### Glossary
Agile PLM is a comprehensive enterprise PLM solution for managing your product value chain.

Audience

This document is intended for administrators and users of the Agile PLM products.

Documentation Accessibility

For information about Oracle's commitment to accessibility, visit the Oracle Accessibility Program website at http://www.oracle.com/pls/topic/lookup?ctx=acc&id=docacc.

Access to Oracle Support

Oracle customers have access to electronic support through My Oracle Support. For information, visit http://www.oracle.com/pls/topic/lookup?ctx=acc&id=info or visit http://www.oracle.com/pls/topic/lookup?ctx=acc&id=trs if you are hearing impaired.

Related Documents

Oracle's Agile PLM documentation set includes Adobe® Acrobat PDF files. The Oracle Technology Network (OTN) Web site http://www.oracle.com/technetwork/documentation/agile-085940.html contains the latest versions of the Agile PLM PDF files. You can view or download these manuals from the Web site, or you can ask your Agile administrator if there is an Agile PLM Documentation folder available on your network from which you can access the Agile PLM documentation (PDF) files.

Conventions

The following text conventions are used in this document:

<table>
<thead>
<tr>
<th>Convention</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>boldface</strong></td>
<td>Boldface type indicates graphical user interface elements associated with an action, or terms defined in text or the glossary.</td>

</tr>
<tr>
<td>------------</td>
<td>---------</td>
</tr>
<tr>
<td>monospace</td>
<td>Monospace type indicates commands within a paragraph, URLs, code in examples, text that appears on the screen, or text that you enter.</td>
</tr>
</tbody>
</table>
This chapter includes:
- Understanding AIS
- Web Services Operations
- Web Services Extensions
- Security Considerations

Understanding AIS

The Agile Integration Services (AIS) are a collection of predefined Web Services in the Agile Integration Framework that enable communication between the Agile Application Server and disparate systems including:

- Enterprise Resource Planning (ERP) systems
- Customer Resource Management (CRM) systems
- Business-to-Business Integration systems (B2B)
- Other Agile PLM systems and supply chain partners

Using AIS to exchange content with other systems simplifies the process for aggregating unprocessed product content, and makes critical product content available in real time to other systems. AIS Web Services also provide import and export capabilities that you can use to:

- Make product content available to Enterprise Application Integration (EAI) systems
- Share product content with product design, manufacturing planning, shop floor, and ERP and CRM applications
- Make product content available to B2B systems that can transfer Agile Application Server data across corporate boundaries to external applications
- Provide content to custom applications
- Import product content data from ERP and other supply-chain applications
Key Features

Key features supported by AIS include:

- Programmatic access to data -- AIS supports programmatic access to data stored in Agile PLM systems.
- Programmatic validation of imported data-- Using the Agile SDK methods, AIS enables checking the imported data for compliance with server rules before they are actually imported.
- Product content accessibility -- AIS provides accessibility to Agile product content outside of corporate firewalls using standard HTTP(S) technology.

**Note:** Export and Import attachment types are not compatible with the .Net attachment types.

- Multiple output format support -- AIS supports the aXML and Product Data eXchange (PDX) 1.0 formats (PDX is defined in Web Services Operations).
- Internet Security safeguards -- AIS communicates with XML-compliant applications using Internet-standard communication and security protocols (HTTP and SSL), for a secure and firewall-friendly interface.
- Multilevel BOM support -- AIS supports converting a multilevel BOM into individual parts data in the XML format.

AIS Architecture

Connection to AIS is established using standard Web service invocation methodologies shown in the following illustration.

AIS Folders

AIS documentation and source files for sample clients are in the AIS_samples.zip folder. You can find this folder in Oracles Technology Network at: [http://www.oracle.com/technetwork/indexes/samplecode/agileplm-sample-520945.html](http://www.oracle.com/technetwork/indexes/samplecode/agileplm-sample-520945.html).

For more information, contact your System Administrator, or refer to your Agile PLM installation Guide. The AIS_samples.zip file includes the following folders:

- documentation - Documents the Web Services that are supported by the Agile Import/Export APIs.
- lib - Contains the common JAR files used by AIS samples.
- sample - Contains the source code of a sample Import/Export Web service client.

Understanding AIS Web Services

AIS Web Services is a technology for building distributed applications. These services, which are available over the Internet, use a standardized XML messaging system and are not tied to any one operating system or programming language. Through Web Services, you can encapsulate existing business processes, publish them as services, search for and subscribe to other services, and exchange information throughout and beyond the enterprise. Web Services are based on universally agreed upon specifications for structured data exchange, messaging, discovery of services, interface description, and business process design.
A Web service makes remote procedure calls (RPC) across the Internet. It uses:

- HTTP(S) or other transport protocols such as HTTP to transport requests and responses.
- Simple Object Access Protocol (SOAP) to communicate the request and response information.

Key advantages of Web Services are:

- Service-oriented Architecture (SOA) -- Unlike packaged products, Web Services can be delivered as streams of services that allow access from any platform. SOAs are a new approach to enterprise application integration by building applications from software services.
- Interoperability -- Web Services ensure complete interoperability between systems.
- Integration -- Web Services facilitate flexible integration solutions, particularly if you are connecting applications running on different platforms or written in different languages.
- Modularity -- Web Services offer a modular approach to programming. Each business function in an application can be exposed as a separate Web service. Smaller modules reduce errors and result in more reusable components.
- Accessibility -- Business services can be completely decentralized. They can be distributed over the Internet and accessed by a wide variety of communications devices.
- Efficiency -- Web Services constructed from applications meant for internal use can be used externally without changing code. Incremental development using Web Services is relatively simple because Web Services are declared and implemented in a human readable format.

Web Services have certain limitations of the technology as it exists today, for example, supported software and specifications, problems using certain versions of applications or tools. In view of these constraints, consider the following when developing Web service applications:

- When developing Web service applications, avoid advanced operations such as distributed garbage collection, object activation, or call by reference. SOAP as a simple mechanism for handling data and requests over a transport medium is not designed to handle these operations.
- Web Services are network-based and are therefore affected by network traffic. The latency for any Web service invocation can often be measured in hundreds of milliseconds. Thus, the extent of functionality provided by the service must be significant enough to warrant making a high-latency call.
- Web Services do not work well with conversational programming languages. Thus, when designing services that you want to expose, make the service as independent as possible from these development tools.
**Web Services Architecture**

Web services architecture is best defined in terms of its roles and protocol stack:

- **Web service roles:**
  - Service provider - The provider of the service by implementing and making it available on the Internet.
  - Service requester - The user of the service who accesses the service by opening a network connection and sending an XML request.
  - Service registry - This is a centralized directory of services where developers can publish new services or find existing ones.

- **Web service protocol stack:**
  - Service transport layer - Uses HTTP to transport messages between applications. Other transports will be supported in future AIS releases.
  - XML messaging layer - Encodes messages in XML format by using SOAP, a platform-independent XML protocol used to exchange information between computers. It defines an envelope specification for encapsulated data being transferred, the data encoding rules, and remote procedure call (RPC) conventions.
  - Service description layer - Describes the public interface to a specific Web service by using the Web Service Description Language (WSDL) protocol.
    * WSDL defines an XML grammar for describing network services as collections of communication endpoints capable of exchanging messages, which contain either document-oriented or procedure-oriented information. The operations and messages are described abstractly, and then bound to a network protocol and message format.
    * WSDL allows description of endpoints and their messages regardless of what message formats or network protocols are used to communicate.
    * A WSDL document defines services as collections of network endpoints (called ports). A port is defined by associating a network address with a reusable binding. A collection of ports defines a service.

**Note:** AIS Web services do not currently support UDDI or other service discovery layers.

---

**Web Services Operations**

AIS enable you to export data programmatically into structured XML documents and import data into the Agile PLM system with the following prebuilt Web service operations:

- **exportData** -- A Web service operation that extracts data from an Agile PLM system. The `exportDataRequest` element encapsulates all the information needed to extract data from an Agile PLM system. The exportData Web service operation supports the following formats:
  - **Product Data eXchange (PDX)** -- A standardized XML format to represent structured product content. PDX provides a means for partners in the e-supply chain (OEMs, EMS providers, and component suppliers) to exchange product content and changes (BOMs, AMLs, ECRs, ECOs).
Agile XML (also known as aXML) -- The Agile XML format is an XML representation of Agile's business schema. The aXML file contains all product content managed in Agile such as items, change details, manufacturer information, cost, drawings and other files. As a representation of schema elements across all Agile products, aXML will evolve with Agile's business schema over time.

The list and location of Agile aXML schema files for different releases of the application are available at the following sites:

- Release 8.5 - The URL -
  http://www.oracle.com/technology/products/applications/xml/plm/2003/12/aXML.xsd

- Release 9.0 -
  http://www.oracle.com/technology/products/applications/xml/plm/2004/02/aXML.xsd

- Release 9.0SP4 -

- Release 9.1 -

- Release 9.2, 9.2.0.x -

- Release 9.2.1, 9.2.1.x -
  http://www.oracle.com/technology/products/applications/xml/plm/2006/03/aXML.xsd

- Release 9.2.2, 9.2.2.1, 9.2.2.2, 9.2.2.3 -

- Release 9.2.2.4, 9.2.2.5, 9.2.2.6, and 9.2.2.7 -
  http://www.oracle.com/technology/products/applications/xml/plm/2008/05/aXML.xsd

- Release 9.3 and 9.3.0.1 -

- Release 9.3.1 and 9.3.1.1 -

- Release 9.3.1 and 9.3.1.1 -
- **Release 9.3.2** -

- **Release 9.3.3** -

- **Release 9.3.4** -

- **Release 9.3.5** -

**exportPartList** -- A Web service operation that takes a multilevel BOM and "flattens" it into a list of the items and associated manufacturer parts as well as their quantities in the BOM; it then returns the data in aXML format. That is, it enables you to extract a rolled up set of parts, and the related Quantities Per Top Level Assembly (QPTLA). The `exportPartListRequest` element encapsulates all the information needed to extract a flattened partlist from an Agile PLM system.

---

**Note:** The value of the QPTLA is computed as the sum over recursive products starting from the top of the BOM tree. `exportPartList` calculates the QPTLA for each unique item-revision pair, and returns the results in the Part Quantities element of the resulting aXML output.

---

**importData** -- A Web service operation that imports data into the Agile PLM system. The `importDataRequest` element encapsulates all the information needed to request an import operation. The source for the import data can be an Agile database, a third party Product Data Management (PDM) system, or an Enterprise Resource Planning (ERP) system. The Agile server stores information about customer-specific items. It also maintains the relationships that assembly parts have with BOM components and that parent items have with approved manufacturers.

**importSupplierResponse** -- A Web service operation that imports an RFQ response from a supplier. The response is associated with an existing RFQ in the Agile PLM system.

---

**Note:** The `importSupplierResponse` Web service operation is deprecated and may not be supported in future releases. Use `importData` instead. For more information, see "Importing Supplier Responses" on page 4-7.

---

These Web service operations are invoked by submitting a properly formatted XML document to AIS. The contents of the XML document define the parameters that determine how the operation should be performed. For more information about using the prebuilt AIS Web Services, see Chapter 2, "Using AIS Web Services."
Web Services Extensions

You can use the Agile SDK to develop Web service extensions (WSX) that leverage the functionality of AIS while extending the functionality of the Agile PLM system. For example, if you need to extract data from the Agile server and then transform it before sending it to another ERP system, you could create a custom Web service that leverages the Export web service. For more information about web service extensions, refer to the Agile SDK Developer Guide.

Security Considerations

AIS communicates with XML-compliant applications using Internet-standard communication and security protocols (HTTP and SSL). You can encrypt communication between AIS and its Web server clients (via the Web server) using Secure Sockets Layer (SSL) and a server-side certificate, to provide authentication, privacy, and message integrity. Using standard Java cryptography libraries, you can encrypt and decrypt files, create security keys, digitally sign a file, and verify a digital signature.

User name and password security is enforced whenever a client attempts to invoke an Agile Integration Service operation.

For more information about Java security and cryptography support, refer to the following Web page:

This chapter includes:

- Tools that you can use to develop client applications
- Client Programming Languages
- Accessing AIS Web Services
- Checking Your AIS System
- About AIS Java Samples
- Creating a Web Service Client

**Tools that You Can Use to Develop Client Applications**

There is no single tool set to access Web Services. Tools that you choose are a function of the environment that you use to develop your clients. Essentially, you need tools to enable generating and processing XML files and HTTP request/response messages. You can use different implementations of SOAP tools regardless of the source language to build Web service clients.

**Client Programming Languages**

Oracle tests, certifies, and recommends Java to develop AIS clients.

WSDL is only supported with J2EE.

This is a list of some of the Web sites where you can find more information about these development tools:

- Apache Axis -- Open source SOAP implementation for Java. See the following Web site: [http://ws.apache.org/axis/](http://ws.apache.org/axis/)
- GlassFish Application Server -- GlassFish is a complete Java EE 5 Application Server. See Java Web Services Developer Pack at [https://glassfish.java.net/download.html](https://glassfish.java.net/download.html).

---

**Note:** The latest version of GlassFish Application Server is Java EE 7 Application Server, but this version is not certified for
Microsoft .Net -- An XML Web Services platform for Microsoft Windows that can be used to create Web service clients. See the following Web site for more information: http://msdn.microsoft.com/en-us/netframework/

**Note:** AIS was only tested with Java. Other tools and environments such as VB .Net should work, but AIS was not tested and is not supported for these tools and environments (operability with .Net (Visual C#) was tested with an earlier version of AIS).

SOAP::Lite for Perl -- A Perl implementation of the SOAP protocol. Refer to the following web site: http://www.soaplite.com/

### Accessing AIS Web Services

In general, to access AIS Web Services, you must:

1. Generate a SOAP request -- In many cases, a Web-Service-aware code library will be able to generate client-side stubs that generate an appropriately formatted SOAP request.

2. Submit that request to AIS via HTTP or HTTPS -- Once an appropriate set of client-side Java **stubs** are generated, a client application can use these stubs to submit a request.

3. Process the SOAP response -- The client-side stubs usually are responsible for processing the SOAP response and converting the response into an appropriate set of return objects.

The AIS samples provide comprehensive examples of how SOAP and Web service-related libraries can simplify this process. The following sections illustrate using the ExportData sample in "Running the Java Samples" on page 2-5 and the above steps in greater detail.

### Checking Your AIS System

Before compiling and running the AIS Web services Java and Web client samples, make sure the clients are functioning properly on the Agile PLM Application Server. For more information, refer to the Agile PLM Installation Guide.

### About AIS Java Samples

AIS provides several Java Web service client samples for you to download. These samples use Axis to connect with the AIS Web service engine to generate client-side stubs. You can use these sample clients to export and import data. They provide command-line interfaces to the ExportData, ExportPartlist, and ImportData Web service operations.

These AIS Java samples do not expose all AIS functionalities. They are only sample clients. For example, they enable running only one query at a time, while AIS supports running multiple queries and then aggregating the results. You may choose to develop AIS clients with additional functionality. The samples provide source code that you can use to practice developing your own AIS clients. For more information about functionalities supported by the Export and Import Web Services, refer to the Export and Import XML Schema documentation in Agile PLM's Import/Export User Guide.

Before building and running the AIS samples, download the following required tools:
The supported Java 2 SDK SE Versions 1.5, 1.6, 1.7 or 1.8. You can select and download the version of your choice from:
http://www.oracle.com/technetwork/java/javasebusiness/downloads/
java-archive-downloads-javase5-419410.html

The Apache Project’s Ant build tool, version 1.6 is available at:
http://ant.apache.org/

Installing the Java SDK

This section provides instructions to install the Java SDK on Windows and on Solaris platforms. You can skip this section if you already have the proper version of Java installed.

To install the Java SDK on Windows:
1. Double-click the distribution and follow the installation procedures.
2. Set the system variable JAVA_HOME to point to the home directory of your Java SDK installation (for example, D:\j2sdk150).

To install the Java SDK on UNIX:
1. Execute the distribution (for example, ./j2sdk-1_5_0-solaris-sparc.sh) and follow the installation procedures.
2. Set the environment variable JAVA_HOME to point to the home directory of your Java SDK installation (for example, /home/<user>/j2sdk150).
3. Depending on the shell that you are using, execute .profile or .cshrc to set up your environment.

Installing Ant

This section provides the instructions for installing Ant on Windows and on Solaris.

To install Ant on Windows:
1. Extract the contents of the ZIP archive to a local directory and follow the installation procedures.
   The Ant distribution for Windows is a ZIP file. For example, apache-ant-1.6.0-bin.zip).
2. Open a command prompt window and verify that Ant can be invoked by entering the following command: %ANT_HOME%\bin\ant -version
   The following output should be displayed: Apache Ant version 1.6.0 compiled on <date>

To install the Ant on UNIX:
1. Extract the contents of the tar archive to a local directory (for example, /home/user/ant) and follow the procedures.
   The ANT distribution for UNIX is a tar file. For example, apache-ant-1.6.0-bin.tar.gz).
2. Depending on the shell you are using, execute .profile or .cshrc files to set up your environment.
3. From a command prompt, verify that Ant can be invoked by entering the following command: $ANT_HOME/bin/ant -version
Upon successful installation, the following message appears:

Apache Ant version 1.6.0 compiled on \<date>.

Building the Java Samples

Building the Java samples is straightforward. You need the Ant build tool, which is available for download at: http://ant.apache.org/. For procedures, see "Installing Ant" on page 2-3. Run Ant within the samples directory, pointing the URL to your AIS installation.

If you generated client stubs for the AIS samples from the WSDL, they will run on any other computer. Alternately, if you have the WSDL, you can use it to generate the client stubs on another computer.

To build the AIS Java samples on Windows:
1. Open a command prompt window and navigate to the AIS samples folder described in "AIS Folders" on page 1-2, which contains the file build.xml.
2. Type the following command:

   `%ANT_HOME%/bin/ant -Dais.url=https://<hostname:port/virtualPath>/ws -Dusername=<username> -Dpassword= <password target>`

   Where:
   - **hostname** - This is the name of the Agile server.
   - **port** - This is the application server port. For WebLogic Server, type 7001
   - **target** - This identifies the AIS sample to build. Available build targets are export, import, and all. The default target is all. If you do not specify a target, all AIS samples will be built.
   - **username** - This is the Agile PLM user name
   - **password** - This is the Agile PLM password

3. After you build the samples, use the runner file in the AIS samples directory to run the samples. It contains all the necessary CLASSPATH initializations for the samples.

   **Note:** Agile PLM requires both username and password to build the Java samples. The makefile execution will fail if the three parameters are not set.

To build the AIS Java samples on UNIX:
1. Navigate to the AIS samples directory and locate the file build.xml and then type the following command:

   `$ANT_HOME/bin/ant -Dais.url=http://<hostname:port/virtualPath/ws target>`

2. After you build a sample, use the runner file in the AIS samples directory to run the sample. This file contains all the necessary CLASSPATH initializations for the samples. For more information, refer to the comments (in Javadoc) for each sample.

3. If you are connecting to a secure URL that uses SSL, type the following command instead.
To build Java AIS samples on servers with Secure Sockets Layer (SSL) enabled:
1. Get the self-signed certificate from the server.
2. Install the self-signed certificate into your Java development environment.
3. Build the sample programs as described above by connecting to the server using HTTPS.
4. Run the sample programs as usual but include the command line parameter -P. For example:
   runner importer.ImportData -P HTTPS <insert other parameters here>

The Readme.txt file that is installed with the AIS samples includes more information about obtaining a certificate, installing it in your Java environment, and building and running the AIS samples on an SSL-enabled system.

5. After you build the samples, use the runner file in the AIS samples directory to run the samples. This file contains the necessary CLASSPATH initializations for the samples.

Running the Java Samples
Depending on your operating environment (Windows or Solaris), once you perform the build, one of the following files will appear in the AIS samples directory:

- On Windows, the file is runner.bat
- On Solaris, the file is runner.sh

These files contain the necessary CLASSPATH initializations and you can use them to simplify the process of invoking a sample application.

The invocations below will print out usage statements for each of the examples. You can use these usage statements along with the additional documentation provided on the samples to determine how to run the samples in a meaningful fashion.

To print out usage statements for the Clients, type the following commands:
> runner export.ExportData
> runner export.ExportPartList
> runner importer.ImportData
> runner importer.ImportSupplierResponse
> runner importer.ValidateData

export.ExportData Usage
Usage: export.ExportData <options>

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-a axml</td>
<td>This selects the aXML output format instead of the default PDX output format.</td>
</tr>
<tr>
<td>-c criteria</td>
<td>This is the search criteria for locating objects to export. The criteria must be formatted using the Agile SDK query language. For more information, refer to Agile PLM SDK Developer Guide.</td>
</tr>
</tbody>
</table>
This is the Agile PLM virtual path. For example, if you access Agile Web Client via [http://www.sample.com/agile/PLMServlet](http://www.sample.com/agile/PLMServlet), the virtual path is "Agile". When you install the Agile PLM system, the default virtual path is "Agile".

This is the predefined filter name or ID. If you have administrator privileges, you can define Agile PLM filters using the Agile Java Client.

This is the ad hoc filter flag. The legal values for this argument derive from the <filters> element shown in the Export XML Schema documentation. The filter flags correspond to child elements with names ending in "Filter," like ChangeFilter and ItemFilter. The basic pattern for this option is filter-name.attribute.value where:

- filter-name corresponds to the name of the XML element, such as ItemFilter (You can omit the "Filter" suffix).
- attribute corresponds to the name of the attribute that is defined (for example, "Page Two").
- value corresponds to the value for the attribute. If the attribute is a boolean, the value is optional and defaults to "true." For the Attachments attribute, the value "Tables and Files" causes the attachment table and all the referenced files to be exported. Following is an example of a filter flag:

```
-F "Item.TitleBlock" "Item.Attachments.TableAndFiles"
"Item.BOM.Recurse"
```

If you are extracting data to PDX files, the filter flag should be a superclass filter such as ItemFilter or ChangeFilter. In the following example, ChangeFilter is used.

```
rubber export.ExportData -h agilesvr -l 7001 -u aisuser -p agile -t ECO -c "[Number] is not null" -F "ChangeFilter.CoverPage" -o eco.pdx
```

For aXML files, the filter flag must be a class filter such as PartFilter or ECOFilter. In the following example, ECOFilter is used.

```
rubber export.ExportData -h agilesvr -l 7001 -u aisuser -p agile -t ECO -c "[Number] is not null" -F "ECOFilter.CoverPage" -o eco.axml -a axml
```

For a complete list of filter types, refer to the Export XML Schema Documentation in Agile PLM’s Import/Export User Guide.

This is the Agile PLM server machine. The default is localhost.

This is the port on which the Agile PLM server is listening. The default is 80.

This is the output file name. It defaults to: either out.pdx or out.axml, depending on the output format.

This is the user’s password.

This is the URL protocol. Valid values are either HTTP (the default) or HTTPS.

This is the manufacturing site for which data is extracted. If you do not specify a manufacturing site, data is extracted for all sites.

This is the type of the required object. Type either the class name or the predefined object type Default: Items. For a list of predefined object types, refer to Export XML schema documentation in Agile PLM’s Import/Export User Guide.

This is the Export XML schema, export.xsd. You can find this file in the samples folder described in “AIS Folders” on page 1-2.

<td>-F &quot;Item.TitleBlock&quot; &quot;Item.Attachments.TableAndFiles&quot; &quot;Item.BOM.Recurse&quot;</td>
</tr>
<tr>
<td></td>
<td>If you are extracting data to PDX files, the filter flag should be a superclass filter such as ItemFilter or ChangeFilter. In the following example, ChangeFilter is used.</td>
</tr>
<tr>
<td></td>
<td>runner export.ExportData -h agilesvr -l 7001 -u aisuser -p agile -t ECO -c &quot;[Number] is not null&quot; -F &quot;ChangeFilter.CoverPage&quot; -o eco.pdx</td>
</tr>
<tr>
<td></td>
<td>For aXML files, the filter flag must be a class filter such as PartFilter or ECOFilter. In the following example, ECOFilter is used.</td>
</tr>
<tr>
<td></td>
<td>runner export.ExportData -h agilesvr -l 7001 -u aisuser -p agile -t ECO -c &quot;[Number] is not null&quot; -F &quot;ECOFilter.CoverPage&quot; -o eco.axml -a axml</td>
</tr>
<tr>
<td>-h host</td>
<td>This is the Agile PLM server machine. The default is localhost.</td>
</tr>
<tr>
<td>-l port</td>
<td>This is the port on which the Agile PLM server is listening. The default is 80.</td>
</tr>
<tr>
<td>-o output-file</td>
<td>This is the output file name. It defaults to: either out.pdx or out.axml, depending on the output format.</td>
</tr>
<tr>
<td>-p password</td>
<td>This is the user’s password.</td>
</tr>
<tr>
<td>-P protocol</td>
<td>This is the URL protocol. Valid values are either HTTP (the default) or HTTPS.</td>
</tr>
<tr>
<td>-s site</td>
<td>This is the manufacturing site for which data is extracted. If you do not specify a manufacturing site, data is extracted for all sites.</td>
</tr>
<tr>
<td>-t type</td>
<td>This is the type of the required object. Type either the class name or the predefined object type Default: Items. For a list of predefined object types, refer to Export XML schema documentation in Agile PLM’s Import/Export User Guide.</td>
</tr>
<tr>
<td></td>
<td>This is the Export XML schema, export.xsd. You can find this file in the samples folder described in “AIS Folders” on page 1-2.</td>
</tr>
</tbody>
</table>
The `export.ExportData` client does not have an option to specify an item’s revision. When you use the client to export items, the latest released revision is exported. However, you can develop an AIS client that lets you specify a revision to export. For more information, refer to the Export XML Schema documentation in Agile PLM’s Import/Export User Guide.

These examples show how to run the `export.ExportData` client.

- runner `export.ExportData -h agilesvr -u aisuser -p e-agile -l 7001 -c "[Title Block.Number] equal to 'P00014'" -t Part -F "Item.TitleBlock" "Item.PageTwo" "Item.Attachments.TableAndFiles" "Item.BOM.Recurse" -o P00014.pdx

- runner `export.ExportData -h agilesvr -u aisuser -p agile -l 7001 -c "[Title Block.Number] equal to '1000-02'" -f "Default Item Filter" -t Item -s "San Jose" -o D:\data\out.pdx

- runner `export.ExportData -h agilesvr -u aisuser -p e-agile -l 7001 -c "[Title Block.Number] equal to '1000-02'" -f "Default Manufacturer Filter" -t Manufacturer -a axml

Substitute appropriate port numbers. For Weblogic use port 7001. For readability, these examples use attribute name, such as [Title Block.Number], instead of IDs. Agile strongly recommends using attribute IDs. If you use attribute names, make sure they are fully qualified to avoid ambiguity.
export.ExportPartlist Usage

Usage: export.ExportPartlist <options>

Table 2–1  Available export.ExportPartlist options

importer.ValidateData Usage

Usage: importer.ValidateData <options>

The options are exactly the same as the importer.ImportData Web service. See the command “importer.ImportData Usage” on page 2-10.

Creating a Web Service Client

Using the ExportData sample, this section provides the procedures to create a Web service client application for AIS.
Generating the SOAP Request

You can generate an appropriate SOAP request using client-side stubs. You can also generate client-side stubs. The Web-Service-aware code libraries are able to generate client-side stubs on your behalf. This entails using a code generation utility along with the WSDL for the desired Web service.

AIS provided samples that make use of Axis in order to connect with the AIS Web service engine. Axis provides a WSDL2Java utility that you can use for this purpose; other Web-Service-aware libraries will have their own client-side stub generation facility (for example, .Net includes a wsdl.exe utility). In the case of the samples, the client-side stub generation occurs during the samples' build process. Within the build.xml file is the following Ant target:

```xml
<target name="generate-export-stubs" depends="init"
   unless="exp-stubs.present">
  <echo>Generating export Java client-side stubs from WSDL...</echo>
  <java fork="true"
       class="org.apache.axis.wsdl.WSDL2Java"
       failonerror="true">
    <classpath refid="build.classpath"/>
    <arg line="-o ${built.scratch.dir}/gen"/>
    <arg line="-p export"/>
    <arg line="${ais.url}/Export?wsdl"/>
  </java>
</target>
```

Axis also includes an Ant task definition that you can use instead of the above <java> task. For more information, visit the Axis Ant Tasks site by pasting this URL in your browser `http://ws.apache.org/axis/java/ant/ant.html`.

The above Ant target is responsible for generating the export-related client-side stubs. This invocation retrieves the Export WSDL from `${ais.url}/Export?wsdl`, generates Java code in the export Java package, and places the source code within the `${built.scratch.dir}/gen` directory. For more information on the WSDL2Java utility, refer to Axis documentation on the Axis Website at `http://ws.apache.org/axis/`.

Once the client-side stubs are generated, the user can use the generated object definitions in order to more easily generate the appropriate SOAP request. These stubs enable the user to focus on the capabilities of the target Web service operation without the need to construct a valid SOAP request. In the ExportData.java sample, you can see that the run method contains all the code used to generate the SOAP request. However, instead of explicitly constructing a SOAP request, the code is concerned with setting up a Java data structure, which will be provided as the parameter to a stub method invocation. The code is more concerned with functionality than formatting, which makes it easier to read, write, and maintain.

Agile and Non-Agile Web Service Clients

The sample.zip folder contains the source code of an Import/Export Web service client. If you use this client, there is no need to modify the code for the client to connect to Axis v1.4. However if you plan to use an in-house, or a third party client, you must modify the code and work with Axis v1.4.

Submitting the SOAP Request

The next step in the Web service operation is to properly submit the generated SOAP request to the Web service engine. When dealing with generated client-side stubs, this
step only requires pointing the stubs to the desired server and invoking a method on the stubs. You do not need to worry about opening a connection or manually marshaling your data onto the wire (Marshaling is the act of taking data from the environment you are in and exporting it to another environment), because the generated stubs will handle these details.

The ExportData.java sample illustrates the above statement in two places:

- The `getExportStub` method is responsible for pointing the client-side stubs to the desired Web service engine.
- The `stub.exportData` method invocation found within the `run` method is responsible for actually submitting the request to the Web service engine. The actual submitting of the request and all the minutiae that entails are managed by the stubs themselves; you do not need to worry about the connecting, submitting, or marshaling particulars.

The details on how you point the stubs to the desired Web service engine and submit the request will vary from code library to code library. For more information, refer to the documentation for your Web-Service-aware code library.

**Processing the SOAP Response**

Similar to submitting a SOAP request, processing a SOAP response is handled with the generated client-side stubs. Without these generated stubs, you must parse the XML-based SOAP response and resolve the many formatting and unmarshaling issues that arise. However, when working with generated stubs, all these details are taken care of so that you will receive the Java objects in a proper form.

The ExportData.java sample illustrates this point clearly. In this sample, you can see that the result of the `stub.exportData` method is a `javax.activation.DataHandler`, which is a convenient way of encapsulating a binary data stream. Rather than requiring you to parse an XML document and interpret the returned data, the stubs automatically do this and return the response’s attachment as a `DataHandler` object.

The details on how SOAP responses are processed vary from code library to code library. For more information, consult the documentation for your Web-Service-aware code library.
Exporting Data

This chapter includes:

- Understanding the Web Service Export Function
- Using the exportData Web Service Operation
- Using the exportPartlist Web Service Operation

Understanding the Web Service Export Function

The following two export Web service operations are delivered as part of AIS:

- **exportData** - A Web service operation that extracts data from an Agile PLM system in one of several data formats.
- **exportPartList** - A Web service operation that takes a multilevel BOM and flattens it into a list of the manufacturer parts and their quantities in the BOM, and returns the data in aXML format.

Using the exportData Web Service Operation

The exportData Web service operation is capable of extracting Agile data in one of several structured formats. This operation can be used to provide integration functionality between your Agile PLM system and other, third-party systems.

This section illustrates how to format an XML request in order to use the exportData Web service operation. For more information on the XML schema that describes an exportData request, see the Export XML Schema documentation in "AIS Folders" on page 1-2. To view the information, select documentation > schemas > export.htm.

The exportDataRequest XML element describes the XML format that you must use when submitting an exportData request to AIS. This enables you to specify the following types of data:

- **Queries** - One or more queries that define what objects is exported.
- **Filters** - One or more filters that define what data from the selected objects is exported.
- **Formats** - The format that is used for the exported data.
- **Sites** - Manufacturing sites for which data should be exported. By default, data for all sites is exported.
- **Export** - Approval Matrix data is exported.
- **Import** - Approval Matrix data is imported.
Using the exportData Web Service Operation

Working with Queries

Using the exportData Web service operation, you can specify parameters related to the object query:

- The query itself (Required)
- The type of object being queried (Required)
- The site to apply to all objects matched by the query (Optional)
- The revision to apply to all objects matched by the query (Optional)

You can specify multiple queries at once, returning multiple result sets. More information on query parameters can be found in the Agile API reference documentation. However, the following section provides a brief introduction to the criteria syntax.

Specifying Query Criteria

This section introduces the basics of Agile SDK query syntax. For complete information on how to construct complex search criteria, refer to Agile SDK Developer Guide - Using Agile APIs.

The value for the criteria parameter for the exportData and exportPartlist is a single string consisting of one or more search conditions. Strings that appear within the search criteria should be enclosed in single quotes (').

Working with Sites

Companies that practice distributed manufacturing use several different sites to manufacture their products. The exportData Web service operation supports exporting data to all manufacturing sites, or to a specific site. Manufacturing sites affect how items and changes are exported. In the case of items, BOMs and AMLs can vary per site. For changes, the Affected Items table specifies which manufacturing sites are affected.

By default, the exportData Web service operation extracts information for all sites. If you specify a manufacturing site, only the data associated with that site is exported. All objects that are not associated with that manufacturing site are filtered out of the query results.

The following examples illustrate using exportData to extract all parts and documents in system and exportPartlist to extract only parts with AMLs.

Example 3–1  Using exportData to extract all parts and documents in the system
runner export.ExportData-h localhost -u admin -p agile -l 7001 -e Agile -c "[Title Block.Number] is not null" -F 'Item.TitleBlock' -t Item -o outpart.pdx

Example 3–2  Using exportPartlist to extract only parts with AMLs
runner export.ExportPartlist -h localhost -u admin -p agile -l 7001 -e Agile -c "[Title Block.Number] is not null" -F 'Item.TitleBlock' -o outpart.pdx

The following XML snippet illustrate different ways to specify a manufacturing site:

```xml
...<site>
    <site-name>Taipei</site-name>
</site>
...
Working with Filters

The exportData Web service operation enables you to define the information that you want to query from the selected objects. These parameters are captured by specifying one or more filters. Filters are either predefined in the Agile PLM system, or they are defined in an ad hoc fashion by the AIS client.

You can specify multiple filters and their effect is cumulative. The resulting filter is the combination of all specified filters. For example, if one filter includes an item’s PageTwo information and a separate filter includes the item’s History information, the effective filter includes both PageTwo and History information.

Predefined Filters

Agile provides several predefined filters to refine query results. You can specify a predefined filter in one of the following three different ways:

- **By ID** - Specify the numeric ID of a defined filter with the Agile administrative data. This information can be found using the Agile API to inspect the Agile administrative data. Use the ID of a defined filter to reduce the risk of a name change that can adversely affect your code.

- **By name** - Specify the name of a defined filter found in the Agile administrative data. This is an easy way to reference previously defined filter definitions.

- **By object type** - Specify different information sets for each type, from the set of available filters, one for each object type.

Note: If you have administrator privileges to the Agile PLM system, you can define new filters. Log into Agile Java Client and choose Admin > System Settings > Agile Contents Service > Filters.

Ad Hoc Filters

Ad hoc filters are defined for a particular purpose and are not stored in the Agile PLM system. The Export XML Schema defines several <filters> elements, such as ItemFilter, ChangeFilter, ManufacturerFilter, and ManufacturerPartFilter. The general usage for ad hoc filters is to specify the filter type, such as ItemFilter, and then supply boolean values for each table that you want included by the filter.

For example, the following ad hoc filter includes the TitleBlock and PageTwo tables for items:

<filters>
Most tables require simple boolean values. However, other tables support enumerated values that enable you to include the associated objects. For example, the BOM table supports the following enumerated values for filters: DoNotInclude (the default setting), TableOnly, SingleLevel, and Recurse.

Note: The filter type that you specify depends on the output format. If you extract data to a PDX file, the filter type should be a superclass filter such as ItemFilter or ChangeFilter. If you extract data to an aXML file, the filter type must be a class filter such as PartFilter or ECOFilter.

An exportData Filter Example
The following code segment illustrates how to combine a predefined filter, “Default Part Filter,” with an ad hoc filter that extracts all Item data, including attachments that may result from the query defined in the query example above.

...<filters>
<!--The following is a predefined filter specified by name-->
<filter-name>Default Part Filter</filter-name>
<!--The following is an ad hoc filter-->
<ItemFilter TitleBlock='true' PageTwo='true'
PageThree='true' History='true'
Attachments='TablesAndFiles'
BOM='Recurse' Changes='true'
WhereUsed='true'
AML='TableOnly' Site='true'/>
</filters>
...

Working with Formats
The exportData Web service operation can export data in either PDX or aXML format. For a description of these formats, see "Web Services Operations" on page 1-4.

For more information on how to specify the supported formats, see the Export XML Schema documentation in "AIS Folders" on page 1-2. To view the information, select documentation > schemas > export.htm.

An exportData Format Example
The following illustrates how to extract data in the PDX format:

...<format>PDX</format>
...

A Sample exportData Web Service Operation
The following is a sample exportDataRequest. It demonstrates a complete exportData Web service operation request:

<exportDataRequest>
<queries>
<query>
<criteria>[Title Block.Number] == '1000-02'</criteria>
Using the exportPartlist Web Service Operation

The exportPartlist Web service operation takes a multilevel BOM and "flattens" it into a list of the manufacturer parts in the BOM and their quantities and returns the data in aXML format. That is, it enables you to extract a rolled up set of parts, and the related Quantities Per Top Level Assembly (QPTLA). The value of the QPTLA is computed as the sum over recursive products starting from the top of the BOM tree. This Web service calculates the QPTLA for each unique item-revision pair, and returns the results in the Part Quantities element of the resulting aXML output.

Example 3-3 Using exportData to export tables supported by the Functional Teams class

Exporting Data 3-5
Note: The exportPartlist Web service exports data only for items with AMLs (approved manufacturer parts and their associated manufacturers). Items without AMLs are ignored.

Working with exportPartlist Queries

The exportPartlist Web service is similar to exportData in the way it accepts query definitions. The main difference is that you do not need to specify the object type against which the query is operating. This is because the queries related to a part list must always be queries against items.

Working with exportPartlist Filters

Filters are specified for the exportPartlist Web service operation similar to the exportData Web service operation. The only difference is which filters can be specified. Because exportData only operates over items, manufacturer parts (that is, AML) and manufacturers (AMLs related to manufacturers), object-related filters are restricted to these three data types.

An exportPartlist Example

The following is an example of the exportPartlistRequest element. It is a simple adaptation of the previous exportData sample and demonstrates a complete exportPartlist Web service operation request.

Example 3–4 Using the exportPartlistRequest element

```xml
<exportPartlistRequest>
<queries>
<query>
$criteria>[Title Block.Number] == '1000-02'</criteria>
</query>
</queries>
<site>
<site-name>Taipei</site-name>
</site>
<filters>
<!--The following is a predefined filter specified by name-->
<filter-name>Default Part Filter</filter-name>
<!--The following is an ad hoc filter -->
<ItemFilter TitleBlock="true" PageTwo="true" PageThree="true" History="true" Attachments="TablesAndFiles" BOM="Recurse" Changes="true" WhereUsed="true" AML="TableOnly" Site="true"/>
</filters>
</exportDataRequest>
```

The following entries are removed from the previous exportData sample to make this adaptation:

- The query element does not include an objectType element. This is because the exportPartlist Web service operation only queries against item objects.
- The format element is not included in the exportPartlistRequest. This is because the exportPartlist Web service operation only exports data in the aXML format.

The preceding XML example is not a complete or valid SOAP request. Rather, this XML document represents the contents of a SOAP request body. In general, you do not need to generate the above XML document manually. Instead, the client-side stubs
generated by a Web-Service-aware code library create an appropriately formatted XML document and place it within a SOAP request. The above sample is an illustration of what the XML request generated by client-side stubs would resemble.

**Note:** To generate the above XML in PDF format, the code that is submitted to the stubs must include at least one such parameter 
- c "[Title Block.Number] == '1000-02' "
- f "Default Part Filter"
- t Item
- s Taipei.
ACP
See Agile Configuration Propagation (ACP)

Activity
A project activity in Agile Product Portfolio Management, such as a program, task, or phase.

Affected Files
Similar to Affected Items, these objects are EC files that are Design Release Candidates.

Agile Configuration Propagation (ACP)
Propagating existing configuration the PLM to the newly installed version of PLM.

ACS
See Agile Content Service (ACS)

Agile Content Service (ACS)
ACS is an event-driven XML-based publishing service that makes the product record available to a wide variety of business applications and users, internally and across the global manufacturing network.

Agile Destination
A package created by an Agile PLM system in the target PLM using Web Services to import from the Attachments tab of the package in the target system.

Agile Integration Services (AIS)
A collection of predefined Web Services in the Agile Integration Framework that enable communication between the Agile Application Server and disparate systems.

Agile Product Portfolio Management
The Agile PLM project management solution that is integrated with the product information in PLM.

AI
Affected Items tab on Change objects in Agile.
**AIS**
See *Agile Integration Services (AIS)*.

**Approved Manufacturer Parts List (AML)**
List of approved manufacturer parts associated with an item.

**AML**
See *Approved Manufacturer Parts List (AML)*.

**API**
See *Application programming interface (API)*.

**Application programming interface (API)**
A set of routines, protocols, and tools for building software applications. An API expresses a software component in terms of its operations, inputs, outputs, and underlying types.

**Assembly**
A product assembly lists the parts in a product and shows the substances and materials that comprise those parts. It is linked to specifications that can restrict how much of a particular substance that product assembly may contain.

**Automated transfer orders (ATO)**
Content published by Agile PLM users in real time with a content transfer order (CTO) or set up subscribers to automatically create automated transfer orders (ATO) based on a schedule or triggered by a workflow status change.

**Baseline**
A snapshot of a project, usually in its initial stage, used as a reference for future comparison in Agile Product Portfolio Management.

**Bill of Material (BOM)**
A hierarchical representation of a product that is made up of other products.

**Bill of Substances (BOS)**
A hierarchical list of substances that are contained in the parts and assemblies that make up a BOM.

**BOM**
See *Bill of Material (BOM)*.

**BOS**
See *Bill of Substances (BOS)*.

**CAD**
See *Computer-aided design (CAD)*
Commodity
A class of goods that is in demand, that is supplied without qualitative differentiation regardless of supplier.

Computer-aided design (CAD)
The use of computer systems to assist in the creation, modification, analysis, or optimization of a design. CAD software is used to increase the productivity of the designer, improve the quality of design, improve communications through documentation, and to create a database for manufacturing. CAD output is often in the form of electronic files for print, machining, or other manufacturing operations.

Contract (Price)
This is a subclass of the Published Prices class. Contract prices are prices provided by the supplier for a specific item or manufacturer part. This price information applies only for the specified duration and can apply to any project.

Co-Sourcing
The process of leveraging product cost across suppliers.

DCO
See Design Change Order (DCO)

Deliverable
A unit of work required for a project's success, usually fulfilled by generating a digital file. (Word processing documents, spreadsheet documents, PDFs, presentation documents, and so on.) Deliverables can also be Agile PLM objects and processes. Also called ‘content’ in Agile Product Portfolio Management.

Design Change Order (DCO)
A Change Order subclass that is available when the effected File Tab is enabled and provides access to all Agile PLM Workflow functions.

Design File Folder
An EC file folder that is integrated with CAD and PLM files, providing full access to PLM Workflow function.

EC
See Engineering Collaboration (EC)

EC Client
A Java-based UI to access, administer and operated the EC solution.

ECO
See Engineering Change Order (ECO)

Engineering Change Order (ECO)
An object that carries with it all the proposed changes to a product and/or its BOM. When approved and implemented, the proposed changes become effective.
Engineering Collaboration (EC)
An application that provides data and process integration between CAD applications and Agile PLM. It allows CAD designers and engineers to capture and control the data representing a primary source of the product record.

Extensible Markup Language (XML)
A markup language that defines a set of rules for encoding documents in a format that is both human-readable and machine-readable

File Manager
The File Manager manages files in a repository or vault in the file system and provides a place to store and retrieve files locally or remotely. You can install it on the same server as the Agile Application Server or on a separate one. You can also install the File in a redundant configuration and/or distributed across geographic regions.

File Transfer Protocol (FTP)
A standard network protocol used to transfer computer files from one host to another host over a TCP-based network, such as the Internet.

FQPN
See Fully qualified path name (FQPN).

FTP
See File Transfer Protocol (FTP)

Fully qualified file name
The exact name of a file on a computer that is completely specified such that it is unambiguous and cannot be mistaken for any other file on that system.

Fully qualified path name (FQPN)
The full path of a resource, directory or file, stored in a computer. It is composed by the full path to the resource and its syntax depends on the operating system.

Gantt Chart
A project management tool that shows project activities and schedule as a bar chart. The chart lists project activities in sequence, and presents critical information such as the start and end dates of each activity, as well as interdependencies between activities.

Item Master
The product record. It is the entire collection of Items - Parts, Documents, and any other user-defined subclasses of the Items class maintained under change control in the Agile system.

Java Message Service (JMS)
The Java Message Service (JMS) API is a Java Message Oriented Middleware (MOM) API for sending messages between two or more clients.

JMS
See Java Message Service (JMS).
**Lifecycle Phase**
Current state in an object’s workflow.

**LRR**
Latest Released Rev - concerning a Part or Document.

**NCNR**
Non-Cancelable Non Returnable. Applies to an item. NCNR can be a Yes or No, depending on the supplier. You can ask for the NCNR information in the supplier response. This is one of the critical factors in finding the best deal among the supplier responses.

**PDX**
See Product Definition eXchange (PDX).

**PLM**
See Product Lifecycle Management (PLM).

**Percent allocation or % allocation**
The percentage of a resource's time allocated to a specific task or tasks in Agile Product Portfolio Management.

**Percent complete or % complete**
Amount of time and effort expended on a project measured as a percentage of the time and effort required to complete the whole project. Used in Agile Product Portfolio Management.

**Product Definition eXchange (PDX)**
A standard designed for the e-supply chain. This standard is based on the XML format because it provides a simple yet powerful and flexible way to encode structured data into a format that is both human- and computer-readable. In PLM, PDX packages contain product content, such as items.

**Product Lifecycle Management (PLM)**
The process of taking parts/documents from inception to production to phase-out, and all the stages in between.

**Protocol**
A system of digital rules or agreed-upon format for data exchange within or between devices. It determines the type of error checking and data compression used.

**Published Price**
This is a subclass of the Published Prices class. Published prices are prices provided by the suppliers in response to an RFQ and published from the project. The published price information can also be used in other projects.

**PCO**
See Price Change Order
**Price**

An object that carries with it all the proposed changes to a product and/or its BOM. It can be approved and implemented to make the proposed changes effective.

**Price Change Order**

It is an object that carries with it all the proposed changes to a price. It can be approved and implemented to make the proposed changes effective.

**Quote history**

A subclass of the Quote Histories class. Quote history prices are the stored prices from supplier responses that you can use. Any change in the response line of an RFQ is stored in the historical response and is usable at any time.

**Request for Information (RFI)**

A material declaration that lists the parts in a product assembly and shows the substances and materials contained in the part.

**Request for Quote (RFQ)**

A standard business process whose purpose is to invite suppliers into a bidding process to bid on specific products or services.

**Request for Proposal (RFP)**

A solicitation, often made through a bidding process, by an agency or company interested in procuring a commodity, service or valuable asset, to potential suppliers.

**Response Line**

A response line has information about only one item. The negotiation of price and terms for items is dealt with in a response line.

**Resource Pool**

A group of users who can be bulk assigned as resources for a particular project or task in Agile Product Portfolio Management.

**RFI**

See Request for Information (RFI).

**RFP**

See Request for Proposal (RFP)

**RFQ**

See Request for Quote (RFQ)

**RFQ Response**

A medium of communication between the user and the supplier. One response from a supplier can contain multiple response lines for different items. Price data is added to the project automatically when the supplier submits the response.
Schedule Editor
The scheduling engine that handles updates to the project schedule in Agile Product Portfolio Management.

Schema
In computer programming, a schema is the organization or structure for a database. The activity of data modeling leads to a schema.

SDK
See Software Development Kit (SDK or "devkit")

Software Development Kit (SDK or "devkit")
A set of software development tools that allows the creation of applications for a certain software package, software framework, hardware platform, computer system, video game console, operating system, or similar development platform.

Sourcing Project
The entry point of sourcing and product pricing. A sourcing project tracks data required for sourcing and pricing, to perform data analysis for effective pricing.

Standard Cost
Applies to an item. This is the market cost of the item. It is site-specific. The standard cost is for a unit.

Supplier
A supplier of one or several commodities.

Target Cost
Applies to item. This is the expected cost of the item by you or the supplier. This can be a percentage of the standard cost. Target cost is for a unit.

Timesheet
The time entry system in Agile Product Portfolio Management, used to track actual hours spent by resources on project activities and to calculate corresponding labor cost.

TLA
See Top Level Assembly (TLA)

Top Level Assembly (TLA)
The level in a BOM that indicates the ultimate product being manufactured.

Transfer order
Every time Agile Content Service (ACS) publishes product content, it produces a transfer order that keeps track of what, where, and when product content is transferred.

UPK
See User Productivity Kit (UPK)
**User Productivity Kit (UPK)**
The Oracle online help system used in some Oracle products.

**Web Service Extensions (WSX)**
A Web service engine that enables communication between Agile Product Lifecycle Management system and disparate internal and external systems.

**WSX**
See **Web Service Extensions (WSX)**.

**XML**
See **Extensible Markup Language (XML)**.

**XML Schema**
Description of a type of XML document, typically expressed in terms of constraints on the structure and content of documents of that type, above and beyond the basic syntactical constraints imposed by XML rules.
