This software and related documentation are provided under a license agreement containing restrictions on use and disclosure and are protected by intellectual property laws. Except as expressly permitted in your license agreement or allowed by law, you may not use, copy, reproduce, translate, broadcast, modify, license, transmit, distribute, exhibit, perform, publish, or display any part, in any form, or by any means. Reverse engineering, disassembly, or decompilation of this software, unless required by law for interoperability, is prohibited.

The information contained herein is subject to change without notice and is not warranted to be error-free. If you find any errors, please report them to us in writing.

If this is software or related documentation that is delivered to the U.S. Government or anyone licensing it on behalf of the U.S. Government, then the following notice is applicable:

U.S. GOVERNMENT END USERS: Oracle programs, including any operating system, integrated software, any programs installed on the hardware, and/or documentation, delivered to U.S. Government end users are "commercial computer software" pursuant to the applicable Federal Acquisition Regulation and agency-specific supplemental regulations. As such, use, duplication, disclosure, modification, and adaptation of the programs, including any operating system, integrated software, any programs installed on the hardware, and/or documentation, shall be subject to license terms and license restrictions applicable to the programs. No other rights are granted to the U.S. Government.

This software or hardware is developed for general use in a variety of information management applications. It is not developed or intended for use in any inherently dangerous applications, including applications that may create a risk of personal injury. If you use this software or hardware in dangerous applications, then you shall be responsible to take all appropriate fail-safe, backup, redundancy, and other measures to ensure its safe use. Oracle Corporation and its affiliates disclaim any liability for any damages caused by use of this software or hardware in dangerous applications.

Oracle and Java are registered trademarks of Oracle and/or its affiliates. Other names may be trademarks of their respective owners.

Intel and Intel Xeon are trademarks or registered trademarks of Intel Corporation. All SPARC trademarks are used under license and are trademarks or registered trademarks of SPARC International, Inc. AMD, Opteron, the AMD logo, and the AMD Opteron logo are trademarks or registered trademarks of Advanced Micro Devices. UNIX is a registered trademark of The Open Group.

This software or hardware and documentation may provide access to or information about content, products, and services from third parties. Oracle Corporation and its affiliates are not responsible for and expressly disclaim all warranties of any kind with respect to third-party content, products, and services unless otherwise set forth in an applicable agreement between you and Oracle. Oracle Corporation and its affiliates will not be responsible for any loss, costs, or damages incurred due to your access to or use of third-party content, products, or services, except as set forth in an applicable agreement between you and Oracle.

| Changes in Oracle R Enterprise 1.4.....                                          | xiv  |
| New Features in Oracle R Enterprise 1.4 .....                                    | xv   |
| Changes in Oracle R Enterprise 1.3.....                                          | xvi  |
| New Features in Oracle R Enterprise 1.3 .....                                    | xvi  |
| Other Changes in Oracle R Enterprise 1.3 .....                                   | xvi  |
| Changes in Oracle R Enterprise 1.1 .....                                         | xvi  |
| <br><b>1 Introducing Oracle R Enterprise</b> .....                               |      |
| 1.1 About Oracle R Enterprise .....                                              | 1-1  |
| 1.2 Advantages of Oracle R Enterprise .....                                      | 1-2  |
| 1.3 Get Online Help for Oracle R Enterprise Classes, Functions, and Methods..... | 1-3  |
| 1.4 About Transparently Using R on Oracle Database Data .....                    | 1-6  |
| 1.4.1 About the Transparency Layer.....                                          | 1-6  |
| 1.4.2 Transparency Layer Support for R Data Types and Classes .....              | 1-7  |
| 1.5 Typical Operations in Using Oracle R Enterprise.....                         | 1-11 |
| 1.6 Oracle R Enterprise Global Options.....                                      | 1-12 |
| 1.7 Oracle R Enterprise Examples .....                                           | 1-14 |
| 1.7.1 Listing the Oracle R Enterprise Examples .....                             | 1-14 |
| 1.7.2 Running an Oracle R Enterprise Example Script.....                         | 1-15 |

## 2 Getting Started with Oracle R Enterprise

|       |                                                          |      |
|-------|----------------------------------------------------------|------|
| 2.1   | Connecting to an Oracle Database Instance.....           | 2-1  |
| 2.1.1 | About Connecting to the Database .....                   | 2-1  |
| 2.1.2 | Using the ore.connect and ore.disconnect Functions.....  | 2-3  |
| 2.2   | Creating and Managing R Objects in Oracle Database ..... | 2-4  |
| 2.2.1 | Creating R Objects for In-Database Data .....            | 2-4  |
| 2.2.2 | Creating Ordered and Unordered ore.frame Objects .....   | 2-9  |
| 2.2.3 | Moving Data to and from the Database .....               | 2-15 |
| 2.2.4 | Creating and Deleting Database Tables .....              | 2-16 |
| 2.2.5 | Saving and Managing R Objects in the Database .....      | 2-17 |

## 3 Preparing and Exploring Data in the Database

|        |                                                                 |      |
|--------|-----------------------------------------------------------------|------|
| 3.1    | Preparing Data in the Database Using Oracle R Enterprise .....  | 3-1  |
| 3.1.1  | About Preparing Data in the Database .....                      | 3-1  |
| 3.1.2  | Selecting Data.....                                             | 3-2  |
| 3.1.3  | Indexing Data.....                                              | 3-5  |
| 3.1.4  | Combining Data.....                                             | 3-6  |
| 3.1.5  | Summarizing Data .....                                          | 3-7  |
| 3.1.6  | Transforming Data .....                                         | 3-7  |
| 3.1.7  | Sampling Data.....                                              | 3-10 |
| 3.1.8  | Partitioning Data .....                                         | 3-15 |
| 3.1.9  | Preparing Time Series Data .....                                | 3-16 |
| 3.2    | Exploring Data .....                                            | 3-22 |
| 3.2.1  | About the Exploratory Data Analysis Functions.....              | 3-22 |
| 3.2.2  | About the NARROW Data Set for Examples .....                    | 3-23 |
| 3.2.3  | Correlating Data .....                                          | 3-23 |
| 3.2.4  | Cross-Tabulating Data .....                                     | 3-25 |
| 3.2.5  | Analyzing the Frequency of Cross-Tabulations .....              | 3-30 |
| 3.2.6  | Building Exponential Smoothing Models on Time Series Data ..... | 3-30 |
| 3.2.7  | Ranking Data.....                                               | 3-34 |
| 3.2.8  | Sorting Data.....                                               | 3-35 |
| 3.2.9  | Summarizing Data with ore.summary .....                         | 3-36 |
| 3.2.10 | Analyzing Distribution of Numeric Variables .....               | 3-38 |
| 3.2.11 | Principal Component Analysis.....                               | 3-38 |
| 3.2.12 | Singular Value Decomposition.....                               | 3-40 |
| 3.3    | Using a Third-Party Package on the Client.....                  | 3-41 |

## 4 Building Models in Oracle R Enterprise

|       |                                               |     |
|-------|-----------------------------------------------|-----|
| 4.1   | Building Oracle R Enterprise Models .....     | 4-1 |
| 4.1.1 | About OREmodels Functions .....               | 4-1 |
| 4.1.2 | About the longley Data Set for Examples ..... | 4-2 |
| 4.1.3 | Building Linear Regression Models.....        | 4-3 |

|          |                                                                         |      |
|----------|-------------------------------------------------------------------------|------|
| 4.1.4    | Building a Generalized Linear Model .....                               | 4-5  |
| 4.1.5    | Building a Neural Network Model.....                                    | 4-7  |
| 4.1.6    | Building a Random Forest Model.....                                     | 4-9  |
| 4.2      | Building Oracle Data Mining Models.....                                 | 4-11 |
| 4.2.1    | About Building Oracle Data Mining Models using Oracle R Enterprise..... | 4-11 |
| 4.2.2    | Building an Association Rules Model .....                               | 4-13 |
| 4.2.3    | Building an Attribute Importance Model .....                            | 4-16 |
| 4.2.4    | Building a Decision Tree Model.....                                     | 4-17 |
| 4.2.5    | Building General Linearized Models .....                                | 4-18 |
| 4.2.6    | Building a k-Means Model.....                                           | 4-21 |
| 4.2.7    | Building a Naive Bayes Model .....                                      | 4-25 |
| 4.2.8    | Building a Non-Negative Matrix Factorization Model.....                 | 4-27 |
| 4.2.9    | Building an Orthogonal Partitioning Cluster Model .....                 | 4-29 |
| 4.2.10   | Building a Support Vector Machine Model.....                            | 4-31 |
| 4.3      | Cross-Validating Models .....                                           | 4-35 |
| <b>5</b> | <b>Predicting With R Models</b>                                         |      |
| 5.1      | About the ore.predict Function.....                                     | 5-1  |
| 5.2      | Using the ore.predict Function .....                                    | 5-2  |
| <b>6</b> | <b>Using Oracle R Enterprise Embedded R Execution</b>                   |      |
| 6.1      | About Oracle R Enterprise Embedded R Execution.....                     | 6-1  |
| 6.1.1    | Benefits of Embedded R Execution.....                                   | 6-1  |
| 6.1.2    | APIs for Embedded R Execution.....                                      | 6-2  |
| 6.1.3    | Security Considerations for Scripts .....                               | 6-3  |
| 6.1.4    | Support for Parallel Execution .....                                    | 6-4  |
| 6.1.5    | Installing a Third-Party Package for Use in Embedded R Execution.....   | 6-5  |
| 6.2      | R Interface for Embedded R Execution .....                              | 6-9  |
| 6.2.1    | Arguments for Functions that Run Scripts .....                          | 6-9  |
| 6.2.2    | Manage Scripts in R .....                                               | 6-13 |
| 6.2.3    | Using the ore.doEval Function.....                                      | 6-19 |
| 6.2.4    | Using the ore.tableApply Function.....                                  | 6-25 |
| 6.2.5    | Using the ore.groupApply Function .....                                 | 6-26 |
| 6.2.6    | Using the ore.rowApply Function .....                                   | 6-33 |
| 6.2.7    | Using the ore.indexApply Function .....                                 | 6-39 |
| 6.3      | SQL Interface for Embedded R Execution .....                            | 6-43 |
| 6.3.1    | About Oracle R Enterprise SQL Table Functions .....                     | 6-44 |
| 6.3.2    | Manage Scripts in SQL .....                                             | 6-46 |
| 6.3.3    | Manage Datastores in SQL.....                                           | 6-48 |
| <b>A</b> | <b>SQL APIs for Oracle R Enterprise</b>                                 |      |
| A.1      | rqDropDataStore Procedure .....                                         | A-1  |
| A.2      | rqEval Function.....                                                    | A-2  |

|     |                                   |      |
|-----|-----------------------------------|------|
| A.3 | rqGrant Procedure.....            | A-5  |
| A.4 | rqGroupEval Function .....        | A-5  |
| A.5 | rqRevoke Procedure.....           | A-8  |
| A.6 | rqRowEval Function.....           | A-9  |
| A.7 | rqTableEval Function.....         | A-13 |
| A.8 | sys.rqScriptCreate Procedure..... | A-16 |
| A.9 | sys.rqScriptDrop Procedure.....   | A-17 |

## **B Oracle Database Views for Oracle R Enterprise**

|     |                               |     |
|-----|-------------------------------|-----|
| B.1 | ALL_RQ_DATASTORES .....       | B-1 |
| B.2 | ALL_RQ_SCRIPTS.....           | B-2 |
| B.3 | RQUSER_DATASTORECONTENTS..... | B-2 |
| B.4 | RQUSER_DATASTORELIST.....     | B-3 |
| B.5 | USER_RQ_DATASTORE_PRIVS.....  | B-3 |
| B.6 | USER_RQ_DATASTORES.....       | B-4 |
| B.7 | USER_RQ_SCRIPT_PRIVS .....    | B-4 |
| B.8 | USER_RQ_SCRIPTS.....          | B-5 |

## **C R Operators and Functions Supported by Oracle R Enterprise**

### **Index**

---

# Preface

This book describes how to use Oracle R Enterprise.

## Audience

This document is intended for anyone who uses Oracle R Enterprise. Use of Oracle R Enterprise requires knowledge of R and Oracle Database.

## Documentation Accessibility

For information about Oracle's commitment to accessibility, visit the Oracle Accessibility Program website at <http://www.oracle.com/pls/topic/lookup?ctx=acc&id=docacc>.

### Access to Oracle Support

Oracle customers that have purchased support have access to electronic support through My Oracle Support. For information, visit <http://www.oracle.com/pls/topic/lookup?ctx=acc&id=info> or visit <http://www.oracle.com/pls/topic/lookup?ctx=acc&id=trs> if you are hearing impaired.

## Related Documents

The Oracle R Enterprise documentation set includes the following:

- *Oracle R Enterprise Installation and Administration Guide*
- *Oracle R Enterprise Release Notes*

## Oracle R Enterprise Online Resources

The following websites provide useful information for users of Oracle R Enterprise:

- The Oracle R Enterprise page on the Oracle Technology Network (OTN) provides downloads, the latest documentation, and information such as white papers, blogs, discussion forums, presentations, and tutorials. The website is at <http://www.oracle.com/technetwork/database/database-technologies/r/r-enterprise/overview/index.html>.
- The Oracle R Enterprise Discussion Forum at [https://community.oracle.com/community/developer/english/business\\_intelligence/data\\_warehousing/r](https://community.oracle.com/community/developer/english/business_intelligence/data_warehousing/r) supports all aspects of Oracle's R-related offerings, including: Oracle R Enterprise, Oracle R Connector for

Hadoop (part of the Big Data Connectors), and Oracle R Distribution. Use the forum to ask questions and make comments about the software.

- The Oracle R Enterprise Blog (<https://blogs.oracle.com/R/>) discusses best practices, tips, and tricks for applying Oracle R Enterprise and Oracle R Connector for Hadoop in both traditional and Big Data environments.
- For information about R, see the R Project for Statistical Computing at <http://www.r-project.org>.

## Conventions

The following text conventions are used in this document:

| Convention             | Meaning                                                                                                                                |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <b>boldface</b>        | Boldface type indicates graphical user interface elements associated with an action, or terms defined in text or the glossary.         |
| <i>italic</i>          | Italic type indicates book titles, emphasis, or placeholder variables for which you supply particular values.                          |
| <code>monospace</code> | Monospace type indicates commands within a paragraph, URLs, code in examples, text that appears on the screen, or text that you enter. |

---

# Changes in This Release for Oracle R Enterprise

Releases of Oracle R Enterprise often contain new features. The features in the current release and in some previous releases are described in the following topics:

- [Changes in Oracle R Enterprise 1.5](#) (page ix)
- [Changes in Oracle R Enterprise 1.4.1](#) (page xiii)
- [Changes in Oracle R Enterprise 1.4](#) (page xiv)
- [Changes in Oracle R Enterprise 1.3](#) (page xvi)
- [Changes in Oracle R Enterprise 1.1](#) (page xvi)

## Changes in Oracle R Enterprise 1.5

Oracle R Enterprise 1.5 introduces functions for managing Oracle R Enterprise datastores and scripts in the Oracle Database script repository. It also contains a new function in the `OREmodel` package, new transparency layer methods for some functions in the `stats` package, and other enhancements.

## New Features in Oracle R Enterprise 1.5

Oracle R Enterprise 1.5 has new R functions and SQL procedures, new transparency layer methods, and enhancements to some functions.

Oracle R Enterprise 1.5 has new R functions and SQL procedures for managing Oracle R Enterprise datastores and the Oracle R Enterprise R script repository. Users can now share with other users access to datastores and registered R scripts. This release also has a new modeling function, `ore.randomForest`, new `svd` and `prcomp` statistical function methods that take `ore.frame` objects and can use parallel processing, and other enhancements.

The following topics briefly describe the new features.

- [R for Datastore and Script Repository Management](#) (page x)
- [PL/SQL and Data Dictionary Views for Datastore and Script Repository Management](#) (page xi)
- [ore.groupApply Function Changes](#) (page xii)
- [ore.randomForest Modeling Function](#) (page xii)
- [ore.summary Function Changes](#) (page xiii)

- [Statistical Function Method Changes](#) (page xiii)
- [Support for BLOB and CLOB Data Types](#) (page xiii)

## **R for Datastore and Script Repository Management**

Oracle R Enterprise 1.5 provides new R functions for managing Oracle R Enterprise datastores and the R script repository.

The owner of a datastore or registered R script can now share with other users read privilege access to the datastore or script. This release also has new arguments to functions that create datastores and scripts and that give information about them. This datastore and script management functionality has both R and SQL interfaces.

The R functions for managing datastores are the following:

- `ore.delete`, which deletes a datastore, is unchanged.
- `ore.grant` is a new function that grants read privilege access to a datastore or script.
- `ore.load`, which loads objects from a datastore into an R environment, has the new argument `owner` that specifies the datastore owner.
- `ore.revoke` is a new function that revokes read privilege access to a datastore or script.
- `ore.save`, which creates a datastore, has the new argument `grantable` that specifies whether read access can be granted to the datastore.
- `ore.datastore`, which lists information about a datastore, has the new argument `type` that specifies the type of datastore. The values of `type` are the character strings `user` (the default), `grant`, `granted`, and `all`.
- `ore.datastoreSummary`, which provides detailed information about datastores, has the new argument `owner` that specifies a datastore owner.

The R functions for managing scripts are the following:

- `ore.grant` is a new function that grants read privilege access to a datastore or script.
- `ore.revoke` is a new function that revokes read privilege access to a datastore or script.
- `ore.scriptCreate`, which adds an R function to the script repository, has the new arguments `global` and `overwrite`. The argument `global` specifies whether the script is global or private. A global script is a public script that is available to all users. If `global = FALSE`, then access to the script must be granted by the owner to other users. The argument `overwrite` specifies whether the content of a script can be replaced.
- `ore.scriptDrop`, which deletes a script, has the new arguments `global`, which specifies whether the script to drop is global or not, and `silent`, which specifies whether to report an error if the script cannot be dropped.
- `ore.scriptList`, which lists information about scripts, has the new argument `type` that specifies the type of script. The values of `type` are the character strings `user` (the default), `global`, `grant`, `granted`, and `all`.

- `ore.scriptLoad` is a new function that loads a script into the R environment.

## **PL/SQL and Data Dictionary Views for Datastore and Script Repository Management**

Oracle R Enterprise 1.5 provides new PL/SQL procedures for managing Oracle R Enterprise datastores and the R script repository.

The owner of a datastore or registered R script can now share with other users read privilege access to the datastore or script. This release also has new arguments to procedures that create datastores and scripts and that give information about them. This functionality has both R and SQL interfaces. Oracle Database data dictionary views provide information about datastores and scripts.

The SQL procedures for controlling access to Oracle R Enterprise datastores and registered R scripts are described in the following sections:

- [PL/SQL Procedures for Managing Datastores](#) (page xi)
- [PL/SQL Procedures for Managing Scripts](#) (page xi)
- [Data Dictionary Views for Datastores](#) (page xi)
- [Data Dictionary Views for Scripts](#) (page xii)

### **PL/SQL Procedures for Managing Datastores**

The PL/SQL procedures for managing datastores are the following:

- `rqDropDataStore`, which deletes a datastore, is unchanged.
- `rqGrant` is a new procedure that grants read privilege access to a datastore or script.
- `rqRevoke` is a new procedure that revokes read privilege access to a datastore or script.

### **PL/SQL Procedures for Managing Scripts**

The PL/SQL procedures for managing scripts are the following:

- `rqGrant` is a new procedure that grants read privilege access to a datastore or script.
- `rqRevoke` is a new procedure that revokes read privilege access to a datastore or script.
- `rqScriptCreate` has the new arguments `global` and `overwrite`. The argument `global` specifies whether the script is global or private. A global script is a public script that is available to all users. If `global = FALSE`, then access to the script must be granted by the owner to other users. The argument `overwrite` specifies whether the content of a script can be replaced.
- `rqScriptDrop` has the new arguments `global`, which specifies whether the script to drop is global or not, and `silent`, which specifies whether to report an error if a script cannot be dropped.

### **Data Dictionary Views for Datastores**

The Oracle Database dictionary views related to datastores are the following:

- ALL\_RQ\_DATASTORES
- RQUSER\_DATASTORECONTENTS
- USER\_RQ\_DATASTORES
- USER\_RQ\_DATASTORE\_PRIVS

### Data Dictionary Views for Scripts

The Oracle Database dictionary views related to scripts are the following:

- ALL\_RQ\_SCRIPTS
- USER\_RQ\_SCRIPTS
- USER\_RQ\_SCRIPT\_PRIVS

### ore.groupApply Function Changes

Function `ore.groupApply` now supports partitioning on multiple columns.

The `INDEX` argument can now take an `ore.vector` or `ore.frame` object that contains `ore.factor` objects or columns, each of which is the same length as argument `X`. Function `ore.groupApply` uses the `INDEX` object to partition the data in `X` before sending it to function `FUN`.

For an example of the use of the `INDEX` object to partition the data, see [“Partitioning on Multiple Columns”](#) (page 6-29).

### ore.randomForest Modeling Function

The `ore.randomforest` function builds a random forest model on data in an `ore.frame` object.

It uses embedded R execution to grow random forest trees in parallel in R sessions on the database server. It returns an `ore.randomforest` object. In Oracle R Enterprise 1.5, function `ore.randomForest` supports classification but not regression.

The `ore.randomforest` function uses the same algorithm as that adopted by the CRAN R `randomForest` package but it has better runtime memory usage as well as ensemble tree size.

The scoring method `predict` on an `ore.randomforest` model also runs in parallel. Oracle recommends that you set the `cache.model` argument to `TRUE` when sufficient memory is available. Otherwise, you should set `cache.model` to `FALSE` to prevent memory overuse.

To use `ore.randomforest`, you must install either Oracle R Distribution (ORD) 3.2 or the CRAN R `randomForest` package. Oracle recommends that you use the function `ore.randomforest` in ORD 3.2, which offers better performance and scalability than the CRAN R `randomForest`. If you only install the R `randomForest` package, `ore.randomForest` issues a warning message at run time. The CRAN R `randomForest` package is one of the supporting packages in Oracle R Enterprise 1.5.

The global option `ore.parallel` determines the degree of parallelism to use in the Oracle R Enterprise server. The argument `groups` controls the granularity of the `ore.randomForest` model.

For an example of using `ore.randomForest`, see [“Building a Random Forest Model”](#) (page 4-9).

## ore.summary Function Changes

Function `ore.summary` has improved performance. It also has a different signature and the data types for some arguments have changed.

The function's syntax is now the following:

```
ore.summary(data, var, stats = c("n", "mean", "min", "max"),
            class = NULL, types = NULL, ways = NULL, weight = NULL,
            order = NULL, maxid = NULL, minid = NULL, mu = 0,
            no.type = FALSE, no.freq = FALSE)
```

The differences between the `ore.summary` in Oracle R Enterprise Release 1.5 and previous releases are the following:

- The performance of `ore.summary` has improved; it now returns over an order of magnitude faster.
- The arguments `var`, `stats`, and `class` now take a vector of character strings; previously, they took a concatenated string using a comma as the separator.
- Argument `types` is now a list of character string vectors that specifies combinations of columns in the `class` argument.
- Arguments `maxid` and `minid` are named vectors of character strings.
- Arguments `group.by` and `no.level` are not supported.
- Argument `mu` in previous releases was named `mu0`.

For examples of using `ore.summary`, see [“Summarizing Data with ore.summary”](#) (page 3-36).

## Statistical Function Method Changes

Oracle R Enterprise 1.5 provides transparency layer methods for the `stats` package functions `prcomp` and `svd`.

The `prcomp` function performs principal components analysis and the `svd` function performs singular-value decomposition. Those functions now accept `ore.frame` objects and can use parallel execution in the database, which can improve scalability and performance.

## Support for BLOB and CLOB Data Types

Some Oracle R Enterprise functions now support the Oracle Database data types BLOB and CLOB.

Functions `ore.push` and `ore.pull` now support the database data types BLOB and CLOB.

Embedded R execution R functions now support the database data types BLOB and CLOB for input and output objects.

For examples of using BLOB and CLOB data types, see [“Example 6-11](#) (page 6-23)“.

# Changes in Oracle R Enterprise 1.4.1

The following topics describe the changes in Oracle R Enterprise 1.4:

- [New Features in Oracle R Enterprise 1.4.1](#) (page xiv)

- [Other Changes in Oracle R Enterprise 1.4.1](#) (page xiv)

## New Features in Oracle R Enterprise 1.4.1

The following changes are in Oracle R Enterprise 1.4.1:

- The `ore.glm` function now accepts offset terms in the model formula and the function can now be used to fit negative binomial and tweedie families of generalized linear models.
- The `ore.sync` function has an additional optional argument, `query`, that creates an `ore.frame` object from an optimized SQL `SELECT` statement without creating a view in the database. You can use this argument to create a query even when you do not have the `CREATE VIEW` system privilege for the current schema.

---

---

**See Also:**

[Example 2-10](#) (page 2-6)

---

---

- The new global option for serialization, `ore.envAsEmptyenv`, specifies whether referenced environments in an object should be replaced with an empty environment during serialization to an Oracle Database. This option is used by the following functions:
  - `ore.push`, which for a `list` object accepts `envAsEmptyenv` as an optional argument
  - `ore.save`, which has `envAsEmptyenv` as a named argument
  - `ore.doEval` and the other embedded R execution functions, which accept `ore.envAsEmptyenv` as a control argument.

The default values of the above arguments are regulated by the global option `ore.envAsEmptyenv`, but by using the argument you can override the global option value for a function.

---

---

**See Also:**

- ["Oracle R Enterprise Global Options](#) (page 1-12)"
  - ["Optional and Control Arguments](#) (page 6-11)"
  - The online help for the `ore.push` and `ore.save` functions
- 
- 

## Other Changes in Oracle R Enterprise 1.4.1

Other changes in this release are the following:

- The `arules` and `statmod` packages from The Comprehensive R Archive Network (CRAN) are now included in the Oracle R Enterprise supporting packages.

## Changes in Oracle R Enterprise 1.4

The following topics describe the changes in Oracle R Enterprise 1.4:

- [New Features in Oracle R Enterprise 1.4](#) (page xv)

## New Features in Oracle R Enterprise 1.4

The following changes are in Oracle R Enterprise 1.4:

- Additions and improvements to data preparation functions:
  - The new `factanal` function performs factor analysis on a `formula` or an `ore.frame` object that contains numeric columns.
  - Both signatures of the `princomp` function support the `scores`, `subset`, and `na.action` arguments.
  - The new `getXlevels` function creates a list of factor levels that can be used in the `xlev` argument of a `model.matrix` call that involves an `ore.frame` object.
- The new exploratory data analysis function `ore.esm` builds exponential smoothing models for time series data. The function builds a model using either the simple exponential smoothing method or the double exponential smoothing method. The function can preprocess the time series data with operations such as aggregation and the handling of missing values. See "[Building Exponential Smoothing Models on Time Series Data](#) (page 3-30)".
- Additions and improvements to the Oracle R Enterprise regression and neural network modeling functions:
  - The new `ore.glm` function provides methods for fitting generalized linear models, which include logistic regression, probit regression, and poisson regression. See "[Building a Generalized Linear Model](#) (page 4-5)".
  - The `ore.lm` and `ore.stepwise` functions are no longer limited to a total of 1,000 columns when deriving columns in the model formula.
  - The `ore.lm` function now supports a `weights` argument for performing weighted least squares regression.
  - The `anova` function can now perform analysis of variance on an `ore.lm` object.
  - For the `ore.stepwise` function, the values for the `direction` argument have changed. The value `"both"` now prefers drops over adds. The new `direction` argument value `"alternate"` has the previous meaning of the `"both"` value.
  - The `ore.neural` function has several new arguments.
- Additions and improvements to the Oracle Data Mining model algorithm functions:
  - The new `ore.odmAssocRules` function, which builds an Oracle Data Mining association model using the apriori algorithm. See "[Building an Association Rules Model](#) (page 4-13)".
  - The new `ore.odmNMF` function, which builds an Oracle Data Mining model for feature extraction using the Non-Negative Matrix Factorization (NMF) algorithm. See "[Building a Non-Negative Matrix Factorization Model](#) (page 4-27)".

- The new `ore.odmOC` function, which builds an Oracle Data Mining model for clustering using the Orthogonal Partitioning Cluster (O-Cluster) algorithm. See "[Building an Orthogonal Partitioning Cluster Model](#) (page 4-29)".
- An additional global option for Oracle R Enterprise, `ore.parallel`. See "[Oracle R Enterprise Global Options](#) (page 1-12)".

## Changes in Oracle R Enterprise 1.3

The following topics describe the changes in Oracle R Enterprise 1.3:

- [New Features in Oracle R Enterprise 1.3](#) (page xvi)
- [Other Changes in Oracle R Enterprise 1.3](#) (page xvi)

## New Features in Oracle R Enterprise 1.3

The new features in Oracle R Enterprise 1.3 are the following:

- Predicting with R models using in-database data with the `OREpredict` package
- Ordering and indexing with `row.names<-`
- Predicting with Oracle Data Mining models using the `OREodm` package
- Saving and managing R objects in the database
- Date and time data types
- Sampling and partitioning
- Long names for columns
- Automatically connecting to an Oracle Database instance in embedded R scripts
- Building an R neural network using in-database data with the `ore.neural` function

## Other Changes in Oracle R Enterprise 1.3

Other changes in this release are the following:

- Installation and administration information has moved from this manual to *Oracle R Enterprise Installation and Administration Guide*. New features related to installation and administration are described in that book.

## Changes in Oracle R Enterprise 1.1

The new features in Oracle R Enterprise 1.1 are the following:

- Support for additional operating systems:
  - Oracle R Distribution and Oracle R Enterprise are now supported IBM AIX 5.3 and higher and on 10 and higher for both 64-bit SPARC and 64-bit x386 (Intel) processors.
  - The Oracle R Enterprise Server now runs on 64-bit and 32-bit Windows operating systems.

- Improved mathematics libraries in R:
  - You can now use the improved Oracle R Distribution with support for dynamically picking up either the Intel Math Kernel Library (MKL) or the AMD Core Math Library (ACML) with Oracle R Enterprise.
  - On Solaris, Oracle R Distribution dynamically links with Oracle SUN performance library for high speed BLAS and LAPACK operations.
- Support for Oracle Wallet enables R scripts to no longer need to have database authentication credentials in clear text. Oracle R Enterprise is integrated with Oracle Wallet for that purpose.
- Improved installation scripts provide more prerequisite checks and detailed error messages. Error messages provide specific instructions on remedial actions.

---

# Introducing Oracle R Enterprise

This chapter introduces Oracle R Enterprise. The chapter contains the following topics:

- [About Oracle R Enterprise](#) (page 1-1)
- [Advantages of Oracle R Enterprise](#) (page 1-2)
- [Get Online Help for Oracle R Enterprise Classes, Functions, and Methods](#) (page 1-3)
- [About Transparently Using R on Oracle Database Data](#) (page 1-6)
- [Typical Operations in Using Oracle R Enterprise](#) (page 1-11)
- [Oracle R Enterprise Global Options](#) (page 1-12)
- [Oracle R Enterprise Examples](#) (page 1-14)

## 1.1 About Oracle R Enterprise

Oracle R Enterprise is a component of the Oracle Advanced Analytics Option of Oracle Database Enterprise Edition. Oracle R Enterprise is comprehensive, database-centric environment for end-to-end analytical processes in R, with immediate deployment to production environments. It is a set of R packages and Oracle Database features that enable an R user to operate on database-resident data without using SQL and to execute R scripts in one or more embedded R engines that run on the database server.

Using Oracle R Enterprise from your local R session, you have easy access to data in an Oracle Database instance. You can create and use R objects that specify data in database tables. Oracle R Enterprise has overloaded functions that translate R operations into SQL that executes in the database. The database consolidates the SQL and can use the query optimization, parallel processing, and scalability features of the database when it executes the SQL statements. The database returns the results as R objects.

Embedded R execution provides some of the most significant advantages of using Oracle R Enterprise. Using embedded R execution, you can store and run R scripts in the database through either an R interface or a SQL interface or both. You can use the results of R scripts in SQL-enabled tools for structured data, R objects, and images.

---

### See Also:

"[Advantages of Oracle R Enterprise](#) (page 1-2)"

---

## 1.2 Advantages of Oracle R Enterprise

Using Oracle R Enterprise to prepare and analyze data in an Oracle Database instance has many advantages for an R user. With Oracle R Enterprise, you can do the following:

- **Operate on Database-Resident Data Without Using SQL.** Oracle R Enterprise has overloaded open source R methods and functions that transparently convert standard R syntax into SQL. These methods and functions are in packages that implement the Oracle R Enterprise **transparency layer**. With these functions and methods, you can create R objects that access, analyze, and manipulate data that resides in the database. The database can automatically optimize the SQL to improve the efficiency of the query.
- **Eliminate Data Movement.** By keeping the data in the database, you eliminate the time involved in transferring the data to your desktop computer and the need to store the data locally. You also eliminate the need to manage the locally stored data, which includes tasks such as distributing the data files to the appropriate locations, synchronizing the data with changes that are made in the production database, and so on.
- **Keep Data Secure.** By keeping the data in the database, you have the security, scalability, reliability, and backup features of Oracle Database for managing the data.
- **Use the Power of the Database.** By operating directly on database-resident data, you can use the memory and processing power of the database and avoid the memory constraints of your client R session.
- **Use Current Data.** As data is refreshed in the database, you have immediate access to current data.
- **Prepare Data in the Database.** Using the transparency layer functions, prepare large database-resident data sets for predictive analysis through operations such as ordering, aggregating, filtering, recoding, and the use of comprehensive sampling techniques without having to write SQL code.
- **Save R Objects in the Database.** You can save R objects in an Oracle Database instance as persistent database objects that are available to others. You can store R and Oracle R Enterprise objects in an Oracle R Enterprise datastore, which is managed by the Oracle database.
- **Build Models in the Database.** You can build models in the database and store and manage them in an Oracle R Enterprise datastore. You can use functions in packages that you download from CRAN (The Comprehensive R Archive Network) to build models that require large amounts of memory and that use techniques such as ensemble modeling.
- **Score Data in the Database.** You can include your R models in scripts to score database-resident data. You can perform tasks such as the following:
  - Go from model building to scoring in one step because you can use the same R code for scoring. You do not need to translate the scoring logic as required by some standalone analytic servers.
  - Schedule scripts to be run automatically to perform tasks such as bulk scoring.

- Score data in the context of a transaction.
- Perform online what-if scoring.
- Optionally convert a model to SQL, which Oracle Database does automatically for you. You can then deploy the resulting SQL for low-latency scoring tasks.
- **Execute R Scripts in the Database.** Using Oracle R Enterprise **embedded R execution** functionality, you can create, store, and execute R scripts in the database. When the script executes, Oracle Database starts, controls, and manages one or more R engines that can run in parallel on the database server. By executing scripts on the database server, you can take advantage of scalability and performance of the server.

With the embedded R execution functionality, you can do the following:

- Develop and test R scripts interactively and make the scripts available for use by SQL applications
- Use CRAN and other packages in R scripts on the database server
- Operationalize entire R scripts in production applications and eliminate porting R code; avoid reinventing code to integrate R results into existing applications
- Seamlessly leverage Oracle Database as a high performance computing (HPC) environment for R scripts, providing data parallelism and resource management
- Use the processing and memory resources of Oracle Database and the increased efficiency of read/write operations between the database and the embedded R execution R engines
- Use the parallel processing capabilities of the database for data-parallel or task-parallel operations
- Perform parallel simulations
- Generate XML and PNG images that can be used by R or SQL applications
- **Integrate with the Oracle Technology Stack.** You can take advantage of all aspects of the Oracle technology stack to integrate your data analysis within a larger framework for business intelligence or scientific inquiry. For example, you can integrate the results of your Oracle R Enterprise analysis into Oracle Business Intelligence Enterprise Edition (OBIEE).

## 1.3 Get Online Help for Oracle R Enterprise Classes, Functions, and Methods

The Oracle R Enterprise client packages contain the R components that you use to interact with data in an Oracle database. For a list and brief descriptions of the client packages, and for information on installing them, see *Oracle R Enterprise Installation and Administration Guide*.

To get help on Oracle R Enterprise classes, functions, and methods, use R functions such as `help` and `showMethods`. If the name of a class or function has an `ore` prefix, you can supply the name to the `help` function. To get help on an overloaded method of an open-source R function, supply the name of the method and the name of the `ore` class.

**Example 1-1   Getting Help on Oracle R Enterprise Classes, Functions, and Methods**

This example shows several ways of getting information on Oracle R Enterprise classes, functions, and methods. In the listing following the example some code has been modified to display only a portion of the results and the output of some of the functions is not shown.

```
# List the contents of the OREbase package.
ls("package:OREbase")

# Get help for the OREbase package.
help("OREbase")

# Get help on the ore.connect function.

R> help("ore.connect") # Output not shown.

## 1.4 About Transparently Using R on Oracle Database Data

Oracle R Enterprise has overloaded open source R methods and functions that you can use to operate directly on data in an Oracle Database instance. The methods and functions are in packages that implement a transparency layer that translates R functions into SQL.

The Oracle R Enterprise transparency layer packages and the limitations of converting R into SQL are described in the following topics:

- [About the Transparency Layer](#) (page 1-6)
- [Transparency Layer Support for R Data Types and Classes](#) (page 1-7)

---

**See Also:**

["Getting Started with Oracle R Enterprise](#) (page 2-1)"

---

### 1.4.1 About the Transparency Layer

The Oracle R Enterprise transparency layer is implemented by the `OREbase`, `OREgraphics`, and `OREstats` packages. These Oracle R Enterprise packages contain overloaded methods of functions in the open source R `base`, `graphics`, and `stats` packages, respectively. The Oracle R Enterprise packages also contain Oracle R Enterprise versions of some of the open source R functions.

With the methods and functions in these packages, you can create R objects that specify data in an Oracle Database instance. When you execute an R expression that uses such an object, the method or function transparently generates a SQL query and sends it to the database. The database then executes the query and returns the results of the operation as an R object.

A database table or view is represented by an `ore.frame` object, which is a subclass of `data.frame`. Other Oracle R Enterprise classes inherit from corresponding R classes, such as `ore.vector` and `vector`. Oracle R Enterprise maps Oracle Database data types to Oracle R Enterprise classes, such as `NUMBER` to `ore.integer`. For more information on Oracle R Enterprise data types and object mappings, see ["Transparency Layer Support for R Data Types and Classes](#) (page 1-7)".

You can use the transparency layer methods and functions to prepare database-resident data for analysis. You can then use functions in other Oracle R Enterprise packages to build and fit models and use them to score data. For large data sets, you can do the modeling and scoring using R engines embedded in Oracle Database.

**Example 1-2 Finding the Mean of the Petal Lengths by Species in R**

This example illustrates the translation of an R function invocation into SQL. It uses the overloaded Oracle R Enterprise `aggregate` function to get the mean of the petal lengths from the `IRIS_TABLE` object from [Example 1-2](#) (page 1-7).

```
aggplen = aggregate(IRIS_TABLE$Petal.Length,
                    by = list(species = IRIS_TABLE$Species),
                    FUN = mean)

aggplen
```

**Listing for [Example 1-2](#) (page 1-7)**

```
R> aggplen = aggregate(IRIS_TABLE$Petal.Length,
                    by = list(species = IRIS_TABLE$Species),
                    FUN = mean)

R> aggplen
```

|            | species    | x     |
|------------|------------|-------|
| setosa     | setosa     | 1.462 |
| versicolor | versicolor | 4.260 |
| virginica  | virginica  | 5.552 |

**Example 1-3 SQL Equivalent of [Example 1-2](#) (page 1-7)**

This example shows the SQL equivalent of the `aggregate` function in [Example 1-2](#) (page 1-7).

```
SELECT "Species", AVG("Petal.Length")
FROM IRIS_TABLE
GROUP BY "Species"
ORDER BY "Species";
```

| Species    | AVG("PETAL.LENGTH")  |
|------------|----------------------|
| setosa     | 1.462000000000000002 |
| versicolor | 4.26                 |
| virginica  | 5.552                |

**1.4.2 Transparency Layer Support for R Data Types and Classes**

Oracle R Enterprise transparency layer has classes and data types that map R data types to Oracle Database data types. Those classes and data types are described in the following topics:

- [About Oracle R Enterprise Data Types and Classes](#) (page 1-7)
- [About the `ore.frame` Class](#) (page 1-8)
- [Support for R Naming Conventions](#) (page 1-10)
- [About Coercing R and Oracle R Enterprise Class Types](#) (page 1-10)

**1.4.2.1 About Oracle R Enterprise Data Types and Classes**

Oracle R Enterprise has data types that map R data types to SQL data types. In an R session, when you create database objects from R objects or you create R objects from database data, Oracle R Enterprise translates R data types to SQL data types and the reverse where possible.

Oracle R Enterprise creates objects that are instances of Oracle R Enterprise classes. Oracle R Enterprise overloads many standard R functions so that they use Oracle R

Enterprise classes and data types. R language constructs and syntax are supported for objects that are mapped to Oracle Database objects.

**Table 1-1 Mappings Between R, Oracle R Enterprise, and SQL Data Types**

| R Data Type           | Oracle R Enterprise Data Type | SQL Data Type                                                              |
|-----------------------|-------------------------------|----------------------------------------------------------------------------|
| character mode vector | <code>ore.character</code>    | VARCHAR2<br>INTERVAL YEAR TO MONTH                                         |
| integer mode vector   | <code>ore.integer</code>      | NUMBER                                                                     |
| logical mode vector   | <code>ore.logical</code>      | The NUMBER 0 for FALSE and 1 for TRUE                                      |
| numeric mode vector   | <code>ore.number</code>       | BINARY_DOUBLE<br>BINARY_FLOAT<br>FLOAT<br>NUMBER                           |
| Date                  | <code>ore.date</code>         | DATE                                                                       |
| POSIXct<br>POSIXlt    | <code>ore.datetime</code>     | TIMESTAMP<br>TIMESTAMP WITH TIME ZONE<br>TIMESTAMP WITH LOCAL TIME ZONE    |
| difftime              | <code>ore.difftime</code>     | INTERVAL DAY TO SECOND                                                     |
| None                  | Not supported                 | LONG<br>LONG RAW<br>RAW<br>User defined data types<br>Reference data types |

---

**Note:**

Objects of type `ore.datetime` do not support a time zone setting, instead they use the system time zone `Sys.timezone` if it is available or GMT if `Sys.timezone` is not available.

[R Operators and Functions Supported by Oracle R Enterprise](#) (page C-1)

### 1.4.2.2 About the `ore.frame` Class

An `ore.frame` object represents a relational query for an Oracle Database instance. It is the Oracle R Enterprise equivalent of a `data.frame`. Typically, you get `ore.frame` objects that are proxies for database tables. You can then add new columns, or make other changes, to the `ore.frame` proxy object. Any such change does not affect the underlying table. If you then request data from the source table of

the `ore.frame` object, the transparency layer function generates a SQL query that has the additional columns in the select list, but the table is not changed.

In R, the elements of a `data.frame` have an explicit order. You can specify elements by using integer indexing. In contrast, relational database tables do not define any order of rows and therefore cannot be directly mapped to R data structures.

Oracle R Enterprise has both ordered and unordered `ore.frame` objects. If a table has a primary key, which is a set of one or more columns that form a distinct tuple within a row, you can produce ordered results by performing a sort using an `ORDER BY` clause in a `SELECT` statement. However, ordering relational data can be expensive and is often unnecessary for transparency layer operations. For example, ordering is not required to compute summary statistics when invoking the `summary` function on an `ore.frame`.

---

#### See Also:

["Moving Data to and from the Database \(page 2-15\)"](#) for information on `ore.create`

["Creating Ordered and Unordered `ore.frame` Objects \(page 2-9\)"](#).

---

#### **Example 1-4** *Classes of a `data.frame` and a Corresponding `ore.frame`*

This example creates a `data.frame` with columns that contain different data types and displays the structure of the `data.frame`. The example then invokes the `ore.push` function to create a temporary table in the database that contains a copy of the data of the `data.frame`. The `ore.push` invocation also generates an `ore.frame` object that is a proxy for the table. The example displays the classes of the `ore.frame` object and of the columns in the `data.frame` and the `ore.frame` objects.

```
df <- data.frame(a="abc",
                 b=1.456,
                 c=TRUE,
                 d=as.integer(1),
                 e=Sys.Date(),
                 f=as.difftime(c("0:3:20", "11:23:15")))

ore.push(df)
class(of)
class(df$a)
class(of$a)
class(df$b)
class(of$b)
class(df$c)
class(of$c)
class(df$d)
class(of$d)
class(df$e)
class(of$e)
class(df$f)
class(of$f)
```

#### **Listing for Example 1-4 (page 1-9)**

```
R> df <- data.frame(a="abc",
+                  b=1.456,
+                  c=TRUE,
+                  d=as.integer(1),
+                  e=Sys.Date(),
```

```
+                                f=as.diffftime(c("0:3:20", "11:23:15")))
R> ore.push(df)

attr(,"package")
[1] "OREbase"
```

### 1.4.2.3 Support for R Naming Conventions

Oracle R Enterprise uses R naming conventions for `ore.frame` columns instead of the more restrictive Oracle Database naming conventions. The column names of an `ore.frame` can be longer than 30 bytes, can contain double quotes, and can be non-unique.

### 1.4.2.4 About Coercing R and Oracle R Enterprise Class Types

The generic `as.ore` function coerces in-memory R objects to `ore` objects. The more specific functions, such as `as.ore.character`, coerce objects to specific types. The `ore.push` function implicitly coerces R class types to `ore` class types and the `ore.pull` function coerces `ore` class types to R class types. For information on those functions, see ["Moving Data to and from the Database" \(page 2-15\)](#).

**Example 1-5 Coercing R and Oracle R Enterprise Class Types**

This example illustrates coercing R objects to ore objects. creates an R `integer` object and then uses the generic method `as.ore` to coerce it to an ore object, which is an `ore.integer`. The example coerces the R object to various other ore class types. For an example of using `as.factor` in embedded R execution function, see [Example 6-13](#) (page 6-27).

```
x <- 1:10
class(x)
X <- as.ore(x)
class(X)
Xn <- as.ore.numeric(x)
class(Xn)
Xc <- as.ore.character(x)
class(Xc)
Xc
Xf <- as.ore.factor(x)
Xf
```

**Listing for Example 1-5 (page 1-11)**

```
R> x <- 1:10
R> class(x)
[1] "integer"
R> X <- as.ore(x)
R> class(X)
[1] "ore.integer"
attr(,"package")
[1] "OREbase"
R> Xn <- as.ore.numeric(x)
R> class(Xn)
[1] "ore.numeric"
attr(,"package")
[1] "OREbase"
R> Xc <- as.ore.character(x)
R> class(Xc)
[1] "ore.character"
attr(,"package")
[1] "OREbase"
R> Xc
[1] "1" "2" "3" "4" "5" "6" "7" "8" "9" "10"
R> Xf <- as.ore.factor(x)
R> Xf
[1] 1 2 3 4 5 6 7 8 9 10
Levels: 1 10 2 3 4 5 6 7 8 9
```

## 1.5 Typical Operations in Using Oracle R Enterprise

In using Oracle R Enterprise, the following is a typical progression of operations:

1. In an R session, connect to a schema in an Oracle Database instance.
2. Attach the schema and synchronize with the schema objects, which generates Oracle R Enterprise proxy objects for database tables.
3. Prepare the data for analysis and possibly perform exploratory data analysis and data visualization.
4. Build models using functions in the `OREmodels` or `OREdm` packages.

5. Score data using the models either in your local R session or by using embedded R execution.
6. Deploy the results of the analysis to end users.

**Figure 1-1 Typical Oracle R Enterprise Workflow**

This figure illustrates these steps and typical reiterations of them.

"[Getting Started with Oracle R Enterprise](#) (page 2-1)" describes the following operations:

- Connecting to a database.
- Creating Oracle R Enterprise proxy objects for database tables.
- Moving data from a `data.frame` in your local R session to a database table, represented by an `ore.frame` proxy object, and the reverse.

"[Preparing and Exploring Data in the Database](#) (page 3-1)" describes preparing data for analysis and exploring data. Preparing and exploring data may include operations such as the following:

- Selecting data from a data set or table.
- Cleaning the data by filtering out unneeded information.
- Ordering the data.
- Intermediate aggregations of data.
- Time-series analysis.
- Recoding or formatting of data.
- Exploratory data analysis.

"[Building Models in Oracle R Enterprise](#) (page 4-1)" describes building models, including Oracle Data Mining models, using functions in the `OREmodels` and `OREdm` packages.

"[Predicting With R Models](#) (page 5-1)" describes using the `ore.predict` function on Oracle R Enterprise models.

"[Using Oracle R Enterprise Embedded R Execution](#) (page 6-1)" describes how to create and execute R scripts in one or more R engines that run on the database server, and how to save those scripts in the Oracle R Enterprise script repository.

## 1.6 Oracle R Enterprise Global Options

Oracle R Enterprise has global options that affect various functions. [Table 1-2](#) (page 1-13) lists the Oracle R Enterprise global options and descriptions of them.

**Table 1-2 Oracle R Enterprise Global Options**

| Global                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>ore.envAsEmptyenv</code> | <p>A logical value that specifies whether an environment referenced in an object should be replaced with an empty environment during serialization to an Oracle Database. When <code>TRUE</code>, the referenced environment in the object is replaced with an empty environment whose parent is <code>.GlobalEnv</code>, and the objects in the original referenced environment are not serialized. In some cases, this can significantly reduce the size of serialized objects. When <code>FALSE</code>, all of the objects in the referenced environment are serialized, and can be unserialized and loaded into memory. The default value for this option is <code>FALSE</code>.</p> <p>The following Oracle R Enterprise functions use this global option:</p> <ul style="list-style-type: none"> <li>• <code>ore.push</code>, in saving a serialized <code>list</code> object to the database</li> <li>• <code>ore.save</code>, in saving objects to an Oracle R Enterprise datastore</li> <li>• <code>ore.doEval</code> and the other embedded R execution functions for serializing parameters of <code>list</code> type and for serializing some objects returned by an R function during embedded R execution</li> </ul> |
| <code>ore.na.extract</code>    | <p>A logical value used during logical subscripting of an <code>ore.frame</code> or <code>ore.vector</code> object. When <code>TRUE</code>, rows or elements with an <code>NA</code> logical subscript produce rows or elements with <code>NA</code> values, which mimics how R treats missing value logical subscripting of <code>data.frame</code> and <code>vector</code> objects.</p> <p>When <code>FALSE</code>, an <code>NA</code> logical subscript is interpreted as a <code>FALSE</code> value, resulting in the removal of the corresponding row or element. The default value is <code>FALSE</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>ore.parallel</code>      | <p>A preferred degree of parallelism to use in embedded R execution. One of the following:</p> <ul style="list-style-type: none"> <li>• A positive integer greater than or equal to 2 for a specific degree of parallelism</li> <li>• <code>FALSE</code> or 1 for no parallelism</li> <li>• <code>TRUE</code> for the default parallelism of the <code>data</code> argument</li> <li>• <code>NULL</code> for the database default for the operation</li> </ul> <p>The default value is <code>NULL</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>ore.sep</code>           | <p>A character string that specifies the separator to use between multiple column row names of an <code>ore.frame</code>. The default value is <code> </code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>ore.trace</code>         | <p>A logical value that specifies whether iterative Oracle R Enterprise functions should print output at each iteration. The default value is <code>FALSE</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>ore.warn.order</code>    | <p>A logical value that specifies whether Oracle R Enterprise displays a warning message when an <code>ore.frame</code> that lacks row names or an <code>ore.vector</code> that lacks element names is used in a function that requires ordering. The default value is <code>TRUE</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

## 1.7 Oracle R Enterprise Examples

Oracle R Enterprise includes several example scripts that demonstrate the use of Oracle R Enterprise functions. The following topics describe listing the example scripts and running a script:

- [Listing the Oracle R Enterprise Examples](#) (page 1-14)
- [Running an Oracle R Enterprise Example Script](#) (page 1-15)

### 1.7.1 Listing the Oracle R Enterprise Examples

You can display a list of the Oracle R Enterprise example scripts with the `demo` function as shown in the following example.

**Example 1-6 Using demo to List Oracle R Enterprise Examples**

```
demo(package = "ORE")
```

**Listing for Example 1-6 (page 1-14)**

```
R> demo(package = "ORE")
```

Demos in package 'ORE':

|               |                                                       |
|---------------|-------------------------------------------------------|
| aggregate     | Aggregation                                           |
| analysis      | Basic analysis & data processing operations           |
| basic         | Basic connectivity to database                        |
| binning       | Binning logic                                         |
| columnfns     | Column functions                                      |
| cor           | Correlation matrix                                    |
| crosstab      | Frequency cross tabulations                           |
| datastore     | Datastore operations                                  |
| datetime      | Date/Time operations                                  |
| derived       | Handling of derived columns                           |
| distributions | Distribution, density, and quantile functions         |
| do_eval       | Embedded R processing                                 |
| esm           | Exponential smoothing method                          |

| pca          | Principal Component Analysis                         |
| push_pull    | RDBMS <-> R data transfer                            |
| randomForest | Random forest model                                  |
| rank         | Attributed-based ranking of observations             |
| reg          | Ordinary least squares linear regression             |
| row_apply    | Embedded R processing by row chunks                  |
| sampling     | Random row sampling and partitioning of an ore.frame |
| sql_like     | Mapping of R to SQL commands                         |
| stepwise     | Stepwise OLS linear regression                       |
| summary      | Summary functionality                                |
| table_apply  | Embedded R processing of entire table                |

## 1.7.2 Running an Oracle R Enterprise Example Script

You can run an Oracle R Enterprise example script with the `demo` function. Most of the examples use the `iris` data set that is in the `datasets` package that is included in the R distribution.

To run an example script, start R, load the ORE packages with `library(ORE)`, connect to the database, and then use the `demo` function.

[Example 1-7](#) (page 1-15) runs the `basic.R` example script. In the listing that follows the example, only the first several lines of the output of the script are shown. The script creates an in-memory database object, `IRIS_TABLE`, which is an `ore.frame` object. The script then demonstrates that the `iris` data.frame and the `IRIS_TABLE` `ore.frame` have the same structure and contain the same data.

### **Example 1-7** Running the *basic.R* Example Script

```
demo("basic", package = "ORE")
```

#### Listing for [Example 1-7](#) (page 1-15)

```
R> demo("basic", package = "ORE")

      demo(basic)

# Getting Started with Oracle R Enterprise

This chapter describes how to start using Oracle R Enterprise by connecting to an Oracle Database instance and creating Oracle R Enterprise objects and storing them in the database.

This chapter discusses these topics:

- [Connecting to an Oracle Database Instance](#) (page 2-1)
- [Creating and Managing R Objects in Oracle Database](#) (page 2-4)

## 2.1 Connecting to an Oracle Database Instance

To use Oracle R Enterprise, you first connect to an Oracle Database instance as described in the following topics:

- [About Connecting to the Database](#) (page 2-1)
- [Using the `ore.connect` and `ore.disconnect` Functions](#) (page 2-3)

### 2.1.1 About Connecting to the Database

Oracle R Enterprise client components connect an R session to an Oracle Database instance and the Oracle R Enterprise server components. The connection makes the data in a database schema available to the R user. It also makes the processing power, memory, and storage capacities of the database server available to the R session through the Oracle R Enterprise client interface.

This section has the following topics:

- [About Using the `ore.connect` Function](#) (page 2-1)
- [About Using the `ore.disconnect` Function](#) (page 2-3)

#### 2.1.1.1 About Using the `ore.connect` Function

To begin using Oracle R Enterprise, you first connect to a schema in an Oracle Database instance with the `ore.connect` function. Only one Oracle R Enterprise connection can exist at a time during an R session. If an R session is already connected to the database, then invoking `ore.connect` terminates the active connection before opening a new connection. Before attempting to connect, you can discover whether an active connection exists by using the `ore.is.connected` function.

You explicitly end a connection with the `ore.disconnect` function. If you do not invoke `ore.disconnect`, then the connection is automatically terminated when the R session ends. For more information on `ore.disconnect`, see "[About Using the `ore.disconnect` Function](#)" (page 2-3)."

With the `type` argument of `ore.connect`, you specify the type of connection, either ORACLE or HIVE. A HIVE type of connection connects to Hive tables in a Hadoop cluster. An ORACLE type of connection connects to a schema in an Oracle Database instance. The default value of `type` is "ORACLE".

If the connection type is HIVE, then `ore.connect` ignores all other arguments. For information on Oracle R Connector for Hadoop and Hive, see *Oracle Big Data Connectors User's Guide*. The HIVE option applies only if you are using Oracle R Advanced Analytics for Hadoop (ORAAH) in conjunction with a Hadoop cluster. ORAAH is part of the Oracle Big Data Connectors option to the Big Data Appliance.

If the connection type is ORACLE, then you do the following:

- Use the logical `all` argument to specify whether Oracle R Enterprise automatically creates an `ore.frame` object for each table to which the user has access in the schema and makes those `ore.frame` objects visible in the current R session. The `ore.frame` objects contain metadata about the tables. The default value of the `all` argument is FALSE.

If `all = TRUE`, then Oracle R Enterprise implicitly invokes the `ore.sync` and `ore.attach` functions. If `all = FALSE`, then the user must explicitly invoke `ore.sync` to create `ore.frame` objects. To access these objects by name, the user must invoke `ore.attach` to include the names in the search path. For information on those functions, see ["Creating R Objects for In-Database Data \(page 2-4\)"](#).

- Use either the `conn_string` argument, or various combinations of the `user`, `sid`, `host`, `password`, `port`, `service_name`, and `conn_string` arguments to specify information that identifies the connection.

To avoid using a clear-text password, you can specify an Oracle wallet password with the `conn_string` argument. No other arguments are needed. By specifying an Oracle wallet password, you can avoid embedding a database user password in application code, batch jobs, or scripts. For information on creating an Oracle wallet, see *Oracle R Enterprise Installation and Administration Guide*.

With the other connection identifier arguments, you specify a database user name, host name, and password, and either a system identifier (SID) or service name, and, optionally, a TCP port, or you specify a database user name, password, and a `conn_string` argument.

The default value of the `port` argument is 1521, the default value of `host` is "localhost", which specifies the local host, and the default value of `conn_string` is NULL. You specify the local host when your R session is running on the same computer as the Oracle Database instance to which you want to connect.

---

---

**See Also:**

- ["Using the ore.connect and ore.disconnect Functions \(page 2-3\)"](#) for examples of using the various connection identifiers
  - ["Creating R Objects for In-Database Data \(page 2-4\)"](#)
- 
-

### 2.1.1.2 About Using the `ore.disconnect` Function

To explicitly end the connection between an R session and the Oracle Database instance, invoke the `ore.disconnect` function. Oracle R Enterprise implicitly invokes `ore.disconnect` if you do either of the following:

- Quit the R session.
- Invoke `ore.connect` while an Oracle R Enterprise connection is already active.

When you disconnect the active connection, Oracle R Enterprise discards all Oracle R Enterprise objects that you have not explicitly saved in an Oracle R Enterprise datastore. For information on saving objects, see ["Saving and Managing R Objects in the Database" \(page 2-17\)](#).

## 2.1.2 Using the `ore.connect` and `ore.disconnect` Functions

The examples in this section demonstrate the various ways of specifying an Oracle R Enterprise connection to an Oracle Database instance. The examples use sample values for the `ore.connect` argument values. Replace the sample values with the appropriate values for connecting to your database.

### **Example 2-1 Using `ore.connect` and Specifying a SID**

This example invokes the `ore.connect` function and specifies the user, sid, host, password, and port arguments.

```
ore.connect(user = "rquser", sid = "sales", host = "sales-server",
           password = "rquserStrongPassword", port = 1521 )
```

### **Example 2-2 Using `ore.connect` and Specifying a Service Name**

This example demonstrates using a service name rather than a SID. It also specifies connecting to the local host.

```
ore.connect(user = "rquser", host = "localhost",
           password = "rquserStrongPassword",
           service_name = "sales.example.com")
```

### **Example 2-3 Using `ore.connect` and Specifying an Easy Connect String**

This example uses the `conn_string` argument to specify an easy connect string that identifies the connection.

```
ore.connect(user = "rquser", password = "rquserStrongPassword",
           conn_string = "sales-server:1521:sales
             (ADDRESS=(PROTOCOL=tcp) (HOST=sales-server) (PORT=1521))
             (CONNECT_DATA=(SERVICE_NAME=sales.example.com)))")
```

### **Example 2-4 Using `ore.connect` and Specifying a Full Connection String**

This example uses the `conn_string` argument to specify a full connection string that identifies the connection.

```
ore.connect(user = "rquser", password = "rquserStrongPassword",
           conn_string = "DESCRIPTION=
             (ADDRESS=(PROTOCOL=tcp) (HOST=sales-server) (PORT=1521))
             (CONNECT_DATA=(SERVICE_NAME=myserver.example.com)))")
```

**Example 2-5 Using the `conn_string` Argument to Specify an Oracle Wallet**

This example uses the `conn_string` argument to specify an Oracle wallet. The `mydb_test` string is the connection identifier for the Oracle database. The Oracle wallet contains the information needed to create the connection. For information on creating an Oracle wallet for an Oracle R Enterprise connection, see *Oracle R Enterprise Installation and Administration Guide*.

```
ore.connect(conn_string = "mydb_test")
```

**Example 2-6 Using the `conn_string` Argument and Specifying an Empty Connection String**

This example uses an empty connection string to connect to the local host.

```
ore.connect(user = "ruser", password = "ruserStrongPassword", conn_string = "")
```

**Example 2-7 Using the `conn_string` Argument in Connecting to a Pluggable Database**

This example connects to a pluggable database using the `conn_string` argument to specify a service name.

```
ore.connect(conn_string = "pdb1.example.com")
```

**Example 2-8 Using the `service_name` Argument in Connecting to a Pluggable Database**

This example invokes `ore.connect` using a service name, host name, and port number to connect to a pluggable database.

```
ore.connect(service_name = "pdb1.example.com", host = "mypdb", port = 1521)
```

**Example 2-9 Disconnecting an Oracle R Enterprise Session**

This example explicitly disconnects an Oracle R Enterprise session from an Oracle database.

```
ore.disconnect()
```

## 2.2 Creating and Managing R Objects in Oracle Database

With transparency layer functions you can connect to an Oracle Database instance and interact with data structures in a database schema. You can move data to and from the database and create database tables. You can also save R objects in the database. The Oracle R Enterprise functions that perform these actions are described in the following topics.

- [Creating R Objects for In-Database Data](#) (page 2-4)
- [Moving Data to and from the Database](#) (page 2-15)
- [Creating and Deleting Database Tables](#) (page 2-16)
- [Saving and Managing R Objects in the Database](#) (page 2-17)

### 2.2.1 Creating R Objects for In-Database Data

Using Oracle R Enterprise, you can create R proxy objects in your R session from database-resident data as described in the following topics.

- [About Creating R Objects for Database Objects](#) (page 2-5)

- [Using the ore.sync Function](#) (page 2-6)
- [Using the ore.get Function](#) (page 2-7)
- [Using the ore.attach Function](#) (page 2-8)

### 2.2.1.1 About Creating R Objects for Database Objects

When you invoke `ore.connect` in an R session, Oracle R Enterprise creates a connection to a schema in an Oracle Database instance. To gain access to the data in the database tables in the schema, you use the `ore.sync` function. That function creates an `ore.frame` object that is a proxy for a table in a schema. You can use the `ore.attach` function to add an R environment that represents a schema to the R search path. For information on connecting to the database, see "[Connecting to an Oracle Database Instance](#) (page 2-1)".

When you use the `ore.sync` function to create an `ore.frame` object as a proxy for a database table, the name of the `ore.frame` proxy object is the same as the name of the database object. Each `ore.frame` proxy object contains metadata about the corresponding database object.

You can use the proxy `ore.frame` object to select data from the table. When you execute an R operation that selects data from the table, the operation returns the current data from the database object. However, if some application has added a column to the table, or has otherwise changed the metadata of the database object, the `ore.frame` proxy object does not reflect such a change until you again invoke `ore.sync` for the database object.

If you invoke the `ore.sync` function with no tables specified, and if the value of the `all` argument was `FALSE` in the `ore.connect` function call that established the connection to the Oracle database instance, then the `ore.sync` function creates a proxy object for each table in the schema specified by `ore.connect`. You can use the `table` argument to specify the tables for which you want to create `ore.frame` proxy objects.

**Tip:**

To conserve memory resources and save time, you should only add proxies for the tables that you want to use in your R session.

With the `schema` argument, you can specify the schema for which you want to create an R environment and proxy objects. Only one environment for a given database schema can exist at a time. With the `use.keys` argument, you can specify whether you want to use primary keys in the table to order the `ore.frame` object.

**Tip:**

Ordering is expensive in the database. Because most operations in R do not need ordering, you should generally set `use.keys` to `FALSE` unless you need ordering for sampling data or some other purpose. For more information on ordering, see "[Creating Ordered and Unordered ore.frame Objects](#) (page 2-9)".

With the `query` argument, you can specify a SQL `SELECT` statement. This enables you to create an `ore.frame` for a query without creating a view in the database. This can be useful when you not have the `CREATE VIEW` system privilege for the current schema. You cannot use the `schema` argument and the `query` argument in the same `ore.sync` invocation.

You can use the `ore.ls` function to list the `ore.frame` proxy objects that correspond to database tables in the environment for a schema. You can use the `ore.exists` function to find out if an `ore.frame` proxy object for a database table exists in an R environment. The function returns `TRUE` if the proxy object exists or `FALSE` if it does not. You can remove an `ore.frame` proxy object from an R environment with the `ore.rm` function.

### 2.2.1.2 Using the `ore.sync` Function

**Example 2-10** (page 2-6) demonstrates the use of the `ore.sync` function. The example first invokes the `ore.exec` function to create some tables to represent tables existing in the database schema for the `rquser`. The example then invokes `ore.sync` and specifies three tables of the schema. The `ore.sync` invocation creates an R environment for the `rquser` schema and creates proxy `ore.frame` objects for the specified tables in that schema. The example lists the `ore.frame` proxy objects in the current environment. The `TABLE3` table exists in the schema but does not have an `ore.frame` proxy object because it was not included in the `ore.sync` invocation.

The example next invokes `ore.sync` with the `query` argument to create `ore.frame` objects for the specified SQL queries. The example lists the `ore.frame` objects again.

The example then invokes `ore.sync` again and creates an R environment for the `SH` schema and proxy objects in that environment for the specified tables in that schema. The example invokes the `ore.exists` function to find out if the specified table exists in the current environment and then in the `SH` environment. The example lists the R objects in the `SH` environment.

The example next removes the `ore.frame` objects `QUERY1`, `QUERY2`, and `TABLE4` from the `rquser` environment. Finally, the example lists the proxy objects in the environment again.

---

**Note:**

The `ore.rm` function invocation removes the `ore.frame` that is a proxy for the `TABLE4` table from the environment. It does not delete the table from the schema.

---

#### **Example 2-10 Using `ore.sync` to Add `ore.frame` Proxy Objects to an R Environment**

```
# After connecting to a database as rquser, create some tables.
ore.exec("CREATE TABLE TABLE1 AS SELECT * FROM dual")
ore.exec("CREATE TABLE TABLE2 AS SELECT * FROM dual")
ore.exec("CREATE TABLE TABLE3 AS SELECT * FROM dual")
ore.exec("CREATE TABLE TABLE4 AS SELECT * FROM dual")
# Create ore.frame objects for the specified tables.
ore.sync(table = c("TABLE1", "TABLE3", "TABLE4"))
# List the ore.frame proxy objects in the current environment.
ore.ls()
# Create ore.frame objects for the specified queries.
ore.sync(query = c("QUERY1" = "SELECT 0 X, 1 Y FROM dual",
                  "QUERY2" = "SELECT 1 X, 0 Y FROM dual"))
ore.ls()
# The rquser user has been granted SELECT permission on the tables in the
# SH schema.
ore.sync("SH", table = c("CUSTOMERS", "SALES"))
# Find out if the CUSTOMERS ore.frame exists in the rquser environment.
ore.exists("CUSTOMERS")
# Find out if it exists in the SH environment.
```

```

ore.exists("CUSTOMERS", schema = "SH")
# List the ore.frame proxy objects in the SH environment.
ore.ls("SH")
# Remove the ore.frame objects for the specified objects.
ore.rm(c("QUERY1", "QUERY2", "TABLE4"))
# List the ore.frame proxy objects in the current environment again.
ore.ls()

```

### Listing for Example 2-10 (page 2-6)

```

R> # After connecting to a database as ruser, create some tables.
R> ore.exec("CREATE TABLE TABLE1 AS SELECT * FROM dual")
R> ore.exec("CREATE TABLE TABLE2 AS SELECT * FROM dual")
R> ore.exec("CREATE TABLE TABLE3 AS SELECT * FROM dual")
R> ore.exec("CREATE TABLE TABLE4 AS SELECT * FROM dual")
R> # Create ore.frame objects for the specified tables.
R> ore.sync(table = c("TABLE1", "TABLE3", "TABLE4"))
R> # List the ore.frame proxy objects in the current environment.
R> ore.ls()
[1] "TABLE1"      "TABLE3"      "TABLE4"
R> # Create ore.frame objects for the specified queries.
R> ore.sync(query = c("QUERY1" = "SELECT 0 X, 1 Y FROM dual",
+                    "QUERY2" = "SELECT 1 X, 0 Y FROM dual"))
R> ore.ls()
[1] "QUERY1"      "QUERY2"      "TABLE1"      "TABLE3"      "TABLE4"
R> # The ruser user has been granted SELECT permission on the tables in the
R> # SH schema.
R> ore.sync("SH", table = c("CUSTOMERS", "SALES"))
R> # Find out if the CUSTOMERS ore.frame exists in the ruser environment.
R> ore.exists("CUSTOMERS")
[1] FALSE
R> # Find out if it exists in the SH environment.
R> ore.exists("CUSTOMERS", schema = "SH")
[1] TRUE
R> # List the ore.frame proxy objects in the SH environment.
R> ore.ls("SH")
[1] "CUSTOMERS" "SALES"
R> # Remove the ore.frame objects for the specified objects.
R> ore.rm(c("QUERY1", "QUERY2", "TABLE4"))
R> # List the ore.frame proxy objects in the current environment again.
R> ore.ls()
[1] "TABLE1"      "TABLE3"

```

### 2.2.1.3 Using the ore.get Function

After you have created an R environment and `ore.frame` proxy objects with `ore.sync`, you can get a proxy object by name with the `ore.get` function. You can use `ore.get` to get the proxy `ore.frame` for a table and assign it to a variable in R, as in `SH_CUST <- ore.get(name = "CUSTOMERS", schema = "SH")`. The `ore.frame` exists in the R global environment, which can be referred to using `.GlobalEnv`, and so it appears in the list returned by the `ls` function. Also, because this object exists in the R global environment, as opposed an R environment that represents a database schema, it is not listed by the `ore.ls` function.

#### Example 2-11 Using ore.get to Get a Database Table

This example invokes the `ore.sync` function to create an `ore.frame` object that is a proxy for the `CUSTOMERS` table in the `SH` schema. The example then gets the dimensions of the proxy object.

```
ore.sync(schema = "SH", table = "CUSTOMERS", use.keys = FALSE)
dim(ore.get(name = "CUSTOMERS", schema = "SH"))
```

**Listing for Example 2-11 (page 2-7)**

```
R> ore.sync(schema = "SH", table = "CUSTOMERS", use.keys = FALSE)
R> dim(ore.get(name = "CUSTOMERS", schema = "SH"))
[1] 630 15
```

**2.2.1.4 Using the ore.attach Function**

With `ore.attach`, you add an R environment for a database schema to the R search path. When you add the R environment, you have access to database tables by name through the proxy objects created by the `ore.sync` function without needing to specify the schema environment.

The default schema is the one specified in creating the connection and the default position in the search path is 2. You can specify the schema and the position in the `ore.attach` function invocation. You can also specify whether you want the `ore.attach` function to indicate whether a naming conflict occurs when adding the environment. You can detach the environment for a schema from the R search path with the `ore.detach` function.

**Example 2-12 Using ore.attach to Add an Environment for a Database Schema**

This example demonstrates the use of the `ore.attach` function. Comments in the example explain the function invocations.

```
# Connected as ruser.
# Add the environment for the ruser schema to the R search path.
ore.attach()
# Create an unordered ore.frame proxy object in the SH environment for the
# specified table.
ore.sync(schema = "SH", table = "CUSTOMERS", use.keys = FALSE)
# Add the environment for the SH schema to the search path and warn if naming
# conflicts exist.
ore.attach("SH", 3, warn.conflicts = TRUE)
# Display the number of rows and columns in the proxy object for the table.
dim(CUSTOMERS)
# Remove the environment for the SH schema from the search path.
ore.detach("SH")
# Invoke the dim function again.
dim(CUSTOMERS)
```

**Listing for Example 2-12 (page 2-8)**

```
R> # Connected as ruser.
R> # Add the environment for the ruser schema to the R search path.
R> ore.attach()
R> # Create an unordered ore.frame proxy object in the SH environment for the
R> # specified table.
R> ore.sync(schema = "SH", table = "CUSTOMERS", use.keys = FALSE)
R> # Add the environment for the SH schema to the search path and warn if naming
R> # conflicts exist.
R> ore.attach("SH", 3, warn.conflicts = TRUE)
R> # Display the number of rows and columns in the proxy object for the table.
R> dim(CUSTOMERS)
[1] 630 15
R> # Remove the environment for the SH schema from the search path.
R> ore.detach("SH")
R> # Invoke the dim function again.
```

```
R> dim(CUSTOMERS)
Error: object 'CUSTOMERS' not found
```

## 2.2.2 Creating Ordered and Unordered `ore.frame` Objects

Oracle R Enterprise provides the ability to create ordered or unordered `ore.frame` objects. The following topics describe this feature.

- [About Ordering in `ore.frame` Objects](#) (page 2-9)
- [Global Options Related to Ordering](#) (page 2-10)
- [Ordering Using Keys](#) (page 2-10)
- [Ordering Using Row Names](#) (page 2-12)
- [Using Ordered Frames](#) (page 2-13)

### 2.2.2.1 About Ordering in `ore.frame` Objects

R objects such as `vector` and `data.frame` have an implicit ordering of their elements. The data in an Oracle Database table is not necessarily ordered. For some R operations, ordering is useful whereas for other operations it is unnecessary. By ordering an `ore.frame`, you are able to index the `ore.frame` object by using either integer or character indexes.

Using an ordered `ore.frame` object that is a proxy for a SQL query can be time-consuming for a large data set. Therefore, although Oracle R Enterprise attempts to create ordered `ore.frame` objects by default, it also provides the means of creating an unordered `ore.frame` object.

When you invoke the `ore.sync` function to create an Oracle R Enterprise `ore.frame` object as a proxy for a SQL query, you can use the `use.keys` argument to specify whether the `ore.frame` can be ordered or must be unordered.

An `ore.frame` object can be ordered if one or more of the following conditions are true:

- The value of the `use.keys` argument of the `ore.sync` function is `TRUE` and a primary key is defined on the underlying table
- The row names of the `ore.frame` constitute a unique tuple
- The `ore.frame` object is produced by certain functions such as `aggregate` and `cbind`
- All of the `ore.frame` objects that are input arguments to relevant Oracle R Enterprise functions are ordered

An `ore.frame` object is unordered if one or more of the following conditions are true:

- The value of the `use.keys` argument of the `ore.sync` function is `FALSE`
- No primary key is defined on the underlying table and either the row names of the `ore.frame` object are not specified or the row names of the `ore.frame` object are set to `NULL`
- One or more of the `ore.frame` objects that are input arguments to relevant Oracle R Enterprise functions are unordered

An unordered `ore.frame` object has null row names. You can determine whether an `ore.frame` object is ordered by invoking `is.null` on the row names of the objects, as shown in the last lines of [Example 2-13](#) (page 2-11). If the `ore.frame` object is unordered, `is.null` returns an error.

---

**See Also:**

["Indexing Data"](#) (page 3-5)

---

### 2.2.2.2 Global Options Related to Ordering

Oracle R Enterprise has options that relate to the ordering of an `ore.frame` object. The `ore.warn.order` global option specifies whether you want Oracle R Enterprise to display a warning message if you use an unordered `ore.frame` object in a function that requires ordering. If you know what to expect in an operation, then you might want to turn the warnings off so they do not appear in the output. For examples of the warning messages, see [Example 2-13](#) (page 2-11) and [Example 2-14](#) (page 2-12).

You can see what the current setting is, or turn the option on or off, as in the following example.

```
R> options("ore.warn.order")
$ore.warn.order
[1] TRUE
R> options("ore.warn.order" = FALSE)
R> options("ore.warn.order" = TRUE)
```

With the `ore.sep` option, you can specify the separator between the row name values that you use for multi-column keys, as in the following example.

```
R> options("ore.sep")
$ore.sep
[1] "|"
R> options("ore.sep" = "/")
R> options("ore.sep" = "|")
```

### 2.2.2.3 Ordering Using Keys

You can use the primary key of a database table to order an `ore.frame` object, as demonstrated in [Example 2-13](#) (page 2-11). The example loads the spam data set from the `kernlab` package. It adds two columns to the data set.

The example invokes `ore.drop` to drop the named tables if they exist. It then invokes `ore.create` to create two tables from the data set. It invokes `ore.exec` to make the `USERID` and `TS` columns a composite primary key of the `SPAM_PK` table, and invokes `ore.sync` to synchronize the table with its `ore.frame` proxy.

---

**Note:**

The `ore.exec` function executes a SQL statement in the Oracle Database schema. The function is intended for database definition language (DDL) statements that have no return value.

---

[Example 2-13](#) (page 2-11) then displays the first eight rows of each table. The proxy object for the `SPAM_PK` table is an ordered `ore.frame` object. It has row names that

are a combination of the TS and USERID column values separated by the "|" character. The proxy object for the SPAM\_NOPK table is an unordered ore.frame object that has the symbol SPAM\_NOPK. By default, SPAM\_NOPK has row names that are sequential numbers.

### Example 2-13 Ordering Using Keys

```
# Prepare the data.
library(kernlab)
data(spam)
s <- spam
# Create a column that has integer values.
s$TS <- 1001:(1000 + nrow(s))
# Create a column that has integer values with each number repeated twice.
s$USERID <- rep(351:400, each=2, len=nrow(s))
# Ensure that the database tables do not exist.
ore.drop(table='SPAM_PK')
ore.drop(table='SPAM_NOPK')
# Create database tables.
ore.create(s[,c(59:60,1:28)], table="SPAM_PK")
ore.create(s[,c(59:60,1:28)], table="SPAM_NOPK")
# Using a SQL statement, alter the SPAM_PK table to add a composite primary key.
ore.exec("alter table SPAM_PK add constraint SPAM_PK primary key
        (\\"USERID\\",\\"TS\\")")
# Synchronize the table to get the change to it.
ore.sync(table = "SPAM_PK")
# View the data in the tables.
# The row names of the ordered SPAM_PK are the primary key column values.
head(SPAM_PK[,1:8])
# The row names of the unordered SPAM_NOPK are sequential numbers.
# The first warning results from the inner accessing of SPAM_NOPK to subset
# the columns. The second warning is for the invocation of the head
# function on that subset.
head(SPAM_NOPK[,1:8])
# Verify that SPAM_NOPK is unordered.
is.null(row.names(SPAM_NOPK))
```

### Listing for Example 2-13 (page 2-11)

```
R> # Prepare the data.
R> library(kernlab)
R> data(spam)
R> s <- spam
R> # Create a column that has integer values.
R> s$TS <- 1001:(1000 + nrow(s))
R> # Create a column that has integer values with each number repeated twice.
R> s$USERID <- rep(351:400, each=2, len=nrow(s))
R> # Ensure that the database tables do not exist.
R> ore.drop(table='SPAM_PK')
R> ore.drop(table='SPAM_NOPK')
R> # Create database tables.
R> ore.create(s[,c(59:60,1:28)], table="SPAM_PK")
R> ore.create(s[,c(59:60,1:28)], table="SPAM_NOPK")
R> # Using a SQL statement, alter the SPAM_PK table to add a composite primary key.
R> ore.exec("alter table SPAM_PK add constraint SPAM_PK primary key
+          (\\"USERID\\",\\"TS\\")")
R> # Synchronize the table to get the change to it.
R> ore.sync(table = "SPAM_PK")
R> # View the data in the tables.
R> # The row names of the ordered SPAM_PK are the primary key column values.
R> head(SPAM_PK[,1:8])
      TS USERID make address all num3d our over
```

```

1001|351 1001    351 0.00    0.64 0.64    0 0.32 0.00
1002|351 1002    351 0.21    0.28 0.50    0 0.14 0.28
1003|352 1003    352 0.06    0.00 0.71    0 1.23 0.19
1004|352 1004    352 0.00    0.00 0.00    0 0.63 0.00

R> # The row names of the unordered SPAM_NOPK are sequential numbers.
R> # The first warning results from the inner accessing of SPAM_NOPK to subset
R> # the columns. The second warning is for the invocation of the head
R> # function on that subset.
R> head(SPAM_NOPK[,1:8])
      TS USERID make address  all num3d  our over
1 1001    351 0.00    0.64 0.64    0 0.32 0.00
2 1002    351 0.21    0.28 0.50    0 0.14 0.28
3 1003    352 0.06    0.00 0.71    0 1.23 0.19
4 1004    352 0.00    0.00 0.00    0 0.63 0.00
5 1005    353 0.00    0.00 0.00    0 0.63 0.00
6 1006    353 0.00    0.00 0.00    0 1.85 0.00
Warning messages:
1: ORE object has no unique key - using random order
2: ORE object has no unique key - using random order
R> # Verify that SPAM_NOPK is unordered.
R> is.null(row.names(SPAM_NOPK))
Error: ORE object has no unique key

```

#### 2.2.2.4 Ordering Using Row Names

You can use row names to order an `ore.frame` object, as demonstrated in [Example 2-14](#) (page 2-12). The example creates a `data.frame` object in the local R session memory and pushes it to the `ore.frame` object with the symbol `a`, which exists in the memory of the Oracle database to which the R session is connected. The example shows that the `ore.frame` object has the default row names of the R `data.frame` object. Because the `ore.frame` object is ordered, invoking the `row.names` function on it does not produce a warning message.

The example uses the ordered `SPAM_PK` and unordered `SPAM_NOPK` `ore.frame` objects from [Example 2-13](#) (page 2-11) to show that invoking `row.names` on the unordered `SPAM_NOPK` produces a warning message but invoking it on the ordered `SPAM_PK` does not.

The `SPAM_PK` object is ordered by the row names, which are the combined values of the `TS` and `USERID` column values separated by the `"|"` character. The example shows that you can change the row names.

##### **Example 2-14** Ordering Using Row Names

```

# Create an ordered ore.frame by default.
a <- ore.push(data.frame(a=c(1:10,10:1), b=letters[c(1:10,10:1)]))
# Display the values in the b column. Note that because the ore.frame is
# ordered, no warnings appear.
a$b
# Display the default row names for the first six rows of the a column.
row.names(head(a))
# SPAM_NOPK has no unique key, so row.names raises error messages.
row.names(head(SPAM_NOPK))
# Row names consist of TS '|' USERID.
# For display on this page, only the first four row names are shown.
row.names(head(SPAM_PK))
# Reassign the row names to the TS column only
row.names(SPAM_PK) <- SPAM_PK$TS
# The row names now correspond to the TS values only.

```

```
row.names(head(SPAM_PK[,1:4]))
head(SPAM_PK[,1:4])
```

### Listing for Example 2-14 (page 2-12)

```
R> # Create an ordered ore.frame by default.
R> a <- ore.push(data.frame(a=c(1:10,10:1), b=letters[c(1:10,10:1)]))
R> # Display the values in the b column. Note that because the ore.frame is
R> # ordered, no warnings appear.

## 2.2.2.5 Using Ordered Frames

### Example 2-15 Merging Ordered and Unordered ore.frame Objects

This example shows the result of merging two ordered `ore.frame` objects and two unordered `ore.frame` objects.

```
# Prepare the data.
library(kernlab)
data(spam)
s <- spam
# Create a column that has integer values.
s$TS <- 1001:(1000 + nrow(s))
# Create a column that has integer values with each number repeated twice.
s$USERID <- rep(351:400, each=2, len=nrow(s))
# Ensure that the database tables do not exist.
ore.drop(table='SPAM_PK')
ore.drop(table='SPAM_NOPK')
# Create database tables.
ore.create(s[,c(59:60,1:28)], table="SPAM_PK")
ore.create(s[,c(59:60,1:28)], table="SPAM_NOPK")
# Using a SQL statement, alter the SPAM_PK table to add a composite primary key.
ore.exec("alter table SPAM_PK add constraint SPAM_PK primary key
        (\"USERID\", \"TS\")")
```

```

# Synchronize the table to get the change to it.
ore.sync(table = "SPAM_PK")
# Create objects for merging data from unordered ore.frame objects.
x <- SPAM_NOPK[,1:4]
y <- SPAM_NOPK[,c(1,2,4,5)]
m1 <- merge(x, y, by="USERID")
# The merged result m1 produces a warning because it is not an ordered frame.
head(m1,3)
# Create objects for merging data from ordered ore.frame objects.
x <- SPAM_PK[,1:4]
y <- SPAM_PK[,c(1,2,4,5)]
# The merged result m1 does not produce a warning now because it is an
# ordered frame.
m1 <- merge(x, y, by="USERID")
head(m1,3)

```

```

## 2.2.3 Moving Data to and from the Database

You can create a temporary database table, and its corresponding proxy `ore.frame` object, from a local R object with the `ore.push` function. You can create a local R object that contains a copy of data represented by an Oracle R Enterprise proxy object with the `ore.pull` function.

The `ore.push` function translates an R object into an Oracle R Enterprise object of the appropriate data type. The `ore.pull` function takes an `ore` class object and returns an R object. If the input object is an `ore.list`, the `ore.pull` function creates a `data.frame` and translates each the data of each database column into the appropriate R representation.

---

### Note:

You can pull data to a local R `data.frame` only if the data can fit into the R session memory. Also, even if the data fits in memory but is still very large, you may not be able to perform many, or any, R functions in the client R session.

---

[Example 2-16](#) (page 2-15) demonstrates pushing an R `data.frame` object to the database as a temporary database table with an associated `ore.frame` object, `iris_of`, then creating another `ore.frame` object, `iris_of_setosa`, by selecting one column from `iris_of`, and then pulling the `iris_of_setosa` object into the local R session memory as a `data.frame` object. The example displays the class of some of the objects.

Unless you explicitly save them, the temporary database tables and their corresponding Oracle R Enterprise proxy objects that you create with the `ore.push` function are discarded when you quit the R session.

---

### **Example 2-16 Using `ore.push` and `ore.pull` to Move Data**

```
class(iris)
# Push the iris data frame to the database.
iris_of <- ore.push(iris)
class(iris_of)
# Display the data type of the Sepal.Length column in the data.frame.
class(iris$Sepal.Length)
# Display the data type of the Sepal.Length column in the ore.frame.
class(iris_of$Sepal.Length)
# Filter one column of the data set.
iris_of_setosa <- iris_of[iris_of$Species == "setosa", ]
```

```
class(iris_of_setosa)
# Pull the selected column into the local R client memory.
local_setosa = ore.pull(iris_of_setosa)
class(local_setosa)
```

**Listing for [Example 2-16](#) (page 2-15)**

```
R> class(iris)
[1] "data.frame"
R> # Push the iris data frame to the database.
R> iris_of <- ore.push(iris)
R> class(iris_of)
[1] "ore.frame"
attr(,"package")
[1] "OREbase"
R> # Display the data type of the Sepal.Length column in the data.frame.
R> class(iris$Sepal.Length)
[1] "numeric"
R> # Display the data type of the Sepal.Length column in the ore.frame.
R> class(iris_of$Sepal.Length)
[1] "ore.numeric"
attr(,"package")
[1] "OREbase"
R> # Filter one column of the data set.
R> iris_of_setosa <- iris_of[iris_of$Species == "setosa", ]
R> class(iris_of_setosa)
[1] "ore.frame"
attr(,"package")
[1] "OREbase"
R> # Pull the selected column into the local R client memory.
R> local_setosa = ore.pull(iris_of_setosa)
R> class(local_setosa)
[1] "data.frame"
```

## 2.2.4 Creating and Deleting Database Tables

You can use the `ore.create` function to create a persistent table in an Oracle Database schema. Creating the table automatically creates an `ore.frame` proxy object for the table in the R environment that represents your database schema. The proxy `ore.frame` object has the same name as the table. You can delete the persistent table in an Oracle Database schema with the `ore.drop` function.

---

**Caution:**

Only use the `ore.drop` function to delete a database table and its associated `ore.frame` proxy object. Never use it to remove an `ore.frame` object that is not associated with a permanent database table. To remove an `ore.frame` object for a temporary database table, use the `ore.rm` function.

---

**Example 2-17 Using `ore.create` and `ore.drop` to Create and Drop Tables**

This example creates tables in the database and drops some of them.

```
# Create the AIRQUALITY table from the data.frame for the airquality data set.
ore.create(airquality, table = "AIRQUALITY")
# Create data.frame objects.
df1 <- data.frame(x1 = 1:5, y1 = letters[1:5])
df2 <- data.frame(x2 = 5:1, y2 = letters[11:15])
# Create the DF1 and DF2 tables from the data.frame objects.
```

```

ore.create(df1, "DF1")
ore.create(df2, "DF2")
# Create the CARS93 table from the data.frame for the Cars93 data set.
ore.create(Cars93, table = "CARS93")
# List the Oracle R Enterprise proxy objects.
ore.ls()
# Drop the CARS93 object.
ore.drop(table = "CARS93")
# List the Oracle R Enterprise proxy objects again.
ore.ls()

```

#### Listing for [Example 2-17](#) (page 2-16)

```

R> # Create the AIRQUALITY table from the data.frame for the airquality data set.
R> ore.create(airquality, table = "AIRQUALITY")
R> # Create data.frame objects.
R> df1 <- data.frame(x1 = 1:5, y1 = letters[1:5])
R> df2 <- data.frame(x2 = 5:1, y2 = letters[11:15])
R> # Create the DF1_TABLE and DF2_TABLE tables from the data.frame objects.
R> ore.create(df1, "DF1")
R> ore.create(df2, "DF2")
R> # Create the CARS93 table from the data.frame for the Cars93 data set.
R> ore.create(Cars93, table = "CARS93")
R> # List the Oracle R Enterprise proxy objects.
R> ore.ls()
[1] "AIRQUALITY" "CARS93" "DF1" "DF2_"
R> # Drop the CARS93 object.
R> ore.drop(table = "CARS93")
R> # List the Oracle R Enterprise proxy objects again.
R> ore.ls()
[1] "AIRQUALITY" "DF1_" "DF2"

```

## 2.2.5 Saving and Managing R Objects in the Database

Oracle R Enterprise provides datastores that you can use to save Oracle R Enterprise proxy objects, as well as any R object, in an Oracle database. You can grant or revoke read privilege access to a datastore for one or more users. You can restore the saved objects in another R session. The objects in a datastore are also accessible to embedded R execution through both the R and the SQL interfaces.

This section describes the Oracle R Enterprise functions that you can use to create and manage datastores. The section contains the following topics:

- [About Persisting Oracle R Enterprise Objects](#) (page 2-18)
- [About Oracle R Enterprise Datastores](#) (page 2-19)
- [Saving Objects to a Datastore](#) (page 2-19)
- [Control Access to Datastores](#) (page 2-21)
- [Getting Information about Datastore Contents](#) (page 2-22)
- [Restoring Objects from a Datastore](#) (page 2-23)
- [Deleting a Datastore](#) (page 2-25)
- [About Using a datastore in Embedded R Execution](#) (page 2-25)

### 2.2.5.1 About Persisting Oracle R Enterprise Objects

With Oracle R Enterprise datastores, you can save R objects in the database.

R objects, including Oracle R Enterprise proxy objects, exist for the duration of the current R session unless you explicitly save them. The standard R functions for saving and restoring R objects, `save` and `load`, serialize objects in R memory to store them in a file and deserialize them to restore them in memory. However, for Oracle R Enterprise proxy objects, those functions do not save the database objects associated with the proxy objects in an Oracle database; therefore the saved proxy objects do not behave properly in a different R session.

You can save Oracle R Enterprise proxy objects, as well as any R object, with the `ore.save` function. The `ore.save` function specifies an Oracle R Enterprise datastore. A datastore persists in the database when you end the R session. The datastore maintains the referential integrity of the objects it contains. Using the `ore.load` function, you can restore in another R session the objects in the datastore.

Using a datastore, you can do the following:

- Save Oracle R Enterprise and other R objects that you create in one R session and restore them in another R session.
- Pass arguments to R functions for use in embedded R execution.
- Pass objects for use in embedded R execution. You could, for example, use a function in the `OREdm` package to build an Oracle Data Mining model and save it in a datastore. You could then use that model to score data in the database through embedded R execution. For an example of using a datastore in an embedded R execution function, see [Example 6-10](#) (page 6-22).

[Table 2-1](#) (page 2-18) lists the functions that manipulate datastores and provides brief descriptions of them.

**Table 2-1 Functions that Manipulate Datastores**

| Function                          | Description                                                                                        |
|-----------------------------------|----------------------------------------------------------------------------------------------------|
| <code>ore.datastore</code>        | Lists information about a datastore in the current Oracle database schema.                         |
| <code>ore.datastoreSummary</code> | Provides detailed information about the specified datastore in the current Oracle database schema. |
| <code>ore.delete</code>           | Deletes a datastore from the current Oracle database schema.                                       |
| <code>ore.grant</code>            | Grants read access to a datastore.                                                                 |
| <code>ore.lazyLoad</code>         | Lazily restores objects from a datastore into an R environment.                                    |
| <code>ore.load</code>             | Restores objects from a datastore into an R environment.                                           |
| <code>ore.revoke</code>           | Revokes read access to a datastore.                                                                |
| <code>ore.save</code>             | Saves R objects in a new or existing datastore.                                                    |

---

### 2.2.5.2 About Oracle R Enterprise Datastores

Each database schema has a table that stores named Oracle R Enterprise datastores. A datastore can contain Oracle R Enterprise objects and standard R objects.

You create a datastore with the `ore.save` function. When you create a datastore, you specify a name for it. You can save objects in one or more datastores.

As long as a datastore contains an Oracle R Enterprise proxy object for a database object, the database object persists between R sessions. For example, you could use the `ore.odmNB` function in the `OREdm` package to build an Oracle Data Mining Naive Bayes model. If you save the resulting `ore.odmNB` object in a datastore and end the R session, then Oracle Database does not delete the Oracle Data Mining model. If no datastore contains the `ore.odmNB` object and the R session ends, then the database automatically drops the model.

### 2.2.5.3 Saving Objects to a Datastore

The `ore.save` function saves one or more R objects in the specified datastore. By default, Oracle R Enterprise creates the datastore in the current user schema. With the arguments to `ore.save`, you can provide the names of specific objects, or provide a list of objects. You can specify whether read privilege access to the datastore can be granted to other users. You can specify a particular R environment to search for the objects you would like to save. The `overwrite` and `append` arguments are mutually exclusive. If you set the `overwrite` argument to `TRUE`, then you can replace an existing datastore with another datastore of the same name. If you set the `append` argument to `TRUE`, then you can add objects to an existing datastore. With the `description` argument, you can provide some descriptive text that appears when you get information about the datastore. The `description` argument has no effect when used with the `append` argument.

### **Example 2-18** *Saving Objects and Creating a Datastore*

This example demonstrates creating datastores using different combinations of arguments.

```
# Create some R objects.
df1 <- data.frame(x1 = 1:5, y1 = letters[1:5])
df2 <- data.frame(x2 = 5:1, y2 = letters[11:15])
iris_of <- ore.push(iris)
```

```
# Create a database table and an Oracle R Enterprise proxy object for the table.
ore.drop("AIRQUALITY")
```

```
ore.create(airquality, table = "AIRQUALITY")

# List the R objects.
ls()

# List the Oracle R Enterprise proxy objects.
ore.ls()

# Save the proxy object and all objects in the current workspace environment
# to the datastore named ds1 and supply a description.
ore.save(AIRQUALITY, list = ls(), name = "ds1", description = "My private datastore")

# Create some more objects.
x <- stats::runif(20) # x is an object of type numeric.
y <- list(a = 1, b = TRUE, c = "hoopsa")
z <- ore.push(x) # z is an object of type ore.numeric.

# Create another datastore.
ore.save(x, y, name = "ds2", description = "x and y")

# Overwrite the contents of datastore ds2.
ore.save(x, name = "ds2", overwrite = TRUE, description = "only x")

# Append object z to datastore ds2.
ore.save(z, name = "ds2", append = TRUE)
```

#### **Listing for [Example 2-18](#) (page 2-19)**

```
R> # Create some R objects.
R> df1 <- data.frame(x1 = 1:5, y1 = letters[1:5])
R> df2 <- data.frame(x2 = 5:1, y2 = letters[11:15])
R> iris_of <- ore.push(iris)
R>
R> # Create a database table and an Oracle R Enterprise proxy object for the table.
R> ore.drop("AIRQUALITY")
R> ore.create(airquality, table = "AIRQUALITY")
R>
R> # List the R objects.
R> ls()
[1] "df1"      "df2"      "iris_of"
R>
R> # List the Oracle R Enterprise proxy objects.
R> ore.ls()
[1] "AIRQUALITY"
R>
R> # Save the proxy object and all objects in the current workspace environment
R> # to the datastore named ds1 and supply a description.
R> ore.save(AIRQUALITY, list = ls(), name = "ds1", description = "My datastore")
R>
R> # Create some more objects.
R> x <- stats::runif(20) # x is an object of type numeric.
R> y <- list(a = 1, b = TRUE, c = "hoopsa")
R> z <- ore.push(x) # z is an object of type ore.numeric.
R>
R> # Create another datastore.
R> ore.save(x, y, name = "ds2", description = "x and y")
R>
R> # Overwrite the contents of datastore ds2.
R> ore.save(x, name = "ds2", overwrite = TRUE, description = "only x")
R>
```

```
R> # Append object z to datastore ds2.
R> ore.save(z, name = "ds2", append = TRUE)
```

### 2.2.5.4 Control Access to Datastores

With the `ore.grant` and `ore.revoke` functions you can grant or revoke access to an Oracle R Enterprise datastore.

With the `ore.grant` and `ore.revoke` functions, you can control access to datastores. You can grant read access to a specified user to a datastore that you own or revoke the access privilege. The functions `ore.save`, `ore.load`, `ore.datastore`, and `ore.datastoreSummary` have arguments related to the accessibility of datastores.

---

#### Note:

If you use `ore.create` to create a persistent database table and its proxy `ore.frame` object, then save the proxy `ore.frame` object in a grantable datastore, and then use `ore.grant` to grant read privilege access to the datastore, the access applies only to the `ore.frame` object. The read access does not extend to the persistent database table. To grant read permission to the table itself, you must execute an appropriate SQL command.

---

### Example 2-19 Granting and Revoking Access to a Datastore

This example pushes the `airquality` data set from the local R session to the Oracle database, where it exists as the `ore.frame` object `AIRQUALITY` and as a temporary database table with the same name. The example then saves the `AIRQUALITY` object to the datastore `ds3` and specifies that access to the datastore can be granted to other users. It invokes function `ore.datastore` with `type = grantable` to display all of the datastores to which read access has been granted. It grants the read privilege for the `ds3` datastore to `SCOTT`. It then invokes `ore.datastore` with `type = grant` to display the datastores to which read access has been granted. It revokes the read privilege for `SCOTT`, and again displays the datastores to which access has been granted.

```
AIRQUALITY <- ore.push(airquality)
ore.save(AIRQUALITY, name = "ds3",
        description = "My datastore 3", grantable = TRUE)
ore.datastore(type = "grantable")
ore.datastore(type = "grant")
ore.grant("ds3", type = "datastore", user = "SCOTT")
ore.datastore(type = "grant")
ore.revoke("ds3", type = "datastore", user = "SCOTT")
ore.datastore(type = "grant")
```

#### Listing for Example 2-19 (page 2-21)

```
R> AIRQUALITY <- ore.push(airquality)
R> ore.save(AIRQUALITY, name = "ds3",
+         description = "My datastore 3", grantable = TRUE)
R> ore.datastore(type = "grantable")
   datastore.name object.count size      creation.date  description
1          ds3           1 1451 2015-11-30 18:48:25 My datastore 3
R> ore.datastore(type = "grant")
[1] datastore.name grantee
<0 rows> (or 0-length row.names)
R> ore.grant("ds3", type = "datastore", user = "SCOTT")
```

```
R> ore.datastore(type = "grant")
      datastore.name grantee
1          ds3      SCOTT
R> ore.revoke("ds3", type = "datastore", user = "SCOTT")
R> ore.datastore(type = "grant")
[1] datastore.name grantee
<0 rows> (or 0-length row.names)
```

### 2.2.5.5 Getting Information about Datastore Contents

You can get information about a datastore in the current user schema by using the `ore.datastore` and `ore.datastoreSummary` functions.

Using the `ore.datastore` function, you can list basic information about datastores. To get information about a specific type of datastore, you can use the optional character string `type` argument. The valid values for `type` are the following:

- `user`, which lists the datastores created by current session user. This is the default value.
- `private`, which lists the datastores for which read access cannot be granted by the current session user to other users.
- `all`, which lists all of the datastores to which the current session user has read access.
- `grantable`, which lists the datastores the read privilege for which can be granted by the current session user to other users.
- `grant`, which lists the datastores the read privilege for which has been granted by the current session user to other users.
- `granted`, which lists the datastores the read privilege for which has been granted by other users to the current session user.

If you do not specify a type, then function `ore.datastore` returns a `data.frame` object with columns that correspond to the datastore name, the number of objects in the datastore, the datastore size, the creation date, and a description. Rows are sorted by column `datastore.name` in alphabetical order. If you do specify a type, then the function returns a `data.frame` that has a column for the specified type.

You can search for a datastore by name or by using a regular expression pattern.

The `ore.datastoreSummary` function returns information about the R objects saved within a datastore in the user schema in the connected database. The function returns a `data.frame` with columns that correspond to object name, object class, object size, and either the length of the object, if it is a `vector`, or the number of rows and columns, if it is a `data.frame` object. It takes one required argument, the name of a datastore, and has an optional argument, the owner of the datastore.

#### **Example 2-20 Using the `ore.datastore` Function**

This example demonstrates using the `ore.datastore` function. The example uses some of the R objects created in [Example 2-18](#) (page 2-19).

```
# The datastore objects ds1 and ds2 and objects data.frame objects df1 and df2
# were created in Example 2-18 (page 2-19).
ore.save(df1, df2, name = "dfobj", description = "df objects")
ore.save(x, y, z, name = "another_ds", description = "For pattern matching")

# List all of the datastore objects.
ore.datastore()
```

```
# List the specified datastore.
ore.datastore("ds1")

# List the datastore objects with names that include "ds".
ore.datastore(pattern = "ds")
```

#### Listing for [Example 2-20](#) (page 2-22)

```
R> # The datastore objects ds1 and ds2 and objects data.frame objects df1 and df2
R> # were created in Example 2-18 (page 2-19).
R> ore.save(df1, df2, name = "dfobj", description = "df objects")
R> ore.save(x, y, z, name = "another_ds", description = "For pattern matching")
R>
R> # List all of the datastore objects.
R> ore.datastore()
  datastore.name object.count size      creation.date description
1      another_ds          3 1243 2014-07-24 13:31:56 For pattern matching
2           dfobj          2   656 2014-07-24 13:31:46           df objects
3             ds1          4 3162 2014-07-24 13:25:17           My datastore
4             ds2          2 1111 2014-07-24 13:27:26           only x

R> # List the specified datastore.
R> ore.datastore("ds1")
  datastore.name object.count size      creation.date description
1             ds1          4 2908 2013-11-08 10:41:09 My datastore
R>
R> # List the datastore objects with names that include "ds".
R> ore.datastore(pattern = "ds")
  datastore.name object.count size      creation.date      description
1      another_ds          3 1243 2014-07-24 13:31:56  For pattern matching
2             ds1          4 3162 2014-07-24 13:25:17           My datastore
3             ds2          2 1111 2014-07-24 13:27:26           only x
```

#### **Example 2-21 Using the ore.datastoreSummary Function**

This example demonstrates using the `ore.datastoreSummary` function. The example uses the datastores created in [Example 2-18](#) (page 2-19).

```
ore.datastoreSummary("ds1")
ore.datastoreSummary("ds2")
```

#### Listing for [Example 2-21](#) (page 2-23)

```
R> ore.datastoreSummary("ds1")
  object.name      class size length row.count col.count
1  AIRQUALITY ore.frame 1077     6     153         6
2         df1 data.frame  328     2         5         2
3         df2 data.frame  328     2         5         2
4   iris_of ore.frame 1429     5     150         5
R> ore.datastoreSummary("ds2")
  object.name      class size length row.count col.count
1          x   numeric  182     20        NA        NA
2          z ore.numeric  929     20        NA        NA
```

### 2.2.5.6 Restoring Objects from a Datastore

The `ore.load` function restores R objects saved in a datastore to the R global environment, `.GlobalEnv`. The function returns a character vector that contains the names of the restored objects.

You can load all of the saved objects or you can use the `list` argument to specify the objects to load. With the `envir` argument, you can specify an environment in which to load objects.

**Example 2-22 Using the `ore.load` Function to Restore Objects from a Datastore**

This example demonstrates using the `ore.load` function to restore objects from datastores that were created in [Example 2-20](#) (page 2-22). The example runs in the same R session as that example.

```
# List the R objects.
ls()

# List the datastores.
ore.datastore()

# Delete the x and z objects.
rm(x, z)
ls()

# Restore all of the objects in datastore ds2.
ore.load("ds2")

ls()

# After ending the R session and starting another session.
ls()
# The datastore objects persist between sessions.
ore.datastore()

# Restore some of the objects from datastore ds1.
ore.load("ds1", list = c("df1", "df2", "iris_of"))
ls()
```

**Listing for [Example 2-22](#) (page 2-24)**

```
R> # List the R objects.
R> ls()
[1] "df1"      "df2"      "iris_of"  "x"        "y"        "z"
R>
R> # List the datastores.
R> ore.datastore()
  datastore.name object.count size      creation.date description
1    another_ds         3 1243 2014-07-24 13:31:56 For pattern matching
2         dfobj         2   656 2014-07-24 13:31:46             df objects
3          ds1         4 3162 2014-07-24 13:25:17             My datastore
4          ds2         2 1111 2014-07-24 13:27:26             only x
R>
R> # Delete the x and z objects.
R> rm(x, z)
R> ls()
[1] "df1"      "df2"      "iris_of"  "y"
R>
R> # Restore all of the objects in datastore ds2.
R> ore.load("ds2")
[1] "x" "z"
R>
R> ls()
[1] "df1"      "df2"      "iris_of"  "x"        "y"        "z"
R>
R> # After ending the R session and starting another session.
R> ls()
```

```

character(0)
R> # The datastore objects persist between sessions.
R> ore.datastore()
  datastore.name object.count size      creation.date      description
1   another_ds          3 1243 2014-07-24 13:31:56 For pattern matching
2       dfobj           2   656 2014-07-24 13:31:46      df objects
3          ds1           4 3162 2014-07-24 13:25:17      My datastore
4          ds2           2 1111 2014-07-24 13:27:26          only x

R> # Restore some of the objects from datastore ds1.
R> ore.load("ds1", list = c("df1", "df2", "iris_of"))
[1] "df1"      "df2"      "iris_of"
R> ls()
[1] "df1"      "df2"      "iris_of"

```

### 2.2.5.7 Deleting a Datastore

With the `ore.delete` function, you can delete objects from an Oracle R Enterprise datastore or you can delete the datastore itself. To delete a datastore, you specify the name of it. To delete one or more objects from the datastore, you specify the `list` argument. The `ore.delete` function returns the name of the deleted objects or datastore.

When you delete a datastore, Oracle R Enterprise discards all temporary database objects that were referenced by R objects in the deleted datastore. If you have saved an R object in more than one datastore, then Oracle R Enterprise discards a temporary database object only when no object in a datastore references the temporary database object.

#### **Example 2-23 Using the `ore.delete` Function**

This example demonstrates using `ore.delete` to delete an object from a datastore and then to delete the entire datastore. The example uses objects created in [Example 2-18](#) (page 2-19).

```

# Delete the df2 object from the ds1 datastore.
ore.delete("ds1", list = "df2")
# Delete the datastore named ds1.
ore.delete("ds1")

```

#### **Listing for Example 2-23 (page 2-25)**

```

R> # Delete the df2 object from the ds1 datastore.
R> ore.delete("ds1", list = "df2")[1] "df2"
R> # Delete the datastore named ds1.
R> ore.delete("ds1")
[1] "ds1"

```

### 2.2.5.8 About Using a datastore in Embedded R Execution

Saving objects in a datastore makes it very easy to pass arguments to, and reference R objects with, embedded R execution functions. You can save objects that you create in one R session in a single datastore in the database. You can pass the name of this datastore to an embedded R function as an argument for loading within that function. You can use a datastore to easily pass one object or multiple objects.

---

# Preparing and Exploring Data in the Database

This chapter describes how to use Oracle R Enterprise objects to prepare data for analysis and to perform exploratory analysis of the data. All of these functions make it easier for you to prepare very large enterprise database-resident data for modeling. The chapter contains the following topics:

- [Preparing Data in the Database Using Oracle R Enterprise](#) (page 3-1)
- [Exploring Data](#) (page 3-22)
- [Using a Third-Party Package on the Client](#) (page 3-41)

## 3.1 Preparing Data in the Database Using Oracle R Enterprise

Using Oracle R Enterprise, you can prepare data for analysis in the database, as described in the following topics:

- [About Preparing Data in the Database](#) (page 3-1)
- [Selecting Data](#) (page 3-2)
- [Indexing Data](#) (page 3-5)
- [Combining Data](#) (page 3-6)
- [Summarizing Data](#) (page 3-7)
- [Transforming Data](#) (page 3-7)
- [Sampling Data](#) (page 3-10)
- [Partitioning Data](#) (page 3-15)
- [Preparing Time Series Data](#) (page 3-16)

### 3.1.1 About Preparing Data in the Database

Oracle R Enterprise provides functions that enable you to use R to prepare database data for analysis. Using these functions, you can perform typical data preparation tasks on `ore.frame` and other Oracle R Enterprise objects. You can perform data preparation operations on large quantities of data in the database and then pull the results to your local R session for analysis using functions in packages available from The Comprehensive R Archive Network (CRAN).

You can do operations on data such as the following.

- Selecting

- Binning
- Sampling
- Sorting and Ordering
- Summarizing
- Transforming
- Performing data preparation operations on date and time data

Performing these operations is described in the other topics in this chapter.

## 3.1.2 Selecting Data

A typical step in preparing data for analysis is selecting or filtering values of interest from a larger data set. The examples in this section demonstrate selecting data from an `ore.frame` object by column, by row, and by value. The examples are in the following topics:

- [Selecting Data by Column](#) (page 3-2)
- [Selecting Data by Row](#) (page 3-3)
- [Selecting Data by Value](#) (page 3-4)

---

---

**See Also:**

- ["Indexing Data](#) (page 3-5)"
  - The `sql_like.R` example script
- 
- 

### 3.1.2.1 Selecting Data by Column

[Example 3-1](#) (page 3-2) selects columns from an `ore.frame` object. It first creates a temporary database table, with the corresponding proxy `ore.frame` object `iris_of`, from the `iris.data.frame` object. It displays the first three rows of `iris_of`. The example selects two columns from `iris_of` and creates the `ore.frame` object `iris_projected` with them. It then displays the first three rows of `iris_projected`.

#### **Example 3-1** *Selecting Data by Column*

```
iris_of <- ore.push(iris)
head(iris_of, 3)

iris_projected = iris_of[, c("Petal.Length", "Species")]

head (iris_projected, 3)
```

#### **Listing for Example 3-1** (page 3-2)

```
iris_of <- ore.push(iris)
head(iris_of, 3)
  Sepal.Length Sepal.Width Petal.Length Petal.Width Species
1         5.1         3.5         1.4         0.2  setosa
2         4.9         3.0         1.4         0.2  setosa
3         4.7         3.2         1.3         0.2  setosa
```

```
R> iris_projected = iris_of[, c("Petal.Length", "Species")]

R> head(iris_projected, 3)
   Petal.Length Species
1           1.4  setosa
2           1.4  setosa
3           1.3  setosa
```

### 3.1.2.2 Selecting Data by Row

**Example 3-2** (page 3-3) selects rows from an ordered `ore.frame` object. The example first adds a column to the `iris.data.frame` object for use in creating an ordered `ore.frame` object. It invokes the `ore.drop` function to delete the database table `IRIS_TABLE`, if it exists. It then creates a database table, with the corresponding proxy `ore.frame` object `IRIS_TABLE`, from the `iris.data.frame`. The example invokes the `ore.exec` function to execute a SQL statement that makes the `RID` column the primary key of the database table. It then invokes the `ore.sync` function to synchronize the `IRIS_TABLE` `ore.frame` object with the table and displays the first three rows of the proxy `ore.frame` object.

**Example 3-2** (page 3-3) next selects 51 rows from `IRIS_TABLE` by row number and creates the ordered `ore.frame` object `iris_selrows` with them. It displays the first six rows of `iris_selrows`. It then selects 3 rows by row name and displays the result.

#### **Example 3-2** Selecting Data by Row

```
# Add a column to the iris data set to use as row identifiers.
iris$RID <- as.integer(1:nrow(iris) + 100)
ore.drop(table = 'IRIS_TABLE')
ore.create(iris, table = 'IRIS_TABLE')
ore.exec("alter table IRIS_TABLE add constraint IRIS_TABLE
         primary key (\\"RID\\")")
ore.sync(table = "IRIS_TABLE")
head(IRIS_TABLE, 3)

# Select rows by row number.
iris_selrows <- IRIS_TABLE[50:100,]
head(iris_selrows)

# Select rows by row name.
IRIS_TABLE[c("101", "151", "201"),]
```

#### Listing for **Example 3-2** (page 3-3)

```
R> # Add a column to the iris data set to use as row identifiers.
R> iris$RID <- as.integer(1:nrow(iris) + 100)
R> ore.drop(table = 'IRIS_TABLE')
R> ore.create(iris, table = 'IRIS_TABLE')
R> ore.exec("alter table IRIS_TABLE add constraint IRIS_TABLE
+         primary key (\\"RID\\")")
R> ore.sync(table = "IRIS_TABLE")
R> head(IRIS_TABLE, 3)
   Sepal.Length Sepal.Width Petal.Length Petal.Width Species RID
101           5.1          3.5          1.4          0.2  setosa 101
102           4.9          3.0          1.4          0.2  setosa 102
103           4.7          3.2          1.3          0.2  setosa 103
R> # Select rows by row number.
R> iris_selrows <- IRIS_TABLE[50:100,]
R> head(iris_selrows)
```

```

      Sepal.Length Sepal.Width Petal.Length Petal.Width  Species RID
150          5.0         3.3         1.4         0.2    setosa 150
151          7.0         3.2         4.7         1.4 versicolor 151
152          6.4         3.2         4.5         1.5 versicolor 152
153          6.9         3.1         4.9         1.5 versicolor 153
154          5.5         2.3         4.0         1.3 versicolor 154
155          6.5         2.8         4.6         1.5 versicolor 155
R> # Select rows by row name.
R> IRIS_TABLE[c("101", "151", "201"),]
      Sepal.Length Sepal.Width Petal.Length Petal.Width  Species RID
101          5.1         3.5         1.4         0.2    setosa 101
151          7.0         3.2         4.7         1.4 versicolor 151
201          6.3         3.3         6.0         2.5  virginica 201

```

### 3.1.2.3 Selecting Data by Value

You can select portions of a data set, as shown in [Example 3-3](#) (page 3-4). The example pushes the `iris` data set to the database and gets the `ore.frame` object `iris_of`. It filters the data to produce `iris_of_filtered`, which contains the values from the rows of `iris_of` that have a petal length of less than 1.5 and that are in the `Sepal.Length` and `Species` columns. The example also filters the data using conditions, so that `iris_of_filtered` contains the values from `iris_of` that are of the `setosa` or `versicolor` species and that have a petal width of less than 2.0.

#### Example 3-3 Selecting Data by Value

```

iris_of <- ore.push(iris)
# Select sepal length and species where petal length is less than 1.5.
iris_of_filtered <- iris_of[iris_of$Petal.Length < 1.5,
                           c("Sepal.Length", "Species")]

names(iris_of_filtered)
nrow(iris_of_filtered)
head(iris_of_filtered, 3)
# Alternate syntax filtering.
iris_of_filtered <- subset(iris_of, Petal.Length < 1.5)
nrow(iris_of_filtered)
head(iris_of_filtered, 3)
# Using the AND and OR conditions in filtering.
# Select all rows with in which the species is setosa or versicolor.
# and the petal width is less than 2.0.
iris_of_filtered <- iris_of[(iris_of$Species == "setosa" |
                             iris_of$Species == "versicolor") &
                             iris_of$Petal.Width < 2.0,]

nrow(iris_of_filtered)
head(iris_of, 3)

```

#### Listing for Example 3-3 (page 3-4)

```

R> iris_of <- ore.push(iris)
R> # Select sepal length and species where petal length is less than 1.5.
R> iris_of_filtered <- iris_of[iris_of$Petal.Length < 1.5,
+                             c("Sepal.Length", "Species")]
R> names(iris_of_filtered)
[1] "Sepal.Length" "Species"
R> nrow(iris_of_filtered)
[1] 24
R> head(iris_of_filtered, 3)
      Sepal.Length Species
1          5.1    setosa
2          4.9    setosa
3          4.7    setosa

```

```

R> # Alternate syntax filtering.
R> iris_of_filtered <- subset(iris_of, Petal.Length < 1.5)
R> nrow(iris_of_filtered)[1] 24
R> head(iris_of_filtered, 3)
  Sepal.Length Sepal.Width Petal.Length Petal.Width Species
1          5.1          3.5          1.4          0.2  setosa
2          4.9          3.0          1.4          0.2  setosa
3          4.7          3.2          1.3          0.2  setosa
R> # Using the AND and OR conditions in filtering.
R> # Select all rows with in which the species is setosa or versicolor.
R> # and the petal width is less than 2.0.
R> iris_of_filtered <- iris_of[(iris_of$Species == "setosa" |
+                               iris_of$Species == "versicolor") &
+                               iris_of$Petal.Width < 2.0,]
R> nrow(iris_of_filtered)[1] 100
R> head(iris_of, 3)
  Sepal.Length Sepal.Width Petal.Length Petal.Width Species
1          5.1          3.5          1.4          0.2  setosa
2          4.9          3.0          1.4          0.2  setosa
3          4.7          3.2          1.3          0.2  setosa

```

### 3.1.3 Indexing Data

You can use integer or character vectors to index an ordered `ore.frame` object. You can use the indexing to perform sampling and partitioning, as described in "[Sampling Data](#) (page 3-10)" and "[Partitioning Data](#) (page 3-15)".

Oracle R Enterprise supports functionality similar to R indexing with these differences:

- Integer indexing is not supported for `ore.vector` objects.
- Negative integer indexes are not supported.
- Row order is not preserved.

[Example 3-4](#) (page 3-5) demonstrates character and integer indexing. The example uses the ordered `SPAM_PK` and unordered `SPAM_NOPK` `ore.frame` objects from [Example 2-13](#) (page 2-11). The example shows that you can access rows by name and that you can also access a set of rows by supplying a vector of character row names. The example then shows that you can supply the actual integer value. In the example this results in a set of different rows because the `USERID` values start at 1001, as opposed to 1.

#### **Example 3-4 Indexing an `ore.frame` Object**

```

# Index to a specifically named row.
SPAM_PK["2060", 1:4]
# Index to a range of rows by row names.
SPAM_PK[as.character(2060:2064), 1:4]
# Index to a range of rows by integer index.

### 3.1.4 Combining Data

You can join data from `ore.frame` objects that represent database tables by using the `merge` function, as shown in [Example 3-5](#) (page 3-6). The example creates two `data.frame` objects and merges them. It then invokes the `ore.create` function to create a database table for each `data.frame` object. The `ore.create` function automatically generates an `ore.frame` object as a proxy object for the table. The `ore.frame` object has the same name as the table. The example merges the `ore.frame` objects. Note that the order of the results of the two `merge` operations is not the same because the `ore.frame` objects are unordered.

#### **Example 3-5** *Joining Data from Two Tables*

```

# Create data.frame objects.
df1 <- data.frame(x1=1:5, y1=letters[1:5])
df2 <- data.frame(x2=5:1, y2=letters[11:15])

# Combine the data.frame objects.
merge(df1, df2, by.x="x1", by.y="x2")

# Create database tables and ore.frame proxy objects to correspond to
# the local R objects df1 and df2.
ore.create(df1, table="DF1_TABLE")
ore.create(df2, table="DF2_TABLE")

# Combine the ore.frame objects.
merge(DF1_TABLE, DF2_TABLE, by.x="x1", by.y="x2")

```

#### **Listing for Example 3-5** (page 3-6)

```

R> # Create data.frame objects.
R> df1 <- data.frame(x1=1:5, y1=letters[1:5])
R> df2 <- data.frame(x2=5:1, y2=letters[11:15])

R> # Combine the data.frame objects.
R> merge(df1, df2, by.x="x1", by.y="x2")
  x1 y1 y2
1  1  a  o
2  2  b  n
3  3  c  m
4  4  d  l
5  5  e  k

R> # Create database tables and ore.frame proxy objects to correspond to
R> # the local R objects df1 and df2.
R> ore.create(df1, table="DF1_TABLE")
R> ore.create(df2, table="DF2_TABLE")

```

```

R> # Combine the ore.frame objects.
R> merge (DF1_TABLE, DF2_TABLE, by.x="x1", by.y="x2")
  x1 y1 y2
1  5 e  k
2  4 d  l
3  3 c  m
4  2 b  n
5  1 a  o
Warning message:

```

### 3.1.5 Summarizing Data

You can summarize data by using the `aggregate` function, as shown in [Example 3-6](#) (page 3-7). The example pushes the `iris` data set to database memory as the `ore.frame` object `iris_of`. It aggregates the values of `iris_of` by the `Species` column using the `length` function. It then displays the first three rows of the result.

---

#### See Also:

The `aggregate.R` example script

---

#### **Example 3-6 Aggregating Data**

```

# Create a temporary database table from the iris data set and get an ore.frame.
iris_of <- ore.push(iris)
aggdata <- aggregate(iris_of$Sepal.Length,
                     by = list(species = iris_of$Species),
                     FUN = length)
head(aggdata, 3)

```

#### **Listing for Example 3-6 (page 3-7)**

```

# Create a temporary database table from the iris data set and get an ore.frame.
R> iris_of <- ore.push(iris)
R> aggdata <- aggregate(iris_of$Sepal.Length,
+                       by = list(species = iris_of$Species),
+                       FUN = length)
R> head(aggdata, 3)
      species x
setosa      setosa 50
versicolor versicolor 50
virginica   virginica 50

```

### 3.1.6 Transforming Data

In preparing data for analysis, a typical step is to transform data by reformatting it or deriving new columns and adding them to the data set. The examples in this topic demonstrate two ways of formatting data and deriving columns. [Example 3-7](#) (page 3-8) creates a function to format the data in a column and [Example 3-8](#) (page 3-8) does the same thing by using the `transform` function. [Example 3-9](#) (page 3-9) uses the `transform` function to add columns to the data set.

[Example 3-8](#) (page 3-8) does the same thing as [Example 3-7](#) (page 3-8) except that it uses the `transform` function to reformat the data in a column of the data set.

[Example 3-9](#) (page 3-9) uses the `transform` function to add a derived column to the data set and then to add additional columns to it.

**See Also:**

The derived.R example script

**Example 3-7 Formatting Data**

```
# Create a function for formatting data.
petalCategory_fmt <- function(x) {
  ifelse(x > 5, 'LONG',
        ifelse(x > 2, 'MEDIUM', 'SMALL'))
}
# Create an ore.frame in database memory with the iris data set.
iris_of <- ore.push(iris)
# Select some rows from iris_of.
iris_of[c(10, 20, 60, 80, 110, 140),]
# Format the data in Petal.Length column.
iris_of$Petal.Length <- petalCategory_fmt(iris_of$Petal.Length)
# Select the same rows from iris_of.
```

**Listing for Example 3-7 (page 3-8)**

```
R> # Create a function for formatting data.
R> petalCategory_fmt <- function(x) {
+   ifelse(x > 5, 'LONG',
+   ifelse(x > 2, 'MEDIUM', 'SMALL'))
+ }
R> # Create an ore.frame in database memory with the iris data set.
R> iris_of <- ore.push(iris)
R> # Select some rows from iris_of.
R> iris_of[c(10, 20, 60, 80, 110, 140),]
      Sepal.Length Sepal.Width Petal.Length Petal.Width Species
10           4.9         3.1         1.5         0.1    setosa
20           5.1         3.8         1.5         0.3    setosa
60           5.2         2.7         3.9         1.4 versicolor
80           5.7         2.6         3.5         1.0 versicolor
110          7.2         3.6         6.1         2.5  virginica
140          6.9         3.1         5.4         2.1  virginica
R> # Format the data in Petal.Length column.
R> iris_of$Petal.Length <- petalCategory_fmt(iris_of$Petal.Length)
R> # Select the same rows from iris_of.
R> iris_of[c(10, 20, 60, 80, 110, 140),]
      Sepal.Length Sepal.Width Petal.Length Petal.Width Species
10           4.9         3.1         SMALL         0.1    setosa
20           5.1         3.8         SMALL         0.3    setosa
60           5.2         2.7         MEDIUM         1.4 versicolor
80           5.7         2.6         MEDIUM         1.0 versicolor
110          7.2         3.6         LONG         2.5  virginica
140          6.9         3.1         LONG         2.1  virginica
```

**Example 3-8 Using the transform Function**

```
# Create an ore.frame in database memory with the iris data set.
iris_of2 <- ore.push(iris)
# Select some rows from iris_of.
iris_of2[c(10, 20, 60, 80, 110, 140),]
iris_of2 <- transform(iris_of2,
                      Petal.Length = ifelse(Petal.Length > 5, 'LONG',
                                             ifelse(Petal.Length > 2, 'MEDIUM', 'SMALL')))
iris_of2[c(10, 20, 60, 80, 110, 140),]
```

**Listing for Example 3-8 (page 3-8)**

```

R> # Create an ore.frame in database memory with the iris data set.
R> iris_of2 <- ore.push(iris)
R> # Select some rows from iris_of.
R> iris_of2[c(10, 20, 60, 80, 110, 140),]
  Sepal.Length Sepal.Width Petal.Length Petal.Width Species
10           4.9         3.1         1.5         0.1   setosa
20           5.1         3.8         1.5         0.3   setosa
60           5.2         2.7         3.9         1.4 versicolor
80           5.7         2.6         3.5         1.0 versicolor
110          7.2         3.6         6.1         2.5  virginica
140          6.9         3.1         5.4         2.1  virginica
R> iris_of2 <- transform(iris_of2,
+                       Petal.Length = ifelse(Petal.Length > 5, 'LONG',
+                       ifelse(Petal.Length > 2, 'MEDIUM', 'SMALL'))))
R> iris_of2[c(10, 20, 60, 80, 110, 140),]
  Sepal.Length Sepal.Width Petal.Length Petal.Width Species
10           4.9         3.1         SMALL         0.1   setosa
20           5.1         3.8         SMALL         0.3   setosa
60           5.2         2.7         MEDIUM         1.4 versicolor
80           5.7         2.6         MEDIUM         1.0 versicolor
110          7.2         3.6          LONG         2.5  virginica
140          6.9         3.1          LONG         2.1  virginica

```

**Example 3-9 Adding Derived Columns**

```

# Set the page width.
options(width = 80)
# Create an ore.frame in database memory with the iris data set.
iris_of <- ore.push(iris)
names(iris_of)
# Add one column derived from another
iris_of <- transform(iris_of, LOG_PL = log(Petal.Length))
names(iris_of)
head(iris_of, 3)
# Add more columns.
iris_of <- transform(iris_of,
                     SEPALBINS = ifelse(Sepal.Length < 6.0, "A", "B"),
                     PRODUCTCOLUMN = Petal.Length * Petal.Width,
                     CONSTANTCOLUMN = 10)
names(iris_of)
# Select some rows of iris_of.
iris_of[c(10, 20, 60, 80, 110, 140),]

```

### 3.1.7 Sampling Data

Sampling is an important capability for statistical analytics. Typically, you sample data to reduce its size and to perform meaningful work on it. In R you usually must load data into memory to sample it. However, if the data is too large, this isn't possible.

In Oracle R Enterprise, instead of pulling the data from the database and then sampling, you can sample directly in the database and then pull only those records that are part of the sample. By sampling in the database, you minimize data movement and you can work with larger data sets. Note that it is the ordering framework integer row indexing in the transparency layer that enables this capability.

---

#### Note:

Sampling requires using ordered `ore.frame` objects as described in "[Creating Ordered and Unordered `ore.frame` Objects](#) (page 2-9)".

---

The examples in this section illustrate several sampling techniques. Similar examples are in the `sampling.R` example script.

#### Example 3-10 Simple Random Sampling

This example demonstrates a simple selection of rows at random. The example creates a small `data.frame` object and pushes it to the database to create an `ore.frame` object, `MYDATA`. Out of 20 rows, the example samples 5. It uses the R `sample` function to produce a random set of indices that it uses to get the sample from `MYDATA`. The sample, `simpleRandomSample`, is an `ore.frame` object.

```

set.seed(1)
N <- 20
myData <- data.frame(a=1:N,b=letters[1:N])
MYDATA <- ore.push(myData)

```

```
head(MYDATA)
sampleSize <- 5
simpleRandomSample <- MYDATA[sample(nrow(MYDATA), sampleSize), , drop=FALSE]
class(simpleRandomSample)
simpleRandomSample
```

#### Listing for [Example 3-10](#) (page 3-10)

```
R> set.seed(1)
R> N <- 20
R> myData <- data.frame(a=1:N,b=letters[1:N])
R> MYDATA <- ore.push(myData)
R> head(MYDATA)
  a b
1 1 a
2 2 b
3 3 c
4 4 d
5 5 e
6 6 f
R> sampleSize <- 5
R> simpleRandomSample <- MYDATA[sample(nrow(MYDATA), sampleSize), , drop=FALSE]
R> class(simpleRandomSample)
[1] "ore.frame"
attr(,"package")
[1] "OREbase"
R> simpleRandomSample
  a b
2  2 b
7  7 g
10 10 j
12 12 l
19 19 s
```

#### **Example 3-11** *Split Data Sampling*

This example demonstrates randomly partitioning data into training and testing sets. This splitting of the data is normally done in classification and regression to assess how well a model performs on new data. The example uses the MYDATA object created in [Example 3-10](#) (page 3-10).

This example produces a sample set of indices to use as the test data set. It then creates the logical vector `group` that is `TRUE` if the index is in the sample and is `FALSE` otherwise. Next, it uses row indexing to produce the training set where the group is `FALSE` and the test set where the group is `TRUE`. Notice that the number of rows in the training set is 15 and the number of rows in the test set is 5, as specified in the invocation of the `sample` function.

```
set.seed(1)
sampleSize <- 5
ind <- sample(1:nrow(MYDATA), sampleSize)
group <- as.integer(1:nrow(MYDATA) %in% ind)
MYDATA.train <- MYDATA[group==FALSE,]
dim(MYDATA.train)
MYDATA.test <- MYDATA[group==TRUE,]
dim(MYDATA.test)
```

#### Listing for [Example 3-11](#) (page 3-11)

```
R> set.seed(1)
R> sampleSize <- 5
R> ind <- sample(1:nrow(MYDATA), sampleSize)
```

```
R> group <- as.integer(1:nrow(MYDATA) %in% ind)
R> MYDATA.train <- MYDATA[group==FALSE,]
dim(MYDATA.train)
[1] 15 2
R> MYDATA.test <- MYDATA[group==TRUE,]
R> dim(MYDATA.test)
[1] 5 2
```

### **Example 3-12 Systematic Sampling**

This example demonstrates systematic sampling, in which rows are selected at regular intervals. The example uses the `seq` function to create a sequence of values that start at 2 and increase by increments of 3. The number of values in the sequence is equal to the number of rows in MYDATA. The MYDATA object is created in [Example 3-10](#) (page 3-10).

```
set.seed(1)
N <- 20
myData <- data.frame(a=1:20,b=letters[1:N])
MYDATA <- ore.push(myData)
head(MYDATA)
start <- 2
by <- 3
systematicSample <- MYDATA[seq(start, nrow(MYDATA), by = by), , drop = FALSE]
systematicSample
```

### **Listing for Example 3-12 (page 3-12)**

```
R> set.seed(1)
R> N <- 20
R> myData <- data.frame(a=1:20,b=letters[1:N])
R> MYDATA <- ore.push(myData)
R> head(MYDATA)
  a b
1 1 a
2 2 b
3 3 c
4 4 d
5 5 e
6 6 f
R> start <- 2
R> by <- 3
R> systematicSample <- MYDATA[seq(start, nrow(MYDATA), by = by), , drop = FALSE]
systematicSample
  a b
2 2 b
5 5 e
8 8 h
11 11 k
14 14 n
17 17 q
20 20 t
```

### **Example 3-13 Stratified Sampling**

This example demonstrates stratified sampling, in which rows are selected within each group where the group is determined by the values of a particular column. The example creates a data set that has each row assigned to a group. The function `rnorm` produces random normal numbers. The argument 4 is the desired mean for the distribution. The example splits the data according to group and then samples proportionately from each partition. Finally, it row binds the list of subset `ore.frame`

objects into a single `ore.frame` object and then displays the values of the result, `stratifiedSample`.

```
set.seed(1)
N <- 200
myData <- data.frame(a=1:N,b=round(rnorm(N),2),
                    group=round(rnorm(N,4),0))
MYDATA <- ore.push(myData)
head(MYDATA)
sampleSize <- 10
stratifiedSample <- do.call(rbind,
                           lapply(split(MYDATA, MYDATA$group),
                                function(y) {
                                  ny <- nrow(y)
                                  y[sample(ny, sampleSize*ny/N), , drop = FALSE]
                                })))
stratifiedSample

#### **Example 3-14 Cluster Sampling**

This example demonstrates cluster sampling, in which entire groups are selected at random. The example splits the data according to group and then samples among the groups and row binds into a single `ore.frame` object. The resulting sample has data from two clusters, 6 and 7.

```
set.seed(1)
N <- 200
myData <- data.frame(a=1:N,b=round(runif(N),2),
                    group=round(rnorm(N,4),0))
MYDATA <- ore.push(myData)
```

```
head(MYDATA)
sampleSize <- 5
clusterSample <- do.call(rbind,
                          sample(split(MYDATA, MYDATA$group), 2))
unique(clusterSample$group)
```

**Listing for [Example 3-14](#) (page 3-13)**

```
R> set.seed(1)
R> N <- 200
R> myData <- data.frame(a=1:N,b=round(runif(N),2),
+                       group=round(rnorm(N,4),0))
R> MYDATA <- ore.push(myData)
R> head(MYDATA)
  a  b group
1 1 0.27   3
2 2 0.37   4
3 3 0.57   3
4 4 0.91   4
5 5 0.20   3
6 6 0.90   6
R> sampleSize <- 5
R> clusterSample <- do.call(rbind,
+                           sample(split(MYDATA, MYDATA$group), 2))
R> unique(clusterSample$group)
[1] 6 7
```

**Example 3-15 Quota Sampling**

This example demonstrates quota sampling, in which a consecutive number of records are selected as the sample. The example uses the `head` function to select the sample. The `tail` function could also have been used.

```
set.seed(1)
N <- 200
myData <- data.frame(a=1:N,b=round(runif(N),2))
MYDATA <- ore.push(myData)
sampleSize <- 10
quotaSample1 <- head(MYDATA, sampleSize)
quotaSample1
```

**Listing for [Example 3-15](#) (page 3-14)**

```
R> set.seed(1)
R> N <- 200
R> myData <- data.frame(a=1:N,b=round(runif(N),2))
R> MYDATA <- ore.push(myData)
R> sampleSize <- 10
R> quotaSample1 <- head(MYDATA, sampleSize)
R> quotaSample1
  a  b
1  1 0.15
2  2 0.75
3  3 0.98
4  4 0.97
5  5 0.35
6  6 0.39
7  7 0.95
8  8 0.11
9  9 0.93
10 10 0.35
```

### 3.1.8 Partitioning Data

In analyzing large data sets, a typical operation is to randomly partitioning the data set into subsets. You can analyze the partitions by using Oracle R Enterprise embedded R execution, as shown in [Example 3-16](#) (page 3-15). The example creates a `data.frame` object with the symbol `myData` in the local R session and adds a column to it that contains a randomly generated set of values. It pushes the data set to database memory as the object `MYDATA`. The example invokes the embedded R execution function `ore.groupApply`, which partitions the data based on the partition column and then applies the `lm` function to each partition.

---

#### See Also:

["Using Oracle R Enterprise Embedded R Execution \(page 6-1\)"](#)

---

#### Example 3-16 Randomly Partitioning Data

```
N <- 200
k <- 5
myData <- data.frame(a=1:N,b=round(runif(N),2))
myData$partition <- sample(rep(1:k, each = N/k,
                             length.out = N), replace = TRUE)

MYDATA <- ore.push(myData)
head(MYDATA)
results <- ore.groupApply(MYDATA, MYDATA$partition,
                          function(y) {lm(b~a,y)}, parallel = TRUE)

length(results)
results[[1]]
```

#### Listing for [Example 3-16](#) (page 3-15)

```
R> N <- 200
R> k <- 5
R> myData <- data.frame(a=1:N,b=round(runif(N),2))
R> myData$partition <- sample(rep(1:k, each = N/k,
+                               length.out = N), replace = TRUE)
R> MYDATA <- ore.push(myData)
R> head(MYDATA)
  a  b partition
1 1 0.89        2
2 2 0.31        4
3 3 0.39        5
4 4 0.66        3
5 5 0.01        1
6 6 0.12        4
R> results <- ore.groupApply(MYDATA, MYDATA$partition,
+                             function(y) {lm(b~a,y)}, parallel = TRUE)
R> length(results)
[1] 5
R> results[[1]]

Call:
lm(formula = b ~ a, data = y)

Coefficients:
(Intercept)          a
  0.388795    0.001015
```

### 3.1.9 Preparing Time Series Data

Oracle R Enterprise provides you with the ability to perform many data preparation operations on time series data, such as filtering, ordering, and transforming the data. Oracle R Enterprise maps R data types to SQL data types, as shown in [Table 1-1](#) (page 1-8), which allows you to create Oracle R Enterprise objects and perform data preparation operations in database memory.

The following examples demonstrate some operations on time series data.

#### **Example 3-17   Aggregating Date and Time Data**

This example illustrates some of the statistical aggregation functions. For a data set, the example first generates on the local client a sequence of five hundred dates spread evenly throughout 2001. It then introduces a random `difftime` and a vector of random normal values. The example then uses the `ore.push` function to create `MYDATA`, an in-database version of the data. The example invokes the `class` function to show that `MYDATA` is an `ore.frame` object and that the `datetime` column is of class `ore.datetime`. The example displays the first three rows of the generated data. It then uses the statistical aggregation operations of `min`, `max`, `range`, `median`, and `quantile` on the `datetime` column of `MYDATA`.

```
N <- 500
mydata <- data.frame(datetime =
                     seq(as.POSIXct("2001/01/01"),
                         as.POSIXct("2001/12/31"),
                         length.out = N),
                     difftime = as.difftime(runif(N),
                                             units = "mins"),
                     x = rnorm(N))
MYDATA <- ore.push(mydata)
class(MYDATA)
class(MYDATA$datetime)
head(MYDATA, 3)
# statistical aggregations
min(MYDATA$datetime)
max(MYDATA$datetime)
range(MYDATA$datetime)
quantile(MYDATA$datetime,
         probs = c(0, 0.05, 0.10))
```

#### **Listing for Example 3-17 (page 3-16)**

```
R> N <- 500
R> mydata <- data.frame(datetime =
+                       seq(as.POSIXct("2001/01/01"),
+                           as.POSIXct("2001/12/31"),
+                           length.out = N),
+                       difftime = as.difftime(runif(N),
+                                               units = "mins"),
+                       x = rnorm(N))
R> MYDATA <- ore.push(mydata)
R> class(MYDATA)

```

### Example 3-18 Using Date and Time Arithmetic

This example creates a one day shift by taking the `datetime` column of the `MYDATA` `ore.frame` object created in [Example 3-17](#) (page 3-16) and adding a `difftime` of one day. The result is `day1Shift`, which the example shows is of class `ore.datetime`. The example displays the first three elements of the `datetime` column of `MYDATA` and those of `day1Shift`. The first element of `day1Shift` is January 2, 2001.

This example also computes lag differences using the overloaded `diff` function. The difference between the dates is all the same because the 500 dates in `MYDATA` are evenly distributed throughout 2001.

```

day1Shift <- MYDATA$datetime + as.difftime(1, units = "days")
class(day1Shift)
head(MYDATA$datetime,3)
head(day1Shift,3)
lag1Diff <- diff(MYDATA$datetime)
class(lag1Diff)
head(lag1Diff,3)

```

### Listing for Example 3-18 (page 3-17)

```

R> day1Shift <- MYDATA$datetime + as.difftime(1, units = "days")
R> class(day1Shift)
[1] "ore.datetime"
attr(,"package")
[1] "OREbase"
R> head(MYDATA$datetime,3)
[1] "2001-01-01 00:00:00 CST" "2001-01-01 17:30:25 CST" "2001-01-02 11:00:50 CST"
R> head(day1Shift,3)
[1] "2001-01-02 00:00:00 CST" "2001-01-02 17:30:25 CST" "2001-01-03 11:00:50 CST"
R> lag1Diff <- diff(MYDATA$datetime)
R> class(lag1Diff)
[1] "ore.difftime"
attr(,"package")
[1] "OREbase"
R> head(lag1Diff,3)
Time differences in secs
[1] 63025.25 63025.25 63025.25

```

### Example 3-19 Comparing Dates and Times

This example demonstrates date and time comparisons. The example uses the `datetime` column of the `MYDATA` `ore.frame` object created in [Example 3-17](#)

(page 3-16). This example selects the elements of `MYDATA` that have a date earlier than April 1, 2001. The resulting `isQ1` is of class `ore.logical` and for the first three entries the result is `TRUE`. The example finds out how many dates matching `isQ1` are in March. It then sums the logical vector and displays the result, which is that 43 rows are in March. The example next filters rows based on dates that are the end of the year, after December 27. The result is `eoySubset`, which is an `ore.frame` object. The example displays the first three rows returned in `eoySubset`.

```
isQ1 <- MYDATA$datetime < as.Date("2001/04/01")
class(isQ1)
head(isQ1,3)
isMarch <- isQ1 & MYDATA$datetime > as.Date("2001/03/01")
class(isMarch)
head(isMarch,3)
sum(isMarch)
eoySubset <- MYDATA[MYDATA$datetime > as.Date("2001/12/27"), ]
class(eoySubset)
head(eoySubset,3)
```

#### Listing for Example 3-19 (page 3-17)

```
R> isQ1 <- MYDATA$datetime < as.Date("2001/04/01")
R> class(isQ1)
[1] "ore.logical"
attr(,"package")
[1] "OREbase"
R> head(isQ1,3)
[1] TRUE TRUE TRUE
R> isMarch <- isQ1 & MYDATA$datetime > as.Date("2001/03/01")
R> class(isMarch)
[1] "ore.logical"
attr(,"package")
[1] "OREbase"
R> head(isMarch,3)
[1] FALSE FALSE FALSE
R> sum(isMarch)
[1] 43
R> eoySubset <- MYDATA[MYDATA$datetime > as.Date("2001/12/27"), ]
R> class(eoySubset)
[1] "ore.frame"
attr(,"package")
[1] "OREbase"
R> head(eoySubset,3)
```

|     | datetime            | difftime      | x          |

#### Example 3-20 Using Date and Time Accessors

Oracle R Enterprise has accessor functions that you can use to extract various components from `datetime` objects, such as year, month, day of the month, hour, minute, and second. This example demonstrates the use of these functions. The example uses the `datetime` column of the `MYDATA` `ore.frame` object created in [Example 3-17](#) (page 3-16).

This example gets the year elements of the `datetime` column. The invocation of the `unique` function for `year` displays 2001 because it is the only year value in the column. However, for objects that have a range of values, as for example, `ore.mday`, the `range` function returns the day of the month. The result contains a vector with

values that range from 1 through 31. Invoking the range function succinctly reports the range of values, as demonstrated for the other accessor functions.

```
year <- ore.year(MYDATA$datetime)
unique(year)
month <- ore.month(MYDATA$datetime)
range(month)
dayOfMonth <- ore.mday(MYDATA$datetime)
range(dayOfMonth)
hour <- ore.hour(MYDATA$datetime)
range(hour)
minute <- ore.minute(MYDATA$datetime)
range(minute)
second <- ore.second(MYDATA$datetime)
range(second)
```

#### Listing for [Example 3-20](#) (page 3-18)

```
R> year <- ore.year(MYDATA$datetime)
R> unique(year)
[1] 2001
R> month <- ore.month(MYDATA$datetime)
R> range(month)
[1] 1 12
R> dayOfMonth <- ore.mday(MYDATA$datetime)
R> range(dayOfMonth)
[1] 1 31
R> hour <- ore.hour(MYDATA$datetime)
R> range(hour)
[1] 0 23
R> minute <- ore.minute(MYDATA$datetime)
R> range(minute)
[1] 0 59
R> second <- ore.second(MYDATA$datetime)
R> range(second)
[1] 0.00000 59.87976
```

#### **Example 3-21** *Coercing Date and Time Data Types*

This example uses the `as.ore` subclass objects to coerce an `ore.datetime` data type into other data types. The example uses the `datetime` column of the `MYDATA` `ore.frame` object created in [Example 3-17](#) (page 3-16). That column contains `ore.datetime` values. This example first extracts the date from the `MYDATA$datetime` column. The resulting `dateOnly` object has `ore.date` values that contain only the year, month, and day, but not the time. The example then coerces the `ore.datetime` values into objects with `ore.character` and `ore.integer` values that represent the names of days, the number of the day of the year, and the quarter of the year.

```
dateOnly <- as.ore.date(MYDATA$datetime)
class(dateOnly)
head(sort(unique(dateOnly)),3)
nameOfDay <- as.ore.character(MYDATA$datetime, format = "DAY")
class(nameOfDay)
sort(unique(nameOfDay))
dayOfYear <- as.integer(as.character(MYDATA$datetime, format = "DDD"))
class(dayOfYear)
range(dayOfYear)
quarter <- as.integer(as.character(MYDATA$datetime, format = "Q"))
class(quarter)
sort(unique(quarter))
```

**Listing for Example 3-21 (page 3-19)**

```

R> dateOnly <- as.ore.date(MYDATA$datetime)
R> class(dateOnly)[1] "ore.date"
attr(,"package")[1] "OREbase"
R> head(sort(unique(dateOnly)),3)
[1] "2001-01-01" "2001-01-02" "2001-01-03"
R> nameOfDay <- as.ore.character(MYDATA$datetime, format = "DAY")
R> class(nameOfDay)
[1] "ore.character"
attr(,"package")
[1] "OREbase"
R> sort(unique(nameOfDay))
[1] "FRIDAY " "MONDAY " "SATURDAY " "SUNDAY " "THURSDAY " "TUESDAY " "WEDNESDAY"
R> dayOfYear <- as.integer(as.character(MYDATA$datetime, format = "DDD"))
R> class(dayOfYear)
[1] "ore.integer"
attr(,"package")
[1] "OREbase"
R> range(dayOfYear)
[1] 1 365
R> quarter <- as.integer(as.character(MYDATA$datetime, format = "Q"))
R> class(quarter)
[1] "ore.integer"
attr(,"package")
[1] "OREbase"
R> sort(unique(quarter))
[1] 1 2 3 4

```

**Example 3-22 Using a Window Function**

This example uses the window functions `ore.rollmean` and `ore.rolld` to compute the rolling mean and the rolling standard deviation. The example uses the `MYDATA` `ore.frame` object created in [Example 3-17](#) (page 3-16). The example ensures that `MYDATA` is an ordered `ore.frame` by assigning the values of the `datetime` column as the row names of `MYDATA`. The example computes the rolling mean and the rolling standard deviation over five periods. Next, to use the R time series functionality in the `Stats` package, the example pulls data to the client. To limit the data pulled to the client, it uses the vector `is.March` from [Example 3-19](#) (page 3-17) to select only the data points in March. The example creates a time series object using the `ts` function, builds the Arima model, and predicts three points out.

```

row.names(MYDATA) <- MYDATA$datetime
MYDATA$rollmean5 <- ore.rollmean(MYDATA$x, k = 5)
MYDATA$rollsd5 <- ore.rolld (MYDATA$x, k = 5)
head(MYDATA)
marchData <- ore.pull(MYDATA[isMarch,])
tseries.x <- ts(marchData$x)
arima10.x <- arima(tseries.x, c(1,1,0))
predict(arima10.x, 3)
tseries.rm5 <- ts(marchData$rollmean5)
arima10.rm5 <- arima(tseries.rm5, c(1,1,0))
predict(arima10.rm5, 3)

```

**Listing for Example 3-22 (page 3-20)**

```

R> row.names(MYDATA) <- MYDATA$datetime
R> MYDATA$rollmean5 <- ore.rollmean(MYDATA$x, k = 5)
R> MYDATA$rollsd5 <- ore.rolld (MYDATA$x, k = 5)
R> head(MYDATA)

## 3.2 Exploring Data

Oracle R Enterprise provides functions that enable you to perform exploratory data analysis. With these functions, you can perform common statistical operations.

The functions and their uses are described in the following topics:

- [About the Exploratory Data Analysis Functions](#) (page 3-22)
- [About the NARROW Data Set for Examples](#) (page 3-23)
- [Correlating Data](#) (page 3-23)
- [Cross-Tabulating Data](#) (page 3-25)
- [Analyzing the Frequency of Cross-Tabulations](#) (page 3-30)
- [Building Exponential Smoothing Models on Time Series Data](#) (page 3-30)
- [Ranking Data](#) (page 3-34)
- [Sorting Data](#) (page 3-35)
- [Summarizing Data with ore.summary](#) (page 3-36)
- [Analyzing Distribution of Numeric Variables](#) (page 3-38)
- [Principal Component Analysis](#) (page 3-38)
- [Singular Value Decomposition](#) (page 3-40)

---

---

**See Also:**

["Building Models in Oracle R Enterprise](#) (page 4-1)"

### 3.2.1 About the Exploratory Data Analysis Functions

The Oracle R Enterprise functions for exploratory data analysis are in the `OREeda` package. [Table 3-1](#) (page 3-22) lists the functions in that package.

**Table 3-1** *Functions in the OREeda Package*

| Function                  | Description                                                                                                                                                                                                                        |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>ore.corr</code>     | Performs correlation analysis across numeric columns in an <code>ore.frame</code> object.                                                                                                                                          |
| <code>ore.crosstab</code> | Expands on the <code>xtabs</code> function by supporting multiple columns with optional aggregations, weighting, and ordering options. Building a cross-tabulation is a pre-requisite to using the <code>ore.freq</code> function. |
| <code>ore.esm</code>      | Builds exponential smoothing models on data in an ordered <code>ore.vector</code> object.                                                                                                                                          |
| <code>ore.freq</code>     | Operates on output from the <code>ore.crosstab</code> function and automatically determines techniques that are relevant for the table.                                                                                            |

**Table 3-1 (Cont.) Functions in the OREeda Package**

| Function                    | Description                                                                                                                                                                                           |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>ore.rank</code>       | Enables the investigation of the distribution of values along numeric columns in an <code>ore.frame</code> object.                                                                                    |
| <code>ore.sort</code>       | Provides flexible sorting for <code>ore.frame</code> objects.                                                                                                                                         |
| <code>ore.summary</code>    | Provides descriptive statistics for <code>ore.frame</code> objects within flexible row aggregations.                                                                                                  |
| <code>ore.univariate</code> | Provides distribution analysis of numeric columns in an <code>ore.frame</code> object of. Reports all statistics from the <code>ore.summary</code> function plus signed-rank test and extreme values. |

### 3.2.2 About the NARROW Data Set for Examples

Many of the examples of the exploratory data analysis functions use the NARROW data set. NARROW is an `ore.frame` that has 9 columns and 1500 rows, as shown in [Example 3-23](#) (page 3-23). Some of the columns are numeric, others are not.

#### **Example 3-23 The NARROW Data Set**

This example shows the class, dimensions, and names of the NARROW object.

```
R> class(NARROW)
R> dim(NARROW)
R> names(NARROW)
```

#### **Listing for Example 3-23 (page 3-23)**

```
R> class(NARROW)
[1] "ore.frame"
attr(,"package")
[1] "OREbase"
R> dim(NARROW)[1] 1500    9
R> names(NARROW)
[1] "ID"          "GENDER"      "AGE"         "MARITAL_STATUS"
[5] "COUNTRY"     "EDUCATION"   "OCCUPATION"  "YRS_RESIDENCE"
[9] "CLASS"
```

### 3.2.3 Correlating Data

You can use the `ore.corr` function to perform correlation analysis. With the `ore.corr` function, you can do the following:

- Perform Pearson, Spearman or Kendall correlation analysis across numeric columns in an `ore.frame` object.
- Perform partial correlations by specifying a control column.
- Aggregate some data prior to the correlations.
- Post-process results and integrate them into an R code flow.

You can make the output of the `ore.corr` function conform to the output of the `R.corr` function; doing so allows you to use any R function to post-process the output or to use the output as the input to a graphics function.

For details about the function arguments, invoke `help(ore.corr)`.

The following examples demonstrate these operations. Most of the examples use the NARROW data set; for more information, see "[About the Exploratory Data Analysis Functions](#) (page 3-22)".

### Example 3-24 Performing Basic Correlation Calculations

This example demonstrates how to specify the different types of correlation statistics.

```
# Before performing correlations, project out all non-numeric values
# by specifying only the columns that have numeric values.
names(NARROW)
NARROW_NUMS <- NARROW[,c(3,8,9)]
names(NARROW_NUMS)
# Calculate the correlation using the default correlation statistic, Pearson.
x <- ore.corr(NARROW_NUMS,var='AGE,YRS_RESIDENCE,CLASS')
head(x, 3)
# Calculate using Spearman.
x <- ore.corr(NARROW_NUMS,var='AGE,YRS_RESIDENCE,CLASS', stats='spearman')
head(x, 3)
# Calculate using Kendall
x <- ore.corr(NARROW_NUMS,var='AGE,YRS_RESIDENCE,CLASS', stats='kendall')
head(x, 3)
```

#### Listing for Example 3-24 (page 3-24)

```
R> # Before performing correlations, project out all non-numeric values
R> # by specifying only the columns that have numeric values.
R> names(NARROW)
[1] "ID" "GENDER" "AGE" "MARITAL_STATUS" "COUNTRY" "EDUCATION" "OCCUPATION"
[8] "YRS_RESIDENCE" "CLASS" "AGEBINS"
R> NARROW_NUMS <- NARROW[,c(3,8,9)]
R> names(NARROW_NUMS)
[1] "AGE" "YRS_RESIDENCE" "CLASS"

R> # Calculate the correlation using the default correlation statistic, Pearson.
R> x <- ore.corr(NARROW_NUMS,var='AGE,YRS_RESIDENCE,CLASS')
R> head(x, 3)
      ROW      COL PEARSON_T PEARSON_P PEARSON_DF
1      AGE      CLASS 0.2200960    1e-15     1298
2      AGE YRS_RESIDENCE 0.6568534    0e+00     1098
3 YRS_RESIDENCE      CLASS 0.3561869    0e+00     1298
R> # Calculate using Spearman.
R> x <- ore.corr(NARROW_NUMS,var='AGE,YRS_RESIDENCE,CLASS', stats='spearman')
R> head(x, 3)
      ROW      COL SPEARMAN_T SPEARMAN_P SPEARMAN_DF
1      AGE      CLASS 0.2601221    1e-15     1298
2      AGE YRS_RESIDENCE 0.7462684    0e+00     1098
3 YRS_RESIDENCE      CLASS 0.3835252    0e+00     1298
R> # Calculate using Kendall
R> x <- ore.corr(NARROW_NUMS,var='AGE,YRS_RESIDENCE,CLASS', stats='kendall')
R> head(x, 3)
      ROW      COL KENDALL_T KENDALL_P KENDALL_DF
1      AGE      CLASS 0.2147107 4.285594e-31    <NA>
2      AGE YRS_RESIDENCE 0.6332196 0.000000e+00    <NA>
3 YRS_RESIDENCE      CLASS 0.3362078 1.094478e-73    <NA>
```

**Example 3-25 Creating Correlation Matrices**

This example pushes the `iris` data set to a temporary table in the database, which has the proxy `ore.frame` object `iris_of`. It creates correlation matrices grouped by species.

```
iris_of <- ore.push(iris)
x <- ore.corr(iris_of, var = "Sepal.Length, Sepal.Width, Petal.Length",
             partial = "Petal.Width", group.by = "Species")
class(x)
head(x)
```

**Listing for Example 3-25 (page 3-25)**

```
R> iris_of <- ore.push(iris)
R> x <- ore.corr(iris_of, var = "Sepal.Length, Sepal.Width, Petal.Length",
+             partial = "Petal.Width", group.by = "Species")
R> class(x)
[1] "list"
R> head(x)
$setosa
      ROW      COL PART_PEARSON_T PART_PEARSON_P PART_PEARSON_DF
1 Sepal.Length Petal.Length      0.1930601    9.191136e-02         47
2 Sepal.Length  Sepal.Width      0.7255823    1.840300e-09         47
3  Sepal.Width Petal.Length      0.1095503    2.268336e-01         47

$versicolor
      ROW      COL PART_PEARSON_T PART_PEARSON_P PART_PEARSON_DF
1 Sepal.Length Petal.Length      0.62696041    7.180100e-07         47
2 Sepal.Length  Sepal.Width      0.26039166    3.538109e-02         47
3  Sepal.Width Petal.Length      0.08269662    2.860704e-01         47

$virginica
      ROW      COL PART_PEARSON_T PART_PEARSON_P PART_PEARSON_DF
1 Sepal.Length Petal.Length      0.8515725    4.000000e-15         47
2 Sepal.Length  Sepal.Width      0.3782728    3.681795e-03         47
3  Sepal.Width Petal.Length      0.2854459    2.339940e-02         47
```

**See Also:**

The `cor.R` example script

**3.2.4 Cross-Tabulating Data**

Cross-tabulation is a statistical technique that finds an interdependent relationship between two tables of values. The `ore.crosstab` function enables cross-column analysis of an `ore.frame`. This function is a sophisticated variant of the R `table` function.

You must use `ore.crosstab` function before performing frequency analysis using `ore.freq`.

If the result of the `ore.crosstab` function invocation is a single cross-tabulation, the function returns an `ore.frame` object. If the result is multiple cross-tabulations, then the function returns a list of `ore.frame` objects.

For details about function arguments, invoke `help(ore.crosstab)`.

The examples of `ore.corr` use the `NARROW` data set; for more information, see "[About the NARROW Data Set for Examples](#) (page 3-23)".

The most basic use case is to create a single-column frequency table, as shown in [Example 3-26](#) (page 3-26).

### **Example 3-26 Creating a Single Column Frequency Table**

This example filters the NARROW ore . frame, grouping by GENDER.

```
ct <- ore.crosstab(~AGE, data=NARROW)
head(ct)
```

#### **Listing for Example 3-26 (page 3-26)**

```
R> ct <- ore.crosstab(~AGE, data=NARROW)
R> head(ct)
  AGE ORE$FREQ ORE$STRATA ORE$GROUP
17 17      14         1         1
18 18      16         1         1
19 19      30         1         1
20 20      23         1         1
21 21      22         1         1
22 22      39         1         1
```

### **Example 3-27 Analyzing Two Columns**

This example analyses AGE by GENDER and AGE by CLASS.

```
ct <- ore.crosstab(AGE~GENDER+CLASS, data=NARROW)
head(ct)
```

#### **Listing for Example 3-27 (page 3-26)**

```
R> ct <- ore.crosstab(AGE~GENDER+CLASS, data=NARROW)
R> head(ct)
$`AGE~GENDER`
  AGE GENDER ORE$FREQ ORE$STRATA ORE$GROUP
17|F 17      F       5         1         1
17|M 17      M       9         1         1
18|F 18      F       6         1         1
18|M 18      M       7         1         1
19|F 19      F      15         1         1
19|M 19      M      13         1         1
# The remaining output is not shown.
```

### **Example 3-28 Weighting Rows**

To weight rows, include a count based on another column as shown in this example. The example weights values in AGE and GENDER using values in YRS\_RESIDENCE.

```
ct <- ore.crosstab(AGE~GENDER*YRS_RESIDENCE, data=NARROW)
head(ct)
```

#### **Listing for Example 3-28 (page 3-26)**

```
R> ct <- ore.crosstab(AGE~GENDER*YRS_RESIDENCE, data=NARROW)
R> head(ct)
  AGE GENDER ORE$FREQ ORE$STRATA ORE$GROUP
17|F 17      F       1         1         1
17|M 17      M       8         1         1
18|F 18      F       4         1         1
18|M 18      M      10         1         1
19|F 19      F      15         1         1
19|M 19      M      17         1         1
```

**Example 3-29 Ordering Cross-Tabulated Data**

There are several possibilities for ordering rows in a cross-tabulated table, such as the following:

- Default or NAME orders by the columns being analyzed
- FREQ orders by frequency counts
- -NAME or -FREQ does reverse ordering
- INTERNAL bypasses ordering

This example orders by frequency count and then by reverse order by frequency count.

```
ct <- ore.crosstab(AGE~GENDER|FREQ, data=NARROW)
head(ct)
ct <- ore.crosstab(AGE~GENDER|-FREQ, data=NARROW)
head(ct)
```

**Listing for Example 3-29 (page 3-27)**

```
R> ct <- ore.crosstab(AGE~GENDER|FREQ, data=NARROW)
R> head(ct)
  AGE GENDER ORE$FREQ ORE$STRATA ORE$GROUP
66|F  66      F        1          1         1
70|F  70      F        1          1         1
73|M  73      M        1          1         1
74|M  74      M        1          1         1
76|F  76      F        1          1         1
77|F  77      F        1          1         1

R> ct <- ore.crosstab(AGE~GENDER|-FREQ, data=NARROW)
R> head(ct)
  AGE GENDER ORE$FREQ ORE$STRATA ORE$GROUP
27|M  27      M       33          1         1
35|M  35      M       28          1         1
41|M  41      M       27          1         1
34|M  34      M       26          1         1
37|M  37      M       26          1         1
28|M  28      M       25          1         1
```

**Example 3-30 Analyzing Three or More Columns**

This example demonstrates analyzing three or more columns. The result is similar to what the SQL `GROUPING SETS` clause accomplishes.

```
ct <- ore.crosstab(AGE+COUNTRY~GENDER, NARROW)
head(ct)
```

**Listing for Example 3-30 (page 3-27)**

```
R> ct <- ore.crosstab(AGE+COUNTRY~GENDER, NARROW)
R> head(ct)
$`AGE~GENDER`
  AGE GENDER ORE$FREQ ORE$STRATA ORE$GROUP
17|F  17      F        5          1         1
17|M  17      M        9          1         1
18|F  18      F        6          1         1
18|M  18      M        7          1         1
19|F  19      F       15          1         1

# The rest of the output is not shown.
```

### Example 3-31 Specifying a Range of Columns

You can specify a range of columns instead of having to type all the column names, as demonstrated in this example.

```
names(NARROW)
# Because AGE, MARITAL_STATUS and COUNTRY are successive columns,
# you can simply do the following:
ct <- ore.crosstab(AGE-COUNTRY-GENDER, NARROW)
# An equivalent invocation is the following:
ct <- ore.crosstab(AGE+MARITAL_STATUS+COUNTRY-GENDER, NARROW)
```

#### Listing for Example 3-31 (page 3-28)

```
R> names(NARROW)
[1] "ID"          "GENDER"      "AGE"         "MARITAL_STATUS"
[5] "COUNTRY"     "EDUCATION"   "OCCUPATION"  "YRS_RESIDENCE"
[9] "CLASS"
R> # Because AGE, MARITAL_STATUS and COUNTRY are successive columns,
R> # you can simply do the following:
R> ct <- ore.crosstab(AGE-COUNTRY-GENDER, NARROW)
R> # An equivalent invocation is the following:
R> ct <- ore.crosstab(AGE+MARITAL_STATUS+COUNTRY-GENDER, NARROW)
```

### Example 3-32 Producing One Cross-Tabulation Table for Each Value of Another Column

This example produces one cross-tabulation table (AGE, GENDER) for *each* unique value of another column COUNTRY.

```
ct <- ore.crosstab(~AGE/COUNTRY, data=NARROW)
head(ct)
```

#### Listing for Example 3-32 (page 3-28)

```
R> ct <- ore.crosstab(~AGE/COUNTRY, data=NARROW)
R> head(ct)
      AGE ORE$FREQ ORE$STRATA ORE$GROUP
Argentina|17      17          1          1          1
Brazil|17          17          1          1          3
United States of America|17 17      12          1          19
United States of America|18 18      16          1          19
United States of America|19 19      30          1          19
United States of America|20 20      23          1          19
```

### Example 3-33 Producing One Cross-Tabulation Table for Each Set of Value of Two Columns

You can extend the cross-tabulation to more than one column, as shown in this example, which produces one (AGE, EDUCATION) table for each unique combination of (COUNTRY, GENDER).

```
ct <- ore.crosstab(AGE~EDUCATION/COUNTRY+GENDER, data=NARROW)
head(ct)
```

**Listing for Example 3-33 (page 3-28)**

```
R> ct <- ore.crosstab(AGE~EDUCATION/COUNTRY+GENDER, data=NARROW)
R> head(ct)
```

|                                    | AGE | EDUCATION | ORE\$FREQ | ORE\$STRATA | ORE\$GROUP |
|------------------------------------|-----|-----------|-----------|-------------|------------|
| United States of America F 17 10th | 17  | 10th      | 3         | 1           | 33         |
| United States of America M 17 10th | 17  | 10th      | 5         | 1           | 34         |
| United States of America M 17 11th | 17  | 11th      | 1         | 1           | 34         |
| Argentina M 17 HS-grad             | 17  | HS-grad   | 1         | 1           | 2          |
| United States of America M 18 10th | 18  | 10th      | 1         | 1           | 34         |
| United States of America F 18 11th | 18  | 11th      | 2         | 1           | 33         |

**Example 3-34 Augmenting Cross-Tabulation with Stratification**

All of the cross-tabulation tables in the previous examples can be augmented with stratification, as shown in this example.

```
ct <- ore.crosstab(AGE~GENDER^CLASS, data=NARROW)
head(ct)
R> head(ct)
# The previous function invocation is the same as the following:
ct <- ore.crosstab(AGE~GENDER, NARROW, strata="CLASS")
```

**Listing for Example 3-34 (page 3-29)**

```
R> ct <- ore.crosstab(AGE~GENDER^CLASS, data=NARROW)
R> head(ct)
R> head(ct)
```

|        | AGE | GENDER | ORE\$FREQ | ORE\$STRATA | ORE\$GROUP |
|--------|-----|--------|-----------|-------------|------------|
| 0 17 F | 17  | F      | 5         | 1           | 1          |
| 0 17 M | 17  | M      | 9         | 1           | 1          |
| 0 18 F | 18  | F      | 6         | 1           | 1          |
| 0 18 M | 18  | M      | 7         | 1           | 1          |
| 0 19 F | 19  | F      | 15        | 1           | 1          |
| 0 19 M | 19  | M      | 13        | 1           | 1          |

```
# The previous function invocation is the same as the following:
ct <- ore.crosstab(AGE~GENDER, NARROW, strata="CLASS")
```

**Example 3-35 Binning Followed by Cross-Tabulation**

This example does a custom binning by AGE and then calculates the cross-tabulation for GENDER and the bins.

```
NARROW$AGEBINS <- ifelse(NARROW$AGE<20, 1, ifelse(NARROW$AGE<30, 2,
  ifelse(NARROW$AGE<40, 3, 4)))
ore.crosstab(GENDER~AGEBINS, NARROW)
```

**Listing for Example 3-35 (page 3-29)**

```
R> NARROW$AGEBINS <- ifelse(NARROW$AGE<20, 1, ifelse(NARROW$AGE<30, 2,
+ ifelse(NARROW$AGE<40, 3, 4)))
R> ore.crosstab(GENDER~AGEBINS, NARROW)
```

|     | GENDER | AGEBINS | ORE\$FREQ | ORE\$STRATA | ORE\$GROUP |
|-----|--------|---------|-----------|-------------|------------|
| F 1 | F      | 1       | 26        | 1           | 1          |
| F 2 | F      | 2       | 108       | 1           | 1          |
| F 3 | F      | 3       | 86        | 1           | 1          |
| F 4 | F      | 4       | 164       | 1           | 1          |
| M 1 | M      | 1       | 29        | 1           | 1          |
| M 2 | M      | 2       | 177       | 1           | 1          |
| M 3 | M      | 3       | 230       | 1           | 1          |
| M 4 | M      | 4       | 381       | 1           | 1          |

### 3.2.5 Analyzing the Frequency of Cross-Tabulations

The `ore.freq` function analyses the output of the `ore.crosstab` function and automatically determines the techniques that are relevant to an `ore.crosstab` result. The techniques depend on the kind of cross-tabulation tables, which are the following:

- 2-way cross-tabulation tables
  - Various statistics that describe relationships between columns in the cross-tabulation
  - Chi-square tests, Cochran-Mantel-Haenzel statistics, measures of association, strength of association, risk differences, odds ratio and relative risk for 2x2 tables, tests for trend
- N-way cross-tabulation tables
  - N 2-way cross-tabulation tables
  - Statistics across and within strata

The `ore.freq` function uses Oracle Database SQL functions when available.

The `ore.freq` function returns an `ore.frame` in all cases.

Before you use `ore.freq`, you must calculate crosstabs, as shown in [Example 3-36](#) (page 3-30).

For details about the function arguments, invoke `help(ore.freq)`.

#### **Example 3-36 Using the ore.freq Function**

This example pushes the `iris` data set to the database and gets the `ore.frame` object `iris_of`. The example gets a crosstab and invokes the `ore.freq` function on it.

```
IRIS <- ore.push(iris)
ct <- ore.crosstab(Species ~ Petal.Length + Sepal.Length, data = IRIS)
ore.freq(ct)
```

#### **Listing for Example 3-36 (page 3-30)**

```
R> IRIS <- ore.push(iris)
R> ct <- ore.crosstab(Species ~ Petal.Length + Sepal.Length, data = IRIS)
R> ore.freq(ct)
$`Species-Petal.Length`
  METHOD   FREQ DF      PVALUE      DESCR GROUP
1 PCHISQ 181.4667 84 3.921603e-09 Pearson Chi-Square      1

$`Species-Sepal.Length`
  METHOD   FREQ DF      PVALUE      DESCR GROUP
1 PCHISQ 102.6 68 0.004270601 Pearson Chi-Square      1
```

### 3.2.6 Building Exponential Smoothing Models on Time Series Data

The `ore.esm` function builds a simple or a double exponential smoothing model for in-database time series observations in an ordered `ore.vector` object. The function operates on time series data, whose observations are evenly spaced by a fixed interval, or transactional data, whose observations are not equally spaced. The function can aggregate the transactional data by a specified time interval, as well as handle missing values using a specified method, before entering the modeling phase.

The `ore.esm` function processes the data in one or more R engines running on the database server. The function returns an object of class `ore.esm`.

You can use the `predict` method to predict the time series of the exponential smoothing model built by `ore.esm`. If you have loaded the `forecast` package, then you can use the `forecast` method on the `ore.esm` object. You can use the `fitted` method to generate the fitted values of the training time series data set.

For information about the arguments of the `ore.esm` function, invoke `help(ore.esm)`.

### **Example 3-37 Building a Double Exponential Smoothing Model**

This example builds a double exponential smoothing model on a synthetic time series data set. The `predict` and `fitted` functions are invoked to generate the predictions and the fitted values, respectively. [Figure 3-1](#) (page 3-32) shows the observations, fitted values, and the predictions.

```
N <- 5000
ts0 <- ore.push(data.frame(ID=1:N,
                           VAL=seq(1,5, length.out=N)^2+rnorm(N, sd=0.5)))
rownames(ts0) <- ts0$ID
x <- ts0$VAL
esm.mod <- ore.esm(x, model = "double")
esm.predict <- predict(esm.mod, 30)
esm.fitted <- fitted(esm.mod, start=4000, end=5000)
plot(ts0[4000:5000,], pch='.')
lines(ts0[4000:5000, 1], esm.fitted, col="blue")
lines(esm.predict, col="red", lwd=2)
```

**Figure 3-1** *Fitted and Predicted Values Based on the esm.mod Model***Example 3-38** *Building a Time Series Model with Transactional Data*

This example builds a simple smoothing model based on a transactional data set. As preprocessing, it aggregates the values to the day level by taking averages, and fills missing values by setting them to the previous aggregated value. The model is then built on the aggregated daily time series. The function `predict` is invoked to generate predicted values on the daily basis.

```
ts01 <- data.frame(ID=seq(as.POSIXct("2008/6/13"), as.POSIXct("2011/6/16"),
                        length.out=4000), VAL=rnorm(4000, 10))
ts02 <- data.frame(ID=seq(as.POSIXct("2011/7/19"), as.POSIXct("2012/11/20"),
                        length.out=1500), VAL=rnorm(1500, 10))
ts03 <- data.frame(ID=seq(as.POSIXct("2012/12/09"), as.POSIXct("2013/9/25"),
                        length.out=1000), VAL=rnorm(1000, 10))
ts1 = ore.push(rbind(ts01, ts02, ts03))
rownames(ts1) <- ts1$ID
x <- ts1$VAL
esm.mod <- ore.esm(x, "DAY", accumulate = "AVG", model="simple",
                  setmissing="PREV")
esm.predict <- predict(esm.mod)
esm.predict
```

Listing for [Example 3-38](#) (page 3-32)

```

R> ts01 <- data.frame(ID=seq(as.POSIXct("2008/6/13"), as.POSIXct("2011/6/16"),
+                           length.out=4000), VAL=rnorm(4000, 10))
R> ts02 <- data.frame(ID=seq(as.POSIXct("2011/7/19"), as.POSIXct("2012/11/20"),
+                           length.out=1500), VAL=rnorm(1500, 10))
R> ts03 <- data.frame(ID=seq(as.POSIXct("2012/12/09"), as.POSIXct("2013/9/25"),
+                           length.out=1000), VAL=rnorm(1000, 10))
R> ts1 = ore.push(rbind(ts01, ts02, ts03))
R> rownames(ts1) <- ts1$ID
R> x <- ts1$VAL
R> esm.mod <- ore.esm(x, "DAY", accumulate = "AVG", model="simple",
+                    setmissing="PREV")
R> esm.predict <- predict(esm.mod)
R> esm.predict
      ID      VAL
1 2013-09-26 9.962478
2 2013-09-27 9.962478
3 2013-09-28 9.962478
4 2013-09-29 9.962478
5 2013-09-30 9.962478
6 2013-10-01 9.962478
7 2013-10-02 9.962478
8 2013-10-03 9.962478
9 2013-10-04 9.962478
10 2013-10-05 9.962478
11 2013-10-06 9.962478
12 2013-10-07 9.962478

```

**Example 3-39 Building a Double Exponential Smoothing Model Specifying an Interval**

This example uses stock data from the TTR package. It builds a double exponential smoothing model based on the daily stock closing prices. The 30-day predicted stock prices, along with the original observations, are shown in [Figure 3-2](#) (page 3-34).

```

library(TTR)
stock <- "orcl"
xts.data <- getYahooData(stock, 20010101, 20131024)
df.data <- data.frame(xts.data)
df.data$date <- index(xts.data)
of.data <- ore.push(df.data[, c("date", "Close")])
rownames(of.data) <- of.data$date
esm.mod <- ore.esm(of.data$Close, "DAY", model = "double")
esm.predict <- predict(esm.mod, 30)
plot(of.data, type="l")
lines(esm.predict, col="red", lwd=4)

```

**Figure 3-2 Stock Price Prediction**

### 3.2.7 Ranking Data

The `ore.rank` function analyzes distribution of values in numeric columns of an `ore.frame`.

The `ore.rank` function supports useful functionality, including:

- Ranking within groups
- Partitioning rows into groups based on rank tiles
- Calculation of cumulative percentages and percentiles
- Treatment of ties
- Calculation of normal scores from ranks

The `ore.rank` function syntax is simpler than the corresponding SQL queries.

The `ore.rank` function returns an `ore.frame` in all instances.

You can use these R scoring methods with `ore.rank`:

- To compute exponential scores from ranks, use `savage`.
- To compute normal scores, use one of `blom`, `tukey`, or `vw` (van der Waerden).

For details about the function arguments, invoke `help(ore.rank)`.

The following examples illustrate using `ore.rank`. The examples use the `NARROW` data set.

**Example 3-40 Ranking Two Columns**

This example ranks the two columns AGE and CLASS and reports the results as derived columns; values are ranked in the default order, which is ascending.

```
x <- ore.rank(data=NARROW, var='AGE=RankOfAge, CLASS=RankOfClass')
```

**Example 3-41 Handling Ties in Ranking**

This example ranks the two columns AGE and CLASS. If there is a tie, the smallest value is assigned to all tied values.

```
x <- ore.rank(data=NARROW, var='AGE=RankOfAge, CLASS=RankOfClass', ties='low')
```

**Example 3-42 Ranking by Groups**

This example ranks the two columns AGE and CLASS and then ranks the resulting values according to COUNTRY.

```
x <- ore.rank(data=NARROW, var='AGE=RankOfAge, CLASS=RankOfClass',  
group.by='COUNTRY')
```

**Example 3-43 Partitioning into Deciles**

To partition the columns into a different number of partitions, change the value of groups. For example, groups=4 partitions into quartiles. This example ranks the two columns AGE and CLASS and partitions the columns into deciles (10 partitions).

```
x <- ore.rank(data=NARROW, var='AGE=RankOfAge, CLASS=RankOfClass', groups=10)
```

**Example 3-44 Estimating Cumulative Distribution Function**

This example ranks the two columns AGE and CLASS and estimates the cumulative distribution function for both column.

```
x <- ore.rank(data=NARROW, var='AGE=RankOfAge, CLASS=RankOfClass', nplus1=TRUE)
```

**Example 3-45 Scoring Ranks**

This example ranks the two columns AGE and CLASS and scores the ranks in two different ways. The first command partitions the columns into percentiles (100 groups). The `savage` scoring method calculates exponential scores and `blom` scoring calculates normal scores.

```
x <- ore.rank(data=NARROW, var='AGE=RankOfAge,  
CLASS=RankOfClass', score='savage', groups=100, group.by='COUNTRY')  
x <- ore.rank(data=NARROW, var='AGE=RankOfAge, CLASS=RankOfClass', score='blom')
```

## 3.2.8 Sorting Data

The `ore.sort` function enables flexible sorting of a data frame along one or more columns specified by the `by` argument.

The `ore.sort` function can be used with other data pre-processing functions. The results of sorting can provide input to R visualization.

The sorting done by the `ore.sort` function takes place in the Oracle database. The `ore.sort` function supports the database `nls.sort` option.

The `ore.sort` function returns an `ore.frame`.

For details about the function arguments, invoke `help(ore.sort)`.

Most of the following examples use the `NARROW` data set. Some examples use the `ONTIME_S` data set.

**Example 3-46    *Sorting Columns in Descending Order***

This example sorts the columns `AGE` and `GENDER` in descending order.

```
x <- ore.sort(data=NARROW, by='AGE,GENDER', reverse=TRUE)
```

**Example 3-47    *Sorting Different Columns in Different Orders***

This example sorts `AGE` in descending order and `GENDER` in ascending order.

```
x <- ore.sort(data=NARROW, by='-AGE,GENDER')
```

**Example 3-48    *Sorting and Returning One Row per Unique Value***

This example sorts by `AGE` and keep one row per unique value of `AGE`:

```
x <- ore.sort(data=NARROW, by='AGE', unique.key=TRUE)
```

**Example 3-49    *Removing Duplicate Columns***

This example sorts by `AGE` and removes duplicate rows:

```
x <- ore.sort(data=NARROW, by='AGE', unique.data=TRUE)
```

**Example 3-50    *Removing Duplicate Columns and Returning One Row per Unique Value***

This example sorts by `AGE`, removes duplicate rows, and returns one row per unique value of `AGE`.

```
x <- ore.sort(data=NARROW, by='AGE', unique.data=TRUE, unique.key = TRUE)
```

**Example 3-51    *Preserving Relative Order in the Output***

This example maintains the relative order in the sorted output.

```
x <- ore.sort(data=NARROW, by='AGE', stable=TRUE)
```

**Example 3-52    *Sorting Two Columns in Different Orders***

This example sorts `ONTIME_S` by airline name in descending order and departure delay in ascending order.

```
sortedOnTime1 <- ore.sort(data=ONTIME_S, by='-UNIQUECARRIER,DEPDELAY')
```

**Example 3-53    *Sorting Two Columns in Different Orders and Producing Unique Combinations***

This example sorts `ONTIME_S` by airline name and departure delay and selects one of each combination (that is, returns a unique key).

```
sortedOnTime1 <- ore.sort(data=ONTIME_S, by='-UNIQUECARRIER,DEPDELAY',  
                          unique.key=TRUE)
```

### 3.2.9 Summarizing Data with `ore.summary`

The `ore.summary` function calculates descriptive statistics and supports extensive analysis of columns in an `ore.frame`, along with flexible row aggregations.

The `ore.summary` function supports these statistics:

- Mean, minimum, maximum, mode, number of missing values, sum, weighted sum

- Corrected and uncorrected sum of squares, range of values, `stddev`, `stderr`, `variance`
- t-test for testing the hypothesis that the population mean is 0
- Kurtosis, skew, Coefficient of Variation
- Quantiles: `p1`, `p5`, `p10`, `p25`, `p50`, `p75`, `p90`, `p95`, `p99`, `qrange`
- 1-sided and 2-sided Confidence Limits for the mean: `clm`, `rc1m`, `lc1m`
- Extreme value tagging

The `ore.summary` function provides a relatively simple syntax compared with SQL queries that produce the same results.

The `ore.summary` function returns an `ore.frame` in all cases except when the `group.by` argument is used. If the `group.by` argument is used, then `ore.summary` returns a list of `ore.frame` objects, one `ore.frame` per stratum.

For details about the function arguments, invoke `help(ore.summary)`.

#### **Example 3-54 Calculating Default Statistics**

This example calculates the mean, minimum, and maximum values for columns AGE and CLASS and rolls up (aggregates) the GENDER column.

```
ore.summary(NARROW, class = 'GENDER', var = c('AGE', 'CLASS', order = 'freq'))
```

#### **Example 3-55 Calculating Skew and Probability for t Test**

This example calculates the skew of AGE as column A and the probability of the Student's *t* distribution for CLASS as column B.

```
ore.summary(NARROW, class = 'GENDER', var = 'AGE', CLASS', stats = 'skew(AGE) = A,
probt(CLASS) = B')
```

#### **Example 3-56 Calculating the Weighted Sum**

This example calculates the weighted sum for AGE aggregated by GENDER with YRS\_RESIDENCE as weights; in other words, it calculates `sum(var*weight)`.

```
ore.summary(NARROW, class = 'GENDER', var = 'AGE', stats = 'sum = X', weight =
'YRS_RESIDENCE')
```

#### **Example 3-57 Grouping by Two Columns**

This example groups CLASS by GENDER and MARITAL\_STATUS.

```
ore.summary(NARROW, class = c('GENDER', 'MARITAL_STATUS'), var = 'CLASS', ways = 1)
```

#### **Example 3-58 Grouping by All Possible Ways**

This example groups CLASS in all possible ways by GENDER and MARITAL\_STATUS.

```
ore.summary(NARROW, class = c('GENDER', 'MARITAL_STATUS'), var = 'CLASS', ways =
'nway')
```

#### **Example 3-59 Getting the Maximum Values of Columns Using ore.summary**

This example lists the maximum value and corresponding species of the Sepal.Length and Sepal.Width columns in the IRIS `ore.frame`.

```
IRIS <- ore.push(iris)
ore.summary(IRIS, c("Sepal.Length", "Sepal.Width"),
             "max",
             maxid=c(Sepal.Length="Species", Sepal.Width="Species"))
```

**Listing for Example 3-59 (page 3-37)**

```
R> IRIS <- ore.push(iris)
R> ore.summary(IRIS, c("Sepal.Length", "Sepal.Width"),
+             "max",
+             maxid=c(Sepal.Length="Species", Sepal.Width="Species"))
  FREQ MAX(Sepal.Length) MAX(Sepal.Width) MAXID(Sepal.Length->Species)
MAXID(Sepal.Width->Species)
1 150             7.9             4.4
virginica                      setosa
Warning message:

```

### 3.2.10 Analyzing Distribution of Numeric Variables

The `ore.univariate` function provides distribution analysis of numeric variables in an `ore.frame`.

The `ore.univariate` function provides these statistics:

- All statistics reported by the `summary` function
- Signed rank test, Student's t-test
- Extreme values reporting

The `ore.univariate` function returns an `ore.frame` as output in all cases.

For details about the function arguments, invoke `help(ore.univariate)`.

**Example 3-60 Calculating the Default Univariate Statistics**

This example calculates the default univariate statistics for `AGE`, `YRS_RESIDENCE`, and `CLASS`.

```
ore.univariate(NARROW, var="AGE,YRS_RESIDENCE,CLASS")
```

**Example 3-61 Calculating the Default Univariate Statistics**

This example calculates location statistics for `YRS_RESIDENCE`.

```
ore.univariate(NARROW, var="YRS_RESIDENCE", stats="location")
```

**Example 3-62 Calculating the Complete Quantile Statistics**

This example calculates complete quantile statistics for `AGE` and `YRS_RESIDENCE`.

```
ore.univariate(NARROW, var="AGE,YRS_RESIDENCE", stats="quantiles")
```

### 3.2.11 Principal Component Analysis

The overloaded `prcomp` and `princomp` functions perform principal component analysis in parallel in the database.

The `prcomp` function uses a singular value decomposition of the covariance and correlations between variables. The `princomp` function uses eigen decomposition of the covariance and correlations between samples.

The transparency layer methods `ore.frame-prcomp` and `ore.frame-princomp` enable you to use the generic functions `prcomp` and `princomp` on data in an `ore.frame` object. This allows the functions to execute in parallel processes in the database.

For both functions, the methods support the function signature that accepts an `ore.frame` as the `x` argument and the signature that accepts a formula. The `ore.frame` must contain only numeric data. The formula must refer only to numeric variables and have no response variable.

Function `prcomp` returns a `prcomp` object and function `princomp` returns a `princomp` object.

For details about the function arguments, invoke `help('ore.frame-prcomp')` and `help('ore.frame-princomp')`.

---

**Note:**

The `biplot` function is not supported for the objects returned by these transparency layer methods.

---

### **Example 3-63 Using the `prcomp` and `princomp` Functions**

```
USARRESTS <- ore.push(USArrests)

# Using prcomp

prcomp(USARRESTS)
prcomp(USARRESTS, scale. = TRUE)

# Formula interface
prcomp(~ Murder + Assault + UrbanPop, data = USARRESTS, scale. = TRUE)

# Using prcomp

princomp(USARRESTS)
princomp(USARRESTS, cor = TRUE)

# Formula interface
princomp(~ Murder + Assault + UrbanPop, data = USARRESTS, cor = TRUE)
```

### **Listing for Example 3-63 (page 3-39)**

```

### 3.2.12 Singular Value Decomposition

The overloaded `svd` function performs singular value decomposition in parallel in the database.

The `svd` function accepts an `ore.frame` or an `ore.tblmatrix` object as the `x` argument. The `ore.frame-svd` method distributes block SVD computation to parallel processes executing in the database. The method uses the global option `ore.parallel` to determine the degree of parallelism to employ.

The function returns a `list` object that contains the `d` vector and `v` matrix components of a singular value decomposition of argument `x`. It does not return the left singular vector matrix `u`, therefore the argument `nu` is not used.

For details about the function arguments, invoke `help('ore.frame-svd')`.

### Example 3-64 Using the `svd` Function

```
USARRESTS <- ore.push(USArrests)
svd(USARRESTS)
```

#### Listing for Example 3-64 (page 3-41)

## 3.3 Using a Third-Party Package on the Client

In Oracle R Enterprise, if you want to use functions from an open source R package from The Comprehensive R Archive Network (CRAN) or other third-party R package, then you would generally do so in the context of embedded R execution. Using embedded R execution, you can take advantage of the likely greater amount of RAM on the database server.

However, if you want to use a third-party package function in your local R session on data from an Oracle database table, you must use the `ore.pull` function to get the data from an `ore.frame` object to your local session as a `data.frame` object. This is the same as using open source R except that you can extract the data from the database without needing the help of a DBA.

When pulling data from a database table to a local `data.frame`, you are limited to using the amount of data that can fit into the memory of your local machine. On your local machine, you do not have the benefits provided by embedded R execution.

To use a third-party package, you must install it on your system and load it in your R session.

For an example that uses the `kernlab` package, see [Example 2-13](#) (page 2-11).

---

#### See Also:

- ["Installing a Third-Party Package for Use in Embedded R Execution \(page 6-5\)"](#)
  - *R Administration and Installation Guide* at <http://cran.r-project.org/doc/manuals/r-release/R-admin.html>
  - <http://www.r-bloggers.com/installing-r-packages/>
-

**Example 3-65 Downloading, Installing, and Loading a Third-Party Package on the Client**

This example demonstrates downloading, installing, and loading the CRAN package `kernlab`. The `kernlab` package contains kernel-based machine learning methods. The example invokes the `install.packages` function to download and install the package. It then invokes the `library` function to load the package.

```
install.packages("kernlab")
library("kernlab")
```

**Listing for Example 3-65 (page 3-42)**

```
R> install.packages("kernlab")
trying URL 'http://cran.rstudio.com/bin/windows/contrib/3.0/kernlab_0.9-19.zip'
Content type 'application/zip' length 2029405 bytes (1.9 Mb)
opened URL
downloaded 1.9 Mb
```

```
package 'kernlab' successfully unpacked and MD5 sums checked
```

```
The downloaded binary packages are in
  C:\Users\rquser\AppData\Local\Temp\RtmpSKVZql\downloaded_packages
R> library("kernlab")
```

**Example 3-66 Using a kernlab Package Function**

This example invokes the `demo` function to look for example programs in the `kernlab` package. Because the package does not have examples, this example then gets help for the `ksvm` function. The example invokes example code from the help.

```
demo(package = "kernlab")
help(package = "kernlab", ksvm)
data(spam)
index <- sample(1:dim(spam)[1])
spamtrain <- spam[index[1:floor(dim(spam)[1]/2)], ]
spamtest <- spam[index[((ceiling(dim(spam)[1]/2)) + 1):dim(spam)[1]], ]
filter <- ksvm(type~., data=spamtrain, kernel="rbfdot",
+             kpar=list(sigma=0.05), C=5, cross=3)
filter
table(mailtype, spamtest[,58])
```

**Listing for Example 3-66 (page 3-42)**

```
> demo(package = "kernlab")
no demos found
> help(package = "kernlab", ksvm)    # Output not shown.
> data(spam)
> index <- sample(1:dim(spam)[1])
> spamtrain <- spam[index[1:floor(dim(spam)[1]/2)], ]
> spamtest <- spam[index[((ceiling(dim(spam)[1]/2)) + 1):dim(spam)[1]], ]
> filter <- ksvm(type~., data=spamtrain, kernel="rbfdot",
+             kpar=list(sigma=0.05), C=5, cross=3)
> filter

# Building Models in Oracle R Enterprise

Oracle R Enterprise provides functions for building regression models, neural network models, and models based on Oracle Data Mining algorithms.

This chapter has the following topics:

- [Building Oracle R Enterprise Models](#) (page 4-1)
- [Building Oracle Data Mining Models](#) (page 4-11)
- [Cross-Validating Models](#) (page 4-35)

## 4.1 Building Oracle R Enterprise Models

The Oracle R Enterprise package `OREmodels` contains functions with which you can create advanced analytical data models using `ore.frame` objects, as described in the following topics:

- [About OREmodels Functions](#) (page 4-1)
- [About the longley Data Set for Examples](#) (page 4-2)
- [Building Linear Regression Models](#) (page 4-3)
- [Building a Generalized Linear Model](#) (page 4-5)
- [Building a Neural Network Model](#) (page 4-7)
- [Building a Random Forest Model](#) (page 4-9)

### 4.1.1 About OREmodels Functions

The `OREmodels` package contains functions with which you can build advanced analytical data models using `ore.frame` objects. The `OREmodels` functions are the following:

**Table 4-1** *Functions in the OREmodels Package*

| Function                      | Description                                                                                     |
|-------------------------------|-------------------------------------------------------------------------------------------------|
| <code>ore.glm</code>          | Fits and uses a generalized linear model on data in an <code>ore.frame</code> .                 |
| <code>ore.lm</code>           | Fits a linear regression model on data in an <code>ore.frame</code> .                           |
| <code>ore.neural</code>       | Fits a neural network model on data in an <code>ore.frame</code> .                              |
| <code>ore.randomForest</code> | Creates a random forest classification model in parallel on data in an <code>ore.frame</code> . |

**Table 4-1 (Cont.) Functions in the OREmodels Package**

| Function                  | Description                                                                    |
|---------------------------|--------------------------------------------------------------------------------|
| <code>ore.stepwise</code> | Fits a stepwise linear regression model on data in an <code>ore.frame</code> . |

**Note:**

In R terminology, the phrase "fits a model" is often synonymous with "builds a model". In this document and in the online help for Oracle R Enterprise functions, the phrases are used interchangeably.

The `ore.glm`, `ore.lm`, and `ore.stepwise` functions have the following advantages:

- The algorithms provide accurate solutions using out-of-core QR factorization. QR factorization decomposes a matrix into an orthogonal matrix and a triangular matrix.

QR is an algorithm of choice for difficult rank-deficient models.

- You can process data that does not fit into memory, that is, out-of-core data. QR factors a matrix into two matrices, one of which fits into memory while the other is stored on disk.

The `ore.glm`, `ore.lm` and `ore.stepwise` functions can solve data sets with more than one billion rows.

- The `ore.stepwise` function allows fast implementations of forward, backward, and stepwise model selection techniques.

The `ore.neural` function has the following advantages:

- It is a highly scalable implementation of neural networks, able to build a model on even billion row data sets in a matter of minutes. The `ore.neural` function can be run in two modes: in-memory for small to medium data sets and distributed (out-of-core) for large inputs.
- Users can specify the activation functions on neurons on a per-layer basis; `ore.neural` supports many different activation functions.
- Users can specify a neural network topology consisting of any number of hidden layers, including none.

## 4.1.2 About the longley Data Set for Examples

Most of the linear regression and `ore.neural` examples use the longley data set, which is provided by R. It is a small macroeconomic data set that provides a well-known example for collinear regression and consists of seven economic variables observed yearly over 16 years.

### **Example 4-1 Displaying Values from the longley Data Set**

This example pushes the longley data set to a temporary database table that has the proxy `ore.frame` object `longley_of` displays the first six rows of `longley_of`.

```
longley_of <- ore.push(longley)
head(longley_of)
```

**Listing for Example 4-1 (page 4-2)**

```
R> longley_of <- ore.push(longley)
R> dim(longley_of)[1] 16 7
R> head(longley_of)
```

|      | GNP.deflator | GNP     | Unemployed | Armed.Forces | Population | Year | Employed |
|------|--------------|---------|------------|--------------|------------|------|----------|
| 1947 | 83.0         | 234.289 | 235.6      | 159.0        | 107.608    | 1947 | 60.323   |
| 1948 | 88.5         | 259.426 | 232.5      | 145.6        | 108.632    | 1948 | 61.122   |
| 1949 | 88.2         | 258.054 | 368.2      | 161.6        | 109.773    | 1949 | 60.171   |
| 1950 | 89.5         | 284.599 | 335.1      | 165.0        | 110.929    | 1950 | 61.187   |
| 1951 | 96.2         | 328.975 | 209.9      | 309.9        | 112.075    | 1951 | 63.221   |
| 1952 | 98.1         | 346.999 | 193.2      | 359.4        | 113.270    | 1952 | 63.639   |

### 4.1.3 Building Linear Regression Models

The `ore.lm` and `ore.stepwise` functions perform least squares regression and stepwise least squares regression, respectively, on data represented in an `ore.frame` object. A model fit is generated using embedded R map/reduce operations where the map operation creates either QR decompositions or matrix cross-products depending on the number of coefficients being estimated. The underlying model matrices are created using either a `model.matrix` or `sparse.model.matrix` object depending on the sparsity of the model. Once the coefficients for the model have been estimated another pass of the data is made to estimate the model-level statistics.

When forward, backward, or stepwise selection is performed, the  $XtX$  and  $Xty$  matrices are subsetted to generate the F-test p-values based upon coefficient estimates that were generated using a Choleski decomposition of the  $XtX$  subset matrix.

If there are collinear terms in the model, functions `ore.lm` and `ore.stepwise` do not estimate the coefficient values for a collinear set of terms. For `ore.stepwise`, a collinear set of terms is excluded throughout the procedure.

For more information on `ore.lm` and `ore.stepwise`, invoke `help(ore.lm)`.

**Example 4-2 Using ore.lm**

This example pushes the `longley` data set to a temporary database table that has the proxy `ore.frame` object `longley_of`. The example builds a linear regression model using `ore.lm`.

```
longley_of <- ore.push(longley)
# Fit full model
oreFit1 <- ore.lm(Employed ~ ., data = longley_of)
class(oreFit1)
summary(oreFit1)
```

**Listing for Example 4-2 (page 4-3)**

```
R> longley_of <- ore.push(longley)
R> # Fit full model
R> oreFit1 <- ore.lm(Employed ~ ., data = longley_of)
R> class(oreFit1)
[1] "ore.lm"      "ore.model"  "lm"
R> summary(oreFit1)
```

```
Call:
ore.lm(formula = Employed ~ ., data = longley_of)
```

```

### Example 4-3 Using the ore.stepwise Function

This example pushes the `longley` data set to a temporary database table that has the proxy `ore.frame` object `longley_of`. The example builds linear regression models using the `ore.stepwise` function.

```

longley_of <- ore.push(longley)
# Two stepwise alternatives
oreStep1 <-
  ore.stepwise(Employed ~ .^2, data = longley_of, add.p = 0.1, drop.p = 0.1)
oreStep2 <-
  step(ore.lm(Employed ~ 1, data = longley_of),
        scope = terms(Employed ~ .^2, data = longley_of))

```

### Listing for Example 4-3 (page 4-4)

```

R> longley_of <- ore.push(longley)
R> # Two stepwise alternatives
R> oreStep1 <-
+   ore.stepwise(Employed ~ .^2, data = longley_of, add.p = 0.1, drop.p = 0.1)
R> oreStep2 <-
+   step(ore.lm(Employed ~ 1, data = longley_of),
+         scope = terms(Employed ~ .^2, data = longley_of))
Start: AIC=41.17

```

#### 4.1.4 Building a Generalized Linear Model

The `ore.glm` functions fits generalized linear models on data in an `ore.frame` object. The function uses a Fisher scoring iteratively reweighted least squares (IRLS) algorithm.

Instead of the traditional step halving to prevent the selection of less optimal coefficient estimates, `ore.glm` uses a line search to select new coefficient estimates at each iteration, starting from the current coefficient estimates and moving through the Fisher scoring suggested estimates using the formula  $(1 - \alpha) * \text{old} + \alpha * \text{suggested}$  where  $\alpha$  in  $[0, 2]$ . When the `interp` control argument is `TRUE`, the deviance is approximated by a cubic spline interpolation. When it is `FALSE`, the deviance is calculated using a follow-up data scan.

Each iteration consists of two or three embedded R execution map/reduce operations: an IRLS operation, an initial line search operation, and, if `interp = FALSE`, an optional follow-up line search operation. As with `ore.lm`, the IRLS map operation creates QR decompositions when `update = "qr"` or cross-products when `update = "crossprod"` of the `model.matrix`, or `sparse.model.matrix` if argument `sparse = TRUE`, and the IRLS reduce operation block updates those QR decompositions or cross-product matrices. After the algorithm has either converged or reached the maximum number of iterations, a final embedded R map/reduce operation is used to generate the complete set of model-level statistics.

The `ore.glm` function returns an `ore.glm` object.

For information on the `ore.glm` function arguments, invoke `help(ore.glm)`.

##### **Example 4-4 Using the ore.glm Function**

This example loads the `rpart` package and then pushes the `kyphosis` data set to a temporary database table that has the proxy `ore.frame` object `KYPHOSIS`. The example builds a generalized linear model using the `ore.glm` function and one using the `glm` function and invokes the `summary` function on the models.

```
# Load the rpart library to get the kyphosis and solder data sets.
library(rpart)
# Logistic regression
KYPHOSIS <- ore.push(kyphosis)
kyphFit1 <- ore.glm(Kyphosis ~ ., data = KYPHOSIS, family = binomial())
kyphFit2 <- glm(Kyphosis ~ ., data = kyphosis, family = binomial())
summary(kyphFit1)
summary(kyphFit2)
```

##### **Listing for Example 4-4 (page 4-5)**

```
R> # Load the rpart library to get the kyphosis and solder data sets.
R> library(rpart)

### 4.1.5 Building a Neural Network Model

Neural network models can be used to capture intricate nonlinear relationships between inputs and outputs or to find patterns in data. The `ore.neural` function builds a feed-forward neural network for regression on `ore.frame` data. It supports multiple hidden layers with a specifiable number of nodes. Each layer can have one of several activation functions.

The output layer is a single numeric or binary categorical target. The output layer can have any of the activation functions. It has the linear activation function by default.

The output of `ore.neural` is an object of type `ore.neural`.

For information about the arguments to the `ore.neural` function, invoke `help(ore.neural)`.

Modeling with the `ore.neural` function is well-suited for noisy and complex data such as sensor data. Problems that such data might have are the following:

- Potentially many (numeric) predictors, for example, pixel values
- The target may be discrete-valued, real-valued, or a vector of such values
- Training data may contain errors – robust to noise
- Fast scoring
- Model transparency is not required; models difficult to interpret

Typical steps in neural network modeling are the following:

1. Specifying the architecture
2. Preparing the data
3. Building the model
4. Specifying the stopping criteria: iterations, error on a validation set within tolerance
5. Viewing statistical results from model
6. Improving the model

#### **Example 4-5 Building a Neural Network Model**

This example builds a neural network with default values, including a hidden size of 1. The example pushes a subset of the `longley` data set to an `ore.frame` object in database memory as the object `trainData`. The example then pushes a different subset of `longley` to the database as the object `testData`. The example builds a neural network model with `trainData` and then predicts results using `testData`.

```
trainData <- ore.push(longley[1:11, ])
testData <- ore.push(longley[12:16, ])
fit <- ore.neural('Employed ~ GNP + Population + Year', data = trainData)
ans <- predict(fit, newdata = testData)
ans
```

#### **Listing for Example 4-5 (page 4-8)**

```
R> trainData <- ore.push(longley[1:11, ])
R> testData <- ore.push(longley[12:16, ])
R> fit <- ore.neural('Employed ~ GNP + Population + Year', data = trainData)
R> ans <- predict(fit, newdata = testData)
R> ans
  pred_Employed
1      67.97452

```

#### **Example 4-6 Using ore.neural and Specifying Activations**

This example pushes the `iris` data set to a temporary database table that has the proxy `ore.frame` object `IRIS`. The example builds a neural network model using the `ore.neural` function and specifies a different activation function for each layer.

```
IRIS <- ore.push(iris)
fit <- ore.neural(Petal.Length ~ Petal.Width + Sepal.Length,
  data = IRIS,
  hiddenSizes = c(20, 5),
  activations = c("bSigmoid", "tanh", "linear"))
ans <- predict(fit, newdata = IRIS,
  supplemental.cols = c("Petal.Length"))
options(ore.warn.order = FALSE)
head(ans, 3)
summary(ans)
```

#### **Listing for Example 4-6 (page 4-8)**

```

R> IRIS <- ore.push(iris)
R> fit <- ore.neural(Petal.Length ~ Petal.Width + Sepal.Length,
+                   data = IRIS,
+                   hiddenSizes = c(20, 5),
+                   activations = c("bSigmoid", "tanh", "linear"))
R>
R> ans <- predict(fit, newdata = IRIS,
+               supplemental.cols = c("Petal.Length"))
R> options(ore.warn.order = FALSE)

### 4.1.6 Building a Random Forest Model

The `ore.randomForest` function provides an ensemble learning technique for classification of data in an `ore.frame` object.

Function `ore.randomForest` builds a random forest model by growing trees in parallel on the database server. It constructs many decision trees and outputs the class that is the mode of the classes of the individual trees. The function avoids overfitting, which is a common problem for decision trees.

The random forest algorithm, developed by Leo Breiman and Adele Cutler, combines the ideas of bagging and the random selection of variables, which results in a collection of decision trees with controlled variance. The random forest algorithm provides high accuracy, but performance and scalability can be issues for large data sets.

Function `ore.randomForest` executes in parallel for model building and scoring. Parallel execution can occur whether you are using the `randomForest` package in Oracle R Distribution (ORD) or the open source `randomForest` package 4.6-10. Using `ore.randomForest` and ORD can require less memory than using `ore.randomForest` with the open source alternative. If you use the open source `randomForest` package, Oracle R Enterprise issues a warning.

Function `ore.randomForest` uses the global option `ore.parallel` to determine the degree of parallelism to employ. The function returns an `ore.randomForest` object.

An invocation of the scoring method `predict` on an `ore.randomForest` object also runs in parallel on the database server. The `cache.model` argument specifies whether to cache the entire random forest model in memory during prediction. If sufficient memory is available, use the default `cache.model` value of `TRUE` for better performance.

The `grabTree` method returns an `ore.frame` object that contains information on the specified tree. Each row of the `ore.frame` represents one node of the tree.

**Note:**

Function `ore.randomForest` loads a copy of the training data for each embedded R session executing in parallel. For large datasets, this can exceed the amount of available memory. Oracle recommends that you adjust the number of parallel processes and the amount of available memory accordingly. The global option `ore.parallel` specifies the number of parallel processes. For information on controlling the amount of memory used by embedded R execution processes, see *Controlling Memory Used by Embedded R in Oracle R Enterprise Installation and Administration Guide*.

**Example 4-7 Using `ore.randomForest`**

```
# Using the iris dataset
IRIS <- ore.push(iris)
mod <- ore.randomForest(Species~., IRIS)
tree10 <- grabTree(mod, k = 10, labelVar = TRUE)
ans <- predict(mod, IRIS, type="all", supplemental.cols="Species")
table(ans$Species, ans$prediction)

# Using the infert dataset
INFERT <- ore.push(infert)
formula <- case ~ age + parity + education + spontaneous + induced

rfMod <- ore.randomForest(formula, INFERT, ntree=1000, nodesize = 2)
tree <- grabTree(rfMod, k = 500)

rfPred <- predict(rfMod, INFERT, supplemental.cols = "case")

confusion.matrix <- with(rfPred, table(case, prediction))

confusion.matrix
```

**Listing for Example 4-7 (page 4-10)**

```
R> # Using the iris dataset
R> IRIS <- ore.push(iris)
R> mod <- ore.randomForest(Species~., IRIS)
R> tree10 <- grabTree(mod, k = 10, labelVar = TRUE)
R> ans <- predict(mod, IRIS, type="all", supplemental.cols="Species")
R> table(ans$Species, ans$prediction)

      setosa versicolor virginica
setosa      50         0         0

## 4.2 Building Oracle Data Mining Models

This section describes using the functions in the OREdm package of Oracle R Enterprise to build Oracle Data Mining models in R. The section has the following topics:

- [About Building Oracle Data Mining Models using Oracle R Enterprise](#) (page 4-11)
- [Building an Association Rules Model](#) (page 4-13)
- [Building an Attribute Importance Model](#) (page 4-16)
- [Building a Decision Tree Model](#) (page 4-17)
- [Building General Linearized Models](#) (page 4-18)
- [Building a k-Means Model](#) (page 4-21)
- [Building a Naive Bayes Model](#) (page 4-25)
- [Building an Orthogonal Partitioning Cluster Model](#) (page 4-29)
- [Building a Non-Negative Matrix Factorization Model](#) (page 4-27)
- [Building a Support Vector Machine Model](#) (page 4-31)

### 4.2.1 About Building Oracle Data Mining Models using Oracle R Enterprise

Oracle Data Mining can mine tables, views, star schemas, transactional data, and unstructured data. The OREdm functions provide R interfaces that use arguments that conform to typical R usage for corresponding predictive analytics and data mining functions.

This section has the following topics:

- [Oracle Data Mining Models Supported by Oracle R Enterprise](#) (page 4-11)
- [About Oracle Data Mining Models Built by Oracle R Enterprise Functions](#) (page 4-12)

#### 4.2.1.1 Oracle Data Mining Models Supported by Oracle R Enterprise

The functions in the OREdm package provide access to the in-database data mining functionality of Oracle Database. You use these functions to build data mining models in the database.

[Table 4-2](#) (page 4-11) lists the Oracle R Enterprise functions that build Oracle Data Mining models and the corresponding Oracle Data Mining algorithms and functions.

**Table 4-2 Oracle R Enterprise Data Mining Model Functions**

| Oracle R Enterprise Function | Oracle Data Mining Algorithm | Oracle Data Mining Function                           |
|------------------------------|------------------------------|-------------------------------------------------------|
| ore.odmAI                    | Minimum Description Length   | Attribute Importance for Classification or Regression |

**Table 4-2 (Cont.) Oracle R Enterprise Data Mining Model Functions**

| Oracle R Enterprise Function   | Oracle Data Mining Algorithm                | Oracle Data Mining Function   |
|--------------------------------|---------------------------------------------|-------------------------------|
| <code>ore.odmAssocRules</code> | Apriori                                     | Association Rules             |
| <code>ore.odmDT</code>         | Decision Tree                               | Classification                |
| <code>ore.odmGLM</code>        | Generalized Linear Models                   | Classification and Regression |
| <code>ore.odmKMeans</code>     | <i>k</i> -Means                             | Clustering                    |
| <code>ore.odmNB</code>         | Naive Bayes                                 | Classification                |
| <code>ore.odmNMF</code>        | Non-Negative Matrix Factorization           | Feature Extraction            |
| <code>ore.odmOC</code>         | Orthogonal Partitioning Cluster (O-Cluster) | Clustering                    |
| <code>ore.odmSVM</code>        | Support Vector Machines                     | Classification and Regression |

#### 4.2.1.2 About Oracle Data Mining Models Built by Oracle R Enterprise Functions

In each OREdm R model object, the slot name (or `fit.name`) is the name of the underlying Oracle Data Mining model generated by the OREdm function. While the R model exists, the Oracle Data Mining model name can be used to access the Oracle Data Mining model through other interfaces, including:

- Oracle Data Miner
- Any SQL interface, such as SQL\*Plus or SQL Developer

In particular, the models can be used with the Oracle Data Mining SQL prediction functions.

With Oracle Data Miner you can do the following:

- Get a list of available models
- Use model viewers to inspect model details
- Score appropriately transformed data

---

---

**Note:**

Any transformations performed in the R space are not carried over into Oracle Data Miner or SQL scoring.

---

---

Users can also get a list of models using SQL for inspecting model details or for scoring appropriately transformed data.

Models built using OREdm functions are transient objects; they do not persist past the R session in which they were built unless they are explicitly saved in an Oracle R Enterprise datastore. Oracle Data Mining models built using Data Miner or SQL, on the other hand, exist until they are explicitly dropped.

Model objects can be saved or persisted, as described in "[Saving and Managing R Objects in the Database](#) (page 2-17)". Saving a model object generated by an OREdm

function allows it to exist across R sessions and keeps the corresponding Oracle Data Mining object in place. While the `OREdm` model exists, you can export and import it; then you can use it apart from the Oracle R Enterprise R object existence.

## 4.2.2 Building an Association Rules Model

The `ore.odmAssocRules` function implements the apriori algorithm to find frequent itemsets and generate an association model. It finds the co-occurrence of items in large volumes of transactional data such as in the case of market basket analysis. An association rule identifies a pattern in the data in which the appearance of a set of items in a transactional record implies another set of items. The groups of items used to form rules must pass a minimum threshold according to how frequently they occur (the *support* of the rule) and how often the consequent follows the antecedent (the *confidence* of the rule). Association models generate all rules that have support and confidence greater than user-specified thresholds. The apriori algorithm is efficient, and scales well with respect to the number of transactions, number of items, and number of itemsets and rules produced.

The formula specification has the form `~ terms`, where `terms` is a series of column names to include in the analysis. Multiple column names are specified using `+` between column names. Use `~ .` if all columns in data should be used for model building. To exclude columns, use `-` before each column name to exclude. Functions can be applied to the items in `terms` to realize transformations.

The `ore.odmAssocRules` function accepts data in the following forms:

- Transactional data
- Multi-record case data using item id and item value
- Relational data

For examples of specifying the forms of data and for information on the arguments of the function, invoke `help(ore.odmAssocRules)`.

The function `rules` returns an object of class `ore.rules`, which specifies a set of association rules. You can pull an `ore.rules` object into memory in a local R session by using `ore.pull`. The local in-memory object is of class `rules` defined in the `arules` package. See `help(ore.rules)`.

The function `itemsets` returns an object of class `ore.itemsets`, which specifies a set of itemsets. You can pull an `ore.itemsets` object into memory in a local R session by using `ore.pull`. The local in-memory object is of class `itemsets` defined in the `arules` package. See `help(ore.itemsets)`.

### Example 4-8 Using the `ore.odmAssocRules` Function

This example builds an association model on a transactional data set. The packages `arules` and `arulesViz` are required to pull the resulting rules and itemsets into the client R session memory and be visualized. The graph of the rules appears in [Figure 4-1](#) (page 4-16).

```
# Load the arules and arulesViz packages.
library(arules)
library(arulesViz)
# Create some transactional data.
id <- c(1, 1, 1, 2, 2, 2, 3, 3, 3, 3)
item <- c("b", "d", "e", "a", "b", "c", "e", "b", "c", "d", "e")
# Push the data to the database as an ore.frame object.

### 4.2.3 Building an Attribute Importance Model

The `ore.odmAI` function uses the Oracle Data Mining Minimum Description Length algorithm to calculate attribute importance. Attribute importance ranks attributes according to their significance in predicting a target.

Minimum Description Length (MDL) is an information theoretic model selection principle. It is an important concept in information theory (the study of the quantification of information) and in learning theory (the study of the capacity for generalization based on empirical data).

MDL assumes that the simplest, most compact representation of the data is the best and most probable explanation of the data. The MDL principle is used to build Oracle Data Mining attribute importance models.

Attribute Importance models built using Oracle Data Mining cannot be applied to new data.

The `ore.odmAI` function produces a ranking of attributes and their importance values.

**Note:**

OREdm AI models differ from Oracle Data Mining AI models in these ways: a model object is *not* retained, and an R model object is *not* returned. Only the importance ranking created by the model is returned.

For information on the `ore.odmAI` function arguments, invoke `help(ore.odmAI)`.

**Example 4-9 Using the ore.odmAI Function**

This example pushes the `data.frame iris` to the database as the `ore.frame iris_of`. The example then builds an attribute importance model.

```
iris_of <- ore.push(iris)
ore.odmAI(Species ~ ., iris_of)
```

**Listing for Example 4-9 (page 4-17)**

```
R> iris_of <- ore.push(iris)
R> ore.odmAI(Species ~ ., iris_of)
```

Call:

```
ore.odmAI(formula = Species ~ ., data = iris_of)
```

Importance:

|              | importance | rank |
|--------------|------------|------|
| Petal.Width  | 1.1701851  | 1    |
| Petal.Length | 1.1494402  | 2    |
| Sepal.Length | 0.5248815  | 3    |
| Sepal.Width  | 0.2504077  | 4    |

## 4.2.4 Building a Decision Tree Model

The `ore.odmDT` function uses the Oracle Data Mining Decision Tree algorithm, which is based on conditional probabilities. Decision trees generate rules. A rule is a conditional statement that can easily be understood by humans and be used within a database to identify a set of records.

Decision Tree models are classification models.

A decision tree predicts a target value by asking a sequence of questions. At a given stage in the sequence, the question that is asked depends upon the answers to the previous questions. The goal is to ask questions that, taken together, uniquely identify specific target values. Graphically, this process forms a tree structure.

During the training process, the Decision Tree algorithm must repeatedly find the most efficient way to split a set of cases (records) into two child nodes. The `ore.odmDT` function offers two homogeneity metrics, gini and entropy, for calculating the splits. The default metric is gini.

For information on the `ore.odmDT` function arguments, invoke `help(ore.odmDT)`.

**Example 4-10 Using the ore.odmDT Function**

This example creates an input `ore.frame`, builds a model, makes predictions, and generates a confusion matrix.

```
m <- mtcars
m$gear <- as.factor(m$gear)
m$cyl <- as.factor(m$cyl)
m$vs <- as.factor(m$vs)
```

```

m$ID <- 1:nrow(m)
mtcars_of <- ore.push(m)
row.names(mtcars_of) <- mtcars_of
# Build the model.
dt.mod <- ore.odmDT(gear ~ ., mtcars_of)
summary(dt.mod)
# Make predictions and generate a confusion matrix.
dt.res <- predict(dt.mod, mtcars_of, "gear")
with(dt.res, table(gear, PREDICTION))

```

#### Listing for [Example 4-10](#) (page 4-17)

```

R> m <- mtcars
R> m$gear <- as.factor(m$gear)
R> m$cyl <- as.factor(m$cyl)
R> m$vs <- as.factor(m$vs)
R> m$ID <- 1:nrow(m)
R> mtcars_of <- ore.push(m)
R> row.names(mtcars_of) <- mtcars_of
R> # Build the model.
R> dt.mod <- ore.odmDT(gear ~ ., mtcars_of)
R> summary(dt.mod)

Call:
ore.odmDT(formula = gear ~ ., data = mtcars_of)

n = 32

## 4.2.5 Building General Linearized Models

The `ore.odmGLM` function builds Generalized Linear Models (GLM), which include and extend the class of linear models (linear regression). Generalized linear models

relax the restrictions on linear models, which are often violated in practice. For example, binary (yes/no or 0/1) responses do not have same variance across classes.

The Oracle Data Mining GLM is a parametric modeling technique. Parametric models make assumptions about the distribution of the data. When the assumptions are met, parametric models can be more efficient than non-parametric models.

The challenge in developing models of this type involves assessing the extent to which the assumptions are met. For this reason, quality diagnostics are key to developing quality parametric models.

In addition to the classical weighted least squares estimation for linear regression and iteratively re-weighted least squares estimation for logistic regression, both solved through Cholesky decomposition and matrix inversion, Oracle Data Mining GLM provides a conjugate gradient-based optimization algorithm that does not require matrix inversion and is very well suited to high-dimensional data. The choice of algorithm is handled internally and is transparent to the user.

GLM can be used to build classification or regression models as follows:

- **Classification:** Binary logistic regression is the GLM classification algorithm. The algorithm uses the logit link function and the binomial variance function.
- **Regression:** Linear regression is the GLM regression algorithm. The algorithm assumes no target transformation and constant variance over the range of target values.

The `ore.odmGLM` function allows you to build two different types of models. Some arguments apply to classification models only and some to regression models only.

For information on the `ore.odmGLM` function arguments, invoke `help(ore.odmGLM)`.

The following examples build several models using GLM. The input `ore.frame` objects are R data sets pushed to the database.

#### **Example 4-11 Building a Linear Regression Model**

This example builds a linear regression model using the `longley` data set.

```
longley_of <- ore.push(longley)
longfit1 <- ore.odmGLM(Employed ~ ., data = longley_of)
summary(longfit1)
```

#### **Listing for Example 4-11 (page 4-19)**

```
R> longley_of <- ore.push(longley)
R> longfit1 <- ore.odmGLM(Employed ~ ., data = longley_of)
R> summary(longfit1)
```

Call:

```
ore.odmGLM(formula = Employed ~ ., data = longley_of)
```

Residuals:

|  | Min      | 1Q       | Median   | 3Q      | Max     |
|--|----------|----------|----------|---------|---------|
|  | -0.41011 | -0.15767 | -0.02816 | 0.10155 | 0.45539 |

#### **Example 4-12 Using Ridge Estimation for the Coefficients of the ore.odmGLM Model**

This example uses the `longley_of ore.frame` from [Example 4-11](#) (page 4-19). [Example 4-12](#) (page 4-20) invokes the `ore.odmGLM` function and specifies using ridge estimation for the coefficients.

```
longfit2 <- ore.odmGLM(Employed ~ ., data = longley_of, ridge = TRUE,
                      ridge.vif = TRUE)
summary(longfit2)
```

#### **Listing for Example 4-12 (page 4-20)**

```
R> longfit2 <- ore.odmGLM(Employed ~ ., data = longley_of, ridge = TRUE,
+                        ridge.vif = TRUE)
R> summary(longfit2)
```

Call:

```
ore.odmGLM(formula = Employed ~ ., data = longley_of, ridge = TRUE,
           ridge.vif = TRUE)
```

Residuals:

| Min     | 1Q      | Median  | 3Q     | Max    |
|---------|---------|---------|--------|--------|
| -0.4100 | -0.1579 | -0.0271 | 0.1017 | 0.4575 |

```
Residual standard error: 0.3049 on 9 degrees of freedom
Multiple R-squared:  0.9955,    Adjusted R-squared:  0.9925
F-statistic: 330.2 on 6 and 9 DF,  p-value: 4.986e-10
```

#### **Example 4-13 Building a Logistic Regression GLM**

This example builds a logistic regression (classification) model. It uses the `infert` data set. The example invokes the `ore.odmGLM` function and specifies `logistic` as the `type` argument, which builds a binomial GLM.

```
infert_of <- ore.push(infert)
infit1 <- ore.odmGLM(case ~ age+parity+education+spontaneous+induced,
                    data = infert_of, type = "logistic")
infit1
```

#### **Listing for Example 4-13 (page 4-20)**

```

R> infert_of <- ore.push(infert)
R> infit1 <- ore.odmGLM(case ~ age+parity+education+spontaneous+induced,
+                       data = infert_of, type = "logistic")
R> infit1

Response:
case == "1"

Call: ore.odmGLM(formula = case ~ age + parity + education + spontaneous +
  induced, data = infert_of, type = "logistic")

Coefficients:
      (Intercept)          age          parity  education0-5yrs  education12+
yrs      spontaneous      induced
-2.19348      0.03958      -0.82828      1.04424
-0.35896      2.04590      1.28876

Degrees of Freedom: 247 Total (i.e. Null); 241 Residual
Null Deviance: 316.2
Residual Deviance: 257.8      AIC: 271.8

```

#### **Example 4-14 Specifying a Reference Value in Building a Logistic Regression GLM**

This example builds a logistic regression (classification) model and specifies a reference value. The example uses the `infert_of` ore.frame from [Example 4-13](#) (page 4-20).

```

infit2 <- ore.odmGLM(case ~ age+parity+education+spontaneous+induced,
  data = infert_of, type = "logistic", reference = 1)
infit2

```

#### **Listing for Example 4-14 (page 4-21)**

```

infit2 <- ore.odmGLM(case ~ age+parity+education+spontaneous+induced,
  data = infert_of, type = "logistic", reference = 1)
infit2

Response:
case == "0"

Call: ore.odmGLM(formula = case ~ age + parity + education + spontaneous +
  induced, data = infert_of, type = "logistic", reference = 1)

Coefficients:
      (Intercept)          age          parity  education0-5yrs  education12+
yrs      spontaneous      induced

0.35896      -2.04590      -1.28876

Degrees of Freedom: 247 Total (i.e. Null); 241 Residual
Null Deviance: 316.2
Residual Deviance: 257.8      AIC: 271.8

```

## **4.2.6 Building a k-Means Model**

The `ore.odmKM` function uses the Oracle Data Mining *k*-Means (KM) algorithm, a distance-based clustering algorithm that partitions data into a specified number of clusters. The algorithm has the following features:

- Several distance functions: Euclidean, Cosine, and Fast Cosine distance functions. The default is Euclidean.

- For each cluster, the algorithm returns the centroid, a histogram for each attribute, and a rule describing the hyperbox that encloses the majority of the data assigned to the cluster. The centroid reports the mode for categorical attributes and the mean and variance for numeric attributes.

For information on the `ore.odmKM` function arguments, invoke `help(ore.odmKM)`.

#### **Example 4-15 Using the `ore.odmKM` Function**

This example demonstrates the use of the `ore.odmKMeans` function. The example creates two matrices that have 100 rows and two columns. The values in the rows are random variates. It binds the matrices into the matrix `x`, then coerces `x` to a `data.frame` and pushes it to the database as `x_of`, an `ore.frame` object. The example next invokes the `ore.odmKMeans` function to build the KM model, `km.mod1`. It then invokes the `summary` and `histogram` functions on the model. [Figure 4-2](#) (page 4-24) shows the graphic displayed by the `histogram` function.

Finally, the example makes a prediction using the model, pulls the result to local memory, and plots the results. [Figure 4-3](#) (page 4-25) shows the graphic displayed by the `points` function.

```
x <- rbind(matrix(rnorm(100, sd = 0.3), ncol = 2),
            matrix(rnorm(100, mean = 1, sd = 0.3), ncol = 2))
colnames(x) <- c("x", "y")
x_of <- ore.push (data.frame(x))
km.mod1 <- NULL
km.mod1 <- ore.odmKMeans(~., x_of, num.centers=2)
summary(km.mod1)
histogram(km.mod1)
# Make a prediction.
km.res1 <- predict(km.mod1, x_of, type="class", supplemental.cols=c("x","y"))
head(km.res1, 3)
# Pull the results to the local memory and plot them.
km.res1.local <- ore.pull(km.res1)
plot(data.frame(x=km.res1.local$x, y=km.res1.local$y),
      col=km.res1.local$CLUSTER_ID)
points(km.mod1$centers2, col = rownames(km.mod1$centers2), pch = 8, cex=2)
head(predict(km.mod1, x_of, type=c("class","raw"),
          supplemental.cols=c("x","y")), 3)
```

#### **Listing for Example 4-15 (page 4-22)**

```
R> x <- rbind(matrix(rnorm(100, sd = 0.3), ncol = 2),
+             matrix(rnorm(100, mean = 1, sd = 0.3), ncol = 2))
R> colnames(x) <- c("x", "y")
R> x_of <- ore.push (data.frame(x))
R> km.mod1 <- NULL
R> km.mod1 <- ore.odmKMeans(~., x_of, num.centers=2)
R> summary(km.mod1)

### 4.2.7 Building a Naive Bayes Model

The `ore.odmNB` function builds an Oracle Data Mining Naive Bayes model. The Naive Bayes algorithm is based on conditional probabilities. Naive Bayes looks at the historical data and calculates conditional probabilities for the target values by observing the frequency of attribute values and of combinations of attribute values.

Naive Bayes assumes that each predictor is conditionally independent of the others. (Bayes' Theorem requires that the predictors be independent.)

For information on the `ore.odmNB` function arguments, invoke `help(ore.odmNB)`.

#### **Example 4-16 Using the ore.odmNB Function**

This example creates an input `ore.frame`, builds a Naive Bayes model, makes predictions, and generates a confusion matrix.

```
m <- mtcars
m$gear <- as.factor(m$gear)
m$cyl <- as.factor(m$cyl)
m$vs <- as.factor(m$vs)
m$ID <- 1:nrow(m)
mtcars_of <- ore.push(m)
row.names(mtcars_of) <- mtcars_of
# Build the model.
nb.mod <- ore.odmNB(gear ~ ., mtcars_of)
summary(nb.mod)
# Make predictions and generate a confusion matrix.
```

```
nb.res <- predict (nb.mod, mtcars_of, "gear")
with(nb.res, table(gear, PREDICTION))
```

#### Listing for [Example 4-10](#) (page 4-17)

## 4.2.8 Building a Non-Negative Matrix Factorization Model

The `ore.odmNMF` function builds an Oracle Data Mining Non-Negative Matrix Factorization (NMF) model for feature extraction. Each feature extracted by NMF is a linear combination of the original attribution set. Each feature has a set of non-negative coefficients, which are a measure of the weight of each attribute on the feature. If the argument `allow.negative.scores` is `TRUE`, then negative coefficients are allowed.

For information on the `ore.odmNMF` function arguments, invoke `help(ore.odmNMF)`.

### Example 4-17 Using the `ore.odmNMF` Function

This example creates an NMF model on a training data set and scores on a test data set.

```

training.set <- ore.push(npk[1:18, c("N","P","K")])
scoring.set <- ore.push(npk[19:24, c("N","P","K")])
nmf.mod <- ore.odmNMF(~., training.set, num.features = 3)
features(nmf.mod)
summary(nmf.mod)
predict(nmf.mod, scoring.set)

```

### Listing for Example 4-17 (page 4-27)

```

R> training.set <- ore.push(npk[1:18, c("N","P","K")])
R> scoring.set <- ore.push(npk[19:24, c("N","P","K")])

```

```

R> nmf.mod <- ore.odmNMF(~., training.set, num.features = 3)
R> features(nmf.mod)

## 4.2.9 Building an Orthogonal Partitioning Cluster Model

The `ore.odmOC` function builds an Oracle Data Mining model using the Orthogonal Partitioning Cluster (O-Cluster) algorithm. The O-Cluster algorithm builds a hierarchical grid-based clustering model, that is, it creates axis-parallel (orthogonal) partitions in the input attribute space. The algorithm operates recursively. The resulting hierarchical structure represents an irregular grid that tessellates the attribute space into clusters. The resulting clusters define dense areas in the attribute space.

The clusters are described by intervals along the attribute axes and the corresponding centroids and histograms. The `sensitivity` argument defines a baseline density level. Only areas that have a peak density above this baseline level can be identified as clusters.

The *k*-Means algorithm tessellates the space even when natural clusters may not exist. For example, if there is a region of uniform density, *k*-Means tessellates it into *n* clusters (where *n* is specified by the user). O-Cluster separates areas of high density by placing cutting planes through areas of low density. O-Cluster needs multi-modal histograms (peaks and valleys). If an area has projections with uniform or monotonically changing density, O-Cluster does not partition it.

The clusters discovered by O-Cluster are used to generate a Bayesian probability model that is then used during scoring by the `predict` function for assigning data points to clusters. The generated probability model is a mixture model where the mixture components are represented by a product of independent normal distributions for numeric attributes and multinomial distributions for categorical attributes.

If you choose to prepare the data for an O-Cluster model, keep the following points in mind:

- The O-Cluster algorithm does not necessarily use all the input data when it builds a model. It reads the data in batches (the default batch size is 50000). It only reads another batch if it believes, based on statistical tests, that there may still exist clusters that it has not yet uncovered.
- Because O-Cluster may stop the model build before it reads all of the data, it is highly recommended that the data be randomized.
- Binary attributes should be declared as categorical. O-Cluster maps categorical data to numeric values.
- The use of Oracle Data Mining equi-width binning transformation with automated estimation of the required number of bins is highly recommended.
- The presence of outliers can significantly impact clustering algorithms. Use a clipping transformation before binning or normalizing. Outliers with equi-width binning can prevent O-Cluster from detecting clusters. As a result, the whole population appears to fall within a single cluster.

The specification of the `formula` argument has the form `~ terms` where `terms` are the column names to include in the model. Multiple `terms` items are specified using `+` between column names. Use `~ .` if all columns in `data` should be used for model building. To exclude columns, use `-` before each column name to exclude.

For information on the `ore.odmOC` function arguments, invoke `help(ore.odmOC)`.

**Example 4-18 Using the ore.odmOC Function**

This example creates an OC model on a synthetic data set. [Figure 4-4](#) (page 4-31) shows the histogram of the resulting clusters.

```
x <- rbind(matrix(rnorm(100, mean = 4, sd = 0.3), ncol = 2),
            matrix(rnorm(100, mean = 2, sd = 0.3), ncol = 2))
colnames(x) <- c("x", "y")
x_of <- ore.push (data.frame(ID=1:100,x))
rownames(x_of) <- x_of$ID
oc.mod <- ore.odmOC(~., x_of, num.centers=2)
summary(oc.mod)
```

**Listing for Example 4-18 (page 4-30)**

```
R> x <- rbind(matrix(rnorm(100, mean = 4, sd = 0.3), ncol = 2),
+             matrix(rnorm(100, mean = 2, sd = 0.3), ncol = 2))
R> colnames(x) <- c("x", "y")
R> x_of <- ore.push (data.frame(ID=1:100,x))
R> rownames(x_of) <- x_of$ID
R> oc.mod <- ore.odmOC(~., x_of, num.centers=2)
R> summary(oc.mod)
```

Call:

```
ore.odmOC(formula = ~., data = x_of, num.centers = 2)
```

#### 4.2.10 Building a Support Vector Machine Model

The `ore.odmSVM` function builds an Oracle Data Mining Support Vector Machine (SVM) model. SVM is a powerful, state-of-the-art algorithm with strong theoretical foundations based on the Vapnik-Chervonenkis theory. SVM has strong regularization properties. Regularization refers to the generalization of the model to new data.

SVM models have similar functional form to neural networks and radial basis functions, both popular data mining techniques.

SVM can be used to solve the following problems:

- **Classification:** SVM classification is based on decision planes that define decision boundaries. A decision plane is one that separates between a set of objects having different class memberships. SVM finds the vectors ("support vectors") that define the separators that give the widest separation of classes.

SVM classification supports both binary and multiclass targets.

- **Regression:** SVM uses an epsilon-insensitive loss function to solve regression problems.  
SVM regression tries to find a continuous function such that the maximum number of data points lie within the epsilon-wide insensitivity tube. Predictions falling within epsilon distance of the true target value are not interpreted as errors.
- **Anomaly Detection:** Anomaly detection identifies identify cases that are unusual within data that is seemingly homogeneous. Anomaly detection is an important tool for detecting fraud, network intrusion, and other rare events that may have great significance but are hard to find.  
Anomaly detection is implemented as one-class SVM classification. An anomaly detection model predicts whether a data point is typical for a given distribution or not.

The `ore.odmSVM` function builds each of these three different types of models. Some arguments apply to classification models only, some to regression models only, and some to anomaly detection models only.

For information on the `ore.odmSVM` function arguments, invoke `help(ore.odmSVM)`.

#### **Example 4-19 Using the `ore.odmSVM` Function and Generating a Confusion Matrix**

This example demonstrates the use of SVM classification. The example creates `mtcars` in the database from the R `mtcars` data set, builds a classification model, makes predictions, and finally generates a confusion matrix.

```
m <- mtcars
m$gear <- as.factor(m$gear)
m$cyl <- as.factor(m$cyl)
m$vs <- as.factor(m$vs)
m$ID <- 1:nrow(m)
mtcars_of <- ore.push(m)
svm.mod <- ore.odmSVM(gear ~ .-ID, mtcars_of, "classification")
summary(svm.mod)
svm.res <- predict(svm.mod, mtcars_of, "gear")
with(svm.res, table(gear, PREDICTION)) # generate confusion matrix
```

#### **Listing for [Example 4-19](#) (page 4-32)**

```
R> m <- mtcars
R> m$gear <- as.factor(m$gear)
R> m$cyl <- as.factor(m$cyl)
R> m$vs <- as.factor(m$vs)
R> m$ID <- 1:nrow(m)
R> mtcars_of <- ore.push(m)
R>
R> svm.mod <- ore.odmSVM(gear ~ .-ID, mtcars_of, "classification")
R> summary(svm.mod)
Call:
ore.odmSVM(formula = gear ~ . - ID, data = mtcars_of, type = "classification")
```

#### **Example 4-20 Using the ore.odmSVM Function and Building a Regression Model**

This example demonstrates SVM regression. The example creates a data frame, pushes it to a table, and then builds a regression model; note that `ore.odmSVM` specifies a linear kernel.

```
x <- seq(0.1, 5, by = 0.02)
```

```
y <- log(x) + rnorm(x, sd = 0.2)
```

```
dat <- ore.push(data.frame(x=x, y=y))
```

```
# Build model with linear kernel
```

```
svm.mod <- ore.odmSVM(y~x,dat,"regression", kernel.function="linear")
```

```
summary(svm.mod)
```

```
coef(svm.mod)
```

```
svm.res <- predict(svm.mod,dat, supplemental.cols="x")
```

```
head(svm.res,6)
```

#### **Listing for Example 4-20 (page 4-33)**

```
R> x <- seq(0.1, 5, by = 0.02)
```

```
R> y <- log(x) + rnorm(x, sd = 0.2)
```

```
R> dat <- ore.push(data.frame(x=x, y=y))
```

```
R>
```

```
R> # Build model with linear kernel

## 4.3 Cross-Validating Models

Predictive models are usually built on given data and verified on held-aside or unseen data. Cross-validation is a model improvement technique that avoids the limitations of a single train-and-test experiment by building and testing multiple models through repeated sampling from the available data. Its purpose is to offer better insight into how well the model would generalize to new data and to avoid over-fitting and deriving wrong conclusions from misleading peculiarities of the seen data.

The `ore.CV` utility R function uses Oracle R Enterprise for performing cross-validation of regression and classification models. The function `ore.CV` is available for download from the following Oracle R Technologies blog post:

[https://blogs.oracle.com/R/entry/model\\_cross\\_validation\\_with\\_ore](https://blogs.oracle.com/R/entry/model_cross_validation_with_ore)

For a select set of algorithms and cases, the function `ore.CV` performs cross-validation for models that were generated by Oracle R Enterprise regression and classification functions using in-database data.

The `ore.CV` function works with models generated by the following Oracle R Enterprise functions:

- `ore.lm`
- `ore.stepwise`
- `ore.glm`
- `ore.neural`
- `ore.odmDT`
- `ore.odmGLM`
- `ore.odmNB`
- `ore.odmSVM`

You can also use `ore.CV` to cross-validate models generated with some R regression functions through Oracle R Enterprise embedded R execution. Those R functions are the following:

- `lm`
- `glm`
- `svm`

For more information on, and examples of, using `ore.CV`, and to download the function itself, see the blog post:

[https://blogs.oracle.com/R/entry/model\\_cross\\_validation\\_with\\_ore](https://blogs.oracle.com/R/entry/model_cross_validation_with_ore)

---

## Predicting With R Models

This chapter describes the Oracle R Enterprise function `ore.predict` and provides some examples of its use. The chapter contains the following topics:

- [About the ore.predict Function](#) (page 5-1)
- [Using the ore.predict Function](#) (page 5-2)

### 5.1 About the ore.predict Function

Predictive models allow you to predict future behavior based on past behavior. After you build a model, you use it to score new data, that is, to make predictions.

R allows you to build many kinds of models. When you score data to predict new results using an R model, the data to score must be in an R `data.frame`. With the `ore.predict` function, you can use an R model to score database-resident data in an `ore.frame` object.

The `ore.predict` function provides the fastest way to operationalize R-based models for scoring in Oracle Database. The function has no dependencies on PMML or any other plug-ins.

Some advantages of using the `ore.predict` function to score data in the database are the following:

- Uses R-generated models to score in-database data.  
The data to score is in an `ore.frame` object.
- Maximizes the use of Oracle Database as a compute engine.  
The database provides a commercial grade, high performance, scalable scoring engine.
- Simplifies application workflow.  
You can go from a model to SQL scoring in one step.

The `ore.predict` function is a generic function. It has the following usage:

```
ore.predict(object, newdata, ...)
```

The value of the `object` argument is one of the model objects listed in [Table 5-1](#) (page 5-2). The value of the `newdata` argument is an `ore.frame` object that contains the data to score. The `ore.predict` function has methods for use with specific R model classes. The `...` argument represents the various additional arguments that are accepted by the different methods.

Function `ore.predict` has methods that support the model objects listed in [Table 5-1](#) (page 5-2).

**Table 5-1 Models Supported by the ore.predict Function**

| Class of Model | Description of Model                                                                                               |
|----------------|--------------------------------------------------------------------------------------------------------------------|
| glm            | Generalized linear model                                                                                           |
| kmeans         | <i>k</i> -Means clustering model                                                                                   |
| lm             | Linear regression model                                                                                            |
| matrix         | A <code>matrix</code> with no more than 1000 rows, for use in an <code>hclust</code> hierarchical clustering model |
| multinom       | Multinomial log-linear model                                                                                       |
| nnet           | Neural network model                                                                                               |
| ore.model      | An Oracle R Enterprise model from the <code>OREModels</code> package                                               |
| prcomp         | Principal components analysis on a matrix                                                                          |
| princomp       | Principal components analysis on a numeric matrix                                                                  |
| rpart          | Recursive partitioning and regression tree model                                                                   |

For the function signatures of the `ore.predict` methods, invoke the `help` function on the following, as in `help("ore.predict-kmeans")`:

- `ore.predict-glm`
- `ore.predict-kmeans`
- `ore.predict-lm`
- `ore.predict-matrix`
- `ore.predict-multinom`
- `ore.predict-nnet`
- `ore.predict-ore.model`
- `ore.predict-prcomp`
- `ore.predict-princomp`
- `ore.predict-rpart`

## 5.2 Using the ore.predict Function

The following examples demonstrate the use of the `ore.predict` function.

- [Example 5-1](#) (page 5-3)
- [Example 5-2](#) (page 5-3)
- [Example 5-3](#) (page 5-4)

**Example 5-1 Using the ore.predict Function on a Linear Regression Model**

This example builds a linear regression model, `irisModel`, using the `lm` function on the `iris` data frame. It pushes the data set to the database as the temporary table `IRIS` and the corresponding ore.frame proxy, `IRIS`. The example scores the model by invoking `ore.predict` on it and then combines the prediction with `IRIS` ore.frame object. Finally, it displays the first six rows of the resulting object.

```
IRISModel <- lm(Sepal.Length ~ ., data = iris)
IRIS <- ore.push(iris)
IRIS_pred <- ore.predict(IRISModel, IRIS, se.fit = TRUE,
                        interval = "prediction")
IRIS <- cbind(IRIS, IRIS_pred)
head(IRIS)
```

**Listing for Example 5-1 (page 5-3)**

```
R> IRISModel <- lm(Sepal.Length ~ ., data = iris)
R> IRIS <- ore.push(iris)
R> IRIS_pred <- ore.predict(IRISModel, IRIS, se.fit = TRUE,
+                           interval = "prediction")
R> IRIS <- cbind(IRIS, IRIS_pred)
R> head(IRIS)
```

|   | Sepal.Length | Sepal.Width | Petal.Length | Petal.Width | Species | PRED     | SE.PRED    |

6  4.772430  6.005342
```

**Example 5-2 Using the ore.predict Function on a Generalized Linear Regression Model**

This example builds a generalized linear model using the `infert` data set and then invokes the `ore.predict` function on the model.

```
infertModel <-
  glm(case ~ age + parity + education + spontaneous + induced,
```

```

data = infert, family = binomial())
INFERT <- ore.push(infert)
INFERTpred <- ore.predict(infertModel, INFERT, type = "response",
                          se.fit = TRUE)
INFERT <- cbind(INFERT, INFERTpred)
head(INFERT)

```

#### Listing for Example 5-2 (page 5-3)

```

R> infertModel <-
+   glm(case ~ age + parity + education + spontaneous + induced,
+   data = infert, family = binomial())
R> INFERT <- ore.push(infert)
R> INFERTpred <- ore.predict(infertModel, INFERT, type = "response",
+                             se.fit = TRUE)
R> INFERT <- cbind(INFERT, INFERTpred)
R> head(INFERT)

```

|   | education | age | parity | induced | case | spontaneous | stratum | pooled.stratum |
|---|-----------|-----|--------|---------|------|-------------|---------|----------------|
| 1 | 0-5yrs    | 26  | 6      | 1       | 1    | 2           | 1       | 3              |
| 2 | 0-5yrs    | 42  | 1      | 1       | 1    | 0           | 2       | 1              |

#### Example 5-3 Using the ore.predict Function on an ore.model Model

This example pushes the `iris` data set to the database as the temporary table `IRIS` and the corresponding `ore.frame` proxy, `IRIS`. The example builds a linear regression model, `IRISModel2`, using the `ore.lm` function. It scores the model and adds a column to `IRIS`.

```

IRIS <- ore.push(iris)
IRISModel2 <- ore.lm(Sepal.Length ~ ., data = IRIS)
IRIS$PRED <- ore.predict(IRISModel2, IRIS)
head(IRIS, 3)

```

#### Listing for Example 5-3 (page 5-4)

```

R> IRIS <- ore.push(iris)
R> IRISModel2 <- ore.lm(Sepal.Length ~ ., data = IRIS)
R> IRIS$PRED <- ore.predict(IRISModel2, IRIS)
R> head(IRIS, 3)

```

# Using Oracle R Enterprise Embedded R Execution

Embedded R execution in Oracle R Enterprise enables you to invoke R scripts in R sessions that run on the Oracle Database server. This chapter discusses embedded R execution in the following topics:

- [About Oracle R Enterprise Embedded R Execution](#) (page 6-1)
- [R Interface for Embedded R Execution](#) (page 6-9)
- [SQL Interface for Embedded R Execution](#) (page 6-43)

## 6.1 About Oracle R Enterprise Embedded R Execution

In Oracle R Enterprise, embedded R execution is the ability to store R scripts in the Oracle R Enterprise R script repository and to invoke such scripts. When invoked, a script executes in one or more R engines that run on the database server and that are dynamically started and managed by the database. Oracle R Enterprise provides both an R interface and a SQL interface for embedded R execution. From the same R script you can get structured data, an XML representation of R objects and images, and even PNG images through a BLOB column in a database table.

This section has the following topics:

- [Benefits of Embedded R Execution](#) (page 6-1)
- [APIs for Embedded R Execution](#) (page 6-2)
- [Security Considerations for Scripts](#) (page 6-3)
- [Support for Parallel Execution](#) (page 6-4)
- [Installing a Third-Party Package for Use in Embedded R Execution](#) (page 6-5)

### 6.1.1 Benefits of Embedded R Execution

Embedded R execution has the following benefits:

- Eliminates moving data from the Oracle Database server to your local R session.  
As well as being more secure, the transfer of database data between Oracle Database and an internal R engine is much faster than to a separate client R engine.
- Uses the database server to start, manage, and control the execution of R scripts in R engines running on the server.
- Leverages the memory and processing power of the database server machine for R engine execution, which provides better scalability and performance.

- Enables data-parallel and task-parallel execution of user-defined R functions that correspond to special cases of Hadoop Map-Reduce jobs.
- Provides parallel simulations capability.
- Allows the use of open source CRAN packages in R scripts running on the database server.

- Provides the ability to develop and operationalize comprehensive scripts for analytical applications in a single step, without leaving the R environment.

You can directly integrate R scripts used in exploratory analysis into application tasks. You can also immediately invoke R scripts in production to drastically reduce time to market by eliminating porting and enabling instantaneous updates of changes to application code.

- Executing R scripts from SQL enables integration of R script results with Oracle Business Intelligence Enterprise Edition (OBIEE), Oracle BI Publisher, and other SQL-enabled tools for structured data, R objects, and images.

## 6.1.2 APIs for Embedded R Execution

Oracle R Enterprise provides R and SQL application programming interfaces for embedded R execution. The following table lists the R functions and the equivalent SQL functions and procedures for embedded R execution and R script repository management. The function *f* refers to a named R function or an R function defined in a script in the Oracle R Enterprise R script repository.

**Table 6-1 R and SQL APIs for Embedded R Execution**

| R API                       | SQL API                                                                           | Description                                                                                                                                                                                                                                                                                                          |
|-----------------------------|-----------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>ore.doEval</code>     | <code>rqEval</code>                                                               | Executes <i>f</i> with no automatic transfer of data.                                                                                                                                                                                                                                                                |
| <code>ore.tableApply</code> | <code>rqTableEval</code>                                                          | Executes <i>f</i> by passing all rows of the provided input <code>ore.frame</code> as the first argument of <i>f</i> . Provides the first argument of <i>f</i> as a <code>data.frame</code> .                                                                                                                        |
| <code>ore.groupApply</code> | <code>rqGroupEval</code><br>This function must be explicitly defined by the user. | Executes <i>f</i> by partitioning data according to the values of a grouping column. Provides each data partition as a <code>data.frame</code> in the first argument of <i>f</i> . Supports parallel execution of each <i>f</i> invocation in the pool of database server-side R engines.                            |
| <code>ore.rowApply</code>   | <code>rqRowEval</code>                                                            | Executes <i>f</i> by passing a specified number of rows (a <i>chunk</i> ) of the provided input <code>ore.frame</code> . Provides each chunk as a <code>data.frame</code> in the first argument of <i>f</i> . Supports parallel execution of each <i>f</i> invocation in the pool of database server-side R engines. |
| <code>ore.indexApply</code> | No equivalent.                                                                    | Executes <i>f</i> with no automatic transfer of data but provides the index of the invocation, 1 through <i>n</i> , where <i>n</i> is the number of times to invoke the function. Supports parallel execution of each <i>f</i> invocation in the pool of R engines running on the database server.                   |
| <code>ore.grant</code>      | <code>rqGrant</code>                                                              | Grants read privilege access to a datastore or script.                                                                                                                                                                                                                                                               |
| <code>ore.revoke</code>     | <code>rqRevoke</code>                                                             | Revokes read privilege access to a datastore or script.                                                                                                                                                                                                                                                              |

**Table 6-1 (Cont.) R and SQL APIs for Embedded R Execution**

| R API                         | SQL API                           | Description                                                                                           |
|-------------------------------|-----------------------------------|-------------------------------------------------------------------------------------------------------|
| <code>ore.scriptCreate</code> | <code>sys.rqScriptCreate</code>   | Adds the provided R function into the Oracle R Enterprise R script repository with the provided name. |
| <code>ore.scriptDrop</code>   | <code>sys.rqScriptDrop</code>     | Removes the named R function from the Oracle R Enterprise R script repository.                        |
| <code>ore.scriptList</code>   | ALL_RQ_SCRIPTS<br>USER_RQ_SCRIPTS | Lists information about scripts.                                                                      |
| <code>ore.scriptLoad</code>   | No equivalent.                    | Loads the R function of a script into the R environment.                                              |

### 6.1.3 Security Considerations for Scripts

Because R scripts allow access to the database server, the creation of scripts must be controlled. The RQADMIN role is a collection of Oracle Database privileges that a user must have to create scripts and store them in the Oracle R Enterprise R script repository or drop scripts from the repository.

The installation of Oracle R Enterprise on the database server creates the RQADMIN role. The role must be explicitly granted to a user. To grant RQADMIN to a user, start SQL\*Plus as sysdba and enter a GRANT statement such as the following, which grants the role to the user RQUSER:

```
GRANT RQADMIN to RQUSER
```

**Note:**

You should grant RQADMIN only to those users who need it.

When creating a script, the owner can use the `global` argument to specify whether the script is public or private. If `global = TRUE`, then all users have read privilege access to the script. If `global = FALSE`, which is the default, then the owner can share the script by granting access to other users. The owner can revoke the access at any time.

- ["Manage Scripts in SQL \(page 6-46\)"](#)

## 6.1.4 Support for Parallel Execution

Some of the Oracle R Enterprise embedded R execution functions support the use of parallel execution in the database. The `ore.groupApply`, `ore.rowApply`, `rq.groupEval`, and `rq.rowEval` functions support data-parallel execution and the `ore.indexApply` function supports task-parallel execution. This parallel execution capability enables a script to take advantage of high-performance computing hardware such as an Oracle Exadata Database Machine.

The `parallel` argument of the `ore.groupApply`, `ore.rowApply`, and `ore.indexApply` functions specifies the degree of parallelism to use in the embedded R execution. The value of the argument can be one of the following:

- A positive integer greater than or equal to 2 for a specific degree of parallelism
- `FALSE` or 1 for no parallelism
- `TRUE` for the default parallelism of the `data` argument
- `NULL` for the database default for the operation

The default value of the argument is the value of the global option `ore.parallel` or `FALSE` if `ore.parallel` is not set.

A user-defined R function invoked using `ore.doEval` or `ore.tableApply` is not executed in parallel. The function executes in a single R engine.

For the `rq.groupEval`, and `rq.rowEval` functions, the degree of parallelism is specified by a `PARALLEL` hint in the input cursor argument.

In data-parallel execution for the `ore.groupApply` and `rq.groupEval` functions, one or more R engines perform the same R function, or task, on different partitions of data. This functionality enables the building of large numbers of models, for example building tens or hundreds of thousands of predictive models, one model per customer.

In data-parallel execution for the `ore.rowApply` and `rq.rowEval` functions, one or more R engines perform the same R function on disjoint chunks of data. This functionality enables scalable model scoring and predictions on large data sets.

In task-parallel execution for the `ore.indexApply` function, one or more R engines perform the same or different calculations, or task. A number, associated with the index of the execution, is provided to the function. This functionality is valuable in a variety of operations, such as in performing simulations.

Oracle Database handles the management and control of potentially multiple R engines at the database server, automatically partitioning and passing data to R engines executing in parallel. It ensures that all of the R function executions for all of the partitions complete; if not, the Oracle R Enterprise function returns an error. The result from the execution of each user-defined embedded R function is gathered in an `ore.list`. This list remains in the database until the user requires the result.

Embedded R execution also allows for data-parallel execution of user-defined R functions that may use functions from an open source R package from The Comprehensive R Archive Network (CRAN) or other third-party R package. However, third-party packages do not leverage in-database parallelism and are subject to the parallelism constraints of R. Third-party packages can benefit from the data-parallel and task-parallel execution supported in embedded R execution.

## 6.1.5 Installing a Third-Party Package for Use in Embedded R Execution

Embedded R execution allows the use of CRAN or other third-party packages in user-defined R functions executed on the Oracle Database server. To use a third-party package in embedded R execution, the package must be installed on the database server. If you are going to use the package from the R interface for embedded R execution, then the package must also be installed on the client, as well. To avoid incompatibilities, you must install the same version of the package on both the client and server machines.

An Oracle Database Administrator (DBA) can install a package on a database server so that it can be used by embedded R execution functions or by any R user. The DBA can install a package on a single database server or on multiple database servers.

A DBA would typically do the following:

1. Download and install the package from CRAN. Downloading a package from CRAN requires an Internet connection.
2. In an Oracle R Enterprise session running on the server, load the package. Verify that the package is installed correctly by using a function in the package.

To install a package on a single database server, do one of the following:

- In an Oracle R Enterprise session running on the server, invoke the `install.packages` function, as shown in [Example 6-1](#) (page 6-5). The function downloads the package and installs dependencies automatically.
- Download the package source from CRAN using `wget`. If the package depends on any packages that are not in the R distribution in use, then download those packages, also.

From the operating system command line, use the `ORE CMD INSTALL` command to install the package or packages in the same location as the Oracle R Enterprise packages, which is `$ORACLE_HOME/R/Library`. See [Example 6-2](#) (page 6-6).

To install a package, and any dependent packages, on multiple database servers, such as those in an Oracle Real Application Clusters (Oracle RAC) or a multinode Oracle Exadata Database Machine environment, use the Exadata Distributed Command Line Interface (DCLI) utility, as shown in [Example 6-3](#) (page 6-8). For detailed instructions on using DCLI to install packages, see *Oracle R Enterprise Installation and Administration Guide*.

To verify that the package is installed correctly, load the package and use a function in the package, as shown in [Example 6-4](#) (page 6-8).

### **Example 6-1 Installing a Package for a Single Database in an Oracle R Enterprise Session**

This example invokes the `install.packages` function to download the `C50` package from CRAN and to install it. The `C50` package contains functions for creating C5.0 decision trees and rule-based models for pattern recognition.

The output this example, which is not shown, is almost identical to the output of the `ORE CMD INSTALL` command in [Example 6-2](#) (page 6-6).

```
install.packages("c50")
```

**Example 6-2 Installing a Package for a Single Database from the Command Line**

This example demonstrates downloading the C50 package from CRAN and installing it with ORE CMD INSTALL from a Linux command line.

```
wget http://cran.r-project.org/src/contrib/C50_0.1.0-19.tar.gz
```

```
ORE CMD INSTALL C50_0.1.0-19.tar.gz
```

**Lising for [Example 6-2](#) (page 6-6)**

```
$ wget http://cran.r-project.org/src/contrib/C50_0.1.0-19.tar.gz
# The output of wget is not shown.
$ ORE CMD INSTALL C50_0.1.0-19.tar.gz

**Example 6-3 Installing a Package Using DCLI**

This example shows the DCLI command for installing the C50 package. The `dc li -g` flag designates a file containing a list of nodes to install on, and the `-l` flag specifies the user ID to use when executing the commands. For more information on using DCLI, see *Oracle R Enterprise Installation and Administration Guide*.

```
dc li -g nodes -l oracle R CMD INSTALL C50_0.1.0-19.tar.gz
```

**Example 6-4 Using a C50 Package Function**

This example shows starting R, connecting to Oracle R Enterprise on the server, loading the C50 package, and using a function in the package. The example starts R by executing the `ORE` command from the Linux command line. The example connects to Oracle R Enterprise and then loads the C50 package. It invokes the `demo` function to look for example programs in the package. Because the package does not have examples, this example then gets help for the `C5.0` function. The example invokes example code from the help.

```
ORE

library(ORE)
ore.connect(user = "RUSER", sid = "orcl", host = "myhost",
            password = "ruserStrongPassword", port = 1521, all=TRUE)

library(C50)
demo(package = "C50")
?C5.0
data(churn)
treeModel <- C5.0(x = churnTrain[, -20], y = churnTrain$churn)
treeModel
```

**Listing for Example 6-4 (page 6-8)**

```
$ ORE

## 6.2 R Interface for Embedded R Execution

Oracle R Enterprise provides functions that invoke R scripts that run in one or more R engines that are embedded in the Oracle database. Other functions create and store an R function as a script in the Oracle R Enterprise R script repository, grant or revoke read access to a script, list the available scripts, load a script function into the R environment, or drop a script from the repository. This section describes these functions in the following topics:

- [Arguments for Functions that Run Scripts](#) (page 6-9)
- [Manage Scripts Using the R API](#) (page 6-13)
- [Using the ore.doEval Function](#) (page 6-19)
- [Using the ore.tableApply Function](#) (page 6-25)
- [Using the ore.groupApply Function](#) (page 6-26)
- [Using the ore.rowApply Function](#) (page 6-33)
- [Using the ore.indexApply Function](#) (page 6-39)

### 6.2.1 Arguments for Functions that Run Scripts

The Oracle R Enterprise embedded R execution functions `ore.doEval`, `ore.tableApply`, `ore.groupApply`, `ore.rowApply`, and `ore.indexApply` have

arguments that are common to some or all of the functions. Some of the functions also have an argument that is unique to the function.

This section describes the arguments in the following topics:

- [Input Function to Execute](#) (page 6-10)
- [Optional and Control Arguments](#) (page 6-11)
- [Structure of Return Value](#) (page 6-12)
- [Input Data](#) (page 6-12)
- [Parallel Execution](#) (page 6-13)
- [Unique Arguments](#) (page 6-13)

---

**See Also:**

- For function signatures and more details about function arguments, see the online help displayed by invoking `help(ore.doEval)`
  - For examples of the use of the arguments, see "[Using the ore.doEval Function](#) (page 6-19)" and the other topics on using the embedded R execution functions
- 

### 6.2.1.1 Input Function to Execute

The embedded R execution functions all require a function to apply during the execution of the script. You specify the input function with one of the following mutually exclusive arguments:

- `FUN`
- `FUN.NAME` (and optional `FUN.OWNER`)

The `FUN` argument takes a function object as a directly specified function or as one assigned to an R variable. Only a user with the `RQADMIN` role can use the `FUN` argument when invoking an embedded R function.

The `FUN.NAME` argument specifies a script that is stored in the Oracle R Enterprise R script repository. A stored script contains the function to apply when the script runs. Any Oracle R Enterprise user can use the `FUN.NAME` argument when invoking an embedded R function.

The optional argument `FUN.OWNER` specifies the owner of a script in the R script repository. The owner is the user who created the script. Use this argument only with the `FUN.NAME` argument. When `FUN.NAME` is a private script to which you have been granted read privilege access, use `FUN.OWNER` to specify the owner of the private script.

The `RQSYS` schema is the owner of public scripts and the predefined Oracle R Enterprise scripts. For a list of the predefined scripts, invoke `help("ore.doEval")` and see the description of the `FUN.NAME` argument. If `FUN.OWNER` is not specified or is `NULL`, then Oracle R Enterprise looks for the owner in the following order: user of the current session, `RQSYS`. If the owner of the script is not current user or `RQSYS`, then an error occurs.

**Note:**

The Oracle R Enterprise advanced analytics functions in the `OREmodels` package, `ore.glm`, `ore.lm`, `ore.neural`, and `ore.randomForest`, use the embedded R execution framework internally and cannot be used in embedded R execution functions.

### 6.2.1.2 Optional and Control Arguments

All of the embedded R execution functions take optional arguments, which can be named or not. Oracle R Enterprise passes user-defined optional arguments to the input function. You can pass any number of optional arguments to the input function, including complex R objects such as models.

Arguments that start with `ore.` are special control arguments. Oracle R Enterprise does not pass them to the input function, but instead uses them to control what happens before or after the execution of that function. The following control arguments are supported:

- `ore.connect` controls whether to automatically connect to Oracle R Enterprise inside the embedded R execution function. This is equivalent to doing an `ore.connect` call with the same credentials as the client session. The default value is `FALSE`.

If an automatic connection is enabled, the following functionality occurs:

- The embedded R script is connected to the database.
- The connection has the same credentials as the session that invokes the embedded R SQL function.
- The script runs in an autonomous transaction.
- ROracle queries can work with the automatic connection.
- Oracle R Enterprise transparency layer functionality is enabled in the embedded script.
- `ore.drop` controls the input data. If the option value is `TRUE`, a one column `data.frame` is converted to a `vector`. The default value is `TRUE`.
- `ore.envAsEmptyenv` controls whether an environment referenced in an object is replaced with an empty environment during serialization. Some types of input parameters and returned objects, such as `list` and `formula`, are serialized before being saved to the database. If the control argument value is `TRUE`, then the referenced environment in the object is replaced with an empty environment whose parent is `.GlobalEnv` and the objects in the original referenced environment are not serialized. In some cases, this can significantly reduce the size of serialized objects. If the control argument value is `FALSE`, then all of the objects in the referenced environment are serialized and can be unserialized and recovered later. The default value is regulated by the global option `ore.envAsEmptyenv`.
- `ore.na.omit` controls the handling of missing values in the input data. If you specify `ore.na.omit = TRUE`, then rows or vector elements, depending on the `ore.drop` setting, that contain missing values are removed from the input data. If all of the rows in a chunk contain missing values, then the input data for that chunk will be an empty `data.frame` or `vector`. The default value is `FALSE`.

- `ore.graphics` controls whether to start a graphical driver and look for images. The default value is `TRUE`.
- `ore.png.*` specifies additional arguments for the `png` graphics driver if `ore.graphics` is `TRUE`. The naming convention for these arguments is to add an `ore.png.` prefix to the arguments of the `png` function. For example, if `ore.png.height` is supplied, argument `height` is passed to the `png` function. If not set, the standard default values for the `png` function are used.

---

**See Also:**

For more details about control arguments, see the online help displayed by invoking `help(ore.doEval)`

---

### 6.2.1.3 Structure of Return Value

Another argument that applies to all of the embedded R execution functions is `FUN.VALUE`. If the `FUN.VALUE` argument is `NULL`, then the `ore.doEval` and `ore.tableApply` function can return a serialized R object as an `ore.object` class object, and the `ore.groupApply`, `ore.indexApply`, and `ore.rowApply` functions return an `ore.list` object. However, if you specify a `data.frame` or an `ore.frame` with the `FUN.VALUE` argument, then the function returns an `ore.frame` that has the structure of the specified `data.frame` or `ore.frame` object.

To specify that the corresponding output column of an `ore.frame` have a `CLOB` or `BLOB` database data type, you can apply the attribute `ora.type` to a column of a `FUN.VALUE data.frame`. For an example of using `ora.type`, see [Example 6-11](#) (page 6-23).

### 6.2.1.4 Input Data

The `ore.doEval` and `ore.indexApply` functions do not automatically receive any data from the database. They simply execute the function specified by the `FUN` or `FUN.NAME` argument. Any data needed by the input function is either generated within that function or explicitly retrieved from a data source such as Oracle Database, other databases, or flat files. The input function can load data from a file or a table using the `ore.pull` function or other transparency layer function.

The `ore.tableApply`, `ore.groupApply`, and `ore.rowApply` functions require a database table as input data. The table is represented by an `ore.frame`. You supply that data with an `ore.frame` object that you specify with the `X` argument, which is the first argument to the embedded R execution function. The embedded R execution function passes the `ore.frame` object to the user-defined input function as the first argument to that function.

---

**Note:**

The data represented by the `ore.frame` object passed to the user-defined R function is copied from Oracle Database to the database server R engine. The R memory limitations apply. If your database server machine has 32 GB RAM and your data table is 64 GB, then Oracle R Enterprise cannot load the data into the R engine memory.

---

### 6.2.1.5 Parallel Execution

The `ore.groupApply`, `ore.indexApply`, and `ore.rowApply` functions take the `parallel` argument. That argument specifies the degree of parallelism to use in the embedded R execution of the input function. See ["Support for Parallel Execution \(page 6-4\)"](#).

### 6.2.1.6 Unique Arguments

The `ore.groupApply`, `ore.indexApply`, and `ore.rowApply` functions each take an argument unique to the function.

The `ore.groupApply` function takes the `INDEX` argument, which specifies the name of a column by which the rows of the input data are partitioned for processing by the input function.

The `ore.indexApply` function takes the `times` argument, which specifies the number of times to execute the input function.

The `ore.rowApply` function takes the `rows` argument, which specifies the number of rows to pass to each invocation of the input function.

## 6.2.2 Manage Scripts in R

Embedded R execution functions can invoke R functions that are stored as scripts in the Oracle R Enterprise R script repository. You can use the R functions described in this topic to create and manage scripts.

As mentioned in ["Input Function to Execute \(page 6-10\)"](#), the embedded R execution functions can take a `FUN.NAME` argument. That argument specifies the name of a script in the Oracle R Enterprise R script repository. Scripts in the R script repository are also available through the SQL API for embedded R execution.

The R functions for managing scripts are the following:

- `ore.grant`
- `ore.revoke`
- `ore.scriptCreate`
- `ore.scriptList`
- `ore.scriptLoad`
- `ore.scriptDrop`

These functions are described in the following sections:

- [Adding a Script \(page 6-14\)](#)
- [Granting or Revoking Read Access to a Script \(page 6-14\)](#)
- [Listing the Available Scripts \(page 6-15\)](#)
- [Loading a Script into an R Environment \(page 6-15\)](#)
- [Dropping a Script \(page 6-16\)](#)

For an example that uses these functions, see [Example 6-5 \(page 6-16\)](#).

### Adding a Script

To add an R function as a script in the Oracle R Enterprise R script repository, use the `ore.createScript` function. To evoke this function, you must have the RQADMIN role. The `ore.createScript` function has the following syntax:

```
ore.scriptCreate(name, FUN, global, overwrite)
```

The arguments are the following:

| Argument               | Description                                                                                                                                                                                                                                                                                                                 |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>name</code>      | A name for the script in the Oracle R Enterprise R script repository.                                                                                                                                                                                                                                                       |
| <code>fun</code>       | An R function.                                                                                                                                                                                                                                                                                                              |
| <code>global</code>    | A logical value that indicates whether the script is public (global) or private. FALSE (the default) specifies that the script is not public and is visible only to the owner or to users to whom the owner has granted read privilege access; TRUE specifies that the script is public and therefore visible to all users. |
| <code>overwrite</code> | A logical value that indicates whether to replace the R function of the script with the function specified in by the <code>fun</code> argument. TRUE specifies replacing the function, if it exists; FALSE (the default) specifies that the existing contents cannot be replaced.                                           |

If `overwrite = FALSE`, an error condition occurs if a script by the same name already exists in the R script repository; otherwise, `ore.scriptCreate` returns NULL.

### Granting or Revoking Read Access to a Script

The creator of a script can use the `ore.grant` function to grant read access privilege to the script and the `ore.revoke` function to revoke that access. Those functions have the following syntax:

```
ore.grant(name, type = "rqscript", user)
ore.revoke(name, type = "rqscript", user)
```

The arguments are the following:

| Argument          | Description                                                          |
|-------------------|----------------------------------------------------------------------|
| <code>name</code> | The name of a script in the Oracle R Enterprise R script repository. |
| <code>type</code> | For a script, the type is <code>rqscript</code> .                    |
| <code>user</code> | The user to whom to grant or revoke read privilege access.           |

The `name` and `type` arguments are required. If argument `user` is not specified, then read privilege access is granted to or revoked from all users.

An error occurs when one of the following is true:

- The named script is not in the R script repository.
- The `type` argument is not specified.
- The user is not found.

- The read privilege has already been granted to or revoked from the user.
- The named script is public.

### Listing the Available Scripts

To list the scripts available to you, use `ore.scriptList`. You can list scripts by name, by a pattern, or by type. If you have the RQADMIN role, you can list system scripts, as well. The function has the following syntax:

```
ore.scriptList(name, pattern, type)
```

The arguments are the following:

| Argument             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>name</code>    | The name of a script in the Oracle R Enterprise R script repository. Cannot be used when argument <code>pattern</code> is specified.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>pattern</code> | A regular expression pattern. Scripts that match the pattern are listed. Cannot be used when argument <code>name</code> is specified.                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>type</code>    | The type of the script, which can be one of the following: <ul style="list-style-type: none"> <li>• <code>user</code>, which lists scripts owned by the current user</li> <li>• <code>global</code>, which lists public scripts, which are visible to all users</li> <li>• <code>grant</code>, which lists the scripts to which the current user has granted read access to others</li> <li>• <code>granted</code>, which lists the scripts to which the current user has been granted read access by another user</li> <li>• <code>all</code>, which lists all of the user, public, and granted scripts</li> </ul> |

The `ore.scriptList` function returns a `data.frame` that contains the names of the scripts in the R script repository and the function in the script.

### Loading a Script into an R Environment

To load the R function of a script into an R environment, use `ore.scriptLoad`, which has the following syntax:

```
ore.scriptLoad(name, owner, newname, envir)
```

The arguments are the following:

| Argument             | Description                                                          |
|----------------------|----------------------------------------------------------------------|
| <code>name</code>    | The name of a script in the Oracle R Enterprise R script repository. |
| <code>owner</code>   | The owner of the script.                                             |
| <code>newname</code> | A new function name in which to load the script.                     |
| <code>envir</code>   | The R environment in which to load the script.                       |

Specifying the owner of a script is useful when access to the script has been granted to the user who is invoking `ore.scriptLoad`.

Specifying a new function name is useful when the name of the script in the Oracle R Enterprise R script repository is not a valid R function name.

An error occurs when one of the following is true:

- The script is not in the R script repository.
- The current user does not have read access to the script.
- The function specified by the `name` argument is not a valid R function name.
- The `newname` argument is not a valid R function name.

### Dropping a Script

To remove a script from the Oracle R Enterprise R script repository, use the `ore.scriptDrop` function. To invoke this function, you must have the `RQADMIN` role. The `ore.scriptDrop` function has the following syntax:

```
ore.scriptDrop(name, global, silent)
```

The arguments are the following:

| Argument            | Description                                                                                                                                                                                                                                        |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>name</code>   | A name for the script in the Oracle R Enterprise R script repository.                                                                                                                                                                              |
| <code>global</code> | A logical value that indicates whether the script is global (public) or private. <code>TRUE</code> specifies dropping a global script; <code>FALSE</code> (the default) specifies dropping a script owned by the current user.                     |
| <code>silent</code> | A logical value that indicates whether to display an error message if <code>ore.scriptDrop</code> encounters an error condition. <code>TRUE</code> specifies the display of error messages; <code>FALSE</code> (the default) specifies no display. |

An error condition occurs when one of the following is true:

- The script is not in the R script repository.
- If `global = TRUE`, the script is a private script.
- If `global = FALSE`, the script is a public script.

If successful, `ore.scriptDrop` returns `NULL`.

### Example 6-5 Using the R Script Management Functions

```
# Create an ore.frame object from the data.frame for the iris data set.
IRIS <- ore.push(iris)

# Create a private R script for the current user.
ore.scriptCreate("myRandomRedDots", function(divisor = 100){
  id <- 1:10
  plot(1:100, rnorm(100), pch = 21, bg = "red", cex = 2 )
  data.frame(id = id, val = id / divisor)
})

# Create another private R script.
ore.scriptCreate("MYLM",
  function(data, formula, ...) lm(formula, data, ...))

# Create a public script, available to any user.
ore.scriptCreate("GLBGLM",
  function(data, formula, ...)
  glm(formula = formula, data = data, ...),
  global = TRUE)
```

```

# List only my private scripts.
ore.scriptList()

# List my private scripts and the public scripts.
ore.scriptList(type = "all")

# List my private scripts that have the specified pattern.
ore.scriptList(pattern = "MY")

# Grant read access to a private script to all users.
ore.grant("MYLM", type = "rqscript")

# Grant read access to a private script to a specific user.
ore.grant("myRandomRedDots", user = "SCOTT", type = "rqscript")

# List the granted scripts.
ore.scriptList(type = "grant")

# Use the MYLM script in an embedded R execution function.
ore.tableApply(IRIS[1:4], FUN.NAME = "MYLM",
               formula = Sepal.Length ~ .)
# Use the GLBGLM script in an embedded R execution function.
ore.tableApply(IRIS[1:4], FUN.NAME = "GLBGLM",
               formula = Sepal.Length ~ .)

# Load an R script to an R function object
ore.scriptLoad(name = "MYLM")

# Invoke the function.
MYLM(iris, formula = Sepal.Length ~ .)

# Load another R script to an R function object
ore.scriptLoad(name = "GLBGLM", newname = "MYGLM")

# Invoke the function.
MYGLM(iris, formula = Sepal.Length ~ .)

# Drop some scripts.
ore.scriptDrop("MYLM")
ore.scriptDrop("GLBGLM", global = TRUE)

# List all scripts.
ore.scriptList(type = "all")

```

### 6.2.3 Using the ore.doEval Function

The `ore.doEval` function executes the specified input function using data that is generated by the input function. It returns an `ore.frame` object or a serialized R object as an `ore.object` object.

The syntax of the `ore.doEval` function is the following:

```
ore.doEval(FUN, ..., FUN.VALUE = NULL, FUN.NAME = NULL, FUN.OWNER = NULL)
```

---

**See Also:**

["Arguments for Functions that Run Scripts \(page 6-9\)"](#) for descriptions of the arguments to function `ore.doEval`

---

**Example 6-6 Using the ore.doEval Function**

In this example, `RandomRedDots` gets a function that has an argument and that returns a `data.frame` object that has two columns and that plots 100 random normal values. The example then invokes `ore.doEval` function and passes it the `RandomRedDots` function object. The image is displayed at the client, but it is generated by the database server R engine that executed the `RandomRedDots` function.

```
RandomRedDots <- function(divisor = 100){
  id<- 1:10
  plot(1:100, rnorm(100), pch = 21, bg = "red", cex = 2 )
  data.frame(id=id, val=id / divisor)
}
ore.doEval(RandomRedDots)
```

**Listing for [Example 6-6](#) (page 6-20)**

```
R> RandomRedDots <- function(divisor = 100){
+   id<- 1:10
+   plot(1:100, rnorm(100), pch = 21, bg = "red", cex = 2 )
+   data.frame(id=id, val=id / divisor)
+ }
R> ore.doEval(RandomRedDots)
   id val
1   1 0.01
2   2 0.02
3   3 0.03
4   4 0.04
5   5 0.05
6   6 0.06
7   7 0.07
8   8 0.08
9   9 0.09
10 10 0.10
```

**Figure 6-1** *Display of Random Red Dots***Example 6-7** *Using the ore.doEval Function with an Optional Argument*

You can provide arguments to the input function as optional arguments to the `doEval` function. This example invokes the `doEval` function with an optional argument that overrides the `divisor` argument of the `RandomRedDots` function.

```
ore.doEval(RandomRedDots, divisor = 50)
```

**Listing for Example 6-7** (page 6-21)

```
R> ore.doEval(RandomRedDots, divisor = 50)
  id val
1  1 0.02
2  2 0.04
3  3 0.06
4  4 0.08
5  5 0.10
6  6 0.12
7  7 0.14
8  8 0.16
9  9 0.18
10 10 0.20
# The graph displayed by the plot function is not shown.
```

**Example 6-8 Using the ore.doEval Function with the FUN.NAME Argument**

If the input function is stored in the Oracle R Enterprise R script repository, then you can invoke the `ore.doEval` function with the `FUN.NAME` argument. This example first invokes `ore.scriptDrop` to ensure that the R script repository does not contain a script with the name `myRandomRedDots`. The example adds the `RandomRedDots` function from [Example 6-6](#) (page 6-20) to the repository under the name `myRandomRedDots`. This example invokes the `ore.doEval` function and specifies `myRandomRedDots`. The result is assigned to the variable `res`.

The return value of the `RandomRedDots` function is a `data.frame` but in this example the `ore.doEval` function returns an `ore.object` object. To get back the `data.frame` object, the example invokes `ore.pull` to pull the result to the client R session.

```
ore.scriptDrop("myRandomRedDots")
ore.scriptCreate("myRandomRedDots", RandomRedDots)
res <- ore.doEval(FUN.NAME = "myRandomRedDots", divisor = 50)
class(res)
res.local <- ore.pull(res)
class(res.local)
```

**Listing for Example 6-8 (page 6-22)**

```
R> ore.scriptDrop("myRandomRedDots")
R> ore.scriptCreate("myRandomRedDots", RandomRedDots)
R> res <- ore.doEval(FUN.NAME = "myRandomRedDots", divisor = 50)
R> class(res)
[1] "ore.object"
attr(,"package")
[1] "OREembed"
R> res.local <- ore.pull(res)
R> class(res.local)
[1] "data.frame"
```

**Example 6-9 Using the ore.doEval Function with the FUN.VALUE Argument**

To have the `doEval` function return an `ore.frame` object instead of an `ore.object`, use the argument `FUN.VALUE` to specify the structure of the result, as shown in this example.

```
res.of <- ore.doEval(FUN.NAME="myRandomRedDots", divisor = 50,
                    FUN.VALUE= data.frame(id = 1, val = 1))
class(res.of)
```

**Listing for Example 6-9 (page 6-22)**

```
R> res.of <- ore.doEval(FUN.NAME="myRandomRedDots", divisor = 50,
+                     FUN.VALUE= data.frame(id = 1, val = 1))
R> class(res.of)
[1] "ore.frame"
attr(,"package")
[1] "OREbase"
```

**Example 6-10 Using the doEval Function with the ore.connect Argument**

This example demonstrates using the special optional argument `ore.connect` to connect to the database in the embedded R function, which enables the use of objects stored in a datastore. The example creates the `RandomRedDots2` function object, which is the same as the `RandomRedDots` function from [Example 6-6](#) (page 6-20) except the `RandomRedDots2` function has an argument that takes the name of a

datastore. The example creates the `myVar` variable and saves it in the datastore named `datastore_1`. The example then invokes the `doEval` function and passes it the name of the datastore and passes the `ore.connect` control argument set to `TRUE`.

```
RandomRedDots2 <- function(divisor = 100, datastore.name = "myDatastore"){
  id <- 1:10
  plot(1:100, rnorm(100), pch = 21, bg = "red", cex = 2 )
  ore.load(datastore.name) # Contains the numeric variable myVar.
  data.frame(id = id, val = id / divisor, num = myVar)
}
myVar <- 5
ore.save(myVar, name = "datastore_1")
ore.doEval(RandomRedDots2, datastore.name = "datastore_1", ore.connect = TRUE)
```

#### Listing for Example 6-10 (page 6-22)

```
R> RandomRedDots2 <- function(divisor = 100, datastore.name = "myDatastore"){
+   id <- 1:10
+   plot(1:100, rnorm(100), pch = 21, bg = "red", cex = 2 )
+   ore.load(datastore.name) # Contains the numeric variable myVar.
+   data.frame(id = id, val = id / divisor, num = myVar)
+ }
R> ore.doEval(RandomRedDots2, datastore.name = "datastore_1", ore.connect = TRUE)
   id val num
1   1 0.01  5
2   2 0.02  5
3   3 0.03  5
4   4 0.04  5
5   5 0.05  5
6   6 0.06  5
7   7 0.07  5
8   8 0.08  5
9   9 0.09  5
10 10 0.10  5
# The graph displayed by the plot function is not shown.
```

#### Example 6-11 Using the `ora.type` Attribute

This example demonstrates using the `ora.type` attribute to specify database data types of CLOB and BLOB for columns in the `data.frame` object specified by the `FUN.VALUE` argument.

```
eval1 <- ore.doEval(function() "Hello, world")
eval2 <-
  ore.doEval(function()
    data.frame(x = "Hello, world", stringsAsFactors = FALSE))
eval3 <-
  ore.doEval(function()
    data.frame(x = "Hello, world", stringsAsFactors = FALSE),
    FUN.VALUE =
    data.frame(x = character(), stringsAsFactors = FALSE))
out.df <- data.frame(x = character(), y = raw(), stringsAsFactors = FALSE)
attr(out.df$x, "ora.type") <- "clob"
attr(out.df$y, "ora.type") <- "blob"
eval4 <-
  ore.doEval(function() {
    res <- data.frame(x = "Hello, world", stringsAsFactors = FALSE)
    res$y[[1L]] <- charToRaw("Hello, world")
    res},
    FUN.VALUE = out.df)
eval1
class(eval1) # ore.object
```

```
eval2
class(eval2) # ore.object
eval3
class(eval3) # ore.frame
eval4$x
rawToChar(ore.pull(eval4$y))
```

**Listing for [Example 6-11](#) (page 6-23)**

```
R> eval1 <- ore.doEval(function() "Hello, world")
R> eval2 <-
+   ore.doEval(function()
+       data.frame(x = "Hello, world", stringsAsFactors = FALSE))
R> eval3 <-
+   ore.doEval(function()
+       data.frame(x = "Hello, world", stringsAsFactors = FALSE),
+       FUN.VALUE =
+       data.frame(x = character(), stringsAsFactors = FALSE))
R> out.df <- data.frame(x = character(), y = raw(), stringsAsFactors = FALSE)
R> attr(out.df$x, "ora.type") <- "clob"
R> attr(out.df$y, "ora.type") <- "blob"
R> eval4 <-
+   ore.doEval(function() {
+       res <- data.frame(x = "Hello, world", stringsAsFactors = FALSE)
+       res$y[[1L]] <- charToRaw("Hello, world")
+       res},
+       FUN.VALUE = out.df)
R> eval1
[1] "Hello, world"
R> class(eval1)
[1] "ore.object"
attr(,"package")
[1] "OREembed"
R> eval2
      x
1 Hello, world
R> class(eval2)
[1] "ore.object"
attr(,"package")
[1] "OREembed"
R> eval3
      x
1 Hello, world

## 6.2.4 Using the ore.tableApply Function

The `ore.tableApply` function invokes an R script with an `ore.frame` as the input data. The `ore.tableApply` function passes the `ore.frame` to the user-defined input function as the first argument to that function. The `ore.tableApply` function returns an `ore.frame` object or a serialized R object as an `ore.object` object.

The syntax of the `ore.tableApply` function is the following:

```
ore.tableApply(X, FUN, ..., FUN.VALUE = NULL, FUN.NAME = NULL, FUN.OWNER = NULL)
```

---

### See Also:

- ["Arguments for Functions that Run Scripts" \(page 6-9\)](#) for descriptions of the arguments to function `ore.tableApply`
  - ["Installing a Third-Party Package for Use in Embedded R Execution" \(page 6-5\)](#)
- 

### Example 6-12 Using the ore.tableApply Function

This example uses the `ore.tableApply` function to build a Naive Bayes model on the `iris` data set. The `naiveBayes` function is in the `e1071` package, which must be installed on both the client and database server machine R engines. As the first argument to the `ore.tableApply` function, the `ore.push(iris)` invocation creates a temporary database table and an `ore.frame` that is a proxy for the table. The second argument is the input function, which has as an argument `dat`. The `ore.tableApply` function passes the `ore.frame` table proxy to the input function as the `dat` argument. The input function creates a model, which the `ore.tableApply` function returns as an `ore.object` object.

```
library(e1071)
nbmod <- ore.tableApply(
  ore.push(iris),
  function(dat) {
    library(e1071)
    dat$Species <- as.factor(dat$Species)
    naiveBayes(Species ~ ., dat)
  })
class(nbmod)
nbmod
```

### Listing for Example 6-12 (page 6-25)

```
R> nbmod <- ore.tableApply(
+   ore.push(iris),
+   function(dat) {
+     library(e1071)
+     dat$Species <- as.factor(dat$Species)
+     naiveBayes(Species ~ ., dat)
+   })
R> class(nbmod)
[1] "ore.object"
attr(,"package")
[1] "OREembed"
R> nbmod
```

Naive Bayes Classifier for Discrete Predictors

```

## 6.2.5 Using the ore.groupApply Function

The `ore.groupApply` function invokes an R script with an `ore.frame` as the input data. The `ore.groupApply` function passes the `ore.frame` to the user-defined input function as the first argument to that function. The `INDEX` argument to the `ore.groupApply` function specifies the name of a column of the `ore.frame` by which Oracle Database partitions the rows for processing by the user-defined R function. The `ore.groupApply` function can use data-parallel execution, in which one or more R engines perform the same R function, or task, on different partitions of data.

The syntax of the `ore.groupApply` function is the following:

```
ore.groupApply(X, INDEX, FUN, ..., FUN.VALUE = NULL, FUN.NAME = NULL, FUN.OWNER =
NULL,
              parallel = getOption("ore.parallel", NULL))
```

The `ore.groupApply` function returns an `ore.list` object or an `ore.frame` object.

Examples of the use of the `ore.groupApply` function are in the following topics:

- ["Partitioning on a Single Column" \(page 6-27\)](#)
- ["Partitioning on Multiple Columns" \(page 6-29\)](#)

---

**See Also:**

- ["Arguments for Functions that Run Scripts" \(page 6-9\)](#) for descriptions of the arguments to function `ore.groupApply`
  - ["Installing a Third-Party Package for Use in Embedded R Execution" \(page 6-5\)](#)
- 

**6.2.5.1 Partitioning on a Single Column**

[Example 6-13](#) (page 6-27) uses the `C50` package, which has functions that build decision tree and rule-based models. The package also provides training and testing data sets. [Example 6-13](#) (page 6-27) builds `C5.0` models on the `churnTrain` training data set from the `churn` data set of the `C50` package, with the goal of building one churn model on the data for each state. The example does the following:

- Loads the `C50` package and then the churn data set.
- Uses the `ore.create` function to create the `CHURN_TRAIN` database table and its proxy `ore.frame` object from `churnTrain`, a `data.frame` object.
- Specifies `CHURN_TRAIN`, the proxy `ore.frame` object, as the first argument to the `ore.groupApply` function and specifies the `state` column as the `INDEX` argument. The `ore.groupApply` function partitions the data on the `state` column and invokes the user-defined function on each partition.
- Creates the variable `modList`, which gets the `ore.list` object returned by the `ore.groupApply` function. The `ore.list` object contains the results from the execution of the user-defined function on each partition of the data. In this case, it is one `C5.0` model per state, with each model stored as an `ore.object` object.
- Specifies the user-defined function. The first argument of the user-defined function receives one partition of the data, which in this case is all of the data associated with a single state.

The user-defined function does the following:

- Loads the `C50` package so that it is available to the function when it executes in an R engine in the database.
- Deletes the `state` column from the `data.frame` so that the column is not included in the model.
- Converts the columns to factors because, although the `ore.frame` defined factors, when they are loaded to the user-defined function, factors appear as character vectors.
- Builds a model for a state and returns it.
- Uses the `ore.pull` function to retrieve the model from the database as the `mod.MA` variable and then invokes the `summary` function on it. The class of `mod.MA` is `C5.0`.

**Example 6-13 Using the ore.groupApply Function**

```
library(C50)
data("churn")
```

```
ore.create(churnTrain, "CHURN_TRAIN")

modList <- ore.groupApply(
  CHURN_TRAIN,
  INDEX=CHURN_TRAIN$state,
  function(dat) {
    library(C50)
    dat$state <- NULL
    dat$churn <- as.factor(dat$churn)
    dat$area_code <- as.factor(dat$area_code)
    dat$international_plan <- as.factor(dat$international_plan)
    dat$voice_mail_plan <- as.factor(dat$voice_mail_plan)
    C5.0(churn ~ ., data = dat, rules = TRUE)
  });
mod.MA <- ore.pull(modList$MA)
summary(mod.MA)
```

**Listing for [Example 6-13](#) (page 6-27)**

```
R> library(C50)
R> data(churn)
R>
R> ore.create(churnTrain, "CHURN_TRAIN")
R>
R> modList <- ore.groupApply(
+   CHURN_TRAIN,
+   INDEX=CHURN_TRAIN$state,
+   function(dat) {
+     library(C50)
+     dat$state <- NULL
+     dat$churn <- as.factor(dat$churn)
+     dat$area_code <- as.factor(dat$area_code)
+     dat$international_plan <- as.factor(dat$international_plan)
+     dat$voice_mail_plan <- as.factor(dat$voice_mail_plan)
+     C5.0(churn ~ ., data = dat, rules = TRUE)
+   });
R> mod.MA <- ore.pull(modList$MA)
R> summary(mod.MA)
```

Call:

```

### 6.2.5.2 Partitioning on Multiple Columns

The `ore.groupApply` function takes a single column or multiple columns as the `INDEX` argument.

[Example 6-14](#) (page 6-30) uses data from the `CHURN_TRAIN` data set to build an `rpart` model that produces rules on the partitions of data specified, which are the `voice_mail_plan` and `international_plan` columns. The example uses the `Rtable` function to show the number of rows to expect in each partition.

The example next invokes the `ore.scriptDrop` function to ensure that no script by the specified name exists in the Oracle Database R script repository. It then uses the `ore.scriptCreate` function to define a script named `my_rpartFunction` and to store it in the repository. The stored script defines a function that takes a data source and a prefix to use for naming Oracle R Enterprise datastore objects. Each invocation of the function `my_rpartFunction` receives data from one of the partitions identified by the values in the `voice_mail_plan` and `international_plan` columns. Because the source partition columns are constants, the function sets them to `NULL`. It converts the character vectors to factors, builds a model to predict churn, and saves it in an appropriately named datastore. The function creates a list to return the specific partition column values, the distribution of churn values, and the model itself.

The example then loads the `rpart` library, sets the datastore prefix, and invokes `ore.groupApply` using the values from the `voice_mail_plan` and `international_plan` columns as the `INDEX` argument and `my_rpartFunction` as the value of the `FUN.NAME` argument to invoke the user-defined function stored in the R script repository. The `ore.groupApply` function uses an optional argument to pass the `datastorePrefix` variable to the user-defined function. It uses the optional

argument `ore.connect` to connect to the database when executing the user-defined function. The `ore.groupApply` function returns an `ore.list` object as the variable `res`.

The example displays the first entry in the list returned. It then invokes the `ore.load` function to load the model for the case where the customer has both the voice mail plan and the international plan.

**Example 6-14 Using `ore.groupApply` for Partitioning Data on Multiple Columns**

```
library(C50)
data(churn)
ore.drop("CHURN_TRAIN")
ore.create(churnTrain, "CHURN_TRAIN")

table(CHURN_TRAIN$international_plan, CHURN_TRAIN$voice_mail_plan)

## 6.2.6 Using the ore.rowApply Function

The `ore.rowApply` function invokes an R script with an `ore.frame` as the input data. The `ore.rowApply` function passes the `ore.frame` to the user-defined input function as the first argument to that function. The `rows` argument to the `ore.rowApply` function specifies the number of rows to pass to each invocation of the user-defined R function. The last chunk of rows may have fewer rows than the number specified. The `ore.rowApply` function can use data-parallel execution, in which one or more R engines perform the same R function, or task, on different partitions of data.

The syntax of the `ore.rowApply` function is the following:

```
ore.rowApply(X, FUN, ..., FUN.VALUE = NULL, FUN.NAME = NULL, rows = 1, FUN.OWNER =
NULL,
            parallel = getOption("ore.parallel", NULL))
```

The `ore.rowApply` function returns an `ore.list` object or an `ore.frame` object.

---

- ["Arguments for Functions that Run Scripts" \(page 6-9\)](#) for descriptions of the arguments to function `ore.rowApply`
- 

[Example 6-15](#) (page 6-34) uses the `e1071` package, previously downloaded from CRAN. The example also uses the `nbmod` object, which is the Naive Bayes model created in [Example 6-12](#) (page 6-25).

[Example 6-15](#) (page 6-34) does the following:

- Loads the package `e1071`.
- Pushes the `iris` data set to the database as the `IRIS` temporary table and `ore.frame` object.
- Creates a copy of `IRIS` as `IRIS_PRED` and adds the `PRED` column to `IRIS_PRED` to contain the predictions.
- Invokes the `ore.rowApply` function, passing the `IRIS ore.frame` as the data source for user-defined R function and the user-defined R function itself.
- The user-defined function does the following:
  - Loads the package `e1071` so that it is available to the R engine or engines that run in the database.
  - Converts the `Species` column to a factor because, although the `ore.frame` defined factors, when they are loaded to the user-defined function, factors appear as character vectors.
  - Invokes the `predict` method and returns the `res` object, which contains the predictions in the column added to the data set.
- The example pulls the model to the client R session.
- Passes `IRIS_PRED` as the argument `FUN.VALUE`, which specifies the structure of the object that the `ore.rowApply` function returns.

- Specifies the number of rows to pass to each invocation of the user-defined function.
- Displays the class of `res`, and invokes the `table` function to display the Species column and the PRED column of the `res` object.

**Example 6-15 Using the `ore.rowApply` Function**

```
library(e1071)
IRIS <- ore.push(iris)
IRIS_PRED <- IRIS
IRIS_PRED$PRED <- "A"
res <- ore.rowApply(
  IRIS,
  function(dat, nbmod) {
    library(e1071)
    dat$Species <- as.factor(dat$Species)
    dat$PRED <- predict(nbmod, newdata = dat)
    dat
  },
  nbmod = ore.pull(nbmod),
  FUN.VALUE = IRIS_PRED,
  rows = 10)
class(res)
table(res$Species, res$PRED)
```

**Listing for Example 6-15 (page 6-34)**

```
R> library(e1071)
R> IRIS <- ore.push(iris)
R> IRIS_PRED <- IRIS
R> IRIS_PRED$PRED <- "A"
R> res <- ore.rowApply(
+   IRIS ,
+   function(dat, nbmod) {
+     library(e1071)
+     dat$Species <- as.factor(dat$Species)
+     dat$PRED <- predict(nbmod, newdata = dat)
+     dat
+   },
+   nbmod = ore.pull(nbmod),
+   FUN.VALUE = IRIS_PRED,
+   rows = 10)
R> class(res)
[1] "ore.frame"
attr(,"package")
[1] "OREbase"
R> table(res$Species, res$PRED)
```

|            | setosa | versicolor | virginica |
|------------|--------|------------|-----------|
| setosa     | 50     | 0          | 0         |
| versicolor | 0      | 47         | 3         |
| virginica  | 0      | 3          | 47        |

As [Example 6-13](#) (page 6-27) does, [Example 6-16](#) (page 6-36) uses the C50 package to score churn data (that is, to predict which customers are likely to churn) using C5.0 models. However, instead of partitioning the data by a column, [Example 6-16](#) (page 6-36) partitions the data by a number of rows. The example scores the customers from the specified state in parallel. The example uses datastores and saves functions to the Oracle R Enterprise R script repository, which allows the functions to be used by the Oracle R Enterprise SQL API functions.

[Example 6-16](#) (page 6-36) first loads C50 package and the data sets. The example deletes the datastores with names containing `myC5.0modelFL`, if they exist. It invokes `ore.drop` to delete the `CHURN_TEST` table, if it exists, and then invokes `ore.create` to create the `CHURN_TEST` table from the `churnTest` data set.

The example next invokes `ore.getLevels`, which returns a list of the levels for each factor column. The invocation excludes the first column, which is state, because the levels for that column are not needed. Getting the levels first can ensure that all possible levels are provided during model building, even if some rows do not have values for some of the levels. The `ore.delete` invocation ensures that no datastore with the specified name exists and the `ore.save` invocation saves the `xlevels` object in the datastore named `myXlevels`.

[Example 6-16](#) (page 6-36) creates a user-defined function, `myC5.0FunctionForLevels`, that generates a C5.0 model. The function uses the list of levels returned by function `ore.getXlevels` instead of computing the levels using the `as.factor` function as the user-defined function does in [Example 6-13](#) (page 6-27). It uses the levels to convert the column type from character vector to factor. The function `myC5.0FunctionForLevels` returns the value `TRUE`. The example saves the function in the Oracle R Enterprise R script repository.

The example next gets a list of datastores that have names that include the specified string and deletes those datastores if they exist.

The example then invokes `ore.groupApply`, which invokes function `myC5.0FunctionForLevels` on each state in the `CHURN_TEST` data. To each `myC5.0FunctionForLevels` invocation, `ore.groupApply` passes the datastore that contains the `xlevels` object and a prefix to use in naming the datastore generated by `myC5.0FunctionForLevels`. It also passes the `ore.connect` control argument to connect to the database in the embedded R function, which enables the use of objects stored in a datastore. The `ore.groupApply` invocation returns a list that contains the results of all of the invocations of `myC5.0FunctionForLevels`.

The example pulls the result over to the local R session and verifies that `myC5.0FunctionForLevels` returned `TRUE` for each state in the data source.

[Example 6-16](#) (page 6-36) next creates another user-defined another function, `myScoringFunction`, and stores it in the Oracle R Enterprise R script repository. The function scores a C5.0 model for the levels of a state and returns the results in a `data.frame`.

The example then invokes function `ore.rowApply`. It filters the input data to use only data for the state of Massachusetts. It specifies `myScoringFunction` as the function to invoke and passes that user-defined function the name of the datastore that contains the `xlevels` object and a prefix to use in loading the datastore that contains the C5.0 model for the state. The `ore.rowApply` invocation specifies invoking `myScoringFunction` on 200 rows of the data set in each parallel R engine. It uses the `FUN.VALUE` argument so that `ore.rowApply` returns an `ore.frame` that contains the results of all of the `myScoringFunction` invocations. The variable `scores` gets the results of the `ore.rowApply` invocation.

Finally, [Example 6-16](#) (page 6-36) prints the `scores` object and then uses the table function to display the confusion matrix for the scoring.

**See Also:**

[Example A-8](#) (page A-11) for an invocation of the `rqRowEval` function that produces the same result as the `ore.rowApply` function in [Example 6-16](#) (page 6-36)

**Example 6-16 Using the `ore.rowApply` Function with Datastores and Scripts**

```
library(C50)
data(churn)

## 6.2.7 Using the ore.indexApply Function

The `ore.indexApply` function executes the specified user-defined input function using data that is generated by the input function. It supports task-parallel execution, in which one or more R engines perform the same or different calculations, or task. The `times` argument to the `ore.indexApply` function specifies the number of times that the input function executes in the database. Any required data must be explicitly generated or loaded within the input function.

The syntax of the `ore.indexApply` function is the following:

```
ore.indexApply(times, FUN, ..., FUN.VALUE = NULL, FUN.NAME = NULL, FUN.OWNER = NULL,
               parallel = getOption("ore.parallel", NULL))
```

The `ore.indexApply` function returns an `ore.list` object or an `ore.frame` object.

Examples of the use of the `ore.indexApply` function are in the following topics:

- ["Simple Example of Using the ore.indexApply Function" \(page 6-39\)](#)
- ["Column-Parallel Use Case" \(page 6-40\)](#)
- ["Simulations Use Case" \(page 6-41\)](#)

---

### See Also:

- ["Arguments for Functions that Run Scripts" \(page 6-9\)](#) for descriptions of the arguments to function `ore.indexApply`
- 

### 6.2.7.1 Simple Example of Using the ore.indexApply Function

[Example 6-17](#) (page 6-39) invokes `ore.indexApply` and specifies that it execute the input function five times in parallel. It displays the class of the result, which is `ore.list`, and then displays the result.

#### **Example 6-17 Using the ore.indexApply Function**

```

res <- ore.indexApply(5,
  function(index) {
    paste("IndexApply:", index)
  },
  parallel = TRUE)
class(res)
res

```

Listing for [Example 6-17](#) (page 6-39)

```
R> res <- ore.indexApply(5,
+   function(index) {
+     paste("IndexApply:", index)
+   },
+   parallel = TRUE)
R> class(res)
[1] "ore.list"
attr(,"package")
[1] "OREEmbed"
R> res
$`1`
[1] "IndexApply: 1"

$`2`
[1] "IndexApply: 2"

$`3`
[1] "IndexApply: 3"

$`4`
[1] "IndexApply: 4"

$`5`
[1] "IndexApply: 5"
```

#### 6.2.7.2 Column-Parallel Use Case

[Example 6-18](#) (page 6-40) uses the R summary function to compute in parallel summary statistics on the first four numeric columns of the `iris` data set. The example combines the computations into a final result. The first argument to the `ore.indexApply` function is 4, which specifies the number of columns to summarize in parallel. The user-defined input function takes one argument, `index`, which will be a value between 1 and 4 and which specifies the column to summarize.

The example invokes the `summary` function on the specified column. The `summary` invocation returns a single row, which contains the summary statistics for the column. The example converts the result of the `summary` invocation into a `data.frame` and adds the column name to it.

The example next uses the `FUN.VALUE` argument to the `ore.indexApply` function to define the structure of the result of the function. The result is then returned as an `ore.frame` object with that structure.

#### **Example 6-18** *Using the ore.indexApply Function and Combining Results*

```
res <- NULL
res <- ore.indexApply(4,
  function(index) {
    ss <- summary(iris[, index])
    attr.names <- attr(ss, "names")
    stats <- data.frame(matrix(ss, 1, length(ss)))
    names(stats) <- attr.names
    stats$col <- names(iris)[index]
    stats
  },
  FUN.VALUE=data.frame(Min. = numeric(0),
    "1st Qu." = numeric(0),
    Median = numeric(0),
    Mean = numeric(0),
    "3rd Qu." = numeric(0),
    Max. = numeric(0),
```

```

        Col = character(0)),
parallel = TRUE)
res

```

#### Listing for [Example 6-18](#) (page 6-40)

```

R> res <- NULL
R> res <- ore.indexApply(4,
+   function(index) {
+     ss <- summary(iris[, index])
+     attr.names <- attr(ss, "names")
+     stats <- data.frame(matrix(ss, 1, length(ss)))
+     names(stats) <- attr.names
+     stats$col <- names(iris)[index]
+     stats
+   },
+   FUN.VALUE=data.frame(Min. = numeric(0),
+     "1st Qu." = numeric(0),
+     Median = numeric(0),
+     Mean = numeric(0),
+     "3rd Qu." = numeric(0),
+     Max. = numeric(0),
+     Col = character(0)),
+   parallel = TRUE)
R> res
  Min. X1st.Qu. Median  Mean X3rd.Qu. Max.      Col

```

### 6.2.7.3 Simulations Use Case

You can use the `ore.indexApply` function in simulations, which can take advantage of high-performance computing hardware like an Oracle Exadata Database Machine. [Example 6-19](#) (page 6-42) takes multiple samples from a random normal distribution to compare the distribution of the summary statistics. Each simulation occurs in a separate R engine in the database, in parallel, up to the degree of parallelism allowed by the database.

[Example 6-19](#) (page 6-42) defines variables for the sample size, the mean and standard deviations of the random numbers, and the number of simulations to perform. The example specifies `num.simulations` as the first argument to the `ore.indexApply` function. The `ore.indexApply` function passes `num.simulations` to the user-defined function as the `index` argument. This input function then sets the random seed based on the index so that each invocation of the input function generates a different set of random numbers.

The input function next uses the `rnorm` function to produce `sample.size` random normal values. It invokes the `summary` function on the vector of random numbers, and then prepares a `data.frame` as the result it returns. The `ore.indexApply` function specifies the `FUN.VALUE` argument so that it returns an `ore.frame` that structures the combined results of the simulations. The `res` variable gets the `ore.frame` returned by the `ore.indexApply` function.

To get the distribution of samples, the example invokes the `boxplot` function on the `data.frame` that is the result of using the `ore.pull` function to bring selected columns from `res` to the client.

**Example 6-19 Using the ore.indexApply Function in a Simulation**

```
res <- NULL
sample.size = 1000
mean.val = 100
std.dev.val = 10
num.simulations = 1000

res <- ore.indexApply(num.simulations,
  function(index, sample.size = 1000, mean = 0, std.dev = 1) {
    set.seed(index)
    x <- rnorm(sample.size, mean, std.dev)
    ss <- summary(x)
    attr.names <- attr(ss, "names")
    stats <- data.frame(matrix(ss, 1, length(ss)))
    names(stats) <- attr.names
    stats$index <- index
    stats
  },
  FUN.VALUE=data.frame(Min. = numeric(0),
    "1st Qu." = numeric(0),
    Median = numeric(0),
    Mean = numeric(0),
    "3rd Qu." = numeric(0),
    Max. = numeric(0),
    Index = numeric(0)),
  parallel = TRUE,
  sample.size = sample.size,
  mean = mean.val, std.dev = std.dev.val)
options("ore.warn.order" = FALSE)
head(res, 3)
tail(res, 3)
boxplot(ore.pull(res[, 1:6]),
  main=sprintf("Boxplot of %d rnorm samples size %d, mean=%d, sd=%d",
    num.simulations, sample.size, mean.val, std.dev.val))
```

**Listing for Example 6-19 (page 6-42)**

```
R> res <- ore.indexApply(num.simulations,
+   function(index, sample.size = 1000, mean = 0, std.dev = 1) {
+     set.seed(index)
+     x <- rnorm(sample.size, mean, std.dev)
+     ss <- summary(x)
+     attr.names <- attr(ss, "names")
+     stats <- data.frame(matrix(ss, 1, length(ss)))
+     names(stats) <- attr.names
+     stats$index <- index
+     stats
+   },
+   FUN.VALUE=data.frame(Min. = numeric(0),
+     "1st Qu." = numeric(0),
+     Median = numeric(0),
+     Mean = numeric(0),

## 6.3 SQL Interface for Embedded R Execution

The SQL interface for Oracle R Enterprise embedded R execution allows you to execute R functions in production database applications. The SQL interface has procedures for the following actions:

- Adding and removing a script from the Oracle R Enterprise R script repository
- Granting or revoking read privilege access to a script by the owner to other users
- Executing an R script in an embedded R session

- Deleting an Oracle R Enterprise datastore

Data dictionary views provide information about scripts and datastores.

This SQL interface is described in the following topics:

- [About Oracle R Enterprise SQL Table Functions](#) (page 6-44)
- [Manage Scripts in SQL](#) (page 6-46)
- [Manage Datastores in SQL](#) (page 6-48)
- [rqEval Function](#) (page A-2)
- [rqGroupEval Function](#) (page A-5)
- [rqRowEval Function](#) (page A-9)
- [rqTableEval Function](#) (page A-13)

### 6.3.1 About Oracle R Enterprise SQL Table Functions

Oracle R Enterprise provides SQL table functions that are equivalents of most of the R interface functions for embedded R execution. Executing a `SELECT FROM TABLE` statement and specifying one of the table functions results in the invocation of the specified R script. The script runs in one or more R engines on the Oracle Database server.

The SQL table functions for embedded R execution are:

- `rqEval`
- `rqGroupEval`
- `rqRowEval`
- `rqTableEval`

The R interface functions and the SQL equivalents are listed in [Table 6-1](#) (page 6-2).

For the `rqGroupEval` function, Oracle R Enterprise provides a generic implementation of the group apply functionality in SQL. You must write a table function that captures the structure of the input cursor.

Some general aspects of the SQL table functions are described in the following topics:

- ["Parameters of the SQL Table Functions](#) (page 6-45)"
- ["Return Value of SQL Table Functions](#) (page 6-45)"
- ["Connecting to Oracle R Enterprise in Embedded R Execution](#) (page 6-46)"

See the reference pages for the functions for more information about them, including examples of their use.

- [rqRowEval Function](#) (page A-9)

[rqTableEval Function](#) (page A-13)

### 6.3.1.1 Parameters of the SQL Table Functions

The SQL table functions have some parameters in common and some functions have parameters that are unique to that function. The parameters of the SQL table functions are the following.

**Table 6-2 SQL Table Function Parameters**

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| INP_CUR   | A cursor that specifies the data that is input to the R function specified by EXP_NAM. For all of the SQL table functions except <code>rqEval</code> , the first argument is a cursor that specifies input data for the R function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| PAR_CUR   | <p>A cursor that specifies arguments to pass to the R function. The parameters cursor consists of a single row of scalar values. An argument can be a string or a numeric value. You can specify multiple arguments in the cursor. Arguments to an R function are case sensitive, so you should put names, such as a column name, in double quotes.</p> <p>In the cursor, you can also specify as scalar values an Oracle R Enterprise control argument or the names of serialized R objects, such as predictive models, that are in an Oracle R Enterprise datastore.</p> <p>The value of this parameters cursor can be NULL if you are not passing any arguments to the R function or any control arguments.</p> |
| OUT_QRY   | An output table definition. The value of this argument can be NULL or a string that defines the structure of the R <code>data.frame</code> returned by the R function specified by EXP_NAM. The string can be a SELECT statement, 'XML', or 'PNG'.                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| GRP_COL   | For the <code>rqGroupEval</code> function, the name of the grouping column.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| ROW_NUM   | For the <code>rqRowEval</code> function, the number of rows to pass to each invocation of the R function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| EXP_NAM   | The name of a script in the Oracle R Enterprise R script repository.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

### 6.3.1.2 Return Value of SQL Table Functions

The Oracle R Enterprise SQL table functions return a table. The structure and contents of the table are determined by the results of the R function passed to the SQL table function and by the OUT\_QRY parameter. The R function can return a `data.frame`

object, other R objects, and graphics. The structure of the table that represents the results of the R function is specified by one of the following `OUT_QRY` values:

- `NULL`, which results in a table that has a serialized object that can contain both data and image objects.
- A table signature specified in a `SELECT` statement, which results in a table that has the defined structure. The result of the R function must be a `data.frame`. No images are returned.
- The string `'XML'`, which results in a table that has a `CLOB` that can contain both structured data and graph images in an XML string. The non-image R objects, such as `data.frame` or `model` objects, are provided first, followed by the base 64 encoding of a PNG representation of the image.
- The string `'PNG'`, which results in a table that has a `BLOB` that contains graph images in PNG format. The table has the column names `name`, `id`, and `image`.

### 6.3.1.3 Connecting to Oracle R Enterprise in Embedded R Execution

To establish a connection to Oracle R Enterprise on the Oracle Database server during the embedded R execution, you can specify the control argument `ore.connect` in the parameters cursor. Doing so establishes a connection using the credentials of the user who invoked the embedded R function. It also automatically loads the `ORE` package. Establishing an Oracle R Enterprise connection is required to save objects in an Oracle R Enterprise R object datastore or to load objects from a datastore. It also allows you to explicitly use the Oracle R Enterprise transparency layer.

## 6.3.2 Manage Scripts in SQL

This topic lists the PL/SQL procedures and Oracle Database data dictionary views for creating and managing R scripts.

The functions in the SQL API for embedded R execution require as an argument a named script that is stored in the Oracle R Enterprise R script repository. The PL/SQL procedures `sys.rqScriptCreate` and `sys.rqScriptDrop` create and drop scripts. To create a script or drop one from the Oracle R Enterprise R script repository requires the `RQADMIN` role.

When using the `sys.rqScriptCreate` function, you must specify a name for the script and an R function script that contains a single R function definition. Calls to the functions `sys.rqScriptCreate` and `sys.rqScriptDrop` must be wrapped in a `BEGIN-END` PL/SQL block. The R script repository stores the R function as a character large object (a `CLOB`), so you must enclose the function definition in single quotes to specify it as a string.

The owner of a script can use the `rqGrant` procedure to grant to another user read privilege access to a script or use the `rqRevoke` procedure to revoke the privilege. To use a script granted to you by another user, you must specify the owner by prepending the owner's name and a period to the name of the script, as in the following:

```
select * from table(rqEval(NULL, 'select 1 x from dual',
'owner_name.script_name'));
```

The owner prefix is not required for a public script or for a script owned by the user.

The following tables list the PL/SQL procedures for managing Oracle R Enterprise R script repository scripts and the data dictionary views that contain information about scripts.

**Table 6-3 PL/SQL Procedures for Managing Scripts**

| PL/SQL Procedure                | Description                                                                                           |
|---------------------------------|-------------------------------------------------------------------------------------------------------|
| <code>rqGrant</code>            | Grants read privilege access to a datastore or script.                                                |
| <code>rqRevoke</code>           | Revokes read privilege access to a datastore or script.                                               |
| <code>sys.rqScriptCreate</code> | Adds the provided R function into the Oracle R Enterprise R script repository with the provided name. |
| <code>sys.rqScriptDrop</code>   | Removes the named R function from the Oracle R Enterprise R script repository.                        |

**Table 6-4 Data Dictionary Views for Scripts**

| Data Dictionary View              | Description                                                                                                                                                           |
|-----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>ALL_RQ_SCRIPTS</code>       | Describes the scripts in the Oracle R Enterprise R script repository that are available to the current user                                                           |
| <code>USER_RQ_SCRIPTS</code>      | Describes the scripts in the Oracle R Enterprise R script repository that are owned by the current user.                                                              |
| <code>USER_RQ_SCRIPT_PRIVS</code> | Describes the scripts in the Oracle R Enterprise R script repository to which the current user has granted read access and the users to whom access has been granted. |
| <code>SYS.RQ_SCRIPTS</code>       | Describes the system scripts in the Oracle R Enterprise R script repository.                                                                                          |

### 6.3.2.1 Creating a Script with the SQL APIs

This example uses the `sys.rqScriptCreate` procedure to create a script in the Oracle R Enterprise R script repository.

This example creates the user-defined function named `myRandomRedDots2`. The user-defined function accepts two arguments, and it returns a `data.frame` object that has two columns and that plots the specified number of random normal values. The `sys.rqScriptCreate` function stores the user-defined function in the Oracle R Enterprise script repository.

```
-- Create a script named myRandomRedDots2 and add it to the R script repository.
-- Specify that the script is private and to overwrite a script with the same name.
```

```

BEGIN
  sys.rqScriptCreate('myRandomRedDots2',
    'function(divisor = 100, numDots = 100) {
      id <- 1:10
      plot(1:numDots, rnorm(numDots), pch = 21, bg = "red", cex = 2 )
      data.frame(id = id, val = id / divisor)}',
    v_global => FALSE,
    v_overwrite => TRUE);
END;
/

-- Grant read privilege access to Scott.
BEGIN
  rqGrant('myRandomRedDots2', 'rqscript', 'SCOTT');
END;
/

-- View the users granted read access to myRandomRedDots2.
select * from USER_RQ_SCRIPT_PRIVS;

NAME                GRANTEE
-----
myRandomRedDots     SCOTT

-- Revoke the read privilege access from Scott.
BEGIN
  rqRevoke('myRandomRedDots2', 'rqscript', 'SCOTT');
END;
/

-- Remove the script from the R script repository.
BEGIN
  sys.rqScriptDrop('myRandomRedDots2');
END;
/

```

### 6.3.3 Manage Datastores in SQL

Oracle R Enterprise provides PL/SQL procedures and Oracle Database data dictionary views for the basic management of datastores in SQL. The following tables list the procedures and views.

**Table 6-5 PL/SQL Procedures for Managing Datastores**

| PL/SQL Procedures | Description                                             |
|-------------------|---------------------------------------------------------|
| rqGrant           | Grants read privilege access to a datastore or script.  |
| rqRevoke          | Revokes read privilege access to a datastore or script. |
| rqDropDataStore   | Deletes a datastore.                                    |

**Table 6-6 Data Dictionary Views for Datastores**

| Views                | Description                                                                                           |
|----------------------|-------------------------------------------------------------------------------------------------------|
| ALL_RQ_DATASTORES    | Describes the datastores available to the current user, including whether the datastore is grantable. |
| RQUSER_DATASTORELIST | Describes the datastores in the Oracle Database schema..                                              |

**Table 6-6 (Cont.) Data Dictionary Views for Datastores**

| Views                    | Description                                                                                        |
|--------------------------|----------------------------------------------------------------------------------------------------|
| RQUSER_DATASTORECONTENTS | Describes the objects in the datastores in the Oracle Database schema.                             |
| USER_RQ_DATASTORE_PRIVS  | Describes the datastores and the users to whom the current user has granted read privilege access. |
| USER_RQ_DATASTORES       | Describes the datastores owned by the current user, including whether the datastore is grantable.  |

# SQL APIs for Oracle R Enterprise

The Oracle R Enterprise SQL APIs comprise SQL table functions for executing R functions in one or more embedded R sessions on the Oracle R Enterprise Server database, and PL/SQL procedures for managing Oracle R Enterprise datastores and for managing scripts in the Oracle R Enterprise R script repository.

The SQL APIs for Oracle R Enterprise are described in the following topics:

## SQL Table Functions for Embedded R Execution

## A.1 rqDropDataStore Procedure

The `rqDropDataStore` procedure deletes a datastore from an Oracle Database schema.

### Syntax

```
rqDropDataStore (  
    DS_NAME      VARCHAR2      IN)
```

### Parameters

| Parameter | Description                        |
|-----------|------------------------------------|
| DS_NAME   | The name of the datastore to drop. |

**Example A-1 Dropping a Datastore**

This example deletes the datastore `datastore_1` from the current user schema.

```
rqDropDataStore('datastore_1')
```

## A.2 rqEval Function

The `rqEval` function executes the R function in the script specified by the `EXP_NAM` parameter. You can pass arguments to the R function with the `PAR_CUR` parameter.

The `rqEval` function does not automatically receive any data from the database. The R function generates the data that it uses or it explicitly retrieves it from a data source such as Oracle Database, other databases, or flat files.

The R function returns an R `data.frame` object, which appears as a SQL table in the database. You define the form of the returned value with the `OUT_QRY` parameter.

**Syntax**

```
rqEval (
  PAR_CUR    REF CURSOR    IN
  OUT_QRY    VARCHAR2      IN)
EXP_NAM      VARCHAR2      IN)
```

**Parameters**

| Parameter | Description                                                                                                        |
|-----------|--------------------------------------------------------------------------------------------------------------------|
| PAR_CUR   | A cursor that contains argument values to pass to the R function specified by the <code>EXP_NAME</code> parameter. |

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| OUT_QRY   | <p>One of the following:</p> <ul style="list-style-type: none"> <li>• <code>NULL</code>, which returns a serialized object that can contain both data and image objects.</li> <li>• A SQL <code>SELECT</code> statement that specifies the column names and data types of the table returned by <code>rqEval</code>. Any image data is discarded. You can provide a prototype row using the dual dummy table or you can base the <code>SELECT</code> statement on an existing table or view. The R function must return a <code>data.frame</code>.</li> <li>• The string <code>'XML'</code>, which specifies that the table returned contains a CLOB that is an XML string. The XML can contain both structured data and images, with structured or semi-structured R objects first, followed by the image or images generated by the R function. Images are returned as a base 64 encoding of the PNG representation.</li> <li>• The string <code>'PNG'</code>, which specifies that the table returned contains a BLOB that has the image or images generated by the R function in PNG format.</li> </ul> |
| EXP_NAM   | The name of a script in the Oracle R Enterprise R script repository.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## Return Value

Function `rqEval` returns a table that has the structure specified by the `OUT_QRY` parameter value.

## Examples

### Example A-2 Using `rqEval`

This example creates the script `myRandomRedDots2`. The value of the first parameter to `rqEval` is `NULL`, which specifies that no arguments are supplied to the function `myRandomRedDots2`. The value of second parameter is a string that specifies a SQL statement that describes the column names and data types of the `data.frame` returned by `rqEval`. The value of third parameter is the name of the script in the Oracle R Enterprise R script repository.

```
-- Create a script named myRandomRedDots2 and add it to the R script repository.
-- Specify that the script is private and to overwrite a script with the same name.
BEGIN
  sys.rqScriptCreate('myRandomRedDots2',
    'function(divisor = 100, numDots = 100) {
      id <- 1:10
      plot(1:numDots, rnorm(numDots), pch = 21, bg = "red", cex = 2 )
      data.frame(id = id, val = id / divisor)}',
    v_global => FALSE,
    v_overwrite => TRUE);
END;
/

SELECT *
FROM table(rqEval(NULL, 'SELECT 1 id, 1 val FROM dual', 'myRandomRedDots2'));
```

In Oracle SQL Developer, the results of the `SELECT` statement are:

| ID | VAL |
|----|-----|
| 1  | .01 |
| 2  | .02 |
| 3  | .03 |
| 4  | .04 |
| 5  | .05 |
| 6  | .06 |
| 7  | .07 |
| 8  | .08 |
| 9  | .09 |
| 10 | .1  |

10 rows selected

### **Example A-3** *Passing Arguments to the R Function invoked by `rqEval`*

This example provides arguments to the R function by specifying a cursor as the first parameter to `rqEval`. The cursor specifies multiple arguments in a single row of scalar values.

```
SELECT *
FROM table(rqEval(cursor(SELECT 50 "divisor", 500 "numDots" FROM dual),
  'SELECT 1 id, 1 val FROM dual',
  'myRandomRedDots2'));
```

In Oracle SQL Developer, the results of the `SELECT` statement are:

| ID | VAL |
|----|-----|
| 1  | .02 |
| 2  | .04 |
| 3  | .06 |
| 4  | .08 |
| 5  | .1  |
| 6  | .12 |
| 7  | .14 |
| 8  | .16 |
| 9  | .18 |
| 10 | .2  |

10 rows selected

### **Example A-4** *Specifying PNG as the Output Table Definition*

This example creates a script named `PNG_Example` and stores it in the Oracle R Enterprise R script repository. The invocation of `rqEval` specifies an `OUT_QRY` value of `'PNG'`.

```
BEGIN
  sys.rqScriptDrop('PNG_Example');
  sys.rqScriptCreate('PNG_Example',
    'function(){
      dat <- data.frame(y = log(1:100), x = 1:100)
      plot(lm(y ~ x, dat))
    }');
END;
/
SELECT *
FROM table(rqEval(NULL, 'PNG', 'PNG_Example'));
```

In Oracle SQL Developer, the results of the `SELECT` statement are:

| NAME  | ID    | IMAGE  |
|-------|-------|--------|
| ----- | ----- | -----  |
|       | 1     | (BLOB) |
|       | 2     | (BLOB) |
|       | 3     | (BLOB) |
|       | 4     | (BLOB) |

### A.3 rqGrant Procedure

The `rqGrant` procedure grants read privilege access to an Oracle R Enterprise datastore or to a script in the Oracle R Enterprise R script repository.

#### Syntax

```
rqGrant (
  V_NAME    VARCHAR2    IN
  V_TYPE    VARCHAR2    IN
  V_USER    VARCHAR2    IN    DEFAULT)
```

#### Parameters

| Parameter | Description                                                                                              |
|-----------|----------------------------------------------------------------------------------------------------------|
| V_NAME    | The name of an Oracle R Enterprise datastore or a script in the Oracle R Enterprise R script repository. |
| V_TYPE    | For a datastore, the type is <code>datastore</code> ; for a script, the type is <code>rqscript</code> .  |
| V_USER    | The name of the user to whom to grant access.                                                            |

#### Example A-5 Granting Read Access to a Script

```
-- Grant read privilege access to Scott.
BEGIN
  rqGrant('myRandomRedDots2', 'rqscript', 'SCOTT');
END;
/
```

[rqRevoke Procedure](#) (page A-8)

### A.4 rqGroupEval Function

The `rqGroupEval` function is a user-defined function that identifies a grouping column. The user defines an `rqGroupEval` function in PL/SQL using the SQL object `rqGroupEvalImpl`, which is a generic implementation of the group apply functionality in SQL. The implementation supports data-parallel execution, in which one or more R engines perform the same R function, or task, on different partitions of data. The data is partitioned according to the values of the grouping column.

Only one grouping column is supported. If you have multiple columns, then combine the columns into one column and use the new column as the grouping column.

The *rqGroupEval* function executes the R function in the script specified by the `EXP_NAM` parameter. You pass data to the R function with the `INP_CUR` parameter. You can pass arguments to the R function with the `PAR_CUR` parameter.

The R function returns an R `data.frame` object, which appears as a SQL table in the database. You define the form of the returned value with the `OUT_QRY` parameter.

To create an *rqGroupEval* function, you create the following two PL/SQL objects:

- A PL/SQL package that specifies the types of the result to return.
- A function that takes the return value of the package and uses the return value with `PIPELINED_PARALLEL_ENABLE` set to indicate the column on which to partition data.

### Syntax

```
rqGroupEval (
    INP_CUR    REF CURSOR    IN
    PAR_CUR    REF CURSOR    IN
    OUT_QRY    VARCHAR2      IN
    GRP_COL    VARCHAR2      IN
    EXP_NAM    VARCHAR2      IN)
```

### Parameters

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| INP_CUR   | A cursor that specifies the data to pass to the R function specified by the <code>EXP_NAME</code> parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| PAR_CUR   | A cursor that contains argument values to pass to the R function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| OUT_QRY   | One of the following: <ul style="list-style-type: none"> <li>• <code>NULL</code>, which returns a serialized object that can contain both data and image objects.</li> <li>• A SQL <code>SELECT</code> statement that specifies the column names and data types of the table returned by <code>rqEval</code>. Any image data is discarded. You can provide a prototype row using the dual dummy table or you can base the <code>SELECT</code> statement on an existing table or view. The R function must return a <code>data.frame</code>.</li> <li>• The string <code>'XML'</code>, which specifies that the table returned contains a CLOB that is an XML string. The XML can contain both structured data and images, with structured or semi-structured R objects first, followed by the image or images generated by the R function. Images are returned as a base 64 encoding of the PNG representation.</li> <li>• The string <code>'PNG'</code>, which specifies that the table returned contains a BLOB that has the image or images generated by the R function in PNG format.</li> </ul> |
| GRP_COL   | The name of the grouping column by which to partition the data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| Parameter | Description                                                          |
|-----------|----------------------------------------------------------------------|
| EXP_NAM   | The name of a script in the Oracle R Enterprise R script repository. |

### Return Value

The user-defined *rqGroupEval* function returns a table that has the structure specified by the OUT\_QRY parameter value.

### Examples

[Example A-6](#) (page A-8) has a PL/SQL block that drops the script `myC5.0Function` to ensure that the script does not exist in the Oracle R Enterprise R script repository. It then creates a function and stores it as the script `myC5.0Function` in the R script repository.

The R function accepts two arguments: the data on which to operate and a prefix to use in creating datastores. The function uses the C50 package to build C5.0 models on the churn data set from C50. The function builds one churn model on the data for each state.

The `myC5.0Function` function loads the C50 package so that the function body has access to it when the function executes in an R engine on the database server. The function then creates a datastore name using the datastore prefix and the name of a state. To exclude the state name from the model, the function deletes the column from the `data.frame`. Because factors in the `data.frame` are converted to character vectors when they are loaded in the user-defined embedded R function, the `myC5.0Function` function explicitly converts the character vectors back to R factors.

The `myC5.0Function` function gets the data for the state from the specified columns and then creates a model for the state and saves the model in a datastore. The R function returns TRUE to have a simple value that can appear as the result of the function execution.

[Example A-6](#) (page A-8) next creates a PL/SQL package, `churnPkg`, and a user-defined function, `churnGroupEval`. In defining an *rqGroupEval* function implementation, the PARALLEL\_ENABLE clause is optional but the CLUSTER BY clause is required.

Finally, the example executes a SELECT statement that invokes the `churnGroupEval` function. In the INP\_CUR argument of the `churnGroupEval` function, the SELECT statement specifies the PARALLEL hint to use parallel execution of the R function and the data set to pass to the R function. The INP\_CUR argument of the `churnGroupEval` function specifies connecting to Oracle R Enterprise and the datastore prefix to pass to the R function. The OUT\_QRY argument specifies returning the value in XML format, the GRP\_NAM argument specifies using the state column of the data set as the grouping column, and the EXP\_NAM argument specifies the `myC5.0Function` script in the R script repository as the R function to invoke.

For each of 50 states plus Washington, D.C., the SELECT statement returns from the `churnGroupEval` table function the name of the state and an XML string that contains the value TRUE.

```

BEGIN
  sys.rqScriptDrop('myC5.0Function');
  sys.rqScriptCreate('myC5.0Function',
    'function(dat, datastorePrefix) {
      library(C50)
      datastoreName <- paste(datastorePrefix, dat[1, "state"], sep = "_")
      dat$state <- NULL
      dat$churn <- as.factor(dat$churn)
      dat$area_code <- as.factor(dat$area_code)
      dat$international_plan <- as.factor(dat$international_plan)
      dat$voice_mail_plan <- as.factor(dat$voice_mail_plan)
      mod <- C5.0(churn ~ ., data = dat, rules = TRUE)
      ore.save(mod, name = datastoreName)
      TRUE
    }');
END;
/

CREATE OR REPLACE PACKAGE churnPkg AS
  TYPE cur IS REF CURSOR RETURN CHURN_TRAIN%ROWTYPE;
END churnPkg;
/

CREATE OR REPLACE FUNCTION churnGroupEval(
  inp_cur churnPkg.cur,
  par_cur SYS_REFCURSOR,
  out_qry VARCHAR2,
  grp_col VARCHAR2,
  exp_txt CLOB)
RETURN SYS.AnyDataSet
PIPELINED PARALLEL_ENABLE (PARTITION inp_cur BY HASH ("state"))
CLUSTER inp_cur BY ("state")
USING rqGroupEvalImpl;
/

SELECT *
FROM table(churnGroupEval(
  cursor(SELECT * /*+ parallel(t,4) */ FROM CHURN_TRAIN t),
  cursor(SELECT 1 AS "ore.connect",
    'myC5.0model' AS "datastorePrefix" FROM dual),
  'XML', 'state', 'myC5.0Function'));

```

## A.5 rqRevoke Procedure

The `rqRevoke` procedure revokes read privilege access to an Oracle R Enterprise datastore or to a script in the Oracle Database R script repository.

**Syntax**

```

rqGrant (
  V_NAME      VARCHAR2      IN
  V_TYPE      VARCHAR2      IN
  V_USER      VARCHAR2      IN      DEFAULT)

```

**Parameters**

| Parameter | Description                                                                                          |
|-----------|------------------------------------------------------------------------------------------------------|
| V_NAME    | The name of an Oracle R Enterprise datastore or a script in the Oracle Database R script repository. |
| V_TYPE    | For a datastore, the type is datastore; for a script, the type is rqscript.                          |
| V_USER    | The name of the user from whom to revoke access.                                                     |

**Example A-7 Revoking Read Access to a Script**

```
-- Revoke read privilege access to Scott.
BEGIN
    rqRevoke('myRandomRedDots2', 'rqscript', 'SCOTT');
END;
/
```

## A.6 rqRowEval Function

The `rqRowEval` function executes the R function in the script specified by the `EXP_NAM` parameter. You pass data to the R function with the `INP_CUR` parameter. You can pass arguments to the R function with the `PAR_CUR` parameter. The `ROW_NUM` parameter specifies the number of rows that should be passed to each invocation of the R function. The last chunk may have fewer rows than the number specified.

The `rqRowEval` function supports data-parallel execution, in which one or more R engines perform the same R function, or task, on disjoint chunks of data. Oracle Database handles the management and control of the potentially multiple R engines that run on the database server machine, automatically chunking and passing data to the R engines executing in parallel. Oracle Database ensures that R function executions for all chunks of rows complete, or the `rqRowEval` function returns an error.

The R function returns an `R data.frame` object, which appears as a SQL table in the database. You define the form of the returned value with the `OUT_QRY` parameter.

**Syntax**

```
rqRowEval (
    INP_CUR    REF CURSOR    IN
    PAR_CUR    REF CURSOR    IN
    OUT_QRY    VARCHAR2      IN
    ROW_NUM    NUMBER        IN
    EXP_NAM    VARCHAR2      IN)
```

**Parameters****Table A-1 Parameters of the rqRowEval Function**

| Parameter | Description                                                                                                  |
|-----------|--------------------------------------------------------------------------------------------------------------|
| INP_CUR   | A cursor that specifies the data to pass to the R function specified by the <code>EXP_NAME</code> parameter. |

**Table A-1 (Cont.) Parameters of the rqRowEval Function**

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PAR_CUR   | A cursor that contains argument values to pass to the R function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| ROW_NUM   | The number of rows to include in each invocation of the R function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| EXP_NAM   | The name of a script in the Oracle Database R script repository.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

### Return Value

Function `rqRowEval` returns a table that has the structure specified by the `OUT_QRY` parameter value.

### Examples

[Example A-8](#) (page A-11) uses the C50 package to score churn data (that is, to predict which customers are likely to churn) using C5.0 decision tree models. The example scores the customers from the specified state in parallel. This example produces the same result as the invocation of function `ore.rowApply` in [Example 6-16](#) (page 6-36).

#### Tip:

[Example A-8](#) (page A-11) uses the CHURN\_TEST table and the `myXLevels` datastore created by [Example 6-16](#) (page 6-36) so in R you should invoke the functions that create the table and that get the `xlevels` object and save it in the `myXLevels` datastore in [Example 6-16](#) (page 6-36) before running [Example A-8](#) (page A-11).

As [Example A-6](#) (page A-8) does, [Example A-8](#) (page A-11) creates a user-defined function and saves the function in the Oracle Database R script repository. The user-defined function creates a C5.0 model for a state and saves the model in a datastore. In [Example A-8](#) (page A-11), however, the user-defined function

`myC5.0FunctionForLevels` uses the list of levels created in [Example 6-16](#) (page 6-36) instead of computing the levels using the `as.factor` function as function `myC5.0Function` does in [Example A-6](#) (page A-8). The function `myC5.0FunctionForLevels` returns the value `TRUE`.

As [Example A-6](#) (page A-8) does, [Example A-8](#) (page A-11) creates the PL/SQL package `churnPkg` and the function `churnGroupEval`. [Example A-6](#) (page A-8) declares a cursor to get the names of the datastores that include the string `myC5.0modelFL` and then executes a PL/SQL block that deletes those datastores. The example next executes a `SELECT` statement that invokes the `churnGroupEval` function. The `churnGroupEval` function invokes the `myC5.0FunctionForLevels` function to generate the C5.0 models and save them in datastores.

[Example A-8](#) (page A-11) then creates the `myScoringFunction` function and stores it in the R script repository. The function scores a C5.0 model for the levels of a state and returns the results in a `data.frame`.

Finally, [Example A-8](#) (page A-11) executes a `SELECT` statement that invokes the `rqRowEval` function. The input cursor to the `rqRowEval` function uses the `PARALLEL` hint to specify the degree of parallelism to use. The cursor specifies the `CHURN_TEST` table as the data source and filters the rows to include only those for Massachusetts. All rows processed use the same predictive model.

The parameters cursor specifies the `ore.connect` control argument to connect to Oracle R Enterprise on the database server and specifies values for the `datastorePrefix` and `xlevelsDatastore` arguments to the `myScoringFunction` function.

The `SELECT` statement for the `OUT_QRY` parameter specifies the format of the output. The `ROW_NUM` parameter specifies 200 as the number of rows to process at a time in each parallel R engine. The `EXP_NAME` parameter specifies `myScoringFunction` in the R script repository as the R function to invoke.

#### **Example A-8 Using an rqRowEval Function**

```
BEGIN
  sys.rqScriptDrop('myC5.0FunctionForLevels');
  sys.rqScriptCreate('myC5.0FunctionForLevels',
    'function(dat, xlevelsDatastore, datastorePrefix) {
      library(C50)
      state <- dat[1,"state"]
      datastoreName <- paste(datastorePrefix, dat[1, "state"], sep = "_")
      dat$state <- NULL
      ore.load(name = xlevelsDatastore) # To get the xlevels object.
      for (j in names(xlevels))
        dat[[j]] <- factor(dat[[j]], levels = xlevels[[j]])
      c5mod <- C5.0(churn ~ ., data = dat, rules = TRUE)
      ore.save(c5mod, name = datastoreName)
      TRUE
    }');
END;
/

CREATE OR REPLACE PACKAGE churnPkg AS
  TYPE cur IS REF CURSOR RETURN CHURN_TEST%ROWTYPE;
END churnPkg;
/

CREATE OR REPLACE FUNCTION churnGroupEval(
  inp_cur churnPkg.cur,
  par_cur SYS_REFCURSOR,

## A.7 rqTableEval Function

The `rqTableEval` function executes the R function in the script specified by the `EXP_NAM` parameter. You pass data to the R function with the `INP_CUR` parameter. You can pass arguments to the R function with the `PAR_CUR` parameter.

The R function returns an R `data.frame` object, which appears as a SQL table in the database. You define the form of the returned value with the `OUT_QRY` parameter.

### Syntax

```

rqTableEval (
    INP_CUR      REF CURSOR      IN
    PAR_CUR      REF CURSOR      IN
    OUT_QRY      VARCHAR2        IN
    EXP_NAM      VARCHAR2        IN)

```

## Parameters

**Table A-2 Parameters of the `rqTableEval` Function**

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| INP_CUR   | A cursor that specifies the data to pass to the R function specified by the EXP_NAME parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| PAR_CUR   | A cursor that contains argument values to pass to the input function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| OUT_QRY   | One of the following: <ul style="list-style-type: none"> <li>• <code>NULL</code>, which returns a serialized object that can contain both data and image objects.</li> <li>• A SQL <code>SELECT</code> statement that specifies the column names and data types of the table returned by <code>rqEval</code>. Any image data is discarded. You can provide a prototype row using the dual dummy table or you can base the <code>SELECT</code> statement on an existing table or view. The R function must return a <code>data.frame</code>.</li> <li>• The string <code>'XML'</code>, which specifies that the table returned contains a CLOB that is an XML string. The XML can contain both structured data and images, with structured or semi-structured R objects first, followed by the image or images generated by the R function. Images are returned as a base 64 encoding of the PNG representation.</li> <li>• The string <code>'PNG'</code>, which specifies that the table returned contains a BLOB that has the image or images generated by the R function in PNG format.</li> </ul> |
| EXP_NAM   | The name of a script in the Oracle R Enterprise R script repository.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## Return Value

Function `rqTableEval` returns a table that has the structure specified by the `OUT_QRY` parameter value.

## Examples

[Example A-9](#) (page A-15) first has a PL/SQL block that drops the script `myNaiveBayesModel` to ensure that the script does not exist in the Oracle R Enterprise R script repository. It then creates a function and stores it as the script `myNaiveBayesModel` in the repository.

The R function accepts two arguments: the data on which to operate and the name of a datastore. The function builds a Naive Bayes model on the `iris` data set. Naive Bayes is found in the `e1071` package.

The `myNaiveBayesModel` function loads the `e1071` package so that the function body has access to it when the function executes in an R engine on the database server. Because factors in the `data.frame` are converted to character vectors when they are loaded in the user-defined embedded R function, the `myNaiveBayesModel` function explicitly converts the character vector to an R factor.

The `myNaiveBayesModel` function gets the data from the specified column and then creates a model and saves it in a datastore. The R function returns `TRUE` to have a simple value that can appear as the result of the function execution.

[Example A-9](#) (page A-15) next executes a `SELECT` statement that invokes the `rqTableEval` function. In the `INP_CUR` argument of the `rqTableEval` function, the `SELECT` statement specifies the data set to pass to the R function. The data is from the `IRIS` table that was created by invoking `ore.create(iris, "IRIS")`, which is not shown in the example. The `INP_CUR` argument of the `rqTableEval` function specifies the name of a datastore to pass to the R function and specifies the `ore.connect` control argument to establish an Oracle R Enterprise connection to the database during the embedded R execution of the user-defined R function. The `OUT_QRY` argument specifies returning the value in XML format, and the `EXP_NAM` argument specifies the `myNaiveBayesModel` script in the R script repository as the R function to invoke.

#### **Example A-9 Using the rqTableEval Function**

```
BEGIN
  sys.rqScriptDrop('myNaiveBayesModel');
  sys.rqScriptCreate('myNaiveBayesModel',
    'function(dat, datastoreName) {
      library(e1071)
      dat$Species <- as.factor(dat$Species)
      nbmod <- naiveBayes(Species ~ ., dat)
      ore.save(nbmod, name = datastoreName)
      TRUE
    }');
END;
/

SELECT *
FROM table(rqTableEval(
  cursor(SELECT * FROM IRIS),
  cursor(SELECT 'myNaiveBayesDatastore' "datastoreName",
    1 as "ore.connect" FROM dual),
  'XML', 'myNaiveBayesModel'));
```

The `SELECT` statement returns from the `rqTableEval` table function an XML string that contains the value `TRUE`.

The `myNaiveBayesDatastore` datastore now exists and contains the object `nbmod`, as shown by the following `SELECT` statement.

```
SQL> SELECT * from rquser_DataStoreContents
      2 WHERE dsname = 'myNaiveBayesDatastore';
```

| DSNAME                | OBJNAME | CLASS      | OBJSIZE | LENGTH | NROW | NCOL |
|-----------------------|---------|------------|---------|--------|------|------|
| myNaiveBayesDatastore | nbmod   | naiveBayes | 1485    | 4      |      |      |

In a local R session, you could load the model and display it, as in the following:

```
R> ore.load("myNaiveBayesDatastore")
[1] "nbmod"
R> nbmod
$apriori

A.8 sys.rqScriptCreate Procedure

The sys.rqScriptCreate procedure creates a script and adds it to the Oracle R Enterprise R script repository.

Syntax

```
sys.rqScriptCreate (
  V_NAME      VARCHAR2  IN
  V_SCRIPT    CLOB      IN
  V_GLOBAL    BOOLEAN   IN    DEFAULT
  V_OVERWRITE BOOLEAN   IN    DEFAULT)
```

| Parameter | Description                                                                           |
|-----------|---------------------------------------------------------------------------------------|
| V_NAME    | A name for the script in the Oracle R Enterprise R script repository.                 |
| V_SCRIPT  | The R function definition to store in the script.                                     |
| V_GLOBAL  | TRUE specifies that the script is public; FALSE specifies that the script is private. |

| Parameter   | Description                                                                                                                                                              |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| V_OVERWRITE | If the R script repository already has a script with the same name as V_NAME, then TRUE replaces the content of that script with V_SCRIPT and FALSE does not replace it. |

**Related Topics:**

[Creating a Script with the SQL APIs](#) (page 6-47)

[Manage Scripts in SQL](#) (page 6-46)

## A.9 sys.rqScriptDrop Procedure

The `sys.rqScriptDrop` procedure removes a script from the Oracle R Enterprise R script repository.

**Syntax**

```
sys.rqScriptCreate (
  V_NAME      VARCHAR2   IN
  V_GLOBAL    BOOLEAN    IN      DEFAULT
  V_SILENT    BOOLEAN    IN      DEFAULT)
```

| Parameter | Description                                                                                                                                                              |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| V_NAME    | A name for the script in the Oracle R Enterprise R script repository.                                                                                                    |
| V_GLOBAL  | TRUE specifies that the script is public; FALSE specifies that the script is private.                                                                                    |
| V_SILENT  | If the R script repository already has a script with the same name as V_NAME, then TRUE replaces the content of that script with V_SCRIPT and FALSE does not replace it. |

## B.1 ALL\_RQ\_DATASTORES

ALL\_RQ\_DATASTORES describes the datastores available to the current user.

| Column  | Datatype         | Null        | Description                             |
|---------|------------------|-------------|-----------------------------------------|
| DSOWNER | VARCHAR2 ( 256 ) | NOT<br>NULL | The owner of the datastore.             |
| DSNAME  | VARCHAR2 ( 128 ) | NOT<br>NULL | The name of the datastore.              |
| NOBJ    | NUMBER           | NOT<br>NULL | The number of objects in the datastore. |
| DSSIZE  | NUMBER           | NOT<br>NULL | The size of the datastore.              |

| Column      | Datatype       | Null            | Description                                                                                 |
|-------------|----------------|-----------------|---------------------------------------------------------------------------------------------|
| CDATE       | DATE           | NOT<br>NULL     | The creation date of the datastore.                                                         |
| DESCRIPTION | VARCHAR2(2000) | NULL<br>allowed | A description of the datastore.                                                             |
| GRANTABLE   | VARCHAR2(1)    | NOT<br>NULL     | Whether read privilege access to the datastore can be granted by the owner to another user. |

**Related Topics:**

[About Oracle R Enterprise Datastores](#) (page 2-19)

[Manage Datastores in SQL](#) (page 6-48)

## B.2 ALL\_RQ\_SCRIPTS

ALL\_RQ\_SCRIPTS describes the scripts in the Oracle Database R script repository that are available to the current user.

| Column | Datatype      | Null        | Description                   |
|--------|---------------|-------------|-------------------------------|
| OWNER  | VARCHAR2(256) | NOT<br>NULL | The owner of the script.      |
| NAME   | VARCHAR2(128) | NOT<br>NULL | The name of the script.       |
| SCRIPT | CLOB          | NOT<br>NULL | The R function of the script. |

**Related Topics:**

[USER\\_RQ\\_SCRIPT\\_PRIVS](#) (page B-4)

[USER\\_RQ\\_SCRIPTS](#) (page B-5)

## B.3 RQUSER\_DATASTORECONTENTS

RQUSER\_DATASTORECONTENTS contains information about the contents of Oracle R Enterprise datastores.

| Column  | Datatype      | Null     | Description                                |
|---------|---------------|----------|--------------------------------------------|
| DSNAME  | VARCHAR2(128) | NOT NULL | The name of the datastore.                 |
| OBJNAME | VARCHAR2(128) | NOT NULL | The names of the objects in the datastore. |
| CLASS   | VARCHAR2(128) | NOT NULL | The R class of an object.                  |
| DSSIZE  | NUMBER        | NOT NULL | The size of an object.                     |
| LENGTH  | NUMBER        | NOT NULL | The size of an object.                     |

| Column | Datatype | Null            | Description                         |
|--------|----------|-----------------|-------------------------------------|
| NROW   | NUMBER   | NULL<br>allowed | The number of rows in an object.    |
| NCOL   | NUMBER   | NULL<br>allowed | The number of columns in an object. |

**Related Topics:**

[ALL\\_RQ\\_DATASTORES](#) (page B-1)

[RQUSER\\_DATASTORELIST](#) (page B-3)

## B.4 RQUSER\_DATASTORELIST

RQUSER\_DATASTORELIST contains information about Oracle R Enterprise datastores.

| Column      | Datatype       | Null            | Description                           |
|-------------|----------------|-----------------|---------------------------------------|
| DSNAME      | VARCHAR2(128)  | NOT NULL        | The name of the datastore.            |
| NOBJ        | NUMBER         | NOT NULL        | The number of objects in a datastore. |
| DSSIZE      | NUMBER         | NOT NULL        | The size of the datastore.            |
| CDATE       | DATE           | NOT NULL        | The date the datastore was created.   |
| DESCRIPTION | VARCHAR2(2000) | NULL<br>allowed | The description of the datastore.     |

**Related Topics:**

## B.5 USER\_RQ\_DATASTORE\_PRIVS

USER\_RQ\_DATASTORE\_PRIVS describes the datastores and the users to whom the current user has granted read privilege access.

| Column  | Datatype      | Null     | Description                                              |
|---------|---------------|----------|----------------------------------------------------------|
| DSNAME  | VARCHAR2(128) | NOT NULL | The name of a datastore.                                 |
| GRANTEE | VARCHAR2(30)  | NOT NULL | The user to whom read privilege access has been granted. |

**Related Topics:**

## B.6 USER\_RQ\_DATASTORES

USER\_RQ\_DATASTORES describes datastores created by the current user.

| Column      | Datatype       | Null            | Description                                                                                 |
|-------------|----------------|-----------------|---------------------------------------------------------------------------------------------|
| DSNAME      | VARCHAR2(128)  | NOT<br>NULL     | The name of a datastore.                                                                    |
| NOBJ        | NUMBER         | NOT<br>NULL     | The number of objects in the datastore.                                                     |
| DSSIZE      | NUMBER         | NOT<br>NULL     | The size of the datastore.                                                                  |
| CDATE       | DATE           | NOT<br>NULL     | The creation date of the datastore.                                                         |
| DESCRIPTION | VARCHAR2(2000) | NULL<br>allowed | A description of the datastore.                                                             |
| GRANTABLE   | VARCHAR2(1)    | NOT<br>NULL     | Whether read privilege access to the datastore can be granted by the owner to another user. |

# R Operators and Functions Supported by Oracle R Enterprise

The Oracle R Enterprise packages support many R operators and functions that you can use with Oracle R Enterprise objects. This appendix lists the R operators and functions that Oracle R Enterprise supports.

The Oracle R Enterprise sample programs described in "[Oracle R Enterprise Examples](#) (page 1-14)" include several examples using each category of these functions with Oracle R Enterprise data types.

You are not restricted to using this list of functions. If a specific function that you need is not supported by Oracle R Enterprise, you can pull data from the database into the R engine memory using `ore.pull` to create an in-memory R object first, and use any R function.

The following operators and functions are supported. See R documentation for syntax and semantics of these operators and functions. Syntax and semantics for these items are unchanged when used on a corresponding database-mapped data type (also known as an Oracle R Enterprise data type). For a list of Oracle R Enterprise data types, see "[Transparency Layer Support for R Data Types and Classes](#) (page 1-7)".

- **Mathematical transformations:** `abs`, `sign`, `sqrt`, `ceiling`, `floor`, `trunc`, `cummax`, `cummin`, `cumprod`, `cumsum`, `log`, `loglo`, `log10`, `log2`, `log1p`, `acos`, `acosh`, `asin`, `asinh`, `atan`, `atanh`, `exp`, `expm1`, `cos`, `cosh`, `sin`, `sinh`, `tan`, `atan2`, `tanh`, `gamma`, `lgamma`, `digamma`, `trigamma`, `factorial`, `lfactorial`, `round`, `signif`, `pmin`, `pmax`, `zapsmall`, `rank`, `diff`, `besselI`, `besselJ`, `besselK`, `besselY`

  - **Data processing:** eval, with, within, transform
  - **Apply variants:** tapply, aggregate, by
  - **Special value checks:** is.na, is.finite, is.infinite, is.nan
  - **Metadata functions:** nrow, NROW, ncol, NCOL, nlevels, names, names<-, row, col, dimnames, dimnames<-, dim, length, row.names, row.names<-, rownames, rownames<-, colnames, levels, reorder
  - **Graphics:** arrows, boxplot, cdplot, co.intervals, coplot, hist, identify, lines, matlines, matplot, matpoints, pairs, plot, points, polygon, polypath, rug, segments, smoothScatter, sunflowerplot, symbols, text, xspline, xy.coords
  - **Conversion functions:** as.logical, as.integer, as.numeric, as.character, as.vector, as.factor, as.data.frame
  - **Type check functions:** is.logical, is.integer, is.numeric, is.character, is.vector, is.factor, is.data.frame
  - **Character manipulation:** nchar, tolower, toupper, casefold, chartr, sub, gsub, substr
  - **Other ore.frame functions:** data.frame, max.col, scale
  - **Hypothesis testing:** binom.test, chisq.test, ks.test, prop.test, t.test, var.test, wilcox.test
  - **Various Distributions:** Density, cumulative distribution, and quantile functions for standard distributions
  - **ore.matrix function:** show, is.matrix, as.matrix, %\*% (matrix multiplication), t, crossprod (matrix cross-product), tcrossprod (matrix cross-product A times transpose of B), solve (invert), backsolve, forwardsolve, all appropriate mathematical functions (abs, sign, and so on), summary (max, min, all, and so on), mean

## A

---

- access control
  - for datastores, [2-21](#), [6-48](#)
  - for scripts, [6-13](#), [6-46](#)
- accessor functions, [3-18](#)
- aggregate function, [1-7](#), [3-7](#)
- aggregating data, [3-7](#)
- aggregation functions, [3-16](#)
- ALL\_RQ\_DATASTORES view, [B-1](#)
- ALL\_RQ\_SCRIPTS view, [B-2](#)
- apriori algorithm, [4-13](#)
- arima function, [3-20](#)
- arules package, [xiv](#)
- as.Date function, [3-17](#)
- as.difftime function, [3-16](#), [3-17](#)
- as.integer function, [3-19](#)
- as.ore class, [3-19](#)
- as.ore function, [1-10](#)
- as.ore.character function, [1-10](#), [3-19](#)
- as.ore.date function, [3-19](#)
- association models, [4-13](#)
- attaching a schema, [2-8](#)
- attribute importance models, [4-16](#)

## C

---

- C50 package, [6-5](#), [6-27](#), [6-34](#), [A-7](#), [A-10](#)
- class inheritance, [1-6](#)
- coercing class types, [1-10](#)
- columns
  - deriving, [3-7](#)
  - partitioning on, [6-29](#)
- combining data, [3-6](#)
- Comprehensive R Archive Network
  - See CRAN packages
- connecting an R session, [2-1](#)
- connection types, [2-2](#)
- connections, specifying, [2-2](#)
- control arguments for embedded R execution, [6-11](#)
- CRAN packages, [xiv](#), [1-2](#), [3-1](#), [3-41](#), [6-4](#), [6-5](#)
- creating a table, [2-16](#)
- creating proxy objects, [2-5](#)

- cross-validating models, [4-35](#)

## D

---

- data
  - distribution analysis of, [3-38](#)
  - exploring, [3-22](#)
  - indexing, [3-5](#)
  - joining, [3-6](#)
  - partitioning, [3-15](#)
  - preparing, [1-2](#), [3-1](#)
  - ranking, [3-34](#)
  - sampling, [3-10](#)
  - scoring, [1-2](#)
  - selecting, [3-2](#)
  - sorting, [3-35](#)
  - summarizing, [3-7](#), [3-36](#)
  - transforming, [3-7](#)
- data types
  - coercing to another type, [3-19](#)
- datastores
  - about, [2-19](#)
  - access control, [2-21](#)
  - deleting, [2-25](#)
  - getting information about, [2-22](#)
  - in embedded R execution, [2-25](#), [6-34](#), [A-7](#), [A-10](#), [A-14](#)
  - managing in SQL, [6-48](#)
  - restoring objects from, [2-23](#)
  - saving objects in, [2-17](#), [2-19](#)
  - sharing, [x](#), [xi](#)
- datatypes
  - BLOB and CLOB, [xiii](#)

- Decision Tree algorithm, [4-17](#)
- decision tree models, [4-17](#)
- demo function, [1-15](#)
- demos, [1-14](#)
- detaching a schema, [2-8](#)
- diff function, [3-16](#), [3-17](#)
- do.call function, [3-12](#), [3-13](#)

dropping a table, [2-16](#)

## E

---

e1071 package, [6-25](#)  
easy connect string, specifying, [2-3](#)  
embedded R execution  
    about, [6-1](#)  
    APIs for, [6-2](#)  
    control arguments, [6-11](#)  
    parallel execution, [6-4](#), [6-13](#)  
    R interface for, [6-9](#)  
    security, [6-3](#)  
    SQL interface for, [6-43](#)  
example scripts, [1-14](#)  
executing SQL statements, [2-10](#)  
exploratory data analysis  
    data set for examples, [3-23](#)  
exponential smoothing models, [3-30](#)

## F

---

filtering data, [2-15](#)  
forecast package, [3-31](#)  
formatting data, [3-7](#)

## G

---

generalized linear models, [4-5](#), [4-18](#)  
glm function, [4-5](#)  
global options  
    ore.envAsEmptyenv, [1-13](#)  
    ore.na.extract, [1-13](#)  
    ore.parallel, [1-13](#)  
    ore.sep, [1-13](#)  
    ore.trace, [1-13](#)  
    ore.warn.order, [1-13](#)

## H

---

Hadoop cluster, [2-2](#)  
HIVE connection type, [2-2](#)

## I

---

indexing data, [3-5](#)  
install.packages function, [3-41](#)  
IRLS algorithm, [4-5](#)  
is.null function, [2-10](#)

## K

---

k-Means models, [4-21](#)  
kernlab package, [2-10](#), [3-41](#)  
keys  
    ordering with, [2-10](#)

kyphosis data set, [4-5](#)

## L

---

lapply function, [3-12](#)  
least squares regression, [4-3](#)  
library function, [3-41](#)  
linear regression model, [4-3](#)  
longley data set, [4-2](#)

## M

---

map/reduce operations, [4-5](#)  
max function, [3-16](#)  
min function, [3-16](#)  
Minimum Description Length algorithm, [4-16](#)  
models  
    association, [4-13](#)  
    attribute importance, [4-16](#)  
    cross-validating, [4-35](#)  
    decision tree, [4-17](#)  
    generalized linear, [4-5](#), [4-18](#)  
    k-Means, [4-21](#)  
    linear regression, [4-3](#)  
    Naive Bayes, [4-25](#)  
    neural network, [4-7](#)  
    Non-Negative Matrix Factorization, [4-27](#)  
    Oracle Data Mining, [4-11](#)  
    Orthogonal Partitioning Cluster, [4-29](#)  
    parametric, [4-19](#)  
    predictive, [5-1](#)  
    randomForest, [4-9](#)  
    Support Vector Machine, [4-31](#)

## N

---

Naive Bayes models, [4-25](#)  
naming conventions, [1-10](#)  
NARROW data set, [3-23](#)  
neural network models, [4-1](#), [4-7](#)  
NMF models, [4-27](#)

## O

---

O-Cluster models, [4-29](#)  
open source R packages, [3-41](#), [6-4](#)  
Oracle Advanced Analytics, [1-1](#)  
ORACLE connection type, [2-2](#)  
Oracle Data Mining models, [4-1](#), [4-11](#)  
Oracle R Advanced Analytics for Hadoop, [2-2](#)  
Oracle Wallet, [2-2](#), [2-4](#)  
ordering ore.frame objects, [1-8](#), [2-9](#)  
ore.attach function, [2-5](#), [2-8](#)  
ore.character objects, [3-19](#)  
ore.connect control argument for embedded R  
    execution, [6-11](#)

ore.connect function, [2-1](#), [2-2](#)  
 ore.corr function, [3-22](#), [3-23](#)  
 ore.create function, [2-16](#)  
 ore.crosstab function, [3-22](#), [3-25](#)  
 ore.CV function, [4-35](#)  
 ore.datastore function, [2-18](#), [2-22](#)  
 ore.datastoreSummary function, [2-18](#), [2-22](#)  
 ore.date objects, [3-19](#)  
 ore.datetime objects, [3-19](#)  
 ore.delete function, [2-18](#), [2-25](#)  
 ore.detach function, [2-8](#)  
 ore.disconnect function, [2-1](#), [2-3](#)  
 ore.doEval function, [6-19](#)  
 ore.drop control argument for embedded R execution, [6-11](#)  
 ore.drop function, [2-16](#)  
 ore.envAsEmptyenv control argument for embedded R execution, [6-11](#)  
 ore.envAsEmptyenv global option, [1-13](#)  
 ore.esm function, [3-22](#), [3-30](#)  
 ore.exec function, [2-10](#), [3-3](#)  
 ore.exists function, [2-6](#)  
 ore.frame objects  
     about, [1-8](#)  
     as proxy for a table, [2-5](#)  
     column naming conventions, [1-10](#)  
     ordering, [1-8](#)  
     subclass of data.frame, [1-6](#)  
 ore.freq function, [3-22](#), [3-30](#)  
 ore.get function, [2-7](#)  
 ore.glm function, [4-2](#), [4-5](#)  
 ore.grant, [2-21](#)  
 ore.grant function, [2-18](#), [6-13](#)  
 ore.graphics control argument for embedded R execution, [6-12](#)  
 ore.groupApply function, [xii](#), [3-15](#), [6-26](#)  
 ore.hour function, [3-18](#)  
 ore.indexApply function, [6-39](#)  
 ore.integer objects, [3-19](#)  
 ore.is.connected function, [2-1](#)  
 ore.lazyLoad function, [2-18](#)  
 ore.list class, [2-15](#)  
 ore.lm function, [4-2](#), [4-3](#)  
 ore.load function, [2-18](#), [2-23](#)  
 ore.logical class, [3-17](#)  
 ore.ls function, [2-6](#)  
 ore.mday function, [3-18](#)  
 ore.minute function, [3-18](#)  
 ore.month function, [3-18](#)  
 ore.na.extract global option, [1-13](#)  
 ore.na.omit control argument for embedded R execution, [6-11](#)  
 ore.neural function, [4-2](#), [4-7](#)  
 ore.odmAI function, [4-16](#)  
 ore.odmAssocRules function, [4-13](#)  
 ore.odmDT function, [4-17](#)  
 ore.odmGLM function, [4-18](#)  
 ore.odmKM function, [4-21](#)  
 ore.odmNB function, [4-25](#)  
 ore.odmNMF function, [4-27](#)  
 ore.odmOC function, [4-29](#)  
 ore.odmSVM function, [4-31](#)  
 ore.parallel global option, [1-13](#)  
 ore.png control arguments for embedded R execution, [6-12](#)  
 ore.pull function, [1-10](#), [2-15](#), [3-20](#)  
 ore.push function, [1-10](#), [2-15](#), [4-3](#)  
 ore.randomForest function, [4-9](#)  
 ore.rank function, [3-22](#), [3-34](#)  
 ore.revoke, [2-18](#), [2-21](#)  
 ore.revoke function, [6-13](#)  
 ore.rm function, [2-6](#)  
 ore.rollmean function, [3-20](#)  
 ore.rollsd function, [3-20](#)  
 ore.rowApply function, [6-33](#)  
 ore.save function, [2-18](#), [2-19](#)  
 ore.scriptCreate function, [6-13](#)  
 ore.scriptDrop function, [6-13](#)  
 ore.scriptList function, [6-13](#)  
 ore.scriptLoad function, [6-13](#)  
 ore.second function, [3-18](#)  
 ore.sep global option, [1-13](#), [2-10](#)  
 ore.sort function, [3-22](#), [3-35](#)
