodemo.storefront.pageDefs"
  EnableTokenValidation="false">
  <parameters/>
  <executables>
    <page path="oracle.fodemo.storefront.pageDefs.
      templates_StoreFrontTemplatePageDef"
      id="pageTemplateBinding"/>
    <iterator Binds="MyOrderItems" RangeSize="25"
      DataControl="StoreServiceAMDataControl"
      id="MyOrderItemsIterator"/>
    <iterator Binds="MyOrders" RangeSize="-1"
      DataControl="StoreServiceAMDataControl" id="MyOrdersIterator"/>
    .
    .
    .
  </executables>
  <bindings>
    <action id="Commit" InstanceName="StoreServiceAMDataControl"
      DataControl="StoreServiceAMDataControl" RequiresUpdateModel="true"
      Action="commitTransaction"/>
    <action id="Rollback" InstanceName="StoreServiceAMDataControl"
      DataControl="StoreServiceAMDataControl" RequiresUpdateModel="false"
      Action="rollbackTransaction"/>
    <methodAction id="executeMyOrdersForCustomerVO" RequiresUpdateModel="true"
      Action="invokeMethod"
      MethodName="executeMyOrdersForCustomerVO"
      IsViewObjectMethod="false"
      DataControl="StoreServiceAMDataControl"
```

```

        InstanceName="StoreServiceAMDataControl.dataProvider"/>
<tree IterBinding="MyOrdersIterator" id="MyOrders">
  <nodeDefinition DefName="oracle.fodemo.storefront.store.queries.OrdersVO">
    <AttrNames>
      <Item Value="OrderId"/>
      <Item Value="OrderDate"/>
      <Item Value="OrderShippedDate"/>
      <Item Value="OrderStatusCode"/>
      <Item Value="OrderTotal"/>
      <Item Value="CustomerId"/>
      <Item Value="ShipToName"/>
      <Item Value="ShipToAddressId"/>
      <Item Value="ShipToPhoneNumber"/>
      <Item Value="ShippingOptionId"/>
      <Item Value="PaymentOptionId"/>
      <Item Value="CalculatedOrderTotal"/>
      <Item Value="TotalShippingCost"/>
      <Item Value="DiscountAmount"/>
      <Item Value="InvoiceTotal"/>
      <Item Value="LastUpdateDate"/>
      <Item Value="TypedCouponCode"/>
    </AttrNames>
  </nodeDefinition>
</tree>
<attributeValues IterBinding="MyOrdersIterator" id="OrderDate1">
  <AttrNames>
    <Item Value="OrderDate"/>
  </AttrNames>
</attributeValues>
<attributeValues IterBinding="MyOrdersIterator" id="OrderId1">
  <AttrNames>
    <Item Value="OrderId"/>
  </AttrNames>
</attributeValues>
.
.
.
</bindings>
</pageDefinition>

```

In later chapters, you will see how the page definition file is used to define and edit the bindings for specific UI components. For a description of all the possible elements and attributes in the page definition file, see [Section A.8, "pageNamePageDef.xml."](#)

### 12.6.2.1 Bindings Binding Objects

There are three types of Bindings binding objects used to bind UI components to objects on the data control:

- Value: Displays data in UI components by referencing an iterator binding. Each discrete UI component on a page that will display data from the data control is bound to a value binding object. Value binding objects include:
  - Attribute Values: Binds text fields to a specific attribute in an object (also referred to as an *attribute binding* object.)
  - List: Binds the list items to all values of an attribute in a data collection.
  - Tree: Binds an entire table to a data collection and can also bind the root node of a tree to a data collection.

- Button (boolean): Binds a checkbox to a boolean value for an attribute.
- Graph: Binds a graph directly to the source data.
- Method Action: Binds command components, such as buttons or links, to custom methods on the data control. A method action binding object encapsulates the details about how to invoke a method and what parameters (if any) the method is expecting.
- Action: Binds command components, such as buttons or links, to built-in data control operations (such as, Commit or Rollback) or to built-in collection-level operations (such as, Create, Delete, Next, or Previous).

Collectively, the binding objects are referred to as *control* binding objects, because they work with the UI controls on a page.

[Example 12–6](#) shows a sample bindings element, which defines one action binding called `Commit`, one attribute binding for a text field called `PaymentOptionId1`, and one list binding called `PaymentTypeCode`.

#### **Example 12–6 bindings Element of a Page Definition File**

```
<bindings>
  <action id="Commit" InstanceName="StoreServiceAMDataControl"
    DataControl="StoreServiceAMDataControl" RequiresUpdateModel="true"
    Action="commitTransaction" />
  <attributeValues IterBinding="PaymentOptionsForUserIterator"
    id="PaymentOptionId1">
    <AttrNames>
      <Item Value="PaymentOptionId" />
    </AttrNames>
  </attributeValues>
  <list IterBinding="PaymentOptionsForUserIterator" id="PaymentTypeCode"
    Uses="LOV_PaymentTypeCode" StaticList="false">
    <AttrNames>
      <Item Value="PaymentTypeCode" />
    </AttrNames>
  </list>
</bindings>
```

The binding object defined in the action element encapsulates the information needed to invoke the built-in `commit` operation on the `StoreServiceAMDataControl` data control. The value of `true` in the `RequiresUpdateModel` attribute specifies that the model layer needs to be updated before the operation is executed.

If this operation also raised a contextual event, an event definition would appear well. If the page contained bindings that consumed an event, the event mapping would also appear. For more information, see [Section 28.7, "Creating Contextual Events."](#)

The `attributeValues` element defines the value bindings for the text fields on the page. In the example, the `PaymentOptionId1` attribute binding will display the value of the `PaymentOptionId`, which is defined in the `AttrNames` element. The `IterBinding` attribute references the iterator binding that manages the data to be displayed in the text field (for more information, see [Section 12.6.2.2, "Executable Binding Objects"](#)).

The `PaymentTypeCode` element defines the list binding used to display the list of payment type codes by accessing the LOV created on the `PaymentOptions` view object. For more information about creating lists using LOVs on view objects, see [Chapter 25, "Creating Databound Selection Lists and Shuttles."](#)

### 12.6.2.2 Executable Binding Objects

There are seven types of executable binding objects:

- **Iterator:** Binds to an iterator that iterates over view object collections. There is one iterator binding for each collection used on the page. All of the value bindings on the page must refer to an iterator binding in order for the component values to be populated with data at runtime.

When you drop a collection or an attribute of a collection on the page, an iterator binding is automatically added as an executable. Iterator binding objects bind to an underlying ADF `RowSetIterator` object, which manages the current object and current range information. The iterator binding exposes the current object and range state to the other binding objects used by the page. The iterator *range* represents the current set of objects to be displayed on the page. The maximum number of objects in the current range is defined in the `rangeSize` attribute of the iterator. For example, if a collection in the data control contains products and the iterator range size is 25, the first 25 products in the collection are displayed on the page. If the user scrolls down, the next set of 25 is displayed, and so on. If the user scrolls up, the previous set of 25 is displayed. If your view object uses range paging, then you can configure the iterator binding to return a set of ranges at one time. For more information, see [Section 39.1.5, "Efficiently Scrolling Through Large Result Sets Using Range Paging."](#)

---

---

**Note:** If you have two pages each with an iterator binding bound to the iterator on the same view object (which you will if you drop the same collection, for example, on two different pages), then you should ensure that the `rangeSize` attribute is the same for both pages' iterator bindings. If not, the page with a smaller range size may cause the iterator to reexecute, causing unexpected results on the other page.

---

---

- **Method Iterator:** Binds to an iterator that iterates over the collections returned by custom methods in the data control.

A method iterator binding is always related to a method action binding object. The method action binding encapsulates the details about how to invoke the method and what parameters (if any) the method is expecting. The method action binding is itself bound to the method iterator, which provides the data.

You will see method iterator executable binding objects only if you drop a method return collection or an attribute of a method return collection from a custom method on the data control. If you are using only application module data controls, you will see only iterator binding objects.

- **Variable Iterator:** Binds to an iterator that exposes all the variables in the binding container to the other bindings. While there is an iterator binding for each collection, there is only one variable iterator binding for all variables used on the page. (The variable iterator is like an iterator pointing to a collection that contains only one data object whose attributes are the binding container variables.)

Page variables are local to the binding container and exist only while the binding container object exists. When you use a data control method (or an operation) that requires a parameter that is to be collected from the page, JDeveloper automatically defines a variable for the parameter in the page definition file. Attribute bindings can reference the page variables.

A variable iterator can contain one of two types of variables: `variable` and `variableUsage`. A `variable` type variable is a simple value holder, while a

`variableUsage` type variable is a value holder that is related to a view object's named bind parameter. Defining a variable as a `variableUsage` type allows it to inherit the default value and UI control hints from the view object named bind variable to which it is bound.

- **Invoke Action:** Binds to a method that invokes the operations or methods defined in action or method action bindings during any phase of the page lifecycle.

**Tip:** If you know you want a method to execute before the page is rendered, you should use a method call activity in the task flow to invoke the method, rather than an invoke action in the page definition file. Using the method call activity makes invoking page logic easier, and allows you to show more information on the task flow, making the diagram more readable and useful to anyone else who might be using it. However, if you need the method to be executed in more than one phase of the page's lifecycle, or if you plan to reuse the page and page definition file and want the method to be tied to the page, or if your application does not use ADFc, then you should use an invoke action to invoke the method.

- **Page:** Binds to the template's page definition file (if a template is used). For more information about how this works with templates, see [Section 20.2, "Using Page Templates."](#)

---

**Note:** You can also use the page element to bind to another page definition file. However, at runtime, only the current incoming page's (or if the rendered page is different from the incoming, the rendered page's) binding container is automatically prepared by the framework during the current request. Therefore, to successfully access a bound value in another page from the current page, you must programmatically prepare that page's binding container in the current request (for example, using a backing bean). Otherwise, the bound values in that page may not be available or valid in the current request.

---

- **Search Region:** Binds named criteria to the iterator, so that the search can be executed.
- **Task Flow:** Instantiates the binding container for a region's task flow.

At runtime, executable bindings are refreshed based on the value of their `Refresh` attribute. Refreshing an iterator binding reconnects it with its underlying `RowSetIterator` object. Refreshing an invoke action binding invokes the action. Before refreshing any bindings, the ADF runtime evaluates any `Refresh` and `RefreshCondition` attributes specified in the executables. The `Refresh` attribute specifies the ADF lifecycle phase within which the executable should be invoked. The `RefreshCondition` attribute specifies the conditions under which the executable should be invoked. You can specify the `RefreshCondition` value using a boolean EL expression. If you leave the `RefreshCondition` attribute blank, it evaluates to `true`.

By default, the `Refresh` value is set to `deferred`. This means the binding will not be executed unless its value is accessed (for example by an EL expression on a JSF page). Once called, it will not reexecute unless any parameter values for the binding have changed, or if the binding itself has changed.

For more information about how bindings are refreshed and how to set the `Refresh` and `RefreshCondition` attributes, see [Section 21.2, "The JSF and ADF Page Lifecycles."](#)

[Example 12-7](#) shows an example of executable binding objects.

**Example 12-7 executable Binding Objects in a Page Definition File**

```
<executables>
  <page path="/oracle.fodemo.storefront.pageDefs.
                                templates_StoreFrontTemplatePageDef"
        id="pageTemplateBinding" />
  <iterator Binds="MyOrderItems" RangeSize="25"
           DataControl="StoreServiceAMDataControl"
           id="MyOrderItemsIterator" />
  <iterator Binds="MyOrders" RangeSize="-1"
           DataControl="StoreServiceAMDataControl" id="MyOrdersIterator" />
```

The iterator binding named `MyOrderItems` was created by dropping the `MyOrderItems` collection on the page as a table. The iterator binding named `MyOrders` was created by dropping the `MyOrders` collection, which has a master-detail relationship with the `MyOrderItems` collection. For more information, see [Chapter 24, "Displaying Master-Detail Data."](#)

The `Binds` attribute of the `iterator` element defines the collection the iterator will iterate over. The `RangeSize` attribute defines the number of objects the iterator is to display on the page at one time. A `RangeSize` value of `-1` causes the iterator to display *all* the objects from the collection.

**Tip:** Normally, an iterator binding's default range size is 25. However, when an iterator binding is created from the Edit List Binding dialog, the range size defaults to `-1` so that all choices display in the list, not just the first 25.

**Performance Tip:** When you want to reduce the number of roundtrips the iterator requires to fetch the data objects from the view object in the ADF Business Components layer, you can set the `rangeSize` attribute to `-1`, and the objects will be fetched in a single round trip to the server, rather than in multiple trips as the user navigates through the objects.

## 12.7 Creating ADF Data Binding EL Expressions

To display data from the data model, web page UI components are bound to binding objects using JSF Expression Language (EL) expressions. These EL expressions reference a specific binding object in a binding container. At runtime, the JSF runtime evaluates an EL expression and pulls the value from the binding object to populate the component with data when the page is displayed. If the user updates data in the UI component, the JSF runtime pushes the value back into the corresponding binding object based on the same EL expression.

**Tip:** There may be cases when you need to use EL expressions within managed beans. For information on working with EL expressions within managed beans, see the "Creating EL Expressions" section in the *Oracle Fusion Middleware Web User Interface Developer's Guide for Oracle Application Development Framework*.

## 12.7.1 How to Create an ADF Data Binding EL Expression

When you use the Data Controls panel to create a component, the ADF data binding expressions are created for you. The expressions are added to every component attribute that will either display data from or reference properties of a binding object. Each prebuilt expression references the appropriate binding objects defined in the page definition file. You can edit these binding expressions or create your own, as long as you adhere to the basic ADF binding expression syntax. ADF data binding expressions can be added to any component attribute that you want to populate with data from a binding object.

In JSF pages, a typical ADF data binding EL expression uses the following syntax to reference any of the different types of binding objects in the binding container:

```
{bindings.BindingObject.propertyName}
```

where:

- `bindings` is a variable that identifies that the binding object being referenced by the expression is located in the binding container of the current page. All ADF data binding EL expressions must start with the `bindings` variable.
- `BindingObject` is the ID, or for attributes the name, of the binding object as it is defined in the page definition file. The binding `objectID` or name is unique to that page definition file. An EL expression can reference any binding object in the page definition file, including parameters, executables, or value bindings.
- `propertyName` is a variable that determines the default display characteristics of each databound UI component and sets properties for the binding object at runtime. There are different binding properties for each type of binding object. For more information about binding properties, see [Section 12.7.2, "What You May Need to Know About ADF Binding Properties."](#)

For example, in the following expression that might appear on a JSF page:

```
{bindings.ProductName.inputValue}
```

the `bindings` variable references a bound value in the current page's binding container. The binding object being referenced is `ProductName`, which is an attribute binding object. The binding property is `inputValue`, which returns the value of the first `ProductName` attribute.

**Tip:** While the binding expressions in the page definition file can use either a dollar sign (\$) or hash sign (#) prefix, the EL expressions in JSF pages can use only the hash sign (#) prefix.

As stated previously, when you use the Data Controls panel to create UI components, these expressions are built for you. However, you can also manually create them if you need to. The JDeveloper Expression Builder is a dialog that helps you build EL expressions by providing lists of binding objects defined in the page definition files, as well as other valid objects to which a UI component may be bound. It is particularly useful when creating or editing ADF databound expressions because it provides a hierarchical list of ADF binding objects and their most commonly used properties. For information about binding properties, see [Section 12.7.2, "What You May Need to Know About ADF Binding Properties."](#)

### 12.7.1.1 Opening the Expression Builder from the Property Inspector

You can select an item in the visual editor, and then create EL expressions for specific attributes using the Property Inspector.

**To open the Expression Builder from the Property Inspector:**

1. Select a UI component in the Structure window or the visual editor.
2. In the Property Inspector, click the dropdown list next to a field, and choose **Expression Builder**.

**12.7.1.2 Using the Expression Builder**

Once the Expression Builder is open, you can use it to create EL expressions.

**To use the Expression Builder:**

1. Open the Expression Builder dialog.
2. Use the Expression Builder to edit or create ADF binding expressions using the following features:
  - Use the **Variables** tree to select items that you want to include in the binding expression. The tree contains a hierarchical representation of the binding objects. Each icon in the tree represents various types of binding objects that you can use in an expression (see [Table 12–3](#) for a description of each icon).  
To narrow down the tree, you can either use the dropdown filter or enter search criteria in the search field. Double-click an item in the tree to move it to the **Expression** box.
  - Use the operator buttons to add logical or mathematical operators to the expression.

**Tip:** You can also type the expression directly in the **Expression** box.

**Table 12–3 Icons Under the ADF Bindings Node of the Expression Builder**

Icon	Description
 bindings	Represents the <code>bindings</code> container variable, which references the binding container of the current page. Opening the <code>bindings</code> node exposes all the binding objects for the current page.
 data	Represents the <code>data</code> binding variable, which references the entire binding context (created from all the <code>.cpx</code> files in the application). Opening the <code>data</code> node exposes all the page definition files in the application.
	Represents an action binding object. Opening a node that uses this icon exposes a list of valid action binding properties.
	Represents an iterator binding object. Opening a node that uses this icon exposes a list of valid iterator binding properties.
	Represents an attribute binding object. Opening a node that uses this icon exposes a list of valid attribute binding properties.
	Represents a list binding object. Opening a node that uses this icon exposes a list of valid list binding properties.
	Represents a table or tree binding object. Opening a node that uses this icon exposes a list of valid table and tree binding properties.
	Represents an ADF binding object property. For more information about ADF properties, see <a href="#">Section 12.7.2, "What You May Need to Know About ADF Binding Properties."</a>

**Table 12-3 (Cont.) Icons Under the ADF Bindings Node of the Expression Builder**

Icon	Description
	Represents a parameter binding object.
	Represents a JavaBean.
	Represents a method.

## 12.7.2 What You May Need to Know About ADF Binding Properties

When you create a databound component using the Expression Builder, the EL expression might reference specific ADF binding properties. At runtime, these binding properties can define such things as the default display characteristics of a databound UI component or specific parameters for iterator bindings. The ADF binding properties are defined by Oracle APIs. For a full list of the available properties for each binding type, see [Appendix B, "Oracle ADF Binding Properties."](#)

Values assigned to certain properties are defined in the page definition file. For example, iterator bindings have a property called `RangeSize`, which specifies the number of rows the iterator should display at one time. The value assigned to `RangeSize` is specified in the page definition file, as shown in [Example 12-8](#).

### Example 12-8 Iterator Binding Object with the RangeSize Property

```
<iterator Binds="ProductsByCategory1" RangeSize="25"
  DataControl="StoreFrontModuleDataControl"
  id="Products2Iterator" />
```

## 12.8 Using Simple UI First Development

While the Data Controls panel enables you to design and create bound components in a single drag-and-drop action, in some cases, it may be preferable to create the basic UI components first and add the bindings later. For example, if your page will use declarative components, you will first need to drop the declarative component, and then bind it to the correct ADF control. Declarative components are reusable, composite UI components that are made up of other ADF Faces components. Once imported into a project, declarative components can be dropped onto a page from the Component Palette, similar to standard ADF Faces components. While the entire declarative component cannot use ADF data binding, you can use ADF data binding on the individual components that make up the declarative component, once the declarative component is dropped on the page. For more information about declarative components, see the "Using Declarative Components" section of the *Oracle Fusion Middleware Web User Interface Developer's Guide for Oracle Application Development Framework*.

---

**Note:** If you know the UI components on your page will eventually use ADF data binding, but you need to develop the pages before the data controls are ready, then you should consider using placeholder data controls, rather than manually binding the components. Using placeholder data controls will provide the same declarative development experience as using developed data controls. For more information, see [Chapter 29, "Designing a Page Using Placeholder Data Controls."](#)

---

When designing web pages, keep in mind that ADF bindings can be added only to certain ADF Faces tags or their equivalent JSF HTML tags. [Table 12–4](#) lists the ADF Faces and JSF tags to which you can later add ADF bindings.

**Tip:** To enable the use of JSF Reference Implementation UI component tags with ADF bindings, you must choose the **Include JSF HTML Widgets for JSF Databinding** option in the **ADF View Settings** of the project properties. However, using ADF Faces tags, especially with ADF bindings, provides greater functionality than does using the reference implementation JSF tags.

**Table 12–4 Tags That Can Be Used for ADF Bindings**

ADF Faces Tags Used in ADF Bindings	Equivalent JSF HTML Tags
<b>Text Fields</b>	
af:inputText	h:inputText
af:outputText	h:outputText
af:outputLabel	h:outputLabel
af:inputDate	n/a
<b>Tables</b>	
af:table	h:dataTable
<b>Actions</b>	
af:commandButton	h:commandButton
af:commandLink	h:commandLink
af:commandMenuItem	n/a
af:commandToolBarButton	n/a
<b>Selection Lists</b>	
af:inputListOfValues	n/a
af:selectOneChoice	h:selectOneMenu
af:selectOneListbox	h:selectOneListbox
af:selectOneRadio	h:selectOneRadio
af:selectBooleanCheckbox	h:selectBooleanCheckbox
<b>Queries</b>	
af:query	n/a
af:quickQuery	n/a
<b>Trees</b>	
af:tree	n/a
af:treeTable	n/a

Before adding binding to the UI components, ensure that you follow these guidelines:

- When creating the JSF page using the Create JSF JSP wizard, choose the **Do not Automatically Expose UI Components in a Managed Bean** option in the **Page Implementation** section.

This option turns off JDeveloper's auto-binding feature, which automatically associates every UI component in the page to a corresponding property in the backing bean for eventual programmatic manipulation. If you intend to add ADF bindings to a page, do not use the auto-binding feature. If you use the auto-binding feature, you will have to remove the managed bean bindings later, after you have added the ADF bindings. The managed bean UI component property bindings do not affect the ADF bindings, but their presence may be confusing in the JSF code. For information about managed beans, see [Section 20.4, "Using a Managed Bean in a Fusion Web Application."](#)

- Add the ADF Faces tag libraries.

While you can add ADF bindings to JSF components, the ADF Faces components provide greater functionality, especially when combined with ADF bindings.

## 12.8.1 How to Apply ADF Model Data Binding to Existing UI Components

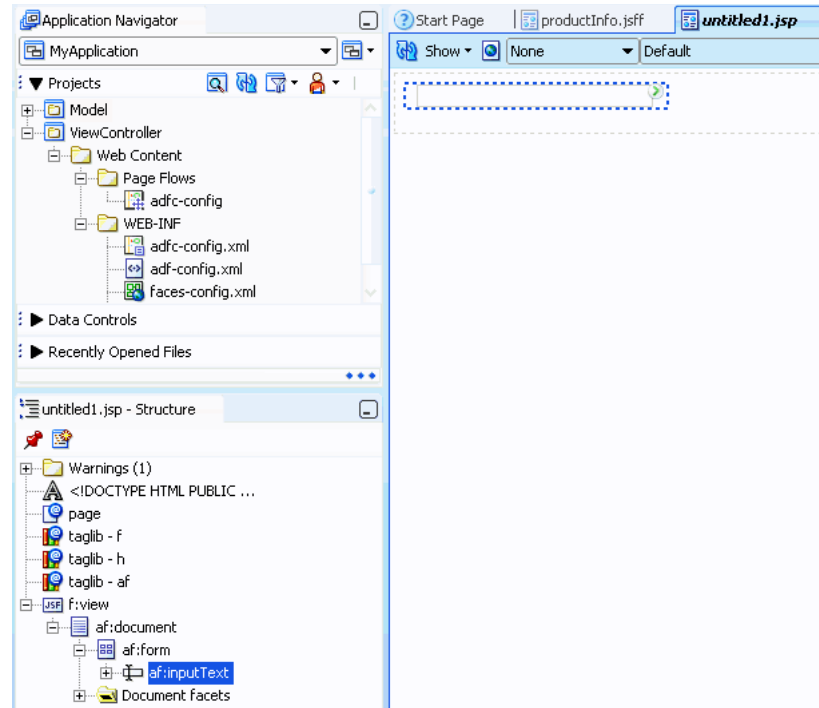

You apply ADF model binding to components using the Structure window.

### To apply ADF Model data binding:

1. In the Design page of the visual editor, select the UI component to which you want to add ADF bindings.

The component must be one of the tags listed in [Table 12-4](#). When you select a component in the visual editor, JDeveloper simultaneously selects that component tag in the Structure window, as shown in [Figure 12-16](#).

**Figure 12-16** The Structure Window in JDeveloper

2. In the Structure window, right-click the UI component, and from the context menu, choose **Bind to ADF Control**.

---

---

**Note:** Your project must already contain data controls for the **Bind to ADF Control** menu option to appear. If yours does not, you should consider using placeholder data controls, as described in [Chapter 29, "Designing a Page Using Placeholder Data Controls."](#)

---

---

3. In the Bind to ADF Control dialog, select the data control to which you want the UI component bound. JDeveloper will notify you if you choose a control that is not compatible with the selected UI component.

## 12.8.2 What Happens When You Apply ADF Model Data Binding to UI Components

When you use the Data Controls panel all of the required ADF objects are automatically created for you, as described in [Section 12.3.2, "What Happens When You Use the Data Controls Panel."](#)

---

---

## Integrating Web Services Into a Fusion Web Application

This chapter describes how to call a third-party web service in a Fusion web application and work directly with the service proxy and service data objects (SDOs) programmatically for all common remote service data access tasks. It also describes how to create ADF data controls for third-party web services when you want to work with the web service in the user interface.

This chapter includes the following sections:

- [Section 13.1, "Introduction to Web Services in Fusion Web Applications"](#)
- [Section 13.2, "Calling a Web Service from an Application Module"](#)
- [Section 13.3, "Creating Web Service Data Controls"](#)
- [Section 13.4, "Securing Web Service Data Controls"](#)

### 13.1 Introduction to Web Services in Fusion Web Applications

*Web services* allow enterprises to expose business functionality irrespective of the platform or language of the originating application because the business functionality is exposed in such a way that it is abstracted to a message composed of standard XML constructs that can be recognized and used by other applications.

Web services are modular business services that can be easily integrated and reused, and it is this that makes them ideally suited as components within SOA. JDeveloper helps you to create top-down web services (services created starting from a WSDL), bottom-up web services (created from the underlying implementation such as a Java class or a PL/SQL stored procedure in a database), and services created from existing functionality such as exposing an application module as a service.

You can consume web services in web applications, and common reasons for wanting to do so are:

- To add functionality which would be time-consuming to develop with the application, but which is readily available as a web service
- To access an application that runs on different architecture
- To access an application that is owned by another team when their application must be independently installed, upgraded, and maintained, especially when its data is not replicated locally (for example, when other methods of accessing their application cannot be used)

## 13.2 Calling a Web Service from an Application Module

In a service-oriented architecture, your Oracle ADF application module may need to take advantage of functionality offered by a web service that is not based on an application module. A web service can be implemented in any programming language and can reside on any server on the network. Each web service identifies the methods in its API by describing them in a standard, language-neutral XML format. This XML document, whose syntax adheres to the Web Services Description Language (WSDL), enables JDeveloper to understand the names of the web service's methods, as well as the data types of the parameters they might expect and their eventual return value.

---

---

**Note:** Application modules can also be exposed as web services so that they can be consumed across modules of the deployed Fusion web application. For details about reusing ADF Business Components using external services, see [Chapter 11, "Integrating Service-Enabled Application Modules."](#)

---

---

JDeveloper's built-in web services wizards make this an easy task. Create a web service proxy class using the wizard, then call the service using method calls you add to a local Java object.

### 13.2.1 How to Call an External Service Programmatically

To call a web service from an application module, you create a web service proxy class for the service you want to invoke. A web service proxy is a generated Java class that represents the web service inside your application. It encapsulates the service URL of the web service and handles the lower-level details of making the call.

To work with a web service, you need to know the URL that identifies its WSDL document. If you have received the WSDL document as an email attachment, for example, and saved it to your local hard drive, the URL could be similar to:

```
file:///D:/temp/SomeService.wsdl
```

Alternatively, the URL could be an HTTP-based URL like:

```
http://someserver.somecompany.com/SomeService/SomeService.wsdl
```

Some web services make their WSDL document available by using a special parameter to modify the service URL. For example, a web service that expects to receive requests at the HTTP address of `http://someserver.somecompany.com/SomeService` might publish the corresponding WSDL document using the same URL with an additional parameter on the end, like this:

```
http://someserver.somecompany.com/SomeService?WSDL
```

Since there is no established standard, you will just need to know what the correct URL to the WSDL document is. With the URL information, you can then create a web service proxy class to call the service.

ADF Business Components services have URLs to the service of the following formats:

- On Integrated WebLogic Server, the URL has the format `http://host:port/EJB-context-root/@WebService-name?WSDL`, for example:

```
http://localhost:8888/EJB-StoreFrontService/StoreFrontService?WSDL
```

- On Oracle WebLogic Server, the URL has the format `http://host:port/context-root/@WebService-name?WSDL`, for example:

```
http://localhost:8888/StoreFrontService/StoreFrontService?WSDL
```

The web service proxy class presents a set of Java methods that correspond to the web service's public API. By using the web service proxy class, you can call any method in the web service in the same way as you work with the methods of any other local Java class.

To call a web service from an application module using a proxy class, you perform the following tasks:

1. Create a web service proxy class for the web service. To create a web service proxy class for a web service that you need to call, use the Create Web Service Proxy wizard.
2. Implement the methods in the proxy class to access the desired web services.
3. Create an instance of the web service proxy class in your application module and invoke one or more methods on the web service proxy object.

### 13.2.1.1 Creating a Web Service Proxy Class to Programmatically Access the Service

To create a web service proxy class for a web service you need to call, use the Create Web Service Proxy wizard.

#### To create a web service proxy class to programmatically access the service:

1. In the Application Navigator, right-click the project in which you want to create the web service proxy, and choose **New**.
2. In the New Gallery, expand **Business Tier**, select **Web Services** and then **Web Service Proxy**, and click **OK**.
3. On the Select Web Service Description page of the wizard, enter or choose a Java package name for the generated web service proxy class.
4. Enter the URL for the WSDL of the service you want to call in your application, and then tab out of the field.

If the **Next** button does not enable, click **Why Not?** to understand what problem JDeveloper encountered when trying to read the WSDL document. If necessary, fix the problem after verifying the URL and repeat this step.

5. When the wizard displays **Next** enabled, then JDeveloper has recognized and validated the WSDL document. You can click **Next** and continue.
6. Continue through the pages of the wizard to specify details about the web service proxy. For more information about each page of the wizard, press F1 or click **Help**.
7. Click **Finish**.

### 13.2.1.2 Calling the Web Service Proxy Template to Invoke the Service

After you create the web service proxy, you must implement the methods in the proxy class to access the desired web services.

**To call the web service proxy template to invoke the service:**

1. Open the proxy client class, called `port_nameClient.java`, in the source editor, and locate the comment `// Add your own code to call the desired methods`, which is in the main method.
2. Add the appropriate code to invoke the web service.
3. Deploy the full set of client module classes that JDeveloper has generated, and reference this class in your application.

**13.2.1.3 Calling a Web Service Method Using the Proxy Class in an Application Module**

After you've generated the web service proxy class, you can use it inside a custom method of your application module, as shown in [Example 13–1](#). The method creates an instance of the web service proxy class and calls the web service method from the web service proxy class for the result.

**Example 13–1 Web Service Proxy Class Calls Web Service Method**

```
// In YourModuleImpl.java
public void performSomeApplicationTask(String symbol) throws Exception {
    // application-specific code here
    :
    // Create an instance of the web service proxy class
    StockQuoteServiceSoapHttpClient svc =
        new StockQuoteServiceSoapHttpClient();
    // Call a method on the web service proxy class and get the result
    QuoteInfo quote = svc.quoteForSymbol(symbol);
    float currentPrice = quote.getPrice();
    // more application-specific code here
}
```

**13.2.2 How to Create a New Web Service Connection**

After developing a web service proxy, you can generate additional connections for the proxy that you can use in testing and deployment situations. For example, you might want to create a connection that includes user name and password for testing purposes.

The connection information is stored in the `connections.xml` file along with the other connections in your application. This abstraction of the endpoint URL also allows you to edit the connection after deployment using Enterprise Manager without requiring modification to the client code.

**To create a new web service connection:**

1. In the Application Navigator, right-click a web service proxy and choose **Create ADF Web Service Connection**.

The New ADF Web Service Connection dialog displays the default settings for a connection associated with the selected proxy.

2. Modify the connection information as necessary, and click **OK**.

---

---

**WARNING:** If you create a new web service connection with the same name as an existing connection, the existing connection will be overwritten with the new information.

---

---

After you create a new web service connection, you can modify your client to use this connection. You could use code similar to that shown in [Example 13–2](#) to access the connection from your client.

**Example 13–2 Accessing a Web Service Connection from a Client**

```
Context ctx = ADFContext.getCurrent().getConnectionsContext();
WebServiceConnection wsc = (WebServiceConnection) ctx.lookup("MyAppModuleService");
MyAppModuleService proxy = wsc.getJaxWSPort(MyAppModuleService.class);
```

The argument that you pass to the `lookup()` method is the name that you gave to the web service connection. In this example, it is `MyAppModuleService`.

### 13.2.3 What Happens When You Create the Web Service Proxy

JDeveloper generates the web service proxy class in the package you've indicated with a name that reflects the name of the web service port it discovered in the WSDL document. The web service port name might be a human-readable name like `StockQuoteService`, or could be a less-friendly name like `StockQuoteServiceSoapHttpPort`. The port name is decided by the developer that published the web service you are using. If the port name of the service were `StockQuoteServiceSoapHttpPort`, for example, JDeveloper would generate a web proxy class named `StockQuoteServiceSoapHttpPortClient`.

The web service proxy displays in the Application Navigator as a single, logical node called `WebServiceNameProxy`. For example, the node for the `StockQuoteService` web service would appear in the navigator with the name `StockQuoteServiceProxy`. As part of generating the proxy class, in addition to the main web service proxy class that you use to invoke the server, JDeveloper generates a number of auxiliary classes and interfaces. You can see these files in the Application Navigator under the `WebServiceNameProxy` node. The generated files are used as part of the lower-level implementation of invoking the web service.

The only auxiliary generated classes you need to reference are those created to hold structured web service parameters or return types. For example, imagine that the `StockQuoteService` web service has a `quoteForSymbol()` method that accepts one `String` parameter and returns a floating-point value indicating the current price of the stock. If the designer of the web service chose to return a simple floating-point number, then the web service proxy class would have a corresponding method like this:

```
public float quoteForSymbol(String symbol)
```

If instead the designer of the web service thought it useful to return multiple pieces of information as the result, then the service's WSDL file would include a named structure definition describing the multiple elements it contains. For example, assume that the service returns both the symbol name and the current price as a result. To contain these two data elements, the WSDL file might define a structure named `QuoteInfo` with an element named `symbol` of string type and an element named `price` of floating-point type. In this situation, when JDeveloper generates the web service proxy class, the Java method signature would instead look like this:

```
public QuoteInfo quoteForSymbol(String symbol)
```

The `QuoteInfo` return type references one of the auxiliary classes that comprises the web service proxy implementation. It is a simple bean whose properties reflect the names and types of the structure defined in the WSDL document. In a similar way, if the web service accepts parameters whose values are structures or arrays of structures,

then you will work with these structures in your Java code using the corresponding generated beans.

### 13.2.4 What Happens at Runtime: When You Call a Web Service Using a Web Service Proxy Class

When you invoke a web service from an application module, the web service proxy class handles the lower-level details of using the XML-based web services protocol described in SOAP. In particular, it does the following:

- Creates an XML document to represent the method invocation
- Packages any method arguments in XML
- Sends the XML document to the service URL using an HTTP POST request
- Unpackages the XML-encoded response from the web service

If the method you invoke has a return value, your code receives it as an appropriately typed object to work with in your application module code.

### 13.2.5 What You May Need to Know About Web Service Proxies

When you are implementing web service proxies in an application, you might want to use a try-catch block to handle web service exceptions or invoke an application module with a web service proxy class. The following sections contain additional information you might need to know about these and other features with regard to web service proxies.

#### 13.2.5.1 Using a Try-Catch Block to Handle Web Service Exceptions

By using the generated web service proxy class, invoking a remote web service becomes as easy as calling a method in a local Java class. The only distinction to be aware of is that the web service method call could fail if there is a problem with the HTTP request involved. The method calls that you perform against a web service proxy should anticipate the possibility that the request might fail by wrapping the call with an appropriate `try...catch` block. [Example 13–3](#) improves on the simpler example (shown in [Section 13.2.1.3, "Calling a Web Service Method Using the Proxy Class in an Application Module"](#)) by catching the web service exception. In this case, it simply rethrows the error as a `JboException`, but you could implement more appropriate error handling in your own application.

#### **Example 13–3 Wrapping Web Service Method Calls with a Try-Catch Block**

```
// In YourModuleImpl.java
public void performSomeApplicationTask(String symbol) {
    // application-specific code here
    // :
    QuoteInfo quote = null;
    try {
        // Create an instance of the web service proxy class
        StockQuoteServiceSoapHttpClient svc =
            new StockQuoteServiceSoapHttpClient();
        // Call a method on the web service proxy class and get the result
        quote = svc.quoteForSymbol(symbol);
    }
    catch (Exception ex) {
        throw new JboException(ex);
    }
    float currentPrice = quote.getPrice();
}
```

```
// more application-specific code here
}
```

### 13.2.5.2 Separating Application Module and Web Services Transactions

You will use some web services to access reference information. However, other services you call may modify data. This data modification might be in your own company's database if the service was written by a member of your own team or another team in your company. If the web service is outside your firewall, of course the database being modified will be managed by another company.

In either of these situations, it is important to understand that any data modifications performed by a web service you invoke will occur in their own distinct transaction, unrelated to the application module's current unit of work. For example, if you have invoked a web service that modifies data and then you later call `rollback()` to cancel the pending changes in the application module's current unit of work, this has no effect on the changes performed by the web service you called in the process. You may need to invoke a corresponding web service method to perform a compensating change to account for your rollback of the application module's transaction.

### 13.2.5.3 Setting Browser Proxy Information

If the web service you need to call resides outside your corporate firewall, you need to ensure that you have set the appropriate Java system properties to configure the use of an HTTP proxy server. The Java system properties to configure are:

- `http.proxyHost` — Set this to the name of the proxy server.
- `http.proxyPort` — Set this to the HTTP port number of the proxy server (often 80).
- `http.nonProxyHosts` — Optionally set this to a vertical-bar-separated list of servers not requiring the user of a proxy server (for example, `localhost|127.0.0.1|*.yourcompany.com`).

Within JDeveloper, you can configure an HTTP proxy server on the Web Browser and Proxy page of the Preferences dialog. When you run your application, JDeveloper includes appropriate `-D` command-line options to set these three system properties based on the settings you've indicated in this dialog.

### 13.2.5.4 Invoking Application Modules with a Web Service Proxy Class

If you use a web service proxy class to invoke an Oracle ADF service-based application module, you lose the ability to optimize the call when the calling component and the service you are calling are colocated. As an alternative, you can use the service interface approach described in [Chapter 11, "Integrating Service-Enabled Application Modules."](#)

## 13.3 Creating Web Service Data Controls

The most common way of using web services in an application developed using Oracle ADF is to create a data control for an external web service. A typical reason for doing this is to add functionality that is readily available as a web service, but which would be time consuming to develop with the application, or to access an application that runs on a different architecture.

Additionally, you can reuse components created by Oracle ADF to make them available as web services for other applications to access.

### 13.3.1 How to Create a Web Service Data Control

JDeveloper allows you to create a data control for an existing web service using just the WSDL for the service. You can browse to a WSDL on the local file system, locate one in a UDDI registry, or enter the WSDL URL directly.

---

---

**Note:** If you are working behind a firewall and you want to use a web service that is outside the firewall, you must configure the Web Browser and Proxy settings in JDeveloper. For more information, see [Section 13.2.5.3, "Setting Browser Proxy Information."](#)

---

---

**To create a web service data control:**

1. In the Application Navigator, right-click an application and choose **New**.
2. In the New Gallery, expand **Business Tier**, select **Web Services** and then **Web Service Data Control**, and click **OK**.
3. Follow the wizard instructions to complete creating the data control.
4. In the Create Web Service Data Control wizard, on the Data Source page, specify a name for the data control, a WSDL URL, and the specific web service to be accessed by the data control.
5. On the Data Control Operations page, select the operations you want the data control to support.

If you want to include header parameters when invoking the SOAP request, select **Include Http Header Parameter**. For more information, see [Section 13.3.2, "How to Include a Header Parameter for a Web Service Data Control."](#)

6. On the Response Format page, specify the format of the SOAP response.
7. On the Endpoint Authentication page, specify the authentication details for the endpoint URL, and click **Finish**.

### 13.3.2 How to Include a Header Parameter for a Web Service Data Control

When using a web service data control, you may want to add an *enterprise ID* to the HTTP header when invoking the SOAP request. This enterprise ID in the request allows the web service data control to specify which cloud service the request will be directed to.

To configure the web service data control to use a header parameter, you select **Include Http Header Parameter** on the Data Control Operations page of the Create Web Service Data Control wizard. After creating the data control, you will be able to see the **HttpHeader** parameter in the Data Controls panel under the **Parameters** node of the web service data control's methods. You will also notice that `AdapterDataControl` element for the web service data control (in the `.dcx` file) contains an `<httpHeaders paramName="HttpHeader" />` element.

To use the `HttpHeader` parameter, you will need to create a backing bean in the view controller project for the web service data control. The value for the `HttpHeader` parameter is provided through the backing bean. The backing bean must have a property of the type `Map` and the name/value pairs for the http headers should be added to that property. Additionally, the `Map` must be of type `<String, List<String>>` or `<String, String>`, and you should expose the property with getter and setter methods, as shown [Example 13-4](#).

**Example 13–4 Backing Bean to Support Http Header Parameters in a Web Service Data Control**

```

public class BackingBean {
    private Map<String, Object> httpHeadersMap = new HashMap<String, Object>();
    public BackingBean() {
        List<String> headersList = new ArrayList<String>();
        headersList.add("Oracle");
        httpHeadersMap.put("enterpriseID", headersList);
    }
    public void setHttpHeadersMap(Map<String, Object> httpHeadersMap) {
        this.httpHeadersMap = httpHeadersMap;
    }
    public Map<String, Object> getHttpHeadersMap() {
        return httpHeadersMap;
    }
}

```

When you drag and drop the operation from the Data Controls panel onto a page as an ADF Parameter Form, remove the **HttpHeader** from the list of fields. Then, in the Edit Action Binding dialog, under the **Parameters** section specify the value for **HttpHeader** parameter by providing an expression that points to the backing bean Map property.

**13.3.3 How to Adjust the Endpoint for a Web Service Data Control**

After developing a web service data control, you can modify the endpoint. This is useful, for example, when you migrate the application from a test environment to production.

**To change the endpoint for a web service data control:**

1. In the Application Navigator, select the `.dcx` file for the web service data control.
2. In the Structure window, right-click the web service data control and choose **Edit Web Service Connection** from the context menu.
3. In the Edit Web Service Connection dialog, make the necessary changes to the endpoint URL and port name.
4. Click **OK**.

**13.3.4 How to Refresh a Web Service Data Control**

After creating a web service data control, you might find that a web service operation has changed in its method signature, return type, or structure. When this happens, you can update the data control without having to re-create it.

**To refresh an operation in a web service data control:**

1. In the Application Navigator, select the `.dcx` file for the web service data control.
2. In the Structure window, right-click the desired web service operation and choose **Update** from the context menu.

JDeveloper queries the web service and updates the web service data control to reflect the current state of the selected operation.

**13.3.5 What You May Need to Know About Web Service Data Controls**

As with other kinds of data controls, you can design a databound user interface by dragging an item from the Data Controls panel and dropping it on a page as a specific

UI component. For more information, see [Section 12.3.1, "How to Use the Data Controls Panel."](#)

In the Data Controls panel, each data control object is represented by an icon. [Table 13–1](#) describes what each icon represents, where it appears in the Data Controls panel hierarchy, and what components it can be used to create.

**Table 13–1 Data Controls Panel Icons and Object Hierarchy for Web Services**

Icon	Name	Description	Used to Create...
	Data Control	<p>Represents a data control. You cannot use the data control itself to create UI components, but you can use any of the child objects listed under it. Depending on how your web services are defined, there may be more than one data control.</p> <p>Typically, there is one data control for each web service. However, you may have additional data controls that were created for other types of business services (for example, application modules). For information about creating data controls for application modules, see <a href="#">Chapter 12, "Using ADF Model in a Fusion Web Application."</a></p>	Serves as a container for other objects and is not used to create anything
	Collection	<p>Represents a named data collection. A <i>data collection</i> represents a set of data objects (also known as a <i>row set</i>) in the data model. Each object in a data collection represents a specific structured data item (also known as a <i>row</i>) in the data model. Throughout this guide, <i>data collection</i> and <i>collection</i> are used interchangeably.</p> <p>For more information about using collections on a data control to create forms, see <a href="#">Chapter 22, "Creating a Basic Databound Page."</a></p> <p>For more information about using collections to create tables, see <a href="#">Chapter 23, "Creating ADF Databound Tables."</a></p> <p>For more information about using master-detail relationships to create UI components, see <a href="#">Chapter 24, "Displaying Master-Detail Data."</a></p> <p>For information about creating graphs, charts, and other visualization UI components, see <a href="#">Chapter 26, "Creating Databound ADF Data Visualization Components."</a></p>	Forms, tables, graphs, trees, range navigation components, and master-detail components.
	Attribute	<p>Represents a discrete data element in an object (for example, an attribute in a row). Attributes appear as children under the collections or method returns to which they belong.</p> <p>For information about using attributes to create fields on a page, see <a href="#">Section 22.2, "Using Attributes to Create Text Fields."</a></p> <p>For information about creating lists, see <a href="#">Chapter 25, "Creating Databound Selection Lists and Shuttles."</a></p>	Label, text field, date, list of values, and selection list components.
	Structured Attribute	<p>Represents a returned object that is not one of the Java primitive types (which are represented as attributes) and is also not a collection of any type. An example of a structured attribute would be a domain, which is a developer-created data type used to simplify application maintenance.</p> <p>For more information about domains, see <a href="#">Section 38.1, "Creating Custom, Validated Data Types Using Domains."</a></p>	Label, text field, date, list of values, and selection list components

**Table 13–1 (Cont.) Data Controls Panel Icons and Object Hierarchy for Web Services**

Icon	Name	Description	Used to Create...
	Method	<p>Represents an operation in the data control or one of its exposed structures that may accept parameters, perform some business logic and optionally return single value, a structure or a collection of those.</p> <p>For more information about using methods that accept parameters, see <a href="#">Section 28.2.2.2, "Using Parameters in a Method."</a></p>	<p>Command components</p> <p>For methods that accept parameters: command components and parameterized forms</p>
	Method Return	<p>Represents an object that is returned by a custom method. The returned object can be a single value or a collection.</p> <p>If a custom method returns anything at all, it is usually a single scalar value. However, some custom methods can return collections.</p> <p>A method return appears as a child under the method that returns it. The objects that appear as children under a method return can be attributes of the collection, other methods that perform actions related to the parent collection, and operations that can be performed on the parent collection.</p> <p>When a single-value method return is dropped, the method is not invoked automatically by the framework. You either need to also create an invoke action as an executable, or drop the corresponding method as a button to invoke the method. For more information about executables, see <a href="#">Section 12.6.2.2, "Executable Binding Objects."</a></p>	<p>The same components as for collections and attributes.</p> <p>For named criteria: query or quick query forms. For more information, see <a href="#">Chapter 27, "Creating ADF Databound Search Forms."</a></p>
	Operation	<p>Represents a built-in data control operation that performs actions on the parent object. Data control operations are located in an <b>Operations</b> node under collections or method returns, and also under the root data control node. The operations that are children of a particular collection or method return operate on those objects only, while operations under the data control node operate on all the objects in the data control.</p> <p>If an operation requires one or more parameters, they are listed in a <b>Parameters</b> node under the operation.</p> <p>The standard operations supported by the web service data control are for form navigation: First, Last, Next, and Previous. Because the web service data control is not an updateable data control, you cannot use built-in operations like commit, rollback, and execute.</p>	<p>UI command components, such as buttons, links, and menus.</p> <p>For more information, see <a href="#">Section 22.4, "Incorporating Range Navigation into Forms,"</a> and <a href="#">Section 22.5, "Creating a Form to Edit an Existing Record."</a></p>
	Parameter	<p>Represents a parameter value that is declared by the method or operation under which it appears. Parameters appear in the <b>Parameters</b> node under a method or operation.</p> <p>Array and structured parameters are exposed as updateable structured attributes and collections under the data control, which can be dropped as an ADF form or an updateable table on the UI. You can use the UI to build a parameter that is an array or a complex object (not a standard Java type).</p>	<p>Label, text, and selection list components.</p>

## 13.4 Securing Web Service Data Controls

Web services allow applications to exchange data and information through defined application programming interfaces. SSL (Secure Sockets Layer) provides secure data transfer over unreliable networks, but SSL only works point to point. Once the data reaches the other end, the SSL security is removed and the data becomes accessible in its raw format. A complex web service transaction can have data in multiple messages being sent to different systems, and SSL cannot provide the end-to-end security that would keep the data invulnerable to eavesdropping.

Any form of security for web services has to address the following issues:

- The authenticity and integrity of data
- Data privacy and confidentiality
- Authentication and authorization
- Non-repudiation
- Denial of service attacks

Throughout this section the "client" is the web service data control, which sends SOAP messages to a deployed web service. The deployed web service may be:

- A web service running on Oracle WebLogic Server
- A web service running anywhere in the world that is accessible through the Internet

### 13.4.1 WS-Security Specification

The WS-Security specification unifies multiple security technologies to make secure web services interoperable between systems and platforms. You can view the specification at

<http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0.pdf>.

WS-Security addresses the following aspects of web services security issues:

- Authentication and authorization  
The identity of the sender of the data is verified, and the security system ensures that the sender has privileges to perform the data transaction.  
The type of authentication can be a basic username/password pair transmitted in plain text, or trusted X509 certificate chains. SAML assertion tokens can also be used to allow the client to authenticate against the service, or allow it to participate in a federated SSO environment, where authenticated details are shared between domains in a vendor-independent manner.
- Data authenticity, integrity, and non-repudiation  
XML digital signatures, which use industry-standard messages, digest algorithms to digitally sign the SOAP message.
- Data privacy  
XML encryption that uses industry-standard encryption algorithms to encrypt the message.
- Denial of service attacks  
Defines XML structures to time-stamp the SOAP message. The server uses the time stamp to invalidate the SOAP message after a defined interval.

### 13.4.2 Using Key Stores

A web service data control can be configured for message-level security using either Java Key Store (JKS) or the Oracle Wallet. For information on setting up and using Oracle Wallet, see the Oracle Technology Network at <http://www.oracle.com/technetwork>.

For more information about creating and using key stores for message protection, see the section about managing keystores, wallets, and certificates in the *Oracle Fusion*

*Middleware Administrator's Guide*, and the section about configuring policies in the *Oracle Fusion Middleware Security and Administrator's Guide for Web Services*.

### 13.4.3 How to Define Web Service Data Control Security

After you create a web services data control in a JDeveloper project, you can define security for the data control using the Edit Data Control Policies dialog.

#### To define security for a web service data control:

1. In the Application Navigator, select the web service data control `.dcx` file.
2. In the Structure window, right-click the web service data control, and choose **Define Web Service Security**.  
  
JDeveloper displays the Edit Data Control Policies dialog, which shows the Policy Store location. To select an alternative policy store, use the **WS Policy Store** page of the Preferences dialog.
3. From the **Ports** dropdown list, select the port to which you want the specified policies are applied.
4. From the **MTOM** dropdown list, select the MTOM (message transmission optimization mechanism) policy you want to use. If you leave this field blank, no MTOM policy is used.
5. From the **Reliability** dropdown list, select the reliability policy you want to use. If you leave this field blank, no reliability policy is used.
6. From the **Addressing** dropdown list, select the addressing policy you want to use. If you leave this field blank, no addressing policy is used.
7. In the **Security** list, you can optionally specify additional security policies to apply. To add a policy, click the Add security policy icon.
8. In the **Management** list, you can optionally specify additional management policies to apply. To add a policy, click the Add management policy icon.
9. If necessary, you can also remove policies from the **Security** list and the **Management** list by selecting the appropriate policy and clicking the corresponding delete icon.
10. You can optionally override properties for the policies in the **Security** list and the **Management** list by clicking **Override Properties**.
11. After you have selected the appropriate policies for your web service data control, click **OK** to apply your selections and close the dialog.

For more information about predefined policies and configuring policies and their properties, see the *Oracle Fusion Middleware Security and Administrator's Guide for Web Services*.

# Part III

---

## Creating ADF Task Flows

Part III contains the following chapters:

- [Chapter 14, "Getting Started with ADF Task Flows"](#)
- [Chapter 15, "Working with Task Flow Activities"](#)
- [Chapter 16, "Using Parameters in Task Flows"](#)
- [Chapter 17, "Using Task Flows as Regions"](#)
- [Chapter 18, "Creating Complex Task Flows"](#)
- [Chapter 19, "Using Dialogs in Your Application"](#)

---

## Getting Started with ADF Task Flows

This chapter describes how to create ADF task flows that enable navigation, encapsulation, reuse, managed bean lifecycles, and transactions within an application. It includes the basic steps for creating a task flow diagram, adding activities and control flows to it, and running the finished task flow.

This chapter includes the following sections:

- [Section 14.1, "Introduction to ADF Task Flows"](#)
- [Section 14.2, "Creating a Task Flow"](#)
- [Section 14.3, "Adding Activities to a Task Flow"](#)
- [Section 14.4, "Testing ADF Task Flows"](#)
- [Section 14.5, "Refactoring to Create New ADF Task Flows and Templates"](#)
- [Section 14.6, "What You Should Know About Task Flow Constraints"](#)

### 14.1 Introduction to ADF Task Flows

*ADF task flows* provide a modular approach for defining control flow in an application. Instead of representing an application as a single large JSF page flow, you can break it up into a collection of reusable task flows. Each task flow contains a portion of the application's navigational graph. The nodes in the task flows are activities. An *activity node* represents a simple logical operation such as displaying a page, executing application logic, or calling another task flow. The transactions between the activities are called *control flow cases*.

[Figure 14-1](#) shows two view activities called `Create` and `Confirm`. These view activities are similar to page nodes within a JSF page flow.

**Figure 14-1** ADF Task Flow

Task flows can invoke managed beans. For more information about defining managed beans for use with a task flow, the supported memory scopes, and other related information, see [Section 14.2.4, "What You May Need to Know About Memory Scope for Task Flows"](#) and [Section 20.4, "Using a Managed Bean in a Fusion Web Application"](#).

## 14.1.1 Task Flow Advantages

ADF task flows offer significant advantages over standard JSF page flows, as described in [Table 14-1](#).

**Table 14-1 ADF Task Flow Advantages**

JSF Page Flow	ADF Task Flow
The entire application must be represented in a single page navigation file ( <code>faces-config.xml</code> ). Although you can have multiple copies of <code>faces-config.xml</code> in a project, the application loads these files as one at runtime.	The application can be broken up into a series of modular flows that call one another.
All nodes within a JSF page flow must be JSF pages. No other types of objects can exist within the JSF page flow.	You can add to the task flow diagram nodes such as views, method calls, and calls to other task flows.
Navigation is only between pages.	Navigation is between pages as well as other activities, including routers. For more information, see <a href="#">Section 15.4, "Using Router Activities"</a> .
Application fragments cannot be reused.	ADF task flows are reusable within the same or an entirely different application.  After you break up your application into task flows, you may decide to reuse task flows containing common functionality.  For more information see <a href="#">Chapter 33, "Reusing Application Components"</a> .
There is no shared memory scope between multiple requests except for session scope.	Shared memory scope (for example, page flow scope) enables data to be passed between activities within the task flow. Page flow scope defines a unique storage area for each instance of an ADF bounded task flow.

## 14.1.2 Task Flow Types

The two types of ADF task flow are:

- **Unbounded task flow:** A set of activities, control flow rules, and managed beans that interact to allow a user to complete a task. An ADF unbounded task flow consists of all activities and control flows in an application that are not included within any bounded task flow.
- **Bounded task flow:** A specialized form of task flow that, in contrast to an unbounded task flow, has a single entry point and zero or more exit points. It contains its own set of private control flow rules, activities, and managed beans. An ADF bounded task flow allows reuse, parameters, transaction management, and reentry.

For a description of the activity types that you can add to an ADF unbounded or bounded task flow see [Chapter 15, "Working with Task Flow Activities"](#).

A bounded task flow is also known as a *task flow definition*. By default, JDeveloper proposes the following filename for the source file of a bounded task flow:

```
task-flow-definitionN.xml
```

where *N* is a number that increments each time that you create a new bounded task flow.

The file contains the metadata for the bounded task flow. Multiple task flow definitions (bounded task flows) can be included within the same task flow definition file.

A typical application is a combination of an unbounded and one or more bounded task flows. For example, JDeveloper, by default, creates an empty unbounded task flow (source file name is `adfc-config.xml`) when you create a Fusion web application using the Fusion Web Application template. At runtime, the Fusion web application can call bounded task flows from activities that you added to this unbounded task flow.

As shown in [Figure 14–2](#), the first activity to execute in an application is often a view activity within an ADF unbounded task flow. A view activity represents a JSF page that displays as part of the application. The activity shown in [Figure 14–2](#) starts with the Home view activity and then calls a bounded task flow. The `calltoLogin_taskFlow` activity calls a bounded task flow that enables a user to log into the application.

**Figure 14–2 Unbounded Task Flow Calling a Bounded Task Flow**

You can also design an application in which all application activities reside within the ADF unbounded flow. This mimics a Struts or JSF application, but doesn't take advantage of ADF bounded task flow functionality. To take full advantage of task flow functionality, use ADF bounded task flows.

#### 14.1.2.1 Unbounded Task Flows

A Fusion web application always contains an *ADF unbounded task flow*, which contains the entry point or points to the application. [Figure 14–3](#) displays the diagram for the unbounded task flow from the Fusion Order Demo Application. This task flow contains a number of view activities that are all entry points to the application.

**Figure 14–3 Unbounded Task Flow in Fusion Order Demo Application**

You typically use an unbounded instead of a bounded task flow if:

- You want to take advantage of ADF Controller features not offered by bounded task flows, such as bookmarkable view activities. For more information, see [Section 15.2.3, "Bookmarking View Activities"](#).
- The task flow will not be called by another task flow.
- The application has multiple points of entry. In [Figure 14-3](#), the task flow can be entered through any of the pages represented by the view activity icons on the unbounded task flows.

Pages are associated with view activities. The icon for a view activity displays a page image like this:

- You want to bookmark more than one activity on the task flow. See [Section 15.2.3, "Bookmarking View Activities"](#) for more information.

An unbounded task flow cannot declaratively specify parameters. In addition, it cannot contain a *default activity*, an activity designated as the first to run in the unbounded task flow. This is because an unbounded task flow does not have a single point of entry. To perform any of these requires an ADF bounded task flow.

In order to take advantage of completely declarative ADF Controller transaction and reentry support, use a bounded rather than an unbounded task flow.

#### 14.1.2.2 Bounded Task Flows

An *ADF bounded task flow* is used to encapsulate a reusable portion of an application. A bounded task flow is similar to a Java method in that it:

- Has a single entry point
- May accept input parameters
- May generate return values
- Has its own collection of activities and control flow rules
- Has its own memory scope and managed bean lifespan (a page flow scope instance)

The `checkout-task-flow` activity in [Figure 14-3](#) is a call to an ADF bounded task flow. An unbounded task flow can call an ADF bounded task flow, but cannot be called by another task flow. A bounded task flow can call another bounded task flow, which can call another and so on. There is no limit to the depth of the calls.

The checkout process is created as a separate ADF bounded task flow, as shown in [Figure 14-4](#).

**Figure 14–4 Checkout Bounded Task Flow in Fusion Order Demo Application**

The reasons for creating the checkout-task-flow activity as a called bounded task flow are:

- The bounded task flow always specifies a default activity, a single point of entry that must execute immediately upon entry of the bounded task flow.

In the checkout task flow, the activity labeled `reconcileShoppingCart` invokes a method that returns a list of items that an anonymous user (one who has not yet logged in to the application) may have chosen to purchase. Any items chosen before authentication are included in the shopping cart after the user has logged in. Because it is the default activity, the method is always invoked before the shopping cart order page displays.

- `checkout-task-flow` is reusable. For example, it can be included in other applications requiring an item checkout process. The bounded task flow can also be reused within the same application.
- Any managed beans you decide to use within `checkout-task-flow` can be specified in page flow scope, so are isolated from the rest of the application.

The main features of ADF bounded task flows are summarized in [Table 14–2](#).

**Table 14–2 ADF Bounded Task Flow Features**

Feature	Description
Well-defined boundary	An ADF bounded task flow consists of its own set of private control flow rules, activities, and managed beans. A caller requires no internal knowledge of such things as page names, method calls, child bounded task flows, managed beans, and control flow rules within the bounded task flow boundary. Input parameters can be passed into the bounded task flow, and output parameters can be passed out on exit of the bounded task flow. Data controls can be shared between task flows.

**Table 14–2 (Cont.) ADF Bounded Task Flow Features**

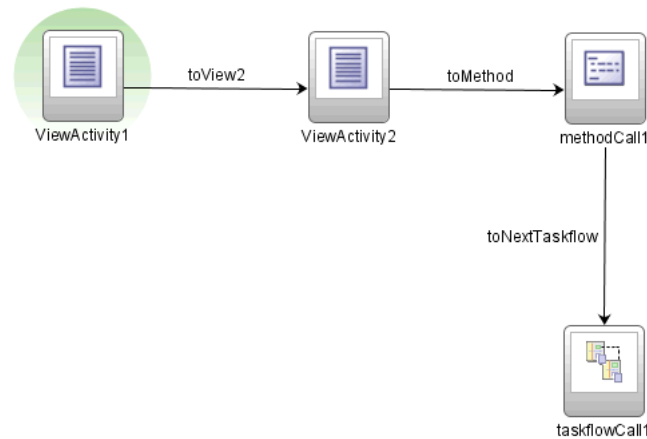

Feature	Description
Single point of entry	An ADF bounded task flow has a single point of entry, a default activity that executes before all other activities in the task flow. For more information, see <a href="#">Section 14.2.3, "What You May Need to Know About the Default Activity in an ADF Bounded Task Flow"</a> .
Page flow memory scope	You can specify page flow scope as the memory scope for passing data between activities within the ADF bounded task flow. Page flow scope defines a unique storage area for each instance of an ADF bounded task flow. Its lifespan is the ADF bounded task flow, which is longer than request scope and shorter than session scope. For more information, see <a href="#">Section 14.2.4, "What You May Need to Know About Memory Scope for Task Flows"</a> .
Addressable	You can access an ADF bounded task flow by specifying its unique identifier within the XML source file for the bounded task flow and the file name of the XML source file. For more information, see <a href="#">Section 15.6.8, "What Happens When You Add a Task Flow Call Activity"</a> .
Reuse	<p>You can identify an entire group of activities as a single entity, an ADF bounded task flow, and reuse the bounded task flow in another application within an ADF region. For example, the Hot Items and Start Shopping tabs on the home page of the Fusion Order Demo application reuse the same task flow embedded in a region. Different parameters are passed to each region to determine the lists of products that display. For more information, see <a href="#">Section 17.2, "Creating an ADF Region"</a>.</p> <p>You can also reuse an existing bounded task flow simply by calling it. For example, one task flow can call another bounded task flow using a task flow call activity or a URL.</p> <p>In addition, you can use task flow templates to capture common behaviors for reuse across different ADF bounded task flows. For more information, see <a href="#">Section 18.13, "Creating a Task Flow Template"</a>.</p>
Parameters and return values	<p>A caller can pass input parameters to an ADF bounded task flow and accept return values from it. For more information, see <a href="#">Section 16.3, "How to Pass Parameters to an ADF Bounded Task Flow"</a>.</p> <p>In addition, you can share data controls between bounded task flows. For more information, see <a href="#">Section 18.3, "Sharing Data Controls Between Task Flows."</a></p>
Transaction management	An ADF bounded task flow can represent a transactional unit of work. You can declaratively specify options on the bounded task flow that determine whether, when entering the task flow, the task flow creates a new transaction, joins an existing one or is not part of the existing transaction. For more information, see <a href="#">Section 18.4, "Managing Transactions"</a> .
Reentry	You can specify options on the bounded task flow that determine whether or not it can be reentered. For more information, see <a href="#">Section 18.5, "Reentering a Bounded Task Flow"</a> .
On-demand loading of metadata	ADF bounded task flow metadata is loaded on demand when entering an ADF bounded task flow.
Security	You can secure an ADF bounded task flow by defining the privileges that are required for someone to use it.

### 14.1.3 Control Flows

A task flow consists of activities and control flow cases that define the transitions between activities. In [Figure 14-5](#), the control flow labeled `toView2` defines the transition between `ViewActivity1` and `ViewActivity2`. `ViewActivity1` displays before `ViewActivity2` when the task flow in [Figure 14-5](#) executes.

**Figure 14-5 Task Flow with Activities and Control Flow Cases**

[Figure 14-5](#) contains a method call (`methodCall1`) that invokes after `ViewActivity2` and before it calls the `taskflowCall1` bounded task flow. In a task flow, you invoke an activity such as a method before or after a page renders. Invoking a method outside of a particular page can facilitate reuse because you can reuse the page in other contexts that don't require the method (for example, a different task flow).

Control flow rules are based on JSF navigation rules, but capture additional information. JSF navigation is always between pages, whereas control flow rules describe transitions between activities. For example, a control flow rule can indicate a transition between a view activity and a subsequent method call activity. Or, it can indicate that control passes from the page to another task flow.

Save point restore, task flow return, and URL view activities cannot be the source of a control flow rule.

The basic structure of a control flow rule mimics a JSF navigation rule. [Table 14-3](#) describes how metadata maps from JSF navigation rules to control flow rules.

**Table 14-3 Mapping of JSF Navigation Rules to Control Flow Rules**

JSF Navigation Rule	Control Flow Rule
Navigation Rule	Control Flow Rule
From View ID	From Activity ID
Navigation Case	Control Flow Case
From Action	From Action
From Outcome	From Outcome
To View ID	To Activity ID

---

**Note:** When using ADF task flows, perform all application navigation using ADF Controller control flow rules instead of using navigation rules in `faces-config.xml`.

ADF Controller delegates navigation handling when no matching control flow cases are found in ADF Controller metadata. However, not all ADF Controller functionality is guaranteed to work correctly if navigation is performed by a non-ADF Controller `NavigationHandler`.

---

A wildcard control flow rule represents a control flow `from-activity-id` that contains a trailing wildcard (`foo*`) or a single wildcard character (`*`). Use the single wildcard character when you want to pass control from any activity in the task flow to the wildcard control flow rule. Alternatively, use a trailing wildcard when you want to constrain the activities that can pass control to the wildcard control flow rule.

In [Figure 14-6](#), the wildcard control flow rule contains a single wildcard character, indicating that control can pass to the activities connected to it in the task flow diagram from any activity within the task flow.

**Figure 14-6 Wildcard Control Flow Rule With Single Wildcard**

The trailing wildcard in [Figure 14-7](#) indicates that control flow can pass to the `loginPage` view from any valid source activity whose `activity-id` begins with the characters `storefront`.

**Figure 14-7 Wildcard Control Flow Rule with Trailing Wildcard**

## 14.2 Creating a Task Flow

A task flow is made up of the task flow itself, plus a number of activities with control flow rules between those activities. In most cases, the majority of the activities are view activities which represent the different pages in the flow. When some method or operation needs to be called, for example before a page is rendered, you use a method call activity with a control flow rule from that activity to the appropriate next activity. When you want to call another task flow, you use a task flow call activity. If the flow requires some sort of branching, you use a router activity. At the end of a bounded task flow, you use a return activity which allows the flow to exit and control is sent back to the flow that called this bounded task flow.

---

---

**Note:** If your application uses Facelets XHTML files in the view layer, you manually configure navigation in a task flow's source file between the view activities that reference these Facelets XHTML files.

---

---

For more detailed information and procedures regarding the individual components of a task flow, including the metadata created for each and additional configuration that you can set, see [Section 14.3, "Adding Activities to a Task Flow."](#)

### 14.2.1 How to Create a Task Flow

The processes for creating ADF bounded and unbounded task flows are similar. The main difference is that you select the **Create as Bounded Task Flow** checkbox in the Create Task Flow dialog to create an ADF bounded task flow.

---

---

**Note:** When you create the project, you may not need to create an unbounded task flow for it. If **ADF Page Flow** is specified as a selected technology on the Technology Scope page of the Project Properties dialog, the new `adfc-config.xml` source file is automatically created within the project. The `adfc-config.xml` source file is the main source file for an unbounded task flow.

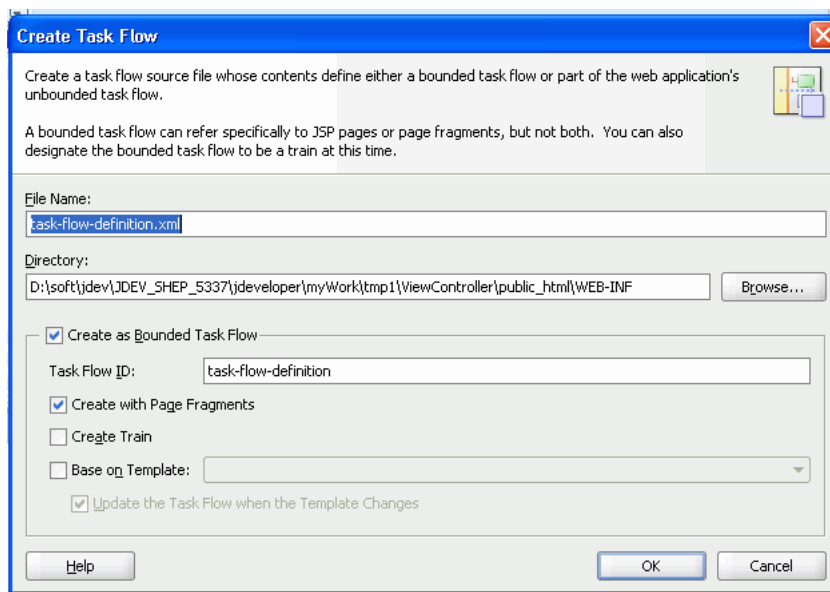

---

---

**To create a task flow:**

1. Create the task flow:
  - a. In the Application Navigator, right-click the project where you want to create the task flow and choose **New**.
  - b. In the New Gallery, expand **Web Tier**, select **JSF** and then **ADF Task Flow** and click **OK**.

The dialog shown in [Figure 14–8](#) displays.

**Figure 14–8 Create Task Flow Dialog**

- c. In the Create Task Flow dialog, the **Create as Bounded Task Flow** checkbox is selected by default. Deselect it to create a source file that will be incorporated into the application's unbounded task flow.

Deselecting the checkbox automatically changes the default value in the **File Name** field. This value will be used to name the XML source file for the ADF task flow you are creating. The XML source file contains metadata describing the activities and control flow rules in the task flow.

**Tip:** The default name for an unbounded task flow is `adf-config.xml`. The default name for the source file for a bounded task flow matches the value specified in the **Task Flow ID** field.

Because a single project can contain multiple task flows, a number may be added to the default value in the **File Name** field in order to give the source file a unique name, for example, `task-flow-definition3.xml`.

Clear the **Create with Page Fragments** checkbox that is selected by default if you want the view activities that you add to the task flow to reference JSF pages. Leave the **Create with Page Fragments** checkbox selected if you want the view activities that you add to the task flow to reference page fragments files (`.jsff`).

- d. Click **OK**.

A diagram representing the task flow displays in the editor.

**Tip:** You can view a thumbnail of the entire task flow diagram by clicking the diagram and then choosing **View > Thumbnail** from the main menu.

- e. After you create the task flow, you can update it using the diagram, overview, and source editors

You can also use the Structure window to update the task flow.

**Tip:** There are other ways to create task flows, for example, by refactoring the contents of an existing ADF task flow into a new task flow. For more information, see [Section 14.5, "Refactoring to Create New ADF Task Flows and Templates"](#).

2. Drag an activity from the ADF Task Flow page in the Component Palette onto the diagram. Normally, you would start with a view activity. For more detailed procedures for adding any type of activity, see [Section 14.3.1, "How to Add Additional Activities to an ADF Task Flow."](#)

- If you drag a view activity onto the diagram, you can double-click it to display the wizard for the page or page fragment that the task flow is configured to invoke. Use the wizard to define characteristics for the page or page fragment. For more information, see [Section 15.2, "Using View Activities"](#).

---

**Note:** You can also add a view activity to a task flow by dragging a page from the Application Navigator and dropping it on the diagram for the task flow.

---

- If you drag a router activity onto the diagram, you can use the Property Inspector to create an expression whose evaluation will determine which control flow rule will be followed. For more information, see [Section 15.4, "Using Router Activities."](#)
  - If you drag a method call activity onto the diagram, you can use the Property Inspector to configure the method to be called. For more information, see [Section 15.5, "Using Method Call Activities."](#)
  - If you drag a task flow call activity onto the diagram, you can double-click it to display the Create Bounded Task Flow dialog where you can define settings for a new bounded task flow. For more information, see [Section 15.6, "Using Task Flow Call Activities"](#).
  - If you are creating a bounded task flow, and you drag a task flow return activity onto the diagram, you can use the Property Inspector to configure the activity. For more information, see [Section 15.7, "Using Task Flow Return Activities."](#)
3. Create control flow cases between the activities (for more information and detailed procedures, see [Section 14.3.3, "How to Add Control Flows"](#)):
    - a. In the ADF Task Flow page of the Component Palette, select **Control Flow Case**.
    - b. On the diagram, click a source activity, for example a view, and then click the destination activity. For example in [Figure 14–15](#), two activities have been linked with a control flow. Both source (`view1`) and the destination (`view2`) activities are linked.
    - c. Set the outcome value, using either the **From Action** attribute (if the outcome is to be determine by a method) or the **From Outcome** attribute (if the outcome can be set as a `String`).
  4. If you are creating a bounded task flow, once that flow is complete, you may want to designate one of the activities as the default activity. Doing so ensures that specific activity will be executed first whenever the task flow is run. By default, the first activity you added to the task flow is the default. To change to a different activity, right-click the appropriate activity in the diagram and choose **Mark**

**Activity > Default Activity.** For more information, see [Section 14.2.3, "What You May Need to Know About the Default Activity in an ADF Bounded Task Flow."](#)

## 14.2.2 What Happens When You Create a Task Flow

A new XML source file is created every time you create a new ADF unbounded or bounded task flow. By default, the XML source file for an ADF unbounded task flow is called `adfc-config.xml`.

As shown in [Example 14–1](#), `<adfc-config>` appears first as the top-level element in all ADF Controller XML source files. Bounded task flows, activities and control flow rules are defined inside the `<adfc-config>` element. Bounded task flows are identified within the source file by the `<task-flow-definition>` metadata element.

### Example 14–1 ADF Bounded Task Flow XML Source File

```
<?xml version="1.0" encoding="windows-1252" ?>
<adfc-config xmlns="http://xmlns.oracle.com/adf/controller" version="1.2" id="__
1">
  <task-flow-definition id="task-flow-definition">
    <use-page-fragments/>
  </task-flow-definition>
</adfc-config>
```

An ADF bounded task flow is identified by its task flow reference, which is comprised of a unique combination of identifier and document name. [Example 14–2](#) shows a sample task flow reference within a task flow call activity.

### Example 14–2 Task Flow Reference

```
<adfc-config xmlns="http://xmlns.oracle.com/adf/Controller" version="1.2">
  <task-flow-definition id="task-flow-definition">
    <use-page-fragments/>
    .
    .
    <task-flow-call id="taskFlowCall">
      <task-flow-reference>
        <document>/WEB-INF/target-task-flow-definition.xml</document>
        <id>my-task-flow</id>
      </task-flow-reference>
    </task-flow-call>
    .
    .
  </task-flow-definition>
</adfc-config>
```

---

---

**Note:** If you use JDeveloper to create the ADF bounded task flow, specify only one ID (indicating one bounded task flow) per document.

---

---

You assign both identifier and document name when you create the ADF bounded task flow. As shown in [Example 14–2](#), the identifier is the value in the **Task Flow ID** field. The document name is the value in the **File Name** field.

### 14.2.3 What You May Need to Know About the Default Activity in an ADF Bounded Task Flow

The default activity is the first activity to execute in an ADF bounded task flow. For example, the default activity always executes first when a task flow call activity passes control to the ADF bounded task flow.

ADF unbounded task flows do not have default activities.

As shown in [Figure 14-9](#), a green circle identifies the default activity in a task flow diagram.

**Figure 14-9** Default Activity in ADF Bounded Task Flow

The first activity that you add to a new ADF bounded task flow diagram is automatically identified as the default activity. You can also right-click any activity in the task flow diagram and choose **Mark Activity > Default Activity**. The default can be any activity type and it can be located anywhere in the control flow of the ADF bounded task flow. To find the default activity, right-click anywhere on the task flow diagram and choose **Go to Default Activity**.

An ADF bounded task flow can have only one default activity. If you mark a second activity as the default, the first is unmarked automatically. To unmark an activity manually, right-click the activity in the task flow diagram and choose **Unmark Activity > Default Activity**.

You should not specify a train stop in the middle of a train as a default activity (for more information, see [Section 18.11, "Creating a Train"](#)).

[Example 14-3](#) contains sample metadata for a default activity called `SurveyPrompt` in a bounded task flow:

**Example 14-3** Default Activity Metadata in a Bounded Task Flow

```
<task-flow-definition id="survey">
  <default-activity>SurveyPrompt</default-activity>
  <view id="SurveyPrompt">
    <page>/SurveyPrompt.jsff</page>
  </view>
  <use-page-fragments/>
</task-flow-definition>
```

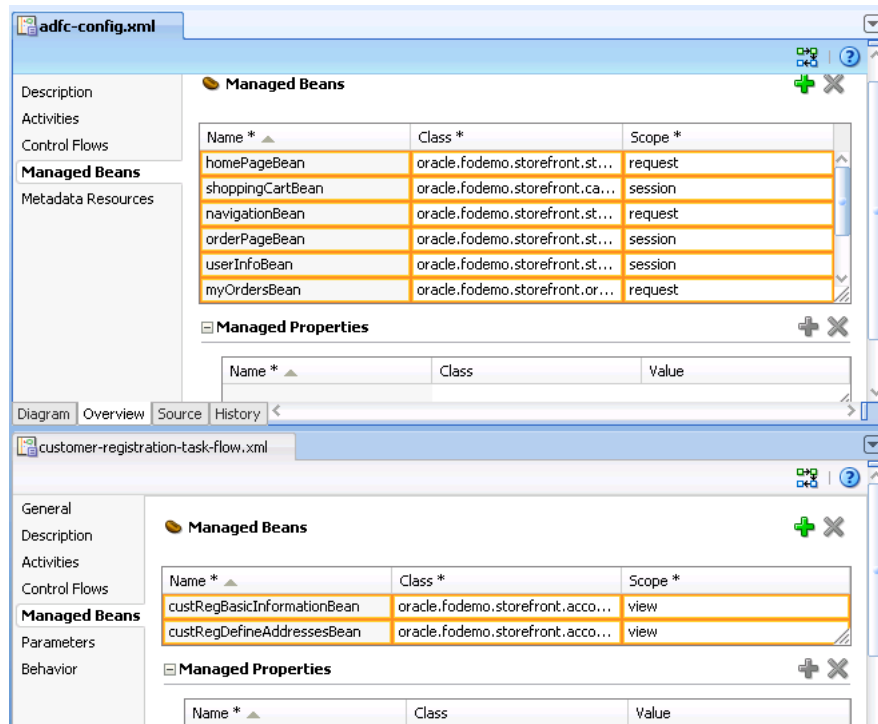

### 14.2.4 What You May Need to Know About Memory Scope for Task Flows

Each task flow in your Fusion web application defines a `pageFlow` scope to manage state. The `pageFlow` scope begins when the task flow begins and ends when the task flow ends. A `pageFlow` scope defines a unique storage area for each instance of a task flow within an application which is used to pass data values between the activities in the task flow. When one task flow calls another, the calling task flow cannot access the

called task flow’s pageFlow scope. This means, for example, that a UI component on a page referenced by a task flow’s view activity cannot access the pageFlow scope of another task flow even if this task flow is an ADF region embedded in the same page as the UI component.

You can register multiple managed beans with task flows. [Figure 14–10](#) shows examples from the Fusion Order Demo application where the default unbounded task flow (`adfc-config.xml`) and the customer registration task flow reference multiple managed beans with varying scope values. You can determine the scope assigned to a managed bean.

**Figure 14–10 Managed Beans Registered with Task Flows**

[Table 14–4](#) lists available scopes for managed beans and describes when it is appropriate to use each scope in a managed bean that you register with a task flow. The table lists the scopes in order of their life span. For example, the application scope has a longer life span than the request scope.

**Table 14–4 Memory Scope for ADF Managed Beans**

Scope	Description
application	The application scope lasts until the application stops. Values that you store in a managed bean with this scope are available to every session and every request that uses the application.  Avoid using this scope in a task flow because it persists beyond the life span of the task flow.

**Table 14–4 (Cont.) Memory Scope for ADF Managed Beans**

Scope	Description
session	<p>The session scope begins when a user first accesses a page in the application and ends when the user's session times out due to inactivity, or when the application invalidates the session.</p> <p>Use this scope only for information that is relevant to the whole session, such as user or context information. Avoid using it to pass values from one task flow to another. Instead, use parameters to pass values between task flows. Using parameters gives your task flow a clear contract with other task flows that call it or are called by it. Another reason to avoid use of session scope is because it may persist beyond the life span of the task flow.</p>
pageFlow	<p>Choose this scope if you want the managed bean to be accessible across the activities within a task flow. A managed bean that has a pageFlow scope shares state with pages from the task flow that access it. A managed bean that has a pageFlow scope exists for the life span of the task flow.</p> <p>If another task flow's page references the managed bean, the managed bean creates a separate instance of this object and adds it to the pageFlow scope of its task flow.</p>
view	<p>Use this scope for managed bean objects that are needed only within the current view activity and not across view activities. It defines scope for each view port that ADF Controller manages, for example, a root browser window or an ADF region.</p> <p>The life span of this scope begins and ends when the current <code>viewId</code> of a view port changes. If you specify <code>view</code>, the application retains managed bean objects used on a page as long as the user continues to interact with the page. These objects are automatically released when the user leaves the page.</p>
request	Use request scope when the managed bean does not need to persist longer than the current request.
backingBean	<p>A backing bean is a convention to describe a managed bean that stores accessors for UI components and event handling code on a JSF page. It exists for the duration of a request and should not be used to maintain state.</p> <p>Use this scope if it is possible that your task flow appears in two ADF regions on the same JSF page and you want to isolate each instance of ADF region.</p>

When you register a managed bean with a task flow, JDeveloper generates an entry similar to the following in the task flow's source file:

```
<managed-bean id="__15">
  <managed-bean-name id="__16">egBackingBean</managed-bean-name>
  <managed-bean-class id="__13">oracle...egBackingBean</managed-bean-class>
  <managed-bean-scope id="__14">backingBean</managed-bean-scope>
</managed-bean>
```

The `<managed-bean-scope>` element holds the value for the scope of the managed bean (`backingBean` in the example).

When you bind a UI component to a managed bean, JDeveloper appends `Scope` to the scope name in the EL expression that it generates to reference the managed bean. For example, the binding attribute of a table component that references the managed bean has the following EL expression:

```
<af:table id="cartTab"
  ...
  binding="#{backingBeanScope.egBackingBean.table}"
  ...
</af:table>
```

Restrict the scope of the managed bean that you reference through a UI component's binding attribute to `backingBean` or `request` scope. Instances of UI components cannot be serialized. Objects in scopes other than `backingBean` and `request` are expected to be serializable. For this reason, you should not bind UI components to managed beans that have a scope other than `backingBean` or `request`. Note that JDeveloper defaults the binding attribute for UI components and region fragments to use the `backingBean` scope.

---

**Note:** Write EL expressions that explicitly qualify the scope to access when writing EL expressions to access custom scopes unique to Oracle ADF (`pageFlow`, `backingBean`, and `view` scopes). For example, write an EL expression to access a `pageFlow` scope as follows:

```
#{pageFlowScope.inpTxttBB.uiComponent}
```

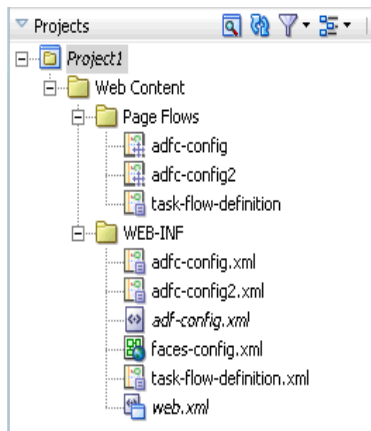

---

## 14.2.5 What Happens at Runtime: Using ADF Task Flows

A single application can have multiple ADF unbounded task flow XML source files and multiple ADF bounded task flow XML source files. The set of files that are combined to produce the ADF unbounded task flow is referred to as the application's *ADF Controller bootstrap configuration files*. An ADF unbounded task flow is assembled at runtime by combining one or more ADF Controller bootstrap configuration files. All activities within the bootstrap configuration files that are not contained within an ADF bounded task flow are considered to be within the ADF unbounded task flow.

The names of the source files within a single application must be different. The example in [Figure 14–11](#) contains two unbounded task flows (`adfc-config`, `adfc-config2`) and a bounded task flow (`task-flow-definition`).

**Figure 14–11** Application with Two ADF Unbounded Task Flow XML Source Files

## 14.3 Adding Activities to a Task Flow

After you create a task flow, you add activities to the task flow and configure the control flow between the activities. The Component Palette in JDeveloper displays available activities and control flows. You drag and drop the activities and control flows from the Component Palette to the diagram for the task flow. You can then configure control flow between the activities so that the task flow performs the task you want it to perform.

### 14.3.1 How to Add Additional Activities to an ADF Task Flow

After you create a task flow, a task flow diagram and the Component Palette automatically display. The task flow diagram is a visual editor on which you can add the activities and control flows for the task flow. You can add them to the diagram by dragging them from the Component Palette.

#### To add an activity to an ADF task flow:

1. In the Application Navigator, double-click a task flow source file.

For example, [Figure 14-12](#) shows the editor and the Component Palette that automatically appears when you double-click a task flow source file (`task-flow-definition.xml`).

**Figure 14-12 Task Flow Diagram**

2. Drag an activity from the ADF Task Flow page in the Component Palette onto the diagram.
  - If you drag a view activity onto the diagram, you can double-click it to display the Create JSF Page Fragment wizard, where you can define characteristics for the page or page fragment. For more information, see [Section 15.2, "Using View Activities"](#).
  - If you drag a task flow call activity onto the diagram, you can double-click it to display the Create Bounded Task Flow dialog where you can define settings for a new bounded task flow. For more information, see [Section 15.6, "Using Task Flow Call Activities"](#).

**Tip:** Each activity you drag to the task flow diagram can display optional status icons and a tooltip that provides additional information about the activity. For example, after you drag a view activity to the task flow diagram, it may display a warning icon until you associate it with a JSF page.

To turn on the icons, select **Show** at the top of the task flow diagram, and then select **Status** and one of the following:

- **Error:** Displays when there is a problem in the task flow metadata which prevents it from running. For example, a view activity in the metadata can contain a `<bookmark>` or `<redirect>` element, but not both.
- **Warning:** Displays when an activity is incomplete. For example, a view activity that doesn't have a physical page associated with it or a task flow call that doesn't have a task flow reference associated with it are both considered incomplete activities. The resulting task flow metadata may prevent it from running.

You can drag your mouse over a secondary icon to read a tooltip describing the icon's meaning.

### 14.3.2 What Happens When You Add an Activity to an ADF Task Flow

As shown in [Figure 14-13](#), the Component Palette contains separate sections for components and diagram annotations. The contents of the **Components** section differ slightly depending on whether you are creating an ADF bounded or an unbounded task flow. For example, if you are creating an ADF bounded task flow, the **Components** section contains an additional task flow return activity.

[Figure 14-13](#) displays the activities you can add to an ADF task flow.

**Figure 14-13 ADF Unbounded Task Flow Component Palette**

### 14.3.3 How to Add Control Flows

A *control flow case* identifies how control passes from one activity to the next in the application. To create a control flow, you select **Control Flow Case** in the ADF Task Flow page of the Component Palette and drag it from a source activity to a target

activity. Dragging the control flow case between the two activities automatically creates a control flow comprised of the following:

- `control-flow-rule`: Identifies the source activity using a `from-activity-id`.
- `control-flow-case`: Identifies the target activity using a `to-activity-id`.

Once you identify an activity as the source for a control flow case, any additional control flow case that has the activity as its source is organized under the same control flow rule. In [Figure 14-14](#), there is one `control-flow-rule` that identifies `view1` as the source activity, and two `control-flow` cases that identify the target activities `view2` and `view3`.

**Tip:** You can drag and drop an activity onto an existing control flow. This splits the existing control flow into two, with the activity in the center.

There can be multiple control flow cases for each control flow rule.

**Figure 14-14** Multiple Control Flow Cases from a Single Activity

[Example 14-4](#) shows the metadata for the multiple control flow cases shown in [Figure 14-14](#).

**Example 14-4** Control Flow Rule Metadata Within a Bounded Task Flow

```

<task-flow-definition id="task-flow-definition">
.
.
.
  <control-flow-rule>
    <from-activity-id>view1</from-activity-id>
    <control-flow-case>
      <from-outcome>toView2</from-outcome>
      <to-activity-id>view2</to-activity-id>
    </control-flow-case>
    <control-flow-case>
      <from-outcome>toView3</from-outcome>
      <to-activity-id>view3</to-activity-id>
    </control-flow-case>
  </control-flow-rule>
.
.
.

```

```
</task-flow-definition>
```

Use the task flow diagram as a starting point for creating basic control flows between activities. Later, you can edit control flow properties in the Structure window, Property Inspector or overview editor for the task flow diagram.

**To define a control flow case directly in the task flow diagram:**

1. In the Application Navigator, double-click a task flow source file, for example, `adfc-config.xml`, to display the task flow diagram.
2. In the ADF Task Flow page of the Component Palette, select **Control Flow Case**.
3. On the diagram, click a source activity, for example a view, and then click the destination activity. For example in [Figure 14–15](#), two activities have been linked with a control flow. Both source (`view1`) and the destination activities are linked.

**Figure 14–15 Control Flow Case**

JDeveloper adds the control flow case to the diagram. Each line that JDeveloper adds between activities represents a control flow case. The arrow indicates the direction of the control flow case. The `from-outcome` contains a value that can be matched against values specified in the `action` attribute of UI components.

4. To change the `from-outcome`, select the text next to the control flow in the diagram. By default, this text is the wildcard `*` character as shown in [Figure 14–15](#). You can overwrite the text with a new `from-outcome`, for example, `toView2`.
5. To change the `from-activity-id` (identifies the source activity) or `to-activity-id` (identifies the target activity), drag either end of the arrow in the diagram to a new activity.

**Tips:** After you select the control flow in the task flow diagram, you can also change its properties in the Property Inspector or the Structure window. The Structure window is helpful for displaying the relationship between control rules and cases.

You can also click **Control Flows** on the overview editor for the task flow diagram to add cases, as shown in [Figure 14–16](#). To add a case, make sure that the **From Activity** (source activity) and the **To Activity** (target activity) for the rule have already been added to the task flow.

**Figure 14–16 Control Flows on Overview Editor for the Task Flow**

Control Flows + X

From Activity ▲	From Outcome	To Activity
view1	toView2	view2
view1	toView3	view3

### 14.3.4 How to Add a Wildcard Control Flow Rule

You can add a wildcard control flow rule to an unbounded or bounded task flow. The steps for adding it are similar to those for adding any activity to a task flow diagram.

#### To add a wildcard control flow rule:

1. In the Application Navigator, double-click a task flow source file, for example, `adfc-config.xml`, to display the task flow diagram.
2. Drag **Wildcard Control Flow Rule** from the ADF Task Flow page of the Component Palette and drop it on the task flow diagram.
3. Select **Control Flow Case** from the ADF Task Flow page list of the Component Palette.
4. In the task flow diagram, drag the control flow case from the wildcard control flow rule to the target activity.

The target can be any activity type.

5. By default, the label below the wildcard control flow rule is `*`, which corresponds to a single `*` character in its `from-activity-id` value. To change this value, select the wildcard control flow rule in the diagram. In the Property Inspector for the wildcard control flow rule, enter a new value in the **From Activity ID** field. For example, enter `project*`. The wildcard must be a trailing character in the new label.

**Tip:** You can also change the `from-activity-id` value in the overview editor for the task flow diagram.

### 14.3.5 What Happens When You Create a Control Flow Rule

Understanding the elements that define the rules in the source file for the task flow helps when creating control flow rules directly in the ADF task flow diagram, ADF task flow overview editor, or Structure window, or when adding them directly in the XML source file. [Example 14-5](#) shows the general syntax of a control flow rule element in the task flow source file.

#### Example 14-5 Control Flow Rule Syntax in the Source File

```
<control-flow-rule>
  <from-activity-id>from-view-activity</from-activity-id>
  <control-flow-case>
    <from-action>actionmethod</from-action>
    <from-outcome>outcome</from-outcome>
    <to-activity-id>destinationActivity</to-activity-id>
  </control-flow-case>
</control-flow-rule>
```

Control flow rules can consist of the following metadata:

- `control-flow-rule`: A mandatory wrapper element for control flow case elements.
- `from-activity-id`: The identifier of the activity where the control flow rule originates, for example, `source`.

A trailing wildcard (\*) character in `from-activity-id` is supported. The rule will apply to all activities that match the wildcard pattern. For example, `login*` matches any logical activity ID name beginning with the literal `login`. If you specify a single wildcard character in the metadata (not a trailing wildcard), the control flow automatically converts to a wildcard control flow rule activity in the diagram. For more information, see [Section 14.3.4, "How to Add a Wildcard Control Flow Rule"](#).

- `control-flow-case`: A mandatory wrapper element for each case in the control flow rule. Each case defines a different control flow for the same source activity. A control flow rule must have at least one control flow case.
- `from-action`: An optional element that limits the application of the rule to outcomes from the specified action method. The action method is specified as an EL binding expression, such as `{backing_bean.cancelButton_action}`.

In [Example 14-5](#), control passes to `destinationActivity` only if `outcome` is returned from `actionmethod`.

The value in `from-action` applies only to a control flow originating from a view activity, not from any other activity types. Wildcards are not supported in `from-action`.

- `from-outcome`: Identifies a control flow case that will be followed based on a specific originating activity outcome. All possible originating activity outcomes should be accommodated with control flow cases.

If you leave both the `from-action` and the `from-outcome` elements empty, the case applies to all outcomes not identified in any other control flow cases defined for the activity, thus creating a default case for the activity. Wildcards are not supported in `from-outcome`.

- `to-activity-id`: A mandatory element that contains the complete identifier of the activity to which the navigation is routed if the control flow case is performed. Each control flow case can specify a different `to-activity-id`.

### 14.3.6 What Happens at Runtime: Evaluating Control Flow Rules

At runtime, ADF Controller evaluates control flow rules from the most specific to the least specific match to determine the next transition between activities. Evaluation is based on the following priority, which is similar to that for JSF navigation rules:

1. `from-activity-id, from-action, from-outcome`
2. `from-activity-id, from-outcome`
3. `from-activity-id`

ADF Controller first searches for a match in all three elements: `from-activity-id`, `from-action`, and `from-outcome`. If there is no match, ADF Controller searches for a match in just the `from-activity-id` and `from-outcome` elements. Finally, ADF Controller searches for a match in the `from-activity-id` element alone.

If ADF Controller cannot find a control flow rule within its metadata to match a request, it will allow the standard JSF navigation handler to find a match.

An unbounded task flow can have more than one ADF Controller XML source file. Because control flow rules can be defined in more than one ADF Controller XML source file, similar rules may be defined in different files. If there is a conflict in which two or more cases have the same `from-activity-id`, and the same `from-action` or `from-outcome` values, the last case (as listed in the `adfc-config.xml`,

bootstrap, or bounded task flow source file) is used. If the conflict is among rules defined in different source files, the rule in the last source file to be loaded is used.

## 14.4 Testing ADF Task Flows

The procedure for running and debugging task flows differs depending on whether the task flow is bounded or unbounded, whether it contains pages or page fragments, or whether it accepts input parameters.

The Configure Default Domain dialog displays the first time you run the application and start a new domain in Integrated WebLogic Server. Use the dialog to define an administrator password for the new domain. Passwords you enter can be eight characters or more and must have a numeric character.

### 14.4.1 How to Run a Bounded Task Flow That Contains Pages

You can run or debug an ADF bounded task flow that contains view activities that are pages.

For information on running a bounded task flow that contains view activities that are page fragments, see [Section 14.4.2, "How to Run a Bounded Task Flow That Uses Page Fragments"](#).

---

---

**Note:** You can select a view activity inside an ADF task flow diagram or the Application Navigator and choose **Run** to run an ADF bounded task flow.

In an ADF bounded task flow, you must designate the view as a default activity and run the ADF unbounded task flow from the Application Navigator. For more information, see [Section 14.2.3, "What You May Need to Know About the Default Activity in an ADF Bounded Task Flow"](#).

If the first activity that runs in the ADF task flow is an activity type other than view, you must use an ADF bounded task flow.

---

---

#### To run or debug a bounded task flow that uses pages:

- In the task flow diagram, right-click the task flow and choose either **Run** or **Debug**.
- You can also run the task flow directly by entering its URL in the browser, for example.  
`http://mymachine:8988/StoreFrontModule-StoreFrontUI-context-root/faces/home`
- You can right-click the bounded task flow in the Application Navigator and choose either **Run** or **Debug**.

### 14.4.2 How to Run a Bounded Task Flow That Uses Page Fragments

ADF bounded task flows that use page fragments are intended to run only within an ADF region. A *page fragment* is a JSF JSP document that is rendered as content in another JSF page. For more information, see [Section 17.1.3.1, "Page Fragments and ADF Regions"](#).

**To run or debug a bounded task flow that uses page fragments:**

1. Create a JSF page containing a region that is bound to the bounded task flow. When you drop a bounded task flow containing page fragments onto a JSF page, JDeveloper does this automatically for you.
2. Create a view activity in the project's unbounded task flow that refers to the page. See [Section 14.3.1, "How to Add Additional Activities to an ADF Task Flow"](#) for more information.
3. Right-click the view activity in the Application Navigator or in the task flow diagram and choose **Run**.

### 14.4.3 How to Run a Bounded Task Flow That Has Parameters

Before you run a bounded task flow with parameters, you must first run a bounded task flow containing pages. For more information about bounded task flow input parameters, see [Chapter 16, "Using Parameters in Task Flows"](#).

**To run a bounded task flow that has input parameter definitions:**

1. If the bounded task flow has defined input parameters, the Set Run Configuration dialog displays after you select either **Run** or **Debug**, as shown in [Figure 14–17](#).

**Figure 14–17** Set Run Configuration dialog

2. In the **Input Parameters** list, enter values that you want to be passed as input parameters to the task flow. If you do not specify a value, the input parameter is not used when calling the bounded task flow.

Each required input parameter in the list displays with an asterisk, as shown in [Figure 14–17](#). You must specify the parameter value as a literal string. You cannot specify an EL expression.

3. Click **OK**.

### 14.4.4 How to Run a JSF Page

You can run a JSF page by right-clicking the page in the Application Navigator and choosing **Run**. However, if the page contains navigation UI components, such as a button or link, navigation is not guaranteed to work.

**To run a JSF Page with fully functioning navigation:**

1. Create a bounded or unbounded task flow. See [Section 14.2.1, "How to Create a Task Flow"](#) for more information.
2. Add a view activity to the task flow. See [Section 14.3.1, "How to Add Additional Activities to an ADF Task Flow"](#) for more information.

3. In the Application Navigator, select the JSF page you want to run and drop it on top of the view activity in the task flow diagram.  
This associates the view activity with the JSF page.
4. In the diagram, right-click the view activity and choose **Run**.

#### 14.4.5 How to Run an ADF Unbounded Task Flow

To run or debug an unbounded task flow, you must select a specific view activity with which to start.

##### To run a view activity in an ADF unbounded task flow:

- In the task flow diagram, right-click the view activity and choose either **Run** or **Debug**.  
The unbounded task flow runs beginning with the selected view activity.
- If you have selected something other than a single view activity (or have nothing selected), you are prompted to select one in the Set Run Configuration dialog.

#### 14.4.6 How to Set a Run Configuration for a Project

A *run configuration* contains settings that determine how projects run, such as specifying the first activity to run in a task flow. You can define one or more run configurations for a project. Within a run configuration, you can designate an ADFc source file as the default run target. When you run the project, the source file is the first to run.

##### To define a default task flow run target:

1. Select the project in the Application Navigator.
2. From the main menu, choose **Run > Choose Active Run Configuration > Manage Run Configurations**.
3. In the Manage Run Configurations dialog, choose **Run/Debug/Profile** and choose **New**.
4. In the New dialog, enter the name for the new run configuration.
5. If you want to base the new configuration on an existing one, choose a configuration in the **Copy Configuration Settings** dropdown list.
6. Click **OK** to exit the dialog.
7. Click **Edit**.
8. In the **Default Run Target** dropdown list in the Edit Run Configuration dialog, select a source file for the ADF task flow that should run first when you run the project.  
Once you choose a task flow, you can set a view activity (for an unbounded task flow) or input parameters (for bounded task flows).
9. In the left panel of the Edit Configuration dialog, click **ADF Task Flow**.
10. In the **Task Flow** dropdown list, located on the right panel, select the ADF task flow containing the run target.
11. If you are running an unbounded task flow, the Edit Run Configuration dialog displays the **Run Target Activity** list. Select the view activity that will run first in the application.

**12. Click Open.**

The next time you run the project, the saved run configuration will be available in the **Run > Choose Active Run Configuration** menu.

If you are running a bounded task flow that has been set up to accept input parameters, a dialog will display a section for specifying values for all input parameters defined for the bounded task flow. See [Chapter 14.4.3, "How to Run a Bounded Task Flow That Has Parameters"](#) for more information.

## 14.5 Refactoring to Create New ADF Task Flows and Templates

You can convert existing activities, JSF page flows, and JSF pages into new ADF Controller components such as ADF bounded task flows and task flow templates.

### 14.5.1 How to Create an ADF Bounded Task Flow from Selected Activities

You can create a new ADF bounded task flow based on activities you select in an existing ADF bounded or unbounded task flow.

**To create a new ADF bounded task flow from selected activities:**

1. In the editor, open the ADF unbounded or bounded task flow containing the activities you want to use in the new task flow.
2. In the task flow diagram, select one or more activities.

**Tip:** To select multiple activities in a diagram, click the left mouse button and drag the cursor over the activities.

You can also press the Ctrl key while selecting each activity.

3. Right-click your selection and choose **Extract Task Flow**.

The Create Task Flow dialog displays, which allows you to create a new ADF bounded task flow. For more information, see [Section 14.2, "Creating a Task Flow"](#).

When you are done, the new ADF bounded task flow displays in the editor. The properties shown in [Table 14–5](#) are automatically set for the new task flow.

**Table 14–5 Properties Updated in the New ADF Bounded Task Flow**

Property	Value
Task flow definition ID	Value you entered in the <b>Task Flow ID</b> field in the Create Task Flow dialog.
Default activity	Determined as the destination of all incoming control flow cases. If more than one destination exists, an error is flagged and the entire operation is rolled back.
Control flow rules	Control flow cases with selected source activities are included in the new ADF bounded task. A <i>source activity</i> is an activity from which a control flow leads. The new ADF bounded task flow includes the following types of control flow cases: <ul style="list-style-type: none"> <li>▪ Both the source and target activities in the control flow case were selected to create the new task flow.</li> <li>▪ Only the source activity was selected to create the new task flow. Destinations are changed to the corresponding new task flow return activities added for each outcome.</li> </ul>

The following changes automatically occur in the originating task flow (the task flow containing the activities you selected as the basis for the new task flow):

- A new task flow call activity is added to the originating task flow. The task flow call activity calls the new ADF bounded task flow.
- The selected activities are removed from the originating task flow.
- Existing control flow cases associated with the activities you selected are removed from the originating task flow. They are replaced with new control flow cases:
  - An incoming control flow case to the old activity is redirected to the new task flow call activity.
  - An outgoing control flow case from the old activity is redirected from the new task flow call activity.

## 14.5.2 How to Create a Task Flow from JSF Pages

You can create a new ADF bounded task flow based on selected pages in a JSF page flow. Only pages that are part of a flow (that is, those that are linked by JSF navigation cases) are converted to view activities in the new task flow.

### To create a new task flow from selected JSF pages in a page flow.

1. In the editor, open the page flow containing the pages you want to use in the new bounded task flow.
2. In the task flow diagram, select one or more JSF pages.

**Tip:** To select multiple elements in a diagram, click the left mouse button and drag the cursor over the elements.

You can also press the Ctrl key while selecting each element.

3. Right-click your selection and choose **Generate ADF Task Flow**.

The Create Task Flow dialog displays, which allows you to create a new ADF unbounded or bounded task flow. For more information, see [Section 14.2, "Creating a Task Flow"](#).

## 14.5.3 How to Convert ADF Bounded Task Flows

You can convert an existing ADF bounded task flow to an unbounded task flow or change whether the views it contains are pages or page fragments. [Table 14–6](#) describes the results of each conversion.

**Table 14–6** *Converting ADF Bounded Task Flows*

Conversion	Result
ADF bounded task flow to unbounded task flow	Loses all metadata not valid for unbounded task flows, such as parameter definitions and transactions.
ADF bounded task flow to use JSF pages	Converts page fragments associated with any view activities in the task flow to JSF pages. Old page fragments are saved if you select the <b>Keep Page Fragment</b> checkbox. New JSF page names default to the name of the old page fragment.
ADF bounded task flow to use page fragments	Converts all pages associated with view activities in the ADF bounded task flow to page fragments. Old pages are saved if you select the <b>Keep Page</b> checkbox. New page fragment names default to the name of the old page

**To convert an ADF bounded task flow:**

1. In the editor, open the bounded task flow diagram.
2. Right-click anywhere in the diagram other than on an activity or control flow.
3. Choose a menu item such as **Convert to Unbounded Task Flow** or **Convert to Task Flow with Page Fragments**.

If the bounded task flow contains fragments, the menu item will be **Convert to Task Flow with Pages**.

## 14.6 What You Should Know About Task Flow Constraints

Table 14–7 summarizes assumptions about and constants for using task flows, activities, and other associated ADF Controller features.

**Table 14–7 ADF Controller Features Assumptions and Constraints**

Feature Area	Assumption/Constraint	Description
ADF Controller objects and diagram UI	JSF view layer	ADF Controller operates only in a JSF 1.2 environment. Oracle’s web-based Fusion web application strategy focuses on JSF as the sole view layer technology.
	Dependent on ADF Faces	ADF Controller extensions are implemented on top of ADF Faces. They are dependent on the ADF Faces libraries, but ADF Controller can run against any JSF implementation, providing these libraries are present.
	Navigation and state management encapsulated	ADF Controller encapsulates both navigation and, to some extent, state management. JSF and the Servlet API are still available for the basic management of state at the application, session, and request levels.
	Model layer	ADF model layer is used to implement the application’s model layer.
	Dependent on MDS	ADF Controller metadata is stored in MDS. However, MDS is currently not capable of loading <code>faces-config.xml</code> .  If the customization features that MDS provides are required, you should use ADF task flows exclusively in order to define managed beans and control flow rules.
	No supported migration path from struts or model 1	There is no support for a migration from Struts or Model 1 to the Fusion ADF Controller.  However, you can create a new ADF bounded task flow based on selected pages in a JSF page flow. For more information, see <a href="#">Section 14.5.2, "How to Create a Task Flow from JSF Pages"</a> .

**Table 14–7 (Cont.) ADF Controller Features Assumptions and Constraints**

<b>Feature Area</b>	<b>Assumption/ Constraint</b>	<b>Description</b>
Bounded task flow	Exposed as page flow-scoped state	ADF Controller manages implementation of a page flow scoped-state. Any auto-management functions provided by the framework, such as back button support and state cleanup function, assume page flow-scoped data. In order for an application to fully implement such functions for all of its pages, the entire application should be exposed as an ADF bounded task flow, using nested bounded task flows as needed. The application should store any state requiring versioning within the page flow scope.
Page flow scope	Transactional boundaries	The developer will use ADF bounded task flows to manage transaction boundaries.
	Access availability within ADF lifecycle	An application cannot attempt to access the page flow scope early in the ADF lifecycle before ADF Controller is ready to provide it.  Page flow scope is not guaranteed to be available for access until after Before and After listeners have executed on the Restore View phase. ADF Controller uses before and after listeners on the Restore View phase to synchronize the server side state with the request. This is where things such as browser back-button detection and bookmark dereference are handled.
Navigation	Navigation	When using ADF Controller task flows, perform all application navigation should be performed using ADF Controller control flow rules instead of using navigation rules in <code>faces-config.xml</code> .  Although the ADF Controller delegates navigation handling when no matching control flow cases are found in ADF Controller metadata, not all ADF Controller functionality is guaranteed to work correctly if navigation is performed by a non-ADF Controller <code>NavigationHandler</code> .

---

## Working with Task Flow Activities

This chapter describes how to use activities in your ADF task flows. The chapter contains detailed information about each task flow activity that displays in the Component Palette and its properties.

This chapter includes the following sections:

- [Section 15.1, "Introduction to Activity Types"](#)
- [Section 15.2, "Using View Activities"](#)
- [Section 15.3, "Using URL View Activities"](#)
- [Section 15.4, "Using Router Activities"](#)
- [Section 15.5, "Using Method Call Activities"](#)
- [Section 15.6, "Using Task Flow Call Activities"](#)
- [Section 15.7, "Using Task Flow Return Activities"](#)
- [Section 15.8, "Using Save Point Restore Activities"](#)
- [Section 15.9, "Using Parent Action Activities"](#)
- [Section 15.10, "Using Task Flow Activities with Page Definition Files"](#)

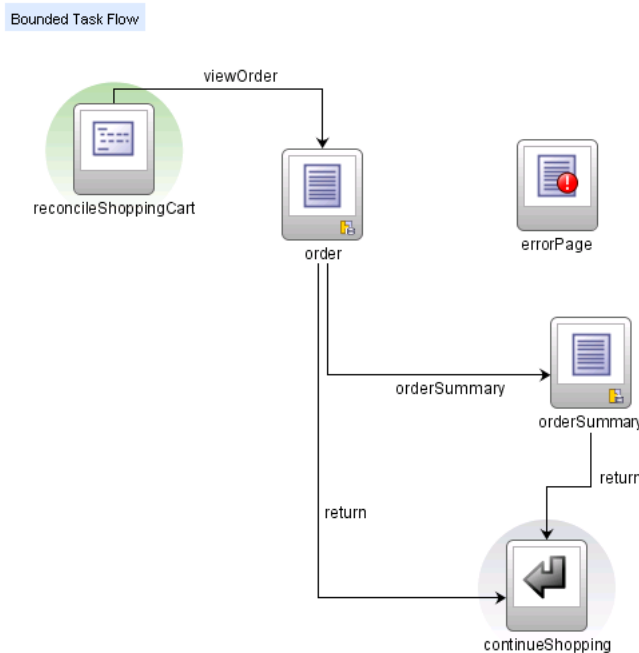

### 15.1 Introduction to Activity Types

An *activity* represents a piece of work that is performed when the task flow runs. It displays in the task flow's overview editor as a node. You can add most activities to both bounded and unbounded task flows, although some activity types can be added only to a bounded task flow.

The bounded task flow shown in [Figure 15-1](#) contains activities that run in order to check out of the application:

1. A call to a method synchronizes the items a user may have chosen before logging in with those selected after logging in
2. A page (view activity) that displays the items the user has currently selected and another page that summarizes the order
3. An activity that causes control to return back to the calling unbounded task flow shown in [Figure 15-1](#)

**Figure 15–1 Checkout Bounded Task Flow in Fusion Order Demo Application**

A task flow consists of activities and control flow cases that define the transitions between activities. Table 15–1 describes the types of activities and control flows you can add to a task flow.

**Table 15–1 Task Flow Activities and Control Flows**

Icon	Component Name	Description
	Method Call	Invokes a method, typically a method on a managed bean. A method call activity can be placed anywhere within an application’s control flow to invoke application logic based on control flow rules. See <a href="#">Section 15.5, "Using Method Call Activities"</a> for more information.
	Parent Action	Allows a bounded task flow to generate outcomes that are passed to its parent view activity. See <a href="#">Section 15.9, "Using Parent Action Activities"</a> for more information.
	Router	Evaluates an EL expression and returns an outcome based on the value of the expression. For example, a router in a credit check task flow might evaluate the return value from a previous method call and generate success, failure, or retry outcomes based on various cases. These outcomes can then be used to route control to other activities in the task flow. See <a href="#">Section 15.4, "Using Router Activities"</a> for more information.
	Save Point Restore	Restores a previous persistent save point, including application state and data, in an application supporting save for later functionality. See <a href="#">Section 18.9, "Using Save Points in Task Flows"</a> for more information.

**Table 15–1 (Cont.) Task Flow Activities and Control Flows**

Icon	Component Name	Description
	Task Flow Call	Calls a bounded task flow from an unbounded task flow or another bounded task flow. See <a href="#">Section 15.6, "Using Task Flow Call Activities"</a> for more information.
	Task Flow Return	Identifies when a bounded task flow completes and sends control flow back to the caller. (Available for bounded task flows only). See <a href="#">Section 15.7, "Using Task Flow Return Activities"</a> for more information.
	URL View	Redirects the root view port (for example, a browser page) to any URL-addressable resource, even from within the context of an ADF region. See <a href="#">Section 15.3, "Using URL View Activities"</a> for more information.
	View	Displays a JSF page or page fragment. Multiple view activities can represent the same page or same page fragment. See <a href="#">Section 15.2, "Using View Activities"</a> for more information. See <a href="#">Section 20.3, "Creating a Web Page"</a> for more information about pages and page fragments.
	Control Flow Case	Identifies how control passes from one activity to the next in the application. See <a href="#">Section 14.1.3, "Control Flows"</a> for more information.
	Wildcard Control Flow Rule	Represents a control flow case that can originate from any activities whose IDs match a wildcard expression. For example, it can represent a control case <code>from-activity-id</code> containing a trailing wildcard such as <code>foo*</code> . See <a href="#">Section 14.3.4, "How to Add a Wildcard Control Flow Rule"</a> for more information.

[Table 15–2](#) describes the annotations (notes and attachments) you can add to a task flow.

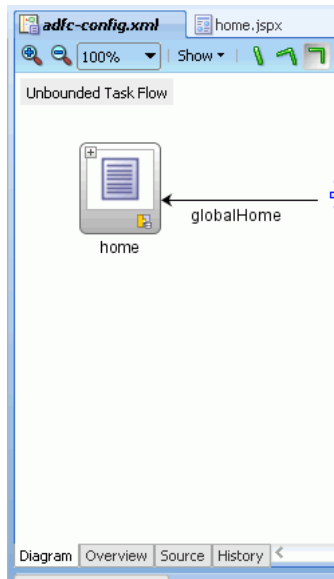

**Table 15–2 Task Flow Diagram Annotations**

Icon	Icon Name	Description
	Note	Adds a note to the task flow diagram. You can select the note in the diagram to add or edit text.
	Note Attachment	Attaches an existing note to an activity or a control flow case in the diagram.

## 15.2 Using View Activities

The primary type of task flow activity is a view, which displays a JSF page or page fragment. A *page fragment* is a JSF JSP document that is rendered as content in another JSF page. Page fragments are typically used in bounded task flows. The bounded task flow can be added to a page as region. For more information, see [Section 17.2, "Creating an ADF Region"](#).

[Figure 15–2](#) shows the home view activity in the Fusion Order Demo application.

**Figure 15–2 View Activity**

**Tip:** Click the + icon in the upper-left part of the view activity to see a thumbnail preview of the referenced page or page fragment.

A view activity is associated in metadata with a physical JSF page or page fragment. The view activity is identified by an `id` attribute. The page or page fragment name is identified by a `<page>` element in the task flow metadata:

```
<view id="home">
  <page>/home.jspx</page>
</view>
```

The view activity ID and page name do not have to be the same.

The file extension for a page fragment is `.jsff`:

```
<view id="Home">
  <page>WEB-INF/Home.jsff</page>
</view>
```

### 15.2.1 Adding a View Activity

The steps for adding a view activity are similar to those for adding any activity to a task flow diagram. For more information, see [Section 14.3.1, "How to Add Additional Activities to an ADF Task Flow"](#). After you add the view activity, you can double-click it to display the Create JSF JSP Page wizard, which enables you to create a new page or page fragment. You also use the wizard to define characteristics for the page or page fragment. JDeveloper automatically associates the completed page or page fragment with the view activity.

You can also drag an existing page or page fragment from the Application Navigator and drop it on top of a view activity.

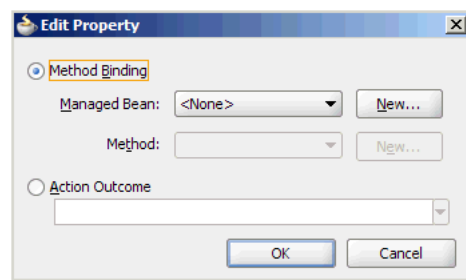

If you drag a page or page fragment to any other location on the diagram, a new view activity associated with the page or page fragment is automatically created. During creation, a default `id` for the view activity is automatically generated (for example `Home`) based on the name of the page or page fragment.

## 15.2.2 Transitioning Between View Activities

*Transitioning* refers to one view activity passing control to another view activity. For example, control flow can be initiated at runtime by selecting a UI component on a page, such as a button or link. The **Action** attribute of the UI component should be set to the corresponding control flow case `from-outcome` leading to the next task flow activity. You can navigate from a view activity to another activity using either a constant or dynamic value on the **Action** attribute of the UI component.

- **Constant:** The value of the **Action** attribute of the component is an action outcome, as shown in [Figure 15-3](#). Action outcome is a constant value that always triggers the same control flow case. When an end user clicks the component, the activity specified in the control flow case is performed. There are no alternative control flows.

**Figure 15-3** Edit Property dialog

- **Dynamic:** The value of the **Action** attribute of the component is bound to a managed bean or a method. The value of the method binding determines the next control flow case that should be performed.

For example, the method might verify user input on a page and return one value if the input is valid and another value if the input is invalid. Each of these different action values could trigger different navigation cases, causing the application to navigate to one of two possible target pages.

For more information about components that are bound to data control operations, see [Section 28.2, "Creating Command Components to Execute Methods"](#).

### 15.2.2.1 How to Transition to a View Activity

Before you begin, you should already have a target view activity, as well as a JSF page on which you will add a component. The component's action will be based on the `from-outcome` of the control flow case leading to the target activity.

#### To transition to a view activity:

1. Add a UI component to the JSF page using one of the following techniques:
  - Open the JSF page. From the **ADF Faces Common Components** list in the Component Palette, drag a navigation UI component such as a button or link onto the JSF page.
  - Open the JSF page. From the Data Controls panel, drag and drop an operation or a method onto the JSF page and choose **Rich Command Button** or **Rich Command Link** from the context menu.
2. Select the UI component and open the Property Inspector.
3. On the Common page, expand the **Button Action** section.

4. From the dropdown menu next to **Action**, choose **Edit**.
5. Select **Action Outcome**.
6. From the **Action Outcome** dropdown list select a value.

The list contains control flow case `from-outcomes` already defined for the view activity associated with the page.

**Tips:** The `action` attribute of the UI component can be bound either to a literal string to hardcode a navigation case, or it can be bound to a method binding expression that points to a method, which takes no arguments and returns a String. It can't be bound to any other type of EL expression.

7. Click **OK**.

### 15.2.2.2 What Happens When You Transition Between Activities

[Example 15–1](#) contains an example of a control flow case defined in the XML source file for a bounded or unbounded task flow.

#### **Example 15–1 Control Flow Case Defined in XML Source File**

```
<control-flow-rule>
  <from-activity-id>Start</from-activity-id>
  <control-flow-case>
    <from-outcome>toOffices</from-outcome>
    <to-activity-id>WesternOffices</to-activity-id>
  </control-flow-case>
</control-flow-rule>
```

As shown in [Example 15–2](#), a button on a JSF page associated with the Start view activity specifies `toOffices` as the **action** attribute. When the user clicks the button, control flow passes to the `WesternOffices` activity specified as the `to-activity-id` in the control flow metadata.

#### **Example 15–2 Static Navigation Button Defined in a View Activity**

```
<af:commandButton text="Go" action="toOffices">
```

## 15.2.3 Bookmarking View Activities

Bookmarking is available only for view activities within unbounded task flows.

When an end user bookmarks a page associated with a view activity, the URL that displays in the browser's address field for the view is saved as the bookmark. In most cases, this URL cannot be used to redisplay the page associated with the view. For example, the URL may contain Microsoft OS Windows state information that cannot be used to redisplay the page.

The bookmark URL should contain information that enables dynamic content on the page to be reproduced. For example, if an end user bookmarks a page displaying a customer's contact information, the bookmark URL needs to contain not only the page but also some identifier for the customer. This will enable contact information for the same customer to display when he returns to the page using the bookmark.

To ensure that the URL for a page displayed in a browser can be used as a bookmark, identify the view activity associated with the page as bookmarkable.

At runtime, you can identify if a view activity within an unbounded task flow has been designated as bookmarkable using the `ViewBookmarkable()` method. The method is located off the view port context.

After you designate a view activity as bookmarkable, you can optionally specify one or more URL parameters. The value of `url-parameter` is an EL expression. The EL expression specifies where the parameters that will be included in the URL are retrieved when the bookmarkable URL is generated. The EL expression also stores a value from the URL when the bookmarkable URL is dereferenced. The `converter` option identifies a method that performs conversion and validation when parameters are passed via bookmarkable view activity URLs.

In addition, you can specify an optional method that is invoked after updating the application model with submitted URL parameter values and before rendering the view activity. You can use this method to retrieve additional information based on URL parameter key values.

Instead of designating the view activity as bookmarkable, you can specify the `redirect` option. `redirect` causes ADF Controller to create a new browser URL for the view activity. The original URL for the view activity is no longer used. For more information, see [Section 15.2.3.2, "How to Specify HTTP Redirect"](#) for more information.

[Example 15-3](#) contains the URL syntax for a bookmarked view activity.

**Example 15-3 Unbounded Task Flow View Activity URL Syntax**

```
<server root>/<app_context>/faces/<view activity id>?<param name>=<param value>&...
```

The syntax of the URL for the bookmarked view activity is:

- `<server root>`: Provided by customization at site or admin level, for example, `http://mycompany.com/internalApp`.
- `<app context>`: The web application context root, for example, `myapp`. The context root is the base path of a web application. For example, `<app_context>` maps to the physical location of the WEB-INF node on the server.
- `faces`: The faces servlet mapping. The value in `faces` points to the node containing the `faces-config.xml` configuration file.
- `<view activity id>`: The identifier for the bookmarked view activity, for example, `edit-customers`.
- `<param name>`: The name of the bookmarked view activity URL parameter, for example, `customer-id`.
- `<param value>`: The parameter value, derived from an EL expression, for example, `{pageFlowScope.employee.id}`. The value of the EL expression must be capable of being represented as a string.

[Example 15-4](#) contains a sample URL for a bookmarkable view activity in an unbounded task flow.

**Example 15-4 Sample URL for Bookmarkable View Activity**

```
http://mycompany.com/internalApp/MyApp/faces/edit-customers?customer-id=1234&...
```

### 15.2.3.1 How to Create a Bookmarkable View Activity

To create a bookmarkable view activity, designate a view activity as bookmarkable, specify a URL parameter in the bookmark, and specify a method that is executed after the bookmark is dereferenced.

#### To designate a view activity as bookmarkable:

1. In the unbounded task flow diagram, select the view activity.
2. In the Property Inspector, click **Bookmark**.
3. In the **bookmark** dropdown list, select **true**.
4. Expand the **URL Parameters** section to add optional URL parameters that will be included in the URL for the bookmarked view activity:
  - **name**: A name for the parameter.
  - **value**: A settable EL expression that, when evaluated, specifies the parameter value, for example, `#{pageFlowScope.employeeID}`. The value must be capable of being represented as a string.
  - **converter**: (optional): An EL expression to an object that implements `oracle.adf.controller.URLParameterConverter`.

The **value** is where the parameters that will be included in the URL are retrieved from when the bookmarkable URL is generated. In addition, parameters are stored here when the bookmarkable URL is dereferenced.

If the EL expression entered in value returns `NULL`, the parameter is omitted from the bookmarked view activity URL.

The **name** and **value** are used to append a bookmark parameter to the view activity URL, as shown in [Example 15-4](#).

5. In the **converter** field, you can enter an optional value binding to use for each bookmark URL parameter value, for example, `#{pageFlowScope.employee.idConverter}`.

A URL parameter converter's `getAsObject()` method takes a single string value as its input parameter and returns an object of the appropriate type. ADF Controller invokes the converter method on the URL parameters before applying the parameter value to the application's model objects. Similarly, the converter's `getAsString()` method takes an object as its input parameter and returns a string representation that is used on the URL.

In a JSF application, data values are converted and validated using the converters and validators specified with the UI components on the submitting page. In a Fusion web application using a bookmark URL, there is no submitting page to handle the conversion and validation. Therefore, you have the option of designating a converter to use for each URL parameter.

### 15.2.3.2 How to Specify HTTP Redirect

The `redirect` option specified for a view activity indicates that ADF Controller should issue an HTTP redirect for a view activity request. The redirected request creates a new browser URL for the view activity. The original view URL is no longer used.

When specified, the redirect will occur from a client `GET` request. For HTTP `GETs`, the `#{bindings}` EL scope is invalid until ADF Controller and ADF Model layer set up a new bindings context for the page. Therefore, the redirected input parameter for the view activity cannot be mapped.

A view activity can be identified as either bookmarkable or identified with the redirect option, but not both.

---

**Note:** If you want `http://www.mycompany.org/x.html` to instead display what is at `http://www.mycompany.org/y.html`, do not use refresh techniques such as:

```
<META HTTP-EQUIV=REFRESH CONTENT="1;
URL=http://www.example.org/bar">
```

This technique could adversely affect back button behavior. If an end user clicks a browser back button, the refresh occurs again, and navigation is forward, not backward as expected.

In this situation, use HTTP redirect instead.

---

#### To specify HTTP redirect for a view activity:

1. In the unbounded task flow diagram, select the view activity.
2. In the Property Inspector, click **Common**.
3. In the **redirect** dropdown list, select **true**.

#### 15.2.3.3 What Happens When You Designate a View as Bookmarkable

When you designate a view activity as bookmarkable, a bookmark element is added to the metadata for the view activity, as shown in [Example 15–5](#). The bookmark element can optionally contain metadata specifying URL parameters and a method that is executed after the bookmark is dereferenced.

##### **Example 15–5 Sample Metadata for a Bookmarkable View Activity**

```
<view id="employee-view">
  <page>/folderA/folderB/display-employee-info.jsp</page>
  <bookmark>
    <url-parameter>
      <name>employee-id</name>
      <value>#{pageFlowScope.employee.id}</value>
      <converter>#{pageFlowScope.employee.validateId}</converter>
    </url-parameter>
    <method>#{pageFlowScope.employee.queryData}</method>
  </bookmark>
</view>
```

## 15.3 Using URL View Activities

You can use a URL view activity to redirect the root view port (for example, a browser page) to any URL-addressable resource, even from within the context of an ADF region. URL addressable resources include:

- Bounded task flows
- View activities in an unbounded task flow
- Addresses external to the current web application (for example, <http://www.oracle.com>)

To display the resource, you must specify an EL expression that is evaluated at runtime to generate the URL to the resource. In addition, you can specify EL

expressions that, when evaluated, are added as parameters and parameter values to the URL.

A URL view activity redirects the client regardless of the view port (root view port or an ADF region) from which it is executed. The `<redirect>` element of a view activity performs in a similar way, except that it can be used only if the view activity is within the root view port. The `<redirect>` element is ignored within the context of an ADF region. For more information, see [Section 15.2.3.2, "How to Specify HTTP Redirect"](#).

Redirecting elsewhere within the same application using URL view activities (not the `<redirect>` element) is handled similarly to back button navigation since the task flow stack is cleaned up. Redirecting out of the web application is handled like dereferencing a URL to a site external to the application.

### 15.3.1 How to Add a URL View Activity to a Task Flow

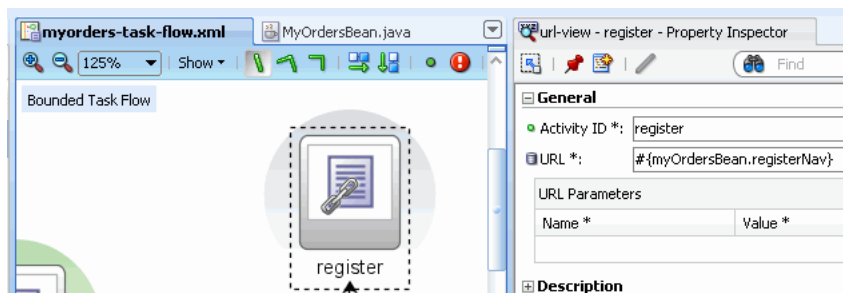

You can add a URL view activity to a bounded or unbounded task flow.

#### To add a URL view activity to a task flow:

1. Drag a URL view activity from the ADF Task Flow page in the Component Palette onto the diagram.
2. In the task flow diagram, select the URL view activity.
3. On the General page of the Property Inspector, in the **Activity ID** field, enter an ID that identifies the URL view activity.
4. Click the button next to the **URL** field to invoke the Expression Builder and write an EL expression that renders a URL at runtime.

For example, [Figure 15–4](#) shows a URL activity (**register**) in the Fusion Order Demo application's `myorders-task-flow.xml` bounded task flow with an EL expression (`{myOrdersBean.registerNav}`) that retrieves a URL at runtime.

**Figure 15–4 URL View Activity**

5. Expand the **URL Parameters** section to add optional URL parameters that will be included in the URL:
  - **name:** A name for the parameter.
  - **value:** An EL expression that, when evaluated, generates the parameter value.
  - **converter:** A settable EL expression that, when evaluated, specifies a method to perform conversion and validation when parameters are passed via bookmarkable view activity URLs. For more information, see [Section 30.3, "Enabling ADF Security"](#).

### 15.3.2 Constructing a URL for Use Within a Portlet

When constructing a URL for use in a task flow's URL view activity that may be used within the context of a portlet, construct the URL by calling one of the following:

- `ControllerContext.getLocalViewActivityURL()`
- `ControllerContext.getGlobalViewActivityURL()`, passing in the target `viewId`

or a fully qualified absolute URL, a context path relative URL, or a URL that is relative to the current view.

---

**Note:** If you call the `ControllerContext.getLocalViewActivityURL()` or `ControllerContext.getGlobalViewActivityURL()` methods to construct the redirect URL, do not call `ExternalContext.encodeActionURL()` with the response before calling `ExternalContext.redirect()`.

This is because the methods already incorporate the necessary encoding of the URL.

---

When a URL view activity is used within a task flow in a portlet, the following behavior occurs:

- If the redirect URL refers to a location within the portlet application and doesn't contain a `queryString` parameter named `x_DirectLink` whose value is `true`, then the portlet within the containing page will navigate to this new view.
- Otherwise, a client redirect is issued, resulting in the user being directed away from the application or containing page and to the URL.

## 15.4 Using Router Activities

You can use a router activity to declaratively route control to activities based on logic specified in an EL expression. Figure 15-5 shows how a router might be used to branch to multiple control flows leading from it to different activities.

**Figure 15-5 Router for Alternate Control Flow Cases**

Each control flow can correspond to a different router case. Each router case contains the following elements, which are used to choose the activity to which control is next routed:

- **expression:** An EL expression evaluating to either `true` or `false`, for example, `#{(pageFlowScope.welcomeUserRegistrationBean.userSelection eq 'Customer')}`

The first expression that evaluates to `true` is used to determine the corresponding outcome.

- **outcome:** A value returned by the router activity if the EL expression evaluates to `true`, for example, `newCustomer`.

If the router outcome matches a `from-outcome` on a control flow case, control passes to the activity that the control flow case points to. If none of the cases for the router activity evaluates to `true`, or if no cases are specified, the outcome specified in the router **default outcome** field (if any) is used.

For example, suppose you want to base control flow on whether a user clicks the **Create a New Customer** or **Create a New Employee** button on the `welcomeUserRegistration` page fragment shown in [Figure 15-5](#).

You could add an EL expression for one of the router cases that evaluates whether the user entered in the input text field on the user registration page fragment is a new customer. You would next specify an expected `outcome`, for example, `newCustomer`. As shown in [Figure 15-5](#), if the expression evaluates to `true`, control passes to the `customer-registration-task-flow` task flow call activity, based on the control flow case `from-outcome, newCustomer`.

---

---

#### Best Practice:

If your routing condition can be expressed in EL, use a router.

Using a router allows you to do more when you are designing the task flow that contains it. The router activity allows you to show more information about the condition on the task flow, thus making it more readable and useful to someone else who looks at your diagram.

Using a router activity also makes it easier to modify your application later. For example, you may want to modify or add a routing condition later.

---

---

#### To define a control flow using the router activity:

1. From the ADF Task Flow page of the Component Palette, drag a router activity to the task flow diagram.
2. In the task flow diagram, select the router activity.
3. From the main menu, choose **View > Property Inspector**.
4. On the Common page of the Property Inspector, enter an **id**.

The ID is an identifier that is used to reference the router activity within the metadata, for example, `router1`.

5. Click the **Add** icon next to **Cases**.
6. Specify values for each of the router's cases.

A case is a condition that, when evaluated to `true`, returns an outcome. For each case, you must enter:

- **expression:** An EL expression evaluating to `true` or `false`.

The expression can reference an input text field in a view activity. For example, suppose the value of the field is `#{pageFlowScope.value}`. The expression could be `#{pageFlowScope.value=='view2'}`, meaning that the specified outcome will be returned if a user enters `view2` in the field.

- **outcome:** Returned by the router activity when its corresponding expression evaluates `true`.

You must account for each outcome with a matching control flow case or a wildcard control flow rule in your task flow diagram. For example, for each case `outcome`, you can ensure there is a corresponding `from-outcome` specified for a control flow case element leading from the router activity in the diagram. In [Figure 15-5](#), the value for both the case outcome and the control flow case element `from-outcome` is `newCustomer`. This ensures that control flow will pass to the `newCustomer` activity, the target of the control flow element.

7. In the Property Inspector, enter a default-outcome.

This outcome is returned if none of the cases for the router activity evaluates to `true`, or if no cases are specified.

[Example 15-6](#) identifies a default outcome, `toRegion3`. Control flow goes to the case whose `from outcome` is `toRegion3`. `Router1` is returned by the router activity when none of its cases evaluates to `true`.

#### **Example 15-6 Router Metadata Defining a Default Outcome**

```
<router id="Router1">
  <case>
    <expression>#{binding.Region.InputValue='1'}</expression>
    <outcome>toRegion1</outcome>
  </case>
  <case>
    <expression>#{binding.Region.InputValue='2'}</expression>
    <outcome>toRegion2</outcome>
  </case>
  <case>
    <expression>#{binding.Region.InputValue='3'}</expression>
    <outcome>toRegion3</outcome>
  </case>
  <default-outcome>toRegion3</default-outcome>
</router>
```

## 15.5 Using Method Call Activities

In a standard JSF application, application logic can be invoked only from actions specified within the JSF page markup. A *method call* activity allows you to call a custom or built-in method that invokes application logic from anywhere within an application's control flow. You can specify methods to perform tasks such as initialization before displaying a page, cleanup after exiting a page, exception handling, and so forth.

As shown in [Figure 15-6](#), the Fusion Order Demo application uses a method call activity in the Employee Registration bounded task flow. The activity calls `userRegistrationCreate`, a method exposed on the `StoreServiceAM` data control.

**Figure 15–6 Method Call Activity in employee-registration-task-flow**

You can set an outcome for the method that specifies a control flow case to pass control to after the method finishes. For more information, see [Section 14.1.3, "Control Flows"](#). You can specify the outcome as either:

- **fixed-outcome:** On successful completion, the method always returns this single outcome, for example, `success`. If the method doesn't complete successfully, an outcome isn't returned. If the method type is void, you must specify a fixed-outcome, not a `to-string`.
- **to-string:** If specified as true, the outcome is based on calling the `toString()` method on the Java object returned by the method. For example, if `toString()` returns `editBasicInfo`, navigation goes to the `editBasicInfo` control flow case shown in [Figure 15–6](#).

As shown in [Example 15–7](#), the method outcome and the method result are two different values. The `<return-value>` element specifies where to put the result of the `calculateSalesTax` method. The `<outcome>` element indicates which control flow case to use after the method finishes.

**Example 15–7 Method Call Activity Metadata with Return and Outcome Elements**

```

<method-call id="calculateSalesTax">
  <method>#{pageFlowScope.taxService.calculateSalesTax}</method>
  <return-value>#{pageFlowScope.result}</return-value>
  <outcome>
    <fixed-outcome>gotoError</fixed-outcome>
  </outcome>
</method-call>
  
```

### 15.5.1 How to Add a Method Call Activity

Before you begin, you should have already created a bounded or unbounded task flow. For more information, see [Section 14.2, "Creating a Task Flow"](#). Drag a method call activity from the Component Palette to the task flow diagram. You can associate the method call activity with an existing method by dropping a data control operation from the Data Controls panel directly onto the method call activity in the task flow diagram.

In the Fusion Order Demo application, for example, you could drag a `setCurrentRowWithKey` or `setCurrentRowWithKeyValues` operation to the diagram from the Data Control Iterator to display or select the current row in a table.

---

**Note:** Parameters for data control method parameters are defined in the page definition for the corresponding page rather than within ADF Controller metadata. For more information, see [Section 28.3, "Setting Parameter Values Using a Command Component"](#).

---

You can also drag methods and operations directly to the task flow diagram. A new method call activity is created automatically after you drop it on the diagram. You can specify an EL expression and other options for the method.

**Tip:** To identify the method that a method call activity invokes, right-click the method call activity in the diagram of the task flow and choose **Go to Method**. JDeveloper navigates to the method that the method call activity invokes.

#### To add a method call activity to a task flow:

1. In the Component Palette, drag a method call activity from the ADF Task Flow page to the diagram for the task flow.

The method call activity optionally displays a default id, `methodCall1`, and a warning icon that indicates that a method EL expression has not yet been specified.

For more information about turning on the warning icons, see [Section 14.3.1, "How to Add Additional Activities to an ADF Task Flow"](#).

2. If you want to change the default ID, click the text that appears under the method call activity in the task flow diagram.

You can enter a name for the method call, for example, `addItemToCart`.

3. In the task flow diagram, select the method call activity.
4. On the General page of the Property Inspector, enter an EL expression for the method in the **Method** field.

For example, you can enter an EL binding expression such as `#{bindings.addItemstoCart.execute}`.

---

**Note:** The `bindings` variable in the EL expression indicates an ADF model binding from the current binding container. In order to specify the `bindings` variable, you must specify a binding container definition or page definition. See [Section 12.6, "Working with Page Definition Files"](#).

---

You can also use the Edit Property dialog box shown in [Figure 15-7](#) to build the EL expression for the method:

- a. In the General page of the Property Inspector, from the dropdown menu next to the **Method** field, choose **Expression Builder**.

- b. In the Expression Builder dialog, expand a node, for example, **ADF Bindings** and choose a method. Or, under the **ADF Managed Beans** node, navigate to the managed bean containing the method you want to call and select the method.
- c. Click **Insert Into Expression**.

The Expression Builder dialog should look similar to [Figure 15-7](#). In [Figure 15-7](#), for example, the `addItemToCart` method and `shoppingCartBean` combine to form the EL expression shown at the top of the Expression Builder.

**Figure 15-7 EL Expression for Method in Expression Builder Dialog**

- d. Click **OK**.

**Tip:** If the method call activity is going to invoke a managed bean method, double-click the method call activity in the diagram for the task flow. This invokes a dialog where you can specify the managed bean method you want to invoke.

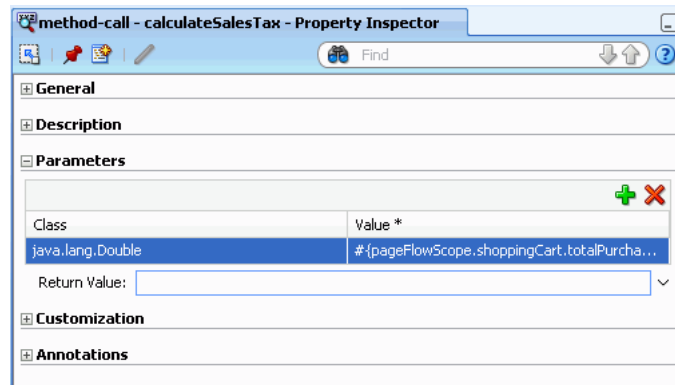

5. In the General page of the Property Inspector, specify one of the following in the Outcome section:
  - **Fixed Outcome:** On successful completion, the method always returns this single outcome, for example, `success`. If the method doesn't complete successfully, an outcome isn't returned. If the method type is void, you must specify a **fixed-outcome**, not a **to-string**.
  - **toString():** If you select **true**, the outcome is based on calling the `toString()` method on the Java object returned by the method.

## 15.5.2 How to Specify Method Parameters and Return Values

You can specify parameters and return values for a method. [Figure 15–8](#) shows a single parameter defined for a method called `calculateSalesTax`. The **value** field contains an EL expression that evaluates to the parameter value.

**Figure 15–8 Method Parameters in Property Inspector**

If parameters haven't already been created by associating the method call activity to an existing method, add the parameters yourself.

### To add method parameters:

1. Follow the steps in [Section 15.5.1](#) to add a method call activity to a task flow diagram.
2. In the task flow diagram, select the method call activity.
3. In the Property Inspector, click **Parameters**.
4. On the Parameter page, expand the **Parameters** section.
5. Click the plus **Add** icon.
6. In the **class** field, enter the parameter class, for example, `java.lang.Double`.
7. In the **value** field, enter an EL expression indicating where the value for the parameter will be retrieved, for example, `#{pageFlowScope.shoppingCart.totalPurchasePrice}`.

**Tip:** You can click the icon next to the **value** field and choose **Expression Builder** to search for the method parameters.

8. In the **return-value** field, enter an EL expression indicating where to store the method return value, for example, `#{pageFlowScope.Return}`.
9. Click **OK**.
10. Repeat the above steps to add additional parameters.

## 15.5.3 What Happens When You Add a Method Call Activity

After you specify parameters and return values for a method, the XML source file is updated. [Example 15–8](#) shows how a method call to `userRegistrationCreate` appears in the XML source file for a bounded task flow.

**Example 15–8 Call to userRegistrationCreate method**

```

<method-call id="userRegistrationCreate">
  <method>#{bindings.userRegistrationCreate.execute}</method>
  <outcome>
    <fixed-outcome>editBasicInfo</fixed-outcome>
  </outcome>
</method-call>

```

## 15.6 Using Task Flow Call Activities

You can use a task flow call activity to call a bounded task flow from either an unbounded or bounded task flow. A task flow call activity allows you to call a bounded task flow located within the same or a different application.

The called bounded task flow executes its default activity first. There is no limit to the number of bounded task flow that can be called. For example, a called bounded task flow can call another bounded task flow, which can call another, and so on.

To pass parameters into a bounded task flow, you must specify input parameter values on the task flow call activity. These values must correspond to the input parameter definitions on the called bounded task flow. For more information, see [Section 15.6.3, "How to Specify Input Parameters on a Task Flow Call Activity"](#).

- The value on the task flow call activity **Input Parameter** specifies where the value will be taken from within the calling task flow.
- The value on the **Input Parameter Definition** for the called task flow specifies where the value will be stored within the called bounded task flow once it is passed.

**Tip:** When a bounded task flow is associated with a task flow call activity, input parameters are automatically inserted on the task flow call activity based on the input parameter definitions defined on the bounded task flow. Therefore, the application developer needs only to assign values to the task flow call activity input parameters.

By default, all objects are passed by reference. Primitive types (for example, int, long, or boolean) are always passed by value.

The technique for passing return values out of the bounded task flow to the caller is similar to the way that input parameters are passed. See [Section 16.4, "Specifying Return Values"](#) for more information.

### 15.6.1 How to Call a Bounded Task Flow Using a Task Flow Call Activity

Add a task flow call activity to the calling bounded or unbounded task flow to call a bounded task flow.

**To call a bounded task flow:**

1. Open the calling task flow in the diagram editor.
2. In the ADF Task Flow page of the Component Palette, drag a **Task Flow Call** activity and drop it on the calling task flow.
3. Identify the called task flow using one of the following techniques:
  - In the task flow diagram, double-click the task flow call activity.

The Create Bounded Task Flow dialog displays, where you specify options for creating a new bounded task flow.

- Drag an existing bounded task flow from the Application Navigator and drop it on the task flow call activity.

**Tips:** You can drop a bounded task flow on a page or page fragment. If the bounded task flow consists of pages (not page fragments), you can choose to add a Go Link or Go Button UI component on the page where you drop the task flow. An end user can click the button or link to call the task flow. This may in turn automatically generate the task flow call activity if the page is already associated with an existing view activity in a task flow.

You cannot drop a bounded task flow from one application to a task flow diagram contained in another application using the Application Navigator, even though both applications appear in the navigator. In addition, you cannot drop a bounded task flow contained in one project onto a task flow diagram contained in another project.

Instead, you can package the bounded task flow in an ADF library, then reuse it in your current application or project. You can then drag the bounded task flow from the Resource Catalog or from the Component Palette page that is created when you import the library. For more information, see [Section 33.1.2, "Using the Resource Palette"](#).

- If you know the name of the bounded task flow that you want to invoke, carry out the following steps:
  - a. In the task flow diagram, select the task flow call activity.
  - b. On the General page of the Property Inspector, select **Static** from the Task Flow Reference dropdown list.
  - c. In the **Document** field, enter the name of the source file for the bounded task flow to call. For example, `called-task-flow-definition.xml`.
  - d. In the **ID** field, enter the bounded task flow ID contained in the XML source file for the called bounded task flow, for example, `targetTaskFlow`.
- If you do not know the name of the bounded task flow to invoke and it is dependent on an end user selection at runtime, carry out the following steps:
  - a. In the task flow diagram, select the task flow call activity.
  - b. On the General page of the Property Inspector, select **Dynamic** from the Task Flow Reference dropdown list.
  - c. Select **Expression Builder** from the dropdown menu displayed to the right of the **Dynamic Task Flow Reference** property.
  - d. Write an EL expression that identifies the ID of the bounded task flow to invoke at runtime.

[Figure 15-9](#) shows the checkout-task-flow task flow call activity in an unbounded task flow of the Fusion Order Demo application. This task flow call activity invokes the checkout-task-flow located in the `checkout-task-flow.xml` file.

**Figure 15–9 Task Flow Call Activity That Invokes a Bounded Task Flow**

## 15.6.2 What Happens When You Call a Bounded Task Flow Using a Task Flow Call Activity

JDeveloper generates metadata entries in the source file for the task flow that calls the bounded task flow. [Example 15–9](#) shows an example from the Fusion Order Demo application's `adfc-config.xml` that references the `checkout-task-flow.xml` bounded task flow. At runtime, the task flow call activity calls the `checkout` bounded task flow.

### **Example 15–9 Task Flow Call Activity in Fusion Order Demo Application's `adfc-config.xml` File**

```
<task-flow-call id="checkout-task-flow">
  <task-flow-reference>
    <document>/WEB-INF/checkout-task-flow.xml</document>
    <id>checkout-task-flow</id>
  </task-flow-reference>
</task-flow-call>
```

## 15.6.3 How to Specify Input Parameters on a Task Flow Call Activity

The suggested method for mapping parameters between a task flow call activity and its called bounded task flow is to first specify input parameter definitions for the called bounded task flow. Then you can drag the bounded task flow from the Application Navigator and drop it on the task flow call activity. The task flow call activity input parameters will be created automatically based on the bounded task flow's input parameter definition. For more information, see [Section 16.3, "How to Pass Parameters to an ADF Bounded Task Flow"](#).

You can, of course, first specify input parameters on the task flow call activity. Even if you have defined them first, they will automatically be replaced based on the input parameter definitions of the called bounded task flow, once it is associated with the task flow call activity.

If you haven't yet created the called bounded task flow, you may still find it useful to specify input parameters on the task flow call activity. Doing so at this point allows you to identify any input parameters you expect the task flow call activity to eventually map when calling a bounded task flow.

### **To specify input parameters on a task flow call activity:**

1. Select the task flow call activity in the diagram for the task flow.
2. In the Property Inspector, expand the **Parameters** section and click the **Add** icon to enter a name for the parameter.

**Tip:** Dropping a bounded task flow on a task flow call activity in a diagram automatically populates the name field.

3. Enter a parameter value, for example, `{pageFlowScope.callingTaskflowParm}`.

The value specifies where the parameter value will be taken from within the calling task flow.

By default, all objects are passed by reference. Primitive types (for example, `int`, `long`, or `boolean`) are always passed by value.

4. After you have specified an input parameter, you can specify a corresponding input parameter definition for the called bounded task flow. For more information, see [Section 16.3, "How to Pass Parameters to an ADF Bounded Task Flow"](#).

### 15.6.4 How to Call a Bounded Task Flow Using a URL

You can call a bounded task flow that does not use page fragments (`.jsff`) in another web application using a URL. You use a task flow call activity to call the bounded task flow that you want to invoke. You write an EL expression for the task flow call activity's `remote-app-url` property that, when evaluated, returns a URL.

In addition to writing a value for the `remote-app-url` property, you specify values for task flow reference properties that identify the bounded task flow to call. The task flow reference and the `remote-app-url` property are combined at runtime to generate a URL to the called bounded task flow in the remote web application.

You also need to set visibility properties for the bounded task flow in the remote web application that you want to call so that it invokes when it receives the URL generated from the task flow call activity in the calling task flow.

Be aware that JSF portlets provide all content from the same web application. As a result, do not configure your web application to invoke a remote task flow using a URL if plan to use your web application in a JSF portlet.

#### To call a bounded task flow using a URL:

1. Open the task flow in your web application that you want to configure to invoke a bounded task flow in a remote web application.
2. In the ADF Task Flow page of the Component Palette, from the Activities panel, drag a **Task Flow Call** activity and drop it on the diagram for the task flow.
3. In the Property Inspector, expand the **General** section and write values for the properties to invoke a bounded task flow.

For more information, see [Section 15.6.1, "How to Call a Bounded Task Flow Using a Task Flow Call Activity"](#).

4. For the **Remote Application URL** property, use the Expression Builder to write an EL expression that, when evaluated, returns a string with the parts required to construct a URL of the remote web application.

For example, the following example EL expression invokes a managed bean method that returns a string with the parts required to construct a URL:

```
{myOrdersBean.createOrder}
```

5. Open the bounded task flow that you specified values for in step 3.

---

---

**Note:** The bounded task flow you specify cannot use page fragments (.jspx).

---

---

6. In the Structure window, right-click the node for the bounded task flow (task flow definition) and choose **Go to Properties**.
7. In the Property Inspector, expand the **General** category and set values for the following properties:
  - **URL Invoke:** select `url-invoke-allowed` from the dropdown list if you want to allow a URL to invoke the bounded task flow. Select `url-invoke-disallowed` if you do not want to allow a URL to invoke the bounded task flow. Selecting this value returns a HTTP 403 status code if a URL attempts to invoke the bounded task flow. The default value (calculated) allows a URL to invoke the bounded task flow if the bounded task flow does not specify an initializer and it has a view activity as its default activity. If the bounded task flow does not meet these conditions, a HTTP 403 status code is returned. Selecting `url-invoke-allowed` or `url-invoke-disallowed` overrides the default behavior.
  - **Library Internal:** set to `true` if you want the bounded task flow to be internal when you package it in an ADF Library JAR. The default value is `false`.  
For more information about packaging a bounded task flow in an ADF Library JAR, see [Section 33.2, "Packaging a Reusable ADF Component into an ADF Library"](#).
8. Save and close the bounded task flow.

### 15.6.5 What Happens When You Configure a Bounded Task Flow to be Invoked by a URL

JDeveloper generates metadata entries in the source file of the task flow that invokes the task flow call activity to the bounded task flow in a remote web application.

[Example 15–10](#) shows an example entries for a task flow call activity.

**Example 15–10 Metadata Entries for a Task Flow Call Activity to a Bounded Task Flow**

```
<task-flow-call id="createOrder">
  <task-flow-reference>
    <document id="__6">myorders-task-flow.xml</document>
    <id id="__5">myorders-task-flow</id>
  </task-flow-reference>
  <remote-app-url id="__7">#{myOrdersBean.createOrder}</remote-app-url>
</task-flow-call>
```

The `createOrder` method in [Example 15–10](#) returns a string with the URL syntax required to invoke a bounded task flow. For more information about the URL syntax, including descriptions of the required parts in the returned string and an example URL, see [Section 15.6.6, "What You May Need to Know About Calling a Bounded Task Flow Using a URL."](#)

JDeveloper also generates entries in the source file for the bounded task flow to invoke when you configure it so it can be called by a URL. [Example 15–11](#) shows sample metadata entries that allow a bounded task flow to be invoked by a URL.

**Example 15–11 Metadata Entries to Allow a URL Invoke a Bounded Task Flow**

```
<task-flow-definition id="task-flow-definition3">
  <visibility id="__2">
    <url-invoke-allowed/>
    <library-internal/>
  </visibility>
</task-flow-definition>
```

**15.6.6 What You May Need to Know About Calling a Bounded Task Flow Using a URL**

Adding a context parameter in your local application's deployment descriptor may ease the administration of interaction with a remote web application.

**Context Parameter for Remote Web Application**

Consider adding a context parameter to the deployment descriptor (`web.xml`) for your Fusion web application (local application) if you use a URL to invoke a bounded task flow in another Fusion web application (remote application). Set the value of the context parameter to the URL of the remote application. Use the context parameter name when writing EL expressions in the local application, as shown in the following example where `remoteAppUrl` is the name of the context parameter:

```
#{initParam.remoteAppUrl}
```

If the URL of the remote application changes, you can update the context parameter to reference the changed URL.

**URL Syntax to Invoke a Bounded Task Flow**

Typically, you write an EL expression that references a managed bean method which, in turn, retrieves the required parts of the URL or you could write an EL expression that renders the URL directly, as shown in [Example 15–12](#).

**Example 15–12 Example URL to Invoke a Bounded Task Flow**

```
http://somecompany.com/internalApp/MyApp/faces/adf.task-flow?adf.tfId=displayHelp&
adf.tfDoc=%2FWEB-INF%2Fdisplayhelp.xml&topic=createPurchaseOrder
```

[Example 15–13](#) describes the parts of the URL syntax to invoke a bounded task flow.

**Example 15–13 URL Syntax for a Call to a Bounded Task Flow Using Named Parameters**

```
<server root>/<app_context>/faces/adf.task-flow?adf.tfid=<task flow definition
ID>&adf.tfDoc=<document name>&<named parameter>=<named parameter value>
```

The following list describes each part of the URL syntax in [Example 15–13](#):

- `<server root>`: Provided by customization at site or admin level. For example:  

```
http://mycompany.com/internalApp
```

The `<server root>` value depends on the application server where you deploy the bound task flow. The bounded task flow URL is a resource within the JSF servlet's URL path.
- `<app context>`: The Web application context root, for example, `MyApp`. The context root is the base path of a Web application.
- `faces`: Faces servlet mapping.

- `adf.task-flow`: A reserved keyword that identifies the ADF Controller for the remote web application.
- `adf.tfId`: A URL parameter that supplies the task flow ID to call.
- `<task flow ID>`: The identifier of the bounded task flow to call, for example, `displayHelp`. This is the same task flow ID that is used when calling locally. Note that this identifier is not the same as the task flow call activity instance ID. The parameter value must be represented as a string.
- `adf.tfDoc`: A URL parameter that supplies the document name containing the bounded task flow ID to be called.
- `<document name>`: A document name containing the bounded task flow ID to be called, for example, `%2FWEB-INF%2FtoUppercase%2FdisplayHelp.xml`. If you are handcrafting the bounded task flow URL, you are responsible for the appropriate encoding.
- `<named parameter>`: (optional) The name of an input parameter definition for the called bounded task flow, for example, `topic`. You must supply all required input parameter definitions.
- `<named parameter value>`: (optional) The value of the input parameter.

---

**Note:** URL parameter names that begin with an underscore ('\_') are intended for internal use only and should not be used. Although you may see these names on URLs generated by ADF Controller, you should not attempt to use or depend on them.

---

### Object Type for Parameter Converters

Parameter converters, if specified, can be used to convert task flow parameter values to and from the string representations used in a URL. A parameter converter is an EL expression that evaluates to an object of the following type:

```
oracle.adf.controller.UrlParameterConverter
```

If you do not specify a parameter converter, a default converter checks the parameters for cross-site-scripting (XSS) attacks. If you know that the parameter values used in your application contain special characters, you should create your own implementation of `UrlParameterConverter` and use it to perform conversion of the task flow parameter values.

## 15.6.7 How to Specify Before and After Listeners

Task flow call activity before and after listeners are used to identify the start and end of a bounded task flow. Specifying a listener in the task flow call activity means that the listener executes on that specific usage of the called bounded task flow.

You specify the listener as an EL expression for a method that will be called upon entry or exit of a bounded task flow, for example,

```
<before-listener>#{global.showState}</before-listener>. The method cannot have parameters.
```

- **Before listener:** An EL expression for a Java method called before a bounded task flow is entered. It is used when the caller needs to know when a bounded task flow is being initiated.

- After listener: An EL expression for a Java method called after a bounded task flow returns. It is used when the caller needs to know when a bounded task flow exits and control flow returns to the caller.

If multiple before listeners or multiple after listeners are specified, they are called in the order in which they appear in the source document for the unbounded or bounded task flow. A task flow call activity can have only have before listener and one after listener.

In order for the task flow call after listeners to be called, control flow must return from the bounded task flow using a control flow rule. If an end user leaves a bounded task flow using the browser back button or other URL, task flow call after listeners will not be called. You must use a bounded task flow finalizer to release all acquired resources and perform cleanup of a bounded task flow that the end user left by clicking a browser back button. See [Section 18.2, "Using Initializers and Finalizers"](#) for more information.

**To specify a before or after listener on a task flow call activity:**

1. In the diagram of the calling bounded task flow, select the task flow call activity.
2. In the Property Inspector, click **Listeners**.
3. Click the button next to either **before-listener** or **after-listener**.
4. In the Expression Builder dialog, drill down to the Java class containing the method for the listener.
5. Open the class node and select the listener method.

When you are done, your EL expression might look like  
`#{pageFlowscope.managedBean.methodListener}`.

6. Click **OK**.

## 15.6.8 What Happens When You Add a Task Flow Call Activity

After you add a task flow call activity to a task flow diagram, you must specify a reference to the called bounded task flow using one of the methods described in [Section 15.6.1, "How to Call a Bounded Task Flow Using a Task Flow Call Activity"](#). For example, if you drop an existing bounded task flow on the task flow call activity, JDeveloper generates the task flow reference automatically. The task flow reference is used to invoke the called bounded task flow.

If the task flow reference is static, each task flow reference consists of:

- **id**: The bounded task flow id contained in the XML source file for the called bounded task flow. For example, a called task flow might have an ID called `targetFlow`. The same XML source file can contain multiple bounded task flows, each bounded task flow identified by a unique ID.

---

**Note:** If you use JDeveloper to create the bounded task flow, there is only one bounded task flow per document.

---

- **document**: The name of the XML source file containing the ID of the called bounded task flow. If **document** is not specified, `adfc-config.xml` is assumed. The document is a physical XML file and must be accessible via MDS.

[Example 15-14](#) contains an example static task flow reference within a task flow call activity. In order to invoke a bounded task flow, you need to know its id and name of the file containing the id.

**Example 15-14 Static Task Flow Reference**

```
<adfc-config xmlns="http://xmlns.oracle.com/adf/controller" version="1.2" id="__
1">
...
  <task-flow-definition id="task-flow-definition">
    <default-activity>view1</default-activity>
    <task-flow-call id="taskFlowCall">
      <task-flow-reference>
        <document>/WEB-INF/called-task-flow-definition.xml</document>
        <id>called-task-flow-definition</id>
      </task-flow-reference>
    </task-flow-call>
  </task-flow-definition>
...
</adfc-config>
```

[Example 15-15](#) shows the metadata that JDeveloper generates for a dynamic task flow reference within a task flow call activity.

**Example 15-15 Dynamic Task Flow Reference**

```
<?xml version="1.0" encoding="windows-1252" ?>
<adfc-config xmlns="http://xmlns.oracle.com/adf/controller" version="1.2"
id="__1">
  <task-flow-definition id="bounded_tf">
    <default-activity id="__2">taskFlowCall1</default-activity>
    <task-flow-call id="taskFlowCall1">
      <dynamic-task-flow-reference id="__3">#{EL_Expression_Retrieve_
TaskflowID}</dynamic-task-flow-reference>
    </task-flow-call>
  </task-flow-definition>
</adfc-config>
```

## 15.6.9 What Happens at Runtime When a Task Flow Call Activity Invokes a Task Flow

The ADF Controller performs the following steps when a bounded task flow is called using a task flow call activity:

1. Verifies that the user is authorized to call the bounded task flow.
2. Invokes task flow call activity before listener or listeners, if specified (see [Section 15.6.7, "How to Specify Before and After Listeners"](#)).
3. Evaluates the input parameter values on the bounded task flow.
4. Pushes the called bounded task flow onto the stack and initializes its page flow scope.
5. Sets input parameter values in the called bounded task flow's context.
6. Invokes a bounded task flow initializer method, if one is specified (see [Section 18.2, "Using Initializers and Finalizers"](#) for more information).
7. Executes the bounded task flow's default activity.

## 15.7 Using Task Flow Return Activities

A task flow return activity identifies the point in an application's control flow where a bounded task flow completes and sends control flow back to the caller. You can use a task flow return activity only within a bounded task flow.

A gray circle around a task flow return activity icon indicates that the activity is an exit point for a bounded task flow. A bounded task flow can have zero to many task flow return activities. [Figure 15–10](#) shows a bounded task flow with task flow return activities named **Login** and **addNewCust**.

**Figure 15–10 Multiple Task Flow Return Activities**

Each task flow return activity specifies an outcome that is returned to the calling task flow. For example, the outcome for the `rollbackReturn` task flow return activity in the Fusion Order Demo application customer registration bounded task flow is `cancelCreateCust`.

[Figure 15–11](#) shows an extract of the customer registration bounded task flow (`customer-registration-task-flow.xml`). This task flow contains two task flow return activities (`rollbackReturn` and `commitReturn`). The `rollbackReturn` task flow return activity's outcome is `cancelCreateCust`. In contrast, the `commitReturn` task flow return activity's outcome returns `globalhome`.

**Figure 15–11 Task Flow Return Activities Specifying Different Outcomes**

The outcome returned to the task flow that invokes the customer registration task flow depends on the end user action. You can configure control flow cases in the invoking task flow to determine the next action by the invoking task flow. Set the `from-outcome` element of a control flow case to the value returned by the task flow

return activity's outcome to invoke an action based on that outcome. This determines control flow upon return from the customer registration task flow.

Set a value for the **Restore Save Point** property to specify if model changes made in a bounded task flow are saved or discarded when the bounded task flow exits by using a task flow return activity. Set to `true` to roll back transactions to the ADF Model save point that was created when the Fusion web application first entered the bounded task flow. The default value is `false`. You can specify a value for this property only if the bounded task flow on which the task flow return activity is located was entered without starting a new transaction. For more information, see [Section 18.4.1, "How to Enable Transactions in a Bounded Task Flow"](#).

**To add a task flow return activity to a bounded task flow:**

1. Drag a task flow return activity from the ADF Task Flow page in the Component Palette to the diagram for the bounded task flow.
2. In the task flow diagram, select the task flow return activity.
3. On the Common page of the Property Inspector, expand the **Outcome** section.
4. In the **Name** field, enter an outcome, for example, `preferredCustomer`.

Specifying this returns an outcome to the caller when the bounded task flow exits. You can specify only one outcome per task flow return activity. The calling task flow should define control flow rules to handle control flow upon return. See [Section 14.3.3, "How to Add Control Flows"](#) for more information.

5. In the Property Inspector, expand the **Behavior** section.
6. In the **Reentry** dropdown list, choose one of the following options:
  - **reentry-allowed**: Reentry is allowed on any view activity within the bounded task flow.
  - **reentry-not-allowed**: Reentry of the bounded task flow is not allowed.

If you specify **reentry-not-allowed** on a bounded task flow, an end user can still click the browser back button and return to a page within the bounded task flow. However, if the user does anything on the page such as clicking a button, an exception (for example, `InvalidTaskFlowReentry`) is thrown indicating the bounded task flow was reentered improperly. The actual reentry condition is identified upon the submit of the reentered page.

Your selection defines the default behavior when the bounded task flow is reentered by an end user clicking a browser's Back button. This selection applies only if **reentry-outcome-dependent** has been set on the bounded task flow where the task flow return activity is located. For more information, see [Section 18.5, "Reentering a Bounded Task Flow"](#).

7. In the **End Transaction** dropdown list, choose one of the following options:
  - **commit**: Select to commit the existing transaction to the database.
  - **rollback**: Select to roll back the transaction to what it was on entry of the called task flow. This has the same effect as canceling the transaction, since it rolls back a new transaction to its initial state when it was started on entry of the bounded task flow.

If you do not specify commit or rollback, the transaction is left open to be closed by calling bounded task flow.

8. In the **Restore Save Point** dropdown list, select **true** when either of the following conditions apply:

- If **Always Begin New Transaction** (`new-transaction`) is not selected on the bounded task flow on which the task flow return activity is located
- ADF model changes made within a bounded task flow should be discarded when exiting using the task flow call activity. The transaction is rolled back to the save point created on entry of the bounded task flow.

For more information, see [Section 18.4.1, "How to Enable Transactions in a Bounded Task Flow"](#).

## 15.8 Using Save Point Restore Activities

The save point restore activity allows you to restore a previous persistent save point in an application supporting save for later functionality. A save point captures a snapshot of the Fusion web application at a specific instance. Save point restore enables the application to restore whatever was captured when the save point was originally created.

When a save point is restored, ADF Controller terminates the saved application and restarts the application that was executing when the end user performed a save. The end user's original location in the application is displayed. Once the `save-point-id` is restored, it is deleted from its method of persistence (database or Java object cache).

A save point restore activity is not required within every individual application supporting save for later capabilities. It is only required within the applications responsible for restoring the previously persistent `save-point-ids`. For example, a save point restore activity would not be required within a Create Expense Report application, but would be within the application used to select previously saved expense reports for further updates.

[Section 18.9, "Using Save Points in Task Flows"](#) contains detailed information about enabling save for later capabilities in a task flow and provides an example of how to use the save point restore activity to retrieve the saved application state and data.

## 15.9 Using Parent Action Activities

A bounded task flow running in an ADF region may need to trigger navigation of its parent view activity. The parent action activity allows a bounded task flow to generate outcomes that are passed to its parent view activity. The outcomes are used to navigate the task flow containing the parent view activity rather than navigating the task flow of the ADF region.

- **Parent Outcome:** Specifies a value passed to the parent viewport to navigate the enclosing view's task flow rather than navigating the region's task flow where the parent action activity is defined.
- **Outcome:** Specifies a control flow outcome within the region after the parent outcome is queued to the parent.

This is useful in cases where the parent does not navigate as a result of the parent outcome sent by the region and the region does not want to continue displaying the same view. If you do not specify a value for outcome, the region's `viewId` remains unchanged.

For more information, see [Section 17.7.1, "How to Trigger Navigation Outside of an ADF Region's Task Flow"](#).

## 15.10 Using Task Flow Activities with Page Definition Files

Page definition files define the binding objects that populate data at runtime. They are typically used in a Fusion web application to bind page UI components to data controls. A number of task flow activities can also use page definition files to bind to data controls. These are:

- Method call

You can drag and drop a data control operation from the Data Control panel onto a task flow to create a method call activity or onto an existing method call activity. In both cases, the method call activity binds to the data control operation.

- Router

Associating a page definition file with a router activity creates a binding container. At runtime, this binding container makes sure that the router activity references the correct binding values when it evaluates the router activity cases' EL expressions. Each router activity case specifies an `outcome` to return if its EL expression evaluates to `true`. For this reason, only add data control operations to the page definition file that evaluate to `true` or `false`.

- Task flow call

Associating a page definition file with a task flow call activity creates a binding container. At runtime, the binding container is in context when the task flow call activity passes input parameters. The binding container makes sure that the task flow call activity references the correct values if it references binding values when passing input parameters from a calling task flow to a called task flow.

- View

You cannot directly associate a view activity with a page definition file. Instead, you associate the page that the view activity references.

If you right-click any of the above task flow activities (except view activity) in the diagrammer for a task flow, JDeveloper displays an option on the context menu that enables you to create a page definition file (**Create Page Definition**) if one does not yet exist. If a page definition file does exist, JDeveloper displays a context menu option for all task flow activities to go to the page definition file (**Go to Page Definition**). JDeveloper also displays a context menu option (**Edit Binding**) when you right-click a method call activity that is associated with a page definition file.

A task flow activity that is associated with a page definition file displays an icon in the lower-right section of the task flow activity icon. [Figure 15–12](#) shows an example for each of the task flow activities.

**Figure 15–12 Task Flow Activities Associated with Page Definition Files**

### 15.10.1 How to Associate a Page Definition File with a Task Flow Activity

JDeveloper provides a context menu option that you can access from the task flow activity. You use this context menu option to associate the task flow activity with a page definition file.

#### To associate a page definition file with a task flow activity

1. In the diagrammer for the task flow, right-click the task flow activity for which you want to create a page definition file.
2. Choose **Create Page Definition** from the context menu that appears.
3. In the resulting page definition file, add the bindings that you want your task flow activity to reference at runtime.

For more information about page definition files, see [Section 12.6, "Working with Page Definition Files"](#).

### 15.10.2 What Happens When You Associate a Page Definition File with a Task Flow Activity

At design time, JDeveloper generates a page definition file for the task flow activity. The filename of the page definition file comprises the originating task flow and either the name of the task flow activity or the data control operation to invoke. For example, `taskflowName_taskflowName_methodCall1PageDef.xml` or `taskflowName_taskflowName_CreateInsertPageDef.xml`.

JDeveloper also generates an EL expression from the task flow activity to the binding in the created page definition file. [Example 15–16](#) shows a method call activity that references a `CreateInsert` action binding.

#### **Example 15–16 Task Flow Activity Referencing an Action Binding**

```
<method-call id="CreateInsert">
  <method>#{bindings.CreateInsert.execute}</method>
  <outcome>
    <fixed-outcome>CreateInsert</fixed-outcome>
  </outcome>
</method-call>
```

At runtime, a binding container makes sure that a task flow activities' EL expressions reference the correct value.

---

---

## Using Parameters in Task Flows

This chapter describes how to specify parameters in view activities and in ADF bounded task flows.

This chapter includes the following sections:

- [Section 16.1, "Introduction to Parameters in Task Flows"](#)
- [Section 16.2, "Passing Parameters to a View Activity"](#)
- [Section 16.3, "How to Pass Parameters to an ADF Bounded Task Flow"](#)
- [Section 16.4, "Specifying Return Values"](#)
- [Section 16.5, "Specifying EL Binding Expressions"](#)

### 16.1 Introduction to Parameters in Task Flows

You can use view activity input page parameters as aliases. The alias allows you to map bounded task flow input parameters to page parameters. The view activity input page parameters map managed beans and any information available to the calling task flow to a managed bean on the page itself. To pass values out of view activities, store values in page flow scope or managed beans. For information about using view activities in a task flow, see [Section 15.2, "Using View Activities"](#).

For example, the page might specify `#{pageFlowScope.empno}` as a page parameter and a bounded task flow might specify `#{pageFlowScope.employeeID}` as the value of an input parameter definition.

The `from`-value on the view activity input page parameter would be `#{pageFlowScope.employeeID}` and the `to`-value would be `#{pageFlowScope.empno}`. This enables reuse of both the page definition and bounded task flow because you don't have to redefine parameters for every context in which each is used.

Other values contained within the task flow can be mapped to input page parameters, not just bounded task flow input parameter definition values.

### 16.2 Passing Parameters to a View Activity

[Figure 16-1](#) illustrates how to specify an input page parameter mapping. You can pass a parameter to the Employee activity as a `pageFlowScope` value or a value on a managed bean. The Employee activity can pass a value to the Target activity by placing it within `pageFlowScope` or a managed bean to the Target activity, based on the EL expression you specified in the `to`-value.

**Figure 16–1 Task Flow with Two Activities****To set an input page parameter value and retrieve it:**

1. In the editor, open the task flow diagram.
2. In the task flow diagram, select the view activity.
3. In the Property Inspector, click **Page Parameters**.
4. In the **Input Page Parameter** section, click the **Add** icon.
5. Enter a `from-value` using an EL expression that, when evaluated, specifies where the input page parameter value will be passed from, for example, `#{pageFlowScope.EmployeeID}`.

The task flow shown in [Figure 16–1](#) can set an input parameter definition value that the view activity can retrieve. To retrieve the parameter value, you can specify a `from-value` on the view activity that matches the **Value** specified for the ADF bounded task flow input parameter definition.

6. Enter a `to-value` using an EL expression that, when evaluated, specifies where the page associated with the view activity can retrieve the value of the input page parameter, for example, `#{pageFlowScope.EmployeeNo}`.

The `to-value` is the second part of the view activity input page parameter. It specifies where the page associated with the view can retrieve the value of the view parameter.

## 16.3 How to Pass Parameters to an ADF Bounded Task Flow

A called ADF bounded task flow can accept input parameters and can pass return values to the caller upon exit. See [Section 16.4, "Specifying Return Values"](#) for more information.

---

---

**Note:** Instead of explicitly passing a data controls as parameters between task flows, you can simply share them by specifying the `data-control-scope` option on the called bounded task flow. For more information, see [Section 18.3, "Sharing Data Controls Between Task Flows."](#)

---

---

To pass an input parameter to a bounded task flow, you must specify one or more:

- Input parameters on the task flow call activity. These specify where the calling task flow will store parameter values.
- Input parameter definitions on the called bounded task flow. These specify where the called bounded task flow can retrieve parameter values.

If you call a bounded task flow using a URL rather than a task flow call activity, you pass parameters and values on the URL itself. For more information, see [Section 15.6.4, "How to Call a Bounded Task Flow Using a URL"](#).

The input parameter name specified for each option will be the same in order to map input parameter values back into the called bounded task flow. The `value` for each corresponds to the mapping between where the value will be retrieved within the caller and the called task flow.

If you don't specify a value for the input parameter, the value defaults to `#{pageFlowScope.parmname}`, where `parmname` is the name of your parameter.

You can specify on the input parameter definition for the called bounded task flow whether an input parameter is required. If a required input parameter is not received, an error occurs (these are flagged at design time as well as at runtime). An input parameter definition that is identified as not required can be ignored during task flow call activity creation.

By default, all objects are passed by reference. Task flow call activity input parameters can be passed by reference only if managed bean objects are passed, not individual values. By default, primitive types (for example, `int`, `long`, or `boolean`) are passed by value.

The pass by value checkbox applies only to objects, not primitives and is used to override the default setting of passing by reference. Mixing the two, however, can lead to unexpected behavior in cases where parameters reference each other. If input parameter A on the task flow call activity is passed by value and if input parameter B on the task flow call activity is passed by reference, and B has a reference to A, the result can be two different instances of A and B.

[Example 16–1](#) shows an input parameter definition specified on a bounded task flow.

#### **Example 16–1 Input Parameter Definition**

```
<task-flow-definition id="sourceTaskflow">
.
.
.
  <input-parameter-definition>
    <name>inputParameter1</name>
    <value>#{pageFlowScope.parmValue1}</value>
    <class>java.lang.String</class>
  </input-parameter-definition>
.
.
.
</task-flow-definition>
```

[Example 16–2](#) shows the input parameter metadata that would be specified on the task flow call activity that called the bounded task flow shown in [Example 16–1](#).

#### **Example 16–2 Input Parameter on Task Flow Call Activity**

```
<task-flow-call id="taskFlowCall1">
.
.
.
  <input-parameter>
    <name>inputParameter1</name>
    <value>#{pageFlowScope.newCustomer}</value>
    <pass-by-value/>
  </input-parameter>
.
.
.
```

```
</task-flow-call>
```

**Tip:**

You can set parameters for a page using an ADF task flow rather than dropping a parameterized form from the data control panel or using a form with a method which takes parameters that are invoked using an invoke action.

The first technique is a way of passing parameters to a page. The others are ways of consuming parameters on a page. If a page needs parameters, you should pass them by using task flow parameters or by setting scope variables.

The following steps describe passing an input parameter from a source task flow to a target bounded task flow using a task flow call activity. Although you can pass parameter values from any activity on the source task flow, the passed parameter in the steps below will contain the value of an input text field on a page in the source task flow.

Before you begin:

- Create a calling and called task flow (see [Section 14.2, "Creating a Task Flow"](#) for more information). The caller can be a bounded or unbounded task flow. The called task flow must be a bounded task flow.
- On the calling task flow, add the activities shown in [Figure 16–2](#). The page associated with the view on the calling task flow should contain an input text field and a button. When an end user clicks the button on the JSF page, control should pass to the task flow call activity.

**Figure 16–2 Calling Task Flow**

**To pass an input parameter to an ADF bounded task flow:**

1. Select the input text component on the JSF page.
2. In the Property Inspector, enter a value for the input text component.  
You can specify the value as an EL expression, for example `{pageFlowScope.inputValue}`.
3. In the Application Navigator, double-click the name of the called task flow to open its diagram.
4. Click the **Overview** tab for the called task flow.
5. Click **Parameters** and expand the **Input Parameter Definition** node.
6. Click the **Add** icon next to **Input Parameter Definition**.
7. In the **Name** field, enter a name for the parameter, for example, `inputParm1`.

8. In the **Value** field, enter an EL expression where the parameter value is stored and referenced, for example, `{pageFlowScope.inputValue}`.
9. In the editor, open the diagram for the calling task flow.
10. In the Application Navigator, drag the called ADF bounded task flow and drop it on top of the task flow call activity that is located on the calling task flow.

Dropping a bounded task flow on top of a task flow call activity in a diagram automatically creates a task flow reference to the bounded task flow. As shown in [Figure 16–3](#), the task flow reference contains the bounded task flow ID and a document name. The document name points to the XML source file that contains the ID.

**Figure 16–3 Task Flow Reference in Property Inspector**

11. In the Property Inspector for the task flow call activity, click **Parameters** and expand the **Input Parameters** section.
12. Enter a name that identifies the input parameter.
 

Because you dropped the bounded task flow on a task flow call activity having defined input parameters, the name should already be specified. You must keep the same input parameter name.
13. Enter a parameter value, for example, `{pageFlowScope.parm1}`.
 

The value on the task flow call activity input parameter specifies where the calling task flow will store parameter values.

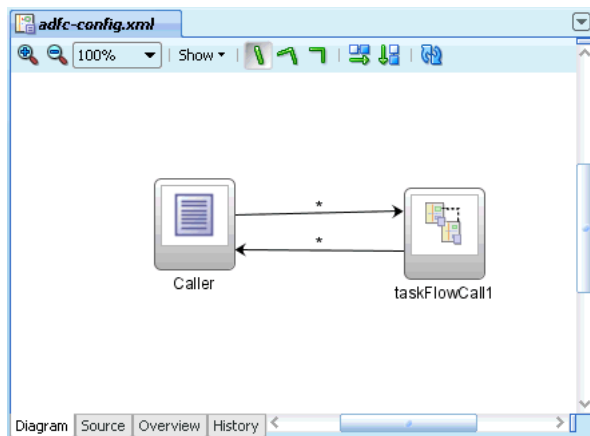

The value on the input parameter definition for the called task flow specifies where the value will be retrieved from for use within the called bounded task flow once it is passed.
14. At runtime, the called task flow is able to use the input parameter. Since you specified `pageFlowScope` as the `value` in the input parameter definition for the called task flow, you can use the parameter value anywhere in the called ADF bounded task flow. For example, you can pass it to a view activity on the called bounded task flow. For more information, see [Section 15.2.2.2, "What Happens When You Transition Between Activities"](#).

## 16.4 Specifying Return Values

As shown in [Figure 16–4](#), a task flow return activity causes the ADF bounded task flow to return to the task flow that called it. The called bounded task flow can pass return values back to the calling task flow.

**Figure 16–4 ADF Bounded Task Flow Returning to a Calling Task Flow**

As shown in [Figure 16–5](#), the values are returned to the calling task flow.

**Figure 16–5 ADF Unbounded Task Flow Calling a Bounded Task**

To return a value, you must specify:

- Return value definitions on the called bounded task flow. These specify where to read the return value from.
- Return values on the task flow call activity in the calling task flow. These specify where the calling task flow can find return values

The caller of the bounded task flow can choose to ignore return value definition values by not identifying any task flow call activity return values back to the caller.

Return values on the task flow call activity are passed back by reference. Nothing inside the ADF bounded task flow will still reference them, so there is no need to pass by value and make a copy.

Before you begin the following steps:

- Create a calling task flow (can be either bounded or unbounded) and a target bounded task flow

**To specify a return value for a called ADF bounded task flow:**

1. Open the ADF bounded task flow that will be called in the overview editor.
2. Click **Parameters** and expand the **Return Value Definitions** section.
3. Click the **Add** icon next to **Return Value Definitions**.
4. In the **Name** field, enter a name to identify the return value, for example, `Return1`.

5. In the **Value** field, enter an EL expression that specifies where to read the return value from. For example, `#{pageFlowScope.ReturnValueDefinition}`.
6. In the task flow overview editor, open the calling ADF task flow.
7. In the Component Palette, drag the task flow call activity from the ADF Task Flow list and drop it on the diagram for the ADF calling task flow.
8. In the task flow diagram, select the task flow call activity.
9. In the Property Inspector, click **Parameters** and expand the **Return Values** section.
10. In the **name** field, enter a name to identify the return value, for example, `Return1`.

The name of the return value must match the name of the return value definition on the called bounded task flow.

**Tip:** If you drop the bounded task flow that you intend to call on the task flow call activity, the **name** field will already be specified. Therefore, the **name** field for the return value will automatically match the name of the return value definition on the called bounded task flow.

11. In the **value** field, enter an EL expression that specifies where the calling task flow can find return values, for example, `#{pageFlowScope.ReturnValue}`.

## 16.5 Specifying EL Binding Expressions

If a bounded task flow is implemented using a task flow call activity, as an ADF region or as an ADF dynamic region, you can specify parameter values using standard EL expression syntax. For example, you can specify parameters using `#{bindings.bindingId.inputValue}` or `#{bindings.bindingId}` or simply `#{inputValue}` syntax.

[Example 16–3](#) shows an example of a task flow binding for an ADF region.

### **Example 16–3** ADF Region taskFlow Binding

```
<taskFlow id="Department1" taskFlowId="/WEB-INF/Department.xml#Department"
  xmlns="http://xmlns.oracle.com/adf/Controller/binding"
  Refresh="ifNeeded">
  <parameters>
    <parameter id="DepartmentId" value="#{bindings.DepartmentId.inputValue}"
      xmlns="http://xmlns.oracle.com/adfm/uimodel"/>
  </parameters>
</taskFlow>
```

Appending `inputValue` to the parameter value binding EL expression ensures that the parameter is assigned the value of the binding rather than the actual binding object.

If you use the syntax in [Example 16–3](#) without appending `inputValue` `#{bindings.bindingId}`, the binding object (not the value of the binding) is passed. Therefore, the binding will end up being evaluated within the wrong context (the context of the task flow call, ADF region, or ADF dynamic region instead of the context of the page) and multiple data control instances will be created, eventually setting the wrong data control context in the frame.

---

---

## Using Task Flows as Regions

This chapter describes how to render ADF task flows in JSF pages or page fragments using ADF regions.

This chapter includes the following sections:

- [Section 17.1, "Introduction to Using Task Flows in ADF Regions"](#)
- [Section 17.2, "Creating an ADF Region"](#)
- [Section 17.3, "Specifying Parameters for an ADF Region"](#)
- [Section 17.4, "Specifying Parameters for ADF Regions Using Parameter Maps"](#)
- [Section 17.5, "Refreshing an ADF Region"](#)
- [Section 17.6, "Configuring Activation of an ADF Region"](#)
- [Section 17.7, "Navigating Outside an ADF Region's Task Flow"](#)
- [Section 17.8, "Configuring Transaction Management in an ADF Region"](#)
- [Section 17.9, "Creating ADF Dynamic Regions"](#)
- [Section 17.10, "Adding Additional Task Flows to an ADF Dynamic Region"](#)
- [Section 17.11, "Configuring a Page To Render an Unknown Number of Regions"](#)

### 17.1 Introduction to Using Task Flows in ADF Regions

You can render a bounded task flow in a JSF page or page fragment (`.jsff`) by using an ADF region. An ADF region comprises the following:

- An `af:region` tag that appears in the page or page fragment where you render the region
- An instance object that implements `RegionModel` from the following package:  
`oracle.adf.view.rich.model`

For more information about `RegionModel`, see the *Oracle Fusion Middleware Java API Reference for Oracle ADF Faces*

- One or other of the following:
  - A task flow binding (`taskFlow`) in the page definition that identifies the bounded task flow to use in the ADF region
  - A multi task flow binding (`taskFlowmultiTaskFlow`) in the page definition that identifies the list of bounded task flow to use in the ADF region

When first rendered, the ADF region's content is that of the first view activity in the bounded task flow. The view activities used in the bounded task flow must be associated with page fragments, not pages.

You can pass values to the ADF Region using task flow binding input parameters or contextual events. In addition, you can configure the task flow binding's `parametersMap` property to determine what input parameters the task flow binding passes from the bounded task flow to the ADF region.

ADF regions can be configured so that you determine when the region activates or refreshes. You can also configure an ADF region and a bounded task flow so that navigation control stops in the bounded task flow and passes to the page that contains the ADF region. Finally, you can create dynamic regions (ADF dynamic regions) where the task flow binding determines at runtime what bounded task flow renders in the region and configure a dynamic region link so that end users can change the bounded task flow that renders in the ADF dynamic region at runtime.

### 17.1.1 Benefits of Executing a Task Flow in an ADF Region

A primary reason for executing a bounded task flow as an ADF region is reuse. You can isolate specific pieces of application functionality in a bounded task flow and an ADF region in order to reuse it throughout the application. You can extract, configure, and package application functionality within a bounded task flow so that it can be added to other pages using an ADF region. ADF regions can be reused wherever needed, which means they are not dependent on a parent page. This also means that you can isolate the presentation of the parent pages from the ADF region; menus, buttons, and navigation areas are not affected by what is displayed in the ADF region. If you modify a bounded task flow, the changes apply to any ADF region that uses the task flow.

### 17.1.2 Task Flows and ADF Region Use Cases and Examples

[Figure 17-1](#) shows the Registration page (`register.jspx`) in the Fusion Order Demo application which renders two ADF regions. One of these regions (Registration Help) is static; it appears regardless of actions that an end user invokes elsewhere on the Registration page. It displays help information for the end user by rendering the view activities defined in the Fusion Order Demo application's `help-task-flow.xml` task flow. For more information about creating this type of region, see [Section 17.2, "Creating an ADF Region."](#)

The second region that `register.jspx` renders is a dynamic region (ADF dynamic region). The task flow that it renders depends on the end user's action. If the end user clicks **Register as a customer** on the registration page, the ADF dynamic region renders the customer registration task flow (`customer-registration-task-flow.xml`). Alternatively, if the end user clicks **Register as an employee**, the ADF dynamic region renders the employee registration task flow (`employee-registration-task-flow.xml`). For more information about creating this type of region, see [Section 17.9, "Creating ADF Dynamic Regions."](#)

**Figure 17–1 ADF Dynamic Region and ADF Region in the Fusion Order Demo Application**

The task flows that you render in an ADF region can be simple (for example, the help task flow has one view activity that renders help information) or can involve a number of steps where you guide end users through a process to complete a task, as in the case of the customer registration task flow.

Figure 17–2 shows parts of the customer registration task flow. It contains view activities that allow end users to review information they enter (for example, `reviewCustomerInfo`), an exception handler activity to display a message when an error occurs (`errorPage`), and task flow return activities to cancel or commit the changes that end users make. All these task flow activities can be rendered within an ADF region.

**Figure 17–2 Customer Registration Bounded Task Flow in Fusion Order Demo Application**

One special case is the task flow return activity. In many cases, you cannot return control when the bounded task flow finishes execution because there is no caller (except the page or page fragment that hosts the bounded task flow) to which you can

return control. For this reason, design control flow appropriately in a bounded task flow that you intend to render in an ADF region.

### 17.1.3 Additional Functionality for Task Flows that Render in ADF Regions

You may find it helpful to understand how a task flow that renders in an ADF region interacts with other task flow and ADF functionality. Review the information in the following sections before you attempt to render a task flow in an ADF region.

#### 17.1.3.1 Page Fragments and ADF Regions

A page fragment is a JSF JSP document (file extension is `.jspx`) that renders as content in another JSF page. A page fragment should not have more than one root component. Wrapping multiple root components in a single root component is recommended so that you optimize the display performance of the page fragment. In addition, if a page fragment has only one visual root component and a `popup` component (which is invisible to end users until invoked), it is also recommended to wrap these components in a single root component. For example, place the `popup` component in a `panelStretchLayout` component's bottom facet with the `bottomHeight` attribute set to 0 pixels.

If a page fragment has more than one root component, the Fusion web application logs a message at runtime, as shown in [Example 17-1](#), where `r1` identifies the ADF region that renders the page fragment.

#### **Example 17-1 Log Message for a Page Fragment with Multiple Root Components**

```
<RegionRenderer> <encodeAll> The region component with id: r1
has detected a page fragment with multiple root components.
Fragments with more than one root component may not display
correctly in a region and may have a negative impact on
performance. It is recommended that you restructure the page
fragment to have a single root component.
```

Apart from having only one root component element, a page fragment must not contain any of the following tags:

- `<af:document>`
- `<f:view>`
- `<f:form>`
- `<html>`
- `<head>`
- `<body>`

These tags can only appear once in a document and do not support nesting in a JSF JSP page. For example, a page fragment embedded in a page cannot have an `<html>` tag because the JSF JSP page already has one.

[Example 17-2](#) contains an example of a simple page fragment. Unlike a JSF JSP page, it contains no `<f:view>` or `<f:form>` tags.

#### **Example 17-2 Page Fragment Source Code**

```
<?xml version='1.0' encoding='UTF-8'?>
<jsp:root xmlns:jsp="http://java.sun.com/JSP/Page" version="2.1"
          xmlns:af="http://xmlns.oracle.com/adf/faces/rich">
  <af:commandButton text="commandButton 1" id="cb1"/>
```

```
</jsp:root>
```

You must nest a page fragment that you include in another JSF page within a region (`af:region` tag). A bounded task flow that you add to a JSF JSP page as a region cannot call pages; it must call page fragments.

### 17.1.3.2 View Ports and ADF Regions

A view port is a display area capable of navigating independently of other view ports. A browser window and an ADF region are both examples of view ports. The root view port displays the main page in a browser window. The root view port may have child view ports, for example, regions on the page, but does not have a parent view port.

Java classes that implement the `ViewPortContext` interface in the `oracle.adf.controller` package get you more information about view ports. For more information, see the *Oracle Fusion Middleware Java API Reference for Oracle ADF Controller*.

### 17.1.3.3 Security and ADF Regions

You can set security on a bounded task flow that displays in an ADF region and associated page definitions. If an end user displays a page that contains an ADF region that the user is not authorized to view, the contents of the ADF region do not display. No authentication mechanism is triggered. For more information, see [Chapter 30, "Enabling ADF Security in a Fusion Web Application"](#).

### 17.1.3.4 Parent Page Determines the Capabilities of an ADF Region

In some cases, a page may need to determine the capabilities currently available within one of the ADF regions that it contains. For example, the page may need to initiate control flow within the ADF region based on its current state using the `queueActionEventInRegion()` method. *Region capabilities* are used by a parent page to identify the current outcomes of one of its regions based on the region's current state. They identify to the parent page whether or not an outcome is possible within the region.

The following scenario describes how region capabilities might typically be used in an application:

1. An ADF region within a page displays its associated page fragment.
2. A user selects a button or performs some other action in the ADF region.
3. The parent page identifies the outcomes (region capabilities) for the ADF region.
4. The parent page updates its buttons based on the ADF region capabilities.

The syntax of an EL expression to determine an ADF region's capabilities is as follows:

```
#{bindings.[regionId].regionModel.capabilities['outcome']}
```

where `regionId` is the ID of the ADF region component on the page and `outcome` is the possible outcome being verified within the ADF region.

Region capabilities require the availability of the specified ADF region's `regionModel` through an EL expression. The EL expression should never access bindings in any other binding container other than the current binding container. Region capabilities cannot be used in some cases. For example, a nested ADF region where a `regionModel` cannot be reached within the current binding container. This is because a nested region's nested binding container might not yet exist or might have already been released.

## 17.2 Creating an ADF Region

You create an ADF region by dragging and dropping a bounded task flow that contains at least one view activity or one task flow call activity to the page where you want to render the ADF region. This makes sure that the ADF region you create has content to display at runtime.

The bounded task flow's view activities must be associated with page fragments (.jsff). If you attempt to drag and drop a bounded task flow that is associated with pages rather than page fragments, JDeveloper does not display the context menu that allows you to create an ADF region. You can convert a bounded task flow that uses pages to use page fragments. For more information, see [Section 14.5.3, "How to Convert ADF Bounded Task Flows."](#)

The context menu that JDeveloper displays to create an ADF region presents options to create a non-dynamic and a dynamic region. A dynamic region (ADF dynamic region) determines the bounded task flow that it renders at runtime. For more information about creating an ADF dynamic region, see [Section 17.9, "Creating ADF Dynamic Regions."](#) You determine, at design time, the bounded task flow that a non-dynamic region (ADF region) displays.

Before you create an ADF region, you need to do the following:

- Create a bounded task flow with one or more view activities associated with page fragments or one task flow call activity to a task flow with view activities  
For more information, see [Section 14.2, "Creating a Task Flow."](#)
- Create a page to host the ADF region

### 17.2.1 How to Create an ADF Region

Drag a bounded task flow from the Application Navigator to the page where you want to render an ADF region.

**To create an ADF region:**

1. In the Application Navigator, drag the bounded task flow onto the JSF page and drop it where you want to locate the ADF region.
2. From the context menu that appears, choose **Create > Region**.

The Edit Task Flow Binding dialog appears if the bounded task flow that you drop on the JSF page has an input parameter defined, as described in [Section 16.3, "How to Pass Parameters to an ADF Bounded Task Flow."](#) For more information about specifying parameters for an ADF region, see [Section 17.3, "Specifying Parameters for an ADF Region."](#)

**Figure 17–3 Edit Task Flow Binding Dialog for an ADF Region**

3. In the Structure window, right-click the node for the ADF region that you added (**af:region**) and choose **Go to Properties**.
4. Review or modify (as appropriate) the following properties which JDeveloper automatically populates with default values in the Property Inspector for the ADF region:
  - **Id:** An ID that the JSF page uses to reference the ADF region, for example, `r1`.
  - **Value:** An EL reference to the ADF region model, for example, `#{bindings.region1.regionModel}`. This is the region model that describes the behavior of the region.
  - **Rendered:** If `true` (the default value), the ADF region renders when the JSF page renders.
5. For information about how to map parameters between the view activity associated with the JSF page and the ADF region, see [Section 17.3, "Specifying Parameters for an ADF Region"](#).

## 17.2.2 What Happens When You Create an ADF Region

When you drop a bounded task flow onto a JSF page to create an ADF region, JDeveloper adds an `af:region` tag to the page. The `af:region` tag references an object that implements `RegionModel`. [Example 17–3](#) shows a sample of the metadata that JDeveloper adds to the JSF page.

### **Example 17–3 Metadata Added to a JSF Page to Create an ADF Region**

```
<af:region value="#{bindings.tf_register_employee1.regionModel}"
  id="r1"/>
```

JDeveloper also adds a task flow binding to the page definition file of the page that hosts the ADF region. [Example 17–4](#) shows a sample of the metadata that JDeveloper adds. The task flow binding provides a bridge between the ADF region and the bounded task flow. It binds a specific instance of an ADF region to its associated bounded task flow and maintains all information specific to the bounded task flow. The `taskFlowId` attribute specifies the directory path and the name of the source file for the bounded task flow.

### **Example 17–4 Metadata Added to Page Definition to Create a Task Flow Binding**

```
<taskFlow id="tf_register_employee1"
  taskFlowId="/WEB-INF/tf_register_employee.xml#tf_register_employee"
  activation="deferred"
  xmlns="http://xmlns.oracle.com/adf/controller/binding"/>
```

The bounded task flow preserves all of the data bindings when you drop it on the JSF page. At runtime, a request for a JSF page containing an ADF region initially handles like any other request for a JSF page. As the JSF page definition executes, data loads in to the JSF page. When the component tree for the parent JSF page encounters the `<af:region>` tag, it executes it in order to determine the first page fragment of content to display. Once it determine the first page fragment of content, it adds the appropriate UI components from the page fragment to the component tree for the parent JSF page.

The task flow binding creates an object for its task flow that implements the following interface in order to get the current view activity:

```
oracle.adf.controller.ViewPortContext
```

The task flow binding's `taskFlowId` attribute can also reference an EL expression that evaluates to one of the following:

- `java.lang.String`
- `oracle.adf.controller.TaskFlowId`

You use this capability if you create an ADF dynamic region. For more information, see [Section 17.9, "Creating ADF Dynamic Regions."](#)

## 17.3 Specifying Parameters for an ADF Region

You can make input parameters that you defined for a bounded task flow available to an ADF region by adding them to the task flow binding that the ADF region references. Use EL expressions to reference input parameters available in memory scopes, managed beans, or the ADF binding layer.

Specifying input parameters is one method of providing information to an ADF region. An alternative method is to use contextual events. The nature of the information that you want to provide to the ADF region determines the method you choose to provide the information. For example, choose:

- Input parameters if the required information is at the beginning of the task flow and a change in the value of this information requires a restart of the task flow.

For example, you have a page that contains a table of employees. An ADF region on that page contains a task flow to enroll a selected employee in a benefits program. A change in the selected employee requires that you restart the benefits enrollment task flow from the beginning for the newly selected employee. Using input parameters to the task flow is the right decision for this use case.

You can pass input parameters by reference or by value. If you pass by reference, an update on the main page for the selected employee's information, such as last name, is automatically reflected in the task flow running in the ADF region without restarting the task flow.

- Contextual events if you can only determine the information to exchange after the start of a task flow and a change in the information does not require a restart of the task flow. For example, the Fusion Order Demo application uses contextual events to display the appropriate help topic when the customer registration task flow renders in the `register.jspx` page. For more information about contextual events, see [Section 28.7, "Creating Contextual Events."](#)

For information about creating an ADF region and adding task flow bindings, see [Section 17.2, "Creating an ADF Region."](#) For information about how to define an input

parameter for a bounded task flow, see [Section 16.3, "How to Pass Parameters to an ADF Bounded Task Flow"](#).

### 17.3.1 How to Specify Parameters for an ADF Region

Use EL expressions to specify parameters available in memory scopes, managed beans, or the ADF binding layer as input for the ADF region.

#### To specify input parameters for an ADF region:

1. In the Application Navigator, right-click the JSF page that holds the ADF region and choose **Go to Page Definition**.
2. In the overview editor for the page definition file, expand the **Model** section and select the task flow binding for which you want to specify parameters.
3. Click the Edit icon to display the Edit Task Flow Binding dialog, as shown in [Figure 17-4](#).

If you defined input parameters for the bounded task flow, as described in [Section 16.3, "How to Pass Parameters to an ADF Bounded Task Flow"](#), the Edit Task Flow Binding dialog lists these parameters in the Input Parameters section.

---

**Note:** You can write an EL expression that references a list of input parameters specified in a managed bean using the Input Parameters Map field of the Edit Task Flow Binding dialog. For more information about implementing this functionality, see [Section 17.4, "Specifying Parameters for ADF Regions Using Parameter Maps."](#)

---

**Figure 17-4** Edit Task Flow Binding Dialog

4. Write an EL expression that retrieves the value of each input parameter you want to specify for the ADF region. Note that you must write an EL expression for parameters that you defined as required. For example, write an EL expression similar to the following:

```
#{pageFlowScope.inputParameter1}
```

5. Click **OK**.

### 17.3.2 What Happens When You Specify Parameters for an ADF Region

JDeveloper writes entries that are child elements of the `taskFlow` element in the page definition of the JSF page, as illustrated in example [Example 17-5](#).

**Example 17–5 Metadata Entries to Specify Input Parameters for an ADF Region**

```

<taskFlow id="tflow_tf11"
    taskFlowId="/WEB-INF/tflow_tf1.xml#tflow_tf1"
    activation="deferred"
    xmlns="http://xmlns.oracle.com/adf/controller/binding">
  <parameters>
    <parameter id="inputParameter1"
      value="#{pageFlowScope.inputParameter1}"/>
    <parameter id="inputParameter2"
      value="#{pageFlowScope.inputParameter2}"/>
  </parameters>
</taskFlow>

```

At runtime, the values specified by the EL expression in the value attribute are passed to the ADF region.

## 17.4 Specifying Parameters for ADF Regions Using Parameter Maps

In addition (or as an alternative) to listing all the input parameters on the task flow binding, as described in [Section 17.3, "Specifying Parameters for an ADF Region,"](#) you can use the `parametersMap` property of the task flow binding to specify a parameter map object on a managed bean. The parameter map object that you reference must be of a type that implements the following interface:

```
java.util.Map
```

The parameter map object that you reference specifies keys that map to the values you want to input to the ADF region. Using this approach reduces the number of `parameter` child elements that appear under the task flow binding (`taskFlow`) element or the multi task flow binding (`multiTaskFlow`) in the page definition for the page. This approach also allows you more flexibility in determining what input parameters pass to the ADF region. In particular, it provides a way to pass parameters to ADF dynamic regions as the number of input parameters can differ between the different task flow bindings in an ADF dynamic region. For more information, see [Section 17.9, "Creating ADF Dynamic Regions."](#)

You can configure an ADF region or an ADF dynamic region's task flow binding to reference a parameter map. You can also configure a multi task flow binding to reference a parameter map. Make sure that the name of an input parameter you define for a bounded task flow matches the name of a key that you define in the parameter map object.

If you specify a parameter with the same `id` attribute in a `<parameter>` element and in a `<parametersMap>` element, the `<parametersMap>` element always takes precedence. This is because the `<parametersMap>` element may need to override the static value of the parameter if you create an ADF dynamic region, as described in [Section 17.9, "Creating ADF Dynamic Regions."](#)

### 17.4.1 How to Create a Parameter Map to Specify Input Parameters for an ADF Region

You configure the task flow binding's `parametersMap` property to reference the parameter map object that defines the key-value pairs you want to pass to the ADF region.

**To create a parameter map to specify input parameters for an ADF region:**

1. Create a managed bean or edit an existing managed bean so that it returns an object that implements the `java.util.Map` interface.

Configure the managed bean so the object returns key-value pairs with the values that you want to pass to the ADF region. For more information about managed beans, see [Section 20.4, "Using a Managed Bean in a Fusion Web Application."](#)

2. In the Application Navigator, right-click the JSF page that holds the ADF region and choose **Go to Page Definition**.
3. In the overview editor for the page definition file, expand the **Model** section and select the task flow binding or multi task flow binding for which you want to specify a parameter map and then click the **Edit** icon.

The type of task flow binding that you select determines the dialog that appears.

4. In the Edit Task Flow Binding dialog or the Edit Multi Task Flow Binding, select **Expression Builder** from the **Input Parameters Map** dropdown menu.
5. Write or build an EL expression that references a parameter map. For example, write an EL expression similar to the following:

```
#{pageFlowScope.userInfoBean.parameterMap}
```

6. Click **OK**.

## 17.4.2 What Happens When You Create a Parameter Map to Specify Input Parameters

At runtime, the task flow binding or multi task flow binding evaluates the EL expression specified for its `parametersMap` property. It returns values to the ADF region from the managed bean for keys that match the name of the input parameters defined for the bounded task flow that render in the ADF region.

[Example 17-6](#) shows code snippets from a managed bean that puts two values (`isLoggedIn` and `principalName`) into a parameter map named `parameterMap`.

### **Example 17-6** Managed Bean Defining a Parameter Map

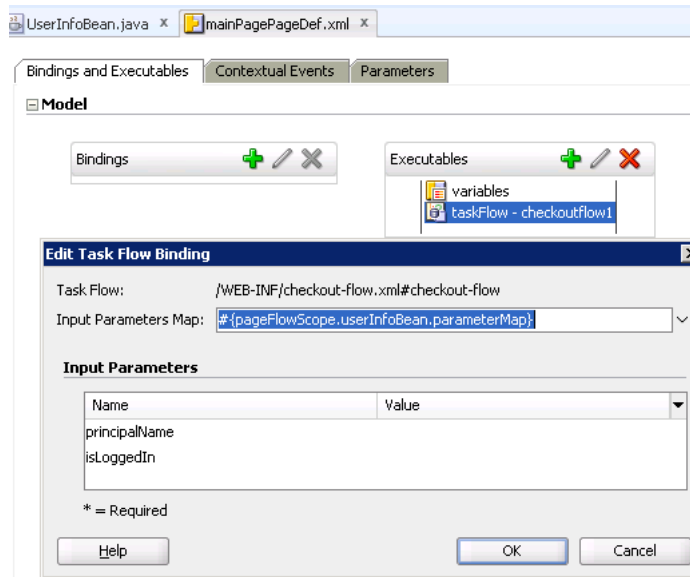

```
import java.util.HashMap;
import java.util.Map;

public class UserInfoBean {
    private Map<String, Object> parameterMap = new HashMap<String, Object>();

    public Map getParameterMap() {

        parameterMap.put("isLoggedIn", getSecurity().isAuthenticated());
        parameterMap.put("principalName", getSecurity().getPrincipalName());
        return parameterMap;
    }
}
```

[Figure 17-5](#) shows the Edit Task Flow Binding dialog after you close the Expression Builder dialog, having specified the parameter map object (`parameterMap`) shown in [Example 17-6](#). The **Input Parameters** field in the Edit Task Flow Binding dialog lists the input parameters defined for the bounded task flow associated with this ADF region (`checkout-flow`). The task flow binding retrieves the values for these parameters from the managed bean shown in [Example 17-6](#).

**Figure 17–5 EL Expression Referencing Parameter Map on Task Flow Binding**

**Example 17–7** shows the metadata that appears for the task flow binding in the page definition file of the page that renders the ADF region. The metadata for the task flow binding references both the bounded task flow (`taskFlowId` attribute) and the managed bean (`parametersMap`).

**Example 17–7 Task Flow Binding Specifying a Parameter Map**

```
<taskFlow id="checkoutflow1"
  taskFlowId="/WEB-INF/checkout-flow.xml#checkout-flow"
  activation="deferred"
  xmlns="http://xmlns.oracle.com/adf/controller/binding"
  parametersMap="#{pageFlowScope.userInfoBean.parameterMap}"/>
```

You specify the `<parameterMap>` element in the page definition. The position of the `<parameterMap>` element within the `<parameters>` list determines whether or not values in the parameter map are used. The `<parameterMap>` element specifies an EL expression that returns an object that implements `java.util.Map`. The object contains task flow input parameter key/value pairs. The parameter set for the task flow is built from the order that is specified in the task flow binding.

---

**Note:** If you specify `Refresh="ifNeeded"`, parameters are not supported in the `<parameterMap>` element. The only condition that determines whether the region need to be refreshed is the boolean value returned by the evaluation of `RefreshCondition`. For more information, see [Section 17.5.2, "What You May Need to Know About Refreshing an ADF Region"](#).

---

## 17.5 Refreshing an ADF Region

You can configure when an ADF Region refreshes and whether it invokes a task flow. An ADF Region can only invoke a task flow when the ADF Region is in an active state. An ADF Region in an inactive state cannot invoke a task flow and returns a null value for the ID of the referenced task flow to the parent page.

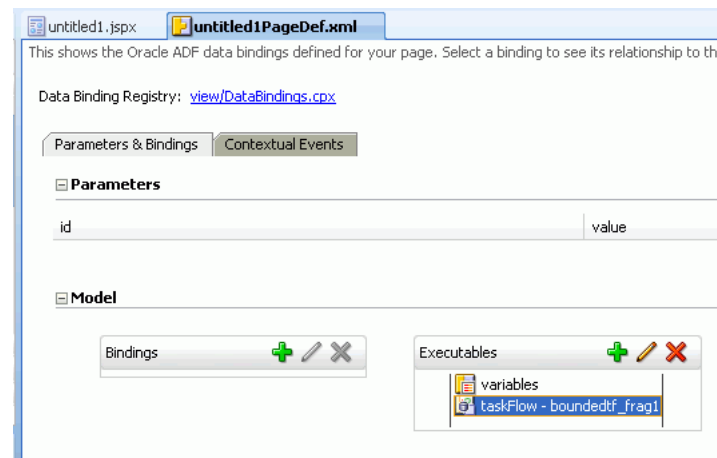

## 17.5.1 How to Configure the Refresh of an ADF Region

You set values for the task flow binding of the task flow associated with the ADF Region to determine when an ADF Region switches from an inactive to an active state and to determine when an ADF Region refreshes.

### To configure the refreshing of an ADF Region:

1. In the Application Navigator, select the page that contains the ADF Region, right-click and choose **Go to Page Definition**.
2. In the page definition file, expand the **Model** view and select the task flow binding in the **Executables** section, as illustrated in Figure 17-6.

**Figure 17-6 Task Flow Binding**

3. In the Property Inspector, select a value from the dropdown list beside the Refresh property, as described in the following list:
  - **default:** refresh the ADF Region once when the page that hosts the ADF Region appears or when the EL expression you set as a value for the RefreshCondition property in step 4 returns `true`.
  - **ifNeeded:** refresh the ADF Region if the value of a task flow binding parameter changes. Do not set a value for the RefreshCondition property in step 4 if you select this value.
4. If you selected **default** as the value for the Refresh property, select **Edit** from the dropdown list beside the RefreshCondition property to invoke the Expression Builder and write an EL expression that returns a boolean value at runtime. If the EL expression returns `true`, the ADF Region refreshes.
5. In the Property Inspector, select a value from the dropdown list beside the activation property, as described in the following list:
  - **conditional:** activates the ADF region if the EL expression set as a value for the task flow binding `active` property returns `true`.
  - **deferred:** select this option if your application uses Facelets XHTML pages in the view layer and you want to activate the ADF region when a Facelets XHTML page first requests a `viewID`. If your application uses JSP technology in the view layer, selecting this option has the same effect as selecting **immediate** (the ADF region activates immediately) provided that the parent component for the ADF region is not a `popup` or `panelTabbed` component

that has its `childCreation` attribute set to `deferred`. If this latter scenario occurs, the parent component (`popup` or `panelTabbed`) determines behavior.

This option is recommended if your application uses Facelets XHTML pages. For more information about Facelets with ADF Faces, see the "Getting Started with ADF Faces" chapter in the *Oracle Fusion Middleware Web User Interface Developer's Guide for Oracle Application Development Framework*.

- **immediate**: activates the ADF region immediately. This is the default value.

The value that you select in the dropdown list determines when an ADF region switches from an inactive to an active state. An ADF region must have an active state before it can invoke a task flow.

6. If you selected **conditional** as the value for the activation property, select **Edit** from the dropdown list beside the active property to invoke the Expression Builder and write an EL expression that returns a boolean value at runtime. If the EL expression returns `true`, the ADF Region invokes the task flow.

## 17.5.2 What You May Need to Know About Refreshing an ADF Region

An ADF region initially refreshes when the parent JSF page on which the region is located first displays. During the initial refresh, any ADF region task flow binding parameter values are passed in from the parent page. The parameter values are used to display the initial page fragment within the ADF region. If the bounded task flow relies on input parameter values that are not available when the page is first created, make sure that your task flow behaves correctly if the input parameter values are null by, for example, using a `NullPointerException` object. Alternatively (or additionally), make sure that the task flow does not activate until the input parameters become available by configuring the task flow binding's `active` property.

An ADF region task flow binding can be refreshed again based on one of the following task flow binding attributes:

- `taskFlowId`  
This attribute specifies the directory path and the name of the source file for the bounded task flow. The ADF region refreshes if this attribute value changes.
- Neither `Refresh` or `RefreshCondition` attributes are specified (default)  
If neither the `Refresh` nor `RefreshCondition` task flow binding attribute is specified, the ADF Region is refreshed only once at the time the parent page is first displayed unless you configure a value for the task flow binding's `active` property.
- `RefreshCondition="{EL.expression}"`  
The ADF region is refreshed a single time when its `RefreshCondition` evaluates `true`. The `RefreshCondition` must evaluate to a boolean value.  
At the time the `RefreshCondition` is evaluated, if the variable `bindings` is used within the EL Expression, the context refers to the binding container of the parent page, not the page fragment displayed within the ADF region.  
`RefreshCondition` is independent of the change of value of binding parameters. If the task flow binding parameters do not change, nothing within the ADF region will change.
- `Refresh="ifNeeded"`  
Any change to a task flow binding parameter value causes the ADF region to refresh.

If the ADF region task flow binding does not have parameters, `Refresh="ifNeeded"` is equivalent to not specifying the `Refresh` attribute.

If you set `Refresh` to `ifNeeded`, the `RefreshCondition` attribute should not be specified.

`Refresh="ifNeeded"` is not supported if you pass parameters to the task flow binding using a dynamic parameter map. You must instead use the `RefreshCondition="{EL.Expression}"`.

For more information about specifying parameter values using a parameter map, see [Section 17.4, "Specifying Parameters for ADF Regions Using Parameter Maps."](#)

The `RefreshCondition` and `Refresh` properties are mutually exclusive. The `Refresh="ifNeeded"` property takes precedence over `RefreshCondition`. If the `bindings` variable is used within the EL expression at the time `RefreshCondition` is evaluated, the context refers to the binding container of the parent page, not the page fragment displayed within the ADF region. The expression is evaluated during the `PrepareRender` phase of the ADF page lifecycle. For more information, see [Chapter 21, "Understanding the Fusion Page Lifecycle"](#).

[Example 17-8](#) contains a sample task flow binding located within the page definition of a page on which an ADF region has been added.

#### **Example 17-8 Refresh Option Specified in ADF Region Binding**

```
<taskFlow id="Department1" taskFlowId="/WEB-INF/Department#Department"
  Refresh="ifNeeded"
  xmlns="http://xmlns.oracle.com/adf/controller/binding">
  <parameters>
    <parameter id="DepartmentId" value="{bindings.DepartmentId.inputValue}"
      xmlns="http://xmlns.oracle.com/adfm/uimodel"/>
  </parameters>
</taskFlow>
```

You do not need to refresh an ADF region to refresh the data controls inside the ADF region. During the ADF lifecycle, the refresh events telling the iterators to update will be propagated to the binding container of the current page of the ADF region.

## 17.6 Configuring Activation of an ADF Region

You can configure when an ADF region activates. This determines when the task flow contained in the ADF region activates. Configuring the activation of ADF regions can optimize the performance of a Fusion web application's page. For example, a page that contains 5 ADF regions may reference 5 task flows. You may not want these 5 task flows to execute simultaneously when the Fusion web application page loads so you configure an `activation` property to determine when a task flow executes.

### 17.6.1 How to Configure Activation of an ADF Region

You configure the `activation` property for the task flow binding associated with the ADF region to determine when to activate the ADF region.

#### **To configure the activation of an ADF Region:**

1. In the Application Navigator, select the page that contains the ADF region(s), right-click and choose **Go to Page Definition**.
2. In the page definition file, expand the **Model** view and select the task flow binding in the **Executables** section, as illustrated in [Figure 17-7](#).

**Figure 17–7 Task Flow Bindings for ADF Region Configured for Activation**

3. In the Property Inspector, select a value from the dropdown list beside the activation property, as described in the following list:
  - **conditional**: activates the ADF region if the EL expression set as a value for the task flow binding `active` property returns `true`.
  - **deferred**: select this option if your application uses Facelets XHTML pages in the view layer and you want to activate the ADF region when a Facelets XHTML page first requests a `viewID`. If your application uses JSP technology in the view layer, selecting this option has the same effect as selecting **immediate** (the ADF region activates immediately).

This option is recommended if your application uses Facelets XHTML pages. For more information about Facelets with ADF Faces, see the "Getting Started with ADF Faces" chapter in the *Oracle Fusion Middleware Web User Interface Developer's Guide for Oracle Application Development Framework*.

- **immediate**: activates the ADF region immediately. This is the default value.
- The value that you select in the dropdown list determines when an ADF region switches from an inactive to an active state. An ADF region must have an active state before it can invoke a task flow.
4. If you selected **conditional** as the value for the `activation` property, select **Edit** from the dropdown list beside the `active` property to invoke the Expression Builder and write an EL expression that returns a boolean value at runtime. If the EL expression returns `true`, the ADF region invokes the task flow. If the EL expression returns `false`, the ADF region deactivates a task flow that was active in the ADF region.

## 17.6.2 What Happens When You Configure Activation of an ADF Region

The behavior of the ADF region at runtime depends on the options that you set for the activation property.

Figure 17–8 shows the default behavior where all task flows in ADF regions execute when the page loads the ADF regions (Tab # 1, Tab # 2, Tab # 3).

**Figure 17–8 Default Activation of ADF Regions**

Figure 17–9 shows an example where the activation property was set to `deferred` and the application uses Facelets. The regions in Tab # 1 and Tab # 2 have an active state because the end user navigated to these regions. The region in Tab # 3 is inactive.

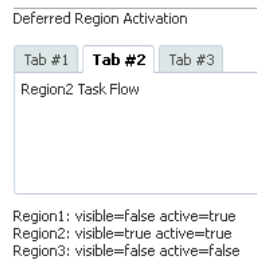

**Figure 17–9 Deferred Activation of ADF Regions**

Figure 17–10 shows an example where the activation property was set to `conditional` and the active property to an EL expression that returns a boolean value at runtime. The region in Tab # 1 is in an active state because the EL expression specified for the active property returns `true`. The regions in Tab # 2 and Tab # 3 are inactive because the EL expression specified for the active property returns `false`.

Note that the following events occur if a region deactivates a task flow (the value returned by the active property changes from `true` to `false`):

- A task flow with an active transaction rolls back the transaction.  
For more information about transaction options in task flows, see [Section 18.4, "Managing Transactions."](#)
- If a task flow has a data control frame with a `data-control-scope` value of `isolated`, the task flow releases the data control frame and any data controls in the data control frame.  
For more information about data controls, see [Section 18.3, "Sharing Data Controls Between Task Flows."](#)
- ADF Controller releases the view port data structures for the region (including `pageFlow` and view scopes).  
For more information about view ports, see [Section 17.1.3.2, "View Ports and ADF Regions."](#) For more information about memory scopes, see [Section 14.2.4, "What You May Need to Know About Memory Scope for Task Flows."](#)

**Figure 17–10 Conditional Activation of ADF Regions**

Conditional Region Activation

Region1: visible=true active=true  
 Region2: visible=false active=false  
 Region3: visible=false active=true

## 17.7 Navigating Outside an ADF Region's Task Flow

A bounded task flow running in an ADF region may need to trigger navigation of its parent view activity or to navigate to the root page of its application. The parent action activity exposes properties (`parent-outcome` and `root-outcome`) that you configure if you want to implement either of these use cases.

For example, you might specify a value for `parent-outcome` if you have a page that displays employee information and an ADF region that contains an enroll button for an employee. After the enroll page completes and the ADF region returns, the employee information page refreshes with the next employee.

---

**Note:** An ADF region does not maintain state when you navigate away from the region.

---

### 17.7.1 How to Trigger Navigation Outside of an ADF Region's Task Flow

You add a parent action activity to the bounded task that runs in the ADF region and configure it so that it navigates to the parent's view activity.

**To trigger navigation outside of an ADF region's task flow:**

1. In the Application Navigator, double-click the XML file for the bounded task flow that runs in the ADF region.
2. In the ADF Task Flow page of the Component Palette, select **Parent Action** and drag it to the bounded task flow.
3. Select the parent action activity in the diagram for the bounded task flow.
4. In the Property Inspector, choose the appropriate option:
  - **Parent Outcome:** enter a literal value or write an EL expression that returns an outcome so that the parent action activity navigates to the parent view activity. The outcome is then used to navigate the parent view activity's task flow rather than navigating the ADF region's bounded task flow.  
  
The parent view activity's task flow should contain a control flow case or wildcard control flow rule that accepts the value you specify for `parent-outcome`.
  - **Root Outcome:** enter a literal value or write an EL expression that returns an outcome so that the parent action activity navigates to the root page of the application.

---

**Note:** **Parent Outcome** and **Root Outcome** are mutually exclusive.

---

5. (Optional) In the **Outcome** field, enter a literal value that specifies an outcome for control flow within the ADF region after the parent action activity adds `parent-outcome` or `root-outcome` to the appropriate queue.

Specifying an `outcome` element is useful in cases where the parent view activity or root page does not navigate as a result of the `parent-outcome` or `root-outcome` sent by the parent action activity. In addition, the ADF region should not continue to display the same view. If you do not specify a value for `outcome`, the ADF region's `viewId` remains unchanged.

## 17.7.2 What Happens When You Configure Navigation Outside a Task Flow

At design time, JDeveloper writes entries to the source file for the bounded task flow based on the property values you set for the parent action activity. [Example 17-9](#) shows sample entries that JDeveloper generates when you write a literal value for the Parent Outcome and Outcome properties of the parent action activity.

### **Example 17-9 Metadata for a Parent Action Activity with a Parent Outcome**

```
<parent-action id="parentAction1">
  <parent-outcome>parent_outcome</parent-outcome>
  <outcome id="__2">outcome</outcome>
</parent-action>
```

[Example 17-10](#) shows sample entries that JDeveloper generates when you write a literal value for the Root Outcome and Outcome properties of the parent action activity.

### **Example 17-10 Metadata for a Parent Action Activity with a Root Outcome**

```
<parent-action id="parentAction1">
  <root-outcome>root_outcome</root-outcome>
  <outcome id="__2">outcome</outcome>
</parent-action>
```

At runtime, the bounded task flow navigates to its parent view activity or the root page of the Fusion web application depending on the property that you configured for the parent action activity.

## 17.8 Configuring Transaction Management in an ADF Region

ADF task flows provide options to implement transactions, as described in [Section 18.4, "Managing Transactions."](#) You can choose whether a task flow shares or isolates its data controls with a calling task flow by setting a value for its `data-control-scope` property, as described in [Section 18.3, "Sharing Data Controls Between Task Flows."](#) Whether a task flow creates a new transaction depends on the values you choose for the `transaction` and `data-control-scope` properties, as described in [Section 18.4.3, "What You May Need to Know About Sharing Data Controls and Managing Transactions."](#)

If, for example, you share a task flow's data control with a calling task flow, a new transaction is created if you configure the task flow's `transaction` option to **Always Begin New Transaction** (`new-transaction`) or to **Use Existing Transaction If Possible** (`requires-transaction`). The `requires-transaction` option creates a new transaction only if a transaction does not already exist. The created transaction has the same lifespan as the ADF region that renders the task flow. This may cause behavior that you do not intend when the task flow renders in an ADF region. For

example, if an ADF region refreshes, it restarts the task flow that it renders and causes the following events to occur:

- Discards the current view port that the ADF region uses

---

---

**Note:** Save points require a root view port to work. For more information about view ports, see [Section 17.1.3.2, "View Ports and ADF Regions."](#) For more information about save points, see [Section 18.9, "Using Save Points in Task Flows."](#)

---

---

- Releases the data control that the task flow uses  
This may cause the loss of changes made in the parent page of the calling task flow because it shares the data control of the task flow that renders in the ADF region.
- Executes a commit or rollback if the End Transaction property of the task flow's task flow return activity specifies one of these actions. For more information, see [Section 15.7, "Using Task Flow Return Activities."](#)

There are a number of ways to prevent the inadvertent termination of a task flow's transaction by the refresh of an ADF region. All these options disassociate the lifespan of the transaction in the task flow that renders in an ADF region from the lifespan of the ADF region. These options make sure that the region's parent page owns the transaction and/or that the transaction starts before the region renders. Choose the most appropriate option for your application:

- Set the transaction option on the taskflow that renders in the ADF region to **Always Use Existing Transaction** (`requires-existing-transaction`). This throws an exception if a transaction does not exist and prevents the ADF region from owning the transaction.
- Set the calling task flow's transaction option to **Always Begin New Transaction** (`new-transaction`) so that the lifespan of the transaction is associated with the lifespan of the parent page.
- Invoke the `DataControlFrame` interface's `beginTransaction()` method in the action that navigates to the parent page that contains the region.
- Configure a method call activity that invokes the `DataControlFrame` interface's `beginTransaction()` method from a managed bean with a request scope before navigating to the parent page of the ADF region.

The following code begins a transaction:

```
public void beginTransaction()
{
    BindingContext context = BindingContext.getCurrent();

    String dcFrameName = context.getCurrentDataControlFrame();
    DataControlFrame dcFrame = context.findDataControlFrame(dcFrameName);
    dcFrame.beginTransaction(new TransactionProperties());
}
```

If you share the data controls of a task flow with a calling task flow, use the `rollback` or `commit` options exposed by the task flow's task flow return activity to commit or rollback changes rather than programmatically use the methods exposed by the ADF Model layer's `DataControlFrame` interface. Using the methods exposed by the `DataControlFrame` interface closes the transaction and may cause the task flow that renders in the ADF region to create a new transaction.

## 17.9 Creating ADF Dynamic Regions

An ADF dynamic region is an ADF region where the task flow binding dynamically determines the value of its `taskFlowId` attribute at runtime. This allows the Fusion web application to determine which bounded task flow to execute within the ADF dynamic region based on the result of evaluation of the task flow binding's `taskFlowId` attribute.

Figure 17–11 shows a runtime example from the Fusion Order Demo application where the `register.jspx` page renders a different registration task flow in its center facet in response to the command component button that the end user clicks. For example, if the end user clicks **Register as an employee** the Fusion Order Demo application renders the `employee-registration-task-flow` in the ADF dynamic region.

At runtime, the ADF dynamic region swaps the task flows that it renders during the Prepare Render lifecycle phase. To give components from a previous task flow the opportunity to participate smoothly in the lifecycle phases, do not navigate off the `regionModel` until the JSF Invoke Application lifecycle phase. It is good practice, therefore, not to navigate a task flow in a dynamic region in response to contextual events. For more information about lifecycle phases, see [Chapter 21, "Understanding the Fusion Page Lifecycle,"](#) and for more information about contextual events, see [Section 28.7, "Creating Contextual Events."](#)

**Figure 17–11 Customer Registration Task Flow in an ADF Dynamic Region**

The screenshot displays a web application interface for customer registration. On the left, there are two buttons: "Register as a customer" and "Register as an employee". The main content area is a registration form with a progress indicator at the top showing four steps: "Basic Information", "Address", "Payment options", and "Review". The "Basic Information" step is currently active. The form includes various input fields and dropdown menus for personal details such as name, address, contact information, and interests. A "Registration Help" sidebar is located on the right side of the form.

You create an ADF dynamic region by dragging and dropping a bounded task flow to the page where you want to render the ADF dynamic region. The view activities in the bounded task flow must be associated with page fragments (`.jspx`).

If you attempt to drag and drop a bounded task flow that is associated with pages rather than page fragments, JDeveloper does not display the context menu that allows you to create an ADF dynamic region. You can convert a bound task flow that uses pages to use page fragments. For more information, see [Section 14.5.3, "How to Convert ADF Bounded Task Flows."](#)

After you create an ADF dynamic region, you can add additional bounded task flows to the dynamic region by creating ADF dynamic region links, as described in [Section 17.10, "Adding Additional Task Flows to an ADF Dynamic Region."](#)

## 17.9.1 How to Create an ADF Dynamic Region

Drag and drop bounded task flows to the page where you want to render the ADF dynamic region.

### To create an ADF dynamic region:

1. In the Application Navigator, select and open the JSF page where you want to create the ADF dynamic region.
2. Drag and drop the first bounded task flow onto the JSF page.
3. From the context menu that JDeveloper displays, choose **Create > Dynamic Region**.
4. Choose the appropriate option in the Choose Managed Bean for Dynamic Region dialog that JDeveloper displays:

- If you want an existing managed bean to store the bounded task flow's ID, select an existing managed bean from the **Managed Bean** dropdown list.

The managed bean passes the value of the bounded task flow's ID into the task flow binding of the ADF dynamic region.

- If no managed bean exists for the page, click the **Add** icon next to the **Managed Bean** dropdown list to create a new one. Enter values in the dialog that appears as follows:
    - a. **Bean Name:** Enter a name for the new managed bean. For example, enter `DynamicRegionBean`.
    - b. **Class Name:** Enter the name of the new managed bean class.
    - c. **Package:** Enter the name of the package that is to contain the managed bean or browse to locate it.
    - d. **Extends:** Enter the name of the Java class that the managed bean extends. The default value is `java.lang.Object`.
    - e. **Scope:** This field is read-only and its value is set to `backingBean`. For more information about the memory scope for managed beans, see [Section 14.2.4, "What You May Need to Know About Memory Scope for Task Flows."](#)
    - f. Click **OK** to close the dialogs where you configure the managed bean.
5. Choose the appropriate option in the Edit Task Flow Binding dialog that JDeveloper displays:
    - Click **OK** if you do not want specify input parameters or an input parameter map for the ADF dynamic region.
    - Specify input parameters for the ADF dynamic region.

For more information, see [Section 17.3, "Specifying Parameters for an ADF Region."](#)

[Figure 17-12](#) shows the Edit Task Flow Binding dialog that JDeveloper displays after you configure a managed bean.

---

**Note:** You can write an EL expression that references a list of input parameters specified in a managed bean using the Input Parameters Map field of the Edit Task Flow Binding dialog. For more information about implementing this functionality, see [Section 17.4, "Specifying Parameters for ADF Regions Using Parameter Maps."](#)

---

**Figure 17–12** Edit Task Flow Binding Dialog for an ADF Dynamic Region

6. Click OK.

## 17.9.2 What Happens When You Create an ADF Dynamic Region

When you drop a bounded task flow onto a JSF page to create an ADF dynamic region, JDeveloper adds an `af:region` tag to the page. The `af:region` tag contains a reference to a task flow binding. [Example 17–11](#) shows a sample of the metadata that JDeveloper adds to the JSF page.

**Example 17–11** Metadata Added to a JSF Page to Create an ADF Dynamic Region

```
<af:region value="#{bindings.dynamicRegion1.regionModel}" id="r1"/>
```

JDeveloper also adds a task flow binding to the page definition file of the page that hosts the ADF dynamic region. [Example 17–12](#) shows a sample of the metadata that JDeveloper adds. The task flow binding provides a bridge between the ADF dynamic region and the bounded task flow. It binds the ADF dynamic region to the bounded task flow and maintains all information specific to the bounded task flow.

**Example 17–12** Metadata Added to Page Definition to Create a Task Flow Binding

```
<taskFlow id="dynamicRegion1"
  taskFlowId("#{backingBeanScope.ManagedBeanName.dynamicTaskFlowId}"
  activation="deferred"
  xmlns="http://xmlns.oracle.com/adf/controller/binding"/>
```

The `taskFlowId` attribute in the task flow binding metadata specifies the managed bean that determines at runtime what bounded task flow to associate with the ADF dynamic region. JDeveloper creates this managed bean or modifies an existing managed bean to store this data. [Example 17–13](#) shows extracts of the code that JDeveloper writes to the managed bean.

**Example 17–13 Managed Bean Entries to Retrieve Bounded Task Flow for an ADF Dynamic Region**

```
import oracle.adf.controller.TaskFlowId;
...
    private String taskFlowId = "/directoryPath/toTaskFlow";
...
    public TaskFlowId getDynamicTaskFlowId() {
        return TaskFlowId.parse(taskFlowId);
    }
...

```

At runtime, the managed bean stores the value of the bounded task flow's ID (`taskFlowId`) that displays inside the ADF dynamic region. The managed bean swaps the different bounded task flows into the task flow binding of the ADF dynamic region.

When an ADF dynamic region reinitializes, the Fusion web application must reinitialize the task flow binding associated with the ADF dynamic region. This includes evaluating if there are new input parameters and input parameter values to pass to the ADF dynamic region.

## 17.10 Adding Additional Task Flows to an ADF Dynamic Region

An ADF dynamic region link swaps a bounded task flow for another bounded task flow within an ADF dynamic region. An end user clicks a command component (for example, a button or a link) to update the ADF dynamic region with the new bounded task flow.

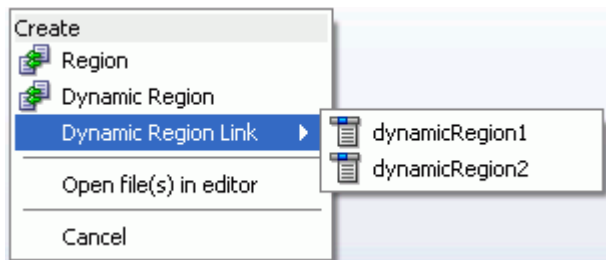

For example, a bounded task flow in the ADF dynamic region displays general information about an employee such as an ID and photo. When the end user clicks a link command component labeled **Details**, the ADF dynamic region updates with a table containing more information about the employee from another bounded task flow. The end user's action (clicking the link) invokes a method on the ADF dynamic region's managed bean. The value of the new bounded task flow is passed to the method, and the ADF dynamic region refreshes with the new bounded task flow. The new bounded task flow now displays within the ADF dynamic region.

By default, a ADF dynamic region link swaps another bounded task flow in for the original, but cannot swap back to the original. To toggle back to the original bounded task flow, you could add a second ADF dynamic region link on the page that, when clicked, swaps the current task flow back to the original one.

You can add an ADF dynamic region link if you already have at least one ADF dynamic region on a page and are adding a new bounded task flow as an ADF dynamic region to the same page. After you drop the bounded task flow on the page and choose to create an ADF dynamic region link, a menu displays all of the dynamic regions currently on the page, as shown in [Figure 17–13](#).

JDeveloper displays a list of the current dynamic regions in a document when you choose **Dynamic Region Link** from the menu that appears after you drag and drop a bounded task that you want to add as an option to an existing dynamic region in the document, as shown in [Figure 17–13](#).

**Figure 17–13 ADF Dynamic Region Link Menu**

Use this menu to select the ADF dynamic region within which you want to display the contents of the bounded task flow.

**Tip:** You can use the values in the dynamic region link in other UI components. For example, you could create a selection list in which each of the items in the list links to a different bounded task flow. All of the linked bounded task flows would display in the same dynamic region. The links perform a method in the class behind the managed bean created to swap the bounded task flow it displays.

### 17.10.1 How to Create an ADF Dynamic Region Link

You drag and drop a bounded task flow to a page that already contains an ADF dynamic region and you select **Dynamic Region Link** on the context menu that JDeveloper displays to view a list of ADF dynamic regions to which you can create a link.

#### To create an ADF dynamic region link:

1. In the Application Navigator, select and open the JSF page where you want to create the ADF dynamic region link.

This procedure assumes that you have already added at least one ADF dynamic region to the JSF page that you open. For information about adding an ADF dynamic region to a JSF page, see [Section 17.9, "Creating ADF Dynamic Regions."](#)

2. Drag a bounded task flow and drop it anywhere on the page.

The view activities of the bounded task flow must be associated with page fragments. You can convert a bounded task flow that uses pages to use page fragments. For more information, see [Section 14.5.3, "How to Convert ADF Bounded Task Flows."](#)

3. From the context menu that JDeveloper displays, choose **Dynamic Region Link**.

A menu displays a list of all ADF dynamic regions that have already been added to the page.

4. Select the name of the ADF dynamic region in which you want to display the contents of the bounded task flow.
5. Click OK.

### 17.10.2 What Happens When You Create an ADF Dynamic Region

JDeveloper adds a command link to the page, as shown in [Example 17–14](#). JDeveloper also updates the managed bean for the ADF dynamic region and updates the corresponding task flow binding with any new parameters.

**Example 17–14 Dynamic Region Link**

```
<af:commandLink text="region2" action="#{RegionBean.region2}"
  id="dynamicRegionLink1" />
```

## 17.11 Configuring a Page To Render an Unknown Number of Regions

You can configure a page at design time when you do not know the number of regions that render in the page at runtime. For example, you want to add or remove regions to tabs using the `panelTabbed` component. Each tab that you add or remove renders a region that references a bounded task flow.

To implement this functionality, you configure the JSF page definition file's `multiTaskFlow` element to reference a list of task flow bindings contained in a managed bean with a pageFlow scope of the following type:

```
oracle.adf.controller.binding.TaskFlowBindingAttributes
```

[Example 17–15](#) shows the code for the class of a managed bean named `MultiBean` that returns a list containing two task flows.

**Example 17–15 Managed Bean Returning a List of Task Flow Bindings**

```
package view;

import java.util.ArrayList;
import java.util.List;

import oracle.adf.controller.TaskFlowId;
import oracle.adf.controller.binding.TaskFlowBindingAttributes;

public class MultiBean {
    private List<TaskFlowBindingAttributes> mTaskFlowBindingAttrs = new
        ArrayList<TaskFlowBindingAttributes>(5);

    public MultiBean() {
        TaskFlowBindingAttributes tfAttr = new TaskFlowBindingAttributes();
        tfAttr.setId("region1");
        tfAttr.setTaskFlowId(new TaskFlowId("/WEB-INF/r1.xml", "r1"));
        mTaskFlowBindingAttrs.add(tfAttr);

        tfAttr = new TaskFlowBindingAttributes();
        tfAttr.setId("region2");
        tfAttr.setTaskFlowId(new TaskFlowId("/WEB-INF/r2.xml", "r2"));
        mTaskFlowBindingAttrs.add(tfAttr);
    }

    public List<TaskFlowBindingAttributes> getTaskFlowList() {
        return mTaskFlowBindingAttrs;
    }
}
```

For more information about the `TaskFlowBindingAttributes` class, see the *Oracle Fusion Middleware Java API Reference for Oracle ADF Controller*. For information about how to create a managed bean, see [Section 20.4.1, "How to Use a Managed Bean to Store Information."](#)

At runtime, the `multiTaskFlow` binding references a list of one or more task flows that an end user can add or remove to the page using command components that you

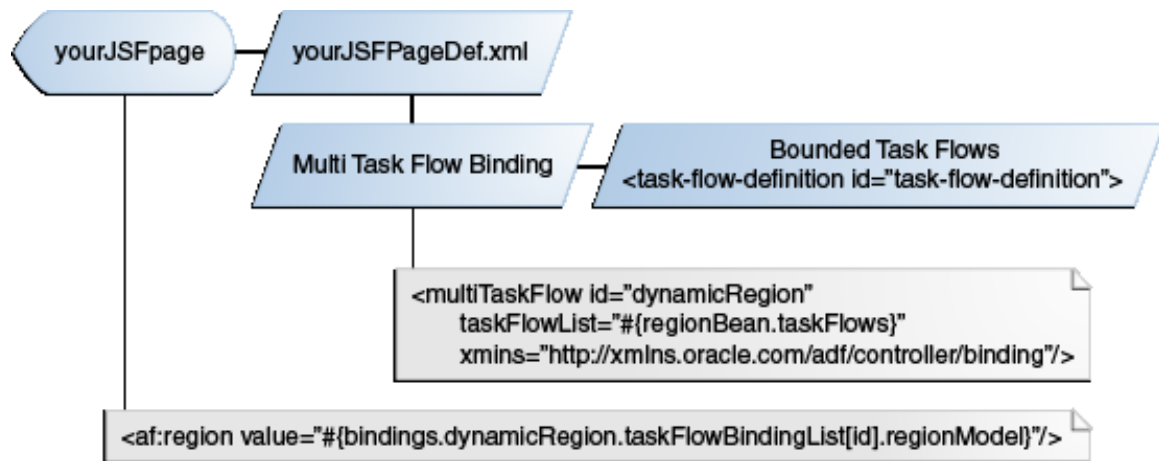

also expose. [Figure 17–14](#) shows the relationships between the different parts that make up this use case.

---

**Note:** The page fragments that the bounded task flows render must use the Facelets document type.

---

**Figure 17–14** ADF Regions Derived from a Multi Task Flow Binding

### 17.11.1 How to Configure a Page to Render an Unknown Number of Regions

Configure the JSF page definition file's `multiTaskFlow` element to reference a list of bounded task flows. This list can be modified at runtime by adding or removing elements of type `TaskFlowBindingAttributes`.

#### To configure a page to render an unknown number of regions:

1. In the Application Navigator, right-click the JSF page where you want to add or remove ADF regions at runtime and choose **Go to Page Definition**.
2. If a confirmation dialog appears, click **Yes**.
3. In the overview editor, click the **Binding and Executables** tab, and then click the **Add** icon in the Executables section.
4. In the Insert Item dialog, select **ADF Task Flow Bindings** from the dropdown menu, then select **multiTaskFlow** as the item to create and click **OK**.
5. In the Insert multiTaskFlow dialog, enter the following values:
  - **id\***: Enter a unique ID for the multi task flow binding.
  - **taskFlowList \***: Enter an EL expression that returns the list of `TaskFlowBindingAttributes` to return at runtime. For example, to return the list in [Example 17–15](#), enter the following EL expression:  

```
#{pageFlowScope.multiBean.taskFlowList}
```
6. In the Application Navigator, double-click the JSF page where you want end users to add or remove ADF regions at runtime.
7. In the ADF Faces page of the Component Palette, from the Operations panel, drag and drop a **For Each** onto the component in the Structure window that you want to enclose the For Each component.

8. In the Property Inspector for the For Each component, enter values in the following fields:
  - **Items:** Enter an EL expression that references the method that return the list of task flow bindings from the multi task flow binding runtime object.  
For example, enter an EL expression similar to the following:  
`#{bindings.multiRegion1.taskFlowBindingList}`
  - **Var:** Enter a value to identify the list of task flow bindings.
9. In the JSF page that contains the For Each component, insert a Region component inside the For Each component that references the Region component's region model using an EL expression, as shown in [Example 17–16](#).

**Example 17–16 ADF Region Referencing a Region Model**

```
<af:forEach var="tf" items="#{bindings.multiRegion1.taskFlowBindingList}">
  <af:panelBox text="#{tf.name}" id="pb1">
    <f:facet name="toolbar"/>
    <af:region value="#{tf.regionModel}" id="r1"/>
  </af:panelBox>
</af:forEach>
```

### 17.11.2 What Happens When You Configure a Page to Render an Unknown Number of Regions

Metadata similar to that shown in [Example 17–17](#) appears in the JSF page definition file for the multi task flow binding.

**Example 17–17 Metadata Added to Page Definition to Create a Multi Task Flow Binding**

```
<multiTaskFlow id="multiRegion1"
  taskFlowList="${pageFlowScope.multiBean.taskFlowList}" activation="deferred"
  xmlns="http://xmlns.oracle.com/adf/controller/binding"/>
```

The `taskFlowList` attribute in the multi task flow binding metadata specifies the managed bean. The managed bean stores the list of objects describing the task flows that can be added to the page at runtime.

### 17.11.3 What You May Need to Know About Configuring a Page to Render an Unknown Number of Regions

- Attempt to limit the number of ADF regions that you create in a page to 10.
- Each task flow binding inherits attributes defined for the multi task flow binding unless you override this behavior using the methods exposed by `TaskFlowBindingAttributes`.
- Each task flow binding inherits parameters defined in the multi task flow binding in addition to those defined using the `parametersMap` property, as described in [Section 17.4, "Specifying Parameters for ADF Regions Using Parameter Maps."](#)

---

---

## Creating Complex Task Flows

This chapter describes how to use advanced features of ADF task flows in an ADF application.

This chapter includes the following sections:

- [Section 18.1, "Introduction to Complex Task Flows"](#)
- [Section 18.2, "Using Initializers and Finalizers"](#)
- [Section 18.3, "Sharing Data Controls Between Task Flows."](#)
- [Section 18.4, "Managing Transactions"](#)
- [Section 18.5, "Reentering a Bounded Task Flow"](#)
- [Section 18.6, "Executing a Bounded Task Flow Directly From a JSF Page"](#)
- [Section 18.7, "Handling Exceptions in Task Flows"](#)
- [Section 18.8, "Configuring Your Application to Use Save Points"](#)
- [Section 18.9, "Using Save Points in Task Flows"](#)
- [Section 18.10, "Minimizing the Number of Active Root View Ports in an Application"](#)
- [Section 18.11, "Creating a Train"](#)
- [Section 18.12, "Running Multiple Task Flows"](#)
- [Section 18.13, "Creating a Task Flow Template"](#)
- [Section 18.14, "Creating a Page Hierarchy"](#)
- [Section 18.15, "Using BPEL with Task Flows"](#)

### 18.1 Introduction to Complex Task Flows

After creating a basic unbounded or bounded task flow and adding task flow activities to it, you can perform specialized tasks such as transaction management and reentry.

For basic information about using task flow activities, see [Chapter 15, "Working with Task Flow Activities"](#).

If you want to work with ADF regions, see [Chapter 17, "Using Task Flows as Regions"](#).

To work with parameters, see [Chapter 16, "Using Parameters in Task Flows"](#).

## 18.2 Using Initializers and Finalizers

An *initializer* is custom code that is invoked when a bounded task flow is entered. A *finalizer* is custom code that is invoked when a bounded task flow is exited via a task flow return activity or because an exception occurred. The finalizer is a method on a managed bean. Common finalizer tasks include releasing all resources acquired by the bounded task flow and performing cleanup before exiting the task flow.

You specify both the initializer and the finalizer as an EL expression for a method on a managed bean, for example:

```
#{pageFlowScope.modelBean.releaseResources}
```

There are two techniques for running initializer code at the beginning of the bounded task flow, depending on whether or not the task flow may be reentered via a browser back button:

- No reentry via back button expected: Designate a method call activity as the default activity (first to execute) in the bounded task flow. The method call activity calls a custom method containing the initializer code. For more information, see [Section 15.5, "Using Method Call Activities"](#) and [Section 22.4.5, "What You May Need to Know About the Browser Back Button and Navigating Through Records"](#).
- Back button reentry possible: Specify an initializer method using an option on the bounded task flow metadata. For more information, see [Section 14.2, "Creating a Task Flow"](#). Use this technique if you expect that a user may reenter the task flow using a browser back button. In such a case, the designated default activity for the bounded task flow may never be called, but a method designated using the Initializer method will.

## 18.3 Sharing Data Controls Between Task Flows

When one task flow calls another, the task flows can either share an instance of a data control, or create two separate isolated instances of the same data control so the task flows can maintain independent state. The internal object that task flows use to share their data controls or to store their own isolated data control is known as a *data control frame*.

Task flows making use of the task flow transaction management options when committing or rolling back use the data control frame to know which data controls to perform the transaction operations on. A data control frame is created at runtime for your application's unbounded task flow and any bounded task flow with a `data-control-scope` value of `isolated`. When a task flow specifies a `data-control-scope` value of `shared`, the called task flow uses the data control frame of the calling task flow rather than creating its own. This allows the called task flow to share data control instances attached to the data control frame. Alternatively, if a called task flow specifies a `data-control-scope` value of `isolated`, a new data control frame is created and a new instance of any data controls used by the bounded task flow will be attached to the newly-created data control frame.

To specify whether data controls are shared between the calling and called task flows, you must set a `data-control-scope` value of either `shared` or `isolated` on the called bounded task flow. The default value is `shared`.

If `data-control-scope` is set to `shared` on both the calling and called bounded task flow, the data control frame used will be the one for the calling task flow.

In [Figure 18–1](#), the bounded task flows BTF1, BTF2, and BTF3 use the data control frame created for the application's unbounded task flow (UTF1) because these bounded task flows all have a `data-control-scope` value of `shared`. In contrast,

the bounded task flow BTF4 uses a different data control frame because it has a `data-control-scope` value of `isolated`. It shares this data control frame with the bounded task flow that it calls (BTF5) because this latter bounded task flow has a `data-control-scope` value of `shared`.

**Figure 18–1** *Sharing and Isolating Data Control Frames*

The value that you set for the `data-control-scope` element of a called task flow determines if a calling task flow and a called task flow share flow data controls. Other factors, such as whether a task flow renders in a page or page fragment, do not change this behavior.

### 18.3.1 How to Share a Data Control Between Task Flows

You share data controls between task flows by specifying a value for the `data-control-scope` element of the called task flow.

#### Before you begin:

- Create a calling and called task flow as described in [Section 14.2, "Creating a Task Flow."](#)

#### To share a data control between task flows:

1. In the Application Navigator, double-click the called task flow.
2. In the Property Inspector, expand the **Behavior** section and select the **Share data controls with calling task flow** checkbox.

---

**Note:** After you select the **Share data controls with calling task flow** checkbox, you may need to configure transaction options for the task flow. For more information, see [Section 18.4.3, "What You May Need to Know About Sharing Data Controls and Managing Transactions."](#)

---

### 18.3.2 What Happens When You Share a Data Control Between Task Flows

JDeveloper writes an entry in the source file for the called task flow when you select the **Share data controls with calling task flow** checkbox, as illustrated in [Example 18–1](#).

#### Example 18–1 Metadata to Share Data Controls Between Task Flows

```

<task-flow-definition id="task-flow-definition">
  ...
  <data-control-scope>
    <shared/>
  </data-control-scope>
  ...

```

```
</task-flow-definition>
```

### 18.3.3 What Happens at Runtime: How Task Flows Share Data Controls

An end user can open the same application more than once in different browser windows or browser tabs. If an end user does this, each window or tab has its own view port, and each window or tab is isolated from all other windows or tabs within the same HTTP session. As a result, the windows or tabs do not share data controls and, therefore, state. The windows or tabs start with a new data control frame as if they were running with an isolated data control scope. The exception to this rule is if an end user opens a modal dialog in a secondary browser window, then the primary and secondary browser windows have the same server-side state and share data controls. For more information about using modal dialogs, see [Section 19.2, "Running a Bounded Task Flow in a Modal Dialog."](#) For more information about view ports, see [Section 17.1.3.2, "View Ports and ADF Regions."](#)

## 18.4 Managing Transactions

In the context of systems relating to databases, a *transaction* is a persisted collection of work items that can be committed or rolled back together as a group. ADF, through technologies such as ADF Business Components, offers all the advantages that transactions provide. However, support for transactions does not stop at the ADF Model layer. In the ADF Controller layer, bounded task flows optionally provide their own abstract implementation of transactions over the underlying ADF Model layer. This implementation allows you to control transactions from the task flow and also declaratively manage the transaction boundaries.

The transaction options that you can configure on a called bounded task flow can be grouped into two categories:

- You delegate transaction management to the ADF Model layer by choosing the **<No Controller Transaction>** option for the called bounded task flow. The called bounded task flow does not use the ADF Controller's task flow transaction management facilities to commit or rollback all data controls attached to the task flow and associated data control frame. Instead, you must individually commit and rollback data controls attached to the task flow.
- You use one of the following ADF task flow transaction management options:
  - **Always Begin New Transaction:** A new transaction starts when the bounded task flow is entered, regardless of whether or not a transaction is in progress. The new transaction completes when the bounded task flow exits.
  - **Always Use Existing Transaction:** When called, the bounded task flow participates in an existing transaction already in progress.
  - **Use Existing Transaction If Possible:** When called, the bounded task flow either participates in an existing transaction if one exists, or starts a new transaction upon entry of the bounded task flow if one does not exist.

---

**Best Practice:** Oracle recommends that you choose one of the above categories for transaction management when you chain task flows together. That is, do not configure a set of task flows that call each other where one or more task flows in the set use the **<No Controller Transaction>** option and one or more of the remaining task flows in the set use one of the ADF task flow transaction management options (**Always Begin New Transaction** and so on). This type of configuration can lead to complex runtime behavior.

---

If a called bounded task flow starts a new ADF task flow transaction (based on the `transaction` option that you selected), you can specify whether the transaction commits or rolls back when the task flow returns to its caller. The commit and rollback options are set on the task flow return activity that returns control back to the calling task flow. The same task flow that starts a transaction must also resolve the transaction.

In a called bounded task flow, you can specify two different return task flow activities that result in either committing or rolling back a transaction in the called bounded task flow. Each of the task flow return activities pass control back to the same calling task flow. The difference is that one task flow return activity specifies the commit option, while the other specifies the rollback option. As shown in [Figure 18–2](#), if transaction processing successfully completes, control flow passes to the success task flow return activity, which specifies options to commit the transaction. If the transaction is cancelled before completion, the cancel task flow activity specifies options to roll back the transaction.

**Figure 18–2 Task Flow Return Activities in Called Bounded Task Flow**

Use the `restore-save-point` option on the task flow return activity if you want to discard the changes an end user makes within a called bounded task flow when the called bounded task flow exits. ADF Controller rolls back to the previous ADF Model save point that was created when the bounded task flow was entered. The `restore-save-point` option applies only to cases when a bounded task flow is entered by joining an existing transaction (either the `requires-existing-transaction` or `requires-transaction` option is also specified) and a save point is created upon entry.

If you use the ADF task flow transaction management features that commit and rollback the data controls associated with the data control frame of the current task flow, you must use task flow return activities with their `End Transaction` property set to `commit` or `rollback`, or programmatically commit the associated data control

frame. Alternatively if you use the <No Controller Transaction> setting or you only want to commit or rollback one data control, use the associated commit or rollback operations from the Data Controls panel or programmatically execute the associated commit and rollback bindings.

In the Fusion Order Demo application, a number of task flows create transactions. For example, the `customer-registration-task-flow.xml` task flow uses the ADF task flow transaction management's **Use Existing Transaction if Possible** option. This task flow allows a user of the Fusion Order Demo application to register as a customer, as shown in [Figure 18–3](#).

**Figure 18–3 Task Flow Transaction**

### 18.4.1 How to Enable Transactions in a Bounded Task Flow

You define the transaction options on a bounded task flow that is called by another task flow. Add a task flow return activity on the called bounded task flow that returns control to the task flow that calls the bounded task flow.

#### To enable a bounded task flow to run as a transaction:

1. In the Applications Navigator, double-click the called bounded task flow.
2. In the overview editor for the called bounded task flow, click **Behavior** and expand the **Transaction** section.
3. Choose one of the following from the dropdown list:
  - **<No Controller Transaction>**: The called bounded task flow does not use the task flow transaction management facilities to commit or rollback all data controls attached to the task flow and associated data control frame. Instead, you must individually commit and rollback data controls attached to the task flow. The Data Controls panel exposes operations that you can invoke using command components to commit and rollback data controls. For more information, see [Section 22.5, "Creating a Form to Edit an Existing Record."](#)

- **Always Use Existing Transaction:** When called, the bounded task flow participates in an existing transaction already in progress.
- **Use Existing Transaction If Possible:** When called, the bounded task flow either participates in an existing transaction if one exists, or starts a new transaction upon entry of the bounded task flow if one does not exist.
- **Always Begin New Transaction:** A new transaction starts when the bounded task flow is entered, regardless of whether or not a transaction is in progress. The new transaction completes when the bounded task flow exits.

---

**Note:** After choosing a transaction option, you may also need to select the **Share data controls with calling task flow** option for the bounded task flow to determine whether there are any interactions between the options. For more information, see [Section 18.4.3, "What You May Need to Know About Sharing Data Controls and Managing Transactions."](#)

---

4. Optionally, deselect the **Share data controls with calling task flow** checkbox so that data controls are not shared with the calling task flow if you chose one of the following options in Step 3:
  - **Use Existing Transaction If Possible**
  - **Always Begin New Transaction**

The default behavior is to share data controls. For more information, see [Section 18.4.3, "What You May Need to Know About Sharing Data Controls and Managing Transactions."](#)
5. Optionally, select the **No save point on task flow entry** checkbox to prevent the creation of an ADF Model save point on task flow entry if you chose one of the following options in Step 3:
  - **Always Use Existing Transaction**
  - **Use Existing Transaction If Possible**

An ADF Model save point is a saved snapshot of the ADF Model state. Selecting the **No save point on task flow entry** checkbox means that overhead associated with a save point is not created for the transaction.
6. Select the task flow return activity in the called bounded task flow.
7. In the Property Inspector, expand the **Behavior** section.
8. If the called bounded task flow supports creation of a new transaction (bounded task flow specifies **Use Existing Transaction If Possible** or **Always Begin New Transaction** options), select one of the following in the **End Transaction** dropdown list:
  - **commit:** Select to commit the existing transaction to the database.
  - **rollback:** Select to roll back a new transaction to its initial state on task flow entry. This has the same effect as cancelling the transaction.
9. In the **Restore Save Point** dropdown list, select **true** if you want changes the user makes within the called bounded task flow to be discarded when the task flow exits. The save point that was created upon task flow entry will be restored.

## 18.4.2 What Happens When You Specify Transaction Options

[Example 18–2](#) shows the metadata for transaction options on a called bounded task flow. The `<new-transaction>` element indicates that a new transaction always starts when the called bounded task flow is invoked. The `<new-transaction>` element is generated when you select **Always Begin New Transaction** value in the Transaction section's dropdown list.

### **Example 18–2 Called Bounded Task Flow Metadata**

```
<task-flow-definition id="trans-taskflow-definition">
  <default-activity>taskFlowReturn1</default-activity>
  <transaction>
    <new-transaction/>
  </transaction>
  <task-flow-return id="taskFlowReturn1">
    <outcome>
      <name>success</name>
      <commit/>
    </outcome>
  </task-flow-return>
</task-flow-definition>
```

[Example 18–2](#) also shows the metadata for transaction options on the task flow return activity on the called task flow. The `<commit/>` element commits the existing transaction to the database. The `<outcome>` element specifies a literal outcome, for example, `success`, that is returned to the caller when the bounded task flow exits. The calling ADF task flow can define control flow rules based on this outcome. For more information about defining control flow upon return, see [Section 15.7, "Using Task Flow Return Activities."](#)

## 18.4.3 What You May Need to Know About Sharing Data Controls and Managing Transactions

Data controls cannot be shared across more than one transaction at the same time. If your task flow is involved in managing transactions, the value you select for the `data-control-scope` option may affect the `transaction` option settings for a bounded task flow. [Table 18–1](#) describes how these options interact.

The ADF Model layer exposes the `DataControlFrame` interface to manage a transaction in which the data controls within the frame participate. The `DataControlFrame` interface exposes methods such as:

- `beginTransaction()`
- `commit()`
- `rollback()`

Similarly, ADF Controller allows a task flow to demarcate a transaction boundary, to begin a transaction at task flow entry, and to either commit or roll back the transaction on task flow exit. It does this by invoking methods exposed by ADF Model layer's `DataControlFrame` interface.

ADF Controller supports the transaction options listed in [Table 18–1](#). The behavior of these transaction options depends on whether you select or deselect the **Share data controls with calling task flow** checkbox (XML element: `<data-control-scope>`) in the overview editor for a task flow.

**Table 18–1 Transaction Settings Behavior**

Transaction Setting	Share Data Control Scope	Isolate Data Control Scope
<No Controller Transaction>	The <code>DataControlFrame</code> is shared without the need for an open transaction on the frame.	A new <code>DataControlFrame</code> is created without an open transaction.
<b>Always Begin New Transaction</b> XML element: <code>&lt;new-transaction/&gt;</code>	Begins a new transaction if one is not already open and throws an exception if one is already open.	Always begins a new transaction.
<b>Always Use Existing Transaction</b> XML element: <code>&lt;requires-existing-transaction/&gt;</code>	Throws an exception if the transaction is not already open.	Invalid. The checkbox cannot be deselected.
<b>Use Existing Transaction if Possible</b> XML element: <code>&lt;requires-transaction/&gt;</code>	Begins a new transaction if one is not already open.	Always begins a new transaction.

A number of examples illustrate how bounded task flows interact when you configure different combinations of values for the data control scope and transaction properties described in [Table 18–1](#):

- Isolate two bounded task flow transactions completely so that they can be committed or rolled back separately. For more information, see [Section 18.4.3.1, "Creating Completely Separate Transactions."](#)
- Guarantee that two bounded task flows share a transaction to save connection resources and stop the transaction if the called bounded task flow cannot join the transaction of the calling bounded task flow. For more information, see [Section 18.4.3.2, "Guaranteeing a Called Bounded Task Joins an Existing Transaction."](#)
- Call a bounded task flow that joins the transaction of the calling bounded task flow if one exists and, if not, creates its own transaction. For more information, see [Section 18.4.3.3, "Using an Existing Transaction if Possible."](#)

The above list describes common use cases rather than all possible configuration options.

### 18.4.3.1 Creating Completely Separate Transactions

[Figure 18–4](#) shows a number of task flows that are configured to create separate transactions. Two bounded task flows are chained together in [Figure 18–4](#) yet maintain completely separate transactions. This implementation may be appropriate where you have a call center agent taking an order from a customer and entering the order details in your application. At some point near the end of the order process, the customer realizes that the delivery address that they have provided is incorrect. To assist the call center agent, you designed your application so that it updates and commits the delivery address in a separate transaction to the transaction for the order details (order number, quantity, and so on). In the scenario where the customer wishes to modify the delivery address, the call center agent does not need to roll back changes to the order details in order to modify the delivery address because a separate transaction manages the order details.

In [Figure 18–4](#), the unbounded task flow calls Bounded Task Flow #1. This results in the creation of Data Control Frame #1 because Bounded Task Flow #1 is configured as follows:

- A `data-control-scope` value of `isolated`
- **Always Begin New Transaction**

Bounded Task Flow #1 exposes attributes from two different view objects as data control fields (viewObject1.X and viewObject2.Y). X and Y are initially set to 10 and 20 respectively. The end user, while accessing Bounded Task Flow #1, updates X from 10 to 30 and leaves Y unchanged. This marks the transaction as changed or "dirty". That is, there are changes in the transaction that must be committed or rolled back.

Bounded Task Flow #1 calls Bounded Task Flow #2. The application creates Data Control Frame #2 because Bounded Task Flow #2 is configured as follows:

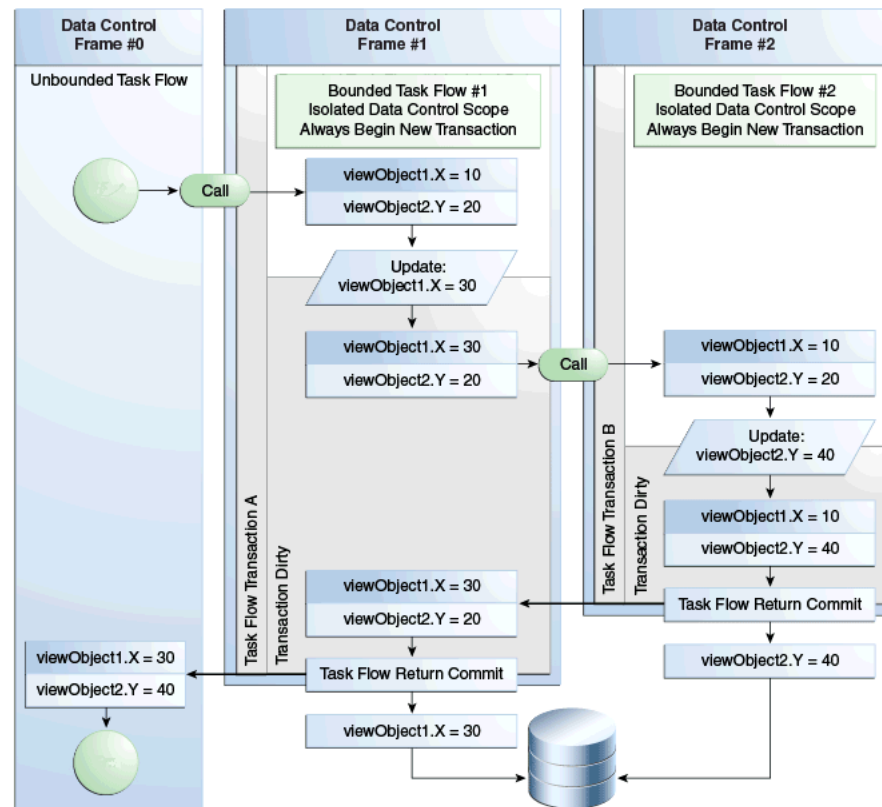

- A data-control-scope value of `isolated`
- **Always Begin New Transaction**

Note that the transaction of Data Control Frame #1 has yet to be committed and that Data Control Frame #2 has a separate database connection and a separate task flow transaction. As a result, the initial values of the data control fields X and Y in Bounded Task Flow #2 are 10 and 20. The end user, while accessing Bounded Task Flow #2, updates Y to 40 and leaves X unchanged. This marks the transaction for Bounded Task Flow #2 as dirty. Bounded Task Flow #2 next calls a task flow return activity that commits the change to Y to the database and returns control to Bounded Task Flow #1. As Bounded Task Flow #2 did not modify the value of X, no change for this data control field occurs.

Because Bounded Task Flow #1 has a separate data control frame (Data Control Frame #1) and transaction, the values of the data control fields X and Y in Bounded Task Flow #1 remain at 30 and 20, their values when Bounded Task Flow #1 called Bounded Task Flow #2. Bounded Task Flow #1 now calls a task flow return activity (set to commit), saving the value of X to the database. The value of Y remains unchanged because Bounded Task #1's transaction did not modify the value of Y.

On returning to the unbounded task flow and refreshing the values of X and Y from the database, the updated values of 30 and 40 are returned.

Figure 18–4 Completely Separate Transactions

#### 18.4.3.2 Guaranteeing a Called Bounded Task Joins an Existing Transaction

Figure 18–5 shows two bounded task flows in a configuration that guarantees that the second bounded task flow joins the transaction of the first bounded task flow that calls it. An example scenario where such an implementation may be appropriate is if your application creates invoices and, separately, the individual lines of the invoice. When creating an invoice line, it does not make sense that an invoice line is created without the parent invoice that is to contain the invoice line. If you were to build two separate task flows to create the invoice and invoice lines, the invoice line task flow needs to enforce that it wants to join a transaction of the calling task flow, in this case the invoice task flow, rather than creating a separate transaction.

Figure 18–5 illustrates how the above use case can be addressed by configuring an unbounded task flow that calls a bounded task flow (Bounded Task Flow #1). The unbounded task flow has its own data control frame (Data Control Frame #1). Bounded Task Flow #1 starts a transaction and also has a data control frame (Data Control Frame #0) because it is configured as follows:

- A data-control-scope value of `isolated`
- **Always Begin New Transaction**

Bounded Task Flow #1 exposes attributes from two different view objects as data control fields (`viewObject1.X` and `viewObject2.Y`). `X` and `Y` are initially set to 10 and 20 respectively. The end user, while accessing Bounded Task Flow #1, updates `X` from 10 to 30 and leaves `Y` unchanged. This marks Task Flow Transaction A associated with Data Control Frame #1 as changed or "dirty". That is, there are changes in the transaction that must be committed or rolled back.

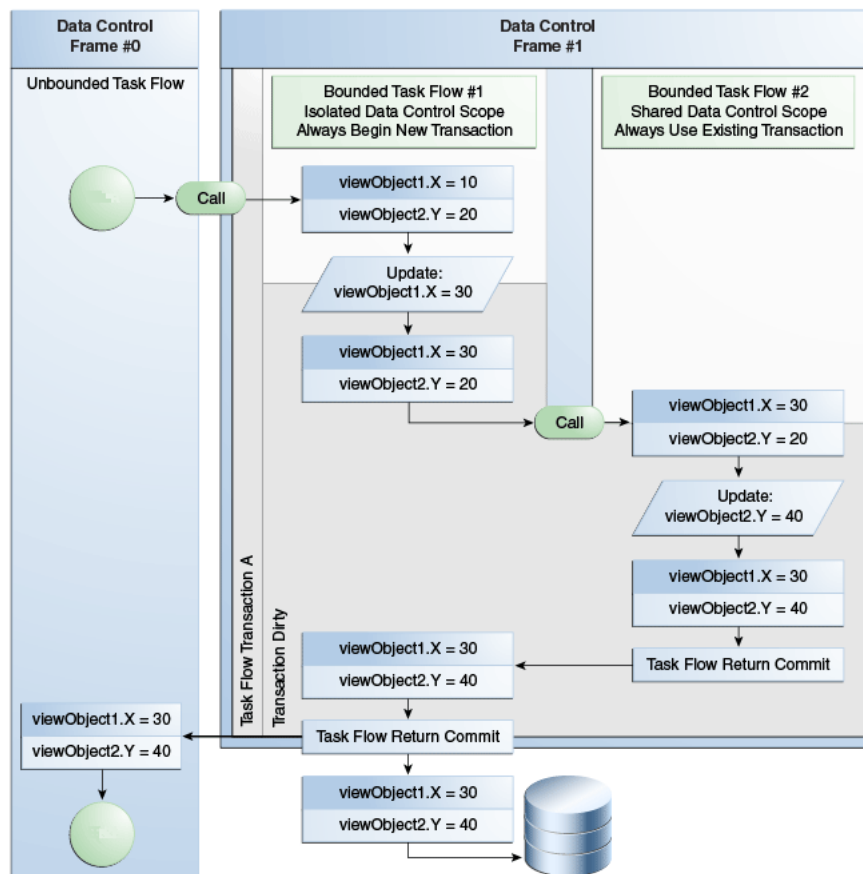

Bounded Task Flow #1 calls Bounded Task Flow #2. Bounded Task Flow #2 is configured as follows:

- A data-control-scope value of shared
- **Always Use Existing Transaction**

Because of this configuration, no new data control frames are created. Bounded Task Flow #2 uses the same data control frame (Data Control Frame #1) as Bounded Task Flow #1. The changes applied to X in Bounded Task Flow #1 are visible to Bounded Task Flow #2. Updates made to Y in Bounded Task Flow #2 are visible to Bounded Task Flow #1 when it receives control back from Bounded Task Flow #2 after it executes a task flow return activity that specifies a commit. This update to Y is visible in Bounded Task Flow #1 because of the shared data control scope, not because of the commit option that the task flow return activity of Bounded Task Flow #2 specifies.

Remember that the commit and rollback options of a task flow return activity are only valid for the bounded task flow that starts a transaction. That is why the commit of Bounded Task Flow #1's task flow return activity finalizes changes in the database and not Bounded Task Flow #2.

**Figure 18–5 Guaranteed Joined Transactions**

### 18.4.3.3 Using an Existing Transaction if Possible

Section 18.4.3.2, "Guaranteeing a Called Bounded Task Joins an Existing Transaction," described how to configure a bounded task flow to call a second bounded task flow and guarantee that the called bounded task flow joins the transaction of the calling

bounded task flow. The effect of changing the configuration of the calling bounded task flow to have:

- A `data-control-scope` value of `isolated`
- **<No Controller Transaction>**

while leaving the called bounded task flow unchanged is to stop execution of the bounded task flows and throw the following error message at runtime:

```
ADFC-00006: Existing transaction is required when calling task flow '{0}'
```

The above scenario illustrates the benefit of configuring the called bounded task flow as follows:

- A `data-control-scope` value of `shared`
- **Use Existing Transaction if Possible**

This latter configuration means that the called bounded task flow creates a transaction if the calling bounded task flow has not created a transaction.

Another configuration option for a called bounded task that guarantees it creates its own transaction is to configure it as follows:

- A `data-control-scope` value of `isolated`
- **Use Existing Transaction if Possible**

This causes the called bounded task flow to create its own transaction regardless of the transaction options that you configure for the calling bounded task flow. The effect is the same as if you set the called bounded task flow to use **Always Begin New Transaction**.

#### 18.4.4 What You May Need to Know About ADF Business Component Database Connections and Task Flow Transaction Options

ADF Controller shares the ADF Business Component application modules' database connections in an application that has more than one root application module (and each application module has a database connection) where task flow transaction options combine to share connections. That is, you configured a set of chained task flows in your application that have a `data-control-scope` value of `shared` in combination with the following transaction options:

- **Always Begin New Transaction**
- **Always Use Existing Transaction**
- **Use Existing Transaction if Possible**

This implementation helps to reduce the number of database connections that each user creates and, as a result, makes the application more scalable. This is particularly useful when you add task flows and root application modules to your application through ADF Library JARs.

A set of chained task flows is where task flows call other task flows so that your application contains a chain with two or more task flows. For example, in [Figure 18–1](#) the unbounded task flow UTF1 calls the bounded task flow BTF1 that in turn calls the bounded task flow BTF2, and so on.

---

---

**Note:** Remember to configure your application's chained task flows to use a `data-control-scope` value of `isolated` if you do not want root application modules to share database connections.

---

---

However, you may want to configure different behavior where you want to have separate root application modules connect to different data sources within the same ADF Model project. For example, you may want to show data from two different database systems or you need to connect to two different schemas in the same database.

To implement this last scenario (have the root application modules maintain their own database connections), you set the `transaction` property's value to `No Controller Transaction` (the default value) for the task flows in your application. This makes sure that each root application module manages its own database connection in isolation and that the ADF Controller does not manage the transaction behavior of the ADF Business Components.

## 18.5 Reentering a Bounded Task Flow

To deal with cases in which the end user clicks the back button to navigate back into a bounded task flow that was already exited, you can specify `task-flow-reentry` options for the bounded task flow. These options specify whether a page in the bounded task flow can be reentered.

Upon reentry, bounded task flow input parameters are evaluated using the current state of the application, not the application state existing at the time of the original bounded task flow entry.

---

---

**Note:** Different browsers handle the back button differently. In order to ensure that back button navigation is properly detected across all browsers, the view activities within the task flow need to be properly configured. When a task flows uses the `reentry-not-allowed` or `reentry-outcome-dependent` option, the `redirect` attribute on each view activity within the task flow should be set to `true`. See [Section 15.3, "Using URL View Activities"](#) for more information on how to configure view activities.

---

---

### 18.5.1 How to Set Reentry Behavior

You can set reentry behavior on a bounded task flow.

**To set reentry behavior:**

1. Open the bounded task flow in the overview editor.
2. Click **Behavior**.
3. In the **Task Flow Reentry** list, choose one of the following:
  - **reentry-allowed:** Reentry is allowed on any view activity within the bounded task flow.
  - **reentry-not-allowed:** Reentry of the bounded task flow is not allowed. If you specify `reentry-not-allowed` on a bounded task flow, an end user can still click the browser back button and return to a page within the bounded task flow. However, if the user does anything on the page such as clicking a button,

an exception (for example, `InvalidTaskFlowReentry`) is thrown indicating the bounded task flow was reentered improperly. The actual reentry condition is identified upon the submit of the reentered page.

You can set up an exception handler to display the exception and route control flow in order to navigate to the default activity of the called bounded task flow. If the bounded task flow was not called from another bounded task flow, a normal web error is posted and handled as specified in the `web.xml` file.

- **reentry-outcome-dependent:** Reentry of a bounded task flow using the browser back button is dependent on the outcome that was received when the same bounded task flow was previously exited via task flow return activities. If specified, any task flow return activities on the called bounded task flow must also specify either `reentry-allowed` or `reentry-not-allowed` to define outcome-dependent reentry behavior.

If you choose this option, the user can navigate to a task flow using a back button based solely on how the user originally exited the task flow. For example, a task flow representing a shopping cart can be reentered if the user exited by canceling an order, but not if the user exited by completing the order.

## 18.5.2 How to Set Outcome-Dependent Options

You can set outcome-dependent options on bounded task flows that have specified the `reentry-outcome-dependent` option, as described in [Section 18.5.1, "How to Set Reentry Behavior."](#)

### To set outcome-dependent options:

1. In the task flow diagram for the bounded task flow, select the task flow return activity.

For information about adding a task flow return activity, see [Section 15.7, "Using Task Flow Return Activities."](#)

2. In the Property Inspector, expand the **General** section.
3. In the **Name** field, enter the name of literal outcome, for example, `success` or `failure`.
4. Expand the **Behavior** section.
5. In the **Reentry** dropdown list, choose one of the following options:
  - **reentry-allowed:** Reentry is allowed on any view activity within the bounded task flow.
  - **reentry-not-allowed:** Reentry of the bounded task flow is not allowed. If you specify `reentry-not-allowed` on a bounded task flow, an end user can still click the browser back button and return to a page within the bounded task flow. However, if the user does anything on the page such as clicking a button, an exception (for example, `InvalidTaskFlowReentry`) is thrown indicating the bounded task flow was reentered improperly. The actual reentry condition is identified upon the submit of the reentered page.

You can set up an exception handler to display the exception and route control flow in order to navigate to the default activity of the called bounded task flow. If the bounded task flow was not called from another bounded task flow, a normal web error is posted and handled as specified in the `web.xml` file.

### 18.5.3 What You Should Know About Managed Bean Values Upon Task Flow Reentry

When an end user reenters a bounded task flow using a browser's back button, and reentry is allowed, the value of a managed bean is reset to the value of the managed bean before the end user exited the bounded task flow. The managed bean value is reset before a view activity in the reentered bounded task flow renders. Any changes that occur before the reentry of the bounded task flow are lost. To change this behavior, specify the `<redirect>` element on the view activity in the reentered bounded task flow. When the end user reenters the bounded task flow using the back button, the managed bean has the new value from the parent task flow, not the original value from the child task flow that is reentered.

## 18.6 Executing a Bounded Task Flow Directly From a JSF Page

You can drag and drop a bounded task directly from the Application Navigator onto a JSF page. If the bounded task flow contains view activities that are page fragments, JDeveloper adds it to the JSF page as an ADF region. For example, the home page of the Fusion Order demo application contains a bounded task flow that displays a summary of items that the end user has added to a shopping cart page of the Fusion Order demo application. All view activities in the bounded task flow are page fragments, so the bounded task flow will be dropped on the Fusion Order demo application home page as a region. The contents of the shopping cart summary will display within a physical region on the home page of the Fusion Order demo application. For more information, see [Chapter 17, "Using Task Flows as Regions"](#).

However, if the bounded task flow contains view activities that are pages, JDeveloper proposes a choice of adding a task flow call as a button or a link. At runtime, end users can click the button or link to invoke the bounded task flow.

#### To add a bounded task flow containing pages to a JSF page:

1. In the Application Navigator, drag the source file for the ADF bounded task flow onto the page and drop it where you want to locate the button or link.

You can find task flows in the Application Navigator under the Page Flows or WEB-INF nodes.

2. Choose **Create** and either **Task Flow Call as Button** or **Task Flow Call as Link**.

As shown in [Figure 18–6](#), the bounded task flow appears on the JSF page as either a button or link UI component.

**Figure 18–6 Button and Link UI Components**

## 18.7 Handling Exceptions in Task Flows

During execution of a task flow, exceptions can occur that may require some kind of exception handling, for example:

- A method call activity throws an exception.
- A custom method you have written as a task flow initializer or finalizer throws an exception.
- A user is not authorized to execute the activity.

To handle exceptions thrown from an activity or caused by some other type of ADF Controller error, you can designate one activity in a bounded or unbounded task flow as an exception handler.

When a task flow throws an exception, control flow passes to the designated exception handling activity. For example, the exception handling activity might be a view activity that displays an error message. Alternatively, the activity might be a router activity that passes control flow to a method based on an EL expression that evaluates the type of exception. For example:

```
{someException == "oracle.adf.controller.ControllerException" }
```

After control flow passes to the exception handling activity, flow from the exception handling activity uses standard control flow rules. For example, you designate a router activity as the exception handling activity. At runtime, the task flow passes control to the exception handling activity (in this example, a router activity) in response to an exception. In addition to designating the router activity as an exception handler, you can define task flow control cases that the router invokes based on the type of exception that it has to handle. This allows you to manage your end user's application session gracefully when an exception occurs. For more information, see [Section 14.1.3, "Control Flows."](#)

You can optionally specify an exception handler for both bounded and unbounded task flows. Each task flow can have only a single exception handler. However, a task flow called from another task flow can have a different exception handler from that of the caller. In addition, a region on a page can have a different exception handler from that of the task flow containing the page. The exception handler activity can be any supported activity type, for example, a view or router activity.

If a bounded task flow does not have a designated exception handler activity, control passes to an exception handler activity in a calling bounded task flow, if there is a calling task flow and if it contains an exception handler activity. The exception is propagated up the task flow stack until either an exception handler activity or the top-level unbounded task flow is reached. If no exception handler is found, the exception is propagated to the web container.

If a bounded task flow does have a designated exception handler activity, make sure the exception handler activity leaves the application in a valid state after it handles an exception. One way to do this is to redirect to a view activity in the same task flow after the exception handler activity.

### 18.7.1 How to Designate an Activity as an Exception Handler

You can designate an exception handler activity for a bounded task flow running as an ADF region. If an exception occurs in the bounded task flow and it is not handled by the task flow's exception handler, the exception is not propagated up the task flow stack of the parent page. Instead, it becomes an unhandled exception.

#### To designate an activity as an exception handler for a task flow:

1. Right-click the activity in the task flow diagram, and choose **Mark Activity > Exception Handler**.

A red exclamation point is superimposed on the activity in the task flow to indicate that it is an exception handler. [Figure 18-7](#) shows an example.

**Figure 18–7 Example of an Activity Designated as an Exception Handler**

ex\_handler

- To unmark the activity, right-click the activity in the task flow diagram, and choose **Unmark Activity > Exception Handler**.

If you mark an activity as an exception handler in a task flow that already has a designated exception handler, the old handler is unmarked.

## 18.7.2 What Happens When You Designate an Activity as an Exception Handler

After you designate an activity to be the exception handling activity for a task flow, JDeveloper updates the task flow metadata with an `<exception-handler>` element that specifies the ID of the activity, as shown in [Example 18–3](#).

### Example 18–3 `<exception-handler>` element

```
<exception-handler id="__8>activityID</exception-handler>
```

## 18.7.3 How to Designate Custom Code as an Exception Handler

Rather than designate a task flow activity as the activity to invoke, you can write custom code to invoke when a task flow throws an exception. This requires you to:

- Write a Java class that extends the class `ExceptionHandler` from the following package:
 

```
oracle.adf.view.rich.context.ExceptionHandler
```
- Register the Java class that you write as a service in the `.adf\META-INF` directory of your Fusion web application

[Example 18–4](#) shows custom code that checks if an exception thrown by a task flow corresponds to a particular type of error message (`ADF_FACES-30108`). If it is, the custom code redirects the task flow to the `faces/SessionExpired.jspx` page.

### Example 18–4 Custom Code for an Exception Handler

```
package oracle.fodemo.frmwkext;

import javax.faces.context.ExternalContext;
import javax.faces.context.FacesContext;
import javax.faces.event.PhaseId;
import oracle.adf.view.rich.context.ExceptionHandler;

public class CustomExceptionHandler extends ExceptionHandler {

    public CustomExceptionHandler() {
        super();
    }

    public void handleException(FacesContext facesContext, Throwable throwable,
                               PhaseId phaseId) throws Throwable {
```

```

String error_message;
error_message = throwable.getMessage();

if (error_message != null &&
    error_message.indexOf("ADF_FACES-30108") > -1) {
    ExternalContext ectx = facesContext.getExternalContext();
    ectx.redirect("faces/SessionExpired.jsp");
}

else {
    super.handleException(facesContext, throwable, phaseId);
}
}
}

```

**Before you begin:**

It may help to understand other options for handling exceptions in task flows. For more information, see [Section 18.7, "Handling Exceptions in Task Flows."](#)

For information about the APIs that you can use to write custom code, see the following reference documents:

- *Oracle Fusion Middleware Java API Reference for Oracle ADF Controller*
- *Oracle Fusion Middleware Java API Reference for Oracle ADF Faces*

**To designate custom code as an exception handler:**

1. In the Application Navigator, expand the project where you want to write the custom and navigate to the **Application Sources/META-INF** node.
2. Create a folder named **services** under the META-INF node.
3. Create a text file named **oracle.adf.view.rich.context.ExceptionHandler** in the **services** folder.
4. Write the package name and class name of the code custom that you wrote to handle exceptions in the text file named **oracle.adf.view.rich.context.ExceptionHandler**.

For example, if you want to register the custom code in [Example 18-4](#), write the following:

```
oracle.fodemo.frmwkext.CustomExceptionHandler
```

5. Save and close the text file.

**18.7.4 What Happens When You Designate Custom Code as an Exception Handler**

At runtime, the task flow passes control to the custom code that you specified if the task flow throws an exception.

**18.7.5 What You May Need to Know About Handling Exceptions During Transactions**

Designate an exception handling activity for a bounded task flow that is enabled to run as a transaction. A Fusion web application attempts to commit a transaction if you set `commit` as the value for a task flow return activity's End Transaction property on a bounded task flow that runs as a transaction. If an exception occurs when the Fusion web application attempts to commit a transaction, the exception handling activity receives control and provides the end user with an opportunity to correct the

exception. You can use the exception handling activity (for example, a view activity) to display a warning message to an end user with information about how to correct the exception and how to recommit the transaction. For information about enabling a bounded task flow as a transaction and setting `commit` as a value for the `End Transaction` property, see [Section 18.4.1, "How to Enable Transactions in a Bounded Task Flow."](#)

### 18.7.6 What You May Need to Know About Handling Validation Errors

For validation errors on a JSF page, you can rely on standard JSF to attach validator error messages to specific components on a page or to the whole page. A component-level validator typically attaches an error message inline with the specific UI component. There is no need to pass control to an exception handler activity.

In addition, your application should define validation logic on data controls that are executed during the `Validate Model Updates` phase of the JSF lifecycle. In this way, data errors are found as they are submitted to the server without waiting until attempting the final commit.

Validations done during the `Validate Model Updates` phase typically do not have direct access to the UI components because the intention is to validate the model after the model has been updated. These validations are often things like checking to see whether dependent fields are in sync. In these cases, the error message is usually attached to the whole page, which this logic can access.

You should attach errors detected during the `Validate Model Updates` phase to the JSF page, and call `FacesContext.renderResponse()`. This signals that following this phase, the current (submitting) page should be rendered showing the attached error messages. There is no need to pass control to an exception handler activity.

For more information, see [Chapter 8, "Implementing Validation and Business Rules Programmatically"](#).

## 18.8 Configuring Your Application to Use Save Points

Before you can add save points to a task flow, as described in [Section 18.9, "Using Save Points in Task Flows"](#) and configure related functionality, you need to make sure that the Fusion web application allows save points. To do this, you define a value for the `<savepoint-datasource>` element in the `adf-config.xml` file to specify the JNDI name for the data source that contains the save points' database table. You may also need to run a SQL script (`adfc_create_save_point_table.sql`), as described in [Section 18.8.3, "What You May Need to Know About the Database Table for Save Points,"](#) to create the database table that stores save points. Once your Fusion web application starts using save points, you can use another SQL script (`adfc_cleanup_save_point_table.sql`) to delete expired save points.

### 18.8.1 How to Configure Your Fusion Web Application to Use Save Points

You define a value for the `<savepoint-datasource>` element in your application's `adf-config.xml` file to specify the JNDI name for the data source that contains the save points' database table. Optionally, you can also specify an expiration time for save points.

#### To configure your Fusion web application to allow save points:

1. With the Fusion web application open in JDeveloper, open the Application Resources pane in the Application Navigator.

2. Expand **Descriptors**, then expand **ADF META-INF**.
3. Right-click `adf-config.xml` and choose **Open** from the context menu.
4. On the Controller page of the overview editor, write a value for the Data Source property to specify the JNDI name for the data source that contains the save points' database table.

For example, write the following:

```
java:comp/env/jdbc/Connection1DS
```

where `Connection1` is the JDeveloper connection name.

5. Optionally, write a value in seconds for the Expiration property to specify the time between when a task flow creates a save point and when the save point manager removes it. The default value is 86400 seconds.

For more information, see [Section 18.9.9, "What You May Need to Know About the Time-to-Live Period for a Save Point."](#)

6. Save the `adf-config.xml` file.

## 18.8.2 What Happens When You Configure a Fusion Web Application to Use Save Points

JDeveloper generates an entry, similar to that illustrated in [Example 18-5](#), in the `adf-config.xml` file to specify the JNDI name for the data source that contains the save points' database table.

### **Example 18-5 Save Point Data Source Definition in `adf-config.xml`**

```
<adf-controller-config xmlns="http://xmlns.oracle.com/adf/controller/config">
  ...
  <savepoint-datasource>
    java:comp/env/jdbc/Connection1DS
  </savepoint-datasource>
  <savepoint-expiration>
    86399
  </savepoint-expiration>
</adf-controller-config>
```

For more information about the `adf-config.xml` file, see [Section A.11, "adf-config.xml."](#)

## 18.8.3 What You May Need to Know About the Database Table for Save Points

A database table named `ORADFCSAVPT` stores save points. If this database table does not exist, it is created the first time that a save point is created if your Fusion web application has the necessary permissions to create a database table. If your Fusion web application does not have the necessary permissions, you or an administrator with the necessary permissions can use SQL scripts to create and maintain the `ORADFCSAVPT` database table. These SQL scripts are:

- `adfc_cleanup_save_point_table.sql`

Each save point in the `ORADFCSAVPT` database table has an expiration date. Use this script to delete save points that have passed their expiration date.

- `adfc_create_save_point_table.sql`

Use this script to create the `ORADFCSAVPT` database table that stores save points.

You can find these SQL scripts in the following directory of your JDeveloper installation:

```
jdev_install\oracle_common\common\sql
```

## 18.9 Using Save Points in Task Flows

You can configure a task flow to capture the state of a Fusion web application at a particular instance creating what is called a *save point*. This allows you to save application state if, for example, a user leaves a page without finalizing it. The application state can be restored at a later point.

[Table 18–2](#) describes what information a save point captures.

**Table 18–2** *Saved Application State Information*

Saved State Information	Description
User Interface State	<p>UI state of the current page, including selected tabs, selected checkboxes, selected table rows, and table column sort order.</p> <p>This state assumes the end user cannot select the browser back button on save point restore.</p>
Managed Beans	<p>State information saved in several possible memory scopes, including session and page flow scope. The managed beans must be serializable in order to be saved. If you have page flow scope beans that are not serializable and you attempt to create a save point, a runtime exception occurs.</p> <p>Request scope is not supported since its lifespan is a single HTTP request and its lifespan can't be used to store cross request application state.</p> <p>Save points will not save and restore application-scoped managed beans since they're not passivated in failover scenarios. Therefore, the application is always responsible for ensuring that all required application-scoped state is available.</p> <p>Potential naming conflicts for managed beans already existing within the session scope at restore time will not occur because multiple managed beans using the same name should not be implemented within an application.</p>
Navigation State	<p>Task flow call stack, which ADF Controller maintains as one task flow calls another at runtime.</p> <p>The task flow call stack tracks where the end user is in the application and the navigation path for getting there. The task flow stack also identifies the starting point of any persisted data transactions originated for the end user.</p>
ADF Model State	<p>Fusion web applications use ADF Model to represent the persisted data model and business logic service providers. The ADF Model holds any data model updates made from when the current bounded task flow begins. The model layer determines any limits on the saved state lifetime. For more information, see <a href="#">Chapter 40, "Application State Management."</a></p>

You add a method call activity to a bounded task flow that invokes a `createSavePoint` method to create save points. Later, you use a save point restore activity to restore application state and data associated with the created save points.

The same save point can be used if a user repeatedly performs a save for later on a task flow instance that executes in one session within the same browser window. The new save point overwrites the existing save point when a user performs a save for later following navigation from page to page in a task flow. For more information about restoring a save point, see [Section 18.9.3, "How to Restore a Save Point."](#)

You can specify the `createSavePoint` method exposed by the `currentViewPort` node of the ADF Controller Objects in the Expression Builder. Alternatively, you can write a custom method that updates the save point with the values of attributes you specify in your custom method, as illustrated in [Example 18–6](#).

**Example 18–6** *Example Custom Method for Creating a Save Point*

```
package viewController;
```

```

import java.io.Serializable;

import oracle.adf.controller.ControllerContext;
import oracle.adf.controller.savepoint.SavePointManager;

public class SaveForLater implements Serializable {
    public SaveForLater() {
        super();
    }

    public String saveTaskFlow() {
        ControllerContext cc = ControllerContext.getInstance();
        if (cc != null) {
            SavePointManager mgr = cc.getSavePointManager();
            if (mgr != null) {
                String id = mgr.createSavePoint();
                System.out.println("Save point is being set " + id);
                ...
            }
        }
    }
}

```

The `SavePointListener` interface exposes methods that notify clients when save point events occur. The following package contains the `SavePointListener` interface:

```
oracle.adf.controller.savepoint
```

---

---

**Note:** All save points created inside a bounded task flow are deleted when the bounded task flow exits.

---

---

## 18.9.1 How to Add a Save Point to a Task Flow

You drag and drop a method call activity to the task flow and configure it to invoke the `createSavePoint` method or to invoke a custom method if you created one.

### Before you begin:

Using a save point in a Fusion web application requires that you leave the value of the `jbo.locking.mode` property set to the default value `optimistic`. The value `pessimistic` causes an old session to lock until the session has timed out. In pessimistic mode, if you run an application and change data without committing changes to the database, you may get an error when you create a save point and try to restore it at a later point. For information about the `jbo.locking.mode` property, see [Section 40.11.1, "How to Set Applications to Use Optimistic Locking."](#)

### To add a save point to a task flow:

1. Open the bounded task flow that you want to configure and navigate to the diagram editor.
2. In the ADF Task Flow page of the Component Palette, from the Component panel, drag and drop a **Method Call** activity onto the diagram.
3. In the Property Inspector, expand the **General** node and write an EL expression for the Method property to specify the save point method that the method call activity invokes.

If you use the Expression Builder to specify the `createSavePoint` method exposed by the `currentViewPort` node of the ADF Controller Objects, the resulting EL expression is similar to the following:

```
#{controllerContext.currentViewPort.createSavePoint}
```

4. Use a control flow to connect the method call activity with other activities in the bounded task flow.

For more information, see [Section 14.3.3, "How to Add Control Flows."](#)

5. Optionally, configure save point options in the Fusion web application's `adf-config.xml` file to determine, for example, if implicit save points can be created for the application.

For more information, see [Section 18.9.7, "How to Enable Implicit Save Points."](#)

## 18.9.2 What Happens When You Add Save Points to a Task Flow

JDeveloper generates entries similar to those shown in [Example 18–7](#) in the task flow's source file when you configure a method call activity to invoke the `createSavePoint` method.

### *Example 18–7 Method Call Metadata to Invoke the createSavePoint Method*

```
<method-call id="methodCall1">  
  <method id="__3">#{controllerContext.currentViewPort.createSavePoint}</method>  
</method-call>
```

## 18.9.3 How to Restore a Save Point

Use the save point restore activity to restore a previously persisted save point for an application. The save point restore activity uses the save point that was originally created by invoking the `createSavePoint` method to identify the save point to restore.

You can obtain a list of the current persisted save points with `createSavePoint`. However, ADF Controller does not determine which save points to restore. A user must select the save point from a list or the application developer must select it programmatically. The savepoint ID is then passed to a save point restore activity to perform the restore.

### **To add a save point restore activity to a bounded or unbounded task flow:**

1. Open the bounded or unbounded task flow where you want to add the save point restore activity and navigate to the diagram editor.
2. In the ADF Task Flow page of the Component Palette, from the Components panel, drag a **Save Point Restore** activity and drop it on the diagram for the task flow.
3. In the Property Inspector, expand the **General** node and write an EL expression for the **Save Point ID** property that, when evaluated, retrieves the save point that was originally created when the `createSavePoint` method was invoked.

If you use the Expression Builder to specify the `getSavePoint` method of the ADF Controller Objects, the resulting EL expression is similar to the following:

```
#{SessionScope.myBean.savepointID}
```

## 18.9.4 What Happens When You Restore a Save Point

JDeveloper generates entries similar to [Example 18–8](#) in the task flow's source file when you add a save point restore activity that gets a save point ID.

**Example 18–8 Metadata for a Save Point Restore Activity in a Task Flow**

```
<save-point-restore id="savePointRestore1">
  <save-point-id id="__4">#{sessionScope.myBean.savepointID}</save-point-id>
</save-point-restore>
```

**18.9.5 How to Use the Save Point Restore Finalizer**

When using the save point restore activity, you may need to invoke application-specific logic as part of restoring the application state. You can write an EL expression for the Save Point Restore Finalizer property of a bounded task flow that specifies a finalizer method. The bounded task flow invokes the specified method after the task flow's state has been restored. It performs any necessary logic to make sure that the application's state is correct before proceeding with the restore.

**To use the save point restore finalizer:**

1. In the Structure window, right-click the node for the bounded task flow (`task-flow-definition`) and select **Go to Properties**.
2. In the Property Inspector, expand the **General** tab, and select **Expression Builder** from the **Save Point Restore Finalizer** dropdown menu.
3. Write an EL expression that specifies the finalizer method to invoke.

**18.9.6 What Happens When a Task Flow Invokes a Save Point Restore Finalizer**

JDeveloper generates entries similar to [Example 18–9](#) in the task flow's source file when you write an EL expression for the Save Point Restore Finalizer property.

**Example 18–9 Metadata to Invoke a Save Point Restore Finalizer**

```
<task-flow-definition id="task-flow-definition1">
  <save-point-restore-finalizer id="__2">#{sessionScope.MyBean.invokeFinalizer}
  </save-point-restore-finalizer>
</task-flow-definition>
```

**18.9.7 How to Enable Implicit Save Points**

A save point in a task flow can be categorized as *implicit* or *explicit*. An explicit save point requires an end user action before a bounded or unbounded task flow creates a save point. For example, an end user clicks a button that invokes a method call activity that, in turn, creates a save point.

An implicit save point can only originate from a bounded task flow. It includes everything from when the originating task flow creates a save point. It occurs when data is saved automatically because:

- A session times out due to end user inactivity
- An end user logs out without saving the data
- An end user closes the only browser window, thus logging out of the application
- An end user navigates away from the current application using control flow rules (for example, uses a `goLink` component to go to an external URL) and having unsaved data.

Enabling implicit save points requires you to add an element to your Fusion web application's `adf-config.xml` file and to make the bounded task flow critical.

You configure the `adf-config.xml` file in your application and the bounded task flow(s) for which you want to create implicit save points. Enabling implicit save points involves a performance cost because your Fusion web application has to do extra work that it would otherwise not do. This is why you have to explicitly enable implicit save points in your application and specify the task flows to which it applies.

**To enable implicit save points:**

1. In the Application Resources panel of the Application Navigator, expand **Descriptors**, then expand **ADF META-INF**.
2. Right-click `adf-config.xml` and choose **Open** from the context menu.
3. On the Controller page of the overview editor, select the **Enable Implicit Savepoints** checkbox.

JDeveloper generates the following entry in the `adf-config.xml` file:

```
<adf-controller-config xmlns="http://xmlns.oracle.com/adf/controller/config">
  ...
  <enable-implicit-savepoints>true</enable-implicit-savepoints>
</adf-controller-config>
```

For more information about the `adf-config.xml` file, see [Section A.11, "adf-config.xml."](#)

4. In the Application Navigator, double-click the source file for the bounded task flow.
5. In the overview editor, click the **Behavior** navigation tab and select the **Critical** checkbox.

## 18.9.8 What You May Need to Know About Enabling Implicit Save Points

If multiple windows are open when the implicit save point is created, a different save point is created for each browser window. This includes everything from the root view port of the browser window on down. You can write an EL expression for the Method property of a method call activity to retrieve the list of implicit save points using the `savePointManager` node under ADF Controller Objects. The resulting EL expression is similar to the following:

```
ControllerContext.savePointManager.listSavePointIds
```

Implicit save points are generated only if a critical task flow is present in any of the page flow stacks for any view port under the current root view port. An implicit save point is not generated if the request is for an ADF Controller resource, such as:

- Task flow call activity
- Task flow return activity
- Save point restore activity
- A dialog

Implicit save points are deleted when the task flow at the bottom of the stack completes or a new implicit save point is generated, whichever comes earlier.

## 18.9.9 What You May Need to Know About the Time-to-Live Period for a Save Point

An application-level property (`savepoint-expiration`) that is defined in the `adf-config.xml` file determines the period between when a task flow creates a save

point and when the save point manager removes it (time-to-live period). The default value is 86400 seconds (24 hours).

You can change the time-to-live period for individual save points by calling the `setSavePointTimeToLive` method on an instance of `SavePointManger` from the following package:

```
oracle.adf.controller.savepoint
```

An instance of `SavePointManager` can be obtained as follows:

```
SavePointManager mgr = ControllerContext.getInstance().getSavePointManager();
```

[Example 18–10](#) shows the syntax for the `setSavePointTimeToLive` method.

**Example 18–10 Syntax for the `setSavePointTimeToLive` Method**

```
public void setSavePointTimeToLive(long timeInSeconds) {
}
```

If you supply a value for the `setSavePointTimeToLive` method argument (`timeInSeconds` in [Example 18–10](#)) equal to or less than zero, the default value is used (86400).

The `SavePointManger` defines methods that help you manage save points. For example, it defines `getSavePoint` and `removeSavePoint` methods that can retrieve and remove save points. Note that the `removeSavePoint` method does not get called automatically when a save point expires. You must explicitly call the `removeSavePoint` method to remove save points (including expired save points) from the `ORADFCSAVPT` database table. Alternatively, Oracle ADF provides a SQL script (`adfc_cleanup_save_point_table.sql`) that removes expired save points. For more information, see [Section 18.8.3, "What You May Need to Know About the Database Table for Save Points."](#)

Consider calling the `setSavePointTimeToLive` method at the same time that you call the method to create save points, as illustrated in [Example 18–6](#). For more information about the `SavePointManger`, see the *Oracle Fusion Middleware Java API Reference for Oracle ADF Controller*.

## 18.10 Minimizing the Number of Active Root View Ports in an Application

You can minimize the number of active root view ports in an application by specifying a value for the Maximum Root View Ports property (`<max-root-view-ports>`) in the application's `adf-config.xml` file. This limits the memory footprint of the application and can help to prevent denial-of-service attacks.

The default value is 20. The lowest permissible value is 5. To prevent accidental misuse, the application ignores any value below 5 and enforces a value of 5.

Specify a value of -1 if you want to disable this feature and allow an unlimited number of active root view ports in the application.

### 18.10.1 How to Minimize the Number of Active Root View Ports

You specify a value for the `<max-root-view-ports>` property in the application's `adf-config.xml` file.

**To minimize the number of active root view ports:**

1. With the Fusion web application open in JDeveloper, open the Application Resources pane in the Application Navigator.
2. Expand **Descriptors**, then expand **ADF META-INF**.
3. Right-click `adf-config.xml` and choose **Open** from the context menu.
4. On the Controller page of the overview editor, write a value for the Maximum Root View Ports property to specify the maximum number of active root view ports for the application.
5. Save the `adf-config.xml` file.

## 18.10.2 What Happens When You Minimize the Number of Active Root View Ports

JDeveloper generates an entry, similar to that illustrated in [Example 18–11](#), in the `adf-config.xml` file to specify the maximum number of active root view ports for the application.

**Example 18–11 Maximum Number of Root View Ports in `adf-config.xml`**

```
<?xml version="1.0" encoding="UTF-8" ?>
<adf-config xmlns="http://xmlns.oracle.com/adf/config"
            xmlns:config="http://xmlns.oracle.com/bc4j/configuration"
            xmlns:adf="http://xmlns.oracle.com/adf/config/properties">
    ...
    <adf-controller-config xmlns="http://xmlns.oracle.com/adf/controller/config">
        <max-root-view-ports>
            19
        </max-root-view-ports>
    </adf-controller-config>
</adf-config>
```

At runtime, once the specified root view port limit is reached, any request to create a new root view port automatically expires the least-recently-used root view port first. Attempts to subsequently use the expired root view port result in a `ViewExpiredException`.

## 18.11 Creating a Train

A train represents a progression of related activities that guides an end user to the completion of a task. The end user clicks a series of train stops, each stop linking to a particular page. [Figure 18–8](#) shows a train in the Fusion Order demo application that is called when an end user clicks the **Register as a customer** link on the registration page.

**Figure 18–8 Self-Registration Train in Fusion Order Demo Application**

This train contains four steps, each corresponding to a JSF page where the end user can enter and review registration information. The train stops are:

- Basic Information
- Address
- Payment Options
- Review

Each JSF page in the train contains an ADF Faces Train UI component similar to that shown in [Figure 18–9](#). It enables the user to navigate through the train stops in an order specified in the underlying train model.

**Figure 18–9 Train UI Component**

The optional Train Button Bar component shown in [Figure 18–10](#) contains buttons that provide an additional means to navigate backwards and forwards through the stops. This component can be used in conjunction with the train component to provide multiple ways to navigate through train stops.

**Figure 18–10 Train Button Bar UI Component**

### 18.11.1 Bounded Task Flows as Trains

You can create a train based on activities in a bounded task flow that specifies the `<train/>` element in its metadata. You cannot create a train from activities in an unbounded task flow.

**Tip:** You can also create a task flow template that has the `<train/>` element in its metadata, and then create a bounded task flow based on the template.

Each bounded task flow can have a single train only. If the bounded task flow logically includes multiple trains, you must add each train to a separate bounded task flow.

Figure 18–11 displays the bounded task flow that the Fusion Order Demo application uses to create the self-registration train shown in Figure 18–8.

**Figure 18–11 Customer Registration Task Flow**

Figure 18–12 contains a simplified detail of the first two train stops in customer-registration-task-flow. In the figure, an icon (two blue circles) identifies each train stop in the train. The dotted line connecting each stop indicates the sequence in which the end user visits them. For more information, see Section 18.11.2, "Train Sequences". Although you can't drag the dotted line to change the sequence, you can right-click a train stop and choose options to move the train stop forwards or backwards in the sequence. Each train stop is usually a view activity corresponding to a JSF page, although you can also add a task flow call activity as a train stop.

**Figure 18–12** Detail of Customer Registration Task Flow

The task flow call activity is used to group sets of activities together as a train stop or to call a child train. For example, there are cases when other activities, such as router and method call activities, should be considered part of a train stop along with the corresponding view activity. A method call activity might need to precede a view activity for initialization purposes. When grouped this way, the activities can be performed as a set each time the train stop is visited. For more information, see [Section 18.11.4, "What You May Need to Know About Grouping Activities"](#).

Branching using router activities and control flow cases is supported on the task flow diagram containing the train, as well as in child bounded task flows called from the train. For more information, see [Section 18.11.7, "What You May Need to Know About Branching"](#).

## 18.11.2 Train Sequences

By default, train stops are sequential. A user can select a *sequential* train stop only after visiting the train stop that is before it in the sequence. A *nonsequential* train stop can be performed in any order.

A single train can contain both sequential and nonsequential stops. In [Figure 18–13](#), the first step is the current train stop. The second step is sequential because the user can click it only after visiting the first stop. The third step is nonsequential because it can be clicked immediately after the user visits the first stop without also having to visit the second stop.

When the first step is the current stop, the end user cannot click the fifth and sixth steps, indicating that they are sequential.

**Figure 18–13** Train with Sequential and Nonsequential Stops

You can set the sequential option on the view activity (or task flow call activity) for each train stop to specify whether it has sequential or nonsequential behavior. The sequential option contains an EL expression that evaluates end-user input or some other factor, for example, `{myTrainModel.isSequential}`. When the EL

expression evaluates to `true`, the train stop behaves as sequential. When it evaluates to `false`, the train stop behaves as nonsequential.

In addition, you can alter the overall train sequence by skipping over individual train stops. The skip option on the activity corresponding to the train stop uses an EL expression that evaluates end-user input or some other factor to determine whether to skip over the train stop. If it evaluates to `true`, the train stop appears disabled and will be passed over. The end user is taken to the next enabled stop in the train. In addition, the train stop will be skipped if the end user clicks a **Next** or **Previous** button.

---

---

**Note:** If you want the train to execute by default at some train stop other than the first one, use the skip option. For example, if you want the train to begin executing at train stop 3, specify skip on train stops 1 and 2. This is better than marking a view activity associated with a train stop as the default activity for the bounded task flow, which can cause unpredictable results. For more information, see [Section 14.2.3, "What You May Need to Know About the Default Activity in an ADF Bounded Task Flow"](#).

---

---

### 18.11.3 How to Create a Train

To use a bounded task flow as a train, its metadata must contain the `<train/>` element. There are several ways to include this element in the metadata:

- Select the **Create Train** checkbox in the Create Task Flow dialog box. For more information, see [Section 14.2, "Creating a Task Flow."](#)
- Select the **Create Train** checkbox in the Create ADF Task Flow Template dialog box and then use the template to create a new bounded task flow. For more information, see [Section 18.13, "Creating a Task Flow Template."](#)
- Right-click an existing bounded task flow diagram in the editor and choose **Train > Create Train**.
- Open an existing bounded task flow in the overview editor, click **Behavior** and select the **Train** checkbox.

#### To create a train:

1. In the editor, open a bounded task flow that is usable as a train.

You must include the `<train/>` element in the bounded task flow's metadata by following one of the methods described above.
2. Drag each view activity or JSF page you want to include in the train from the Application Navigator to the bounded task flow diagram.
  - If you drag a JSF page, JDeveloper automatically adds a view activity to the diagram.
  - If you drag a view activity, you can double-click it later to create a new JSF page.

**Tip:** Don't worry about adding pages or view activities to the diagram in a particular order. You can adjust the train sequence later.
3. To rearrange the order of train stops, right-click the stop corresponding to an activity in the diagram. Choose **Train**, and then choose a menu item to move the train stop within the sequence, for example, **Move Forward** or **Move Backward**.

4. By default, train stops are sequential. You can optionally define whether the train stop behaves nonsequentially.
  - a. In the bounded task flow diagram, select the activity associated with the nonsequential train stop.
  - b. In the Property Inspector for the activity, click **Train Stop**.
  - c. In the **sequential** field, enter an EL expression, for example, `#{myTrainModel.isSequential}`.

You can also specify a literal value, for example, `true`.

If the EL expression evaluates to `true`, the train stop will be sequential. If `false`, the train stop will be nonsequential.

5. By default, a train stop will not be skipped. You can optionally designate that the train stop can be skipped based on the result of an EL expression.
  - a. In the bounded task flow diagram, select the activity associated with the nonsequential train stop.
  - b. In the Property Inspector, click **Train Stop**.
  - c. In the **skip** field, enter an EL expression, for example, `#{myTrainModel.shouldSkip}`.

If the EL expression evaluates to `true`, the train stop will be skipped. If `false`, the train stop will be not be skipped.

6. In the diagram, double-click each view activity that is being used as a train stop. Double-clicking the view activity opens a dialog to create a new JSF page. If a JSF page is already associated with the view activity, the existing page displays.
7. Open the JSF page in the editor.
8. For each JSF page in the train, select a **Train** and, optionally, a **Train Button Bar** UI component from the Common Components section of the ADF Faces page of the Component Palette. Drag the UI component onto the JSF page.

The train and train button bar UI components are not automatically added to pages and page fragments corresponding to the view activities within a bounded task flow for a train. You must add them manually to each page or page fragment. You can also add them using a page template.

After you add the components to the page, they are automatically bound to the train model. For more information about creating a train model, see the *Oracle Fusion Middleware Web User Interface Developer's Guide for Oracle Application Development Framework*.

#### 18.11.4 What You May Need to Know About Grouping Activities

Activities such as routers and method calls can be grouped with a view activity to form a single train stop. As shown in [Figure 18–11](#), in the customer registration bounded task flow, the `createAddress` method call activity and the `addressDetails` view activity are grouped with the `defineAddress` view activity to create the second stop in the train. The activities are performed as a set each time the train stop is visited. `createAddress` validates user input on the Address page and `defineAddress` is an optional page where the end user can enter additional address information. Because the page is optional and is accessed using a link on the Address page, it is not included in the bounded task flow as a separate train stop. Instead, it is grouped as one of the activities for the `createAddress` train stop.

---

---

**Note:** The approach for grouping a set of activities to form a train stop is to use a child bounded task flow (see [Section 18.11.5, "What You May Need to Know About Grouping Activities in Child Task Flows"](#)). The advantage of this approach is that all activities in the group are always performed together regardless of whether the train stop is being visited for the first time or on later returns.

If you don't use a child bounded task flow, all activities from the leading nonview activity through the next view activity will be considered part of the train stop's execution.

---

---

Although this approach groups a set of activities for a train stop within a child bounded task flow, you can provide the same functionality without a call to a child bounded task flow. Instead you can group the activities on the parent bounded task flow, as shown in [Figure 18-14](#). All activities leading from the first nonview activity through the next view activity are considered part of the implied train stop's execution.

To group activities without a child bounded task flow, you must ensure that:

- All non-view and non-task flow call activities for the train stop, such as routers and methods calls, follow the view or task flow call activity being used as the train stop.

This associates the activities with the train stop and not with the previous stop in the train.

- A wildcard control flow leads to first activity of the train stop.

You must specify a value for `from-outcome` (for example `gotoCollateSurveyAnswers`) on the control flow leading from the wildcard control flow. This value must match the value you specify for the train `outcome` on the view activity that is used as the train stop.

The wildcard control flow ensures that if an end user returns to a previously visited train stop, all activities will be performed beginning with the activity the wildcard control flow points to.

In [Figure 18-14](#), the `SurveyPage2` train stop consists of the following group of activities that execute in the following order:

**Figure 18–14 Grouping Activities Without Using a Task Flow Call Activity**

1. Wildcard control flow leading to first activity of the train stop, `CollateSurveyAnswers`.

---

**Note:** The train stop `outcome` element is used only if an activity such as a method call activity or router is placed prior to the view activity train stop. The element allows you to specify a custom outcome that results in navigation to the train stop.

---

2. Method call to `CollateSurveyAnswers` method.
3. `SurveyPage2` view.

### 18.11.5 What You May Need to Know About Grouping Activities in Child Task Flows

You can also group related activities along with a corresponding view activity in a child bounded task flow. Then you can designate a task flow call activity as train stop in the train. For more information, see (Section 15.6, "Using Task Flow Call Activities"). The task flow call activity calls the child bounded task flow. The group of activities are always performed together regardless of whether the train stop is being visited for the first time or on later returns.

---

**Best practice:**

When activities are grouped in a called child bounded task flow, nonview activities such as routers and methods calls typically precede the view activity in the control flow. You can include multiple view activities within the child bounded task flow, although in most cases there will be only one.

---

To group activities in the called child bounded task flow, you must ensure that:

- All non view activities for the train stop, such as routers and methods calls, precede the view activity in the control flow of the child bounded task flow.

- The child task flow contains a single view activity, unless the view activities are dialogs or helper pages originating from the main train stop view activity.

Figure 18–15 shows the `SurveyTaskFlow` train stop, a task flow call activity that calls a child bounded task flow.

**Figure 18–15 Task Flow Call Activity Train Stop**

The child bounded task flow is shown in Figure 18–25

**Figure 18–16 Called Child Bounded Task Flow**

All of the activities in the child bounded task flow are performed together every time the `SurveyTaskFlow` train is visited, regardless of whether the end user is visiting the first time or later.

If you use a child bounded task flow to group a set of activities, you must add a task flow return activity to the child task flow. The task flow return activity leads back to the parent bounded task flow, thus continuing the train. The task flow return activity should specify a value in `outcome`, for example, `done`, that will be used when returning to the parent train. In addition, you must manually add a control flow to the parent task flow that will be used to continue control flow within the train after returning from the child task flow.

As shown in Figure 18–15 and Figure 18–16, the value specified in the `from-outcome` for the control flow case (`done`) matches the task flow return activity **outcome** value.

### 18.11.6 What You May Need To Know About Using Child Trains

A train can use a task flow call activity as a train stop to invoke a child bounded task flow representing another train. The child bounded task flow must be created as its own train (that is, it must have the `<train/>` element in its metadata) and contain its own train stops. There is no limit to the depth of calls that are allowed to child trains.

### 18.11.7 What You May Need to Know About Branching

You can branch using router activities and control flow cases within a group of activities that are grouped to represent a single train stop, for example, the wildcard control flow rule router, and methods calls under step 2 in Figure 18–17.

You cannot branch between the activities that represent each train stop in a train. For example, you can not branch between steps 1, 2, and 3 in Figure 18–17.

**Figure 18–17 Branching within Grouped Activities for a Single Train Stop**

## 18.12 Running Multiple Task Flows

Multiple task flows may run simultaneously within a Fusion web application and within the same HTTP session. In many cases, you can run each task flow in a separate browser window. For example a customer support representative might work multiple customer cases simultaneously, each within its own browser window.

Task flows can be initiated to display within new browser windows from either a request by the application or the browser.

- Application requests new window

For example, the application itself requests a new browser window. This might occur when the end user clicks a button, a row in a table, or a link that results in a new browser window being launched. The UI component's JavaScript specifies the URL to load.

- Browser requests new window

New browser windows can also be initiated when end users press Ctrl+N (Ctrl+T using Mozilla FireFox) or choose the **File > New Window**.

In Microsoft Internet Explorer, pressing Ctrl+N opens up the application home page as defined in the `web.xml` file. The server state of the new window will be separate from the original window.

An application may also use different frames, multiple portlets, or ADF regions within a single browser window. A *view port* describes the area that displays a view and its independent navigation. A view port can be in a full browser window, a frame, a portlet, or an ADF region.

Each view port maintains a task flow stack that represents an end user's current navigational state. A view port's task flow stack begins with the application's top-level task flow as the first entry on the stack. As the end user navigates into a bounded task flow, additional entries are pushed onto the stack representing the bounded task flow. As the end user navigates out of bounded task flows, entries are removed from the stack. If the end user navigates away from the parent page, any child modes and modal dialogs are closed.

---

---

**Best Practice:** Although it is not necessary to notify the ADF Controller when a browser window is closed, it is at good design practice for the framework. This gives ADF Controller an opportunity to clean up resources allocated to the browser window's view port, such as managed beans and open, unresolved transactions.

---

---

### 18.12.1 Understanding How the ViewPortInstance Works in ADF Regions

View ports can also be created when a page with a bounded task flow region is rendered. When a request for the first activity in a Fusion web application is received, ADF Controller creates a view port and a `ViewPortContext` corresponding to the main browser window. Each ADF region has an associated `ViewPortContext` instance. The `ViewPortContext` instance is created during the Restore View phase of the JSF lifecycle.

ADF Controller uses the `ViewPortContext` instance every time it needs to interact with JSF RI `FacesContext`. The `ViewPortContext` is responsible for dispatching all calls to `FacesContext` directly or to ADF view APIs. For example, when the ADF Controller finds a new view activity for the view port, it calls `ViewPortContext.setRootViewId`. For the bounded task flow representing the root page, this call results in calling `FacesContext.setRootViewId`. For bounded task flows embedded inside an ADF region, the `ViewPortContext` keeps track of the root view ID. When ADF View is ready to assemble the page markup for the root page, it can access the ADF region component's view ID stored on `ViewPortContext`.

For example, once a page containing ADF regions is rendered, an end user might click a button inside an ADF region causing a form submit:

1. ADF Controller handles the request in the context of a view port created for the ADF region.
2. The correct `ViewPortContext` is set up by the ADF region before the ADF Controller `NavigationHandler` is called.
3. Based on `from-action` and `from-outcome` values, ADF Controller produces the ID of the next view activity for the bounded task flow region and sets it on the `ViewPortContext`.
4. ADF view will use the view activity ID in the Render Response stage of the JSF lifecycle to pick up new markup for the ADF region. Because the `NavigationHandler` is called in the Region context, the root view ID for the main page is not be reset.
5. When the end user navigates away from the page, the bounded task flow region is destroyed. The view layer again notifies ADF Controller in order for resources allocated to the ADF region to be released.

## 18.13 Creating a Task Flow Template

You can create a task flow template that other developers can use as a starting point when creating new bounded task flows.

---

---

**Note:** You cannot use a task flow template as the basis for creating a new unbounded task flow.

---

---

The task flow template enables reuse because any bounded task flow based on it has the same set of activities, control flows, input parameters, and managed bean definitions that the template contains. In addition, you can specify that changes to the template be automatically propagated to any task flow or template that is created based on the template.

For example, suppose you have set up an activity to be used as an exception handler for a bounded task flow, such as a view activity associated with a page for global exception handling. Or, the exception handler might be set up to handle exceptions typically expected to occur in a task flow. If you expect multiple bounded task flows to rely on the same error handler, you might consider adding the error handler to a task flow template. New task flows created based on the template automatically have the exception handling activity added to the template. See [Section 18.7, "Handling Exceptions in Task Flows"](#) for more information.

You can base a new task flow template on an existing task flow template. You can also refactor an existing bounded task flow to create a new task flow template. For more information, see [Section 14.5.3, "How to Convert ADF Bounded Task Flows"](#).

If you select the **Update the Task Flow When the Template Changes** checkbox in the Create ADF Task Flow or Create ADF Task Flow Template dialog, the template will be reused by reference. Any changes you make to the template will be propagated to any bounded task flow or task flow template based on it.

### 18.13.1 How to Copy and Reference a Task Flow Template

There are two methods for reusing a task flow templates.

- Reuse by copy

Deselect the **Update the task flow when the template changes** checkbox when creating a new bounded task flow, as shown in [Figure 18-18](#). If you deselect the checkbox, the bounded task flow is independent of the template. Changes to the template are not propagated to the bounded task flow.

For example, if you add view activities associated with JSF pages to the template, the new bounded task flow will display the views and any control flows between them, and it will retain the view associations with JSF pages. If you add a train on a task flow template, any bounded task flow created from it contains page navigation for the train.

- Reuse by reference

Select the **Update the task flow when the template changes** checkbox when creating a new bounded task flow, as shown in [Figure 18-18](#), or when creating a new task flow template. Changes to the parent task flow template propagate to any bounded task flow or template based on it.

You can change, update, or disassociate the parent task flow template of a child bounded task flow or task flow template at any point during development of the child.

At runtime, the contents of a child bounded task flow or a child template reused by reference are combined additively with the contents of the parent template. Any collision between the parent template and child task flow or child template are won by the child. For example, suppose you created a parent task flow template containing a train, and then created a child bounded task flow based on the parent template. Later, you deselect the **Train** checkbox on the Behavior page of the overview editor for bounded task flows. The difference in how the **Train** checkbox is set for the parent template and the child task flow is a collision.

Table 18–3 describes the specific combination algorithm used for each element. As shown in the table, in the event of a collision between train settings, the child task flow overrides the parent task flow template.

**Table 18–3 Collision Resolution between Parent Template and Children**

<b>Bounded Task Flow Metadata</b>	<b>Combination Algorithm</b>
Default activity	Child bounded task flow or child task flow template overrides parent task flow template.
Transaction	Child bounded task flow or child task flow template overrides parent task flow template as an entire block of metadata, including all subordinate elements.
Task flow reentry	Child bounded task flow or child task flow template overrides parent task flow template as an entire block of metadata, including all subordinate elements.
Control flow rules	<p>Combination algorithm occurs at the control flow case level, not the control flow rule level. Control flow cases fall into the following categories:</p> <ul style="list-style-type: none"> <li>■ Both from action and from outcome specified</li> <li>■ Only from action specified</li> <li>■ Only from outcome specified</li> <li>■ Neither from action nor from outcome specified</li> </ul> <p>Each of these categories is merged additively. The child bounded task flow or template overrides parent task flow template for identical matches within each of the four categories.</p>
Input parameter definitions	Child bounded task flow or child task flow template overrides parent task flow template for identical input parameter definition names.
Return value definitions	Child bounded task flow or child task flow template overrides parent task flow template for identical return value definition names.
Activities	Child bounded task flow or child task flow template overrides parent task flow template for identical activity IDs.
Managed beans	Child bounded task flow or child task flow template overrides parent task flow template for identical managed bean names.
Initializer	Child bounded task flow or child task flow template overrides parent task flow template.
Finalizer	Child bounded task flow or child task flow template overrides parent task flow template.
Critical	Child bounded task flow or child task flow template overrides parent task flow template.
Use page fragments	Child bounded task flow or child task flow template overrides parent task flow template.
Exception handler	Child bounded task flow or child task flow template overrides parent task flow template.
Security - permission	<p>Child bounded task flow or child task flow template overrides parent task flow template.</p> <p>Privilege maps are additive. Child bounded task flow or child task flow template overrides parent task flow template for identical privilege map operations.</p>

**Table 18–3 (Cont.) Collision Resolution between Parent Template and Children**

Bounded Task Flow Metadata	Combination Algorithm
Security - transport guarantee	Child bounded task flow or child task flow template overrides parent task flow template.
Train	Child bounded task flow or child task flow template overrides parent task flow template.

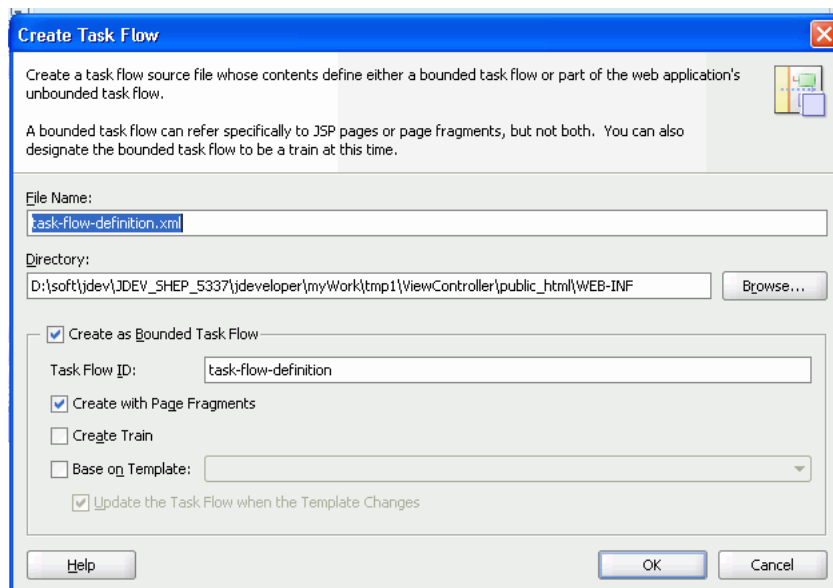

Validations at both design time and runtime verify that the resulting parent-child extension hierarchy does not involve cycles of the same task flow template.

### 18.13.2 How to Create a Task Flow Template from Another Task Flow

The process for creating a new task flow template from an existing template is similar to the process for creating a bounded task flow based on a template. For more information, see [Section 14.2, "Creating a Task Flow"](#).

### 18.13.3 How to Use a Task Flow Template

After you create a task flow template, you can use it as the basis for creating a new bounded task flow or a new task flow template. As shown in [Figure 18–18](#), the Create Task Flow dialog has fields for creating a bounded task flow based on the template file name and the ID. You must specify both the file name and ID of the template. These fields are available only if you select the **Create as Bounded Task Flow** checkbox.

**Figure 18–18 Create Task Flow Dialog**

You can base a new template on an existing template. The Create ADF Task Flow Template dialog box contains fields for creating a task flow template based on the file name and the template ID of an existing task flow template.

You cannot run a task flow template on its own. For more information, see [Section 14.4, "Testing ADF Task Flows"](#).

## 18.13.4 How to Create a Task Flow Template

The process for creating a new task flow template is similar to creating a bounded task flow. This section describes how to create a new task flow template. You can also convert an existing bounded task flow to a task flow template and vice versa. For more information, see [Section 18.13.2, "How to Create a Task Flow Template from Another Task Flow"](#).

### To create a task flow template from scratch:

1. In the Application Navigation, right-click the project where you want to create the task flow and choose **New**.
2. In the New Gallery, expand **Web Tier**.
3. Select **JSF**, and then **ADF Task Flow Template** and click **OK**.

The value in **File Name** is used to name the XML source file for the task flow template you are creating. The source file includes the activities and control flow rules that are in the task flow template. The default name for the XML source file is `task-flow-template.xml`.

4. In the Create ADF Task Flow Template dialog, the **Create with Page Fragments** checkbox is selected by default. If you expect that a bounded task flow based on the template will be used as an ADF region, select this option.

If you want to add JSF pages instead of JSF page fragments to the task flow template, deselect the checkbox.

5. Click **OK**.

A diagram for the task flow template automatically opens in the editor.

6. You can add activities, control flows, and other items to the template.

Anything that you can add to a bounded task flow can be added to the task flow template.

7. When you are finished, save your work.

The template will be available for use when you create a bounded task flow or task flow template.

## 18.13.5 What Happens When You Create a Task Flow Template

As shown in [Example 18–12](#), an XML file is created each time you create a new task flow template using JDeveloper. You can find the XML file in the Application Navigator in the location that you specified in the **Directory** field of the Create ADF Task Flow Template dialog, for example, `.../WEB-INF`.

The contents of the XML source file for the task flow template can be similar to those of a bounded task flow. One difference is the inclusion of the `<task-flow-template>` tag.

### *Example 18–12 Task flow template source file*

```
<?xml version="1.0" encoding="windows-1252" ?>
<adfc-config xmlns="http://xmlns.oracle.com/adf/controller" version="1.2" id="__
1">
  <task-flow-template id="task-flow-template">
    <default-activity>view1</default-activity>
    <view id="view1">view1.jsff</view>
  </task-flow-template>
```

```
</adfc-config>
```

### 18.13.6 What You May Need to Know About Task Flow Templates That Use Bindings

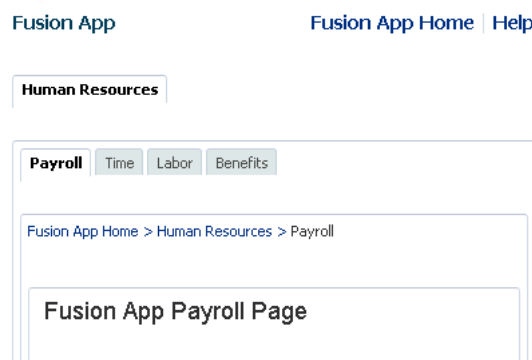

If you use a task flow template that contains bindings, you must change the component IDs of task flows based on the task flow template. Doing this ensures that the IDs are unique. Task flows generated from the template inherit the same ID as the template. This may cause an exception at runtime.

For more information, see [Section 20.2.1, "How to Use ADF Data Binding in ADF Page Templates"](#).

## 18.14 Creating a Page Hierarchy

Creating a page hierarchy is a useful way of organizing the JSF pages in your Fusion web application so that end users can more easily navigate the application. End users access information on the pages by navigating a path of links. [Figure 18–19](#) shows a sample page hierarchy.

**Figure 18–19** Page Hierarchy

To navigate this hierarchy, an end user clicks links on each page to drill down or up to another level of the hierarchy. For example, clicking **Human Resources** on the Fusion App home page displays the Human Resources page hierarchy shown in [Figure 18–19](#). Clicking the link on the **Benefits** tab displays the page hierarchy shown in [Figure 18–20](#).

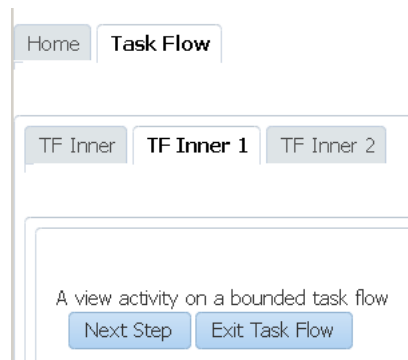

**Figure 18–20 Benefits Page**

The user can click links on the Benefits page to display other pages, for example, the Medical, Dental or Vision pages. The breadcrumbs on each page indicate where the current page fits in the hierarchy. The user can click each node in a breadcrumb to navigate to other pages in the hierarchy. The bold tab labels match the path to the current page shown the breadcrumbs.

Pages referenced by view activities in a bounded task flow can also be included in any page hierarchy that you generate. [Figure 18–21](#) shows the runtime view of a page hierarchy that renders view activities referenced by a bounded task flow.

**Figure 18–21 Runtime Menu Hierarchy Including a Bounded Task Flow**

You can use ADF Controller with an `XMLMenuModel` implementation to create the previously-discussed page hierarchies. If you do, JDeveloper generates the following for you:

- Control flow metadata that determines the view or page to display when an end user selects a menu item
- An `XMLMenuModel` metadata file
- Default navigation widgets such as **Previous** and **Next** button
- Breadcrumbs
- Managed bean configuration

If you decide not to use ADF Controller, you can create the page hierarchy using an `XMLMenuModel` implementation. For more information about this method of building a page hierarchy, see the "Using a Menu Model to Create a Page Hierarchy" section in

the *Oracle Fusion Middleware Web User Interface Developer's Guide for Oracle Application Development Framework*.

### 18.14.1 How to Create a Page Hierarchy

Create an unbounded task flow or open an existing one. Add view activities or bounded task flows to the unbounded task flow. Each view activity or bounded task flow that you add to the unbounded task flow contains references to pages to appear in the proposed page hierarchy. Use JDeveloper's Create ADF Menu Model dialog to generate an XMLMenuModel metadata file. Organize the item nodes in the generated XMLMenuModel metadata file to create the page hierarchy you want. Connect submenus to parent menus to finalize the hierarchy.

Figure 18–22 shows an example page hierarchy that consists of view activities:

- The top-level menu (**Home Page**) is the root parent page. It contains a single tab that links to the **Human Resources** submenu.

In JDeveloper, **Home Page** page is represented as an item node and **Human Resources** page as a shared node.

- **Human Resources** has four tab links to **Payroll**, **Time**, **Labor**, and **Benefits** pages.

In this menu, **Human Resources** is a group node that references child item nodes (**Payroll**, **Time**, and **Labor**) and a shared node (**Benefits**) that references the Benefits submenu.

- **Benefits** is a group node that references child item nodes (**Medical**, **Dental**, and **Vision**) pages.

**Figure 18–22 Menu Hierarchy**

---

---

**Note:** It is possible to create the entire menu hierarchy in one menu model. However, breaking a menu hierarchy into submenus makes maintenance easier. In addition, breaking the menu hierarchy into smaller submenu models enables each separate development organization to develop its own menu. These separate menus can later be combined using shared nodes to create the complete menu hierarchy.

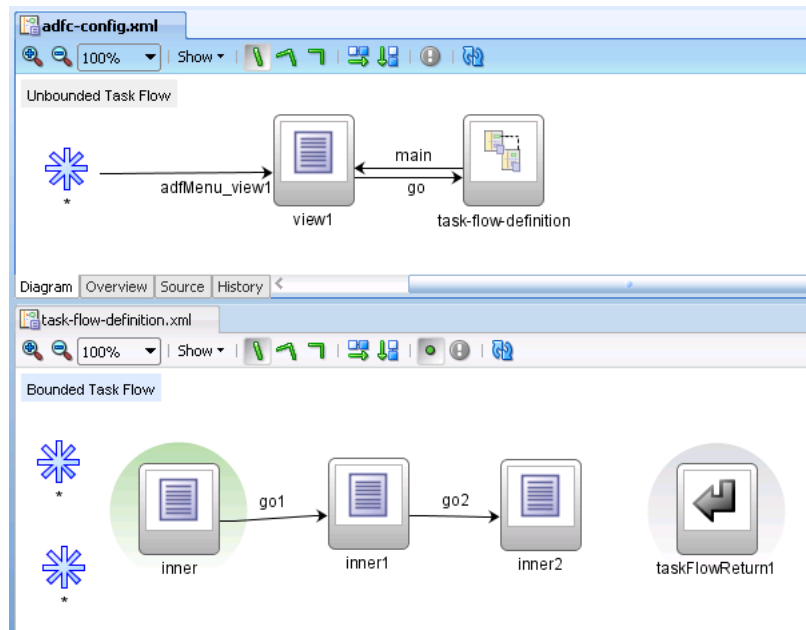

---

---

Figure 18–23 shows the corresponding design-time view in JDeveloper of the unbounded and bounded task flows that render the page hierarchy shown in Figure 18–21. The unbounded task flow (`adfc-config.xml`) contains a view activity (**view1**) and a task flow call activity (**task-flow-definition**) that invokes the bounded task flow (`task-flow-definition.xml`) shown in the lower part of Figure 18–23.

**Figure 18–23 Design Time Menu Hierarchy Including a Bounded Task Flow**

### 18.14.1.1 How to Create an XMLMenuModel Metadata File

You use JDeveloper's Create ADF Menu Model dialog to generate an `XMLMenuModel` metadata file once you have defined what menus (unbounded task flows) and nodes (pages) you want to appear in the final page hierarchy.

**To create the XMLMenuModel metadata file:**

1. Create an unbounded task flow for each menu in the final page hierarchy.

For example, to achieve the page hierarchy illustrated in Figure 18–22, you create two unbounded task flows (Human Resources menu and Benefits menu).

For more information about creating an unbounded task flow, see Section 14.2.1, "How to Create a Task Flow".

**Tip:** Prefix the name of the file for unbounded task flows that you create with `adfc-` to help you to identify the file as the source of an unbounded task flow, as opposed to a bounded task flow.

2. Add view activities that reference pages to each unbounded task flow. The pages referenced by the view activities correspond to the menu nodes in the menu.

For example, the Benefits menu contains one group node (benefits) and three item nodes (medical, dental and vision) so you add four view activities to the unbounded task flow for the Benefits menu, as illustrated in [Figure 18–24](#).

**Figure 18–24 View Activities on a Task Flow**

Do not add view activities for menus that include other menus using shared nodes. For example, the Human Resources menu in [Figure 18–22](#) has a tab called **Benefits** that references the Benefits menu using a shared node. The bounded task flow for the Benefits menu already includes a view activity for Benefits so there is no need to add a view activity to the bounded task flow for the Human Resources menu.

For more information about adding view activities, see [Section 15.2.1, "Adding a View Activity"](#).

---

**Note:** If the page hierarchy includes pages referenced by a bounded task flow, add a task flow call activity to the unbounded task flow that calls the bounded task flow.

---

3. In the Application Navigator, right-click the file(s) for each of the unbounded task flows you created in Step 1 and choose **Create ADF Menu Model**.
4. In the Create ADF Menu Model dialog, enter a file name for the XMLMenuModel metadata file and a directory to store it.
5. Click OK.

### 18.14.1.2 How to Create a Submenu with a Hierarchy of Group and Child Nodes

You open the XMLMenuModel metadata file you created and convert the item nodes that you want to make group nodes to group nodes. You then create a hierarchy where a group node is a parent to one or more item nodes.

#### To create a submenu with a hierarchy of group and item nodes:

1. In the Application Navigator, select and open the XMLMenuModel metadata file.  
An item node appears in the Structure window for each view activity in the unbounded task flow. By default, no hierarchy is defined.
2. Drag and drop the item nodes to become child nodes of the item node that you are going to convert to a group node.

Each item node that you convert to a group node must have at least one child item node. For example, to create the menu hierarchy in [Figure 18–22](#), you convert the item node for Benefits to a group node, you drag and drop the item nodes for Medical, Dental, and Vision so that they become child nodes of the Benefit item node.

3. In the Structure window, right-click the parent item node and choose **Convert To groupNode**.
4. Enter a new identifier or accept the default value in the **id** field of the groupNode Properties dialog that appears  

The identifier must be unique among all of the nodes in all of the `XMLMenuModel` metadata files. It is good practice to specify a value that identifies the node. For example, if you change the Benefits node to a group node, you can update its default ID, `itemNode_benefits`, to `groupNode_benefits`.
5. In the **idref** field of the groupNode Properties dialog, enter the ID of one of the other nodes in the menu, for example, `itemNode_Medical`.  

The value you enter can be an ID of a child item node that is a group node or an item node.
6. Enter or change the existing default value in the **label** field to match what you want to appear at runtime.  

For example, you might change `label_benefits` to `Benefits`.
7. Accept the rest of the default values in the fields and click **Finish**  

A Confirm Convert dialog asks if you want to delete the `action` and `focusViewID` attributes on the `groupNode` element. Group nodes do not use these attributes, always click **OK**
8. Click **OK**

### 18.14.1.3 How to Attach a Menu Hierarchy to Another Menu Hierarchy

You use a shared node element to link two menus together. For example, the Human Resources menu illustrated in the menu hierarchy in [Figure 18-22](#) contains four submenus (Payroll, Time, Labor, and Benefits). The Benefits submenu is itself a menu with submenu entries. In the `XMLMenuModel` metadata file for the Human Resources menu, you convert the item node for the Benefits submenu to a shared node. You write an EL expression for an attribute (`ref`) of the newly-created shared node that references the `XMLMenuModel` metadata file for the Benefits menu.

#### To attach a menu hierarchy to another hierarchy using a shared node:

1. In the Application Navigator, select and open the `XMLMenuModel` metadata file for the menu that is going to reference the other menu.
2. In the Structure window, select a node, right-click and select the appropriate menu options to insert a `sharedNode` element.
3. In the **ref** field of the Insert sharedNode dialog that appears, enter an EL expression to reference the `XMLMenuModel` metadata file for the other menu.
4. Click **OK**.

---

**Note:** If your page hierarchy has more than one unbounded task flow, ensure that the file name for each additional unbounded task flow appears as a value for the `<metadata-resources>` element in the `adfc_config.xml` file. For more information, see [Section 18.14.2, "What Happens When You Create a Page Hierarchy"](#).

---

## 18.14.2 What Happens When You Create a Page Hierarchy

Changes occur in a number of different files when you create a page hierarchy.

### Changes to the adfc-config.xml File

When you create a new unbounded task flow, JDeveloper automatically adds a reference in the `adfc-config.xml` file to the source file for the newly-created unbounded task flow. In [Example 18–13](#), `adfc-unbounded_tflow.xml` is the name of the source file for a newly-created unbounded task flow.

#### **Example 18–13 Unbounded task flow referenced by adfc-config.xml**

```
<?xml version="1.0" encoding="windows-1252" ?>
<adfc-config xmlns="http://xmlns.oracle.com/adf/controller" version="1.2"
  id="__1">
  <metadata-resource id="__2">/WEB-INF/adfc-unbounded_
tflow.xml</metadata-resource>
</adfc-config>
```

For more information about `adfc-config.xml`, see [Section A.9, "adfc-config.xml"](#).

At runtime, the Fusion web application loads the `adfc-config.xml` file when it first starts. The `adfc-config.xml` file can contain:

- ADF navigation metadata for an unbounded task flow
- ADF activity metadata for an unbounded task flow
- Managed bean definitions used by ADF activities

### XMLMenuModel Metadata File

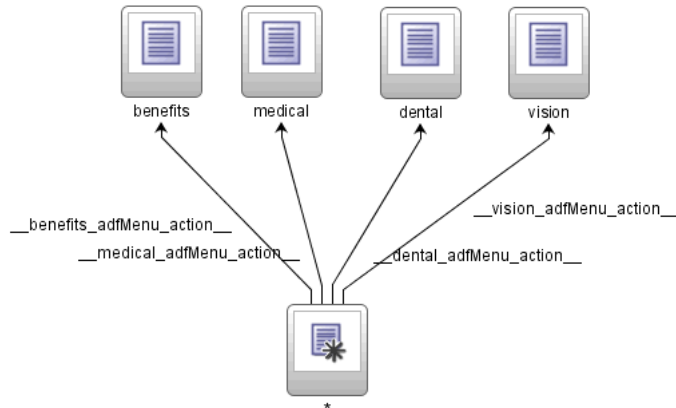

JDeveloper generates an `XMLMenuModel` metadata file with nodes for each of the view activities that you added to the unbounded task flow, as illustrated in [Example 18–3](#).

#### **Example 18–14 Example XMLMenuModel Metadata File**

```
<?xml version="1.0" encoding="windows-1252" ?>
<menu xmlns="http://myfaces.apache.org/trinidad/menu">
  <groupNode id="groupNode_benefits" label="Benefits" idref="itemNode_medical">
    <itemNode id="itemNode_medical" label="label_medical"
      action="adfMenu_medical" focusViewId="/medical"/>
    <itemNode id="itemNode_dental" label="label_dental" action="adfMenu_dental"
      focusViewId="/dental"/>
    <itemNode id="itemNode_vision" label="label_vision" action="adfMenu_vision"
      focusViewId="/vision"/>
  </groupNode>
</menu>
```

### Diagram for an Unbounded Task Flow

JDeveloper updates the file for the unbounded task flow with the control flow rules and managed beans used to navigate the page hierarchy. [Figure 18–25](#) shows the updated unbounded task flow in the diagrammer that corresponds unbounded task flow in [Figure 18–24](#).

**Figure 18–25 Updated Unbounded Task Flow**

## 18.15 Using BPEL with Task Flows

Business Process Execution Language (BPEL) is a language for composing multiple services into an end-to-end business process. You can use BPEL with task flows to:

- Invoke a BPEL process from an unbounded or bounded task flow to perform a function or use services
- Call a bounded task flow from the BPEL process manager in order to model user interactions with a web interface

For more information about BPEL, see the *Oracle Fusion Middleware Developer's Guide for Oracle SOA Suite*.

### 18.15.1 How to Invoke a BPEL Process from a Task Flow

You can use any of the following techniques for calling a BPEL process from an unbounded or bounded task flow:

- Bind an existing method call activity on the task flow diagram to a managed bean method wrapping the BPEL process call as a Java component. For more information, see [Section 15.5, "Using Method Call Activities"](#).
- Bind an existing method call activity on the task flow diagram to an action binding performing the BPEL process call as a web service. For more information, see [Section 15.5, "Using Method Call Activities"](#) for more information. The web service data control is the preferred approach to use when calling as a Web Service.

During runtime, the application will place the request to the BPEL process in the form of a payload. The BPEL process receives the payload and responds with a payload containing the information the application requested. The BPEL process outcome is to continue control flow in the unbounded or bounded task flow.

### 18.15.2 How to Call a Bounded Task Flow from BPEL

BPEL workflow services allow human interactions to be interspersed between tasks within end-to-end flows. During a BPEL process flow, a task is assigned to a user or role and then it waits for a response. The user will act on the task using the BPEL worklist application. The worklist application is able to initiate a bounded task flow assigned as part of the user's task. Bounded task flow functionality can be used while

still taking advantage of the human interaction framework of a BPEL process (for example, notifications, escalation policy, and worklist).

---

---

## Using Dialogs in Your Application

This chapter describes how you can use ADF Controller and ADF task flows to create dialogs or, alternatively, how to use the ADF Faces dialog framework in an ADF application.

This chapter includes the following sections:

- [Section 19.1, "Introduction to Using Dialogs in Your Application"](#)
- [Section 19.2, "Running a Bounded Task Flow in a Modal Dialog"](#)
- [Section 19.3, "Using the ADF Faces Dialog Framework"](#)

### 19.1 Introduction to Using Dialogs in Your Application

Use dialogs if you want to show information to end users in a secondary browser window external to the browser window that displays the end user's current page. For example, you want to display help information to end users to assist them with a task in the primary browser window or you want end users to select a value from a list of values. The help information example is a use case a modeless dialog is appropriate. A *modeless dialog* allows end users work in both the primary window and the dialog at the same time. For the use case where you want an end user to select a value, a modal dialog is more appropriate. A *modal dialog* prevents an end user accessing the page that invoked the dialog until they execute an action requested by the dialog (for example, select a value).

Use the ADF Faces dialog framework if you want to configure modeless dialogs for your end users. If you plan to configure modal dialogs for your end users, configure an ADF Controller bounded task flow to invoke one or more dialogs.

### 19.2 Running a Bounded Task Flow in a Modal Dialog

You can configure a bounded task flow to run in a modal dialog, retrieve input from an end user, and return to the view activity that called the bounded task flow with the retrieved input.

[Figure 19-1](#) shows an example of the configuration required.

**Figure 19–1 Task Flow Activities to Invoke a Modal Dialog**

### 19.2.1 How to Run a Bounded Task Flow in a Modal Dialog

In an existing task flow, add a view activity and a task flow call activity to a bounded task flow. The view activity invokes a page where an end user can invoke an action that, in turn, invokes the bounded task flow to appear in a modal dialog.

#### To run a bounded task flow in a modal dialog box:

1. In the diagram editor for the existing task flow, double-click the view activity to open the associated page.
2. Select the UI component that the end user clicks at runtime to invoke the bounded task flow as a modal dialog box (for example, a `commandButton` component).
3. In the Property Inspector, expand the **Common** section and set the `action` attribute to the control flow case to invoke the bounded task flow.

For example, `callTarget` in [Figure 19–1](#).

4. Set the `useWindow` attribute to `true` to invoke the bounded task flow in a popup dialog.
5. Return to the diagram editor for the existing task flow and select the task flow call activity.
6. In the Property Inspector, expand the **Behavior** section and set the `run-as-dialog` attribute to `true` to run the bounded task flow as a dialog.
7. For the `display-type` attribute, select `external-window` (the default value) if you want to render the dialog in an external browser window or `inline-popup` if you want to render the dialog in the same browser window.

### 19.2.2 How to Return a Value From a Modal Dialog

You can configure a bounded task flow that renders in a modal dialog to return a value to the view activity that invoked the bounded task flow when the end user dismisses the modal dialog. The returned value can, for example, be displayed in an input component on the page associated with the view activity.

You must configure the bounded task flow that is called by the task flow call activity to declare input and output parameters. For more information, see [Section 16.3, "How to Pass Parameters to an ADF Bounded Task Flow"](#).

You specify a method binding for a method with one argument (a return event) as the value for the `returnListener` attribute of the command component (for example, a `commandButton` component). The `returnListener` attribute sets this value in the input component on the page associated with the view activity. Specify a backing bean for the input component and set the input component's `partialTrigger` attribute to the ID of the command component.

You also need to specify:

- A return value definition on the called bounded task flow to indicate where to take the return value from upon exit of the called bounded task flow.
- Return values on the task flow call activity in the existing task flow to indicate where the existing task flow can find return values.

For more information, see [Section 16.4, "Specifying Return Values"](#).

For more information about creating backing beans, input components, and command components, see the "Using Input Components and Defining Forms" chapter in the *Oracle Fusion Middleware Web User Interface Developer's Guide for Oracle Application Development Framework*.

#### Before you begin:

Configure a bounded task flow to run in a modal dialog. For more information, see [Section 19.2.1, "How to Run a Bounded Task Flow in a Modal Dialog"](#).

#### To specify a return value:

1. In the diagram editor for the existing task flow, select the task flow call activity.
2. In the Property Inspector, expand the **Behavior** section and set the `run-as-dialog` attribute to `true`.
3. Set the `dialog-return-value` to the name of the return value definition you specified for the target bounded task flow.

For information about how to specify the return value definition on a bounded task flow, see [Section 16.4, "Specifying Return Values"](#).

4. In the Application Navigator, double-click the page that launches the modal dialog.
5. Select the input component on the page and, in the Property Inspector, expand the **Behavior** section to specify an EL expression for the `partialTriggers` attribute.

The EL expression you specify identifies the command component, accepts the return value of the command component, and specifies a backing bean. For example, enter an EL expression with syntax similar to the following:

```
{pageFlowScope.backingBean.gotoModalDialog}
```

Where `gotoModalDialog` identifies the command component.

6. Select the command component and, in the Property Inspector, expand the **Behavior** section.
7. In the **Secondary Window**, enter an EL expression that references a return listener method in the page's backing bean as a value for the `returnListener` attribute.

The return listener method you specify processes the return event that is generated when an end user dismisses the modal dialog. Enter an EL expression with syntax similar to the following:

```
{pageBean.listenerMethod}
```

### 19.2.3 What You May Need to Know About Running a Bounded Task Flow in a Modal Dialog

A bounded task flow can run in an ADF region. The ADF region can be in an `af:popup` UI component.

You cannot specify `dialog:syntax` in navigation rules within the `faces-config.xml` file if your Fusion web application uses ADF Controller features such as task flows. However, you can use the `dialog:syntax` in the control flow rules that you specify in the `adfc-config.xml` file.

[Example 19–1](#) shows an example of what you can specify in the `adfc-config.xml` file.

**Example 19–1** *adfc-config.xml* file with `dialog:syntax`

```
<?xml version="1.0" encoding="windows-1252" ?>
<adfc-config xmlns="http://xmlns.oracle.com/adf/controller" version="1.2" id="__
1">
  <view id="view1"
    <page>/view1.jspx</page>
  </view>
  <view id="dialog">
    <page>/dialog/untitled1.jspx</page>
  </view>
  <control-flow-rule>
    <from-activity-id>test</from-activity-id>
    <control-flow-case>
      <from-outcome>dialog:test</from-outcome>
      <to-activity-id>dialog</to-activity-id>
    </control-flow-case>
  </control-flow-rule>
</adfc-config>
```

## 19.3 Using the ADF Faces Dialog Framework

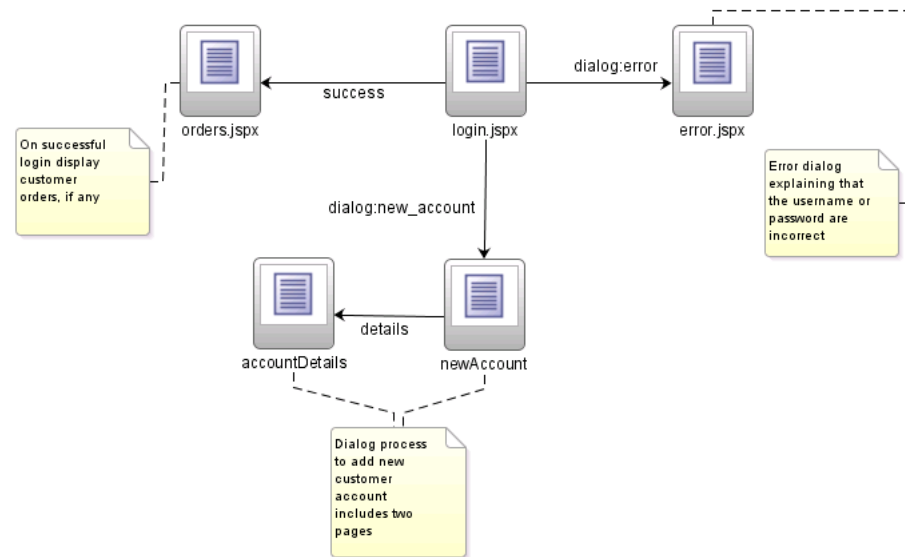

You can use the ADF Faces dialog framework to create modal and modeless dialogs in an application that does not use the ADF Controller and task flows. The dialog framework enables you to display a page or series of pages in a new browser window instead of displaying it in the same window (using the same view ID) as the current page. There may also be cases where you want to use a series of inline dialogs, that is, dialogs that are part of the parent page, but that have a flow of their own, but that do not use a separate view ID. This is important for applications that do not support popups such as, for example, applications that run on client devices or that use the Active Data Service described in [Chapter 42, "Using the Active Data Service."](#) Ordinarily, you would need to use JavaScript to open the dialog and manage the process. With the dialog framework, ADF Faces has made it easy to open a new browser window as well as manage dialogs and processes without using JavaScript.

---

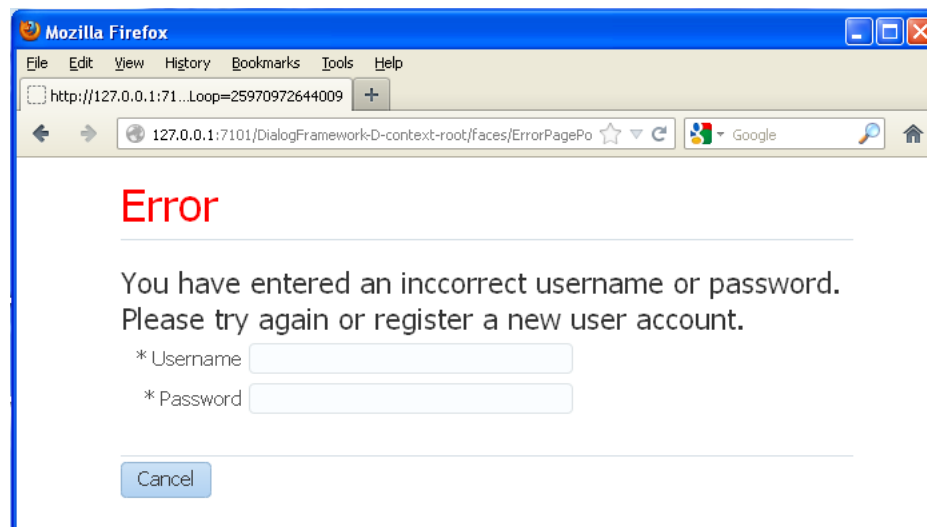

**Note:** If your application uses the Fusion technology stack with the ADF Controller, then you should use task flows to create dialogs launched in a separate window, or multiple dialog processes. For more information, see [Section 19.2, "Running a Bounded Task Flow in a Modal Dialog"](#).

---

Consider a simple application that requires users to log in to see their orders. [Figure 19–2](#) shows the page flow for the application, which consists of five pages - `login.jspx`, `orders.jspx`, `new_account.jspx`, `account_details.jspx`, and `error.jspx`.

**Figure 19–2 Page Flow of an External Dialog Sample Application**

When an existing user logs in successfully, the application displays the Orders page, which shows the user's orders, if any. When a user does not log in successfully, the Error page displays in a separate popup dialog window, as shown in [Figure 19–3](#).

**Figure 19–3 Error Page Popup**

On the Error page there is a **Cancel** button. When the user clicks **Cancel**, the popup dialog closes and the application returns to the Login page and the original flow, as shown in [Figure 19–4](#).

**Figure 19–4 Login Page**

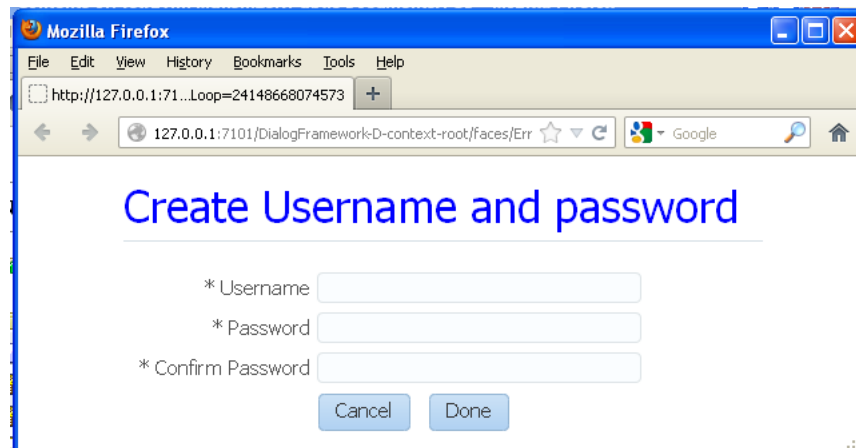

The screenshot shows a web page titled "Login Page" in blue text. Below the title is a horizontal line. There are two input fields: the first is labeled "\* Username" and the second is labeled "\* Password". Below these fields are two buttons: "Log in" and "New user?".

When a new user clicks the **New User** link on the Login page, the New Account page displays in a popup dialog in a new window, as shown in [Figure 19–5](#).

**Figure 19–5 New Account Page in a Separate Window**

The screenshot shows a Mozilla Firefox browser window. The address bar contains the URL "http://127.0.0.1:7101...trl-state=vpq4fr7tl\_4". The page title is "Account Information". The page content includes four input fields labeled "First Name", "Last Name", "Street", and "Postal Code". Below these fields is a "Details" button.

After entering information such as first name and last name, the user then clicks the **Details** button to display the Account Details page in the same popup dialog, as shown in [Figure 19–6](#). In the Account Details page, the user enters other information and confirms a password for the new login account. There are two buttons on the Account Details page - **Cancel** and **Done**.

**Figure 19–6 Account Details Page in a Popup Dialog**

If the new user decides not to proceed with creating a new login account and clicks **Cancel**, the popup dialog closes and the application returns to the Login page. If the new user clicks **Done**, the popup dialog closes and the application returns to the Login page where the **Username** field is now populated with the user's first name, as shown in [Figure 19–7](#). The new user can then proceed to enter the new password and log in successfully.

**Figure 19–7 Login page with Username Field Populated**

## Login Page

\* Username

\* Password

[New user?](#)

---

**Note:** The dialog framework should not be used to have more than one dialog open at a time, or to launch dialogs that have a life span outside of the life span of the base page.

---

To make it easy to support dialog page flows in your applications, ADF Faces has built in the dialog functionality to action components (such as `commandMenuItem` and `commandButton`). For ADF Faces to know whether or not to open a page in a new flow from an action component, the following conditions must exist:

- There must be a JSF navigation rule with an outcome that begins with `dialog::`.
- The command component's action outcome must begin with `dialog::`.
- The `useWindow` attribute on the command component must be `true`.

---

---

**Note:** If the `useWindow` attribute is `false`, or if you configure the popup to be a separate window (and not inline) and the client device does not support popups, ADF Faces automatically shows the page in the current window instead of using a popup window; code changes are not required to facilitate this action.

---

---

The page that is displayed in a dialog is an ordinary JSF page, but for purposes of explaining how to implement external dialogs in this chapter, a page that is displayed in a popup dialog is called the *dialog* page, and a page from which the dialog is opened is called the *originating* page. A *dialog process* starts when the originating page opens a dialog (which can contain one dialog page or a series of dialog pages), and ends when the user dismisses the dialog and returns to the originating page.

The tasks for supporting a dialog page flow in an application are:

1. Define a JSF navigation rule for opening a dialog.
2. Create the JSF page from which a dialog is opened.
3. Create the dialog page and return a dialog value.
4. Optional: Pass a value into a dialog.
5. Handle the return value.

The tasks can be performed in any order.

### 19.3.1 How to Define a JSF Navigation Rule for Opening a Dialog

You manage the navigation into a dialog flow by defining a standard JSF navigation rule with a special `dialog: outcome`.

**To define a navigation rule to open a dialog:**

1. In the `adfc-config.xml` file, create a page flow for your originating page and dialog pages. For detailed procedures, see [Section 14.3.3, "How to Add Control Flows"](#).
2. When creating navigation rules to the dialog pages, the outcome must begin with `dialog:.` For example, in the login sample application shown in [Figure 19-2](#), the outcome from the Login page to the New Account dialog page is `dialog:newAccount`.

At runtime, the dialog navigation rules on their own simply show the specified pages in the originating page. But when used with command components with `dialog:` action outcomes and with `useWindow` attributes set to `true`, ADF Faces knows to open the pages in dialogs.

### 19.3.2 How to Create the JSF Page That Opens a Dialog

In the originating page, you need to use a command component to launch the dialog. The command component's action value needs to be the outcome to the dialog that is to be launched.

**To create the JSF Page that opens a dialog**

1. Create a JSF page.

For more information, see the "Creating a View Page" section in the *Oracle Fusion Middleware Web User Interface Developer's Guide for Oracle Application Development Framework*.

## 2. Add a command component to the page.

For more information about adding a command component to a page, see the "Using Buttons and Links for Navigation" section in *Oracle Fusion Middleware Web User Interface Developer's Guide for Oracle Application Development Framework*.

Note the following when setting the attributes on the command component:

- **action:** Set the action attribute to the outcome that navigates to the dialog, as created in [Section 19.3.1, "How to Define a JSF Navigation Rule for Opening a Dialog."](#)

**Tip:** The action value can be either a static string or the return of a method on a managed bean.

For example, the action attribute on the command component of the Login page is bound to a method that determines whether to navigate to the Orders page or to the Error dialog page, based on the returned outcome. If the method returns `dialog:error`, the error dialog opens. If the method returns `success`, the user navigates to the orders page.

- **useWindow:** Set to `true` to have the dialog open.

**Tip:** When set to `false`, ADF Faces shows the dialog page in the current window after preserving all of the state of the current page - you do not have to write any code to facilitate this.

- **windowHeight** and **windowWidth:** Set the desired size of the dialog window. These values will set the `contentWidth` and `contentHeight` attributes on the popup component for the dialog.

**Tip:** While the user can change the values of these attributes at runtime, the values will not be retained once the user leaves the page unless you configure your application to use change persistence. For information about enabling and using change persistence, see the "Allowing User Customization on JSF Pages" chapter in the *Oracle Fusion Middleware Web User Interface Developer's Guide for Oracle Application Development Framework*.

- **partialSubmit:** Set to `true`. This prevents the originating page from reloading (and hence being visible only momentarily) when the popup dialog is displayed.
- **windowEmbedStyle:** Set to `inlineDocument` if you want the ensuing dialog to open in a popup that belongs to the originating page. Set to `window` if you want the ensuing dialog to open in a separate browser.
- **windowModalityType:** Set to `applicationModal` if you want the dialog to be modal. Modal dialogs do not allow the user to return to the originating page until the dialog has been dismissed. Set to `modeless` if you want the user to be able to go back and forth between the originating page and the dialog.

When a command component is about to open a dialog, it delivers a `LaunchEvent` event. The `LaunchEvent` event stores information about the component that is

responsible for opening a popup dialog, and the root of the component tree to display when the dialog process starts. A `LaunchEvent` can also pass a map of parameters into the dialog. For more information, see [Section 19.3.5, "How to Pass a Value into a Dialog."](#)

### 19.3.3 How to Create the Dialog Page and Return a Dialog Value

A dialog page is just like any other JSF page, with one exception. In a dialog page, you must provide a way to tell ADF Faces when the dialog process finishes, that is, when the user dismisses the dialog or series of dialogs.

For example, the New Account page and Account Details page belong in the same dialog process. A dialog process can have as many pages as you desire, you only need to notify the framework that the dialog process has ended once.

You do this declaratively using the `returnActionListener` tag as a child to the command component used to close the dialog. However, if you need to provide a return value or other action event processing, you can bind the `actionListener` attribute on the command component to a method that calls the `AdfFacesContext.returnFromDialog()` method. This method lets you send back a return value in the form of a `java.lang.Object` or a `java.util.Map` of parameters. You do not have to know where you are returning the value to - ADF Faces automatically takes care of it.

At runtime, the `AdfFacesContext.returnFromDialog()` method tells ADF Faces when the user dismisses the dialog. This method can be called whether the dialog page is shown in a popup dialog or in the main window. If a popup dialog is used, ADF Faces automatically closes it.

#### To close a dialog window an optionally return a value:

1. To the dialog page, add a command component. If that component will be used to close the window, set the `immediate` attribute to `true`.

If the button will be used to navigate to another page in the dialog process, configure the button as though it were standard navigation, and set the `useWindow` attribute to `false`, which will cause the next page to display in the same dialog window, preserving the state of the previous page.

2. If you need to end the dialog process and close the dialog, but do not need to return a value, in the Component Palette, from the Operations panel, drag a **Return Action Listener** and drop it as a child to the command component.

The `returnActionListener` tag calls the `returnFromDialog` method on the `AdfFacesContext` object - no backing bean code is needed.

No attributes are used with the `af:returnActionListener` tag. The `immediate` attribute on the `af:commandButton` component is set to `true`: if the user clicks **Cancel** without entering values in the required **Password** and **Confirm Password** fields, the default JSF `ActionListener` can execute during the Apply Request Values phase instead of the Invoke Application phase, thus bypassing input validation. For more information, see the "Using the JSF Lifecycle with ADF Faces" chapter in the *Oracle Fusion Middleware Web User Interface Developer's Guide for Oracle Application Development Framework*.

3. If you need to end the dialog process and do need to return a value, create a method on a managed bean that handles the `action` event and returns the needed values using the `returnFromDialog` method on the current instance of `AdfFacesContext`.

---

---

**Note:** The `AdfFacesContext.returnFromDialog()` method returns null. This is all that is needed in the backing bean to handle the Cancel action event.

---

---

For example, when the user clicks **Done** on the Account Details page, the process ends and returns the user input values. [Example 19–2](#) shows the code for the event handler method to which **Done** button is bound. The method gets the customer information, then either creates a Faces message for an incorrect password, or sets the values on the new customer object and return that object.

**Example 19–2 Action Listener Method for the Done Button in a Managed Bean**

```
public void done(ActionEvent e)
{
    AdfFacesContext afContext = AdfFacesContext.getCurrentInstance();
    String firstname = afContext.getPageFlowScope().get("firstname").toString();
    String lastname = afContext.getPageFlowScope().get("lastname").toString();
    String street = afContext.getPageFlowScope().get("street").toString();
    String zipCode = afContext.getPageFlowScope().get("zipCode").toString();
    String country = afContext.getPageFlowScope().get("country").toString();
    String password = afContext.getPageFlowScope().get("password").toString();
    String confirmPassword =
        afContext.getPageFlowScope().get("confirmPassword").toString();
    if (!password.equals(confirmPassword))
    {
        FacesMessage fm = new FacesMessage();
        fm.setSummary("Confirm Password");
        fm.setDetail("You've entered an incorrect password. Please verify that you've
            entered a correct password!");
        FacesContext.getCurrentInstance().addMessage(null, fm);
    }
    else
    {
        //Get the return value
        Customer cst = new Customer();
        cst.setFirstName(firstname);
        cst.setLastName(lastname);
        cst.setStreet(street);
        cst.setPostalCode(zipCode);
        cst.setCountry(country);
        cst.setPassword(password);
        // And return it
        afContext.getCurrentInstance().returnFromDialog(cst, null);
        afContext.getPageFlowScope().clear();
    }
}
```

### 19.3.4 What Happens at Runtime: Raising the Return Event from the Dialog

When the dialog is dismissed, ADF Faces generates a return event (`ReturnEvent`). The `AdfFacesContext.returnFromDialog()` method sends a return value as a property of the return event. The return event is delivered to the return listener (`ReturnListener`) that is registered on the command component that opened the dialog (for example, the **New User** `commandLink` on the Login page). How you would handle the return value is described in [Section 19.3.7, "How to Handle the Return Value."](#)

## 19.3.5 How to Pass a Value into a Dialog

To pass a value into a dialog, you use a `LaunchListener` listener bound to a handler method for the `LaunchEvent`. You can use the `getDialogParameters()` method to add a parameter to a `Map` using a key-value pair.

### To Pass a Value into a Dialog:

1. Create a handler method for the `LaunchEvent` that uses the `getDialogParameters` method to get the parameters from a dialog.

For example, in the sample application, a new user can enter a name in the **Username** field on the Login page, and then click the **New User?** link. When the New Account dialog page displays in a popup dialog, the **First Name** input field is automatically populated with the name that was entered in the Login page. To accomplish this, you create a handler that uses the `getDialogParameters` method to put the value of the username field into the dialog, as shown in [Example 19-3](#).

#### **Example 19-3** *LaunchEvent Listener Method for the New User Command Link in a Backing Bean*

```
public void handleLaunch(LaunchEvent event)
{
    //Pass the current value of the field into the dialog
    Object usr = username;
    event.getDialogParameters().put("firstname", getUsername());
}
// Use by inputText value binding
private String username;
public String getUsername()
{
    return username;
}
public void setUsername(String username)
{
    this.username = username;
}
```

2. Bind the `launchListener` attribute of the command component used to navigate to the next page, to the handler method created in Step 1.

[Example 19-4](#) shows the code for the `commandLink` component, whose `launchListener` attribute is bound to the handler method.

#### **Example 19-4** *Input Field and New User Command Link on the Login Page*

```
<af:inputText label="Username" value="#{backing_login.username}"/>
<af:commandLink id="cmdLink" text="New User?"
    action="dialog:newAccount"
    useWindow="true" partialSubmit="true"
    launchListener="#{backing_login.handleLaunch}"
    returnListener="#{backing_login.handleReturn}"
    windowHeight="200" windowWidth="500" />
```

3. On the resulting page, use the `pageFlowScope` object to retrieve the key and value via a special EL expression in the format `#{pageFlowScope.someKey}`, as shown in [Example 19-5](#)

**Example 19–5 Input Field on the New Account Page**

```
<af:inputText label="First name" value="#{pageFlowScope.firstname}"/>
```

**19.3.6 What Happens at Runtime: Handling the LaunchEvent**

In ADF Faces, a process always gets a copy of all the values that are in the `pageFlowScope` of the page from which a dialog is launched. When the `getDialogParameters()` method has added parameters to a `Map`, those parameters also become available in `pageFlowScope`, and any page in the dialog process can get the values out of `pageFlowScope` by referring to the `pageFlowScope` objects via EL expressions.

---

**Note:** Unlike `sessionScope`, `pageFlowScope` values are visible only in the current page flow or process. If the user opens a new window and starts navigating, that series of windows has its own process; values stored in each window remain independent. Clicking on the browser's Back button automatically resets `pageFlowScope` to its original state. When you return from a process the `pageFlowScope` is back to the way it was before the process started. To pass values out of a process you would use `AdfFacesContext.returnFromDialog()`, `sessionScope` or `applicationScope`.

---

**19.3.7 How to Handle the Return Value**

To handle a return value once the dialog is dismissed, you register a return listener on the command component that launched the dialog. For example, in the sample application, once a new user enters information, that information needs to be handled once the dialog process is complete.

**To handle the return value:**

1. Create a handler method for the `returnEvent`. You use the `getReturnValue()` method to retrieve the return value, because the return value is automatically added as a property of the `ReturnEvent`.

[Example 19–6](#) shows the code for the return listener method that handles the return value.

**Example 19–6 Return Listener Method for the New User Link in a Backing Bean**

```
public void handleReturn(ReturnEvent event)
{
    if (event.getReturnValue() != null)
    {
        Customer cst;
        String name;
        String psw;
        cst = (Customer)event.getReturnValue();
        name = cst.getFirstName();
        psw = cst.getPassword();
        CustomerList.getCustomers().add(cst);
        inputText1.setSubmittedValue(null);
        inputText1.setValue(name);
        inputText2.setSubmittedValue(null);
        inputText2.setValue(psw);
    }
}
```

```
    }  
}
```

2. Bind the `returnListener` attribute on the command component that launched the dialog to the `returnEvent` handler method created in Step 1.

### 19.3.8 What Happens at Runtime: Handling the ReturnEvent on the Launching Component

At runtime in the sample application, when ADF Faces delivers a `ReturnEvent` to the `ReturnListener` registered on the `commandLink` component, the `handleReturn()` method is called and the return value is processed accordingly. The new user is added to a customer list, and as a convenience to the user any previously submitted values in the Login page are cleared and the input fields are populated with the new information.

# Part IV

---

## Creating a Databound Web User Interface

Part IV contains the following chapters:

- [Chapter 20, "Getting Started with Your Web Interface"](#)
- [Chapter 21, "Understanding the Fusion Page Lifecycle"](#)
- [Chapter 22, "Creating a Basic Databound Page"](#)
- [Chapter 23, "Creating ADF Databound Tables"](#)
- [Chapter 24, "Displaying Master-Detail Data"](#)
- [Chapter 25, "Creating Databound Selection Lists and Shuttles"](#)
- [Chapter 26, "Creating Databound ADF Data Visualization Components"](#)
- [Chapter 27, "Creating ADF Databound Search Forms"](#)
- [Chapter 28, "Creating More Complex Pages"](#)
- [Chapter 29, "Designing a Page Using Placeholder Data Controls"](#)

---

## Getting Started with Your Web Interface

This chapter describes how to use the Data Controls panel and ADF Model data binding to create databound UI components on JSF pages of a Fusion web application. It describes how to use page templates and page fragments to build a page. It also describes how to use managed beans to store logic for the page.

This chapter includes the following sections:

- [Section 20.1, "Introduction to Developing a Web Application with ADF Faces"](#)
- [Section 20.2, "Using Page Templates"](#)
- [Section 20.3, "Creating a Web Page"](#)
- [Section 20.4, "Using a Managed Bean in a Fusion Web Application"](#)

### 20.1 Introduction to Developing a Web Application with ADF Faces

Most of what you need to know to get started with your web interface is covered in the *Oracle Fusion Middleware Web User Interface Developer's Guide for Oracle Application Development Framework*. However, using the ADF Model layer for data binding instead of JSF managed beans provides additional functionality, such as the ability to declaratively bind components to your business services. For more information on what ADF Model can provide, see [Section 1.2.2, "ADF Model Layer."](#) This chapter provides a high-level overview of the web interface development process as detailed in the Faces guide, and also provides information about the additional functionality available when you use ADF Model data binding.

Following the development process outlined in [Chapter 1, "Introduction to Building Fusion Web Applications with Oracle ADF"](#), developing a web application with ADF Faces and using ADF Model for data binding involves the following steps:

- Creating ADF Faces templates for your pages (optional)
- Creating the individual pages and page fragments for regions to be used within a page
- Creating any needed managed beans

Additionally, the lifecycle of a Fusion web application is different from that of a standard JSF or ADF Faces application. For more information about how the lifecycle works, see [Chapter 21, "Understanding the Fusion Page Lifecycle."](#)

### 20.2 Using Page Templates

As you design the flow of your application, you can begin to think about the design of your pages. To ensure consistency throughout your application, you use ADF page

templates. These page templates provide structure and consistency for other developers building web pages. Page templates typically contain static areas which cannot be changed when they are used, and dynamic areas, where developers can place content specific to the page they are building.

For example, the StoreFront module of the Fusion Order Demo application contains a page template that provides a top area for branding and navigation, a bottom area for copyright information, and a center area for the main content of the page. Page developers do not need to do anything to the branding and copyright information when they use the template. They need only to develop the main content area.

In addition to using ADF Faces components to build a page template, you can add attributes to the template definition. These attributes provide placeholders for specific information that the page developer needs to provide when using the page template. For example, the page template in the StoreFront module application contains an attribute for a welcome message. When page developers use this page template, they can add a different welcome message for each page.

You can also add facet references to the page template. These references act as placeholders for content on the page. [Figure 20–1](#) shows a rendition of how the StoreFrontTemplate template used in the StoreFront module application uses facet references.

**Figure 20–1 Facets in the StoreFrontTemplate**

In this page template, facet references are used inside four different `panelSplitter` components. When the home page was created using this page template, the navigational links were placed in the Header facet and the accordion panels that hold the navigation trees and search panels were placed in the Start facet. The cart summary was placed in the End facet, and the main portion of the page was placed in the Center facet. The copyright information was placed in the Bottom facet.

When you choose to add databound components to a page template, an associated page definition file and the other metadata files that support ADF Model layer data

binding are created. Each component is bound in the same fashion as for standard JSF pages, as described in [Chapter 12, "Using ADF Model in a Fusion Web Application."](#) You can also create model parameters for the page template. The values for these parameters can then be set at runtime by the calling page.

For example, if you wanted a list of products to appear on each page that uses the page template, you could drag and drop the `productName` attribute of the `Products` collection as a list. Or, if you wanted the pages to display the currently selected product ID, you could create a model parameter for the page template that would evaluate to that product's ID.

---

---

**Note:** Page templates are primarily a project artifact. While they can be reused between projects and applications, they are not fully self-contained and will always have some dependencies to external resources, for example, any ADF data binding, `Strings` from a message bundle, images, and managed beans.

---

---

If a page template does not contain databound components, it can be referenced dynamically by the calling page using an EL expression. That is, the page template to be used can be determined at runtime. For instance, a page may use `templateA` or `templateB` based on user selection. When you add a page template to a page, an `af:pageTemplate` tag is added to the page. The `af:pageTemplate` tag includes a `viewId` attribute that specifies the page template the page will use. You can set `viewId` with an EL expression to a managed bean method that returns the page template ID, as shown in [Example 20-1](#).

**Example 20-1 Page with Dynamic Page Template (not Databound Page Template Only)**

```
<af:pageTemplate
  id="pt1"
  viewId="#{myBean.templateViewId}"
```

If the page template has databound components, setting the `viewId` with an EL expression is not enough. Because databound components require access to the binding container, you must specify the page template as well as its associated binding container.

For databound page templates, you use the `pageTemplateModel` to manage both the page template ID and the associated binding container. In the JSF page, instead of using the `viewId` attribute, you set the `value` attribute to the `pageTemplateModel`. You must also modify the page executable section of the calling page's page definition file and create a managed bean with methods to process the page template IDs. For detailed instructions, see [Section 20.2.3, "How to Add a Databound Page Template to a Page Dynamically."](#)

## 20.2.1 How to Use ADF Data Binding in ADF Page Templates

Creating a page template for use in an application that uses ADF Business Components and ADF Model layer data binding is the same as creating a standard ADF Faces page template, as documented in the "Using Page Templates" section of the *Oracle Fusion Middleware Web User Interface Developer's Guide for Oracle Application Development Framework*. Once you create the template, you can drag and drop items from the Data Controls panel. JDeveloper automatically adds the page definition file when you drag and drop items from this panel.

The Create JSF Page Template wizard also allows you to create model parameters for use by the template.

**To add model parameters to a template:**

1. Create a page template following the instructions in the "How to Create a Page Template" section of the *Oracle Fusion Middleware Web User Interface Developer's Guide for Oracle Application Development Framework*. However, do not complete the dialog.
2. In the Create JSF Page Template dialog, select **Create Associated ADFm Page Definition**.

---

---

**Note:** You only need to select this checkbox if you wish to add parameters. JDeveloper automatically adds the page definition file when you drag and drop items from the Data Controls panel.

---

---

3. Click the **Model Parameters** tab.
4. Click the **Add** icon.
5. Enter the following for the parameter:
  - **Id:** Enter a name for the parameter.
  - **Value:** Enter a value or an EL expression that can resolve to a value. If needed, click the Invoke Expression Builder (...) button to open the Expression Builder. You can use this to build the expression. For more information about EL expressions and the EL expression builder, see [Chapter 12.7, "Creating ADF Data Binding EL Expressions."](#)
  - **Option:** Select the option that determines how the parameter value will be specified.
    - **optional:** The binding definition's value is used only if the parameter is not specifically set by the caller. This is the default.
    - **final:** The binding definition has the expression to access the value that should be used for this parameter.
    - **mandatory:** The parameter value has to be set by the caller.
  - **Read Only:** Select if the parameter's value is to be read-only and should not be overwritten
6. Create more parameters as needed. Use the order buttons to arrange the parameters into the order in which you want them to be evaluated.

You can now use the Data Controls panel to add databound UI components to the page, as you would for a standard JSF page, as described in the remaining chapters in this part of the book.

---

---

**Note:** If your template contains any method actions bound to a method iterator, you cannot change the value of the `refresh` attribute on the iterator to anything other than `Default`. If set to anything other than `Default`, the method will not execute.

---

---

## 20.2.2 What Happens When You Use ADF Model Layer Bindings on a Page Template

When you add ADF databound components to a template or create model parameters for a template, a page definition file is created for the template, and any model parameters are added to that file.

---

**Note:** This section describes what happens for a statically assigned page template. For information about dynamic templates, see [Section 20.2.3, "How to Add a Databound Page Template to a Page Dynamically."](#)

---

[Example 20–2](#) shows what the page definition file for a template for which you created a `productId` model parameter might look like.

### **Example 20–2** Model Parameters in a Page Definition for a Template

```
<parameters>
  <parameter id="productID" readonly="true"
    value="#{bindings.productId.inputValue}"/>
</parameters>
<executables/>
<bindings/>
```

Parameter binding objects declare the parameters that the page evaluates at the beginning of a request. For more information about binding objects and the ADF lifecycle, see [Chapter 12, "Using ADF Model in a Fusion Web Application."](#) However, since a template itself is never executed, the page that uses the template (the *calling* page) must access the binding objects created for the template (including parameters or any other type of binding objects created by dragging and dropping objects from the Data Controls panel onto the template).

In order to access the template's binding objects, the page definition file for the calling page must instantiate the binding container represented by the template's page definition file. As a result, a reference to the template's page definition is inserted as an executable into the calling page's page definition file, as shown in [Example 20–3](#).

### **Example 20–3** Reference to Template's Page Definition as an Executable

```
<executables>
  <page path="oracle.foddemo.storefront.pageDefs.templates_MyTemplatePageDef"
    id="pageTemplateBinding"/>
</executables>
```

In this example, the calling page was built using the `MyTemplate` template. Because the page definition file for the `MyTemplate` template appears as an executable for the calling page, when the calling page's binding container is instantiated, it will in turn instantiate the `MyTemplatePageDef`'s binding container, thus allowing access to the parameter values or any other databound values.

Because there is an ID for this reference (in this case, `pageTemplateBinding`), the calling page can have components that are able to access values from the template. When you create a JSF page from a template, instead of you having to repeat the code contained within the template, you can use the `af:pageTemplate` tag on the calling page. This tag contains the path to the template JSF page.

Additionally, when the template contains any ADF data binding, the value of that tag is the ID set for the calling page's reference to the template's page definition, as shown

in [Example 20–4](#). This binding allows the component access to the binding values from the template.

**Example 20–4 Page Template Page Definition Reference**

```
<af:pageTemplate viewId="/MyTemplate.jspx"
    value="#{bindings.pageTemplateBinding}".../>
```

### 20.2.3 How to Add a Databound Page Template to a Page Dynamically

You can dynamically add a page template without databound components by using an EL expression to select the page template. For more information on how to do this, see [Section 20.2, "Using Page Templates."](#)

You can also statically add a page template with databound components. For more information on how to do this, see [Section 20.2.1, "How to Use ADF Data Binding in ADF Page Templates."](#)

This section describes how to dynamically add a page template with databound components to a page.

You use the `pageTemplateModel` to dynamically manage a page template and its binding container. You use an EL expression in the page definition file to set the page template Id. You create managed bean methods to return the page template Id.

**To add a databound page template to a page dynamically:**

1. Add the page template to the page as described in [Section 20.2.1, "How to Use ADF Data Binding in ADF Page Templates."](#)
2. In the JSF page source editor, remove the `viewId` attribute and change the `value` attribute to the `pageTemplateModel`. You do not need to create a `pageTemplateModel` explicitly. You can use the `pageTemplateModel` from the corresponding page definition file's page executable binding. For example, for a page executable binding called `pageTemplate1`, you would add the following line under the `af:pageTemplate` tag:

```
value="#{bindings.pageTemplate1.templateModel}"/>
```

3. In the page definition file `<executable>` section, make the following changes to the `<page>` section:
  - Remove the `path` attribute. It is no longer needed. The `pageTemplateModel` manages databound components' access to the binding container.
  - Change the `id` attribute to the page executable binding. In this example, it is `pageTemplate1`.
  - Add a `Refresh` attribute and set it to `ifNeeded`.
  - Add a `viewId` attribute and set it to an EL expression with a managed bean method that returns the current page template Id.

For example, for a page executable binding of `pageTemplate1`, the `id` attribute would also be `pageTemplate1`:

```
<executables>
  <page id="pageTemplate1"
    viewId="#{myBean.templateViewId}"
    Refresh="ifNeeded"/>
  ...
</executables>
```

4. Create a `pageFlowScope` managed bean with a method that returns the current page template Id.

The managed bean code should be similar to that of [Example 20–5](#). In this example, `gettemplateViewId()` obtains the user's page template selection and returns the page template Id. `setMDTemplateViewId()` sets the page template to be `MDPageTemplate` and `setPopupTemplateViewId()` sets the page template to be `PopupPageTemplate`.

**Example 20–5 Managed Bean Code to Process Page Templates Dynamically**

```
public class myClass {
    final private String MDPageTemplate = "/MDPageTemplate.jspx";
    final private String PopupPageTemplate = "/PopupPageTemplate.jspx";
    private String templateViewId;

    public myClass() {
        super();
        templateViewId = MDPageTemplate;
    }
    public String gettemplateViewId() {
        return templateViewId;
    }
    public void setMDTemplateViewId(ActionEvent ae) {
        templateViewId = MDPageTemplate;
    }
    public void setPopupTemplateViewId(ActionEvent ae) {
        templateViewId = PopupPageTemplate;
    }
}
```

## 20.2.4 What Happens at Runtime: How Pages Use Templates

When a page is created using a template that contains ADF data binding, the following happens:

1. The calling page follows the standard JSF/ADF lifecycle, as documented in [Chapter 21, "Understanding the Fusion Page Lifecycle."](#) As the page enters the Restore View phase, the URL for the calling page is sent to the binding context, which finds the corresponding page definition file.
2. During the Initialize Context phase, the binding container for the calling page is created based on the page definition file.
3. During the Prepare Model phase, the page template executable is refreshed. At this point, the binding container for the template is created based on the template's page definition file, and added to the binding context.
4. The lifecycle continues, with UI components and bindings from both the page and the template being processed.

## 20.3 Creating a Web Page

Creating a web page for an application that uses ADF Model layer data binding is no different than described in the "Creating a View Page" section in the *Oracle Fusion Middleware Web User Interface Developer's Guide for Oracle Application Development Framework*. You can create pages either by double-clicking a view activity in a task flow or by using the New Gallery. When creating the page (or dropping a view activity onto a task flow), you can choose to create the page as a JSF JSP or as a JSF JSP fragment. JSF

fragments provide a simple way to create reusable page content in a project, and are what you use when you wish to use task flows as regions on a page. When you modify a JSF page fragment, the JSF pages that consume the page fragment are automatically updated.

---

**Note:** Although JDeveloper supports XHTML files to be used in applications that use Facelets, the `faces-config.xml` and `adfc-config.xml` diagrammers do not support XHTML. In order to add navigation to these files, you have to manually edit the code by clicking the **Source** tab.

---

When you begin adding content to your page, you typically use the Component Palette and Data Controls panel of JDeveloper. The Component Palette contains all the ADF Faces components needed to declaratively design your page. Once you have the basic layout components placed on the page, you can then drag and drop items from the Data Controls panel to create ADF Model databound UI components. The remaining chapters in this part of the book explain in detail the different types of databound components and pages you can create using ADF Model data binding.

## 20.4 Using a Managed Bean in a Fusion Web Application

Managed beans are Java classes that you register with the application using various configuration files. When the JSF application starts up, it parses these configuration files, and the beans listed within them are made available. The managed beans can be referenced in an EL expression, allowing access to the beans' properties and methods. Whenever a managed bean is referenced for the first time and it does not already exist, the Managed Bean Creation Facility instantiates the bean by calling the default constructor method on it. If any properties are also declared, they are populated with the declared default values.

Often, managed beans handle events or some manipulation of data that is best handled at the front end. For a more complete description of how managed beans are used in a standard JSF application, see the Java EE tutorial on Oracle's Technology Network web site

(<http://www.oracle.com/technetwork/java/javasee/overview/index.html>).

**Best Practice:** Use managed beans to store logic that is related to the UI rendering only. All application data and processing should be handled by logic in the business layer of the application. Similar to how you store data-related logic in the database using PL/SQL rather than a Java class, the rule of thumb in a Fusion web application is to store business-related logic in the middle tier. This way, you can expose this logic as business service methods, which can then become accessible to the ADF Model layer and be available for data binding.

In an application that uses ADF data binding and ADF task flows, managed beans are registered in different configuration files from those used for a standard JSF application. In a standard JSF application, managed beans are registered in the `faces-config.xml` configuration file. In a Fusion web application, managed beans can be registered in the `faces-config.xml` file, the `adfc-config.xml` file, or a task flow definition file. Which configuration file you use to register a managed bean depends on what will need to access that bean, whether or not it needs to be customized at runtime, what the bean's scope is, and in what order all the beans in the

application need to be instantiated. [Table 20–1](#) describes how registering a bean in each type of configuration file affects the bean.

---

**Note:** Registering managed beans within the `faces-config.xml` file is not recommended in a Fusion web application.

Managed beans accessed within the task flow definition must be registered in that task flow's definition file.

---

**Table 20–1** *Effects of Managed Bean Configuration Placement*

Managed Bean Placement	Effect
<code>adfc-config.xml</code>	<ul style="list-style-type: none"> <li>■ Managed beans can be of any scope. However, any backing beans for page fragments or declarative components should use <code>BackingBean</code> scope. For more information regarding scope, see <a href="#">Section 21.3, "Object Scope Lifecycles."</a></li> <li>■ When executing within an unbounded task flow, <code>faces-config.xml</code> will be checked for managed bean definitions before the <code>adfc-config.xml</code> file.</li> <li>■ Lookup precedence is enforced per scope. Request-scoped managed beans take precedence over session-scoped managed beans. Therefore, a request-scoped managed bean named <code>foo</code> in the <code>adfc-config.xml</code> file will take precedence over a session-scoped managed bean named <code>foo</code> in the current task flow definition file.</li> <li>■ Already instantiated beans take precedence over new instances being instantiated. Therefore, an existing session-scoped managed bean named <code>foo</code> will always take precedence over a request-scoped bean named <code>foo</code> defined in the current task flow definition file.</li> </ul>

**Table 20–1 (Cont.) Effects of Managed Bean Configuration Placement**

Managed Bean Placement	Effect
Task flow definition file	<ul style="list-style-type: none"> <li>■ Managed bean can be of any scope. However, managed beans of <code>pageFlow</code> scope or <code>view</code> scope that are to be accessed within the task flow definition must be defined within the task flow definition file. Any backing beans for page fragments in a task flow should use <code>BackingBean</code> scope.</li> <li>■ Managed bean definitions within task flow definition files will be visible only to activities executing within the same task flow.</li> <li>■ When executing within a bounded task flow, <code>faces-config.xml</code> will be checked for managed bean definitions before the currently executing task flow definition. If no match is found in either location, <code>adfc-config.xml</code> and other bootstrap configuration files will be consulted. However, this lookup in other <code>adfc-config.xml</code> and bootstrap configuration files will only occur for session- or application-scoped managed beans.</li> <li>■ Lookup precedence is enforced per scope. Request-scoped managed beans take precedence over session-scoped managed beans. Therefore, a request-scoped managed bean named <code>foo</code> in the <code>adfc-config.xml</code> file will take precedence over a session-scoped managed bean named <code>foo</code> in the current task flow definition file.</li> <li>■ Already instantiated beans take precedence over new instances being instantiated. Therefore, an existing session-scoped managed bean named <code>foo</code> will always take precedence over a request-scoped bean named <code>foo</code> registered in the current task flow definition file.</li> <li>■ Customizations are allowed.</li> </ul>
<code>faces-config.xml</code>	<ul style="list-style-type: none"> <li>■ Managed beans can be of any scope other than <code>pageFlow</code> scope or <code>view</code> scope.</li> <li>■ When searching for any managed bean, the <code>faces-config.xml</code> file is always consulted first. Other configuration files will be searched only if a match is not found. Therefore, beans registered in the <code>faces-config.xml</code> file will always win any naming conflict resolution.</li> <li>■ No customizations can be made.</li> </ul>

As a general rule for Fusion web applications, a bean that may be used in more than one page or task flow, or one that is used by pages within the main unbounded task flow (`adfc-config`), should be registered in the `adfc-config.xml` configuration file. A managed bean that will be used only by a specific task flow should be registered in that task flow's definition file. There should be no beans registered in the `faces-config.xml` file.

---

**Note:** If you create managed beans from dialogs within JDeveloper, the bean is registered in the `adfc-config.xml` file, if it exists.

---

For example, in the `StoreFront` module, the `myOrdersBean` managed bean is used by the `myOrders.jspx` page to handle the case where a user decides to cancel editing an order, and the edits have already been committed to the model but have not yet been

persisted to the database. Because this bean is used by a page within the `adfc-config` unbounded task flow, it is registered in the `adfc-config.xml` file. The `custRegBasicInformationBean` is a managed bean used by the `basicInformation` JSF fragment to handle the selections in the shuttle component on that page. Because it is used solely within the `customer-registration` task flow, it is registered in the `customer-registration-task-flow` definition file.

This section describes how to create a managed bean for use within a task flow (either the default `adfc-config` flow or any bounded task flow). For more information regarding managed beans and how they are used as backing beans for JSF pages, see the "Creating and Using Managed Beans" section in the *Oracle Fusion Middleware Web User Interface Developer's Guide for Oracle Application Development Framework*.

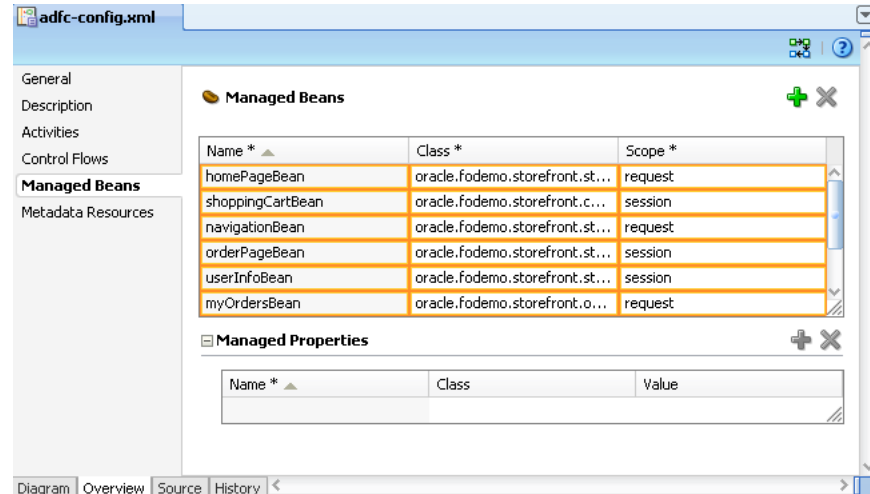

## 20.4.1 How to Use a Managed Bean to Store Information

Within the editors for a task flow definition, you can create a managed bean and register it with the JSF application at the same time.

### To create a managed bean for a task flow:

1. In the Application Navigator, double-click either the `adfc-config.xml` file or any other task flow definition file.
2. At the bottom of the window, click the **Overview** tab.
3. In the overview editor, click the **Managed Beans** navigation tab. [Figure 20–2](#) shows the editor for the `adfc-config.xml` file.

**Figure 20–2** Managed Beans in the `adfc-config.xml` File

4. Click the **Add** icon to add a row to the **Managed Beans** table.
5. In the fields, enter the following:
  - **managed-bean-name:** A name for the bean.
  - **managed-bean-class:** If the corresponding class has already been created for the bean, use the browse (...) button for the **managed-bean-class** field to search for and select the class. If a class does not exist, enter the name you'd like to use. Be sure to include any package names as well. You can then use the drop-down menu to choose **Generate Class**, and the Java file will be created for you.

- **managed-bean-scope:** The bean's scope. For more information about the different object scopes, see [Section 21.3, "Object Scope Lifecycles."](#)

---

**Note:** When determining what scope to register a managed bean with or to store a value in, keep the following in mind:

- Always try to use the narrowest scope possible.
- If your managed bean takes part in component binding by accepting and returning component instances (that is, if UI components on the page use the binding attribute to bind to component properties on the bean), then the managed bean must be stored in `BackingBean` scope. If it can't be stored in one of those scopes (for example, if it needs to be stored in `sessionScope` for high availability reasons), then instead of using component binding, you need to use the `ComponentReference` API. For more information, see the "What You May Need to Know About Component Bindings and Managed Beans" section of the *Oracle Fusion Middleware Web User Interface Developer's Guide for Oracle Application Development Framework*
- Use the `sessionScope` scope only for information that is relevant to the whole session, such as user or context information. Avoid using the `sessionScope` scope to pass values from one page to another.
- You can also set the scope to `none`. While not technically a scope, `none` means that the bean will not live within any particular scope, but will instead be instantiated each time it is referenced. You should set a bean's scope to `none` when it is referenced by another bean.

- 
6. You can optionally add needed properties for the bean. With the bean selected in the **Managed Beans** table, click the **Add** icon for the **Managed Properties** table. Enter a property name (other fields are optional).

---

**Note:** While you can declare managed properties using this editor, the corresponding code is not generated on the Java class. You will need to add that code by creating private member fields of the appropriate type and then using the **Generate Accessors** menu item on the context menu of the source editor to generate the corresponding getter and setter methods for these bean properties.

---

## 20.4.2 What Happens When You Create a Managed Bean

When you use the configuration editor to create a managed bean and elect to generate the Java file, JDeveloper creates a stub class with the given name and a default constructor. [Example 20-6](#) shows the code added to the `MyBean` class stored in the `view` package.

### **Example 20-6** Generated Code for a Managed Bean

```
package view;
```

```
public class MyBean {
    public MyBean() {
    }
}
```

You now need to add the logic required by your task flow or page. You can then refer to that logic using an EL expression that refers to the `managed-bean-name` value given to the managed bean. For example, to access the `myInfo` property on the bean, the EL expression would be:

```
#{my_bean.myInfo}
```

JDeveloper also adds a `managed-bean` element to the appropriate task definition file. [Example 20-7](#) shows the `managed-bean` element created for the `MyBean` class.

**Example 20-7 Managed Bean Configuration on the `adfc-config.xml` File**

```
<managed-bean>
  <managed-bean-name>my_bean</managed-bean-name>
  <managed-bean-class>view.MyBean</managed-bean-class>
  <managed-bean-scope>session</managed-bean-scope>
</managed-bean>
```

### 20.4.3 How to Set Managed Bean Memory Scopes in a Server-Cluster Environment

Typically, in an application that runs in a clustered environment, a portion of the application's state is serialized and copied to another server or a data store at the end of each request so that the state is available to other servers in the cluster.

---

**Note:** If the managed bean will be calling `set` and `get` methods on ADF Faces components, you cannot serialize the managed beans because ADF Faces components are not serializable. You will need to access the ADF Faces components in another way. For more information, see the “What You May Need to Know About Component Bindings and Managed Beans” section of the *Oracle Fusion Middleware Web User Interface Developer’s Guide for Oracle Application Development Framework*.

---

When you are designing an application to run in a clustered environment, you must:

- Ensure that all managed beans with a lifespan longer than one request are serializable (that is, they implement the `java.io.Serializable` interface). Specifically, beans stored in session scope, page flow scope, and view scope need to be serializable.

**Tip:** To identify failures with objects stored in page flow scope and view scope, use `writeObject()`. This method provides additional information in an exception about the object and scope that failed to serialize. Additional information might be a region's page flow scope and the key of the object.

- Make sure that the framework is aware of changes to managed beans stored in ADF scopes (view scope and page flow scope).

When a value within a managed bean in either view scope or page flow scope is modified, the application needs to notify the framework so that it can ensure that the bean's new value is replicated.

In [Example 20–8](#), an attribute of an object in view scope is modified.

**Example 20–8 Code That Modifies an Object in viewScope**

```
Map<String, Object> viewScope =
    AdfFacesContext.getCurrentInstance().getViewScope();
MyObject obj = (MyObject)viewScope.get("myObjectName");
Obj.setFoo("newValue");
```

Without additional code, the framework will be unaware of this change and it will not know that a new value needs to be replicated within the cluster. To inform the framework that an object in an ADF scope has been modified and that replication is needed, use the `markScopeDirty()` method, as shown in [Example 20–9](#). The `markScopeDirty()` method accepts only `viewScope` and `pageFlowScope` as parameters.

**Example 20–9 Additional Code to Notify Oracle ADF of Changes to an Object**

```
ControllerContext ctx = ControllerContext.getInstance();
ctx.markScopeDirty(viewScope);
```

This code is needed for any request that modifies an existing object in one of the ADF scopes. If the scope itself is modified by the scope's `put()`, `remove()`, or `clear()` methods, it is not necessary to notify the framework.

If an application is not deployed to a clustered environment, the tracking of changes to ADF memory scopes is not needed, and by default, this functionality is disabled. To enable ADF Controller to track changes to ADF memory scopes and replicate the page flow scope and view scope within the server cluster, set the `<adf-scope-ha-support>` parameter in the `adf-config.xml` file to `true`. Because scope replication has a small performance overhead, it should be enabled only for applications running in a server-cluster environment.

[Example 20–10](#) shows `adf-scope-ha-support` set to `true` in the `adf-config.xml` file.

**Example 20–10 adf-scope-ha-support Parameter in the adf-config.xml File**

```
<?xml version="1.0" encoding="US-ASCII" ?>
<adf-config xmlns="http://xmlns.oracle.com/adf/config"
  xmlns:adfc="http://xmlns.oracle.com/adf/controller/config">
  <adfc:adf-controller-config>
  ...
  <adfc:adf-scope-ha-support>true</adfc:adf-scope-ha-support>
  ...
  </adfc:adf-controller-config>
  ...
</adf-config>
```

---

## Understanding the Fusion Page Lifecycle

This chapter describes the ADF page lifecycle, its phases, and how to best use the lifecycle within a Fusion web application.

This chapter includes the following sections:

- [Section 21.1, "Introduction to the Fusion Page Lifecycle"](#)
- [Section 21.2, "The JSF and ADF Page Lifecycles"](#)
- [Section 21.3, "Object Scope Lifecycles"](#)
- [Section 21.4, "Customizing the ADF Page Lifecycle"](#)

### 21.1 Introduction to the Fusion Page Lifecycle

When a page is submitted and a new page requested, the application invokes both the ADF Faces page lifecycle, which extends the standard JSF request lifecycle, and the ADF page lifecycle. The extended JSF lifecycle handles submitting the values on the page, validating component values, navigating pages, displaying components on the resulting page, and saving and restoring state. The JSF lifecycle phases use a UI component tree to manage the display of the faces components. This tree is a runtime representation of a JSF page: each UI component tag in a page corresponds to a UI component instance in the tree. The `FacesServlet` servlet manages the request processing lifecycle in JSF applications. `FacesServlet` creates an object called `FacesContext`, which contains the information necessary for request processing, and invokes an object that executes the lifecycle. For more details about the extended JSF lifecycle, see the "Using the JSF Lifecycle with ADF Faces" chapter of the *Oracle Fusion Middleware Web User Interface Developer's Guide for Oracle Application Development Framework*.

The ADF page lifecycle handles preparing and updating the data model, validating the data at the model layer, and executing methods on the business layer. The ADF page lifecycle uses the binding container to make data available for easy referencing by the page during the current page request.

The combined JSF and ADF page lifecycle is only one sequence within a larger sequence of events that begins when an HTTP request arrives at the application server and continues until the page is returned to the client. This overall sequence of events can be called the *web page lifecycle*. It follows processing through the model, view, and controller layers as defined by the MVC architecture. The page lifecycle is not a rigidly defined set of events, but is rather a set of events for a typical use case. [Figure 21-1](#) shows a sequence diagram of the lifecycle of a web page request using JSF and Oracle ADF in tandem.

**Figure 21-1 Lifecycle of a Web Page Request Using JSF and Oracle ADF**

The basic flow of processing a web page request using JSF and Oracle ADF happens as follows:

1. A web request for `http://yourserver/yourapp/faces/some.jsp` arrives from the client to the application server.
2. The `ADFBindingFilter` object looks for the ADF binding context in the HTTP session, and if it is not yet present, initializes it for the first time. Some of the functions of the `ADFBindingFilter` include finding the name of the binding context metadata file, and finding and constructing an instance of each data control.
3. The `ADFBindingFilter` object invokes the `beginRequest()` method on each data control participating in the request. This method gives the data control a notification at the start of every request so that it can perform any necessary setup.
4. The `JSF Lifecycle` object, which is responsible for orchestrating the standard processing phases of each request, notifies the `ADFPhaseListener` class during each phase of the lifecycle, so that it can perform custom processing to coordinate the JSF lifecycle with the ADF Model data binding layer. For more information about the details of the JSF and ADF page lifecycle phases, see [Section 21.2, "The JSF and ADF Page Lifecycles."](#)

---

---

**Note:** The `FacesServlet` class (in `javax.faces.webapp`), configured in the `web.xml` file of a JSF application, is responsible for initially creating the `JSFLifecycle` class (in `javax.faces.lifecycle`) to handle each request. However, since it is the `Lifecycle` class that does all the interesting work, the `FacesServlet` class is not shown in the diagram.

---

---

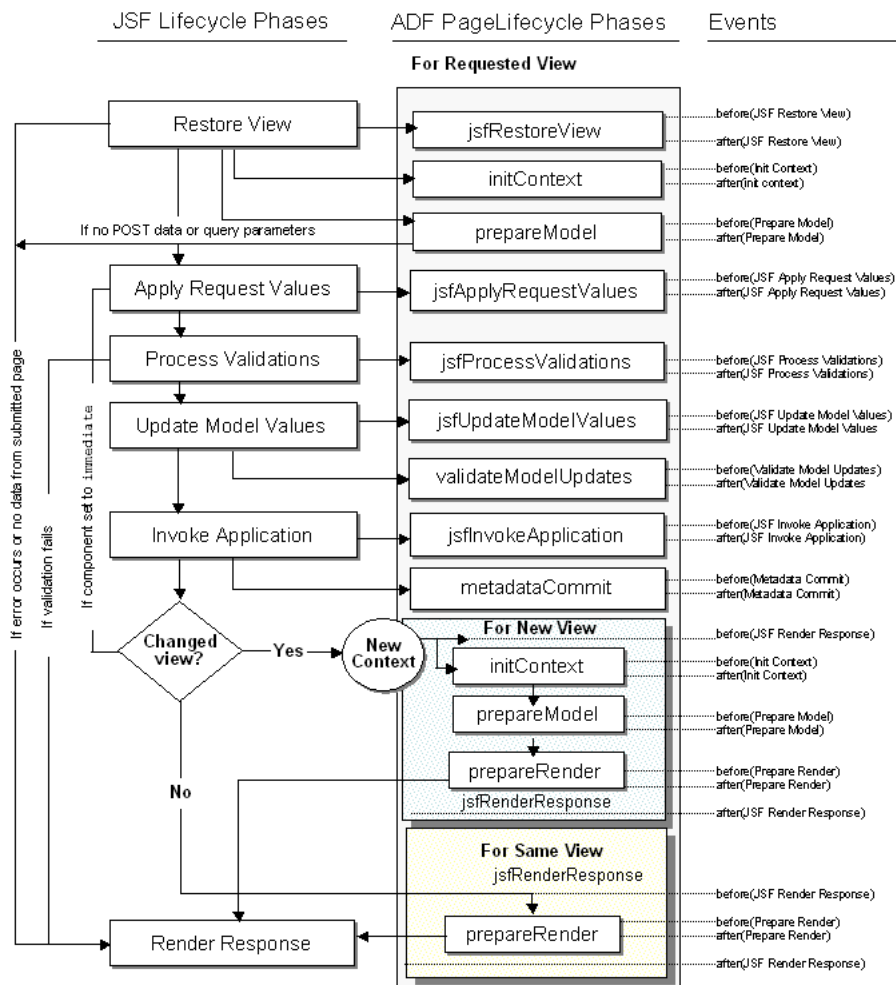

5. The `ADFPhaseListener` object creates an `ADFPagesLifecycle` object to handle each request and delegates appropriate before and after phase methods to corresponding methods in the `ADFPagesLifecycle` class. If the appropriate binding container for the page has never been used before during the user's session, it is created.
6. The first time an application module data control is referenced during the request, it acquires an instance of the application module from the application module pool.
7. The `JSFLifecycle` object forwards control to the page to be rendered.
8. The UI components on the page access value bindings and iterator bindings in the page's binding container and render the formatted output to appear in the browser.
9. The `ADFBindingFilter` object invokes the `endRequest()` method on each data control participating in the request. This method gives a data control notification at the end of every request, so that they can perform any necessary resource cleanup.
10. An application module data control uses the `endRequest` notification to release the instance of the application module back to the application module pool.
11. The user sees the resulting page in the browser.

The ADF page lifecycle also contains phases that are defined simply to notify ADF page lifecycle listeners before and after the corresponding JSF phase is executed (that is, there is no implementation for these phases). These phases allow you to create custom listeners and register them with any phase of both the JSF and ADF page lifecycles, so that you can customize the ADF page lifecycle if needed, both globally or at the page level.

## 21.2 The JSF and ADF Page Lifecycles

Figure 21–2 shows how the JSF and ADF phases integrate in the lifecycle of a page request. For more information about how the JSF lifecycle operates on its own, see the "Using the JSF Lifecycle with ADF Faces" chapter of the *Oracle Fusion Middleware Web User Interface Developer's Guide for Oracle Application Development Framework*.

**Figure 21–2 Lifecycle of a Page Request in a Fusion Web Application**

In a JSF application that uses the ADF Model layer, the phases in the page lifecycle are as follows:

- Restore View:** The URL for the requested page is passed to the `bindingContext` object, which finds the page definition file that matches the URL. The component tree of the requested page is either newly built or restored. All the component tags, event handlers, converters, and validators on the submitted page have access to the `FacesContext` instance. If the component tree is empty, (that is, there is no data from the submitted page), the page lifecycle proceeds directly to the Render Response phase.

If any discrepancies between the request state and the server-side state are detected, an error will be thrown and the page lifecycle jumps to the Render Response phase.

- JSF Restore View:** Provides before and after phase events for the Restore View phase. You can create a listener and register it with the before or after event of this phase, and the application will behave as if the listener were registered with the Restore View phase. The Initialize Context phase of the ADF Model page lifecycle listens for the `after(JSF Restore View)` event and then executes. The ADF Controller uses listeners for the before and after events of this phase to synchronize the server-side state with the request. For example, it is in this phase

that browser back button detection and bookmark reference are handled. After the before and after listeners are executed, the page flow scope is available.

- **Initialize Context:** The page definition file is used to create the `bindingContainer` object, which is the runtime representation of the page definition file for the requested page. The `LifecycleContext` class used to persist information throughout the ADF page lifecycle phases is instantiated and initialized with values for the associated request, binding container, and lifecycle.
- **Prepare Model:** The ADF page lifecycle enters the Prepare Model phase by calling the `BindingContainer.refresh(PREPARE_MODEL)` method. During the Prepare Model phase, `BindingContainer` page parameters are prepared and then evaluated. If parameters for a task flow exist, they are passed into the flow.

Next, any executables that have their `refresh` attribute set to `prepareModel` are refreshed based on the order of entry in the page definition file's `<executables>` section and on the evaluation of their `RefreshCondition` properties (if present). When an executable leads to an iterator binding refresh, the corresponding data control will be executed, and that leads to execution of one or more collections in the service objects. If an iterator binding fails to refresh, a JBO exception will be thrown and the data will not be available to display. For more information, see [Section 21.2.1, "What You May Need to Know About Using the Refresh Property Correctly."](#)

If the incoming request contains no `POST` data or query parameters, then the lifecycle forwards to the Render Response phase.

If the page was created using a template, and that template contains bindings using the ADF Model layer, the template's page definition file is used to create the binding container for the template. The container is then added to the binding context.

If any `taskFlow` executable bindings exist (for example, if the page contains a region), the `taskFlow` binding creates an `ADF Controller ViewPortContext` object for the task flow, and any nested binding containers for pages in the flow are then executed.

- **Apply Request Values:** Each component in the tree extracts new values from the request parameters (using its `decode` method) and stores those values locally. Most associated events are queued for later processing. If you have set a component's `immediate` attribute to `true`, then the validation, conversion, and events associated with the component are processed during this phase and the lifecycle skips the Process Validations, Update Model Values, and Invoke Application phases. Additionally, any associated iterators are invoked. For more information about ADF Faces validation and conversion, see the "Validating and Converting Input" chapter in the *Oracle Fusion Middleware Web User Interface Developer's Guide for Oracle Application Development Framework*.
- **JSF Apply Request Values:** Provides before and after phase events for the Apply Request Values phase. You can create a listener and register it with the before or after event of this phase, and the application will behave as if the listener were registered with the Apply Request Values phase.
- **Process Validations:** Local values of components are converted and validated on the client. If there are errors, the lifecycle jumps to the Render Response phase. At the end of this phase, new component values are set, any validation or conversion error messages and events are queued on `FacesContext`, and any value change events are delivered. Exceptions are also caught by the binding container and cached.

- **JSF Process Validations:** Provides before and after phase events for the Process Validations phase. You can create a listener and register it with the before or after event of this phase, and the application will behave as if the listener were registered with the Process Validations phase.
- **Update Model Values:** The component's validated local values are moved to the model and the local copies are discarded. For any updateable components (such as an `inputText` component), corresponding iterators are refreshed, if the refresh condition is set to the default (`deferred`) and the refresh condition (if any) evaluates to `true`.

If you are using a backing bean for a JSF page to manage your UI components, any UI attributes bound to a backing bean property will also be refreshed in this phase.

- **JSF Update Model Values:** Provides before and after phase events for the Update Model Values phase. You can create a listener and register it with the before or after event of this phase, and the application will behave as if the listener were registered with the Update Model Values phase.
- **Validate Model Updates:** The updated model is now validated against any validation routines set on the model. Exceptions are caught by the binding container and cached.
- **Invoke Application:** Any action bindings for command components or events are invoked.
- **JSF Invoke Application:** Provides before and after phase events for the Invoke Application phase. You can create a listener and register it with the before or after event of this phase, and the application will behave as if the listener were registered with the Invoke Application phase.
- **Metadata Commit:** Changes to runtime metadata are committed. This phase stores any runtime changes made to the application using the Metadata Service (MDS). For more information about using MDS to persist runtime changes, see [Chapter 34, "Customizing Applications with MDS."](#)
- **Initialize Context (only if navigation occurred in the Invoke Application lifecycle):** The Initialize Context phase listens for the `beforeJSFRenderResponse` event to execute. The page definition file for the next page is initialized.
- **Prepare Model (only if navigation occurred in the Invoke Application lifecycle):** Any page parameters contained in the next page's definition are set.
- **Prepare Render:** The binding container is refreshed to allow for any changes that may have occurred in the Apply Request Values or Validation phases. Any iterators that correspond to read-only components (such as an `outputText` component) are refreshed. Any dynamic regions are switched, if needed. The `prepareRender` event is sent to all registered listeners, as is the `afterJSFRenderResponse` event.

---

**Note:** Instead of displaying `prepareRender` as a valid phase for a selection, JDeveloper displays `renderModel`, which represents the `refresh(RENDER_MODEL)` method called on the binding container.

---

- **Render Response:** The components in the tree are rendered as the Java EE web container traverses the tags in the page. State information is saved for subsequent requests and the Restore View phase.

In order to lessen the wait time required to display both a page and any associated data, certain ADF Faces components such as the `table` component, use data streaming for their initial request. When a page contains one or more of these components, the page goes through the normal lifecycle. However, instead of fetching the data during that request, a special separate request is run. Because the page has just rendered, only the Render Response phase executes for the components that use data streaming, and the corresponding data is fetched and displayed. If the user's action (for example scrolling in a table), causes a subsequent data fetch another request is executed. Tables, trees, tree tables, and data visualization components all use data streaming.

- JSF Render Response: Provides before and after phase events for the Render Response phase. You can create a listener and register it with the before or after event of this phase, and the application will behave as if the listener were registered with the Render Response phase.

### 21.2.1 What You May Need to Know About Using the Refresh Property Correctly

For scalability reasons, at runtime the iterator bindings in the binding container release any reference they have to a row set iterator at the end of each request. During the next request, each iterator binding rebinds itself to a "live" row set iterator that is tracking the current row of some data collection. The process of rebinding an ADF iterator binding during the ADF page lifecycle is known as *refreshing* the iterator. By default, this happens only once, on demand, when the iterator is first accessed by the client layer during the lifecycle. This initial access to the iterator typically occurs during page rendering, while EL expressions in the page, which reference the iterator or a control binding related to that iterator, are being evaluated. Alternatively, you can write code that programmatically causes the first access to the iterator to be before the Prepare Render phase. To force the iterator binding to refresh its row set iterator earlier in the lifecycle, you can set the `refresh` attribute on the iterator binding to a value other than the default.

**Tip:** Refreshing an iterator binding does not forcibly reexecute its query each time. The first time the view object instance's row set iterator is accessed during a particular user's session, it will implicitly execute the view object's query if it was not already executed, as long as a search binding in the page definition related to that iterator has not already cleared the row set in preparation for allowing the user to enter search criteria before executing the query.

Subsequent refreshing of the iterator binding related to that view object instance on page requests that are part of the same logical unit of work will only access the row set iterator again, not forcibly reexecute the query. When you want reexecuting the query to refresh its data, use the `Execute` or `ExecuteWithParams` built-in operation, or programmatically call the `executeQuery()` method on the iterator binding.

The `refresh` and `refreshCondition` attributes are used to determine when and whether to invoke an executable, such as an iterator binding, or an `invokeAction`. The value of the `refresh` attribute determines the lifecycle phase in which to invoke the executable, while the value of the `refreshCondition` attribute provides an optional boolean condition whose outcome determines whether the refresh will occur at the indicated lifecycle phase or not. By default, when JDeveloper adds an executable to a page definition (for example, when you drop an operation as a command component), the `refresh` attribute for the executable binding is set to `deferred`,
