Abstract

This manual provides an introduction to administering various features of Oracle Linux 7 systems.

Document generated on: 2019-06-21 (revision: 7713)
# Table of Contents

Preface ......................................................................................................................... xiii  
I System Configuration .................................................................................................. 1  
  1 Yum ........................................................................................................................... 5  
    1.1 About Yum .............................................................................................................. 5  
    1.2 About ULN ........................................................................................................... 5  
    1.3 Yum Configuration ............................................................................................... 5  
      1.3.1 Configuring Use of a Proxy Server .................................................................. 6  
      1.3.2 Yum Repository Configuration ...................................................................... 7  
      1.3.3 Downloading the Oracle Linux Yum Server Repository Files ...................... 8  
      1.3.4 Using Yum Utilities to Manage Configuration .............................................. 9  
    1.4 Using Yum from the Command Line ................................................................... 9  
    1.5 Yum Groups ......................................................................................................... 11  
    1.6 Using the Yum Security Plugin ........................................................................... 11  
    1.7 Switching CentOS or Scientific Linux Systems to Use the Oracle Linux Yum Server ........................................................................................................... 13  
    1.8 Creating and Using a Local ULN Mirror .............................................................. 14  
    1.9 Creating a Local Yum Repository Using an ISO Image ...................................... 14  
    1.10 Setting up a Local Yum Server Using an ISO Image .......................................... 15  
    1.11 For More Information About Yum .................................................................... 16  
  2 Ksplice ...................................................................................................................... 17  
    2.1 Overview of Oracle Ksplice ................................................................................. 17  
      2.1.1 Supported Kernels ......................................................................................... 17  
      2.1.2 About Ksplice Updates ............................................................................... 18  
      2.1.3 Patching and Updating Your System ......................................................... 18  
    2.2 About the Ksplice Client Software ...................................................................... 18  
      2.2.1 About the Ksplice Enhanced Client ............................................................ 19  
      2.2.2 About the Ksplice Uptrack Client .............................................................. 19  
    2.3 Choosing a Ksplice Client .................................................................................. 20  
    2.4 Preparing to Use Oracle Ksplice ........................................................................ 20  
  3 Boot and Service Configuration ................................................................................. 23  
    3.1 About systemd .................................................................................................... 23  
    3.2 About the Boot Process ..................................................................................... 24  
    3.3 About the GRUB 2 Boot Loader ........................................................................ 25  
    3.4 Kernel Boot Parameters ..................................................................................... 26  
    3.5 Modifying Kernel Boot Parameters Before Booting ......................................... 27  
    3.6 Modifying Kernel Boot Parameters in GRUB 2 ............................................... 28  
    3.7 About System-State Targets ............................................................................. 28  
      3.7.1 Displaying the Default and Active System-State Targets ............................ 29  
      3.7.2 Changing the Default and Active System-State Targets ......................... 30  
      3.7.3 Shutting Down, Suspending, or Rebooting the System ............................... 31  
      3.7.4 Starting and Stopping Services .................................................................. 32  
      3.7.5 Enabling and Disabling Services ............................................................... 32  
      3.7.6 Displaying the Status of Services ............................................................... 33  
      3.7.7 Controlling Access to System Resources ............................................... 34  
      3.7.8 Modifying systemctl Configuration Files .............................................. 35  
      3.7.9 Running systemctl on a Remote System ................................................ 35  
  4 System Configuration Settings ............................................................................... 37  
    4.1 About /etc/sysconfig Files ............................................................................... 37  
    4.2 About the /proc Virtual File System ................................................................ 38  
      4.2.1 Virtual Files and Directories Under /proc .............................................. 39  
      4.2.2 Changing Kernel Parameters ................................................................... 42  
      4.2.3 Parameters that Control System Performance ........................................ 44
4.2.4 Parameters that Control Kernel Panics .................................................. 45
4.3 About the /sys Virtual File System .......................................................... 46
  4.3.1 Virtual Directories Under /sys ............................................................. 47
4.4 System Date and Time Settings .................................................................. 47
5 Kernel Modules ............................................................................................... 49
  5.1 About Kernel Modules ............................................................................... 49
  5.2 Listing Information about Loaded Modules .............................................. 49
  5.3 Loading and Unloading Modules ............................................................... 50
  5.4 About Module Parameters ....................................................................... 51
  5.5 Specifying Modules to be Loaded at Boot Time ....................................... 52
  5.6 Weak Update Modules ............................................................................. 52
6 Device Management ....................................................................................... 55
  6.1 About Device Files ................................................................................... 55
  6.2 About the Udev Device Manager ............................................................. 57
  6.3 About Udev Rules ................................................................................... 57
  6.4 Querying Udev and Sysfs ......................................................................... 60
  6.5 Modifying Udev Rules ............................................................................ 63
7 Task Management ........................................................................................... 65
  7.1 About Automating Tasks ........................................................................ 65
  7.2 Configuring cron Jobs ............................................................................. 65
    7.2.1 Controlling Access to Running cron Jobs ........................................ 66
  7.3 Configuring anacron Jobs ....................................................................... 67
  7.4 Running One-time Tasks ......................................................................... 68
    7.4.1 Changing the Behavior of Batch Jobs ............................................... 68
8 System Monitoring and Tuning ................................................................. 71
  8.1 About sosreport ...................................................................................... 71
  8.1.1 Configuring and Using sosreport ...................................................... 71
  8.2 About System Performance Tuning ........................................................ 72
    8.2.1 About Performance Problems ......................................................... 72
  8.2.2 Monitoring Usage of System Resources ........................................... 73
  8.2.3 Using the Graphical System Monitor ............................................... 76
  8.2.4 About OSWatcher Black Box ........................................................... 76
9 System Dump Analysis .................................................................................. 79
  9.1 About Kdump ........................................................................................... 79
  9.1.1 Configuring and Using Kdump ............................................................ 79
  9.1.2 Files Used by Kdump ......................................................................... 81
  9.1.3 Using Kdump with OCFS2 ............................................................... 81
  9.2 Using the crash Debugger ....................................................................... 81
    9.2.1 Installing the crash Packages ........................................................... 82
    9.2.2 Running crash ............................................................................... 82
    9.2.3 Kernel Data Structure Analysis Commands .................................... 84
  9.2.4 System State Commands .................................................................. 85
  9.2.5 Helper Commands ............................................................................ 89
  9.2.6 Session Control Commands ............................................................... 89
  9.2.7 Guidelines for Examining a Dump File ............................................. 90
II Networking and Network Services .......................................................... 91
10 Network Configuration ................................................................................. 95
  10.1 About Network Interfaces ..................................................................... 95
  10.2 About Network Interface Names .......................................................... 97
  10.3 About Network Configuration Files ...................................................... 98
    10.3.1 /etc/hosts ....................................................................................... 98
    10.3.2 /etc/nsswitch.conf ................................................................. 98
    10.3.3 /etc/resolv.conf .......................................................................... 98
    10.3.4 /etc/sysconfig/network .............................................................. 99

# Oracle® Linux

16 High Availability Configuration ................................................................. 145
  16.1 About Oracle Linux high availability services ................................ 145
  16.2 Installing Pacemaker and Corosync .................................................. 145
  16.3 Configuring Your First Cluster and Service .................................... 146
  16.4 Fencing Configuration ................................................................. 149
  16.5 More Information ............................................................................ 152
17 Load Balancing Configuration ................................................................. 153
  17.1 About HAProxy ............................................................................... 153
  17.2 Installing and Configuring HAProxy ................................................ 153
    17.2.1 About the HAProxy Configuration File ................................... 154
  17.3 Configuring Simple Load Balancing Using HAProxy ......................... 154
    17.3.1 Configuring HAProxy for Session Persistence ......................... 156
  17.4 About Keepalived ........................................................................... 157
  17.5 Installing and Configuring Keepalived ............................................ 158
    17.5.1 About the Keepalived Configuration File ................................. 158
  17.6 Configuring Simple Virtual IP Address Fallback Using Keepalived ...... 159
  17.7 Configuring Load Balancing Using Keepalived in NAT Mode ............ 161
    17.7.1 Configuring Firewall Rules for Keepalived NAT-Mode Load Balancing .... 165
    17.7.2 Configuring Back-End Server Routing for Keepalived NAT-Mode Load Balancing .... 166
  17.8 Configuring Load Balancing Using Keepalived in DR Mode ............... 166
    17.8.1 Configuring Firewall Rules for Keepalived DR-Mode Load Balancing ... 169
  17.9 Configuring Keepalived for Session Persistence and Firewall Marks .... 170
  17.10 Making HAProxy Highly Available Using Keepalived ...................... 170
  17.11 About Keepalived Notification and Tracking Scripts ...................... 173
  17.12 Making HAProxy Highly Available Using Oracle Clusterware .......... 175
18 VNC Service Configuration .................................................................... 179
  18.1 About VNC ..................................................................................... 179
  18.2 Configuring a VNC Server ................................................................ 179
  18.3 Connecting to VNC Desktop .............................................................. 181
III Storage and File Systems ................................................................. 183
19 Storage Management ........................................................................... 189
  19.1 About Disk Partitions ..................................................................... 189
    19.1.1 Managing Partition Tables Using fdisk ..................................... 190
    19.1.2 Managing Partition Tables Using parted ................................. 192
    19.1.3 Mapping Partition Tables to Devices ...................................... 194
  19.2 About Swap Space .......................................................................... 194
    19.2.1 Viewing Swap Space Usage .................................................. 195
    19.2.2 Creating and Using a Swap File ............................................. 195
    19.2.3 Creating and Using a Swap Partition ..................................... 195
    19.2.4 Removing a Swap File or Swap Partition ............................... 196
  19.3 About Logical Volume Manager ....................................................... 196
    19.3.1 Initializing and Managing Physical Volumes ............................ 196
    19.3.2 Creating and Managing Volume Groups ................................ 197
    19.3.3 Creating and Managing Logical Volumes ............................... 198
    19.3.4 Creating Logical Volume Snapshots ...................................... 198
    19.3.5 Creating and Managing Thinly-Provisioned Logical Volumes .......... 199
    19.3.6 Using snapper with Thinly-Provisioned Logical Volumes .......... 200
  19.4 About Software RAID ................................................................. 201
    19.4.1 Creating Software RAID Devices ........................................ 202
  19.5 Creating Encrypted Block Devices .................................................. 203
  19.6 SSD Configuration Recommendations for Btrfs, ext4, and Swap .......... 204
  19.7 About Linux-IO Storage Configuration ........................................... 205
21 Local File System Administration ......................................................... 231
21.1 About Local File Systems .................................................................... 231
21.2 About the Btrfs File System ................................................................. 233
21.3 Creating a Btrfs File System ................................................................. 233
21.4 Modifying a Btrfs File System ............................................................... 235
21.5 Compressing and Defragmenting a Btrfs File System ......................... 235
21.6 Resizing a Btrfs File System ............................................................... 236
21.7 Creating Subvolumes and Snapshots .................................................... 236
21.7.1 Using snapper with Btrfs Subvolumes ............................................ 238
21.7.2 Cloning Virtual Machine Images and Linux Containers ................. 239
21.8 Using the Send/Receive Feature .......................................................... 239
21.8.1 Using Send/Receive to Implement Incremental Backups .................. 240
21.9 Using Quota Groups ........................................................................... 240
21.10 Replacing Devices on a Live File System ............................................ 241
21.11 Creating Snapshots of Files ............................................................... 241
21.12 Converting an Ext2, Ext3, or Ext4 File System to a Btrfs File System .... 241
  21.12.1 Converting a Non-root File System ......................................... 241
21.13 About the Btrfs root File System ....................................................... 242
  21.13.1 Creating Snapshots of the root File System .................................. 243
  21.13.2 Mounting Alternate Snapshots as the root File System ............... 244
  21.13.3 Deleting Snapshots of the root File System .................................. 244
21.14 Converting a Non-root Ext2 File System to Ext3 ................................. 244
21.15 Converting a root Ext2 File System to Ext3 ....................................... 245
21.16 Creating a Local OCFS2 File System .................................................. 246
21.17 About the XFS File System ............................................................... 246
  21.17.1 About External XFS Journals ..................................................... 248
  21.17.2 About XFS Write Barriers .......................................................... 248
29.1.5 Upgrading Virtualization Packages .................................................. 412
29.1.6 Checking the libvirt Daemon Status ............................................. 412
29.2 Oracle VirtIO Drivers for Microsoft Windows ..................................... 412
  29.2.1 Supported Releases, Operating Systems, and Configuration Limits .......... 413
  29.2.2 Installing the Oracle VirtIO Drivers for Microsoft Windows .................. 414
  29.2.3 Upgrading the Oracle VirtIO Drivers for Microsoft Windows ................. 421
  29.2.4 Silently Installing or Upgrading the Oracle VirtIO Drivers for Microsoft Windows ........................................................... 422
  29.2.5 Uninstalling the Oracle VirtIO Drivers for Microsoft Windows ............... 423
  29.2.6 Known Limitations and Workarounds .......................................... 424
Preface

The Oracle Linux Administrator's Guide provides introductory information about administering various features of Oracle Linux 7 systems, including system configuration, networking, network services, storage devices, file systems, authentication, and security.

Audience

This document is intended for administrators who need to configure and administer Oracle Linux. It is assumed that readers are familiar with web technologies and have a general understanding of using the Linux operating system, including knowledge of how to use a text editor such as emacs or vim, essential commands such as cd, chmod, chown, ls, mkdir, mv, ps, pwd, and rm, and using the man command to view manual pages.

Document Organization

The document is organized as follows:

- **Part I, “System Configuration”** describes how to configure software and kernel updates, booting, kernel and module settings, and devices, how to schedule tasks, and how to monitor and tune your system.

- **Part II, “Networking and Network Services”** describes how to configure network interfaces, network addresses, name service, network time services, basic web and email services, load balancing, and high availability.

- **Part III, “Storage and File Systems”** describes how to configure storage devices and how to create and manage local, shared, and cluster file systems.

- **Part IV, “Authentication and Security”** describes how to configure user account databases and authentication, how to add group and user accounts, how to administer essential aspects of system security, and how to configure and use the OpenSSH tools.

- **Part V, “Virtualization”** describes how to configure containers to isolate applications from the other processes that are running on a host system.

Related Documents

The documentation for this product is available at:

Conventions

The following text conventions are used in this document:

<table>
<thead>
<tr>
<th>Convention</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>boldface</strong></td>
<td>Boldface type indicates graphical user interface elements associated with an action, or terms defined in text or the glossary.</td>
</tr>
<tr>
<td><em>italic</em></td>
<td>Italic type indicates book titles, emphasis, or placeholder variables for which you supply particular values.</td>
</tr>
<tr>
<td><strong>monospace</strong></td>
<td>Monospace type indicates commands within a paragraph, URLs, code in examples, text that appears on the screen, or text that you enter.</td>
</tr>
</tbody>
</table>
Documentation Accessibility

For information about Oracle's commitment to accessibility, visit the Oracle Accessibility Program website at http://www.oracle.com/pls/topic/lookup?ctx=acc&id=docacc.

Access to Oracle Support

Oracle customers that have purchased support have access to electronic support through My Oracle Support. For information, visit http://www.oracle.com/pls/topic/lookup?ctx=acc&id=info or visit http://www.oracle.com/pls/topic/lookup?ctx=acc&id=trs if you are hearing impaired.
Part I System Configuration

This section contains the following chapters:

- **Chapter 1, Yum** describes how you can use the `yum` utility to install and upgrade software packages.
- **Chapter 2, Ksplice** describes how to configure Ksplice Uptrack to update the kernel on a running system.
- **Chapter 3, Boot and Service Configuration** describes the Oracle Linux boot process, how to use the GRUB boot loader, how to change the run level of a system, and how to configure the services that are available at each run level.
- **Chapter 4, System Configuration Settings** describes the files and virtual file systems that you can use to change configuration settings for your system.
- **Chapter 5, Kernel Modules** describes how to load, unload, and modify the behavior of kernel modules.
- **Chapter 6, Device Management** describes how the system uses device files and how the udev device manager dynamically creates or removes device node files.
- **Chapter 7, Task Management** describes how to configure the system to run tasks automatically within a specific period of time, at a specified time and date, or when the system is lightly loaded.
- **Chapter 8, System Monitoring and Tuning** describes how to collect diagnostic information about a system for Oracle Support, and how to monitor and tune the performance of a system.
- **Chapter 9, System Dump Analysis** describes how to configure a system to create a memory image in the event of a system crash, and how to use the `crash` debugger to analyse the memory image in a crash dump or for a live system.
# Table of Contents

1 Yum .......................................................................................................................... 5
  1.1 About Yum ............................................................................................................. 5
  1.2 About ULN ............................................................................................................ 5
  1.3 Yum Configuration ............................................................................................... 5
    1.3.1 Configuring Use of a Proxy Server ................................................................. 6
    1.3.2 Yum Repository Configuration ...................................................................... 7
    1.3.3 Downloading the Oracle Linux Yum Server Repository Files ..................... 8
    1.3.4 Using Yum Utilities to Manage Configuration ............................................. 9
  1.4 Using Yum from the Command Line .................................................................... 9
  1.5 Yum Groups ......................................................................................................... 11
  1.6 Using the Yum Security Plugin ............................................................................ 11
  1.7 Switching CentOS or Scientific Linux Systems to Use the Oracle Linux Yum Server ..................................................................................................................... 13
  1.8 Creating and Using a Local ULN Mirror ............................................................. 14
  1.9 Creating a Local Yum Repository Using an ISO Image ...................................... 14
  1.10 Setting up a Local Yum Server Using an ISO Image .......................................... 15
  1.11 For More Information About Yum ..................................................................... 16

2 Ksplice ......................................................................................................................... 17
  2.1 Overview of Oracle Ksplice .................................................................................. 17
    2.1.1 Supported Kernels ......................................................................................... 17
    2.1.2 About Ksplice Updates .................................................................................. 18
    2.1.3 Patching and Updating Your System ............................................................ 18
  2.2 About the Ksplice Client Software ....................................................................... 18
    2.2.1 About the Ksplice Enhanced Client ............................................................... 19
    2.2.2 About the Ksplice Uptrack Client ................................................................ 19
  2.3 Choosing a Ksplice Client ..................................................................................... 20
  2.4 Preparing to Use Oracle Ksplice .......................................................................... 20

3 Boot and Service Configuration ................................................................................. 23
  3.1 About systemd ...................................................................................................... 23
  3.2 About the Boot Process ....................................................................................... 24
  3.3 About the GRUB 2 Boot Loader .......................................................................... 25
  3.4 Kernel Boot Parameters ....................................................................................... 26
  3.5 Modifying Kernel Boot Parameters Before Booting .......................................... 27
  3.6 Modifying Kernel Boot Parameters in GRUB 2 .................................................. 28
  3.7 About System-State Targets ............................................................................... 28
    3.7.1 Displaying the Default and Active System-State Targets ......................... 29
    3.7.2 Changing the Default and Active System-State Targets ......................... 30
    3.7.3 Shutting Down, Suspending, or Rebooting the System .............................. 31
    3.7.4 Starting and Stopping Services ................................................................... 32
    3.7.5 Enabling and Disabling Services ................................................................. 32
    3.7.6 Displaying the Status of Services ............................................................... 33
    3.7.7 Controlling Access to System Resources .................................................. 34

This chapter describes how you can use the yum utility to install and upgrade software packages.

1.1 About Yum

Oracle Linux provides the yum utility which you can use to install or upgrade RPM packages. The main benefit of using yum is that it also installs or upgrades any package dependencies. yum downloads the packages from repositories such as those that are available on the Oracle Linux yum server, but you can also set up your own repositories on systems that do not have Internet access.

The Oracle Linux yum server is a convenient way to install Oracle Linux and Oracle VM packages, including bug fixes, security fixes and enhancements, rather than installing them from installation media. You can access the server at https://yum.oracle.com/.

You can also subscribe to the Oracle Linux and Oracle VM errata mailing lists to be notified when new packages are released. You can access the mailing lists at https://oss.oracle.com/mailman/listinfo/el-errata and https://oss.oracle.com/mailman/listinfo/oraclevm-errata.

1.2 About ULN

The repositories available on the Oracle Linux yum server are aligned with the channels that are available on the Unbreakable Linux Network (ULN), with the exception of ULN channels that are limited to Oracle Linux Premier Support customers. These include channels for products such as Ksplice and DTrace.

ULN is tightly integrated with yum. If you have registered your system with ULN, you can use yum commands with ULN channels to maintain the software on your system, as described in Oracle Linux Unbreakable Linux Network User's Guide.

1.3 Yum Configuration

The main configuration file for yum is /etc/yum.conf. The global definitions for yum are located under the [main] section heading of the yum configuration file. The following table lists the important directives.
### Directive Description

<table>
<thead>
<tr>
<th>Directive</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cachedir</td>
<td>Directory used to store downloaded packages.</td>
</tr>
<tr>
<td>debuglevel</td>
<td>Logging level, from 0 (none) to 10 (all).</td>
</tr>
<tr>
<td>exactarch</td>
<td>If set to 1, only update packages for the correct architecture.</td>
</tr>
<tr>
<td>exclude</td>
<td>A space separated list of packages to exclude from installs or updates, for example: exclude=VirtualBox-4.* kernel*.</td>
</tr>
<tr>
<td>gpgcheck</td>
<td>If set to 1, verify the authenticity of the packages by checking the GPG signatures. You might need to set gpgcheck to 0 if a package is unsigned, but you should be wary that the package could have been maliciously altered.</td>
</tr>
<tr>
<td>gpgkey</td>
<td>Pathname of the GPG public key file.</td>
</tr>
<tr>
<td>installonly_limit</td>
<td>Maximum number of versions that can be installed of any one package.</td>
</tr>
<tr>
<td>keepcache</td>
<td>If set to 0, remove packages after installation.</td>
</tr>
<tr>
<td>logfile</td>
<td>Pathname of the yum log file.</td>
</tr>
<tr>
<td>obsoletes</td>
<td>If set to 1, replace obsolete packages during upgrades.</td>
</tr>
<tr>
<td>plugins</td>
<td>If set to 1, enable plugins that extend the functionality of yum.</td>
</tr>
<tr>
<td>proxy</td>
<td>URL of a proxy server including the port number. See Section 1.3.1, “Configuring Use of a Proxy Server”.</td>
</tr>
<tr>
<td>proxy_password</td>
<td>Password for authentication with a proxy server.</td>
</tr>
<tr>
<td>proxy_username</td>
<td>User name for authentication with a proxy server.</td>
</tr>
<tr>
<td>reposdir</td>
<td>Directories where yum should look for repository files with a .repo extension. The default directory is /etc/yum.repos.d.</td>
</tr>
</tbody>
</table>

See the **yum.conf(5)** manual page for more information.

The following listing shows an example **[main]** section from the yum configuration file.

```ini
[main]
cachedir=/var/cache/yum
keepcache=0
debuglevel=2
logfile=/var/log/yum.log
exactarch=1
obsoletes=1
gpgkey=file://media/RPM-GPG-KEY
gpgcheck=1
plugins=1
installonly_limit=3
```

It is possible to define repositories below the **[main]** section in **/etc/yum.conf** or in separate repository configuration files. By default, yum expects any repository configuration files to be located in the **/etc/yum.repos.d** directory unless you use the **reposdir** directive to define alternate directories.

### 1.3.1 Configuring Use of a Proxy Server

If your organization uses a proxy server as an intermediary for Internet access, specify the **proxy** setting in **/etc/yum.conf** as shown in the following example.

```ini
proxy=http://proxysvr.example.com:3128
```

If the proxy server requires authentication, additionally specify the **proxy_username** and **proxy_password** settings.
Yum Repository Configuration

proxy=http://proxysvr.example.com:3128
proxy_username=yumacc
proxy_password=clydenw

If you use the yum plugin (yum-rhn-plugin) to access the ULN, specify the enableProxy and httpProxy settings in /etc/sysconfig/rhn/up2date as shown in this example.

enableProxy=1
httpProxy=http://proxysvr.example.com:3128

If the proxy server requires authentication, additionally specify the enableProxyAuth, proxyUser, and proxyPassword settings.

enableProxy=1
httpProxy=http://proxysvr.example.com:3128
enableProxyAuth=1
proxyUser=yumacc
proxyPassword=clydenw

Caution

All yum users require read access to /etc/yum.conf or /etc/sysconfig/rhn/up2date. If these files must be world-readable, do not use a proxy password that is the same as any user’s login password, and especially not root’s password.

1.3.2 Yum Repository Configuration

The yum configuration file or yum repository configuration files can contain one or more sections that define repositories.

The following table lists the basic directives for a repository.

<table>
<thead>
<tr>
<th>Directive</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>baseurl</td>
<td>Location of the repository channel (expressed as a file://, ftp://, http://, or https:// address). This directive must be specified.</td>
</tr>
<tr>
<td>enabled</td>
<td>If set to 1, permit yum to use the channel.</td>
</tr>
<tr>
<td>name</td>
<td>Descriptive name for the repository channel. This directive must be specified.</td>
</tr>
</tbody>
</table>

Any other directive that appears in this section overrides the corresponding global definition in [main] section of the yum configuration file. See the yum.conf(5) manual page for more information.

The following listing shows an example repository section from a configuration file.

```
[ol6_u2_base]
name=Oracle Linux 6 U2 - $basearch - base
baseurl=https://yum.oracle.com/repo/OracleLinux/OL6/2/base/$basearch
gpgkey=file:///etc/pki/rpm-gpg/RPM-GPG-KEY
gpgcheck=1
enabled=1
```

In this example, the values of gpgkey and gpgcheck override any global setting. yum substitutes the name of the current system’s architecture for the variable $basearch.

yum automatically searches the /etc/yum.repos.d directory for files with the suffix .repo and appends these to the configuration when it is processing. Use this directory to define repository files for repositories that you want to make available.
1.3.3 Downloading the Oracle Linux Yum Server Repository Files

The Oracle Linux yum server provides a direct mapping of all of the Unbreakable Linux Network (ULN) channels that are available to the public without any specific support agreement. The repository labels used for each repository on the Oracle Linux yum server map directly onto the channel names on ULN. See the Oracle Linux Unbreakable Linux Network User’s Guide for more information about the channel names and common suffixes used for channels and repositories.

Prior to January 2019, Oracle shipped a single yum repository configuration file for each Oracle Linux release. This configuration file is copied into /etc/yum.repos.d/public-yum-ol7.repo at installation, but can also be downloaded from the Oracle Linux yum server directly to obtain updates.

The original configuration file is deprecated in favor of modular repository files that are managed and updated automatically via yum in the form of RPM packages that are more targeted in scope. For example, core repository configuration files required for Oracle Linux 7 are available in the oraclelinux-release-el7 package. This package includes all of the repository configuration required to install base packages for the release, including packages from the ol7_latest, ol7_addons repositories and all of the supported repositories for UEK.

The modular yum repository configuration files released as packages that can be maintained via yum can help to simplify repository management and also ensure that your yum repository definitions are kept up to date automatically, whenever you update your system.

A list of all available RPM files to manage all of the possible yum repository configurations for your release can be obtained by running:

```bash
# yum list *release-el7*
```

To install the yum repository configuration for a particular set of software that you wish to use, use yum to install the corresponding package. For example, to install the yum repository configuration for the Oracle Linux Software Collection Library, run:

```bash
# yum install oracle-softwarecollection-release-el7
```

If your system is still configured to use the original single yum repository configuration file at /etc/yum.repos.d/public-yum-ol7.repo, you should update your system to transition to the current approach to handling yum repository configuration. To do this, ensure that your system is up to date and then run the /usr/bin/ol_yum_configure.sh script:

```bash
# yum update
# /usr/bin/ol_yum_configure.sh
```

The /usr/bin/ol_yum_configure.sh script checks the /etc/yum.repos.d/public-yum-ol7.repo file to determine which repositories are already enabled and installs the appropriate corresponding packages before renaming the original configuration file to /etc/yum.repos.d/public-yum-ol7.repo.sav to disable it in favor of the more recent modular repository configuration files.

If, for some reason, you manage to remove all configuration to access the Oracle Linux yum server repositories, you should create a temporary yum repository configuration file at /etc/yum.repos.d/ol7-temp.repo with the following as the minimum required content:

```bash
[ol7_latest]
name=Oracle Linux $releasever Latest ($basearch)
baseurl=https://yum.oracle.com/repo/OracleLinux/OL7/latest/$basearch/
gpgkey=file:///etc/pki/rpm-gpg/RPM-GPG-KEY-oracle
gpgcheck=1
enabled=1
```
Then reinstall the `oraclelinux-release-el7` package to restore the default yum configuration:

```
# yum reinstall oraclelinux-release-el7
# rm /etc/yum.repos.d/ol7-temp.repo
```

For more information on manually setting up Oracle Linux yum server repository configuration files, see [https://yum.oracle.com/getting-started.html](https://yum.oracle.com/getting-started.html).

You can enable or disable repositories in each repository configuration file by setting the value of the `enabled` directive to 1 or 0 for each repository listed in the file, as required. The preferred method of enabling or disabling repositories under Oracle Linux 7 is to use the `yum-config-manager` command as described in Section 1.3.4, “Using Yum Utilities to Manage Configuration”.

### 1.3.4 Using Yum Utilities to Manage Configuration

The `yum-utils` package includes several utilities that can help you to manage configuration and apply updates safely to your existing configuration. Most significant of these is `yum-config-manager`.

To install the `yum-utils` package:

```
# yum install -y yum-utils
```

You can use `yum-config-manager` to add repositories either at a specified URL, or within a specified repository file. For example, to add the legacy repository configuration file for Oracle Linux 7 from the Oracle Linux yum server:

```
```

*Note*

The legacy repository configuration file is unmaintained and deprecated. The information in this file may not be current and newer repositories may not be listed.

You can use the same command to automatically generate a repository configuration file for a valid yum repository, by pointing to the URL where the repository is hosted. For example, to create a new configuration file in `/etc/repos.d` for the Unbreakable Enterprise Kernel Release 5 repository. run:

```
# yum-config-manager --add-repo https://yum.oracle.com/repo/OracleLinux/OL7/UEKR5/x86_64
```

To enable a repository using `yum-config-manager`, use the `--enable` option. For example, to enable the `ol7_addons` repository, run:

```
# yum-config-manager --enable ol7_addons
```

You can use the `--disable` option in a similar way to disable a repository.

The `yum-config-manager` tool can also be used to set other configuration options using the `--setopt` and `--save` options. See the `yum-config-manager(1)` manual page for more information.

For a list of the tools included in the yum-utils package and a description of what these tools can do, see the `yum-utils(1)` manual page for more information.

### 1.4 Using Yum from the Command Line

The following table shows some examples of common tasks that you can perform using `yum`.

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>yum repolist</td>
<td>Lists all enabled repositories.</td>
</tr>
</tbody>
</table>
## Using Yum from the Command Line

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>yum list</strong></td>
<td>Lists all packages that are available in all enabled repositories and all packages that are installed on your system.</td>
</tr>
<tr>
<td><strong>yum list installed</strong></td>
<td>Lists all packages that are installed on your system.</td>
</tr>
<tr>
<td><strong>yum list available</strong></td>
<td>Lists all packages that are available to be installed in all enabled repositories.</td>
</tr>
<tr>
<td><strong>yum search string</strong></td>
<td>Searches the package descriptions for the specified string.</td>
</tr>
<tr>
<td><strong>yum provides feature</strong></td>
<td>Finds the name of the package to which the specified file or feature belongs. For example: yum provides /etc/sysconfig/atd</td>
</tr>
<tr>
<td><strong>yum info package</strong></td>
<td>Displays detailed information about a package. For example:</td>
</tr>
<tr>
<td></td>
<td>yum info bind</td>
</tr>
<tr>
<td><strong>yum install package</strong></td>
<td>Installs the specified package, including packages on which it depends. For example: yum install ocfs2-tools</td>
</tr>
<tr>
<td><strong>yum check-update</strong></td>
<td>Checks whether updates exist for packages that are already installed on your system.</td>
</tr>
<tr>
<td><strong>yum update package</strong></td>
<td>Updates the specified package, including packages on which it depends. For example: yum upgrade nfs-utils</td>
</tr>
<tr>
<td><strong>yum update</strong></td>
<td>Updates all packages, including packages on which they depend.</td>
</tr>
<tr>
<td><strong>yum remove package</strong></td>
<td>Removes the specified package. For example:</td>
</tr>
<tr>
<td></td>
<td>yum erase nfs-utils</td>
</tr>
<tr>
<td><strong>yum erase package</strong></td>
<td>Removes the specified package. This command has the same effect as the yum remove command.</td>
</tr>
<tr>
<td><strong>yum update</strong></td>
<td>Updates all packages, including packages on which they depend.</td>
</tr>
<tr>
<td><strong>yum clean all</strong></td>
<td>Removes all cached package downloads and cached headers that contain information about remote packages. Running this command can help to clear problems that can result from unfinished transactions or out-of-date headers.</td>
</tr>
<tr>
<td><strong>yum help</strong></td>
<td>Displays help about yum usage.</td>
</tr>
<tr>
<td><strong>yum help command</strong></td>
<td>Displays help about the specified yum command. For example:</td>
</tr>
<tr>
<td></td>
<td>yum help upgrade</td>
</tr>
<tr>
<td><strong>yum shell</strong></td>
<td>Runs the yum interactive shell.</td>
</tr>
</tbody>
</table>

See the yum(8) manual page for more information.

To list the files in a package, use the repoquery utility, which is included in the yum-utils package. For example, the following command lists the files that the btrfs-progs package provides.

```
# repoquery -l btrfs-progs
/sbin/btrfs
/sbin/btrfs-convert
/sbin/btrfs-debug-tree
```
Note

*Yum* makes no distinction between installing and upgrading a kernel package. *Yum* always installs a new kernel regardless of whether you specify *update* or *install*.

### 1.5 Yum Groups

A set of packages can themselves be organized as a *yum group*. Examples include the groups for Eclipse, fonts, and system administration tools. The following table shows the *yum* commands that you can use to manage these groups.

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>yum grouplist</code></td>
<td>Lists installed groups and groups that are available for installation.</td>
</tr>
<tr>
<td><code>yum groupinfo groupname</code></td>
<td>Displays detailed information about a group.</td>
</tr>
<tr>
<td><code>yum groupinstall groupname</code></td>
<td>Installs all the packages in a group.</td>
</tr>
<tr>
<td><code>yum groupupdate groupname</code></td>
<td>Updates all the packages in a group.</td>
</tr>
<tr>
<td><code>yum groupremove groupname</code></td>
<td>Removes all the packages in a group.</td>
</tr>
</tbody>
</table>

### 1.6 Using the Yum Security Plugin

The security plugin is integrated with *yum* in Oracle Linux 7 and allows you to obtain a list of all of the errata that are available for your system, including security updates. You can also use Oracle Enterprise Manager 12c Cloud Control or management tools such as Katello, Pulp, Red Hat Satellite, Spacewalk, and SUSE Manager to extract and display information about errata.

To list the errata that are available for your system, enter:

```bash
# yum updateinfo list
```

<table>
<thead>
<tr>
<th>.Erratum ID</th>
<th>Package Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>ELBA-2018-2000 bugfix</td>
<td>NetworkManager-1:1.10.2-16.el7_5.x86_64</td>
</tr>
<tr>
<td>ELBA-2018-2000 bugfix</td>
<td>NetworkManager-adsi-1:1.10.2-16.el7_5.x86_64</td>
</tr>
<tr>
<td>ELBA-2018-2000 bugfix</td>
<td>NetworkManager-config-server-1:1.10.2-16.el7_5.noarch</td>
</tr>
<tr>
<td>ELBA-2018-2000 bugfix</td>
<td>NetworkManager-glib-1:1.10.2-16.el7_5.x86_64</td>
</tr>
<tr>
<td>ELBA-2018-2000 bugfix</td>
<td>NetworkManager-libnm-1:1.10.2-16.el7_5.x86_64</td>
</tr>
<tr>
<td>ELBA-2018-2000 bugfix</td>
<td>NetworkManager-ppp-1:1.10.2-16.el7_5.x86_64</td>
</tr>
<tr>
<td>ELBA-2018-2000 bugfix</td>
<td>NetworkManager-team-1:1.10.2-16.el7_5.x86_64</td>
</tr>
<tr>
<td>ELBA-2018-2000 bugfix</td>
<td>NetworkManager-tui-1:1.10.2-16.el7_5.x86_64</td>
</tr>
<tr>
<td>ELBA-2018-2000 bugfix</td>
<td>NetworkManager-wifi-1:1.10.2-16.el7_5.x86_64</td>
</tr>
<tr>
<td>ELBA-2018-1994 bugfix</td>
<td>binutils-2.27-28.base.el7_5.1.x86_64</td>
</tr>
<tr>
<td>ELBA-2018-1980 bugfix</td>
<td>control-center-filesystem-1:1.3.26.2-9.el7_5.x86_64</td>
</tr>
<tr>
<td>ELBA-2018-4142 bugfix</td>
<td>dracut-033-535.0.2.el7.x86_64</td>
</tr>
<tr>
<td>ELBA-2018-4142 bugfix</td>
<td>dracut-config-rescue-033-535.0.2.el7.x86_64</td>
</tr>
<tr>
<td>ELBA-2018-4142 bugfix</td>
<td>dracut-network-033-535.0.2.el7.x86_64</td>
</tr>
<tr>
<td>ELEA-2018-0838 enhancement</td>
<td>filesystem-3.2-25.el7.x86_64</td>
</tr>
<tr>
<td>ELSA-2018-2113 Critical/Sec.</td>
<td>firefox-60.1.0-4.0.1.el7_5.x86_64</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
</tr>
</tbody>
</table>

The output from the command sorts the available errata in order of their IDs, and it also specifies whether each erratum is a security patch (*severity/Sec.*), a bug fix (*bugfix*), or a feature enhancement (*enhancement*). Security patches are listed by their severity: *Important, Moderate, or Low.*
You can use the `--sec-severity` option to filter the security errata by severity, for example:

```
# yum updateinfo list --sec-severity= Moderate
ELSA-2018-1852 Moderate/Sec. kernel-3.10.0-862.3.3.el7.x86_64
ELSA-2018-1852 Moderate/Sec. kernel-devel-3.10.0-862.3.3.el7.x86_64
ELSA-2018-1852 Moderate/Sec. kernel-headers-3.10.0-862.3.3.el7.x86_64
ELSA-2018-1852 Moderate/Sec. kernel-tools-3.10.0-862.3.3.el7.x86_64
ELSA-2018-1852 Moderate/Sec. kernel-tools-libs-3.10.0-862.3.3.el7.x86_64
ELSA-2018-2123 Moderate/Sec. python-2.7.5-69.0.1.el7_5.x86_64
ELSA-2018-1852 Moderate/Sec. python-perf-3.10.0-862.3.3.el7.x86_64
... 
```

To list the security errata by their Common Vulnerabilities and Exposures (CVE) IDs instead of their errata IDs, specify the keyword `cves` as an argument:

```
# yum updateinfo list cves
CVE-2017-7762 Critical/Sec. firefox-60.1.0-4.0.1.el7_5.x86_64
CVE-2018-12359 Critical/Sec. firefox-60.1.0-4.0.1.el7_5.x86_64
CVE-2018-12363 Critical/Sec. firefox-60.1.0-4.0.1.el7_5.x86_64
CVE-2018-12366 Critical/Sec. firefox-60.1.0-4.0.1.el7_5.x86_64
CVE-2018-5156 Critical/Sec. firefox-60.1.0-4.0.1.el7_5.x86_64
CVE-2018-5188 Critical/Sec. firefox-60.1.0-4.0.1.el7_5.x86_64
CVE-2018-6126 Critical/Sec. firefox-60.1.0-4.0.1.el7_5.x86_64
CVE-2018-12360 Critical/Sec. firefox-60.1.0-4.0.1.el7_5.x86_64
CVE-2018-12362 Critical/Sec. firefox-60.1.0-4.0.1.el7_5.x86_64
CVE-2018-12365 Critical/Sec. firefox-60.1.0-4.0.1.el7_5.x86_64
CVE-2018-12020 Important/Sec. gnupg2-2.0.22-5.el7_5.x86_64
CVE-2018-3665 Moderate/Sec. kernel-3.10.0-862.3.3.el7.x86_64
CVE-2018-3639 Important/Sec. kernel-3.10.0-862.6.3.el7.x86_64
CVE-2017-11600 Important/Sec. kernel-3.10.0-862.6.3.el7.x86_64
... 
```

Similarly, the keywords `bugfix`, `enhancement`, and `security` filter the list for all bug fixes, enhancements, and security errata.

You can use the `--cve` option to display the errata that correspond to a specified CVE, for example:

```
# yum updateinfo list --cve CVE-2018-3665
ELSA-2018-1852 Moderate/Sec. kernel-3.10.0-862.3.3.el7.x86_64
ELSA-2018-1852 Moderate/Sec. kernel-devel-3.10.0-862.3.3.el7.x86_64
ELSA-2018-1852 Moderate/Sec. kernel-headers-3.10.0-862.3.3.el7.x86_64
ELSA-2018-1852 Moderate/Sec. kernel-tools-3.10.0-862.3.3.el7.x86_64
ELSA-2018-1852 Moderate/Sec. kernel-tools-libs-3.10.0-862.3.3.el7.x86_64
ELSA-2018-4144 Important/Sec. kernel-uek-firmware-4.1.12-124.16.4.el7uek.noarch
ELSA-2018-1852 Moderate/Sec. python-perf-3.10.0-862.3.3.el7.x86_64
updateinfo list done
```

To display more information, specify `info` instead of `list`, for example:

```
# yum updateinfo info --cve CVE-2018-3665
===============================================================================
kernel security update
===============================================================================
Update ID : ELSA-2018-1852
Release : Oracle Linux 7
Type : security
Status : final
Issued : 2018-06-14
CVEs : CVE-2018-3665
Description : [3.10.0-862.3.3.OE7]
  - Oracle Linux certificates (Alexey Petrenko)
  - Oracle Linux RHCK Module Signing Key was
    compiled into kernel
```
Switching CentOS or Scientific Linux Systems to Use the Oracle Linux Yum Server

1.7 Switching CentOS or Scientific Linux Systems to Use the Oracle Linux Yum Server

You can use the centos2ol.sh script to convert CentOS 5 and 6 or Scientific Linux 5 and 6 systems to Oracle Linux. The script configures yum to use the Oracle Linux yum server and installs a few additional packages that are required. There is no need to reboot the system.

To perform the switch to Oracle Linux, run the following commands as root:

```
# curl -sO https://linux.oracle.com/switch/centos2ol.sh
```
Creating and Using a Local ULN Mirror

1.8 Creating and Using a Local ULN Mirror

For information on how to create and use a yum server that acts as a local mirror of the ULN channels, see Creating and Using a Local ULN Mirror in the Oracle Linux Unbreakable Linux Network User’s Guide.

1.9 Creating a Local Yum Repository Using an ISO Image

Note

The system must have sufficient storage space to host a full Oracle Linux Media Pack DVD image (approximately 4.1 GB for Oracle Linux 7 Update 5).

To create a local yum repository (for example, if a system does not have Internet access):

1. On a system with Internet access, download a full Oracle Linux DVD image from the Oracle Software Delivery Cloud at https://edelivery.oracle.com/linux onto removable storage (such as a USB memory stick). For example, V975367-01.iso contains the Oracle Linux 7 Update 5 Media Pack for x86 (64 bit).

Note

You can verify that the ISO was copied correctly by comparing its checksum with the digest value that is listed on edelivery.oracle.com, for example:

```
# sha1sum V975367-01.iso
4B08559B6176F701563C2E49553C89491C0F8F4E V975367-01.iso
```

2. Transfer the removable storage to the system on which you want to create a local yum repository, and copy the DVD image to a directory in a local file system.

```
# cp /media/USB_stick/V975367-01.iso /ISOs
```

3. Create a suitable mount point, for example /var/OSimage/OL7.5_x86_64, and mount the DVD image on it.

```
# mkdir -p /var/OSimage/OL7.5_x86_64
# mount -o loop,ro /ISOs/V975367-01.iso /var/OSimage/OL7.5_x86_64
```

Note

Include the read-only mount option (ro) to avoid changing the contents of the ISO by mistake.

4. Create an entry in /etc/fstab so that the system always mounts the DVD image after a reboot.

```
/ISOs/V975367-01.iso /var/OSimage/OL7.5_x86_64 iso9660 loop,ro 0 0
```

5. Disable all existing yum repositories.

In the /etc/yum.repos.d directory, edit any existing repository files and disable all entries by setting enabled=0. If you have the yum-utils package installed, as described in Section 1.3.4, “Using Yum Utilities to Manage Configuration”, you can disable all repositories by running:

```
# yum-config-manager --disable \*
```
6. Create the following entries in a new repository file (for example, `/etc/yum.repos.d/OL75.repo`).

```
[OL75]
name=Oracle Linux 7.5 x86_64
baseurl=file:///var/OSimage/OL7.5_x86_64
gpgkey=file:///etc/pki/rpm-gpg/RPM-GPG-KEY
gpgcheck=1
enabled=1
```

7. Clean up the `yum` cache.

```
# yum clean all
```

8. Test that you can use `yum` to access the repository.

```
# yum repolist
Loaded plugins: refresh-packagekit, security
... repo id     repo name                                status
OL75          Oracle Linux 7.5 x86_64                  5,070
repolist: 5,070
```

### 1.10 Setting up a Local Yum Server Using an ISO Image

To set up a local yum server (for example, if you have a network of systems that do not have Internet access):

1. Choose one of the systems to be the yum server, and create a local yum repository on it as described in Section 1.9, "Creating a Local Yum Repository Using an ISO Image".

2. Install the Apache HTTP server from the local yum repository.

```
# yum install httpd
```

3. If SELinux is enabled in enforcing mode on your system:

   a. Use the `semanage` command to define the default file type of the repository root directory hierarchy as `httpd_sys_content_t`:

      ```
      /usr/sbin/semanage fcontext -a -t httpd_sys_content_t "/var/OSimage(/.*)?"
      ```

   b. Use the `restorecon` command to apply the file type to the entire repository.

      ```
      /sbin/restorecon -R -v /var/OSimage
      ```

   **Note**
The `semanage` and `restorecon` commands are provided by the `policycoreutils-python` and `policycoreutils` packages.

4. Create a symbolic link in `/var/www/html` that points to the repository:

```
# ln -s /var/OSimage /var/www/html/OSimage
```

5. Edit the HTTP server configuration file, `/etc/httpd/conf/httpd.conf`, as follows:

   a. Specify the resolvable domain name of the server in the argument to `ServerName`.

      ```
      ServerName server_addr:80
      ```

      If the server does not have a resolvable domain name, enter its IP address instead.
b. Verify that the setting of the `Options` directive in the `<Directory "/var/www/html">` section specifies `Indexes` and `FollowSymLinks` to allow you to browse the directory hierarchy, for example:

```
Options Indexes FollowSymLinks
```

c. Save your changes to the file.

6. Start the Apache HTTP server, and configure it to start after a reboot.

```
# systemctl start httpd
# systemctl enable httpd
```

7. If you have enabled a firewall on your system, configure it to allow incoming HTTP connection requests on TCP port 80, for example:

```
# firewall-cmd --zone=zone --add-port=80/tcp
# firewall-cmd --permanent --zone=zone --add-port=80/tcp
```

8. Disable all existing yum repositories on the server and each client system.

In the `/etc/yum.repos.d` directory, edit any existing repository files and disable all entries by setting `enabled=0`. If you have the `yum-utils` package installed, as described in Section 1.3.4, "Using Yum Utilities to Manage Configuration", you can disable all repositories by running:

```
# yum-config-manager --disable *
```

9. Edit the repository file on the server (for example, `/etc/yum.repos.d/OL75.repo`):

```
[OL75]
name=Oracle Linux 7.5 x86_64
baseurl=http://server_addr/OSimage/OL7.5_x86_64
gpgkey=file:///etc/pki/rpm-gpg/RPM-GPG-KEY
gpgcheck=1
enabled=1
```

Replace `server_addr` with the IP address or resolvable host name of the local yum server.

10. On each client, copy the repository file from the server to the `/etc/yum.repos.d` directory.

11. On the server and each client, test that you can use `yum` to access the repository.

```
# yum repolist
Loaded plugins: refresh-packagekit, security
... 
repo id          repo name                                 status
OL75            Oracle Linux 7.5 x86_64                    5,070
repolist: 5,070
```

1.11 For More Information About Yum

For more information about yum, see `http://yum.baseurl.org/`.

Frequently asked questions about the Oracle Linux yum server are answered at `https://yum.oracle.com/faq.html`.

For more information about how to download the latest packages from the Unbreakable Linux Network and make the packages available through a local yum server, see `https://www.oracle.com/technetwork/articles/servers-storage-admin/yum-repo-setup-1659167.html`.

2.4 Preparing to Use Oracle Ksplice ....................................................... 20

This chapter provides a high-level overview of Oracle Ksplice. For detailed information and instructions, see the Oracle Linux Ksplice User’s Guide.

2.1 Overview of Oracle Ksplice

Linux systems receive regular security updates to core operating system components that necessitate patching and rebooting. Traditionally, applying such updates would require you to obtain and install the updated RPMs, schedule downtime, and reboot the server to the new package version, with any critical updates. However, as system setups become more complex, with many interdependencies, access to services and applications must remain as undisrupted as possible, as scheduling such reboots becomes more difficult and costly.

Oracle Ksplice provides a way for you to keep your systems secure and highly available by enabling you to update them with the latest kernel and key user-space security and bug fix updates, and Xen hypervisor updates on Oracle VM Server 3.4.5 and later.

Note

When using Ksplice to patch the Xen hypervisor on Oracle VM Server 3.4.5 and later, the minimum version that is required is xen-4.4.4-196.el6.x86_64.rpm.

Oracle Ksplice updates the running operating system without requiring a reboot. Your systems remains up to date with OS vulnerability patches and downtime is minimized. A Ksplice update takes effect immediately upon application. Note that a Ksplice update is not the same as an on-disk change that requires a subsequent reboot to take effect. However, note that on-disk updates are still required when using Ksplice to ensure that package binaries are updated to the most recent version and can be used in the event that the system or processes are restarted. On-disk updates are handled by subscribing to the Unbreakable Linux Network (ULN) or by using a local ULN mirror.

Oracle creates each Ksplice update from a package update that originates either from Oracle or the open source community.

To learn more about Ksplice, go to http://www.ksplice.com/.

2.1.1 Supported Kernels

You can use Ksplice to bring the following Oracle Linux kernels up to date with the latest important security and bug fix patches:

- All Oracle Unbreakable Enterprise Kernel versions for Oracle Linux 5, Oracle Linux 6, or Oracle Linux 7, starting with 2.6.32-100.28.9 (released March 16, 2011).
• All Oracle Linux 6 and Oracle Linux 7 kernels, starting with the official release.

• All Oracle Linux 5 Red Hat Compatible Kernels, starting with Oracle Linux 5.4 (2.6.18-164.el5, released September 9, 2009).

• All Oracle Linux 5 Red Hat Compatible Kernels with bug fixes added by Oracle, starting with Oracle Linux 5.6 (2.6.18-238.0.0.0.1.el5, released January 22, 2011).

To confirm whether a particular kernel is supported, install the Ksplice Uptrack client or Ksplice Enhanced Client on a system that is running the kernel.

Note
If your system is currently running Red Hat Enterprise Linux and you have recently migrated to Oracle Linux Premier Support, you can use Ksplice to update the existing Red Hat Enterprise Linux kernel. You do not need to switch to the Red Hat Compatible Kernel to use Ksplice kernel patches. These patches are available on ULN as uptrack-updates-kernel_version packages in the Ksplice for Oracle Linux channels.

For questions about supported kernels, send e-mail to ksplice-support_ww@oracle.com.

2.1.2 About Ksplice Updates

When a critical bug or security vulnerability is discovered in the Linux kernel, Oracle produces a new kernel release and prepares a rebootless update corresponding to that release. The rebootless update is securely distributed using the Oracle Ksplice Uptrack server and the Unbreakable Linux Network (ULN) and is applied to your systems by the Ksplice Uptrack client or Ksplice Enhanced client with zero downtime. Your infrastructure is again up to date and secure.

Note
The Ksplice Uptrack API does not currently support user space or Xen updates. However, the enhanced version of the Ksplice online client can patch shared libraries for user-space processes that are running on an Oracle Linux 6 or Oracle Linux 7 system.

For more detailed information, see About Ksplice Updates in Chapter 1 of the Oracle Linux Ksplice User’s Guide.

2.1.3 Patching and Updating Your System

Ksplice patches enable you to keep a system up to date while it is running. You should also use the yum command to install the regular kernel RPM packages for released errata that are available from the Unbreakable Linux Network (ULN) or the Oracle Linux yum server. Your system will then be ready for the next maintenance window or reboot. When you restart the system, you can boot it from a newer kernel version. Ksplice Uptrack uses the new kernel as a baseline for applying patches as they become available.

For more detailed information, see Patching and Updating Your System in Chapter 1 of the Oracle Linux Ksplice User’s Guide.

2.2 About the Ksplice Client Software

This section describes the different Ksplice client software types that are available in Oracle Linux. A description of each Ksplice client type, as well as information about when you might use each client, is provided.
2.2.1 About the Ksplice Enhanced Client

The Ksplice Enhanced client is available for Oracle Linux 6 and Oracle Linux 7, but not for Oracle Linux 5. The enhanced version of the Ksplice online client supports kernel and user-space updates and can also be used to patch the Xen hypervisor on Oracle VM Server Release 3.4.5 and later.

**Note**

To use Ksplice to patch the Xen hypervisor on Oracle VM 3.4.5 and later, the minimum Xen hypervisor version is `xen-4.4.4-196.el6.x86_64.rpm`.

The Ksplice Enhanced client can patch in-memory pages of Ksplice aware shared libraries such as `glibc` and `openssl` for user-space processes, in addition to the kernel updates applied by the traditional Ksplice Uptrack client. User-space patching enables you to install bug fixes and protect your system against security vulnerabilities without having to restart processes and services. Both an online and an offline version of the enhanced client are available.

You manage the Ksplice Enhanced client by using the `ksplice` command rather than `uptrack` commands. Note that the enhanced client shares the same configuration file as the Uptrack client, which is located at `/etc/uptrack/uptrack.conf`. For more information, see *Working With the Ksplice Enhanced Client*.

The offline version of the Ksplice Enhanced client removes the requirement that a server on your intranet have a direct connection to the Oracle Uptrack server or to ULN. All available Ksplice updates for each supported kernel version or user-space package are bundled into an RPM that is specific to that version. This package is updated every time a new Ksplice patch becomes available for the kernel. In this way, you can create a local ULN mirror that acts as a mirror for the Ksplice aware channels for Oracle Linux on ULN.

At regular intervals, you can download the latest Ksplice update packages to this server. After installing the offline Ksplice Enhanced client on your local systems, they can then connect to the local ULN mirror to receive updates.

For information about when you might want to use the Ksplice Enhanced client in offline mode, see Section 2.3, “Choosing a Ksplice Client”.

When you have set up a local ULN mirror to act as a Ksplice mirror, you can then configure your other systems to receive `yum` updates, as well as Ksplice updates. For task-related information, see *Installing and Configuring the Ksplice Offline Enhanced Client*.

2.2.2 About the Ksplice Uptrack Client

The Ksplice Uptrack client enables you to apply the latest kernel security errata for Common Vulnerabilities and Exposures (CVEs) without halting the system or restarting any applications. Ksplice Uptrack applies the updated patches in the background with negligible impact, and usually only requires a pause of a few milliseconds. You can use Ksplice Uptrack as well as continue to upgrade your kernel through the usual mechanism, such as running the `yum` command.

Ksplice Uptrack is freely available for Oracle customers who subscribe to Oracle Linux Premier Support and Oracle Cloud Infrastructure services. If you are an Oracle Linux Basic, Basic Limited, or Network Support subscriber, contact your sales representatives to discuss a potential upgrade of your subscription to a Premier Support plan.

The Ksplice Offline client removes the requirement that a server on your intranet have a direct connection to the Oracle Uptrack server. All available Ksplice updates for each supported kernel version are bundled into an RPM that is specific to that version. This package is updated every time a new Ksplice patch becomes available for the kernel.
Choosing a Ksplice Client

A Ksplice Offline client does not require a network connection to be able to apply the update package to the kernel. For example, you could use the `yum` command to install the update package directly from a memory stick. However, a more typical method would be to create a local ULN mirror that acts as a mirror of the Ksplice for Oracle Linux channels on ULN. At regular intervals, you download the latest Ksplice update packages to this server. After installing the Ksplice Offline client on your local systems, the systems can connect to the local ULN mirror to receive updates without requiring access to the Oracle Uptrack server. See "Configuring a Local ULN Mirror to Act as a Ksplice Mirror" for more information.

For information about when you might want to use the Ksplice Uptrack client in offline mode, see Section 2.3, “Choosing a Ksplice Client”.

**Note**

You cannot use the web interface or the Ksplice Uptrack API to monitor systems that are running Ksplice Offline client, as such systems are not registered with https://uptrack.ksplice.com.

### 2.3 Choosing a Ksplice Client

To determine which Ksplice client will best suit your needs, refer to information that is described in the following table.

<table>
<thead>
<tr>
<th>Ksplice Client</th>
<th>User Space Support</th>
<th>Xen Hypervisor Patching Support</th>
<th>Legacy Compatibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ksplice Enhanced Client</td>
<td>Supported</td>
<td>Supported</td>
<td>Not supported</td>
</tr>
<tr>
<td>Ksplice Uptrack Client</td>
<td>Not supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
</tbody>
</table>

### 2.4 Preparing to Use Oracle Ksplice

Refer to the following information before installing and configuring Ksplice:

- Determine which Ksplice client will best suit your needs. Depending on which Ksplice client you are using, you might be required to perform additional tasks. See Section 2.3, “Choosing a Ksplice Client”.
- Register your system with the Unbreakable Linux Network (ULN).

To use the Oracle Ksplice, your system must have access to the Internet, and you must register your system with the Unbreakable Linux Network (ULN) first, unless the system is configured to use the Oracle Ksplice client as an offline client. If your client is configured to function as an offline client, you must configure a local ULN mirror that the client can access to receive updates. For more information, see Oracle Linux Unbreakable Linux Network User's Guide.

- Ensure that you have a valid Oracle Linux Premier, Premier Limited, or Oracle Premier Support for Systems and Operating Systems subscription and a valid Customer Support Identifier (CSI).

If you have one of the Oracle Linux Premier subscriptions previously mentioned and a valid CSI, your account is automatically registered to use the Ksplice Uptrack server. You can log in to the Ksplice Uptrack server web interface at https://uptrack.ksplice.com by using your Oracle Single Sign-on (SSO) credentials. After logging into the server, you can view the status of your registered systems, the patches that have been applied, and the patches that are available. For more detailed information about Ksplice and ULN registration, see the Oracle Linux Ksplice User's Guide.

- If you plan to use an offline mode of either the Ksplice Enhanced client or the Ksplice Uptrack client, you must set up a local ULN mirror that the client can access to receive updates. See Configuring a Local ULN Mirror to Act as a Ksplice Mirror for task-related information.
- Using Ksplice with Spacewalk also requires that you set up a local ULN mirror. For further details, see Configuring a Spacewalk Server to Act as a Ksplice Mirror.

  3.7.8 Modifying systemd Configuration Files ............................ 35
  3.7.9 Running systemctl on a Remote System ............................. 35

This chapter describes the Oracle Linux boot process, how to use the GRUB 2 boot loader, how to change the systemd target for a system, and how to configure the services that are available for a target.

3.1 About systemd

systemd is the new system and service manager in Oracle Linux 7 that replaces the Upstart init daemon while providing backward compatibility for legacy Oracle Linux 6 service scripts. systemd offers the following benefits over init:

- Services are started in parallel wherever possible using socket-based activation and D-Bus.
- Daemons can be started on demand.
- Processes are tracked using control groups (cgroups).
- Snapshotting of the system state and restoration of the system state from a snapshot is supported.
- Mount points can be configured as systemd targets.

systemd is the first process that starts after the system boots, and is the final process that is running when the system shuts down. systemd controls the final stages of booting and prepares the system for use. systemd also speeds up booting by loading services concurrently.

systemd allows you to manage various types of units on a system, including services (name.service) and targets (name.target), devices (name.device), file system mount points (name.mount), and sockets (name.socket). For example, the following command instructs the system to mount the temporary file system (tmpfs) on /tmp at boot time:

```bash
# systemctl enable tmp.mount
```
3.2 About the Boot Process

Understanding the Oracle Linux boot process can help you if you need to troubleshoot problems while booting a system. The boot process involves several files and errors in these files is the usual cause of boot problems.

When an Oracle Linux system boots, it performs the following operations:

1. The computer's BIOS performs a power-on self-test (POST), and then locates and initializes any peripheral devices including the hard disk.

2. The BIOS reads the Master Boot Record (MBR) into memory from the boot device. (For GUID Partition Table (GPT) disks, this MBR is the protective MBR on the first sector of the disk.) The MBR stores information about the organization of partitions on that device. On a computer with x86 architecture, the MBR occupies the first 512 bytes of the boot device. The first 446 bytes contain boot code that points to the boot loader program, which can be on the same device or on another device. The next 64 bytes contain the partition table. The final two bytes are the boot signature, which is used for error detection.

   The default boot loader program used on Oracle Linux is GRUB 2, which stands for GRand Unified Bootloader version 2.

3. The boot loader loads the vmlinuz kernel image file into memory and extracts the contents of the initramfs image file into a temporary, memory-based file system (tmpfs).

4. The kernel loads the driver modules from the initramfs file system that are needed to access the root file system.

5. The kernel starts the systemd process with a process ID of 1 (PID 1). systemd is the ancestor of all processes on a system. systemd reads its configuration from files in the /etc/systemd directory. The /etc/systemd/system.conf file controls how systemd handles system initialization.

   systemd reads the file linked by /etc/systemd/system/default.target, for example /usr/lib/systemd/system/multi-user.target, to determine the default system target.

   Note

   You can use a kernel boot parameter to override the default system target. See Section 3.4, “Kernel Boot Parameters”.

The system target file defines the services that systemd starts.

systemd brings the system to the state defined by the system target, performing system initialization tasks such as:

• Setting the host name.
• Initializing the network.
• Initializing SELinux based on its configuration.
• Printing a welcome banner.
• Initializing the system hardware based on kernel boot arguments.
• Mounting the file systems, including virtual file systems such as the /proc file system.
• Cleaning up directories in /var.
• Starting swapping.

See Section 3.7, “About System-State Targets”.

6. If you have made /etc/rc.local executable and you have copied /usr/lib/systemd/system/rc-local.service to /etc/systemd/system, systemd runs any actions that you have defined in /etc/rc.local. However, the preferred way of running such local actions is to define your own systemd unit.

For information on systemd and on how to write systemd units, see the systemd(1), systemd-system.conf(5), and systemd.unit(5) manual pages.

3.3 About the GRUB 2 Boot Loader

GRUB 2 can load many operating systems in addition to Oracle Linux and it can chain-load proprietary operating systems. GRUB 2 understands the formats of file systems and kernel executables, which allows it to load an arbitrary operating system without needing to know the exact location of the kernel on the boot device. GRUB 2 requires only the file name and drive partitions to load a kernel. You can configure this information by using the GRUB 2 menu or by entering it on the command line.

**Note**

Do not edit the GRUB 2 configuration file directly. On BIOS-based systems, the configuration file is /boot/grub2/grub.cfg. On UEFI-based systems, the configuration file is /boot/efi/EFI/redhat/grub.cfg.

The `grub2-mkconfig` command generates the configuration file using the template scripts in /etc/grub.d and menu-configuration settings taken from the configuration file, /etc/default/grub.

The default menu entry is determined by the value of the GRUB_DEFAULT parameter in /etc/default/grub. The value saved allows you to use the `grub2-set-default` and `grub2-reboot` commands to specify the default entry. `grub2-set-default` sets the default entry for all subsequent reboots and `grub2-reboot` sets the default entry for the next reboot only.

If you specify a numeric value as the value of GRUB_DEFAULT or as an argument to either `grub2-reboot` or `grub2-set-default`, GRUB 2 counts the menu entries in the configuration file starting at 0 for the first entry.

To set the UEK as the default boot kernel:

1. Display the menu entries that are defined in the configuration file, for example:

   ```
   # grep '^menuentry' /boot/grub2/grub.cfg
   menuentry 'Oracle Linux Everything, with Linux 3.10.0-123.el7.x86_64' ... {
   menuentry 'Oracle Linux Everything, with Linux 3.8.13-35.2.1.el7uek.x86_64' ... {
   menuentry 'Oracle Linux Everything, with Linux 0-rescue-052e316f566e4a3391c3f2b4174b' ... {
   ```

   In this example for a BIOS-based system, the configuration file is /boot/grub2/grub.cfg, which contains menu entries 0, 1, and 2 that correspond to the RHCK, UEK, and the rescue kernel respectively.

2. Enter the following commands to make the UEK (entry 1) the default boot kernel:

   ```
   # grub2-set-default 1
   # grub2-mkconfig -o /boot/grub2/grub.cfg
   ```
Kernel Boot Parameters

Alternatively, you can specify the value of the text of the entry as a string enclosed in quotes.

```
# grub2-set-default 'Oracle Linux Everything, with Linux 3.8.13-35.2.1.el7uek.x86_64'
# grub2-mkconfig -o /boot/grub2/grub.cfg
```

For more information about using, configuring, and customizing GRUB 2, see the GNU GRUB Manual, which is also installed as `/usr/share/doc/grub2-tools-2.00/grub.html`.

### 3.4 Kernel Boot Parameters

The following table lists commonly-used kernel boot parameters.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0, 1, 2, 3, 4, 5, or 6, or systemd.unit=runlevelN.target</td>
<td>Specifies the nearest systemd-equivalent system-state target to an Oracle Linux 6 run level. N can take an integer value between 0 and 6. For a description of system-state targets, see Section 3.7, &quot;About System-State Targets&quot;.</td>
</tr>
<tr>
<td>1, s, S, single, or systemd.unit=rescue.target</td>
<td>Specifies the rescue shell. The system boots to single-user mode prompts for the root password.</td>
</tr>
<tr>
<td>3 or systemd.unit=multi-user.target</td>
<td>Specifies the systemd target for multi-user, non-graphical login.</td>
</tr>
<tr>
<td>5 or systemd.unit=graphical.target</td>
<td>Specifies the systemd target for multi-user, graphical login.</td>
</tr>
<tr>
<td>-b, emergency, or systemd.unit=emergency.target</td>
<td>Specifies emergency mode. The system boots to single-user mode and prompts for the root password. Fewer services are started than when in rescue mode.</td>
</tr>
<tr>
<td>KEYBOARDTYPE=kbtype</td>
<td>Specifies the keyboard type, which is written to <code>/etc/sysconfig/keyboard</code> in the initramfs.</td>
</tr>
<tr>
<td>KEYTABLE=kbtype</td>
<td>Specifies the keyboard layout, which is written to <code>/etc/sysconfig/keyboard</code> in the initramfs.</td>
</tr>
<tr>
<td>LANG=language_territory.codeset</td>
<td>Specifies the system language and code set, which is written to <code>/etc/sysconfig/i18n</code> in the initramfs.</td>
</tr>
<tr>
<td>max_loop=N</td>
<td>Specifies the number of loop devices (/dev/loop*) that are available for accessing files as block devices. The default and maximum values of N are 8 and 255.</td>
</tr>
<tr>
<td>nouptrack</td>
<td>Disables Ksplice Uptrack updates from being applied to the kernel.</td>
</tr>
<tr>
<td>quiet</td>
<td>Reduces debugging output.</td>
</tr>
<tr>
<td>rd_LUKS_UUID=UUID</td>
<td>Activates an encrypted Linux Unified Key Setup (LUKS) partition with the specified UUID.</td>
</tr>
<tr>
<td>rd_LVM_VG=vg/lv_vol</td>
<td>Specifies an LVM volume group and volume to be activated.</td>
</tr>
<tr>
<td>rd_NO_LUKS</td>

Modifying Kernel Boot Parameters Before Booting

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rhgb</td>
<td>Specifies that the Red Hat graphical boot display should be used to indicate the progress of booting.</td>
</tr>
<tr>
<td>rn_NO_DM</td>
<td>Disables Device-Mapper (DM) RAID detection.</td>
</tr>
<tr>
<td>rn_NO_MD</td>
<td>Disables Multiple Device (MD) RAID detection.</td>
</tr>
<tr>
<td>ro root=/devmapper/vg-lv_root</td>
<td>Specifies that the root file system is to be mounted read only, and specifies the root file system by the device path of its LVM volume (where vg is the name of the volume group).</td>
</tr>
<tr>
<td>rw root=UUID=UUID</td>
<td>Specifies that the root (/) file system is to be mounted read-writable at boot time, and specifies the root partition by its UUID.</td>
</tr>
<tr>
<td>selinux=0</td>
<td>Disables SELinux.</td>
</tr>
<tr>
<td>SYSFONT=font</td>
<td>Specifies the console font, which is written to /etc/sysconfig/i18n in the initramfs.</td>
</tr>
</tbody>
</table>

The kernel boot parameters that were last used to boot a system are recorded in /proc/cmdline, for example:

```
# cat /proc/cmdline
BOOT_IMAGE=/vmlinuz-3.10.0-123.el7.x86_64 root=UUID=52c1cab6-969f-4872-958d-47f8518267de ro rootflags=subvol=root vconsole.font=latarcyrheb-sun16 crashkernel=auto vconsole.keymap=uk rhgb quiet LANG=en_GB.UTF-8
```

For more information, see the kernel-command-line(7) manual page.

### 3.5 Modifying Kernel Boot Parameters Before Booting

To modify boot parameters before booting a kernel:

1. In the GRUB boot menu, use the arrow keys to highlight the required kernel and press the space bar. Figure 3.1 shows the GRUB menu with the UEK selected.

   **Figure 3.1 GRUB Menu with the UEK selected**

2. Press E to edit the boot configuration for the kernel.
3. Use the arrow keys to scroll down the screen until the cursor is at the start of the boot configuration line for the kernel, which starts `linux16`.

4. Edit the line to change the boot parameters.

   For example, press End to go to the end of the line, and enter an additional boot parameter.

   Figure 3.2 shows the kernel boot line with the additional parameter `systemd.target=runlevel1.target`, which starts the rescue shell.

   **Figure 3.2 Kernel Boot Line with an Additional Parameter to Select the Rescue Shell**

5. Press Ctrl+X to boot the system.

### 3.6 Modifying Kernel Boot Parameters in GRUB 2

To modify the boot parameters in the GRUB 2 configuration so that they are applied by default at every reboot:

1. Edit `/etc/default/grub` and modify the parameters in the `GRUB_CMDLINE_LINUX` definition, for example:

   ```
   GRUB_CMDLINE_LINUX="vconsole.font=latarcyrheb-sun16 vconsole.keymap=uk crashkernel=auto rd.lvm.lv=ol/swap rd.lvm.lv=ol/root biosdevname=0 rhgb quiet systemd.unit=runlevel3.target"
   ```

   This example adds the parameter `systemd.unit=runlevel3.target` so that the system boots into multi-user, non-graphical mode by default.

2. Rebuild `/boot/grub2/grub.cfg`:

   ```
   # grub2-mkconfig -o /boot/grub2/grub.cfg
   ```

   The change takes effect for subsequent system reboots of all configured kernels.

### 3.7 About System-State Targets

`systemd` defines system-state targets allow you to start a system with only the services that are required for a specific purpose. For example, a server can run more efficiently with `multi-user.target`, because it does not run the X Window System at that run level. It is best to perform diagnostics, backups, and upgrades with `rescue.target` when only `root` can use the system. Each run level defines the
services that **systemd** stops or starts. For example, **systemd** starts network services for **multi-user.target** and the X Window System for **graphical.target**, whereas it stops both of these services for **rescue.target**.

Table 3.1, “System-State Targets and Equivalent Run-Level Targets” shows the commonly-used system-state targets and their equivalent run-level targets, where compatibility with Oracle Linux 6 run levels is required.

### Table 3.1 System-State Targets and Equivalent Run-Level Targets

<table>
<thead>
<tr>
<th>System-State Targets</th>
<th>Equivalent Run-Level Targets</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>graphical.target</td>
<td>runlevel5.target</td>
<td>Set up a multi-user system with networking and display manager.</td>
</tr>
<tr>
<td>multi-user.target</td>
<td>runlevel2.target</td>
<td>Set up a non-graphical multi-user system with networking.</td>
</tr>
<tr>
<td></td>
<td>runlevel3.target</td>
<td></td>
</tr>
<tr>
<td></td>
<td>runlevel4.target</td>
<td></td>
</tr>
<tr>
<td>poweroff.target</td>
<td>runlevel0.target</td>
<td>Shut down and power off the system.</td>
</tr>
<tr>
<td>reboot.target</td>
<td>runlevel6.target</td>
<td>Shut down and reboot the system.</td>
</tr>
<tr>
<td>rescue.target</td>
<td>runlevel1.target</td>
<td>Set up a rescue shell.</td>
</tr>
</tbody>
</table>

The **runlevel* targets** are implemented as symbolic links.

The nearest equivalent **systemd** target to the Oracle Linux 6 run levels 2, 3, and 4 is **multi-user.target**.

For more information, see the **systemd.target(5)** manual page.

### 3.7.1 Displaying the Default and Active System-State Targets

To display the default system-state target, use the `systemctl get-default` command, for example:

```
# systemctl get-default
graphical.target
```

To display the currently active targets on a system, use the `systemctl list-units` command, for example:

```
# systemctl list-units --type target
UNIT                        LOAD   ACTIVE SUB    DESCRIPTION
basic.target                loaded active active Basic System
cryptsetup.target           loaded active active Encrypted Volumes
getty.target                loaded active active Login Prompts
graphical.target            loaded active active Graphical Interface
local-fs-pre.target         loaded active active Local File Systems (Pre)
local-fs.target             loaded active active Local File Systems
multi-user.target           loaded active active Multi-User System
network.target              loaded active active Network
nfs.target                  loaded active active Network File System Server
paths.target                loaded active active Paths
remote-fs.target            loaded active active Remote File Systems
slices.target               loaded active active Slices
sockets.timer               loaded active active Sockets
sound.timer                 loaded active active Sound Card
swap.timer                  loaded active active Swap
sysinit.timer               loaded active active System Initialization
timers.timer                loaded active active Timers
Changing the Default and Active System-State Targets

LOAD = Reflects whether the unit definition was properly loaded.
ACTIVE = The high-level unit activation state, i.e. generalization of SUB.
SUB = The low-level unit activation state, values depend on unit type.

17 loaded units listed. Pass --all to see loaded but inactive units, too.
To show all installed unit files use 'systemctl list-unit-files'.

This sample output for a system with the graphical target active shows that this target depends on 16 other active targets, including network and sound to support networking and sound.

To display the status of all targets on the system, specify the --all option:

```
# systemctl list-units --type target --all
```

<table>

</tbody>
</table>

LOAD = Reflects whether the unit definition was properly loaded.
ACTIVE = The high-level unit activation state, i.e. generalization of SUB.
SUB = The low-level unit activation state, values depend on unit type.

28 loaded units listed.
To show all installed unit files use 'systemctl list-unit-files'.

For more information, see the systemctl(1) and systemd.target(5) manual pages.

### 3.7.2 Changing the Default and Active System-State Targets

Use the `systemctl set-default` command to change the default system-state target, for example:

```
# systemctl set-default multi-user.target
rm '/etc/systemd/system/default.target'
lz -s '/usr/lib/systemd/system/multi-user.target' '/etc/systemd/system/default.target'
```

**Note**

This command changes the target to which the default target is linked, but does not change the state of the system.
To change the currently active system target, use the `systemctl isolate` command, for example:

```
# systemctl isolate multi-user.target
```

Listing all targets shows that `graphical` and `sound` targets are not active:

```
# systemctl list-units --type target --all

UNIT                   LOAD   ACTIVE   SUB    DESCRIPTION
basic.target           loaded active active Basic System
cryptsetup.target      loaded active active Encrypted Volumes
emergency.target       loaded inactive dead   Emergency Mode
final.target           loaded inactive dead   Final Step
getty.target           loaded active active Login Prompts
graphical.target       loaded inactive dead   Graphical Interface
local-fs-pre.target    loaded active active Local File Systems (Pre)
local-fs.target        loaded active active Local File Systems
multi-user.target      loaded active active Multi-User System
network-online.target  loaded inactive dead   Network is Online
network.target         loaded active active Network
nfs.target             loaded active active Network File System Server
nss-lookup.target      loaded inactive dead   Host and Network Name Lookups
nss-user-lookup.target loaded inactive dead   User and Group Name Lookups
paths.target           loaded active active Paths
remote-fs-pre.target   loaded inactive dead   Remote File Systems (Pre)
remote-fs.target       loaded active active Remote File Systems
rescue.target          loaded inactive dead   Rescue Mode
shutdown.target        loaded inactive dead   Shutdown
slices.target          loaded active active Slices
sockets.target         loaded active active Sockets
sound.target           loaded inactive dead   Sound Card
swap.target            loaded active active Swap
sysinit.target         loaded active active System Initialization
syslog.target          not-found inactive dead   syslog.target
timers.target          loaded active active Timers
umount.target          loaded inactive dead   Unmount All Filesystems

LOAD   = Reflects whether the unit definition was properly loaded.
ACTIVE = The high-level unit activation state, i.e. generalization of SUB.
SUB    = The low-level unit activation state, values depend on unit type.

28 loaded units listed.
To show all installed unit files use 'systemctl list-unit-files'.

For more information, see the `systemctl(1)` manual page.

## 3.7.3 Shutting Down, Suspending, or Rebooting the System

Table 3.2, "systemctl Commands for Shutting Down, Suspending, or Rebooting a System" shows the `systemctl` commands for shutting down rebooting, or otherwise suspending the operation of a system.

**Table 3.2 systemctl Commands for Shutting Down, Suspending, or Rebooting a System**

<table>
<thead>
<tr>
<th>systemctl Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>systemctl halt</td>
<td>Halt the system.</td>
</tr>
<tr>
<td>systemctl hibernate</td>
<td>Put the system into hibernation.</td>
</tr>
<tr>
<td>systemctl hybrid-sleep</td>
<td>Put the system into hibernation and suspend its operation.</td>
</tr>
<tr>
<td>systemctl poweroff</td>
<td>Halt and power off the system.</td>
</tr>
<tr>
<td>systemctl reboot</td>
<td>Reboot the system.</td>
</tr>
</tbody>
</table>
### Starting and Stopping Services

<table>
<thead>
<tr>
<th>systemctl Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>systemctl suspend</td>
<td>Suspend the system.</td>
</tr>
</tbody>
</table>

For more information, see the `systemctl(1)` manual page.

#### 3.7.4 Starting and Stopping Services

To start a service, use the `systemctl` command with the `start` argument, for example:

```
# systemctl start sshd
```

For legacy scripts in `/etc/init.d` that have not been ported as `systemd` services, you can run the script directly with the `start` argument:

```
#/etc/init.d/yum-cron start
```

To stop a service, use the `stop` argument to `systemctl`:

```
# systemctl stop sshd
```

**Note**

Changing the state of a service only lasts as long as the system remains at the same state. If you stop a service and then change the system-state target to one in which the service is configured to run (for example, by rebooting the system), the service restarts. Similarly, starting a service does not enable the service to start following a reboot. See Section 3.7.5, “Enabling and Disabling Services”.

`systemctl` supports the `disable`, `enable`, `reload`, `restart`, `start`, `status`, and `stop` actions for services. For other actions, you must either run the script that the service provides to support these actions, or for legacy scripts, the `/etc/init.d` script with the required action argument. For legacy scripts, omitting the argument to the script displays a usage message, for example:

```
#/etc/init.d/yum-cron
Usage: /etc/init.d/yum-cron {start|stop|status|restart|reload|force-reload|condrestart}
```

For more information, see the `systemctl(1)` manual page.

#### 3.7.5 Enabling and Disabling Services

You can use the `systemctl` command to enable or disable a service from starting when the system starts, for example:

```
# systemctl enable httpd
ln -s '/usr/lib/systemd/system/httpd.service' \
     '/etc/systemd/system/multi-user.target.wants/httpd.service'
```

The command enables a service by creating a symbolic link for the lowest-level system-state target at which the service should start. In the example, the command creates the symbolic link `httpd.service` for the `multi-user` target.

Disabling a service removes the symbolic link:

```
# systemctl disable httpd
rm '/etc/systemd/system/multi-user.target.wants/httpd.service'
```

You can use the `is-enabled` subcommand to check whether a service is enabled:
Displaying the Status of Services

### 3.7.6 Displaying the Status of Services

You can use the `is-active` subcommand to check whether a service is running (`active`) or not running (`inactive`):

```bash
# systemctl is-active httpd
active
# systemctl is-active nfs
inactive
```

You can use the `status` action to view a detailed summary of the status of a service, including a tree of all the tasks in the control group (cgroup) that the service implements:

```bash
# systemctl status httpd
httpd.service - The Apache HTTP Server
   Loaded: loaded (/usr/lib/systemd/system/httpd.service; enabled)
   Active: active (running) since Mon 2014-04-28 15:02:40 BST; 1s ago
   Main PID: 6452 (httpd)
     Status: "Processing requests..."
   CGroup: /system.slice/httpd.service
            └─ 6452 /usr/sbin/httpd -DFOREGROUND
```

A cgroup is a collection of processes that are bound together so that you can control their access to system resources. In the example, the cgroup for the `httpd` service is `httpd.service`, which is in the `system.slice`.

Slices divide the cgroups on a system into different categories. To display the slice and cgroup hierarchy, use the `systemd-cgls` command:

```bash
# systemd-cgls
├─ user.slice
│   └─ user-1000.slice
│       └─ session-12.scope
│           └─ 3152 gdm-session-worker [pam/gdm-password]
│           └─ 3169 /usr/bin/gnome-keyring-daemon --daemonize --login
│           └─ 3171 gnome-session --session gnome-classic...
│           └─ 3763 /usr/libexec/evolution-calendar-factory
├─ user-0.slice
│   └─ session-13.scope
│       └─ 3810 sshd: root@pts/0
│       └─ 3836 -bash
│       └─ 4015 systemd-cgls
│       └─ 4016 systemd-cgls
│       └─ session-6.scope
│           └─ 3030 /usr/sbin/anacron -s
```

For more information, see the `systemctl(1)` manual page.
system.slice contains services and other system processes. user.slice contains user processes, which run within transient cgroups called scopes. In the example, the processes for the user with ID 1000 are running in the scope session-12.scope under the slice /user.slice/user-1000.slice.

You can use the systemctl command to limit the CPU, I/O, memory, and other resources that are available to the processes in service and scope cgroups. See Section 3.7.7, “Controlling Access to System Resources”.

For more information, see the systemctl(1) and systemd-cgls(1) manual pages.

### 3.7.7 Controlling Access to System Resources

You can use the systemctl command to control a cgroup’s access to system resources, for example:

```
# systemctl set-property httpd.service CPUShares=512 MemoryLimit=1G
```

**CPUShare** controls access to CPU resources. As the default value is 1024, a value of 512 halves the access that the processes in the cgroup have to CPU time. Similarly, **MemoryLimit** controls the maximum amount of memory that the cgroup can use.

**Note**

You do not need to specify the .service extension to the name of a service.

If you specify the --runtime option, the setting does not persist across system reboots.

```
# systemctl --runtime set-property httpd CPUShares=512 MemoryLimit=1G
```

Alternatively, you can change the resource settings for a service under the [Service] heading in the service’s configuration file in /usr/lib/systemd/system. After editing the file, make systemd reload its configuration files and then restart the service:
You can run general commands within scopes and use `systemctl` to control the access that these transient cgroups have to system resources. To run a command within a scope, use the `systemd-run` command:

```
# systemctl daemon-reload
# systemctl restart service
```

If you do not want to create the group under the default `system` slice, you can specify another slice or the name of a new slice.

**Note**

If you do not specify the `--scope` option, the control group is created as a service rather than as a scope.

For example, run a command named `mymonitor` in `mymon.scope` under `myslice.slice`:

```
# systemctl-run --scope --unit=mymon --slice=myslice mymonitor
Running as unit mymon.scope.
```

You can then use `systemctl` to control the access that a scope has to system resources in the same way as for a service. However, unlike a service, you must specify the `.scope` extension, for example:

```
# systemctl --runtime set-property mymon.scope CPUShares=256
```

For more information see the `systemctl(1)`, `systemd-cgls(1)`, and `systemd.resource-control(5)` manual pages.

### 3.7.8 Modifying systemd Configuration Files

If you want to change the configuration of `systemd`, copy the `service`, `target`, `mount`, `socket` or other file from `/usr/lib/systemd/system` to `/etc/systemd/system` and edit this copy of the original file. The version of the file in `/etc/systemd/system` takes precedence over the version in `/usr/lib/systemd/system`, and is not overwritten when you update a package that touches files in `/usr/lib/systemd/system`. To make `systemd` revert to using the original version of the file, either rename or delete the modified copy of the file in `/etc/systemd/system`.

### 3.7.9 Running systemctl on a Remote System

If the `sshd` service is running on a remote Oracle Linux 7 system, you can use the `--H` option with `systemctl` to control the system remotely, as shown in this example:

```
# systemctl -H root@10.0.0.2 status sshd
root@10.0.0.2's password: password
sshd.service - OpenSSH server daemon
    Loaded: loaded (/usr/lib/systemd/system/sshd.service; enabled)
    Active: active (running) since Fri 2014-05-23 09:27:22 BST; 5h 43min ago
    Process: 1498 ExecStartPre=/usr/sbin/sshd-keygen (code=exited, status=0/SUCCESS)
    Main PID: 1524 (sshd)
    CGroup: /system.slice/sshd.service
```

For more information see the `systemctl(1)` manual page.
This chapter describes the files and virtual file systems that you can use to change configuration settings for your system.

4.1 About /etc/sysconfig Files

The /etc/sysconfig directory contains files that control your system's configuration. The contents of this directory depend on the packages that you have installed on your system.

Some of the files that you might find in the /etc/sysconfig directory include:

- **atd**: Specifies additional command line arguments for the atd daemon.
- **authconfig**: Specifies whether various authentication mechanisms and options may be used. For example, the entry USEMKHOMEDIR=no disables the creation of a home directory for a user when he or she first logs in.
- **autofs**: Defines custom options for automatically mounting devices and controlling the operation of the automounter.
- **crond**: Passes arguments to the crond daemon at boot time.
- **firewalld**: Passes arguments to the firewall daemon (firewalld) at boot time.
- **grub**: Specifies default settings for the GRUB 2 boot loader. This file is a symbolic link to /etc/default/grub. For more information, see Section 3.3, “About the GRUB 2 Boot Loader”.
- **init**: Controls how the system appears and functions during the boot process.
- **keyboard**: Specifies the keyboard.
- **modules** (directory): Contains scripts that the kernel runs to load additional modules at boot time. A script in the modules directory must have the extension .modules and it must have 755 executable permissions. For an example, see the bluez-uinput.module script that loads the uinput module. For more information, see Section 5.5, “Specifying Modules to be Loaded at Boot Time”.

4.2 About the /proc Virtual File System

This chapter describes the virtual file system /proc, which allows you to access and configure kernel parameters and other settings.

4.2.1 Virtual Files and Directories Under /proc

4.2.2 Changing Kernel Parameters

4.2.3 Parameters that Control System Performance

4.2.4 Parameters that Control Kernel Panics

4.3 About the /sys Virtual File System

4.3.1 Virtual Directories Under /sys

4.4 System Date and Time Settings
About the /proc Virtual File System

named

Passes arguments to the name service daemon at boot time. The named daemon is a Domain Name System (DNS) server that is part of the Berkeley Internet Name Domain (BIND) distribution. This server maintains a table that associates host names with IP addresses on the network.

nfs

Controls which ports remote procedure call (RPC) services use for NFS v2 and v3. This file allows you to set up firewall rules for NFS v2 and v3. Firewall configuration for NFS v4 does not require you to edit this file.

ntpd

Passes arguments to the network time protocol (NTP) daemon at boot time.

samba

Passes arguments to the smbd, nmbd, and winbindd daemons at boot time to support file-sharing connectivity for Windows clients, NetBIOS-over-IP naming service, and connection management to domain controllers.

selinux

Controls the state of SELinux on the system. This file is a symbolic link to /etc/selinux/config. For more information, see Section 26.2.3, “Setting SELinux Modes”.

snapper

Defines a list of btrfs file systems and thinly-provisioned LVM volumes whose contents can be recorded as snapshots by the snapper utility. For more information, see Section 21.7.1, “Using snapper with Btrfs Subvolumes” and Section 19.3.6, “Using snapper with Thinly-Provisioned Logical Volumes”.

sysstat

Configures logging parameters for system activity data collector utilities such as sadc.

For more information, see /usr/share/doc/initscripts*/sysconfig.txt.

Note

In previous release of Oracle Linux, the host name of the system was defined in /etc/sysconfig/network. The host name is now defined in /etc/hostname and can be changed by using the hostnamectl command. System-wide default localization settings such as the default language, keyboard, and console font were defined in /etc/sysconfig/i18n. These settings are now defined in /etc/locale.conf and /etc/vconsole.conf.

For more information, see the hostname(5), hostnamectl(1), locale.conf(5), and vconsole.conf(5) manual pages.

4.2 About the /proc Virtual File System

The files in the /proc directory hierarchy contain information about your system hardware and the processes that are running on the system. You can change the configuration of the kernel by writing to certain files that have write permission.

The name of the proc file system stems from its original purpose on the Oracle Solaris operating system, which was to allow access by debugging tools to the data structures inside running processes. Linux added this interface and extended it to allow access to data structures in the kernel. Over time, /proc became quite disordered and the sysfs file system was created in an attempt to tidy it up. For more information, see Section 4.3, “About the /sys Virtual File System”.

Files under the /proc directory are virtual files that the kernel creates on demand to present a browsable view of the underlying data structures and system information. As such, /proc is an example of a virtual file system. Most virtual files are listed as zero bytes in size, but they contain a large amount of information when viewed.

Virtual files such as /proc/interrupts, /proc/meminfo, /proc/mounts, and /proc/partitions provide a view of the system’s hardware. Others, such as /proc/filesystems and the files under /proc/sys provide information about the system’s configuration and allow this configuration to be modified.

Files that contain information about related topics are grouped into virtual directories. For example, a separate directory exists in /proc for each process that is currently running on the system, and the directory's name corresponds to the numeric process ID. /proc/1 corresponds to the systemd process, which has a PID of 1.

You can use commands such as cat, less, and view to examine virtual files within /proc. For example, /proc/cpuinfo contains information about the system's CPUs:

```
# cat /proc/cpuinfo
processor         : 0
vendor_id         : GenuineIntel
cpu family        : 6
model             : 42
model name        : Intel(R) Core(TM) i5-2520M CPU @ 2.50GHz
stepping          : 7
cpu MHz           : 2393.714
cache size        : 6144 KB
physical id       : 0
siblings          : 2
core id           : 0
cpu cores         : 2
apicid            : 0
initial apicid    : 0
fpu               : yes
fpu_exception     : yes
cpuid level       : 5
wp                : yes
...
```

Certain files under /proc require root privileges for access or contain information that is not human-readable. You can use utilities such as lspci, free, and top to access the information in these files. For example, lspci lists all PCI devices on a system:

```
# lspci
00:00.0 Host bridge: Intel Corporation 440FX - 82441FX PMC [Natoma] (rev 02)
00:01.0 ISA bridge: Intel Corporation 82371SB PIIX3 ISA [Natoma/Triton II]
00:01.1 IDE interface: Intel Corporation 82371AB/EB/MB PIIX4 IDE (rev 01)
00:02.0 VGA compatible controller: InnoTek Systemberatung GmbH VirtualBox Graphics Adapter
00:03.0 Ethernet controller: Intel Corporation 82540EM Gigabit Ethernet Controller (rev 02)
00:04.0 System peripheral: InnoTek Systemberatung GmbH VirtualBox Guest Service
00:05.0 Multimedia audio controller: Intel Corporation 82801AA AC'97 Audio Controller (rev 01)
00:06.0 USB controller: Apple Inc. KeyLargo/Intrepid USB
00:07.0 Bridge: Intel Corporation 82371AB/EB/MB PIIX4 ACPI (rev 08)
00:08.0 USB controller: Intel Corporation 82801FB/FRM/FR/W/FW (ICH6 Family) USB2 EHCI Controller (rev 02)
00:0d.0 SATA controller: Intel Corporation 82801HM/HEM (ICH8M/ICH8M-E) SATA Controller [AHCI mode] (rev 02)
...
```

### 4.2.1 Virtual Files and Directories Under /proc

The following table lists the most useful virtual files and directories under the /proc directory hierarchy.
### Table 4.1 Useful Virtual Files and Directories Under `/proc`

<table>
<thead>
<tr>
<th>Virtual File or Directory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>PID</strong> (Directory)</td>
<td>Provides information about the process with the process ID (<strong>PID</strong>). The directory’s owner and group is same as the process's. Useful files under the directory include:</td>
</tr>
<tr>
<td>cmdline</td>
<td>Command path.</td>
</tr>
<tr>
<td>cwd</td>
<td>Symbolic link to the process's current working directory.</td>
</tr>
<tr>
<td>environ</td>
<td>Environment variables.</td>
</tr>
<tr>
<td>exe</td>
<td>Symbolic link to the command executable.</td>
</tr>
<tr>
<td>fd/N</td>
<td>File descriptors.</td>
</tr>
<tr>
<td>maps</td>
<td>Memory maps to executable and library files.</td>
</tr>
<tr>
<td>root</td>
<td>Symbolic link to the effective root directory for the process.</td>
</tr>
<tr>
<td>stack</td>
<td>The contents of the kernel stack.</td>
</tr>
<tr>
<td>status</td>
<td>Run state and memory usage.</td>
</tr>
<tr>
<td>buddyinfo</td>
<td>Provides information for diagnosing memory fragmentation.</td>
</tr>
<tr>
<td><strong>bus</strong> (directory)</td>
<td>Contains information about the various buses (such as <strong>pci</strong> and <strong>usb</strong>) that are available on the system. You can use commands such as <strong>lspci</strong>, <strong>lspcmcia</strong>, and <strong>lsusb</strong> to display information for such devices.</td>
</tr>
<tr>
<td>cgroups</td>
<td>Provides information about the resource control groups that are in use on the system.</td>
</tr>
<tr>
<td>cmdline</td>
<td>Lists parameters passed to the kernel at boot time.</td>
</tr>
<tr>
<td>cpuinfo</td>
<td>Provides information about the system’s CPUs.</td>
</tr>
<tr>
<td>crypto</td>
<td>Provides information about all installed cryptographic cyphers.</td>
</tr>
<tr>
<td>devices</td>
<td>Lists the names and major device numbers of all currently configured characters and block devices.</td>
</tr>
<tr>
<td>dma</td>
<td>Lists the direct memory access (DMA) channels that are currently in use.</td>
</tr>
<tr>
<td><strong>driver</strong> (directory)</td>
<td>Contains information about drivers used by the kernel, such as those for non-volatile RAM (<strong>nvram</strong>), the real-time clock (<strong>rtc</strong>), and memory allocation for sound (<strong>snd-page-alloc</strong>).</td>
</tr>
<tr>
<td>execdomains</td>
<td>Lists the execution domains for binaries that the Oracle Linux kernel supports.</td>
</tr>
<tr>
<td>filesystems</td>
<td>Lists the file system types that the kernel supports. Entries marked with <strong>nodev</strong> are not in use.</td>
</tr>
<tr>
<td>Virtual File or Directory</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>fs (directory)</td>
<td>Contains information about mounted file systems, organized by file system type.</td>
</tr>
<tr>
<td>interrupts</td>
<td>Records the number of interrupts per interrupt request queue (IRQ) for each CPU since system startup.</td>
</tr>
<tr>
<td>iomem</td>
<td>Lists the system memory map for each physical device.</td>
</tr>
<tr>
<td>ioports</td>
<td>Lists the range of I/O port addresses that the kernel uses with devices.</td>
</tr>
<tr>
<td>irq (directory)</td>
<td>Contains information about each IRQ. You can configure the affinity between each IRQ and the system CPUs.</td>
</tr>
<tr>
<td>kcore</td>
<td>Presents the system's physical memory in core file format that you can examine using a debugger such as crash or gdb. This file is not human-readable.</td>
</tr>
<tr>
<td>kmsg</td>
<td>Records kernel-generated messages, which are picked up by programs such as dmesg.</td>
</tr>
<tr>
<td>loadavg</td>
<td>Displays the system load averages (number of queued processes) for the past 1, 5, and 15 minutes, the number of running processes, the total number of processes, and the PID of the process that is running.</td>
</tr>
<tr>
<td>locks</td>
<td>Displays information about the file locks that the kernel is currently holding on behalf of processes. The information provided includes:</td>
</tr>
<tr>
<td></td>
<td>• lock class (FLOCK or POSIX)</td>
</tr>
<tr>
<td></td>
<td>• lock type (ADVISORY or MANDATORY)</td>
</tr>
<tr>
<td></td>
<td>• access type (READ or WRITE)</td>
</tr>
<tr>
<td></td>
<td>• process ID</td>
</tr>
<tr>
<td></td>
<td>• major device, minor device, and inode numbers</td>
</tr>
<tr>
<td></td>
<td>• bounds of the locked region</td>
</tr>
<tr>
<td>mdstat</td>
<td>Lists information about multiple-disk RAID devices.</td>
</tr>
<tr>
<td>meminfo</td>
<td>Reports the system's usage of memory in more detail than is available using the free or top commands.</td>
</tr>
<tr>
<td>modules</td>
<td>Displays information about the modules that are currently loaded into the kernel. The lsmod command formats and displays the same information, excluding the kernel memory offset of a module.</td>
</tr>
<tr>
<td>mounts</td>
<td>Lists information about all mounted file systems.</td>
</tr>
<tr>
<td>net (directory)</td>
<td>Provides information about networking protocol, parameters, and statistics. Each directory and virtual file describes aspects of the configuration of the system's network.</td>
</tr>
<tr>
<td>partitions</td>
<td>Lists the major and minor device numbers, number of blocks, and name of partitions mounted by the system.</td>
</tr>
<tr>
<td>scsi/device_info</td>
<td>Provides information about supported SCSI devices.</td>
</tr>
<tr>
<td>scsi/scsi</td>
<td>Provide information about configured SCSI devices, including vendor, model, channel, ID, and LUN data.</td>
</tr>
<tr>
<td>scsi/sg/*/</td>
<td></td>
</tr>
<tr>
<td>self</td>
<td>Symbolic link to the process that is examining /proc.</td>
</tr>
</tbody>
</table>
## Changing Kernel Parameters

<table>
<thead>
<tr>
<th>Virtual File or Directory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>slabinfo</td>
<td>Provides detailed information about slab memory usage.</td>
</tr>
<tr>
<td>softirqs</td>
<td>Displays information about software interrupts (softirqs). A softirq is similar to a hardware interrupt (hardirq) and allow the kernel to perform asynchronous processing that would take too long during a hardware interrupt.</td>
</tr>
<tr>
<td>stat</td>
<td>Records information about the system since it was started, including:</td>
</tr>
<tr>
<td></td>
<td>cpu</td>
</tr>
<tr>
<td></td>
<td>cpuN</td>
</tr>
<tr>
<td>swaps</td>
<td>Provides information on swap devices. The units of size and usage are kilobytes.</td>
</tr>
<tr>
<td>sys (directory)</td>
<td>Provides information about the system and also allows you to enable, disable, or modify kernel features. You can write new settings to any file that has write permission. See Section 4.2.2, “Changing Kernel Parameters”.</td>
</tr>
<tr>
<td></td>
<td>The following subdirectory hierarchies of /proc/sys contain virtual files, some of whose values you can usefully alter:</td>
</tr>
<tr>
<td></td>
<td>dev</td>
</tr>
<tr>
<td></td>
<td>fs</td>
</tr>
<tr>
<td></td>
<td>kernel</td>
</tr>
<tr>
<td></td>
<td>net</td>
</tr>
<tr>
<td>sysvipc (directory)</td>
<td>Provides information about the usage of System V Interprocess Communication (IPC) resources for messages (msg), semaphores (sem), and shared memory (shm).</td>
</tr>
<tr>
<td>tty (directory)</td>
<td>Provides information about the available and currently used terminal devices on the system. The drivers virtual file lists the devices that are currently configured.</td>
</tr>
<tr>
<td>vmstat</td>
<td>Provides information about virtual memory usage.</td>
</tr>
</tbody>
</table>

For more information, see the proc(5) manual page.

### 4.2.2 Changing Kernel Parameters

Some virtual files under /proc, and under /proc/sys in particular, are writable and you can use them to adjust settings in the kernel. For example, to change the host name, you can write a new value to /proc/sys/kernel/hostname:

```bash
# echo www.mydomain.com > /proc/sys/kernel/hostname
```

Other files take value that take binary or Boolean values. For example, the value of /proc/sys/net/ipv4/ip_forward determines whether the kernel forwards IPv4 network packets.
Changing Kernel Parameters

You can use the `sysctl` command to view or modify values under the `/proc/sys` directory.

```
# cat /proc/sys/net/ipv4/ip_forward
0
# echo 1 > /proc/sys/net/ipv4/ip_forward
# cat /proc/sys/net/ipv4/ip_forward
1
```

Note

Even `root` cannot bypass the file access permissions of virtual file entries under `/proc`. If you attempt to change the value of a read-only entry such as `/proc/partitions`, there is no kernel code to service the `write()` system call.

To display all of the current kernel settings:

```
# sysctl -a
kernel.sched_child_runs_first = 0
kernel.sched_min_granularity_ns = 2000000
kernel.sched_min_granularity_ns = 1000000
kernel.sched_max_granularity_ns = 2000000
kernel.sched_shares_ratelimit = 500000
...
```

Note

The delimiter character in the name of a setting is a period (.) rather than a slash (/) in a path relative to `/proc/sys`. For example, `net.ipv4.ip_forward` represents `net/ipv4/ip_forward` and `kernel.msgmax` represents `kernel/msgmax`.

To display an individual setting, specify its name as the argument to `sysctl`:

```
# sysctl net.ipv4.ip_forward
net.ipv4.ip_forward = 0
```

To change the value of a setting, use the following form of the command:

```
# sysctl -w net.ipv4.ip_forward=1
net.ipv4.ip_forward = 1
```

Changes that you make in this way remain in force only until the system is rebooted. To make configuration changes persist after the system is rebooted, you must add them to the `/etc/sysctl.d` directory as a configuration file. Any changes that you make to the files in this directory take effect when the system reboots or if you run the `sysctl --system` command, for example:

```
# echo 'net.ipv4.ip_forward=1' > /etc/sysctl.d/ip_forward.conf
# grep -r ip_forward /etc/sysctl.d
/etc/sysctl.d/ip_forward.conf:net.ipv4.ip_forward=1
# sysctl net.ipv4.ip_forward
net.ipv4.ip_forward = 0
# sysctl --system
* Applying /usr/lib/sysctl.d/00-system.conf ...
  net.bridge.bridge-nf-call-iptables = 0
  net.bridge.bridge-nf-call-arptables = 0
* Applying /usr/lib/sysctl.d/50-default.conf ...
  kernel.sysrq = 16
  kernel.core_uses_pid = 1
  net.ipv4.conf.default.rp_filter = 1
  net.ipv4.conf.all.rp_filter = 1
  net.ipv4.conf.default.accept_source_route = 0
```
Parameters that Control System Performance

For more information, see the `sysctl(8)` and `sysctl.d(5)` manual pages.

### 4.2.3 Parameters that Control System Performance

The following parameters control aspects of system performance:

- **`fs.file-max`**
  Specifies the maximum number of open files for all processes. Increase the value of this parameter if you see messages about running out of file handles.

- **`net.core.netdev_max_backlog`**
  Specifies the size of the receiver backlog queue, which is used if an interface receives packets faster than the kernel can process them. If this queue is too small, packets are lost at the receiver, rather than on the network.

- **`net.core.rmem_max`**
  Specifies the maximum read socket buffer size. To minimize network packet loss, this buffer must be large enough to handle incoming network packets.

- **`net.core.wmem_max`**
  Specifies the maximum write socket buffer size. To minimize network packet loss, this buffer must be large enough to handle outgoing network packets.

- **`net.ipv4/tcp_available_congestion_control`**
  Displays the TCP congestion avoidance algorithms that are available for use. Use the `modprobe` command if you need to load additional modules such as `tcp_wbit` to implement the `htcp` algorithm.

- **`net.ipv4.tcp_congestion_control`**
  Specifies which TCP congestion avoidance algorithm is used.

- **`net.ipv4/tcp_max_syn_backlog`**
  Specifies the number of outstanding `SYN` requests that are allowed. Increase the value of this parameter if you see `synflood` warnings in your logs, and investigation shows that they are occurring because the server is overloaded by legitimate connection attempts.

- **`net.ipv4.tcp_rmem`**
  Specifies minimum, default, and maximum receive buffer sizes that are used for a TCP socket. The maximum value cannot be larger than `net.core.rmem_max`.

- **`net.ipv4.tcp_wmem`**
  Specifies minimum, default, and maximum send buffer sizes that are used for a TCP socket. The maximum value cannot be larger than `net.core.wmem_max`.

- **`vm.swappiness`**
  Specifies how likely the kernel is to write loaded pages to swap rather than drop pages from the system page cache. When set to 0, swapping only occurs to avoid an out of memory condition. When set to 100, the kernel swaps aggressively. For a desktop system, setting a lower value
can improve system responsiveness by decreasing latency. The default value is 60.

Caution
This parameter is intended for use with laptops to reduce power consumption by the hard disk. Do not adjust this value on server systems.

4.2.4 Parameters that Control Kernel Panics

The following parameters control the circumstances under which a kernel panic can occur:

- **kernel.hung_task_panic** (UEK R3 only) If set to 1, the kernel panics if any kernel or user thread sleeps in the `TASK_UNINTERRUPTIBLE` state (*D state*) for more than `kernel.hung_task_timeout_secs` seconds. A process remains in *D state* while waiting for I/O to complete. You cannot kill or interrupt a process in this state.

  The default value is 0, which disables the panic.

  Tip
  To diagnose a hung thread, you can examine `/proc/PID/stack`, which displays the kernel stack for both kernel and user threads.

- **kernel.hung_task_timeout_secs** (UEK R3 only) Specifies how long a user or kernel thread can remain in *D state* before a warning message is generated or the kernel panics (if the value of `kernel.hung_task_panic` is 1). The default value is 120 seconds. A value of 0 disables the timeout.

- **kernel.nmi_watchdog** If set to 1 (default), enables the non-maskable interrupt (NMI) watchdog thread in the kernel. If you want to use the NMI switch or the OProfile system profiler to generate an undefined NMI, set the value of `kernel.nmi_watchdog` to 0.

- **kernel.panic** Specifies the number of seconds after a panic before a system will automatically reset itself.

  If the value is 0, the system hangs, which allows you to collect detailed information about the panic for troubleshooting. This is the default value.

  To enable automatic reset, set a non-zero value. If you require a memory image (`vmcore`), allow enough time for Kdump to create this image. The suggested value is 30 seconds, although large systems will require a longer time.

- **kernel.panic_on_io_nmi** If set to 0 (default), the system tries to continue operations if the kernel detects an I/O channel check (IOCHK) NMI that usually indicates an uncorrectable hardware error. If set to 1, the system panics.

- **kernel.panic_on_oops** If set to 0, the system tries to continue operations if the kernel encounters an oops or BUG condition. If set to 1 (default), the system delays a few seconds to give the kernel log daemon, `klogd`, time to record the oops output before the panic occurs.
In an OCFS2 cluster, set the value to 1 to specify that a system must panic if a kernel oops occurs. If a kernel thread required for cluster operation crashes, the system must reset itself. Otherwise, another node might not be able to tell whether a node is slow to respond or unable to respond, causing cluster operations to hang.

**kernel.panic_on_stackoverflow** (RHCK only) If set to 0 (default), the system tries to continue operations if the kernel detects an overflow in a kernel stack. If set to 1, the system panics.

**kernel.panic_on_unrecovered_nmi** If set to 0 (default), the system tries to continue operations if the kernel detects an NMI that usually indicates an uncorrectable parity or ECC memory error. If set to 1, the system panics.

**kernel.softlockup_panic** If set to 0 (default), the system tries to continue operations if the kernel detects a soft-lockup error that causes the NMI watchdog thread to fail to update its time stamp for more than twice the value of kernel.watchdog_thresh seconds. If set to 1, the system panics.

**kernel.unknown_nmi_panic** If set to 1, the system panics if the kernel detects an undefined NMI. You would usually generate an undefined NMI by manually pressing an NMI switch. As the NMI watchdog thread also uses the undefined NMI, set the value of kernel.unknown_nmi_panic to 0 if you set kernel.nmi_watchdog to 1.

**kernel.watchdog_thresh** Specifies the interval between generating an NMI performance monitoring interrupt that the kernel uses to check for hard-lockup and soft-lockup errors. A hard-lockup error is assumed if a CPU is unresponsive to the interrupt for more than kernel.watchdog_thresh seconds. The default value is 10 seconds. A value of 0 disables the detection of lockup errors.

**vm.panic_on_oom** If set to 0 (default), the kernel’s OOM-killer scans through the entire task list and attempts to kill a memory-hogging process to avoid a panic. If set to 1, the kernel panics but can survive under certain conditions. If a process limits allocations to certain nodes by using memory policies or cpusets, and those nodes reach memory exhaustion status, the OOM-killer can kill one process. No panic occurs in this case because other nodes' memory might be free and the system as a whole might not yet be out of memory. If set to 2, the kernel always panics when an OOM condition occurs. Settings of 1 and 2 are for intended for use with clusters, depending on your preferred failover policy.

### 4.3 About the /sys Virtual File System

In addition to /proc, the kernel exports information to the /sys virtual file system (sysfs). Programs such as the dynamic device manager, udev, use /sys to access device and device driver information. The implementation of /sys has helped to tidy up the /proc file system as most hardware information has been moved to /sys.

**Note**

/sys exposes kernel data structures and control points, which implies that it might contain circular references, where a directory links to an ancestor directory. As a result, a find command used on /sys might never terminate.
4.3.1 Virtual Directories Under /sys

The following table lists useful virtual directories under the /sys directory hierarchy.

<table>
<thead>
<tr>
<th>Virtual Directory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>block</td>
<td>Contains subdirectories for block devices. For example: /sys/block/sda.</td>
</tr>
<tr>
<td>bus</td>
<td>Contains subdirectories for each supported physical bus type, such as pci, pcmcia, scsi, or usb. Under each bus type, the devices directory lists discovered devices, and the drivers directory contains directories for each device driver.</td>
</tr>
<tr>
<td>class</td>
<td>Contains subdirectories for every class of device that is registered with the kernel.</td>
</tr>
<tr>
<td>devices</td>
<td>Contains the global device hierarchy of all devices on the system. The platform directory contains peripheral devices such as device controllers that are specific to a particular platform. The system directory contains non-peripheral devices such as CPUs and APICs. The virtual directory contains virtual and pseudo devices. See Chapter 6, Device Management.</td>
</tr>
<tr>
<td>firmware</td>
<td>Contains subdirectories for firmware objects.</td>
</tr>
<tr>
<td>module</td>
<td>Contains subdirectories for each module loaded into the kernel. You can alter some parameter values for loaded modules. See Section 5.4, “About Module Parameters”.</td>
</tr>
<tr>
<td>power</td>
<td>Contains attributes that control the system's power state.</td>
</tr>
</tbody>
</table>

For more information, see https://www.kernel.org/doc/Documentation/filesystems/sysfs.txt.

4.4 System Date and Time Settings

System time is based on the POSIX time standard, where time is measured as the number of seconds that have elapsed since 00:00:00 Coordinated Universal Time (UTC), Thursday, 1 January 1970. A day is defined as 86400 seconds and leap seconds are subtracted automatically.

Date and time representation on a system can be set to match a specific timezone. To list all of the available timezones, run:

```
# timedatectl list-timezones
```

To set the system timezone to match a value returned from the available timezones, you can run:

```
# timedatectl set-timezone America/Los_Angeles
```

Substitute America/Los_Angeles with a valid timezone entry.

This command sets a symbolic link from /etc/localtime to point to the appropriate zone information file in /usr/share/zoneinfo/. The setting takes effect immediately. Some long running processes that might use /etc/localtime to detect the current system timezone, may not detect a subsequent change in system timezone until the process is restarted.

Note that timezones are largely used for display purposes or to handle user input. Changing timezone does not change the time for the system clock. You can change the presentation for system time in any console by setting the TZ environment variable. For example, to see the current time in Tokyo, you can run:
You can check your system’s current date and time configuration by running the `timedatectl` command on its own:

```
# timedatectl
Local time: Thu 2018-10-25 13:11:30 BST
Universal time: Thu 2018-10-25 12:11:30 UTC
RTC time: Thu 2018-10-25 12:11:17
Time zone: Europe/London (BST, +0100)
NTP enabled: yes
NTP synchronized: yes
RTC in local TZ: no
DST active: yes
Last DST change: DST began at
    Sun 2018-03-25 00:59:59 GMT
    Sun 2018-03-25 02:00:00 BST
Next DST change: DST ends (the clock jumps one hour backwards) at
    Sun 2018-10-28 01:59:59 GMT
    Sun 2018-10-28 01:00:00 GMT
```

To set system time manually, you can use the `timedatectl set-time` command. For example, you can run:

```
# timedatectl set-time "2018-10-28 01:59:59"
```

This command sets the current system time based on the time specified assuming the currently set system timezone. The command also updates the system Real Time Clock (RTC).

Consider configuring your system to use network time synchronization for accurate time-keeping. This can be particularly important when setting up high-availability or when using network-based file systems. See Chapter 13, Network Time Configuration for more information on configuring network time services that use NTP. If you configure an NTP service, enable NTP by running:

```
# timedatectl set-ntp true
```

This command enables and starts the `chronyd` service, if available.
Chapter 5 Kernel Modules

Table of Contents

5.1 About Kernel Modules ........................................................................................................................................................................... 49
5.2 Listing Information about Loaded Modules ........................................................................................................................................ 49
5.3 Loading and Unloading Modules ......................................................................................................................................................... 50
5.4 About Module Parameters ................................................................................................................................................................... 51
5.5 Specifying Modules to be Loaded at Boot Time ................................................................................................................................ 52
5.6 Weak Update Modules ...................................................................................................................................................................... 52

This chapter describes how to load, unload, and modify the behavior of kernel modules.

5.1 About Kernel Modules

The boot loader loads the kernel into memory. You can add new code to the kernel by including the source files in the kernel source tree and recompiling the kernel. Kernel modules, which can be dynamically loaded and unloaded on demand, provide device drivers that allow the kernel to access new hardware, support different file system types, and extend its functionality in other ways. To avoid wasting memory on unused device drivers, Oracle Linux supports loadable kernel modules (LKMs), which allow a system to run with only the device drivers and kernel code that it requires loaded into memory.

5.2 Listing Information about Loaded Modules

Use the `lsmod` command to list the modules that are currently loaded into the kernel.

```
# lsmod
Module                  Size  Used by
nls_utf8                1405  1
fuse                   59164  0
tun                    12079  0
autofs4                22739  3
...
ppdev                   7901  0
parport_pc             21262  0
parport                33812  2 ppdev,parport_pc
...
```

Note

This command produces its output by reading the `/proc/modules` file.

The output shows the module name, the amount of memory it uses, the number of processes using the module and the names of other modules on which it depends. In the sample output, the module `parport` depends on the modules `ppdev` and `parport_pc`, which are loaded in advance of `parport`. Two processes are currently using all three modules.

To display detailed information about a module, use the `modinfo` command, for example:

```
# modinfo ahci
filename:       /lib/modules/2.6.32-300.27.1.el6uek.x86_64/kernel/drivers/ata/ahci.ko
version:        3.0
license:        GPL
description:    AHCI SATA low-level driver
author:         Jeff Garzik
```
The output includes the following information:

- **filename**: Absolute path of the kernel object file.
- **version**: Version number of the module.
- **description**: Short description of the module.
- **srcversion**: Hash of the source code used to create the module.
- **alias**: Internal alias names for the module.
- **depends**: Comma-separated list of any modules on which this module depends.
- **vermagic**: Kernel version that was used to compile the module, which is checked against the current kernel when the module is loaded.
- **parm**: Module parameters and descriptions.

Modules are loaded into the kernel from kernel object (.ko) files in the `/lib/modules/kernel_version/kernel` directory. To display the absolute path of a kernel object file, specify the `-n` option, for example:

```
# modinfo -n parport
/lib/modules/2.6.32-300.27.1.el6uek.x86_64/kernel/drivers/parport/parport.ko
```

For more information, see the `lsmod(5)` and `modinfo(8)` manual pages.

## 5.3 Loading and Unloading Modules

The `modprobe` command loads kernel modules, for example:

```
# modprobe nfs
# lsmod | grep nfs
nfs   266415   0
lockd  66530   1  nfs
fscache 41704   1  nfs
nfs_acl 2477   1  nfs
auth_rpcgss 38976   1  nfs
sunrpc 204268   5  nfs,lockd,nfs_acl,auth_rpcgss
```

Use the `-v` verbose option to show if any additional modules are loaded to resolve dependencies.

```
# modprobe -v nfs
insmod /lib/modules/2.6.32-300.27.1.el6uek.x86_64/kernel/net/sunrpc/auth_gss/auth_rpcgss.ko
insmod /lib/modules/2.6.32-300.27.1.el6uek.x86_64/kernel/fs/nfs_common/nfs_acl.ko
insmod /lib/modules/2.6.32-300.27.1.el6uek.x86_64/kernel/fs/fscache/fscache.ko
...
```

To determine the dependencies, the `modprobe` command queries the `/lib/modules/kernel_version/modules.dep` file, which the `depmod` utility creates when you install kernel modules.
Note
modprobe does not reload modules that are already loaded. You must first unload a module before you can load it again.

Use the \texttt{-r} option to unload kernel modules, for example:

\begin{verbatim}
# modprobe -rv nfs
rmmod /lib/modules/2.6.32-300.27.1.el6uek.x86_64/kernel/fs/nfs/nfs.ko
rmmod /lib/modules/2.6.32-300.27.1.el6uek.x86_64/kernel/fs/lockd/lockd.ko
rmmod /lib/modules/2.6.32-300.27.1.el6uek.x86_64/kernel/fs/fscache/fscache.ko
...
\end{verbatim}

Modules are unloaded in the reverse order that they were loaded. Modules are not unloaded if a process or another loaded module requires them.

\begin{tightitemize}
\item Note
modprobe uses the \texttt{insmod} and \texttt{rmmod} utilities to load and unload modules. As \texttt{insmod} and \texttt{rmmod} do not resolve module dependencies, do not use these utilities.
\end{tightitemize}

For more information, see the \texttt{modprobe(8)} and \texttt{modules.dep(5)} manual pages.

5.4 About Module Parameters

Modules accept parameters that you can specify using \texttt{modprobe} to modify a module's behavior:

\begin{verbatim}
# modprobe module_name parameter=value ...
\end{verbatim}

Use spaces to separate multiple parameter/value pairs. Array values are represented by a comma-separated list, for example:

\begin{verbatim}
# modprobe foo arrayparm=1,2,3,4
\end{verbatim}

You can also change the values of some parameters for loaded modules and built-in drivers by writing the new value to a file under \texttt{/sys/module/module_name/parameters}, for example:

\begin{verbatim}
# echo 0 > /sys/module/ahci/parameters/skip_host_reset
\end{verbatim}

The \texttt{/etc/modprobe.d} directory contains \texttt{.conf} configuration files specify module options, create module aliases, and override the usual behavior of \texttt{modprobe} for modules with special requirements. The \texttt{/etc/modprobe.conf} file that was used with earlier versions of \texttt{modprobe} is also valid if it exists. Entries in the \texttt{/etc/modprobe.conf} and \texttt{/etc/modprobe.d/* .conf} files use the same syntax.

The following are commonly used commands in \texttt{modprobe} configuration files:

\begin{description}
\item[alias] Creates an alternate name for a module. The alias can include shell wildcards. For example, create an alias for the \texttt{sd-mod} module:

\begin{verbatim}
alias block-major-8-* sd_mod
\end{verbatim}

As a result, a command such as \texttt{modprobe block-major-8-0} has the same effect as \texttt{modprobe sd_mod}.

\item[blacklist] Ignore a module's internal alias that is displayed by the \texttt{modinfo} command. This command is typically used if the associated hardware is not required, if two or more modules both support the same devices, or if a module invalidly claims to support a device. For example, blacklist the alias for the frame-buffer driver \texttt{cirrusfb}:
Specifying Modules to be Loaded at Boot Time

blacklist cirrusfb

The `/etc/modprobe.d/blacklist.conf` file prevents hotplug scripts from loading a module, usually so that a different driver binds the module instead, regardless of which driver happens to be probed first.

install

Runs a shell command instead of loading a module into the kernel. For example, load the module `snd-emu10k1-synth` instead of `snd-emu10k1`:

```
install snd-emu10k1 /sbin/modprobe --ignore-install snd-emu10k1 && \\
/sbin/modprobe snd-emu10k1-synth
```

options

Defines options for a module. For example, define the `nohwcrypt` and `qos` options for the `b43` module:

```
options b43 nohwcrypt=1 qos=0
```

remove

Runs a shell command instead of unloading a module. For example, unmount `/proc/fs/nfsd` before unloading the `nfsd` module:

```
remove nfsd { /bin/umount /proc/fs/nfsd > /dev/null 2>&1 || ; ; } ; \\
/sbin/modprobe -r --first-time --ignore-remove nfsd
```

For more information, see the `modprobe.conf(5)` manual page.

5.5 Specifying Modules to be Loaded at Boot Time

The system loads most modules automatically at boot time. If necessary, you can specify an additional module that should be loaded.

To specify a module to be loaded at boot time:

1. Create a file in the `/etc/sysconfig/modules` directory. The file name must have the extension `.modules`, for example `foo.modules`.

2. Edit the file to create the script that loads the module.

   The script to load a module can be a simple `modprobe` call, for example:

   ```
   #!/bin/sh
   modprobe foo
   ```

   or more complex to include error handling:

   ```
   #!/bin/sh
   if [ ! -c /dev/foo ] ; then
     exec /sbin/modprobe foo > /dev/null 2>&1
   fi
   ```

3. Use the following command to make the script executable:

   ```
   chmod 755 /etc/sysconfig/modules/foo.modules
   ```

5.6 Weak Update Modules

External modules, such as drivers installed using a driver update disk, are usually installed into `/lib/modules/kernel-version/extra`. Modules stored in this directory are given preference over matching
modules included with the kernel, itself, when you attempt to load them. This means that external drivers and modules can be installed to override kernel modules where hardware issues may need resolution. For each subsequent kernel update, it is important that the external module is made available to each compatible kernel to avoid potential boot issues resulting from driver incompatibilities with the affected hardware.

Since the requirement to load the external module with each compatible kernel update is system critical, a mechanism is in place so that external modules can be loaded as weak update modules for compatible kernels. Weak update modules are made available by creating symbolic links to compatible modules in the `/lib/modules/kernel-version/weak-updates` directory. The package manager handles this process automatically when it detects driver modules installed in any `/lib/modules/kernel-version/extra` directories for compatible kernels. For example, installation of the `kmod-megaraid_sas-uek` driver update package on the Driver Update Disk for the Oracle Linux 7 update 4 release may install:

```
/lib/modules/4.1.12-61.1.18.el7uek.x86_64/extra/megaraid_sas
/lib/modules/4.1.12-61.1.18.el7uek.x86_64/extra/megaraid_sas/megaraid_sas.ko
```

The new driver module is installed into the `extra` directory for the `4.1.12-61.1.18.el7uek.x86_64`, which was the kernel version that was originally used to build the module.

A subsequent kernel update means that the system is now running the `4.1.12-112.14.13.el7uek.x86_64` version of the kernel. This kernel is compatible with the module installed for the previous kernel, so the external module is automatically added, as a symbolic link, in the `weak-updates` directory as part of the installation process:

```
# ls -l /lib/modules/4.1.12-112.14.13.el7uek.x86_64/weak-updates/megaraid_sas/*.ko
lrwxrwxrwx. 1 root root 76 Jan 30 04:52 /lib/modules/4.1.12-112.14.13.el7uek.x86_64/weak-updates/megaraid_sas/megaraid_sas.ko -> /lib/modules/4.1.12-61.1.18.el7uek.x86_64/extra/megaraid_sas/megaraid_sas.ko
```

This means that the external module is loaded for subsequent kernel updates.

In most cases, weak updates make sense and ensure that no extra work must be done to carry an external module through subsequent kernel updates. This prevents possible driver related boot issues after kernel upgrades and maintains the predictable running of a system and its hardware.

In some cases you may wish to remove weak update modules for a newer kernel. For instance, if an issue has been resolved for a driver that is shipped in the newer kernel and you would prefer to use this driver over the external module that you installed as part of a driver update.

You can remove weak update modules by removing the symbolic links for each kernel, manually. For example:

```
# rm -rf /lib/modules/4.1.12-112.14.13.el7uek.x86_64/weak-updates/megaraid_sas/
```

For more information about external driver modules and driver update disks, see Oracle Linux 7 Installation Guide at:

https://docs.oracle.com/cd/E52668_01/E54695/html/ol7-install-dud.html
Chapter 6 Device Management

Table of Contents

6.1 About Device Files ................................................................. 55
6.2 About the Udev Device Manager .................................................. 57
6.3 About Udev Rules ...................................................................... 57
6.4 Querying Udev and Sysfs ............................................................. 60
6.5 Modifying Udev Rules ................................................................. 63

This chapter describes how the system uses device files and how the udev device manager dynamically creates or removes device node files.

6.1 About Device Files

The /dev directory contains device files (also sometimes known as device special files and device nodes) that provide access to peripheral devices such as hard disks, to resources on peripheral devices such as disk partitions, and pseudo devices such as a random number generator.

The /dev directory has several subdirectory hierarchies, each of which holds device files that relate to a certain type of device. For example, the /dev/disk/id-by-uuid directory contains device files for hard disks named according to the universally unique identifier (UUID) for the disk. The device files in subdirectories such as these are actually implemented as symbolic links to device files in /dev. You can access the same device using the file in /dev or the corresponding link to the file listed in /dev/disk/id-by-uuid.

If you use the ls -l command to list the files under /dev, you see that some device files are shown as being either type b for block or type c for character. These devices have a pair of numbers associated with them instead of a file size. These major and minor numbers identify the device to the system.

```bash
# ls -l /dev
total 0
crw-rw----. 1 root root 10, 56 Mar 17 08:17 autofs
drwxr-xr-x. 2 root root 640 Mar 17 08:17 block
drwxr-xr-x. 2 root root 80 Mar 17 08:16 bsg
drwxr-xr-x. 3 root root 60 Mar 17 08:16 bus
lrwxrwxrwx. 1 root root 3 Mar 17 08:17 cdrom -> sr0
drwxr-xr-x. 2 root root 2880 Mar 17 08:17 char
cr--------. 1 root root 5, 1 Mar 17 08:17 console
lrwxrwxrwx. 1 root root 11 Mar 17 08:17 core -> /proc/kcore
drwxr-xr-x. 4 root root 100 Mar 17 08:17 cpu
crw-rw----. 1 root root 10, 61 Mar 17 08:17 cpu_dma_latency
drwxr-xr-x. 6 root root 120 Mar 17 08:16 disk
brw-rw----. 1 root disk 253, 0 Mar 17 08:17 dm-0
brw-rw----. 1 root disk 253, 1 Mar 17 08:17 dm-1
... crw-rw-rw-. 1 root root 1, 3 Mar 17 08:17 /dev/null
... drwxr-xr-x. 2 root root 0 Mar 17 08:16 pts
... crw-rw-rw-. 1 root root 1, 8 Mar 17 08:17 random
... brw-rw----. 1 root disk 8, 0 Mar 17 08:17 sda
brw-rw----. 1 root disk 8, 1 Mar 17 08:17 sda1
brw-rw----. 1 root disk 8, 2 Mar 17 08:17 sda2
... lrwxrwxrwx. 1 root root 15 Mar 17 08:17 stderr -> /proc/self/fd/2
lrwxrwxrwx. 1 root root 15 Mar 17 08:17 stdin -> /proc/self/fd/0
```
Block devices support random access to data, seeking media for data, and usually allow data to be buffered while it is being written or read. Examples of block devices include hard disks, CD-ROM drives, flash memory, and other addressable memory devices. The kernel writes data to or reads data from a block device in blocks of a certain number of bytes. In the sample output, \texttt{sda} is the block device file that corresponds to the hard disk, and it has a major number of 8 and a minor number of 0. \texttt{sda1} and \texttt{sda2} are partitions of this disk, and they have the same major number as \texttt{sda} (8), but their minor numbers are 1 and 2.

Character devices support streaming of data to or from a device, and data is not usually buffered nor is random access permitted to data on a device. The kernel writes data to or reads data from a character device one byte at a time. Examples of character devices include keyboards, mice, terminals, pseudo-terminals, and tape drives. \texttt{tty0} and \texttt{tty1} are character device files that correspond to terminal devices that allow users to log in from serial terminals or terminal emulators. These files have major number 4 and minor numbers 0 and 1.

Pseudo-terminals slave devices emulate real terminal devices to interact with software. For example, a user might log in on a terminal device such as \texttt{/dev/tty1}, which then uses the pseudo-terminal master device \texttt{/dev/pts/ptmx} to interact with an underlying pseudo-terminal device. The character device files for pseudo-terminal slaves and master are located in the \texttt{/dev/pts} directory:

```
# ls -l /dev/pts
total 0
lrwx------. 1 guest tty  136, 0 Mar 17 10:11 0
lrwx------. 1 guest tty  136, 1 Mar 17 10:53 1
c---------. 1 root  root   5, 2 Mar 17 08:16 ptmx
```

Some device entries, such as \texttt{stdin} for the standard input, are symbolically linked via the \texttt{self} subdirectory of the \texttt{proc} file system. The pseudo-terminal device file to which they actually point depends on the context of the process.

```
# ls -l /proc/self/fd/[012]
total 0
lrwx-------. 1 root root  64 Mar 17 10:02 0 -> /dev/pts/1
lrwx-------. 1 root root  64 Mar 17 10:02 1 -> /dev/pts/1
lrwx-------. 1 root root  64 Mar 17 10:02 2 -> /dev/pts/1
```

Character devices such as \texttt{null}, \texttt{random}, \texttt{urandom}, and \texttt{zero} are examples of pseudo-devices that provide access to virtual functionality implemented in software rather than to physical hardware.

\texttt{/dev/null} is a data sink. Data that you write to \texttt{/dev/null} effectively disappears but the write operation succeeds. Reading from \texttt{/dev/null} returns \texttt{EOF} (end-of-file).

\texttt{/dev/zero} is a data source of an unlimited number of zero-value bytes.

\texttt{/dev/random} and \texttt{/dev/urandom} are data sources of streams of pseudo-random bytes. To maintain high-entropy output, \texttt{/dev/random} blocks if its entropy pool does not contain sufficient bits of noise. \texttt{/dev/urandom} does not block and, as a result, the entropy of its output might not be as consistently high as that of \texttt{/dev/random}. However, neither \texttt{/dev/random} nor \texttt{/dev/urandom} are considered to be truly random enough for the purposes of secure cryptography such as military-grade encryption.
6.2 About the Udev Device Manager

The udev device manager dynamically creates or removes device node files at boot time or if you add a device to or remove a device from the system with a 2.6 version kernel or later. When creating a device node, udev reads the device’s /sys directory for attributes such as the label, serial number, and bus device number.

Udev can use persistent device names to guarantee consistent naming of devices across reboots, regardless of their order of discovery. Persistent device names are especially important when using external storage devices.

The configuration file for udev is /etc/udev/udev.conf, in which you can define the following variables:

- **udev_log**: The logging priority, which can be set to err, info and debug. The default value is err.
- **udev_root**: Specifies the location of the device nodes. The default value is /dev.

For more information, see the udev(7) manual page.

6.3 About Udev Rules

Udev uses rules files that determine how it identifies devices and creates device names. The udev service (systemd-udevd) reads the rules files at system startup and stores the rules in memory. If the kernel discovers a new device or an existing device goes offline, the kernel sends an event action (uevent) notification to udev, which matches the in-memory rules against the device attributes in /sys to identify the device. As part of device event handling, rules can specify additional programs that should run to configure a device. Rules files, which have the file extension .rules, are located in the following directories:

- **/lib/udev/rules.d**: Contains default rules files. Do not edit these files.
- **/etc/udev/rules.d/**: Contains customized rules files. You can modify these files.
- **/dev/.udev/rules.d/**: Contains temporary rules files. Do not edit these files.

Udev processes the rules files in lexical order, regardless of which directory they are located. Rules files in /etc/udev/rules.d override files of the same name in /lib/udev/rules.d.

The following rules are extracted from the file /lib/udev/rules.d/50-udev-default.rules and illustrate the syntax of udev rules.

```bash
# do not edit this file, it will be overwritten on update
SUBSYSTEM=="block", SYMLINK{unique}+="block/%M:%m"
SUBSYSTEM!="block", SYMLINK{unique}+="char/%M:%m"
KERNEL="pty[pqrstuvwxyzabcdef][0123456789abcdef]", GROUP="tty", MODE="0660"
```
About Udev Rules

KERNEL=="tty[pqrstuvwxyzabcdef][0123456789abcdef]", GROUP="tty", MODE="0660"
...

# mem
KERNEL=="null|zero|full|random|urandom", MODE="0666"
KERNEL=="mem|kmem|port|nvram", GROUP="kmem", MODE="0640"
...

# block
SUBSYSTEM=="block", GROUP="disk"
...

# network
KERNEL=="tun", MODE="0666"
KERNEL=="rfkill", MODE="0644"

# CPU
KERNEL=="cpu[0-9]++", MODE="0444"
...

# do not delete static device nodes
ACTION=="remove", NAME=="", TEST=="/lib/udev/devices/%k", 
  OPTIONS+="ignore_remove"
ACTION=="remove", NAME=="?*", TEST=="/lib/udev/devices/$name", 
  OPTIONS+="ignore_remove"

Comment lines begin with a # character. All other non-blank lines define a rule, which is a list of one or more comma-separated key-value pairs. A rule either assigns a value to a key or it tries to find a match for a key by comparing its current value with the specified value. The following table shows the assignment and comparison operators that you can use.

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>=</td>
<td>Assign a value to a key, overwriting any previous value.</td>
</tr>
<tr>
<td>+=</td>
<td>Assign a value by appending it to the key's current list of values.</td>
</tr>
<tr>
<td>:</td>
<td>Assign a value to a key. This value cannot be changed by any further rules.</td>
</tr>
<tr>
<td>==</td>
<td>Match the key's current value against the specified value for equality.</td>
</tr>
<tr>
<td>!=</td>
<td>Match the key's current value against the specified value for equality.</td>
</tr>
</tbody>
</table>

You can use the following shell-style pattern matching characters in values.

<table>
<thead>
<tr>
<th>Character</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>?</td>
<td>Matches a single character.</td>
</tr>
<tr>
<td>*</td>
<td>Matches any number of characters, including zero.</td>
</tr>
<tr>
<td>[]</td>
<td>Matches any single character or character from a range of characters specified within the brackets. For example, tty[sS][0-9] would match ttys7 or ttyS7.</td>
</tr>
</tbody>
</table>

The following table lists commonly used match keys in rules.

<table>
<thead>
<tr>
<th>Match Key</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACTION</td>
<td>Matches the name of the action that led to an event. For example, ACTION=&quot;add&quot; or ACTION=&quot;remove&quot;.</td>
</tr>
<tr>
<td>ENV{key}</td>
<td>Matches a value for the device property key. For example, ENV{DEVTYPE}&quot;disk&quot;.</td>
</tr>
<tr>
<td>KERNEL</td>
<td>Matches the name of the device that is affected by an event. For example, KERNEL=&quot;dm-*&quot; for disk media.</td>
</tr>
<tr>
<td>NAME</td>
<td>Matches the name of a device file or network interface. For example, NAME=&quot;?*&quot; for any name that consists of one or more characters.</td>
</tr>
</tbody>
</table>
About Udev Rules

Match Key | Description
---|---
SUBSYSTEM | Matches the subsystem of the device that is affected by an event. For example, `SUBSYSTEM=="tty"`.

TEST | Tests if the specified file or path exists. For example, `TEST=="/lib/udev/devices/$name"`, where `$name` is the name of the currently matched device file.

Other match keys include `ATTR{filename}`, `ATTRS{filename}`, `DEVPATH`, `DRIVER`, `DRIVERS`, `KERNELS`, `PROGRAM`, `RESULT`, `SUBSYSTEMS`, and `SYMLINK`.

The following table lists commonly used assignment keys in rules.

<table>
<thead>
<tr>
<th>Assignment Key</th>
<th>Description</th>
</tr>
</thead>
</table>
| ENV{key} | Specifies a value for the device property `key`. For example, `GROUP="disk"`.
| GROUP | Specifies the group for a device file. For example, `GROUP="disk"`.
| IMPORT{type} | Specifies a set of variables for the device property, depending on `type`:
  | `cmdline` | Import a single property from the boot kernel command line. For simple flags, udev sets the value of the property to 1. For example, `IMPORT{cmdline}="nodmraid"`.
  | `db` | Interpret the specified value as an index into the device database and import a single property, which must have already been set by an earlier event. For example, `IMPORT{db}="DM_UDEV_LOW_PRIORITY_FLAG"`.
  | `file` | Interpret the specified value as the name of a text file and import its contents, which must be in environmental key format. For example, `IMPORT{file}="keyfile"`.
  | `parent` | Interpret the specified value as a key-name filter and import the stored keys from the database entry for the parent device. For example `IMPORT{parent}="ID_*"`.
  | `program` | Run the specified value as an external program and imports its result, which must be in environmental key format. For example `IMPORT{program}="usb_id --export %p"`.
| MODE | Specifies the permissions for a device file. For example, `MODE="0640"`.
| NAME | Specifies the name of a device file. For example, `NAME="em1"`.
| OPTIONS | Specifies rule and device options. For example, `OPTIONS+="ignore_remove"`, which means that the device file is not removed if the device is removed.
| OWNER | Specifies the owner for a device file. For example, `GROUP="root"`.
| RUN | Specifies a command to be run after the device file has been created. For example, `RUN="/usr/bin/eject $kernel"`, where `$kernel` is the kernel name of the device.
| SYMLINK | Specifies the name of a symbolic link to a device file. For example, `SYMLINK+="disk/by-uuid/$env{ID_FS_UUID_ENC}"`, where `$env{}` is substituted with the specified device property.

Other assignment keys include `ATTR{key}`, `GOTO`, `LABEL`, `RUN`, and `WAIT_FOR`.

The following table shows string substitutions that are commonly used with the `GROUP`, `MODE`, `NAME`, `OWNER`, `PROGRAM`, `RUN`, and `SYMLINK` keys.
### String Substitution

<table>
<thead>
<tr>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specifies the value of a device attribute from a file under <code>/sys</code>. For example, <code>ENV{MATCHADDR}=&quot;$attr{address}&quot;</code>.</td>
<td><code>$attr{file}</code> or <code>%s{file}</code></td>
</tr>
<tr>
<td>The device path of the device in the <code>sysfs</code> file system under <code>/sys</code>. For example, <code>RUN=&quot;keyboard-force-release.sh $devpath common-volume-keys&quot;</code>.</td>
<td><code>$devpath</code> or <code>%p</code></td>
</tr>
<tr>
<td>Specifies the value of a device property. For example, <code>SYMLINK=&quot;disk/by-id/md-name-$env{MD_NAME}-part%n&quot;</code>.</td>
<td><code>$env(key)</code> or <code>%E(key)</code></td>
</tr>
<tr>
<td>The kernel name for the device.</td>
<td><code>$kernel</code> or <code>%k</code></td>
</tr>
<tr>
<td>Specifies the major number of a device. For example, <code>IMPORT{program}=&quot;udisks-dm-export %M %m&quot;</code>.</td>
<td><code>$major</code> or <code>%M</code></td>
</tr>
<tr>
<td>Specifies the minor number of a device. For example, <code>RUN=&quot;$env{LVM_SBIN_PATH}/lvm pvscan --cache --major $major --minor $minor&quot;</code>.</td>
<td><code>$minor</code> or <code>%m</code></td>
</tr>
<tr>
<td>Specifies the device file of the current device. For example, <code>TEST=&quot;/lib/udev/devices/$name&quot;</code>.</td>
<td><code>$name</code></td>
</tr>
</tbody>
</table>

Udev expands the strings specified for `RUN` immediately before its program is executed, which is after udev has finished processing all other rules for the device. For the other keys, udev expands the strings while it is processing the rules.

For more information, see the `udev(7)` manual page.

### 6.4 Querying Udev and Sysfs

You can use the `udevadm` command to query the udev database and `sysfs`.

For example, to query the `sysfs` device path relative to `/sys` that corresponds to the device file `/dev/sda`:

```sh
# udevadm info --query=path --name=/dev/sda
/devices/pci0000:00/0000:00:0d.0/host0/target0:0:0:0/0:0:0:0/block/sda
```

To query the symbolic links that point to `/dev/sda`:

```sh
# udevadm info --query=symlink --name=/dev/sda
devclass: block
block/8:0
disk/by-id/ata-VBOX_HARDDISK_VB6ad0115d-356e4c09
disk/by-id/scsi-SATA_VBOX_HARDDISK_VB6ad0115d-356e4c09
disk/by-path/pci-0000:00:0d.0-scsi-0:0:0:0
```

The paths are relative to `udev_root` (by default, `/dev`).

To query the properties of `/dev/sda`:

```sh
# udevadm info --query=property --name=/dev/sda
UDEV_LOG=3
DEVPATH="/lib/udev/devices/pci0000:00/0000:00:0d.0/host0/target0:0:0/0:0:0:0/block/sda"
MAJOR=8
MINOR=0
```
To query all information for `/dev/sda`:

```bash
# udevadm info --query=all --name=/dev/sda
```

```bash
P: /devices/pci0000:00/0000:00:0d.0/host0/target0:0:0/0:0:0:0/block/sda
N: sda
W: 37
S: block/8:0

  ATTRS{numa_node}=="-1"
```
The command starts at the device specified by its device path and walks up the chain of parent devices. For every device that it finds, it displays all possible attributes for the device and its parent devices in the match key format for udev rules.

For more information, see the `udevadm(8)` manual page.

### 6.5 Modifying Udev Rules

The order in which rules are evaluated is important. Udev processes rules in lexical order. If you want to add your own rules, you need udev to find and evaluate these rules before the default rules.

The following example illustrates how to implement a udev rules file that adds a symbolic link to the disk device `/dev/sdb`.

1. Create a rule file under `/etc/udev/rules.d` with a file name such as `10-local.rules` that udev will read before any other rules file.

   For example, the following rule in `10-local.rules` creates the symbolic link `/dev/my_disk`, which points to `/dev/sdb`:

   ```
   KERNEL=="sdb", ACTION=="add", SYMLINK="my_disk"
   ```

   Listing the device files in `/dev` shows that udev has not yet applied the rule:

   ```
   # ls /dev/sd* /dev/my_disk
   ls: cannot access /dev/my_disk: No such file or directory
   /dev/sda  /dev/sda1  /dev/sda2  /dev/sdb
   ```

2. To simulate how udev applies its rules to create a device, you can use the `udevadm test` command with the device path of `sdb` listed under the `/sys/class/block` hierarchy, for example:

   ```
   # udevadm test /sys/class/block/sdb
   calling: test
   version ...
   This program is for debugging only, it does not run any program
   specified by a RUN key. It may show incorrect results, because
   some values may be different, or not available at a simulation run.
   ...
   LINK 'my_disk' /etc/udev/rules.d/10-local.rules:1
   ...
   creating link '/dev/my_disk' to '/dev/sdb'
   creating symlink '/dev/my_disk' to 'sdb'
   ...
   ACTION=add
   DEVLINKS=/dev/disk/by-id/ata-VBOX_HARDDISK_VB186e4ce2-f80f170d
   /dev/disk/by-uuid/a7dc508d-5bcc-4112-b96e-f40b19e369fe
   /dev/my_disk
   ...
   ```

3. Restart the `systemd-udevd` service:

   ```
   # systemctl restart systemd-udevd
   ```
After udev processes the rules files, the symbolic link `/dev/my_disk` has been added:

```bash
# ls -F /dev/sd* /dev/my_disk
/dev/my_disk@ /dev/sda /dev/sda1 /dev/sda2 /dev/sdb
```

To undo the changes, remove `/etc/udev/rules.d/10-local.rules` and `/dev/my_disk` and run `systemctl restart systemd-udevd` again.
Chapter 7 Task Management

Table of Contents

7.1 About Automating Tasks ................................................................. 65
7.2 Configuring cron Jobs ................................................................... 65
  7.2.1 Controlling Access to Running cron Jobs ................................ 66
7.3 Configuring anacron Jobs ............................................................... 67
7.4 Running One-time Tasks ................................................................. 68
  7.4.1 Changing the Behavior of Batch Jobs ...................................... 68

This chapter describes how to configure the system to run tasks automatically within a specific period of time, at a specified time and date, or when the system is lightly loaded.

7.1 About Automating Tasks

You can use automated tasks to perform periodic backups, monitor the system, run custom scripts, and other administrative tasks.

The cron and anacron utilities allow you to schedule the execution of recurring tasks (jobs) according to a combination of the time, day of the month, month, day of the week, and week. cron allows you to schedule jobs to run as often as every minute. If the system is down when a job is scheduled, cron does not run the job when the system restarts. anacron allows you to schedule a system job to run only once per day. However, if a scheduled job has not been run, that job runs when the system restarts. anacron is mainly intended for use on laptop computers.

You do not usually need to run cron and anacron directly. The crond daemon executes scheduled tasks on behalf of cron and it starts anacron once every hour. crond looks in /etc/crontab or in files in /etc/cron.d for system cron job definitions, and /var/spool/cron for cron job definitions belonging to users. crond checks each job definition to see whether it should run in the current minute. If a job is scheduled for execution, crond runs it as the owner of the job definition file or, for system cron jobs, the user specified in the job definition (if any).

crond runs the 0anacron script in the /etc/cron.hourly directory as root once per hour according to the schedule in /etc/cron.d/0hourly. If anacron is not already running and the system is connected to mains and not battery power, crond starts anacron.

anacron runs the scripts in the /etc/cron.daily, /etc/cron.weekly, and /etc/cron.monthly directories as root once per day, week or month, according to the job definitions that are scheduled in /etc/anacrontab.

7.2 Configuring cron Jobs

System cron jobs are defined in crontab-format files in /etc/crontab or in files in /etc/cron.d. A crontab file usually consists of definitions for the SHELL, PATH, MAILTO, and HOME variables for the environment in which the jobs run, followed by the job definitions themselves. Comment lines start with a # character. Job definitions are specified in the following format:

```
minute hour day month day-of-week user command
```

where the fields are:

- `minute`: 0-59.
Controlling Access to Running cron Jobs

**hour**  0-23.

**day**  1-31.

**month**  1-12 or jan, feb,..., dec.

**day-of-week**  0-7 (Sunday is 0 or 7) or sun, mon,..., sat.

**user**  The user to run the command as, or * for the owner of the crontab file.

**command**  The shell script or command to be run.

For the **minute** through **day-of-week** fields, you can use the following special characters:

* (asterisk) All valid values for the field.

- (dash) A range of integers, for example, 1-5.

, (comma) A list of values, for example, 0,2,4.

/ (forward slash) A step value, for example, /3 in the **hour** field means every three hours.

For example, the following entry would run a command every five minutes on weekdays:

```
0-59/5 * * * 1-5 * command
```

Run a command at one minute past midnight on the first day of the months April, June, September, and November:

```
1 0 1 4,6,9,11 * * command
```

**root** can add job definition entries to /etc/crontab, or add crontab-format files to the /etc/cron.d directory.

```
Note
```

If you add an executable job script to the /etc/cron.hourly directory, crond runs the script once every hour. Your script should check that it is not already running.

For more information, see the crontab(5) manual page.

### 7.2.1 Controlling Access to Running cron Jobs

If permitted, users other than **root** can configure cron tasks by using the crontab utility. All user-defined crontab-format files are stored in the /var/spool/cron directory with the same name as the users that created them.

**root** can use the /etc/cron.allow and /etc/cron.deny files to restrict access to cron. crontab checks the access control files each time that a user tries to add or delete a cron job. If /etc/cron.allow exists, only users listed in it are allowed to use cron, and /etc/cron.deny is ignored. If /etc/cron.allow does not exist, users listed in /etc/cron.deny are not allowed to use cron. If neither file exists, only **root** can use cron. The format of both /etc/cron.allow and /etc/cron.deny is one user name on each line.

To create or edit a crontab file as a user, log in as that user and type the command crontab -e, which opens your crontab file in the vi editor (or the editor specified by the EDITOR or VISUAL environment
variables). The file has the same format as /etc/crontab except that the user field is omitted. When you save changes to the file, these are written to the file /var/spool/cron/username. To list the contents of your crontab file, use the crontab -l command. To delete your crontab file, use the crontab -r command.

For more information, see the crontab(1) manual page.

7.3 Configuring anacron Jobs

System anacron jobs are defined in /etc/anacrontab, which contains definitions for the SHELL, PATH, MAILTO, RANDOM_DELAY, and START_HOURS_RANGE variables for the environment in which the jobs run, followed by the job definitions themselves. Comment lines start with a # character.

RANDOM_DELAY is the maximum number of random time in minutes that anacron adds to the delay parameter for a job. The default minimum delay is 6 minutes. The random offset is intended to prevent anacron overloading the system with too many jobs at the same time.

START_HOURS_RANGE is the time range of hours during the day when anacron can run scheduled jobs.

Job definitions are specified in the following format:

```
period  delay  job-id  command
```

where the fields are:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>period</td>
<td>Frequency of job execution specified in days or as @daily, @weekly, or @monthly for once per day, week, or month.</td>
</tr>
<tr>
<td>delay</td>
<td>Number of minutes to wait before running a job.</td>
</tr>
<tr>
<td>job-id</td>
<td>Unique name for the job in log files.</td>
</tr>
<tr>
<td>command</td>
<td>The shell script or command to be run.</td>
</tr>
</tbody>
</table>

The following entries are taken from the default /etc/anacrontab file:

```
SHELL=/bin/sh
PATH=/sbin:/bin:/usr/sbin:/usr/bin
MAILTO=root
# the maximal random delay added to the base delay of the jobs
RANDOM_DELAY=45
# the jobs will be started during the following hours only
START_HOURS_RANGE=3-22
```

```
#period in days  delay in minutes  job-identifier   command
1                5              cron.daily       nice run-parts /etc/cron.daily
7                25             cron.weekly      nice run-parts /etc/cron.weekly
@monthly         45             cron.monthly     nice run-parts /etc/cron.monthly
```

By default, anacron runs jobs between 03:00 and 22:00 and randomly delays jobs by between 11 and 50 minutes. The job scripts in /etc/cron.daily, run anywhere between 03:11 and 03:50 every day if the system is running, or after the system is booted and the time is less than 22:00. The run-parts script sequentially executes every program within the directory specified as its argument.

Scripts in /etc/cron.weekly run once per week with a delay offset of between 31 and 70 minutes.

Scripts in /etc/cron.monthly run once per week with a delay offset of between 51 and 90 minutes.

For more information, see the anacron(8) and anacrontab(5) manual pages.
7.4 Running One-time Tasks

You can use the `at` command to schedule a one-time task to run at a specified time, or the `batch` command to schedule a one-time task to run when the system load average drops below 0.8. The `atd` service must be running to use `at` or `batch`.

```
# systemctl is-active atd
active
```

`at` takes a time as its argument and reads the commands to be run from the standard input. For example, run the commands in the file `atjob` in 20 minutes time:

```
# at now + 20 minutes < ./atjob
job 1 at 2013-03-19 11:25
```

The `atq` command shows the `at` jobs that are queued to run:

```
# atq
1 2013-03-19 11:25 a root
```

The `batch` command also reads command from the standard input, but it does not run until the system load average drops below 0.8. For example:

```
# batch < batchjob
job 2 at 2013-03-19 11:31
```

To cancel one or more queued jobs, specify their job numbers to the `atrm` command, for example:

```
# atrm 1 2
```

For more information, see the `at(1)` manual page.

7.4.1 Changing the Behavior of Batch Jobs

The load average of a system, as displayed by the `uptime` and `w` commands, represents the average number of processes that are queued to run on the CPUs or CPU cores over a given time period. Typically, a system might not considered overloaded until the load average exceeds 0.8 times the number of CPUs or CPU cores. On such systems, you would usually want `atd` to be able to run batch jobs when the load average drops below the number of CPUs or CPU cores, rather than the default limit of 0.8. For example, on a system with 4 CPU cores, you could set the load-average limit above which `atd` will not run batch jobs to 3.2.

If you know that a batch job typically takes more than a minute to run, you can also change the minimum interval that `atd` waits between starting batch jobs. The default minimum interval is 60 seconds.

To change the load-average limit and minimum interval time for batch jobs:

1. Edit the `atd` configuration file, `/etc/sysconfig/atd`, uncomment the line that defines the `OPTS` variable, and edit the line to specify the new load-average limit and minimum interval time, for example:
   ```
   OPTS="-b 100 -l 3"
   ``
   This example sets the minimum interval to 100 seconds and the load-average limit to 3.

2. Restart the `atd` service:
   ```
   # systemctl restart atd
   ```

3. Verify that the `atd` daemon is running with the new minimum interval and load-average limit:
Changing the Behavior of Batch Jobs

```
# systemctl status atd
atd.service - Job spooling tools
 Loaded: loaded (/usr/lib/systemd/system/atd.service; enabled)
 Active: active (running) since Mon 2014-04-28 15:37:04 BST; 2min 53s ago
   Main PID: 6731 (atd)
      CGroup: /system.slice/atd.service
             └─ 6731 /usr/sbin/atd -f -b 100 -l 3

Apr 28 15:37:04 localhost.localdomain systemd[1]: Started Job spooling tools.
```

For more information, see the `systemctl(1)` and `atd(8)` manual pages.
Chapter 8 System Monitoring and Tuning

Table of Contents

8.1 About sosreport ................................................................. 71
  8.1.1 Configuring and Using sosreport .................................. 71
8.2 About System Performance Tuning ...................................... 72
  8.2.1 About Performance Problems ....................................... 72
  8.2.2 Monitoring Usage of System Resources ............................. 73
  8.2.3 Using the Graphical System Monitor ................................. 76
  8.2.4 About OSWatcher Black Box .................................... 76

This chapter describes how to collect diagnostic information about a system for Oracle Support, and how to monitor and tune the performance of a system.

8.1 About sosreport

The sosreport utility collects information about a system such as hardware configuration, software configuration, and operational state. You can also use sosreport to enable diagnostics and analytical functions. To assist in troubleshooting a problem, sosreport records the information in a compressed file that you can send to a support representative.

8.1.1 Configuring and Using sosreport

If the sos package is not already installed on your system, use yum to install it.

Use the following command to list the available plugins and plugin options.

```
$ sosreport -l
```

The following plugins are currently enabled:

- acpid: acpid related information
- anaconda: Anaconda / Installation information
- ...

The following plugins are currently disabled:

- amd: Amd automounter information
- cluster: cluster suite and GFS related information
- ...

The following plugin options are available:

- apache.log: off gathers all apache logs
- auditd.syslogsize: 15 max size (MiB) to collect per syslog file
- ...

See the sosreport(1) manual page for information about how to enable or disable plugins, and how to set values for plugin options.

To run sosreport:

1. Enter the command, specifying any options that you need to tailor the report to report information about a problem area.
# sosreport [options ...]

For example, to record only information about Apache and Tomcat, and to gather all the Apache logs:

```
# sosreport -o apache,tomcat -k apache.log=on
```

```
sosreport (version 2.2)
.
.
Press ENTER to continue, or CTRL-C to quit.
```

To enable all boolean options for all loaded plugins except the rpm.rpmva plugin that verifies all packages, and which takes a considerable time to run:

```
# sosreport -a -k rpm.rpmva=off
```

2. Type Enter, and enter additional information when prompted.

```
Please enter your first initial and last name [email_address]: AName
Please enter the case number that you are generating this report for: case#

Running plugins. Please wait ...

Completed [55/55] ...
Creating compressed archive...

Your sosreport has been generated and saved in:
/tmp/sosreport-AName.case#-datestamp-ID.tar.xz

The md5sum is: checksum

Please send this file to your support representative.
```

```
sosreport saves the report as an xz-compressed tar file in /tmp.
```

For more information, see the sosreport(1) manual page.

8.2 About System Performance Tuning

Performance issues can be caused by any of a system’s components, software or hardware, and by their interaction. Many performance diagnostics utilities are available for Oracle Linux, including tools that monitor and analyze resource usage by different hardware components and tracing tools for diagnosing performance issues in multiple processes and their threads.

8.2.1 About Performance Problems

Many performance issues are the result of configuration errors. You can avoid such errors by using a validated configuration that has been pre-tested for the supported software, hardware, storage, drivers, and networking components. A validated configuration incorporates the best practices for Oracle Linux deployment and has undergone real-world testing of the complete stack. Oracle publishes more than 100 validated configurations, which are freely available for download. You should also refer to the release notes for recommendations on setting kernel parameters.

A typical problem involves out of memory errors and generally poor performance when running Oracle Database. The cause of this problem is likely to be that the system is not configured to use the HugePages feature for the System Global Area (SGA). With HugePages, you can set the page size to between 2MB and 256MB, so reducing the total number of pages that the kernel needs to manage. The memory associated with HugePages cannot be swapped out, which forces the SGA to remain resident in memory.
The following utilities allow you to collect information about system resource usage and errors, and can help you to identify performance problems caused by overloaded disks, network, memory, or CPUs:

- **dmesg**: Displays the contents of the kernel ring buffer, which can contain errors about system resource usage. Provided by the `util-linux-ng` package.
- **dstat**: Displays statistics about system resource usage. Provided by the `dstat` package.
- **free**: Displays the amount of free and used memory in the system. Provided by the `procps` package.
- **iostat**: Reports I/O statistics. Provided by the `sysstat` package.
- **iostop**: Monitors disk and swap I/O on a per-process basis. Provided by the `iostop` package.
- **ip**: Reports network interface statistics and errors. Provided by the `iproute` package.
- **mpstat**: Reports processor-related statistics. Provided by the `sysstat` package.
- **sar**: Reports information about system activity. Provided by the `sysstat` package.
- **ss**: Reports network interface statistics. Provided by the `iproute` package.
- **top**: Provides a dynamic real-time view of the tasks that are running on a system. Provided by the `procps` package.
- **uptime**: Displays the system load averages for the past 1, 5, and 15 minutes. Provided by the `procps` package.
- **vmstat**: Reports virtual memory statistics. Provided by the `procps` package.

Many of these utilities provide overlapping functionality. For more information, see the individual manual page for the utility.

See Section 4.2.3, “Parameters that Control System Performance” for a list of kernel parameters that affect system performance.

### 8.2.2 Monitoring Usage of System Resources

You need to collect and monitor system resources regularly to provide you with a continuous record of a system. Establish a baseline of acceptable measurements under typical operating conditions. You can then use the baseline as a reference point to make it easier to identify memory shortages, spikes in resource usage, and other problems when they occur. Monitoring system performance also allows you to plan for future growth and to see how configuration changes might affect future performance.

To run a monitoring command every `interval` seconds in real time and watch its output change, use the `watch` command. For example, the following command runs the `mpstat` command once per second:

```bash
# watch -n interval mpstat
```

Alternatively, many of the commands allow you to specify the sampling interval in seconds, for example:

```bash
# mpstat interval
```
If installed, the `sar` command records statistics every 10 minutes while the system is running and retains this information for every day of the current month. The following command displays all the statistics that `sar` recorded for day `DD` of the current month:

```
# sar -A -f /var/log/sa/saDD
```

To run `sar` command as a background process and collect data in a file that you can display later by using the `-f` option:

```
# sar -o datafile interval count >/dev/null 2>&1 &
```

where `count` is the number of samples to record.

Oracle OSWatcher Black Box (OSWbb) and OSWbb analyzer (OSWbba) are useful tools for collecting and analysing performance statistics. For more information, see Section 8.2.4, “About OSWatcher Black Box”.

### 8.2.2.1 Monitoring CPU Usage

The `uptime`, `mpstat`, `sar`, `dstat`, and `top` utilities allow you to monitor CPU usage. When a system's CPU cores are all occupied executing the code of processes, other processes must wait until a CPU core becomes free or the scheduler switches a CPU core to run their code. If too many processes are queued too often, this can represent a bottleneck in the performance of the system.

The commands `mpstat -P ALL` and `sar -u -P ALL` display CPU usage statistics for each CPU core and averaged across all CPU cores.

The `%idle` value shows the percentage of time that a CPU was not running system code or process code. If the value of `%idle` is near 0% most of the time on all CPU cores, the system is CPU-bound for the workload that it is running. The percentage of time spent running system code (`%system` or `%sys`) should not usually exceed 30%, especially if `%idle` is close to 0%.

The system load average represents the number of processes that are running on CPU cores, waiting to run, or waiting for disk I/O activity to complete averaged over a period of time. On a busy system, the load average reported by `uptime` or `sar -q` should usually be not greater than two times the number of CPU cores over periods as long as 5 or 15 minutes. If the load average exceeds four times the number of CPU cores for long periods, the system is overloaded.

In addition to load averages (`ldavg-*`), the `sar -q` command reports the number of processes currently waiting to run (the `run-queue size`, `runq-sz`) and the total number of processes (`plist_sz`). The value of `runq-sz` also provides an indication of CPU saturation.

Determine the system's average load under normal loads where users and applications do not experience problems with system responsiveness, and then look for deviations from this benchmark over time. A dramatic rise in the load average can indicate a serious performance problem.

A combination of sustained large load average or large run queue size and low `%idle` can indicate that the system has insufficient CPU capacity for the workload. When CPU usage is high, use a command such as `dstat` or `top` to determine which processes are most likely to be responsible. For example, the following `dstat` command shows which processes are using CPUs, memory, and block I/O most intensively:

```
# dstat --top-cpu --top-mem --top-bio
```

The `top` command provides a real-time display of CPU activity. By default, `top` lists the most CPU-intensive processes on the system. In its upper section, `top` displays general information including the load averages over the past 1, 5 and 15 minutes, the number of running and sleeping processes (tasks), and total CPU and memory usage. In its lower section, `top` displays a list of processes, including the process ID number (PID), the process owner, CPU usage, memory usage, running time, and the command name.
By default, the list is sorted by CPU usage, with the top consumer of CPU listed first. Type f to select which fields top displays, o to change the order of the fields, or O to change the sort field. For example, entering on sorts the list on the percentage memory usage field (%MEM).

### 8.2.2.2 Monitoring Memory Usage

The `sar -r` command reports memory utilization statistics, including %memused, which is the percentage of physical memory in use.

`sar -B` reports memory paging statistics, including pgscank/s, which is the number of memory pages scanned by the kswapd daemon per second, and pgscand/s, which is the number of memory pages scanned directly per second.

`sar -W` reports swapping statistics, including pswpin/s and pswpout/s, which are the numbers of pages per second swapped in and out per second.

If %memused is near 100% and the scan rate is continuously over 200 pages per second, the system has a memory shortage.

Once a system runs out of real or physical memory and starts using swap space, its performance deteriorates dramatically. If you run out of swap space, your programs or the entire operating system are likely to crash. If `free` or `top` indicate that little swap space remains available, this is also an indication you are running low on memory.

The output from the `dmesg` command might include notification of any problems with physical memory that were detected at boot time.

### 8.2.2.3 Monitoring Block I/O Usage

The `iostat` command monitors the loading of block I/O devices by observing the time that the devices are active relative to the average data transfer rates. You can use this information to adjust the system configuration to balance the I/O loading across disks and host adapters.

`iostat -x` reports extended statistics about block I/O activity at one second intervals, including %util, which is the percentage of CPU time spent handling I/O requests to a device, and avgqu-sz, which is the average queue length of I/O requests that were issued to that device. If %util approaches 100% or avgqu-sz is greater than 1, device saturation is occurring.

You can also use the `sar -d` command to report on block I/O activity, including values for %util and avgqu-sz.

The `iotop` utility can help you identify which processes are responsible for excessive disk I/O. `iotop` has a similar user interface to `top`. In its upper section, `iotop` displays the total disk input and output usage in bytes per second. In its lower section, `iotop` displays I/O information for each process, including disk input output usage in bytes per second, the percentage of time spent swapping in pages from disk or waiting on I/O, and the command name. Use the left and right arrow keys to change the sort field, and press A to toggle the I/O units between bytes per second and total number of bytes, or O to toggle between displaying all processes or only those processes that are performing I/O.

### 8.2.2.4 Monitoring File System Usage

The `sar -v` command reports the number of unused cache entries in the directory cache (dentunusd) and the numbers of in-use file handles (file-nr), inode handlers (inode-nr), and pseudo terminals (pty-nr).

`iostat -n` reports I/O statistics for each NFS file system that is mounted.
8.2.2.5 Monitoring Network Usage

The `ip -s link` command displays network statistics and errors for all network devices, including the numbers of bytes transmitted (TX) and received (RX). The `dropped` and `overrun` fields provide an indicator of network interface saturation.

The `ss -s` command displays summary statistics for each protocol.

8.2.3 Using the Graphical System Monitor

The GNOME desktop environment includes a graphical system monitor that allows you to display information about the system configuration, running processes, resource usage, and file systems.

To display the System Monitor, use the following command:

```
# gnome-system-monitor
```

The **Resources** tab displays:

- CPU usage history in graphical form and the current CPU usage as a percentage.
- Memory and swap usage history in graphical form and the current memory and swap usage.
- Network usage history in graphical form, the current network usage for reception and transmission, and the total amount of data received and transmitted.

To display the System Monitor Manual, press `F1` or select **Help > Contents**.

8.2.4 About OSWatcher Black Box

Oracle OSWatcher Black Box (OSWbb) collects and archives operating system and network metrics that you can use to diagnose performance issues. OSWbb operates as a set of background processes on the server and gathers data on a regular basis, invoking such Unix utilities as `vmstat`, `mpstat`, `netstat`, `iostat`, and `top`.

OSWbb is particularly useful for Oracle RAC (Real Application Clusters) and Oracle Grid Infrastructure configurations. The RAC-DDT (Diagnostic Data Tool) script file includes OSWbb, but does not install it by default.

8.2.4.1 Installing OSWbb

To install OSWbb:

1. Log on to My Oracle Support (MOS) at [https://support.oracle.com](https://support.oracle.com).
3. Copy the file to the directory where you want to install OSWbb, and run the following command:

```
# tar xvf oswbbVERS.tar
```

`VERS` represents the version number of OSWatcher, for example 730 for OSWatcher 7.30.

Extracting the tar file creates a directory named `oswbb`, which contains all the directories and files that are associated with OSWbb, including the `startOSWbb.sh` script.
4. To enable the collection of `iostat` information for NFS volumes, edit the `OSWatcher.sh` script in the `oswbb` directory, and set the value of `nfs_collect` to 1:

```
nfs_collect=1
```

### 8.2.4.2 Running OSWbb

To start OSWbb, run the `startOSWbb.sh` script from the `oswbb` directory.

```
#/startOSWbb.sh [frequency duration]
```

The optional frequency and duration arguments specifying how often in seconds OSWbb should collect data and the number of hours for which OSWbb should run. The default values are 30 seconds and 48 hours. The following example starts OSWbb recording data at intervals of 60 seconds, and has it record data for 12 hours:

```
#/startOSWbb.sh 60 12
... Testing for discovery of OS Utilities...
VMSTAT found on your system.
IOSTAT found on your system.
MPSTAT found on your system.
IFCONFIG found on your system.
NETSTAT found on your system.
TOP found on your system.

Testing for discovery of OS CPU COUNT
oswbb is looking for the CPU COUNT on your system
CPU COUNT will be used by oswbba to automatically look for cpu problems

CPU COUNT found on your system.
CPU COUNT = 4

Discovery completed.

Starting OSWatcher Black Box v7.3.0 on date and time
With SnapshotInterval = 60
With ArchiveInterval = 12
... Data is stored in directory: `OSWbba_archive`
Starting Data Collection...

oswbb heartbeat: date and time
oswbb heartbeat: date and time + 60 seconds
...

`OSWbba_archive` is the path of the archive directory that contains the OSWbb log files.

To stop OSWbb prematurely, run the `stopOSWbb.sh` script from the `oswbb` directory.

```
#/stopOSWbb.sh
```

OSWbb collects data in the following directories under the `oswbb/archive` directory:

<table>
<thead>
<tr>
<th>Directory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oswifconfig</td>
<td>Contains output from <code>ifconfig</code>.</td>
</tr>
<tr>
<td>oswiostat</td>
<td>Contains output from <code>iostat</code>.</td>
</tr>
<tr>
<td>oswmeminfo</td>
<td>Contains a listing of the contents of <code>/proc/meminfo</code>.</td>
</tr>
<tr>
<td>oswmpstat</td>
<td>Contains output from <code>mpstat</code>.</td>
</tr>
</tbody>
</table>
### Directory Description

<table>
<thead>
<tr>
<th>Directory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oswnetstat</td>
<td>Contains output from <code>netstat</code>.</td>
</tr>
<tr>
<td>oswprvtnet</td>
<td>If you have enable private network tracing for RAC, contains information about the status of the private networks.</td>
</tr>
<tr>
<td>oswps</td>
<td>Contains output from <code>ps</code>.</td>
</tr>
<tr>
<td>oswslabinfo</td>
<td>Contains a listing of the contents of <code>/proc/slabinfo</code>.</td>
</tr>
<tr>
<td>oswtop</td>
<td>Contains output from <code>top</code>.</td>
</tr>
<tr>
<td>oswvmstat</td>
<td>Contains output from <code>vmstat</code>.</td>
</tr>
</tbody>
</table>

OSWbb stores data in hourly archive files named `system_name_utility_name_timestamp.dat`. Each entry in a file is preceded by a timestamp.

#### 8.2.4.3 Analysing OSWbb Archived Files

From release v4.0.0, you can use the OSWbb analyzer (OSWbba) to provide information on system slowdowns, system hangs and other performance problems, and also to graph data collected from `iostat`, `netstat`, and `vmstat`. OSWbba requires that you have installed Java version 1.4.2 or higher on your system. You can use `yum` to install Java, or you can download a Java RPM for Linux from [http://www.java.com](http://www.java.com).

Use the following command to run OSWbba from the `oswbb` directory:

```bash
# java -jar oswbba.jar -i OSWbba_archive
```

`OSWbba_archive` is the path of the archive directory that contains the OSWbb log files.

You can use OSWbba to display the following types of performance graph:

- Process run, wait and block queues.
- CPU time spent running in system, user, and idle mode.
- Context switches and interrupts.
- Free memory and available swap.
- Reads per second, writes per second, service time for I/O requests, and percentage utilization of bandwidth for a specified block device.

You can also use OSWbba to save the analysis to a report file, which reports instances of system slowdown, spikes in run queue length, or memory shortage, describes probable causes, and offers suggestions of how to improve performance.

```bash
# java -jar oswbba.jar -i OSWbba_archive -A
```

For more information about OSWbb and OSWbba, refer to the *OSWatcher Black Box User Guide* (Article ID 301137.1) and the *OSWatcher Black Box Analyzer User Guide* (Article ID 461053.1), which are available from My Oracle Support (MOS) at [https://support.oracle.com](https://support.oracle.com).
Chapter 9 System Dump Analysis

  9.2.5 Helper Commands .................................................... 89
  9.2.6 Session Control Commands ....................................... 89
  9.2.7 Guidelines for Examining a Dump File ......................... 90

This chapter describes how to configure a system to create a memory image in the event of a system crash, and how to use the crash debugger to analyse the memory image in a crash dump or for a live system.

9.1 About Kdump

Kdump is the Linux kernel crash-dump mechanism. Oracle recommends that you enable the Kdump feature. In the event of a system crash, Kdump creates a memory image (vmcore) that can help in determining the cause of the crash. Enabling Kdump requires you to reserve a portion of system memory for exclusive use by Kdump. This memory is unavailable for other uses.

Kdump uses kexec to boot into a second kernel whenever the system crashes. kexec is a fast-boot mechanism which allows a Linux kernel to boot from inside the context of a kernel that is already running without passing through the bootloader stage.

9.1.1 Configuring and Using Kdump

During installation, you are given the option of enabling Kdump and specifying the amount of memory to reserve for it. If you prefer, you can enable kdump at a later time as described in this section.

If the kexec-tools and system-config-kdump packages are not already installed on your system, use yum to install them.

To enable Kdump by using the Kernel Dump Configuration GUI.

1. Enter the following command.

```
# system-config-kdump
```

The Kernel Dump Configuration GUI starts. If Kdump is currently disabled, the green Enable button is selectable and the Disable button is greyed out.

2. Click Enable to enable Kdump.

3. You can select the following settings tags to adjust the configuration of Kdump.

<table>
<thead>
<tr>
<th>Basic Settings</th>
<th>Allows you to specify the amount of memory to reserve for Kdump. The default setting is 128 MB.</th>
</tr>
</thead>
</table>

Configuring and Using Kmoud

| Target Settings | Allows you to specify the target location for the vmcore dump file on a locally accessible file system, to a raw disk device, or to a remote directory using NFS or SSH over IPv4. The default location is /var/crash. You cannot save a dump file on an eCryptfs file system, on remote directories that are NFS mounted on the rootfs file system, or on remote directories that access require the use of IPv6, SMB, CIFS, FCoE, wireless NICs, multipathed storage, or iSCSI over software initiators to access them. |
| Filtering Settings | Allows to select which type of data to include in or exclude from the dump file. Selecting or deselecting the options alters the value of the argument that Kmoud specifies to the -d option of the core collector program, makedumpfile. |
| Expert Settings | Allows you to choose which kernel to use, edit the command line options that are passed to the kernel and the core collector program, choose the default action if the dump fails, and modify the options to the core collector program, makedumpfile. The Unbreakable Enterprise Kernel supports the use of the crashkernel=auto setting for UEK Release 3 Quarterly Update 1 and later. If you use the crashkernel=auto setting, the output of the dmesg command shows crashkernel=XM@0M, which is normal. The setting actually reserves 128 MB plus 64 MB for each terabyte of physical memory. |

Note

You cannot configure crashkernel=auto for Xen or for the UEK prior to UEK Release 3 Quarterly Update 1. Only standard settings such as crashkernel=128M@48M are supported. For systems with more than 128 GB of memory, the recommended setting is crashkernel=512M@64M. You can select one of five default actions should the dump fail: mount rootfs and run /sbin/init | Mount the root file system and run init. The /etc/init.d/kmoud script attempts to save the dump to /var/crash, which requires a large amount of memory to be reserved. reboot | Reboot the system, losing the vmcore. This is the default action. shell | Enter a shell session inside the initramfs so that you can
Files Used by Kdump

attempt to record the core. To reboot the system, exit the shell.

halt
Halt the system.

poweroff
Power down the system.

Click Help for more information on these settings.

4. Click Apply to save your changes. The GUI displays a popup message to remind you that you must reboot the system for the changes to take effect.

5. Click OK to dismiss the popup messages.

7. Reboot the system at a suitable time.

9.1.2 Files Used by Kdump

The Kernel Dump Configuration GUI modifies the following files:

<table>
<thead>
<tr>
<th>File</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>/boot/grub2/grub.cfg</td>
<td>Appends the crashkernel option to the kernel line to specify the amount of reserved memory and any offset value.</td>
</tr>
<tr>
<td>/etc/kdump.conf</td>
<td>Sets the location where the dump file can be written, the filtering level for the makedumpfile command, and the default behavior to take if the dump fails. See the comments in the file for information about the supported parameters.</td>
</tr>
</tbody>
</table>

If you edit these files, you must reboot the system for the changes to take effect.

For more information, see the kdump.conf(5) manual page.

9.1.3 Using Kdump with OCFS2

By default, a fenced node in an OCFS2 cluster restarts instead of panicking so that it can quickly rejoin the cluster. If the reason for the restart is not apparent, you can change the node's behavior so that it panics and generates a vmcore for analysis.

To configure a node to panic when it next fences, run the following command on the node after the cluster starts:

```
# echo panic > /sys/kernel/config/cluster/cluster_name/fence_method
```

where cluster_name is the name of the cluster. To set the value after each reboot of the system, add this line to /etc/rc.local. To restore the default behavior, set the value of fence_method to reset instead of panic and remove the line from /etc/rc.local.

For more information, see Section 23.3.5, “Configuring the Behavior of Fenced Nodes”.

9.2 Using the crash Debugger

The crash utility allows you to analyze the state of the Oracle Linux system while it is running or of a core dump that resulted from a kernel crash. crash has been merged with the GNU Debugger gdb to provide source code debugging capabilities.
Installing the crash Packages

9.2.1 Installing the crash Packages

To use crash, you must install the crash package and the appropriate debuginfo and debuginfo-common packages.

To install the required packages:

1. Install the latest version of the crash package:

   ```
   # yum install crash
   ```

2. Download the appropriate debuginfo and debuginfo-common packages for the vmcore or kernel that you want to examine from https://oss.oracle.com/ol7/debuginfo/:

   - If you want to examine the running Unbreakable Enterprise Kernel on the system, use commands such as the following to download the packages:

     ```
     # export DLP="https://oss.oracle.com/ol7/debuginfo"
     # wget ${DLP}/kernel-uek-debuginfo-`uname -r`.rpm
     # wget ${DLP}/kernel-uek-debuginfo-common-`uname -r`.rpm
     ```

   - If you want to examine the running Red Hat Compatible Kernel on the system, use commands such as the following to download the packages:

     ```
     # export DLP="https://oss.oracle.com/ol7/debuginfo"
     # wget ${DLP}/kernel-debuginfo-`uname -r`.rpm
     # wget ${DLP}/kernel-debuginfo-common-`uname -r`.rpm
     ```

   - If you want to examine a vmcore file that relates to a different kernel than is currently running, download the appropriate debuginfo and debuginfo-common packages for the kernel that produce the vmcore, for example:

     ```
     # export DLP="https://oss.oracle.com/ol7/debuginfo"
     # wget ${DLP}/kernel-uek-debuginfo-4.1.12-112.14.15.el7uek.x86_64.rpm
     # wget ${DLP}/kernel-uek-debuginfo-common-4.1.12-112.14.15.el7uek.x86_64.rpm
     ```

   **Note**

   If the vmcore file was produced by Kdump, you can use the following crash command to determine the version:

   ```
   # crash --osrelease /var/tmp/vmcore/2013-0211-2358.45-host03.28.core
   2.6.39-200.24.1.el6uek.x86_64
   ```

3. Install the debuginfo and debuginfo-common packages, for example:

   ```
   # rpm -Uhv kernel-uek-debuginfo-4.1.12-112.14.15.el7uek.x86_64.rpm
   kernel-uek-debuginfo-common-4.1.12-112.14.15.el7uek.x86_64.rpm
   ```

The vmlinux kernel object file (also known as the namelist file) that crash requires is installed in /usr/lib/debug/lib/modules/kernel_version/.

9.2.2 Running crash

**Warning**

Running crash on a live system is dangerous and can cause data corruption or total system failure. Do not use crash to examine a production system unless so directed by Oracle Support.
To examine the currently running kernel:

```bash
# crash
```

To determine the version of the kernel that produced a `vmcore` file:

```bash
# crash --osrelease /var/tmp/vmcore/2013-0211-2358.45-host03.28.core
2.6.39-200.24.1.el6uek.x86_64
```

To examine a `vmcore` file, specify the path to the file as an argument, for example:

```bash
# crash /var/tmp/vmcore/2013-0211-2358.45-host03.28.core
```

The appropriate `vmlinux` file must exist in `/usr/lib/debug/lib/modules/kernel_version/`.

If the `vmlinux` file is located elsewhere, specify its path before the path to the `vmcore` file, for example:

```bash
# crash /var/tmp/namelist/vmlinux-host03.28 /var/tmp/vmcore/2013-0211-2358.45-host03.28.core
```

The following `crash` output is from a `vmcore` file that was dumped after a system panic:

```
KERNEL: /usr/lib/debug/lib/modules/2.6.39-200.24.1.el6uek.x86_64/vmlinux
DUMPFILE: /var/tmp/vmcore/2013-0211-2358.45-host03.28.core
CPUS: 2
UPTIME: 04:24:54
LOAD AVERAGE: 0.00, 0.01, 0.05
TASKS: 84
NODENAME: host03.mydom.com
RELEASE: 2.6.39-200.24.1.el6uek.x86_64
VERSION: #1 SMP Sat Jun 23 02:39:07 EDT 2012
MACHINE: x86_64 (2992 MHz)
MEMORY: 2 GB
PANIC: "Oops: 0002" (check log for details)
PID: 1696
COMMAND: "insmod"
TASK: c74de000
CPU: 0
STATE: TASK_RUNNING (PANIC)
```

The output includes the number of CPUs, the load average over the last 1 minute, last 5 minutes, and last 15 minutes, the number of tasks running, the amount of memory, the panic string, and the command that was executing at the time the dump was created. In this example, an attempt by `insmod` to install a module resulted in an `oops` violation.

At the `crash>` prompt, you can enter `help` or `?` to display the available `crash` commands. Enter `help command` to display more information for a specified command.

`crash` commands can be grouped into several different groups according to purpose:

- **Kernel Data Structure Analysis Commands**: Display kernel text and data structures. See Section 9.2.3, “Kernel Data Structure Analysis Commands”.
- **System state commands**: Examine kernel subsystems on a system-wide or a per-task basis. See Section 9.2.4, “System State Commands”.
- **Helper commands**: Perform calculation, translation, and search functions. See Section 9.2.5, “Helper Commands”
Session control commands Control the crash session. See Section 9.2.6, “Session Control Commands”

For more information, see the crash(8) manual page.

9.2.3 Kernel Data Structure Analysis Commands

The following crash commands take advantage of gdb integration to display kernel data structures symbolically:

* The pointer-to command can be used instead struct or union. The gdb module calls the appropriate function. For example:

```
crash> *buffer_head
struct buffer_head {
  long unsigned int b_state;
  struct buffer_head *b_this_page;
  struct page *b_page;
  sector_t b_blocknr;
  size_t b_size;
  char *b_data;
  struct block_device *b_bdev;
  bh_end_io_t *b_end_io;
  void *b_private;
  struct list_head b_assoc_buffers;
  struct address_space *b_assoc_map;
  atomic_t b_count;
}
SIZE: 104
```

dis Disassembles source code instructions of a complete kernel function, from a specified address for a specified number of instructions, or from the beginning of a function up to a specified address. For example:

```
crash> dis fixup_irqs
0xffffffff81014486 <fixup_irqs>:    push   %rbp
0xffffffff81014487 <fixup_irqs+1>:  mov    %rsp,%rbp
0xffffffff8101448a <fixup_irqs+4>:  push   %r15
0xffffffff8101448c <fixup_irqs+6>:  push   %r14
0xffffffff8101448e <fixup_irqs+8>:  push   %r13
0xffffffff81014490 <fixup_irqs+10>: push   %r12
0xffffffff81014492 <fixup_irqs+12>: push   %rbx
0xffffffff81014493 <fixup_irqs+13>: sub    $0x18,%rsp
0xffffffff81014497 <fixup_irqs+17>: nopl  0x0(%rax,%rax,1)
...
```

p Displays the contents of a kernel variable. For example:

```
crash> p init_mm
init_mm = {5} =
  mmap = 0x0,
  mm_rb = {
  rb_node = 0x0
  },
  mmap_cache = 0x0,
  get_unmapped_area = 0,
  unmap_area = 0,
  mmap_base = 0,
  task_size = 0,
  cached_hole_size = 0,
  free_area_cache = 0,
  pgd = 0xffffffff81001000,
...
System State Commands

**struct**
Displays either a structure definition, or a formatted display of the contents of a structure at a specified address. For example:

```
crash> struct cpu
struct cpu {
    int node_id;
    int hotpluggable;
    struct sys_device sysdev;
}
SIZE: 88
```

**sym**
Translates a kernel symbol name to a kernel virtual address and section, or a kernel virtual address to a symbol name and section. You can also query (-q) the symbol list for all symbols containing a specified string or list (-l) all kernel symbols. For example:

```
crash> sym jiffies
ffffffff81b45880 (A) jiffies

crash> sym -q runstate
c590 (d) per_cpu__runstate

crash> sym -l
0 (D) __per_cpu_start
0 (D) per_cpu__irq_stack_union
4000 (D) per_cpu__gdt_page
5000 (d) per_cpu__exception_stacks
b000 (d) per_cpu__idt_desc
b010 (d) per_cpu__xen_cr0_value
b018 (D) per_cpu__xen_vcpu
b020 (D) per_cpu__xen_cpuinfo
b060 (d) per_cpu__mc_buffer
...```

**union**
Similar to the `struct` command, displaying kernel data types that are defined as unions instead of structures.

**whatis**
Displays the definition of structures, unions, typedefs or text or data symbols. For example:

```
crash> whatis linux_binfmt
struct linux_binfmt {
    struct list_head lh;
    struct module *module;
    int (*load_binary)(struct linux_binprm *, struct pt_regs *);
    int (*load_shlib)(struct file *);
    int (*core_dump)(long int, struct pt_regs *, struct file *, long unsigned int);
    long unsigned int min_coredump;
    int hasvdso;
}
SIZE: 64
```

### 9.2.4 System State Commands

The following commands display kernel subsystems on a system-wide or per-task basis:

**bt**
Displays a kernel stack trace of the current context or of a specified PID or task. In the case of a dump that followed a kernel panic, the
command traces the functions that were called leading up to the panic. For example:

```
bt
```

```
PID: 10651 TASK: d1347000 CPU: 1 COMMAND: "insmod"
  #0 [d1547e44] die at c010785a
  #1 [d1547e54] do_invalid_op at c0107b2c
  #2 [d1547f0c] error_code (via invalid_op) at c01073dc
...
```

You can use the `-l` option to display the line number of the source file that corresponds to each function call in a stack trace.

```
bt -l
```

```
PID: 1 TASK: ffff88007d032040 CPU: 1 COMMAND: "init"
  #0 [ffff88007d035878] schedule at ffffffff8144fdd4
    /usr/src/debug/kernel-2.6.32/linux-2.6.32.x86_64/kernel/sched.c: 3091
  #1 [ffff88007d035950] schedule_h timeout_range at ffffffff814508e4
    /usr/src/debug/kernel-2.6.32/linux-2.6.32.x86_64/arch/x86/include/asm/current.h: 14
  #2 [ffff88007d0359f0] poll_schedule_timeout at ffffffff811297d5
    /usr/src/debug/kernel-2.6.32/linux-2.6.32.x86_64/arch/x86/include/asm/current.h: 14
  #3 [ffff88007d035a10] do_select at ffffffff811292d2
    /usr/src/debug/kernel-2.6.32/linux-2.6.32.x86_64/fs/select.c: 500
  #4 [ffff88007d035d80] core_sys_select at ffffffff8112a04c
    /usr/src/debug/kernel-2.6.32/linux-2.6.32.x86_64/fs/select.c: 575
  #5 [ffff88007d035f10] sys_select at ffffffff8112a326
    /usr/src/debug/kernel-2.6.32/linux-2.6.32.x86_64/fs/select.c: 615

RIP: 00007fce20a66243  RSP: 00007fff552c1038  RFLAGS: 00000246

```

bt is probably the most useful crash command. It has a large number of options that you can use to examine a kernel stack trace. For more information, enter help bt.

```
dev
```

Displays character and block device data. The `-d` and `-i` options display disk I/O statistics and I/O port usage. For example:

```
dev
```

```
CHRDEV NAME CDEV OPERATIONS
1 mem ffff88007d2a66c0 memory_fops
4 /dev/vc/0 ffffffff821f6e30 console_fops
4 tty ffff88007a395008 tty_fops
4 ttyS ffff88007a3d3808 tty_fops
5 /dev/tty ffffffff821f48c0 tty_fops
...
BLKDEV NAME GENDISK OPERATIONS
1 ramdisk ffff88007a3de800 brd_fops
259 blkext (none)
7 loop ffff880037809800 lo_fops
8 sd ffff880037e9800 sd_fops
9 md (none)
...
dev -d
```

```
MAJOR GENDISK NAME REQUEST QUEUE TOTAL ASYNC SYNC DRV
8 0xffff880037e9800 sda 0xffff880037b513e0 10 0 10 0
11 0xffff880037e9800 sr0 0xffff880037b50b10 0 0 0 0
253 0xffff880037902c00 dm-0 0xffff88003705b420 0 0 0 0
```
## System State Commands

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>files</strong></td>
<td>Displays information about files that are open in the current context or in the context of a specific PID or task. For example:</td>
</tr>
<tr>
<td><strong>fuser</strong></td>
<td>Displays the tasks that reference a specified file name or inode address as the current root directory, current working directory, open file descriptor, or that memory map the file. For example:</td>
</tr>
<tr>
<td><strong>irq</strong></td>
<td>Displays interrupt request queue data. For example:</td>
</tr>
<tr>
<td><strong>kmem</strong></td>
<td>Displays the state of the kernel memory subsystems. For example:</td>
</tr>
</tbody>
</table>
System State Commands

<table>
<thead>
<tr>
<th>TOTAL SWAP</th>
<th>1032190</th>
<th>3.9 GB</th>
<th>----</th>
</tr>
</thead>
<tbody>
<tr>
<td>SWAP USED</td>
<td>2067</td>
<td>8.1 MB</td>
<td>0% of TOTAL SWAP</td>
</tr>
<tr>
<td>SWAP FREE</td>
<td>1030123</td>
<td>3.9 GB</td>
<td>99% of TOTAL SWAP</td>
</tr>
</tbody>
</table>

**kmem** has a large number of options. For more information, enter `help kmem`.

**log**

Displays the kernel message buffer in chronological order. This is the same data that `dmesg` displays but the output can include messages that never made it to `syslog` or disk.

**mach**

Displays machine-specific information such as the `cpuinfo` structure and the physical memory map.

**mod**

Displays information about the currently installed kernel modules. The `-s` and `-S` options load debug data (if available) from the specified module object files to enable symbolic debugging.

**mount**

Displays information about currently mounted file systems.

**net**

Displays network-related information.

**ps**

Displays information about processes. For example:

```
> 13362  11853   0  ffff88007b25a500  RU   6.9  277632 145612  crash
```

**pte**

Translates a page table entry (PTE) to the physical page address and page bit settings. If the PTE refers to a swap location, the command displays the swap device and offset.

**runq**

Displays the list of tasks that are on the run queue of each CPU.

**sig**

Displays signal-handling information for the current context or for a specified PID or task.

**swap**

Displays information about the configured swap devices.

**task**

Displays the contents of the `task_struct` for the current context or for a specified PID or task.

**timer**

Displays the entries in the timer queue in chronological order.

**vm**

Displays the virtual memory data, including the addresses of `mm_struct` and the page directory, resident set size, and total virtual memory size for the current context or for a specified PID or task.

**vtop**

Translates a user or kernel virtual address to a physical address. The command also displays the PTE translation, `vm_area_struct` data for user virtual addresses, `mem_map` page data for a physical page, and the swap location or file location if the page is not mapped.

**waitq**

Displays tasks that are blocked on a specified wait queue.
9.2.5 Helper Commands

The following commands perform calculation, translation, and search functions:

- `ascii` Translates a hexadecimal value to ASCII. With no argument, the command displays an ASCII chart.
- `btop` Translates a hexadecimal address to a page number.
- `eval` Evaluates an expression and displays the result in hexadecimal, decimal, octal, and binary. For example:

  ```
  crash> eval 4g / 0x100
  hexadecimal: 1000000 (16MB)
  decimal: 16777216
  octal: 100000000
  binary: 0000000000000000000000000000000000000001000000000000000000000000
  ```
- `list` Displays the contents of a linked list of data objects, typically structures, starting at a specified address.
- `ptob` Translates a page number to its physical address (byte value).
- `ptov` Translates a physical address to a kernel virtual address.
- `search` Searches for a specified value in a specified range of user virtual memory, kernel virtual memory, or physical memory.
- `rd` Displays a selected range of user virtual memory, kernel virtual memory, or physical memory using the specified format.
- `wr` Writes a value to a memory location specified by symbol or address.

**Warning**

To avoid data loss or data corruption, take great care when using the `wr` command.

9.2.6 Session Control Commands

The following commands control the `crash` session:

- `alias` Defines an alias for a command. With no argument, the command displays the current list of aliases.
- `exit`, `q`, or `quit` Ends the `crash` session.
- `extend` Loads or unloads the specified `crash` extension shared object libraries.
- `foreach` Execute a `bt`, `files`, `net`, `task`, `set`, `sig`, `vm`, or `vtop` command on multiple tasks.
- `gdb` Passes any arguments to the GNU Debugger for processing.
- `repeat` Repeats a command indefinitely until you type `Ctrl-C`. This command is only useful when you use `crash` to examine a live system.
- `set` Sets the context to a specified PID or task. With no argument, the command displays the current context.
9.2.7 Guidelines for Examining a Dump File

The steps for debugging a memory dump from a kernel crash vary widely according to the problem. The following guidelines suggest some basic investigations that you can try:

- Use `bt` to trace the functions that led to the kernel panic.

- Use `bt -a` to trace the active task on each CPU. There is often a relationship between the panicking task on one CPU and the running tasks on the other CPUs. If the listed command is `cpu_idle` or `swapper`, no task was running on a CPU.

- Use `bt -l` to display the line number of the source files corresponding to each function call in the stack trace.

- Use `kmem -i` to obtain a summary of memory and swap usage. Look for a `SLAB` value greater than 500 MB and a `SWAP USED` value greater than 0%.

- Use `ps | grep UN` to check for processes in the `TASK_UNINTERRUPTIBLE` state (`D state`), usually because they are waiting on I/O. Such processes contribute to the load average and cannot be killed.

- Use `files` to display the files that a process had open.

You can shell indirection operators to save output from a command to a file for later analysis or to pipe the output through commands such as `grep`, for example:

```
crash> foreach files > files.txt
PID: 3685 TASK: ffff880058714580 CPU: 1 COMMAND: "bash"
PID: 11853 TASK: ffff88001c6826c0 CPU: 0 COMMAND: "bash"
```
Part II Networking and Network Services

This section contains the following chapters:

- **Chapter 10, Network Configuration** describes how to configure a system’s network interfaces and network routing.

- **Chapter 11, Network Address Configuration** describes how to configure a DHCP server, DHCP client, and Network Address Translation.

- **Chapter 12, Name Service Configuration** describes how to use BIND to set up a DNS name server.

- **Chapter 13, Network Time Configuration** describes how to configure the chrony, Network Time Protocol (NTP), or Precision Time Protocol (PTP) daemons for setting the system time.

- **Chapter 14, Web Service Configuration** describes how to configure a basic HTTP server.

- **Chapter 15, Email Service Configuration** describes email programs and protocols that are available with Oracle Linux, and how to set up a basic Sendmail client.

- **Chapter 16, High Availability Configuration** describes how to use Pacemaker and Corosync to set up high availability cluster configurations with networked systems.

- **Chapter 17, Load Balancing Configuration** describes how to use Keepalived and HAProxy to set up load balancing for networked systems.

- **Chapter 18, VNC Service Configuration** describes how to enable a VNC server to provide remote access to a graphical desktop.

10.9 Configuring Network Routing ......................................................... 107

This chapter describes how to configure a system's network interfaces and network routing.

10.1 About Network Interfaces

Each physical and virtual network device on an Oracle Linux system has an associated configuration file named ifcfg-interface in the /etc/sysconfig/network-scripts directory, where interface is the name of the interface. For example:

```
# cd /etc/sysconfig/network-scripts
# ls ifcfg-*
ifcfg-em1 ifcfg-em2 ifcfg-lo
```

In this example, there are two configuration files for motherboard-based Ethernet interfaces, ifcfg-em1 and ifcfg-em2, and one for the loopback interface, ifcfg-lo. The system reads the configuration files at boot time to configure the network interfaces.

On your system, you might see other names for network interfaces. See Section 10.2, “About Network Interface Names”.

The following are sample entries from an ifcfg-em1 file for a network interface that obtains its IP address using the Dynamic Host Configuration Protocol (DHCP):

```ini
DEVICE="em1"
NM_CONTROLLED="yes"
ONBOOT=yes
USERCTL=no
TYPE=Ethernet
BOOTPROTO= dhcp
DEFROUTE=yes
IPV4_FAILURE_FATAL=yes
IPV6INIT=no
```
If the interface is configured with a static IP address, the file contains entries such as the following:

```
DEVICE="em1"
NM_CONTROLLED="yes"
ONBOOT=yes
USERCTL=no
TYPE=Ethernet
BOOTPROTO=none
DEFROUTE=yes
IPV4_FAILURE_FATAL=yes
IPV6INIT=no
NAME="System em1"
UUID=5fb06bd0-0bb0-7ffb-45f1-d6edd65f3e03
HWADDR=08:00:27:16:C3:33
IPADDR=192.168.1.101
NETMASK=255.255.255.0
BROADCAST=192.168.1.255
PEERDNS=yes
PEERROUTES=yes
```

The following configuration parameters are typically used in interface configuration files:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>BOOTPROTO</strong></td>
<td>How the interface obtains its IP address:</td>
</tr>
<tr>
<td><strong>bootp</strong></td>
<td>Bootstrap Protocol (BOOTP).</td>
</tr>
<tr>
<td><strong>dhcp</strong></td>
<td>Dynamic Host Configuration Protocol (DHCP).</td>
</tr>
<tr>
<td><strong>none</strong></td>
<td>Statically configured IP address.</td>
</tr>
<tr>
<td><strong>BROADCAST</strong></td>
<td>IPv4 broadcast address.</td>
</tr>
<tr>
<td><strong>DEFROUTE</strong></td>
<td>Whether this interface is the default route.</td>
</tr>
<tr>
<td><strong>DEVICE</strong></td>
<td>Name of the physical network interface device (or a PPP logical device).</td>
</tr>
<tr>
<td><strong>GATEWAYN</strong></td>
<td>IPv4 gateway address for the interface. As an interface can be associated with several combinations of IP address, network mask prefix length, and gateway address, these are numbered starting from 0.</td>
</tr>
<tr>
<td><strong>HWADDR</strong></td>
<td>Media access control (MAC) address of an Ethernet device.</td>
</tr>
<tr>
<td><strong>IPADDR</strong></td>
<td>IPv4 address of the interface.</td>
</tr>
<tr>
<td><strong>IPV4_FAILURE_FATAL</strong></td>
<td>Whether the device is disabled if IPv4 configuration fails.</td>
</tr>
<tr>
<td><strong>IPV6_DEFAULTGW</strong></td>
<td>IPv6 gateway address for the interface. For example:</td>
</tr>
<tr>
<td></td>
<td>IPv6_DEFAULTGW=2001:0daa::2%em1.</td>
</tr>
<tr>
<td><strong>IPV6_FAILURE_FATAL</strong></td>
<td>Whether the device is disabled if IPv6 configuration fails.</td>
</tr>
</tbody>
</table>
| **IPV6ADDR**            | IPv6 address of the interface in CIDR notation, including the network mask prefix length. For example: IPv6ADDR="2001:0db8:1e11:115b::1/32"
| **IPV6INIT**            | Whether to enable IPv6 for the interface.                                   |
### About Network Interface Names

Network interface names are based on information derived from the system BIOS or alternatively from a device's firmware, system path, or MAC address. This feature ensures that interface names persist across system reboots, hardware reconfiguration, and updates to device drivers and the kernel.

If you enable the `biosdevname` boot option (`.biosdevname=1`), the `biosdevname` plugin to the udev device manager assigns names to network interfaces as follows:

- Ethernet interfaces on the motherboard are named `emN`, where \( N \) is the number of the interface starting from 1.
- Network interfaces on a PCI card are named `pSpP`, where \( S \) is the slot number and \( P \) is the port number.
- Virtual interfaces are named `pSpP_V`, where \( S \) is the slot number, \( P \) is the port number, and \( V \) is the virtual interface number.

If `biosdevname` is set to 0 (the default), `systemd` naming assigns the prefixes, `en`, `wl`, and `ww` to Ethernet, wireless LAN, and wireless WAN interfaces respectively. The prefix is followed by a suffix based on the hardware configuration, system bus configuration, or MAC address of the device:

- `oN` Onboard device with index number \( N \).
- `pB_sS[F][dD]` PCI device with bus number \( B \), slot number \( S \), function number \( F \), and device ID \( D \).
- `pB_sS[F][uP]..[cC][iI]` USB device with bus number \( B \), slot number \( S \), function number \( F \), port number \( P \), configuration number \( C \), and interface number \( I \).
- `sS[F][dD]` Hot-plug device with slot number \( S \), function number \( F \), and device ID \( D \).
- `xM` Device with MAC address \( M \).
For example, an Ethernet port on the motherboard might be named `eno1` or `em1`, depending on whether the value of `biosdevname` is 0 or 1.

The kernel assigns a legacy, unpredictable network interface name (ethN and wlanN) only if it cannot discover any information about the device that would allow it to disambiguate the device from other such devices. You can use the `net.ifnames=0` boot parameter to reinstate the legacy naming scheme.

**Caution**

Using the `net.ifnames` or `biosdevname` boot parameters to change the naming scheme can rendering existing firewall rules invalid. Changing the naming scheme can also affect other software that refers to network interface names.

### 10.3 About Network Configuration Files

The following sections describe additional network configuration files that you might need to configure on a system.

#### 10.3.1 /etc/hosts

The `/etc/hosts` file associates host names with IP addresses. It allows the system to look up (resolve) the IP address of a host given its name, or the name given the IP address. Most networks use DNS (Domain Name Service) to perform address or name resolution. Even if your network uses DNS, it is usual to include lines in this file that specify the IPv4 and IPv6 addresses of the loopback device, for example:

```
127.0.0.1   localhost localhost.localdomain localhost4 localhost4.localdomain4
::1         localhost localhost.localdomain localhost6 localhost6.localdomain6
```

The first and second column contains the IP address and host name. Additional columns contain aliases for the host name.

For more information, see the `hosts(5)` manual page.

#### 10.3.2 /etc/nsswitch.conf

The `/etc/nsswitch.conf` file configures how the system uses various databases and name resolution mechanisms. The first field of entries in this file identifies the name of the database. The second field defines a list of resolution mechanisms in the order in which the system attempts to resolve queries on the database.

The following example hosts definition from `/etc/nsswitch.conf` indicates that the system first attempts to resolve host names and IP addresses by querying files (that is, `/etc/hosts`) and, if that fails, next by querying a DNS server, and last of all, by querying NIS+ (NIS version 3):

```
hosts:      files dns nisplus
```

For more information, see the `nsswitch.conf(5)` manual page.

#### 10.3.3 /etc/resolv.conf

The `/etc/resolv.conf` file defines how the system uses DNS to resolve host names and IP addresses. This file usually contains a line specifying the search domains and up to three lines that specify the IP addresses of DNS server. The following entries from `/etc/resolv.conf` configure two search domains and three DNS servers:

```
search us.mydomain.com mydomain.com
nameserver 192.168.154.3
nameserver 192.168.154.4
```
If your system obtains its IP address from a DHCP server, it is usual for the system to configure the contents of this file with information also obtained using DHCP.

For more information, see the `resolv.conf(5)` manual page.

### 10.3.4 /etc/sysconfig/network

The `/etc/sysconfig/network` file specifies additional information that is valid to all network interfaces on the system. The following entries from `/etc/sysconfig/network` define that IPv4 networking is enabled, IPv6 networking is not enabled, the host name of the system, and the IP address of the default network gateway:

```
NETWORKING=yes
NETWORKING_IPV6=no
HOSTNAME=host20.mydomain.com
GATEWAY=192.168.1.1
```

For more information, see `/usr/share/doc/initscripts*/sysconfig.txt`.

### 10.4 Command-line Network Configuration Interfaces

If the NetworkManager service is running, you can use the `nmcli` command to display the state of the system's physical network interfaces, for example:

```bash
# nmcli device status
DEVICE  TYPE      STATE
em1     ethernet  connected
em2     ethernet  connected
lo      loopback  unmanaged
```

You can use the `ip` command to display the status of an interface, for debugging, or for system tuning. For example, to display the status of all active interfaces:

```bash
# ip addr show
1: lo: <LOOPBACK,UP,LOWER_UP> mtu 16436 qdisc noqueue state UNKNOWN
   link/loopback 00:00:00:00:00:00 brd 00:00:00:00:00:00
   inet 127.0.0.1/8 scope host lo
     inet6 ::1/128 scope host
     valid_lft forever preferred_lft forever
2: em1: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc pfifo_fast state UP qlen 1000
   link/ether 08:00:27:16:c3:33 brd ff:ff:ff:ff:ff:ff
   inet 10.0.2.15/24 brd 10.0.2.255 scope global em1
     inet6 fe80::a00:27ff:fe16:c333/64 scope link
     valid_lft forever preferred_lft forever
```

For each network interface, the output shows the current IP address, and the status of the interface. To display the status of a single interface such as `em1`, specify its name as shown here:

```bash
# ip addr show dev em1
2: em1: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc pfifo_fast state UP qlen 1000
   link/ether 08:00:27:16:c3:33 brd ff:ff:ff:ff:ff:ff
   inet 10.0.2.15/24 brd 10.0.2.255 scope global em1
   inet6 fe80::a00:27ff:fe16:c333/64 scope link
     valid_lft forever preferred_lft forever
```

You can also use `ip` to set properties and activate a network interface. The following example sets the IP address of the `em2` interface and activates it:

```bash
# ip addr add 10.1.1.1/24 dev em2
# ip link set em2 up
```
Note

You might be used to using the `ifconfig` command to perform these operations. However, `ifconfig` is considered obsolete and will eventually be replaced altogether by the `ip` command.

Any settings that you configure for network interfaces using `ip` do not persist across system reboots. To make the changes permanent, set the properties in the `/etc/sysconfig/network-scripts/ifcfg-interface` file.

Any changes that you make to an interface file in `/etc/sysconfig/network-scripts` do not take effect until you restart the network service or bring the interface down and back up again. For example, to restart the network service:

```
# systemctl restart network
```

To restart an individual interface, you can use the `ifup` or `ifdown` commands, which invoke the script in `/etc/sysconfig/network-scripts` that corresponds to the interface type, for example:

```
# ifdown em1
# ifup em1
```

Alternatively, you can use the `ip` command to stop and start network activity on an interface without completely tearing down and rebuilding its configuration:

```
# ip link set em1 down
# ip link set em1 up
```

The `ethtool` utility is useful for diagnosing potentially mismatched settings that affect performance, and allows you to query and set the low-level properties of a network device. Any changes that you make using `ethtool` do not persist across a reboot. To make the changes permanent, modify the settings in the device's `ifcfg-interface` file in `/etc/sysconfig/network-scripts`.

For more information, see the `ethtool(8)`, `ifup(8)`, `ip(8)`, and `nmcli(1)` manual pages.

### 10.5 Configuring Network Interfaces Using Graphical Interfaces

Note

The `NetworkManager` service and the `nmcli` command are included in the `NetworkManager` package. The Network Connections editor is included in the `nm-connection-editor` package.

The `NetworkManager` service dynamically detects and configures network connections. You can click on the network icon in the GNOME notification area to obtain information about the status of the network interfaces and to manage network connections:

- To enable or disable a network interface from the pull-down menu, use the On/Off toggle.
- To display the Settings window, select **Network Settings** from the drop-down menu.

Figure 10.2 shows the Network Settings editor.
To edit an existing interface, select it from the list and click the gear icon. You can add a profile to any interface to provide alternate configurations that you can use at any point in time. You can equally use this window to configure a network proxy or add an enable a Virtual Private Network (VPN) connection.

To perform more complex configuration and to add additional connection types, use the Network Connections editor. This tool allows you to configure wired, wireless, mobile broadband, VPN, Digital Subscriber Link (DSL), and virtual (bond, bridge, team, and VLAN) interfaces. You can open this window by using the `nm-connection-editor` command. Figure 10.2 shows the Network Connections editor.
Figure 10.2 Network Connections Editor

To create a new network interface, click the + icon, select the type of interface (hardware, virtual, or VPN) and click Create. To edit an existing interface, select it from the list and click the gear icon. To remove a selected interface, click the - icon.

You can also use the nmcli command to manage network connections through NetworkManager. For more information, see the nmcli(1) manual page.

10.6 About Network Interface Bonding

Network interface bonding combines multiple network connections into a single logical interface. A bonded network interface can increase data throughput by load balancing or can provide redundancy by allowing failover from one component device to another. By default, a bonded interface appears like a normal network device to the kernel, but it sends out network packets over the available slave devices by using a simple round-robin scheduler. You can configure bonding module parameters in the bonded interface’s configuration file to alter the behavior of load-balancing and device failover.

Basic load-balancing modes (balance-rr and balance-xor) work with any switch that supports EtherChannel or trunking. Advanced load-balancing modes (balance-tlb and balance-alb) do not impose requirements on the switching hardware, but do require that the device driver for each component interfaces implement certain specific features such as support for ethtool or the ability to modify the hardware address while the device is active. For more information see /usr/share/doc/iputils-*/README.bonding.

10.6.1 Configuring Network Interface Bonding

The bonding driver that is provided with the Oracle Linux kernel allows you to aggregate multiple network interfaces, such as em1 and em2, into a single logical interface such as bond0. You can use the Network Settings editor to create the bond and then add network interfaces to this bond. Alternatively, you can use the nmcli command to create and configure the bond.

To create and configure a bonded interface from the command line:
1. Create the bond:

```
# nmcli con add type bond con-name bond0 ifname bond0 mode balance-rr
```

This example sets the name of the bond to `bond0` and its mode to `balance-rr`. For more information about the available options for load balancing or ARP link monitoring, see `/usr/share/doc/iputils-*/*/README.bonding` and the `nmcli(1)` manual page.

2. Add each interface to the bond:

```
# nmcli con add type bond-slave ifname em1 master bond0
# nmcli con add type bond-slave ifname em2 master bond0
```

These commands add the `em1` and `em2` interfaces to `bond0`.

3. Restart the `NetworkManager` service:

```
# systemctl restart NetworkManager
```

After restarting the service, the bonded interface is available for use.

### 10.7 About Network Interface Teaming

**Note**

Network interface teaming requires Unbreakable Enterprise Kernel Release 3 (UEK R3) Quarterly Update 7 or later.

Network interface teaming is similar to network interface bonding and provides a way of implementing link aggregation that is relatively maintenance-free, as well as being simpler to modify, expand, and debug as compared with bonding.

A lightweight kernel driver implements teaming and the `teamd` daemon implements load-balancing and failover schemes termed **runners**. The following standard runners are defined:

- **activebackup**: Monitors the link for changes and selects the active port that is used to send packets.
- **broadcast**: Sends packets on all member ports.
- **lacp**: Provides load balancing by implementing the Link Aggregation Control Protocol 802.3ad on the member ports.
- **loadbalance**: In passive mode, uses the BPF hash function to select the port that is used to send packets.
  
  In active mode, uses a balancing algorithm to distribute outgoing packets over the available ports.
- **random**: Selects a port at random to send each outgoing packet.

**Note**

UEK R3 does not currently support this runner mode.

- **roundrobin**: Transmits packets over the available ports in a round-robin fashion.

For specialized applications, you can create customized runners that `teamd` can interpret. The `teamdctl` command allows you to control the operation of `teamd`. 
Configuring Network Interface Teaming

For more information, see the `teamd.conf(5)` manual page.

### 10.7.1 Configuring Network Interface Teaming

You can configure a teamed interface by creating JSON-format definitions that specify the properties of the team and each of its component interfaces. The teamd daemon then interprets these definitions. You can use the JSON-format definitions to create a team interface by starting the teamd daemon manually, by editing interface definition files in `/etc/sysconfig/network-scripts`, by using the nmcli command, or by using the Network Configuration editor (`nm-connection-editor`). This section describes the first of these methods.

To create a teamed interface by starting teamd manually:

1. Create a JSON-format definition file for the team and its component ports. For sample configurations, see the files under `/usr/share/doc/teamd-*/example_configs/`.

   The following example, which is based on the contents of the file `activebackup_ethtool_1.conf`, defines an active-backup configuration where `em4` is configured as the primary port and `em3` as the backup port and these ports are monitored by `ethtool`.

   ```json
   {
     "device": "team0",
     "runner": {"name": "activebackup"},
     "link_watch": {"name": "ethtool"},
     "ports": {
       "em3": {
         "prio": -10,
         "sticky": true
       },
       "em4": {
         "prio": 100
       }
     }
   }
   ```

2. Use the `ip` command to bring down the component ports:

   ```
   # ip link set em3 down
   # ip link set em4 down
   ```

   Active interfaces cannot be added to a team.

3. Start an instance of the teamd daemon and have it create the teamed interface by reading the configuration file (in this example, `/root/team_config/team0.conf`):

   ```
   # teamd -g -f /root/team_config/team0.conf -d
   ```

   Using team device "team0".
   Using PID file "/var/run/teamd/team0.pid"
   Using config file "/root/team_config/team0.conf"

   The `-g` option displays debugging messages and can be omitted.

4. Use the `ip` command to set the IP address and network mask prefix length of the teamed interface:

   ```
   # ip addr add 10.0.0.5/24 dev team0
   ```

   For more information, see the `teamd(8)` manual page.

### 10.7.2 Adding Ports to and Removing Ports from a Team

To add a port to a team, use the teamdctl command, for example:
Changing the Configuration of a Port in a Team

To remove a port from a team:

```
# teamdctl team0 port remove em5
```

For more information, see the `teamdctl(8)` manual page.

### 10.7.3 Changing the Configuration of a Port in a Team

You can use the `teamdctl` command to update the configuration of a constituent port of a team, for example:

```
# teamdctl team0 port config update em3 '{"prio": -10, "sticky": false}'
```

Enclose the JSON-format definition in single quotes and do not split it over multiple lines.

For more information, see the `teamdctl(8)` manual page.

### 10.7.4 Removing a Team

To remove a team, use the following command to kill the `teamd` daemon:

```
# teamd -t team0 -k
```

For more information, see the `teamd(8)` manual page.

### 10.7.5 Displaying Information About Teams

To display the network state of the teamed interface, use the `ip` command:

```
# ip addr show dev team0
```

You can use the `teamnl` command to display information about the component ports of the team:

```
# teamnl team0 ports
```

To display the current state of the team, use the `teamdctl` command, for example:

```
# teamdctl team0 state
```
You can also use `teamdctl` to display the JSON configuration of the team and each of its constituent ports:

```bash
# teamdctl team0 config dump
{
  "device": "team0",
  "link_watch": {
    "name": "ethtool"
  },
  "mcast_rejoin": {
    "count": 1
  },
  "notify_peers": {
    "count": 1
  },
  "ports": {
    "em3": {
      "prio": -10,
      "sticky": true
    },
    "em4": {
      "prio": 100
    }
  },
  "runner": {
    "name": "activebackup"
  }
}
```

For more information, see the `teamdctl(8)` and `teamnl(8)` manual pages.

### 10.8 Configuring VLANs with Untagged Data Frames

A virtual local area network (VLAN) consists of a group of machines that can communicate as if they were attached to the same physical network. A VLAN allows you to group systems regardless of their actual physical location on a LAN. In a VLAN that uses untagged data frames, you create the broadcast domain by assigning the ports of network switches to the same permanent VLAN ID or PVID (other than 1, which is the default VLAN). All ports that you assign with this PVID are in a single broadcast domain. Broadcasts between devices in the same VLAN are not visible to other ports with a different VLAN, even if they exist on the same switch.

You can use the Network Settings editor or the `nmcli` command to create a VLAN device for an Ethernet interface.

To create a VLAN device from the command line, enter:

```bash
# nmcli con add type vlan con-name bond0-pvid10 ifname bond0-pvid10 dev bond0 id 10
```

This example sets up the VLAN device `bond0-pvid10` with a PVID of 10 for the bonded interface `bond0`. In addition to the regular interface, `bond0`, which uses the physical LAN, you now have a VLAN device, `bond0-pvid10`, which can use untagged frames to access the virtual LAN.

#### Note

You do not need to create virtual interfaces for the component interfaces of a bonded interface. However, you must set the PVID on each switch port to which they connect.
Using the ip Command to Create VLAN Devices

You can also use the command to set up a VLAN device for a non-bonded interface, for example:

```bash
# nmcli con add type vlan con-name em1-pvid5 ifname em1-pvid5 dev em1 id 5
```

To obtain information about the configured VLAN interfaces, view the files in the `/proc/net/vlan` directory.

### 10.8.1 Using the ip Command to Create VLAN Devices

The `ip` command provides an alternate method of creating VLAN devices. However, such devices do not persist across system reboots.

To create a VLAN interface `em1.5` for `em1` with a PVID of 5:

```bash
# ip link add link em1 name em1.5 type vlan id 5
```

For more information, see the `ip(8)` manual page.

### 10.9 Configuring Network Routing

A system uses its routing table to determine which network interface to use when sending packets to remote systems. If a system has only a single interface, it is sufficient to configure the IP address of a gateway system on the local network that routes packets to other networks.

To create a default route for IPv4 network packets, include an entry for `GATEWAY` in the `/etc/sysconfig/network` file. For example, the following entry configures the IP address of the gateway system:

```
GATEWAY=192.0.2.1
```

If your system has more than one network interface, you can specify which interface should be used:

```
GATEWAY=192.0.2.1
GATEWAYDEV=em1
```

A single statement is usually sufficient to define the gateway for IPv6 packets, for example:

```
IPV6_DEFAULTGW="2001:db8:1e10:115b::2%em1"
```

Any changes that you make to `/etc/sysconfig/network` do not take effect until you restart the network service:

```
# systemctl restart network
```

To display the routing table, use the `ip route show` command, for example:

```
# ip route show
10.0.2.0/24 dev em1  proto kernel  scope link  src 10.0.2.15
default via 10.0.2.2 dev em1  proto static
```

This example shows that packets destined for the local network (10.0.2.0/24) do not use the gateway. The default entry means that any packets destined for addresses outside the local network are routed via the gateway 10.0.2.2.

**Note**

You might be used to using the `route` command to configure routing. However, `route` is considered obsolete and will eventually be replaced altogether by the `ip` command.
You can also use the `netstat -rn` command to display this information:

```
Kernel IP routing table
Destination     Gateway         Genmask         Flags   MSS Window  Irtt Iface
10.0.2.0        0.0.0.0         255.255.255.0   U         0 0          0 em1
0.0.0.0         10.0.2.2        0.0.0.0         UG        0 0          0 em1
```

To add or delete a route from the table, use the `ip route add` or `ip route del` commands. For example, to replace the entry for the static default route:

```
# ip route del default
# ip route show
10.0.2.0/24 dev em1  proto kernel  scope link  src 10.0.2.15
# ip route del default via 10.0.2.1 dev em1 proto static
# ip route show
10.0.2.0/24 dev em1  proto kernel  scope link  src 10.0.2.15
default via 10.0.2.2 dev em1  proto static
```

To add a route to the network 10.0.3.0/24 via 10.0.3.1 over interface `em2`, and then delete that route:

```
# ip route add 10.0.3.0/24 via 10.0.3.1 dev em2
# ip route show
10.0.2.0/24 dev em1  proto kernel  scope link  src 10.0.2.15
10.0.3.0/24 via 10.0.3.1 dev em2
# ip route del 10.0.3.0/24
# ip route show
10.0.2.0/24 dev em1  proto kernel  scope link  src 10.0.2.15
```

The `ip route get` command is a useful feature that allows you to query the route on which the system will send packets to reach a specified IP address, for example:

```
# ip route get 23.6.118.140
23.6.118.140 via 10.0.2.2 dev em2  src 10.0.2.15
    cache  mtu 1500 advmss 1460 hoplimit 64
```

In this example, packets to 23.6.118.140 are sent out of the `em1` interface via the gateway 10.0.2.2.

Any changes that you make to the routing table using `ip route` do not persist across system reboots. To permanently configure static routes, you can configure them by creating a `route-interface` file in `/etc/sysconfig/network-scripts` for the interface. For example, you would configure a static route for the `em1` interface in a file named `route-em1`. An entry in these files can take the same format as the arguments to the `ip route add` command.

For example, to define a default gateway entry for `em1`, create an entry such as the following in `route-em1`:

```
default via 10.0.2.1 dev em1
```

The following entry in `route-em2` would define a route to 10.0.3.0/24 via 10.0.3.1 over `em2`:

```
10.0.3.0/24 via 10.0.3.1 dev em2
```

Any changes that you make to a `route-interface` file do not take effect until you restart either the network service or the interface.

For more information, see the `ip(8)` and `netstat(8)` manual pages.
Chapter 11 Network Address Configuration

Table of Contents

11.1 About the Dynamic Host Configuration Protocol .......................................................... 109
11.2 Configuring a DHCP Server ......................................................................................... 109
11.3 Configuring a DHCP Client ....................................................................................... 110
11.4 About Network Address Translation ........................................................................ 111

This chapter describes how to configure a DHCP server, DHCP client, and Network Address Translation.

11.1 About the Dynamic Host Configuration Protocol

The Dynamic Host Configuration Protocol (DHCP) allows client systems to obtain network configuration information from a DHCP server each time that they connect to the network. The DHCP server is configured with a range of IP addresses and other network configuration parameters that clients need.

When you configure an Oracle Linux system as a DHCP client, the client daemon, `dhclient`, contacts the DHCP server to obtain the networking parameters. As DHCP is broadcast-based, the client must be on the same subnet as either a server or a relay agent. If a client cannot be on the same subnet as the server, a DHCP relay agent can be used to pass DHCP messages between subnets.

The server provides a lease for the IP address that it assigns to a client. The client can request specific terms for the lease, such as the duration. You can configure a DHCP server to limit the terms that it can grant for a lease. Provided that a client remains connected to the network, `dhclient` automatically renews the lease before it expires. You can configure the DHCP server to provide the same IP address to a client based on the MAC address of its network interface.

The advantages of using DHCP include:

• centralized management of IP addresses

• ease of adding new clients to a network

• reuse of IP addresses reducing the total number of IP addresses that are required

• simple reconfiguration of the IP address space on the DHCP server without needing to reconfigure each client

For more information about DHCP, see RFC 2131.

11.2 Configuring a DHCP Server

To configure an Oracle Linux system as a DHCP server:

1. Install the `dhcp` package:

```
# yum install dhcp
```

2. Edit the `/etc/dhcp/dhcpd.conf` file to store the settings that the DHCP server can provide to the clients.

The following example configures the domain name, a range of client addresses on the 192.168.2.0/24 subnet from 192.168.2.101 through 192.168.2.254 together with the IP addresses of the default
Configuring a DHCP Client

gateway and the DNS server, the default and maximum lease times in seconds, and a static IP address for the application server svr01 that is identified by its MAC address:

```
option domain-name "mydom.org";
option domain-name-servers 192.168.2.1, 10.0.1.4;
option broadcast-address 192.168.2.255;
option routers 192.168.2.1;

subnet 192.168.2.0 netmask 255.255.255.0 {
    range 192.168.2.101 192.168.2.254;
    default-lease-time 10800;
    max-lease-time 43200;
}

host svr01 {
    hardware ethernet 80:56:3e:00:10:00;
    fixed-address 192.168.2.100;
    max-lease-time 86400;
}
```

The DHCP server sends the information in the `option` lines to each client when it requests a lease on an IP address. An option applies only to a subnet if you define it inside a `subnet` definition. In the example, the options are global and apply to both the `subnet` and `host` definitions. The `subnet` and `host` definitions have different settings for the maximum lease time.

**Note**

In Oracle Linux 7, the DHCP server no longer reads its configuration from `/etc/sysconfig/dhcpd`. Instead, it reads `/etc/dhcp/dhcpd.conf` to determine the interfaces on which it should listen.

For more information and examples, see `/usr/share/doc/dhcp-version/dhcpd.conf.sample` and the `dhcpp(8)` and `dhcp-options(5)` manual pages.

3. Touch the `/var/lib/dhcpd/dhcpd.leases` file, which stores information about client leases:

```
# touch /var/lib/dhcpd/dhcpd.leases
```

4. Enter the following commands to start the DHCP service and ensure that it starts after a reboot:

```
# systemctl start dhcpd
# systemctl enable dhcpd
```

For information about configuring a DHCP relay, see the `dhcrelay(8)` manual page.

### 11.3 Configuring a DHCP Client

To configure an Oracle Linux system as a DHCP client:

1. Install the `dhclient` package:

```
# yum install dhclient
```

2. Edit `/container/name/rootfs/etc/sysconfig/network-scripts/ifcfg-iface`, where `iface` is the name of the network interface, and change the value of `BOOTPROTO` to read as:

```
BOOTPROTO=dhcp
```

3. Edit `/etc/sysconfig/network` and verify that it contains the following setting:

```
NETWORKING=yes
```
4. To specify options for the client, such as the requested lease time and the network interface on which to request an address from the server, create the file `/etc/dhclient.conf` containing the required options.

   The following example specifies that the client should use the `em2` interface, request a lease time of 24 hours, and identify itself using its MAC address:

   ```
   interface "em2" {
     send dhcp-lease-time 86400;
     send dhcp-client-identifier 80:56:3e:00:10:00;
   }
   ```

   For more information, see the `dhclient.conf(5)` manual page.

5. Restart the network interface or the network service to enable the client, for example:

   ```
   # systemctl restart network
   ```

   When the client has requested and obtained a lease, information about this lease is stored in `/var/lib/dhclient/dhclient-interface.leases`.

   For more information, see the `dhclient(8)` manual page.

### 11.4 About Network Address Translation

Network Address Translation (NAT) assigns a public address to a computer or a group of computers inside a private network with a different address scheme. The public IP address masquerades all requests as going to one server rather than several servers. NAT is useful for limiting the number of public IP addresses that an organization must finance, and for providing extra security by hiding the details of internal networks.

The `netfilter` kernel subsystem provides the `nat` table to implement NAT in addition to its tables for packet filtering. The kernel consults the `nat` table whenever it handles a packet that creates a new incoming or outgoing connection.

**Note**

If your want a system to be able to route packets between two of its network interfaces, you must turn on IP forwarding:

```
# echo 1 > /proc/sys/net/ipv4/ip_forward
```

You can use the Firewall Configuration GUI (`firewall-config`) to configure masquerading and port forwarding.

12.6 Performing DNS Lookups ............................................... 120

This chapter describes how to use BIND to set up a DNS name server.

12.1 About DNS and BIND

The Domain Name System (DNS) is a network-based service that maps (resolves) domain names to IP addresses. For a small, isolated network, you could use entries in the /etc/hosts file to provide the mapping, but most networks that are connected to the Internet use DNS.

DNS is a hierarchical and distributed database, where each level of the hierarchy is delimited by a period (.). Consider the following fully qualified domain name (FQDN):

wiki.us.mydom.com

The root domain, represented by the final period in the FQDN, is usually omitted, except in DNS configuration files:

wiki.us.mydom.com

In this example, the top-level domain is com, mydom is a subdomain of com, us is a subdomain of mydom, and wiki is the host name. Each of these domains are grouped into zones for administrative purposes. A DNS server, or name server, stores the information that is needed to resolve the component domains inside a zone. In addition, a zone’s DNS server stores pointers to the DNS servers that are responsible for resolving each subdomain.

If a client outside the us.mydom.com domain requests that its local name server resolve a FQDN such as wiki.us.mydom.com into an IP address for which the name server is not authoritative, the name server queries a root name server for the address of a name server that is authoritative for the com domain. Querying this name server returns the IP address of a name server for mydom.com. In turn, querying this name server returns the IP address of the name server for us.oracle.com, and querying this final name server returns the IP address for the FQDN. This process is known as a recursive query, where the local name server handles each referral from an external name server to another name server on behalf of the resolver.

Iterative queries rely on the resolver being able to handle the referral from each external name server to trace the name server that is authoritative for the FQDN. Most resolvers use recursive queries and so cannot use name servers that support only iterative queries. Fortunately, most

Oracle Linux provides the Berkeley Internet Name Domain (BIND) implementation of DNS. The bind package includes the DNS server daemon (named), tools for working with DNS such as rndc, and a number of configuration files, including:
About Types of Name Servers

You can configure several types of name server using BIND, including:

- **Master name server**: Authoritative for one or more domains, a master name server maintains its zone data in several database files, and can transfer this information periodically to any slave name servers that are also configured in the zone. In older documentation, master name servers are known as primary name servers. An organization might maintain two master name servers for a zone: one master outside the firewall to provide restricted information about the zone for publicly accessible hosts and services, and a hidden or *stealth* master inside the firewall that holds details of internal hosts and services.

- **Slave name server**: Acting as a backup to a master name server, a slave name server maintains a copy of the zone data, which it periodically refreshes from the master's copy. In older documentation, slave name servers are known as secondary name servers.

- **Stub name server**: A master name server for a zone might also be configured as a stub name server that maintains information about the master and slave name servers of child zones.

- **Caching-only name server**: Performs queries on behalf of a client and stores the responses in a cache after returning the results to the client. It is not authoritative for any domains and the information that it records is limited to the results of queries that it has cached.

- **Forwarding name server**: Forwards all queries to another name server and caches the results, which reduces local processing, external access, and network traffic.

In practice, a name server can be a combination of several of these types in complex configurations.

12.3 About DNS Configuration Files

Domains are grouped into zones and zones are configured through the use of zone files. Zone files store information about domains in the DNS database. Each zone file contains directives and resource records. Optional directives apply settings to a zone or instruct a name server to perform certain tasks. Resource records specify zone parameters and define information about the systems (*hosts*) in a zone.

For examples of BIND configuration files, see `/usr/share/doc/bind-version/sample/`.

12.3.1 /etc/named.conf

The main configuration file for *named* is `/etc/named.conf`, which contains settings for *named* and the top-level definitions for zones, for example:
include "/etc/rndc.key";

controls {
    inet 127.0.0.1 allow { localhost; } keys { "rndc-key"; }
};

zone "us.mydom.com" {
    type master;
    file "master-data";
    allow-update { key "rndc-key"; }
    notify yes;
}

zone "mydom.com" IN {
    type slave;
    file "sec/slave-data";
    allow-update { key "rndc-key"; }
    masters {10.1.32.1;};
}

zone "2.168.192.in-addr.arpa" IN {
    type master;
    file "reverse-192.168.2";
    allow-update { key "rndc-key"; }
    notify yes;
}

The `include` statement allows external files to be referenced so that potentially sensitive data such as key hashes can be placed in a separate file with restricted permissions.

The `controls` statement defines access information and the security requirements that are necessary to use the `rndc` command with the `named` server:

- `inet` Specifies which hosts can run `rndc` to control `named`. In this example, `rndc` must be run on the local host (127.0.0.1).
- `keys` Specifies the names of the keys that can be used. The example specifies using the key named `rndc-key`, which is defined in `/etc/rndc.key`. Keys authenticate various actions by `named` and are the primary method of controlling remote access and administration.

The `zone` statements define the role of the server in different zones.

The following zone options are used:

- `type` Specifies that this system is the master name server for the zone `us.mydom.com` and a slave server for `mydom.com.2.168.192.in-addr.arpa` is a reverse zone for resolving IP addresses to host names. See Section 12.3.3, "About Resource Records for Reverse-name Resolution”.
- `file` Specifies the path to the zone file relative to `/var/named`. The zone file for `us.mydom.com` is stored in `/var/named/master-data` and the transferred zone data for `mydom.com` is cached in `/var/named/sec/slave-data`.
- `allow-update` Specifies that a shared key must exist on both the master and a slave name server for a zone transfer to take place from the master to the slave. The following is an example record for a key in `/etc/rndc.key`:

```plaintext
key "rndc-key" {
    algorithm hmac-md5;
    secret "XQX8NmM4l+RfbbSdqcqOeJg==";
}
```
You can use the `rndc-confgen -a` command to generate a key file.

### notify
Specifies whether to notify the slave name servers when the zone information is updated.

### masters
Specifies the master name server for a slave name server.

The next example is taken from the default `/etc/named.conf` file that is installed with the `bind` package, and which configures a caching-only name server.

```plaintext
options {
    listen-on port 53 { 127.0.0.1; };
    listen-on-v6 port 53 { ::1; };
    directory        "/var/named";
    dump-file        "/var/named/data/cache_dump.db";
    statistics-file  "/var/named/data/named_stats.txt";
    memstatistics-file "/var/named/data/named_mem_stats.txt";
    allow-query { localnets; };
    recursion yes;
    dnssec-enable yes;
    dnssec-validation yes;
    dnssec-lookaside auto;

    /* Path to ISC DLV key */
    bindkeys-file "/etc/named.iscdlv.key";

    managed-keys-directory "/var/named/dynamic";
};

logging {
    channel default_debug {
        file "data/named.run";
        severity dynamic;
    };
};

zone "." IN {
    type hint;
    file "named.ca";
};

include "/etc/named.rfc1912.zones";
include "/etc/named.root.key";
```

The **options** statement defines global server configuration options and sets defaults for other statements.

- **listen-on**: The port on which `named` listens for queries.
- **directory**: Specifies the default directory for zone files if a relative pathname is specified.
- **dump-file**: Specifies where `named` dumps its cache if it crashes.
- **statistics-file**: Specifies the output file for the `rndc stats` command.
- **memstatistics-file**: Specifies the output file for `named` memory-usage statistics.
- **allow-query**: Specifies which IP addresses may query the server. `localnets` specifies all locally attached networks.
- **recursion**: Specifies whether the name server performs recursive queries.
- **dnssec-enable**: Specifies whether to use secure DNS (DNSSEC).
### 12.3.2 About Resource Records in Zone Files

A resource record in a zone file contains the following fields, some of which are optional depending on the record type:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Domain name or IP address.</td>
</tr>
<tr>
<td>TTL (time to live)</td>
<td>The maximum time that a name server caches a record before it checks whether a newer one is available.</td>
</tr>
<tr>
<td>Class</td>
<td>Always IN for Internet.</td>
</tr>
<tr>
<td>Type</td>
<td>Type of record, for example:</td>
</tr>
<tr>
<td>A (address)</td>
<td>IPv4 address corresponding to a host.</td>
</tr>
<tr>
<td>AAAA (address)</td>
<td>IPv6 address corresponding to a host.</td>
</tr>
<tr>
<td>CNAME (canonical name)</td>
<td>Alias name corresponding to a host name.</td>
</tr>
<tr>
<td>MX (mail exchange)</td>
<td>Destination for email addressed to the domain.</td>
</tr>
<tr>
<td>NS (name server)</td>
<td>Fully qualified domain name of an authoritative name server for a domain.</td>
</tr>
<tr>
<td>PTR (pointer)</td>
<td>Host name corresponding to an IP address for address to name lookups (reverse-name resolution).</td>
</tr>
<tr>
<td>SOA (start of authority)</td>
<td>Authoritative information about a zone, such as the master name server, the email address of the domain's administrator, and the domain's serial number. All records following a SOA record relate to the zone that it defines up to the next SOA record.</td>
</tr>
<tr>
<td>Data</td>
<td>The information that the record stores, such as an IP address in an A record, or a host name in a CNAME or PTR record.</td>
</tr>
</tbody>
</table>

The following example shows the contents of a typical zone file such as `/var/named/master-data`. 
About Resource Records for Reverse-name Resolution

A comment on a line is preceded by a semicolon (;).

The $TTL directive defines the default time-to-live value for all resource records in the zone. Each resource record can define its own time-to-live value, which overrides the global setting.

The SOA record is mandatory and included the following information:

- **us.mydom.com**: The name of the domain.
- **dns.us.mydom.com**: The fully qualified domain name of the name server, including a trailing period (.) for the root domain.
- **root.us.mydom.com**: The email address of the domain administrator.
- **serial**: A counter that, if incremented, tells named to reload the zone file.
- **refresh**: The time after which a master name server notifies slave name servers that they should refresh their database.
- **retry**: If a refresh fails, the time that a slave name server should wait before attempting another refresh.
- **expire**: The maximum elapsed time that a slave name server has to complete a refresh before its zone records are no longer considered authoritative and it will stop answering queries.
- **minimum**: The minimum time for which other servers should cache information obtained from this zone.

An NS record declares an authoritative name server for the domain.

Each A record specifies the IP address that corresponds to a host name in the domain.

The CNAME record creates the alias www for svr01.

For more information, see the BIND documentation in /usr/share/doc/bind-version/arm.

12.3.3 About Resource Records for Reverse-name Resolution

Forward resolution returns an IP address for a specified domain name. Reverse-name resolution returns a domain name for a specified IP address. DNS implements reverse-name resolution by using the special in-addr.arpa and ip6.arpa domains for IPv4 and IPv6.
Configuring a Name Server

The characteristics for a zone's `in-addr.arpa` or `ip6.arpa` domains are usually defined in `/etc/named.conf`, for example:

```plaintext
zone "2.168.192.in-addr.arpa" IN {
    type master;
    file "reverse-192.168.2";
    allow-update { key "rndc-key"; }
    notify yes;
};
```

The zone's name consists of `in-addr.arpa` preceded by the network portion of the IP address for the domain with its dotted quads written in reverse order.

If your network does not have a prefix length that is a multiple of 8, see RFC 2317 for the format that you should use instead.

The PTR records in `in-addr.arpa` or `ip6.arpa` domains define host names that correspond to the host portion of the IP address. The following example is take from the `/var/named/reverse-192.168.2` zone file:

```plaintext
$TTL 86400 ;
@ IN SOA dns.us.mydom.com. root.us.mydom.com. (57 ;
28800 ;
7200 ;
2419200 ;
86400 ;
)
    IN NS      dns.us.mydom.com.
1             IN  PTR     dns.us.mydom.com.
1             IN  PTR     us.mydom.com.
2             IN  PTR     svr01.us.mydom.com.
101           IN  PTR     host01.us.mydom.com.
102           IN  PTR     host02.us.mydom.com.
103           IN  PTR     host03.us.mydom.com.
...
```

For more information, see the BIND documentation in `/usr/share/doc/bind-version/arm`.

12.4 Configuring a Name Server

By default, the BIND installation allows you to configure a caching-only name server using the configuration settings that are provided in `/etc/named.conf` and files that it includes. This procedure assumes that you will either use the default settings or configure new `named` configuration and zone files.

To configure a name server:

1. Install the bind package:

   ```bash
   # yum install bind
   ```

2. If `NetworkManager` is enabled on the system, edit the `/etc/sysconfig/network-scripts/ifcfg-interface` file, and add the following entry:

   ```plaintext
   DNS1=127.0.0.1
   ```

   This line causes `NetworkManager` to add the following entry to `/etc/resolv.conf` when the network service starts:

   ```plaintext
   nameserver 127.0.0.1
   ```
This entry points the resolver at the local name server.

If you have disabled `NetworkManager`, edit `/etc/resolv.conf` to include the `nameserver 127.0.0.1` entry.

3. If required, modify the `named` configuration and zone files.

4. Configure the system firewall to allow incoming TCP connections to port 53 and incoming UDP datagrams on port 53:
   ```
   # firewall-cmd --zone=zone --add-port=53/tcp --add-port=53/udp
   # firewall-cmd --permanent --zone=zone --add-port=53/tcp --add-port=53/udp
   ```

5. Restart the `network` service, restart the `named` service, and configure `named` to start following system reboots:
   ```
   # systemctl restart network
   # systemctl start named
   # systemctl enable named
   ```

### 12.5 Administering the Name Service

The `rndc` command allows you to administer the `named` service, either locally or from a remote machine (if permitted in the `controls` section of the `/etc/named.conf` file). To prevent unauthorized access to the service, `rndc` must be configured to listen on the selected port (by default, port 953), and both named and `rndc` must have access to the same key. To generate a suitable key, use the `rndc-confgen` command:

```
# rndc-confgen -a
wrote key file "/etc/rndc.key"
```

To ensure that only `root` can read the file:

```
# chmod o-rwx /etc/rndc.key
```

To check the status of the `named` service:

```
# rndc status
number of zones: 3
debug level: 0
xfers running: 0
xfers deferred: 0
soa queries in progress: 0
query logging is OFF
recursive clients: 0/1000
tcp clients: 0/100
server is up and running
```

If you modify the `named` configuration file or zone files, `rndc reload` instructs `named` to reload the files:

```
# rndc reload
server reload successful
```

For more information, see the `named(8)`, `rndc(8)` and `rndc-confgen(8)` manual pages.

### 12.6 Performing DNS Lookups

The `host` utility is recommended for performing DNS lookups. Without any arguments, `host` displays a summary of its command-line arguments and options. For example, look up the IP address for `host01`:

```
$ host host01
```
Perform a reverse lookup for the domain name that corresponds to an IP address:

```
$ host 192.168.2.101
```

Query DNS for the IP address that corresponds to a domain:

```
$ host dns.us.mydoc.com
```

Use the `-v` and `-t` options to display verbose information about records of a certain type:

```
$ host -v -t MX www.mydom.com
```

```
Trying "www.mydom.com"
;; ->>HEADER<<- opcode: QUERY, status: NOERROR, id: 49643
;; flags: qr rd ra; QUERY: 1, ANSWER: 2, AUTHORITY: 1, ADDITIONAL: 0

;; QUESTION SECTION:
;www.mydom.com. IN MX

;; ANSWER SECTION:
www.mydom.com.acme.net. 1240 IN CNAME d4077.c.miscacme.net.

;; AUTHORITY SECTION:
c.miscacme.net. 2000 IN SOA m0e.miscacme.net. hostmaster.miss.com. ...
```

Received 163 bytes from 10.0.0.1#53 in 40 ms

The `-a` option (equivalent to `-v -t ANY`) displays all available records for a zone:

```
$ host -a www.us.mydom.com
```

```
Trying "www.us.mydom.com"
;; ->>HEADER<<- opcode: QUERY, status: NOERROR, id: 40030
;; flags: qr rd ra; QUERY: 1, ANSWER: 1, AUTHORITY: 0, ADDITIONAL: 0

;; QUESTION SECTION:
;www.us.mydom.com. IN ANY

;; ANSWER SECTION:
```

Received 72 bytes from 10.0.0.1#53 in 32 ms

For more information, see the `host(1)` manual page.
Chapter 13 Network Time Configuration

Table of Contents

13.1 About the chronyd Daemon ................................................................. 123
  13.1.1 Configuring the chronyd Service .................................................. 123
13.2 About the NTP Daemon ................................................................. 125
  13.2.1 Configuring the ntpd Service ...................................................... 125
13.3 About PTP ....................................................................................... 127
  13.3.1 Configuring the PTP Service ....................................................... 128
  13.3.2 Using PTP as a Time Source for NTP .......................................... 130

This chapter describes how to configure a system to use the chrony, Network Time Protocol (NTP), or Precision Time Protocol (PTP) daemons for setting the system time.

13.1 About the chronyd Daemon

The chrony package provides a chronyd service daemon and chronyc utility that enable mobile systems and virtual machines to update their system clock after a period of suspension or disconnection from a network.

The chronyd service is primarily designed to allow mobile systems and virtual machines to update their system clock after a period of suspension or disconnection from a network. However, you can also use it to implement a simple NTP client or a NTP server. When used as an NTP server, chronyd can synchronise with higher stratum NTP servers or it can act as a stratum 1 server using time signals received from the Global Positioning System (GPS) or radio broadcasts such as DCF77, MSF, or WWVB.

You can use the chronyc command to manage the chronyd service.

Note

chronyd uses NTP version 3 (RFC 1305), whose features are compatible with NTP version 4 (RFC 5905). However, chronyd does not support several important features of NTP version 4 nor does it support the use of PTP.

13.1.1 Configuring the chronyd Service

To configure the chronyd service on a system:

1. Install the chrony package.

   # yum install chrony

2. Edit /etc/chrony.conf to set up the configuration for chronyd.

   Note

   The default configuration assumes that the system has network access to public NTP servers with which it can synchronise. The firewall rules for your internal networks might well prevent access to these servers but instead allow access to local NTP servers.

   The following example shows a sample configuration for a system that can access three NTP servers:

   server NTP_server_1
Configuring the chronyd Service

server NTP_server_2
server NTP_server_3
driftfile /var/lib/chrony/drift
keyfile /etc/chrony.keys
commandkey 1
generatecommandkey

The `commandkey` directive specifies the `keyfile` entry that `chronyd` uses to authenticate both `chronyc` commands and NTP packets. The `generatecommandkey` directive causes `chronyd` to generate an SHA1-based password automatically when the service starts.

To configure `chronyd` to act as an NTP server for a specified client or subnet, use the `allow` directive, for example:

server NTP_server_1
server NTP_server_2
server NTP_server_3
allow 192.168.2/24
driftfile /var/lib/chrony/drift
keyfile /etc/chrony.keys
commandkey 1
generatecommandkey

If a system has only intermittent access to NTP servers, the following configuration might be appropriate:

server NTP_server_1 offline
server NTP_server_2 offline
server NTP_server_3 offline
driftfile /var/lib/chrony/drift
keyfile /etc/chrony.keys
commandkey 1
generatecommandkey

If you specify the `offline` keyword, `chronyd` does not poll the NTP servers until it is told that network access is available. You can use the `chronyc -a online` and `chronyc -a offline` command to inform `chronyd` of the state of network access.

3. If remote access to the local NTP service is required, configure the system firewall to allow access to the NTP service in the appropriate zones, for example:

```
# firewall-cmd --zone=zone --add-service=ntp
success
# firewall-cmd --zone=zone --permanent --add-service=ntp
success
```

4. Start the `chronyd` service and configure it to start following a system reboot.

```
# systemctl start chronyd
# systemctl enable chronyd
```

You can use the `chronyc` command to display information about the operation of `chronyd` or to change its configuration, for example:

```
# chronyc -a
chrony version version
...
200 OK
chronyc> sources
210 Number of sources = 4
MS Name/IP address Stratum Poll Reach LastRx Last sample
^-+ service1-eth3.debrecen.hp 2 6 37 21 -2117us[-2302us] +/- 50ms
```
**13.2 About the NTP Daemon**

The `ntpd` daemon can synchronise the system clock with remote NTP servers, with local reference clocks, or with GPS and radio time signals. `ntpd` provides a complete implementation of NTP version 4 (RFC 5905) and is also compatibility with versions 3 (RFC 1305), 2 (RFC 1119), and 1 (RFC 1059).

You can configure `ntpd` to run in several different modes, as described at http://doc.ntp.org/4.2.6p5/assoc.html, using both symmetric-key and public-key cryptography, as described at http://doc.ntp.org/4.2.6p5/authopt.html.

**13.2.1 Configuring the ntpd Service**

To configure the `ntpd` service on a system:

1. Install the `ntp` package.
   
   ```bash
   # yum install ntp
   ```

2. Edit `/etc/ntp.conf` to set up the configuration for `ntpd`.

---

```bash
chronyc> sourcestats
210 Number of sources = 4
Name/IP Address NP NR Span Frequency Freq Skew Offset Std Dev
---------------------------------------------------------------
service1-eth3.debrecen.hp 5 4 259 -0.394 41.803 -2706us 502us
ns2.telecom.lt 5 4 260 -3.948 61.422 +822us 813us
strato-ssd.vpn0.de 5 3 259 1.609 68.932 -581us 801us
kvm1.websters-computers.c 5 5 258 -0.263 9.586 +2008us 118us
chronyc> tracking
Reference ID : 212.59.0.2 (ns2.telecom.lt)
Stratum : 3
Ref time (UTC) : Tue Sep 30 12:33:16 2014
System time : 0.000354079 seconds slow of NTP time
Last offset : -0.000186183 seconds
RMS offset : 0.000186183 seconds
Frequency : 28.734 ppm slow
Residual freq : -0.489 ppm
Skew : 11.013 ppm
Root delay : 0.065965 seconds

Update interval : 64.4 seconds
Leap status : Normal
chronyc> exit
```

Using the `-a` option to `chronyc` is equivalent to entering the `authhash` and `password` subcommands, and avoids you having to specify the hash type and password every time that you use `chronyc`:

```bash
# cat /etc/chrony.keys
1 SHA1 HEX:4701E4D70E44B8D0736C8A862CFB6B8919FE340E
# chronyc
... chronyc> authhash SHA1
chronyc> password HEX:4701E4D70E44B8D0736C8A862CFB6B8919FE340E
200 OK
```

For more information, see the `chrony(1)` and `chronyc(1)` manual pages, /usr/share/doc/chrony-version/chrony.txt, or use the `info chrony` command.
Note

The default configuration assumes that the system has network access to public NTP servers with which it can synchronise. The firewall rules for your internal networks might well prevent access to these servers but instead allow access to local NTP servers.

The following example shows a sample NTP configuration for a system that can access three NTP servers:

```bash
server NTP_server_1
server NTP_server_2
server NTP_server_3
server 127.127.1.0
fudge 127.127.1.0 stratum 10
driftfile /var/lib/ntp/drift
restrict default nomodify notrap nopeer noquery
```

The `server` and `fudge` entries for 127.127.1.0 cause `ntpd` to use the local system clock if the remote NTP servers are not available. The `restrict` entry allows remote systems only to synchronise their time with the local NTP service.

For more information about configuring `ntpd`, see [http://doc.ntp.org/4.2.6p5/manyopt.html](http://doc.ntp.org/4.2.6p5/manyopt.html).

3. Create the drift file.

```bash
# touch /var/lib/ntp/drift
```

4. If remote access to the local NTP service is required, configure the system firewall to allow access to the NTP service in the appropriate zones, for example:

```bash
# firewall-cmd --zone=zone --add-service=ntp
success
# firewall-cmd --zone=zone --permanent --add-service=ntp
success
```

5. Start the `ntpd` service and configure it to start following a system reboot.

```bash
# systemctl start ntpd
# systemctl enable ntpd
```

You can use the `ntpq` and `ntpstat` commands to display information about the operation of `ntpd`, for example:

```bash
# ntpq -p
remote refid st t when poll reach delay offset jitter
*ns1.proserve.nl 193.67.79.202 2 u 21 64 377 31.420 10.742 3.689
~pomaz.hu 84.2.46.19 3 u 22 64 377 59.133 13.719 5.958
+server.104media 193.67.79.202 2 u 24 64 377 32.110 13.436 5.222
+public-timehost 193.11.166.20 2 u 28 64 377 57.214 9.304 6.311
```

```bash
# ntpstat
synchronised to NTP server (80.84.224.85) at stratum 3
time correct to within 76 ms
polling server every 64
```

For more information, see the `ntpd(8)`, `ntpd.conf(5)`, `ntpq(8)`, and `ntpstat(8)` manual pages and [http://doc.ntp.org/4.2.6p5/](http://doc.ntp.org/4.2.6p5/).
13.3 About PTP

PTP allows you to synchronise system clocks on a local area network to a higher accuracy than NTP. Provided that network drivers support either hardware or software time stamping, a PTP clock can use the time stamps in PTP messages to compensate for propagation delays across a network. Software time stamping allows PTP to synchronise systems to within a few tens of microseconds. With hardware time stamping, PTP can synchronise systems to within a few tenths of a microsecond. If you require high-precision time synchronization of systems, use hardware time stamping. Both the UEK R3 and RHCK kernels support PTP version 2 as defined in IEEE 1588.

A typical PTP configuration on an enterprise local area network consists of:

- One or more **grandmaster clock** systems.
  
  A grandmaster clock is typically implemented as specialized hardware that can use high-accuracy GPS signals or lower-accuracy code division multiple access (CDMA) signals, radio clock signals, or NTP as a time reference source. If several grandmaster clocks are available, the best master clock (BMC) algorithm selects the grandmaster clock based on the settings of their priority1, clockClass, clockAccuracy, offsetScaledLogVariance, and priority2 parameters and their unique identifier, in that order.

- Several **boundary clock** systems.
  
  Each boundary clock is slaved to a grandmaster clock on one subnetwork and relays PTP messages to one or more additional subnetworks. A boundary clock is usually implemented as a function of a network switch.

- Multiple **slave clock** systems.
  
  Each slave clock on a subnetwork is slaved to a boundary clock, which acts as the master clock for that slave clock.

A simpler configuration is to set up a single grandmaster clock and multiple slave clocks on the same network segment, which removes any need for an intermediate layer of boundary clocks.

Grandmaster and slave clock systems that use only one network interface for PTP are termed **ordinary clocks**.

Boundary clocks require at least two network interfaces for PTP: one interface acts as a slave to a grandmaster clock or a higher-level boundary clock; the other interfaces act as masters to slave clocks or lower-level boundary clocks.

Synchronization of boundary and slave clock systems is achieved by sending time stamps in PTP messages. By default, PTP messages are sent in UDPv4 datagrams. It is also possible to configure PTP to use UDPv6 datagrams or Ethernet frames as its transport mechanism.

To be able to use PTP with a system, the driver for at least one of the system's network interfaces must support either software or hardware time stamping. To find out whether the driver for a network interface supports time stamping, use the `ethtool` command as shown in the following example:

```
# ethtool -T em1
Time stamping parameters for em1:
Capabilities:
  hardware-transmit  (SOF_TIMESTAMPING_TX_HARDWARE)
  software-transmit  (SOF_TIMESTAMPING_TX_SOFTWARE)
  hardware-receive   (SOF_TIMESTAMPING_RX_HARDWARE)
  software-receive   (SOF_TIMESTAMPING_RX_SOFTWARE)
  software-system-clock  (SOF_TIMESTAMPINGSOFTWARE)
```
The output from `ethtool` in this example shows that the `em1` interface supports both hardware and software time stamping capabilities.

With software time stamping, `ptp4l` synchronises the system clock to an external grandmaster clock. If hardware time stamping is available, `ptp4l` can synchronise the PTP hardware clock to an external grandmaster clock. In this case, you use the `phc2sys` daemon to synchronise the system clock with the PTP hardware clock.

### 13.3.1 Configuring the PTP Service

To configure the PTP service on a system:

1. Install the `linuxptp` package.
   
   ```
   # yum install linuxptp
   ```

2. Edit `/etc/sysconfig/ptp4l` and define the start-up options for the `ptp4l` daemon.
   
   Grandmaster clocks and slave clocks require that you define only one interface. For example, to use hardware time stamping with interface `em1` on a slave clock:
   
   ```
   OPTIONS="-f /etc/ptp4l.conf -i em1 -s"
   ```

   To use software time stamping instead of hardware time stamping, specify the `-S` option:
   
   ```
   OPTIONS="-f /etc/ptp4l.conf -i em1 -S -s"
   ```

   **Note**
   
   The `-s` option specifies that the clock operates only as a slave (`slaveOnly` mode). Do not specify this option for a grandmaster clock or a boundary clock.

   For a grandmaster clock, omit the `-s` option, for example:
   
   ```
   OPTIONS="-f /etc/ptp4l.conf -i em1"
   ```

   A boundary clock requires that you define at least two interfaces, for example:
   
   ```
   OPTIONS="-f /etc/ptp4l.conf -i em1 -i em2"
   ```

   You might need to edit the file `/etc/ptp4l.conf` to make further adjustments to the configuration of `ptp4l`, for example:

   - For a grandmaster clock, set the value of the `priority1` parameter to a value between 0 and 127, where lower values have higher priority when the BMC algorithm selects the grandmaster clock. For a configuration that has a single grandmaster clock, a value of 127 is suggested.

   - If you set the value of `summary_interval` to an integer value \( N \) instead of 0, `ptp4l` writes summary clock statistics to `/var/log/messages` every \( 2^N \) seconds instead of every second (\( 2^0 = 1 \)). For example, a value of 10 would correspond to an interval of \( 2^{10} \) or 1024 seconds.

   - The `logging_level` parameter controls the amount of logging information that `ptp4l` records. The default value of `logging_level` is 6, which corresponds to `LOG_INFO`. To turn off logging completely, set the value of `logging_level` to 0. Alternatively, specify the `-q` option to `ptp4l`.  

---

hardware-raw-clock (SOF_TIMESTAMPING_RAW_HARDWARE)

...
For more information, see the `ptp4l(8)` manual page.

3. Configure the system firewall to allow access by PTP event and general messages to UDP ports 319 and 320 in the appropriate zone, for example:

```bash
# firewall-cmd --zone=zone --add-port=319/udp --add-port=320/udp
success
# firewall-cmd --permanent --zone=zone --add-port=319/udp --add-port=320/udp
success
```

4. Start the `ptp4l` service and configure it to start following a system reboot.

```bash
# systemctl start ptp4l
# systemctl enable ptp4l
```

5. To configure `phc2sys` on a clock system that uses hardware time stamping:

   a. Edit `/etc/sysconfig/phc2sys` and define the start-up options for the `phc2sys` daemon.

      On a boundary clock or slave clock, synchronise the system clock with the PTP hardware clock that is associated with the slave network interface, for example:

      ```sh
      OPTIONS="-c CLOCK_REALTIME -s em1 -w"
      ```

      **Note**
      The slave network interface on a boundary clock is the one that it uses to communicate with the grandmaster clock.

      The `-w` option specifies that `phc2sys` waits until `ptp4l` has synchronised the PTP hardware clock before attempting to synchronise the system clock.

      On a grandmaster clock, which derives its system time from a reference time source such as GPS, CDMA, NTP, or a radio time signal, synchronise the network interface's PTP hardware clock from the system clock, for example:

      ```sh
      OPTIONS="-c em1 -s CLOCK_REALTIME -w"
      ```

      For more information, see the `phc2sys(8)` manual page.

   b. Start the `phc2sys` service and configure it to start following a system reboot.

      ```bash
      # systemctl start phc2sys
      # systemctl enable phc2sys
      ```

You can use the `pmc` command to query the status of `ptp4l` operation. The following example shows the results of running `pmc` on a slave clock system that is directly connected to the grandmaster clock system without any intermediate boundary clocks:

```bash
# pmc -u -b 0 'GET TIME_STATUS_NP'
sending: GET TIME_STATUS_NP
080027.ffee.7f327b-0 seq 0 RESPONSE MANAGEMENT TIME_STATUS_NP
master_offset -98434
ingress_time 1412169090025854874
cumulativeScaledRateOffset +1.000000000
scaledLastGmPhaseChange 0
gmTimeBaseIndicator 0
lastGmPhaseChange 0x0000000000000000000000000000000000000000
gmPresent true
gmIdentity 080027.ffee.d9e453
# pmc -u -b 0 'GET CURRENT_DATA_SET'
```
13.3.2 Using PTP as a Time Source for NTP

To make the PTP-adjusted system time on an NTP server available to NTP clients, include the following entries in `/etc/ntp.conf` on the NTP server to define the local system clock as the time reference:

```plaintext
server    127.127.1.0
fudge     127.127.1.0 stratum 0
```

**Note**

Do not configure any additional `server` lines in the file.

For more information, see Section 13.2.1, “Configuring the ntpd Service”.

Useful information in this output includes:

- **gmIdentity**: The unique identifier of the grandmaster clock, which is based on the MAC address of its network interface.
- **gmPresent**: Whether an external grandmaster clock is available. This value is displayed as `false` on the grandmaster clock itself.
- **meanPathDelay**: An estimate of how many nanoseconds by which synchronization messages are delayed.
- **offsetFromMaster**: The most recent measurement of the time difference in nanoseconds relative to the grandmaster clock.
- **stepsRemoved**: The number of network steps between this system and the grandmaster clock.

Chapter 14 Web Service Configuration

This chapter describes how to configure a basic HTTP server.

14.1 About the Apache HTTP Server

Oracle Linux provides the Apache HTTP Server, which is an open-source web server developed by the Apache Software Foundation. The Apache server hosts web content, and responds to requests for this content from web browsers such as Firefox.

14.2 Installing the Apache HTTP Server

To install the Apache HTTP server:

1. Enter the following command:

   `# yum install httpd`

2. Start the server, and configure it to start after system reboots:

   `# apachectl start`
   `# systemctl enable httpd`

3. Check for configuration errors:

   `# apachectl configtest`

4. Create firewall rules to allow access to the ports on which the HTTP server listens, for example:

   `# firewall-cmd --zone=zone --add-service=http`
   `# firewall-cmd --permanent --zone=zone --add-service=http`

14.3 Configuring the Apache HTTP Server

Note

Any changes that you make to the configuration of the Apache HTTP server do not take effect until you restart the server:

`# apachectl restart`

The main configuration file for the Apache HTTP server is `/etc/httpd/conf/httpd.conf`. You can modify the directives in this file to customize Apache for your environment.
The directives include:

**Allow from client [client ...] | all**

Specifies a list of clients that can access content or all to serve content to any client. The **Order** directive determines the order in which **httpd** evaluates **Allow** and **Deny** directives.

**Deny from client [client ...] | all**

Specifies a list of clients that cannot access content or all to disallow all clients. The **Order** directive determines the order in which **httpd** evaluates **Allow** and **Deny** directives.

**DocumentRoot directory-path**

The top level directory for Apache server content. The **apache** user requires read access to any files and read and execute access to the directory and any of its sub-directories. Do not place a slash at the end of the directory path.

For example:

```
DocumentRoot /var/www/html
```

If you specify a different document root or link to content that is not under /var/www/html and SELinux is enabled in enforcing mode on your system, change the default file type of the directory hierarchy that contains the content to **httpd_sys_content_t**:

1. Use the **semanage** command to define the default file type of the content directory as **httpd_sys_content_t**:

   ```
   # /usr/sbin/semanage fcontext -a -t httpd_sys_content_t "content_dir(/.*)?"
   ```

2. Use the **restorecon** command to apply the file type to the entire content directory hierarchy.

   ```
   # /sbin/restorecon -R -v content_dir
   ```

**ErrorLog filename | syslog[:facility]**

If set to a file name, specifies the file, relative to **ServerRoot**, to which **httpd** sends error messages.

If set to **syslog**, specifies that **httpd** send errors to **rsyslogd**. A **facility** argument specifies the **rsyslogd** facility. The default facility is **local7**.

For example:

```
ErrorLog logs/error_log
```

**Listen [IP_address:port]**

Accept incoming requests on the specified port or IP address and port combination. By default, the **httpd** server accepts requests on port 80 for all network interfaces. For a port number other than 80, HTTP requests to the server must include the port number.

For example:

```
Listen 80
Listen 192.168.2.1:8080
```

**LoadModule module path**

The Apache HTTP server can load external modules (dynamic shared objects or DSOs) to extend its functionality. The **module** argument is the name of the DSO, and **filename** is the path name of the module relative to **ServerRoot**.
For example:

```bash
LoadModule auth_basic_module modules/mod_auth_basic.so
```

**Order deny,allow | allow,deny**

Specifies the order in which `httpd` evaluates Allow and Deny directives.

For example, permit access only to clients from the `mydom.com` domain:

```bash
Order deny,allow
Deny from all
Allow from .mydom.com
```

The following directives would not permit access by any client:

```bash
Order allow,deny
Deny from all
Allow from .mydom.com
```

**ServerName FQDN[:port]**

Specifies the fully qualified domain name or IP address of the `httpd` server and an optional port on which the server listens. The FQDN must be resolvable to an IP address. If you do not specify a FQDN, the server performs a reverse-name lookup on the IP address. If you do not specify a port, the server uses the port corresponding to the incoming request.

For example:

```bash
ServerName www.mydom.com:80
```

**ServerRoot directory-path**

The top of the directory hierarchy where the `httpd` server keeps its configuration, error, and log files. Do not place a slash at the end of the directory path.

For example:

```bash
ServerRoot /etc/httpd
```

**Timeout seconds**

Specifies the number of seconds that `httpd` waits for network operations to finish before reporting a timeout error. The default value is 60 seconds.

**UserDir directory-path ... | disabled [user user ...] | enabled user ...**

If set to `disabled`, disallows users identified by the space-separated `user` argument to publish content from their home directories. If no users are specified, all users are disallowed.

If set to `enabled`, allows users identified by the space-separated `user` argument to publish content from their home directories, provided that they are not specified as an argument to `disabled`.

`directory-path` is the name of a directory from which `httpd` publishes content. A relative path is assumed to be relative to a user’s home directory. If you specify more than one directory path, `httpd` tries each alternative in turn until find a web page. If `directory-path` is not defined, the default is `~/public_html`. Do not place a slash at the end of the directory path.
Testing the Apache HTTP Server

For example:

```
UserDir disabled root guest
UserDir enabled oracle alice
UserDir www http://www.mydom.com/
```

The root and guest users are disabled from content publishing. Assuming that ServerName is set to www.mydom.com, browsing http://www.example.com/~alice displays alice's web page, which must be located at ~alice/www or http://www.example.com/alice (that is, in the directory alice relative to ServerRoot).

**Note**
You would usually change the settings in the `<IfModule mod_userdir.c>` container to allow users to publish user content.

For more information, see [http://httpd.apache.org/docs/current/mod/directives.html](http://httpd.apache.org/docs/current/mod/directives.html).

14.4 Testing the Apache HTTP Server

To test that an Apache HTTP server is working:

- From the local system, direct a browser on the local system to http://localhost.
- From a remote system, direct a browser to http:// followed by the value of the ServerName directive specified in the configuration file (/etc/httpd/conf/httpd.conf).

If the browser displays the Apache 2 Test Page, the server is working correctly.

To test that the server can deliver content, create an HTML file named `index.html` in the directory specified by the DocumentRoot directive (by default, /var/www/html). After reloading the page, the browser should display this HTML file instead of the Apache 2 Test Page.

14.5 Configuring Apache Containers

Apache containers are special directives that group other directives, often to create separate web directory hierarchies with different characteristics. A container is delimited by the XML-style tags `<type>` and `</type>`, where `type` is the container type.

The following are examples of container types:

- `<Directory directory-path>`

  Applies the contained directives to directories under `directory-path`. The following example applies the Deny, Allow, and AllowOverride directives to all files and directories under /var/www/html/sandbox.

  ```
  <Directory /var/www/html/sandbox>
  Deny from all
  Allow from 192.168.2.
  AllowOverride All
  </Directory>
  ```

  The AllowOverride directive is only used in Directory containers and specifies which classes of directives are allowed in .htaccess files. (.htaccess configuration files typically contain user
authentication directives for a web directory.) The directive classes control such aspects as authorization, client access, and directory indexing. You can specify the argument All to permit all classes of directives in .htaccess files, a space-separated list of directive classes to permit only those classes, or None to make the server ignore .htaccess files altogether.

Note

If SELinux is enabled on the system, you must change the default file type if the file system hierarchy specified by <Directory> is not under /var/www/html.

<IfModule []]module> Applies directives if the specified module has been loaded, or, when the exclamation point (!) is specified, if the module has not been loaded.

The following example disallows user-published content if mod_userdir.c has been loaded:

```
<IfModule mod_userdir.c>
    UserDir disabled
</IfModule>
```

<Limit method ...> Places limits on the specified HTTP methods (such as GET, OPTIONS, POST, and PUT) for use with a Uniform Resource Identifier (URI).

The following example limits systems in mydom.com to using only the GET and PUT methods to perform HTTP downloads and uploads:

```
<Limit GET PUT>
    Order deny,allow
    Deny from all
    Allow from .example.com
</Limit>
```

Systems outside mydom.com cannot use GET and PUT with the URI.

<LimitExcept method ...> Places limits on all except the specified HTTP methods for use with a Uniform Resource Identifier (URI).

The following example disallows any system from using any method other than GET and POST:

```
<LimitExcept GET POST>
    Order deny,allow
    Deny from all
</Limit>
```

VirtualHost IP_address:port ... Specifies a group of directives that define a container for a virtual host. See Section 14.6, “Configuring Apache Virtual Hosts”.

14.5.1 About Nested Containers

The following example illustrates how you can nest containers, using <Limit> and <LimitExcept> containers to permit GET, POST, and OPTIONS to be used with user directories under /home/*/public_html.

```
<Directory /home/*/public_html>
```
In the example, the AllowOverride directive specifies the following directive classes:

**AuthConfig**  Permits the use of the authorization directives.

**FileInfo**  Permits the use of directives that control document types.

**Limit**  Permits the use of directives that control host access.

The Options directive controls the features of the server for the directory hierarchy, for example:

**FollowSymLinks**  Follow symbolic links under the directory hierarchy.

**Includes**  Permits server-side includes.

**IncludesNoExec**  Prevents the server from running \#exec cmd and \#exec cgi server-side includes.

**Indexes**  Generates a web directory listing if the DirectoryIndex directive is not set.

**MultiViews**  Allows the server to determine the file to use that best matches the client's requirements based on the MIME type when several versions of the file exist with different extensions.

**SymLinksIfOwnerMatch**  Allows the server to follow a symbolic link if the file or directory being pointed to has the same owner as the symbolic link.

For more information, see [http://httpd.apache.org/docs/current/mod/directives.html](http://httpd.apache.org/docs/current/mod/directives.html).

### 14.6 Configuring Apache Virtual Hosts

The Apache HTTP server supports virtual hosts, meaning that it can respond to requests that are directed to multiple IP addresses or host names that correspond to the same host machine. You can configure each virtual host to provide different content and to behave differently.

You can configure virtual hosts in two ways:

- **IP-based Virtual Hosts (host-by-IP)**

  Each virtual host has its own combination of IP address and port. The server responds to the IP address with which the host name resolves. Host-by-IP is needed to server HTTPS requests because of restrictions in the SSL (Secure Sockets Layer) protocol.

- **Name-based Virtual Hosts (host-by-name)**

  All virtual hosts share a common IP address. Apache responds to the request by mapping the host name in the request to ServerName and ServerAlias directives for the virtual host in the configuration file.
To configure a virtual host, you use the `<VirtualHost hostname>` container. You must also divide all served content between the virtual hosts that you configure.

The following example shows a simple name-based configuration for two virtual hosts:

```html
NameVirtualHost *:80

<VirtualHost *:80>
  ServerName websvr1.mydom.com
  ServerAlias www.mydom-1.com
  DocumentRoot /var/www/http/websvr1
  ErrorLog websvr1.error_log
</VirtualHost>

<VirtualHost *:80>
  ServerName websvr2.mydom.com
  ServerAlias www.mydom-2.com
  DocumentRoot /var/www/http/sebsvr2
  ErrorLog websvr2.error_log
</VirtualHost>
```

For more information, see [http://httpd.apache.org/docs/2.2/vhosts/](http://httpd.apache.org/docs/2.2/vhosts/).

15.6 Configuring a Sendmail Client .................................................................................................... 142

This chapter describes email programs and protocols that are available with Oracle Linux, and how to set up a basic Sendmail client.

15.1 About Email Programs

A Mail User Agent is an email client application that allows you to create and read email messages, set up mailboxes to store and organize messages, and send outbound messages to a Mail Transfer Agent (MTA). Many MUAs can also retrieve email messages from remote servers using the Post Office Protocol (POP) or Internet Message Access Protocol (IMAP).

A Mail Transfer Agent (MTA) transports email messages between systems by using the Simple Mail Transport Protocol (SMTP). The mail delivery services from the client program to a destination server possibly traverses several MTAs in its route. Oracle Linux offers two MTAs, Postfix and Sendmail, and also includes the special purpose MTA, Fetchmail for use with SLIP and PPP.

A Mail Delivery Agent (MDA) performs the actual delivery of an email message. The MTA invokes an MDA, such as Procmail, to place incoming email in the recipient’s mailbox file. MDAs distribute and sort messages on the local system that email client application can access.

15.2 About Email Protocols

Several different network protocols are required to deliver email messages. These protocols work together to allow different systems, often running different operating systems and different email programs, to send, transfer, and receive email.

15.2.1 About SMTP

The Simple Mail Transfer Protocol (SMTP) is a transport protocol that provides mail delivery services between email client applications and servers, and between the originating server and the destination server. You must specify the SMTP server when you configure outgoing email for an email client application.

SMTP does not require authentication. Anyone can use SMTP to send email, including junk email and unsolicited bulk email. If you administer an SMTP server, you can configure relay restrictions that limit users from sending email through it. Open relay servers do not have any such restrictions. Both Postfix and Sendmail are SMTP server programs that use SMTP. Unless you own a domain in which you want to receive email, you do not need to set up an SMTP server.
15.2.2 About POP and IMAP

The Post Office Protocol (POP) is an email access protocol that email client applications use to retrieve email messages from the mailbox on a remote server, typically maintained by an Internet Service Provider (ISP). POP email clients usually delete the message on the server when it has been successfully retrieved or within a short time period thereafter.

The Internet Message Access Protocol (IMAP) is an email access protocol that email client applications use to retrieve email messages from a remote server, typically maintained by their organization. The entire message is downloaded only when you open it, and you can delete messages from the server without first downloading them. Email is retained on the server when using IMAP.

Both POP and IMAP allow you to manage mail folders and create multiple mail directories to organize and store email.

The dovecot package provides the dovecot service that implements both an IMAP server and a POP server.

By default, the dovecot service runs IMAP and POP together with their secure versions that use Secure Socket Layer (SSL) encryption for client authentication and data transfer sessions. The IMAP and POP servers provided by dovecot are configured to work as installed. It is usually unnecessary to modify the configuration file, /etc/dovecot.conf.

For more information, see the dovecot(1) manual page and /usr/share/doc/dovecot-version.

15.3 About the Postfix SMTP Server

Postfix is configured as the default MTA on Oracle Linux. Although Postfix does not have as many features as Sendmail, it is easier to administer than Sendmail and its features are sufficient to meet the requirements of most installations. You should only use Sendmail if you want to use address re-writing rules or mail filters (milters) that are specific to Sendmail. Most mail filters function correctly with Postfix. If you do use Sendmail, disable or uninstall Postfix to avoid contention over network port usage.

Postfix has a modular design that consists of a master daemon and several smaller processes. Postfix stores its configuration files in the /etc/postfix directory, including:

- **access**: Specifies which hosts are allowed to connect to Postfix.
- **main.cf**: Contains global configuration options for Postfix.
- **master.cf**: Specifies how the Postfix master daemon and other Postfix processes interact to deliver email.
- **transport**: Specifies the mapping between destination email addresses and relay hosts.

By default, Postfix does not accept network connections from any system other than the local host. To enable mail delivery for other hosts, edit /etc/postfix/main.cf and configure their domain, host name, and network information.

Restart the Postfix service after making any configuration changes:

```bash
# systemctl restart postfix
```

For more information, see postfix(1) and other Postfix manual pages, Section 15.5, “Forwarding Email”, /usr/share/doc/postfix-version, and http://www.postfix.org/documentation.html.
15.4 About the Sendmail SMTP Server

Sendmail is highly configurable and is the most commonly used MTA on the Internet. Sendmail is mainly used to transfer email between systems, but it is capable of controlling almost every aspect of how email is handled.

Sendmail is distributed in the following packages:

**procmail** Contains Procmail, which acts as the default local MDA for Sendmail. This package is installed as a dependency of the **sendmail** package.

**sendmail** Contains the Sendmail MTA.

**sendmail-cf** Contains configuration files for Sendmail.

To install the Sendmail packages, enter:

```
# yum install sendmail sendmail-cf
```

For more information, see the `sendmail(8)` manual page.

15.4.1 About Sendmail Configuration Files

The main configuration file for Sendmail is `/etc/mail/sendmail.cf`, which is not intended to be manually edited. Instead, make any configuration changes in the `/etc/mail/sendmail.mc` file.

If you want Sendmail to relay email from other systems, change the following line in `sendmail.mc`:

```
DAEMON_OPTIONS(`Port=smtp,Addr=127.0.0.1, Name=MTA')
dnl
```

so that it reads:

```
dnl # DAEMON_OPTIONS(`Port=smtp,Addr=127.0.0.1, Name=MTA')
dnl
```

The leading `dnl` stands for delete to new line, and effectively comments out the line.

After you have edited `sendmail.mc`, restart the `sendmail` service to regenerate `sendmail.cf`:

```
# systemctl restart sendmail
```

Alternatively, you can use the `make` script in `/etc/mail`:

```
#/etc/mail/make all
```

However, Sendmail does not use the regenerated configuration file until you restart the server.

Other important Sendmail configuration files in `/etc/mail` include:

**access** Configures a relay host that processes outbound mail from the local host to other systems. This is the default configuration:

<table>
<thead>
<tr>
<th>Connect: localhost.localdomain</th>
<th>RELAY</th>
</tr>
</thead>
<tbody>
<tr>
<td>Connect: localhost</td>
<td>RELAY</td>
</tr>
<tr>
<td>Connect: 127.0.0.1</td>
<td>RELAY</td>
</tr>
</tbody>
</table>

To configure Sendmail to relay mail from other systems on a local network, add an entry such as the following:

| Connect: 192.168.2            | RELAY |
15.5 Forwarding Email

You can forward incoming email messages with the Postfix local delivery agent or with Sendmail by configuring the /etc/aliases file. Entries in this file can map inbound addresses to local users, files, commands, and remote addresses.

The following example redirects email for postmaster to root, and forwards email sent to admin on the local system to several other users, including usr04, who is on a different system:

```
postmaster:   root
admin:        usr01, usr02, usr03, usr04@another-system.com
```

To direct email to a file, specify an absolute path name instead of the destination address. To specify a command, precede it with a pipe character (|). The next example erases email sent to nemo by sending it to /dev/null, and runs a script named aggregator to process emails sent to fixme:

```
nemo:         /dev/null
fixme:        |/usr/local/bin/aggregator
```

After changing the file, run the command newaliases to rebuild the indexed database file.

For more information, see the aliases(5) manual page.

15.6 Configuring a Sendmail Client

A Sendmail client sends outbound mail to another SMTP server, which is typically administered by an ISP or the IT department of an organization, and this server then relays the email to its destination.

To configure a Sendmail client:

1. If the account on the SMTP server requires authentication:

   a. Create an auth directory under /etc/mail that is accessible only to root:

   ```
   # mkdir /etc/mail/auth
   # chmod 700 /etc/mail/auth
   ```

   b. In the auth directory, create a file smtp-auth that contains the authentication information for the SMTP server, for example:

   ```
   smtp-auth:          smtp-authconf
   ```
### Configuring a Sendmail Client

1. Create a file containing the following configuration:
   ```
   # echo 'AuthInfo:smtp.isp.com: "U:username" "P:password"' > /etc/mail/auth/smtp-auth
   ```
   where `smtp.isp.com` is the FQDN of the SMTP server, and `username` and `password` are the name and password of the account.

c. Create the database file from `smtp-auth`, and make both files read-writable only by `root`:
   ```
   # cd /etc/mail/auth
   # makemap hash smtp-auth < smtp-auth
   # chmod 600 smtp-auth smtp-auth.db
   ```

2. Edit `/etc/mail/sendmail.mc`, and change the following line:
   ```
   dnl define('SMART_host', 'smtp.your.provider')dnl
   ```
   to read:
   ```
   define('SMART_host', 'smtp.isp.com')dnl
   ```
   where `smtp.isp.com` is the FQDN of the SMTP server.

3. If the account on the SMTP server requires authentication, add the following lines after the line that defines `SMART_host`:
   ```
   define('RELAY_MAILER_ARGS', 'TCP $h port')
   define('confAUTH_MECHANISMS', 'EXTERNAL GSSAPI DIGEST-MD5 CRAM-MD5 LOGIN PLAIN')
   FEATURE('authinfo','hash /etc/mail/auth/smtp-auth.db')
   define('confAUTH_OPTIONS', 'A p y')
   ```
   where `port` is the port number used by the SMTP server (for example, 587 for SMARTTLS or 465 for SSL/TLS).

4. Edit `/etc/sysconfig/sendmail` and set the value of `DAEMON` to `no`:
   ```
   DAEMON=no
   ```
   This entry disables `sendmail` from listening on port 25 for incoming email.

5. Restart the `sendmail` service:
   ```
   # systemctl restart sendmail
   ```
   To test the configuration, send email to an account in another domain.

This configuration does not receive or relay incoming email. You can use a client application to receive email via POP or IMAP.

This chapter describes how to configure the Pacemaker and Corosync technologies to create an HA cluster that delivers continuous access to services running across multiple nodes.

16.1 About Oracle Linux high availability services

Oracle Linux high availability services comprises several open-source packages, including Corosync and Pacemaker, to provide the tools to achieve high availability for applications and services running on Oracle Linux. You may download Corosync, Pacemaker and the functional sub packages from the Unbreakable Linux Network at https://linux.oracle.com or the Oracle Linux yum server at https://yum.oracle.com.

Corosync is an open source cluster engine that includes an API to implement a number of high availability features, including an availability manager that can restart a process when it fails, a configuration and statistics database and a quorum system that can notify applications when quorum is achieved or lost.

Corosync is installed in conjunction with Pacemaker, an open source high availability cluster resource manager responsible for managing the life-cycle of software deployed on a cluster and for providing high availability services. High availability services are achieved by detecting and recovering from node and resource level failures via the API provided by the cluster engine.

Pacemaker also ships with the Pacemaker Command Shell (pcs) that can be used to access and configure the cluster and its resources. The pcs daemon runs as a service on each node in the cluster, making it possible to synchronize configuration changes across all of the nodes in the cluster.

Oracle provides support for Corosync and Pacemaker used for an active-passive 2-node (1:1) cluster configuration on Oracle Linux 7 Update 3 or higher. Support for clustering services does not imply support for Oracle products clustered using these services.

16.2 Installing Pacemaker and Corosync

On each node in the cluster, install the pcs and pacemaker software packages along with all available resource and fence agents from the Oracle Linux yum server or from the Unbreakable Linux Network.

```
# yum install pcs pacemaker resource-agents fence-agents-all
```

If you are running firewalld, you should add the high-availability service on each of the nodes, so that the service components are able to communicate across the network. This step typically enables TCP ports 2224 (used by the pcs daemon), 3121 (for Pacemaker Remote nodes), 21064 (for DLM resources); and UDP ports 5405 (for Corosync clustering) and 5404 (for Corosync multicast, if this is configured).

```
# firewall-cmd --permanent --add-service=high-availability
# firewall-cmd --add-service=high-availability
```
To use the pcs command to configure and manage your cluster, a password must be set on each node for the hacluster user. It is helpful if the password that you set for this user is the same on each node. Use the passwd command on each node to set the password:

```
# passwd hacluster
```

To use the pcs command, the pcsd service must be running on each of the nodes in the cluster. You can set this service to run and to start at boot using the following commands:

```
# systemctl start pcsd.service
# systemctl enable pcsd.service
```

### 16.3 Configuring Your First Cluster and Service

In this example, a cluster is configured across two nodes hosted on systems with the resolvable hostnames of node1 and node2. Each system is installed and configured using the instructions provided in Section 16.2, “Installing Pacemaker and Corosync”.

The cluster is configured to run a service, Dummy, that is included in the resource-agents package that you should have installed along with the pacemaker packages. This tool simply keeps track of whether it is running or not. We configure Pacemaker with an interval parameter that determines how long it should wait between checks to determine whether the Dummy process has failed.

We manually stop the Dummy process outside of the Pacemaker tool to simulate a failure and use this to demonstrate how the process is restarted automatically on an alternate node.

**Creating the cluster**

1. Authenticate the pcs cluster configuration tool for the hacluster user on each node in your configuration. To do this, run the following command on one of the nodes that will form part of the cluster:

```
# pcs cluster auth node1 node2 -u hacluster
```

Replace node1 and node2 with the resolvable hostnames of the nodes that will form part of the cluster. The tool will prompt you to provide a password for the hacluster user. You should provide the password that you set for this user when you installed and configured the Pacemaker software on each node.

2. To create the cluster, use the pcs cluster setup command. You must specify a name for the cluster and the resolvable hostnames for each node in the cluster:

```
# pcs cluster setup --name pacemaker1 node1 node2
```

Replace pacemaker1 with an appropriate name for the cluster. Replace node1 and node2 with the resolvable hostnames of the nodes in the cluster.

3. Start the cluster on all nodes. You can do this manually using the pcs command:

```
# pcs cluster start --all
```

You can also do this by starting the pacemaker and corosync services from systemd:

```
# systemctl start pacemaker.service
# systemctl start corosync.service
```

Optionally, you can enable these services to start at boot time, so that if a node reboots it automatically rejoins the cluster:
Configuring Your First Cluster and Service

### Setting Cluster Parameters

1. Fencing is an advanced feature that helps protect your data from being corrupted by nodes that may be failing or unavailable. Pacemaker uses the term **stonith** (shoot the other node in the head) to describe fencing options. Since this configuration depends on particular hardware and a deeper understanding of the fencing process, we recommend disabling the fencing feature for this example.

   ```
   # pcs property set stonith-enabled=false
   
   Fencing is an important part of setting up a production level HA cluster and is disabled in this example to keep things simple. If you intend to take advantage of stonith, see Section 16.4, “Fencing Configuration” for more information.
   ```

2. Since this example is a two-node cluster, you can disable the no-quorum policy, as quorum requires a minimum of three nodes to make any sense. Quorum is only achieved when more than half of the nodes agree on the status of the cluster. In this example, quorum can never be reached, so configure the cluster to ignore the quorum state:

   ```
   # pcs property set no-quorum-policy=ignore
   
   3. Configure a migration policy. In this example we configure the cluster to move the service to a new node after a single failure:

   ```
   # pcs resource defaults migration-threshold=1
   ```

### Creating a service and testing failover

Services are created and are usually configured to run a resource agent that is responsible for starting and stopping processes. Most resource agents are created according to the OCF (Open Cluster Framework) specification defined as an extension for the Linux Standard Base (LSB). There are many handy resource agents for commonly used processes included in the resource-agents packages, including a variety of heartbeat agents that track whether commonly used daemons or services are still running.

In this example we set up a service that uses a Dummy resource agent created precisely for the purpose of testing Pacemaker. We use this agent because it requires the least possible configuration and does not make any assumptions about your environment or the types of services that you intend to run with Pacemaker.

1. To add the service as a resource, use the `pcs resource create` command. Provide a name for the service. In the example below, we use the name `dummy_service` for this resource:

   ```
   # pcs resource create dummy_service ocf:pacemaker:Dummy op monitor interval=120s
   ```

   To invoke the Dummy resource agent, a notation (`ocf:pacemaker:Dummy`) is used to specify that it conforms to the OCF standard, that it runs in the pacemaker namespace and that the Dummy script should be used. If you were configuring a heartbeat monitor service for an Oracle Database, you might use the `ocf:heartbeat:oracle` resource agent.

   The resource is configured to use the monitor operation in the agent and an interval is set to check the health of the service. In this example we set the interval to 120s to give the service some time to fail while you are demonstrating failover. By default, this is usually set to 20 seconds, but may be modified depending on the type of service and your own environment.
2. As soon as you create a service, the cluster attempts to start the resource on a node using the resource agent’s start command. You can see the resource start and run status by running the `pcs status` command:

```bash
# pcs status
Cluster name: pacemaker1
Stack: corosync
Current DC: node1 (version 1.1.16-12.el7-94ff4df) - partition with quorum
Last updated: Wed Jan 17 06:35:18 2018
Last change: Wed Jan 17 03:08:00 2018 by root via cibadmin on node1

2 nodes configured
1 resource configured

Online: [ node2 node1 ]

Full list of resources:
  dummy_service   (ocf::pacemaker:Dummy): Started node2

Daemon Status:
  corosync: active/enabled
  pacemaker: active/enabled
  pcsd: active/enabled
```

3. Simulate service failure by force stopping the service directly, using `crm_resource`, so that the cluster is unaware that the service has been manually stopped.

```bash
# crm_resource --resource dummy_service --force-stop
```

4. Run `crm_mon` in interactive mode so that you can wait until you see the node fail and a Failed Actions message is displayed. You should see the service restart on the alternate node.

```bash
# crm_mon
Stack: corosync
Current DC: node1 (version 1.1.16-12.el7-94ff4df) - partition with quorum
Last updated: Wed Jan 17 06:41:04 2018
Last change: Wed Jan 17 06:39:02 2018 by root via cibadmin on node1

2 nodes configured
1 resource configured

Online: [ node2 node1 ]

Active resources:
  dummy_service   (ocf::pacemaker:Dummy): Started node1

Failed Actions:
  * dummy_service_monitor_120000 on node2 'not running' (7): call=16, status=complete, exitreason='none', last-rc-change='Wed Jan 17 06:41:02 2018', queued=0ms, exec=0ms

You can use the Ctrl-C key combination to exit out of `crm_mon` at any point.

5. You can try to reboot the node where the service is running to see that failover also occurs in the case of node failure. Note that if you have not enabled the corosync and pacemaker services to start on boot, you may need to start the service on the node that you have rebooted, manually. For example:

```bash
# pcs cluster start node1
```
16.4 Fencing Configuration

Fencing or `stonith` is used to protect data when nodes become unresponsive. If a node fails to respond, it may still be accessing data. To be sure that your data is safe, you can use fencing to prevent a live node from having access to the data until the original node is truly offline. To do this, you must configure a device that can ensure that a node is taken offline. There are a number of fencing agents available that can be configured for this purpose. In general, `stonith` relies on particular hardware and service protocols that can force reboot or shutdown nodes physically to protect the cluster.

In this section, different configurations using some of the available fencing agents are presented as examples. Note that these examples make certain presumptions about hardware and assume that you are already aware of how to set up, configure and use the hardware concerned. The examples are provided for basic guidance and it is recommended that you also refer to upstream documentation to familiarize yourself with some of the concepts presented here.

Before proceeding with any of these example configurations, you must ensure that `stonith` is enabled for your cluster configuration:

```bash
# pcs property set stonith-enabled=true
```

After you have configured `stonith`, you can check your configuration to ensure that it is set up correctly by running the following commands:

```bash
# pcs stonith show --full
# pcs cluster verify -V
```

To check the status of your `stonith` configuration, run:

```bash
# pcs stonith
```

To check the status of your cluster, run:

```bash
# pcs status
```

### IPMI LAN Fencing

Intelligent Platform Management Interface (IPMI) is an interface to a subsystem that provides management features of the host system’s hardware and firmware and includes facilities to power cycle a system over a dedicated network without any requirement to access the system’s operating system. The `fence_ipmilan` fencing agent can be configured for the cluster so that `stonith` can be achieved across the IPMI LAN.

If your systems are configured for IPMI, you can run the following commands on one of the nodes in the cluster to enable the `ipmilan` fencing agent and to configure `stonith` for both nodes:

```bash
# pcs stonith create ipmilan_n1_fencing fence_ipmilan pcmk_host_list=node1 delay=5 \ ipaddr=203.0.113.1 login=root passwd=password lanplus=1 op monitor interval=60s
# pcs stonith create ipmilan_n2_fencing fence_ipmilan pcmk_host_list=node2 \ ipaddr=203.0.113.2 login=root passwd=password lanplus=1 op monitor interval=60s
```

In the above example, the host named `node1` has an IPMI LAN interface configured on the IP `203.0.113.1`. The host named `node2` has an IPMI LAN interface configured on the IP `203.0.113.2`. The root user password for the IPMI login on both systems is specified here as `password`. In each instance, you should replace these configuration variables with the appropriate information to match your own environment.

Note that the delay option should only be set to one node. This helps to ensure that in the rare case of a fence race condition only one node is killed and the other continues to run. Without this option set, it is possible that both nodes believe they are the only surviving node and simultaneously reset each other.
Warning

The IPMI LAN agent exposes the login credentials of the IPMI subsystem in plain text. Your security policy should ensure that it is acceptable for users with access to the Pacemaker configuration and tools to also have access to these credentials and the underlying subsystems concerned.

SCSI Fencing

The SCSI Fencing agent is used to provide storage level fencing. This protects storage resources from being written to by two nodes at the same time, using SCSI-3 PR (Persistent Reservation). Used in conjunction with a watchdog service, a node can be reset automatically via stonith when it attempts to access the SCSI resource without a reservation.

To configure an environment in this way, install the watchdog service on both nodes and copy the provided fence_scsi_check script to the watchdog configuration before enabling the service:

```bash
# yum install watchdog
# cp /usr/share/cluster/fence_scsi_check /etc/watchdog.d/
# systemctl enable --now watchdog
```

To use this fencing agent, you must also enable the iscsid service provided in the iscsi-initiator-utils package on both nodes:

```bash
# yum install -y iscsi-initiator-utils
# systemctl enable --now iscsid
```

Once both nodes are configured with the watchdog service and the iscsid service, you can configure the fence_scsi fencing agent on one of the cluster nodes to monitor a shared storage device, such as an iSCSI target. For example:

```bash
# pcs stonith create scsi_fencing fence_scsi pcmk_host_list="node1 node2" \
    devices="/dev/sdb" meta provides="unfencing"
```

In the example, node1 and node2 are the hostnames of the nodes in the cluster and /dev/sdb is the shared storage device. You should replace these variables with the appropriate information to match your own environment.

SBD Fencing

Storage Based Death (SBD) is a daemon that can run on a system and monitor shared storage and that can use a messaging system to track cluster health. SBD can trigger a reset in the event that the appropriate fencing agent determines that stonith should be implemented.

To set up and configure SBD fencing, stop the cluster by running the following command on one of the nodes:

```bash
# pcs cluster stop --all
```

On each node, install and configure the SBD daemon:

```bash
# yum install sbd
```

Edit /etc/sysconfig/sbd to set the SBD_DEVICE parameter to identify the shared storage device. For example, if your shared storage device is available on /dev/sdc, edit the file to contain the line:

```bash
SBD_DEVICE="/dev/sdc"
```

Enable the SBD service in systemd:
On one of the nodes, create the SDB messaging layout on the shared storage device and confirm that it is in place. For example, to set up and verify messaging on the shared storage device at `/dev/sdc`, run the following commands:

```bash
# systemctl enable --now sbd

sbd -d /dev/sdc create
sbd -d /dev/sdc list
```

Finally, start the cluster and configure the fence_sbd fencing agent for the shared storage device. For example, to configure the shared storage device, `/dev/sdc`, run the following commands on one of the nodes:

```bash
# pcs cluster start --all

pcs stonith create sbd_fencing fence_sbd devices=/dev/sdc
```

**IF-MIB Fencing**

IF-MIB fencing takes advantage of SNMP to access the IF-MIB on an Ethernet network switch and to shutdown the port on the switch to effectively take a host offline. This leaves the host running, but disconnects it from the network. It is worth bearing in mind that any FibreChannel or InfiniBand connections could remain intact, even after the Ethernet connection has been terminated, which could mean that data made available on these connections could still be at risk. As a result, it is best to configure this as a fallback fencing mechanism. See Configuring Fencing Levels for more information on how to use multiple fencing agents together to maximise stonith success.

To configure IF-MIB fencing, ensure that your switch is configured for SNMP v2c at minimum and that SNMP SET messages are enabled. For example, on an Oracle Switch, via the ILOM CLI, you could run:

```bash
# set /SP/services/snmp/ sets=enabled
# set /SP/services/snmp/ v2c=enabled
```

On one of the nodes in your cluster, configure the fence_ifmib fencing agent for each node in your environment. For example:

```bash
# pcs stonith create ifmib_n1_fencing fence_ifmib pcmk_host_list=node1 \ ipaddr=203.0.113.10 community=private port=1 delay=5 op monitor interval=60s
# pcs stonith create ifmib_n2_fencing fence_ifmib pcmk_host_list=node2 \ ipaddr=203.0.113.10 community=private port=2 op monitor interval=60s
```

In the above example, the switch SNMP IF-MIB is accessible at the IP address `203.0.113.10`. The host `node1` is connected to port `1` on the switch. The host `node2` is connected to port `2` on the switch. You should replace these variables with the appropriate information to match your own environment.

**Configuring Fencing Levels**

If you have configured multiple fencing agents, you may want to set different fencing levels. Fencing levels allow you to prioritize different approaches to fencing and can provide a valuable mechanism to provide fallback options should a default fencing approach fail.

Each fencing level is attempted in ascending order starting from level 1. If the fencing agent configured for a particular level fails, the fencing agent from the next level is attempted instead.

For example, you may wish to configure IPMI-LAN fencing at level 1, but fallback to IF-MIB fencing as a level 2 option. Using the example configurations from IPMI LAN Fencing and IF-MIB Fencing, you could run the following commands on one of the nodes to set the fencing levels for each configured agent:

```bash
# pcs stonith level add 1 node1 ipmilan_n1_fencing
```
16.5 More Information

More information and documentation on Pacemaker and Corosync can be found at http://clusterlabs.org/pacemaker/doc/.

17.12 Making HAProxy Highly Available Using Oracle Clusterware .................. 175

This chapter describes how to configure the Keepalived and HAProxy technologies for balancing access to network services while maintaining continuous access to those services.

17.1 About HAProxy

HAProxy is an application layer (Layer 7) load balancing and high availability solution that you can use to implement a reverse proxy for HTTP and TCP-based Internet services.

The configuration file for the haproxy daemon is /etc/haproxy/haproxy.cfg. This file must be present on each server on which you configure HAProxy for load balancing or high availability.

For more information, see http://www.haproxy.org/#docs, the /usr/share/doc/haproxy-version documentation, and the haproxy(1) manual page.

17.2 Installing and Configuring HAProxy

To install HAProxy:

1. Install the haproxy package on each front-end server:

   # yum install haproxy

2. Edit /etc/haproxy/haproxy.cfg to configure HAProxy on each server. See Section 17.2.1, “About the HAProxy Configuration File”.

3. Enable IP forwarding and binding to non-local IP addresses:

   # echo "net.ipv4.ip_forward = 1" >> /etc/sysctl.conf
   # echo "net.ipv4.ip_nonlocal_bind = 1" >> /etc/sysctl.conf
   # sysctl -p
net.ipv4.ip_forward = 1
net.ipv4.ip_nonlocal_bind = 1

4. Enable access to the services or ports that you want HAProxy to handle.

For example, to enable access to HTTP and make this rule persist across reboots, enter the following commands:

```
# firewall-cmd --zone=zone --add-service=http
success
# firewall-cmd --permanent --zone=zone --add-service=http
success
```

To allow incoming TCP requests on port 8080:

```
# firewall-cmd --zone=zone --add-port=8080/tcp
success
# firewall-cmd --permanent --zone=zone --add-port=8080/tcp
success
```

5. Enable and start the haproxy service on each server:

```
# systemctl enable haproxy
ln -s '/usr/lib/systemd/system/haproxy.service' '/etc/systemd/system/multi-user.target.wants/haproxy.service'
# systemctl start haproxy
```

If you change the HAPerxy configuration, reload the haproxy service:

```
# systemctl reload haproxy
```

### 17.2.1 About the HAPerxy Configuration File

The /etc/haproxy/haproxy.cfg configuration file is divided into the following sections:

- **global**: Defines global settings such as the syslog facility and level to use for logging, the maximum number of concurrent connections allowed, and how many processes to start in daemon mode.

- **defaults**: Defines default settings for subsequent sections.

- **listen**: Defines a complete proxy, implicitly including the frontend and backend components.

- **frontend**: Defines the ports that accept client connections.

- **backend**: Defines the servers to which the proxy forwards client connections.

For examples of how to configure HAPerxy, see:

- Section 17.3, “Configuring Simple Load Balancing Using HAPerxy”
- Section 17.10, “Making HAPerxy Highly Available Using Keepalived”
- Section 17.12, “Making HAPerxy Highly Available Using Oracle Clusterware”

### 17.3 Configuring Simple Load Balancing Using HAPerxy

The following example uses HAPerxy to implement a front-end server that balances incoming requests between two back-end web servers, and which is also able to handle service outages on the back-end servers.
Figure 17.1 shows an HAProxy server (10.0.0.10), which is connected to an externally facing network (10.0.0/24) and to an internal network (192.168.1/24). Two web servers, `websvr1` (192.168.1.71) and `websvr2` (192.168.1.72), are accessible on the internal network. The IP address 10.0.0.10 is in the private address range 10.0.0/24, which cannot be routed on the Internet. An upstream network address translation (NAT) gateway or a proxy server provides access to and from the Internet.

Figure 17.1 Example HAProxy Configuration for Load Balancing

You might use the following configuration in `/etc/haproxy/haproxy.cfg` on the server:

```
# Handle Incoming HTTP Connection Requests
listen  http-incoming
  mode http
  bind 10.0.0.10:80

# Use each server in turn, according to its weight value
balance roundrobin

# Verify that service is available
option httpchk OPTIONS * HTTP/1.1\r\nHost: www

# Insert X-Forwarded-For header
option forwardfor

# Define the back-end servers, which can handle up to 512 concurrent connections each
server websvr1 192.168.1.71:80 weight 1 maxconn 512 check
server websvr2 192.168.1.72:80 weight 1 maxconn 512 check
```
This configuration balances HTTP traffic between the two back-end web servers `websvr1` and `websvr2`, whose firewalls are configured to accept incoming TCP requests on port 80.

After implementing simple `/var/www/html/index.html` files on the web servers and using `curl` to test connectivity, the following output demonstrate how HAProxy balances the traffic between the servers and how it handles the `httpd` service stopping on `websvr1`:

```bash
$ while true; do curl http://10.0.0.10; sleep 1; done
This is HTTP server websvr1 (192.168.1.71).
This is HTTP server websvr2 (192.168.1.72).
This is HTTP server websvr1 (192.168.1.71).
This is HTTP server websvr2 (192.168.1.72).
... This is HTTP server websvr2 (192.168.1.72).
<html><body><h1>503 Service Unavailable</h1>No server is available to handle this request.</body></html>
This is HTTP server websvr2 (192.168.1.72).
This is HTTP server websvr2 (192.168.1.72).
This is HTTP server websvr2 (192.168.1.72).
... This is HTTP server websvr2 (192.168.1.72).
This is HTTP server websvr2 (192.168.1.72).
This is HTTP server websvr2 (192.168.1.72).
This is HTTP server websvr1 (192.168.1.71).
This is HTTP server websvr2 (192.168.1.72).
This is HTTP server websvr1 (192.168.1.71).
... ^C
$
```

In this example, HAProxy detected that the `httpd` service had restarted on `websvr1` and resumed using that server in addition to `websvr2`.

By combining the load balancing capability of HAProxy with the high availability capability of Keepalived or Oracle Clusterware, you can configure a backup load balancer that ensures continuity of service in the event that the master load balancer fails. See Section 17.10, “Making HAProxy Highly Available Using Keepalived” and Section 17.12, “Making HAProxy Highly Available Using Oracle Clusterware”.

See Section 17.2, “Installing and Configuring HAProxy” for details of how to install and configure HAProxy.

### 17.3.1 Configuring HAProxy for Session Persistence

Many web-based application require that a user session is persistently served by the same web server.

If you want web sessions to have persistent connections to the same server, you can use a balance algorithm such as `hdr`, `rdp-cookie`, `source`, `url`, or `url_param`.

If your implementation requires the use of the `leastconn`, `roundrobin`, or `static-rr` algorithm, you can implement session persistence by using server-dependent cookies.

To enable session persistence for all pages on a web server, use the `cookie` directive to define the name of the cookie to be inserted and add the `cookie` option and server name to the `server` lines, for example:

```bash
cookie WEBSVR insert
server websvr1 192.168.1.71:80 weight 1 maxconn 512 cookie 1 check
server websvr2 192.168.1.72:80 weight 1 maxconn 512 cookie 2 check
```

HAProxy includes an additional `Set-Cookie:` header that identifies the web server in its response to the client, for example: `Set-Cookie: WEBSVR=N; path=page_path`. If a client subsequently
specifies the WEBSVR cookie in a request, HAProxy forwards the request to the web server whose server cookie value matches the value of WEBSVR.

The following example demonstrates how an inserted cookie ensures session persistence:

```
$ while true; do curl http://10.0.0.10; sleep 1; done
This is HTTP server websvr1 (192.168.1.71).
This is HTTP server websvr2 (192.168.1.72).
This is HTTP server websvr1 (192.168.1.71).
^C
$ curl http://10.0.0.10 -D /dev/stdout
HTTP/1.1 200 OK
Date: ...
Server: Apache/2.4.6 ()
Last-Modified: ...
ETag: "26-5125afd089491"
Accept-Ranges: bytes
Content-Length: 38
Content-Type: text/html; charset=UTF-8
Set-Cookie: WEBSVR=2; path=/
```

To enable persistence selectively on a web server, use the cookie directive to specify that HAProxy should expect the specified cookie, usually a session ID cookie or other existing cookie, to be prefixed with the server cookie value and a ~ delimiter, for example:

```
cookie SESSIONID prefix
server websvr1 192.168.1.71:80 weight 1 maxconn 512 cookie 1 check
server websvr2 192.168.1.72:80 weight 1 maxconn 512 cookie 2 check
```

If the value of SESSIONID is prefixed with a server cookie value, for example: Set-Cookie: SESSIONID=N-Session_ID; HAPerxy strips the prefix and delimiter from the SESSIONID cookie before forwarding the request to the web server whose server cookie value matches the prefix.

The following example demonstrates how using a prefixed cookie enables session persistence:

```
$ while true; do curl http://10.0.0.10 --cookie "SESSIONID=1~1234;"; sleep 1; done
This is HTTP server websvr1 (192.168.1.71).
This is HTTP server websvr2 (192.168.1.72).
This is HTTP server websvr2 (192.168.1.72).
This is HTTP server websvr2 (192.168.1.72).
^C
```

A real web application would usually set the session ID on the server side, in which case the first HAProxy response would include the prefixed cookie in the Set-Cookie: header.

### 17.4 About Keepalived

Keepalived uses the IP Virtual Server (IPVS) kernel module to provide transport layer (Layer 4) load balancing, redirecting requests for network-based services to individual members of a server cluster. IPVS monitors the status of each server and uses the Virtual Router Redundancy Protocol (VRRP) to implement high availability.

The configuration file for the keepalived daemon is /etc/keepalived/keepalived.conf. This file must be present on each server on which you configure Keepalived for load balancing or high availability.
For more information, see http://www.keepalived.org/documentation.html, the /usr/share/doc/keepalived-version documentation, and the keepalived(8) and keepalived.conf(5) manual pages.

17.5 Installing and Configuring Keepalived

To install Keepalived:

1. Install the keepalived package on each server:

```bash
# yum install keepalived
```

2. Edit /etc/keepalived/keepalived.conf to configure Keepalived on each server. See Section 17.5.1, “About the Keepalived Configuration File”.

3. Enable IP forwarding:

```bash
# echo "net.ipv4.ip_forward = 1" >> /etc/sysctl.conf
# sysctl -p
net.ipv4.ip_forward = 1
```

4. Add firewall rules to allow VRRP communication using the multicast IP address 224.0.0.18 and the VRRP protocol (112) on each network interface that Keepalived will control, for example:

```bash
# firewall-cmd --direct --permanent --add-rule ipv4 filter INPUT 0
   --in-interface enp0s8 --destination 224.0.0.18 --protocol vrrp -j ACCEPT
success
# firewall-cmd --direct --permanent --add-rule ipv4 filter OUTPUT 0
   --out-interface enp0s8 --destination 224.0.0.18 --protocol vrrp -j ACCEPT
success
# firewall-cmd --reload
success
```

5. Enable and start the keepalived service on each server:

```bash
# systemctl enable keepalived
ln -s '/usr/lib/systemd/system/keepalived.service'
   '/etc/systemd/system/multi-user.target.wants/keepalived.service'
# systemctl start keepalived
```

If you change the Keepalived configuration, reload the keepalived service:

```bash
# systemctl reload keepalived
```

17.5.1 About the Keepalived Configuration File

The /etc/keepalived/keepalived.conf configuration file is divided into the following sections:

- **global_defs**
  Defines global settings such as the email addresses for sending notification messages, the IP address of an SMTP server, the timeout value for SMTP connections in seconds, a string that identifies the host machine, the VRRP IPv4 and IPv6 multicast addresses, and whether SNMP traps should be enabled.

- **static_ipaddress**, **static_routes**
  Define static IP addresses and routes, which VRRP cannot change. These sections are not required if the addresses and routes are already defined on the servers and these servers already have network connectivity.

- **vrrp_sync_group**
  Defines a VRRP synchronization group of VRRP instances that fail over together.
**vrrp_instance**
Defines a moveable virtual IP address for a member of a VRRP synchronization group's internal or external network interface, which accompanies other group members during a state transition. Each VRRP instance must have a unique value of *virtual_router_id*, which identifies which interfaces on the master and backup servers can be assigned a given virtual IP address. You can also specify scripts that are run on state transitions to *BACKUP, MASTER, and FAULT*, and whether to trigger SMTP alerts for state transitions.

**vrrp_script**
Defines a tracking script that Keepalived can run at regular intervals to perform monitoring actions from a *vrrp_instance* or *vrrp_sync_group* section.

**virtual_server_group**
Defines a virtual server group, which allows a real server to be a member of several virtual server groups.

**virtual_server**
Defines a virtual server for load balancing, which is composed of several real servers.

For examples of how to configure Keepalived, see:

- Section 17.6, “Configuring Simple Virtual IP Address Failover Using Keepalived”
- Section 17.7, “Configuring Load Balancing Using Keepalived in NAT Mode”
- Section 17.8, “Configuring Load Balancing Using Keepalived in DR Mode”
- Section 17.10, “Making HAProx Highl Available Using Keepalived”

### 17.6 Configuring Simple Virtual IP Address Failover Using Keepalived

A typical Keepalived high-availability configuration consists of one master server and one or more backup servers. One or more virtual IP addresses, defined as *VRRP instances*, are assigned to the master server's network interfaces so that it can service network clients. The backup servers listen for multicast VRRP advertisement packets that the master server transmits at regular intervals. The default advertisement interval is one second. If the backup nodes fail to receive three consecutive VRRP advertisements, the backup server with the highest assigned priority takes over as the master server and assigns the virtual IP addresses to its own network interfaces. If several backup servers have the same priority, the backup server with the highest IP address value becomes the master server.

The following example uses Keepalived to implement a simple failover configuration on two servers. One server acts as the master, the other acts as a backup, and the master server has a higher priority than the backup server.

*Figure 17.2* shows how the virtual IP address 10.0.0.100 is initially assigned to the master server (10.0.0.71). When the master server fails, the backup server (10.0.0.72) becomes the new master server and is assigned the virtual IP address 10.0.0.100.
Configuring Simple Virtual IP Address Failover Using Keepalived

Figure 17.2 Example Keepalived Configuration for Virtual IP Address Failover

You might use the following configuration in /etc/keepalived/keepalived.conf on the master server:

global_defs {
    notification_email {
        root@mydomain.com
    }
    notification_email_from svr1@mydomain.com
    smtp_server localhost
    smtp_connect_timeout 30
}

vrrp_instance VRRP1 {
    state MASTER
    # Specify the network interface to which the virtual address is assigned
    interface enp0s8
    # The virtual router ID must be unique to each VRRP instance that you define
    virtual_router_id 41
    # Set the value of priority higher on the master server than on a backup server
    priority 200
    advert_int 1
    authentication {
        auth_type PASS
        auth_pass 1066
    }
    virtual_ipaddress {
        10.0.0.100/24
    }
}

The configuration of the backup server is the same except for the values of notification_email_from, state, priority, and possibly interface if the system hardware configuration is different:

global_defs {
    notification_email {
        root@mydomain.com
    }
    notification_email_from svr2@mydomain.com
    smtp_server localhost
}
Configuring Load Balancing Using Keepalived in NAT Mode

The following example uses Keepalived in NAT mode to implement a simple failover and load balancing configuration on two servers. One server acts as the master, the other acts as a backup, and the master server has a higher priority than the backup server. Each of the servers has two network interfaces, where one interface is connected to the side facing an external network (192.168.1.0/24) and the other interface is connected to an internal network (10.0.0.0/24) on which two web servers are accessible.

```c
smtp_connect_timeout 30
}

vrp_instance VRRP1 {
    state BACKUP
    Specify the network interface to which the virtual address is assigned
    interface enp0s8
    virtual_router_id 41
    Set the value of priority lower on the backup server than on the master server
    priority 100
    advert_int 1
    authentication {
        auth_type PASS
        auth_pass 1066
    }
    virtual_ipaddress {
        10.0.0.100/24
    }
}
```

In the event that the master server (`svr1`) fails, keepalived assigns the virtual IP address 10.0.0.100/24 to the `enp0s8` interface on the backup server (`svr2`), which becomes the master server.

To determine whether a server is acting as the master, you can use the `ip` command to see whether the virtual address is active, for example:

```
# ip addr list enp0s8
3: enp0s8: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc pfifo_fast state UP qlen 1000
    link/ether 08:00:27:cb:a6:8d brd ff:ff:ff:ff:ff:ff
    inet 10.0.0.72/24 brd 10.0.0.255 scope global enp0s8
    inet 10.0.0.100/24 scope global enp0s8
    inet6 fe80::a00:27ff:fecb:a68d/64 scope link
        valid_lft forever preferred_lft forever
```

Alternatively, search for Keepalived messages in `/var/log/messages` that show transitions between states, for example:

```
...51:55 ... VRRP_Instance(VRRP1) Entering BACKUP STATE
...
...53:08 ... VRRP_Instance(VRRP1) Transition to MASTER STATE
...53:09 ... VRRP_Instance(VRRP1) Entering MASTER STATE
...53:09 ... VRRP_Instance(VRRP1) setting protocol VIPs.
...53:09 ... VRRP_Instance(VRRP1) Sending gratuitous ARPs on enp0s8 for 10.0.0.100
```

**Note**

Only one server should be active as the master at any time. If more than one server is configured as the master, it is likely that there is a problem with VRRP communication between the servers. Check the network settings for each interface on each server and check that the firewall allows both incoming and outgoing VRRP packets for multicast IP address 224.0.0.18.

See Section 17.5, “Installing and Configuring Keepalived” for details of how to install and configure Keepalived.

### 17.7 Configuring Load Balancing Using Keepalived in NAT Mode

The following example uses Keepalived in NAT mode to implement a simple failover and load balancing configuration on two servers. One server acts as the master, the other acts as a backup, and the master server has a higher priority than the backup server. Each of the servers has two network interfaces, where one interface is connected to the side facing an external network (192.168.1.0/24) and the other interface is connected to an internal network (10.0.0.0/24) on which two web servers are accessible.
Figure 17.3 shows that the Keepalived master server has network addresses 192.168.1.10, 192.168.1.1 (virtual), 10.0.0.10, and 10.0.0.100 (virtual). The Keepalived backup server has network addresses 192.168.1.11 and 10.0.0.11. The web servers websvr1 and websvr2 have network addresses 10.0.0.71 and 10.0.0.72 respectively.

**Figure 17.3 Example Keepalived Configuration for Load Balancing in NAT Mode**

You might use the following configuration in `/etc/keepalived/keepalived.conf` on the master server:

```plaintext
global_defs {  
notification_email {  
  root@mydomain.com  
}  
notification_email_from svr1@mydomain.com  
smtp_server localhost  
smtp_connect_timeout 30  
}  

vrrp_sync_group VRRP1 {  
  # Group the external and internal VRRP instances so they fail over together  
  group {  
    external  
    internal  
  }  
}

vrrp_instance external {  
  state MASTER  
  interface enp0s8  
  virtual_router_id 91  
  priority 200  
  advert_int 1  
  authentication {  
    auth_type PASS  
    auth_pass 1215  
  }  
}
```
Configuring Load Balancing Using Keepalived in NAT Mode

```plaintext
# Define the virtual IP address for the external network interface
virtual_ipaddress {
    192.168.1.1/24
}
}

vrrp_instance internal {
    state MASTER
    interface enp0s9
    virtual_router_id 92
    priority 200
    advert_int 1
    authentication {
        auth_type PASS
        auth_pass 1215
    }
    # Define the virtual IP address for the internal network interface
    virtual_ipaddress {
        10.0.0.100/24
    }
}

# Define a virtual HTTP server on the virtual IP address 192.168.1.1
virtual_server 192.168.1.1 80 {
    delay_loop 10
    protocol TCP
    # Use round-robin scheduling in this example
    lb_algo rr
    # Use NAT to hide the back-end servers
    lb_kind NAT
    # Persistence of client sessions times out after 2 hours
    persistence_timeout 7200
    real_server 10.0.0.71 80 {
        weight 1
        TCP_CHECK {
            connect_timeout 5
            connect_port 80
        }
    }
    real_server 10.0.0.72 80 {
        weight 1
        TCP_CHECK {
            connect_timeout 5
            connect_port 80
        }
    }
}

This configuration is similar to that given in Section 17.6, “Configuring Simple Virtual IP Address Failover Using Keepalived” with the additional definition of a vrrp_sync_group section so that the network interfaces are assigned together on failover, and a virtual_server section to define the real back-end servers that Keepalived uses for load balancing. The value of lb_kind is set to NAT (Network Address Translation), which means that the Keepalived server handles both inbound and outbound network traffic from and to the client on behalf of the back-end servers.

The configuration of the backup server is the same except for the values of notification_email_from, state, priority, and possibly interface if the system hardware configuration is different:

```plaintext
global_defs {
    notification_email {
        root@mydomain.com
    }
}
```
Configuring Load Balancing Using Keepalived in NAT Mode

```
notification_email_from svr2@mydomain.com
smtp_server localhost
smtp_connect_timeout 30
}

vrrp_sync_group VRRP1 {
  # Group the external and internal VRRP instances so they fail over together
  group {
    external
    internal
  }
}

vrrp_instance external {
  state BACKUP
  interface enp0s8
  virtual_router_id 91
  priority 100
  advert_int 1
  authentication {
    auth_type PASS
    auth_pass 1215
  }
  # Define the virtual IP address for the external network interface
  virtual_ipaddress {
    192.168.1.1/24
  }
}

vrrp_instance internal {
  state BACKUP
  interface enp0s9
  virtual_router_id 92
  priority 100
  advert_int 1
  authentication {
    auth_type PASS
    auth_pass 1215
  }
  # Define the virtual IP address for the internal network interface
  virtual_ipaddress {
    10.0.0.100/24
  }
}

# Define a virtual HTTP server on the virtual IP address 192.168.1.1
virtual_server 192.168.1.1 80 {
  delay_loop 10
  protocol TCP
  # Use round-robin scheduling in this example
  lb_algo rr
  # Use NAT to hide the back-end servers
  lb_kind NAT
  # Persistence of client sessions times out after 2 hours
  persistence_timeout 7200

  real_server 10.0.0.71 80 {
    weight 1
    TCP_CHECK {
      connect_timeout 5
      connect_port 80
    }
  }

  real_server 10.0.0.72 80 {
    weight 1
    TCP_CHECK {
      connect_timeout 5
      connect_port 80
    }
  }
```
Two further configuration changes are required:

- Configure firewall rules on each Keepalived server (master and backup) that you configure as a load balancer as described in Section 17.7.1, “Configuring Firewall Rules for Keepalived NAT-Mode Load Balancing”.

- Configure a default route for the virtual IP address of the load balancer’s internal network interface on each back-end server that you intend to use with the Keepalived load balancer as described in Section 17.7.2, “Configuring Back-End Server Routing for Keepalived NAT-Mode Load Balancing”.

See Section 17.5, “Installing and Configuring Keepalived” for details of how to install and configure Keepalived.

### 17.7.1 Configuring Firewall Rules for Keepalived NAT-Mode Load Balancing

If you configure Keepalived to use NAT mode for load balancing with the servers on the internal network, the Keepalived server handles all inbound and outbound network traffic and hides the existence of the back-end servers by rewriting the source IP address of the real back-end server in outgoing packets with the virtual IP address of the external network interface.

To configure a Keepalived server to use NAT mode for load balancing:

1. Configure the firewall so that the interfaces on the external network side are in a different zone from the interfaces on the internal network side.

   The following example demonstrates how to move interface `enp0s9` to the `internal` zone while interface `enp0s8` remains in the `public` zone:

   ```bash
   # firewall-cmd --get-active-zones
   public
   interfaces: enp0s8 enp0s9
   # firewall-cmd --zone=public --remove-interface=enp0s9
   success
   # firewall-cmd --zone=internal --add-interface=enp0s9
   success
   # firewall-cmd --permanent --zone=public --remove-interface=enp0s9
   success
   # firewall-cmd --permanent --zone=internal --add-interface=enp0s9
   success
   # firewall-cmd --get-active-zones
   internal
   interfaces: enp0s9
   public
   interfaces: enp0s8
   ```

2. Configure NAT mode (masquerading) on the external network interface, for example:

   ```bash
   # firewall-cmd --zone=public --add-masquerade
   success
   # firewall-cmd --permanent --zone=public --add-masquerade
   success
   # firewall-cmd --zone=public --query-masquerade
   yes
   # firewall-cmd --zone=internal --query-masquerade
   no
   ```
3. If not already enabled for your firewall, configure forwarding rules between the external and internal network interfaces, for example:

```bash
# firewall-cmd --direct --permanent --add-rule ipv4 filter FORWARD 0 \ 
  -i enp0s8 -o enp0s9 --state RELATED,ESTABLISHED -j ACCEPT
success
# firewall-cmd --direct --permanent --add-rule ipv4 filter FORWARD 0 \ 
  -i enp0s9 -o enp0s8 -j ACCEPT
success
# firewall-cmd --direct --permanent --add-rule ipv4 filter FORWARD 0 \ 
  -j REJECT --reject-with icmp-host-prohibited
success
# firewall-cmd --reload
```

4. Enable access to the services or ports that you want Keepalived to handle.

   For example, to enable access to HTTP and make this rule persist across reboots, enter the following commands:

```bash
# firewall-cmd --zone=public --add-service=http
success
# firewall-cmd --permanent --zone=public --add-service=http
success
```

17.7.2 Configuring Back-End Server Routing for Keepalived NAT-Mode Load Balancing

   On each back-end real servers that you intend to use with the Keepalived load balancer, ensure that the routing table contains a default route for the virtual IP address of the load balancer’s internal network interface.

   For example, if the virtual IP address is 10.0.0.100, you can use the `ip` command to examine the routing table and to set the default route:

```bash
# ip route show
10.0.0.0/24 dev enp0s8  proto kernel  scope link  src 10.0.0.71
# ip route add default via 10.0.0.100 dev enp0s8
# ip route show
default via 10.0.0.100 dev enp0s8
10.0.0.0/24 dev enp0s8  proto kernel  scope link  src 10.0.0.71
```

   To make the default route for enp0s8 persist across reboots, create the file `/etc/sysconfig/network-scripts/route-enp0s8`:

```bash
# echo "default via 10.0.0.100 dev enp0s8" > /etc/sysconfig/network-scripts/route-enp0s8
```

17.8 Configuring Load Balancing Using Keepalived in DR Mode

   The following example uses Keepalived in direct routing (DR) mode to implement a simple failover and load balancing configuration on two servers. One server acts as the master, the other acts as a backup, and the master server has a higher priority than the backup server. Each of Keepalived servers has a single network interface and the servers are connected to the same network segment (10.0.0.0/24) on which two web servers are accessible.

   Figure 17.4 shows that the Keepalived master server has network addresses 10.0.0.11 and 10.0.0.1 (virtual). The Keepalived backup server has network address 10.0.0.12. The web servers `websvr1` and `websvr2` have network addresses 10.0.0.71 and 10.0.0.72 respectively. In additional, both web servers are configured with the virtual IP address 10.0.0.1 to make them accept packets with that destination address. Incoming requests are received by the master server and redirected to the web servers, which respond directly.
You might use the following configuration in `/etc/keepalived/keepalived.conf` on the master server:

```plaintext
global_defs {
    notification_email {
        root@mydomain.com
    }
    notification_email_from svr1@mydomain.com
    smtp_server localhost
    smtp_connect_timeout 30
}

vrrp_instance external {
    state MASTER
    interface enp0s8
    virtual_router_id 91
    priority 200
    advert_int 1
    authentication {
        auth_type PASS
        auth_pass 1215
    }
    virtual_ipaddress {
        10.0.0.1/24
    }
}

virtual_server 10.0.0.1 80 {
    delay_loop 10
    protocol TCP
    lb_algo rr
    # Use direct routing
    lb_kind DR
    persistence_timeout 7200

    real_server 10.0.0.71 80 {
        weight 1
        TCP_CHECK {
            connect_timeout 5
            connect_port 80
        }
    }
    real_server 10.0.0.72 80 {
        weight 1
        TCP_CHECK {
            connect_timeout 5
            connect_port 80
        }
    }
}
```
Configuring Load Balancing Using Keepalived in DR Mode

The virtual server configuration is similar to that given in Section 17.7, “Configuring Load Balancing Using Keepalived in NAT Mode” except that the value of `lb_kind` is set to DR (Direct Routing), which means that the Keepalived server handles all inbound network traffic from the client before routing it to the back-end servers, which reply directly to the client, bypassing the Keepalived server. This configuration reduces the load on the Keepalived server but is less secure as each back-end server requires external access and is potentially exposed as an attack surface. Some implementations use an additional network interface with a dedicated gateway for each web server to handle the response network traffic.

The configuration of the backup server is the same except for the values of `notification_email_from`, `state`, `priority`, and possibly `interface` if the system hardware configuration is different:

```plaintext
global_defs {
  notification_email {
    root@mydomain.com
  }
  notification_email_from svr2@mydomain.com
  smtp_server localhost
  smtp_connect_timeout 30
}

vrrp_instance external {
  state BACKUP
  interface enp0s8
  virtual_router_id 91
  priority 100
  advert_int 1
  authentication {
    auth_type PASS
    auth_pass 1215
  }
  virtual_ipaddress {
    10.0.0.1/24
  }
}

virtual_server 10.0.0.1 80 {
  delay_loop 10
  protocol TCP
  lb_algo rr
  # Use direct routing
  lb_kind DR
  persistence_timeout 7200
  real_server 10.0.0.71 80 {
    weight 1
    TCP_CHECK {
      connect_timeout 5
      connect_port 80
    }
  }
  real_server 10.0.0.72 80 {
```
Configuring Firewall Rules for Keepalived DR-Mode Load Balancing

Two further configuration changes are required:

- Configure firewall rules on each Keepalived server (master and backup) that you configure as a load balancer as described in Section 17.8.1, “Configuring Firewall Rules for Keepalived DR-Mode Load Balancing”.

- Configure the `arp_ignore` and `arp_announce` ARP parameters and the virtual IP address for the network interface on each back-end server that you intend to use with the Keepalived load balancer as described in Section 17.8.2, “Configuring the Back-End Servers for Keepalived DR-Mode Load Balancing”.

See Section 17.5, “Installing and Configuring Keepalived” for details of how to install and configure Keepalived.

17.8.1 Configuring Firewall Rules for Keepalived DR-Mode Load Balancing

Enable access to the services or ports that you want Keepalived to handle.

For example, to enable access to HTTP and make this rule persist across reboots, enter the following commands:

```
# firewall-cmd --zone=public --add-service=http
success
# firewall-cmd --permanent --zone=public --add-service=http
success
```

17.8.2 Configuring the Back-End Servers for Keepalived DR-Mode Load Balancing

The example configuration requires that the virtual IP address is configured on the master Keepalived server and on each back-end server. The Keepalived configuration maintains the virtual IP address on the master Keepalived server.

Only the master Keepalived server should respond to ARP requests for the virtual IP address. You can set the `arp_ignore` and `arp_announce` ARP parameters for the network interface of each back-end server so that they do not respond to ARP requests for the virtual IP address.

To configure the ARP parameters and virtual IP address on each back-end server:

1. Configure the ARP parameters for the primary network interface, for example `enp0s8`:

   ```
   # echo "net.ipv4.conf.enp0s8.arp_ignore = 1" >> /etc/sysctl.conf
   # echo "net.ipv4.conf.enp0s8.arp_announce = 2" >> /etc/sysctl.conf
   # sysctl -p
   net.ipv4.conf.enp0s8.arp_ignore = 1
   net.ipv4.conf.enp0s8.arp_announce = 2
   ```

2. To define a virtual IP address that persists across reboots, edit `/etc/sysconfig/network-scripts/ifcfg-<iface>` and add `IPADDR1` and `PREFIX1` entries for the virtual IP address, for example:
This example defines the virtual IP address 10.0.0.1 for `enp0s8` in addition to the existing real IP address of the back-end server.

3. Reboot the system and verify that the virtual IP address has been set up:

```
# ip addr show enp0s8
2: enp0s8: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc pfifo_fast state UP qlen 1000
   link/ether 08:00:27:cb:a6:8d brd ff:ff:ff:ff:ff:ff
   inet 10.0.0.72/24 brd 10.0.0.255 scope global enp0s8
   inet 10.0.0.1/24 brd 10.0.0.255 scope global secondary enp0s8
   inet6 fe80::a00:27ff:fecb:a68d/64 scope link
       valid_lft forever preferred_lft forever
```

17.9 Configuring Keepalived for Session Persistence and Firewall Marks

Many web-based application require that a user session is persistently served by the same web server.

If you enable the load balancer in Keepalived to use persistence, a client connects to the same server provided that the timeout period (`persistence_timeout`) has not been exceeded since the previous connection.

Firewall marks are another method for controlling session access so that Keepalived forwards a client's connections on different ports, such as HTTP (80) and HTTPS (443), to the same server, for example:

```
# firewall-cmd --direct --permanent --add-rule ipv4 mangle PREROUTING 0 -d virtual_IP_addr/32 -p tcp --multiport --dports 80,443 -j MARK --set-mark 123
success
# firewall-cmd --reload
```

These commands set a firewall mark value of 123 on packets that are destined for ports 80 or 443 at the specified virtual IP address.

You must also declare the firewall mark (`fwmark`) value to Keepalived by setting it on the virtual server instead of a destination virtual IP address and port, for example:

```
virtual_server fwmark 123 { ...
```

This configuration causes Keepalived to route the packets based on their firewall mark value rather than the destination virtual IP address and port. When used in conjunction with session persistence, firewall marks help ensure that all ports used by a client session are handled by the same server.

17.10 Making HAProxy Highly Available Using Keepalived

The following example uses Keepalived to make the HAProxy service fail over to a backup server in the event that the master server fails.
Figure 17.5 shows two HAProxy servers, which are connected to an externally facing network (10.0.0/24) as 10.0.0.11 and 10.0.0.12 and to an internal network (192.168.1/24) as 192.168.1.11 and 192.168.1.12. One HAProxy server (10.0.0.11) is configured as a Keepalived master server with the virtual IP address 10.0.0.10 and the other (10.0.0.12) is configured as a Keepalived backup server. Two web servers, `websvr1` (192.168.1.71) and `websvr2` (192.168.1.72), are accessible on the internal network. The IP address 10.0.0.10 is in the private address range 10.0.0/24, which cannot be routed on the Internet. An upstream network address translation (NAT) gateway or a proxy server provides access to and from the Internet.

Figure 17.5 Example of a Combined HAProxy and Keepalived Configuration with Web Servers on a Separate Network

The HAProxy configuration on both 10.0.0.11 and 10.0.0.12 is very similar to Section 17.3, “Configuring Simple Load Balancing Using HAProxy”. The IP address on which HAProxy listens for incoming requests is the virtual IP address that Keepalived controls.

```
global
daemon
    log 127.0.0.1 local0 debug
    maxconn 50000
    nbproc 1
defaults
    mode http
    timeout connect 5s
    timeout client 25s
    timeout server 25s
    timeout queue 10s

# Handle Incoming HTTP Connection Requests on the virtual IP address controlled by Keepalived
listen http-incoming
    mode http
    bind 10.0.0.10:80
# Use each server in turn, according to its weight value
    balance roundrobin
```
It is also possible to configure HAProxy and Keepalived directly on the web servers as shown in Figure 17.6. As in the previous example, one HAProxy server (10.0.0.11) is configured as the Keepalived master server with the virtual IP address 10.0.0.10 and the other (10.0.0.12) is configured as a Keepalived backup server. The HAProxy service on the master listens on port 80 and forwards incoming requests to one of the \texttt{httpd} services, which listen on port 8080.

**Figure 17.6 Example of a Combined HAProxy and Keepalived Configuration with Integrated Web Servers**

The HAProxy configuration is the same as the previous example except for the IP addresses and ports of the web servers.

```conf
... server websvr1 10.0.0.11:8080 weight 1 maxconn 512 check
server websvr2 10.0.0.12:8080 weight 1 maxconn 512 check
```

The firewall on each server must be configured to accept incoming TCP requests on port 8080.

The Keepalived configuration for both example configurations is similar to that given in Section 17.6, “Configuring Simple Virtual IP Address Failover Using Keepalived”.

The master server has the following Keepalived configuration:

```conf
global_defs {
    notification_email {
        root@mydomain.com
    }
    notification_email_from haproxy1@mydomain.com
    smtp_server localhost
    smtp_connect_timeout 30
}

vrrp_instance VRRP1 {
    state MASTER
    # Specify the network interface to which the virtual address is assigned
    interface enp0s8
    # The virtual router ID must be unique to each VRRP instance that you define
    virtual_router_id 41
}
About Keepalived Notification and Tracking Scripts

```plaintext
# Set the value of priority higher on the master server than on a backup server
priority 200
advert_int 1
authentication {
    auth_type PASS
    auth_pass 1066
}
virtual_ipaddress {
    10.0.0.10/24
}

The configuration of the backup server is the same except for the values of
notification_email_from, state, priority, and possibly interface if the system hardware
configuration is different:

global_defs {
    notification_email {
        root@mydomain.com
    }
    notification_email_from haproxy2@mydomain.com
    smtp_server localhost
    smtp_connect_timeout 30
}

vrrp_instance VRRP1 {
    state BACKUP
    # Specify the network interface to which the virtual address is assigned
    interface enp0s8
    virtual_router_id 41
    # Set the value of priority lower on the backup server than on the master server
    priority 100
    advert_int 1
    authentication {
        auth_type PASS
        auth_pass 1066
    }
    virtual_ipaddress {
        10.0.0.10/24
    }
}

In the event that the master server (haproxy1) fails, keepalived assigns the virtual IP address
10.0.0.10/24 to the enp0s8 interface on the backup server (haproxy2), which becomes the master
server.

See Section 17.2, “Installing and Configuring HAProxy” and Section 17.5, “Installing and Configuring
Keepalived” for details of how to install and configure HAProxy and Keepalived.

17.11 About Keepalived Notification and Tracking Scripts

Notification scripts are executable programs that Keepalived invokes when a server changes state. You
can implements notification scripts to perform actions such as reconfiguring a network interface or starting,
reloading or stopping a service.

To invoke a notification script, include one the following lines inside a vrrp_instance or
vrrp_sync_group section:

`notify program_path`  Invokes `program_path` with the following arguments:

$1  Set to INSTANCE or GROUP, depending on whether
```
Keepalived invoked the program from `vrrp_instance` or `vrrp_sync_group`.

$2

Set to the name of the `vrrp_instance` or `vrrp_sync_group`.

$3

Set to the end state of the transition: `BACKUP`, `FAULT`, or `MASTER`.

Invokes `program_path` when the end state of a transition is `BACKUP`.

If a program has arguments, enclose both the program path and the arguments in quotes.

Invokes `program_path` when the end state of a transition is `FAULT`.

Invokes `program_path` when the end state of a transition is `MASTER`.

The following executable script could be used to handle the general-purpose version of `notify`:

```bash
#!/bin/bash

ENDSTATE=$3
NAME=$2
TYPE=$1

case $ENDSTATE in
  "BACKUP") # Perform action for transition to BACKUP state
    exit 0
    ;;
  "FAULT")  # Perform action for transition to FAULT state
    exit 0
    ;;
  "MASTER") # Perform action for transition to MASTER state
    exit 0
    ;;
  *)        # Unknown state
    echo "Unknown state $ENDSTATE for VRRP $TYPE $NAME"*
    exit 1
    ;;
esac
```

Tracking scripts are programs that Keepalived runs at regular intervals, according to a `vrrp_script` definition:

```bash
vrrp_script script_name {
  script       "program_path arg ..."
  interval i   # Run script every i seconds
  fall f       # If script returns non-zero f times in succession, enter FAULT state
  rise r       # If script returns zero r times in succession, exit FAULT state
  timeout t    # Wait up to t seconds for script before assuming non-zero exit code
  weight w     # Reduce priority by w on fall
}
```

`program_path` is the full pathname of an executable script or binary.
You can use tracking scripts with a `vrrp_instance` section by specifying a `track_script` clause, for example:

```plaintext
vrrp_instance instance_name {
    state MASTER
    interface enp0s8
    virtual_router_id 21
    priority 200
    advert_int 1
    virtual_ipaddress {
        10.0.0.10/24
    }
    track_script {
        script_name ...
    }
}
```

If a configured script returns a non-zero exit code \( f \) times in succession, Keepalived changes the state of the VRRP instance or group to `FAULT`, removes the virtual IP address 10.0.0.10 from `enp0s8`, reduces the priority value by \( w \) and stops sending multicast VRRP packets. If the script subsequently returns a zero exit code \( r \) times in succession, the VRRP instance or group exits the `FAULT` state and transitions to the `MASTER` or `BACKUP` state depending on its new priority.

If you want a server to enter the `FAULT` state if one or more interfaces goes down, you can also use a `track_interface` clause, for example:

```plaintext
track_interface {
    enp0s8
    enp0s9
}
```

A possible application of tracking scripts is to deal with a potential split-brain condition in the case that some of the Keepalived servers lose communication. For example, a script could track the existence of other Keepalived servers or use shared storage or a backup communication channel to implement a voting mechanism. However, configuring Keepalived to avoid a split brain condition is complex and it is difficult to avoid corner cases where a scripted solution might not work.

For an alternative solution, see Section 17.12, “Making HAProxy Highly Available Using Oracle Clusterware”.

### 17.12 Making HAProxy Highly Available Using Oracle Clusterware

When Keepalived is used with two or more servers, loss of network connectivity can result in a split-brain condition, where more than one server acts as the master, and which can result in data corruption. To avoid this scenario, Oracle recommends that you use HAProxy in conjunction with a *shoot the other node in the head* (STONITH) solution such as Oracle Clusterware to support virtual IP address failover in preference to Keepalived.

Oracle Clusterware is a portable clustering software solution that allow you to configure independent servers so that they cooperate as a single cluster. The individual servers within the cluster cooperate so that they appear to be a single server to external client applications.

The following example uses Oracle Clusterware with HAProxy for load balancing to HTTPD web server instances on each cluster node. In the event that the node running HAProxy and an HTTPD instance fails, the services and their virtual IP addresses fail over to the other cluster node.

Figure 17.7 shows two cluster nodes, which are connected to an externally facing network. The nodes are also linked by a private network that is used for the cluster heartbeat. The nodes have shared access to
certified SAN or NAS storage that holds the voting disk and Oracle Cluster Registry (OCR) in addition to service configuration data and application data.

**Figure 17.7 Example of an Oracle Clusterware Configuration with Two Nodes**

For a high-availability configuration, Oracle recommends that the network, heartbeat, and storage connections are multiply redundant and that at least three voting disks are configured.

The following steps outline how to configure such a cluster:

1. Install Oracle Clusterware on each system that will serve as a cluster node.
2. Install the `haproxy` and `httpd` packages on each node.
3. Use the `appvipcfg` command to create a virtual IP address for HAProxy and a separate virtual IP address for each HTTPD service instance. For example, if there are two HTTPD service instances, you would need to create three different virtual IP addresses.
4. Implement cluster scripts to start, stop, clean, and check the HAProxy and HTTPD services on each node. These scripts must return 0 for success and 1 for failure.
5. Use the shared storage to share the configuration files, HTML files, logs, and all directories and files that the HAProxy and HTTPD services on each node require to start.
   
   If you have an Oracle Linux Support subscription, you can use OCFS2 or ASM/ACFS with the shared storage as an alternative to NFS or other type of shared file system.

6. Configure each HTTPD service instance so that it binds to the correct virtual IP address. Each service instance must also have an independent set of configuration, log, and other required files, so that all of the service instances can coexist on the same server if one node fails.
7. Use the `crsctl` command to create a cluster resource for HAProxy and for each HTTPD service instance. If there are two or more HTTPD service instances, binding of these instances should initially be distributed amongst the cluster nodes. The HAProxy service can be started on either node initially.
You can use Oracle Clusterware as the basis of a more complex solution that protects a multi-tiered system consisting of front-end load balancers, web servers, database servers and other components.

For more information, see the Oracle Clusterware 11g Administration and Deployment Guide and the Oracle Clusterware 12c Administration and Deployment Guide.
Chapter 18 VNC Service Configuration

Table of Contents

18.1 About VNC ............................................................................................................. 179
18.2 Configuring a VNC Server .................................................................................... 179
18.3 Connecting to VNC Desktop .................................................................................. 181

This chapter describes how to enable a Virtual Network Computing (VNC) server to provide remote access to a graphical desktop.

18.1 About VNC

Virtual Network Computing (VNC) is a system for sharing a graphical desktop over a network. A VNC client (the "viewer") connects to, and can control, a desktop that is shared by a VNC server on a remote system. Because VNC is platform independent, you can use any operating system with a VNC client to connect to a VNC server. VNC makes remote administration using graphical tools possible.

By default, all communication between a VNC client and a VNC server is not secure. You can secure VNC communication by using an SSH tunnel. Using an SSH tunnel also reduces the number of firewall ports that need to be open. Oracle recommends that you use SSH tunnels.

18.2 Configuring a VNC Server

To configure a VNC server:

1. Install the tigervnc-server package:

   ```
   # yum install tigervnc-server
   ```

2. Create the VNC environment for the VNC users.

   Each VNC desktop on the system runs a VNC server as a particular user. This user must be able to log in to the system with a user name and either a password or an SSH key (if the VNC desktop is to be accessed through an SSH tunnel).

   Use the vncpasswd command to create a password for the VNC desktop. The password must be created by the user that runs the VNC server and not root, for example:

   ```
   # su - vncuser
   $ vncpasswd
   Password: password
   Verify: password
   ```

   The password must contain at least six characters. If the password is longer than eight characters, only the first eight characters are used for authentication. An obfuscated version of the password is stored in $HOME/.vnc/passwd unless the name of a file is specified with the vncpasswd command.

3. Create a service unit configuration file for each VNC desktop that is to be made available on the system.

   a. Copy the vncserver@.service template file, for example:

   ```
   # cp /lib/systemd/system/vncserver@.service /etc/systemd/system/vncserver@:.display.service
   ```
where \textit{display} is the unique display number of the VNC desktop starting from 1. Use a backslash character (\) to escape the colon (:) character.

Each VNC desktop is associated with a user account. For ease of administration if you have multiple VNC desktops, you can include the name of the VNC user in the name of the service unit configuration file, for example:

\begin{verbatim}
# cp /lib/systemd/system/vncserver@.service \\
/etc/systemd/system/vncserver-vncuser:\:display.service
\end{verbatim}

b. Edit the service unit configuration files.

Replace any instances of \texttt{<USER>} with the user name of the user that will run the VNC desktop, for example:

\begin{verbatim}
ExecStart=/sbin/runuser -l vncuser -c "/usr/bin/vncserver %i"
PIDFile=/home/vncuser/.vnc/%H%i.pid
\end{verbatim}

Optionally, you can add command-line arguments for the VNC server. In the following example, the VNC server only accepts connections from \texttt{localhost}, which means the VNC desktop can only be accessed locally or through an SSH tunnel; and the size of the window has been changed from the default 1024x768 to 640x480 using the \texttt{geometry} flag:

\begin{verbatim}
ExecStart=/sbin/runuser -l vncuser -c "/usr/bin/vncserver %i -localhost -geometry 640x480"
PIDFile=/home/vncuser/.vnc/%H%i.pid
\end{verbatim}

4. Start the VNC desktops.

a. Make \texttt{systemd} reload its configuration files:

\begin{verbatim}
# systemctl daemon-reload
\end{verbatim}

b. For each VNC desktop, start the service, and configure the service to start following a system reboot. Remember that if you specified a username in the name of the service unit configuration file, you must specify this. Equally, you should use the same display number that you specified for the service unit configuration file name. For example:

\begin{verbatim}
# systemctl start vncserver-vncuser:\:display.service
# systemctl enable vncserver-vncuser:\:display.service
\end{verbatim}

\begin{itemize}
  \item \textbf{Note}\hfill
  \begin{itemize}
    \item If you make any changes to a service unit configuration file, you must reload the configuration file and restart the service.
  \end{itemize}
\end{itemize}

5. Configure the firewall to allow access to the VNC desktops.

If users will access the VNC desktops through an SSH tunnel and the SSH service is enabled on the system, you do not need to open additional ports in the firewall. SSH is enabled by default. For information on enabling SSH, see Section 27.3, "Configuring an OpenSSH Server".

If users will access the VNC desktops directly, you must open the required port for each desktop. The required ports can be calculated by adding the VNC desktop service display number to 5900 (the default VNC server port). So if the display number is 1, the required port is 5901 and if the display number is 67, the required port is 5967.

To open ports 5900 to 5903, you can use the following commands:
### Connecting to VNC Desktop

1. Install the TigerVNC client *(vncviewer)*.

```
# yum install tigervnc
```

2. Start the TigerVNC client and connect to a desktop.

To connect directly to a VNC desktop, you can start the TigerVNC client and enter `host:display` to specify the host name or IP address of the VNC server and the display number of the VNC desktop to connect to. Alternatively, you can specify the VNC desktop as an argument for the `vncviewer` command. For example:

```
$ vncviewer myhost.example.com:1
```
To connect to a VNC desktop through an SSH tunnel, use the `vncviewer -via` option for the command to specify the user name and host for the SSH connection, and use `localhost:display` to specify the VNC desktop. For example:

```
$ vncviewer -via vncuser@myhost.example.com localhost:67
```

See the `vncviewer(1)` manual page for more information.
Part III Storage and File Systems

This section contains the following chapters:

• Chapter 19, *Storage Management* describes how to configure and manage disk partitions, swap space, logical volumes, software RAID, block device encryption, iSCSI storage, and multipathing.

• Chapter 20, *File System Administration* describes how to create, mount, check, and repair file systems, how to configure Access Control Lists, how to configure and manage disk quotas.

• Chapter 21, *Local File System Administration* describes administration tasks for the btrfs, ext3, ext4, OCFS2, and XFS local file systems.

• Chapter 22, *Shared File System Administration* describes administration tasks for the NFS and Samba shared file systems, including how to configure NFS and Samba servers.

  19.8.1 Configuring Multipathing .................................................. 212

This chapter describes how to configure and manage disk partitions, swap space, logical volumes, software RAID, block device encryption, iSCSI storage, and multipathing.

**19.1 About Disk Partitions**

Partitioning a disk drive divides it into one or more reserved areas (*partitions*) and stores information about these partitions in the partition table on the disk. The operating system treats each partition as a separate disk that can contain a file system.

Oracle Linux requires one partition for the root file system. It is usual to use two other partitions for swap space and the boot file system. On x86 and x86_64 systems, the system BIOS can usually access only the first 1024 cylinders of the disk at boot time. Configuring a separate boot partition in this region on the disk allows the GRUB bootloader to access the kernel image and other files that are required to boot the system.

You can create additional partitions to simplify backups, to enhance system security, and to meet other needs, such as setting up development sandboxes and test areas. Data that frequently changes, such as user home directories, databases, and log file directories, is typically assigned to separate partitions to facilitate backups.
Managing Partition Tables Using fdisk

The partitioning scheme for hard disks with a master boot record (MBR) allows you to create up to four primary partitions. If you need more than four partitions, you can divide one of the primary partitions into up to 11 logical partitions. The primary partition that contains the logical partitions is known as an extended partition. The MBR scheme supports disks up to 2 TB in size.

On hard disks with a GUID Partition Table (GPT), you can configure up to 128 partitions and there is no concept of extended or logical partitions. You should configure a GPT if the disk is larger than 2 TB.

You can create and manage MBRs by using the fdisk command. If you want to create a GPT, use parted instead.

Note
When partitioning a block storage device, align primary and logical partitions on one-megabyte (1048576 bytes) boundaries. If partitions, file system blocks, or RAID stripes are incorrectly aligned and overlap the boundaries of the underlying storage's sectors or pages, the device controller has to modify twice as many sectors or pages than if correct alignment is used. This recommendation applies to most block storage devices, including hard disk drives (spinning rust), solid state drives (SSDs), LUNs on storage arrays, and host RAID adapters.

19.1.1 Managing Partition Tables Using fdisk

Caution
If any partition on the disk to be configured using fdisk is currently mounted, unmount it before running fdisk on the disk. Similarly, if any partition is being used as swap space, use the swapoff command to disable the partition.

Before running fdisk on a disk that contains data, first back up the data on to another disk or medium.

You cannot use fdisk to manage a GPT hard disk.

You can use the fdisk utility to create a partition table, view an existing partition table, add partitions, and delete partitions. Alternatively, you can also use the cfdisk utility, which is a text-based, graphical version of fdisk.

You can use fdisk interactively or you can use command-line options and arguments to specify partitions. When you run fdisk interactively, you specify only the name of the disk device as an argument, for example:

```
# fdisk /dev/sda
```

WARNING: DOS-compatible mode is deprecated. It's strongly recommended to switch off the mode (command 'c') and change display units to sectors (command 'u').

Command (m for help):

If you disable DOS-compatibility mode, fdisk aligns partitions on one-megabyte boundaries. It is recommended that you turn off DOS-compatibility mode and use display units of 512-byte sectors by specifying the -c and -u options or by entering the c and u commands.

Enter c to switch off DOS-compatibility mode, u to use sectors, and p to display the partition table:

```
Command (m for help): c
DOS Compatibility flag is not set
```
Command (m for help): u
Changing display/entry units to sectors

Command (m for help): p

Disk /dev/sda: 42.9 GB, 42949672960 bytes
255 heads, 63 sectors/track, 5221 cylinders, total 83886080 sectors
Units = sectors of 1 * 512 = 512 bytes
Sector size (logical/physical): 512 bytes / 512 bytes
I/O size (minimum/optimal): 512 bytes / 512 bytes
Disk identifier: 0x0002a95d

<table>
<thead>
<tr>
<th>Device</th>
<th>Boot</th>
<th>Start</th>
<th>End</th>
<th>Blocks</th>
<th>Id</th>
<th>System</th>
</tr>
</thead>
<tbody>
<tr>
<td>/dev/sda1 *</td>
<td></td>
<td>2048</td>
<td>1026047</td>
<td>512000</td>
<td>83</td>
<td>Linux</td>
</tr>
<tr>
<td>/dev/sda2</td>
<td></td>
<td>1026048</td>
<td>83886079</td>
<td>41430016</td>
<td>8e</td>
<td>Linux LVM</td>
</tr>
</tbody>
</table>

The example output shows that /dev/sda is a 42.9 GB disk. As modern hard disks support logical block addressing (LBA), any information about the numbers of heads and sectors per track is irrelevant and probably fictitious. The start and end offsets of each partition from the beginning of the disk are shown in units of sectors. The partition table is displayed after the device summary, and shows:

- **Device**: The device that corresponds to the partition.
- **Boot**: Specifies * if the partition contains the files that the GRUB bootloader needs to boot the system. Only one partition can be bootable.
- **Start and End**: The start and end offsets in sectors. All partitions are aligned on one-megabyte boundaries.
- **Blocks**: The size of the partition in one-kilobyte blocks.
- **Id and System**: The partition type. The following partition types are typically used with Oracle Linux:
  - **5 Extended**: An extended partition that can contain up to four logical partitions.
  - **82 Linux swap**: Swap space partition.
  - **83 Linux**: Linux partition for a file system that is not managed by LVM. This is the default partition type.
  - **8e Linux LVM**: Linux partition that is managed by LVM.

The n command creates a new partition. For example, to create partition table entries for two Linux partitions on /dev/sdc, one of which is 5 GB in size and the other occupies the remainder of the disk:

```bash
# fdisk -cu /dev/sdc
...
Command (m for help): n
Command action
  e    extended
  p    primary partition (1-4)
P
Partition number (1-4): 1
First sector (2048-25165823, default 2048): 2048
Last sector, +sectors or +size(K,M,G) (2048-25165823, default 25165823): +5G
Command (m for help): n
```
The `t` command allows you to change the type of a partition. For example, to change the partition type of partition 2 to **Linux LVM**: 

```
Command (m for help): t
Partition number (1-4): 2
Hex code (type L to list codes): 8e
```

After creating the new partition table, use the `w` command to write the table to the disk and exit `fdisk`.

```
Command (m for help): w
The partition table has been altered!
Calling ioctl() to re-read partition table.
Syncing disks.
```

If you enter `q` instead, `fdisk` exits without committing the changes to disk.

For more information, see the `cfdisk(8)` and `fdisk(8)` manual pages.

### 19.1.2 Managing Partition Tables Using parted

**Caution**

If any partition on the disk to be configured using `parted` is currently mounted, unmount it before running `parted` on the disk. Similarly, if any partition is being used as swap space, use the `swapoff` command to disable the partition.

Before running `parted` on a disk that contains data, first back up the data on to another disk or medium.

You can use the `parted` utility to label a disk, create a partition table, view an existing partition table, add partitions, change the size of partitions, and delete partitions. `parted` is more advanced than `fdisk` as it supports more disk label types, including GPT disks, and it implements a larger set of commands.
Managing Partition Tables Using parted

You can use `parted` interactively or you can specify commands as arguments. When you run `parted` interactively, you specify only the name of the disk device as an argument, for example:

```
# parted /dev/sda
GNU Parted 2.1
Using /dev/sda
Welcome to GNU Parted! Type 'help' to view a list of commands.
(parted)
```

**The `print` command displays the partition table:**

```
(parted) print
Model: ATA VBOX HARDDISK (scsi)
Disk /dev/sda: 42.9GB
Sector size (logical/physical): 512B/512B
Partition Table: msdos
Number  Start   End     Size    Type     File system  Flags
1      1049kB  525MB   524MB   primary  ext4         boot
2      525MB   42.9GB  42.4GB  primary               lvm
```

**The `mklabel` command creates a new partition table:**

```
# parted /dev/sdd
GNU Parted 2.1
Using /dev/sda
Welcome to GNU Parted! Type 'help' to view a list of commands.
(parted) mklabel
New disk label type? gpt
Warning: The existing disk label on /dev/sdd will be destroyed and all data on this disk will be lost. Do you want to continue? Yes/No? y
```

Typically, you would set the disk label type to `gpt` or `msdos` for an Oracle Linux system, depending on whether the disk device supports GPT. You are prompted to confirm that you want to overwrite the existing disk label.

**The `mkpart` command creates a new partition:**

```
(parted) mkpart
Partition name? []? <Enter>
File system type? [ext2]? ext4
Start? 1
End? 5GB
```

For disks with an `msdos` label, you are also prompted to enter the partition type, which can be `primary`, `extended`, or `logical`. The file system type is typically set to one of `fat16`, `fat32`, `ext4`, or `linux-swap` for an Oracle Linux system. If you are going to create an `btrfs`, `ext*`, `ocfs2`, or `xfs` file system on the partition, specify `ext4`. Unless you specify units such as GB for gigabytes, the start and end offsets of a partition are assumed to be in megabytes. To specify the end of the disk for `End`, enter a value of `-0`.

```
To display the new partition, use the `print` command:
```
```
(parted) print
Number  Start   End     Size    File system  Name  Flags
1      1049kB  5000MB  4999MB  ext4
```

To exit parted, enter `quit`.

**Note**

`parted` commands such as `mklabel` and `mkpart` commit the changes to disk immediately. Unlike `fdisk`, you do not have the option of quitting without saving your changes.
19.1.3 Mapping Partition Tables to Devices

You can use the `kpartx` utility to map the partitions of any block device or file that contains a partition table and partition images. `kpartx` reads the partition table and creates device files for the partitions in `/dev/mapper`. Each device file represents a disk volume or a disk partition on a device or within an image file.

The `-l` option lists any partitions that it finds, for example in an installation image file:

```
# kpartx -l system.img
loop0p1 : 0 204800 /dev/loop0 2048
loop0p2 : 0 12288000 /dev/loop0 206848
loop0p3 : 0 4096000 /dev/loop0 212494848
loop0p4 : 0 2 /dev/loop0 16590848
```

This output shows that the drive image contains four partitions, and the first column are the names of the device files that can be created in `/dev/mapper`.

The `-a` option creates the device mappings:

```
# kpartx -a system.img
# ls /dev/mapper
control  loop0p1  loop0p2  loop0p3  loop0p4
```

If a partition contains a file system, you can mount it and view the files that it contains, for example:

```
# mkdir /mnt/sysimage
# mount /dev/mapper/loop0p1 /mnt/sysimage
# ls /mnt/sysimage
config-2.6.32-220.el6.x86_64
config-2.6.32-300.3.1.el6uek.x86_64
efi
grub
initramfs-2.6.32-220.el6.x86_64.img
initramfs-2.6.32-300.3.1.el6uek.x86_64.img
...
# umount /mnt/sysimage
```

The `-d` option removes the device mappings:

```
# kpartx -d system.img
# ls /dev/mapper
control
```

For more information, see the `kpartx(8)` manual page.

19.2 About Swap Space

Oracle Linux uses swap space when your system does not have enough physical memory to store the text (code) and data pages that the processes are currently using. When your system needs more memory, it writes inactive pages to swap space on disk, freeing up physical memory. However, writing to swap space has a negative impact on system performance, so increasing swap space is not an effective solution to shortage of memory. Swap space is located on disk drives, which have much slower access times than physical memory. If your system often resorts to swapping, you should add more physical memory, not more swap space.

You can configure swap space on a swap file in a file system or on a separate swap partition. A dedicated swap partition is faster, but changing the size of a swap file is easier. Configure a swap partition if you
know how much swap space your system requires. Otherwise, start with a swap file and create a swap partition when you know what your system requires.

### 19.2.1 Viewing Swap Space Usage

To view a system's usage of swap space, examine the contents of `/proc/swaps`:

```
# cat /proc/swaps
Filename                Type        Size      Used   Priority
/dev/sda2               partition   4128760   388    -1
/swapfile               file        999992    0      -2
```

In this example, the system is using both a 4-gigabyte swap partition on `/dev/sda2` and a one-gigabyte swap file, `/swapfile`. The Priority column shows that the system preferentially swaps to the swap partition rather than to the swap file.

You can also view `/proc/meminfo` or use utilities such as `free`, `top`, and `vmstat` to view swap space usage, for example:

```
# grep Swap /proc/meminfo
SwapCached:          248 kB
SwapTotal:       5128752 kB
SwapFree:        5128364 kB
```

```
# free | grep Swap
Swap:      5128752        388    5128364
```

### 19.2.2 Creating and Using a Swap File

[Note]
Configuring a swap file on a btrfs file system is not supported.

To create and use a swap file:

1. Use the `dd` command to create a file of the required size (for example, one million one-kilobyte blocks):

   ```
   # dd if=/dev/zero of=/swapfile bs=1024 count=1000000
   ```

2. Initialize the file as a swap file:

   ```
   # mkswap /swapfile
   ```

3. Enable swapping to the swap file:

   ```
   # swapon /swapfile
   ```

4. Add an entry to `/etc/fstab` for the swap file so that the system uses it following the next reboot:

   ```
   /swapfile       swap       swap       defaults       0 0
   ```

### 19.2.3 Creating and Using a Swap Partition

To create and use a swap partition:

1. Use `fdisk` to create a disk partition of type `82` (Linux swap) or `parted` to create a disk partition of type `linux-swap` of the size that you require.

2. Initialize the partition (for example, `/dev/sda2`) as a swap partition:

   ```
   # mkswap /dev/sda2
   ```
3. Enable swapping to the swap partition:

```
# swapon /swapfile
```

4. Add an entry to `/etc/fstab` for the swap partition so that the system uses it following the next reboot:

```
/dev/sda2       swap       swap       defaults       0 0
```

### 19.2.4 Removing a Swap File or Swap Partition

To remove a swap file or swap partition from use:

1. Disable swapping to the swap file or swap partition, for example:

```
# swapoff /swapfile
```

2. Remove the entry for the swap file or swap partition from `/etc/fstab`.

3. Optionally, remove the swap file or swap partition if you do not want to use it in future.

### 19.3 About Logical Volume Manager

You can use Logical Volume Manager (LVM) to manage multiple physical volumes and configure mirroring and striping of logical volumes to provide data redundancy and increase I/O performance. In LVM, you first create volume groups from physical volumes, which are storage devices such as disk array LUNs, software or hardware RAID devices, hard drives, and disk partitions. You can then create logical volumes in a volume group. A logical volume functions as a partition that in its implementation might be spread over multiple physical disks.

You can create file systems on logical volumes and mount the logical volume devices in the same way as you would a physical device. If a file system on a logical volume becomes full with data, you can increase the capacity of the volume by using free space in the volume group so that you can then grow the file system (provided that the file system has that capability). If necessary, you can add physical storage devices to a volume group to increase its capacity.

LVM is non-disruptive and transparent to users. You can increase the size of logical volumes and change their layout dynamically without needing to schedule system down time to reconfigure physical storage.

LVM uses the device mapper (DM) that provides an abstraction layer that allows the creation of logical devices above physical devices and provides the foundation for software RAID, encryption, and other storage features.

### 19.3.1 Initializing and Managing Physical Volumes

Before you can create a volume group, you must initialize the physical devices that you want to use as physical volumes with LVM.

**Caution**

If the devices contain any existing data, back up the data.

To set up a physical device as a physical volume, use the `pvcreate` command:

```
# pvcreate [options] device ...
```

For example, set up `/dev/sdb`, `/dev/sdc`, `/dev/sdd`, and `/dev/sde` as physical volumes:

```
# pvcreate -v /dev/sd[bde]
Set up physical volume for "/dev/sdb" with 6313482 available
```
Creating and Managing Volume Groups

sectors
Zeroing start of device /dev/sdb
Physical volume "/dev/sdb" successfully created
...

To display information about physical volumes, you can use the `pvdisplay`, `pvs`, and `pvscan` commands.

To remove a physical volume from the control of LVM, use the `pvremove` command:

```
pvremove device
```

Other commands that are available for managing physical volumes include `pvchange`, `pvck`, `pvmove`, and `pvresize`.

For more information, see the `lvm(8)`, `pvcreate(8)`, and other LVM manual pages.

### 19.3.2 Creating and Managing Volume Groups

Having initialized the physical volumes, you can add them to a new or existing volume group.

To create a volume group, use the `vgcreate` command:

```
vgcreate [options] volume_group physical_volume ...
```

For example, create the volume group `myvg` from the physical volumes `/dev/sdb`, `/dev/sdc`, `/dev/sdd`, and `/dev/sde`:

```
vgcreate -v myvg /dev/sd[bcdde]
Wiping cache of LVM-capable devices
Adding physical volume '/dev/sdb' to volume group 'myvg'
Adding physical volume '/dev/sdc' to volume group 'myvg'
Adding physical volume '/dev/sdd' to volume group 'myvg'
Adding physical volume '/dev/sde' to volume group 'myvg'
Archiving volume group "myvg" metadata (seqno 0).
Creating volume group backup "/etc/lvm/backup/myvg" (seqno 1).
Volume group "myvg" successfully created
```

LVM divides the storage space within a volume group into physical extents, which are the smallest unit that LVM uses when allocating storage to logical volumes. The default size of an extent is 4 MB.

The allocation policy for the volume group and logical volume determines how LVM allocates extents from a volume group. The default allocation policy for a volume group is `normal`, which applies rules such as not placing parallel stripes on the same physical volume. The default allocation policy for a logical volume is `inherit`, which means that the logical volume uses the same policy as for the volume group. You can change the default allocation policies by using the `lvchange` or `vgchange` commands, or you can override the allocation policy when you create a volume group or logical volume. Other allocation policies include `anywhere`, `contiguous`, and `cling`.

To add physical volumes to a volume group, use the `vgextend` command:

```
vgextend [options] volume_group physical_volume ...
```

To remove physical volumes from a volume group, use the `vgreduce` command:

```
vgreduce [options] volume_group physical_volume ...
```

To display information about volume groups, you can use the `vgdisplay`, `vgs`, and `vgscan` commands.

To remove a volume group from LVM, use the `vgremove` command:

```
vgremove volume_group
```
Other commands that are available for managing volume groups include `vgchange`, `vgck`, `vgexport`, `vgimport`, `vgmerge`, `vgrename`, and `vgsplit`.

For more information, see the `lvm(8)`, `vgcreate(8)`, and other LVM manual pages.

### 19.3.3 Creating and Managing Logical Volumes

Having create a volume group of physical volumes, you can create logical volumes from the storage space that is available in the volume group.

To create a logical volume, use the `lvcreate` command:

```
# lvcreate [options] --size size --name logical_volume volume_group
```

For example, create the logical volume `mylv` of size 2 GB in the volume group `myvg`:

```
# lvcreate -v --size 2g --name mylv myvg
```

```
Setting logging type to disk
Finding volume group "myvg"
Archiving volume group "myvg" metadata (seqno 1).
Creating logical volume mylv
Creating volume group backup "/etc/lvm/backup/myvg" (seqno 2).
...`n```

`lvcreate` uses the device mapper to create a block device file entry under `/dev` for each logical volume and uses udev to set up symbolic links to this device file from `/dev/mapper` and `/dev/volume_group`. For example, the device that corresponds to the logical volume `mylv` in the volume group `myvg` might be `/dev/dm-3`, which is symbolically linked by `/dev/mapper/myvolg-myvol` and `/dev/myvolg/myvol`.

**Note**

Always use the devices in `/dev/mapper` or `/dev/volume_group`. These names are persistent and are created automatically by the device mapper early in the boot process. The `/dev/dm-*` devices are not guaranteed to be persistent across reboots.

Having created a logical volume, you can configure and use it in the same way as you would a physical storage device. For example, you can configure a logical volume as a file system, swap partition, Automatic Storage Management (ASM) disk, or raw device.

To display information about logical volumes, you can use the `lvdisplay`, `lvs`, and `lvscan` commands.

To remove a logical volume from a volume group, use the `lvremove` command:

```
# lvremove volume_group/logical_volume
```

**Note**

You must specify both the name of the volume group and the logical volume.

Other commands that are available for managing logical volumes include `lvchange`, `lvconvert`, `lvmdiskscan`, `lvmсад`, `lvmsar`, `lvrename`, and `lvresize`.

For more information, see the `lvm(8)`, `vgcreate(8)`, and other LVM manual pages.

### 19.3.4 Creating Logical Volume Snapshots

You can also use `lvcreate` with the `--snapshot` option to create a snapshot of an existing logical volume such as `mylv` in the volume group `myvg`, for example:
Creating and Managing Thinly-Provisioned Logical Volumes

You can mount and modify the contents of the snapshot independently of the original volume or preserve it as a record of the state of the original volume at the time that you took the snapshot. The snapshot usually takes up less space than the original volume, depending on how much the contents of the volumes diverge over time. In the example, we assume that the snapshot only requires one quarter of the space of the original volume. You can use the value shown by the Snap% column in the output from the `lvs` command to see how much data is allocated to the snapshot. If the value of Snap% approaches 100%, indicating that a snapshot is running out of storage, use `lvresize` to grow it. Alternatively, you can reduce a snapshot's size to save storage space. To merge a snapshot with its original volume, use the `lvconvert` command, specifying the `--merge` option.

To remove a logical volume snapshot from a volume group, use the `lvremove` command as you would for a logical volume:

```
# lvremove volume_group/logical_volume_snapshot
```

For more information, see the `lvcreate(8)` and `lvremove(8)` manual pages.

### 19.3.5 Creating and Managing Thinly-Provisioned Logical Volumes

Thinly-provisioned logical volumes have virtual sizes that are typically greater than the physical storage on which you create them. You create thinly-provisioned logical volumes from storage that you have assigned to a special type of logical volume termed a **thin pool**. LVM assigns storage on demand from a thin pool to a thinly-provisioned logical volume as required by the applications that access the volume. You need to use the `lvs` command to monitor the usage of the thin pool so that you can increase its size if its available storage is in danger of being exhausted.

To create a thin pool, use the `lvcreate` command with the `--thin` option:

```
# lvcreate --size size --thin volume_group/thin_pool_name
```

For example, create the thin pool `mytp` of size 1 GB in the volume group `myvg`:

```
# lvcreate --size 1g --thin myvg/mytp
Logical volume "mytp" created
```

You can then use `lvcreate` with the `--thin` option to create a thinly-provisioned logical volume with a size specified by the `--virtualsize` option, for example:

```
# lvcreate --virtualsize size --thin volume_group/thin_pool_name
   --name logical_volume
```

For example, create the thinly-provisioned logical volume `mytv` with a virtual size of 2 GB using the thin pool `mytp`, whose size is currently less than the size of the volume:

```
# lvcreate --virtualsize 2g --thin myvg/mytp --name mytv
Logical volume "mytv" created
```

If you create a thin snapshot of a thinly-provisioned logical volume, do not specify the size of the snapshot, for example:

```
# lvcreate --snapshot --name mytv-snapshot myvg/mytv
Logical volume "mytv-snapshot" created
```

If you were to specify a size for the thin snapshot, its storage would not be provisioned from the thin pool. If there is sufficient space in the volume group, you can use the `lvresize` command to increase the size of a thin pool, for example:
Using snapper with Thinly-Provisioned Logical Volumes

For details of how to use the `snapper` command to create and manage thin snapshots, see Section 19.3.6, “Using snapper with Thinly-Provisioned Logical Volumes”.

For more information, see the `lvcreate(8)` and `lvresize(8)` manual pages.

19.3.6 Using snapper with Thinly-Provisioned Logical Volumes

You can use the `snapper` utility to create and manage thin snapshots of thinly-provisioned logical volumes.

To set up the snapper configuration for an existing mounted volume:

```bash
# snapper -c config_name create-config -f "lvm(fs_type)" fs_name
```

Here `config_name` is the name of the configuration, `fs_type` is the file system type (`ext4` or `xfs`), and `fs_name` is the path of the file system. The command adds an entry for `config_name` to `/etc/sysconfig/snapper`, creates the configuration file `/etc/snapper/configs/config_name`, and sets up a `.snapshots` subdirectory for the snapshots.

By default, `snapper` sets up a `cron.hourly` job to create snapshots in the `.snapshot` subdirectory of the volume and a `cron.daily` job to clean up old snapshots. You can edit the configuration file to disable or change this behavior. For more information, see the `snapper-configs(5)` manual page.

There are three types of snapshot that you can create using `snapper`:

- **post**
  - You use a post snapshot to record the state of a volume after a modification. A post snapshot should always be paired with a pre snapshot that you take immediately before you make the modification.

- **pre**
  - You use a pre snapshot to record the state of a volume before a modification. A pre snapshot should always be paired with a post snapshot that you take immediately after you have completed the modification.

- **single**
  - You can use a single snapshot to record the state of a volume but it does not have any association with other snapshots of the volume.

For example, the following commands create pre and post snapshots of a volume:

```bash
# snapper -c config_name create -t pre -p N
... Modify the volume's contents ...
# snapper -c config_name create -t post --pre-num N -p N'
```

The `-p` option causes `snapper` to display the number of the snapshot so that you can reference it when you create the post snapshot or when you compare the contents of the pre and post snapshots.

To display the files and directories that have been added, removed, or modified between the pre and post snapshots, use the `status` subcommand:

```bash
# snapper -c config_name status N..N'
```

To display the differences between the contents of the files in the pre and post snapshots, use the `diff` subcommand:

```bash
# snapper -c config_name diff N..N'
```
### About Software RAID

The Redundant Array of Independent Disks (RAID) feature allows you to spread data across the drives to increase capacity, implement data redundancy, and increase performance. RAID is usually implemented either in hardware on intelligent disk storage that exports the RAID volumes as LUNs, or in software by the operating system. Oracle Linux kernel uses the multidisk (MD) driver to support software RAID by creating virtual devices from two or more physical storage devices. You can use MD to organize disk drives into RAID devices and implement different RAID levels.

The following software RAID levels are commonly used with Oracle Linux:

<table>
<thead>
<tr>
<th>RAID Level</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linear RAID (spanning)</td>
<td>Combines drives as a larger virtual drive. There is no data redundancy or performance benefit. Resilience decreases because the failure of a single drive renders the array unusable.</td>
</tr>
<tr>
<td>RAID-0 (striping)</td>
<td>Increases performance but does not provide data redundancy. Data is broken down into units (stripes) and written to all the drives in the array. Resilience decreases because the failure of a single drive renders the array unusable.</td>
</tr>
<tr>
<td>RAID-1 (mirroring)</td>
<td>Provides data redundancy and resilience by writing identical data to each drive in the array. If one drive fails, a mirror can satisfy I/O requests. Mirroring is an expensive solution because the same information is written to all of the disks in the array.</td>
</tr>
<tr>
<td>RAID-5 (striping with distributed parity)</td>
<td>Increases read performance by using striping and provides data redundancy. The parity is distributed across all the drives in an array but it does not take up as much space as a complete mirror. Write performance is reduced to some extent from RAID-0 by having to calculate parity information and write this information in addition to the data. If one disk in the array fails, the parity information is used to reconstruct data to satisfy I/O requests. In this mode, read performance and resilience are degraded until you replace the failed drive and it is repopulated with data and parity information. RAID-5 is intermediate in expense between RAID-0 and RAID-1.</td>
</tr>
<tr>
<td>RAID-6 (striping with double distributed parity)</td>
<td>A more resilient variant of RAID-5 that can recover from the loss of two drives in an array. RAID-6 is used when data redundancy and resilience are important, but performance is not. RAID-6 is intermediate in expense between RAID-5 and RAID-1.</td>
</tr>
<tr>
<td>RAID 0+1 (mirroring of striped disks)</td>
<td>Combines RAID-0 and RAID-1 by mirroring a striped array to provide both increased performance and data redundancy. Failure of a single disk causes one of the mirrors to be unusable until you replace the disk</td>
</tr>
</tbody>
</table>
Creating Software RAID Devices

RAID 1+0 (striping of mirrored disks or RAID-10) Combines RAID-0 and RAID-1 by striping a mirrored array to provide both increased performance and data redundancy. Failure of a single disk causes part of one mirror to be unusable until you replace the disk and repopulate it with data. Resilience is degraded while only a single mirror retains a complete copy of the data. RAID 1+0 is usually as expensive as or slightly more expensive than RAID-1.

19.4.1 Creating Software RAID Devices

To create a software RAID device:

1. Use the `mdadm` command to create the MD RAID device:

   ```
   # mdadm --create md_device --level=RAID_level [options] --raid-devices=N device ...
   ```

   For example, to create a RAID-1 device `/dev/md0` from `/dev/sdf` and `/dev/sdg`:

   ```
   # mdadm --create /dev/md0 --level=1 -raid-devices=2 /dev/sdf[fg]
   ```

   Create a RAID-5 device `/dev/md1` from `/dev/sdb`, `/dev/sdc`, and `/dev/sdd`:

   ```
   # mdadm --create /dev/md1 --level=5 -raid-devices=3 /dev/sd[bcd]
   ```

   If you want to include spare devices that are available for expansion, reconfiguration, or replacing failed drives, use the `--spare-devices` option to specify their number, for example:

   ```
   # mdadm --create /dev/md1 --level=5 -raid-devices=3 --spare-devices=1 /dev/sd[bcde]
   ```

   **Note**
   
   The number of RAID and spare devices must equal the number of devices that you specify.

2. Add the RAID configuration to `/etc/mdadm.conf`:

   ```
   # mdadm --examine --scan >> /etc/mdadm.conf
   ```

   **Note**
   
   This step is optional. It helps `mdadm` to assemble the arrays at boot time.

   For example, the following entries in `/etc/mdadm.conf` define the devices and arrays that correspond to `/dev/md0` and `/dev/md1`:

   ```
   DEVICE /dev/sd[c-g]
   ARRAY /dev/md0 devices=/dev/sdf, /dev/sdg
   ARRAY /dev/md1 spares=1 devices=/dev/sdb, /dev/sdc, /dev/sdd, /dev/sde
   ```

   For more examples, see the sample configuration file `/usr/share/doc/mdadm-3.2.1/mdadm.conf-example`.

Having created an MD RAID device, you can configure and use it in the same way as you would a physical storage device. For example, you can configure it as an LVM physical volume, file system, swap partition, Automatic Storage Management (ASM) disk, or raw device.
You can view `/proc/mdstat` to check the status of the MD RAID devices, for example:

```
# cat /proc/mdstat
Personalities : [raid1]
mdo : active raid1 sdg[1] sdf[0]
```

To display summary and detailed information about MD RAID devices, you can use the `--query` and `--detail` options with `mdadm`.

For more information, see the `md(4), mdadm(8), and mdadm.conf(5)` manual pages.

### 19.5 Creating Encrypted Block Devices

The device mapper supports the creation of encrypted block devices using the `dm-crypt` device driver. You can access data on encrypted devices at boot time only if you enter the correct password. As the underlying block device is encrypted and not the file system, you can use `dm-crypt` to encrypt disk partitions, RAID volumes, and LVM physical volumes, regardless of their contents.

When you install Oracle Linux, you have the option of configure encryption on system volumes other than the partition from which the system boots. If you want to protect the bootable partition, consider using any password protection mechanism that is built into the BIOS or setting up a GRUB password.

You use the `cryptsetup` utility to set up Linux Unified Key Setup (LUKS) encryption on the device and to manage authentication.

To set up the mapped device for an encrypted volume:

1. Initialize a LUKS partition on the device and set up the initial key, for example:
   
   ```
   # cryptsetup luksFormat /dev/sdd
   WARNING!
   ===========
   This will overwrite data on /dev/sdd irrevocably.
   Are you sure? (Type uppercase yes): YES
   Enter LUKS passphrase: passphrase
   Verify passphrase: passphrase
   ```

2. Open the device and create the device mapping:

   ```
   # cryptsetup luksOpen /dev/sdd cryptfs
   Enter passphrase for /dev/sdd: passphrase
   In this example, the encrypted volume is accessible as `/dev/mapper/cryptfs`.
   ```

3. Create an entry for the encrypted volume in `/etc/crypttab`, for example:

   ```
   # <target name> <source device> <key file> <options>
   cryptfs /dev/sdd none luks
   ```

   This entry causes the operating system to prompt you to enter the passphrase at boot time.

Having created an encrypted volume and its device mapping, you can configure and use it in the same way as you would a physical storage device. For example, you can configure it as an LVM physical volume, file system, swap partition, Automatic Storage Management (ASM) disk, or raw device. For example, you would create an entry in the `/etc/fstab` to mount the mapped device (`/dev/mapper/cryptfs`), not the physical device (`/dev/sdd`).

To verify the status of an encrypted volume, use the following command:

```
# cryptsetup status cryptfs
/dev/mapper/cryptfs is active.
type: LUKS1
```
cipher: aes-cbc-essiv:sha256
device: /dev/xvdd1
offset: 4096 sectors
size: 6309386 sectors
mode: read/write

Should you need to remove the device mapping, unmount any file system that the encrypted volume contains, and run the following command:

```
# cryptsetup luksClose /dev/mapper/cryptfs
```

For more information, see the `cryptsetup(8)` and `crypttab(5)` man pages.

### 19.6 SSD Configuration Recommendations for Btrfs, ext4, and Swap

When partitioning an SSD, align primary and logical partitions on one-megabyte (1048576 bytes) boundaries. If partitions, file system blocks, or RAID stripes are incorrectly aligned and overlap the boundaries of the underlying storage’s pages, which are usually either 4 KB or 8 KB in size, the device controller has to modify twice as many pages than if correct alignment is used.

For btrfs and ext4 file systems, specifying the `discard` option with `mount` sends discard (TRIM) commands to an underlying SSD whenever blocks are freed. This option can extend the working life of the device but it has a negative impact on performance, even for SSDs that support queued discards. The recommended alternative is to use the `fstrim` command to discard empty blocks that the file system is not using, especially before reinstalling the operating system or before creating a new file system on an SSD. Schedule `fstrim` to run when it will have minimal impact on system performance. You can also apply `fstrim` to a specific range of blocks rather than the whole file system.

**Note**

Using a minimal journal size of 1024 file-system blocks for ext4 on an SSD improves performance. However, it is not recommended that you disable journalling altogether as it improves the robustness of the file system.

Btrfs automatically enables SSD optimization for a device if the value of `/sys/block/device/queue/rotational` is 0. If btrfs does not detect a device as being an SSD, you can enable SSD optimization by specifying the `ssd` option to `mount`.

**Note**

By default, btrfs enables SSD optimization for Xen Virtual Devices (XVD) because the value of `rotational` for these devices is 0. To disable SSD optimization, specify the `nossd` option to `mount`.

Setting the `ssd` option does not imply that `discard` is also set.

If you configure swap files or partitions on an SSD, reduce the tendency of the kernel to perform anticipatory writes to swap, which is controlled by the value of the `vm.swappiness` kernel parameter and displayed as `/proc/sys/vm/swappiness`. The value of `vm.swappiness` can be in the range 0 to 100, where a higher value implies a greater propensity to write to swap. The default value is 60. The suggested value when swap has been configured on SSD is 1. You can use the following commands to change the value:

```
# echo "vm.swappiness = 1" >> /etc/sysctl.conf
# sysct1 -p
...
19.7 About Linux-IO Storage Configuration

Oracle Linux 7 with both UEK R3 and RHCK uses the Linux-IO Target (LIO) to provide the block-storage SCSI target for FCoE, iSCSI, and Mellanox InfiniBand (iSER and SRP). You can manage LIO by using the `targetcli` shell provided in the `targetcli` package.

Fibre Channel over Ethernet (FCoE) encapsulates Fibre Channel packets in Ethernet frames, which allows them to be sent over Ethernet networks. To configure FCoE storage, you also need to install the `fcoe-utils` package, which provides the `fcoemon` service and the `fcoeadm` command.

The Internet Small Computer System Interface (iSCSI) is an IP-based standard for connecting storage devices. iSCSI encapsulates SCSI commands in IP network packets, which allows data transfer over long distances and sharing of storage by client systems. As iSCSI uses the existing IP infrastructure, it does not require the purchase and installation of fiber-optic cabling and interface adapters that are needed to implement Fibre Channel (FC) storage area networks.

A client system (iSCSI initiator) accesses the storage server (iSCSI target) over an IP network. To an iSCSI initiator, the storage appears to be locally attached.

An iSCSI target is typically a dedicated, network-connected storage device but it can also be a general-purpose computer.

Figure 19.1 shows a simple network where several iSCSI initiators are able to access the shared storage that is attached to an iSCSI target.

A hardware-based iSCSI initiator uses a dedicated iSCSI HBA. Oracle Linux supports iSCSI initiator functionality in software. The kernel-resident device driver uses the existing network interface card (NIC) and network stack to emulate a hardware iSCSI initiator. As the iSCSI initiator functionality is not available at the level of the system BIOS, you cannot boot an Oracle Linux system from iSCSI storage.

To improve performance, some network cards implement TCP/IP Offload Engines (TOE) that can create a TCP frame for the iSCSI packet in hardware. Oracle Linux does not support TOE, although suitable drivers may be available directly from some card vendors.

For more information about LIO, see http://linux-iscsi.org/wiki/Main_Page.

19.7.1 Configuring an iSCSI Target

The following procedure describes how to set up a basic iSCSI target on an Oracle Linux system by using block storage backends. Note that you can use other storage backend types to set up an iSCSI target.
Configuring an iSCSI Target

When you use the `targetcli` command, it saves the current configuration to the JSON-format file `/etc/target/saveconfig.json`. See the `targetcli(8)` manual page for additional information.

To set up a basic iSCSI target on an Oracle Linux system by using block storage backends:

1. Run the `targetcli` interactive shell:

```
# targetcli
targetcli shell version 2.1.fb31
Copyright 2011-2013 by Datera, Inc and others.
For help on commands, type 'help'.
```

List the object hierarchy, which is initially empty:

```
/> ls
- / ................................................................. [...]
  - backstores ................................................. [...]
    - block ............................................. [Storage Objects: 0]
    - fileio ............................................ [Storage Objects: 0]
    - pscsi ............................................. [Storage Objects: 0]
    - ramdisk ......................................... [Storage Objects: 0]
  - iscsi .................................................. [Targets: 0]
  - loopback ........................................... [Targets: 0]
```

2. Change to the `/backstores/block` directory and create a block storage object for the disk partitions that you want to provide as LUNs, for example:

```
/> cd /backstores/block
/backstores/block> create name=LUN_0 dev=/dev/sdb
Created block storage object LUN_0 using /dev/sdb.
/backstores/block> create name=LUN_1 dev=/dev/sdc
Created block storage object LUN_1 using /dev/sdc.
```

The names that you assign to the storage objects are arbitrary.

```
Note
The device path varies, based on the Oracle Linux instance's disk configuration.
```

3. Change to the `/iscsi` directory and create an iSCSI target:

```
/> cd /iscsi
/iscsi> create
Created target iqn.2013-01.com.mydom.host01.x8664:sn.ef8e14f87344.
Created TPG 1.
```

List the target portal group (TPG) hierarchy, which is initially empty:

```
/iscsi> ls
- iscsi .................................................. [Targets: 1]
  - iqn.2013-01.com.mydom.host01.x8664:sn.ef8e14f87344 ..................
    - tpg1 ........................................... [no-gen-acls, no-auth]
      - acls ........................................ [ACLs: 0]
      - luns ....................................... [LUNs: 0]
      - portals ................................... [Portals: 0]
```

4. Change to the `luns` subdirectory of the TPG directory hierarchy and add the LUNs to the target portal group:

```
/iscsi> cd iqn.2013-01.com.mydom.host01.x8664:sn.ef8e14f87344/tpg1/luns
/iscsi/iqn.20...344/tpg1/luns> create /backstores/block/LUN_0
Created LUN 0.
/iscsi/iqn.20...344/tpg1/luns> create /backstores/block/LUN_1
```
5. Change to the portals subdirectory of the TPG directory hierarchy and specify the IP address and TCP port of the iSCSI endpoint:

```
    /iscsi/iqn.20...344/tpg1/luns> cd ../portals
    /iscsi/iqn.20.../tpg1/portals> create 10.150.30.72 3260
    Using default IP port 3260
    Created network portal 10.150.30.72:3260.
```

If you omit the TCP port number, the default value is **3260**.

### Note

If the portal creation fails, and a message similar to the following is displayed, it is most likely because a default portal was previously created:

```
    Could not create NetworkPortal in configFS
```

In this case, first delete the default portal, then repeat Step 5 to create the new portal.

```
    /iscsi/iqn.20.../tpg1/portals> delete 0.0.0.0 ip_port=3260
```

6. Enable TCP port 3260 by running either of the following commands:

```
    # firewall-cmd --permanent --add-port=3260/tcp
    # firewall-cmd --permanent --add-service iscsi-target
```

7. List the object hierarchy, which now shows the configured block storage objects and TPG:

```
    /iscsi/iqn.20.../tpg1/portals> ls /
    o- / ............................................................. [...] 
      o- backstores .................................................. [...] 
      | o- block ........................................................ [Storage Objects: 1] 
      |   | o- LUN_0 ................................... [/dev/sdb (10.0GiB) write-thru activated] 
      |   | o- LUN_1 ................................... [/dev/sdc (10.0GiB) write-thru activated] 
      | o- fileio .................................................... [Storage Objects: 0] 
      | o- pscsi ..................................................... [Storage Objects: 0] 
      | o- ramdisk .................................................... [Storage Objects: 0] 
      o- iscsi ........................................................ [Targets: 1] 
      | o- iq.2013-01.com.mydom.host01.x8664:sn.ef8e14f87344 ............... [TPGs: 1] 
      | o- tpg1 ............................................... [no-gen-acls, no-auth] 
      |   | o- acl ......................................................... [ACLs: 0] 
      |   | o- luns ....................................................... [LUNs: 1] 
      |   |   | o- lun0 ........................................ [/dev/sdb] 
      |   |   | o- lun1 ........................................ [/dev/sdc] 
      |   o- portals .................................................... [Portals: 1] 
      |     o- 10.150.30.72:3260 ......................................... [OK] 
      o- loopback ..................................................... [Targets: 0]
```

8. Configure the access rights for logins by initiators. For example, to configure demonstration mode that does not require authentication, change to the TGP directory and set the values of the **authentication** and **demo_mode_write_protect** attributes to 0 and **generate_node_acls** and **cache_dynamic_acls** to 1:

```
    /iscsi/iqn.20.../tpg1/portals> cd ..
    /iscsi/iqn.20.../tpg1> set attribute authentication=0 demo_mode_write_protect=0 generate_node_acls=1 cache_dynamic_acls=1
    Parameter authentication is now '0'.
    Parameter demo_mode_write_protect is now '0'.
    Parameter generate_node_acls is now '1'.
    Parameter cache_dynamic_acls is now '1'.
```
9. Change to the root directory and save the configuration.

```
/iscsi/igm.20...14f87344/tpg1> cd /
/> saveconfig
Last 10 configs saved in /etc/target/backup.
Configuration saved to /etc/target/saveconfig.json
```

10. Enable the target service.

```
# systemctl enable target.service
```

**Note**

Saving the configuration and enabling the target service ensures that the changes persist across system reboots. Note also that failure to run these commands can result in an empty configuration.

### 19.7.2 Restoring a Saved Configuration for an iSCSI target

To restore a saved configuration for an iSCSI target, start the `targetcli` interactive shell and then run the following command:

```
# targetcli
```

```
targetcli shell version 2.1.fb46
Copyright 2011-2013 by Datera, Inc and others.
For help on commands, type 'help'.
```

```
/> restoreconfig /etc/target/saveconfig.json
```

where `/etc/target/saveconfig.json` is the most recently saved configuration.

Or, you can run the following command to restore saved configurations from previous versions:

```
/> restoreconfig /etc/target/backup/saveconfig-20180516-18:53:29.json
```

### 19.7.3 Configuring an iSCSI Initiator

To configure an Oracle Linux system as an iSCSI initiator:

1. Install the `iscsi-initiator-utils` package:

```
# yum install iscsi-initiator-utils
```

2. Use a discovery method to discover the iSCSI targets at the specified IP address.

   You can use either the `SendTargets` or the Internet Storage Name Service (iSNS) discovery method.

   For example, you would use the `SendTargets` discovery method as follows:

   ```
   # iscsiadm -m discovery -t sendtargets -p 10.150.30.72
   10.150.30.72:3260,1 iqn.2013-01.com.mydom.host01.x8664:sn.ef8e14f87344
   ```

   This command also starts the `iscsid` service if it is not already running.
• If the network connection fails, adjust the firewall settings for your network to allow communication with the iSCSI target:

```
# iptables -D INPUT -j REJECT --reject-with icmp-host-prohibited
# iptables -D FORWARD -j REJECT --reject-with icmp-host-prohibited
```

• Then, re-run the command using the `SendTargets` discovery method:

```
# iscsiadm -m discovery -t sendtargets -p 10.150.30.72
10.150.30.72:3260,1 iqn.2013-01.com.mydom.host01.x8664:sn.ef8e14f87344
```

3. Display information about the targets that are now stored in the discovery database by running the following command:

```
# iscsiadm -m discoverydb -t st -p 10.150.30.72
# BEGIN RECORD 6.2.0.873-14
discovery.type = sendtargets
discovery.sendtargets.address = 10.150.30.72
discovery.sendtargets.port = 3260
discovery.sendtargets.auth.authmethod = None
discovery.sendtargets.auth.username = <empty>
discovery.sendtargets.auth.password = <empty>
discovery.sendtargets.auth.username_in = <empty>
discovery.sendtargets.auth.password_in = <empty>
discovery.sendtargets.timeo.login_timeout = 15
discovery.sendtargets.use_discoveryd = No
discovery.sendtargets.discoveryd.poll_inval = 30
discovery.sendtargets.reopen_max = 5
discovery.sendtargets.timeo.auth_timeout = 45
discovery.sendtargets.timeo.active_timeout = 30
discovery.sendtargets.iscsi.MaxRecvDataSegmentLength = 32768
# END RECORD
```

4. Establish a session and log in to a specific target:

```
# iscsiadm -m node -T iqn.2013-01.com.mydom.host01.x8664:sn.ef8e14f87344
  -p 10.150.30.72:3260 -l
```

5. Verify that the session is active and display the available LUNs:

```
# iscsiadm -m session -P 3
iSCSI Transport Class version 2.0-870
version 6.2.0.873-14
Target: iqn.2003-01.com.mydom.host01.x8664:sn.ef8e14f87344 (non-flash)
  Current Portal: 10.0.0.2:3260,1
  Persistent Portal: 10.0.0.2:3260,1
***********
Interface:
***********
  Iface Name: default
  Iface Transport: tcp
  Iface IPAddress: 10.0.0.2
  Iface HWaddress: <empty>
  Iface Netdev: <empty>
  SID: 5
iSCSI Connection State: LOGGED IN
iSCSI Session State: LOGGED_IN
Internal iscsid Session State: NO CHANGE
```
The LUNs are represented as SCSI block devices (sd*) in the local /dev directory, for example:

```
# fdisk -l | grep /dev/sd[bc]
Disk /dev/sdb: 10.7 GB, 10737418240 bytes, 20971520 sectors
Disk /dev/sdc: 10.7 GB, 10737418240 bytes, 20971520 sectors
```

To distinguish between target LUNs, examine the paths under /dev/disk/by-path:

```
# ls -l /dev/disk/by-path/
lwxrwxrwx 1 root root 9 May 15 21:05
   ip-10.150.30.72:3260-iscsi-iqn.2013-01.com.mydom.host01.x8664:
      sn.ef8e14f87344-lun-0 -> ../../sdb
   ip-10.150.30.72:3260-iscsi-iqn.2013-01.com.mydom.host01.x8664:
      sn.ef8e14f87344-lun-1 -> ../../sdc
```

You can view the initialization messages for the LUNs in the /var/log/messages file as follows:

```
# grep sdb /var/log/messages
...  May 18 14:19:36 localhost kernel: [12079.963376] sd 8:0:0:0: [sdb] Attached SCSI disk ...
```

You can configure and use a LUN in the same way that you would any other physical storage device, for example, as an LVM physical volume, a file system, a swap partition, an Automatic Storage Management (ASM) disk, or a raw device.

Specify the _netdev option when creating mount entries for iSCSI LUNs in /etc/fstab, for example:

```
UUID=084591f8-6b8b-c857-f002-ecf8a3b387f3 /iscsi_mount_point ext4 _netdev 0 0
```

This option indicates the file system resides on a device that requires network access, and prevents the system from attempting to mount the file system until the network has been enabled.

**Note**

Specify an iSCSI LUN in /etc/fstab by using UUID=UUID rather than the device path. A device path can change after re-connecting the storage or rebooting the system. You can use the blkid command to display the UUID of a block device.

Any discovered LUNs remain available across reboots provided that the target continues to serve those LUNs and you do not log the system off the target.

For more information, see the iscsiadm(8) and iscsid(8) manual pages.

### 19.7.4 Updating the Discovery Database

If the LUNs that are available on an iSCSI target change, you can use the iscsiadm command on an iSCSI initiator to update the entries in its discovery database. The following example assume that the target supports the SendTargets discovery method.
To add new records that are not currently in the database:

```bash
# iscsiadm --mode discoverydb --type st -p 10.150.30.72 -o new --discover
```

To update existing records in the database:

```bash
# iscsiadm -m discoverydb -t st -p 10.150.30.72 -o update --discover
```

To delete records from the database that are no longer supported by the target:

```bash
# iscsiadm -m discoverydb -t st -p 10.150.30.72 -o delete --discover
```

For more information, see the `iscsiadm(8)` manual page.

## 19.8 About Device Multipathing

Multiple paths to storage devices can provide connection redundancy, failover capability, load balancing, and improved performance. Device-Mapper Multipath (DM-Multipath) is a multipathing tool that allows you to represent multiple I/O paths between a server and a storage device as a single path.

You would be most likely to configure multipathing with a system that can access storage on a Fibre Channel-based storage area network (SAN). You can also use multipathing on an iSCSI initiator if redundant network connections exist between the initiator and the target.

**Figure 19.2** shows a simple DM-Multipath configuration where two I/O paths are configured between a server and a disk on a SAN-attached storage array:

- Between host bus adapter `hba1` on the server and controller `ctrl1` on the storage array.
- Between host bus adapter `hba2` on the server and controller `ctrl2` on the storage array.

**Figure 19.2 DM-Multipath Mapping of Two Paths to a Disk over a SAN**

Without DM-Multipath, the system treats each path as being separate even though it connects the server to the same storage device. DM-Multipath creates a single multipath device, `/dev/mapper/mpathN`, that subsumes the underlying devices, `/dev/sdc` and `/dev/sdf`.

You can configure the multipathing service (`multipathd`) to handle I/O from and to a multipathed device in one of the following ways:
Active/Active  I/O is distributed across all available paths, either by round-robin assignment or dynamic load-balancing.

Active/Passive (standby failover) I/O uses only one path. If the active path fails, DM-Multipath switches I/O to a standby path. This is the default configuration.

**Note**
DM-Multipath can provide failover in the case of path failure, such as in a SAN fabric. Disk media failure must be handled by using either a software or hardware RAID solution.

### 19.8.1 Configuring Multipathing

The procedure in this section demonstrates how to set up a simple multipath configuration.

To configure multipathing on a server with access to SAN-attached storage:

1. Install the `device-mapper-multipath` package:

   ```sh
   # yum install device-mapper-multipath
   ```

2. You can now choose one of two configuration paths:

   - To set up a basic standby failover configuration without editing the `/etc/multipath.conf` configuration file, enter the following command:
     ```sh
     # mpathconf --enable --with_multipathd y
     ```
     This command also starts the `multipathd` service and configures the service to start after system reboots.
     
     Skip the remaining steps of this procedure.

   - To edit `/etc/multipath.conf` and set up a more complex configuration such as active/active, follow the remaining steps in this procedure.

3. Initialize the `/etc/multipath.conf` file:

   ```sh
   # mpathconf --enable
   ```

4. Edit `/etc/multipath.conf` and define `defaults`, `blacklist`, `blacklist_exceptions`, `multipaths`, and `devices` sections as required, for example:

```plaintext
defaults {
  udev_dir              /dev
  polling_interval      10
  path_selector         "round-robin 0"
  path_grouping_policy  multibus
  getuid_callout        "/lib/udev/scsi_id --whitelisted --device=/dev/%n"
  prio                  alua
  path_checker          readsector0
  rr_min_io             100
  max_fds               8192
  rr_weight             priorities
  fallback              immediate
  no_path_retry         fail
  user_friendly_names   yes
}

blacklist {
  # Blacklist by WWID
```

---

**212**
Configuring Multipathing

```plaintext
wwid "**"

# Blacklist by device name
devnode "^([ram|raw|loop|fd|md|-][st|scd|st][0-9]*)""

# Blacklist by device type
device {
  vendor    "COMPAQ"
  product   "HSV110 (C)COMPAQ"
}
}

blacklist_exceptions {
  wwid "3600508b4000156d700012000000b0000"
  wwid "360000970000292602744533032443941"
}

multipaths {
  multipath {
    wwid                  3600508b4000156d700012000000b0000
    alias                 blue
    path_grouping_policy  multibus
    path_checker          readsector0
    path_selector         "round-robin 0"
    failback              manual
    rr_weight             priorities
    no_path_retry         5
  }
  multipath {
    wwid                  360000970000292602744533032443941
    alias                 green
  }
}

devices {
  device {
    vendor                "SUN"
    product               "(StorEdge 3510|T4"
    path_grouping_policy  multibus
    getuid_callout        "/sbin/scsi_id --whitelisted --device=/dev/%n"
    path_selector         "round-robin 0"
    failback              manual
    features              "0"
    hardware_handler      "0"
    path_checker          directio
    prio                  const
    rr_weight             uniform
    rr_min_io             1000
  }
}

The sections have the following purposes:

- **defaults**: Defines default multipath settings, which can be overridden by settings in the `devices` section, and which in turn can be overridden by settings in the `multipaths` section.

- **blacklist**: Defines devices that are excluded from multipath topology discovery. Blacklisted devices cannot subsumed by a multipath device.

The example shows the three ways that you can use to exclude devices: by WWID (`wwid`), by device name (`devnode`), and by device type (`device`).
blacklist_exceptions Defines devices that are included in multipath topology discovery, even if the devices are implicitly or explicitly listed in the blacklist section.

multipaths Defines settings for a multipath device that is identified by its WWID.

The alias attribute specifies the name of the multipath device as it will appear in /dev/mapper instead of a name based on either the WWID or the multipath group number.

To obtain the WWID of a SCSI device, use the scsi_id command:

```bash
# scsi_id --whitelisted --replace-whitespace --device=device_name
```

devices Defines settings for individual types of storage controller. Each controller type is identified by the vendor, product, and optional revision settings, which must match the information in sysfs for the device.

You can find details of the storage arrays that DM-Multipath supports and their default configuration values in /usr/share/doc/device-mapper-multipath-version/multipath.conf.defaults, which you can use as the basis for entries in /etc/multipath.conf.

To add a storage device that DM-Multipath does not list as being supported, obtain the vendor, product, and revision information from the vendor, model, and rev files under /sys/block/device_name/device.

The following entries in /etc/multipath.conf would be appropriate for setting up active/passive multipathing to an iSCSI LUN with the specified WWID.

```bash
defaults {
    user_friendly_names yes
    getuid_callout "/bin/scsi_id --whitelisted --replace-whitespace --device=/dev/%n"
}
multipaths {
    multipath {
        wwid 360000970000292602744533030303730
    }
}
```

In this standby failover configuration, I/O continues through a remaining active network interface if a network interfaces fails on the iSCSI initiator.

For more information about configuring entries in /etc/multipath.conf, refer to the multipath.conf(5) manual page.

5. Start the multipathd service and configure the service to start after system reboots:

```bash
# systemctl start multipathd
# systemctl enable multipathd
```

Multipath devices are identified in /dev/mapper by their World Wide Identifier (WWID), which is globally unique. Alternatively, if you set the value of user_friendly_names to yes in the defaults section of /etc/multipath.conf or by specifying the --user_friendly_names n option to mpathconf, the
Configuring Multipathing

device is named mpathN where N is the multipath group number. An alias attribute in the multipaths section of /etc/multipath.conf specifies the name of the multipath device instead of a name based on either the WWID or the multipath group number.

You can use the multipath device in /dev/mapper to reference the storage in the same way as you would any other physical storage device. For example, you can configure it as an LVM physical volume, file system, swap partition, Automatic Storage Management (ASM) disk, or raw device.

To display the status of DM-Multipath, use the mpathconf command, for example:

```
# mpathconf
multipath is enabled
find_multipaths is enabled
user_friendly_names is enabled
dm_multipath modules is loaded
multipathd is running
```

To display the current multipath configuration, specify the -ll option to the multipath command, for example:

```
# multipath -ll
mpath1(360000970000292602744533030303730) dm-0 SUN,(StorEdge 3510|T4 size=20G features='0' hwhandler='0' wp=rw
  `- policy='round-robin 0' prio=1 status=active
    `- 5:0:0:2 sdb 8:16    active ready running
  `- policy='round-robin 0' prio=1 status=active
    `- 5:0:0:3 sdc 8:32    active ready running
```

In this example, /dev/mapper/mpath1 subsumes two paths (/dev/sdb and /dev/sdc) to 20 GB of storage in an active/active configuration using round-robin I/O path selection. The WWID that identifies the storage is 360000970000292602744533030303730 and the name of the multipath device under sysfs is dm-0.

If you edit /etc/multipath.conf, restart the multipathd service to make it re-read the file:

```
# systemctl restart multipathd
```

For more information, see the mpathconf(8), multipath(8), multipathd(8), multipath.conf(5), and scsi_id(8) manual pages.

  20.11.1 About Mount Options .................................................. 232

This chapter describes how to create, mount, check, and repair file systems, how to configure Access Control Lists, and how to configure and manage disk quotas.

20.1 Making File Systems

The `mkfs` command builds a file system on a block device:

```
# mkfs [options] device
```

`mkfs` is a front end for builder utilities in `/sbin` such as `mkfs.ext4`. You can use either the `mkfs` command with the `-t fstype` option or the builder utility to specify the type of file system to build. For example, the following commands are equivalent ways of creating an `ext4` file system with the label `Projects` on the device `/dev/sdb1`:

```
# mkfs -t ext4 -L Projects /dev/sdb1
# mkfs.ext4 -L Projects /dev/sdb1
```

If you do not specify the file system type to `makefs`, it creates an `ext2` file system.

To display the type of a file system, use the `blkid` command:

```
# blkid /dev/sdb1
/dev/sdb1: UUID="ad8113d7-b279-4da8-b6e4-cfba045f66ff" TYPE="ext4" LABEL="Projects"
```

The `blkid` command also displays information about the device such as its UUID and label.

Each file system type supports a number of features that you can enable or disable by specifying additional options to `mkfs` or the build utility. For example, you can use the `J` option to specify the size and location of the journal used by the `ext3` and `ext4` file system types.

For more information, see the `blkid(8)`, `mkfs(8)`, and `mkfs.fstype(8)` manual pages.
20.2 Mounting File Systems

To access a file system's contents, you must attach its block device to a mount point in the directory hierarchy. You can use the `mkdir` command to create a directory for use as a mount point, for example:

```
# mkdir /var/projects
```

You can use an existing directory as a mount point, but its contents are hidden until you unmount the overlying file system.

The `mount` command attaches the device containing the file system to the mount point:

```
# mount [options] device mount_point
```

You can specify the device by its name, UUID, or label. For example, the following commands are equivalent ways of mounting the file system on the block device `/dev/sdb1`:

```
# mount /dev/sdb1 /var/projects
# mount UUID="ad8113d7-b279-4da8-b6e4-cfba045f66ff" /var/projects
# mount LABEL="Projects" /var/projects
```

If you do not specify any arguments, `mount` displays all file systems that the system currently has mounted, for example:

```
# mount
/devmapper/vg_host01-lv_root on / type ext4 (rw) ...
```

In this example, the LVM logical volume `/dev/mapper/vg_host01-lv_root` is mounted on `/`. The file system type is `ext4` and it is mounted for both reading and writing. (You can also use the command `cat /proc/mounts` to display information about mounted file systems.)

The `df` command displays information about how much space remains on mounted file systems, for example:

```
# df -h
Filesystem Size Used Avail Use% Mounted on
/devmapper/vg_host01-lv_root 36G 12G 22G 36% /
...
```

You can use the `-B` (bind) option to the `mount` command to attach a block device at multiple mount points. You can also remount part of a directory hierarchy, which need not be a complete file system, somewhere else. For example, the following command mounts `/var/projects/project1` on `/mnt`:

```
# mount -B /var/projects/project1 /mnt
```

Each directory hierarchy acts as a mirror of the other. The same files are accessible in either location, although any submounts are not replicated. These mirrors do not provide data redundancy.

You can also mount a file over another file, for example:

```
# touch /mnt/foo
# mount -B /etc/hosts /mnt/foo
```

In this example, `/etc/hosts` and `/mnt/foo` represent the same file. The existing file that acts as a mount point is not accessible until you unmount the overlying file.

The `-B` option does not recursively attach any submounts below a directory hierarchy. To include submounts in the mirror, use the `-R` (recursive bind) option instead.

When you use `-B` or `-R`, the file system `mount` options remain the same as those for the original mount point. To modify, the mount options, use a separate remount command, for example:
20.2.1 About Mount Options

To modify the behavior of `mount`, use the `-o` flag followed by a comma-separated list of options or specify the options in the `/etc/fstab` file. The following are some of the options that are available:

- **auto**  Allows the file system to be mounted automatically by using the `mount -a` command.
- **exec**  Allows the execution of any binary files located in the file system.
- **loop**  Uses a loop device (`/dev/loop*`) to mount a file that contains a file system image. See Section 20.5, “Mounting a File Containing a File System Image”, Section 20.6, “Creating a File System on a File”, and the `losetup(8)` manual page.

### Note

The default number of available loop devices is 8. You can use the kernel boot parameter `max_loop=N` to configure up to 255 devices. Alternatively, add the following entry to `/etc/modprobe.conf`:

```
options loop max_loop=N
```

where `N` is the number of loop devices that you require (from 0 to 255), and reboot the system.
About the File System Mount Table

noauto Disallows the file system from being mounted automatically by using `mount -a`.

noexec Disallows the execution of any binary files located in the file system.

nouser Disallows any user other than `root` from mounting or unmounting the file system.

remount Remounts the file system if it is already mounted. You would usually combine this option with another option such as `ro` or `rw` to change the behavior of a mounted file system.

ro Mounts a file system as read-only.

rw Mounts a file system for reading and writing.

user Allows any user to mount or unmount the file system.

For example, mount `/dev/sdd1` as `/test` with read-only access and only root permitted to mount or unmount the file system:

```
# mount -o nouser,ro /dev/sdd1 /test
```

Mount an ISO image file on `/mount/cdrom` with read-only access by using the loop device:

```
# mount -o ro,loop ./OracleLinux-R6-U1-Server-x86_64-dvd.iso /media/cdrom
```

Remount the `/test` file system with both read and write access, but do not permit the execution of any binary files that are located in the file system:

```
# mount -o remount,rw,noexec /test
```

## 20.3 About the File System Mount Table

The `/etc/fstab` file contains the file system mount table, and provides all the information that the `mount` command needs to mount block devices or to implement binding of mounts. If you add a file system, create the appropriate entry in `/etc/fstab` to ensure that the file system is mounted at boot time. The following are sample entries from `/etc/fstab`:

```
/dev/sda1   /boot  ext4 defaults  1 2
/dev/sda2   /    ext4 defaults  1 1
/dev/sda3   swap  swap defaults  0 0
LABEL=Projects /var/projects ext4 defaults  1 2
```

The first field is the device to mount specified by the device name, UUID, or device label, or the specification of a remote file system. A UUID or device label is preferable to a device name if the device name could change, for example:

```
LABEL=Projects /var/projects ext4 defaults  1 2
```

The second field is either the mount point for a file system or `swap` to indicate a swap partition.

The third field is the file system type, for example `ext4` or `swap`.

The fourth field specifies any mount options.

The fifth column is used by the `dump` command. A value of 1 means dump the file system; 0 means the file system does not need to be dumped.

The sixth column is used by the file system checker, `fsck`, to determine in which order to perform file system checks at boot time. The value should be 1 for the root file system, 2 for other file systems. A value of 0 skips checking, as is appropriate for swap, file systems that are not mounted at boot time, or for binding of existing mounts.
For bind mounts, only the first four fields are specified, for example:

<table>
<thead>
<tr>
<th>path</th>
<th>mount_point</th>
<th>none</th>
<th>bind</th>
</tr>
</thead>
</table>

The first field specifies the path of the file system, directory hierarchy, or file that is to be mounted on the mount point specified by the second field. The mount point must be a file if the path specifies a file; otherwise, it must be a directory. The third and fourth fields are specified as none and bind.

For more information, see the `fstab(5)` manual page.

## 20.4 Configuring the Automounter

The automounter mounts file systems when they are accessed, rather than maintaining connections for those mounts at all times. When a file system becomes inactive for more than a certain period of time, the automounter unmounts it. Using automounting frees up system resources and improves system performance.

The automounter consists of two components: the `autofs` kernel module and the `automount` user-space daemon.

To configure a system to use automounting:

1. Install the `autofs` package and any other packages that are required to support remote file systems:

   ```bash
   # yum install autofs
   ```

2. Edit the `/etc/auto.master` configuration file to define map entries. Each map entry specifies a mount point and a map file that contains definitions of the remote file systems that can be mounted, for example:

   ```
   /-          /etc/auto.direct
   /misc       /etc/auto.misc
   /net        -hosts
   ```

   Here, the `/`, `/misc`, and `/net` entries are examples of a direct map, an indirect map, and a host map respectively. Direct map entries always specify `/` as the mount point. Host maps always specify the keyword `-hosts` instead of a map file.

   A direct map contains definitions of directories that are automounted at the specified absolute path. In the example, the `auto.direct` map file might contain an entry such as:

   ```
   /usr/man   -fstype=nfs,ro,soft             host01:/usr/man
   ```

   This entry mounts the file system `/usr/man` exported by `host01` using the options `ro` and `soft`, and creates the `/usr/man` mount point if it does not already exist. If the mount point already exists, the mounted file system hides any existing files that it contains.

   As the default file system type is NFS, the previous example can be shortened to read:

   ```
   /usr/man   -ro,soft                        host01:/usr/man
   ```

   An indirect map contains definitions of directories (keys) that are automounted relative to the mount point `/misc` specified in `/etc/auto.master`. In the example, the `/etc/auto.misc` map file might contain entries such as the following:

   ```
   xyz     -ro,soft                        host01:/xyz
   cd      -fstype=iso9600,ro,nosuid,nodev  :/dev/cdrom
   abc     -fstype=ext3                     :/dev/hda1
   fenetres -fstype=cifs,credentials=credfile ://fenetres/c
   ```
Mounting a File Containing a File System Image

The `/misc` directory must already exist, but the automounter creates a mount point for the keys `xyz`, `cd`, and so on if they do not already exist, and removes them when it unmounts the file system. For example, entering a command such as `ls /misc/xyz` causes the automounter to mount the `/xyz` directory exported by `host01` as `/misc/xyz`.

The `cd` and `abc` entries mount local file systems: an ISO image from the CD-ROM drive on `/misc/cd` and an ext3 file system from `/dev/hda1` on `/misc/abc`. The `fenetres` entry mounts a Samba share as `/misc/fenetres`.

If a host map entry exists and a command references an NFS server by name relative to the mount point (`/net`), the automounter mounts all directories that the server exports below a subdirectory of the mount point named for the server. For example, the command `cd /net/host03` causes the automounter to mount all exports from `host03` below the `/net/host03` directory. By default, the automounter uses the mount options `nosuid,nodev,intr` options unless you override the options in the host map entry, for example:

```
/net       -hosts    -suid,dev,nointr
```

Note

The name of the NFS server must be resolvable to an IP address in DNS or in the `/etc/hosts` file.

For more information, including details of using maps with NIS, NIS+, and LDAP, see the hosts.master(5) manual page.

3. Start the `autofs` service, and configure the service to start following a system reboot:

```
# systemctl stat autofs
# systemctl enable autofs
```

You can configure various settings for `autofs` in `/etc/sysconfig/autofs`, such as the idle timeout value after which a file system is automatically unmounted.

If you modify `/etc/auto.master` or `/etc/sysconfig/autofs`, restart the `autofs` service to make it re-read these files:

```
# systemctl restart autofs
```

For more information, see the automount(8), autofs(5), and auto.master(5) manual pages.

### 20.5 Mounting a File Containing a File System Image

A loop device allows you to access a file as a block device. For example, to mount a file that contains a DVD ISO image on the directory mount point `/ISO`:

```
# mount -t iso9660 -o ro,loop /var/ISO_files/V33411-01.iso /ISO
```

If required, create a permanent entry for the file system in `/etc/fstab`:

```
/var/ISO_files/V33411-01.iso /ISO iso9660 ro,loop 0 0
```

### 20.6 Creating a File System on a File

To create a file system on a file within another file system:

1. Create an empty file of the required size, for example:
# Checking and Repairing a File System

## 2. Create a file system on the file:

```bash
# mkfs.ext4 -F /fsfile
```

```bash
mke2fs 1.41.12 (17-May-2010)
Filesystem label=
OS type: Linux
Block size=4096 (log=2)
Fragment size=4096 (log=2)
Stride=0 blocks, Stripe width=0 blocks
62592 inodes, 250000 blocks
12500 blocks (5.00%) reserved for the super user
First data block=0
Maximum filesystem blocks=260046848
8 block groups
32768 blocks per group, 32768 fragments per group
7824 inodes per group
Superblock backups stored on blocks:
 32768, 98304, 163840, 229376
Writing inode tables: done
Creating journal (4096 blocks): done
Writing superblocks and filesystem accounting information: done
This filesystem will be automatically checked every 33 mounts or 180 days, whichever comes first. Use tune2fs -c or -i to override.
```

## 3. Mount the file as a file system by using a loop device:

```bash
# mount -o loop /fsfile /mnt
```

The file appears as a normal file system:

```bash
# mount
```

```bash
... 
/fsfile on /mnt type ext4 (rw,loop=/dev/loop0)
```

```bash
# df -h
```

```bash
Filesystem Size Used Avail Use% Mounted on
... 
/fsfile 962M 18M 896M 2% /mnt
```

If required, create a permanent entry for the file system in `/etc/fstab`:

```bash
/fsfile /mnt ext4 rw,loop 0 0
```

## 20.7 Checking and Repairing a File System

The `fsck` utility checks and repairs file systems. For file systems other than `/` (root) and `/boot`, `mount` invokes file system checking if more than a certain number of mounts have occurred or more than 180 days have elapsed without checking having being performed. You might want to run `fsck` manually if a file system has not been checked for several months.

**Warning**

Running `fsck` on a mounted file system can corrupt the file system and cause data loss.

To check and repair a file system:
1. Unmount the file system:

   ```
   # umount filesystem
   ```

2. Use the `fsck` command to check the file system:

   ```
   # fsck [-y] filesystem
   ```

   `filesystem` be a device name, a mount point, or a label or UUID specifier, for example:

   ```
   # fsck UUID=ad8113d7-b279-4da8-b6e4-cfba045f66ff
   ```

   By default, `fsck` prompts you to choose whether it should apply a suggested repair to the file system. If you specify the `–y` option, `fsck` assumes a `yes` response to all such questions.

   For the `ext2`, `ext3`, and `ext4` file system types, other commands that are used to perform file system maintenance include `dumpe2fs` and `debugfs`. `dumpe2fs` prints super block and block group information for the file system on a specified device. `debugfs` is an interactive file system debugger that requires expert knowledge of the file system architecture. Similar commands exist for most file system types and also require expert knowledge.

   For more information, see the `fsck(8)` manual page.

### 20.7.1 Changing the Frequency of File System Checking

To change the number of mounts before the system automatically checks the file system for consistency:

```
# tune2fs -c mount_count device
```

where `device` specifies the block device corresponding to the file system.

A `mount_count` of 0 or -1 disables automatic checking based on the number of mounts.

**Tip**

Specifying a different value of `mount_count` for each file system reduces the probability that the system checks all the file systems at the same time.

To specify the maximum interval between file system checks:

```
# tune2fs -i interval[unit] device
```

The `unit` can be `d`, `w`, or `m` for days, weeks, or months. The default unit is `d` for days. An `interval` of 0 disables checking that is based on the time that has elapsed since the last check. Even if the interval is exceeded, the file system is not checked until it is next mounted.

For more information, see the `tune2fs(8)` manual page.

### 20.8 About Access Control Lists

POSIX Access Control Lists (ACLs) provide a richer access control model than traditional UNIX Discretionary Access Control (DAC) that sets read, write, and execute permissions for the owner, group, and all other system users. You can configure ACLs that define access rights for more than just a single user or group, and specify rights for programs, processes, files, and directories. If you set a default ACL on a directory, its descendents inherit the same rights automatically. You can use ACLs with btrfs, ext3, ext4, OCFS2, and XFS file systems and with mounted NFS file systems.

An ACL consists of a set of rules that specify how a specific user or group can access the file or directory with which the ACL is associated. A regular ACL entry specifies access information for a single file or
directory. A default ACL entry is set on directories only, and specifies default access information for any file within the directory that does not have an access ACL.

### 20.8.1 Configuring ACL Support

To enable ACL support:

1. Install the `acl` package:
   ```bash
   # yum install acl
   ```

2. Edit `/etc/fstab` and change the entries for the file systems with which you want to use ACLs so that they include the appropriate option that supports ACLs, for example:

   ```
   LABEL=/work /work ext4 acl 0 0
   ```

   For mounted Samba shares, use the `cifsacl` option instead of `acl`.

3. Remount the file systems, for example:
   ```bash
   # mount -o remount /work
   ```

### 20.8.2 Setting and Displaying ACLs

To add or modify the ACL rules for file, use the `setfacl` command:

```bash
# setfacl -m rules file ...
```

The rules take the following forms:

- `[d:]u:user[:permissions]`  Sets the access ACL for the user specified by name or user ID. The permissions apply to the owner if a user is not specified.

- `[d:]g:group[:permissions]`   Sets the access ACL for a group specified by name or group ID. The permissions apply to the owning group if a group is not specified.

- `[d:]m[:][:permissions]` Sets the effective rights mask, which is the union of all permissions of the owning group and all of the user and group entries.

- `[d:]o[:][:permissions]` Sets the access ACL for other (everyone else to whom no other rule applies).

The permissions are `r`, `w`, and `x` for read, write, and execute as used with `chmod`.

The `d:` prefix is used to apply the rule to the default ACL for a directory.

To display a file’s ACL, use the `getfacl` command, for example:

```bash
# getfacl foofile
# file: foofile
# owner: bob
# group: bob
user::rw-
user::fiona:r--
user::jack:rw-
user::jill:rw-
group::r--
mask::r--
other::r--
```
If extended ACLs are active on a file, the `ls` option to `ls` displays a plus sign (`+`) after the permissions, for example:

```
# ls -l foofile
-rw-r--r--+ 1 bob bob 105322 Apr 11 11:02 foofile
```

The following are examples of how to set and display ACLs for directories and files.

Grant read access to a file or directory by a user.

```
# setfacl -m u:user:r file
```

Display the name, owner, group, and ACL for a file or directory.

```
# getfacl file
```

Remove write access to a file for all groups and users by modifying the effective rights mask rather than the ACL.

```
# setfacl -m m::rx file
```

The `-x` option removes rules for a user or group.

Remove the rules for a user from the ACL of a file.

```
# setfacl -x u:user file
```

Remove the rules for a group from the ACL of a file.

```
# setfacl -x g:group file
```

The `-b` option removes all extended ACL entries from a file or directory.

```
# setfacl -b file
```

Copy the ACL of file `f1` to file `f2`.

```
# getfacl f1 | setfacl --set-file=- f2
```

Set a default ACL of read and execute access for other on a directory:

```
# setfacl -m d:o:rx directory
```

Promote the ACL settings of a directory to default ACL settings that can be inherited.

```
# getfacl --access directory | setfacl -d -M- directory
```

The `-k` option removes the default ACL from a directory.

```
# setfacl -k directory
```

For more information, see the `acl(5)`, `setfacl(1)`, and `getfacl(1)` manual pages.

### 20.9 About Disk Quotas

**Note**

For information about how to configure quotas for the XFS file system, see Section 21.23, “Setting Quotas on an XFS File System”.

You can set disk quotas to restrict the amount of disk space (`blocks`) that users or groups can use, to limit the number of files (`inodes`) that users or groups can create, and to notify you when usage is reaching a
specified limit. A hard limit specifies the maximum number of blocks or inodes available to a user or group on the file system. Users or groups can exceed a soft limit for a period of time known as a grace period.

### 20.9.1 Enabling Disk Quotas on File Systems

To enable user or group disk quotas on a file system:

1. Install or update the quota package:

   ```
   # yum install quota
   ```

2. Include the `usrquota` or `grpquota` options in the file system's `/etc/fstab` entry, for example:

   ```
   /dev/sdb1   /home   ext4   usrquota,grpquota   0   0
   ```

3. Remount the file system:

   ```
   # mount -o remount /home
   ```

4. Create the quota database files:

   ```
   # quotacheck -cug /home
   ```

   This command creates the files `aquota.user` and `aquota.group` in the root of the file system (`/home` in this example).

For more information, see the `quotacheck(8)` manual page.

### 20.9.2 Assigning Disk Quotas to Users and Groups

To configure the disk quota for a user:

1. Enter the following command for a user:

   ```
   # edquota username
   ```

   or for a group:

   ```
   # edquota -g group
   ```

   The command opens a text file opens in the default editor defined by the `EDITOR` environment variable, allowing you to specify the limits for the user or group, for example:

   ```
   Disk quotas for user guest (uid 501)
   Filesystem  blocks  soft  hard  inodes  soft  hard
   /dev/sdb1   10325     0     0    1054     0     0
   ```

   The `blocks` and `inodes` entries show the user's currently usage on a file system.

   **Tip**

   Setting a limit to 0 disables quota checking and enforcement for the corresponding `blocks` or `inodes` category.

2. Edit the soft and hard block limits for number of blocks and inodes, and save and close the file.

   Alternatively, you can use the `setquota` command to configure quota limits from the command-line. The `-p` option allows you to apply quota settings from one user or group to another user or group.

   For more information, see the `edquota(8)` and `setquota(8)` manual pages.
20.9.3 Setting the Grace Period

To configure the grace period for soft limits:

1. Enter the following command:

   ```
   # edquota -t
   ```

   The command opens a text file opens in the default editor defined by the `EDITOR` environment variable, allowing you to specify the grace period, for example:

   ```
   Grace period before enforcing soft limits for users:
   Time units may be: days, hours, minutes, or seconds
   Filesystem     Block grace period     Inode grace period
   /dev/sdb1            7days                  7days
   ```

2. Edit the grace periods for the soft limits on the number of blocks and inodes, and save and close the file.

For more information, see the `edquota(8)` manual page.

20.9.4 Displaying Disk Quotas

To display a user's disk usage:

```
# quota username
```

To display a group's disk usage:

```
# quota -g group
```

To display information about file systems where usage is over the quota limits:

```
# quota -q
```

Users can also use the `quota` command to display their own and their group's usage.

For more information, see the `quota(1)` manual page.

20.9.5 Enabling and Disabling Disk Quotas

To disable disk quotas for all users, groups on a specific file system:

```
# quotaoff -guv filesystem
```

To disable disk quotas for all users, groups, and file systems:

```
# quotaoff -aguv
```

To re-enable disk quotas for all users, groups, and file systems:

```
# quotaon -aguv
```

For more information, see the `quotaon(1)` manual page.

20.9.6 Reporting on Disk Quota Usage

To display the disk quota usage for a file system:

```
# repquota filesystem
```
Maintaining the Accuracy of Disk Quota Reporting

To display the disk quota usage for all file systems:

```
# repquota -a
```

For more information, see the `repquota(8)` manual page.

### 20.9.7 Maintaining the Accuracy of Disk Quota Reporting

Uncontrolled system shutdowns can lead to inaccuracies in disk quota reports.

To rebuild the quota database for a file system:

1. Disable disk quotas for the file system:
   
   ```
   # quotaoff -guv filesystem
   ```

2. Unmount the file system:
   
   ```
   # umount filesystem
   ```

3. Enter the following command to rebuild the quota databases:
   
   ```
   # quotacheck -guv filesystem
   ```

4. Mount the file system:
   
   ```
   # mount filesystem
   ```

5. Enable disk quotas for the file system:
   
   ```
   # quotaoff -guv filesystem
   ```

For more information, see the `quotacheck(8)` manual page.

This chapter describes administration tasks for the btrfs, ext3, ext4, OCFS2, and XFS local file systems.

21.1 About Local File Systems

Oracle Linux supports a large number of local file system types that you can configure on block devices, including:

btrfs

Btrfs is a copy-on-write file system that is designed to address the expanding scalability requirements of large storage subsystems. It supports snapshots, a roll-back capability, checksum functionality for
About Local File Systems

data integrity, transparent compression, and integrated logical volume management.

The maximum supported file or file system size is 50 TB.

For more information, see Section 21.2, "About the Btrfs File System".

**ext3**

The ext3 file system includes journaling capabilities to improve reliability and availability. Consistency checks after a power failure or an uncontrolled system shutdown are unnecessary. **ext2** file systems are upgradeable to ext3 without reformatting.

See Section 21.14, "Converting a Non-root Ext2 File System to Ext3" and Section 21.15, "Converting a root Ext2 File System to Ext3".

The maximum supported file and file system sizes are 2 TB and 16 TB.

**ext4**

In addition to the features of ext3, the ext4 file system supports extents (contiguous physical blocks), pre-allocation, delayed allocation, faster file system checking, more robust journaling, and other enhancements.

The maximum supported file or file system size is 50 TB.

**ocfs2**

Although intended as a general-purpose, high-performance, high-availability, shared-disk file system intended for use in clusters, it is possible to use Oracle Cluster File System version 2 (OCFS2) as a standalone, non-clustered file system.

Although it might seem that there is no benefit in mounting OCFS2 locally as compared to alternative file systems such as ext4 or btrfs, you can use the **relink** command with OCFS2 to create copy-on-write clones of individual files in a similar way to using the **cp --reflink** command with the btrfs file system. Typically, such clones allow you to save disk space when storing multiple copies of very similar files, such as VM images or Linux Containers. In addition, mounting a local OCFS2 file system allows you to subsequently migrate it to a cluster file system without requiring any conversion.

See Section 21.16, "Creating a Local OCFS2 File System".

The maximum supported file or file system size is 16 TB.

**vfat**

The vfat file system (also known as FAT32) was originally developed for MS-DOS. It does not support journaling and lacks many of the features that are available with other file system types. It is mainly used to exchange data between Microsoft Windows and Oracle Linux systems.

The maximum supported file size or file system size is 2 GB.

**xfs**

XFS is a high-performance journaling file system, which provides high scalability for I/O threads, file system bandwidth, file and file system size, even when the file system spans many storage devices.

The maximum supported file and file system sizes are 16 TB and 500 TB respectively.

For more information, see Section 21.17, "About the XFS File System".
To see what file system types your system supports, use the following command:

```bash
ls /sbin/mkfs.*
```

<table>
<thead>
<tr>
<th>/sbin/mkfs.btrfs</th>
<th>/sbin/mkfs.ext3</th>
<th>/sbin/mkfs.msdos</th>
</tr>
</thead>
<tbody>
<tr>
<td>/sbin/mkfs.cramfs</td>
<td>/sbin/mkfs.ext4</td>
<td>/sbin/mkfs.vfat</td>
</tr>
<tr>
<td>/sbin/mkfs.ext2</td>
<td>/sbin/mkfs.ext4dev</td>
<td>/sbin/mkfs.xfs</td>
</tr>
</tbody>
</table>

These executables are used to make the file system type specified by their extension. `mkfs.msdos` and `mkfs.vfat` are alternate names for `mkdosfs`. `mkfs.cramfs` creates a compressed ROM, read-only cramfs file system for use by embedded or small-footprint systems.

### 21.2 About the Btrfs File System

The btrfs file system is designed to meet the expanding scalability requirements of large storage subsystems. As the btrfs file system uses B-trees in its implementation, its name derives from the name of those data structures, although it is not a true acronym. A B-tree is a tree-like data structure that enables file systems and databases to efficiently access and update large blocks of data no matter how large the tree grows.

The btrfs file system provides the following important features:

- Copy-on-write functionality allows you to create both readable and writable snapshots, and to roll back a file system to a previous state, even after you have converted it from an ext3 or ext4 file system.
- Checksum functionality ensures data integrity.
- Transparent compression saves disk space.
- Transparent defragmentation improves performance.
- Integrated logical volume management allows you to implement RAID 0, RAID 1, or RAID 10 configurations, and to dynamically add and remove storage capacity.

**Note**

Configuring a swap file on a btrfs file system is not supported.

You can find more information about the btrfs file system at https://btrfs.wiki.kernel.org/index.php/Main_Page.

### 21.3 Creating a Btrfs File System

**Note**

If the `btrfs-progs` package is not already installed on your system, use `yum` to install it.

You can use the `mkfs.btrfs` command to create a btrfs file system that is laid out across one or more block devices. The default configuration is to stripe the file system data and to mirror the file system metadata across the devices. If you specify a single device, the metadata is duplicated on that device unless you specify that only one copy of the metadata is to be used. The devices can be simple disk partitions, loopback devices (that is, disk images in memory), multipath devices, or LUNs that implement RAID in hardware.

The following table illustrates how to use the `mkfs.btrfs` command to create various btrfs configurations.
# Creating a Btrfs File System

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
</table>
| `mkfs.btrfs block_device` | Create a btrfs file system on a single device. For example:  
`mkfs.btrfs /dev/sdb1` |
| `mkfs.btrfs -L label block_device` | Create a btrfs file system with a label that you can use when mounting the file system. For example:  
`mkfs.btrfs -L myvolume /dev/sdb2` |
| **Note** | The device must correspond to a partition if you intend to mount it by specifying the name of its label. |
| `mkfs.btrfs -m single block_device` | Create a btrfs file system on a single device, but do not duplicate the metadata on that device. For example:  
`mkfs.btrfs -m single /dev/sdc` |
| `mkfs.btrfs block_device1 block_device2 ...` | Stripe the file system data and mirror the file system metadata across several devices. For example:  
`mkfs.btrfs /dev/sdd /dev/sde` |
| `mkfs.btrfs -m raid0 block_device1 block_device2 ...` | Stripe both the file system data and metadata across several devices. For example:  
`mkfs.btrfs -m raid0 /dev/sdd /dev/sde` |
| `mkfs.btrfs -d raid1 block_device1 block_device2 ...` | Mirror both the file system data and metadata across several devices. For example:  
`mkfs.btrfs -d raid1 /dev/sdd /dev/sde` |
| `mkfs.btrfs -d raid10 -m raid10 block_device1 block_device2 block_device3 block_device4` | Stripe the file system data and metadata across several mirrored devices. You must specify an even number of devices, of which there must be at least four. For example:  
`mkfs.btrfs -d raid10 -m raid10 /dev/sdf \  
/dev/sdg /dev/sdh /dev/sdi /dev/sdj /dev/sdk` |

When you want to mount the file system, you can specify it by any of its component devices, for example:

```bash
# mkfs.btrfs -d raid10 -m raid10 /dev[sdfghijk]  
# mount /dev/sdf /raid10_mountpoint
```

To find out the RAID configuration of a mounted btrfs file system, use this command:

```bash
# btrfs filesystem df mountpoint
```

**Note**  
The `btrfs filesystem df` command displays more accurate information about the space used by a btrfs file system than the `df` command does.

Use the following form of the `btrfs` command to display information about all the btrfs file systems on a system:
21.4 Modifying a Btrfs File System

The following table shows how you can use the `btrfs` command to add or remove devices, and to rebalance the layout of the file system data and metadata across the devices.

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>btrfs device add device mountpoint</code></td>
<td>Add a device to the file system that is mounted on the specified mount point. For example: <code>btrfs device add /dev/sdd /myfs</code></td>
</tr>
<tr>
<td><code>btrfs device delete device mountpoint</code></td>
<td>Remove a device from a mounted file system. For example: <code>btrfs device delete /dev/sde /myfs</code></td>
</tr>
<tr>
<td><code>btrfs device delete missing mountpoint</code></td>
<td>Remove a failed device from the file system that is mounted in degraded mode. For example: <code>btrfs device remove missing /myfs</code></td>
</tr>
<tr>
<td><code>btrfs filesystem balance mountpoint</code></td>
<td>After adding or removing devices, redistribute the file system data and metadata across the available devices.</td>
</tr>
</tbody>
</table>

To mount a file system in degraded mode, specify the `-o degraded` option to the `mount` command.

For a RAID configuration, if the number of devices would fall below the minimum number that are required, you must add the replacement device before removing the failed device.

21.5 Compressing and Defragmenting a Btrfs File System

You can compress a btrfs file system to increase its effective capacity, and you can defragment it to increase I/O performance.

To enable compression of a btrfs file system, specify one of the following `mount` options:

<table>
<thead>
<tr>
<th>Mount Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>compress=lzo</td>
<td>Use LZO compression.</td>
</tr>
<tr>
<td>compress=zlib</td>
<td>Use zlib compression.</td>
</tr>
</tbody>
</table>

LZO offers a better compression ratio, while zlib offers faster compression.

You can also compress a btrfs file system at the same time that you defragment it.

To defragment a btrfs file system, use the following command:

```
btrfs filesystem defragment filesystem_name
```

To defragment a btrfs file system and compress it at the same time:
Resizing a Btrfs File System

You can also defragment, and optionally compress, individual file system objects, such as directories and files, within a btrfs file system.

Note
You can set up automatic defragmentation by specifying the `autodefrag` option when you mount the file system. However, automatic defragmentation is not recommended for large databases or for images of virtual machines.

Defragmenting a file or a subvolume that has a copy-on-write copy results breaks the link between the file and its copy. For example, if you defragment a subvolume that has a snapshot, the disk usage by the subvolume and its snapshot will increase because the snapshot is no longer a copy-on-write image of the subvolume.

21.6 Resizing a Btrfs File System

You can use the `btrfs` command to increase the size of a mounted btrfs file system if there is space on the underlying devices to accommodate the change, or to decrease its size if the file system has sufficient available free space. The command does not have any effect on the layout or size of the underlying devices.

For example, to increase the size of `/mybtrfs1` by 2 GB:

```
# btrfs filesystem resize +2g /mybtrfs1
```

Decrease the size of `/mybtrfs2` by 4 GB:

```
# btrfs filesystem resize -4g /mybtrfs2
```

Set the size of `/mybtrfs3` to 20 GB:

```
# btrfs filesystem resize 20g /mybtrfs3
```

21.7 Creating Subvolumes and Snapshots

The top level of a btrfs file system is a subvolume consisting of a named b-tree structure that contains directories, files, and possibly further btrfs subvolumes that are themselves named b-trees that contain directories and files, and so on. To create a subvolume, change directory to the position in the btrfs file system where you want to create the subvolume and enter the following command:

```
# btrfs subvolume create subvolume_name
```

Snapshots are a type of subvolume that records the contents of their parent subvolumes at the time that you took the snapshot. If you take a snapshot of a btrfs file system and do not write to it, the snapshot records the state of the original file system and forms a stable image from which you can make a backup. If you make a snapshot writable, you can treat it as a alternate version of the original file system. The copy-on-write functionality of btrfs file system means that snapshots are quick to create, and consume very little disk space initially.

Note
Taking snapshots of a subvolume is not a recursive process. If you create a snapshot of a subvolume, every subvolume or snapshot that the subvolume contains is mapped to an empty directory of the same name inside the snapshot.
Creating Subvolumes and Snapshots

The following table shows how to perform some common snapshot operations:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>btrfs subvolume snapshot pathname</code></td>
<td>Create a snapshot <code>snapshot_path</code> of a parent subvolume or snapshot specified by <code>pathname</code>. For example:</td>
</tr>
<tr>
<td><code>btrfs subvolume snapshot /mybtrfs /mybtrfs/snapshot1</code></td>
<td></td>
</tr>
<tr>
<td><code>btrfs subvolume list pathname</code></td>
<td>List the subvolumes or snapshots of a subvolume or snapshot specified by <code>pathname</code>. For example:</td>
</tr>
<tr>
<td><code>btrfs subvolume list /mybtrfs</code></td>
<td></td>
</tr>
<tr>
<td><code>btrfs subvolume set-default ID pathname</code></td>
<td>By default, mount the snapshot or subvolume specified by its ID instead of the parent subvolume. For example:</td>
</tr>
<tr>
<td><code>btrfs subvolume set-default 4 /mybtrfs</code></td>
<td></td>
</tr>
<tr>
<td><code>btrfs subvolume get-default pathname</code></td>
<td>Displays the ID of the default subvolume that is mounted for the specified subvolume. For example:</td>
</tr>
<tr>
<td><code>btrfs subvolume get-default /mybtrfs</code></td>
<td></td>
</tr>
</tbody>
</table>

You can mount a btrfs subvolume as though it were a disk device. If you mount a snapshot instead of its parent subvolume, you effectively roll back the state of the file system to the time that the snapshot was taken. By default, the operating system mounts the parent btrfs volume, which has an ID of 0, unless you use `set-default` to change the default subvolume. If you set a new default subvolume, the system will mount that subvolume instead in future. You can override the default setting by specifying either of the following `mount` options:

<table>
<thead>
<tr>
<th>Mount Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>subvolid=snapshot-ID</code></td>
<td>Mount the subvolume or snapshot specified by its subvolume ID instead of the default subvolume.</td>
</tr>
<tr>
<td><code>subvol=pathname/snapshot_path</code></td>
<td>Mount the subvolume or snapshot specified by its pathname instead of the default subvolume.</td>
</tr>
</tbody>
</table>

| Note | The subvolume or snapshot must be located in the root of the btrfs file system. |

When you have rolled back a file system by mounting a snapshot, you can take snapshots of the snapshot itself to record its state.

When you no longer require a subvolume or snapshot, use the following command to delete it:

```
# btrfs subvolume delete subvolume_path
```
Note
Deleting a subvolume deletes all subvolumes that are below it in the b-tree hierarchy. For this reason, you cannot remove the topmost subvolume of a btrfs file system, which has an ID of 0.

For details of how to use the `snapper` command to create and manage btrfs snapshots, see Section 21.7.1, "Using snapper with Btrfs Subvolumes".

21.7.1 Using snapper with Btrfs Subvolumes

You can use the `snapper` utility to create and manage snapshots of btrfs subvolumes.

To set up the snapper configuration for an existing mounted btrfs subvolume:

```bash
# snapper -c config_name create-config -f btrfs fs_name
```

Here `config_name` is the name of the configuration and `fs_name` is the path of the mounted btrfs subvolume. The command adds an entry for `config_name` to `/etc/sysconfig/snapper`, creates the configuration file `/etc/snapper/configs/config_name`, and sets up a `.snapshots` subvolume for the snapshots.

For example, the following command sets up the `snapper` configuration for a btrfs root file system:

```bash
# snapper -c root create-config -f btrfs /
```

By default, `snapper` sets up a `cron.hourly` job to create snapshots in the `.snapshot` subdirectory of the subvolume and a `cron.daily` job to clean up old snapshots. You can edit the configuration file to disable or change this behavior. For more information, see the `snapper-configs(5)` manual page.

There are three types of snapshot that you can create using `snapper`:

- **post**: You use a post snapshot to record the state of a subvolume after a modification. A post snapshot should always be paired with a pre snapshot that you take immediately before you make the modification.

- **pre**: You use a pre snapshot to record the state of a subvolume before a modification. A pre snapshot should always be paired with a post snapshot that you take immediately after you have completed the modification.

- **single**: You can use a single snapshot to record the state of a subvolume but it does not have any association with other snapshots of the subvolume.

For example, the following commands create pre and post snapshots of a subvolume:

```bash
# snapper -c config_name create -t pre -p N
... Modify the subvolume's contents...
# snapper -c config_name create -t post --pre-num N -p N'
```

The `-p` option causes `snapper` to display the number of the snapshot so that you can reference it when you create the post snapshot or when you compare the contents of the pre and post snapshots.

To display the files and directories that have been added, removed, or modified between the pre and post snapshots, use the `status` subcommand:

```bash
# snapper -c config_name status N..N'
```
21.7.2 Cloning Virtual Machine Images and Linux Containers

You can use a btrfs file system to provide storage space for virtual machine images and Linux Containers. The ability to quickly clone files and create snapshots of directory structures makes btrfs an ideal candidate for this purpose. For details of how to use the snapshot feature of btrfs to implement Linux Containers, see Chapter 28, Linux Containers.

21.8 Using the Send/Receive Feature

The send/receive feature requires that you boot the system using UEK R3.

The send operation compares two subvolumes and writes a description of how to convert one subvolume (the parent subvolume) into the other (the sent subvolume). You would usually direct the output to a file for later use or pipe it to a receive operation for immediate use.

The simplest form of the send operation writes a complete description of a subvolume:

```
btrfs send [-v] [-f sent_file] ... subvol
```

You can specify multiple instances of the `-v` option to display increasing amounts of debugging output. The `-f` option allows you to save the output to a file. Both of these options are implicit in the following usage examples.

The following form of the send operation writes a complete description of how to convert one subvolume into another:

```
btrfs send -p parent_subvol sent_subvol
```

If a subvolume such as a snapshot of the parent volume, known as a clone source, will be available during the receive operation from which some of the data can be recovered, you can specify the clone source to reduce the size of the output file:

```
btrfs send [-p parent_subvol] -c clone_src [-c clone_src] ... subvol
```

You can specify the `-c` option multiple times if there is more than one clone source. If you do not specify the parent subvolume, btrfs chooses a suitable parent from the clone sources.

You use the receive operation to regenerate the sent subvolume at a specified path:

```
btrfs receive [-f sent_file] mountpoint
```
21.8.1 Using Send/Receive to Implement Incremental Backups

The following procedure is a suggestion for setting up an incremental backup and restore process for a subvolume.

1. Create a read-only snapshot of the subvolume to serve as an initial reference point for the backup:

   ```bash
   # btrfs subvolume snapshot -r /vol /vol/backup_0
   ```

2. Run `sync` to ensure that the snapshot has been written to disk:

   ```bash
   # sync
   ```

3. Create a subvolume or directory on a btrfs file system as a backup area to receive the snapshot, for example, `/backupvol`.

4. Send the snapshot to `/backupvol`:

   ```bash
   # btrfs send /vol/backup_0 | btrfs receive /backupvol
   ```

   This command creates the subvolume `/backupvol/backup_0`.

   Having created the reference backup, you can then create incremental backups as required.

5. To create an incremental backup:

   a. Create a new snapshot of the subvolume:

      ```bash
      # btrfs subvolume snapshot -r /vol /vol/backup_1
      ```

   b. Run `sync` to ensure that the snapshot has been written to disk:

      ```bash
      # sync
      ```

   c. Send only the differences between the reference backup and the new backup to the backup area:

      ```bash
      # btrfs send -p /vol/backup_0 /vol/backup_1 | btrfs receive /backupvol
      ```

      This command creates the subvolume `/backupvol/backup_1`.

21.9 Using Quota Groups

**Note**

The quota groups feature requires that you boot the system using UEK R3.

To enable quotas, use the following command on a newly created btrfs file system before any creating any subvolumes:

```bash
# btrfs quota enable volume
```

To assign a quota-group limit to a subvolume, use the following command:

```bash
# btrfs qgroup limit size /volume/subvolume
```

For example:

```bash
# btrfs qgroup limit 1g /myvol/subvol1
# btrfs qgroup limit 512m /myvol/subvol2
```

To find out the quota usage for a subvolume, use the `btrfs qgroup show path` command:
21.10 Replacing Devices on a Live File System

Note
The device replacement feature requires that you boot the system using UEK R3.

You can replace devices on a live file system. You do not need to unmount the file system or stop any tasks that are using it. If the system crashes or loses power while the replacement is taking place, the operation resumes when the system next mounts the file system.

Use the following command to replace a device on a mounted btrfs file system:

```
# btrfs replace start source_dev target_dev [-r] mountpoint
```

`source_dev` and `target_dev` specify the device to be replaced (source device) and the replacement device (target device). `mountpoint` specifies the file system that is using the source device. The target device must be the same size as or larger than the source device. If the source device is no longer available or you specify the `-r` option, the data is reconstructed by using redundant data obtained from other devices (such as another available mirror). The source device is removed from the file system when the operation is complete.

You can use the `btrfs replace status mountpoint` and `btrfs replace cancel mountpoint` commands to check the progress of the replacement operation or to cancel the operation.

21.11 Creating Snapshots of Files

You can use the `--reflink` option to the `cp` command to create lightweight copies of a file within the same subvolume of a btrfs file system. The copy-on-write mechanism saves disk space and allows copy operations to be almost instantaneous. The btrfs file system creates a new inode that shares the same disk blocks as the existing file, rather than creating a complete copy of the file's data or creating a link that points to the file's inode. The resulting file appears to be a copy of the original file, but the original data blocks are not duplicated. If you subsequently write to one of the files, the btrfs file system makes copies of the blocks before they are written to, preserving the other file's content.

For example, the following command creates the snapshot `bar` of the file `foo`:

```
# cp --reflink foo bar
```

21.12 Converting an Ext2, Ext3, or Ext4 File System to a Btrfs File System

You can use the `btrfs-convert` utility to convert an ext2, ext3, or ext4 file system to btrfs. The utility preserves an image of the original file system in a snapshot named `ext2_saved`. This snapshot allows you to roll back the conversion, even if you have made changes to the btrfs file system.

Note
You cannot convert the root file system or a bootable partition, such as `/boot`, to btrfs.

21.12.1 Converting a Non-root File System

Caution
Before performing a file system conversion, make a backup of the file system from which you can restore its state.
To convert an ext2, ext3, or ext4 file system other than the root file system to btrfs:

1. Unmount the file system.

   `# umount mountpoint`

2. Run the correct version of fsck (for example, fsck.ext4) on the underlying device to check and correct the integrity of file system.

   `# fsck.extN -f device`

3. Convert the file system to a btrfs file system.

   `# btrfs-convert device`

4. Edit the file /etc/fstab, and change the file system type of the file system to btrfs, for example:

   `/dev/sdb               /myfs          btrfs    defaults  0 0`

5. Mount the converted file system on the old mount point.

   `# mount device mountpoint`

21.13 About the Btrfs root File System

Oracle Linux 7 installation allows you to create a btrfs root file system. The mounted root file system is a snapshot (named install) of the root file system taken at the end of installation. To find out the ID of the parent of the root file system subvolume, use the following command:

`# btrfs subvolume list /
ID 258 top level 5 path install`

In this example, the installation root file system subvolume has an ID of 5. The subvolume with ID 258 (install) is currently mounted as /. Figure 21.1, “Layout of the root File System Following Installation” illustrates the layout of the file system:

Figure 21.1 Layout of the root File System Following Installation

```
/    ) Top level ID 5
   -- bin     ) Directory in subvolume ID 5
   boot
   dev
   etc
   home
   install   ) Default subvolume ID 258
      -- bin     ) Directory in subvolume ID 258
      boot
      dev
      etc
      lib
      lib64
      media
      misc
```

The top-level subvolume with ID 5 records the contents of the root file system file system at the end of installation. The default subvolume (install) with ID 258 is currently mounted as the active root file system.
Creating Snapshots of the root File System

The `mount` command shows the device that is currently mounted as the root file system:

```
# mount
/dev/mapper/vg_btrfs-lv_root on / type btrfs (rw)
...```

To mount the installation root file system volume, you can use the following commands:

```
# mkdir /instroot
# mount -o subvolid=5 /dev/mapper/vg-btrfs-lv-root /instroot
```

If you list the contents of `/instroot`, you can see both the contents of the installation root file system volume and the `install` snapshot, for example:

```
# ls /instroot
bin   cgroup  etc   install  lib64  misc  net  proc  sbin  srv  tmp  var
boot  dev     home  lib      media  mnt   opt  root  selinux  sys  usr
```

The contents of `/` and `/instroot/install` are identical as demonstrated in the following example where a file (`foo`) created in `/instroot/install` is also visible in `/`:

```
# touch /instroot/install/foo
# ls /
bin  cgroup  etc  home  lib  media  mnt  opt  root  selinux  sys  us
boot  dev  foo  instroot  lib64  misc  net  proc  sbin  srv  t
# ls /instroot/install
bin  cgroup  etc  home  lib  media  mnt  opt  root  selinux  sys  us
boot  dev  foo  instroot  lib64  misc  net  proc  sbin  srv  t
# rm -f /foo
# ls /
bin  cgroup  etc  instroot  lib64  misc  net  proc  sbin  srv  tmp  var
boot  dev  home  lib  media  mnt  opt  root  selinux  sys  us
# ls /instroot/install
bin  cgroup  etc  instroot  lib64  misc  net  proc  sbin  srv  tmp  var
boot  dev  home  lib  media  mnt  opt  root  selinux  sys  us
```

### 21.13.1 Creating Snapshots of the root File System

To take a snapshot of the current root file system:

1. Mount the top level of the root file system on a suitable mount point.
   ```
   # mount -o subvolid=5 /dev/mapper/vg-btrfs-lv-root /mnt
   ```

2. Change directory to the mount point and take the snapshot. In this example, the `install` subvolume is currently mounted as the root file system system.
   ```
   # cd /mnt
   # btrfs subvolume snapshot install root_snapshot_1
   Create a snapshot of 'install' in './root_snapshot_1'
   ```

3. Change directory to `/` and unmount the top level of the file system.
   ```
   # cd /
   # umount /mnt
   ```

The list of subvolumes now includes the newly created snapshot.

```
# btrfs subvolume list /
ID 258 top level 5 path install
ID 260 top level 5 path root_snapshot_1
```
21.13.2 Mounting Alternate Snapshots as the root File System

If you want to roll back changes to your system, you can mount a snapshot as the root file system by specifying its ID as the default subvolume, for example:

```
# btrfs subvolume set-default 260 /
```

Reboot the system for the change to take effect.

21.13.3 Deleting Snapshots of the root File System

To delete a snapshot:

1. Mount the top level of the file system, for example:

```
# mount -o subvolid=5 /dev/mapper/vg-btrfs-lv-root /mnt
```

2. Change directory to the mount point and delete the snapshot.

```
# cd /mnt
# btrfs subvolume delete install
Delete subvolume '/mnt/install'
```

3. Change directory to `/` and unmount the top level of the file system.

```
# cd /
# umount /mnt
```

The list of subvolumes now does not include `install`.

```
# btrfs subvolume list /
ID 260 top level 5 path root_snapshot_1
```

21.14 Converting a Non-root Ext2 File System to Ext3

**Caution**

Before performing a file system conversion, make a backup of the file system from which you can restore its state.

To convert a non-root ext2 file system to ext3:

1. Unmount the ext2 file system:

```
# umount filesystem
```

2. Use `fsck.ext2` to check the file system.

```
bash-4.1# fsck.ext2 -f device
```

3. Use the following command with the block device corresponding to the ext2 file system:

```
# tune2fs -j device
```

The command adds an ext3 journal inode to the file system.

4. Use `fsck.ext3` to check the file system.

```
bash-4.1# fsck.ext3 -f device
```
Converting a root Ext2 File System to Ext3

5. Correct any entry for the file system in /etc/fstab so that its type is defined as ext3 instead of ext2.

6. You can now remount the file system whenever convenient:

```
# mount filesystem
```

For more information, see the `tune2fs(8)` manual page.

## 21.15 Converting a root Ext2 File System to Ext3

⚠️ **Caution**

Before performing a root file system conversion, make a full system backup from which you can restore its state.

To convert a root ext2 file system to ext3:

1. Use the following command with the block device corresponding to the root file system:

```
# tune2fs -j device
```

The command adds an ext3 journal to the file system as the file `.journal`.

2. Run the `mount` command to determine the device that is currently mounted as the root file system.

In the following example, the root file system corresponds to the disk partition `/dev/sda2`:

```
# mount /dev/sda2 on / type ext2 (rw)
```

3. Shut down the system.

4. Boot the system from an Oracle Linux boot CD, DVD or ISO. You can download the ISO from [https://edelivery.oracle.com/linux](https://edelivery.oracle.com/linux).

5. From the installation menu, select **Rescue Installed System**. When prompted, choose a language and keyboard, select **Local CD/DVD** as the installation media, select **No** to bypass starting the network interface, and select **Skip** to bypass selecting a rescue environment.

6. Select **Start shell** to obtain a `bash` shell prompt (`bash-4.1#`) at the bottom of the screen.

7. If the existing root file system is configured as an LVM volume, use the following command to start the volume group (for example, `vg_host01`):

```
bash-4.1# lvchange -ay vg_host01
```

8. Use `fsck.ext3` to check the file system.

```
bash-4.1# fsck.ext3 -f device
```

where `device` is the root file system device (for example, `/dev/sda2`).

The command moves the `.journal` file to the journal inode.

9. Create a mount point (`/mnt1`) and mount the converted root file system on it.

```
bash-4.1# mkdir /mnt1
bash-4.1# mount -t ext3 device /mnt1
```
Creating a Local OCFS2 File System

10. Use the `vi` command to edit `/mnt1/etc/fstab`, and change the file system type of the root file system to `ext3`, for example:

```
/dev/sda2        /       ext3    defaults  1 1
```

11. Create the file `.autorelabel` in the root of the mounted file system.

```
bash-4.1# touch /mnt1/.autorelabel
```

The presence of the `.autorelabel` file in `/` instructs SELinux to recreate the security attributes of all files on the file system.

**Note**

If you do not create the `.autorelabel` file, you might not be able to boot the system successfully. If you forget to create the file and the reboot fails, either disable SELinux temporarily by specifying `selinux=0` to the kernel boot parameters, or run SELinux in permissive mode by specifying `enforcing=0`.

12. Unmount the converted root file system.

```
bash-4.1# umount /mnt1
```

13. Remove the boot CD, DVD, or ISO, and reboot the system.

For more information, see the `tune2fs(8)` manual page.

### 21.16 Creating a Local OCFS2 File System

To create an OCFS2 file system that will be locally mounted and not associated with a cluster, use the following command:

```
# mkfs.ocfs2 -M local --fs-features=local -N 1 [options] device
```

For example, create a locally mountable OCFS2 volume on `/dev/sdc1` with one node slot and the label `localvol`:

```
# mkfs.ocfs2 -M local --fs-features=local -N 1 -L "localvol" /dev/sdc1
```

You can use the `tunefs.ocfs2` utility to convert a local OCFS2 file system to cluster use, for example:

```
# umount /dev/sdc1
# tunefs.ocfs2 -M cluster --fs-features=cluster -N 8 /dev/sdc1
```

This example also increases the number of node slots from 1 to 8 to allow up to eight nodes to mount the file system.

For information about using OCFS2 with clusters, see Chapter 23, *Oracle Cluster File System Version 2*.

### 21.17 About the XFS File System

XFS is a high-performance journaling file system that was initially created by Silicon Graphics, Inc. for the IRIX operating system and later ported to Linux. The parallel I/O performance of XFS provides high scalability for I/O threads, file system bandwidth, file and file system size, even when the file system spans many storage devices.

A typical use case for XFS is to implement a several-hundred terabyte file system across multiple storage servers, each server consisting of multiple FC-connected disk arrays.

XFS is supported for use with the root (`/`) or `boot` file systems on Oracle Linux 7.
About the XFS File System

XFS has a large number of features that make it suitable for deployment in an enterprise-level computing environment that requires the implementation of very large file systems:

- XFS implements journaling for metadata operations, which guarantees the consistency of the file system following loss of power or a system crash. XFS records file system updates asynchronously to a circular buffer (the journal) before it can commit the actual data updates to disk. The journal can be located either internaly in the data section of the file system, or externally on a separate device to reduce contention for disk access. If the system crashes or loses power, it reads the journal when the file system is remounted, and replays any pending metadata operations to ensure the consistency of the file system. The speed of this recovery does not depend on the size of the file system.

- XFS is internally partitioned into allocation groups, which are virtual storage regions of fixed size. Any files and directories that you create can span multiple allocation groups. Each allocation group manages its own set of inodes and free space independently of other allocation groups to provide both scalability and parallelism of I/O operations. If the file system spans many physical devices, allocation groups can optimize throughput by taking advantage of the underlying separation of channels to the storage components.

- XFS is an extent-based file system. To reduce file fragmentation and file scattering, each file's blocks can have variable length extents, where each extent consists of one or more contiguous blocks. XFS's space allocation scheme is designed to efficiently locate free extents that it can use for file system operations. XFS does not allocate storage to the holes in sparse files. If possible, the extent allocation map for a file is stored in its inode. Large allocation maps are stored in a data structure maintained by the allocation group.

- To maximize throughput for XFS file systems that you create on an underlying striped, software or hardware-based array, you can use the su and sw arguments to the -d option of the mkfs.xfs command to specify the size of each stripe unit and the number of units per stripe. XFS uses the information to align data, inodes, and journal appropriately for the storage. On lvm and md volumes and some hardware RAID configurations, XFS can automatically select the optimal stripe parameters for you.

- To reduce fragmentation and increase performance, XFS implements delayed allocation, reserving file system blocks for data in the buffer cache, and allocating the block when the operating system flushes that data to disk.

- XFS supports extended attributes for files, where the size of each attribute's value can be up to 64 KB, and each attribute can be allocated to either a root or a user name space.

- Direct I/O in XFS implements high throughput, non-cached I/O by performing DMA directly between an application and a storage device, utilising the full I/O bandwidth of the device.

- To support the snapshot facilities that volume managers, hardware subsystems, and databases provide, you can use the xfs_freeze command to suspend and resume I/O for an XFS file system. See Section 21.22, “Freezing and Unfreezing an XFS File System”.

- To defragment individual files in an active XFS file system, you can use the xfs-fsr command. See Section 21.25, “Defragmenting an XFS File System”.

- To grow an XFS file system, you can use the xfs_growfs command. See Section 21.21, “Growing an XFS File System”.

- To back up and restore a live XFS file system, you can use the xfsdump and xfsrestore commands. See Section 21.24, “Backing up and Restoring XFS File Systems”.

- XFS supports user, group, and project disk quotas on block and inode usage that are initialized when the file system is mounted. Project disk quotas allow you to set limits for individual directory hierarchies.
within an XFS file system without regard to which user or group has write access to that directory hierarchy.

21.17.1 About External XFS Journals

The default location for an XFS journal is on the same block device as the data. As synchronous metadata writes to the journal must complete successfully before any associated data writes can start, such a layout can lead to disk contention for the typical workload pattern on a database server. To overcome this problem, you can place the journal on a separate physical device with a low-latency I/O path. As the journal typically requires very little storage space, such an arrangement can significantly improve the file system's I/O throughput. A suitable host device for the journal is a solid-state drive (SSD) device or a RAID device with a battery-backed write-back cache.

To reserve an external journal with a specified size when you create an XFS file system, specify the `--logdev=device,size=size` option to the `mkfs.xfs` command. If you omit the `size` parameter, `mkfs.xfs` selects a journal size based on the size of the file system. To mount the XFS file system so that it uses the external journal, specify the `--logdev=device` option to the `mount` command.

21.17.2 About XFS Write Barriers

A write barrier assures file system consistency on storage hardware that supports flushing of in-memory data to the underlying device. This ability is particularly important for write operations to an XFS journal that is held on a device with a volatile write-back cache.

By default, an XFS file system is mounted with a write barrier. If you create an XFS file system on a LUN that has a battery-backed, non-volatile cache, using a write barrier degrades I/O performance by requiring data to be flushed more often than necessary. In such cases, you can remove the write barrier by mounting the file system with the `--nobARRIER` option to the `mount` command.

21.17.3 About Lazy Counters

With lazy-counters enabled on an XFS file system, the free-space and inode counters are maintained in parts of the file system other than the superblock. This arrangement can significantly improve I/O performance for application workloads that are metadata intensive.

Lazy counters are enabled by default, but if required, you can disable them by specifying the `--lazy-count=0` option to the `mkfs.xfs` command.

21.18 Installing the XFS Packages

Note
You can also obtain the XFS packages from the Oracle Linux Yum Server.

To install the XFS packages on a system:

1. Log in to ULN, and subscribe your system to the `ol7_x86_64_latest` channel.

2. On your system, use `yum` to install the `xfsprogs` and `xfsdump` packages:

   ```bash
   # yum install xfsprogs xfsdump
   ```

3. If you require the XFS development and QA packages, additionally subscribe your system to the `ol7_x86_64_optional` channel and use `yum` to install them:
21.19 Creating an XFS File System

You can use the `mkfs.xfs` command to create an XFS file system, for example.

```
# mkfs.xfs /dev/vg0/lv0
meta-data=/dev/vg0/lv0 isize=256 agcount=32, agsize=8473312 blks
  =                    sectsz=512 attr-2, projid32bit=0
data = bsize=4096 blocks=271145984, imaxpct=25
  = sunit=0      swidth=0 blks
naming =version 2 bsize=4096 ascii-ci=0
log = internal log bsize=4096 blocks=32768, version=2
  = sectsz=512 sunit=0 blks, lazy-count=1
realtime =none extsz=4096 blocks=0, rtextents=0
```

To create an XFS file system with a stripe-unit size of 32 KB and 6 units per stripe, you would specify the `su` and `sw` arguments to the `-d` option, for example:

```
# mkfs.xfs -d su=32k,sw=6 /dev/vg0/lv1
```

For more information, see the `mkfs.xfs(8)` manual page.

21.20 Modifying an XFS File System

**Note**

You cannot modify a mounted XFS file system.

You can use the `xfs_admin` command to modify an unmounted XFS file system. For example, you can enable or disable lazy counters, change the file system UUID, or change the file system label.

To display the existing label for an unmounted XFS file system and then apply a new label:

```
# xfs_admin -l /dev/sdb
label = 
# xfs_admin -L "VideoRecords" /dev/sdb
writing all SBs
new label = "VideoRecords"
```

**Note**

The label can be a maximum of 12 characters in length.

To display the existing UUID and then generate a new UUID:

```
# xfs_admin -u /dev/sdb
UUID = cd4f1cc4-15d8-45f7-afa4-2ae87d1db2ed
# xfs_admin -U generate /dev/sdb
writing all SBs
new UUID = c1b9d5a2-f162-11cf-9ece-0020afc76f16
```

To clear the UUID altogether:

```
# xfs_admin -U nil /dev/sdb
Clearing log and setting UUID
writing all SBs
new UUID = 00000000-0000-0000-0000-000000000000
```

To disable and then re-enable lazy counters:

```
```
Growing an XFS File System

For more information, see the `mkfs_admin(8)` manual page.

21.21 Growing an XFS File System

<table>
<thead>
<tr>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>You cannot grow an XFS file system that is currently unmounted.</td>
</tr>
<tr>
<td>There is currently no command to shrink an XFS file system.</td>
</tr>
</tbody>
</table>

You can use the `xfs_growfs` command to increase the size of a mounted XFS file system if there is space on the underlying devices to accommodate the change. The command does not have any effect on the layout or size of the underlying devices. If necessary, use the underlying volume manager to increase the physical storage that is available. For example, you can use the `vgextend` command to increase the storage that is available to an LVM volume group and `lvextend` to increase the size of the logical volume that contains the file system.

You cannot use the `parted` command to resize a partition that contains an XFS file system. You must instead recreate the partition with a larger size and restore its contents from a backup if you deleted the original partition or from the contents of the original partition if you did not delete it to free up disk space.

For example, to increase the size of `/myxfs1` to 4 TB, assuming a block size of 4 KB:

```
# xfs_growfs -D 1073741824 /myxfs1
```

To increase the size of the file system to the maximum size that the underlying device supports, specify the `-d` option:

```
# xfs_growfs -d /myxfs1
```

For more information, see the `xfs_growfs(8)` manual page.

21.22 Freezing and Unfreezing an XFS File System

If you need to take a hardware-based snapshot of an XFS file system, you can temporarily stop write operations to it.

<table>
<thead>
<tr>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>You do not need to explicitly suspend write operations if you use the <code>lvcreate</code> command to take an LVM snapshot.</td>
</tr>
</tbody>
</table>

To freeze and unfreeze an XFS file system, use the `-f` and `-u` options with the `xfs_freeze` command, for example:

```
# xfs_freeze -f /myxfs
# ... Take snapshot of file system ...
# xfs_freeze -u /myxfs
```

<table>
<thead>
<tr>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>You can also use the <code>xfs_freeze</code> command with <code>btrfs</code>, <code>ext3</code>, and <code>ext4</code> file systems.</td>
</tr>
</tbody>
</table>
For more information, see the `xfs_freeze(8)` manual page.

## 21.23 Setting Quotas on an XFS File System

The following table shows the `mount` options that you can specify to enable quotas on an XFS file system:

<table>
<thead>
<tr>
<th>Mount Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>gqnoenforce</td>
<td>Enable group quotas. Report usage, but do not enforce usage limits.</td>
</tr>
<tr>
<td>gquota</td>
<td>Enable group quotas and enforce usage limits.</td>
</tr>
<tr>
<td>pqnoenforce</td>
<td>Enable project quotas. Report usage, but do not enforce usage limits.</td>
</tr>
<tr>
<td>pquota</td>
<td>Enable project quotas and enforce usage limits.</td>
</tr>
<tr>
<td>uqnoenforce</td>
<td>Enable user quotas. Report usage, but do not enforce usage limits.</td>
</tr>
<tr>
<td>uquota</td>
<td>Enable user quotas and enforce usage limits.</td>
</tr>
</tbody>
</table>

To show the block usage limits and the current usage in the `myxfs` file system for all users, use the `xfs_quota` command:

```bash
# xfs_quota -x -c 'report -h' /myxfs
```

### Blocks

<table>
<thead>
<tr>
<th>User ID</th>
<th>Used</th>
<th>Soft</th>
<th>Hard</th>
</tr>
</thead>
<tbody>
<tr>
<td>root</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>guest</td>
<td>0</td>
<td>200M</td>
<td>250M</td>
</tr>
</tbody>
</table>

The following forms of the command display the free and used counts for blocks and inodes respectively in the manner of the `df -h` command:

```bash
# xfs_quota -c 'df -h' /myxfs
```

### Filesystem

<table>
<thead>
<tr>
<th>Filesystem</th>
<th>Size</th>
<th>Used</th>
<th>Avail</th>
<th>Pathname</th>
</tr>
</thead>
<tbody>
<tr>
<td>/dev/vg0/lv0</td>
<td>200.0G</td>
<td>32.2M</td>
<td>20.0G</td>
<td>/myxfs</td>
</tr>
</tbody>
</table>

```bash
# xfs_quota -c 'df -ih' /myxfs
```

### Filesystem

<table>
<thead>
<tr>
<th>Filesystem</th>
<th>Inodes</th>
<th>Used</th>
<th>Free</th>
<th>Pathname</th>
</tr>
</thead>
<tbody>
<tr>
<td>/dev/vg0/lv0</td>
<td>21.0m</td>
<td>4</td>
<td>21.0m</td>
<td>/myxfs</td>
</tr>
</tbody>
</table>

If you specify the `-x` option to enter expert mode, you can use subcommands such as `limit` to set soft and hard limits for block and inode usage by an individual user, for example:

```bash
# xfs_quota -x -c 'limit bsoft=200m bhard=250m isoft=200 ihard=250 guest' /myxfs
```

Of course, this command requires that you mounted the file system with user quotas enabled.

To set limits for a group on an XFS file system that you have mounted with group quotas enabled, specify the `-g` option to `limit`, for example:

```bash
# xfs_quota -x -c 'limit -g bsoft=5g bhard=6g devgrp' /myxfs
```

For more information, see the `xfs_quota(8)` manual page.

## 21.23.1 Setting Project Quotas

User and group quotas are supported by other file systems, such as `ext4`. The XFS file system additionally allows you to set quotas on individual directory hierarchies in the file system that are known as `managed trees`. Each managed tree is uniquely identified by a `project ID` and an optional `project name`. Being able to control the disk usage of a directory hierarchy is useful if you do not otherwise want to set
quota limits for a privileged user (for example, /var/log) or if many users or groups have write access to a directory (for example, /var/tmp).

To define a project and set quota limits on it:

1. Mount the XFS file system with project quotas enabled:

   ```
   # mount -o pquota device mountpoint
   ```

   For example, to enable project quotas for the /myxfs file system:

   ```
   # mount -o pquota /dev/vg0/lv0 /myxfs
   ```

2. Define a unique project ID for the directory hierarchy in the /etc/projects file:

   ```
   # echo project_ID:mountpoint/directory >> /etc/projects
   ```

   For example, to set a project ID of 51 for the directory hierarchy /myxfs/testdir:

   ```
   # echo 51:/myxfs/testdir >> /etc/projects
   ```

3. Create an entry in the /etc/projid file that maps a project name to the project ID:

   ```
   # echo project_name:project_ID >> /etc/projid
   ```

   For example, to map the project name testproj to the project with ID 51:

   ```
   # echo testproj:51 >> /etc/projid
   ```

4. Use the `project` subcommand of `xfs_quota` to define a managed tree in the XFS file system for the project:

   ```
   # xfs_quota -x -c 'project -s project_name' mountpoint
   ```

   For example, to define a managed tree in the /myxfs file system for the project testproj, which corresponds to the directory hierarchy /myxfs/testdir:

   ```
   # xfs_quota -x -c 'project -s testproj' /myxfs
   ```

5. Use the `limit` subcommand to set limits on the disk usage of the project:

   ```
   # xfs_quota -x -c 'limit -p arguments project_name' mountpoint
   ```

   For example, to set a hard limit of 10 GB of disk space for the project testproj:

   ```
   # xfs_quota -x -c 'limit -p bhard=10g testproj' /myxfs
   ```

For more information, see the `projects(5)`, `projid(5)`, and `xfs_quota(8)` manual pages.

### 21.24 Backing up and Restoring XFS File Systems

The `xfsdump` package contains the `xfsdump` and `xfsrestore` utilities. `xfsdump` examines the files in an XFS file system, determines which files need to be backed up, and copies them to the storage medium. Any backups that you create using `xfsdump` are portable between systems with different endian architectures. `xfsrestore` restores a full or incremental backup of an XFS file system. You can also restore individual files and directory hierarchies from backups.

**Note**

Unlike an LVM snapshot, which immediately creates a sparse clone of a volume, `xfsdump` takes time to make a copy of the file system data.
You can use the `xfsdump` command to create a backup of an XFS file system on a device such as a tape drive, or in a backup file on a different file system. A backup can span multiple physical media that are written on the same device, and you can write multiple backups to the same medium. You can write only a single backup to a file. The command does not overwrite existing XFS backups that it finds on physical media. You must use the appropriate command to erase a physical medium if you need to overwrite any existing backups.

For example, the following command writes a level 0 (base) backup of the XFS file system, `/myxfs` to the device `/dev/st0` and assigns a session label to the backup:

```
# xfsdump -l 0 -L "Backup level 0 of /myxfs `date`" -f /dev/st0 /myxfs
```

You can make incremental dumps relative to an existing backup by using the command:

```
# xfsdump -l level -L "Backup level level of /myxfs `date`" -f /dev/st0 /myxfs
```

A level 1 backup records only file system changes since the level 0 backup, a level 2 backup records only the changes since the latest level 1 backup, and so on up to level 9.

If you interrupt a backup by typing `Ctrl-C` and you did not specify the `-J` option (suppress the dump inventory) to `xfsdump`, you can resume the dump at a later date by specifying the `-R` option:

```
# xfsdump -R -l 1 -L "Backup level 1 of /myxfs `date`" -f /dev/st0 /myxfs
```

In this example, the backup session label from the earlier, interrupted session is overridden.

You use the `xfsrestore` command to find out information about the backups you have made of an XFS file system or to restore data from a backup.

The `xfsrestore -I` command displays information about the available backups, including the session ID and session label. If you want to restore a specific backup session from a backup medium, you can specify either the session ID or the session label.

For example, to restore an XFS file system from a level 0 backup by specifying the session ID:

```
# xfsrestore -f /dev/st0 -S c76b3156-c37c-5b6e-7564-a0963ff8ca8f /myxfs
```

If you specify the `-r` option, you can cumulatively recover all data from a level 0 backup and the higher-level backups that are based on that backup:

```
# xfsrestore -r -f /dev/st0 -v silent /myxfs
```

The command searches the archive looking for backups based on the level 0 backup, and prompts you to choose whether you want to restore each backup in turn. After restoring the backup that you select, the command exits. You must run this command multiple times, first selecting to restore the level 0 backup, and then subsequent higher-level backups up to and including the most recent one that you require to restore the file system data.

**Note**

After completing a cumulative restoration of an XFS file system, you should delete the `housekeeping` directory that `xfsrestore` creates in the destination directory.

You can recover a selected file or subdirectory contents from the backup medium, as shown in the following example, which recovers the contents of `/myxfs/profile/examples` to `/tmp/profile/examples` from the backup with a specified session label:

```
# xfsrestore -f /dev/sr0 -L "Backup level 0 of /myxfs Sat Mar 2 14:47:59 GMT 2013" "
-s profile/examples /usr/tmp
```
Alternatively, you can interactively browse a backup by specifying the \texttt{-i} option:

\begin{verbatim}
# xfsrestore -f /dev/sr0 -i
\end{verbatim}

This form of the command allows you browse a backup as though it were a file system. You can change directories, list files, add files, delete files, or extract files from a backup.

To copy the entire contents of one XFS file system to another, you can combine \texttt{xfsdump} and \texttt{xfsrestore}, using the \texttt{-J} option to suppress the usual dump inventory housekeeping that the commands perform:

\begin{verbatim}
# xfsdump -J - /myxfs | xfsrestore -J - /myxfsclone
\end{verbatim}

For more information, see the \texttt{xfsdump(8)} and \texttt{xfsrestore(8)} manual pages.

### 21.25 Defragmenting an XFS File System

You can use the \texttt{xfs_fsr} command to defragment whole XFS file systems or individual files within an XFS file system. As XFS is an extent-based file system, it is usually unnecessary to defragment a whole file system, and doing so is not recommended.

To defragment an individual file, specify the name of the file as the argument to \texttt{xfs_fsr}.

\begin{verbatim}
# xfs_fsr pathname
\end{verbatim}

If you run the \texttt{xfs_fsr} command without any options, the command defragments all currently mounted, writeable XFS file systems that are listed in /etc/mtab. For a period of two hours, the command passes over each file system in turn, attempting to defragment the top ten percent of files that have the greatest number of extents. After two hours, the command records its progress in the file /var/tmp/.fsrlast_xfs, and it resumes from that point if you run the command again.

For more information, see the \texttt{xfs_fsr(8)} manual page.

### 21.26 Checking and Repairing an XFS File System

\begin{note}

If you have an Oracle Linux Premier Support account and encounter a problem mounting an XFS file system, send a copy of the /var/log/messages file to Oracle Support and wait for advice.

\end{note}

If you cannot mount an XFS file system, you can use the \texttt{xfs_repair \textasciitilde n} command to check its consistency. Usually, you would only run this command on the device file of an unmounted file system that you believe has a problem. The \texttt{xfs_repair \textasciitilde n} command displays output to indicate changes that would be made to the file system in the case where it would need to complete a repair operation, but will not modify the file system directly.

If you can mount the file system and you do not have a suitable backup, you can use \texttt{xfsdump} to attempt to back up the existing file system data. However, the command might fail if the file system's metadata has become too corrupted.

You can use the \texttt{xfs_repair} command to attempt to repair an XFS file system specified by its device file. The command replays the journal log to fix any inconsistencies that might have resulted from the file system not being cleanly unmounted. Unless the file system has an inconsistency, it is usually not necessary to use the command, as the journal is replayed every time that you mount an XFS file system.

\begin{verbatim}
# xfs_repair device
\end{verbatim}
If the journal log has become corrupted, you can reset the log by specifying the `-L` option to `xfs_repair`.

**Warning**

Resetting the log can leave the file system in an inconsistent state, resulting in data loss and data corruption. Unless you are experienced in debugging and repairing XFS file systems using `xfs_db`, it is recommended that you instead recreate the file system and restore its contents from a backup.

If you cannot mount the file system or you do not have a suitable backup, running `xfs_repair` is the only viable option unless you are experienced in using `xfs_db`.

`xfs_db` provides an internal command set that allows you to debug and repair an XFS file system manually. The commands allow you to perform scans on the file system, and to navigate and display its data structures. If you specify the `-x` option to enable expert mode, you can modify the data structures.

```
xfs_db [-x] device
```

For more information, see the `xfs_db(8)` and `xfs_repair(8)` manual pages, and the `help` command within `xfs_db`.

   22.3.3 Accessing Samba Shares from a Windows Client .................... 265
   22.3.4 Accessing Samba Shares from an Oracle Linux Client .................. 265

This chapter describes administration tasks for the NFS and Samba shared file systems.

22.1 About Shared File Systems

Oracle Linux supports the following shared file system types:

**NFS**
The Network File System (NFS) is a distributed file system that allows a client computer to access files over a network as though the files were on local storage. See Section 22.2, “About NFS”.

**Samba**
Samba enables the provision of file and print services for Microsoft Windows clients and can integrate with a Windows workgroup, NT4 domain, or Active Directory domain. See Section 22.3, “About Samba”.

22.2 About NFS

A Network File System (NFS) server can share directory hierarchies in its local file systems with remote client systems over an IP-based network. After an NFS server exports a directory, NFS clients mount this directory if they have been granted permission to do so. The directory appears to the client systems as if it were a local directory. NFS centralizes storage provisioning and can improve data consistency and reliability.

Oracle Linux 7 supports the following versions of the NFS protocol:

- NFS version 3 (NFSv3), specified in RFC 1813.
- NFS version 4 (NFSv4), specified in RFC 3530.

NFSv3 relies on Remote Procedure Call (RPC) services, which are controlled by the `rpcbind` service. `rpcbind` responds to requests for an RPC service and sets up connections for the requested service. In addition, separate services are used to handle locking and mounting protocols. Configuring a firewall to cope with the various ranges of ports that are used by all these services can be complex and error prone.

NFSv4 does not use `rpcbind` as the NFS server itself listens on TCP port 2049 for service requests. The mounting and locking protocols are also integrated into the NFSv4 protocol, so separate services are also not required for these protocols. These refinements mean that firewall configuration for NFSv4 is no more difficult than for a service such as HTTP.

22.2.1 Configuring an NFS Server

To configure an NFS server:
Configuring an NFS Server

1. Install the `nfs-utils` package:

   ```
   # yum install nfs-utils
   ```

2. Edit the `/etc/exports` file to define the directories that the server will make available for clients to mount, for example:

   ```
   /var/folder 192.0.2.102(rw,async)
   /usr/local/apps *(all-squash,anonuid=501,anongid=501,ro)
   /var/projects/proj1 192.168.1.0/24(ro) mgmtpc(rw)
   ```

   Each entry consists of the local path to the exported directory, followed by a list of clients that can mount the directory with client-specific mount options in parentheses. If this example:

   - The client system with the IP address 192.0.2.102 can mount `/var/folder` with read and write permissions. All writes to the disk are asynchronous, which means that the server does not wait for write requests to be written to disk before responding to further requests from the client.
   - All clients can mount `/usr/local/apps` read-only, and all connecting users including `root` are mapped to the local unprivileged user with UID 501 and GID 501.
   - All clients on the 192.168.1.0 subnet can mount `/var/projects/proj1` read-only, and the client system named `mgmtpc` can mount the directory with read-write permissions.

   **Note**

   There is no space between a client specifier and the parenthesized list of options.

   For more information, see the `exports(5)` manual page.

3. Start the `nfs-server` service, and configure the service to start following a system reboot:

   ```
   # systemctl start nfs-server
   # systemctl enable nfs-server
   ```

4. If the server will serve NFSv4 clients, edit `/etc/idmapd.conf` and edit the definition for the Domain parameter to specify the DNS domain name of the server, for example:

   ```
   Domain = mydom.com
   ```

   This setting prevents the owner and group being unexpectedly listed as the anonymous user or group `(nobody or nogroup)` on NFS clients when the `all_squash` mount option has not been specified.

5. If you need to allow access through the firewall for NFSv4 clients only, use the following commands:

   ```
   # firewall-cmd --zone=zone --add-service=nfs
   # firewall-cmd --permanent --zone=zone --add-service=nfs
   ```

   This configuration assumes that `rpc.nfsd` listens for client requests on TCP port 2049.

6. If you need to allow access through the firewall for NFSv3 clients as well as NFSv4 clients:

   a. Edit `/etc/sysconfig/nfs` and create port settings for handling network mount requests and status monitoring:

   ```
   # Port rpc.mountd should listen on.
   MOUNTD_PORT=892
   # Port rpc.statd should listen on.
   STATD_PORT=662
   ```
Configuring an NFS Server

The port values shown in this example are the default settings that are commented-out in the file.

b. Edit `/etc/sysctl.conf` and configure settings for the TCP and UDP ports on which the network lock manager should listen:

```bash
fs.nfs.nlm_tcpport = 32803
fs.nfs.nlm_udpport = 32769
```

c. To verify that none of the ports that you have specified in `/etc/sysconfig/nfs` or `/etc/sysctl.conf` is in use, enter the following commands:

```bash
# lsof -i tcp:32803
# lsof -i udp:32769
# lsof -i :892
# lsof -i :662
```

If any port is in use, use the `lsof -i` command to determine an unused port and amend the setting in `/etc/sysconfig/nfs` or `/etc/sysctl.conf` as appropriate.

d. Shut down and reboot the server.

```
# systemctl reboot
```

NFS fails to start if one of the specified ports is in use, and reports an error in `/var/log/messages`. Edit `/etc/sysconfig/nfs` or `/etc/sysctl.conf` as appropriate to use a different port number for the service that could not start, and attempt to restart the `nfslock` and `nfs-server` services. You can use the `rpcinfo -p` command to confirm on which ports RPC services are listening.

e. Restart the firewall service and configure the firewall to allow NFSv3 connections:

```
# systemctl restart firewalld
# firewall-cmd --zone=zone --add-port=2049/tcp --add-port=2049/udp
# firewall-cmd --zone=zone --add-port=111/tcp --add-port=111/udp
# firewall-cmd --zone=zone --add-port=32803/tcp --add-port=32769/udp
# firewall-cmd --zone=zone --add-port=892/tcp --add-port=892/udp
# firewall-cmd --zone=zone --add-port=662/tcp --add-port=662/udp
```

The port values shown in this example assume that the default port settings in `/etc/sysconfig/nfs` and `/etc/sysctl.conf` are available for use by RPC services. This configuration also assumes that `rpc.nfsd` and `rpcbind` listen on ports 2049 and 111 respectively.

7. Use the `showmount -e` command to display a list of the exported file systems, for example:

```
# showmount -e
Export list for host01.mydom.com
/var/folder 192.0.2.102
/usr/local/apps *
/var/projects/proj1 192.168.1.0/24 mgmtpc
```

`showmount -a` lists the current clients and the file systems that they have mounted, for example:

```
# showmount -a
mgmtpc.mydom.com:/var/projects/proj1
```
22.2.2 Mounting an NFS File System

To mount an NFS file system on a client:

1. Install the `nfs-utils` package:
   
   ```
   # yum install nfs-utils
   ```

2. Use `showmount -e` to discover what file systems an NFS server exports, for example:
   
   ```
   # showmount -e host01.mydom.com
   Export list for host01.mydom.com
   /var/folder 192.0.2.102
   /usr/local/apps *
   /var/projects/proj1 192.168.1.0/24 mgmtpc
   ```

3. Use the `mount` command to mount an exported NFS file system on an available mount point:
   
   ```
   # mount -t nfs -o ro,nosuid host01.mydoc.com:/usr/local/apps /apps
   ```
   
   This example mounts `/usr/local/apps` exported by `host01.mydoc.com` with read-only permissions on `/apps`. The `nosuid` option prevents remote users from gaining higher privileges by running a `setuid` program.

4. To configure the system to mount an NFS file system at boot time, add an entry for the file system to `/etc/fstab`, for example:
   
   ```
   host01.mydoc.com:/usr/local/apps      /apps      nfs      ro,nosuid  0 0
   ```
   
   For more information, see the `mount(8)`, `nfs(5)`, and `showmount(8)` manual pages.

22.3 About Samba

Samba is an open-source implementation of the Server Message Block (SMB) protocol that allows Oracle Linux to interoperate with Windows systems as both a server and a client. Samba can share Oracle Linux files and printers with Windows systems, and it enables Oracle Linux users to access files on Windows systems. Samba uses the NetBIOS over TCP/IP protocol that allows computer applications that depend on the NetBIOS API to work on TCP/IP networks.

22.3.1 Configuring a Samba Server

To configure a Samba server:

1. Install the `samba` and `samba-winbind` packages:
# yum install samba samba-winbind

2. Edit `/etc/samba/smb.conf` and configure the sections to support the required services, for example:

```ini
[global]
security = ADS
realm = MYDOM.REALM
password server = krbsvr.mydom.com
load printers = yes
printing = cups
printcap name = cups

[printers]
comment = All Printers
path = /var/spool/samba
browseable = no
guest ok = yes
writable = no
printable = yes
printer admin = root, @ntadmins, @smbprintadm

[homes]
comment = User home directories
valid users = @smbusers
browseable = no
writable = yes
guest ok = no

[apps]
comment = Shared /usr/local/apps directory
path = /usr/local/apps
browseable = yes
writable = no
guest ok = yes
```

The `[global]` section contains settings for the Samba server. In this example, the server is assumed to be a member of an Active Directory (AD) domain that is running in native mode. Samba relies on tickets issued by the Kerberos server to authenticate clients who want to access local services.

For more information, see Section 22.3.2, “About Samba Configuration for Windows Workgroups and Domains”.

The `[printers]` section specifies support for print services. The `path` parameter specifies the location of a spooling directory that receives print jobs from Windows clients before submitting them to the local print spooler. Samba advertises all locally configured printers on the server.

The `[homes]` section provide a personal share for each user in the `smbusers` group. The settings for `browseable` and `writable` prevent other users from browsing home directories, while allowing full access to valid users.

The `[apps]` section specifies a share named `apps`, which grants Windows users browsing and read-only permission to the `/usr/local/apps` directory.

3. Configure the system firewall to allow incoming TCP connections to ports 139 and 445, and incoming UDP datagrams on ports 137 and 138:

```bash
# firewall-cmd --zone=zone \
   --add-port=139/tcp --add-port=445/tcp --add-port=137-138/udp
# firewall-cmd --permanent --zone=zone \
   --add-port=139/tcp --add-port=445/tcp --add-port=137-138/udp
```

Add similar rules for other networks from which Samba clients can connect.
The `nmdb` daemon services NetBIOS Name Service requests on UDP port 137 and NetBIOS Datagram Service requests on UDP port 138.

The `smbd` daemon services NetBIOS Session Service requests on TCP port 139 and Microsoft Directory Service requests on TCP port 445.

4. Start the `smb` service, and configure the service to start following a system reboot:

```
# systemctl start smb
# systemctl enable smb
```

If you change the `/etc/samba/smb.conf` file and any files that it references, the `smb` service will reload its configuration automatically after a delay of up to one minute. You can force `smb` to reload its configuration by sending a `SIGHUP` signal to the service daemon:

```
# killall -SIGHUP smbd
```

Making `smb` reload its configuration has no effect on established connections. You must restart the `smb` service or the existing users of the service must disconnect and then reconnect.

To restart the `smb` service, use the following command:

```
# systemctl restart smb
```

For more information, see the `smb.conf(5)` and `smbd(8)` manual pages and [http://www.samba.org/samba/docs/](http://www.samba.org/samba/docs/).

### 22.3.2 About Samba Configuration for Windows Workgroups and Domains

Windows systems on an enterprise network usually belong either to a workgroup or to a domain.

Workgroups are usually only configured on networks that connect a small number of computers. A workgroup environment is a peer-to-peer network where systems do not rely on each other for services and there is no centralized management. User accounts, access control, and system resources are configured independently on each system. Such systems can share resources only if configured to do so.

A Samba server can act as a standalone server within a workgroup.

More typically, corporate networks configure domains to allow large numbers of networked systems to be administered centrally. A domain is a group of trusted computers that share security and access control. Systems known as domain controllers provide centralized management and security. Windows domains are usually configured to use Active Directory (AD), which uses the Lightweight Directory Access Protocol (LDAP) to implement versions of Kerberos and DNS providing authentication, access control to domain resources, and name service. Some Windows domains use Windows NT4 security, which does not use Kerberos to perform authentication.

A Samba server can be a member of an AD or NT4 security domain, but it cannot operate as a domain controller. As domain member Samba server must authenticate itself with a domain controller and so is controlled by the security rules of the domain. The domain controller authenticates clients, and the Samba server controls access to printers and network shares.

#### 22.3.2.1 Configuring Samba as a Standalone Server

A standalone Samba server can be a member of a workgroup. The following `[global]` section from `/etc/samba/smb.conf` shows an example of how to configure a standalone server using share-level security:
The client provides only a password and not a user name to the server. Typically, each share is associated with a *valid users* parameter and the server validates the password against the hashed passwords stored in `/etc/passwd`, `/etc/shadow`, NIS, or LDAP for the listed users. Using share-level security is discouraged in favor of user-level security, for example:

```
[global]
security = share
workgroup = workgroup_name
netbios name = netbios_name
```

In the user security model, a client must supply a valid user name and password. This model supports encrypted passwords. If the server successfully validates the client's user name and password, the client can mount multiple shares without being required to specify a password. Use the `smbpasswd` command to create an entry for a user in the Samba password file, for example:

```
smbpasswd -a guest
```

```
New SMB password: password
Retype new SMB password: password
Added user guest.
```

The user must already exist as a user on the system. If a user is permitted to log into the server, he or she can use the `smbpasswd` command to change his or her password.

If a Windows user has a different user name from his or her user name on the Samba server, create a mapping between the names in the `/etc/samba/smbusers` file, for example:

```
root = admin administrator root
nobody = guest nobody pcguest smbguest
eddie = ejones
fiona = fchau
```

The first entry on each line is the user name on the Samba server. The entries after the equals sign (=) are the equivalent Windows user names.

```
Note
```

Only the user security model uses Samba passwords.

The server security model, where the Samba server relies on another server to authenticate user names and passwords, is deprecated as it has numerous security and interoperability issues.

### 22.3.2.2 Configuring Samba as a Member of an ADS Domain

In the Activity Directory Server (ADS) security model, Samba acts as a domain member server in an ADS realm, and clients use Kerberos tickets for Active Directory authentication. You must configure Kerberos and join the server to the domain, which creates a machine account for your server on the domain controller.

To add a Samba server to an Active Directory domain:

1. Edit `/etc/samba/smb.conf` and configure the `[global]` section to use ADS:

```
[global]
```

```
security = user
workgroup = workgroup_name
netbios name = netbios_name
```
About Samba Configuration for Windows Workgroups and Domains

```
security = ADS
realm = KERBEROS.REALM
```

It might also be necessary to specify the password server explicitly if different servers support AD services and Kerberos authentication:

```
password server = kerberos_server.your_domain
```

2. Install the `krb5-server` package:

```
# yum install krb5-server
```

3. Create a Kerberos ticket for the `Administrator` account in the Kerberos domain, for example:

```
# kinit Administrator@MYDOMAIN.COM
```

This command creates the Kerberos ticket that is required to join the server to the AD domain.

4. Join the server to the AD domain:

```
# net ads join -S winads.mydom.com -U Administrator% password
```

In this example, the AD server is `winads.mydom.com` and `password` is the password for the Administrator account.

The command creates a machine account in Active Directory for the Samba server and allows it to join the domain.

5. Restart the `smb` service:

```
# systemctl restart smb
```

### 22.3.2.3 Configuring Samba as a Member of a Windows NT4 Security Domain

**Note**

If the Samba server acts as a Primary or Backup Domain Controller, do not use the domain security model. Configure the system as a standalone server that uses the user security model instead. See Section 22.3.2.1, “Configuring Samba as a Standalone Server”.

The domain security model is used with domains that implement Windows NT4 security. The Samba server must have a machine account in the domain (a domain security trust account). Samba authenticates user names and passwords with either a primary or a secondary domain controller.

To add a Samba server to an NT4 domain:

1. On the primary domain controller, use the Server Manager to add a machine account for the Samba server.

2. Edit `/etc/samba/smb.conf` and configure the `[global]` section to use ADS:

```
[global]
security = domain
workgroup = DOMAIN
netbios name = SERVERNAME
```

3. Join the server to the domain:

```
# net rpc join -S winpdc.mydom.com -U Administrator% password
```
In this example, the primary domain controller is `winpdc.mydom.com` and `password` is the password for the Administrator account.

4. Restart the `smb` service:

```
# systemctl restart smb
```

5. Create an account for each user who is allowed access to shares or printers:

```
# useradd -s /sbin/nologin username
# passwd username
```

In this example, the account's login shell is set to `/sbin/nologin` to prevent direct logins.

### 22.3.3 Accessing Samba Shares from a Windows Client

To access a share on a Samba server from Windows, open Computer or Windows Explorer, and enter the host name of the Samba server and the share name using the following format:

```
\server_name\share_name
```

If you enter `\server_name`, Windows displays the directories and printers that the server is sharing. You can also use the same syntax to map a network drive to a share name.

### 22.3.4 Accessing Samba Shares from an Oracle Linux Client

**Note**

To be able to use the commands described in this section, use `yum` to install the `samba-client` and `cifs-utils` packages.

You can use the `findsmb` command to query a subnet for Samba servers. The command displays the IP address, NetBIOS name, workgroup, operating system and version for each server that it finds.

Alternatively, you can use the `smbtree` command, which is a text-based SMB network browser that displays the hierarchy of known domains, servers in those domains, and shares on those servers.

The GNOME and KDE desktops provide browser-based file managers that you can use to view Windows shares on the network. Enter `smb:` in the location bar of a file manager to browse network shares.

To connect to a Windows share from the command line, use the `smbclient` command:

```
$ smbclient //server_name/share_name [-U username]
```

After logging in, enter `help` at the `smb:` prompt to display a list of available commands.

To mount a Samba share, use a command such as the following:

```
# mount -t cifs //server_name/share_name mountpoint -o credentials=credfile
```

where the credentials file contains settings for `username`, `password`, and `domain`, for example:

```
username=eddie
password=clydenw
domain=MYDOMWKG
```

The argument to `domain` can be the name of a domain or a workgroup.
Accessing Samba Shares from an Oracle Linux Client

Caution

As the credentials file contains a plain-text password, use `chmod` to make it readable only by you, for example:

```bash
# chmod 400 credfile
```

If the Samba server is a domain member server in an AD domain and your current login session was authenticated by the Kerberos server in the domain, you can use your existing session credentials by specifying the `sec=krb5` option instead of a credentials file:

```bash
# mount -t cifs //server_name/share_name mountpoint -o sec=krb5
```

For more information, see the `findsmb(1)`, `mount.cifs(8)`, `smbclient(1)`, and `smbtree(1)` manual pages.

23.5 For More Information About OCFS2 ...................................................................................... 282

This chapter describes how to configure and use the Oracle Cluster File System Version 2 (OCFS2) file system.

23.1 About OCFS2

Oracle Cluster File System version 2 (OCFS2) is a general-purpose, high-performance, high-availability, shared-disk file system intended for use in clusters. It is also possible to mount an OCFS2 volume on a standalone, non-clustered system.

Although it might seem that there is no benefit in mounting ocfs2 locally as compared to alternative file systems such as ext4 or btrfs, you can use the refflink command with OCFS2 to create copy-on-write clones of individual files in a similar way to using the cp --refflink command with the btrfs file system. Typically, such clones allow you to save disk space when storing multiple copies of very similar files, such as VM images or Linux Containers. In addition, mounting a local OCFS2 file system allows you to subsequently migrate it to a cluster file system without requiring any conversion. Note that when using the refflink command, the resulting filesystem behaves like a clone of the original filesystem. This means that their UUIDs are identical. When using refflink to create a clone, you must change the UUID using the tunefs.ocfs2 command. See Section 23.2.10, “Querying and Changing Volume Parameters” for more information.

Almost all applications can use OCFS2 as it provides local file-system semantics. Applications that are cluster-aware can use cache-coherent parallel I/O from multiple cluster nodes to balance activity across the cluster, or they can use of the available file-system functionality to fail over and run on another node in the event that a node fails. The following examples typify some use cases for OCFS2:
• Oracle VM to host shared access to virtual machine images.
• Oracle VM and VirtualBox to allow Linux guest machines to share a file system.
• Oracle Real Application Cluster (RAC) in database clusters.
• Oracle E-Business Suite in middleware clusters.

OCFS2 has a large number of features that make it suitable for deployment in an enterprise-level computing environment:

• Support for ordered and write-back data journaling that provides file system consistency in the event of power failure or system crash.

• Block sizes ranging from 512 bytes to 4 KB, and file-system cluster sizes ranging from 4 KB to 1 MB (both in increments of powers of 2). The maximum supported volume size is 16 TB, which corresponds to a cluster size of 4 KB. A volume size as large as 4 PB is theoretically possible for a cluster size of 1 MB, although this limit has not been tested.

• Extent-based allocations for efficient storage of very large files.

• Optimized allocation support for sparse files, inline-data, unwritten extents, hole punching, reflinks, and allocation reservation for high performance and efficient storage.

• Indexing of directories to allow efficient access to a directory even if it contains millions of objects.

• Metadata checksums for the detection of corrupted inodes and directories.

• Extended attributes to allow an unlimited number of name:value pairs to be attached to file system objects such as regular files, directories, and symbolic links.

• Advanced security support for POSIX ACLs and SELinux in addition to the traditional file-access permission model.

• Support for user and group quotas.

• Support for heterogeneous clusters of nodes with a mixture of 32-bit and 64-bit, little-endian (x86, x86_64, ia64) and big-endian (ppc64) architectures.

• An easy-to-configure, in-kernel cluster-stack (O2CB) with a distributed lock manager (DLM), which manages concurrent access from the cluster nodes.

• Support for buffered, direct, asynchronous, splice and memory-mapped I/O.

• A tool set that uses similar parameters to the ext3 file system.

23.2 Installing and Configuring OCFS2

The procedures in the following sections describe how to set up a cluster to use OCFS2.

• Section 23.2.1, “Preparing a Cluster for OCFS2”
• Section 23.2.2, “Configuring the Firewall”
• Section 23.2.3, “Configuring the Cluster Software”
• Section 23.2.4, “Creating the Configuration File for the Cluster Stack”
• Section 23.2.5, “Configuring the Cluster Stack”
• Section 23.2.6, “Configuring the Kernel for Cluster Operation”
23.2.1 Preparing a Cluster for OCFS2

For best performance, each node in the cluster should have at least two network interfaces. One interface is connected to a public network to allow general access to the systems. The other interface is used for private communication between the nodes; the cluster heartbeat that determines how the cluster nodes coordinate their access to shared resources and how they monitor each other’s state. These interface must be connected via a network switch. Ensure that all network interfaces are configured and working before continuing to configure the cluster.

You have a choice of two cluster heartbeat configurations:

- Local heartbeat thread for each shared device. In this mode, a node starts a heartbeat thread when it mounts an OCFS2 volume and stops the thread when it unmounts the volume. This is the default heartbeat mode. There is a large CPU overhead on nodes that mount a large number of OCFS2 volumes as each mount requires a separate heartbeat thread. A large number of mounts also increases the risk of a node fencing itself out of the cluster due to a heartbeat I/O timeout on a single mount.

- Global heartbeat on specific shared devices. You can configure any OCFS2 volume as a global heartbeat device provided that it occupies a whole disk device and not a partition. In this mode, the heartbeat to the device starts when the cluster comes online and stops when the cluster goes offline. This mode is recommended for clusters that mount a large number of OCFS2 volumes. A node fences itself out of the cluster if a heartbeat I/O timeout occurs on more than half of the global heartbeat devices. To provide redundancy against failure of one of the devices, you should therefore configure at least three global heartbeat devices.

Figure 23.1 shows a cluster of four nodes connected via a network switch to a LAN and a network storage server. The nodes and the storage server are also connected via a switch to a private network that they use for the local cluster heartbeat.

Figure 23.1 Cluster Configuration Using a Private Network

It is possible to configure and use OCFS2 without using a private network but such a configuration increases the probability of a node fencing itself out of the cluster due to an I/O heartbeat timeout.
23.2.2 Configuring the Firewall

Configure or disable the firewall on each node to allow access on the interface that the cluster will use for private cluster communication. By default, the cluster uses both TCP and UDP over port 7777.

To allow incoming TCP connections and UDP datagrams on port 7777, use the following commands:

```
# firewall-cmd --zone=zone --add-port=7777/tcp --add-port=7777/udp
# firewall-cmd --permanent --zone=zone --add-port=7777/tcp --add-port=7777/udp
```

23.2.3 Configuring the Cluster Software

Ideally, each node should be running the same version of the OCFS2 software and a compatible version of the Oracle Linux Unbreakable Enterprise Kernel (UEK). It is possible for a cluster to run with mixed versions of the OCFS2 and UEK software, for example, while you are performing a rolling update of a cluster. The cluster node that is running the lowest version of the software determines the set of usable features.

Use `yum` to install or upgrade the following packages to the same version on each node:

- `kernel-uek`
- `ocfs2-tools`

**Note**

If you want to use the global heartbeat feature, you must install `ocfs2-tools-1.8.0-11` or later.

23.2.4 Creating the Configuration File for the Cluster Stack

You can create the configuration file by using the `o2cb` command or a text editor.

To configure the cluster stack by using the `o2cb` command:

1. Use the following command to create a cluster definition.

   ```
   # o2cb add-cluster cluster_name
   ```

   For example, to define a cluster named `mycluster` with four nodes:

   ```
   # o2cb add-cluster mycluster
   ```

   The command creates the configuration file `/etc/ocfs2/cluster.conf` if it does not already exist.

2. For each node, use the following command to define the node.

   ```
   # o2cb add-node cluster_name node_name --ip ip_address
   ```

   The name of the node must be the same as the value of system's `HOSTNAME` that is configured in `/etc/sysconfig/network`. The IP address is the one that the node will use for private communication in the cluster.

   For example, to define a node named `node0` with the IP address `10.1.0.100` in the cluster `mycluster`:

   ```
   # o2cb add-node mycluster node0 --ip 10.1.0.100
   ```

   Note that OCFS2 only supports IPv4 addresses.

3. If you want the cluster to use global heartbeat devices, use the following commands.
Creating the Configuration File for the Cluster Stack

```bash
# o2cb add-heartbeat cluster_name device1
# o2cb add-heartbeat cluster_name device2
# o2cb heartbeat-mode cluster_name global
```

**Note**

You must configure global heartbeat to use whole disk devices. You cannot configure a global heartbeat device on a disk partition.

For example, to use `/dev/sdd`, `/dev/sdg`, and `/dev/sdj` as global heartbeat devices:

```bash
# o2cb add-heartbeat mycluster /dev/sdd
# o2cb add-heartbeat mycluster /dev/sdg
# o2cb add-heartbeat mycluster /dev/sdj
# o2cb heartbeat-mode mycluster global
```

4. Copy the cluster configuration file `/etc/ocfs2/cluster.conf` to each node in the cluster.

**Note**

Any changes that you make to the cluster configuration file do not take effect until you restart the cluster stack.

The following sample configuration file `/etc/ocfs2/cluster.conf` defines a 4-node cluster named `mycluster` with a local heartbeat.

```ini
node:
    name = node0
    cluster = mycluster
    number = 0
    ip_address = 10.1.0.100
    ip_port = 7777

node:
    name = node1
    cluster = mycluster
    number = 1
    ip_address = 10.1.0.101
    ip_port = 7777

node:
    name = node2
    cluster = mycluster
    number = 2
    ip_address = 10.1.0.102
    ip_port = 7777

node:
    name = node3
    cluster = mycluster
    number = 3
    ip_address = 10.1.0.103
    ip_port = 7777

cluster:
    name = mycluster
    heartbeat_mode = local
    node_count = 4
```

If you configure your cluster to use a global heartbeat, the file also include entries for the global heartbeat devices.
The cluster heartbeat mode is now shown as `global`, and the heartbeat regions are represented by the UUIDs of their block devices.

If you edit the configuration file manually, ensure that you use the following layout:

- The `cluster:`, `heartbeat:` and `node:` headings must start in the first column.
- Each parameter entry must be indented by one tab space.
- A blank line must separate each section that defines the cluster, a heartbeat device, or a node.

### 23.2.5 Configuring the Cluster Stack

To configure the cluster stack:

1. Run the following command on each node of the cluster:

   ```bash
   # /sbin/o2cb.init configure
   ```

   The following table describes the values for which you are prompted.
### Configuring the Cluster Stack

<table>
<thead>
<tr>
<th>Prompt</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Load O2CB driver on boot (y/n)</td>
<td>Whether the cluster stack driver should be loaded at boot time. The default response is n.</td>
</tr>
<tr>
<td>Cluster stack backing O2CB</td>
<td>The name of the cluster stack service. The default and usual response is o2cb.</td>
</tr>
<tr>
<td>Cluster to start at boot (Enter &quot;none&quot; to clear)</td>
<td>Enter the name of your cluster that you defined in the cluster configuration file, /etc/ocfs2/cluster.conf.</td>
</tr>
<tr>
<td>Specify heartbeat dead threshold (&gt;=7)</td>
<td>The number of 2-second heartbeats that must elapse without response before a node is considered dead. To calculate the value to enter, divide the required threshold time period by 2 and add 1. For example, to set the threshold time period to 120 seconds, enter a value of 61. The default value is 31, which corresponds to a threshold time period of 60 seconds.</td>
</tr>
<tr>
<td>Specify network idle timeout in ms (&gt;=5000)</td>
<td>The time in milliseconds that must elapse before a network connection is considered dead. The default value is 30,000 milliseconds.</td>
</tr>
<tr>
<td>Specify network keepalive delay in ms (&gt;=1000)</td>
<td>The maximum delay in milliseconds between sending keepalive packets to another node. The default and recommended value is 2,000 milliseconds.</td>
</tr>
<tr>
<td>Specify network reconnect delay in ms (&gt;=2000)</td>
<td>The minimum delay in milliseconds between reconnection attempts if a network connection goes down. The default and recommended value is 2,000 milliseconds.</td>
</tr>
</tbody>
</table>

To verify the settings for the cluster stack, enter the `/sbin/o2cb.init status` command:

```
# /sbin/o2cb.init status
Driver for "configfs": Loaded
Filesystem "configfs": Mounted
Stack glue driver: Loaded
Stack plugin "o2cb": Loaded
Driver for "ocfs2_dlmfs": Loaded
Filesystem "ocfs2_dlmfs": Mounted
Checking O2CB cluster "mycluster": Online
    Heartbeat dead threshold: 61
    Network idle timeout: 30000
    Network keepalive delay: 2000
    Network reconnect delay: 2000
    Heartbeat mode: Local
Checking O2CB heartbeat: Active
```
In this example, the cluster is online and is using local heartbeat mode. If no volumes have been configured, the O2CB heartbeat is shown as *Not active* rather than *Active*.

The next example shows the command output for an online cluster that is using three global heartbeat devices:

```
# /sbin/o2cb.init status
Driver for "configfs": Loaded
Filesystem "configfs": Mounted
Stack glue driver: Loaded
Stack plugin "o2cb": Loaded
Driver for "ocfs2_dlmfs": Loaded
Filesystem "ocfs2_dlmfs": Mounted
Checking O2CB cluster "mycluster": Online
  Heartbeat dead threshold: 61
  Network idle timeout: 30000
  Network keepalive delay: 2000
  Network reconnect delay: 2000
  Heartbeat mode: Global
Checking O2CB heartbeat: Active
7DA5015346C245E6A41AA85E2E7EA3CF /dev/sdd
4F9FBB0D9B6341729F21A8891B9A05BD /dev/sgd
B423C7EEE9FC426790FC411972C91CC3 /dev/sgd
```

2. Configure the `o2cb` and `ocfs2` services so that they start at boot time after networking is enabled:

```
# systemctl enable o2cb
# systemctl enable ocfs2
```

These settings allow the node to mount OCFS2 volumes automatically when the system starts.

### 23.2.6 Configuring the Kernel for Cluster Operation

For the correct operation of the cluster, you must configure the kernel settings shown in the following table:

<table>
<thead>
<tr>
<th>Kernel Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>panic</code></td>
<td>Specifies the number of seconds after a panic before a system will automatically reset itself.</td>
</tr>
<tr>
<td></td>
<td>If the value is 0, the system hangs, which allows you to collect detailed information about the panic for troubleshooting. This is the default value.</td>
</tr>
<tr>
<td></td>
<td>To enable automatic reset, set a non-zero value. If you require a memory image (vmcore), allow enough time for Kdump to create this image. The suggested value is 30 seconds, although large systems will require a longer time.</td>
</tr>
<tr>
<td><code>panic_on_oops</code></td>
<td>Specifies that a system must panic if a kernel oops occurs. If a kernel thread required for cluster operation crashes, the system must reset itself. Otherwise, another node might not be able to tell whether a node is slow to respond or unable to respond, causing cluster operations to hang.</td>
</tr>
</tbody>
</table>

On each node, enter the following commands to set the recommended values for `panic` and `panic_on_oops`:

```
# sysctl kernel.panic = 30
# sysctl kernel.panic_on_oops = 1
```

To make the change persist across reboots, add the following entries to the `/etc/sysctl.conf` file:
23.2.7 Starting and Stopping the Cluster Stack

The following table shows the commands that you can use to perform various operations on the cluster stack.

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>/sbin/o2cb.init status</td>
<td>Check the status of the cluster stack.</td>
</tr>
<tr>
<td>/sbin/o2cb.init online</td>
<td>Start the cluster stack.</td>
</tr>
<tr>
<td>/sbin/o2cb.init offline</td>
<td>Stop the cluster stack.</td>
</tr>
<tr>
<td>/sbin/o2cb.init unload</td>
<td>Unload the cluster stack.</td>
</tr>
</tbody>
</table>

23.2.8 Creating OCFS2 volumes

You can use the `mkfs.ocfs2` command to create an OCFS2 volume on a device. If you want to label the volume and mount it by specifying the label, the device must correspond to a partition. You cannot mount an unpartitioned disk device by specifying a label. The following table shows the most useful options that you can use when creating an OCFS2 volume.

<table>
<thead>
<tr>
<th>Command Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-b block-size</td>
<td>Specifies the unit size for I/O transactions to and from the file system, and the size of inode and extent blocks. The supported block sizes are 512 (512 bytes), 1K, 2K, and 4K. The default and recommended block size is 4K (4 kilobytes).</td>
</tr>
<tr>
<td>--block-size block-size</td>
<td></td>
</tr>
<tr>
<td>-C cluster-size</td>
<td>Specifies the unit size for space used to allocate file data. The supported cluster sizes are 4K, 8K, 16K, 32K, 64K, 128K, 256K, 512K, and 1M (1 megabyte). The default cluster size is 4K (4 kilobytes).</td>
</tr>
<tr>
<td>--cluster-size cluster-size</td>
<td></td>
</tr>
<tr>
<td>--fs-feature-level=feature-level</td>
<td>Allows you select a set of file-system features:</td>
</tr>
<tr>
<td></td>
<td>default</td>
</tr>
<tr>
<td></td>
<td>max-compat</td>
</tr>
<tr>
<td></td>
<td>max-features</td>
</tr>
<tr>
<td>--fs_features=feature</td>
<td>Allows you to enable or disable individual features such as support for sparse files, unwritten extents, and backup superblocks. For more information, see the <code>mkfs.ocfs2(8)</code> manual page.</td>
</tr>
<tr>
<td>-J size=journal-size</td>
<td>Specifies the size of the write-ahead journal. If not specified, the size is determined from the file system usage type that you specify to the <code>-T</code> option, and, otherwise, from the volume size. The default size of the</td>
</tr>
</tbody>
</table>
Creating OCFS2 volumes

<table>
<thead>
<tr>
<th>Command Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>journal is 64M (64 MB) for datafiles, 256M (256 MB) for mail, and 128M (128 MB) for vmstore.</td>
</tr>
<tr>
<td>-L volume-label</td>
<td>Specifies a descriptive name for the volume that allows you to identify it easily on different cluster nodes.</td>
</tr>
<tr>
<td>--label volume-label</td>
<td></td>
</tr>
<tr>
<td>-N number</td>
<td>Determines the maximum number of nodes that can concurrently access a volume, which is limited by the number of node slots for system files such as the file-system journal. For best performance, set the number of node slots to at least twice the number of nodes. If you subsequently increase the number of node slots, performance can suffer because the journal will no longer be contiguously laid out on the outer edge of the disk platter.</td>
</tr>
<tr>
<td>--node-slots number</td>
<td></td>
</tr>
<tr>
<td>-T file-system-usage-type</td>
<td>Specifies the type of usage for the file system:</td>
</tr>
<tr>
<td>datafiles</td>
<td>Database files are typically few in number, fully allocated, and relatively large. Such files require few metadata changes, and do not benefit from having a large journal.</td>
</tr>
<tr>
<td>mail</td>
<td>Mail server files are typically many in number, and relatively small. Such files require many metadata changes, and benefit from having a large journal.</td>
</tr>
<tr>
<td>vmstore</td>
<td>Virtual machine image files are typically few in number, sparsely allocated, and relatively large. Such files require a moderate number of metadata changes and a medium sized journal.</td>
</tr>
</tbody>
</table>

For example, create an OCFS2 volume on /dev/sdc1 labeled as myvol using all the default settings for generic usage on file systems that are no larger than a few gigabytes. The default values are a 4 KB block and cluster size, eight node slots, a 256 MB journal, and support for default file-system features.

```
# mkfs.ocfs2 -L "myvol" /dev/sdc1
```

Create an OCFS2 volume on /dev/sdd2 labeled as dbvol for use with database files. In this case, the cluster size is set to 128 KB and the journal size to 32 MB.

```
# mkfs.ocfs2 -L "dbvol" -T datafiles /dev/sdd2
```

Create an OCFS2 volume on /dev/sde1 with a 16 KB cluster size, a 128 MB journal, 16 node slots, and support enabled for all features except refcount trees.

```
# mkfs.ocfs2 -C 16K -J size=128M -N 16 --fs-feature-level=max-features \
   --fs-features=norefcount /dev/sde1
```

**Note**

Do not create an OCFS2 volume on an LVM logical volume. LVM is not cluster-aware.
You cannot change the block and cluster size of an OCFS2 volume after it has been created. You can use the `tunefs.ocfs2` command to modify other settings for the file system with certain restrictions. For more information, see the `tunefs.ocfs2(8)` manual page.

If you intend the volume to store database files, do not specify a cluster size that is smaller than the block size of the database.

The default cluster size of 4 KB is not suitable if the file system is larger than a few gigabytes. The following table suggests minimum cluster size settings for different file system size ranges:

<table>
<thead>
<tr>
<th>File System Size</th>
<th>Suggested Minimum Cluster Size</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 GB - 10 GB</td>
<td>8K</td>
</tr>
<tr>
<td>10 GB - 100 GB</td>
<td>16K</td>
</tr>
<tr>
<td>100 GB - 1 TB</td>
<td>32K</td>
</tr>
<tr>
<td>1 TB - 10 TB</td>
<td>64K</td>
</tr>
<tr>
<td>10 TB - 16 TB</td>
<td>128K</td>
</tr>
</tbody>
</table>

### 23.2.9 Mounting OCFS2 Volumes

As shown in the following example, specify the `_netdev` option in `/etc/fstab` if you want the system to mount an OCFS2 volume at boot time after networking is started, and to unmount the file system before networking is stopped.

```bash
myocfs2vol  /dbvol1  ocfs2     _netdev,defaults  0 0
```

**Note**

The file system will not mount unless you have enabled the `o2cb` and `ocfs2` services to start after networking is started. See Section 23.2.5, “Configuring the Cluster Stack”.

### 23.2.10 Querying and Changing Volume Parameters

You can use the `tunefs.ocfs2` command to query or change volume parameters. For example, to find out the label, UUID and the number of node slots for a volume:

```bash
# tunefs.ocfs2 -Q "Label = %V
UUID = %U
NumSlots =%N
" /dev/sdb
Label = myvol
UUID = CBB8D5E0C169497C8B52A0FD555C7A3E
NumSlots = 4
```

Generate a new UUID for a volume:

```bash
# tunefs.ocfs2 -U /dev/sda
# tunefs.ocfs2 -Q "Label = %V
UUID = %U
NumSlots =%N
" /dev/sdb
Label = myvol
UUID = 48E56A2BBAB34A9EB1BE832B3C36AB5C
NumSlots = 4
```

### 23.3 Troubleshooting OCFS2

The following sections describes some techniques that you can use for investigating any problems that you encounter with OCFS2.
23.3.1 Recommended Tools for Debugging

To you want to capture an oops trace, it is recommended that you set up netconsole on the nodes.

If you want to capture the DLM's network traffic between the nodes, you can use tcpdump. For example, to capture TCP traffic on port 7777 for the private network interface em2, you could use a command such as the following:

```
# tcpdump -i em2 -C 10 -W 15 -s 10000 -Sw /tmp/`hostname -s`_tcpdump.log \
   -ttt 'port 7777' &
```

You can use the debugfs.ocfs2 command, which is similar in behavior to the debugfs command for the ext3 file system, and allows you to trace events in the OCFS2 driver, determine lock statuses, walk directory structures, examine inodes, and so on.

For more information, see the debugfs.ocfs2(8) manual page.

The o2image command saves an OCFS2 file system's metadata (including information about inodes, file names, and directory names) to an image file on another file system. As the image file contains only metadata, it is much smaller than the original file system. You can use debugfs.ocfs2 to open the image file, and analyze the file system layout to determine the cause of a file system corruption or performance problem.

For example, the following command creates the image /tmp/sda2.img from the OCFS2 file system on the device /dev/sda2:

```
# o2image /dev/sda2 /tmp/sda2.img
```

For more information, see the o2image(8) manual page.

23.3.2 Mounting the debugfs File System

OCFS2 uses the debugfs file system to allow access from user space to information about its in-kernel state. You must mount the debugfs file system to be able to use the debugfs.ocfs2 command.

To mount the debugfs file system, add the following line to /etc/fstab:

```
ddebugfs /sys/kernel/debug debugfs defaults 0 0
```

and run the mount -a command.

23.3.3 Configuring OCFS2 Tracing

The following table shows some of the commands that are useful for tracing problems in OCFS2.
Debugging File System Locks

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>debugfs.ocfs2 -l</td>
<td>List all trace bits and their statuses.</td>
</tr>
<tr>
<td>debugfs.ocfs2 -l SUPER allow</td>
<td>Enable tracing for the superblock.</td>
</tr>
<tr>
<td>debugfs.ocfs2 -l SUPER off</td>
<td>Disable tracing for the superblock.</td>
</tr>
<tr>
<td>debugfs.ocfs2 -l SUPER deny</td>
<td>Disallow tracing for the superblock, even if implicitly enabled by another tracing mode setting.</td>
</tr>
<tr>
<td>debugfs.ocfs2 -l HEARTBEAT ENTRY EXIT allow</td>
<td>Enable heartbeat tracing. ENTRY and EXIT are set to deny as they exist in all trace paths.</td>
</tr>
<tr>
<td>debugfs.ocfs2 -l HEARTBEAT ENTRY EXIT off</td>
<td>Disable heartbeat tracing. ENTRY and EXIT are set to deny as they exist in all trace paths.</td>
</tr>
<tr>
<td>debugfs.ocfs2 -l ENTRY EXIT deny</td>
<td>Disable tracing for the file system.</td>
</tr>
<tr>
<td>NAMEI INODE allow</td>
<td>Enable tracing for the file system.</td>
</tr>
<tr>
<td>debugfs.ocfs2 -l ENTRY EXIT deny</td>
<td>Disable tracing for the file system.</td>
</tr>
<tr>
<td>debugfs.ocfs2 -l ENTRY EXIT DLM DLM_THREAD allow</td>
<td>Enable tracing for the DLM.</td>
</tr>
<tr>
<td>debugfs.ocfs2 -l ENTRY EXIT DLM DLM_THREAD deny</td>
<td>Disable tracing for the DLM.</td>
</tr>
</tbody>
</table>

One method for obtaining a trace is to enable the trace, sleep for a short while, and then disable the trace. As shown in the following example, to avoid seeing unnecessary output, you should reset the trace bits to their default settings after you have finished.

```
# debugfs.ocfs2 -l ENTRY EXIT NAMEI INODE allow && sleep 10 && 
# debugfs.ocfs2 -l ENTRY EXIT deny NAMEI INODE off
```

To limit the amount of information displayed, enable only the trace bits that you believe are relevant to understanding the problem.

If you believe a specific file system command, such as `mv`, is causing an error, the following example shows the commands that you can use to help you trace the error.

```
# debugfs.ocfs2 -l ENTRY EXIT NAMEI INODE allow
# mv source destination & CMD_PID=$(jobs -p %)
# echo $CMD_PID
# debugfs.ocfs2 -l ENTRY EXIT deny NAMEI INODE off
```

As the trace is enabled for all mounted OCFS2 volumes, knowing the correct process ID can help you to interpret the trace.

For more information, see the `debugfs.ocfs2(8)` manual page.

23.3.4 Debugging File System Locks

If an OCFS2 volume hangs, you can use the following steps to help you determine which locks are busy and the processes that are likely to be holding the locks.

1. Mount the debug file system.
# mount -t debugfs debugfs /sys/kernel/debug

2. Dump the lock statuses for the file system device (/dev/sdx1 in this example).

```bash
# echo "fs_locks" | debugfs.ocfs2 /dev/sdx1 >/tmp/fslocks
```

Lockres: M00000000000006672078b84822 Mode: Protected Read
Flags: Initialized Attached
RO Holders: 0 EX Holders: 0
Pending Action: None Pending Unlock Action: None
Requested Mode: Protected Read Blocking Mode: Invalid

The Lockres field is the lock name used by the DLM. The lock name is a combination of a lock-type identifier, an inode number, and a generation number. The following table shows the possible lock types.

<table>
<thead>
<tr>
<th>Identifier</th>
<th>Lock Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>D</td>
<td>File data.</td>
</tr>
<tr>
<td>M</td>
<td>Metadata.</td>
</tr>
<tr>
<td>R</td>
<td>Rename.</td>
</tr>
<tr>
<td>S</td>
<td>Superblock.</td>
</tr>
<tr>
<td>W</td>
<td>Read-write.</td>
</tr>
</tbody>
</table>

3. Use the Lockres value to obtain the inode number and generation number for the lock.

```bash
# echo "stat <M00000000000006672078b84822>" | debugfs.ocfs2 -n /dev/sdx1
```

Inode: 419616   Mode: 0666   Generation: 2025343010 (0x78b84822)

4. Determine the file system object to which the inode number relates by using the following command.

```bash
# echo "locate <419616>" | debugfs.ocfs2 -n /dev/sdx1
```

419616 /linux-2.6.15/arch/i386/kernel/semaphore.c

5. Obtain the lock names that are associated with the file system object.

```bash
# echo "encode /linux-2.6.15/arch/i386/kernel/semaphore.c" | \
    debugfs.ocfs2 -n /dev/sdx1
```

M00000000000006672078b84822 D000000000006672078b84822 W000000000006672078b84822

In this example, a metadata lock, a file data lock, and a read-write lock are associated with the file system object.

6. Determine the DLM domain of the file system.

```bash
# echo "stats" | debugfs.ocfs2 -n /dev/sdx1 | grep UUID: | while read a b ; do echo $b ; done
```

82DA8137A49A47E4B187F74E09FBBB4B

7. Use the values of the DLM domain and the lock name with the following command, which enables debugging for the DLM.

```bash
# echo R 82DA8137A49A47E4B187F74E09FBBB4B \ 
    M00000000000006672078b84822 > /proc/fs/ocfs2_dlm/debug
```

8. Examine the debug messages.

```bash
# dmesg | tail
```

struct dlm_ctxt: 82DA8137A49A47E4B187F74E09FBBB4B, node=3, key=965960985
lockres: M00000000000006672078b84822, owner=1, state=0 last used: 0,
on purge list: no granted queue:
The DLM supports 3 lock modes: no lock \((\text{type}=0)\), protected read \((\text{type}=3)\), and exclusive \((\text{type}=5)\). In this example, the lock is mastered by node 1 \((\text{owner}=1)\) and node 3 has been granted a protected-read lock on the file-system resource.

9. Run the following command, and look for processes that are in an uninterruptable sleep state as shown by the \(D\) flag in the \text{STAT} column.

\[
\# \text{ps -e -o pid,stat,comm,wchan=WIDE-WCHAN-COLUMN}
\]

At least one of the processes that are in the uninterruptable sleep state will be responsible for the hang on the other node.

If a process is waiting for I/O to complete, the problem could be anywhere in the I/O subsystem from the block device layer through the drivers to the disk array. If the hang concerns a user lock \((\text{flock()}\)), the problem could lie in the application. If possible, kill the holder of the lock. If the hang is due to lack of memory or fragmented memory, you can free up memory by killing non-essential processes. The most immediate solution is to reset the node that is holding the lock. The DLM recovery process can then clear all the locks that the dead node owned, so letting the cluster continue to operate.

### 23.3.5 Configuring the Behavior of Fenced Nodes

If a node with a mounted OCFS2 volume believes that it is no longer in contact with the other cluster nodes, it removes itself from the cluster in a process termed \textit{fencing}. Fencing prevents other nodes from hanging when they try to access resources held by the fenced node. By default, a fenced node restarts instead of panicking so that it can quickly rejoin the cluster. Under some circumstances, you might want a fenced node to panic instead of restarting. For example, you might want to use \texttt{netconsole} to view the oops stack trace or to diagnose the cause of frequent reboots. To configure a node to panic when it next fences, run the following command on the node after the cluster starts:

\[
\# \text{echo panic > /sys/kernel/config/cluster/cluster_name/fence_method}
\]

where \texttt{cluster_name} is the name of the cluster. To set the value after each reboot of the system, add this line to \texttt{/etc/rc.local}. To restore the default behavior, use the value \texttt{reset} instead of \texttt{panic}.

### 23.4 Use Cases for OCFS2

The following sections describe some typical use cases for OCFS2.

#### 23.4.1 Load Balancing

You can use OCFS2 nodes to share resources between client systems. For example, the nodes could export a shared file system by using Samba or NFS. To distribute service requests between the nodes, you can use round-robin DNS, a network load balancer, or specify which node should be used on each client.

#### 23.4.2 Oracle Real Application Cluster (RAC)

Oracle RAC uses its own cluster stack, Cluster Synchronization Services (CSS). You can use O2CB in conjunction with CSS, but you should note that each stack is configured independently for timeouts, nodes, and other cluster settings. You can use OCFS2 to host the voting disk files and the Oracle cluster registry (OCR), but not the grid infrastructure user’s home, which must exist on a local file system on each node.
As both CSS and O2CB use the lowest node number as a tie breaker in quorum calculations, you should ensure that the node numbers are the same in both clusters. If necessary, edit the O2CB configuration file `/etc/ocfs2/cluster.conf` to make the node numbering consistent, and update this file on all nodes. The change takes effect when the cluster is restarted.

### 23.4.3 Oracle Databases

Specify the `noatime` option when mounting volumes that host Oracle datafiles, control files, redo logs, voting disk, and OCR. The `noatime` option disables unnecessary updates to the access time on the inodes.

Specify the `nointr` mount option to prevent signals interrupting I/O transactions that are in progress.

By default, the `init.ora` parameter `filesystemio_options` directs the database to perform direct I/O to the Oracle datafiles, control files, and redo logs. You should also specify the `datavolume` mount option for the volumes that contain the voting disk and OCR. Do not specify this option for volumes that host the Oracle user's home directory or Oracle E-Business Suite.

To avoid database blocks becoming fragmented across a disk, ensure that the file system cluster size is at least as big as the database block size, which is typically 8KB. If you specify the file system usage type as `datafiles` to the `mkfs.ocfs2` command, the file system cluster size is set to 128KB.

To allow multiple nodes to maximize throughput by concurrently streaming data to an Oracle datafile, OCFS2 deviates from the POSIX standard by not updating the modification time (`mtime`) on the disk when performing non-extending direct I/O writes. The value of `mtime` is updated in memory, but OCFS2 does not write the value to disk unless an application extends or truncates the file, or performs a operation to change the file metadata, such as using the `touch` command. This behavior leads to results in different nodes reporting different time stamps for the same file. You can use the following command to view the on-disk timestamp of a file:

```
# debugfs.ocfs2 -R "stat /file_path" device | grep "mtime:
```

### 23.5 For More Information About OCFS2

You can find more information about OCFS2 at [https://oss.oracle.com/projects/ocfs2/documentation/](https://oss.oracle.com/projects/ocfs2/documentation/).
This section contains the following chapters:

- **Chapter 24, Authentication Configuration** describes how to configure various authentication methods that Oracle Linux can use, including NIS, LDAP, Kerberos, and Winbind, and how you can configure the System Security Services Daemon feature to provide centralized identity and authentication management.

- **Chapter 25, Local Account Configuration** describes how to configure and manage local user and group accounts.

- **Chapter 26, System Security Administration** describes the subsystems that you can use to administer system security, including SELinux, the Netfilter firewall, TCP Wrappers, chroot jails, auditing, system logging, and process accounting.

- **Chapter 27, OpenSSH Configuration** describes how to configure OpenSSH to support secure communication between networked systems.

This chapter describes how to configure various authentication methods that Oracle Linux can use, including NIS, LDAP, Kerberos, and Winbind, and how you can configure the System Security Services Daemon feature to provide centralized identity and authentication management.

24.1 About Authentication

Authentication is the verification of the identity of an entity, such as a user, to a system. A user logs in by providing a user name and a password, and the operating system authenticates the user's identity by comparing this information to data stored on the system. If the login credentials match and the user account is active, the user is authenticated and can successfully access the system.

The information that verifies a user's identity can either be located on the local system in the /etc/passwd and /etc/shadow files, or on remote systems using Identity Policy Audit (IPA), the Lightweight Directory Access Protocol (LDAP), the Network Information Service (NIS), or Winbind. In addition, IPSv2,
About Local Oracle Linux Authentication

LDAP, and NIS data files can use the Kerberos authentication protocol, which allows nodes communicating over a non-secure network to prove their identity to one another in a secure manner.

You can use the Authentication Configuration GUI (system-config-authentication) to select the authentication mechanism and to configure any associated authentication options. Alternatively, you can use the authconfig command. Both the Authentication Configuration GUI and authconfig adjust settings in the PAM configuration files that are located in the /etc/pam.d directory. The Authentication Configuration GUI is available if you install the authconfig-gtk package.

Figure 24.1 shows the Authentication Configuration GUI with **Local accounts only** selected.

**Figure 24.1 Authentication Configuration of Local Accounts**

24.2 About Local Oracle Linux Authentication

Unless you select a different authentication mechanism during installation or by using the Authentication Configuration GUI or the authconfig command, Oracle Linux verifies a user's identity by using the information that is stored in the /etc/passwd and /etc/shadow files.

The /etc/passwd file stores account information for each user such as his or her unique user ID (or UID, which is an integer), user name, home directory, and login shell. A user logs in using his or her user name,
but the operating system uses the associated UID. When the user logs in, he or she is placed in his or her home directory and his or her login shell runs.

The `/etc/group` file stores information about groups of users. A user also belongs to one or more groups, and each group can contain one or more users. If you can grant access privileges to a group, all members of the group receive the same access privileges. Each group account has a unique group ID (`GID`, again an integer) and an associated group name.

By default, Oracle Linux implements the `user private group (UPG)` scheme where adding a user account also creates a corresponding UPG with the same name as the user, and of which the user is the only member.

Only the `root` user can add, modify, or delete user and group accounts. By default, both users and groups use shadow passwords, which are cryptographically hashed and stored in `/etc/shadow` and `/etc/gshadow` respectively. These shadow password files are readable only by the `root` user. `root` can set a group password that a user must enter to become a member of the group by using the `newgrp` command. If a group does not have a password, a user can only join the group by `root` adding him or her as a member.

The `/etc/login.defs` file defines parameters for password aging and related security policies.

For more information about the content of these files, see the `group(5), gshadow(5), login.defs(5), passwd(5), and shadow(5)` manual pages.

### 24.2.1 Configuring Local Access

You can use the User Manager GUI (`system-config-users`) to add or delete users and groups and to modify settings such as passwords, home directories, login shells, and group membership. Alternatively, you can use commands such as `useradd` and `groupadd`. The User Manager GUI is available if you install the `system-config-users` package.

To enable local access control, select the **Enable local access control** check box on the Advanced Options tab of the Authentication Configuration GUI (`system-config-authentication`). The system can then read the `/etc/security/access.conf` file for local user authorization rules that specify login combinations that the system accepts or refuses.

*Figure 24.2* shows the Authentication Configuration GUI with the Advanced Options tab selected.
Alternatively, use the following command:

```
# authconfig --enablepamaccess --update
```

Each entry in `/etc/security/access.conf` takes the form:

```
permission : users : origins [ except
```

where:

- **permission**
  - Set to `+` or `−` to grant or deny login respectively.

- **users**
  - Specifies a space-separated list of user or group names or `ALL` for any user or group. Enclose group names in parentheses to distinguish them from user names. You can use the `EXCEPT` operator to exclude a list of users from the rule.

- **origins**
  - Specifies a space-separated list of host names, fully qualified domain names, network addresses, terminal device names, `ALL`, or `NONE`. You can use the `EXCEPT` operator to exclude a list of origins from the rule.
For example, the following rule denies login access by anyone except root from the network 192.168.2.0/24:

```
- : ALL except root : 192.168.2.0/24
```

For more information, see the `access.conf(5)` manual page and Chapter 25, *Local Account Configuration*.

### 24.2.2 Configuring Fingerprint Reader Authentication

If appropriate hardware is installed and supported, the system can use fingerprint scans to authenticate users.

To enable fingerprint reader support, select the `Enable fingerprint reader support` check box on the Advanced Options tab of the Authentication Configuration GUI (`system-config-authentication`).

Alternatively, use the following command:

```
# authconfig --enablefingerprint --update
```

### 24.2.3 Configuring Smart Card Authentication

If appropriate hardware is installed and supported, the system can use smart cards to authenticate users. The `pam_pkcs11` package provides a PAM login module that enables X.509 certificate-based user authentication. The module uses the Name Service Switch (NSS) to manage and validate PKCS #11 smart cards by using locally stored root CA certificates, online or locally accessible certificate revocation lists (CRLs), and the Online Certificate Status Protocol (OCSP).

To enable smart card authentication:

1. Install the `pam_pkcs11` package:
   
   ```
   # yum install pam_pkcs11
   ``

2. Use the following command to install the root CA certificates in the NSS database:

   ```
   # certutil -A -d /etc/pki/nssdb -t "TC,C,C" -n "Root CA certificates" -i CACert.pem
   ```

   where `CACert.pem` is the base-64 format root CA certificate file.

3. Run the Authentication Configuration GUI:

   ```
   # system-config-authentication
   ```

4. On the Advanced Options tab, select the `Enable smart card support` check box.

5. If you want to disable all other login authentication methods, select the `Require smart card for login` check box.

   **Caution**

   Do not select this option until you have tested that can use a smart card to authenticate with the system.

6. From the `Card removal action` menu, select the system's response if a user removes a smart card while logged in to a session:

   - **Ignore**
     
     The system ignores card removal for the current session.
Lock

The system locks the user out of the session.

You can also use the following command to configure smart card authentication:

```
# authconfig --enablesmartcard --update
```

To specify the system's response if a user removes a smart card while logged in to a session:

```
authconfig --smartcardaction=0|1 --update
```

Specify a value of 0 to `--smartcardaction` to lock the system if a card is removed. To ignore card removal, use a value of 1.

Once you have tested that you can use a smart card to authenticate with the system, you can disable all other login authentication methods.

```
# authconfig --enablerequiresmartcard --update
```

24.3 About IPA Authentication

IPA allows you to set up a domain controller for DNS, Kerberos, and authorization policies as an alternative to Active Directory Services. You can enrol client machines with an IPA domain so that they can access information for single sign-on authentication. IPA combines the capabilities of existing well-known technologies such as certificate services, DNS, LDAP, Kerberos, LDAP, and NTP.

24.3.1 Configuring IPA Authentication

To be able to configure IPA authentication, use `yum` to install the `ipa-client` and `ipa-admintools` packages. The `ipa-server` package is only required if you want to configure a system as an IPA server.

You can choose between two versions of IPA in the Authentication Configuration GUI:

- **FreeIPA** (effectively, IPAv1) supports identity management and authentication of users and groups, and does not require you to join your system to an IPA realm. Enter information about the LDAP and Kerberos configuration.

- **IPAv2**, which supports identity management and authentication of machines, requires you to join your system to an IPA realm. Enter information about the IPA domain configuration, optionally choose to configure NTP, and click **Join Domain** to create a machine account on the IPA server. After your system has obtained permission to join the IPA realm, you can select and configure the authentication method.

For more information about configuring IPA, see [http://freeipa.org/page/Documentation](http://freeipa.org/page/Documentation).

24.4 About LDAP Authentication

The Lightweight Directory Access Protocol (LDAP) allows client systems to access information stored on LDAP servers over a network. An LDAP directory server stores information in a directory-based database that is optimized for searching and browsing, and which also supports simple functions for accessing and updating entries in the database.

Database entries are arranged in a hierarchical tree-like structure, where each directory can store information such as names, addresses, telephone numbers, network service information, printer information, and many other types of structured data. Systems can use LDAP for authentication, which allows users to access their accounts from any machine on a network.

The smallest unit of information in an LDAP directory is an entry, which can have one or more attributes. Each attribute of an entry has a name (also known as an `attribute type` or `attribute description`) and one
About LDAP Data Interchange Format

or more values. Examples of types are domain component (dc), common name (cn), organizational unit (ou) and email address (mail). The objectClass attribute allows you to specify whether an attribute is required or optional. An objectClass attribute’s value specifies the schema rules that an entry must obey.

A distinguished name (dn) uniquely identifies an entry in LDAP. The distinguished name consists of the name of the entry (the relative distinguished name or RDN) concatenated with the names of its ancestor entries in the LDAP directory hierarchy. For example, the distinguished name of a user with the RDN uid=arc815 might be uid=arc815,ou=staff,dc=mydom,dc=com.

The following are examples of information stored in LDAP for a user:

```plaintext
# User arc815
dn: uid=arc815,ou=People,dc=mydom,dc=com
cn: John Beck
givenName: John
sn: Beck
uid: arc815
uidNumber: 5159
gidNumber: 626
homeDirectory: /nethome/arc815
loginShell: /bin/bash
mail: johnb@mydom.com
objectClass: top
objectClass: inetOrgPerson
objectClass: posixAccount
objectClass: shadowAccount
userPassword: {SSHA}QYrFtKkqOrifgk8H4EYf68BOJxIIaLga
```

and for a group:

```plaintext
# Group employees
dn: cn=employees,ou=Groups,dc=mydom,dc=com
cn: employees
gidNumber: 626
objectClass: top
objectClass: posixGroup
memberUid: arc815
memberUid: arc891
```

24.4.1 About LDAP Data Interchange Format

LDAP data itself is stored in a binary format. LDAP Data Interchange Format (LDIF) is a plain-text representation of an LDAP entry that allows the import and export LDAP data, usually to transfer the data between systems, but it also allows you to use a text editor to modify the content.

The data for an entry in an LDIF file takes the form:

```
[id] dn: distinguished_name
attribute_type: value | [attribute=value, [attribute=value] value]...
...objectClass: value
..."
```

The optional id number is determined by the application that you use to edit the entry. Each attribute type for an entry contains either a value or a comma-separated list of attribute and value pairs as defined in the LDAP directory schema.

There must be a blank line between each dn definition section or include: line. There must not be any other blank lines or any white space at the ends of lines. White space at the start of a line indicates a continuation of the previous line.
24.4.2 Configuring an LDAP Server

OpenLDAP is an open-source implementation of LDAP that allows you configure an LDAP directory server.

To configure a system as an LDAP server:

1. Install the OpenLDAP packages:

   ```
   # yum install openldap openldap-servers openldap-clients nss-pam-ldapd
   ```

   The OpenLDAP configuration is stored in the following files below /etc/openldap:

   - `ldap.conf`: The configuration file for client applications.
   - `slapd.d/cn=config.ldif`: The default global configuration LDIF file for OpenLDAP.
   - `slapd.d/cn=config/*.ldif`: Configuration LDIF files for the database and schema.

   **Note**
   
   You should never need to edit any files under `/etc/openldap/slapd.d` as you can reconfigure OpenLDAP while the `slapd` service is running.

2. If you want configure `slapd` to listen on port 636 for connections over an SSL tunnel (`ldaps://`), edit `/etc/sysconfig/slapd`, and change the value of `SLAPD_LDAPS` to `yes`:

   ```
   SLAPD_LDAPS=yes
   ```

   If required, you can prevent `slapd` listening on port 389 for `ldap://` connections, by changing the value of `SLAPD_LDAP` to `no`:

   ```
   SLAPD_LDAP=no
   ```

   Ensure that you also define the correct `SLAPD_URLS` for the ports that are enabled. For instance, if you intend to use SSL and you wish `slapd` to listen on port 636, you must specify `ldaps://` as one of the supported URLS. For example:

   ```
   SLAPD_URLS="ldapi:/// ldap:/// ldaps:///"
   ```

3. Configure the system firewall to allow incoming TCP connections on port 389, for example:

   ```
   # firewall-cmd --zone=zone --add-port=389/tcp
   # firewall-cmd --permanent --zone=zone --add-port=389/tcp
   ```

   The primary TCP port for LDAP is 389. If you configure LDAP to use an SSL tunnel (`ldaps`), substitute the port number that the tunnel uses, which is usually 636, for example:

   ```
   # firewall-cmd --zone=zone --add-port=636/tcp
   # firewall-cmd --permanent --zone=zone --add-port=636/tcp
   ```

4. Change the user and group ownership of `/var/lib/ldap` and any files that it contains to `ldap`:

   ```
   # cd /var/lib/ldap
   # chown ldap:ldap ./*
   ```

5. Start the `slapd` service and configure it to start following system reboots:
6. Generate a hash of the LDAP password that you will use with the `olcRootPW` entry in the configuration file for your domain database, for example:

```
# slappasswd -h {SSHA}
New password: password
Re-enter new password: password
{SSHA}lkMShz73MZBic19Q4pfOaXNxpLN3wLr
```

7. Create an LDIF file with a name such as `config-mydom-com.ldif` that contains configuration entries for your domain database based on the following example:

```
# Load the schema files required for accounts
include file:///etc/openldap/schema/cosine.ldif
include file:///etc/openldap/schema/nis.ldif
include file:///etc/openldap/schema/inetorgperson.ldif

# Load the HDB (hierarchical database) backend modules
dn: cn=module,cn=config
objectClass: olcModuleList
cn: module
olcModulepath: /usr/lib64/openldap
olcModuleload: back_hdb

# Configure the database settings
dn: olcDatabase=hdb,cn=config
objectClass: olcDatabaseConfig
objectClass: olcHdbConfig
olcDatabase: {1}hdb
olcSuffix: dc=mydom,dc=com
# The database directory must already exist
# and it should only be owned by ldap:ldap.
# Setting its mode to 0700 is recommended
olcDbDirectory: /var/lib/ldap
olcRootDN: cn=admin,dc=mydom,dc=com
olcRootPW: {SSHA}lkMShz73MZBic19Q4pfOaXNxpLN3wLr
olcDbConfig: set_cachesize 0 10485760 0
olcDbConfig: set_lk_max_objects 2000
olcDbConfig: set_lk_max_locks 2000
olcDbConfig: set_lk_max_lockers 2000
olcDbIndex: objectClass eq
olcLastMod: TRUE
olcDbCheckpoint: 1024 10

# Set up access control
olcAccess: to attr=userPassword
  by dn="cn=admin,dc=mydom,dc=com"
    write by anonymous auth
    by self write
    by * none
olcAccess: to attr=shadowLastChange
  by self write
  by * read
olcAccess: to dn.base="
  by * read
olcAccess: to *
  by dn="cn=admin,dc=mydom,dc=com"
    write by * read
```
Replacing the Default Certificates

**Note**

This configuration file allows you to reconfigure `slapd` while it is running. If you use a `slapd.conf` configuration file, you can also update `slapd` dynamically, but such changes do not persist if you restart the server.

For more information, see the `slapd-config(5)` manual page.

8. Use the `ldapadd` command to add the LDIF file:

```
# ldapadd -Y EXTERNAL -H ldapi:/// -f config-mydom-com.ldif
```

For more information about configuring OpenLDAP, see the `slapadd(8C), slapd(8C), slapd-config(5), and slappasswd(8C)` manual pages, the *OpenLDAP Administrator’s Guide* (usr/share/doc/openldap-servers-version/guide.html), and the latest OpenLDAP documentation at http://www.openldap.org/doc/.

24.4.3 Replacing the Default Certificates

If you configure LDAP to use Transport Layer Security (TLS) or Secure Sockets Layer (SSL) to secure the connection to the LDAP server, you need a public certificate that clients can download. You can obtain certificates from a Certification Authority (CA) or you can use the `openssl` command to create the certificate. See Section 24.4.4, “Creating and Distributing Self-signed CA Certificates”.

Once you have a server certificate, its corresponding private key file, and a root CA certificate, you can replace the default certificates that are installed in `/etc/openldap/certs`.

To display the existing certificate entries that `slapd` uses with TLS, use the `ldapsearch` command:

```
# ldapsearch -LLL -Y EXTERNAL -H ldapi:/// -b "cn=config"
```

To replace the TLS attributes in the LDAP configuration:

1. Create an LDIF file that defines how to modify the attributes, for example:

```
dn: cn=config
changetype: modify
delete: olcTLSCACertificatePath

# Omit the following clause for olcTLSCertificateFile
# if you do not have a separate root CA certificate

dn: cn=config
changetype: modify
add: olcTLSCertificateFile
olcTLSCertificateFile: /etc/ssl/certsCAcert.pem
```

...
Creating and Distributing Self-signed CA Certificates

If you generate only a self-signed certificate and its corresponding key file, you do not need to specify a root CA certificate.

2. Use the `ldapmodify` command to apply the LDIF file:

```bash
# ldapmodify -Y EXTERNAL -H ldapi:/// -f mod-TLS.ldif
SASL/EXTERNAL authentication started
SASL username: gidNumber=0+uidNumber=0,cn=peercred,cn=external,cn=auth
SASL SSF: 0
modifying entry "cn=config"
modifying entry "cn=config"
modifying entry "cn=config"
...
```

3. Verify that the entries have changed:

```bash
# ldapsearch -LLL -Y EXTERNAL -H ldapi:/// -b "cn=config" \
  olcTLSCACertificatePath olcTLSCertificateFile olcTLSCertificateKeyFile
SASL/EXTERNAL authentication started
SASL username: gidNumber=0+uidNumber=0,cn=peercred,cn=external,cn=auth
SASL SSF: 0
dn: cn=config
olcTLSCACertificateFile: /etc/ssl/certs/CAcert.pem
olcTLSCertificateFile: /etc/ssl/certs/server-cert.pem
olcTLSCertificateKeyFile: /etc/ssl/certs/server-key.pem
olcTLSCipherSuite: TLSv1+RSA:!NULL
olcTLSVerifyClient: never
...
```

4. Restart the `slapd` service to make it use the new certificates:

```bash
# systemctl restart slapd
```

For more information, see the `ldapmodify(1), ldapsearch(1) and openssl(1)` manual pages.

### 24.4.4 Creating and Distributing Self-signed CA Certificates

For usage solely within an organization, you might want to create certificates that you can use with LDAP. There are a number of ways of creating suitable certificates, for example:

- Create a self-signed CA certificate together with a private key file.

- Create a self-signed root CA certificate and private key file, and use the CA certificate and its key file to sign a separate server certificate for each server.
The following procedure describes how to use `openssl` to create a self-signed CA certificate and private key file, and then use these files to sign server certificates.

To create the CA certificate and use it to sign a server certificate:

1. Change directory to `/etc/openldap/certs` on the LDAP server:
   ```
   # cd /etc/openldap/certs
   ```

2. Create the private key file `CAcert-key.pem` for the CA certificate:
   ```
   # openssl genrsa -out CAcert-key.pem 1024
   Generating RSA private key, 1024 bit long modulus
   ..........+++++
   ..........+++++
   e is 65537 (0x10001)
   ```

3. Change the mode on the key file to 0400:
   ```
   # chmod 0400 CAcert-key.pem
   ```

4. Create the certificate request `CAcert.csr`:
   ```
   # openssl req -new -key CAcert-key.pem -out CAcert.csr
   You are about to be asked to enter information that will be incorporated into your certificate request.
   What you are about to enter is what is called a Distinguished Name or a DN. There are quite a few fields but you can leave some blank
   For some fields there will be a default value,
   If you enter '.', the field will be left blank.
   ----- 
   Country Name (2 letter code) [XX]: US
   State or Province Name (full name) []: California
   Locality Name (eg, city) [Default City]: Redwood City
   Organization Name (eg, company) [Default Company Ltd]: Mydom Inc
   Organizational Unit Name (eg, section) []: Org
   Common Name (eg, your name or your server's hostname) []: www.mydom.org
   Email Address []: root@mydom.org
   Please enter the following 'extra' attributes to be sent with your certificate request
   A challenge password []: <Enter>
   An optional company name []: <Enter>
   ```

5. Create a CA certificate that is valid for approximately three years:
   ```
   # openssl x509 -req -days 1095 -in CAcert.csr -signkey CAcert-key.pem -out CAcert.pem
   Signature ok
   subject=/C=US/ST=California/L=Redwood City/O=Mydom Inc/OU=Org/CN=www.mydom.org/emailAddress=root@mydom.org
   Getting Private key
   ```

6. For each server certificate that you want to create:
   a. Create the private key for the server certificate:
      ```
      # openssl genrsa -out server-key.pem 1024
      Generating RSA private key, 1024 bit long modulus
      ................+++
      ................+++++
      e is 65537 (0x10001)
      ```
Creating and Distributing Self-signed CA Certificates

Note
If you intend to generate server certificates for several servers, name the certificate, its key file, and the certificate request so that you can easily identify both the server and the service, for example, ldap_host02-cert.pem, ldap_host02-key.pem, and ldap_host02-cert.csr.

b. Change the mode on the key file to 0400, and change its user and group ownership to ldap:

```
# chmod 0400 server-key.pem
# chown ldap:ldap server-key.pem
```

c. Create the certificate request server-cert.csr:

```
# openssl req -new -key server-key.pem -out server-cert.csr
```

You are about to be asked to enter information that will be incorporated into your certificate request.
What you are about to enter is what is called a Distinguished Name or a DN.
There are quite a few fields but you can leave some blank
For some fields there will be a default value,
If you enter '.', the field will be left blank.
-----
Country Name (2 letter code) [XX]: US
State or Province Name (full name) []: California
Locality Name (eg, city) [Default City]: Redwood City
Organization Name (eg, company) [Default Company Ltd]: Mydom Inc
Organizational Unit Name (eg, section) []: Org
Common Name (eg, your name or your server's hostname) []: ldap.mydom.com
Email Address []: root@mydom.com

Please enter the following 'extra' attributes to be sent with your certificate request.
A challenge password []: <Enter>
An optional company name []: <Enter>

Note
For the Common Name, specify the Fully Qualified Domain Name (FQDN) of the server. If the FQDN of the server does not match the common name specified in the certificate, clients cannot obtain a connection to the server.

d. Use the CA certificate and its corresponding key file to sign the certificate request and generate the server certificate:

```
# openssl x509 -req -days 1095 -CAcreateserial
- -in server-cert.csr -CA CAcert.pem -CAkey CACert-key.pem
- -out server-cert.pem
```

Signature ok
subject=/C=US/ST=California/L=Redwood City/O=Mydom
    Inc/OU=Org/CN=ldap.mydom.com/emailAddress=root@mydom.com
Getting CA Private Key

7. If you generate server certificates for other LDAP servers, copy the appropriate server certificate, its corresponding key file, and the CA certificate to /etc/openldap/certs on those servers.

8. Set up a web server to host the CA certificate for access by clients. The following steps assume that the LDAP server performs this function. You can use any suitable, alternative server instead.

   a. Install the Apache HTTP server.

```
# yum install httpd
```
b. Create a directory for the CA certificate under /var/www/html, for example:

```bash
mkdir /var/www/html/certs
```

c. Copy the CA certificate to /var/www/html/certs.

```bash
cp CAcert.pem /var/www/html/certs
```

**Caution**

Do not copy the key files.

d. Edit the HTTP server configuration file, /etc/httpd/conf/httpd.conf, and specify the resolvable domain name of the server in the argument to ServerName.

```
ServerName server_addr:80
```

If the server does not have a resolvable domain name, enter its IP address instead.

Verify that the setting of the Options directive in the `<Directory "/var/www/html">` section specifies Indexes and FollowSymLinks to allow you to browse the directory hierarchy, for example:

```
Options Indexes FollowSymLinks
```

e. Start the Apache HTTP server, and configure it to start after a reboot.

```bash
systemctl start httpd
systemctl enable httpd
```

f. If you have enabled the firewall on your system, configure it to allow incoming HTTP connection requests on TCP port 80, for example:

```bash
firewall-cmd --zone=zone --add-port=80/tcp
firewall-cmd --permanent --zone=zone --add-port=80/tcp
```

### 24.4.5 Initializing an Organization in LDAP

Before you can define people, groups, servers, printers, and other entities for your organization, you must first set up information in LDAP for the organization itself.

To define an organization in LDAP:

1. Create an LDIF file that defines the organization, for example `mydom-com-organization.ldif`:

```ldif
# Organization mydom.com
dn: dc=mydom,dc=com
dc: mydom
objectclass: dcObject
objectClass: organizationalUnit
ou: mydom.com

# Users
dn: ou=People,dc=mydom,dc=com
objectClass: organizationalUnit
ou: people

# Groups
dn: ou=Groups,dc=mydom,dc=com
objectClass: organizationalUnit
```
24.4.6 Adding an Automount Map to LDAP

You can make an automount map such as auto.home available in LDAP so that the automounter mounts a user's home directory on demand.

To add the auto.home map to LDAP:

1. Create an LDIF file that defines entries for the map's name and its contents, for example auto-home.ldif:

```
dn: nisMapName=auto.home,dc=mydom,dc=com
objectClass: top
objectClass: nisMap
nisMapName: auto.home

dn: cn=*,nisMapName=auto.home,dc=mydom,dc=com
objectClass: nisObject
cn: *
nisMapEntry: -rw,sync nfssvr:/nethome/
nisMapName: auto.home
```

where nfssvr is the host name or IP address of the NFS server that exports the users' home directories.

2. If you have configured LDAP authentication, use the following command to add the map to LDAP:

```
# ldapadd -xcWD "cn=admin,dc=mydom,dc=com" -f auto-home.ldif
Enter LDAP Password: user_password
adding new entry "dc=mydom,dc=com"
adding new entry "ou=People,dc=mydom,dc=com"
adding new entry "ou=Groups,dc=mydom,dc=com"
```

If you have configured Kerberos authentication, use kinit to obtain a ticket granting ticket (TGT) for the admin principal, and use this form of the ldapadd command:

```
# ldapadd -f mydom-com-organization.ldif
```

3. Verify that the map appears in LDAP:

```
# ldapsearch -LLL -x -b "dc=mydom,dc=com" nisMapName=auto.home
dn: nisMapName=auto.home,dc=mydom,dc=com
```

For more information, see the ldapadd(1) manual page.
### Adding a Group to LDAP

If you configure users in user private groups (UPGs), define that group along with the user. See Section 24.4.8, “Adding a User to LDAP”.

To add a group to LDAP:

1. Create an LDIF file that defines the group, for example `employees-group.ldif`:

   ```
   # Group employees
dn: cn=employees,ou=Groups,dc=mydom,dc=com
cn: employees
gidNumber: 626
objectClass: top
objectclass: posixGroup
   ```

2. If you have configured LDAP authentication, use the following command to add the group to LDAP:

   ```
   # ldapadd -cxWD "cn=admin,dc=mydom,dc=com" -f employees-group.ldif
   Enter LDAP Password: admin_password
   adding new entry "cn=employees,ou=Groups,dc=mydom,dc=com"
   ```

   If you have configured Kerberos authentication, use `kinit` to obtain a ticket granting ticket (TGT) for the `admin` principal, and use this form of the `ldapadd` command:

   ```
   # ldapadd -f employees-group.ldif
   ```

3. Verify that you can locate the group in LDAP:

   ```
   # ldapsearch -LLL -x -b "dc=mydom,dc=com" gidNumber=626
dn: cn=employees,ou=Groups,dc=mydom,dc=com
cn: employees
gidNumber: 626
objectClass: top
objectclass: posixGroup
   ```

For more information, see the `ldapadd(1)` and `ldapsearch(1)` manual pages.

### Adding a User to LDAP

**Note**

This procedure assumes that:

- LDAP provides information for `ou=People,ou=Groups`, and `nisMapName=auto.home`.
- The LDAP server uses NFS to export the users' home directories. See Section 22.2.2, “Mounting an NFS File System”.

To create an account for a user on the LDAP server:
Adding a User to LDAP

1. If the LDAP server does not already export the base directory of the users' home directories, perform the following steps on the LDAP server:
   
   a. Create the base directory for user directories, for example `/nethome`:
      
      ```
      # mkdir /nethome
      ```
   
   b. Add an entry such as the following to `/etc/exports`:
      
      ```
      /nethome *(rw,sync)
      ```

      You might prefer to restrict which clients can mount the file system. For example, the following entry allows only clients in the 192.168.1.0/24 subnet to mount `/nethome`:
      
      ```
      /nethome 192.168.1.0/24(rw,sync)
      ```
   
   c. Use the following command to export the file system:
      
      ```
      # exportfs -i -o ro,sync *:/nethome
      ```

2. Create the user account, but do not allow local logins:
   
   ```
   # useradd -b base_dir -s /sbin/nologin -u UID -U username
   ```

   For example:
   
   ```
   # useradd -b /nethome -s /sbin/nologin -u 5159 -U arc815
   ```

   The command updates the `/etc/passwd` file and creates a home directory under `/nethome` on the LDAP server.

   The user's login shell will be overridden by the `LoginShell` value set in LDAP.

3. Use the `id` command to list the user and group IDs that have been assigned to the user, for example:
   
   ```
   # id arc815
   uid=5159(arc815) gid=5159(arc815) groups=5159(arc815)
   ```

4. Create an LDIF file that defines the user, for example `arc815-user.ldif`:
   
   ```
   # UPG arc815
dn: cn=arc815,ou=Groups,dc=mydom,dc=com
cn: arc815
gidNumber: 5159
objectclass: top
objectclass: posixGroup

# User arc815
dn: uid=arc815,ou=People,dc=mydom,dc=com
cn: John Beck
givenName: John
sn: Beck
uid: arc815
uidNumber: 5159
gidNumber: 5159
homeDirectory: /nethome/arc815
loginShell: /bin/bash
mail: johnb@mydom.com
objectClass: top
objectClass: inetOrgPerson
objectClass: posixAccount
objectClass: shadowAccount
userPassword: {SSHA}x
```
In this example, the user belongs to a user private group (UPG), which is defined in the same file. The user’s login shell attribute LoginShell is set to /bin/bash. The user’s password attribute userPassword is set to a placeholder value. If you use Kerberos authentication with LDAP, this attribute is not used.

5. If you have configured LDAP authentication, use the following command to add the user to LDAP:

```
# ldapadd -cxWD cn=admin,dc=mydom,dc=com -f arc815-user.ldif
```
Enter LDAP Password: admin_password
adding new entry "cn=arc815,ou=Groups,dc=mydom,dc=com"
adding new entry "uid=arc815,ou=People,dc=mydom,dc=com"

If you have configured Kerberos authentication, use kinit to obtain a ticket granting ticket (TGT) for the admin principal, and use this form of the ldapadd command:

```
# ldapadd -f arc815-user.ldif
```

6. Verify that you can locate the user and his or her UPG in LDAP:

```
# ldapsearch -LLL -x -b "dc=mydom,dc=com" "(|(uid=arc815)(cn=arc815))"  
dn: cn=arc815,ou=Groups,dc=mydom,dc=com  
  cn: arc815  
gidNumber: 5159  
  objectClass: top  
  objectClass: posixGroup  

  dn: uid=arc815,ou=People,dc=mydom,dc=com  
  cn: John Beck  
  givenName: John  
  sn: Beck  
  uid: arc815  
  uidNumber: 5159  
  gidNumber: 5159  
  homeDirectory: /home/arc815  
  loginShell: /bin/bash  
  mail: johnb@mydom.com  
  objectClass: top  
  objectClass: inetOrgPerson  
  objectClass: posixAccount  
  objectClass: shadowAccount
```

7. If you have configured LDAP authentication, set the user password in LDAP:

```
# ldappasswd -xWD "cn=admin,dc=mydom,dc=com"  
  -S "uid=arc815,ou=people,dc=mydom,dc=com"  
New password: user_password  
Re-enter new password: user_password  
Enter LDAP Password: admin_password
```

If you have configured Kerberos authentication, use kinit to obtain a ticket granting ticket (TGT) for the admin principal, and use the kadmin command to add the user (principal) and password to the database for the Kerberos domain, for example:

```
# kadmin -q "addprinc alice@MYDOM.COM"
```

For more information, see the kadmin(1), ldapadd(1), ldappasswd(1), and ldapsearch(1) manual pages.

### 24.4.9 Adding Users to a Group in LDAP

To add users to an existing group in LDAP:
1. Create an LDIF file that defines the users that should be added to the memberuid attribute for the group, for example `employees-add-users.ldif`:

```ldiff
dn: cn=employees,ou=Groups,dc=mydom,dc=com
changetype: modify
add: memberUid
memberUid: arc815

dn: cn=employees,ou=Groups,dc=mydom,dc=com
changetype: modify
add: memberUid
memberUid: arc891
...
```

2. If you have configured LDAP authentication, use the following command to add the group to LDAP:

```
# ldapmodify -xcWD "cn=admin,dc=mydom,dc=com"
  -f employees-add-users.ldif
```

Enter LDAP Password: `user_password`

```
modifying entry "cn=employees,ou=Groups,dc=mydom,dc=com"
...
```

If you have configured Kerberos authentication, use `kinit` to obtain a ticket granting ticket (TGT) for the admin principal, and use this form of the command:

```
# ldapmodify -f employees-add-users.ldif
```

3. Verify that the group has been updated in LDAP:

```
# ldapsearch -LLL -x -b "dc=mydom,dc=com" gidNumber=626
dn: cn=employees,ou=Groups,dc=mydom,dc=com
cn: employees
gidNumber: 626
objectClass: top
objectClass: posixGroup
memberUid: arc815
memberUid: arc891
...
```

24.4.10 Enabling LDAP Authentication

To enable LDAP authentication for an LDAP client by using the Authentication Configuration GUI:

1. Install the `openldap-clients` package:

```
# yum install openldap-clients
```

2. Run the Authentication Configuration GUI:

```
# system-config-authentication
```

3. Select LDAP as the user account database and enter values for:

- **LDAP Search Base DN**: The LDAP Search Base DN for the database. For example: `dc=mydom,dc=com`
- **LDAP Server**: The URL of the LDAP server including the port number. For example, `ldap://ldap.mydom.com:389` or `ldaps://ldap.mydom.com:636`

LDAP authentication requires that you use either LDAP over SSL (`ldaps`) or Transport Layer Security (TLS) to secure the connection to the LDAP server.
4. If you use TLS, click **Download CA Certificate** and enter the URL from which to download the CA certificate that provides the basis for authentication within the domain.

5. Select either **LDAP password** or **Kerberos password** for authentication.

6. If you select Kerberos authentication, enter values for:

   - **Realm**: The name of the Kerberos realm.
   - **KDCs**: A comma-separated list of Key Distribution Center (KDC) servers that can issue Kerberos ticket granting tickets and service tickets.
   - **Admin Servers**: A comma-separated list of Kerberos administration servers.

   Alternatively, you can use DNS to configure these settings:

   - Select the **Use DNS to resolve hosts to realms** check box to look up the name of the realm defined as a **TXT** record in DNS, for example:

     \[
     _kerberos.mydom.com \quad \text{IN TXT "MYDOM.COM"}
     \]

   - Select the **Use DNS to locate KDCs for realms** check box to look up the KDCs and administration servers defined as **SVR** records in DNS, for example:

     \[
     \begin{align*}
     _kerberos._tcp.mydom.com & \quad \text{IN SVR 1 0 88 krbsvr.mydom.com} \\
     _kerberos._udp.mydom.com & \quad \text{IN SVR 1 0 88 krbsvr.mydom.com} \\
     _kpasswd._udp.mydom.com & \quad \text{IN SVR 1 0 464 krbsvr.mydom.com} \\
     _kerberos-adm._tcp.mydom.com & \quad \text{IN SVR 1 0 749 krbsvr.mydom.com}
     \end{align*}
     \]

7. Click **Apply** to save your changes.

   **Figure 24.3** shows the Authentication Configuration GUI with LDAP selected for the user account database and for authentication.
You can also enable LDAP by using the `authconfig` command.

To use LDAP as the authentication source, specify the `--enableldapauth` option together with the full LDAP server URL including the port number and the LDAP Search Base DN, as shown in the following example:

```
authconfig --enableldap --enableldapauth
   --ldapserver=ldaps://ldap.mydom.com:636
   --ldapbasedn="ou=people,dc=mydom,dc=com"
   --update
```

If you want to use TLS, additionally specify the `--enableldaptls` option and the download URL of the CA certificate, for example:

```
authconfig --enableldap --enableldapauth
   --ldapserver=ldap://ldap.mydom.com:389
   --ldapbasedn="ou=people,dc=mydom,dc=com"
   --enableldaptls
   --ldaploadcacert=https://ca-server.mydom.com/CAcert.pem
   --update
```
Enabling LDAP Authentication

The `--enableldap` option configures `/etc/nsswitch.conf` to enable the system to use LDAP and SSSD for information services. The `--enableldapauth` option enables LDAP authentication by modifying the PAM configuration files in `/etc/pam.d` to use the `pam_ldap.so` module.

For more information, see the `authconfig(8)`, `pam_ldap(5)`, and `nsswitch.conf(5)` manual pages.

For information about using Kerberos authentication with LDAP, see Section 24.6.3, "Enabling Kerberos Authentication".

Note

You must also configure SSSD to be able to access information in LDAP. See Section 24.4.10.1, "Configuring an LDAP Client to use SSSD".

If your client uses automount maps stored in LDAP, you must configure `autofs` to work with LDAP. See Section 24.4.10.2, "Configuring an LDAP Client to Use Automount Maps".

24.4.10.1 Configuring an LDAP Client to use SSSD

The Authentication Configuration GUI and `authconfig` configure access to LDAP via `sss` entries in `/etc/nsswitch.conf` so you must configure the System Security Services Daemon (SSSD) on the LDAP client.

To configure an LDAP client to use SSSD:

1. Install the `sssd` and `sssd-client` packages:

   ```bash
   # yum install sssd sssd-client
   ```

2. Edit the `/etc/sssd/sssd.conf` configuration file and configure the sections to support the required services, for example:

   ```ini
   [sssd]
   config_file_version = 2
   domains = default
   services = nss, pam

   [domain/default]
   id_provider = ldap
   ldap_uri = ldap://ldap.mydom.com
   ldap_id_use_start_tls = true
   ldap_search_base = dc=mydom,dc=com
   ldap_tls_cacertdir = /etc/openldap/cacerts
   auth_provider = krb5
   chpass_provider = krb5
   krb5_realm = MYDOM.COM
   krb5_server = krbsvr.mydom.com
   krb5_kpasswd = krbsvr.mydom.com
   cache_credentials = true

   [domain/LDAP]
   id_provider = ldap
   ldap_uri = ldap://ldap.mydom.com
   ldap_search_base = dc=mydom,dc=com
   auth_provider = krb5
   krb5_realm = MYDOM.COM
   krb5_server = kdcsvr.mydom.com
   cache_credentials = true

   min_id = 5000
   ```
Enabling LDAP Authentication

309

max_id = 25000
enumerate = false

[nss]
filter_groups = root
filter_users = root
reconnection_retries = 3
entry_cache_timeout = 300

[pam]
reconnection_retries = 3
offline_credentials_expiration = 2
offline_failed_login_attempts = 3
offline_failed_login_delay = 5

3. Change the mode of /etc/sssd/sssd.conf to 0600:

```bash
# chmod 0600 /etc/sssd/sssd.conf
```

4. Enable the SSSD service:

```bash
# authconfig --update --enablesssd --enablesssdauth
```

For more information, see the `sssd.conf(5)` manual page and Section 24.8, “About the System Security Services Daemon”.

24.4.10.2 Configuring an LDAP Client to Use Automount Maps

If you have configured an automount map for `auto.home` in LDAP, you can configure an LDAP client to mount the users’ home directories when they log in.

To configure an LDAP client to automount users’ home directories:

1. Install the `autofs` package:

```bash
# yum install autofs
```

2. Verify that the `auto.home` map is available:

```bash
# ldapsearch -LLL -x -b "dc=mydom,dc=com" nisMapName=auto.home
```

In this example, the map is available. For details of how to make this map available, see Section 24.4.6, “Adding an Automount Map to LDAP”.

3. If the `auto.home` map is available, edit `/etc/auto.master` and create an entry that tells `autofs` where to find the `auto.home` map in LDAP, for example:

```bash
/nethome   ldap:nisMapName=auto.home,dc=mydom,dc=com
```

If you use LDAP over SSL, specify `ldaps:` instead of `ldap:`.

4. Edit `/etc/autofs_ldap_auth.conf` and configure the authentication settings for `autofs` with LDAP, for example:
This example assumes that Kerberos authentication with the LDAP server uses TLS for the connection. The principal for the client system must exist in the Kerberos database. You can use the `klist -k` command to verify this. If the principal for the client does not exist, use `kadmin` to add the principal.

5. If you use Kerberos Authentication, use `kadmin` to add a principal for the LDAP service on the LDAP server, for example:

```
# kadmin -q "addprinc ldap/ldap.mydom.com@MYDOM.COM
```

6. Restart the `autofs` service, and configure the service to start following a system reboot:

```
# systemctl restart autofs
# systemctl enable autofs
```

The `autofs` service creates the directory `nethome`. When a user logs in, the automounter mounts his or her home directory under `nethome`.

If the owner and group for the user's files are unexpectedly listed as the anonymous user or group (`nobody` or `nogroup`) and `all_squash` has not been specified as a mount option, verify that the Domain setting in `/etc/idmapd.conf` on the NFS server is set to the DNS domain name. Restart the NFS services on the NFS server if you change this file.

For more information, see the `auto.master(5)` and `autofs_ldap_auth.conf(5)` manual pages.

### 24.5 About NIS Authentication

NIS stores administrative information such as user names, passwords, and host names on a centralized server. Client systems on the network can access this common data. This configuration allows to move from machine to machine without having to remember different passwords and copy data from one machine to another. Storing administrative information centrally, and providing a means of accessing it from networked systems, also ensures the consistency of that data. NIS also reduces the overhead of maintaining administration files such as `/etc/passwd` on each system.

A network of NIS systems is an **NIS domain**. Each system within the domain has the same NIS domain name, which is different from a DNS domain name. The DNS domain is used throughout the Internet to refer to a group of systems. an NIS domain is used to identify systems that use files on an NIS server. an NIS domain must have exactly one master server but can have multiple slave servers.

#### 24.5.1 About NIS Maps

The administrative files within an NIS domain are NIS maps, which are `dbm`-format files that you generate from existing configuration files such as `/etc/passwd`, `/etc/shadow`, and `/etc/groups`. Each map is indexed on one field, and records are retrieved by specifying a value from that field. Some source files such as `/etc/passwd` have two maps:

- `passwd.byname` Indexed on user name.
- `passwd.byuid` Indexed on user ID.
The `/var/yp/nicknames` file contains a list of commonly used short names for maps such as `passwd` for `passwd.byname` and `group` for `group.byname`.

You can use the `ypcat` command to display the contents of an NIS map, for example:

```
# ypcat - passwd | grep 1500
guest:$6$gMIxsr3WjLahO...6EE6sdaFPl2m7/NEm0:1500:1500::/nethome/guest:/bin/bash
```

**Note**

As the `ypcat` command displays password hashes to any user, this example demonstrates that NIS authentication is inherently insecure against password-hash cracking programs. If you use Kerberos authentication, you can configure password hashes not to appear in NIS maps, although other information that `ypcat` displays could also be useful to an attacker.

For more information, see the `ypcat(1)` manual page.

### 24.5.2 Configuring an NIS Server

NIS master servers act as a central, authoritative repository for NIS information. NIS slave servers act as mirrors of this information. There must be only one NIS master server in an NIS domain. The number of NIS slave servers is optional, but creating at least one slave server provides a degree of redundancy should the master server be unavailable.

To configure an NIS master or slave server:

1. Install the `ypserv` package:
   ```
   # yum install ypserv
   ```

2. Edit `/etc/sysconfig/network` and add an entry to define the NIS domain, for example:
   ```
   NISDOMAIN=mynisd
   ```

3. Edit `/etc/ypserv.conf` to configure NIS options and to add rules for which hosts and domains can access which NIS maps.

   For example, the following entries allow access only to NIS clients in the `mynisd` domain on the 192.168.1 subnet:
   ```
   192.168.1.0/24: mynisd : * : none
   * : * : * : deny
   ```

   For more information, see the `ypserv.conf(5)` manual page and the comments in `/etc/ypserv.conf`.

4. Create the file `/var/yp/securenets` and add entries for the networks for which the server should respond to requests, for example:

   ```
   # cat > /var/yp/securenets <<<
   255.255.255.255 127.0.0.1
   255.255.255.0 192.168.1.0
   !
   # cat /var/yp/securenets
   255.255.255.255 127.0.0.1
   255.255.255.0 192.168.1.0
   ```

   In this example, the server accepts requests from the local loopback interface and the 192.168.1 subnet.
5. Edit `/var/yp/Makefile`:

   a. Set any required map options and specify which NIS maps to create using the `all` target, for example:

   ```
   all:
   passwd group auto.home
   hosts rpc services netid protocols mail \ 
   netgrp shadow publickey networks ethers bootparams printcap \ 
   amd.home auto.local. passwd.adjunct \ 
   timezone locale netmasks
   ```

   This example allows NIS to create maps for the `/etc/passwd`, `/etc/group`, and `/etc/auto.home` files. By default, the information from the `/etc/shadow` file is merged with the `passwd` maps, and the information from the `/etc/gshadow` file is merged with the `group` maps.

   For more information, see the comments in `/var/yp/Makefile`.

   b. If you intend to use Kerberos authentication instead of NIS authentication, change the values of `MERGE_PASSWD` and `MERGE_GROUP` to `false`:

   ```
   MERGE_PASSWD=false
   MERGE_GROUP=false
   ```

   Note
   These settings prevent password hashes from appearing in the NIS maps.

   c. If you configure any NIS slave servers in the domain, set the value of `NOPUSH` to `false`:

   ```
   NOPUSH=false
   ```

   If you update the maps, this setting allows the master server to automatically push the maps to the slave servers.

6. Configure the NIS services:

   a. Start the `ypserv` service and configure it to start after system reboots:

   ```
   systemctl start ypserv
   systemctl enable ypserv
   ```

   The `ypserv` service runs on the NIS master server and any slave servers.

   b. If the server will act as the master NIS server and there will be at least one slave NIS server, start the `ypxfrd` service and configure it to start after system reboots:

   ```
   systemctl start ypxfrd
   systemctl enable ypxfrd
   ```

   The `ypxfrd` service speeds up the distribution of very large NIS maps from an NIS master to any NIS slave servers. The service runs on the master server only, and not on any slave servers. You do not need to start this service if there are no slave servers.

   c. Start the `yppasswdd` service and configure it to start after system reboots:

   ```
   systemctl start yppasswdd
   systemctl enable yppasswdd
   ```
The `yppasswd` service allows NIS users to change their password in the `shadow` map. The service runs on the NIS master server and any slave servers.

7. Configure the firewall settings:

a. Edit `/etc/sysconfig/network` and add the following entries that define the ports on which the `ypserv` and `ypxfrd` services listen:

```bash
YPSERV_ARGS="-p 834"
YPXFRD_ARGS="-p 835"
```

These entries fix the ports on which `ypserv` and `ypxfrd` listen.

b. Allow incoming TCP connections to ports 111 and 834 and incoming UDP datagrams on ports 111 and 834:

```bash
# firewall-cmd --zone=zone --add-port=111/tcp --add-port=111/udp \
--add-port=834/tcp --add-port=834/udp
# firewall-cmd --permanent --zone=zone --add-port=111/tcp --add-port=111/udp \
--add-port=834/tcp --add-port=834/udp
```

`portmapper` services requests on TCP port 111 and UDP port 111, and `ypserv` services requests on TCP port 834 and UDP port 834.

c. On the master server, if you run the `ypxfrd` service to support transfers to slave servers, allow incoming TCP connections to port 835 and incoming UDP datagrams on port 835:

```bash
# firewall-cmd --zone=zone --add-port=835/tcp --add-port=835/udp
# firewall-cmd --permanent --zone=zone --add-port=835/tcp --add-port=835/udp
```

d. Allow incoming UDP datagrams on the port on which `yppasswd` listens:

```bash
# firewall-cmd --zone=zone \ 
--add-port=`rpcinfo -p | gawk '/yppasswdd/ {print $4}'`/udp
```

**Note**

Do not make this rule permanent. The UDP port number that `yppasswd` uses is different every time that it restarts.

e. Edit `/etc/rc.local` and add the following line:

```bash
firewall-cmd --zone=zone \ 
--add-port=`rpcinfo -p | gawk '/yppasswdd/ {print $4}'`/udp
```

This entry creates a firewall rule for the `yppasswd` service when the system reboots. If you restart `yppasswd`, you must correct the firewall rules manually unless you modify the `/etc/init.d/yppasswd` script.

8. After you have started all the servers, create the NIS maps on the master NIS server:

```bash
# /usr/lib64/yp/ypinit -m
At this point, we have to construct a list of the hosts which will run NIS servers. `nismaster` is in the list of NIS server hosts. Please continue to add the names for the other hosts, one per line. When you are done with the list, type a `<control D>`."
  next host to add: nismaster
  next host to add: nisslave1
  next host to add: nisslave2
```
Adding User Accounts to NIS

next host to add: ^D

The current list of NIS servers looks like this:

nismaster
nisslave1
nisslave2

Is this correct? [y/n: y] y
We need a few minutes to build the databases...
...
localhost has been set up as a NIS master server.

Now you can run ypinit -s nismaster on all slave server.

Enter the host names of the NIS slave servers (if any), type Ctrl-D to finish, and enter y to confirm the list of NIS servers. The host names must be resolvable to IP addresses in DNS or by entries in /etc/hosts.

The ypinit utility builds the domain subdirectory in /var/yp and makes the NIS maps that are defined for the all target in /var/yp/Makefile. If you have configured NOPUSH=false in /var/yp/Makefile and the names of the slave servers in /var/yp/ypservers, the command also pushes the updated maps to the slave servers.

9. On each NIS slave server, run the following command to initialize the server:

```bash
#/usr/lib64/yp/ypinit -s nismaster
```

where nismaster is the host name or IP address of the NIS master server.

For more information, see the ypinit(8) manual page

Note

If you update any of the source files on the master NIS server that are used to build the maps, use the following command on the master NIS server to remake the map and push the changes out to the slave servers:

```bash
# make -C /var/yp
```

24.5.3 Adding User Accounts to NIS

Note

This procedure assumes that:

- NIS provides maps for `passwd`, `group`, and `auto.home`.
- The NIS master server uses NFS to export the users' home directories. See Section 22.2.2, “Mounting an NFS File System”

Warning

NIS authentication is deprecated as it has security issues, including a lack of protection of authentication data.

To create an account for an NIS user on the NIS master server:

1. If the NIS master server does not already export the base directory of the users' home directories, perform the following steps on the NIS master server:
Adding User Accounts to NIS

a. Create the base directory for user directories, for example /nethome:

```
# mkdir /nethome
```

b. Add an entry such as the following to /etc/exports:

```
/nethome    *(rw,sync)
```

You might prefer to restrict which clients can mount the file system. For example, the following entry allows only clients in the 192.168.1.0/24 subnet to mount /nethome:

```
/nethome    192.168.1.0/24(rw,sync)
```

c. Use the following command to export the file system:

```
# exportfs -i -o ro,sync *:/nethome
```

d. If you have configured /var/yp/Makfile to make the auto.home map available to NIS clients, create the following entry in /etc/auto.home:

```
*    -rw,sync    nissvr:/nethome/
```

where nissvr is the host name or IP address of the NIS server.

2. Create the user account:

```
# useradd -b /nethome username
```

The command updates the /etc/passwd file and creates a home directory on the NIS server.

3. Depending on the type of authentication that you have configured:

   - For Kerberos authentication, on the Kerberos server or a client system with kadmin access, use kadmin to create a principal for the user in the Kerberos domain, for example:

```
# kadmin -q "addprinc username@KRBDOMAIN"
```

The command prompts you to set a password for the user, and adds the principal to the Kerberos database.

   - For NIS authentication, use the passwd command:

```
# passwd username
```

The command updates the /etc/shadow file with the hashed password.

4. Update the NIS maps:

```
# make -C /var/yp
```

This command makes the NIS maps that are defined for the all target in /var/yp/Makefile. If you have configured NOPUSH=false in /var/yp/Makefile and the names of the slave servers in /var/yp/ypservers, the command also pushes the updated maps to the slave servers.

**Note**

A Kerberos-authenticated user can use either kpasswd or passwd to change his or her password. An NIS-authenticated user must use the yppasswd command rather than passwd to change his or her password.
Enabling NIS Authentication

24.5.4 Enabling NIS Authentication

To enable NIS authentication for an NIS client by using the Authentication Configuration GUI:

1. Install the `yp-tools` and `ypbind` packages:

   ```
   # yum install yp-tools ypbind
   ```

2. Run the Authentication Configuration GUI:

   ```
   # system-config-authentication
   ```

3. Select NIS as the user account database and enter values for:

   - **NIS Domain**: The name of the NIS domain. For example: `mynisdom`.
   - **NIS Server**: The domain name or IP address of the NIS server. For example, `nissvr.mydom.com`.

4. Select either **Kerberos password** or **NIS password** for authentication.

5. If you select Kerberos authentication, enter values for:

   - **Realm**: The name of the Kerberos realm.
   - **KDCs**: A comma-separated list of Key Distribution Center (KDC) servers that can issue Kerberos ticket granting tickets and service tickets.
   - **Admin Servers**: A comma-separated list of Kerberos administration servers.

   Alternatively, you can use DNS to configure these settings:

   - Select the **Use DNS to resolve hosts to realms** check box to look up the name of the realm defined as a `TXT` record in DNS, for example:

     ```
     _kerberos.mydom.com IN TXT "MYDOM.COM"
     ```

   - Select the **Use DNS to locate KDCs for realms** check box to look up the KDCs and administration servers defined as `SVR` records in DNS, for example:

     ```
     _kerberos._tcp.mydom.com IN SVR 1 0 88 krbsvr.mydom.com
     _kerberos._udp.mydom.com IN SVR 1 0 88 krbsvr.mydom.com
     _kpasswd._udp.mydom.com IN SVR 1 0 464 krbsvr.mydom.com
     _kerberos-adm._tcp.mydom.com IN SVR 1 0 749 krbsvr.mydom.com
     ```

6. Click **Apply** to save your changes.

**Warning**

NIS authentication is deprecated as it has security issues, including a lack of protection of authentication data.

Figure 24.4 shows the Authentication Configuration GUI with NIS selected as the user account database and Kerberos selected for authentication.
Enabling NIS Authentication

**Figure 24.4 Authentication Configuration of NIS with Kerberos Authentication**

You can also enable and configure NIS or Kerberos authentication by using the `authconfig` command.

For example, to use NIS authentication, specify the `--enablenis` option together with the NIS domain name and the host name or IP address of the master server, as shown in the following example:

```
# authconfig --enablenis --nisdomain mynisdom --nisserver nissvr.mydom.com --update
```

The `--enablenis` option configures `/etc/nsswitch.conf` to enable the system to use NIS for information services. The `--nisdomain` and `--nisserver` settings are added to `/etc/yp.conf`.

For more information, see the `authconfig(8)`, `nsswitch.conf(5)`, and `yp.conf(5)` manual pages.
About Kerberos Authentication

For information about using Kerberos authentication with NIS, see Section 24.6.3, “Enabling Kerberos Authentication”.

24.5.4.1 Configuring an NIS Client to Use Automount Maps

If you have configured an automount map for `auto.home` in NIS, you can configure an NIS client to mount the users’ home directories when they log in.

To configure an NIS client to automount users’ home directories:

1. Install the `autofs` package:

```
# yum install autofs
```

2. Create an `/etc/auto.master` file that contains the following entry:

```
/nethome /etc/auto.home
```

3. Verify that the `auto.home` map is available:

```
# ypcat -k auto.home
* -rw,sync nfssvr:/nethome/
```

In this example, the map is available. For details of how to make this map available, see Section 24.5.3, “Adding User Accounts to NIS”.

4. If the `auto.home` map is available, edit the file `/etc/auto.home` to contain the following entry:

```
+auto.home
```

This entry causes the automounter to use the `auto.home` map.

5. Restart the `autofs` service, and configure the service to start following a system reboot:

```
# systemctl restart autofs
# systemctl enable autofs
```

The `autofs` service creates the directory `/nethome`. When a user logs in, the automounter mounts his or her home directory under `/nethome`.

If the owner and group for the user’s files are unexpectedly listed as the anonymous user or group (`nobody` or `nogroup`) and `all_squash` has not been specified as a mount option, verify that the `Domain` setting in `/etc/idmapd.conf` on the NFS server is set to the DNS domain name. Restart the NFS services on the NFS server if you change this file.

24.6 About Kerberos Authentication

Both LDAP and NIS authentication optionally support Kerberos authentication. In the case of IPA, Kerberos is fully integrated. Kerberos provides a secure connection over standard ports, and it also allows offline logins if you enable credential caching in SSSD.

Figure 24.5 illustrates how a Kerberos Key Distribution Center (KDC) authenticates a principal, which can be a user or a host, and grants a Ticket Granting Ticket (TGT) that the principal can use to gain access to a service.
Figure 24.5 Kerberos Authentication

The steps in the process are:

1. A principal name and key are specified to the client.

2. The client sends the principal name and a request for a TGT to the KDC.

   The KDC generates a session key and a TGT that contains a copy of the session key, and uses the Ticket Granting Service (TGS) key to encrypt the TGT. It then uses the principal's key to encrypt both the already encrypted TGT and another copy of the session key.

3. The KDC sends the encrypted combination of the session key and the encrypted TGT to the client.

   The client uses the principal's key to extract the session key and the encrypted TGT.
4. When the client wants to use a service, usually to obtain access to a local or remote host system, it uses the session key to encrypt a copy of the encrypted TGT, the client's IP address, a time stamp, and a service ticket request, and it sends this item to the KDC.

The KDC uses its copies of the session key and the TGS key to extract the TGT, IP address, and time stamp, which allow it to validate the client. Provided that both the client and its service request are valid, the KDC generates a service session key and a service ticket that contains the client's IP address, a time stamp, and a copy of the service session key, and it uses the service key to encrypt the service ticket. It then uses the session key to encrypt both the service ticket and another copy of the service session key.

The service key is usually the host principal's key for the system on which the service provider runs.

5. The KDC sends the encrypted combination of the service session key and the encrypted service ticket to the client.

The client uses its copy of the session key to extract the encrypted service ticket and the service session key.

6. The client sends the encrypted service ticket to the service provider together with the principal name and a time stamp encrypted with the service session key.

The service provider uses the service key to extract the data in the service session ticket, including the service session key.

7. The service provider enables the service for the client, which is usually to grant access to its host system.

If the client and service provider are hosted on different systems, they can each use their own copy of the service session key to secure network communication for the service session.

Note the following points about the authentication handshake:

- Steps 1 through 3 correspond to using the `kinit` command to obtain and cache a TGT.
- Steps 4 through 7 correspond to using a TGT to gain access to a Kerberos-aware service.
- Authentication relies on pre-shared keys.
- Keys are never sent in the clear over any communications channel between the client, the KDC, and the service provider.
- At the start of the authentication process, the client and the KDC share the principal's key, and the KDC and the service provider share the service key. Neither the principal nor the service provider know the TGS key.
- At the end of the process, both the client and the service provider share a service session key that they can use to secure the service session. The client does not know the service key and the service provider does not know the principal's key.
- The client can use the TGT to request access to other service providers for the lifetime of the ticket, which is usually one day. The session manager renews the TGT if it expires while the session is active.

### 24.6.1 Configuring a Kerberos Server

If you want to configure any client systems to use Kerberos authentication, it is recommended that you first configure a Kerberos server. You can then configure any clients that you require.
To configure a Kerberos server that can act as a key distribution center (KDC) and a Kerberos administration server:

1. Configure the server to use DNS and that both direct and reverse name lookups of the server's domain name and IP address work.

   For more information about configuring DNS, see Chapter 12, *Name Service Configuration*.

2. Configure the server to use network time synchronization mechanism such as the Network Time Protocol (NTP), Precision Time Protocol (PTP), or chrony. Kerberos requires that the system time on Kerberos servers and clients are synchronized as closely as possible. If the system times of the server and a client differ by more than 300 seconds (by default), authentication fails.

   For more information, see Chapter 13, *Network Time Configuration*.

3. Install the `krb5-libs`, `krb5-server`, and `krb5-workstation` packages:

   ```
   # yum install krb5-libs krb5-server krb5-workstation
   ```

4. Edit `/etc/krb5.conf` and configure settings for the Kerberos realm, for example:

   ```
   [logging]
   default = FILE:/var/log/krb5libs.log
   kdc = FILE:/var/log/krb5kdc.log
   admin_server = FILE:/var/log/kadmind.log

   [libdefaults]
   default_realm = MYDOM.COM
   dns_lookup_realm = false
   dns_lookup_kdc = false
   ticket_lifetime = 24h
   renew_lifetime = 7d
   forwardable = true

   [realms]
   MYDOM.COM = {
   kdc = krbsvr.mydom.com
   admin_server = krbsvr.mydom.com
   }

   [domain_realm]
   .mydom.com = MYDOM.COM
   mydom.com = MYDOM.COM

   [appdefaults]
   pam = {
       debug = true
       validate = false
   }
   ```

   In this example, the Kerberos realm is `MYDOM.COM` in the DNS domain mydom.com and `krbsvr.mydom.com` (the local system) acts as both a KDC and an administration server. The `[appdefaults]` section configures options for the `pam_krb5.so` module.

   For more information, see the `krb5.conf(5)` and `pam_krb5(5)` manual pages.
5. Edit `/var/kerberos/krb5kdc/kdc.conf` and configure settings for the key distribution center, for example:

```
[kdcdefaults]
  kdc_ports = 88
  kdc_tcp_ports = 88

[realms]
MYDOM.COM = {
  #master_key_type = aes256-cts
  master_key_type = des-hmac-sha1
  default_principal_flags = +preauth
  acl_file = /var/kerberos/krb5kdc/kadm5.acl
  dict_file = /usr/share/dict/words
  admin_keytab = /etc/kadm5.keytab
  supported_enctypes = aes256-cts:normal aes128-cts:normal des3-hmac-sha1:normal \ 
}
```

For more information, see the `kdc.conf(5)` manual page.

6. Create the Kerberos database and store the database password in a stash file:

```
# /usr/sbin/kdb5_util create -s
```

7. Edit `/var/kerberos/krb5kdc/kadm5.acl` and define the principals who have administrative access to the Kerberos database, for example:

```
*/admin@EXAMPLE.COM     *
```

In this example, any principal who has an instance of admin, such as alice/admin@MYDOM.COM, has full administrative control of the Kerberos database for the MYDOM.COM domain. Ordinary users in the database usually have an empty instance, for example bob@MYDOM.COM. These users have no administrative control other than being able to change their password, which is stored in the database.

8. Create a principal for each user who should have the admin instance, for example:

```
# kadmin.local -q "addprinc alice/admin"
```

9. Cache the keys that kadmind uses to decrypt administration Kerberos tickets in `/etc/kadm5.keytab`:

```
# kadmin.local -q "ktadd -k /etc/kadm5.keytab kadmin/admin"
# kadmin.local -q "ktadd -k /etc/kadm5.keytab kadmin/changepw"
```

10. Start the KDC and administration services and configure them to start following system reboots:

```
# systemctl start krb5kdc
# systemctl start kadmin
# systemctl enable krb5kdc
# systemctl enable kadmin
```

11. Add principals for users and the Kerberos server and cache the key for the server's host principal in `/etc/kadm5.keytab` by using either kadmin.local or kadmin, for example:

```
# kadmin.local -q "addprinc bob"
# kadmin.local -q "addprinc -randkey host/krbsvr.mydom.com"
# kadmin.local -q "ktadd -k /etc/kadm5.keytab host/krbsvr.mydom.com"
```

12. Allow incoming TCP connections to ports 88, 464, and 749 and UDP datagrams on UDP port 88, 464, and 749:

```
# firewall-cmd --zone=zone --add-port=88/tcp --add-port=88/udp \
```
Configuring a Kerberos Client

```
--add-port=464/tcp --add-port=464/udp \
--add-port=749/tcp --add-port=749/udp
# firewall-cmd --permanent --zone=zone \
--add-port=88/tcp --add-port=88/udp \
--add-port=464/tcp --add-port=464/udp \
--add-port=749/tcp --add-port=749/udp
```

The `krb5kdc` service requests access on TCP port 88 and UDP port 88, and `kadmind` services requests on TCP ports 464 and 749 and UDP ports 464 and 749.

In addition, you might need to allow TCP and UDP access on different ports for other applications.

For more information, see the `kadmin(1)` manual page.

### 24.6.2 Configuring a Kerberos Client

Setting up a Kerberos client on a system allows it to use Kerberos to authenticate users who are defined in NIS or LDAP, and to provide secure remote access by using commands such as `ssh` with GSS-API enabled or the Kerberos implementation of `telnet`.

To set up a system as a Kerberos client:

1. Configure the client system to use DNS and that both direct and reverse name lookups of the domain name and IP address for both the client and the Kerberos server work.

   For more information about configuring DNS, see Chapter 12, Name Service Configuration.

2. Configure the system to use a network time synchronization protocol such as the Network Time Protocol (NTP). Kerberos requires that the system time on Kerberos servers and clients are synchronized as closely as possible. If the system times of the server and a client differ by more than 300 seconds (by default), authentication fails.

To configure the server as an NTP client:

   a. Install the `ntp` package:

```
# yum install ntp
```

   b. Edit `/etc/ntp.conf` and configure the settings as required. See the `ntp.conf(5)` manual page and [http://www.ntp.org](http://www.ntp.org).

   c. Start the `ntpd` service and configure it to start following system reboots.

```
# systemctl start ntpd
# systemctl enable ntpd
```

3. Install the `krb5-libs` and `krb5-workstation` packages:

```
# yum install krb5-libs krb5-workstation
```

4. Copy the `/etc/krb5.conf` file to the system from the Kerberos server.

5. Use the Authentication Configuration GUI or `authconfig` to set up the system to use Kerberos with either NIS or LDAP, for example:

```
# authconfig --enablenis --enablekrb5 --krb5realm=MYDOM.COM \
--krb5adminserver=krbsvr.mydom.com --krb5kdc=krbsvr.mydom.com \
--update
```

See Section 24.6.3, “Enabling Kerberos Authentication”.
6. On the Kerberos KDC, use either `kadmin` or `kadmin.local` to add a host principal for the client, for example:

```bash
# kadmin.local -q "addprinc -randkey host/client.mydom.com"
```

7. On the client system, use `kadmin` to cache the key for its host principal in `/etc/kadm5.keytab`, for example:

```bash
# kadmin -q "ktadd -k /etc/kadm5.keytab host/client.mydom.com"
```

8. To use `ssh` and related OpenSSH commands to connect from Kerberos client system to another Kerberos client system:

a. On the remote Kerberos client system, verify that `GSSAPIAuthentication` is enabled in `/etc/ssh/sshd_config`:

   ```bash
gssapiAuthentication yes
   ```

b. On the local Kerberos client system, enable `GSSAPIAuthentication` and `GSSAPIDelegateCredentials` in the user's `.ssh/config` file:

   ```bash
gssapiAuthentication yes
gssapidelegateCredentials yes
   ```

   Alternatively, the user can specify the `-K` option to `ssh`.

c. Test that the principal can obtain a ticket and connect to the remote system, for example:

   ```bash
   $ kinit principal_name@MYDOM.COM
   $ ssh username@remote.mydom.com
   ```

   To allow use of the Kerberos versions of `rlogin`, `rsh`, and `telnet`, which are provided in the `krb5-appl-clients` package, you must enable the corresponding services on the remote client.

   For more information, see the `kadmin(1)` manual page.

### 24.6.3 Enabling Kerberos Authentication

To be able to use Kerberos authentication with an LDAP or NIS client, use `yum` to install the `krb5-libs` and `krb5-workstation` packages.

If you use the Authentication Configuration GUI (``system-config-authentication``) and select LDAP or NIS as the user account database, select Kerberos password as the authentication method and enter values for:

- **Realm**
  - The name of the Kerberos realm.

- **KDCs**
  - A comma-separated list of Key Distribution Center (KDC) servers that can issue Kerberos ticket granting tickets and service tickets.

- **Admin Servers**
  - A comma-separated list of Kerberos administration servers.

Alternatively, you can use DNS to configure these settings:

- Select the **Use DNS to resolve hosts to realms** check box to look up the name of the realm defined as a `TXT` record in DNS, for example:

  ```
  _kerberos.mydom.com IN TXT "MYDOM.COM"
  ```

- Select the **Use DNS to locate KDCs for realms** check box to look up the KDCs and administration servers defined as `SRV` records in DNS, for example:
Enabling Kerberos Authentication

Figure 24.6 shows the Authentication Configuration GUI with LDAP selected as the user account database and Kerberos selected for authentication.

**Figure 24.6 Authentication Configuration of LDAP with Kerberos Authentication**

- \_kerberos\_tcp.mydom.com      IN SVR 1 0 88 krbsvr.mydom.com
- \_kerberos\_udp.mydom.com      IN SVR 1 0 88 krbsvr.mydom.com
- \_kpasswd\_udp.mydom.com       IN SVR 1 0 464 krbsvr.mydom.com
- \_kerberos\_adm\_tcp.mydom.com IN SVR 1 0 749 krbsvr.mydom.com
Alternatively, you can use the `authconfig` command to configure Kerberos authentication with LDAP, for example:

```
# authconfig --enableldap \
   --ldapbasedn="dc=mydom,dc=com" --ldapserver=ldap://ldap.mydom.com:389 \
   [--enableldaptls --ldaploadcacert=https://ca-server.mydom.com/CAcert.pem] \
   --krb5realm=MYDOM.COM | --enablekrb5realmdns \
   --krb5kdc=krbsvr.mydom.com --krb5adminserver=krbsvr.mydom.com | --enablekrb5kdcdns \
   --update
```

or with NIS:

```
# authconfig --enablenis \
   --enablekrb5 \
   --krb5realm=MYDOM.COM | --enablekrb5realmdns \
   --krb5kdc=krbsvr.mydom.com --krb5adminserver=krbsvr.mydom.com | --enablekrb5kdcdns \
   --update
```

The `--enablekrb5` option enables Kerberos authentication by modifying the PAM configuration files in `/etc/pam.d` to use the `pam_krb5.so` module. The `--enableldap` and `--enablenis` options configure `/etc/nsswitch.conf` to enable the system to use LDAP or NIS for information services.

For more information, see the `authconfig(8)`, `nsswitch.conf(5)`, and `pam_krb5(5)` manual pages.

### 24.7 About Pluggable Authentication Modules

The Pluggable Authentication Modules (PAM) feature is an authentication mechanism that allows you to configure how applications use authentication to verify the identity of a user. The PAM configuration files, which are located in the `/etc/pam.d` directory, describe the authentication procedure for an application. The name of each configuration file is the same as, or is similar to, the name of the application for which the module provides authentication. For example, the configuration files for `passwd` and `sudo` are named `passwd` and `sudo`.

Each PAM configuration file contains a list (stack) of calls to authentication modules. For example, the following listing shows the default content of the `login` configuration file:

```
#PAM-1.0
auth [user_unknown=ignore success-ok ignore=ignore default=bad] pam_securetty.so
auth include system-auth
auth include postlogin
account required pam_nologin.so
account include system-auth
password include system-auth
# pam_selinux.so close should be the first session rule
session required pam_selinux.so close
session required pam_logind.so
session optional pam_console.so
# pam_selinux.so open should only be followed by sessions to be executed in the user context
session required pam_selinux.so open
session required pam_namespace.so
session optional pam_keyinit.so force revoke
session include system-auth
session include postlogin
-sesstion optional pam_ck_connector.so
```

Comments in the file start with a `#` character. The remaining lines each define an operation type, a control flag, the name of a module such as `pam_rootok.so` or the name of an included configuration file such as `system-auth`, and any arguments to the module. PAM provides authentication modules as shared libraries in `/usr/lib64/security`.
For a particular operation type, PAM reads the stack from top to bottom and calls the modules listed in the configuration file. Each module generates a success or failure result when called.

The following operation types are defined for use:

- **auth**: The module tests whether a user is authenticated or authorized to use a service or application. For example, the module might request and verify a password. Such modules can also set credentials, such as a group membership or a Kerberos ticket.

- **account**: The module tests whether an authenticated user is allowed access to a service or application. For example, the module might check if a user account has expired or if a user is allowed to use a service at a given time.

- **password**: The module handles updates to an authentication token.

- **session**: The module configures and manages user sessions, performing tasks such as mounting or unmounting a user’s home directory.

If the operation type is preceded with a dash (-), PAM does not add an create a system log entry if the module is missing.

With the exception of **include**, the control flags tell PAM what to do with the result of running a module. The following control flags are defined for use:

- **optional**: The module is required for authentication if it is the only module listed for a service.

- **required**: The module must succeed for access to be granted. PAM continues to execute the remaining modules in the stack whether the module succeeds or fails. PAM does not immediately inform the user of the failure.

- **requisite**: The module must succeed for access to be granted. If the module succeeds, PAM continues to execute the remaining modules in the stack. However, if the module fails, PAM notifies the user immediately and does not continue to execute the remaining modules in the stack.

- **sufficient**: If the module succeeds, PAM does not process any remaining modules of the same operation type. If the module fails, PAM processes the remaining modules of the same operation type to determine overall success or failure.

The control flag field can also define one or more rules that specify the action that PAM should take depending on the value that a module returns. Each rule takes the form `value=action`, and the rules are enclosed in square brackets, for example:

```
[user_unknown=ignore success=ok ignore=ignore default=bad]
```

If the result returned by a module matches a value, PAM uses the corresponding action, or, if there is no match, it uses the default action.

The **include** flag specifies that PAM must also consult the PAM configuration file specified as the argument.

Most authentication modules and PAM configuration files have their own manual pages. In addition, the `/usr/share/doc/pam-version` directory contains the PAM System Administrator's Guide (html/Linux-PAM_SAG.html or Linux-PAM_SAG.txt) and a copy of the PAM standard (rfc86.0.txt).
For more information, see the `pam(8)` manual page. In addition, each PAM module has its own manual page, for example `pam_unix(8)`, `postlogin(5)`, and `system-auth(5)`.

24.8 About the System Security Services Daemon

The System Security Services Daemon (SSSD) feature provides access on a client system to remote identity and authentication providers. The SSSD acts as an intermediary between local clients and any back-end provider that you configure.

The benefits of configuring SSSD include:

- **Reduced system load**
  Clients do not have to contact the identification or authentication servers directly.

- **Offline authentication**
  You can configure SSSD to maintain a cache of user identities and credentials.

- **Single sign-on access**
  If you configure SSSD to store network credentials, users need only authenticate once per session with the local system to access network resources.

For more information, see the `authconfig(8)`, `pam_sss(8)`, `sssd(8)`, and `sssd.conf(5)` manual pages and [https://fedorahosted.org/sssd/](https://fedorahosted.org/sssd/).

24.8.1 Configuring an SSSD Server

To configure an SSSD server:

1. Install the `sssd` and `sssd-client` packages:

   ```bash
   # yum install sssd sssd-client
   ```

2. Edit the `/etc/sssd/sssd.conf` configuration file and configure the sections to support the required services, for example:

   ```conf
   [sssd]
   config_file_version = 2
   domains = LDAP
   services = nss, pam

   [domain/LDAP]
   id_provider = ldap
   ldap_uri = ldap://ldap.mydom.com
   ldap_search_base = dc=mydom,dc=com
   auth_provider = krb5
   krb5_server = krbsvr.mydom.com
   krb5_realm = MYDOM.COM
   cache_credentials = true
   min_id = 5000
   max_id = 25000
   enumerate = false

   [nss]
   filter_groups = root
   filter_users = root
   reconnection_retries = 3
   entry_cache_timeout = 300
   ```
The [sssd] section contains configuration settings for SSSD monitor options, domains, and services. The SSSD monitor service manages the services that SSSD provides.

The services entry defines the supported services, which should include nss for the Name Service Switch and pam for Pluggable Authentication Modules.

The domains entry specifies the name of the sections that define authentication domains.

The [domain/LDAP] section defines a domain for an LDAP identity provider that uses Kerberos authentication. Each domain defines where user information is stored, the authentication method, and any configuration options. SSSD can work with LDAP identity providers such as OpenLDAP, Red Hat Directory Server, IPA, and Microsoft Active Directory, and it can use either native LDAP or Kerberos authentication.

The id_provider entry specifies the type of provider (in this example, LDAP). ldap_uri specifies a comma-separated list of the Universal Resource Identifiers (URIs) of the LDAP servers, in order of preference, to which SSSD can connect. ldap_search_base specifies the base distinguished name (dn) that SSSD should use when performing LDAP user operations on a relative distinguished name (RDN) such as a common name (cn).

The auth_provider entry specifies the authentication provider (in this example, Kerberos). krb5_server specifies a comma-separated list of Kerberos servers, in order of preference, to which SSSD can connect. krb5_realm specifies the Kerberos realm. cache_credentials specifies if SSSD caches user credentials such as tickets, session keys, and other identifying information to support offline authentication and single sign-on.

Note
To allow SSSD to use Kerberos authentication with an LDAP server, you must configure the LDAP server to use both Simple Authentication and Security Layer (SASL) and the Generic Security Services API (GSSAPI). For more information about configuring SASL and GSSAPI for OpenLDAP, see http://www.openldap.org/doc/admin24/sasl.html.

The min_id and max_id entries specify upper and lower limits on the values of user and group IDs. enumerate specifies whether SSSD caches the complete list of users and groups that are available on the provider. The recommended setting is False unless a domain contains relatively few users or groups.

The [nss] section configures the Name Service Switch (NSS) module that integrates the SSS database with NSS. The filter_users and filter_groups entries prevent NSS retrieving information about the specified users and groups being retrieved from SSS. reconnection_retries specifies the number of times that SSSD should attempt to reconnect if a data provider crashes. enum_cache_timeout specifies the number of seconds for which SSSD caches user information requests.

The [pam] section configures the PAM module that integrates SSS with PAM. The offline_credentials_expiration entry specifies the number of days for which to allow cached logins if the authentication provider is offline. offline_failed_login_attempts
specifies how many failed login attempts are allowed if the authentication provider is offline. \texttt{offline_failed_login_delay} specifies how many minutes after \texttt{offline_failed_login_attempts} failed login attempts that a new login attempt is permitted.

3. Change the mode of \texttt{/etc/sssd/sssd.conf} to 0600:

\begin{verbatim}
# chmod 0600 /etc/sssd/sssd.conf
\end{verbatim}

4. Enable the SSSD service:

\begin{verbatim}
# authconfig --update --enablesssd --enablesssdauth
\end{verbatim}

\textbf{Note}
If you edit \texttt{/etc/sssd/sssd.conf}, use this command to update the service.

The \texttt{--enablesssd} option updates \texttt{/etc/nsswitch.conf} to support SSS.

The \texttt{--enablesssdauth} option updates \texttt{/etc/pam.d/system-auth} to include the required \texttt{pam_sss.so} entries to support SSSD.

### 24.9 About Winbind Authentication

Winbind is a client-side service that resolves user and group information on a Windows server, and allows Oracle Linux to understand Windows users and groups. To be able to configure Winbind authentication, use \texttt{yum} to install the \texttt{samba-winbind} package. This package includes the \texttt{winbindd} daemon that implements the \texttt{winbind} service.

#### 24.9.1 Enabling Winbind Authentication

If you use the Authentication Configuration GUI and select Winbind as the user account database, you are prompted for the information that is required to connect to a Microsoft workgroup, Active Directory, or Windows NT domain controller. Enter the name of the Winbind domain and select the security model for the Samba server:

\begin{itemize}
  \item \texttt{ads}
    In the Activity Directory Server (ADS) security model, Samba acts as a domain member in an ADS realm, and clients use Kerberos tickets for Active Directory authentication. You must configure Kerberos and join the server to the domain, which creates a machine account for your server on the domain controller.
  \item \texttt{domain}
    In the domain security model, the local Samba server has a machine account (a domain security trust account) and Samba authenticates user names and passwords with a domain controller in a domain that implements Windows NT4 security.
  \item \texttt{server}
    In the server security model, the local Samba server authenticates user names and passwords with another server, such as a Windows NT server.
\end{itemize}

\textbf{Warning}
If the local machine acts as a Primary or Backup Domain Controller, do not use the domain security model. Use the user security model instead.
Enabling Winbind Authentication

Warning
The server security model is deprecated as it has numerous security issues.

user
In the user security model, a client must log in with a valid user name and password. This model supports encrypted passwords. If the server successfully validates the client's user name and password, the client can mount multiple shares without being required to specify a password.

Depending on the security model that you choose, you might also need to specify the following information:

- The name of the ADS realm that the Samba server is to join (ADS security model only).
- The names of the domain controllers. If there are several domain controllers, separate the names with spaces.
- The login template shell to use for the Windows NT user account (ADS and domain security models only).
- Whether to allow user authentication using information that has been cached by the System Security Services Daemon (SSSD) if the domain controllers are offline.

Your selection updates the security directive in the [global] section of the /etc/samba/smb.conf configuration file.

If you have initialized Kerberos, you can click **Join Domain** to create a machine account on the Active Directory server and grant permission for the Samba domain member server to join the domain.

You can also use the **authconfig** command to configure Winbind authentication. To use the user-level security models, specify the name of the domain or workgroup and the host names of the domain controllers. For example:

```
# authconfig --enablewinbind --enablewinbindauth --smbsecurity user \
  [--enablewinbindoffline] --smbservers="ad1.mydomain.com ad2.mydomain.com" \
  --smbworkgroup=MYDOMAIN --update
```

To allow user authentication using information that has been cached by the System Security Services Daemon (SSSD) if the domain controllers are offline, specify the **--enablewinbindoffline** option.

For the domain security model, additionally specify the template shell, for example:

```
# authconfig --enablewinbind --enablewinbindauth --smbsecurity domain \
  [--enablewinbindoffline] --smbservers="ad1.mydomain.com ad2.mydomain.com" \
  --smbworkgroup=MYDOMAIN --update --winbindtemplateshell=/bin/bash --update
```

For the ADS security model, additionally specify the ADS realm and template shell, for example:

```
# authconfig --enablewinbind --enablewinbindauth --smbsecurity ads \
  [--enablewinbindoffline] --smbservers="ad1.mydomain.com ad2.mydomain.com" \
  --smbworkgroup=MYDOMAIN --update --smbrealm MYDOMAIN.COM \
  --winbindtemplateshell=/bin/bash --update
```

For more information, see the **authconfig(8)** manual page.

25.8 Configuring Password Ageing ............................................................................. 336
25.9 Granting sudo Access to Users .......................................................................... 337

This chapter describes how to configure and manage local user and group accounts.

25.1 About User and Group Configuration

You can use the User Manager GUI (`system-config-users`) to add or delete users and groups and to modify settings such as passwords, home directories, login shells, and group membership. Alternatively, you can use commands such as `useradd` and `groupadd`.

Figure 25.1 shows the User Manager GUI with the Users tab selected.

Figure 25.1 User Manager
In an enterprise environment that might have hundreds of servers and thousands of users, user and group account information is more likely to be held in a central repository rather than in files on individual servers. You can configure user and group information on a central server and retrieve this information by using services such as Lightweight Directory Access Protocol (LDAP) or Network Information Service (NIS). You can also create users’ home directories on a central server and automatically mount, or access, these remote file systems when a user logs in to a system.

25.2 Changing Default Settings for User Accounts

To display the default settings for an account use the following command:

```
# useradd -D
GROUP=100
HOME=/home
INACTIVE=-1
EXPIRE=
SHELL=/bin/bash
SKEL=/etc/skel
CREATE_MAIL_SPOOL=yes
```

**INACTIVE** specifies after how many days the system locks an account if a user's password expires. If set to 0, the system locks the account immediately. If set to -1, the system does not lock the account.

**SKEL** defines a template directory, whose contents are copied to a newly created user's home directory. The contents of this directory should match the default shell defined by **SHELL**.

You can specify options to `useradd -D` to change the default settings for user accounts. For example, to change the defaults for **INACTIVE**, **HOME** and **SHELL**:

```
# useradd -D -f 3 -b /home2 -s /bin/sh
```

**Note**

If you change the default login shell, you would usually also create a new **SKEL** template directory with contents that are appropriate to the new shell.

If you specify `/sbin/nologin` for a user's **SHELL**, that user cannot log into the system directly but processes can run with that user's ID. This setting is typically used for services that run as users other than **root**.

The default settings are stored in the `/etc/default/useradd` file.

For more information, see Section 25.8, “Configuring Password Ageing” and the `useradd(8)` manual page.

25.3 Creating User Accounts

To create a user account by using the `useradd` command:

1. Enter the following command to create a user account:

```
# useradd [options] username
```

You can specify options to change the account’s settings from the default ones.

By default, if you specify a user name argument but do not specify any options, `useradd` creates a locked user account using the next available UID and assigns a user private group (UPG) rather than the value defined for **GROUP** as the user's group.
2. Assign a password to the account to unlock it:

```bash
# passwd username
```

The command prompts you to enter a password for the account.

If you want to change the password non-interactively (for example, from a script), use the `chpasswd` command instead:

```bash
echo "username:password" | chpasswd
```

Alternatively, you can use the `newusers` command to create a number of user accounts at the same time.

For more information, see the `chpasswd(8)`, `newusers(8)`, `passwd(1)`, and `useradd(8)` manual pages.

### 25.3.1 About umask and the setgid and Restricted Deletion Bits

Users whose primary group is not a UPG have a `umask` of 0022 set by `/etc/profile` or `/etc/bashrc`, which prevents other users, including other members of the primary group, from modifying any file that the user owns.

A user whose primary group is a UPG has a `umask` of 0002. It is assumed that no other user has the same group.

To grant users in the same group write access to files within the same directory, change the group ownership on the directory to the group, and set the `setgid` bit on the directory:

```bash
# chgrp groupname directory
# chmod g+s directory
```

Files created in such a directory have their group set to that of the directory rather than the primary group of the user who creates the file.

The restricted deletion bit prevents unprivileged users from removing or renaming a file in the directory unless they own either the file or the directory.

To set the restricted deletion bit on a directory:

```bash
# chmod a+t directory
```

For more information, see the `chmod(1)` manual page.

### 25.4 Locking an Account

To lock a user's account, enter:

```bash
# passwd -l username
```

To unlock the account:

```bash
# passwd -u username
```

For more information, see the `passwd(1)` manual page.

### 25.5 Modifying or Deleting User Accounts

To modify a user account, use the `usermod` command:
Creating Groups

For example, to add a user to a supplementary group (other than his or her login group):

```
# usermod -aG groupname username
```

You can use the `groups` command to display the groups to which a user belongs, for example:

```
# groups root
root : root bin daemon sys adm disk wheel
```

To delete a user's account, use the `userdel` command:

```
# userdel username
```

For more information, see the `groups(1)`, `userdel(8)` and `usermod(8)` manual pages.

25.6 Creating Groups

To create a group by using the `groupadd` command:

```
# groupadd [options] groupname
```

Typically, you might want to use the `-g` option to specify the group ID (GID). For example:

```
# groupadd -g 1000 devgrp
```

For more information, see the `groupadd(8)` manual page.

25.7 Modifying or Deleting Groups

To modify a group, use the `groupmod` command:

```
# groupmod [options] username
```

To delete a user's account, use the `groupdel` command:

```
# groupdel username
```

For more information, see the `groupdel(8)` and `groupmod(8)` manual pages.

25.8 Configuring Password Ageing

To specify how users' passwords are aged, edit the following settings in the `/etc/login.defs` file:

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PASS_MAX_DAYS</td>
<td>Maximum number of days for which a password can be used before it must be changed. The default value is 99,999 days.</td>
</tr>
<tr>
<td>PASS_MIN_DAYS</td>
<td>Minimum number of days that is allowed between password changes. The default value is 0 days.</td>
</tr>
<tr>
<td>PASS_WARN_AGE</td>
<td>Number of days warning that is given before a password expires. The default value is 7 days.</td>
</tr>
</tbody>
</table>

For more information, see the `login.defs(5)` manual page.

To change how long a user's account can be inactive before it is locked, use the `usermod` command. For example, to set the inactivity period to 30 days:
Granting sudo Access to Users

To change the default inactivity period for new user accounts, use the `useradd` command:

```
usermod -f 30 username
```

A value of -1 specifies that user accounts are not locked due to inactivity.

For more information, see the `useradd(8)` and `usermod(8)` manual pages.

## 25.9 Granting sudo Access to Users

By default, an Oracle Linux system is configured so that you cannot log in directly as `root`. You must log in as a named user before using either `su` or `sudo` to perform tasks as `root`. This configuration allows system accounting to trace the original login name of any user who performs a privileged administrative action. If you want to grant certain users authority to be able to perform specific administrative tasks via `sudo`, use the `visudo` command to modify the `/etc/sudoers` file.

For example, the following entry grants the user `erin` the same privileges as `root` when using `sudo`, but defines a limited set of privileges to `frank` so that he can run commands such as `systemctl`, `rpm`, and `yum`:

```
erin           ALL=(ALL)       ALL
frank          ALL= SERVICES, SOFTWARE
```

For more information, see the `su(1)`, `sudo(8)`, `sudoers(5)`, and `visudo(8)` manual pages.

   26.9.10 Configuring File System Mounts, File Permissions, and File Ownership .................................................. 371
   26.9.11 Checking User Accounts and Privileges ............................ 373

This chapter describes the subsystems that you can use to administer system security, including SELinux, the Netfilter firewall, TCP Wrappers, chroot jails, auditing, system logging, and process accounting.

26.1 About System Security

Oracle Linux provides a complete security stack, from network firewall control to access control security policies, and is designed to be secure by default.

Traditional Linux security is based on a Discretionary Access Control (DAC) policy, which provides minimal protection from broken software or from malware that is running as a normal user or as root. The SELinux enhancement to the Linux kernel implements the Mandatory Access Control (MAC) policy, which allows you to define a security policy that provides granular permissions for all users, programs, processes, files, and devices. The kernel's access control decisions are based on all the security relevant information available, and not solely on the authenticated user identity. By default, SELinux is enabled when you install an Oracle Linux system.
Oracle Linux has evolved into a secure enterprise-class operating system that can provide the performance, data integrity, and application uptime necessary for business-critical production environments.

Thousands of production systems at Oracle run Oracle Linux and numerous internal developers use it as their development platform. Oracle Linux is also at the heart of several Oracle engineered systems, including the Oracle Exadata Database Machine, Oracle Exalytics In-Memory Machine, Oracle Exalogic Elastic Cloud, and Oracle Database Appliance.

Oracle On Demand services, which deliver software as a service (SaaS) at a customer's site, via an Oracle data center, or at a partner site, use Oracle Linux at the foundation of their solution architectures. Backed by Oracle support, these mission-critical systems and deployments depend fundamentally on the built-in security and reliability features of the Oracle Linux operating system.

Released under an open-source license, Oracle Linux includes the Unbreakable Enterprise Kernel that provides the latest Linux innovations while offering tested performance and stability. Oracle has been a key participant in the Linux community, contributing code enhancements such as Oracle Cluster File System and the Btrfs file system. From a security perspective, having roots in open source is a significant advantage. The Linux community, which includes many experienced developers and security experts, reviews posted Linux code extensively prior to its testing and release. The open-source Linux community has supplied many security improvements over time, including access control lists (ACLs), cryptographic libraries, and trusted utilities.

### 26.2 Configuring and Using SELinux

Traditional Linux security is based on a Discretionary Access Control (DAC) policy, which provides minimal protection from broken software or from malware that is running as a normal user or as root. Access to files and devices is based solely on user identity and ownership. Malware or broken software can do anything with files and resources that the user that started the process can do. If the user is root or the application is setuid or setgid to root, the process can have root-access control over the entire file system.

The National Security Agency created Security Enhanced Linux (SELinux) to provide a finer-grained level of control over files, processes, users and applications in the Linux operating system. The SELinux enhancement to the Linux kernel implements the Mandatory Access Control (MAC) policy, which allows you to define a security policy that provides granular permissions for all users, programs, processes, files, and devices. The kernel's access control decisions are based on all the security relevant information available, and not solely on the authenticated user identity.

When security-relevant access occurs, such as when a process attempts to open a file, SELinux intercepts the operation in the kernel. If a MAC policy rule allows the operation, it continues; otherwise, SELinux blocks the operation and returns an error to the process. The kernel checks and enforces DAC policy rules before MAC rules, so it does not check SELinux policy rules if DAC rules have already denied access to a resource.

The following table describes the SELinux packages that are installed by default with Oracle Linux:

<table>
<thead>
<tr>
<th>Package</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>policycoreutils</td>
<td>Provides utilities such as load_policy, restorecon, secon, setfiles, semodule, sestatus, and setsebool for operating and managing SELinux.</td>
</tr>
<tr>
<td>libselinux</td>
<td>Provides the API that SELinux applications use to get and set process and file security contexts, and to obtain security policy decisions.</td>
</tr>
<tr>
<td>selinux-policy</td>
<td>Provides the SELinux Reference Policy, which is used as the basis for other policies, such as the SELinux targeted policy.</td>
</tr>
</tbody>
</table>
### About SELinux Administration

The following table describes the utilities that you can use to administer SELinux, and the packages that contain each utility.

<table>
<thead>
<tr>
<th>Utility</th>
<th>Package</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>audit2allow</td>
<td>policycoreutils-python</td>
<td>Generates SELinux policy <code>allow_audit</code> rules from logs of denied operations.</td>
</tr>
<tr>
<td>audit2why</td>
<td>policycoreutils-python</td>
<td>Generates SELinux policy <code>don’t_audit</code> rules from logs of denied operations.</td>
</tr>
<tr>
<td>avcstat</td>
<td>libselinux-utils</td>
<td>Displays statistics for the SELinux Access Vector Cache (AVC).</td>
</tr>
<tr>
<td>chcat</td>
<td>policycoreutils-python</td>
<td>Changes or removes the security category for a file or user.</td>
</tr>
<tr>
<td>findcon</td>
<td>setools-console</td>
<td>Searches for file context.</td>
</tr>
</tbody>
</table>

---

The following table describes a selection of useful SELinux packages that are not installed by default:

<table>
<thead>
<tr>
<th>Package</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mcstrans</td>
<td>Translates SELinux levels, such as <code>s0-s0:c0.c1023</code>, to an easier-to-read form, such as <code>SystemLow-SystemHigh</code>.</td>
</tr>
<tr>
<td>policycoreutils-gui</td>
<td>Provides a GUI (<a href="#">system-config-selinux</a>) that you can use to manage SELinux. For example, you can use the GUI to set the system default enforcing mode and policy type.</td>
</tr>
<tr>
<td>policycoreutils-python</td>
<td>Provides additional Python utilities for operating SELinux, such as <code>audit2allow</code>, <code>audit2why</code>, <code>chcat</code>, and <code>semanage</code>.</td>
</tr>
<tr>
<td>selinux-policy-mls</td>
<td>Provides support for the strict Multilevel Security (MLS) policy as an alternative to the SELinux targeted policy.</td>
</tr>
<tr>
<td>setroubleshoot</td>
<td>Provides the GUI that allows you to view <code>setroubleshoot-server</code> messages using the <code>sealert</code> command.</td>
</tr>
<tr>
<td>setroubleshoot-server</td>
<td>Translates access-denial messages from SELinux into detailed descriptions that you can view on the command line using the <code>sealert</code> command.</td>
</tr>
<tr>
<td>setools-console</td>
<td>Provides the Tresys Technology SETools distribution of tools and libraries, which you can use to analyze and query policies, monitor and report audit logs, and manage file context.</td>
</tr>
</tbody>
</table>

Use `yum` or another suitable package manager to install the SELinux packages that you require on your system.

For more information about SELinux, refer to the [SELinux Project Wiki](#), the `selinux(8)` manual page, and the manual pages for the SELinux commands.

### 26.2.1 About SELinux Administration

The following table describes the utilities that you can use to administer SELinux, and the packages that contain each utility.

<table>
<thead>
<tr>
<th>Utility</th>
<th>Package</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>audit2allow</td>
<td>policycoreutils-python</td>
<td>Generates SELinux policy <code>allow_audit</code> rules from logs of denied operations.</td>
</tr>
<tr>
<td>audit2why</td>
<td>policycoreutils-python</td>
<td>Generates SELinux policy <code>don’t_audit</code> rules from logs of denied operations.</td>
</tr>
<tr>
<td>avcstat</td>
<td>libselinux-utils</td>
<td>Displays statistics for the SELinux Access Vector Cache (AVC).</td>
</tr>
<tr>
<td>chcat</td>
<td>policycoreutils-python</td>
<td>Changes or removes the security category for a file or user.</td>
</tr>
<tr>
<td>findcon</td>
<td>setools-console</td>
<td>Searches for file context.</td>
</tr>
<tr>
<td>Utility</td>
<td>Package</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>--------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>fixfiles</td>
<td>policycoreutils</td>
<td>Fixes the security context for file systems.</td>
</tr>
<tr>
<td>getenforce</td>
<td>libselinux-utils</td>
<td>Reports the current SELinux mode.</td>
</tr>
<tr>
<td>getsebool</td>
<td>libselinux-utils</td>
<td>Reports SELinux boolean values.</td>
</tr>
<tr>
<td>indexcon</td>
<td>setools-console</td>
<td>Indexes file context.</td>
</tr>
<tr>
<td>load_policy</td>
<td>policycoreutils</td>
<td>Loads a new SELinux policy into the kernel.</td>
</tr>
<tr>
<td>matchpathcon</td>
<td>libselinux-utils</td>
<td>Queries the system policy and displays the default security context that is associated with the file path.</td>
</tr>
<tr>
<td>replcon</td>
<td>setools-console</td>
<td>Replaces file context.</td>
</tr>
<tr>
<td>restorecon</td>
<td>policycoreutils</td>
<td>Resets the security context on one or more files.</td>
</tr>
<tr>
<td>restorecond</td>
<td>policycoreutils</td>
<td>Daemon that watches for file creation and sets the default file context.</td>
</tr>
<tr>
<td>sandbox</td>
<td>policycoreutils-python</td>
<td>Runs a command in an SELinux sandbox.</td>
</tr>
<tr>
<td>sealert</td>
<td>setroubleshoot-server,</td>
<td>Acts as the user interface to the setroubleshoot system, which diagnoses and explains SELinux AVC denials and provides recommendations on how to prevent such denials.</td>
</tr>
<tr>
<td></td>
<td>setroubleshoot</td>
<td></td>
</tr>
<tr>
<td>seaudit-report</td>
<td>setools-console</td>
<td>Reports from the SELinux audit log.</td>
</tr>
<tr>
<td>sechecker</td>
<td>setools-console</td>
<td>Checks SELinux policies.</td>
</tr>
<tr>
<td>secon</td>
<td>policycoreutils</td>
<td>Displays the SELinux context from a file, program, or user input.</td>
</tr>
<tr>
<td>sediff</td>
<td>setools-console</td>
<td>Compares SELinux polices.</td>
</tr>
<tr>
<td>seinfo</td>
<td>setools-console</td>
<td>Queries SELinux policies.</td>
</tr>
<tr>
<td>selinuxconlist</td>
<td>libselinux-utils</td>
<td>Displays all SELinux contexts that are reachable by a user.</td>
</tr>
<tr>
<td>selinuxdefcon</td>
<td>libselinux-utils</td>
<td>Displays the default SELinux context for a user.</td>
</tr>
<tr>
<td>selinuxenabled</td>
<td>libselinux-utils</td>
<td>Indicates whether SELinux is enabled.</td>
</tr>
<tr>
<td>semanage</td>
<td>policycoreutils-python</td>
<td>Manages SELinux policies.</td>
</tr>
<tr>
<td>semodule</td>
<td>policycoreutils</td>
<td>Manages SELinux policy modules.</td>
</tr>
<tr>
<td>semodule_deps</td>
<td>policycoreutils</td>
<td>Displays the dependencies between SELinux policy packages.</td>
</tr>
<tr>
<td>semodule_expand</td>
<td>policycoreutils</td>
<td>Expands a SELinux policy module package.</td>
</tr>
<tr>
<td>semodule_link</td>
<td>policycoreutils</td>
<td>Links SELinux policy module packages together.</td>
</tr>
<tr>
<td>semodule_package</td>
<td>policycoreutils</td>
<td>Creates a SELinux policy module package.</td>
</tr>
<tr>
<td>sesearch</td>
<td>setools-console</td>
<td>Queries SELinux policies.</td>
</tr>
<tr>
<td>sestatus</td>
<td>policycoreutils</td>
<td>Displays the SELinux mode and the SELinux policy that are in use.</td>
</tr>
<tr>
<td>setenforce</td>
<td>libselinux-utils</td>
<td>Modifies the SELinux mode.</td>
</tr>
<tr>
<td>setsebool</td>
<td>policycoreutils</td>
<td>Sets SELinux boolean values.</td>
</tr>
<tr>
<td>setfiles</td>
<td>policycoreutils</td>
<td>Sets the security context for one or more files.</td>
</tr>
</tbody>
</table>
26.2.2 About SELinux Modes

SELinux runs in one of three modes.

**Disabled**
- The kernel uses only DAC rules for access control. SELinux does not enforce any security policy because no policy is loaded into the kernel.

**Enforcing**
- The kernel denies access to users and programs unless permitted by SELinux security policy rules. All denial messages are logged as AVC (Access Vector Cache) denials. This is the default mode that enforces SELinux security policy.

**Permissive**
- The kernel does not enforce security policy rules but SELinux sends denial messages to a log file. This allows you to see what actions would have been denied if SELinux were running in enforcing mode. This mode is intended to used for diagnosing the behavior of SELinux.

26.2.3 Setting SELinux Modes

You can set the default and current SELinux mode in the Status view of the SELinux Administration GUI (`system-config-selinux`).

Alternatively, to display the current mode, use the `getenforce` command:

```
$ getenforce
Enforcing
```

To set the current mode to **Enforcing**, enter:

```
$ setenforce Enforcing
```

To set the current mode to **Permissive**, enter:

```
$ setenforce Permissive
```

The current value that you set for a mode using `setenforce` does not persist across reboots. To configure the default SELinux mode, edit the configuration file for SELinux, `/etc/selinux/config`, and set the value of the `SELINUX` directive to `disabled`, `enabled`, or `permissive`.

26.2.4 About SELinux Policies

An SELinux policy describes the access permissions for all users, programs, processes, and files, and for the devices upon which they act. You can configure SELinux to implement either Targeted Policy or Multilevel Security (MLS) Policy.

26.2.4.1 Targeted Policy

Applies access controls to a limited number of processes that are believed to be most likely to be the targets of an attack on the system. Targeted processes run in their own SELinux domain, known as a
About SELinux Policies

*confined domain*, which restricts access to files that an attacker could exploit. If SELinux detects that a targeted process is trying to access resources outside the confined domain, it denies access to those resources and logs the denial. Only specific services run in confined domains. Examples are services that listen on a network for client requests, such as `httpd`, `named`, and `sshd`, and processes that run as `root` to perform tasks on behalf of users, such as `passwd`. Other processes, including most user processes, run in an unconfined domain where only DAC rules apply. If an attack compromises an unconfined process, SELinux does not prevent access to system resources and data.

The following table lists examples of SELinux domains.

<table>
<thead>
<tr>
<th>Domain</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>init_t</code></td>
<td>systemd</td>
</tr>
<tr>
<td><code>httpd_t</code></td>
<td>HTTP daemon threads</td>
</tr>
<tr>
<td><code>kernel_t</code></td>
<td>Kernel threads</td>
</tr>
<tr>
<td><code>syslogd_t</code></td>
<td><code>journald</code> and <code>rsyslogd</code> logging daemons</td>
</tr>
<tr>
<td><code>unconfined_t</code></td>
<td>Processes executed by Oracle Linux users run in the unconfined domain</td>
</tr>
</tbody>
</table>

### 26.2.4.2 Multilevel Security (MLS) Policy

Applies access controls to multiple levels of processes with each level having different rules for user access. Users cannot obtain access to information if they do not have the correct authorization to run a process at a specific level. In SELinux, MLS implements the Bell-LaPadula (BLP) model for system security, which applies labels to files, processes and other system objects to control the flow of information between security levels. In a typical implementation, the labels for security levels might range from the most secure, `top secret`, through `secret`, and `classified`, to the least secure, `unclassified`. For example, under MLS, you might configure a program labelled `secret` to be able to write to a file that is labelled `top secret`, but not to be able to read from it. Similarly, you would permit the same program to read from and write to a file labelled `secret`, but only to read `classified` or `unclassified` files. As a result, information that passes through the program can flow upwards through the hierarchy of security levels, but not downwards.

**Note**
You must install the `selinux-policy-mls` package if you want to be able to apply the MLS policy.

### 26.2.4.3 Setting SELinux Policies

**Note**
You cannot change the policy type of a running system.

You can set the default policy type in the **Status** view of the SELinux Administration GUI.

Alternatively, to configure the default policy type, edit `/etc/selinux/config` and set the value of the `SELINUXTYPE` directive to `targeted` or `mls`.

### 26.2.4.4 Customizing SELinux Policies

You can customize an SELinux policy by enabling or disabling the members of a set of boolean values. Any changes that you make take effect immediately and do not require a reboot.
You can set the boolean values in the **Boolean** view of the SELinux Administration GUI.

Alternatively, to display all boolean values together with a short description, use the following command:

```
# semanage boolean -l
```

<table>
<thead>
<tr>
<th>SELinux boolean</th>
<th>State</th>
<th>Default Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ftp_home_dir</td>
<td>(off,</td>
<td>Determine whether ftpd can read and write files in user home directories.</td>
</tr>
<tr>
<td>smartmon_3ware</td>
<td>(off,</td>
<td>Determine whether smartmon can support devices on 3ware controllers.</td>
</tr>
<tr>
<td>mpd_enable_homedirs</td>
<td>(off,</td>
<td>Determine whether mpd can traverse user home directories.</td>
</tr>
<tr>
<td></td>
<td>off)</td>
<td></td>
</tr>
</tbody>
</table>

You can use the `getsebool` and `setsebool` commands to display and set the value of a specific boolean.

```
# getsebool boolean
# setsebool boolean on|off
```

For example, to display and set the value of the `ftp_home_dir` boolean:

```
# getsebool ftp_home_dir
ftp_home_dir --> off
# setsebool ftp_home_dir on
# getsebool ftp_home_dir
ftp_home_dir --> on
```

To toggle the value of a boolean, use the `togglesebool` command as shown in this example:

```
# togglesebool ftp_home_dir
ftp_home_dir: inactive
```

To make the value of a boolean persist across reboots, specify the `-P` option to `setsebool`, for example:

```
# setsebool -P ftp_home_dir on
# getsebool ftp_home_dir
ftp_home_dir --> on
```

### 26.2.5 About SELinux Context

Under SELinux, all file systems, files, directories, devices, and processes have an associated security context. For files, SELinux stores a context label in the extended attributes of the file system. The context contains additional information about a system object: the SELinux user, their role, their type, and the security level. SELinux uses this context information to control access by processes, Linux users, and files.

You can specify the `-Z` option to certain commands (`ls`, `ps`, and `id`) to display the SELinux context with the following syntax:

```
SELinux user:Role:Type:Level
```

where the fields are as follows:

- **SELinux user**
  - An SELinux user account compliments a regular Linux user account. SELinux maps every Linux user to an SELinux user identity that is used in the SELinux context for the processes in a user session.

- **Role**
  - In the Role-Based Access Control (RBAC) security model, a role acts as an intermediary abstraction layer between SELinux process domains
About SELinux Context

or file types and an SELinux user. Processes run in specific SELinux domains, and file system objects are assigned SELinux file types. SELinux users are authorized to perform specified roles, and roles are authorized for specified SELinux domains and file types. A user's role determines which process domains and file types he or she can access, and hence, which processes and files, he or she can access.

**Type**

A type defines an SELinux file type or an SELinux process domain. Processes are separated from each other by running in their own domains. This separation prevents processes from accessing files that other processes use, and prevents processes from accessing other processes. The SELinux policy rules define the access that process domains have to file types and to other process domains.

**Level**

A level is an attribute of Multilevel Security (MLS) and Multicategory Security (MCS). An MLS range is a pair of sensitivity levels, written as `low_level-high_level`. The range can be abbreviated as `low_level` if the levels are identical. For example, `s0` is the same as `s0-s0`. Each level has an optional set of security categories to which it applies. If the set is contiguous, it can be abbreviated. For example, `s0:c0,c3` is the same as `s0:c0,c1,c2,c3`.

### 26.2.5.1 Displaying SELinux User Mapping

To display the mapping between SELinux and Linux user accounts, select the User Mapping view in the SELinux Administration GUI.

Alternatively, enter the following command to display the user mapping:

```
# semanage login -l
```

<table>
<thead>
<tr>
<th>Login Name</th>
<th>SELinux User</th>
<th>MLS/MCS Range</th>
<th>Service</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>default</strong></td>
<td>unconfined_u</td>
<td>s0-s0:c0.c1023</td>
<td>*</td>
</tr>
<tr>
<td>root</td>
<td>unconfined_u</td>
<td>s0-s0:c0.c1023</td>
<td>*</td>
</tr>
<tr>
<td>system_u</td>
<td>system_u</td>
<td>s0-s0:c0.c1023</td>
<td>*</td>
</tr>
</tbody>
</table>

By default, SELinux maps Linux users other than `root` and the default system-level user, `system_u`, to the Linux `__default__` user, and in turn to the SELinux `unconfined_u` user. The MLS/MCS Range is the security level used by Multilevel Security (MLS) and Multicategory Security (MCS).

### 26.2.5.2 Displaying SELinux Context Information

To display the context information that is associated with files, use the `ls -Z` command:

```
# ls -Z
-rw-------. root root system_u:object_r:admin_home_t:s0 anaconda-ks.cfg
-rw-r--r--. root root unconfined_u:object_r:admin_home_t:s0 config
-rw-r--r--. root root system_u:object_r:admin_home_t:s0 initial-setup-ks.cfg
drwxr-xr-x. root root unconfined_u:object_r:admin_home_t:s0 jail
-rw-r--r--. root root unconfined_u:object_r:admin_home_t:s0 team0.cfg
```

To display the context information that is associated with a specified file or directory:

```
# ls -Z /etc/selinux/config
-rw-r--r--. root root system_u:object_r:selinux_config_t:s0 /etc/selinux/config
```

To display the context information that is associated with processes, use the `ps -Z` command:
About SELinux Context

To display the context information that is associated with the current user, use the `id -Z` command:

```
# id -Z
unconfined_u:unconfined_r:unconfined_t:s0-s0:c0.c1023
```

26.2.5.3 Changing the Default File Type

Under some circumstances, you might need to change the default file type for a file system hierarchy. For example, you might want to use a `DocumentRoot` directory other than `/var/www/html` with `httpd`.

To change the default file type of the directory hierarchy `/var/webcontent` to `httpd_sys_content_t`:

1. Use the `semanage` command to define the file type `httpd_sys_content_t` for the directory hierarchy:

```
#/usr/sbin/semanage fcontext -a -t httpd_sys_content_t "/var/webcontent(/.*)?"
```

This command adds the following entry to the file `/etc/selinux/targeted/contexts/files/file_contexts.local`:

```
/var/webcontent(/.*)? system_u:object_r:httpd_sys_content_t:s0
```

2. Use the `restorecon` command to apply the new file type to the entire directory hierarchy.

```
#/sbin/restorecon -R -v /var/webcontent
```

26.2.5.4 Restoring the Default File Type

To restore the default file type of the directory hierarchy `/var/webcontent` after previously changing it to `httpd_sys_content_t`:

1. Use the `semanage` command to delete the file type definition for the directory hierarchy from the file `/etc/selinux/targeted/contexts/files/file_contexts.local`:

```
#/usr/sbin/semanage fcontext -d "/var/webcontent(/.*)?"
```

2. Use the `restorecon` command to apply the default file type to the entire directory hierarchy.

```
#/sbin/restorecon -R -v /var/webcontent
```

26.2.5.5 Relabelling a File System

If you see an error message that contains the string `file_t`, the problem usually lies with a file system having an incorrect context label.

To relabel a file system, use one of the following methods:

- In the Status view of the SELinux Administration GUI, select the Relabel on next reboot option.
- Create the file `.autorelabel` and reboot the system.
- Run the `fixfiles onboot` command and reboot the system.
26.2.6 About SELinux Users

As described in Section 26.2.5, "About SELinux Context", each SELinux user account compliments a regular Oracle Linux user account. SELinux maps every Oracle Linux user to an SELinux user identity that is used in the SELinux context for the processes in a user session.

SELinux users form part of a SELinux policy that is authorized for a specific set of roles and for a specific MLS (Multi-Level Security) range, and each Oracle Linux user is mapped to an SELinux user as part of the policy. As a result, Linux users inherit the restrictions and security rules and mechanisms placed on SELinux users. To define the roles and levels of users, the mapped SELinux user identity is used in the SELinux context for processes in a session. You can display user mapping in the User Mapping view of the SELinux Administration GUI. You can also view the mapping between SELinux and Oracle Linux user accounts from the command line:

```
# semanage login -l
Login Name  SELinux User     MLS/MCS Range
_default_   unconfined_u     s0-s0:c0.c1023
root        unconfined_u     s0-s0:c0.c1023
system_u    system_u         s0-s0:c0.c1023
```

The MLS/MCS Range column displays the level used by MLS and MCS.

By default, Oracle Linux users are mapped to the SELinux user `unconfined_u`.

You can configure SELinux to confine Oracle Linux users by mapping them to SELinux users in confined domains, which have predefined security rules and mechanisms as listed in the following table.

<table>
<thead>
<tr>
<th>SELinux User</th>
<th>SELinux Domain</th>
<th>Permit Running su and sudo?</th>
<th>Permit Network Access?</th>
<th>Permit Logging in Using X Window System?</th>
<th>Permit Executing Applications in $HOME and /tmp?</th>
</tr>
</thead>
<tbody>
<tr>
<td>guest_u</td>
<td>guest_t</td>
<td>No</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>staff_u</td>
<td>staff_t</td>
<td>sudo</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>system_u</td>
<td>ssystem_t</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>user_u</td>
<td>user_t</td>
<td>No</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>xguest_x</td>
<td>xguest_t</td>
<td>No</td>
<td>Firefox only</td>
<td>Yes</td>
<td>No</td>
</tr>
</tbody>
</table>

26.2.6.1 Mapping Oracle Linux Users to SELinux Users

To map an Oracle Linux user `oluser` to an SELinux user such as `user_u`, use the `semanage` command:

```
# semanage login -a -s user_u oluser
```

26.2.6.2 Configuring the Behavior of Application Execution for Users

To help prevent flawed or malicious applications from modifying a user’s files, you can use booleans to specify whether users are permitted to run applications in directories to which they have write access, such as in their home directory hierarchy and `/tmp`.

To allow Oracle Linux users in the `guest_t` and `xguest_t` domains to execute applications in directories to which they have write access:

```
# setsebool -P allow_guest_exec_content on
```
To prevent Linux users in the `staff_t` and `user_t` domains from executing applications in directories to which they have write access:

```bash
# setsebool -P allow_xguest_exec_content on
```

```bash
# setsebool -P allow_staff_exec_content off
# setsebool -P allow_user_exec_content off
```

### 26.2.7 Troubleshooting Access-Denial Messages

The decisions that SELinux has made about allowing denying access are stored in the Access Vector Cache (AVC). If the auditing service (`auditd`) is not running, SELinux logs AVC denial messages to `/var/log/messages`. Otherwise, the messages are logged to `/var/log/audit/audit.log`. If the `setroubleshootd` daemon is running, easier-to-read versions of the denial messages are also written to `/var/log/messages`.

If you have installed the `setroubleshoot` and `setroubleshoot-server` packages, the `auditd` and `setroubleshoot` services are running, and you are using the X Window System, you can use the `sealert -b` command to run the SELinux Alert Browser, which displays information about SELinux AVC denials. To view the details of the alert, click **Show**. To view a recommended solution, click **Troubleshoot**.

If you do not use the SELinux Alert Browser, you can search in `/var/log/audit/audit.log` for messages containing the string **denied**, and in `/var/log/messages` for messages containing the string **SELinux is preventing**. For example:

```bash
# grep denied /var/log/audit/audit.log
```

The main causes of access-denial problems are:

- **The context labels for an application or file are incorrect.**
  
  A solution might be to change the default file type of the directory hierarchy. For example, change the default file type from `/var/webcontent` to `httpd_sys_content_t`:

```bash
#/usr/sbin/semanage fcontext -a -t httpd_sys_content_t" /*/var/webcontent(/.*)?"
#/sbin/restorecon -R -v /var/webcontent
```

- **A Boolean that configures a security policy for a service is set incorrectly.**
  
  A solution might be to change the value of a Boolean. For example, allow users' home directories to be browsable by turning on `httpd_enable_homedirs`:

```bash
# setsebool -P httpd_enable_homedirs on
```

- **A service attempts to access a port to which a security policy does not allow access.**
  
  If the service's use of the port is valid, a solution is to use `semanage` to add the port to the policy configuration. For example, allow the Apache HTTP server to listen on port 8000:

```bash
# semanage port -a -t http_port_t -p tcp 8000
```

- **An update to a package causes an application to behave in a way that breaks an existing security policy.**
  
  You can use the `audit2allow -w -a` command to view the reason why an access denial occurred.
If you then run the `audit2allow -a -M module` command, it creates a type enforcement (.te) file and a policy package (.pp) file. You can use the policy package file with the `semodule -i module.pp` command to stop the error from reoccurring. This procedure is usually intended to allow package updates to function until an amended policy is available. If used incorrectly, it can create potential security holes on your system.

26.3 About Packet-filtering Firewalls

A packet filtering firewall filters incoming and outgoing network packets based on the packet header information. You can create packet filter rules that determine whether packets are accepted or rejected. For example, if you create a rule to block a port, any request is made to that port that is blocked by the firewall, and the request is ignored. Any service that is listening on a blocked port is effectively disabled.

The Oracle Linux kernel uses the Netfilter feature to provide packet filtering functionality for IPv4 and IPv6 packets.

Netfilter consists of two components:

- A `netfilter` kernel component consisting of a set of tables in memory for the rules that the kernel uses to control network packet filtering.

- Utilities to create, maintain, and display the rules that `netfilter` stores. In Oracle Linux 7, the default firewall utility is `firewall-cmd`, which is provided by the `firewalld` package.

  If you prefer, you can enable the `iptables` and `iptables6` services and use the `iptables` and `ip6tables` utilities, provided by the `iptables` package. These were the default utilities for firewall configuration in Oracle Linux 6.

The `firewalld`-based firewall has the following advantages over an `iptables`-based firewall:

- Unlike the `iptables` and `ip6tables` commands, using `firewalld-cmd` does not restart the firewall and disrupt established TCP connections.

- `firewalld` supports dynamic zones, which allow you to implement different sets of firewall rules for systems such as laptops that can connect to networks with different levels of trust. You are unlikely to use this feature with server systems.

- `firewalld` supports D-Bus for better integration with services that depend on firewall configuration.

To implement a general-purpose firewall, you can use the Firewall Configuration GUI (`firewall-config`), provided by the `firewall-config` package.

Figure 26.1 shows the Firewall Configuration GUI.
To create or modify a firewall configuration from the command line, use the `firewall-cmd` utility (or, if you prefer, the `iptables`, or `ip6tables` utilities) to configure the packet filtering rules.

The packet filtering rules are recorded in the `/etc/firewalld` hierarchy for `firewalld` and in the `/etc/sysconfig/iptables` and `/etc/sysconfig/ip6tables` files for `iptables` and `ip6tables`.

### 26.3.1 Controlling the firewalld Firewall Service

The `firewalld` service is enabled by default in Oracle Linux 7. You can use the `systemctl` command to start, stop, or restart the service, and to query its status.

#### 26.3.1.1 Configuring the firewalld Zone

To check the zone for which your system's firewall is configured:

```bash
# firewall-cmd --get-active-zone
```

The command does not display any results if the system has not been assigned to a zone.
Controlling the firewalld Firewall Service

Use the following command to display all available zones:

```
# firewall-cmd --get-zones
block dmz drop external home internal public trusted work
```

To configure your system for the `work` zone on a local network connected via the `em1` interface:

```
# firewall-cmd --zone=work --change-interface=em1
success
```

Querying the current zone now shows that the firewall is configured on the interface `em1` for the `work` zone:

```
# firewall-cmd --get-active-zone
work
  interfaces: em1
```

To make the change permanent, you can change the default zone for the system, for example:

```
# firewall-cmd --get-default-zone
public
# firewall-cmd --set-default-zone=work
success
# firewall-cmd --get-default-zone
work
```

26.3.1.2 Controlling Access to Services

You can permit or deny access to a service by specifying its name. The following command lists the services to which access is allowed on the local system for the `work` zone:

```
# firewall-cmd --zone=work --list-services
ssh samba
```

In this example, the system allows access by SSH and Samba clients.

To permit access by NFS and HTTP clients when the `work` zone is active, use the `--add-service` option:

```
# firewall-cmd --zone=work --add-service=http --add-service=nfs
success
# firewall-cmd --zone=work --list-services
http nfs ssh samba
```

**Note**

If you do not specify the zone, the change is applied to the default zone, not the currently active zone.

To make rule changes persist across reboots, run the command again, additionally specifying the `--permanent` option:

```
# firewall-cmd --permanent --zone=work --add-service=http --add-service=nfs
success
```

To remove access to a service, use the `--remove-service` option, for example:

```
# firewall-cmd --zone=work --remove-service=samba
success
# firewall-cmd --permanent --zone=work --remove-service=samba
success
# firewall-cmd --zone=work --list-services
http nfs ssh
```
26.3.1.3 Controlling Access to Ports

You can permit or deny access to a port by specifying the port number and the associated protocol. The `--list-port` option lists the ports and associated protocols to which you have explicitly allowed access, for example:

```
# firewall-cmd --zone=work --list-ports
3689/tcp
```

You can use the `--add-port` option to permit access:

```
# firewall-cmd --zone=work --add-port=5353/udp
success
# firewall-cmd --permanent --zone=work --add-port=5353/udp
success
# firewall-cmd --zone=work --list-ports
5353/udp 3689/tcp
```

Similarly, the `--remove-port` option removes access to a port. Remember to re-run the command with the `--permanent` option if you want to make the change persist.

To display all the firewall rules that are defined for a zone, use the `--list-all` option:

```
# firewall-cmd --zone=work --list-all
work (default, active)
  interfaces: em1
  sources: 
    services: http nfs ssh
  ports: 5353/udp 3689/tcp
  masquerade: no
  forward-ports:
  icmp-blocks:
  rich rules:
```

For more information, see the `firewall-cmd(1)` manual page.

26.3.2 Controlling the iptables Firewall Service

If you want to use `iptables` instead of `firewalld`, first stop and disable the `firewalld` service before starting the `iptables` firewall service and enabling it to start when the system boots:

```
# systemctl stop firewalld
# systemctl disable firewalld
# systemctl start iptables
# systemctl enable iptables
```

To save any changes that you have made to the firewall rules to `/etc/sysconfig/iptables`, so that the service loads them when it next starts:

```
#/sbin/iptables-save > /etc/sysconfig/iptables
```

To restart the service so that it re-reads its rules from `/etc/sysconfig/iptables`:

```
# systemctl restart iptables
```

To stop the service:

```
# systemctl stop iptables
```

To control IPv6 filtering, use `ip6tables` instead of `iptables`.

For more information, see the `iptables(8)`, and `ip6tables(8)` manual pages.
26.3.2.1 About netfilter Tables Used by iptables and ip6tables

The netfilter tables used by `iptables` and `ip6tables` include:

- **Filter**
  - The default table, which is mainly used to drop or accept packets based on their content.

- **Mangle**
  - This table is used to alter certain fields in a packet.

- **NAT**
  - The Network Address Translation table is used to route packets that create new connections.

The kernel uses the rules stored in these tables to make decisions about network packet filtering. Each rule consists of one or more criteria and a single action. If a criterion in a rule matches the information in a network packet header, the kernel applies the action to the packet. Examples of actions include:

- **ACCEPT**
  - Continue processing the packet.

- **DROP**
  - End the packet’s life without notice.

- **REJECT**
  - As DROP, and additionally notify the sending system that the packet was blocked.

Rules are stored in chains, where each chain is composed of a default policy plus zero or more rules. The kernel applies each rule in a chain to a packet until a match is found. If there is no matching rule, the kernel applies the chain’s default action (policy) to the packet.

Each netfilter table has several predefined chains. The `filter` table contains the following chains:

- **FORWARD**
  - Packets that are not addressed to the local system pass through this chain.

- **INPUT**
  - Inbound packets to the local system pass through this chain.

- **OUTPUT**
  - Locally created packets pass through this chain.

The chains are permanent and you cannot delete them. However, you can create additional chains in the filter table.

26.3.2.2 Listing Firewall Rules

Use the `iptables -L` command to list firewall rules for the chains of the `filter` table. The following example shows the default rules for a newly installed system:

```
# iptables -L
Chain INPUT (policy ACCEPT)
target     prot opt source       destination
ACCEPT     all -- anywhere     anywhere        state RELATED,ESTABLISHED
ACCEPT     icmp -- anywhere     anywhere
ACCEPT     all -- anywhere     anywhere
ACCEPT     tcp -- anywhere     anywhere        state NEW tcp dpt:ssh
ACCEPT     udp -- anywhere     anywhere        state NEW udp dpt:ipp
ACCEPT     udp -- anywhere     224.0.0.251     state NEW udp dpt:mdns
ACCEPT     tcp -- anywhere     anywhere        state NEW tcp dpt:ipp
ACCEPT     udp -- anywhere     anywhere        state NEW udp dpt:ipp
REJECT     all -- anywhere     anywhere        reject-with icmp-host-prohibited

Chain FORWARD (policy ACCEPT)
target     prot opt source       destination
REJECT     all -- anywhere     anywhere        reject-with icmp-host-prohibited
```
Controlling the iptables Firewall Service

In this example, the default policy for each chain is **ACCEPT**. A more secure system could have a default policy of **DROP**, and the additional rules would only allow specific packets on a case-by-case basis.

If you want to modify the chains, specify the **--line-numbers** option to see how the rules are numbered.

```
# iptables -L --line-numbers
Chain INPUT (policy ACCEPT)
num target     prot opt source           destination
1    ACCEPT     all  --  anywhere         anywhere        state RELATED,ESTABLISHED
2    ACCEPT     icmp -- anywhere         anywhere
3    ACCEPT     all  --  anywhere         anywhere
4    ACCEPT     tcp  --  anywhere         anywhere        state NEW tcp dpt:ssh
5    ACCEPT     udp  --  anywhere         anywhere        state NEW udp dpt:ipp
6    ACCEPT     udp  --  anywhere         224.0.0.251     state NEW udp dpt:mdns
7    ACCEPT     tcp  --  anywhere         anywhere        state NEW tcp dpt:ipp
8    ACCEPT     udp  --  anywhere         anywhere        state NEW udp dpt:ipp
9    REJECT     all  --  anywhere         anywhere        reject-with icmp-host-prohibited
```

```
26.3.2.3 Inserting and Replacing Rules in a Chain

Use the **iptables -I** command to insert a rule in a chain. For example, the following command inserts a rule in the **INPUT** chain to allow access by TCP on port 80:

```
# iptables -I INPUT 4 -p tcp -m tcp --dport 80 -j ACCEPT
```

The output from **iptables -L** shows that the new entry has been inserted as rule 4, and the old rules 4 through 9 are pushed down to positions 5 through 10. The TCP destination port of 80 is represented as **http**, which corresponds to the following definition in the **/etc/services** file (the HTTP daemon listens for client requests on port 80):

```
http            80/tcp          www www-http    # WorldWideWeb HTTP
```

To replace the rule in a chain, use the **iptables -R** command. For example, the following command replaces rule 4 in the **INPUT** chain to allow access by TCP on port 443:

```
# iptables -R INPUT 4 -p tcp -m tcp --dport 443 -j ACCEPT
```

The output from **iptables -L** shows that the new entry has been replaced as rule 4, and the old rules 4 through 9 are pushed down to positions 5 through 10. The TCP destination port of 443 is represented as **http**, which corresponds to the following definition in the **/etc/services** file (the HTTP daemon listens for client requests on port 443):

```
http            443/tcp         www www-http    # WorldWideWeb HTTP
```
About TCP Wrappers

The TCP destination port of 443 is represented as `https`, which corresponds to the following definition in the `/etc/services` file for secure HTTP on port 443:

```
https           443/tcp                         # http protocol over TLS/SSL
```

### 26.3.4 Deleting Rules in a Chain

Use the `iptables -D` command to delete a rule in a chain. For example, the following command deletes rule 4 from the `INPUT` chain:

```
# iptables -D INPUT 4
```

To delete all rules in a chain, enter:

```
# iptables -F chain
```

To delete all rules in all chains, enter:

```
# iptables -F
```

### 26.3.5 Saving Rules

To save your changes to the firewall rules so that they are loaded when the `iptables` service next starts, use the following command:

```
# /sbin/iptables-save /etc/sysconfig/iptables
```

The command saves the rules to `/etc/sysconfig/iptables`. For IPv6, you can use `/sbin/ip6tables-save > /etc/sysconfig/ip6tables` to save the rules to `/etc/sysconfig/ip6tables`.

### 26.4 About TCP Wrappers

TCP wrappers provide basic filtering of incoming network traffic. You can allow or deny access from other systems to certain wrapped network services running on a Linux server. A wrapped network service is one that has been compiled against the `libwrap.a` library. You can use the `ldd` command to determine if a network service has been wrapped as shown in the following example for the `sshd` daemon:

```
# ldd /usr/sbin/sshd | grep libwrap
libwrap.so.0 => /lib64/libwrap.so.0 (0x00007f877de07000)
```

When a remote client attempts to connect to a network service on the system, the wrapper consults the rules in the configuration files `/etc/hosts.allow` and `/etc/hosts.deny` files to determine if access is permitted.

The wrapper for a service first reads `/etc/hosts.allow` from top to bottom. If the daemon and client combination matches an entry in the file, access is allowed. If the wrapper does not find a match in `/etc/hosts.allow`, it reads `/etc/hosts.deny` from top to bottom. If the daemon and client combination matches and entry in the file, access is denied. If no rules for the daemon and client combination are found in either file, or if neither file exists, access to the service is allowed.
About chroot Jails

The wrapper first applies the rules specified in `/etc/hosts.allow`, so these rules take precedence over the rules specified in `/etc/hosts.deny`. If a rule defined in `/etc/hosts.allow` permits access to a service, any rule in `/etc/hosts.deny` that forbids access to the same service is ignored.

The rules take the following form:

```
daemon_list : client_list [: command] [: deny]
```

where `daemon_list` and `client_list` are comma-separated lists of daemons and clients, and the optional `command` is run when a client tries to access a daemon. You can use the keyword `ALL` to represent all daemons or all clients. Subnets can be represented by using the `*` wildcard, for example `192.168.2.*`. Domains can be represented by prefixing the domain name with a period (.), for example `.mydomain.com`. The optional `deny` keyword causes a connection to be denied even for rules specified in the `/etc/hosts.allow` file.

The following are some sample rules.

- **Match all clients for `scp`, `sftp`, and `ssh` access (sshd).**

  `sshd : ALL`

- **Match all clients on the 192.168.2 subnet for FTP access (vsftpd).**

  `vsftpd : 192.168.2.*`

- **Match all clients in the `mydomain.com` domain for access to all wrapped services.**

  `ALL : .mydomain.com`

- **Match all clients for FTP access, and displays the contents of the banner file `/etc/banners/vsftpd` (the banner file must have the same name as the daemon).**

  `vsftpd : ALL : banners /etc/banners/`

- **Match all clients on the 200.182.68 subnet for all wrapped services, and logs all such events. The `%c` and `%d` tokens are expanded to the names of the client and the daemon.**

  `ALL : 200.182.68.* : spawn /usr/bin/echo `date` "Attempt by `%c` to connect to `%d`" >> /var/log/tcpwr.log`

- **Match all clients for `scp`, `sftp`, and `ssh` access, and logs the event as an `emerg` message, which is displayed on the console.**

  `sshd : ALL : severity emerg`

- **Match all clients in the `forbid.com` domain for `scp`, `sftp`, and `ssh` access, logs the event, and deny access (even if the rule appears in `/etc/hosts.allow`).**

  `sshd : .forbid.com : spawn /usr/bin/echo `date` "sshd access denied for `%c`" >>/var/log/sshd.log : deny`

For more information, see the `hosts_access(5)` manual page.

### 26.5 About chroot Jails

A chroot operation changes the apparent root directory for a running process and its children. It allows you to run a program with a root directory other than `/`. The program cannot see or access files outside the designated directory tree. Such an artificial root directory is called a chroot jail, and its purpose is to limit the directory access of a potential attacker. The chroot jail locks down a given process and any user ID that it is using so that all they see is the directory in which the process is running. To the process, it appears that the directory in which it is running is the root directory.
Running DNS and FTP Services in a Chroot Jail

Note
The chroot mechanism cannot defend against intentional tampering or low-level access to system devices by privileged users. For example, a chroot root user could create device nodes and mount file systems on them. A program can also break out of a chroot jail if it can gain root privilege and use chroot() to change its current working directory to the real root directory. For this reason, you should ensure that a chroot jail does not contain any setuid or setgid executables that are owned by root.

For a chroot process to be able to start successfully, you must populate the chroot directory with all required program files, configuration files, device nodes, and shared libraries at their expected locations relative to the level of the chroot directory.

26.5.1 Running DNS and FTP Services in a Chroot Jail

If the DNS name service daemon (named) runs in a chroot jail, any hacker that enters your system via a BIND exploit is isolated to the files under the chroot jail directory. Installing the bind-chroot package creates the /var/named/chroot directory, which becomes the chroot jail for all BIND files.

You can configure the vsftpd FTP server to automatically start chroot jails for clients. By default, anonymous users are placed in a chroot jail. However, local users that access an vsftpd FTP server are placed in their home directory. Specify the chroot_local_user=YES option in the /etc/vsftpd/vsftpd.conf file to place local users in a chroot jail based on their home directory.

26.5.2 Creating a Chroot Jail

To create a chroot jail:

1. Create the directory that will become the root directory of the chroot jail, for example:

```bash
# mkdir /home/oracle/jail
```

2. Use the ldd command to find out which libraries are required by the command that you intend to run in the chroot jail, for example /usr/bin/bash:

```bash
# ldd /usr/bin/bash
linux-vdso.so.1 => (0x00007fffdedfe000)
libtinfo.so.5 => /lib64/libtinfo.so.5 (0x0000003877000000)
libdl.so.2 => /lib64/libdl.so.2 (0x0000003861c00000)
libc.so.6 => /lib64/libc.so.6 (0x0000003861800000)
/lib64/ld-linux-x86-64.so.2 (0x0000003861000000)
```

Note
Although the path is displayed as /lib64, the actual path is /usr/lib64 because /lib64 is a symbolic link to /usr/lib64. Similarly, /bin is a symbolic link to /usr/bin. You need to recreate such symbolic links within the chroot jail.

3. Create subdirectories of the chroot jail's root directory that have the same relative paths as the command binary and its required libraries have to the real root directory, for example:

```bash
# mkdir -p /home/oracle/jail/usr/bin
# mkdir -p /home/oracle/jail/usr/lib64
```

4. Create the symbolic links that link to the binary and library directories in the same manner as the symbolic links that exists in the real root directory.
5. Copy the binary and the shared libraries to the directories under the chroot jail's root directory, for example:

```bash
# ln -s /home/oracle/jail/usr/bin /home/oracle/jail/bin
# ln -s /home/oracle/jail/usr/lib64 /home/oracle/jail/lib64
```

26.5.3 Using a Chroot Jail

To run a command in a chroot jail in an existing directory (`chroot_jail`), use the following command:

```bash
# chroot chroot_jail command
```

If you do not specify a command argument, `chroot` runs the value of the `SHELL` environment variable or `/usr/bin/sh` if `SHELL` is not set.

For example, to run `/usr/bin/bash` in a chroot jail (having previously set it up as described in Section 26.5.2, “Creating a Chroot Jail”):

```bash
# chroot /home/oracle/jail
bash-4.2# pwd
/
bash-4.2# ls
bash: ls: command not found
bash-4.2# exit
```

You can run built-in shell commands such as `pwd` in this shell, but not other commands unless you have copied their binaries and any required shared libraries to the chroot jail.

For more information, see the `chroot(1)` manual page.

26.6 About Auditing

Auditing collects data at the kernel level that you can analyze to identify unauthorized activity. Auditing collects more data in greater detail than system logging, but most audited events are uninteresting and insignificant. The process of examining audit trails to locate events of interest can be a significant challenge that you will probably need to automate.

The audit configuration file, `/etc/audit/auditd.conf`, defines the data retention policy, the maximum size of the audit volume, the action to take if the capacity of the audit volume is exceeded, and the locations of local and remote audit trail volumes. The default audit trail volume is `/var/log/audit/audit.log`. For more information, see the `auditd.conf(5)` manual page.

By default, auditing captures specific events such as system logins, modifications to accounts, and `sudo` actions. You can also configure auditing to capture detailed system call activity or modifications to certain files. The kernel audit daemon (`auditd`) records the events that you configure, including the event type, a time stamp, the associated user ID, and success or failure of the system call.

The entries in the audit rules file, `/etc/audit/audit.rules`, determine which events are audited. Each rule is a command-line option that is passed to the `auditctl` command. You should typically configure this file to match your site's security policy.

The following are examples of rules that you might set in the `/etc/audit/audit.rules` file.
Record all unsuccessful exits from `open` and `truncate` system calls for files in the `/etc` directory hierarchy.

```
-a exit,always -S open -S truncate -F /etc -F success=0
```

Record all files opened by a user with UID 10.

```
-a exit,always -S open -F uid=10
```

Record all files that have been written to or that have their attributes changed by any user who originally logged in with a UID of 500 or greater.

```
-a exit,always -S open -F auid>=500 -F perm=wa
```

Record requests for write or file attribute change access to `/etc/sudoers`, and tag such record with the string `sudoers-change`.

```
-w /etc/sudoers -p wa -k sudoers-change
```

Record requests for write and file attribute change access to the `/etc` directory hierarchy.

```
-w /etc/ -p wa
```

Require a reboot after changing the audit configuration. If specified, this rule should appear at the end of the `/etc/audit/audit.rules` file.

```
-e 2
```

You can find more examples of audit rules in `/usr/share/doc/audit-version/stig.rules`, and in the `auditctl(8)` and `audit.rules(7)` manual pages.

Stringent auditing requirements can impose a significant performance overhead and generate large amounts of audit data. Some site security policies stipulate that a system must shut down if events cannot be recorded because the audit volumes have exceeded their capacity. As a general rule, you should direct audit data to separate file systems in rotation to prevent overspill and to facilitate backups.

You can use the `-k` option to tag audit records so that you can locate them more easily in an audit volume with the `ausearch` command. For example, to examine records tagged with the string `sudoers-change`, you would enter:

```
# ausearch -k sudoers-change
```

The `aureport` command generates summaries of audit data. You can set up `cron` jobs that run `aureport` periodically to generate reports of interest. For example, the following command generates a reports that shows every login event from 1 second after midnight on the previous day until the current time:

```
# aureport -l -i -ts yesterday -te now
```

For more information, see the `ausearch(8)` and `aureport(8)` manual pages.

### 26.7 About System Logging

The log files contain messages about the system, kernel, services, and applications. The `journald` logging daemon, which is part of `systemd`, records system messages in non-persistent journal files in memory and in the `/run/log/journal` directory. `journald` forwards messages to the system logging daemon, `rsyslog`. As files in `/run` are volatile, the log data is lost after a reboot unless you create the directory `/var/log/journal`. You can use the `journalctl` command to query the journal logs.
For more information, see the `journalctl(1)` and `systemd-journald.service(8)` manual pages.

The configuration file for `rsyslogd` is `/etc/rsyslog.conf`, which contains global directives, module directives, and rules. By default, `rsyslog` processes and archives only `syslog` messages. If required, you can configure `rsyslog` to archive any other messages that `journald` forwards, including kernel, boot, `initrd`, `stdout`, and `stderr` messages.

Global directives specify configuration options that apply to the `rsyslogd` daemon. All configuration directives must start with a dollar sign (`$`) and only one directive can be specified on each line. The following example specifies the maximum size of the `rsyslog` message queue:

```
$MainMsgQueueSize 50000
```

The available configuration directives are described in the file `/usr/share/doc/rsyslog-version-number/rsyslog_conf_global.html`.

The design of `rsyslog` allows its functionality to be dynamically loaded from modules, which provide configuration directives. To load a module, specify the following directive:

```
$ModLoad MODULE_name
```

Modules have the following main categories:

- **Input modules** gather messages from various sources. Input module names always start with the `im` prefix (examples include `imfile` and `imrelp`).

- **Filter modules** allow `rsyslogd` to filter messages according to specified rules. The name of a filter module always starts with the `fm` prefix.

- **Library modules** provide functionality for other loadable modules. `rsyslogd` loads library modules automatically when required. You cannot configure the loading of library modules.

- **Output modules** provide the facility to store messages in a database or on other servers in a network, or to encrypt them. Output module names always starts with the `om` prefix (examples include `omsnmp` and `omrelp`).

- **Message modification modules** change the content of an `rsyslog` message.

- **Parser modules** allow `rsyslogd` to parse the message content of messages that it receives. The name of a parser module always starts with the `pm` prefix.

- **String generator modules** generate strings based on the content of messages in cooperation with `rsyslog`’s template feature. The name of a string generator module always starts with the `sm` prefix.

Input modules receive messages, which pass them to one or more parser modules. A parser module creates a representation of a message in memory, possibly modifying the message, and passes the internal representation to output modules, which can also modify the content before outputting the message.

An `rsyslog` rule consists of a filter part, which selects a subset of messages, and an action part, which specifies what to do with the selected messages. To define a rule in the `/etc/rsyslog.conf` configuration file, specify a filter and an action on a single line, separated by one or more tabs or spaces.

You can configure `rsyslog` to filter messages according to various properties. The most commonly used filters are:
• Expression-based filters, written in the `rsyslog` scripting language, select messages according to arithmetic, boolean, or string values.

• Facility/priority-based filters filter messages based on facility and priority values that take the form `facility.priority`.

• Property-based filters filter messages by properties such as `timegenerated` or `syslogtag`.

The following table lists the available facility keywords for facility/priority-based filters:

<table>
<thead>
<tr>
<th>Facility Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>auth, authpriv</td>
<td>Security, authentication, or authorization messages.</td>
</tr>
<tr>
<td>cron</td>
<td><code>crond</code> messages.</td>
</tr>
<tr>
<td>daemon</td>
<td>Messages from system daemons other than <code>crond</code> and <code>rsyslogd</code>.</td>
</tr>
<tr>
<td>kern</td>
<td>Kernel messages.</td>
</tr>
<tr>
<td>lpr</td>
<td>Line printer subsystem.</td>
</tr>
<tr>
<td>mail</td>
<td>Mail system.</td>
</tr>
<tr>
<td>news</td>
<td>Network news subsystem.</td>
</tr>
<tr>
<td>syslog</td>
<td>Messages generated internally by <code>rsyslogd</code>.</td>
</tr>
<tr>
<td>user</td>
<td>User-level messages.</td>
</tr>
<tr>
<td>UUCP</td>
<td>UUCP subsystem.</td>
</tr>
<tr>
<td>local0-local7</td>
<td>Local use.</td>
</tr>
</tbody>
</table>

The following table lists the available priority keywords for facility/priority-based filters, in ascending order of importance:

<table>
<thead>
<tr>
<th>Priority Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>debug</td>
<td>Debug-level messages.</td>
</tr>
<tr>
<td>info</td>
<td>Informational messages.</td>
</tr>
<tr>
<td>notice</td>
<td>Normal but significant condition.</td>
</tr>
<tr>
<td>warning</td>
<td>Warning conditions.</td>
</tr>
<tr>
<td>err</td>
<td>Error conditions.</td>
</tr>
<tr>
<td>crit</td>
<td>Critical conditions.</td>
</tr>
<tr>
<td>alert</td>
<td>Immediate action required.</td>
</tr>
<tr>
<td>emerg</td>
<td>System is unstable.</td>
</tr>
</tbody>
</table>

All messages of the specified priority and higher are logged according to the specified action. An asterisk (*) wildcard specifies all facilities or priorities. Separate the names of multiple facilities and priorities on a line with commas (,). Separate multiple filters on one line with semicolons (;). Precede a priority with an exclamation mark (!) to select all messages except those with that priority.

The following are examples of facility/priority-based filters.

Select all kernel messages with any priority.

`kern.*`

Select all mail messages with `crit` or higher priority.

`mail.*!crit`
About System Logging

Select all daemon and kern messages with warning or err priority.

Select all cron messages except those with info or debug priority.

By default, /etc/rsyslog.conf includes the following rules:

- Log all kernel messages to the console.
  kern.* /dev/console
- Log anything (except mail) of level info or higher.
  *.info;mail.none;authpriv.none;cron.none /var/log/messages
- The authpriv file has restricted access.
  authpriv.* /var/log/secure
- Log all the mail messages in one place.
  mail.* -/var/log/maillog
- Log cron stuff
  cron.* /var/log/cron
- Everybody gets emergency messages
  *.emerg *
- Save news errors of level crit and higher in a special file.
  uucp,news.crit /var/log/spooler
- Save boot messages also to boot.log
  local7.* /var/log/boot.log

You can send the logs to a central log server over TCP by adding the following entry to the forwarding rules section of /etc/rsyslog.conf on each log client:

```
*:.* @@logsvr:port
```

where logsvr is the domain name or IP address of the log server and port is the port number (usually, 514).

On the log server, add the following entry to the MODULES section of /etc/rsyslog.conf:

```
$ModLoad imtcp
$InputTCPServerRun port
```

where port corresponds to the port number that you set on the log clients.

To manage the rotation and archival of the correct logs, edit /etc/logrotate.d/syslog so that it references each of the log files that are defined in the RULES section of /etc/rsyslog.conf. You can configure how often the logs are rotated and how many past copies of the logs are archived by editing /etc/logrotate.conf.

It is recommended that you configure Logwatch on your log server to monitor the logs for suspicious messages, and disable Logwatch on log clients. However, if you do use Logwatch, disable high precision timestamps by adding the following entry to the GLOBAL DIRECTIVES section of /etc/rsyslog.conf on each system:
For more information, see the `logrotate(8), logwatch(8), rsyslogd(8)` and `rsyslog.conf(5)` manual pages, the HTML documentation in the `/usr/share/doc/rsyslog-5.8.10` directory, and the documentation at `http://www.rsyslog.com/doc/manual.html`.

### 26.7.1 Configuring Logwatch

Logwatch is a monitoring system that you can configure to report on areas of interest in the system logs. After you install the `logwatch` package, the `/etc/cron.daily/logwatch` script runs every night and sends an email report to `root`. You can set local configuration options in `/etc/logwatch/conf/logwatch.conf` that override the main configuration file `/usr/share/logwatch/default.conf/logwatch.conf`, including:

- Log files to monitor, including log files that are stored for other hosts.
- Names of services to monitor, or to be excluded from monitoring.
- Level of detail to report.
- User to be sent an emailed report.

You can also run `logwatch` directly from the command line.

For more information, see the `logwatch(8)` manual page.

### 26.8 About Process Accounting

The `psacct` package implements the process accounting service in addition to the following utilities that you can use to monitor process activities:

- **ac**
  Displays connection times in hours for a user as recorded in the `wtmp` file (by default, `/var/log/wtmp`).

- **accton**
  Turns on process accounting to the specified file. If you do not specify a file name argument, process accounting is stopped. The default system accounting file is `/var/account/pacct`.

- **lastcomm**
  Displays information about previously executed commands as recorded in the system accounting file.

- **sa**
  Summarizes information about previously executed commands as recorded in the system accounting file.

**Note**
As for any logging activity, ensure that the file system has enough space to store the system accounting and `wtmp` files. Monitor the size of the files and, if necessary, truncate them.

For more information, see the `ac(1), accton(8), lastcomm(1), and sa(8)` manual pages.

### 26.9 Security Guidelines

The following sections provide guidelines that help secure your Oracle Linux system.
26.9.1 Minimizing the Software Footprint

On systems on which Oracle Linux has been installed, remove unneeded RPMs to minimize the software footprint. For example, you could uninstall the X Windows package (xorg-x11-server-Xorg) if it is not required on a server system.

To discover which package provides a given command or file, use the `yum provides` command as shown in the following example:

```bash
# yum provides /usr/sbin/sestatus
... policycoreutils-2.0.83-19.24.0.1.el6.x86_64 : SELinux policy core utilities Repo : installed Matched from:
Other : Provides-match: /usr/sbin/sestatus
```

To display the files that a package provides, use the `repoquery` utility, which is included in the `yum-utils` package. For example, the following command lists the files that the `btrfs-progs` package provides.

```bash
# repoquery -l btrfs-progs
/sbin/btrfs
/sbin/btrfs-convert
/sbin/btrfs-debug-tree
```

To uninstall a package, use the `yum remove` command, as shown in this example:

```bash
# yum remove xinetd
Loaded plugins: refresh-packagekit, security
Setting up Remove Process
Resolving Dependencies
--> Running transaction check
---> Package xinetd.x86_64 2:2.3.14-35.el6_3 will be erased
---> Finished Dependency Resolution
Dependencies Resolved
================================================================================ Package Arch Version Repository Size
================================================================================ Removing:
xinetd x86_64 2:2.3.14-35.el6_3 @ol6_latest 259 k
Transaction Summary
================================================================================ Remove 1 Package(s)
Installed size: 259 k
Is this ok [y/N]: y
```

Complete!
The following table lists packages that you should not install or that you should remove using `yum remove` if they are already installed.

<table>
<thead>
<tr>
<th>Package</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>krb5-appl-clients</td>
<td>Kerberos versions of <code>ftp</code>, <code>rcp</code>, <code>rlogin</code>, <code>rsh</code>, and <code>telnet</code>. If possible, use SSH instead.</td>
</tr>
<tr>
<td>rsh, rsh-server</td>
<td><code>rcp</code>, <code>rlogin</code>, and <code>rsh</code> use unencrypted communication that can be snooped. Use SSH instead.</td>
</tr>
<tr>
<td>samba</td>
<td>Network services used by Samba. Remove this package if the system is not acting as an Active Directory server, a domain controller, or as a domain member, and it does not provide Microsoft Windows file and print sharing functionality.</td>
</tr>
<tr>
<td>talk, talk-server</td>
<td><code>talk</code> is considered obsolete.</td>
</tr>
<tr>
<td>telnet, telnet-server</td>
<td><code>telnet</code> uses unencrypted communication that can be snooped. Use SSH instead.</td>
</tr>
<tr>
<td>tftp, tftp-server</td>
<td>TFTP uses unencrypted communication that can be snooped. Use only if required to support legacy hardware. If possible, use SSH or other secure protocol instead.</td>
</tr>
<tr>
<td>xinetd</td>
<td>The security model used by the Internet listener daemon is deprecated.</td>
</tr>
<tr>
<td>ypbind, ypserv</td>
<td>The security model used by NIS is inherently flawed. Use an alternative such as LDAP or Kerberos instead.</td>
</tr>
</tbody>
</table>

### 26.9.2 Configuring System Logging

Verify that the system logging service `rsyslog` is running:

```
# systemctl status rsyslog
rsyslogd (pid 1632) is running...
```

If the service is not running, start it and enable it to start when the system is rebooted:

```
# systemctl start rsyslog
# systemctl enable rsyslog
```

Ensure that each log file referenced in `/etc/rsyslog.conf` exists and is owned and only readable by `root`:

```
# touch logfile
# chown root:root logfile
# chmod 0600 logfile
```

It is also recommended that you use a central log server and that you configure Logwatch on that server. See Section 26.7, “About System Logging”.

### 26.9.3 Disabling Core Dumps

Core dumps can contain information that an attacker might be able to exploit and they take up a large amount of disk space. To prevent the system creating core dumps when the operating system terminates a program due to a segment violation or other unexpected error, add the following line to `/etc/security/limits.conf`:

```
* hard core 0
```
Minimizing Active Services

You can restrict access to core dumps to certain users or groups, as described in the `limits.conf(5)` manual page.

By default, the system prevents `setuid` and `setgid` programs, programs that have changed credentials, and programs whose binaries do not have read permission from dumping core. To ensure that the setting is permanently recorded, add the following lines to `/etc/sysctl.conf:

```bash
# Disallow core dumping by setuid and setgid programs
fs.suid_dumpable = 0
```

and then run the `sysctl -p` command.

**Note**

A value of 1 permits core dumps that are readable by the owner of the dumping process. A value of 2 permits core dumps that are readable only by `root` for debugging purposes.

### 26.9.4 Minimizing Active Services

Restrict services to only those that a server requires. The default installation for an Oracle Linux server configures a minimal set of services:

- `cupsd` and `lpd` (print services)
- `sendmail` (email delivery service)
- `sshd` (openSSH services)

If possible, configure one type of service per physical machine, virtual machine, or Linux Container. This technique limits exposure if a system is compromised.

If a service is not used, remove the software packages that are associated with the service. If it is not possible to remove a service because of software dependencies, use the `systemctl` command to disable the service.

For services that are in use, apply the latest Oracle support patches and security updates to keep software packages up to date. To protect against unauthorized changes, ensure that the `/etc/services` file is owned by `root` and writable only by `root`.

```bash
# ls -Z /etc/services
-rw-r--r--. root root system_u:object_r:etc_t:SystemLow /etc/services
```

Unless specifically stated otherwise, consider disabling the services in the following table if they are not used on your system:

<table>
<thead>
<tr>
<th>Service</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>anacron</td>
<td>Executes commands periodically. Primarily intended for use on laptop and user desktop machines that do not run continuously.</td>
</tr>
<tr>
<td>automount</td>
<td>Manages mount points for the automatic file-system mounter. Disable this service on servers that do not require automounter functionality.</td>
</tr>
<tr>
<td>bluetooth</td>
<td>Supports the connections of Bluetooth devices. Primarily intended for use on laptop and user desktop machines. Bluetooth provides an additional potential attack surface. Disable this service on servers that do not require Bluetooth functionality.</td>
</tr>
</tbody>
</table>
### Minimizing Active Services

<table>
<thead>
<tr>
<th>Service</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>gpm</td>
<td>(General Purpose Mouse) Provides support for the mouse pointer in a text console.</td>
</tr>
<tr>
<td>hidd</td>
<td>(Bluetooth Human Interface Device daemon) Provides support for Bluetooth input devices such as a keyboard or mouse. Primarily intended for use on laptop and user desktop machines. Bluetooth provides an additional potential attack surface. Disable this service on servers that do not require Bluetooth functionality.</td>
</tr>
<tr>
<td>irqbalance</td>
<td>Distributes hardware interrupts across processors on a multiprocessor system. Disable this service on servers that do not require this functionality.</td>
</tr>
<tr>
<td>iscsi</td>
<td>Controls logging in to iSCSI targets and scanning of iSCSI devices. Disable this service on servers that do not access iSCSI devices.</td>
</tr>
<tr>
<td>iscsid</td>
<td>Implements control and management for the iSCSI protocol. Disable this service on servers that do not access iSCSI devices.</td>
</tr>
<tr>
<td>kdump</td>
<td>Allows a <code>kdump</code> kernel to be loaded into memory at boot time or a kernel dump to be saved if the system panics. Disable this service on servers that you do not use for debugging or testing.</td>
</tr>
<tr>
<td>mcstrans</td>
<td>Controls the SELinux Context Translation System service.</td>
</tr>
<tr>
<td>mdmonitor</td>
<td>Checks the status of all software RAID arrays on the system. Disable this service on servers that do not use software RAID.</td>
</tr>
<tr>
<td>pcsd</td>
<td>(PC/SC Smart Card Daemon) Supports communication with smart-card readers. Primarily intended for use on laptop and user desktop machines to support smart-card authentication. Disable this service on servers that do not use smart-card authentication.</td>
</tr>
<tr>
<td>sandbox</td>
<td>Sets up <code>/tmp</code>, <code>/var/tmp</code>, and home directories to be used with the <code>pam_namespace</code>, <code>sandbox</code>, and <code>xguest</code> application confinement utilities. Disable this service if you do not use these programs.</td>
</tr>
<tr>
<td>setroubleshoot</td>
<td>Controls the SELinux Troubleshooting service, which provides information about SELinux Access Vector Cache (AVC) denials to the <code>sealert</code> tool.</td>
</tr>
<tr>
<td>smartd</td>
<td>Communicates with the Self-Monitoring, Analysis and Reporting Technology (SMART) systems that are integrated into many ATA-3 and later, and SCSI-3 disk drives. SMART systems monitor disk drives to measure reliability, predict disk degradation and failure, and perform drive testing.</td>
</tr>
<tr>
<td>xfs</td>
<td>Caches fonts in memory to improve the performance of X Window System applications.</td>
</tr>
</tbody>
</table>

You should consider disabling the following network services if they are not used on your system:

<table>
<thead>
<tr>
<th>Service</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>avahi-daemon</td>
<td>Implements Apple’s Zero configuration networking (also known as Rendezvous or Bonjour). Primarily intended for use on laptop and user desktop machines to support music and file sharing. Disable this service on servers that do not require this functionality.</td>
</tr>
<tr>
<td>cups</td>
<td>Implements the Common UNIX Printing System. Disable this service on servers that do not need to provide this functionality.</td>
</tr>
<tr>
<td>hplip</td>
<td>Implements HP Linux Imaging and Printing to support faxing, printing, and scanning operations on HP inkjet and laser printers. Disable this service on servers that do not require this functionality.</td>
</tr>
</tbody>
</table>
### Locking Down Network Services

<table>
<thead>
<tr>
<th>Service</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>isdn</td>
<td>(Integrated Services Digital Network) Provides support for network connections over ISDN devices. Disable this service on servers that do not directly control ISDN devices.</td>
</tr>
<tr>
<td>netfs</td>
<td>Mounts and unmounts network file systems, including NCP, NFS, and SMB. Disable this service on servers that do not require this functionality.</td>
</tr>
<tr>
<td>network</td>
<td>Activates all network interfaces that are configured to start at boot time.</td>
</tr>
<tr>
<td>NetworkManager</td>
<td>Switches network connections automatically to use the best connection that is available.</td>
</tr>
<tr>
<td>nfslock</td>
<td>Implements the Network Status Monitor (NSM) used by NFS. Disable this service on servers that do not require this functionality.</td>
</tr>
<tr>
<td>nmb</td>
<td>Provides NetBIOS name services used by Samba. Disable this service and remove the samba package if the system is not acting as an Active Directory server, a domain controller, or as a domain member, and it does not provide Microsoft Windows file and print sharing functionality.</td>
</tr>
<tr>
<td>portmap</td>
<td>Implements Remote Procedure Call (RPC) support for NFS. Disable this service on servers that do not require this functionality.</td>
</tr>
<tr>
<td>rhnsd</td>
<td>Queries the Unbreakable Linux Network (ULN) for updates and information.</td>
</tr>
<tr>
<td>rpcgssd</td>
<td>Used by NFS. Disable this service on servers that do not require this functionality.</td>
</tr>
<tr>
<td>rpcidmapd</td>
<td>Used by NFS. Disable this service on servers that do not require this functionality.</td>
</tr>
<tr>
<td>smb</td>
<td>Provides SMB network services used by Samba. Disable this service and remove the samba package if the system is not acting as an Active Directory server, a domain controller, or as a domain member, and it does not provide Microsoft Windows file and print sharing functionality.</td>
</tr>
</tbody>
</table>

To stop a service and prevent it from starting when you reboot the system, used the following commands:

```bash
# systemctl stop service_name
# systemctl disable service_name
```

### 26.9.5 Locking Down Network Services

**Note**

It is recommended that you do not install the *xinetd* Internet listener daemon. If you do not need this service, remove the package altogether by using the `yum remove xinetd` command.

If you must enable *xinetd* on your system, minimize the network services that *xinetd* can launch by disabling those services that are defined in the configuration files in `/etc/xinetd.d` and which are not needed.

To counter potential Denial of Service (DoS) attacks, you can configure the resource limits for such services by editing `/etc/xinetd.conf` and related configuration files. For example, you can set limits for the connection rate, the number of connection instances to a service, and the number of connections from an IP address:

```bash
# Maximum number of connections per second and
# number of seconds for which a service is disabled
```
# if the maximum number of connections is exceeded
cps             = 50 10

# Maximum number of connections to a service
instances       = 50

# Maximum number of connections from an IP address
per_source      = 10

For more information, see the xinetd(8) and /etc/xinetd.conf(5) manual pages.

## 26.9.6 Configuring a Packet-filtering Firewall

You can configure the Netfilter feature to act as a packet-filtering firewall that uses rules to determine whether network packets are received, dropped, or forwarded.

The primary interfaces for configuring the packet-filter rules are the `iptables` and `ip6tables` utilities and the Firewall Configuration Tool GUI (`firewall-config`). By default, the rules should drop any packets that are not destined for a service that the server hosts or that originate from networks other than those to which you want to allow access.

In addition, Netfilter provides Network Address Translation (NAT) to hide IP addresses behind a public IP address, and IP masquerading to alter IP header information for routed packets. You can also set rule-based packet logging and define a dedicated log file in `/etc/syslog.conf`.

For more information, see Section 26.3, "About Packet-filtering Firewalls".

## 26.9.7 Configuring TCP Wrappers

The TCP wrappers feature mediates requests from clients to services, and control access based on rules that you define in the `/etc/hosts.deny` and `/etc/hosts.allow` files. You can restrict and permit service access for specific hosts or whole networks. A common way of using TCP wrappers is to detect intrusion attempts. For example, if a known malicious host or network attempts to access a service, you can deny access and send a warning message about the event to a log file or to the system console.

For more information, see Section 26.4, "About TCP Wrappers".

## 26.9.8 Configuring Kernel Parameters

You can use several kernel parameters to counteract various kinds of attack.

`kernel.randomize_va_space` controls Address Space Layout Randomization (ASLR), which can help defeat certain types of buffer overflow attacks. A value of 0 disables ASLR, 1 randomizes the positions of the stack, virtual dynamic shared object (VDSO) page, and shared memory regions, and 2 randomizes the positions of the stack, VDSO page, shared memory regions, and the data segment. The default and recommended setting is 2.

`net.ipv4.conf.all.accept_source_route` controls the handling of source-routed packets, which might have been generated outside the local network. A value of 0 rejects such packets, and 1 accepts them. The default and recommended setting is 0.

`net.ipv4.conf.all rp_filter` controls reversed-path filtering of received packets to counter IP address spoofing. A value of 0 disables source validation, 1 causes packets to be dropped if the routing table entry for their source address does not match the network interface on which they arrive, and 2 causes packets to be dropped if source validation by reversed path fails (see RFC 1812). The default setting is 0. A value of 2 can cause otherwise valid packets to be dropped if the local network topology is complex and RIP or static routes are used.
Restricting Access to SSH Connections

`net.ipv4.icmp_echo_ignore_broadcasts` controls whether ICMP broadcasts are ignored to protect against Smurf DoS attacks. A value of 1 ignores such broadcasts, and 0 accepts them. The default and recommended setting is 1.

`net.ipv4.icmp_ignore_bogus_error_message` controls whether ICMP bogus error message responses are ignored. A value of 1 ignores such messages, and 0 accepts them. The default and recommended setting is 1.

To change the value of a kernel parameter, add the setting to `/etc/sysctl.conf`, for example:

```
kernel.randomize_va_space = 1
```

and then run the `sysctl -p` command.

### 26.9.9 Restricting Access to SSH Connections

The Secure Shell (SSH) allows protected, encrypted communication with other systems. As SSH is an entry point into the system, disable it if it is not required, or alternatively, edit the `/etc/ssh/sshd_config` file to restrict its use.

For example, the following setting does not allow `root` to log in using SSH:

```
PermitRootLogin no
```

You can restrict remote access to certain users and groups by specifying the `AllowUsers`, `AllowGroups`, `DenyUsers`, and `DenyGroups` settings, for example:

```
DenyUsers carol dan
AllowUsers alice bob
```

The `ClientAliveInterval` and `ClientAliveCountMax` settings cause the SSH client to time out automatically after a period of inactivity, for example:

```
# Disconnect client after 300 seconds of inactivity
ClientAliveCountMax 0
ClientAliveInterval 300
```

After making changes to the configuration file, restart the `sshd` service for your changes to take effect.

For more information, see the `sshd_config(5)` manual page.

### 26.9.10 Configuring File System Mounts, File Permissions, and File Ownerships

Use separate disk partitions for operating system and user data to prevent a file system full issue from impacting the operation of a server. For example, you might create separate partitions for `/home`, `/tmp`, `/oracle`, and so on.

Establish disk quotas to prevent a user from accidentally or intentionally filling up a file system and denying access to other users.

To prevent the operating system files and utilities from being altered during an attack, mount the `/usr` file system read-only. If you need to update any RPMs on the file system, use the `-o remount,rw` option with the `mount` command to remount `/usr` for both read and write access. After performing the update, use the `-o remount,ro` option to return the `/usr` file system to read-only mode.

To limit user access to non-root local file systems such as `/tmp` or removable storage partitions, specify the `-o noexec, nosuid, nodev` options to `mount`. These option prevent the execution of binaries (but not scripts), prevent the `setuid` bit from having any effect, and prevent the use of device files.
Use the `find` command to check for unowned files and directories on each file system, for example:

```bash
# find mount_point -mount -type f -nouser -o -nogroup -exec ls -l {} \;
# find mount_point -mount -type d -nouser -o -nogroup -exec ls -l {} \;
```

Unowned files and directories might be associated with a deleted user account, they might indicate an error with software installation or deleting, or they might be a sign of an intrusion on the system. Correct the permissions and ownership of the files and directories that you find, or remove them. If possible, investigate and correct the problem that led to their creation.

Use the `find` command to check for world-writable directories on each file system, for example:

```bash
# find mount_point -mount -type d -perm /o+w -exec ls -l {} \;
```

Investigate any world-writable directory that is owned by a user other than a system user. The user can remove or change any file that other users write to the directory. Correct the permissions and ownership of the directories that you find, or remove them.

You can also use `find` to check for `setuid` and `setgid` executables.

```bash
# find path -type f \( -perm -4000 -o -perm -2000 \) -exec ls -l {} \;
```

If the `setuid` and `setgid` bits are set, an executable can perform a task that requires other rights, such as `root` privileges. However, buffer overrun attacks can exploit such executables to run unauthorized code with the rights of the exploited process.

If you want to stop a `setuid` and `setgid` executable from being used by non-`root` users, you can use the following commands to unset the `setuid` or `setgid` bit:

```bash
# chmod u-s file
# chmod g-s file
```

The following table lists programs for which you might want to consider unsetting the `setuid` and `setgid`:

<table>
<thead>
<tr>
<th>Program File</th>
<th>Bit Set</th>
<th>Description of Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>/usr/bin/chage</code></td>
<td>setuid</td>
<td>Finds out password aging information (via the <code>-l</code> option).</td>
</tr>
<tr>
<td><code>/usr/bin/chfn</code></td>
<td>setuid</td>
<td>Changes finger information.</td>
</tr>
<tr>
<td><code>/usr/bin/chsh</code></td>
<td>setuid</td>
<td>Changes the login shell.</td>
</tr>
<tr>
<td><code>/usr/bin/crontab</code></td>
<td>setuid</td>
<td>Edits, lists, or removes a <code>crontab</code> file.</td>
</tr>
<tr>
<td><code>/usr/bin/wall</code></td>
<td>setgid</td>
<td>Sends a system-wide message.</td>
</tr>
<tr>
<td><code>/usr/bin/write</code></td>
<td>setgid</td>
<td>Sends a message to another user.</td>
</tr>
<tr>
<td><code>/usr/bin/Xorg</code></td>
<td>setuid</td>
<td>Invokes the X Windows server.</td>
</tr>
<tr>
<td><code>/usr/libexec/openssh/ssh-keysign</code></td>
<td>setuid</td>
<td>Runs the SSH helper program for host-based authentication.</td>
</tr>
<tr>
<td><code>/usr/sbin/mount.nfs</code></td>
<td>setuid</td>
<td>Mounts an NFS file system.</td>
</tr>
<tr>
<td><code>/usr/sbin/netreport</code></td>
<td>setgid</td>
<td>Requests notification of changes to network interfaces.</td>
</tr>
</tbody>
</table>

Note:

```
/sbin/mount.nfs4, /sbin/umount.nfs, and /sbin/umount.nfs4 are symbolic links to this file.
```
### Checking User Accounts and Privileges

#### Program File

<table>
<thead>
<tr>
<th>Program File</th>
<th>Bit Set</th>
<th>Description of Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>/usr/sbin/usernetctl</td>
<td>setuid</td>
<td>Controls network interfaces. Permission for a user to alter the state of a network interface also requires USERCTL=yes to be set in the interface file. You can also grant users and groups the privilege to run the ip command by creating a suitable entry in the /etc/sudoers file.</td>
</tr>
</tbody>
</table>

#### Note

This list is not exhaustive as many optional packages contain setuid and setgid programs.

#### 26.9.11 Checking User Accounts and Privileges

Check the system for unlocked user accounts on a regular basis, for example using a command such as the following:

```
# for u in `cat /etc/passwd | cut -d: -f1 | sort`; do passwd -S $u; done
```

<table>
<thead>
<tr>
<th>User</th>
<th>Status</th>
<th>Date Changed</th>
<th>Minimum Age</th>
<th>Maximum Age</th>
<th>Warning Period</th>
<th>Inactivity Period</th>
</tr>
</thead>
<tbody>
<tr>
<td>abrt</td>
<td>LK</td>
<td>2012-06-28</td>
<td>0 99999 7 -1</td>
<td>(Password locked.)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>adm</td>
<td>LK</td>
<td>2011-10-13</td>
<td>0 99999 7 -1</td>
<td>(Alternate authentication scheme in use.)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>apache</td>
<td>LK</td>
<td>2012-06-28</td>
<td>0 99999 7 -1</td>
<td>(Password locked.)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>avahi</td>
<td>LK</td>
<td>2012-06-28</td>
<td>0 99999 7 -1</td>
<td>(Password locked.)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>avahi-autoipd</td>
<td>LK</td>
<td>2012-06-28</td>
<td>0 99999 7 -1</td>
<td>(Password locked.)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>bin</td>
<td>LK</td>
<td>2011-10-13</td>
<td>0 99999 7 -1</td>
<td>(Alternate authentication scheme in use.)</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

In the output from this command, the second field shows if a user account is locked (LK), does not have a password (NP), or has a valid password (PS). The third field shows the date on which the user last changed their password. The remaining fields show the minimum age, maximum age, warning period, and inactivity period for the password and additional information about the password's status. The unit of time is days.

Use the `passwd` command to set passwords on any accounts that are not protected.

Use `passwd -l` to lock unused accounts. Alternatively, use `userdel` to remove the accounts entirely.

For more information, see the `passwd(1)` and `userdel(8)` manual pages.

To specify how users’ passwords are aged, edit the following settings in the `/etc/login.defs` file:

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PASS_MAX_DAYS</td>
<td>Maximum number of days for which a password can be used before it must be changed. The default value is 99,999 days.</td>
</tr>
<tr>
<td>PASS_MIN_DAYS</td>
<td>Minimum number of days that is allowed between password changes. The default value is 0 days.</td>
</tr>
<tr>
<td>PASS_WARN_AGE</td>
<td>Number of days warning that is given before a password expires. The default value is 7 days.</td>
</tr>
</tbody>
</table>

For more information, see the `login.defs(5)` manual page.

To change how long a user’s account can be inactive before it is locked, use the `usermod` command. For example, to set the inactivity period to 30 days:

```
# usermod -f 30 username
```

To change the default inactivity period for new user accounts, use the `useradd` command:

```
# useradd -D -f 30
```
A value of -1 specifies that user accounts are not locked due to inactivity.

For more information, see the useradd(8) and usermod(8) manual pages.

Verify that no user accounts other than root have a user ID of 0.

```
# awk -F: " $3 == 0 { print $1 }" /etc/passwd
root
```

If you install software that creates a default user account and password, change the vendor's default password immediately. Centralized user authentication using an LDAP implementation such as OpenLDAP can help to simplify user authentication and management tasks, and also reduces the risk arising from unused accounts or accounts without a password.

By default, an Oracle Linux system is configured so that you cannot log in directly as root. You must log in as a named user before using either su or sudo to perform tasks as root. This configuration allows system accounting to trace the original login name of any user who performs a privileged administrative action. If you want to grant certain users authority to be able to perform specific administrative tasks via sudo, use the visudo command to modify the /etc/sudoers file. For example, the following entry grants the user erin the same privileges as root when using sudo, but defines a limited set of privileges to frank so that he can run commands such as systemctl, rpm, and yum:

```
erin           ALL=(ALL)       ALL
frank          ALL= SERVICES, SOFTWARE
```

### 26.9.11.1 Configuring User Authentication and Password Policies

The Pluggable Authentication Modules (PAM) feature allows you to enforce strong user authentication and password policies, including rules for password complexity, length, age, expiration and the reuse of previous passwords. You can configure PAM to block user access after too many failed login attempts, after normal working hours, or if too many concurrent sessions are opened.

PAM is highly customizable by its use of different modules with customisable parameters. For example, the default password integrity checking module pam_pwquality.so tests password strength. The PAM configuration file (/etc/pam.d/system-auth) contains the following default entries for testing a password's strength:

```
password  requisite   pam_pwquality.so try_first_pass local_users_only retry=3 authtok_type=
password  sufficient  pam_unix.so sha512 shadow nullok try_first_pass use_authtok
password  required    pam_deny.so
```

The line for pam_pwquality.so defines that a user gets three attempts to choose a good password. From the module's default settings, the password length must a minimum of six characters, of which three characters must be different from the previous password. The module only tests the quality of passwords for users who are defined in /etc/passwd.

The line for pam_unix.so specifies that the module tests the password previously specified in the stack before prompting for a password if necessary (pam_pwquality will already have performed such checks for users defined in /etc/passwd), uses SHA-512 password hashing and the /etc/shadow file, and allows access if the existing password is null.

You can modify the control flags and module parameters to change the checking that is performed when a user changes his or her password, for example:

```
password  required  pam_pwquality.so retry=3 minlen=8 difok=5 minclass=-1
password  required  pam_unix.so use_authtok sha512 shadow remember=5
password  required  pam_deny.so
```

The line for pam_pwquality.so defines that a user gets three attempts to choose a good password with a minimum of eight characters, of which five characters must be different from the previous password, and
which must contain at least one upper case letter, one lower case letter, one numeric digit, and one non-alphanumeric character.

The line for `pam_unix.so` specifies that the module does not perform password checking, uses SHA-512 password hashing and the `/etc/shadow` file, and saves information about the previous five passwords for each user in the `/etc/security/opassword` file. As `nullok` is not specified, a user cannot change his or her password if the existing password is null.

The omission of the `try_first_pass` keyword means that the user is always asked for their existing password, even if he or she entered it for the same module or for a previous module in the stack.

For more information, see Section 24.7, “About Pluggable Authentication Modules” and the `pam_deny(8)`, `pam_pwquality(8)`, and `pam_unix(8)` manual pages.

An alternate way of defining password requirements is available by selecting the Password Options tab in the Authentication Configuration GUI (`system-config-authentication`).

Figure 26.2 shows the Authentication Configuration GUI with the Password Options tab selected.

**Figure 26.2 Password Options**

<table>
<thead>
<tr>
<th>Authentication Configuration</th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Identity &amp; Authentication</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Advanced Options</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Password Options</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Minimal Password Requirements**

- Length: 9
- Character Classes: 1

**Required Character Classes**

- Lowercase
- Uppercase
- Digits
- Other characters

**Maximal Consecutive Character Repetition**

- Same Character: 0
- Same Class: 0

**Tip**: These checks are disabled if the value is 0.
You can specify the minimum password length, minimum number of required character classes, which character classes are required, and the maximum number of consecutive characters and consecutive characters from the same class that are permitted.

    27.5.3 Using ssh-keygen to Generate Pairs of Authentication Keys 382
    27.5.4 Enabling Remote System Access Without Requiring a Password 382

This chapter describes how to configure OpenSSH to support secure communication between networked systems.

27.1 About OpenSSH

OpenSSH is suite of network connectivity tools that provides secure communications between systems, including:

- scp Secure file copying.
- sftp Secure File Transfer Protocol (FTP).
- ssh Secure shell to log on to or run a command on a remote system.
- sshd Daemon that supports the OpenSSH services.
- ssh-keygen Creates DSA or RSA authentication keys.

Unlike utilities such as rcp, ftp, telnet, rsh, and rlogin, the OpenSSH tools encrypt all network packets between the client and server, including password authentication.

OpenSSH supports SSH protocol version 1 (SSH1) and version 2 (SSH2). In addition, OpenSSH provides a secure way of using graphical applications over a network by using X11 forwarding. It also provides a way to secure otherwise insecure TCP/IP protocols by using port forwarding.

27.2 OpenSSH Configuration Files

The following OpenSSH global configuration files are located in /etc/ssh:

- moduli Contains key-exchange information that is used to set up a secure connection.
- ssh_config Contains default client configuration settings that can be overridden by the settings in a user’s ~/.ssh/config file.
- ssh_host_dsa_key Contains the DSA private key for SSH2.
- ssh_host_dsa_key.pub Contains the DSA public key for SSH2.
OpenSSH User Configuration Files

```
ssh_host_key
Contains the RSA private key for SSH1.

ssh_host_key.pub
Contains the RSA public key for SSH1.

ssh_host_rsa_key
Contains the RSA private key for SSH2.

ssh_host_rsa_key.pub
Contains the RSA public key for SSH2.

sshd_config
Contains configuration settings for ssdh.
```

Other files can be configured in this directory. For details, see the `sshd(8)` manual page.

For more information, see the `ssh_config(5)`, `sshd(8)`, and `sshd_config(5)` manual pages.

### 27.2.1 OpenSSH User Configuration Files

To use the OpenSSH tools, a user must have an account on both the client and server systems. The accounts do not need to be configured identically on each system.

User configuration files are located in the `.ssh` directory in a user’s home directory (`~/.ssh`) on both the client and server. OpenSSH creates this directory and the `known_hosts` file when the user first uses an OpenSSH utility to connect to a remote system.

#### 27.2.1.1 User Configuration Files in ~/.ssh on the Client

On the client side, the `~/.ssh/known_hosts` file contains the public host keys that OpenSSH has obtained from SSH servers. OpenSSH adds an entry for each new server to which a user connects.

In addition, the `~/.ssh` directory usually contains one of the following pairs of key files:

- `id_dsa` and `id_dsa.pub` Contain a user's SSH2 DSA private and public keys.
- `id_rsa` and `id_rsa.pub` Contains a user's SSH2 RSA private and public keys. SSH2 RSA is most commonly used key-pair type.
- `identity` and `identity.pub` Contains a user's SSH1 RSA private and public keys.

⚠️ **Caution**
The private key file can be readable and writable by the user but must not be accessible to other users.

The optional `config` file contains client configuration settings.

⚠️ **Caution**
A `config` file can be readable and writable by the user but must not be accessible to other users.

For more information, see the `ssh(1)` and `ssh-keygen(1)` manual pages.

#### 27.2.1.2 User Configuration Files in ~/.ssh on the Server

On the server side, the `~/.ssh` directory usually contains the following files:

- `authorized_keys` Contains your authorized public keys. The server uses the signed public key in this file to authenticate a client.
27.3 Configuring an OpenSSH Server

Note
The default Oracle Linux installation includes the openssh and openssh-server packages, but does not enable the sshd service.

To configure an OpenSSH server:

1. Install or update the openssh and openssh-server packages:

   ```
   # yum install openssh openssh-server
   ```

2. Start the sshd service and configure it to start following a system reboot:

   ```
   # systemctl start sshd
   # systemctl enable sshd
   ```

   You can set sshd configuration options for features such as Kerberos authentication, X11 forwarding, and port forwarding in the /etc/ssh/sshd_config file.

   For more information, see the sshd(8) and sshd_config(5) manual pages.

27.4 Installing the OpenSSH Client Packages

Note
The default Oracle Linux installation includes the openssh and openssh-client packages.

To configure an OpenSSH client, install or update the openssh and openssh-client packages:

```
# yum install openssh openssh-client
```

27.5 Using the OpenSSH Utilities

By default, each time you use the OpenSSH utilities to connect to a remote system, you must provide your user name and password to the remote system. When you connect to an OpenSSH server for the first time, the OpenSSH client prompts you to confirm that you are connected to the correct system. In the following example, the ssh command is used to connect to the remote host host04:

```
$ ssh host04
```
The authenticity of host 'host04 (192.0.2.104)' can't be established.
Are you sure you want to continue connecting (yes/no)? yes
Warning: Permanently added 'host04,192.0.2.104' (RSA) to the list of known hosts.

When you enter yes to accept the connection to the server, the client adds the server's public host key to the your ~/.ssh/known_hosts file. When you next connect to the remote server, the client compares the key in this file to the one that the server supplies. If the keys do not match, you see a warning such as the following:

The RSA host key for host has changed, and the key for the according IP address IP_address is unchanged. This could either mean that DNS SPOOFING is happening or the IP address for the host and its host key have changed at the same time.
Offending key for IP in /home/user/.ssh/known_hosts:10
WARNING: REMOTE HOST IDENTIFICATION HAS CHANGED!
IT IS POSSIBLE THAT SOMEONE IS DOING SOMETHING NASTY!
Someone could be eavesdropping on you right now (man-in-the-middle attack)!
It is also possible that the RSA host key has just been changed.
The fingerprint for the RSA key sent by the remote host is fingerprint
Please contact your system administrator.
Add correct host key in /home/user/.ssh/known_hosts to get rid of this message.
Offending key in /home/user/.ssh/known_hosts:53
Host key verification failed.

Unless there is a reason for the remote server’s host key to have changed, such as an upgrade of either the SSH software or the server, you should not try to connect to that machine until you have contacted its administrator about the situation.

27.5.1 Using ssh to Connect to Another System

The ssh command allows you to log in to a remote system, or to execute a command on a remote system:

```bash
$ ssh [options] [user@]host [command]
```

host is the name of the remote OpenSSH server to which you want to connect.

For example, to log in to host04 with the same user name as on the local system, enter:

```bash
$ ssh host04
```

The remote system prompts you for your password on that system.

To connect as a different user, specify the user name and @ symbol before the remote host name, for example:

```bash
$ ssh joe@host04
```

To execute a command on the remote system, specify the command as an argument, for example:

```bash
$ ssh joe@host04 ls ~/.ssh
```
Using scp and sftp to Copy Files Between Systems

**ssh** logs you in, executes the command, and then closes the connection.

For more information, see the **ssh**(1) manual page.

### 27.5.2 Using scp and sftp to Copy Files Between Systems

The **scp** command allows you to copy files or directories between systems. **scp** establishes a connection, copies the files, and then closes the connection.

To upload a local file to a remote system:

```bash
$ scp [options] local_file [user@]host[:remote_file]
```

For example, copy **testfile** to your home directory on **host04**:

```bash
$ scp testfile host04
```

Copy **testfile** to the same directory but change its name to **new_testfile**:

```bash
$ scp testfile host04:new_testfile
```

To download a file from a remote system to the local system:

```bash
$ scp [options] [user@]host[:remote_file] local_file
```

The **-r** option allows you to recursively copy the contents of directories. For example, copy the directory **remdir** and its contents from your home directory on remote **host04** to your local home directory:

```bash
$ scp -r host04:~/remdir ~
```

The **sftp** command is a secure alternative to **ftp** for file transfer between systems. Unlike **scp**, **sftp** allows you to browse the file system on the remote server before you copy any files.

To open an FTP connection to a remote system over SSH:

```bash
$ sftp [options] [user@]host
```

For example:

```bash
$ sftp host04
Connecting to host04... 
guest@host04’s password: password
sftp>
```

Enter **sftp** commands at the **sftp>** prompt. For example, use **put** to upload the file **newfile** from the local system to the remote system and **ls** to list it:

```bash
sftp> put newfile
Uploading newfile to /home/guest/newfile
foo                                           100%  1198     1.2KB/s   00:01
sftp> ls foo
foo
```

Enter **help** or **?** to display a list of available commands. Enter **bye**, **exit**, or **quit** to close the connection and exit **sftp**.

For more information, see the **ssh**(1) and **sftp**(1) manual pages.
27.5.3 Using ssh-keygen to Generate Pairs of Authentication Keys

The `ssh-keygen` command generate a public and private authentication key pair. Such authentication keys allow you to connect to a remote system without needing to supply a password each time that you connect. Each user must generate their own pair of keys. If `root` generates key pairs, only `root` can use those keys.

To create a public and private SSH2 RSA key pair:

```bash
$ ssh-keygen
Generating public/private rsa key pair.
Enter file in which to save the key (/home/guest/.ssh/id_rsa): <Enter>
Created directory '/home/guest/.ssh'.
Enter passphrase (empty for no passphrase): password
Enter same passphrase again: password
Your identification has been saved in /home/guest/.ssh/id_rsa.
Your public key has been saved in /home/guest/.ssh/id_rsa.pub.
The key fingerprint is:
The key's randomart image is:
+---[ RSA 2048]----+
  .=Eo++.o   |
  o  ..B=.   |
  o + .    |
  S * o    |
  . = .    |
  .        |
  .         |
  +-----------------+
```

To generate an SSH1 RSA or SSH2 DSA key pair, specify the `-t rsa1` or `-t dsa` options.

For security, in case an attacker gains access to your private key, you can specify an passphrase to encrypt your private key. If you encrypt your private key, you must enter this passphrase each time that you use the key. If you do not specify a passphrase, you are not prompted.

`ssh-keygen` generates a private key file and a public key file in `~/.ssh` (unless you specify an alternate directory for the private key file):

```bash
$ ls -l ~/.ssh
total 8
-rw-------. 1 guest guest 1743 Apr 13 12:07 id_rsa
-rw-r--r--. 1 guest guest  397 Apr 13 12:07 id_rsa.pub
```

For more information, see the `ssh-keygen(1)` manual page.

27.5.4 Enabling Remote System Access Without Requiring a Password

To be able to use the OpenSSH utilities to access a remote system without supplying a password each time that you connect:

1. Use `ssh-keygen` to generate a public and private key pair, for example:

```bash
$ ssh-keygen
Generating public/private rsa key pair.
Enter file in which to save the key (/home/user/.ssh/id_rsa): <Enter>
Created directory '/home/user/.ssh'.
Enter passphrase (empty for no passphrase): <Enter>
Enter same passphrase again: <Enter>
```
Press Enter each time that the command prompts you to enter a passphrase.

2. Use the `ssh-copy-id` script to append the public key in the local `~/.ssh/id_rsa.pub` file to the `~/.ssh/authorized_keys` file on the remote system, for example:

```bash
$ ssh-copy-id remote_user@host
remote_user@host's password: remote_password
Now try logging into the machine, with "ssh 'remote_user@host'", and check in:

    .ssh/authorized_keys

to make sure we haven't added extra keys that you weren't expecting.
```

When prompted, enter your password for the remote system.

The script also changes the permissions of `~/.ssh` and `~/.ssh/authorized_keys` on the remote system to disallow access by your group.

You can now use the OpenSSH utilities to access the remote system without supplying a password. As the script suggests, you should use `ssh` to log into the remote system to verify that the `~/.ssh/authorized_keys` file contains only the keys for the systems from which you expect to connect. For example:

```bash
$ ssh remote_user@host
Last login: Thu Jun 13 08:33:58 2013 from local_host
host:$ cat .ssh/authorized_keys

ssh-rsa AAAAB3NzaC1yc2EAAAABIA6OabJhWABsZ4F3mcjEPT3axXx10oUcvuCI1M6f5gS/ER...
local_user@local_host
host:$ logout
Connection to host closed.
$
```

3. Verify that the permissions on the remote `~/.ssh` directory and `~/.ssh/authorized_keys` file allow access only by you:

```bash
$ ssh remote_user@host ls -al .ssh
total 4
  drwx------+ 2 remote_user group 5 Jun 12 08:33 .
  drwxr-xr+x 3 remote_user group 9 Jun 12 08:32 ..
-rw-------+ 1 remote_user group 397 Jun 12 08:33 authorized_keys
$ ssh remote_user@host getfacl .ssh
# file: .ssh
# owner: remote_user
# group: group
user::rwx
group::---
mask::rwx
other::---

$ ssh remote_user@host getfacl .ssh/authorized_keys
# file: .ssh/authorized_keys
# owner: remote_user
# group: group
user::rwx
group::---
mask::rwx
other::---
```

If necessary, correct the permissions:

```bash
$ ssh remote_user@host 'umask 077; /sbin/restorecon .ssh'
$ ssh remote_user@host 'umask 077; /sbin/restorecon .ssh/authorized_keys'
```
Note

If your user names are the same on the client and the server systems, you do not need to specify your remote user name and the @ symbol.

4. If your user names are different on the client and the server systems, create a ~/.ssh/config file with permissions 600 on the remote system that defines your local user name, for example:

```bash
$ ssh remote_user@host echo -e "Host *\nUser local_user" '>>' .ssh/config
$ ssh remote_user@host cat .ssh/config
Host *
User local_user
$ ssh remote_user@host 'umask 077; /sbin/restorecon .ssh/config'
```

You should now be able to access the remote system without needing to specify your remote user name, for example:

```bash
$ ssh host ls -l .ssh/config
-rw-------+ 1 remote_user group 37 Jun 12 08:34 .ssh/config
$ ssh host getfacl .ssh/config
# file: .ssh/config
# owner: remote_user
# group: group
user::rw-
group::---
mask::rwx
other::---
```

For more information, see the ssh-copy-id(1), ssh-keygen(1), and ssh_config(5) manual pages.
Part V Virtualization

This section contains the following chapters:

- **Chapter 28, Linux Containers** describes how to use Linux Containers (LXC) to isolate applications and entire operating system images from the other processes that are running on a host system.

- **Chapter 29, Using KVM With Oracle Linux** describes how to use an Oracle Linux system as a hypervisor with Kernel-based Virtual Machine (KVM) and provides information on installing virtualization packages.

  **Note**

This chapter describes how to use Linux Containers (LXC) to isolate applications and entire operating system images from the other processes that are running on a host system. The version of LXC described here is 1.0.7 or later, which has some significant enhancements over previous versions.

For information about how to use the Docker Engine to create application containers, see the Oracle Container Runtime for Docker User’s Guide.

28.1 About Linux Containers

Note

Prior to UEK R3, LXC was a Technology Preview feature that was made available for testing and evaluation purposes, but was not recommended for production systems. LXC is a supported feature with UEK R3 and UEK R4.

The Linux Containers (LXC) feature is a lightweight virtualization mechanism that does not require you to set up a virtual machine on an emulation of physical hardware. The Linux Containers feature takes the cgroups resource management facilities as its basis and adds POSIX file capabilities to implement process and network isolation. You can run a single application within a container (an application container) whose name space is isolated from the other processes on the system in a similar manner to a chroot jail.

However, the main use of Linux Containers is to allow you to run a complete copy of the Linux operating system in a container (a system container) without the overhead of running a level-2 hypervisor such as VirtualBox. In fact, the container is sharing the kernel with the host system, so its processes and file system are completely visible from the host. When you are logged into the container, you only see its file system and process space. Because the kernel is shared, you are limited to the modules and drivers that it has loaded.

Typical use cases for Linux Containers are:
About Linux Containers

- Running Oracle Linux 5, Oracle Linux 6, and Oracle Linux 7 containers in parallel. You can run an Oracle Linux 5 container on an Oracle Linux 7 system with the UEK R3 or UEKR4 kernel, even though UEK R3 and UEK R4 are not supported for Oracle Linux 5. You can also run an i386 container on an x86_64 kernel. For more information, see Section 28.1.1, “Supported Oracle Linux Container Versions”.

- Running applications that are supported only by Oracle Linux 5 in an Oracle Linux 5 container on an Oracle Linux 7 host. However, incompatibilities might exist in the modules and drivers that are available.

- Running many copies of application configurations on the same system. An example configuration would be a LAMP stack, which combines Linux, Apache HTTP server, MySQL, and Perl, PHP, or Python scripts to provide specialised web services.

- Creating sandbox environments for development and testing.

- Providing user environments whose resources can be tightly controlled, but which do not require the hardware resources of full virtualization solutions.

- Creating containers where each container appears to have its own IP address. For example you can use the lxc-sshd template script to create isolated environments for untrusted users. Each container runs an sshd daemon to handle logins. By bridging a container's Virtual Ethernet interface to the host's network interface, each container can appear to have its own IP address on a LAN.

When you use the lxc-start command to start a system container, by default the copy of /sbin/init (for an Oracle Linux 6 or earlier container) or /usr/lib/systemd/systemd (for an Oracle Linux 7 container) in the container is started to spawn other processes in the container's process space. Any system calls or device access are handled by the kernel running on the host. If you need to run different kernel versions or different operating systems from the host, use a full virtualization solution such as Oracle VM or Oracle VM VirtualBox instead of Linux Containers.

There are a number of configuration steps that you need to perform on the file system image for a container so that it can run correctly:

- Disable any init or systemd scripts that load modules to access hardware directly.

- Disable udev and instead create static device nodes in /dev for any hardware that needs to be accessible from within the container.

- Configure the network interface so that it is bridged to the network interface of the host system.

LXC provides a number of template scripts in /usr/share/lxc/templates that perform much of the required configuration of system containers for you. However, it is likely that you will need to modify the script to allow the container to work correctly as the scripts cannot anticipate the idiosyncrasies of your system's configuration. You use the lxc-create command to create a system container by invoking a template script. For example, the lxc-busybox template script creates a lightweight BusyBox system container.

The example system container in this chapter uses the template script for Oracle Linux (lxc-oracle). The container is created on a btrfs file system (/container) to take advantage of its snapshot feature. A btrfs file system allows you to create a subvolume that contains the root file system (rootfs) of a container, and to quickly create new containers by cloning this subvolume.

You can use control groups to limit the system resources that are available to applications such as web servers or databases that are running in the container.

Application containers are not created by using template scripts. Instead, an application container mounts all or part of the host's root file system to provide access to the binaries and libraries that the application requires. You use the lxc-execute command to invoke /usr/sbin/init.lxc (a cut-down version of /sbin/init) in the container. init.lxc mounts any required directories such as /proc, /dev/shm,
and `/dev/mqueue`, executes the specified application program, and then waits for it to finish executing. When the application exits, the container instance ceases to exist.

### 28.1.1 Supported Oracle Linux Container Versions

All versions of Oracle Linux 7, running `kernel-uek-3.8.13-35.3.1` or later, support the following container versions:

- Oracle Linux 5.9 or later
- Oracle Linux 6.5 or later
- Oracle Linux 7.0 or later

Note that subsequent versions of Oracle Linux 7 and UEK are tested to support the listed container versions. Exceptions, if any, are listed in the release notes for the version of Oracle Linux 7 affected.

### 28.2 Configuring Operating System Containers

The procedures in the following sections describe how to set up Linux Containers that contain a copy of the root file system installed from packages on the Oracle Linux yum server.

- Section 28.2.1, “Installing and Configuring the Software”
- Section 28.2.2, “Setting up the File System for the Containers”
- Section 28.2.3, “Creating and Starting a Container”

#### Note

Throughout the following sections in this chapter, the prompts `[root@host ~]#` and `[root@ol6ctr1 ~]#` distinguish between commands run by `root` on the host and in the container.

#### 28.2.1 Installing and Configuring the Software

To install and configure the software that is required to run Linux Containers:

1. Install the `btrfs-progs` package by using the `yum` command.

   ```bash
   [root@host ~]# yum install btrfs-progs
   ```

2. Install the `lxc` and `wget` packages.

   ```bash
   [root@host ~]# yum install lxc wget
   ```

   This command installs all of the required packages. The LXC template scripts are installed in `/usr/share/lxc/templates`. LXC uses `wget` to download packages from the Oracle Linux yum server.

3. Start the LXC network management service, `lxc-net`, and configure the service to start at boot time.

   ```bash
   [root@host ~]# systemctl start lxc-net.service
   [root@host ~]# systemctl enable lxc-net.service
   ```

   LXC includes its own network management service to support network bridging for containers.

4. If you are going to compile applications that require the LXC header files and libraries, install the `lxc-devel` package.

   ```bash
   [root@host ~]# yum install lxc-devel
   ```
28.2.2 Setting up the File System for the Containers

Note
The LXC template scripts assume that containers are created in /container. You must edit the script if your system's configuration differs from this assumption.

To set up the /container file system:

1. Create a btrfs file system on a suitably sized device such as /dev/sdb.

   [root@host ~]# mkfs.btrfs /dev/sdb

2. Mount the /container file system. The /container directory is created automatically when you install LXC.

   [root@host ~]# mount /dev/sdb /container

3. Add an entry for /container to the /etc/fstab file.

   /dev/sdb    /container    btrfs    defaults   0 0

For more information, see Section 21.2, “About the Btrfs File System”.

28.2.3 Creating and Starting a Container

Note
The procedure in this section uses the LXC template script for Oracle Linux (lxc-oracle), which is located in /usr/share/lxc/templates. An Oracle Linux container requires a minimum of 400 MB of disk space.

To create and start a container:

1. Create an Oracle Linux 6 container named ol6ctr1 using the lxc-oracle template script.

   [root@host ~]# lxc-create -n ol6ctr1 -B btrfs -t oracle -- --release=6.latest
   Host is OracleEverything 7.0
   Create configuration file /container/ol6ctr1/config
   Yum installing release 6.latest for x86_64
   ...
   ...
   yum-metadata-parser.x86_64 0:1.1.2-16.el6
   zlib.x86_64 0:1.2.3-29.el6
   Complete!
   Rebuilding rpm database
   Patching container rootfs /container/ol6ctr1/rootfs for Oracle Linux 6.5
   Configuring container for Oracle Linux 6.5
   Added container user:oracle password:oracle
   Added container user:root password:root
   Container : /container/ol6ctr1/rootfs
   Config    : /container/ol6ctr1/config
   Network   : eth0 (veth) on lxcbr0

Note
For LXC version 1.0 and later, you must specify the -B btrfs option if you want to use the snapshot features of btrfs. For more information, see the lxc-create(1) manual page.
Creating and Starting a Container

The `lxc-create` command runs the template script `lxc-oracle` to create the container in `/container/ol6ctrl` with the btrfs subvolume `/container/ol6ctrl/rootfs` as its root file system. The command then uses `yum` to install the latest available update of Oracle Linux 6 from the Oracle Linux yum server. It also writes the container's configuration settings to the file `/container/ol6ctrl/config` and its `fstab` file to `/container/ol6ctrl/fstab`. The default log file for the container is `/container/ol6ctrl/ol6ctrl.log`.

You can specify the following template options after the `--` option to `lxc-create`:

```
-a|--arch=i386|x86_64  Specifies the architecture. The default value is the architecture of the host.
--baseurl=Specify the file URI of a package repository. You must also use the
          --arch and --release options to specify the architecture and the
          release, for example:
          # mount -o loop OracleLinux-R7-GA-Everything-x86_64-dvd.iso /mnt
          # lxc-create -n ol70beta -B btrfs -t oracle -- -R 7.0 -a x86_64
          \|--baseurl=file:///mnt/Server
-P|--patch=path  Patch the rootfs at the specified path.
--privileged[=rt] Allows you to adjust the values of certain kernel parameters under
          the /proc hierarchy.
          The container uses a privilege configuration file, which mounts
          /proc read-only with some exceptions. See Section 28.9,
          “Configuring Kernel Parameter Settings for Oracle Linux
          Containers”.
          This option also enables the CAP_SYS_NICE capability, which
          allows you to set negative nice values (that is, more favored for
          scheduling) for processes from within the container.
          If you specify the =rt (real-time) modifier, you can configure the
          lxc.cgroup.cpu.rt_runtime_us setting in the container's
          configuration file or when you start the container. This setting
          specifies the maximum continuous period in microseconds for which
          the container has access to CPU resources from the base period
          set by the system-wide value of cpu.rt_period_us. Otherwise,
          a container uses the system-wide value of cpu.rt_runtime_us,
          which might cause it to consume too many CPU resources. In
          addition, this modifier ensures that rebooting a container terminates
          all of its processes and boots it to a clean state.
          -R|--release=major.minor  Specifies the major release number and minor update number of the
          Oracle release to install. The value of major can be set to 4, 5, 6,
          or 7. If you specify latest for minor, the latest available release
          packages for the major release are installed. If the host is running
          Oracle Linux, the default release is the same as the release installed
          on the host. Otherwise, the default release is the latest update of
          Oracle Linux 6.
          -r|--rpms=rpm_name  Install the specified RPM in the container.
```

393
About the lxc-oracle Template Script

-t |--templatefs=rootfs  Specifies the path to the root file system of an existing system, container, or Oracle VM template that you want to copy. Do not specify this option with any other template option. See Section 28.4, “Creating Additional Containers”.

-u |--url=repo_URL  Specifies a yum repository other than Oracle Public Yum. For example, you might want to perform the installation from a local yum server. The repository file in configured in /etc/yum.repos.d in the container's root file system. The default URL is https://yum.oracle.com.

2. If you want to create additional copies of the container in its initial state, create a snapshot of the container's root file system, for example:

```
# btrfs subvolume snapshot /container/ol6ctr1/rootfs /container/ol6ctr1/rootfs_snap
```

See Section 21.2, “About the Btrfs File System” and Section 28.4, “Creating Additional Containers”.

3. Start the container ol6ctr1 as a daemon that writes its diagnostic output to a log file other than the default log file.

```
[root@host ~]# lxc-start -n ol6ctr1 -d -o /container/ol6ctrl_debug.log -l DEBUG
```

Note
---
If you omit the -d option, the container's console opens in the current shell.

The following logging levels are available: FATAL, CRIT, WARN, ERROR, NOTICE, INFO, and DEBUG. You can set a logging level for all lxc-* commands.

If you run the ps -ef --forest command on the host system and the process tree below the lxc-start process shows that the /usr/sbin/sshd and /sbin/mingetty processes have started in the container, you can log in to the container from the host. See Section 28.3, “Logging in to Containers”.

28.2.4 About the lxc-oracle Template Script

Note
---
If you amend a template script, you alter the configuration files of all containers that you subsequently create from that script. If you amend the config file for a container, you alter the configuration of that container and all containers that you subsequently clone from it.

The lxc-oracle template script defines system settings and resources that are assigned to a running container, including:

- the default passwords for the oracle and root users, which are set to oracle and root respectively
- the host name (lxc.utsname), which is set to the name of the container
- the number of available terminals (lxc.tty), which is set to 4
- the location of the container's root file system on the host (lxc.rootfs)
- the location of the fstab mount configuration file (lxc.mount)
• all system capabilities that are not available to the container (\texttt{lxc.cap.drop})

• the local network interface configuration (\texttt{lxc.network})

• all whitelisted cgroup devices (\texttt{lxc.cgroup.devices.allow})

The template script sets the virtual network type (\texttt{lxc.network.type}) and bridge (\texttt{lxc.network.link}) to \texttt{veth} and \texttt{lxcbr0}. If you want to use a macvlan bridge or Virtual Ethernet Port Aggregator that allows external systems to access your container via the network, you must modify the container's configuration file. See Section 28.2.5, “About Veth and Macvlan” and Section 28.2.6, “Modifying a Container to Use Macvlan”.

To enhance security, you can uncomment \texttt{lxc.cap.drop} capabilities to prevent root in the container from performing certain actions. For example, dropping the \texttt{sys_admin} capability prevents root from remounting the container's \texttt{fstab} entries as writable. However, dropping \texttt{sys_admin} also prevents the container from mounting any file system and disables the \texttt{hostname} command. By default, the template script drops the following capabilities: \texttt{mac_admin,mac_override,setfcap,setpcap,sys_module,sys_nice,sys_pacct,sys_rawio, and sys_time}.

For more information, see the \texttt{capabilities(7)} and \texttt{lxc.conf(5)} manual pages.

When you create a container, the template script writes the container's configuration settings and mount configuration to \texttt{/container/name/config} and \texttt{/container/name/fstab}, and sets up the container's root file system under \texttt{/container/name/rootfs}.

Unless you specify to clone an existing root file system, the template script installs the following packages under \texttt{rootfs} (by default, from the Oracle Linux Yum Server at \texttt{https://yum.oracle.com}):

<table>
<thead>
<tr>
<th>Package</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{chkconfig}</td>
<td>\texttt{chkconfig} utility for maintaining the \texttt{/etc/rc*.d} hierarchy.</td>
</tr>
<tr>
<td>\texttt{dhclient}</td>
<td>\texttt{DHCP} client daemon (\texttt{dhclient}) and \texttt{dhclient-script}.</td>
</tr>
<tr>
<td>\texttt{initscripts}</td>
<td>\texttt{/etc/inittab} file and \texttt{/etc/init.d} scripts.</td>
</tr>
<tr>
<td>\texttt{openssh-server}</td>
<td>Open source \texttt{SSH} server daemon, \texttt{/usr/sbin/ssh}d.</td>
</tr>
<tr>
<td>\texttt{oraclelinux-release}</td>
<td>Oracle Linux release and information files.</td>
</tr>
<tr>
<td>\texttt{passwd}</td>
<td>\texttt{passwd} utility for setting or changing passwords using PAM.</td>
</tr>
<tr>
<td>\texttt{policycoreutils}</td>
<td>SELinux policy core utilities.</td>
</tr>
<tr>
<td>\texttt{rootfiles}</td>
<td>Basic files required by the \texttt{root} user.</td>
</tr>
<tr>
<td>\texttt{rsyslog}</td>
<td>Enhanced system logging and kernel message trapping daemons.</td>
</tr>
<tr>
<td>\texttt{vim-minimal}</td>
<td>Minimal version of the \texttt{VIM} editor.</td>
</tr>
<tr>
<td>\texttt{yum}</td>
<td>\texttt{yum} utility for installing, updating and managing RPM packages.</td>
</tr>
</tbody>
</table>

The template script edits the system configuration files under \texttt{rootfs} to set up networking in the container and to disable unnecessary services including volume management (LVM), device management (\texttt{udev}), the hardware clock, \texttt{readahead}, and the Plymouth boot system.

## 28.2.5 About Veth and Macvlan

By default, the \texttt{lxc-oracle} template script sets up networking by setting up a \texttt{veth} bridge. In this mode, a container obtains its IP address from the \texttt{dnsmasq} server that the \texttt{lxc-net} service runs on the private
About Veth and Macvlan

virtual bridge network (\texttt{lxcbr0}) between the container and the host. The host allows a container to connect to the rest of the network by using NAT rules in \texttt{iptables}, but these rules do not allow incoming connections to the container. Both the host and other containers on the veth bridge have network access to the container via the bridge.

\textbf{Figure 28.1} illustrates a host system with two containers that are connected via the veth bridge \texttt{lxcbr0}.

\textbf{Figure 28.1 Network Configuration of Containers Using a Veth Bridge}

If you want to allow network connections from outside the host to be able to connect to the container, the container needs to have an IP address on the same network as the host. One way to achieve this configuration is to use a macvlan bridge to create an independent logical network for the container. This network is effectively an extension of the local network that is connected to the host's network interface. External systems can access the container as though it were an independent system on the network, and the container has network access to other containers that are configured on the bridge and to external systems. The container can also obtain its IP address from an external DHCP server on your local network. However, unlike a veth bridge, the host system does not have network access to the container.

\textbf{Figure 28.2} illustrates a host system with two containers that are connected via a macvlan bridge.

\textbf{Figure 28.2 Network Configuration of Containers Using a Macvlan Bridge}

If you do not want containers to be able to see each other on the network, you can configure the Virtual Ethernet Port Aggregator (VEPA) mode of macvlan. \textbf{Figure 28.3} illustrates a host system with two containers that are separately connected to a network by a macvlan VEPA. In effect, each container is connected directly to the network, but neither container can access the other container nor the host via the network.
For information about configuring macvlan, see Section 28.2.6, “Modifying a Container to Use Macvlan” and the \texttt{lxc.conf(5)} manual page.

\section*{28.2.6 Modifying a Container to Use Macvlan}

To modify a container so that it uses the bridge or VEPA mode of macvlan, edit \texttt{/container/name/config} and replace the following lines:

\begin{verbatim}
lxc.network.type = veth
lxc.network.link = lxcbr0
lxc.network.flags = up
\end{verbatim}

with these lines for bridge mode:

\begin{verbatim}
lxc.network.type = macvlan
lxc.network.macvlan.mode = bridge
lxc.network.flags = up
lxc.network.link = eth0
\end{verbatim}

or these lines for VEPA mode:

\begin{verbatim}
lxc.network.type = macvlan
lxc.network.macvlan.mode = vepa
lxc.network.flags = up
lxc.network.link = eth0
\end{verbatim}

In these sample configurations, the setting for \texttt{lxc.network.link} assumes that you want the container's network interface to be visible on the network that is accessible via the host's \texttt{eth0} interface.

\subsection*{28.2.6.1 Modifying a Container to Use a Static IP Address}

By default, a container connected by macvlan relies on the DHCP server on your local network to obtain its IP address. If you want the container to act as a server, you would usually configure it with a static IP address. You can configure DHCP to serve a static IP address for a container or you can define the address in the container's \texttt{config} file.

To configure a static IP address that a container does not obtain using DHCP:

1. Edit \texttt{/container/name/rootfs/etc/sysconfig/network-scripts/ifcfg-interface}, where \texttt{interface} is the name of the network interface, and change the following line:

   \begin{verbatim}
   BOOTPROTO=dhcp
   \end{verbatim}
2. Add the following line to `/container/name/config`:

```plaintext
lxc.network.ipv4 = xxx.xxx.xxx.xxx/prefix_length
```

where `xxx.xxx.xxx.xxx/prefix_length` is the IP address of the container in CIDR format, for example: `192.168.56.100/24`.

**Note**

The address must not already be in use on the network or potentially be assignable by a DHCP server to another system.

You might also need to configure the firewall on the host to allow access to a network service that is provided by a container.

### 28.3 Logging in to Containers

You can use the `lxc-console` command to log in to a running container.

```plaintext
[root@host ~]# lxc-console -n name [-t tty_number]
```

If you do not specify a tty number, you log in to the first available terminal.

For example, log in to a terminal on `ol6ctr1`:

```plaintext
[root@host ~]# lxc-console -n ol6ctr1
```

To exit an `lxc-console` session, type `Ctrl-A` followed by `Q`.

Alternatively, you can use `ssh` to log in to a container if you install the `lxc-0.9.0-2.0.5` package (or later version of this package).

**Note**

To be able to log in using `lxc-console`, the container must be running an `/sbin/mingetty` process for the terminal. Similarly, using `ssh` requires that the container is running the SSH daemon (`/usr/sbin/sshd`).

### 28.4 Creating Additional Containers

To clone an existing container, use the `lxc-clone` command, as shown in this example:

```plaintext
[root@host ~]# lxc-clone -o ol6ctr1 -n ol6ctr2
```

Alternatively, you can use the `lxc-create` command to create a container by copying the root file system from an existing system, container, or Oracle VM template. Specify the path of the root file system as the argument to the `--templatefs` template option:

```plaintext
[root@host ~]# lxc-create -n ol6ctr3 -B btrfs -t oracle -- --templatefs=/container/ol6ctr1/rootfsSnap
```

This example copies the new container's `rootfs` from a snapshot of the `rootfs` that belongs to container `ol6ctr1`. The additional container is created in `/container/ol6ctr3` and a new `rootfs` snapshot is created in `/container/ol6ctr3/rootfs`. 
Note
For LXC version 1.0 and later, you must specify the `-B btrfs` option if you want to use the snapshot features of btrfs. For more information, see the `lxc-create(1)` manual page.

To change the host name of the container, edit the `HOSTNAME` settings in `/container/name/rootfs/etc/sysconfig/network` and `/container/name/rootfs/etc/sysconfig/network-scripts/ifcfg-iface`, where `iface` is the name of the network interface, such as `eth0`.

28.5 Monitoring and Shutting Down Containers

To display the containers that are configured, use the `lxc-ls` command on the host.

```
[root@host ~]# lxc-ls
ol6ctr1
ol6ctr2
```

To display the containers that are running on the host system, specify the `--active` option.

```
[root@host ~]# lxc-ls --active
ol6ctr1
```

To display the state of a container, use the `lxc-info` command on the host.

```
[root@host ~]# lxc-info -n ol6ctr1
Name:          ol6ctr1
State:         RUNNING
PID:           5662
IP:            192.168.122.188
CPU use:       1.63 seconds
BlkIO use:      18.95 MiB
Memory use:    11.53 MiB
KMem use:      0 bytes
Link:          vethJHU5OA
TX bytes:      1.42 KiB
RX bytes:      6.29 KiB
Total bytes: 7.71 KiB
```

A container can be in one of the following states: `ABORTING`, `RUNNING`, `STARTING`, `STOPPED`, or `STOPPING`. Although `lxc-info` might show your container to be in the `RUNNING` state, you cannot log in to it unless the `/usr/sbin/sshd` or `/sbin/mingetty` processes have started running in the container. You must allow time for the `init` or `systemd` process in the container to first start networking and the various other services that you have configured.

To view the state of the processes in the container from the host, either run `ps -ef --forest` and look for the process tree below the `lxc-start` process or use the `lxc-attach` command to run the `ps` command in the container.

```
[root@host ~]# ps -ef --forest
UID  PID  PPID  C  STIME TTY   TIME CMD
...  
root 3171    1     0 09:57 ?    00:00:00 lxc-start -n ol6ctr1 -d
root 3182  3171    0 09:57 ?    00:00:00  \
root 3441  3182    0 09:57 ?    00:00:00  \
root 3464  3182    0 09:57 ?    00:00:00  \
root 3493  3182    0 09:57 ?    00:00:00  \
root 3500  3182    0 09:57 pts/5 00:00:00  \
root 3504  3182    0 09:57 pts/1 00:00:00  \
root 3506  3182    0 09:57 pts/2 00:00:00  \
root 3508  3182    0 09:57 pts/3 00:00:00  \
root 3510  3182    0 09:57 pts/4 00:00:00  \
```
Monitoring and Shutting Down Containers

```plaintext
... [root@host ~]# lxc-attach -n ol6ctr1 -- /bin/ps aux
USER     PID  %CPU  %MEM  VSZ   RSS  TTY   STAT   START   TIME   COMMAND
root      1   0.0   0.1  19284  1516  ?     Ss    04:57   0:00   /sbin/init
root    202   0.0   0.0   9172   588  ?     Ss    04:57   0:00   /sbin/dhclient
root    225   0.0   0.1  245096 1332  ?    Sl    04:57   0:00   /sbin/rsyslogd
root    252   0.0   0.1  66660  1332  ?    Ssl   04:57   0:00   /usr/sbin/sshd
root    259   0.0   0.0   9172   588  lxc/console Ss+  04:57   0:00   /sbin/mingetty
root    263   0.0   0.0   4116   572  lxc/tty1 Ss+  04:57   0:00   /sbin/mingetty
root    265   0.0   0.0   4116   568  lxc/tty2 Ss+  04:57   0:00   /sbin/mingetty
root    267   0.0   0.0   4116   572  lxc/tty3 Ss+  04:57   0:00   /sbin/mingetty
root    269   0.0   0.0   4116   568  lxc/tty4 Ss+  04:57   0:00   /sbin/mingetty
root    283   0.0   0.1  110240 1144  ?    R+    04:59   0:00   /bin/ps aux
```

**Tip**

If a container appears not to be starting correctly, examining its process tree from the host will often reveal where the problem might lie.

If you were logged into the container, the output from the `ps -ef` command would look similar to the following.

```
[root@ol6ctr1 ~]# ps -ef
UID   PID  PPID  C STIME TTY          TIME CMD
root    1     0  0 11:54 ?        00:00:00 /sbin/init
root  193     1  0 11:54 ?        00:00:00 /sbin/dhclient -H ol6ctr1 ...
root  216     1  0 11:54 ?        00:00:00 /sbin/rsyslogd -l ...
root  258     1  0 11:54 ?        00:00:00 /usr/sbin/sshd
root  265     1  0 11:54 lxc/console 00:00:00 /sbin/mingetty ... /dev/console
root  271     1  0 11:54 lxc/tty2 00:00:00 /sbin/mingetty ... /dev/tty2
root  273     1  0 11:54 lxc/tty3 00:00:00 /sbin/mingetty ... /dev/tty3
root  275     1  0 11:54 lxc/tty4 00:00:00 /sbin/mingetty ... /dev/tty4
root  297     1  0 11:57 ?        00:00:00 login -- root
root  301  297  0 12:08 lxc/tty1 00:00:00 -bash
root  312  301  0 12:08 lxc/tty1 00:00:00 ps -ef
```

Note that the process numbers differ from those of the same processes on the host, and that they all descend from process 1, `/sbin/init`, in the container.

To suspend or resume the execution of a container, use the `lxc-freeze` and `lxc-unfreeze` commands on the host.

```
[root@host ~]# lxc-freeze -n ol6ctr1
[root@host ~]# lxc-unfreeze -n ol6ctr1
```

From the host, you can use the `lxc-stop` command with the `--nokill` option to shut down the container in an orderly manner.

```
[root@host ~]# lxc-stop --nokill -n ol6ctr1
```

Alternatively, you can run a command such as `halt` while logged in to the container.

```
[root@ol6ctr1 ~]# halt
Broadcast message from root@ol6ctr1 (/dev/tty2) at 22:52 ...
The system is going down for halt NOW!
lxc-console: Input/output error - failed to read
[root@host ~]#
```

As shown in the example, you are returned to the shell prompt on the host.

To shut down a container by terminating its processes immediately, use `lxc-stop` with the `-k` option.
Starting a Command Inside a Running Container

If you are debugging the operation of a container, this is the quickest method as you would usually destroy the container and create a new version after modifying the template script.

To monitor the state of a container, use the `lxc-monitor` command.

```
[root@host ~]# lxc-monitor -n ol6ctr1
'ol6ctr1' changed state to [STARTING]
'ol6ctr1' changed state to [RUNNING]
'ol6ctr1' changed state to [STOPPING]
'ol6ctr1' changed state to [STOPPED]
```

To wait for a container to change to a specified state, use the `lxc-wait` command.

```
lxc-wait -n $CTR -s ABORTING && lxc-wait -n $CTR -s STOPPED && 
    echo "Container $CTR terminated with an error."
```

28.6 Starting a Command Inside a Running Container

Note

The `lxc-attach` command is supported by UEK R3 with the `lxc-0.9.0-2.0.4` package or later.

You can use `lxc-attach` to execute an arbitrary command inside a container that is already running from outside the container, for example:

```
[root@host ~]# lxc-attach -n ol6ctr1 -- /bin/ps aux
```

For more information, see the `lxc-attach(1)` manual page.

28.7 Controlling Container Resources

Linux containers use cgroups in their implementation, and you can use the `lxc-cgroup` command to control the access that a container has to system resources relative to other containers. For example, to display the CPU cores to which a container can run on, enter:

```
[root@host ~]# lxc-cgroup -n ol6ctr1 cpuset.cpus
```

To restrict a container to cores 0 and 1, you would enter a command such as the following:

```
[root@host ~]# lxc-cgroup -n ol6ctr1 cpuset.cpus 0,1
```

To change a container's share of CPU time and block I/O access, you would enter:

```
[root@host ~]# lxc-cgroup -n ol6ctr1 cpu.shares 256
[root@host ~]# lxc-cgroup -n ol6ctr1 blkio.weight 500
```

Limit a container to 256 MB of memory when the system detects memory contention or low memory; otherwise, set a hard limit of 512 MB:
Configuring ulimit Settings for an Oracle Linux Container

To make the changes to a container's configuration permanent, add the settings to the file `/container/name/config`, for example:

```text
# Permanently tweaked resource settings
lxc.cgroup.cpu.shares=256
lxc.cgroup.blkio.weight=500
```

For more information about the resources that can be controlled, see [http://www.kernel.org/doc/Documentation/cgroups/](http://www.kernel.org/doc/Documentation/cgroups/).

### 28.8 Configuring ulimit Settings for an Oracle Linux Container

A container's `ulimit` setting honors the values of `ulimit` settings such as `memlock` and `nofile` in the container's version of `/etc/security/limits.conf/` provided that these values are lower than or equal to the values on the host system.

The values of `memlock` and `nofile` determine the maximum amount of address space in kilobytes that can be locked into memory by a user process and the maximum number of file descriptors that a user process can have open at the same time.

If you require a higher `ulimit` value for a container, increase the value of the settings in `/etc/security/limits.conf` on the host, for example:

```text
#<domain>      <type>  <item>         <value>
*              soft    memlock       1048576
*              hard    memlock       2097152
*              soft    nofile        5120
*              hard    nofile        10240
```

A process can use the `ulimit` built-in shell command or the `setrlimit()` system call to raise the current limit for a shell above the soft limit. However, the new value cannot exceed the hard limit unless the process is owned by `root`.

You can use `ulimit` to set or display the current soft and hard values on the host or from inside the container, for example:

```text
[root@host ~]# echo "host: nofile = $(ulimit -n)"
host: nofile = 1024
[root@host ~]# echo "host: nofile = $(ulimit -H -n)"
host: nofile = 4096
[root@host ~]# ulimit -n 2048
[root@host ~]# echo "host: nofile = $(ulimit -n)"
host: nofile = 2048
[root@host ~]# lxc-attach -n ol6ctr1 -- echo "container: nofile = $(ulimit -n)"
container: nofile = 1024
```

**Note**

Log out and log in again or, if possible, reboot the host before starting the container in a shell that uses the new soft and hard values for `ulimit`.

### 28.9 Configuring Kernel Parameter Settings for Oracle Linux Containers

If you specify the `--privileged` option with the `lxc-oracle` template script, you can adjust the values of certain kernel parameters for a container under the `/proc` hierarchy.
The container mounts `/proc` read-only with the following exceptions, which are writable:

- `/proc/sys/kernel/msgmax`
- `/proc/sys/kernel/msgmnb`
- `/proc/sys/kernel/msgmni`
- `/proc/sys/kernel/sem`
- `/proc/sys/kernel/shmall`
- `/proc/sys/kernel/shmmx`
- `/proc/sys/kernel/shmmni`
- `/proc/sys/net/ipv4/conf/default/accept_source_route`
- `/proc/sys/net/ipv4/conf/default/rp_filter`
- `/proc/sys/net/ipv4/ip_forward`

Each of these parameters can have a different value than that configured for the host system and for other containers running on the host system. The default value is derived from the template when you create the container. Oracle recommends that you change a setting only if an application requires a value other than the default value.

**Note**

Prior to UEK R3 QU6, the following host-only parameters were not visible within the container due to kernel limitations:

- `/proc/sys/net/core/rmem_default`
- `/proc/sys/net/core/rmem_max`
- `/proc/sys/net/core/wmem_default`
- `/proc/sys/net/core/wmem_max`
- `/proc/sys/net/ipv4/ip_local_port_range`
- `/proc/sys/net/ipv4/tcp_syncookies`

With UEK R3 QU6 and later, these parameters are read-only within the container to allow Oracle Database and other applications to be installed. You can change the values of these parameters only from the host. Any changes that you make to host-only parameters apply to all containers on the host.

### 28.10 Deleting Containers

To delete a container and its snapshot, use the `lxc-destroy` command as shown in the following example.

```
[root@host ~]# lxc-destroy -n ol6ctr2
Delete subvolume '/container/ol6ctr2/rootfs'
```

This command also deletes the `rootfs` subvolume.
28.11 Running Application Containers

You can use the `lxc-execute` command to create a temporary application container in which you can run a command that is effectively isolated from the rest of the system. For example, the following command creates an application container named `guest` that runs `sleep` for 100 seconds.

```bash
[root@host ~]# lxc-execute -n guest -- sleep 100
```

While the container is active, you can monitor it by running commands such as `lxc-ls --active` and `lxc-info -n guest` from another window.

```bash
[root@host ~]# lxc-ls --active
guest
[root@host ~]# lxc-info -n guest
Name:           guest
State:          RUNNING
PID:            11220
CPU use:        0.02 seconds
BlkIO use:      0 bytes
Memory use:     544.00 KiB
KMem use:       0 bytes
```

If you need to customize an application container, you can use a configuration file. For example, you might want to change the container’s network configuration or the system directories that it mounts.

The following example shows settings from a sample configuration file where the `rootfs` is mostly not shared except for mount entries to ensure that `init.lxc` and certain library and binary directory paths are available.

```ini
lxc.utsname = guest
lxc.tty = 1
lxc.pts = 1
lxc.rootfs = /tmp/guest/rootfs
lxc.mount.entry=/usr/lib usr/lib none ro,bind 0 0
lxc.mount.entry=/usr/lib64 usr/lib64 none ro,bind 0 0
lxc.mount.entry=/usr/bin usr/bin none ro,bind 0 0
lxc.mount.entry=/usr/sbin usr/sbin none ro,bind 0 0
lxc.cgroup.cpuset.cpus=1
```

The mount entry for `/usr/sbin` is required so that the container can access `/usr/sbin/init.lxc` on the host system.

In practice, you should limit the host system directories that an application container mounts to only those directories that the container needs to run the application.

**Note**

To avoid potential conflict with system containers, do not use the `/container` directory for application containers.

You must also configure the required directories and symbolic links under the `rootfs` directory:

```bash
[root@host ~]# TMPDIR=/tmp/guest/rootfs
[root@host ~]# mkdir -p $TMPDIR/usr/lib $TMPDIR/usr/lib64
   $TMPDIR/usr/bin $TMPDIR/usr/sbin
   $TMPDIR/dev/pts $TMPDIR/dev/shm $TMPDIR/proc
[root@host ~]# ln -s $TMPDIR/usr/lib $TMPDIR/lib
[root@host ~]# ln -s $TMPDIR/usr/lib64 $TMPDIR/lib64
[root@host ~]# ln -s $TMPDIR/usr/sbin $TMPDIR/sbin
[root@host ~]# ln -s $TMPDIR/usr/sbin $TMPDIR/sbin
```
In this example, the directories include `/dev/pts`, `/dev/shm`, and `/proc` in addition to the mount point entries defined in the configuration file.

You can then use the `-f` option to specify the configuration file (`config`) to `lxc-execute`:

```
[ root@host ~ ] # lxc-execute -n guest -f config /usr/bin/bash
```

```
UID    PID  PPID  C STIME TTY          TIME CMD
0      1       0  0 14:17 ?        00:00:00 /usr/sbin/init.lxc -- /usr/bin/bash
0      4       1  0 14:17 ?        00:00:00 /usr/bin/bash
0      5       4  0 14:17 ?        00:00:00 ps -ef
```

```
bash-4.2# mount
/dev/sda3 on / type btrfs (rw,relatime,seclabel,space_cache)
/dev/sda3 on /usr/lib type btrfs (ro,relatime,seclabel,space_cache)
/dev/sda3 on /usr/lib64 type btrfs (ro,relatime,seclabel,space_cache)
/dev/sda3 on /usr/bin type btrfs (ro,relatime,seclabel,space_cache)
/dev/sda3 on /usr/sbin type btrfs (ro,relatime,seclabel,space_cache)
devpts on /dev/pts type devpts (rw,relatime,seclabel,gid=5,mode=620,ptmxmode=666)
shmfs on /dev/shm type tmpfs (rw,relatime,seclabel)
mqueue on /dev/mqueue type mqueue (rw,relatime,seclabel)
```

```
bash-4.2# ls -l /
```

```
total 16
lrwxrwxrwx.   1 0 0  7 May 21 14:03 bin -> usr/bin
drwxr-xr-x. 230 0 0  0 May 21 12:58 proc
drwxr-xr-x.  1 0 0  8 May 21 14:03 sbin -> usr/sbin
drwxr-xr-x.  1 0 0 52 May 21 14:27 dev
lrwxrwxrwx.   1 0 0  7 May 21 14:03 lib -> usr/lib
lrwxrwxrwx.   1 0 0  9 May 21 14:27 lib64 -> usr/lib64
```

```
bash-4.2# touch /bin/foo
```

```
touch: cannot touch '/bin/foo': Read-only file system
bash-4.2# echo $?
1
```

In this example, running the `ps` command reveals that `bash` runs as a child of `init.lxc.mount` shows the individual directories that the container mounts read-only, such as `/usr/lib`, and `ls -l /` displays the symbolic links that you set up in `rootfs`.

Attempting to write to the read-only `/bin` file system results in an error. If you were to run the same `lxc-execute` command without specifying the configuration file, it would make the entire root file system of the host available to the container in read/write mode.

As for system containers, you can set `cgroup` entries in the configuration file and use the `lxc-cgroup` command to control the system resources to which an application container has access.

**Note**

`lxc-execute` is intended to run application containers that share the host's root file system, and not to run system containers that you create using `lxc-create`. Use `lxc-start` to run system containers.

For more information, see the `lxc-execute(1)` and `lxc.conf(5)` manual pages.

**28.12 For More Information About Linux Containers**

For more information, see https://wiki.archlinux.org/index.php/Linux_Containers and the LXC manual pages.

The Kernel-based Virtual Machine (KVM) feature provides a set of modules that enable you to use the Oracle Linux kernel as a hypervisor. KVM supports x86 and aarch64 processor architectures.

KVM is built into the Oracle Linux Unbreakable Enterprise Kernel (UEK) release by default. On an Oracle Linux system, you can run the following command to verify which modules are loaded in the kernel:

```
# lsmod | grep kvm
kvm_intel  167936  0
kvminteld  516096  1 kvm_intel
```

The KVM modules loaded may vary depending on your processor family and architecture.

29.1 Installing Virtualization Packages

Virtualization packages provide an interface to the KVM hypervisor, as well as user space tools.

29.1.1 Virtualization Packages

Oracle Linux provides several virtualization packages that enable you work with KVM. You can use the `yum` command to install whichever virtualization packages suit your needs. Refer to the man pages or appropriate documentation for each virtualization package that you install. See also the following documentation for more information:

- https://www.linux-kvm.org/
- https://libvirt.org/
- https://www.qemu.org/

In most cases, the following packages are the minimally required for a virtualization host:

- `libvirt`: This package provides an interface to KVM, as well as the `libvirt` daemon for managing guest virtual machines.
• **qemu-kvm**: This package installs the QEMU emulator that performs hardware virtualization so that guests can access host CPU and other resources.

As an alternative to installing virtualization packages individually, you can install virtualization package groups.

The **Virtualization Host** package group contains the minimum set of packages required for a virtualization host. If your Oracle Linux system includes a GUI environment, you can also choose to install the **Virtualization Client** package group.

**Tip**

Use the `yum groupinfo` command to find out which packages are included in a group:

```bash
# yum groupinfo "Virtualization Host"
```

### 29.1.2 Virtualization Package Yum Repositories and ULN Channels

Virtualization packages and their dependencies are available in a variety of locations on the Oracle Linux yum server and on ULN, depending on the system architecture and use case or support requirements.

**Repositories and channels available for x86_64 platforms**

<table>
<thead>
<tr>
<th>Yum repositories</th>
<th>ULN channels</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ol7_latest</td>
<td>ol7_x86_64_latest</td>
<td>The virtualization packages provided in this repository or ULN channel maximize compatibility with RHCK and with RedHat Enterprise Linux. Packages from this repository or ULN channel are fully supported for all kernels.</td>
</tr>
<tr>
<td>ol7_kvm_utils</td>
<td>ol7_x86_64_kvm_utils</td>
<td>The virtualization packages that are provided in this repository or ULN channel take advantage of newer features and functionality available in upstream packages. These packages are also engineered to work with KVM features that are enabled in the latest releases of Unbreakable Enterprise Kernel. If you install these packages, you must also install the latest version of either UEK R4 or UEK R5.</td>
</tr>
</tbody>
</table>

**Note**

The `ol7_kvm_utils` and `ol7_x86_64_kvm_utils` channels distribute 64-bit packages *only*. If you manually installed any 32-bit packages, for example, `libvirt-client`, Yum updates from these channels will fail. To use the `ol7_kvm_utils` and `ol7_x86_64_kvm_utils` channels, you must first remove any 32-bit versions of the packages distributed.
Virtualization Package Yum Repositories and ULN Channels

<table>
<thead>
<tr>
<th>Yum repositories</th>
<th>ULN channels</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>You may choose to configure on-premises virtualization in a similar way to systems in the Oracle Cloud Infrastructure or other Oracle products that use KVM. Oracle Linux delivers specific virtualization packages in this channel to help accomplish this.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Packages in this channel are delivered with limited support. Limited support coverage is only available to packages tested with on Oracle Linux 7 with the Unbreakable Enterprise Kernel. Limitations and requirements are listed below:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• A minimum of Oracle Linux 7 Update 4</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• A minimum of Unbreakable Enterprise Kernel Release 4</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Guest operating systems as supported in Oracle Cloud Infrastructure and described at <a href="https://cloud.oracle.com/compute/pricing">https://cloud.oracle.com/compute/pricing</a></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• KVM guests boot by using iSCSI LUN or IDE emulation</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• In emulated mode, KVM guests boot by using IDE emulation</td>
</tr>
<tr>
<td>ol7_developer</td>
<td>ol7_x86_64_developer</td>
<td>The virtualization packages provided in these repositories or ULN channels take advantage of newer features and functionality available upstream, but are unsupported and are made available for developer use only.</td>
</tr>
<tr>
<td>ol7_developer_kvm</td>
<td>ol7_x86_64_developer_kvm</td>
<td>If you are using the Oracle Linux yum server you can configure these repositories by installing the oraclelinux-developer-release-el7 package and then enabling the repositories by editing the repository files or by using yum-config-manager.</td>
</tr>
</tbody>
</table>

Repositories and channels available for aarch64 platforms

<table>
<thead>
<tr>
<th>Yum repositories</th>
<th>ULN channels</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ol7_latest</td>
<td>ol7_aarch64_latest</td>
<td>The virtualization packages provided in this repository or ULN channel include the latest virtualization packages available and are fully supported on Unbreakable Enterprise Kernel Release 5.</td>
</tr>
<tr>
<td>ol7_developer</td>
<td>ol7_aarch64_developer</td>
<td>The virtualization packages provided in this repository or ULN channel take advantage of newer features and functionality available upstream, but are unsupported and are made available for developer use only.</td>
</tr>
</tbody>
</table>
### Yum repositories | ULN channels | Description
|-----------------|-------------|----------------------------------|
|                 |             | features and functionality available upstream, but are unsupported and are made available for developer use.

**Warning**

Virtualization packages may also be available in the `ol7_developer_EPEL` Yum repository or the `ol7_arch_developer_EPEL` ULN channel. These packages are unsupported and contain features that might never be tested on Oracle Linux and may conflict with virtualization packages from other channels. If you intend to use packages from any of the repositories or channels previously listed, you should first uninstall any virtualization packages installed from this repository. You can also disable this repository or channel, or set exclusions to prevent virtualization packages from being installed from this repository.

Depending on your use case and support requirements, you must enable the repository or ULN channel that you require **before** you install the virtualization packages from that repository or ULN channel.

If you are using ULN, follow these steps to ensure that the system is registered with ULN and that the appropriate channel is enabled for the system:

1. Log in to https://linux.oracle.com with your ULN user name and password.
2. On the Systems tab, click the link named for the system in the list of registered machines.
3. On the System Details page, click **Manage Subscriptions**.
4. On the System Summary page, select each required channel from the list of available channels and click the right arrow to move the channel to the list of subscribed channels.

   Subscribe the system to the `ol7_x86_64_kvm_utils` channel.

5. Click **Save Subscriptions**.

If you are using the Oracle Linux yum server, you can either edit the repository configuration files in `/etc/yum.repos.d/` directly; or, if you have the `yum-utils` package installed, you can use the `yum-config-manager` command, for example:

```
# yum-config-manager --enable ol7_kvm_utils ol7_UER4
```

If you want to prevent `yum` from installing the package versions from a particular repository, you can set an exclude option on these packages for that repository. For instance, to prevent `yum` from installing the virtualization packages in the `ol7_developer_EPEL` repository, run the following command:

```
# yum-config-manager --setopt="ol7_developer_EPEL.exclude=libvirt* qemu*" --save
```

### 29.1.3 Installing Virtualization Packages During System Installation

Use the appropriate procedure to install virtualization packages during system installation. Use the Anaconda installation program to install a single virtualization host. Or, use a kickstart file to install virtualization hosts over the network.

#### 29.1.3.1 Using the Installation Program

To install a virtualization host with the Oracle Linux graphical installation program:

1. Boot the Oracle Linux installation media and proceed to the **Software Selection** screen.
2. Select one of the following virtualization host types:

   **Minimum Virtualization Host**
   a. Select **Virtualization Host** in the **Base Environment** section.
   b. Select **Virtualization Host** in the **Add-ons for Selected Environment** section.

   **Virtualization Host with GUI**
   a. Select **Server with GUI** in the **Base Environment** section.
   b. Select the following package groups in the **Add-ons for Selected Environment** section:
      - Virtualization Client
      - Virtualization Hypervisor
      - Virtualization Tools

3. Follow the prompts to complete the installation.

### 29.1.3.2 Using Kickstart Files

You can install virtualization hosts by specifying individual packages or package groups in the `%packages` section of a kickstart file.

Specify virtualization packages individually, as in the following example:

```bash
%packages
libvirt
qemu-kvm
```

Specify the appropriate package groups for the installation type in the `%packages` section of the kickstart file by using the `@GroupId` format:

```bash
Minimum Virtualization Host
%packages
@virtualization-hypervisor
@virtualization-tools
# The following group is optional. Uncomment the line to include it:
#@virtualization-platform
```

```bash
Virtualization Host with GUI
%packages
@virtualization-hypervisor
@virtualization-tools
@virtualization-client
```

### 29.1.4 Installing Virtualization Packages on an Existing System

1. Log in as the **root** user on the target Oracle Linux system.
2. Ensure that your system has the appropriate Yum repository or ULN channel enabled for the virtualization package versions that you wish to install. See Section 29.1.2, “Virtualization Package Yum Repositories and ULN Channels” for more information.
3. Run the `yum update` command to ensure the system is up to date.
4. Install virtualization packages by doing one of the following:
   - Use the `yum install` command to manually install virtualization packages, for example:
     ```bash
     # yum install libvirt qemu-kvm
     ```
• Use the `yum groupinstall` command to install a virtualization package group, for example:

```bash
# yum groupinstall "Virtualization Host"
```

### 29.1.5 Upgrading Virtualization Packages

Virtualization packages are updated by using the standard `yum update` command. Note that if you want to change the versions of the virtualization packages to match the versions that are shipped in a particular yum repository or ULN channel, you might need to specify the channel or repository from or to which you are installing packages. For example, you would update to the latest supported virtualization packages that are available in the `ol7_kvm_utils` repository as follows:

```bash
# yum --disablerepo="*" --enablerepo="ol7_kvm_utils" update
```

If you want to downgrade packages to a version in an alternate repository or channel, for example, to downgrade from the virtualization packages in the `ol7_kvm_utils` repository to the version of the same packages in the `ol7_latest` repository, you must first remove the existing packages before installing the packages from the alternate repository:

```bash
# yum remove libvirt* qemu*
# yum --disablerepo="*" --enablerepo="ol7_latest" install libvirt qemu-kvm
```

### 29.1.6 Checking the `libvirt` Daemon Status

To check the status of the `libvirt` daemon, run the following command on the virtualization host:

```bash
# systemctl status libvirtd
```

The output should indicate that the `libvirtd` daemon is running, as shown in the following example:

```bash
# systemctl status libvirtd
* libvirtd.service - Virtualization daemon
 Loaded: loaded (/usr/lib/systemd/system/libvirtd.service; enabled; vendor preset: enabled)
 Active: active (running) since time_stamp; xh ago
```

If the daemon is not running, start it by running the following command:

```bash
# systemctl start libvirtd
```

After you verify that the `libvirtd` daemon is running, you can start provisioning guest systems.

To create guests at the command line, use the `virt-install` command. Run `virt-install --help` or `man virt-install` for more information.

To create guests by using a graphic user interface (GUI) tool, use the Virtual Machine Manager. For more information, see: [https://virt-manager.org/](https://virt-manager.org/)

### 29.2 Oracle VirtIO Drivers for Microsoft Windows

The Oracle VirtIO Drivers for Microsoft Windows are paravirtualized drivers for Microsoft Windows guests that are running on KVM hypervisors.

The Oracle VirtIO Drivers for Microsoft Windows improve performance for network and block (disk) devices on Microsoft Windows guests and resolve common issues.

The following instructions describe how to install, use, and troubleshoot the Oracle VirtIO Drivers for Microsoft Windows. Note that these instructions are intended for users and administrators of guests that are running the Microsoft Windows operating system in virtualized environments, where KVM is the hypervisor.
29.2.1 Supported Releases, Operating Systems, and Configuration Limits

The following information pertains to the Oracle Linux and Oracle Cloud Infrastructure releases that are supported with the Oracle VirtIO Drivers for Microsoft Windows, in addition to the supported operating systems for each version of the Oracle VirtIO Drivers for Microsoft Windows.

Information about Microsoft Windows compatibility signing and details on tested and recommended configuration limits for the Oracle VirtIO Drivers for Microsoft Windows is also provided.

29.2.1.1 Supported Environments

The following environments and platforms provide support for the Oracle VirtIO Drivers for Microsoft Windows Release 1.1.4:

- Oracle Cloud Infrastructure
- Oracle Linux 7

29.2.1.2 Supported Guest Operating Systems

The following table lists the supported Microsoft Windows operating systems for the Oracle VirtIO Drivers for Microsoft Windows.

Table 29.1 Microsoft Windows Supported Guest Operating Systems

<table>
<thead>
<tr>
<th>Guest Operating System with Oracle VirtIO Drivers for Microsoft Windows Installed</th>
<th>64-bit</th>
<th>32-bit</th>
</tr>
</thead>
<tbody>
<tr>

**Note**

For information about the supported Microsoft Windows operating systems for the Oracle VirtIO Drivers for Microsoft Windows in the Oracle Cloud Infrastructure environment, see [https://docs.cloud.oracle.com/iaas/Content/Compute/References/bringyourownimage.htm](https://docs.cloud.oracle.com/iaas/Content/Compute/References/bringyourownimage.htm).

**Virtual Machine Configuration**

Virtual machine configuration for the Oracle VirtIO Drivers for Microsoft Windows complies with shape configurations for virtual machines in the Oracle Cloud Infrastructure environment. For more information, see: [https://cloud.oracle.com/infrastructure/compute/virtual-machine/features](https://cloud.oracle.com/infrastructure/compute/virtual-machine/features).

**29.2.1.3 Microsoft Windows Compatibility Signing**

Oracle VirtIO Drivers for Microsoft Windows have not been signed by Microsoft for 32-bit Microsoft Windows operating systems or Microsoft Windows Server 2003. A security alert occurs during installation on a Windows operating system for which Oracle VirtIO Drivers for Microsoft Windows are not signed.

**29.2.2 Installing the Oracle VirtIO Drivers for Microsoft Windows**

Installing the Oracle VirtIO Drivers for Microsoft Windows involves configuring Microsoft Windows policies, running the installation program, and then verifying the installation.

**29.2.2.1 Installing the Oracle VirtIO Drivers for Microsoft Windows on Existing Microsoft Windows Guests**

To install the Oracle VirtIO Drivers for Microsoft Windows on existing Microsoft Windows guests, perform the following procedures:
Installing the Oracle VirtIO Drivers for Microsoft Windows

Configuring Policies for Device Installation

Configure Microsoft Windows policies to allow the installation of the Oracle VirtIO Drivers for Microsoft Windows, if these policies are not already configured. This task prevents the following error from occurring during an installation:

The installation of this device is forbidden by system policy. Contact your system administrator.

To configure policies for installation:

1. Open the Microsoft Windows virtual machine on which you want to install the Oracle VirtIO Drivers for Microsoft Windows.
2. From the Start menu, select Run.
3. Enter gpedit.msc and then click OK.
   The Local Group Policy Editor is displayed.
4. From the Console Tree, display the list of device installation restrictions (Device Installation Restrictions) as follows:
   a. Expand Computer Configuration, and then expand Administrative Templates.
   b. Expand System, and then expand Device Installation.
   c. Select Device Installation Restrictions.
5. Edit the policy settings so that no device installation restrictions are configured.
   Alternatively, review each policy setting to determine the correct configuration for your business needs.
6. Close the Local Group Policy Editor.
7. Restart the Microsoft Windows virtual machine.

When you are finished configuring the policy settings for device installation, you can proceed with the installation of the Oracle VirtIO Drivers for Microsoft Windows.

Installing Oracle VirtIO Drivers for Microsoft Windows

Before You Begin.  Do the following before you start the installation process:

• Obtain the Oracle VirtIO Drivers for Microsoft Windows from Oracle Software Delivery Cloud or MOS.
• Review the list of supported Microsoft Windows operating systems. See Section 29.2.1.2, “Supported Guest Operating Systems”.
• Configure system policies to allow the installation. See Configuring Policies for Device Installation.

You can install the Oracle VirtIO Drivers for Microsoft Windows by using the GUI installation program or by performing a silent installation. Use the graphical installation program if you are installing a single instance of the Oracle VirtIO Drivers for Microsoft Windows. If you plan to silently install multiple instances of the Oracle VirtIO Drivers for Microsoft Windows, you must run the GUI installation program in a command-line window on at least one Microsoft Windows guest to create a response file. You can then use the response file to perform all of the subsequent installations silently.

To install the Oracle VirtIO Drivers for Microsoft Windows:

1. Copy the Oracle VirtIO Drivers for Microsoft Windows installation program Setup.exe to the guest.
2. Start the installation by running **Setup.exe** in one of the following ways:

   - To perform a single installation, double-click **Setup.exe** to start the Oracle VirtIO Drivers for Microsoft Windows installer.
   - To record a response file for automated installations on multiple systems:
     a. Open a command line window.
     b. Navigate to the directory where the **Setup.exe** file is located.
     c. Run **Setup.exe -r** to start the Oracle VirtIO Drivers for Microsoft Windows installer and create a response file for silent installations.

3. If prompted, select **Yes** in the **User Account Control** dialog to allow the Oracle VirtIO Drivers for Microsoft Windows installer to proceed.

   The **Welcome** window is displayed.

4. Click **Next**.

   The **Installation Type** window is displayed.

   **Figure 29.1 Installation Types**

   ![Figure 29.1 Installation Types](image)

   5. Choose the **Default** or **Custom** installation type and then click **Next**.
• Select the **Default** option if you are running Windows guests in an Oracle KVM environment.

• Select the **Custom** option if you are migrating Windows guests from Oracle Cloud Infrastructure Classic (OCI-C) to Oracle Cloud Infrastructure (OCI).

The **Start to install Oracle VirtIO Drivers for Microsoft Windows Release 1.1.4** window is displayed with information about your selection.

6. Click **Install** to start the installation.

• If you selected **Default**, the installer copies the Oracle VirtIO Drivers for Microsoft Windows files and installs the drivers on the guest.

**Figure 29.2 Start Default Installation**

• If you selected **Custom**, the installer copies the Oracle VirtIO Drivers for Microsoft Windows files, installs the drivers on the guest, and configures the guest to support migration from OCI-C to OCI.
Figure 29.3 Start Custom Installation

The Installation Status window is displayed.

7. Once the installation completes, do one of the following:

- If you selected a Default installation, check Yes, I want to restart my computer now and click Finish.
  The virtual machine is restarted.
- If you selected a Custom installation:
  a. Check No, I will restart my computer later and click Finish.
  b. Shut down the Windows guest VM.
  c. Start the Windows guest VM in the OCI environment.

The Oracle VirtIO Drivers for Microsoft Windows are installed in the following directories:

- On 32-bit systems: `C:\Program Files\Oracle Corporation\Oracle Windows VirtIO Drivers`
- On 64-bit systems: `C:\Program Files (x86)\Oracle Corporation\Oracle Windows VirtIO Drivers`
If you used the \texttt{-r} option in the command line, the installation program creates a response file in the \texttt{C:\Windows} directory. You then use the response file, \texttt{setup.iss}, to perform silent installations on other Microsoft Windows guests. See Section 29.2.4, “Silently Installing or Upgrading the Oracle VirtIO Drivers for Microsoft Windows”.

29.2.2.2 Installing the Oracle VirtIO Drivers for Microsoft Windows During Microsoft Windows Guest Installation

\textbf{Before You Begin.} Review the list of supported Microsoft Windows operating systems. See Section 29.2.1.2, “Supported Guest Operating Systems”.

To install the Oracle VirtIO Drivers for Microsoft Windows during the installation of a Microsoft Windows guest, do the following:

1. Create the virtual machine, but do not start it.

2. Attach the Oracle VirtIO Drivers for Microsoft Windows ISO file to the virtual machine as an emulated IDE device.

   Ensure that the Microsoft Windows installation ISO is attached to the virtual machine as the first IDE device. The Oracle VirtIO Drivers for Microsoft Windows ISO file should be the second IDE device.

3. Start the virtual machine and begin the Microsoft Windows installation process.

4. When the disk or partition screen displays, follow the prompts to browse and load drivers.

5. Navigate to the appropriate driver location on the Oracle VirtIO Drivers for Microsoft Windows ISO file and then select them.

The contents of the Oracle VirtIO Drivers for Microsoft Windows ISO file are as follows:

\begin{verbatim}
autorun.inf  # File that automatically runs the installation program.
Setup.exe    # The main graphical installation program.
NetKVM       # Directory that contains the license file for NetKVM drivers.
vioscsi      # Directory that contains the license file for vioscsi drivers.
vioserial    # Directory that contains the license file for vioserial drivers.
viostore     # Directory that contains the license file for viostore drivers.
vio          # Base directory for drivers.
vio/Win10/amd64 # 64-bit drivers.
vio/Win10/i386 # 32-bit drivers. (only Windows 10)
vio/Win8.1    # Drivers for Windows 8.1 and Windows Server 2012 R2.
vio/Win8.1/amd64 # 64-bit drivers.
vio/Win8.1/i386 # 32-bit drivers. (only Windows 8.1)
vio/Win8      # Drivers for Windows 8 and Windows Server 2012.
vio/Win8/amd64 # 64-bit drivers.
vio/Win8/i386 # 32-bit drivers. (only Windows 8)
vio/Win7      # Drivers for Windows 7 and Windows Server 2008 R2.
vio/Win7/amd64 # 64-bit drivers.
vio/Win7/i386 # 32-bit drivers.
vio/Wlh       # Drivers for Windows Vista and Windows Server 2008 (Longhorn).
vio/Wlh/amd64 # 64-bit drivers.
vio/Wlh/i386  # 32-bit drivers.
vio/Wnet      # Drivers for Windows Server 2003 R2.
vio/Wnet/amd64 # 64-bit drivers.
vio/Wnet/i386 # 32-bit drivers.
\end{verbatim}
6. Repeat the preceding step to install additional drivers as necessary and then continue with the Microsoft Windows installation process.

After you install the Microsoft Windows guest, you must configure Microsoft Windows policies. See Section 29.2.1.2, “Supported Guest Operating Systems”.

**29.2.2.3 Optional Configuration Changes**

This section describes optional changes that can be made to the configuration after installation is complete.

**Note**

The optional configuration changes are only relevant if you completed a **Default** type of installation, are running Oracle Linux, and have control of the host system. If you have completed a **Custom** installation and migrated your VM from the OCI-C to OCI environment, you do not have access to the host.

The changes that are described here require that the host system is running the latest supported virtualization packages, which are available in the `ol7_kvm_utils` Yum repository on the Oracle Linux yum server or in the `ol7_x86_64_kvm_utils` or `ol7_aarch64_kvm_utils` channels on ULN.

If you have not already done so, enable the appropriate channel or repository and install the packages from this location before proceeding. See Section 29.1.2, “Virtualization Package Yum Repositories and ULN Channels” for more information. If you perform an upgrade of the virtualization packages, you might need to restart any running virtual machines for the changes to take effect.

**Configuring Block Drivers**

The Oracle VirtIO Drivers for Microsoft Windows provide block drivers that improve disk performance on Microsoft Windows guests. However, guests do not automatically start by using the Oracle VirtIO Drivers for Microsoft Windows storage drivers after installation. As a result, guests cannot use the paravirtualized storage drivers for boot disks. You must configure each guest to use paravirtualized storage drivers instead of emulated disks after installation.

To configure block drivers after installation:

1. Ensure you have installed the Oracle VirtIO Drivers for Microsoft Windows.
2. Stop the guest if it is running.
3. Create a new temporary image that you can add to the guest as a second disk. For example, run:
   ```bash
   qemu-img create -f qcow2 disk_name.qcow2 1G
   ```
4. Add the disk you created to the guest.
5. Specify `virtio` as the bus type for the disk you added and then start the guest. Microsoft Windows will locate the disk drivers and complete the installation at this point.
6. Change the bus type for the boot disk to `virtio` and then start the guest.
   
   Microsoft Windows then installs the Oracle VirtIO Drivers for Microsoft Windows block driver on the boot disk.
7. Detach the temporary disk from the guest.
Setting the MTU Size for Virtual Machines

The Oracle VirtIO Drivers for Microsoft Windows override the maximum transmission unit (MTU) settings in the virtual network adapters for Microsoft Windows guests. After you have successfully installed and verified the Oracle VirtIO Drivers for Microsoft Windows, set the MTU for each guest as follows:

1. Open the Microsoft Windows virtual machine.
2. Open the control panel, then locate and open the **Device Manager** window.
3. Expand **Network adapters** and select the appropriate **Oracle VirtIO Ethernet Adapter**.
4. Right-click the adapter, select **Properties**, and then select the **Advanced** tab.
5. Select the **MTU** property and set the value as appropriate.
6. Click **OK** to save your changes.

29.2.3 Upgrading the Oracle VirtIO Drivers for Microsoft Windows

You can upgrade an existing installation of the Oracle VirtIO Drivers for Microsoft Windows by using the GUI installation program or by performing a silent upgrade. Use the graphical installation program if you are upgrading a single instance of the Oracle VirtIO Drivers for Microsoft Windows. If you plan to silently upgrade multiple instances of the Oracle VirtIO Drivers for Microsoft Windows, you must run the graphical installation program in a command-line window on at least one Microsoft Windows guest to create a response file. You can then use the response file to perform all subsequent upgrades silently.

To upgrade the Oracle VirtIO Drivers for Microsoft Windows:

1. Copy the Oracle VirtIO Drivers for Microsoft Windows installation program, **Setup.exe**, to the guest.
2. Do one of the following:
   - Double click **Setup.exe** to begin the upgrade.
   - Open a command line window and then do the following:
     - Navigate to the directory where the **Setup.exe** file is located.
     - Run the **Setup.exe -r** command to begin the upgrade and create a response file for silent installations.
3. If prompted, select **Yes** in the **User Account Control** dialog to allow the Oracle VirtIO Drivers for Microsoft Windows installer to proceed.
4. Click **Next** to start the upgrade.

The installation program then copies new versions of the Oracle VirtIO Drivers for Microsoft Windows to the system and updates the installed drivers. The **Update Complete** window is displayed.

5. Click **Yes, I want to restart the system now** and then click **Finish** to restart the virtual machine.

If you used the `-r` option in the command line, the installation program creates a response file in the `C:\Windows` directory. You then use the response file, `setup.iss`, to perform silent upgrades on other Microsoft Windows guests. See Section 29.2.4, “Silently Installing or Upgrading the Oracle VirtIO Drivers for Microsoft Windows”.

### 29.2.4 Silently Installing or Upgrading the Oracle VirtIO Drivers for Microsoft Windows

You can use a response file that you create with the graphical installation program to silently install or upgrade the Oracle VirtIO Drivers for Microsoft Windows. The response file provides the prompts that the installation program requires to successfully install or upgrade the Oracle VirtIO Drivers for Microsoft Windows.

**Important**

- Oracle VirtIO Drivers for Microsoft Windows must be signed by Microsoft to perform a silent installation or upgrade. See Section 29.2.1.3, “Microsoft Windows Compatibility Signing”.

- You can perform a silent installation or upgrade only on 64-bit versions of Microsoft Windows later than Windows Vista. You cannot perform a silent installation or upgrade on any 32-bit version of Microsoft Windows or Microsoft Windows 2003 (32-bit or 64-bit).

To install or upgrade the Oracle VirtIO Drivers for Microsoft Windows silently:

1. Complete at least one installation or upgrade of the Oracle VirtIO Drivers for Microsoft Windows by using the GUI installation program to create a response file. See Installing Oracle VirtIO Drivers for Microsoft Windows or Section 29.2.3, “Upgrading the Oracle VirtIO Drivers for Microsoft Windows”.

---

**Figure 29.4 Oracle VirtIO Drivers for Microsoft Windows user account control dialog**

The initial upgrade window is displayed.
2. Locate the response file, setup.iss, in the C:\Windows directory on the file system of the computer where you ran the graphical installation program.

3. Copy setup.iss to the same directory as the Oracle VirtIO Drivers for Microsoft Windows installation program. Alternatively you can specify the location of the response file at the command line.

4. Open a command-line window.

5. Run the Setup.exe -s command to silently install or upgrade the Oracle VirtIO Drivers for Microsoft Windows with the response file.

You can include the following options at the command line:

- `-f1c:path\to\setup.iss` to specify the location of `setup.iss`.

  For example, `Setup.exe -s -f1c:\Users\Username\setup.iss`.

- `-f2c:path\to\setup.log` to specify the location of `setup.log`. By default, log files are written to the the C:\Windows directory, for example, `Setup.exe -s -f2c:\Users\Username\setup.log`.

### 29.2.5 Uninstalling the Oracle VirtIO Drivers for Microsoft Windows

You can uninstall the Oracle VirtIO Drivers for Microsoft Windows through the Microsoft Windows control panel or by running the installation program that you used to install the Oracle VirtIO Drivers for Microsoft Windows.

To uninstall through the Microsoft Windows control panel:

1. Open the control panel and navigate to the Uninstall or change a program section.

   Note that the name of this section might be different, depending on your version of Microsoft Windows.

2. Locate, then select the Oracle VirtIO Drivers for Microsoft Windows.

3. Right-click the Uninstall option.

   The installation program starts and prompts you to confirm the uninstallation.

4. Select Yes when prompted to remove the application.

   The installation program removes the Oracle VirtIO Drivers for Microsoft Windows and deletes the binaries from your system.

5. When prompted, select Yes, restart the system and then click Finish to complete the uninstallation.

To uninstall with the installation program:

1. Double click Setup.exe to start the Oracle VirtIO Drivers for Microsoft Windows installer.

   The installation program starts and prompts you to modify the current installation.
2. Select **Remove** and then click **Next**.

3. Select **Yes** from the pop-up dialog.

   The installation program removes the Oracle VirtIO Drivers for Microsoft Windows and deletes the binaries from your system.

4. When prompted, select **Yes, restart the system** and then click **Finish** to complete the uninstallation.

### 29.2.6 Known Limitations and Workarounds

The following are known limitations and workarounds.

#### 29.2.6.1 Security Alert for Unsigned Drivers

The Oracle VirtIO Drivers for Microsoft Windows have not been signed by Microsoft for 32-bit Microsoft Windows operating systems or Microsoft Windows Server 2003.

**Security Alert on 32-bit Microsoft Windows Operating Systems**

On 32-bit Microsoft Windows operating systems, the installer displays security alerts such as the following for each driver:
Known Limitations and Workarounds

**Figure 29.6 Windows Security Alert**

To continue with the installation, select **Install**.

**Security Alert on Microsoft Windows Server 2003**

On Microsoft Windows Server 2003, the installer displays a security alert similar to the following:

```
Would you like to install this device software?

Name: Oracle VirtualBox SCSI controller
Publisher: Oracle America, Inc.

Always trust software from "Oracle America, Inc." Install Don't install

You should only install driver software from publishers you trust. How can I decide which device software is safe to install?
```

To continue the installation, click **Yes**. Then, click **Continue Anyway** when the installer displays a message similar to the following:
Known Limitations and Workarounds

The software you are installing has not passed Windows Logo testing to verify its compatibility with this version of Windows.

Continuing your installation of this software may impair or destabilize the correct operation of your system either immediately or in the future. Microsoft strongly recommends that you stop this installation now and contact the software vendor for software that has passed Windows Logo testing.

The following image is an example of the preceding security alert.

**Figure 29.8 Continue Software Installation**

---

29.2.6.2 Found New Hardware Wizard Displayed

During the installation or uninstallation of the Oracle VirtIO Drivers for Microsoft Windows, the Found New Hardware wizard is displayed during the installation/uninstallation, and when the guest restarts. This only occurs on a guest with Microsoft Windows Server 2003 (32- or 64-bit) installed.

**Workaround:** Click **Cancel** to ignore the message and close the dialog box.

29.2.6.3 Microsoft Windows Server 2012 Data Center Guests With Failover Clustering Cannot Get IP Address

A Microsoft Windows Server 2012 data center guest may fail to get an IP address from a DHCP server or encounter a UDP connection failure after installing the Windows Server Failover Clustering feature and restarting the guest.

**Note**

This issue does not apply to Microsoft Windows Server 2012 R2. The issue affects only Microsoft Windows Server 2012.

**Workaround:**

- Install the following hotfix to correct this issue: [https://support.microsoft.com/en-us/kb/3062586](https://support.microsoft.com/en-us/kb/3062586).
