### 1. Introduction

#### 1.1 Background

IBM® WebSphere® Application Server 8.5 supports a range of applications, each with their own unique set of features, requirements, and services. Just as no two applications will use an application server in exactly the same way, no single set of tuning parameters will likely provide the best performance for any two different applications.

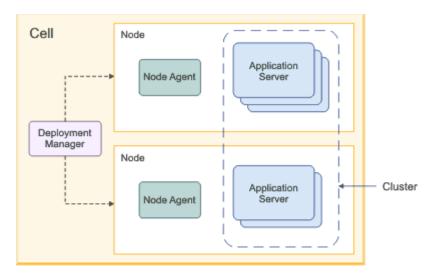

This document explains the best practices followed for Web Sphere application server tuning in the perspective of FLEXCUBE UBS.

### 1.2 Basics of Websphere

IBM websphere application server cluster deployment contains the below key elements

- Cell
- Nodes
  - Deployment Manager Node- "DMGR"
  - > Node- "NodeXX"
  - Node Agent- "NAXX"
- Profiles
- Cluster
- Cluster Members
- Data Sources

#### 1.3 Profile

Following are the details about profile:

#### Cell

A cell is a grouping of nodes into a single administrative domain. In a Network Deployment environment, a cell can consist of multiple nodes (and node groups), which are all administered from a single point, the deployment manager.

#### Node

A node is an administrative grouping of application servers for configuration and operational management within one operating system instance

#### Node Agent

In distributed server configurations, each node has a node agent that works with the deployment manager to manage administration processes. A node agent is created automatically when you add (federate) a stand-alone node to a cell.

#### **Cluster:**

A cluster is a logical collection of application server processes that provides workload balancing and high availability. Application servers that belong to a cluster are members of that cluster and must all have identical application components deployed on them.

A profile is a Websphere runtime environment formed by collection of User data and Product files. Product Files are shared application binaries for Websphere. User data is set of user customizations for a specific runtime environment.

Prominent profile types are:

- Stand-alone Application Server
- An application server environment runs Enterprise Application. Application server is managed from its own administrative console and functions independently from other application server.
- Deployment Manager:

A Deployment Manager manages operations for a logical group or cell of other servers. It is the central administration point of a cell that consists of multiple nodes and node groups in a distributed server configuration. The deployment manager uses the node agent to manage the application servers within one node. A deployment manager provides management capability for multiple federated nodes and can manage nodes that span multiple systems and platforms. A node can only be managed by a single deployment manager and must be federated to the cell of that deployment manager.

Deployment Manager is part of Network Deployment Edition of Websphere.

### 1.4 <u>References</u>

Before proceeding with the document, ensure the below documents are followed for setup

- For resource creation(JDBC Provider, Datasource, Queue connection factory, JMS queue), refer to Resource\_Creation\_WAS.doc
- For cluster configuration, refer to FCUBS\_Cluster\_Creation\_WAS.doc
- For application deployment, refer to FCUBS\_Application\_WAS.doc
- For deployment of Gateway applications, refer to GATEWAY\_Applications\_WAS.doc
- For SSL configuration in Websphere, refer to SSL\_Configuration\_WAS.doc

## 2. JDBC Tuning

The JDBC provider object encapsulates the specific JDBC driver implementation class for access to the specific vendor database of your environment. The datasource object supplies your application with connections for accessing the database. In a typical production environment database and application needs to use the perfect combination of parameters to achieve higher throughput.

# 3. JVM Tuning

### 3.1 JVM Heap Size

When a Java Virtual Machine (JVM) is started, it obtains a large area of memory from the underlying operating system. This area is called the heap, and Java performs its own memory management by allocating areas of the heap as memory is needed by the process. Performance tuning generally starts with the Java Virtual Machine (JVM), which serves as the foundation for the application server. From that point forward, tuning is primarily driven by the application server components that are used by the application.

Every 75 concurrent FLEXCUBE users require one websphere application server of size 4GB. I.e. for 300 concurrent FLEXCUBE users, it is recommended to have 4 websphere application servers.

### 3.2 Thread Pool Size

Each task performed by the server runs on a thread obtained from one of WebSphere Application Server's many thread pools. A thread pool enables components of the server to reuse threads, eliminating the need to create new threads at run time to service each new request. Three of the most commonly used (and tuned) thread pools within the application server are:

Web container: Used when requests come in over HTTP.

Default: Used when requests come in for a message driven bean or if a particular transport chain has not been defined to a specific thread pool.

ORB: Used when remote requests come in over RMI/IIOP for an enterprise bean from an EJB application client, remote EJB interface, or another application server.

## 4. Logging

When working with IBM to debug request processing problems, there might be occasions where low-level tracing components must be enabled to capture details for how the request is processed. These low-level Application server trace components do not have knowledge of the request intent or the potential data within. Therefore, when enabled, it is possible that these tracing components might potentially include sensitive information, in plain text, in the trace file.

It is recommended whenever possible to not enable these types of tracing components on a production system and attempt to simulate the problem on a quality assurance environment to capture the appropriate information.

Navigation Path >> Application Server->APPLICATION\_SERVER\_NAME->Process Definition-> Logging And Tracing

### 4.3 Process Logs

Middleware servers
<u>Middleware servers</u> > <u>MS01</u> > <u>Process definition</u> > <u>MS01</u> > <u>Process Logs</u> Use this page to view or modify settings to specify the files to which standard out and standard error streams write. The process logs are created by redirecting the standard out and standard error streams of a process to independent log files. Native code writes to the process logs. These logs can also contain information that relates to problems in native code or diagnostic information written by the JVM. One set of process logs is created for each application server and all of its applications. Process logs are also created for the deployment manager and each node manager. Changes on the Configuration panel apply when the server is restarted. Changes on the Runtime panel apply immediately.
Configuration Runtime General Properties
* Stdout File Name \${SERVER_LOG_ROOT}/native_stdout.log
* Stderr File Name \${SERVER_LOG_ROOT}/native_stderr.log
Apply OK Reset Cancel

Parameter	Value
Stdout File Name	\${SERVER_LOG_ROOT}/native_stdout.log
Stderr file name	\${SERVER_LOG_ROOT}/native_stderr.log

## 4.4 IBM Service Logs

ddleware servers	? -
<u>Middleware servers</u> > <u>MS01</u> > <u>Process definition</u> > <u>MS01</u> > IBM Service Logs	
Use this page to configure the IBM service log, also known as the activity log. The IBM service log contains both t server messages that are written to the System.out stream and special messages that contain extended service i you can use to analyze problems. One service log exists for all Java virtual machines (JVMs) on a node, including servers and their node agent, if present. A separate activity log is created for a deployment manager in its own lo The IBM Service log is maintained in a binary format. Use the Log Analyzer or Showlog tool to view the IBM service	nformation that all application ogs directory.
Configuration	
General Properties  Enable service log  * File Name:	
\${LOG_ROOT}/activity.log	
* Maximum File Size 2 MB	
Enable Correlation ID	
Apply OK Reset Cancel	

Parameter	Value
Enable Service Log	False
Maximum File Size	2
File Name	\${LOG_ROOT}/activity.log
Enable Correlation Id	True

## 4.5 Change Log Level Details

NCSA Access logging Enable	True
Error logging Enable	True

### 5. Session Management

Web browsers and applications use HTTP to communicate. Since HTTP is a stateless protocol (meaning that each command is executed independently without any knowledge of the commands that came before it), there must be a way to manage sessions between the browser side and the server side. Session management is used to configure session manager properties to control the behavior of Hypertext Transfer Protocol (HTTP) session support.

Navigation Path >> Enterprise Application->APPLICATION\_NAME->Web Module Properties->Session Management

figuration

Enable Cookies	True
Enable URL rewriting	False
Maximum in-memory session count	1000
Session timeout	30 Minutes
Security Integration	False

Parameter	Value
Serialization Session access	True

## 6. Appendix A: Frequently Encountered Errors

Error 1: Websphere is causing too many database locks.

Solution: In order to avoid problems with database locks issue, change the custom property "webSphereDefaultIsolationLevel=2". By default Webpshere uses Repeatable Read isolation level(4) for transactions. Before proceeding with the isolation level change make sure these locks are not caused by the application.

Possible Values	JDBC Isolation Level	Isolation Level
8	TRANSACTION_SERIALIZABLE	Repeatable Read (RR)
4 (default)	TRANSACTION_REPEATABLE_READ	Read Stability (RS)
2	TRANSACTION_READ_COMMITTED	Cursor Stability (CS)
1	TRANSACTION_READ_UNCOMMITTED	Uncommitted Read (UR)
0	TRANSACTION_NONE	No Commit (NC)

Navigation Path >> Resources-> JDBC->Data Sources ->DATA\_SOURCE\_NAME-> Custom Properties

If this property is found then update the value to 4 and Save, else create a new property with below mentiond steps:

- 1. Click New.
- 2. Enter webSphereDefaultIsolationLevel for the name field.
- 3. Enter 2 for the value field.

<u>Data sources</u> > <u>Default Datasource</u> > <u>Custom properties</u> > <b>New</b>
Use this page to specify custom properties that your enterprise information system (EIS) requires for the resource providers and resource factories that you configure. For example, most database vendors require additional custom properties for data sources access the database.
