Oracle customers that have purchased support have access to electronic support through My Oracle Support. For information, visit http://www.oracle.com/pls/topic/lookup?ctx=acc&id=info or visit http://www.oracle.com/pls/topic/lookup?ctx=acc&id=trs if you are hearing impaired.

CONTENTS

CHAPTER 1 About Oracle Cloud Infrastructure 19
- Prefer Online Help? 21
- Need API Documentation? 21

CHAPTER 2 Oracle Cloud Infrastructure's Free Tier 22
- Free Trial 22
- Always Free Resources 23
- Upgrading to a Paid Account 25
- Additional Information 25
- Details of the Always Free Resources 25
- Frequently Asked Questions: Oracle Cloud Infrastructure Free Tier 30

CHAPTER 3 Oracle Cloud Infrastructure for Government 33
- For All Government Cloud Customers 33
- Government Cloud with FedRAMP Authorization 43
- Federal Government Cloud with Impact Level 5 Authorization 50

CHAPTER 4 Service Essentials 58
- Security Credentials 59
- Regions and Availability Domains 62
- IP Address Ranges 69
- Resource Identifiers 75
- Resource Tags 79
- Resource Monitoring 84

Service Limits 104
Viewing All Resources in a Compartment 127
Compartment Quotas 132
Work Requests 151
Console Announcements 155
Prerequisites for Oracle Platform Services on Oracle Cloud Infrastructure 163
Billing and Payment Tools Overview 175
Console Cookies and Local Storage 190
My Services Use Cases 192

CHAPTER 5 Archive Storage 245
Overview of Archive Storage 245

CHAPTER 6 Audit 251
Overview of Audit 251
Contents of an Audit Log Event 253
Viewing Audit Log Events 262
Setting Audit Log Retention Period 267
Bulk Export of Audit Log Events 269

CHAPTER 7 Block Volume 273
Overview of Block Volume 273
iSCSI Commands and Information 282
Volume Groups 284
Creating a Volume 296
Attaching a Volume 299
Connecting to a Volume 305
Listing Volumes 314
Listing Volume Attachments 316
Listing Boot Volume Attachments 317
Renaming a Volume 318
Resizing a Volume 319
Overview of Block Volume Backups 329

Backing Up a Volume ... 338
Policy-Based Backups ... 340
Copying a Volume Backup Between Regions ... 352
Restoring a Backup to a New Volume ... 356
Cloning a Volume ... 359
Disconnecting From a Volume ... 363
Detaching a Volume ... 364
Deleting a Volume ... 366
Move Block Volume Resources Between Compartments ... 367
Block Volume Performance ... 372
Block Volume Metrics ... 398

CHAPTER 8 Compute ... 402

Overview of the Compute Service ... 402
Best Practices for Your Compute Instance ... 407
Protecting Data on NVMe Devices ... 420
Boot Volumes ... 431
Oracle-Provided Images ... 470
Compute Shapes ... 505
Installing and Running Oracle Ksplice ... 513
Managing Custom Images ... 514
Image Import/Export ... 525
Bring Your Own Image (BYOI) ... 533
OS Kernel Updates ... 554
Managing Key Pairs on Linux Instances ... 557
Creating an Instance ... 560
Managing Compute Instances ... 579
Autoscaling ... 599
Managing Cluster Networks ... 609
Dedicated Virtual Machine Hosts ... 615
Connecting to an Instance ... 623
Instance Console Connections ... 628

Adding Users on an Instance ... 638
Displaying the Console for an Instance ... 641
Getting Instance Metadata ... 642
Updating Instance Metadata ... 645
Renaming an Instance ... 648
Moving a Compute Instance to a New Host ... 649
Migrating an Instance from a Local to Remote Boot Volume ... 654
Moving Compute Resources to a Different Compartment ... 658
Stopping and Starting an Instance ... 663
Terminating an Instance ... 667
Enabling Monitoring for Compute Instances ... 669
Compute Metrics ... 685
Compute Performance ... 701
Compute Health Monitoring for Bare Metal Instances ... 704
Microsoft Licensing on Oracle Cloud Infrastructure ... 707
Updating the Linux iSCSI Service to Restart Automatically ... 721

CHAPTER 9 Container Engine for Kubernetes ... 727

Overview of Container Engine for Kubernetes ... 727
Preparing for Container Engine for Kubernetes ... 730
About Kubernetes Clusters and Nodes ... 782
Creating a Kubernetes Cluster ... 784
Downloading a kubeconfig File to Enable Cluster Access ... 794
Modifying a Kubernetes Cluster ... 801
Deleting a Kubernetes Cluster ... 803
Monitoring Clusters ... 804
Monitoring Operations of Container Engine for Kubernetes ... 807
Accessing a Cluster Using kubectl ... 808
Starting the Kubernetes Dashboard ... 809
Deploying a Sample Nginx App on a Cluster Using kubectl ... 812
Pulling Images from Registry during Deployment ... 813
Encrypting Kubernetes Secrets At Rest in Etcd ... 816

Connecting to Worker Nodes Using SSH ... 820
About Access Control and Container Engine for Kubernetes ... 823
Kubernetes Versions and Container Engine for Kubernetes ... 828
'Upgrading' the image running on worker nodes by creating a new node pool ... 834
Creating Load Balancers to Distribute Traffic Between Cluster Nodes ... 835
Creating a Persistent Volume Claim ... 845
Adding OCI Service Broker for Kubernetes to Clusters ... 849
Example: Setting Up an Ingress Controller on a Cluster ... 851

CHAPTER 10 Data Transfer ... 861
Overview of Data Transfer Service ... 861
Disk Data Transfer ... 863
Appliance Data Transfer ... 920
Troubleshooting ... 990

CHAPTER 11 Database ... 995
Overview of the Database Service ... 995
Overview of Autonomous Database ... 1001
Exadata Cloud at Customer ... 1093
Exadata DB Systems ... 1239
Bare Metal and Virtual Machine DB Systems ... 1392
Database Metrics ... 1692
Using Performance Hub to Analyze Database Performance in Oracle Cloud Infrastructure ... 1699
Migrating Databases to the Cloud ... 1705
Troubleshooting ... 1769

CHAPTER 12 DNS and Traffic Management ... 1798
Overview of the DNS Service ... 1798
Overview of the Traffic Management Steering Policies Service ... 1840

CHAPTER 13 Email Delivery ... 1891
Overview of the Email Delivery Service ... 1891

Getting Started with Email Delivery ... 1899
Generate SMTP Credentials for a User ... 1911
Managing Approved Senders ... 1912
Configure SPF ... 1915
Configure SMTP Connection ... 1917
Managing the Suppression List ... 1918
Email Delivery Metrics ... 1920
Integrating Oracle Application Express with Email Delivery ... 1923
Integrating Postfix with Email Delivery ... 1925
Integrating Oracle Enterprise Manager with Email Delivery ... 1928
Integrating Mailx with Email Delivery ... 1930
Integrating Swaks with Email Delivery ... 1931
Integrating JavaMail with Email Delivery ... 1934
Integrating Sendmail with Email Delivery ... 1939
Integrating PeopleSoft with Email Delivery ... 1943
Integrating Python with Email Delivery ... 1948
Troubleshooting Email Delivery ... 1951
Deliverability Best Practices ... 1957

CHAPTER 14 Events ... 1963
Overview of Events ... 1963
Getting Started with Events ... 1968
Matching Events with Filters ... 1985
Events and IAM Policies ... 1992
Managing Rules for Events ... 1994
Contents of an Event Message ... 2019
Services that Produce Events ... 2022
Events Metrics ... 2100

CHAPTER 15 File Storage ... 2106
Overview of File Storage ... 2106
About Security ... 2114

Creating File Systems 2137
Mounting File Systems 2151
Managing File Systems 2183
Managing Mount Targets 2202
Managing Snapshots 2239
Paths in File Systems 2246
Troubleshooting Your File System 2248

CHAPTER 16 Functions 2273

Overview of Functions 2273
Oracle Functions Concepts 2276
How Oracle Functions Works 2278
Preparing for Oracle Functions 2282
Creating, Deploying, and Invoking a Helloworld Function 2316
Creating Applications 2320
Creating and Deploying Functions 2322
Creating Functions from Existing Docker Images 2325
Viewing Functions and Applications 2329
Invoking Functions 2332
Storing and Viewing Function Logs 2339
Updating Functions 2342
Deleting Applications and Functions 2346
Passing Custom Configuration Parameters to Functions 2350
Accessing File Systems from Running Functions 2354
Accessing Other Oracle Cloud Infrastructure Resources from Running Functions 2355
Permissions Granted to Containers Running Functions 2363
Invoking Oracle Functions from Other Oracle Cloud Infrastructure Services 2364
Changing Oracle Functions Default Behavior 2364
Differences between Oracle Functions and Fn Project 2366
Troubleshooting Oracle Functions 2368
Function Metrics 2379

CHAPTER 17 Health Checks 2387
Overview of the Health Checks Service 2387
Getting Started With the Health Checks API 2390
Managing Health Checks 2398
Health Checks Metrics 2404

CHAPTER 18 IAM 2411
Overview of Oracle Cloud Infrastructure Identity and Access Management 2411
Getting Started with Policies 2428
How Policies Work 2431
Common Policies 2441
Advanced Policy Features 2465
Policy Syntax 2471
Policy Reference 2477
User Credentials 2674
Federating with Identity Providers 2677
User Provisioning for Federated Users 2760
Managing User Capabilities for Federated Users 2766
Calling Services from an Instance 2771
Managing Users 2777
Managing Groups 2787
Managing Dynamic Groups 2793
Managing Compartments 2803
Managing Regions 2822
Managing Platform Services Regions 2826
Managing the Tenancy 2829
Managing Policies 2831
Managing User Credentials 2838
Managing Authentication Settings 2851
Managing Multi-Factor Authentication 2855

CHAPTER 19 Key Management 2866
Overview of Key Management 2866
Managing Keys 2870
Managing Vaults 2891
Using Keys 2900
Key Management Metrics 2904
CHAPTER 20 Load Balancing 2909
Overview of Load Balancing 2909
How Load Balancing Policies Work 2923
Connection Management 2926
HTTP "X-" Headers 2928
Session Persistence 2930
Managing a Load Balancer 2936
Managing Backend Sets 2959
Managing Backend Servers 2968
Managing Load Balancer Listeners 2978
Managing Request Routing 2983
Managing Rule Sets 2998
Managing SSL Certificates 3017
Editing Health Check Policies 3029
Viewing the State of a Work Request 3036
Load Balancing Metrics 3038
CHAPTER 21 Marketplace 3053
Overview of Marketplace 3053
Working with Listings 3054
Viewing Terms of Use Agreements for Deployed Applications 3061
CHAPTER 22 Monitoring 3064
Monitoring Overview 3064

Oracle Cloud Infrastructure Security Guide ... 4499
Oracle Cloud Security Response to Intel L1TF Vulnerabilities ... 4614
Oracle Cloud Security Response to Intel Microarchitectural Data Sampling (MDS) Vulnerabilities ... 4624

CHAPTER 30 Storage Gateway ... 4635
Overview of Storage Gateway ... 4635
Features of Storage Gateway ... 4643
Getting Started With Storage Gateway ... 4647
Configuring the Cache for File Systems ... 4648

Understanding Storage Gateway Performance 4659
Interacting With Object Storage 4663
Installing Storage Gateway 4667
Logging In to the Storage Gateway Management Console 4680
Creating Your First File System 4682
Managing File Systems 4688
Managing Storage Gateway 4704
Using Storage Gateway File Management Operations 4708
Monitoring Storage Gateway 4715
Using Storage Gateway Cloud Sync 4720
Best Practices for Using Storage Gateway 4728
Troubleshooting Storage Gateway 4729
Upgrading Storage Gateway 4733
Uninstalling Storage Gateway 4741
Getting Help with Storage Gateway 4742

CHAPTER 31 Streaming Service Overview 4744

Streaming Usage Scenarios 4744
Streaming Concepts 4745
How Streaming Works 4746
Stream Archiving 4747
Limits on Streaming Resources 4747
Resource Identifiers 4748
Ways to Access Oracle Cloud Infrastructure 4749
Using Streaming 4749
Authentication and Authorization 4749
Tagging Resources 4750
Moving Resources to a Different Compartment 4750
Managing Streams 4750
Publishing Messages 4754
Consuming Messages 4756
Using the Streaming SDK 4758

Streaming Metrics 4767

CHAPTER 32 Tagging 4776

Tagging Overview 4776
Managing Tags and Tag Namespaces 4781
Using Cost-Tracking Tags 4799
Using Predefined Values 4802
Using Tag Variables 4806
Managing Tag Defaults 4807

CHAPTER 33 Web Application Firewall 4817

Overview of the Web Application Firewall Service 4817
Getting Started with WAF 4821
Managing WAF Policies 4830
Origin Management 4836
Bot Management 4840
WAF Protection Rules 4848
Access Control 4883
Caching Rules 4891
Threat Intelligence 4895
Settings 4899
Logs 4902

CHAPTER 34 Developer Tools 4912

Software Development Kits and Command Line Interface 4912
Other Tools and Plug-ins 4984
Properties 4994
Tools Configuration 5068
REST APIs 5078

GLOSSARY 5179

RELEASE NOTES 5202

CHAPTER 1 About Oracle Cloud Infrastructure

Oracle Cloud Infrastructure provides bare metal cloud infrastructure that lets you create networking, compute, and storage resources for your enterprise workloads.

If you're new to Oracle Cloud Infrastructure and would like to learn some key concepts and take a quick tutorial, see the *Oracle Cloud Infrastructure Getting Started Guide*.

If you're ready to create cloud resources such as users, access controls, cloud networks, instances, and storage volumes, this guide is right for you. It provides the following information about using Oracle Cloud Infrastructure:

Service	What's Covered	Chapter
Archive Storage	Preserving cold data.	Archive Storage
Audit	Logging activity in your cloud.	Audit
Block Volume	Adding storage capacity to instances.	Block Volume
Compute	Launching compute instances and connecting to them by using an SSH key pair.	Compute
Container Engine for Kubernetes	Defining and creating Kubernetes clusters to enable the deployment, scaling, and management of containerized applications.	Container Engine for Kubernetes
Data Transfer	Migrating large volumes of data.	Data Transfer
Database	Creating and managing database systems and Oracle Databases.	Database

Service	What's Covered	Chapter
Edge Services	Encompasses several services that allow you to manage, secure, and maintain your domains and endpoints.	Edge Services
Email Delivery	Sending large volume email.	Email Delivery
Events	Creating automation in your tenancy.	Events
File Storage	Managing shared file systems, mount targets, and snapshots.	File Storage
Functions	Building and deploying applications and functions.	Functions
IAM	Setting up administrators, users, and groups and specifying their permissions to access to cloud resources.	IAM
Key Management	Creating and managing encryption keys and key vaults to control the encryption of your data.	Key Management
Load Balancing	Setting up load balancers, listeners, backend sets, certificate bundles, and managing health check policies.	Load Balancing
Monitoring	Querying metrics and managing alarms to monitor the health, capacity, and performance of your cloud resources.	Monitoring
Networking	Setting up cloud networks, subnets, gateways, route tables, and security lists.	Networking

Service	What's Covered	Chapter
Notifications	Setting up topics and subscriptions, and publishing messages.	Notifications
Object Storage	Creating and managing buckets to store objects, and uploading and accessing data files.	Object Storage
Registry	Storing, sharing, and managing development artifacts like Docker images in an Oracle-managed registry.	Registry
Search	Searching for Oracle Cloud Infrastructure resources using free text search or advanced queries.	Search
Tagging	Adding metadata tags to your resources.	Tagging

For a description of the terminology used throughout this guide, see the GLOSSARY.

Prefer Online Help?

The information in this guide and the *Getting Started Guide* is also available in the online help at https://docs.cloud.oracle.com/iaas/Content/home.htm.

Need API Documentation?

For general information, see REST APIs. For links to the detailed service API documentation, see the online help at https://docs.cloud.oracle.com/iaas/Content/home.htm.

CHAPTER 2 Oracle Cloud Infrastructure's Free Tier

Oracle Cloud Infrastructure's Free Tier is composed of a free promotional trial that allows you to explore a wide range of Oracle Cloud Infrastructure products, and a set of Always Free offers that never expire.

Free Trial

The Free Trial provides you with $300 of cloud credits that are valid for up to 30 days. You may spend these credits on any eligible Oracle Cloud Infrastructure service.

Getting Started

Start for Free

For more information, and to see a complete list of services available to you during the trial, visit the Free Trial website.

Tip

During sign up, choose the home region carefully. Most Always Free resources can be provisioned only in your home region.

For security purposes, most users will need a mobile phone number and a credit card to create an account. Your credit card will not be charged unless you upgrade your account.

What Happens When Your Trial Period Ends

After your trial ends, your account remains active. There is no interruption to the availability of the Always Free Resources you have provisioned. You can terminate and re-provision Always Free resources as needed.

Paid resources that were provisioned with your credits during your free trial are reclaimed by Oracle unless you upgrade your account.

Pay as You Go accounts are available with no commitment, or contact an Oracle sales representative in your location to learn about monthly and annual flex accounts that offers discounted pricing. See the pricing details learn more.

Always Free Resources

All Oracle Cloud Infrastructure accounts (whether free or paid) have a set of resources that are free of charge for the life of the account. These resources display the **Always Free** label in the Console.

Using the Always Free resources, you can provision a virtual machine (VM) instance, an Oracle Autonomous Database, and the networking, load balancing, and storage resources needed to support the applications that you want build. With these resources, you can do things like run small-scale applications or perform proof-of-concept testing.

The following list summarizes the Oracle Cloud Always Free-eligible resources that you can provision in your tenancy:

- **Compute** (up to two instances)
- **Autonomous Database** (up to two database instances)
- **Load Balancing** (one load balancer)
- **Block Volume** (up to 100 GB total storage)
- **Object Storage** (up to 20 GiB)

For detailed information about the Always Free resources, see Details of the Always Free Resources.

You can find your tenancy's limits for Always Free resources in the Console. To check these limits: Open the navigation menu. Under **Governance and Administration**, go to **Limits, Quotas and Usage**.

Quickly Spinning Up Your Environment Using Terraform

Oracle offers a Terraform configuration file that lets you automatically create the full set of Always Free resources in a few minutes. You don't need to have experience with Terraform to use this file. To set up your Oracle Cloud environment, you log in to your account and then upload the file in the Console using the Resource Manager service. Resource Manager reads the file and provisions the Always Free resources for you with the settings and configuration you need to start creating applications in the cloud.

Note that Terraform refers to the set of resources being provisioned as a "stack". For a general introduction to Terraform and the "infrastructure-as-code" model, see Terraform: Write, Plan, and Create Infrastructure as Code.

To provision your Always Free using Terraform and Resource Manager

1. Download the Always Free Terraform configuration file (a .zip file) to your computer. To do this, navigate to https://github.com/oracle/oci-quickstart-cloudnative and follow the instructions in the `readme.md` file included in this repository.
2. Log into your Oracle Cloud Infrastructure account.
3. Open the navigation menu. Under **Solutions and Platform**, go to **Resource Manager** and click **Stacks**.
4. Click the **Create Stack** button to open the **Create Stack** dialog.
5. Add your downloaded configuration (.zip) file, either by dragging and dropping it onto the dialog's control, or by clicking **Browse** and navigating to the file location.
6. Optionally, provide a name for the new stack. If you don't provide a name, a default name is provided on the server.
7. Optionally, provide a description for the stack.

8. Optionally, select a different compartment from your current compartment in which to create the stack. To do so, select a compartment from the **Create In Compartment** drop-down.
9. Click **Next** to proceed to the **Configure Variables** panel.
10. The variables displayed in the **Configure Variables** panel are auto-populated from the Terraform file that you uploaded. You don't need to change these variables if you are provisioning your Always Free resources using the Terraform file provided by Oracle.
11. Click **Next** to proceed to the **Review** panel.
12. Verify your stack configuration, then click **Create** to create your stack.

Your set of Always Free resources should take no more than a few minutes to provision.

Upgrading to a Paid Account

You can upgrade to a paid account at any time through the Oracle Cloud Infrastructure Console. To do so, click the **Upgrade** link in the banner at the top of the Console web page. If you don't see an **Upgrade** link on the page you are viewing, you can click the **Oracle Cloud** logo at the top of the Console and then look for the Upgrade link in the sidebar on the right side of the Console home page.

Additional Information

See Frequently Asked Questions: Oracle Cloud Infrastructure Free Tier for answers to your questions about Free Tier accounts and resources.

Details of the Always Free Resources

This topic provides reference information on Oracle Cloud Infrastructure's Always Free resources.

Compute

All tenancies get two Always Free Compute virtual machine (VM) instances.

Details of the Always Free Compute instance

- **Shape:** VM.Standard.E2.1.Micro
- **Processor:** 1/8th of an OCPU with the ability to use additional CPU resources
- **Memory:** 1 GB
- **Networking:** Includes one VNIC with one public IP address and up to 480 Mbps network bandwidth
- **Operating System:** Your choice of one of the following Always Free-eligible operating systems:
  - Oracle Linux
  - Canonical Ubuntu Linux
  - CentOS Linux

Tip

The Linux operating systems labeled "Always Free Eligible" in the Console are compatible with Always Free Compute instances and incur no licensing fees. These operating systems are also compatible with paid resources and are available to users of paid accounts. To provision a Compute instance with an operating system that is not Always Free-eligible, you must have a paid account or a Free Trial account with available credits.

See Oracle-Provided Images for more information about the available operating systems. For steps to create an Always Free-eligible Compute instance, see "Tutorial - Launching Your First Linux Instance" in the *Oracle Cloud Infrastructure Getting Started Guide*.

Database

All tenancies get two Always Free Oracle Autonomous Databases. The Autonomous Databases use serverless deployment (meaning Oracle handles the database infrastructure provisioning and maintenance). For current regional availability, see Always Free Availability.

Details of the Always Free Oracle Autonomous Database instance

- **Processor:** 1 Oracle CPU processor (cannot be scaled)
- **Memory:** 8 GB RAM
- **Database Storage:** 20 GB storage (cannot be scaled)
- **Workload Type:** Your choice of either the transaction processing or data warehouse workload type
- **Maximum Simultaneous Database Sessions:** 20

Tip

Always Free Autonomous Databases can be upgraded to paid instances after provisioning if you need features like storage or CPU scaling.

See To create an Always Free Autonomous Database for steps to create an Always Free Autonomous Database.

Load Balancing

All tenancies get one Always Free 10 Mbps load balancer.

Details of the Always Free load balancer

- **Shape:** Micro (10 Mbps)
- **Listeners:** 10
- **Virtual Hostnames:** 10
- **Backend Sets:** 10
- **Backend Servers:** 128

For information about provisioning an Always Free load balancer, see Getting Started with Load Balancing.

Block Volume

All tenancies receive a total of 100 GB of Always Free Block Volume storage, and five volume backups. These amounts apply to both boot volumes and block volumes combined. When you provision a Compute instance, the instance automatically receives a 50 GB boot volume for storage. You can also create and attach block volumes to expand the storage capacity of a Compute instance. For more information, see Creating a Volume and Attaching a Volume.

Details of the Always Free Block Volume resources

- 100 GB total of combined boot volume and block volume Always Free Block Volume storage.
- Five total volume backups (boot volume and block volume combined).

When you create a Compute instance, the default boot volume size for the instance is 50 GB, which counts towards your allotment of 100 GB. You can customize the instance's boot volume size up to 100 GB; however, this will use up your full allotment of storage for Always Free Block Volume resources. Also, because the minimum boot volume size allowed for Compute instances is 50 GB, launching two instances will use all your Always Free Block Volume resources. Alternatively, you can launch one instance with the default boot volume size of 50

GB, and then create and attach a 50 GB block volume to expand the storage capacity of the instance. For more information, see Creating a Volume and Attaching a Volume. Although it is possible to mix paid and Always Free resources, Oracle does not recommend this. If you have used up your allotment of Always Free Block Volume resources, you can free up block storage resources by terminating an Always Free instance and deleting the boot volume, or terminating an Always Free block volume.

You can have a maximum of five Always Free volume backups at any time. This applies to both boot volume and block volume backups. For example, you could have three boot volume backups for your Always Free instance and two block volume backups for your Always Free block volumes. In this example, if you try to create new backups, the operation will fail with an error until you delete existing Always Free volume backups. For more information about volume backups, see Overview of Block Volume Backups and Overview of Boot Volume Backups.

Object Storage

All tenancies get a total of 20 GiB (gibibytes) of Always Free Object Storage.

Details of the Always Free Object Storage resources

If you have a free account (including trial accounts), Always Free Object Storage includes the following:

- 20 GiB of combined Object Storage and Archive Storage
- 50,000 Object Storage API requests per month

If you have a paid account, Always Free Object Storage includes the following:

- 10 GiB of Object Storage
- 10 GiB of Archive Storage
- 50,000 Object Storage API requests per month

Important

If you are participating in an Oracle Cloud Free Trial, you can store unlimited data and can use 20 GiB for free (your usage of the first 20 GiB incurs no deduction of your initial $300 trial credit balance). Upgrade to a paid account to continue access to unlimited storage. If you do not upgrade before your trial ends, your free account will be limited to 20 GiB of combined Object Storage and Archive Storage. If you are using more than the 20 GiB limit when your Free Trial ends, all of your objects will be deleted. You can then upload objects until you reach your Always Free usage limits.

See Putting Data into Object Storage for instructions on using your Always Free Object Storage resources.

Frequently Asked Questions: Oracle Cloud Infrastructure Free Tier

I just signed up and I cannot access specific services. What can I do?

Registering your account with all services and regions can take a few minutes. Check again after a few minutes have passed.

How do I change which resources I want to designate as Always Free?

In short, you cannot. Eligible resources are designated Always Free when they are created. After you provision an Always Free resource, the Always Free status is not transferable to another existing resource. However, you can delete an existing Always Free resource in order to create a new Always Free resource in its place.

What happens when my Free Trial expires or my credits are used up?

When you've reached the end of your 30 day trial, or used all of your Free Trial credits (whichever comes first), you will no longer be able to create new paid resources. However, your account will remain active. Your existing resources will continue to run for a few days, allowing you to upgrade your account and keep your resources before they're reclaimed by Oracle. (Note that reclaimed resources cannot be recovered—they are permanently deleted.)

Resources identified as Always Free will not be reclaimed. After your Free Trial expires, you'll continue to be able to use and manage your existing Always Free resources, and create new Always Free resources according to tenancy limits.

If I upgrade, do I keep my Free Trial credit balance?

Yes, if you upgrade during the Free Trial period, you will not be billed until your remaining credit balance is exhausted. You will be notified by email when billing begins.

After I upgrade my account, can I downgrade?

There is no option to downgrade your account. However, with a paid account, you'll continue to have access to Always Free resources, and you'll only pay for the standard resources you use. No minimums and no prepayment are required for your paid account.

My resources no longer appear. How can I restore them?

If you have a Free Tier account and your resources no longer appear, it is likely that your Free Trial has expired and your paid resources have been reclaimed (terminated). You can verify this if this is the case by doing the following:

1. Log in to the Console
2. Check for a banner at the top of the Console with the following text: "You are using a Free Tier account. To access all services and resources, upgrade to a paid account."

If you see this message, your resources have been reclaimed and cannot be restored.

Is it possible to extend my Free Trial?

If you need additional credits or time, you can schedule a call with an Oracle sales representative using the Upgrade page in the Console. Sales representatives have the authority to extend trials or issue additional credits if appropriate.

If you don't see an **Upgrade** link on the Console page you are viewing, you can click the **Oracle Cloud** logo at the top of the Console and then look for the Upgrade link in the sidebar on the right side of the page.

Is my Free Tier account eligible for support?

Community support through our forums is available to all customers. Customers using only Always Free resources are not eligible for Oracle Support. Limited support is available to Free Tier accounts with Free Trial credits. After you use all of your credits or after your trial period ends (whichever comes first), you must upgrade to a paid account to access Oracle Support. If you choose not to upgrade and continue to use Always Free Services, you will not be eligible to raise a service request in My Oracle Support. See Getting Help and Contacting Support.

CHAPTER 3 Oracle Cloud Infrastructure for Government

Oracle Cloud Infrastructure for government provides cloud services for two levels of government operators:

- Oracle Cloud Infrastructure Government Cloud with FedRAMP authorization
- Oracle Cloud Infrastructure Federal Government Cloud with Impact Level 5 (IL5) authorization

For All Government Cloud Customers

This topic contains information common to both the Government Cloud with FedRAMP authorization and to the Federal Government Cloud with IL5 authorization.

Shared Responsibilities

Oracle Cloud Infrastructure for government offers best-in-class security technology and operational processes to secure its enterprise cloud services. However, for you to securely run your workloads , you must be aware of your security and compliance responsibilities. By design, Oracle provides security of cloud infrastructure and operations (cloud operator access controls, infrastructure security patching, and so on), and you are responsible for securely configuring your cloud resources. Security in the cloud is a shared responsibility between you and Oracle.

For more information about shared responsibilities in the Oracle Cloud, see the following white papers:

- Making Sense of the Shared Responsibility Model
- Oracle Cloud Infrastructure Security

Setting Up an Identity Provider for Your Tenancy

As a Government Cloud customer, you must bring your own identity provider that meets your agency's compliance requirements and supports common access card/personal identity verification card (CAC/PIV) authentication. You can federate Oracle Cloud Infrastructure with SAML 2.0 compliant identity providers that also support CAC/PIV authentication. For instructions on setting up a federation, see Federating with Identity Providers.

Remove the Oracle Cloud Infrastructure Default Administrator User and Any Other Non-Federated Users

When your organization signs up for an Oracle account and Identity Domain, Oracle sets up a *default administrator* for the account. This person will be the first IAM user for your company and will have full administrator access to your tenancy. This user can set up your federation.

After you have successfully set up the federation with your chosen identity provider, you can delete the default administrator user and any other IAM service local users you might have added to assist with setting up your tenancy. Deleting the local, non-federated users ensures that only users in your chosen identity provider can access Oracle Cloud Infrastructure.

To delete the default administrator:

1. Sign in to the Console through your identity provider.

   #### More details

   a. Open a supported browser and go to the Government Cloud Console URL.
   b. Enter your **Cloud Tenant** and click **Continue.**
   c. On the **Single Sign-On** pane, select your identity provider and click **Continue**. You will be redirected to your identity provider to sign in.
   d. Enter your user name and password.

2. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Users**. The list of users is displayed.

3. On the **User Type** filter, select only **Local Users**.
4. For each local user, go to the the Actions icon (three dots) and click **Delete**.

Using a Common Access Card/Personal Identity Verification Card to Sign in to the Console

After you set up CAC/PIV authentication with your identity provider and successfully federate with Oracle Cloud Infrastructure, you can use your CAC/PIV credentials to sign in to the Oracle Cloud Infrastructure Console. See your identity provider's documentation for the specific details for your implementation.

In general, the sign in steps are:

1. Insert your CAC/PIV card into your card reader.
2. Navigate to the Oracle Cloud Infrastructure Console sign in page.
3. If prompted, enter your **Cloud Tenant** name and click **Continue**.
4. Select the Single Sign-On provider and click **Continue**.
5. On your identity provider's sign on page, select the appropriate card, for example, PIV Card.
6. If presented with a certificate picker, choose the appropriate certificate or other attributes set up by your organization.
7. When prompted, enter the PIN.

IPv6 Support for Virtual Cloud Networks

US Government Cloud customers have the option to enable IPv6 addressing for their VCNs. For more information, see IPv6 Addresses.

Setting Up Secure Access for Compute Hosts

You can set up CAC/PIV authentication using third-party tools to enable multi-factor authentication for securely connecting to your compute hosts. Example tools include PuTTY-

CAC for Windows and Open SC for macOS. For more information see the U.S. Government website, PIV Usage Guidelines.

Enabling FIPS Mode for Your Operating System

Government Cloud customers are responsible for enabling FIPS mode for the operating systems on their Compute hosts. To make your operating system compliant with Federal Information Processing Standard (FIPS) Publication 140-2, follow the guidelines for your operating system:

Oracle Linux

Follow the guidance provided at Enabling FIPS Mode on Oracle Linux.

Ubuntu

Follow the guidance provided at Ubuntu Security Certifications.

Windows Server 2008 and 2012

Follow the guidance provided at Data Encryption for Web console and Reporting server Connections.

Windows Server 2016

First, follow the guidance provided at How to Use FIPS Compliant Algorithms.

Next, go to the Microsoft document, FIPS 140 Validation and navigate to the topic Information for System Integrators. Follow the instructions under "Step 2 – Setting FIPS Local/Group Security Policy Flag" to complete the FIPS enablement.

CentOS

The following guidance is for enabling FIPS on CentOS 7.5. These procedures are valid for both VM and bare metal instances, and only in NATIVE mode. These procedures can be modified for both Emulated and PV modes as needed. Note that this procedure provides an

instance that contains the exact FIPS cryptographic modules EXCEPT kernel. However, the kernel module is the same major/minor version but is accelerated in revision, so can be considered compliant under most FIPS compliant models.

After you complete this procedure, Oracle strongly recommends that you do NOT run system-wide yum updates. The system-wide update will remove the FIPS modules contained herein.

Verify that the version of the kernel, FIPS modules, and FIPS software are at the minimum version:

1. Validate the current version of the kernel package meets the requirement:
    a. Current version: `kernel-3.10.0-693.el7`
    b. Execute `rpm -qa | grep kernel-3`
2. Execute the following and validate the major or minor version is the same as the requirements.
    a. Run

    ```
    yum list <package_name>
    ```

    b. Verify that the major/minor version matches the required ones.

    Required packages and versions are:

    - fipscheck - fipscheck-1.4.1-6.el7
    - hmaccalc - hmaccalc-0.9.13-4.el7
    - dracut-fips - dracut-fips-033-502.el7
    - dracut-fips-aesni - dracut-fips-aesni-033-502.el7

    c. For each version of package that is not installed, run

    ```
    yum install <package_name>
    ```

3. Download and install the following packages:
    a. Packages already installed as part of the image:
        i. Create a directory called `preinstall`.
        ii. Download the following packages into this directory:

openssl, openssl-libs – 1.0.2k-8.el7
nss, nss-tools, nss-sysinit – 3.28.4-15.el7_4
nss-util – 3.28.4-3.el7
nss-softokn, nss-softokn-freebl – 3.28.3-8.el7_4
openssh, openssh-clients, openssh-server – 7.4p1-11.el7

iii. In the preinstall directory, run

```
yum - -nogpgcheck downgrade *.rpm
```

b. Packages to be added to the image:

i. Create a directory called `newpackages`.

ii. Download the following packages into this directory:
libreswan – 3.20-3.el7
libgcrypt – 1.5.3-14.el7
gnutls – 3.3.26-9.el7
gmp – 6.0.0-15.el7
nettle – 2.7.1-8.el7

iii. In the `newpackages` directory, run

```
yum - -nogpgcheck localinstall *.rpm
```

The URLs for the packages used for this installation are:

Preinstall:

http://linuxsoft.cern.ch/cern/centos/7/updates/x86_64/Packages/nss-3.28.4-15.el7_4.x86_64.rpm

http://linuxsoft.cern.ch/cern/centos/7/updates/x86_64/Packages/nss-util-3.28.4-3.el7.x86_64.rpm

http://linuxsoft.cern.ch/cern/centos/7/updates/x86_64/Packages/nss-tools-3.28.4-15.el7_4.x86_64.rpm

http://linuxsoft.cern.ch/cern/centos/7/updates/x86_64/Packages/gnutls-3.3.26-9.el7.x86_64.rpm

http://linuxsoft.cern.ch/cern/centos/7/updates/x86_64/Packages/gmp-6.0.0-15.el7.x86_64.rpm

http://linuxsoft.cern.ch/cern/centos/7/updates/x86_64/Packages/nettle-2.7.1-8.el7.x86_64.rpm

Kernel FIPS module and initramfs validation installation.

Perform this procedure as root:

1. Regenerate dracut:

```
dracut -f -v
```

2. Add the fips argument to the end of the default kernel boot command line:
   a. Edit `/etc/default/grub`
   b. At the end of the line starting with "GRUB_CMDLINE_LINUX", add

```
fips=1
```

   inside the double quotes of the command.
   c. Save the result.
3. Generate a new `grub.cfg`:

```
grub2-mkconfig -o /etc/grub2-efi.cfg
```

Configure SSH to limit the encryption algorithms.

1. Sudo to root.
2. Edit `/etc/ssh/sshd_config`.
3. Add the following lines to the bottom of the file:

```
Protocol 2
Ciphers aes128-ctr,aes192-ctr,aes256-ctr,aes128-cbc,3des-cbc,aes192-cbc,aes256-cbc
Macs hmac-sha1
```

4. Reboot the instance.
5. After instance has rebooted, validate that FIPS mode has been enabled in the kernel:
   a. Sudo to root.
   b. Run the following command:

```
cat /proc/sys/crypto/fips-enabled
```

   The result should be '1'.

To further secure CentOS7/RHEL 7.x systems as required by individual agency guidance, follow the checklist contained in the OpenSCAP guide. This guide can be found here: https://static.open-scap.org/ssg-guides/ssg-centos7-guide-index.html

The STIG for evaluating compliance under multiple profiles can be found here: https://iase.disa.mil/stigs/os/unix-linux/Pages/index.aspx . Use the Red Hat Linux 7.x STIG for CentOS 7.5 releases.

Required VPN Connect Parameters for Government Cloud

If you use VPN Connect with the Government Cloud, you must configure the IPSec connection with the following FIPS-compliant IPSec parameters.

For some parameters, Oracle supports multiple values, and the recommended one is highlighted in *red italics*.

Oracle supports the following parameters for IKEv1 or IKEv2. Check the documentation for your particular CPE to confirm which parameters the CPE supports for IKEv1 or IKEv2.

Phase 1 (ISAKMP)

Parameter	Options
ISAKMP protocol	Version 1
Exchange type	Main mode
Authentication method	Pre-shared keys
Encryption algorithm	*AES-256-cbc* AES-192-cbc AES-128-cbc

Parameter	Options
Authentication algorithm	*SHA-2 384* SHA-2 256 SHA-1 (also called SHA or SHA1-96)
Diffie-Hellman group	group 14 (MODP 2048) group 19 (ECP 256) *group 20 (ECP 384) **
IKE session key lifetime	28800 seconds (8 hours)
* Group 20 will be supported in all Oracle Cloud Infrastructure regions very soon.	

Phase 2 (IPSec)

Parameter	Options
IPSec protocol	ESP, tunnel mode
Encryption algorithm	*AES-256-gcm* AES-192-gcm AES-128-gcm AES-256-cbc AES-192-cbc AES-128-cbc
Authentication algorithm	If using GCM (Galois/Counter Mode), no authentication algorithm is required because authentication is included with GCM encryption. If not using GCM, use HMAC-SHA-256-128.

Parameter	Options
IPSec session key lifetime	3600 seconds (1 hour)
Perfect Forward Secrecy (PFS)	enabled, group 14

Oracle's BGP ASN

This section is for network engineers who configure an edge device for FastConnect or VPN Connect.

Oracle's BGP ASN for the Government Cloud depends on the authorization level:

- Government Cloud: 6142
- Federal Government Cloud (Impact Level 5 authorization): 20054

Government Cloud with FedRAMP Authorization

This topic contains information specific to Oracle Cloud Infrastructure Government Cloud with FedRAMP authorization.

Authorizations

Oracle Cloud Infrastructure Government Cloud has obtained the following authorizations:

- FedRAMP Moderate
- DISA Impact Level 2

For information about the Federal Government Cloud, see Federal Government Cloud with Impact Level 5 Authorization.

Regions

The region names and identifiers for the Government Cloud with FedRAMP authorization are shown in the following table:

Region Name	Region Identifier	Region Location	Region Key	Realm Key	Availability Domains
US Gov East (Ashburn)	us-langley-1	Ashburn, VA	LFI	OC2	1
US Gov West (Phoenix)	us-luke-1	Phoenix, AZ	LUF	OC2	1

After your tenancy is created in one of these regions, you can subscribe to the other region. Tenancies in the FedRAMP-authorized regions cannot subscribe to the commercial regions, or to the Federal Government Cloud regions. For information about subscribing to a region, see Managing Regions.

Console Sign-in URLs

To sign in to the FedRAMP-authorized Government Cloud, enter one of the following URLs in a supported browser:

- https://console.us-langley-1.oraclegovcloud.com/
- https://console.us-luke-1.oraclegovcloud.com/

Note

When you're logged in to the Console for one of the Government Cloud regions, the browser times out after 15 minutes of inactivity, and you need to sign in again to use the Console.

Government Cloud API Reference and Endpoints

Oracle Cloud Infrastructure Government Cloud has these APIs and corresponding regional endpoints:

Core Services (covering Networking, Compute, and Block Volume)

The Networking, Compute, and Block Volume services are accessible with the following API:

Core Services API

API reference

- https://iaas.us-langley-1.oraclegovcloud.com
- https://iaas.us-luke-1.oraclegovcloud.com

Database API

API reference

- https://database.us-langley-1.oraclegovcloud.com
- https://database.us-luke-1.oraclegovcloud.com

You can track the progress of long-running Database operations with the Work Requests API.

IAM API

API reference

- https://identity.us-langley-1.oraclegovcloud.com
- https://identity.us-luke-1.oraclegovcloud.com

Note

Use the Endpoint of Your Home Region for All IAM API Calls

When you sign up for Oracle Cloud Infrastructure, Oracle creates a tenancy for you in one region. This is your home region. Your home region is where your IAM resources are defined. When you subscribe to a new region, your IAM resources are replicated in the new region, however, the master definitions reside in your home region and can only be changed there. Make all IAM API calls against your home region endpoint. The changes automatically replicate to all regions. If you try to make an IAM API call against a region that is not your home region, you will receive an error.

Key Management API

API reference

- https://kms.us-langley-1.oraclegovcloud.com
- https://kms.us-luke-1.oraclegovcloud.com

In addition to these endpoints, each vault has a unique endpoint for create, update, and list operations for keys. This endpoint is referred to as the control plane URL or management endpoint. Each vault also has a unique endpoint for cryptographic operations. This endpoint is known as the data plane URL or the cryptographic endpoint.

Object Storage and Archive Storage APIs

Both Object Storage and Archive Storage are accessible with the following APIs:

Object Storage API

API reference

- https://objectstorage.us-langley-1.oraclegovcloud.com
- https://objectstorage.us-luke-1.oraclegovcloud.com

Amazon S3 Compatibility API

API reference

- https://*<object_storage_namespace>*.compat.objectstorage.us-langley-1.oraclegovcloud.com
- https://*<object_storage_namespace>*.compat.objectstorage.us-luke-1.oraclegovcloud.com

Tip

See Understanding Object Storage Namespaces for information regarding how to find your Object Storage namespace.

Swift API (for use with Oracle RMAN)

- https://swiftobjectstorage.us-langley-1.oraclegovcloud.com
- https://swiftobjectstorage.us-luke-1.oraclegovcloud.com

Work Requests API (for Compute and Database work requests)

API reference

- https://iaas.us-langley-1.oraclegovcloud.com
- https://iaas.us-luke-1.oraclegovcloud.com

Services Not Supported in Oracle Cloud Infrastructure Government Cloud

The following services are currently not available for tenancies in the Government Cloud:

Core Infrastructure services and features not available:

- Compute service features:
    - Autoscaling
- Data Transfer service
- File Storage service

Database services not available:

- Autonomous Data Warehouse
- Autonomous Transaction Processing
- Data Safe

Data and AI services not available:

- Digital Assistant

Solutions and Platform services not available:

- Analytics Cloud
- Analytics for Applications
- Container Engine for Kubernetes
- Content and Experience
- DNS Zone Management
- Email Delivery

- Events
- Functions
- Health Checks
- Integration
- Marketplace
- Monitoring
- Notifications
- Registry
- Resource Manager
- Streaming
- Traffic Management Steering Policies

Governance and Administration features not supported

- Auto-federation with Oracle Identity Cloud Service
- WAF service

Infrastructure Tools

- Oracle Cloud Infrastructure Terraform Provider

Integration with Oracle SaaS and PaaS services, including those listed here: Getting Started with Oracle Platform Services

Additional Information for Government Cloud Customers

- Shared Responsibilities
- Setting Up an Identity Provider for Your Tenancy
- Using a Common Access Card/Personal Identity Verification Card to Sign in to the Console

- IPv6 Support for Virtual Cloud Networks
- Setting Up Secure Access for Compute Hosts
- Enabling FIPS Mode for Your Operating System
- Required VPN Connect Parameters for Government Cloud
- Oracle's BGP ASN

Federal Government Cloud with Impact Level 5 Authorization

This topic contains information specific to Oracle Cloud Infrastructure Federal Government Cloud.

Compliance with Defense Cloud Security Requirements

Oracle Cloud Infrastructure Federal Government Cloud supports applications that require Impact Level 5 (IL5) data, as defined in the Department of Defense Cloud Computing Security Requirements Guide (SRG).

Federal Government Cloud Regions

The region names and identifiers for the Oracle Cloud Infrastructure Federal Government Cloud regions are shown in the following table:

Region Name	Region Identifier	Region Key	Realm Key	Availability Domains
US DoD East (Ashburn)	us-gov-ashburn-1	ric	OC3	1
US DoD North (Chicago)	us-gov-chicago-1	pia	OC3	1
US DoD West (Phoenix)	us-gov-phoenix-1	tus	OC3	1

After your tenancy is created in one of the Federal Government Cloud regions, you can subscribe to the other regions in the Federal Government Cloud. Federal Government Cloud tenancies cannot subscribe to any Oracle Cloud Infrastructure regions not belonging to the OC3 realm. For information about subscribing to a region, see Managing Regions.

Federal Government Cloud Console Sign-in URLs

To sign in to the Oracle Cloud Infrastructure Federal Government Cloud, enter one of the following URLs in a supported browser:

- https://console.us-gov-ashburn-1.oraclegovcloud.com/
- https://console.us-gov-chicago-1.oraclegovcloud.com/
- https://console.us-gov-phoenix-1.oraclegovcloud.com/

Note

When you're logged in to the Console for one of the Government Cloud regions, the browser times out after 15 minutes of inactivity, and you need to sign in again to use the Console.

Government Cloud API Reference and Endpoints

Oracle Cloud InfrastructureGovernment Cloud has these APIs and corresponding regional endpoints:

Core Services (covering Networking, Compute, and Block Volume)

The Networking, Compute, and Block Volume services are accessible with the following API:

Core Services API

API reference

- https://iaas.us-gov-ashburn-1.oraclegovcloud.com
- https://iaas.us-gov-chicago-1.oraclegovcloud.com
- https://iaas.us-gov-phoenix-1.oraclegovcloud.com

Database API

API reference

- https://database.us-gov-ashburn-1.oraclegovcloud.com
- https://database.us-gov-chicago-1.oraclegovcloud.com
- https://database.us-gov-phoenix-1.oraclegovcloud.com

You can track the progress of long-running Database operations with the Work Requests API.

IAM API

API reference

- https://identity.us-gov-ashburn-1.oraclegovcloud.com
- https://identity.us-gov-chicago-1.oraclegovcloud.com
- https://identity.us-gov-phoenix-1.oraclegovcloud.com

Note

Use the Endpoint of Your Home Region for All IAM API Calls

When you sign up for Oracle Cloud Infrastructure, Oracle creates a tenancy for you in one region. This is your home region. Your home region is where your IAM resources are defined. When you subscribe to a new region, your IAM resources are replicated in the new region, however, the master definitions reside in your home region and can only be changed there. Make all IAM API calls against your home region endpoint. The changes automatically replicate to all regions. If you try to make an IAM API call against a region that is not your home region, you will receive an error.

Key Management API

API reference

- https://kms.us-gov-ashburn-1.oraclegovcloud.com
- https://kms.us-gov-chicago-1.oraclegovcloud.com
- https://kms.us-gov-phoenix-1.oraclegovcloud.com

In addition to these endpoints, each vault has a unique endpoint for create, update, and list operations for keys. This endpoint is referred to as the control plane URL or management endpoint. Each vault also has a unique endpoint for cryptographic operations. This endpoint is known as the data plane URL or the cryptographic endpoint.

Object Storage and Archive Storage APIs

Both Object Storage and Archive Storage are accessible with the following APIs:

Object Storage API

API reference

- https://objectstorage.us-gov-ashburn-1.oraclegovcloud.com
- https://objectstorage.us-gov-chicago-1.oraclegovcloud.com
- https://objectstorage.us-gov-phoenix-1.oraclegovcloud.com

Amazon S3 Compatibility API

API reference

- https://*<object_storage_namespace>*.compat.objectstorage.us-gov-ashburn-1.oraclegovcloud.com
- https://*<object_storage_namespace>*.compat.objectstorage.us-gov-chicago-1.oraclegovcloud.com
- https://*<object_storage_namespace>*.compat.objectstorage.us-gov-phoenix-1.oraclegovcloud.com

Tip

See Understanding Object Storage Namespaces for information regarding how to find your Object Storage namespace.

Swift API (for use with Oracle RMAN)

- https://swiftobjectstorage.us-gov-ashburn-1.oraclegovcloud.com
- https://swiftobjectstorage.us-gov-chicago-1.oraclegovcloud.com
- https://swiftobjectstorage.us-gov-phoenix-1.oraclegovcloud.com

Work Requests API (for Compute and Database work requests)

API reference

- https://iaas.us-gov-ashburn-1.oraclegovcloud.com
- https://iaas.us-gov-chicago-1.oraclegovcloud.com
- https://iaas.us-gov-phoenix-1.oraclegovcloud.com

Services Not Supported in Oracle Cloud Infrastructure Federal Government Cloud

Currently, the following services are not available for tenancies in the Federal Government Cloud:

Core Infrastructure services and features not available:

- Compute service features:
    - Autoscaling
- FastConnect
- Data Transfer service
- File Storage service

Database services not available:

- Autonomous Data Warehouse
- Autonomous Transaction Processing
- Data Safe

Data and AI services not available:

- Digital Assistant

Solutions and Platform services not available:

- Analytics Cloud
- Analytics for Applications
- Container Engine for Kubernetes
- Content and Experience
- DNS Zone Management
- Email Delivery
- Events
- Functions
- Health Checks
- Integration
- Marketplace
- Monitoring
- Notifications
- Registry
- Resource Manager
- Streaming
- Traffic Management Steering Policies

Governance and Administration features not supported

- Auto-federation with Oracle Identity Cloud Service
- WAF service

Infrastructure Tools

- Oracle Cloud Infrastructure Terraform Provider

Integration with Oracle SaaS and PaaS services, including those listed here: Getting Started with Oracle Platform Services.

Additional Information for Federal Government Cloud Customers

- Shared Responsibilities
- Setting Up an Identity Provider for Your Tenancy
- Using a Common Access Card/Personal Identity Verification Card to Sign in to the Console
- IPv6 Support for Virtual Cloud Networks
- Setting Up Secure Access for Compute Hosts
- Enabling FIPS Mode for Your Operating System
- Required VPN Connect Parameters for Government Cloud
- Oracle's BGP ASN

CHAPTER 4 Service Essentials

The following topics provide essential information that applies across Oracle Cloud Infrastructure.

Security Credentials

The types of credentials you'll use when working with Oracle Cloud Infrastructure.

Regions and Availability Domains

An introduction to the concepts of regions and availability domains.

Resource Identifiers

A description of the different ways your Oracle Cloud Infrastructure resources are identified.

Resource Monitoring

Information about how to monitor your resources.

Resource Tags

Information about Oracle Cloud Infrastructure tags and how to apply them to your resources.

Compartment Quotas

Information about how to control resource consumption within compartments using quotas.

Compartment Explorer

View all resources in a selected compartment, across regions.

Service Limits

A list of the default limits applied to your cloud resources and how to request an increase.

Console Announcements

Information about the announcements that occasionally appear in the Oracle Cloud Infrastructure Console

Prerequisites for Oracle Platform Services on Oracle Cloud Infrastructure

Instructions for setting up the resources required when running an Oracle Platform Service on Oracle Cloud Infrastructure.

Billing and Payment Tools Overview

Information about billing and payment tools that you can use to analyze your service usage and manage your costs.

My Services Use Cases

Use cases for the Oracle Cloud My Services API, to help you interact programmatically with My Services.

Security Credentials

This section describes the types of credentials you'll use when working with Oracle Cloud Infrastructure.

Console Password

- **What it's for:** Using the Console.
- **Format:** Typical password text string.
- **How to get one:** An administrator will provide you with a one-time password.
- **How to use it:** Sign in to the Console the first time with the one-time password, and then change it when prompted. Requirements for the password are displayed there. The one-time password expires in seven days. If you want to change the password later, see To change your Console password. Also, you or an administrator can reset the password in the Console or with the API (see To create or reset another user's Console password). Resetting the password creates a new one-time password that you'll be prompted to change the next time you sign in to the Console. If you're blocked from signing in to the Console because you've tried 10 times in a row unsuccessfully, contact your administrator.
- **Note for Federated Users:** Federated users do not use a Console password. Instead, they sign in to the Console through their identity provider.

API Signing Key

- **What it's for:** Using the API (see Software Development Kits and Command Line Interface and Request Signatures).
- **Format:** RSA key pair in PEM format (minimum 2048 bits required).
- **How to get one:** See Required Keys and OCIDs.
- **How to use it:** In the Console, copy and paste the contents of the PEM public key file from the key pair (see How to Upload the Public Key). Then use the private key with the SDK or with your own client to sign your API requests. Note that after you've uploaded your first API key in the Console, you can use the API to upload any additional ones you want to use. If you provide the wrong kind of key (for example, your instance SSH key, or a key that isn't at least 2048 bits), you'll get an `InvalidKey` error.
- **Example:** The PEM public key looks something like this:

```
-----BEGIN PUBLIC KEY-----
```

```
MIIBIjANBgkqhkiG9w0BAQEFAAOCAQ8AMIIBCgKCAQEAoTFqF...
...

-----END PUBLIC KEY--
```

Instance SSH Key

- **What it's for:** Accessing a compute instance.
- **Format:** For Oracle-provided images, these SSH key types are supported: RSA, DSA, DSS, ECDSA, and Ed25519. If you bring your own image, you're responsible for managing the SSH key types that are supported.
  For RSA, DSS, and DSA keys, a minimum of 2048 bits is recommended. For ECDSA keys, a minimum of 128 bits is recommended.
- **How to get one:** See Creating a Key Pair.
- **How to use it:** When you launch an instance, provide the public key from the key pair.
- **Example:** An RSA public key looks something like this:

```
ssh-rsa AAAAB3BzaC1yc2EAAAADAQABAAABAQD9BRwrUiLDki6P0+jZhwsjS2muM...

... jane.smith@example.com
```

Auth Token

- **What it's for:** Authenticating with third-party APIs that do not support Oracle Cloud Infrastructure's signature-based authentication. For example, use an auth token as your password with Swift clients.
- **Format:** Typical password text string.
- **How to get one:** See Working with Auth Tokens.
- **How to use it:** Usage depends on the service your are authenticating with. Typically, you authenticate with third-party APIs by providing your Oracle Cloud Infrastructure Console login, your auth token provided by Oracle, and your organization's Oracle tenant name.

Regions and Availability Domains

This topic describes the physical and logical organization of Oracle Cloud Infrastructure resources.

About Regions and Availability Domains

Oracle Cloud Infrastructure is hosted in regions and availability domains. A region is a localized geographic area, and an availability domain is one or more data centers located within a region. A region is composed of one or more availability domains. Most Oracle Cloud Infrastructure resources are either region-specific, such as a virtual cloud network, or availability domain-specific, such as a compute instance. Traffic between availability domains and between regions is encrypted.

Availability domains are isolated from each other, fault tolerant, and very unlikely to fail simultaneously. Because availability domains do not share infrastructure such as power or cooling, or the internal availability domain network, a failure at one availability domain within a region is unlikely to impact the availability of the others within the same region.

The availability domains within the same region are connected to each other by a low latency, high bandwidth network, which makes it possible for you to provide high-availability connectivity to the internet and on-premises, and to build replicated systems in multiple availability domains for both high-availability and disaster recovery.

Oracle is adding multiple cloud regions around the world to provide local access to cloud resources for our customers. To accomplish this quickly, we've chosen to launch regions in new geographies with one availability domain.

As regions require expansion, we have the option to add capacity to existing availability domains, to add additional availability domains to an existing region, or to build a new region. The expansion approach in a particular scenario is based on customer requirements as well as considerations of regional demand patterns and resource availability.

For any region with one availability domain, a second availability domain or region in the same country or geo-political area will be made available within a year to enable further options for disaster recovery that support customer requirements for data residency where they exist.

Regions are independent of other regions and can be separated by vast distances—across countries or even continents. Generally, you would deploy an application in the region where it is most heavily used, because using nearby resources is faster than using distant resources. However, you can also deploy applications in different regions for these reasons:

- To mitigate the risk of region-wide events such as large weather systems or earthquakes.
- To meet varying requirements for legal jurisdictions, tax domains, and other business or social criteria.

Regions are grouped into realms. Your tenancy exists in a single realm and can access all regions that belong to that realm. You can't access regions that are not in your realm. Currently, Oracle Cloud Infrastructure has three realms: the commercial realm, and two realms for Government Cloud: FedRAMP authorized and IL5 authorized.

The following table lists the regions in the Oracle Cloud Infrastructure commercial realm:

Region Name	Region Identifier	Region Location	Region Key	Realm Key	Availability Domains
Australia East (Sydney)	ap-sydney-1	Sydney, Australia	SYD	OC1	1
Brazil East (Sao Paulo)	sa-saopaulo-1	Sao Paulo, Brazil	GRU	OC1	1
Canada Southeast (Toronto)	ca-toronto-1	Toronto, Canada	YYZ	OC1	1
Germany Central (Frankfurt)	eu-frankfurt-1	Frankfurt, Germany	FRA	OC1	3
India West (Mumbai)	ap-mumbai-1	Mumbai, India	BOM	OC1	1
Japan East (Tokyo)	ap-tokyo-1	Tokyo, Japan	NRT	OC1	1

Region Name	Region Identifier	Region Location	Region Key	Realm Key	Availability Domains
South Korea Central (Seoul)	ap-seoul-1	Seoul, South Korea	ICN	OC1	1
Switzerland North (Zurich)	eu-zurich-1	Zurich, Switzerland	ZRH	OC1	1
UK South (London)	uk-london-1	London, United Kingdom	LHR	OC1	3
US East (Ashburn)	us-ashburn-1	Ashburn, VA	IAD	OC1	3
US West (Phoenix)	us-phoenix-1	Phoenix, AZ	PHX	OC1	3

To subscribe to a region, see Managing Regions.

For a list of the Oracle Government Cloud regions, see Government Cloud with FedRAMP Authorization and Federal Government Cloud with Impact Level 5 Authorization.

Note

Your Tenancy's Availability Domain Names

Oracle Cloud Infrastructure randomizes the availability domains by tenancy to help balance capacity in the data centers. For example, the availability domain labeled PHX-AD-1 for tenancyA may be a different data center than the one labeled PHX-AD-1 for tenancyB. To keep track of which availability domain corresponds to which data center for each tenancy, Oracle Cloud Infrastructure uses tenancy-specific prefixes for the availability domain names. For example: the availability domains for your tenancy are something like *Uocm:*PHX-AD-1, *Uocm:*PHX-AD-2, and so on.

To get the specific names of your tenancy's availability domains, use the ListAvailabilityDomains operation, which is available in the IAM API. You can also see the names when you use the Console to launch an instance and choose which availability domain to launch the instance into.

Fault Domains

A fault domain is a grouping of hardware and infrastructure within an availability domain. Each availability domain contains three fault domains. Fault domains let you distribute your instances so that they are not on the same physical hardware within a single availability domain. A hardware failure or Compute hardware maintenance event that affects one fault domain does not affect instances in other fault domains.

To control the placement of your compute instances, bare metal DB system instances, or virtual machine DB system instances, you can optionally specify the fault domain for a new instance at launch time. If you do not specify the fault domain, the system selects one for

you. To change the fault domain for an instance, terminate it and launch a new instance in the preferred fault domain.

Use fault domains to do the following things:

- Protect against unexpected hardware failures.
- Protect against planned outages due to Compute hardware maintenance.

For more information:

- For recommendations on using fault domains when provisioning application and database servers, see Fault Domains in Best Practices for Your Compute Instance.
- For more information about using fault domains when provisioning Oracle bare metal and virtual machine DB systems, see Fault Domain Considerations for 2-node Virtual Machine DB Systems and Availability Domain and Fault Domain Considerations for Data Guard.

Service Availability Across Regions

All Oracle Cloud Infrastructure regions offer core infrastructure services, including the following:

- Compute: Compute (Intel based bare metal & VM, DenseIO & Standard), Container Engine for Kubernetes, Registry
- Storage: Block Volume, File Storage, Object Storage, Archive Storage
- Networking: Virtual Cloud Network, Load Balancing, FastConnect (specific partners as available and requested)
- Database: Database, Exadata Cloud Service, Autonomous Data Warehouse, Autonomous Transaction Processing
- Edge: DNS
- Platform: Identity and Access Management, Tagging, Audit, Work Requests

Generally available cloud services beyond those in the preceding list are made available based on regional customer demand. Any service can be made available within a maximum of

three months, with many services deploying more quickly. New cloud services are made available in regions as quickly as possible based on a variety of considerations including regional customer demand, ability to achieve regulatory compliance where applicable, resource availability, and other factors. Because of our low latency interconnect backbone, customers can use cloud services in other geographic regions with effective results when they are not available in their home region, provided that data residency requirements do not prevent them from doing so. We regularly work with customers to help ensure effective access to required services.

Resource Availability

The following sections list the resource types based on their availability: global across regions, within a single region, or within a single availability domain.

Tip

In general: IAM resources are global. DB Systems, instances, and volumes are specific to an availability domain. Everything else is regional. Exception: Subnets were originally designed to be specific to an availability domain. Now, you can create regional subnets, which is what Oracle recommends.

Global Resources

- API signing keys
- compartments
- dynamic groups
- federation resources
- groups
- policies

- tag namespaces
- tag keys
- users

Regional Resources

- alarms
- applications
- buckets: Although buckets are regional resources, they can be accessed from any location if you use the correct region-specific Object Storage URL for the API calls.
- clusters
- cloudevents-rules
- customer-premises equipment (CPE)
- DHCP options sets
- dynamic routing gateways (DRGs)
- encryption keys
- functions
- images
- internet gateways
- jobs
- key vaults
- load balancers
- local peering gateways (LPGs)
- metrics
- NAT gateways
- network security groups
- node pools

- repositories
- reserved public IPs
- route tables
- security lists
- service gateways
- stacks
- subnets: When you create a subnet, you choose whether it's regional or specific to an availability domain. Oracle recommends using regional subnets.
- subscriptions
- topics
- virtual cloud networks (VCNs)
- volume backups: They can be restored as new volumes to any availability domain within the same region in which they are stored.

Availability Domain-Specific Resources

- DB Systems
- ephemeral public IPs
- instances: They can be attached only to volumes in the same availability domain.
- subnets: When you create a subnet, you choose whether it is regional or specific to an availability domain. Oracle recommends using regional subnets.
- volumes: They can be attached only to an instance in the same availability domain.

IP Address Ranges

This topic provides information about public IP address ranges for services that are deployed in Oracle Cloud Infrastructure. Allow traffic to these CIDR blocks to ensure access to the services.

Endpoints for Oracle YUM repos and the Oracle Container Registry are listed on this page. You can use DNS lookup to determine the public IP address for each endpoint.

Public IP Addresses for VCNs and the Oracle Services Network

Public IP address ranges for VCNs and the Oracle Services Network are published to a JSON file which you can download and view manually or consume programmatically.

The *Oracle Services Network* is a conceptual network in Oracle Cloud Infrastructure that is reserved for Oracle services. A service gateway offers private access to the Oracle Services Network from workloads in your VCN and your on-premises network. The published addresses correspond to the service CIDR label called **All *<region>* Services in Oracle Services Network**. For a list of the services available with a service gateway, see Service Gateway: Supported Cloud Services in Oracle Services Network.

Downloading the JSON File

Use this link to download the current list of public IP ranges.

You can poll the published file to check for new IP address ranges as frequently as every 24 hours. We recommend that you poll the published file at least weekly.

JSON File Contents and Syntax

IP addresses are published in the `public_ip_ranges.json` file with the fields in the following table.

Example of the public_ip_ranges.json file

```
{
    "last_updated_timestamp": "2019-11-18T19:55:47.204985",
    "regions": [
        {
            "region": "us-phoenix-1",
            "cidrs": [
                {
```

```
                    "cidr": "129.146.0.0/21",
                    "tags": [
                        "OCI"
                    ]
                },
                {
                    "cidr": "134.70.8.0/21",
                    "tags": [
                        "OSN",
                        "OBJECT_STORAGE"
                    ]
                },
            ]
        }
        {
            "region": "us-ashburn-1",
            "cidrs": [
                {
                    "cidr": "129.213.8.0/21",
                    "tags": [
                        "OCI"
                    ]
                },
                {
                    "cidr": "134.70.24.0/21",
                    "tags": [
                        "OSN",
                        "OBJECT_STORAGE"
                    ]
                }
            ]
        }
    ]
}
```

Field Name	Definition	Type	Example
`last_updated_timestamp`	File creation time in ISO 8601 format. Expressed as *<date>*T*<time>*	string	`"last_updated_timestamp": "2019-11-18T19:55:47.204985"`
`regions`	IP CIDR ranges grouped by region.	array	See preceding Example of the public_ip_ranges.json file
`region`	The region of the IP CIDR ranges. Valid values: Any region in the Oracle Cloud Infrastructure commercial realm. For a complete list of regions, see Regions and Availability Domains.	string	`"region": "us-phoenix-1"`
`cidrs`	A group of IP address CIDR ranges.	array	See preceding Example of the public_ip_ranges.json file

Field Name	Definition	Type	Example
`cidr`	One or more IPv4 IP addresses expressed in CIDR notation.	string	`"cidr": "147.154.0.0/18"`
`tags`	The services associated with the IP address CIDR range. Valid values: • `OCI`: The VCN CIDR blocks. • `OSN`: The CIDR block ranges for the Oracle Services Network. • `OBJECT_STORAGE`: The CIDR block ranges used by the Object Storage service. For more information, see Overview of Object Storage.	array of string values	`"tags": [ "OCI" ]`

Filtering the JSON file contents

After you download the JSON file, you can use a command line tool such as `jq` to filter the contents.

Download `jq`

Here are some examples of how you can use the tool to find and filter the information you need:

Find the creation date of the JSON file:

```
jq .last_updated_timestamp < public_ip_ranges.json
```

Get all IPv4 addresses for a specific region:

```
jq -r '.regions[] | select (.region=="us-phoenix-1") | .cidrs[] | select (.cidr | contains(".")) | .cidr
' < public_ip_ranges.json
```

Public IP Addresses for the Oracle YUM Repos

The Oracle YUM repos have the following regional public endpoints.

Region	YUM Server Endpoint
Australia East (Sydney)	https://yum-ap-sydney-1.oracle.com
Canada Southeast (Toronto)	https://yum-ca-toronto-1.oracle.com
Germany Central (Frankfurt)	https://yum-eu-frankfurt-1.oracle.com
India West (Mumbai)	https://yum-ap-mumbai-1.oracle.com
Japan East (Tokyo)	https://yum-ap-tokyo-1.oracle.com
South Korea Central (Seoul)	https://yum-ap-seoul-1.oracle.com
UK South (London)	https://yum-uk-london-1.oracle.com
US East (Ashburn)	https://yum-us-ashburn-1.oracle.com
US West (Phoenix)	https://yum-us-phoenix-1.oracle.com

You can use DNS lookup to determine the public IP address for each endpoint.

Resource Identifiers

This chapter describes the different ways your Oracle Cloud Infrastructure resources are identified.

Oracle Cloud IDs (OCIDs)

Most types of Oracle Cloud Infrastructure resources have an Oracle-assigned unique ID called an *Oracle Cloud Identifier* (OCID). It's included as part of the resource's information in both the Console and API.

Important

To use the API, you need the OCID for your tenancy. For information about where to find it, see the next section.

OCIDs use this syntax:

```
ocid1.<RESOURCE TYPE>.<REALM>.[REGION][.FUTURE USE].<UNIQUE ID>
```

- **ocid1:** The literal string indicating the version of the OCID.
- **resource type:** The type of resource (for example, `instance`, `volume`, `vcn`, `subnet`, `user`, `group`, and so on).
- **realm:** The realm the resource is in. A *realm* is a set of regions that share entities. Possible values are `oc1` for the commercial realm , `oc2` for the Government Cloud realm, or `oc3` for the Federal Government Cloud realm. The regions in the commercial realm (OC1) belong to the domain `oraclecloud.com`. The regions in the Government Cloud (OC2) belong to the domain `oraclegovcloud.com`.
- **region**: The region the resource is in (for example, `phx`, `iad`, `eu-frankfurt-1`). With the introduction of the Frankfurt region, the format switched from a three-character code to a longer string. This part is present in the OCID only for regional resources or those specific to a single availability domain. If the region is not applicable to the resource, this part might be blank (see the example tenancy ID below).

- **future use:** Reserved for future use. Currently blank.
- **unique ID:** The unique portion of the ID. The format may vary depending on the type of resource or service.

Example OCIDs

Tenancy:

```
ocid1.tenancy.oc1..aaaaaaaaba3pv6wkcr4jqae5f44n2b2m2yt2j6rx32uzr4h25vqstifsfdsq
```

Instance:

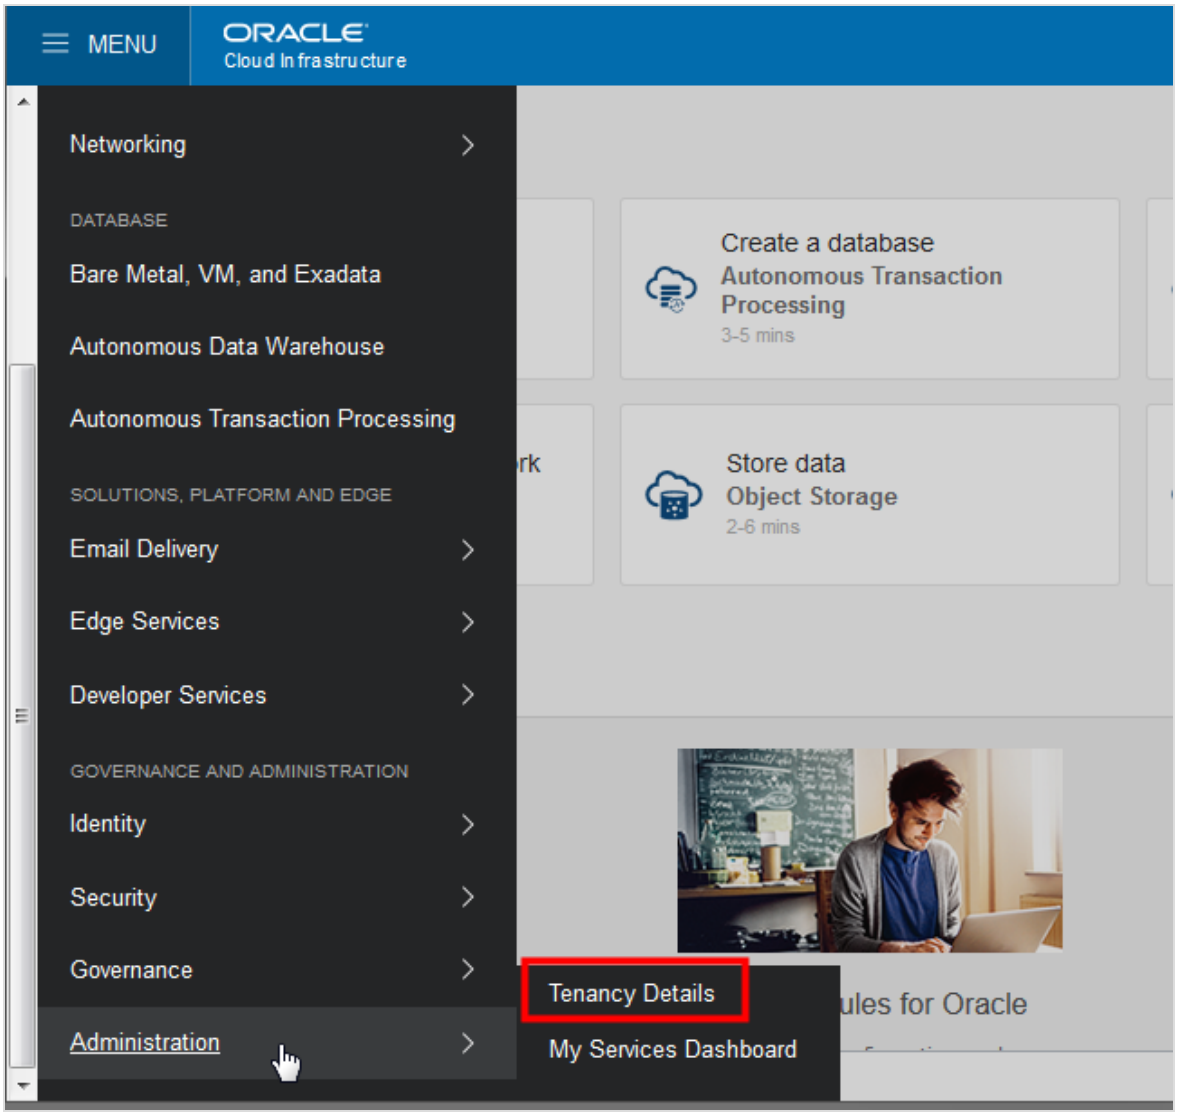
```
ocid1.instance.oc1.phx.abuw4ljrlsfiqw6vzzxb43vyypt4pkodawglp3wqxjqofakrwvou52gb6s5a
```

Where to Find Your Tenancy's OCID

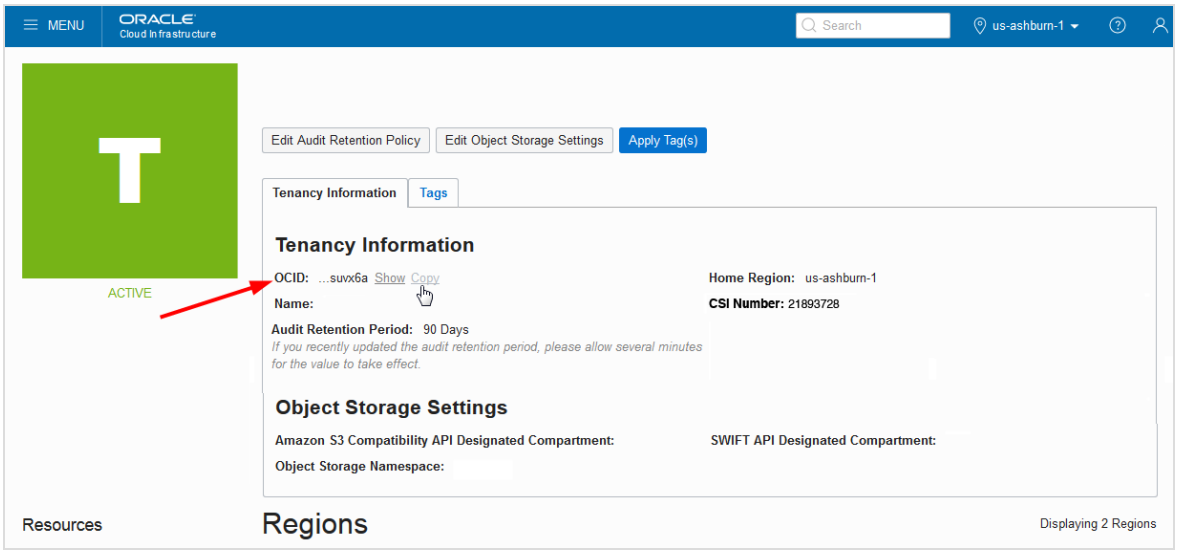
If you use the Oracle Cloud Infrastructure API, you need your tenancy's OCID in order to sign the API requests. You also use the tenancy ID in some of the IAM API operations.

Get the tenancy OCID from the Oracle Cloud Infrastructure Console on the **Tenancy Details** page:

1. Open the navigation menu, under Governance and Administration, go to **Administration** and click **Tenancy Details**.



2. The tenancy OCID is shown under **Tenancy Information**. Click **Copy** to copy it to your clipboard.



The tenancy OCID looks something like this (notice the word "tenancy" in it):

```
ocid1.tenancy.oc1..<unique_ID>
```

Name and Description (IAM Only)

The IAM service requires you to assign a unique, unchangeable *name* to each of your IAM resources (users, groups, dynamic groups, federations, and policies). The name must be unique within the scope of the type of resource (for example, you can only have one user with the name BobSmith). Notice that this requirement is specific to IAM and not the other services.

The name you assign to a user at creation is their login for the Console.

You can use these names instead of the OCID when writing a policy (for example, `Allow group <GROUP NAME> to manage all-resources in compartment <COMPARTMENT NAME>`).

In addition to the name, you must also assign a *description* to each of your IAM resources (although it can be an empty string). It can be a friendly description or other information that helps you easily identify the resource. The description does not have to be unique, and you can change it whenever you like. For example, you might want to use the description to store

the user's email address if you're not already using the email address as the user's unique name.

Display Name

For most of the Oracle Cloud Infrastructure resources you create (other than those in IAM), you can optionally assign a *display name*. It can be a friendly description or other information that helps you easily identify the resource. The display name does not have to be unique, and you can change it whenever you like. The Console shows the resource's display name along with its OCID.

Resource Tags

When you have many resources (for example, instances, VCNs, load balancers, and block volumes) across multiple compartments in your tenancy, it can become difficult to track resources used for specific purposes, or to aggregate them, report on them, or take bulk actions on them. *Tagging* allows you to define keys and values and associate them with resources. You can then use the tags to help you organize and list resources based on your business needs.

There are two types of tags:

Defined tags are set up in your tenancy by an administrator. Only users granted permission to work with the defined tags can apply them to resources.

Free-form tags can be applied by any user with permissions on the resource.

For more detailed information about tags and their features, see Tagging Overview.

Tip

Watch a video to introduce you to the concepts and features of tagging: Introduction to Tagging.

Working with Resource Tags

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

To add a defined tag to an existing resource

To apply a defined tag, you must have permission to use the namespace.

1. Open the Console, go to the details page of the resource you want to tag.
   For example, to tag a compute instance: Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**. A list of the instances in your current compartment is displayed. Find the instance that you want to tag, and click its name to view its details page.
2. Click **Apply Tags**.
3. In the **Apply Tags to the Resource** dialog:
   a. Select the **Tag Namespace**.
   b. Select the **Tag Key**.
   c. In **Value**, either enter a value or select one from the list.
   d. To apply another tag, click **+ Additional Tag**.
   e. When finished adding tags, click **Apply Tag(s)**.

To add a free-form tag to an existing resource

1. Open the Console, go to the details page of the resource you want to tag.

For example, to tag a compute instance: Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**. A list of the instances in your current compartment is displayed. Find the instance that you want to tag, and click its name to view its details page.

2. Click **Apply Tags**.
3. In the **Apply Tags to the Resource** dialog:
    a. Select **None (apply a free-form tag)**.
    b. Enter the **Tag Key**.
    c. Enter a **Value**.
    d. To apply another tag, click **+ Additional Tag**.
    e. When finished adding tags, click **Apply Tag(s)**.

To add a tag during resource creation

You can apply tags during resource creation. The location of the **Apply Tag(s)** option in the dialog varies by resource. The general steps are:

1. In the resource Create dialog, click **Apply Tags**.
   On some resources, you have to click **Show Advanced Options** to apply a tag.
2. In the **Apply Tags to the Resource** dialog:
    a. Select the **Tag Namespace**, or select **None** to apply a free-form tag.
    b. Select or enter the **Tag Key**.
    c. In **Value**, either enter a value or select one from the list.
    d. To apply another tag, click **+ Additional Tag**.
    e. Click **Apply Tag(s)**.

To filter a list of resources by a tag

Open the Console, click the service name and then click the resource you want to view. The

left side of the page shows all the filters currently applied to the list.

For example, to view compute instances: Click **Compute** and then click **Instances**, to see the list of instances in your current compartment.

To filter a list of resources by a defined tag

1. Next to **Tag Filters**, click **add**.
2. In the **Apply a Tag Filter** dialog, enter the following:
    a. **Namespace:** Select the tag namespace.
    b. **Key:** Select a specific key.
    c. **Value:** Select from the following:
        - **Match Any Value** - returns all resources tagged with the selected namespace and key, regardless of the tag value.
        - **Match Any of the Following** - returns resources with the tag value you enter in the text box. Enter a single value in the text box. To specify multiple values for the same namespace and key, click **+** to display another text box. Enter one value per text box.
    d. Click **Apply Filter**.

To filter a list of resources by a free-form tag

1. Next to **Tag Filters**, click **add**.
2. In the **Apply a Tag Filter** dialog, enter the following:
    a. **Key:** Enter the tag key.
    b. **Value:** Select from the following:
        - **Match Any Value** - returns all resources tagged with the selected free-form tag key, regardless of the tag value.

- **Match Any of the Following** - returns resources with the tag value you enter in the text box. Enter a single value in the text box. To specify multiple values for the same key, click **+** to display another text box. Enter one value per text box.

c. Click **Apply Filter**.

To update a tag applied to a resource

1. Open the Console, click the service name and then click the resource you want to view. For example, to view compute instances: Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**. A list of the instances in your current compartment is displayed. Find the instance that you want to update, and click its name to view its details page.
2. Click **Tags**.
   The list of tags applied to the resource is displayed.
3. Find the tag you want to update and click the pencil icon next to it.
4. Enter or select a new value.
5. Click **Save**.

To remove a tag from a resource

1. Open the Console, click the service name and then click the resource you want to view. For example, to view a compute instance: Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**. A list of the instances in your current compartment is displayed. Find the instance that you want to remove the tag from, and click its name to view its details page.
2. Click **Tags**.
   The list of tags applied to the resource is displayed.
3. Find the tag you want to remove and click the pencil icon next to it.

4. Click **Remove Tag**.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

To apply a tag to a resource using the API, use the appropriate resource's `create` or `update` operation.

Resource Monitoring

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources when needed using queries or on a passive basis using alarms. Queries and alarms rely on metrics emitted by your resource to the Monitoring service.

Prerequisites

- IAM policies: To monitor resources, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.
- Metrics exist in Monitoring: The resources that you want to monitor must emit metrics to the Monitoring service.

- Compute instances: To emit metrics, Compute instances must be monitoring-enabled. OracleCloudAgent software installation may also be required. For more information, see Enabling Monitoring for Compute Instances.

Working with Resource Monitoring

Not all resources support monitoring. See Supported Services for the list of resources that support the Monitoring service, which is required for queries and alarms used in monitoring.

The Monitoring service works with the Notifications service to notify you when metrics breach. For more information about these services, see Monitoring Overview and Notifications Overview.

To view default metric charts for a resource

On the page for the resource of interest, under **Resources**, click **Metrics**.

For example, to view metric data for a Compute instance:

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
2. Click the instance you're interested in.
3. On the instance detail page, under **Resources**, click **Metrics**.
   A chart is shown for each metric. For a list of metrics related to Compute instances, see Compute Instance Metrics.

The Console displays the last hour of metric data for the selected resource. A chart is shown for each metric emitted by the selected resource.

For a list of metrics emitted by your resource, see Supported Services.

To view default metric charts for a set of resources

Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Service Metrics**.

The **Service Metrics** page displays the default charts for all resources in the first accessible **Compartment** and **Metric Namespace**. Very small or large values are indicated by International System of Units (SI units), such as M for mega (10 to the sixth power).

Don't see all expected resources or metrics?

- Try a different time range.
- Make sure the correct **Compartment** is selected.
  On the **Service Metrics** page, metric namespaces are shown only when associated resources exist in the selected compartment. For example, the `oci_autonomous_database` namespace is shown only when Autonomous Databases exist in the selected compartment.
- Confirm that the missing resources are emitting metrics. See Enabling Monitoring for Compute Instances.
- Review limits information. Limits information for returned data includes the 100,000 data point maximum and time range maximums (determined by resolution, which relates to interval). See MetricData Reference.

To create a query

1. Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Metrics Explorer**.
   The **Metrics Explorer** page displays an empty chart with fields to build a query.
2. Fill in the fields for a new query.
   - **Compartment**: The compartment containing the resources that you want to monitor. By default, the first accessible compartment is selected.
   - **Metric Namespace**: The service or application emitting metrics for the resources that you want to monitor.

- **Resource Group** (optional): The group that the metric belongs to. A resource group is a custom string provided with a custom metric. Not applicable to service metrics.
- **Metric Name**: The name of the metric. Only one metric can be specified. Metric selections depend on the selected compartment and metric namespace.
  Example: **CpuUtilization**
- **Interval**: The aggregation window.

  Interval values
  - **1m** - 1 minute
  - **5m** - 5 minutes
  - **1h** - 1 hour

Note

For metric queries, the interval you select drives the default resolution of the request, which determines the maximum time range of data returned.

Maximum time range returned for a query

The maximum time range returned for a metric query depends on the resolution. By default, for metric queries, the resolution is the same as the query interval. The maximum time range is calculated using the current time, regardless of any specified end time. Following are the maximum time ranges returned for each interval selection available in the Console.

Interval	Default resolution (metric queries)	Maximum time range returned
1h	1 hour	90 days
5m	5 minutes	30 days
1m	1 minute	7 days

See examples of returned data

Example 1: One-minute interval and resolution up to the current time, sent at 10:00 on January 8th. No resolution or end time is specified, so the resolution defaults to the interval value of `1m`, and the end time defaults to the current time (`2019-01-08T10:00:00.789Z`). This request returns a maximum of 7 days of metric data points. The earliest data point possible within this seven-day period would be 10:00 on January 1st (`2019-01-01T10:00:00.789Z`).

Example 2: Five-minute interval with one-minute resolution up to two days ago, sent at 10:00 on January 8th. Because the resolution drives the maximum time range, a maximum of 7 days of metric data points is returned. While the end time specified was 10:00 on January 6th (`2019-01-06T10:00:00.789Z`), the earliest data point possible within this seven-day period would be 10:00 on January 1st (`2019-01-01T10:00:00.789Z`). Therefore, only 5 days of metric data points can be returned in this example.

For more information about the resolution parameter as used in metric queries, see SummarizeMetricsData.

- **Statistic**: The aggregation function.

Statistic values

- **COUNT**- The number of observations received in the specified time period.
- **MAX** - The highest value observed during the specified time period.
- **MEAN** - The value of Sum divided by Count during the specified time period.
- **MIN** - The lowest value observed during the specified time period.
- **P50** - The value of the 50th percentile.
- **P90** - The value of the 90th percentile.
- **P95** - The value of the 95th percentile.
- **P99** - The value of the 99th percentile.
- **P99.5** - The value of the 99.5th percentile.
- **RATE** - The per-interval average rate of change.
- **SUM** - All values added together.

- **Metric dimensions**: Optional filters to narrow the metric data evaluated.

  Dimension fields

  - **Dimension Name**: A qualifier specified in the metric definition. For example, the dimension `resourceId` is specified in the metric definition for `CpuUtilization`.

    Note

    Long lists of dimensions are trimmed.

    - To view dimensions by name, type one or more characters in the box. A refreshed (trimmed) list shows matching dimension names.
    - To retrieve all dimensions for a given metric, use the following API operation: ListMetrics

  - **Dimension Value**: The value you want to use for the specified dimension. For example, the resource identifier for your instance of interest.
  - **+ Additional dimension**: Adds another name-value pair for a dimension.

- **Aggregate Metric Streams**: Aggregates all results to plot a single aggregated average for all metric streams. This average is plotted as a single line on the metric chart. This operation is helpful when you want to plot a metric as one line for all resources.

3. Click **Update Chart**.
   The chart shows the results of your new query. Very small or large values are indicated by International System of Units (SI units), such as M for mega (10 to the sixth power). Units correspond to the selected metric and do not change by statistic.

   ### Troubleshooting Errors and Query Limits

   If you see an error that the query has exceeded the maximum number of metric streams, then update the query to evaluate a number of metric streams that is within the limit. For example, you can reduce the metric streams by specifying dimensions. You can continue to evaluate all metric streams that were in the original query by spreading the metric streams across multiple queries (or alarms).
   Limits information for returned data includes the 100,000 data point maximum and time range maximums (determined by resolution, which relates to interval). See MetricData Reference.

4. To customize the y-axis label or range, type the label you want into **Y-Axis Label** or type the minimum and maximum values you want into **Y-Axis Min Value** and **Y-Axis Max Value**.
   Only numeric characters are allowed for custom ranges. Custom labels and ranges are not persisted in shared queries (MQL).
5. To view the query as a Monitoring Query Language (MQL) expression, click **Advanced Mode**.
   Advanced Mode is located on the right, under the chart.
   Use Advanced Mode to edit your query using MQL syntax to aggregate results by group. The MQL syntax also supports additional parameter values. For more information about query parameters in Basic Mode and Advanced Mode, see Monitoring Query Language (MQL) Reference.
6. To create another query, click **Add Query** below the chart.

To create an alarm

1. Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Alarm Definitions**.
2. Click **Create alarm**.

Note

You can also create an alarm from a predefined query on the **Service Metrics** page. Expand **Options** and click **Create an Alarm on this Query**. For more information about service metrics, see Viewing Default Metric Charts.

3. On the **Create Alarm** page, under **Define alarm**, fill in or update the alarm settings:

Note

To toggle between Basic Mode and Advanced Mode, click **Switch to Advanced Mode** or **Switch to Basic Mode** (to the right of **Define Alarm**).

Basic Mode (default)

By default, this page uses **Basic Mode**, which separates the metric from its dimensions and its trigger rule.

- **Alarm Name**: User-friendly name for the new alarm. This name is sent as the title for notifications related to this alarm.

Rendering of the title by protocol

Protocol	Rendering of the title
Email	Subject line of the email message.
HTTPS (Custom URL)	Not rendered.
PagerDuty	Title field of the published message.
Slack	Not rendered.

- **Alarm Severity**: The perceived type of response required when the alarm is in the firing state.
- **Alarm Body**: The human-readable content of the notification delivered. Oracle recommends providing guidance to operators for resolving the alarm condition. Consider adding links to standard runbook practices. Example: "High CPU usage alert. Follow runbook instructions for resolution."
- **Tags (optional):** Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.
- **Metric description**: The metric to evaluate for the alarm condition.
    - **Compartment**: The compartment containing the resources that emit the metrics evaluated by the alarm. The selected compartment is also the storage location of the alarm. By default, the first accessible compartment is selected.
    - **Metric Namespace**: The service or application emitting metrics for the resources that you want to monitor.

- **Resource Group** (optional): The group that the metric belongs to. A resource group is a custom string provided with a custom metric. Not applicable to service metrics.
- **Metric Name**: The name of the metric. Only one metric can be specified. Example: **CpuUtilization**
- **Interval**: The aggregation window, or the frequency at which data points are aggregated.

  ### Interval values

  - **1m** - 1 minute
  - **5m** - 5 minutes
  - **1h** - 1 hour

  Note

  For alarm queries, the specified interval has no effect on the resolution of the request. The only valid value of the resolution for an alarm query request is `1m`. For more information about the resolution parameter as used in alarm queries, see Alarm.

- **Statistic**: The aggregation function.

  ### Statistic values

  - **COUNT**- The number of observations received in the specified time

period.

- **MAX** - The highest value observed during the specified time period.
- **MEAN** - The value of Sum divided by Count during the specified time period.
- **MIN** - The lowest value observed during the specified time period.
- **P50** - The value of the 50th percentile.
- **P90** - The value of the 90th percentile.
- **P95** - The value of the 95th percentile.
- **P99** - The value of the 99th percentile.
- **P99.5** - The value of the 99.5th percentile.
- **RATE** - The per-interval average rate of change.
- **SUM** - All values added together.

- **Metric dimensions**: Optional filters to narrow the metric data evaluated.

  Dimension fields

  - **Dimension Name**: A qualifier specified in the metric definition. For example, the dimension `resourceId` is specified in the metric definition for `CpuUtilization`.

    Note

    Long lists of dimensions are trimmed.

    - To view dimensions by name, type one or more characters in the box. A refreshed (trimmed) list shows matching dimension names.
    - To retrieve all dimensions for a given metric, use the following API operation: ListMetrics

  - **Dimension Value**: The value you want to use for the specified dimension. For example, the resource identifier for your instance of interest.
  - **+ Additional dimension**: Adds another name-value pair for a dimension.

- **Trigger rule**: The condition that must be satisfied for the alarm to be in the firing state. The condition can specify a threshold, such as 90% for CPU Utilization, or an absence.

- **Operator**: The operator used in the condition threshold.

  Operator values

  - **greater than**
  - **greater than or equal to**
  - **equal to**
  - **less than**
  - **less than or equal to**
  - **between** (inclusive of specified values)
  - **outside** (inclusive of specified values)
  - **absent**

- **Value**: The value to use for the condition threshold.
- **Trigger Delay Minutes**: The number of minutes that the condition must be maintained before the alarm is in firing state.

Advanced Mode

Click **Advanced Mode** or **Switch to Advanced Mode** to view the alarm query as a Monitoring Query Language (MQL) expression. Edit your query using MQL syntax to aggregate results by group or for additional parameter values. See Monitoring Query Language (MQL) Reference.

- **Alarm Name**: User-friendly name for the new alarm. This name is sent as the title for notifications related to this alarm.

Rendering of the title by protocol

Protocol	Rendering of the title
Email	Subject line of the email message.
HTTPS (Custom URL)	Not rendered.
PagerDuty	Title field of the published message.
Slack	Not rendered.

- **Alarm Severity**: The perceived type of response required when the alarm is in the firing state.
- **Alarm Body**: The human-readable content of the notification delivered. Oracle recommends providing guidance to operators for resolving the alarm condition. Consider adding links to standard runbook practices. Example: "High CPU usage alert. Follow runbook instructions for resolution."
- **Tags (optional):** Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.
- **Metric description, dimensions, and trigger rule**: The metric to evaluate for the alarm condition, including dimensions and the trigger rule.
    - **Compartment**: The compartment containing the resources that emit the metrics evaluated by the alarm. The selected compartment is also the storage location of the alarm. By default, the first accessible compartment is selected.

- **Metric Namespace**: The service or application emitting metrics for the resources that you want to monitor.
- **Resource Group** (optional): The group that the metric belongs to. A resource group is a custom string provided with a custom metric. Not applicable to service metrics.
- **Query Code Editor** box: The alarm query as a Monitoring Query Language (MQL) expression.

  Example alarm query:

  ```
  CpuUtilization[1m]{availabilityDomain=AD1}.groupBy(poolId).percentile(0.9) > 85
  ```

  For query syntax and examples, see Working with Metric Queries.
- **Trigger Delay Minutes**: The number of minutes that the condition must be maintained before the alarm is in firing state.

The chart below the **Define alarm** section dynamically displays the last six hours of emitted metrics according to currently selected fields for the query. Very small or large values are indicated by International System of Units (SI units), such as M for mega (10 to the sixth power).

4. Set up notifications: Under **Notifications**, fill in the fields.

   - **Destinations**:
     - **Destination Service**: The provider of the destination to use for notifications.

       Available options:

       - **Notifications Service**.
     - **Compartment**: The compartment storing the topic to be used for notifications. Can be a different compartment from the alarm and metric. By default, the first accessible compartment is selected.
     - **Topic**: The topic to use for notifications. Each topic supports a subscription protocol, such as PagerDuty.

- **Create a topic**: Sets up a topic and subscription protocol in the selected compartment, using the specified destination service.
  - **Topic Name**: User-friendly name for the new topic. Example: "Operations Team " for a topic used to notify operations staff of firing alarms.
  - **Topic Description**: Description of the new topic.
  - **Subscription Protocol**: Medium of communication to use for the new topic. Configure your subscription for the protocol you want:

    ### Email subscription

    Sends an email message when you publish a message to the subscription's parent topic.

    - **Subscription Protocol**: Select **Email**.
    - **Subscription Email**: Type an email address.

    ### HTTPS (Custom URL) subscription

    Sends specified information when you publish a message to the subscription's parent topic.
    Endpoint format (URL using HTTPS protocol):

    ```
    https://<anyvalidURL>
    ```

    Basic access authentication is supported, allowing you to specify a username and password in the URL, as in `https://user:password@domain.com` or `https://user@domain.com`. The username and password are encrypted over the SSL connection established when using HTTPS. For more information about Basic Access Authentication, see RFC-2617.

Query parameters are not allowed in URLs.

- **Subscription Protocol**: Select **HTTPS (Custom URL)**.
- **Subscription URL**: Type (or copy and paste) the URL you want to use as the endpoint.

PagerDuty subscription

Creates a PagerDuty incident by default when you publish a message to the subscription's parent topic.

Endpoint format (URL):

```
https://events.pagerduty.com/integration/<integrationkey>/enqueue
```

Query parameters are not allowed in URLs.

To create an endpoint for a PagerDuty subscription (set up and retrieve an integration key), see the PagerDuty documentation.

- **Subscription Protocol**: Select **PagerDuty**.
- **Subscription URL**: Type (or copy and paste) the *integration key* portion of the URL for your PagerDuty subscription. (The other portions of the URL are hard-coded.)

Slack subscription

Note

See the following known issue for up-to-date information about creating

Slack subscriptions.

Sends a message to the specified Slack channel by default when you publish a message to the subscription's parent topic.

Endpoint format (URL):

```
https://hooks.slack.com/services/<webhook-token>
```

The *<webhook-token>* portion of the URL contains two slashes (/).

Query parameters are not allowed in URLs.

To create an endpoint for a Slack subscription (using a webhook for your Slack channel), see the Slack documentation.

- **Subscription Protocol**: Select **Slack**.
- **Subscription URL**: Type (or copy and paste) the Slack endpoint, including your webhook token.

- **+ Additional destination service**: Adds another destination service and topic to use for notifications.

Note

Each alarm is limited to one destination per supported destination service.

- **Repeat Notification?**: While the alarm is in the firing state, resends notifications at the specified interval.
- **Notification Interval**: The period of time to wait before resending the notification.

- **Suppress Notifications**: Sets up a suppression time window during which to suspend evaluations and notifications. Useful for avoiding alarm notifications during system maintenance periods.
    - **Suppression Description**
    - **Start Time**
    - **End Time**

5. If you want to disable the new alarm, clear **Enable This Alarm?**.
6. Click **Save alarm**.
   The new alarm is listed on the **Alarm Definitions** page.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

To create a query, use the SummarizeMetricsData operation.

To create an alarm, use the CreateAlarm operation.

Service Limits

This topic describes the service limits for Oracle Cloud Infrastructure and the process for requesting a service limit increase.

About Service Limits and Usage

When you sign up for Oracle Cloud Infrastructure, a set of service limits are configured for your tenancy. The service limit is the quota or allowance set on a resource. For example, your tenancy is allowed a maximum number of compute instances per availability domain. These limits are generally established with your Oracle sales representative when you purchase Oracle Cloud Infrastructure. If you did not establish limits with your Oracle sales

representative, or, if you signed up through the Oracle Store, default or trial limits are set for your tenancy. These limits may be increased for you automatically based on your Oracle Cloud Infrastructure resource usage and account standing. You can also request a service limit increase.

Compartment Quotas

Compartment quotas are similar to Service Limits; the biggest difference is that service limits are set by Oracle, and compartment quotas are set by administrators, using policies that allow them to allocate resources with a high level of flexibility. Compartment quotas are set using *policy statements* written in a simple declarative language that is similar to the IAM policy language.

To learn more, see Compartment Quotas.

Viewing Your Service Limits, Quotas, and Usage

You can view your tenancy's limits, quotas, and usage in the Console. Be aware that:

- The Console may not yet display limits and usage information for all of the Oracle Cloud Infrastructure services or resources.
- The usage level listed for a given resource type could be greater than the limit if the limit was reduced after the resources were created.
- If all the resource limits are listed as 0, this means your account has been suspended. For help, contact Oracle Support.

If you don't yet have a tenancy or a user login for the Console, or if you don't find a particular limit listed in the Console, see Limits by Service for the default tenancy limits.

To view your tenancy's limits and usage (by region)

Note

Required Permission

If you're in the Administrators group, you have permission to view the limits and usage. If you're not, here's an example IAM policy that grants the required permission to users in a group called LimitsAndUsageViewers:

```
Allow group LimitsAndUsageViewers to inspect resource-
availability in tenancy
```

1. Open the Console. Open the navigation menu, under Governance and Administration, go to **Governance**, and then click **Limits, Quotas and Usage**.

Your resource limits, quotas, and usage for the specific region are displayed, broken out by service. You can use the filter drop-down lists at the top of the list to filter by service, scope, resource, and compartment.

When You Reach a Service Limit

When you reach the service limit for a resource, you receive an error when you try to create a new resource of that type. You are then prompted to submit a request to increase your limit. You cannot create a new resource until you are granted an increase to your service limit or you terminate an existing resource. Note that service limits apply to a specific scope, and when the service limit in one scope is reached you may still have resources available to you in other scopes (for example, other availability domains).

Requesting a Service Limit Increase

You can submit a request to increase your service limits from within the Console. If you try to create a resource for which limit has been met, you'll be prompted to submit a limit increase request. Additionally, you can launch the request from the service limits page or at any time by clicking the link under the **Help** menu (?).

Note that the service limit increase is not immediate.

To request a service limit increase

1. Open the **Help** menu (?), go to **Support** and click **Request service limit increase**.
2. Enter the following:
    - **Primary Contact Details:** Enter the name and email address of the person making the request. Enter one email address only. A confirmation will be sent to this address.
    - **Service Category:** Select the appropriate category for your request.
    - **Resource:** Select the appropriate resource.
      Depending on your selection for resource, additional fields might display for more specific information.
    - **Reason for Request:** Enter a reason for your request. If your request is urgent or unusual, please provide details here.
3. Click **Submit Request**.

After you submit the request, the request is reviewed. If your request is awarded, a confirmation email is sent to the address provided in the primary contact details.

If we need additional information about your request, a follow-up email is sent to the address provided in the primary contact details.

Limits by Service

The following tables list the default limits for each service. Note the scope that each limit applies to (for example, per availability domain, per region, per tenant, etc.).

Note

Some services have additional limits. For more information, see the overview of each service.

Analytics Cloud Limits

For Analytics Cloud limits, see Service Limits.

Block Volume Limits

Volume limits apply to each availability domain. Volume backup limits apply to each region.

Resource	Monthly Universal Credits	Pay-as-You-Go or Promo
Block Volumes aggregated size	100 TB	30 TB
Backups	1000	500

Compute Limits

Limits apply to each availability domain, unless otherwise noted.

Bare Metal Servers

Resource	Monthly Universal Credits	Pay-as-You-Go or Promo
BM.Standard.B1.44	Contact Us	Contact Us
BM.Standard2.52	5 (52 cores) (US East (Ashburn), Germany Central (Frankfurt), UK South (London), US West (Phoenix)) 2 (52 cores) (other regions)	Contact Us

Container Engine for Kubernetes Limits

Container Engine for Kubernetes limits are **regional**.

Resource	Monthly Universal Credits	Pay-as-You-Go or Promo
Clusters	3 clusters per OCI region	1 cluster per OCI region
Nodes	1000 nodes per cluster	1000 nodes per cluster

Data Safe Limits

To register an Oracle Database with Data Safe, you must be using a paid account.

Data Transfer Limits

Data Transfer limits are **regional**.

Disk-Based Data Transfer

Resource	Monthly Universal Credits	Pay-As-You-Go
Transfer package	Contact Us	Contact Us

File a service request at My Oracle Support to increase the service limits for Disk-Based Data Transfer. See Requesting a Service Limit Increase for details.

Appliance-Based Data Transfer

Resource	Monthly Universal Credits	Pay-As-You-Go
Transfer appliances	Contact Your CSM	Contact Your CSM

Contact your Oracle Account Manager or Customer Success Manager (CSM) to place an order for transfer appliances. Your service limits are automatically set to the number of transfer appliances ordered. You do not need to file a service request to increase the service limits for Appliance-Based Data Transfer.

Database Limits

Database limits are per availability domain.

See Data Safe limits for information on Data Safe.

Resources	Monthly Flex	Pay-as-You-Go or Promo
Autonomous Database Serverless Deployment - Total OCPUs	128 cores	8 cores
Always Free Autonomous Database	2 instances	2 instances
Always Free Autonomous Database - Total OCPUs	1 core	1 core
Always Free Autonomous Database - Total Block Storage	20 GB	20 GB
VM.Standard1 -Total OCPUs	10 cores	2 cores
VM.Standard2 -Total OCPUs	100 cores (US West (Phoenix), US East (Ashburn)) 50 cores (Germany Central (Frankfurt), uk-london-1)	2 cores
Total VM DB Block Storage (see note)	10TB	2TB
BM.DenseIO1.36 (see availability note)	1 instance	1 instance
BM.DenseIO2.52	1 instance	1 instance
BM.HighIO1.36	1 instance	1 instance
Exadata.Base.48	Contact Us	not available
Exadata.Quarter1.84 - X6	Contact Us	not available

Resources	Monthly Flex	Pay-as-You-Go or Promo
Exadata.Half1.168 - X6	Contact Us	not available
Exadata.Full1.336 - X6	Contact Us	not available
Exadata.Quarter2.92 - X7	Contact Us	not available
Exadata.Half2.184 - X7	Contact Us	not available
Exadata.Full2.368 - X7	Contact Us	not available
BM.RACLocalStorage1.72	Contact Us	Contact Us

Note

- **Autonomous Exadata Infrastructure** - Exadata X7 limits (Exadata.Quarter2.92, Exadata.Half2.184, and Exadata.Full2.368) cover the corresponding Autonomous Exadata Infrastructure shapes.
- **Total VM DB Block Storage** - covers block storage for all VM.Standard1 and VM.Standard2 virtual machine databases.
- **BM.DenseIO1.36** - This DB system shape is available only to monthly universal credit customers with tenancies existing on or before November 9th, 2018, in the US West (Phoenix), US East (Ashburn), and Germany Central (Frankfurt) regions.
- Each of the two Always FreeAutonomous Database available in your tenancy can be provisioned with your choice of Autonomous Transaction Processing or Autonomous Data Warehouse workload types.

DNS Limits

DNS limits are **global**.

Resources	Monthly Universal Credits	Pay-as-You-Go or Promo
Zones	1,000 zones	1,000 zones
Records	25,000 per zone	25,000 per zone
Zone File Size	1 MB	1 MB

Email Delivery Limits

Limits apply to each tenant or availability domain, as specified.

Resource	Monthly Universal Credits	Pay-As-You-Go or Promo
Email volume	50,000 emails per day	200 emails per day
Maximum approved senders	10,000	2,000
SMTP credentials	2 per user	2 per user
Sending rate	18,000 emails per minute	10 emails per minute

Note

Message size is limited to 2 MB, inclusive of message headers, body, and attachments.

Events Limits

Events limits are **regional**.

Resource	Monthly Universal Credits	Pay-as-You-Go or Promo
Rules	50	50

File Storage Limits

Limits apply to each tenant or availability domain, as specified.

Resource	Pre-Paid	Pay-As-You-Go
File systems	100 per tenant per availability domain	100 per tenant per availability domain
Mount targets	2 per tenant per availability domain	2 per tenant per availability domain
Maximum file system size	8 exabytes	8 exabytes

Functions Limits

Limits apply to each tenancy.

Resource	Monthly Universal Credits	Pay-as-You-Go or Promo
Applications	10	10
Functions	20	20

Health Checks Limits

Health Checks limits are **global**.

Resource	Monthly Universal Credits	Pay-as-You-Go or Promo
Endpoint tests	1000 per account	1000 per account

IAM Limits

IAM limits are **global**.

Resource	Monthly Universal Credits	Pay-as-You-Go or Promo
Users in a tenancy	2000	2000
Groups in a tenancy	250	250
Compartments in a tenancy	50	50
Policies in a tenancy	100	100
Statements in a policy	50	50
Users per group in a tenancy	2000	2000
Groups per user in a tenancy	250	250
Identity providers in a tenancy	3	3
Group mappings for an identity provider	250	250

Key Management Limits

Key Management limits are **global**.

Access rules	100 per policy	100 per policy

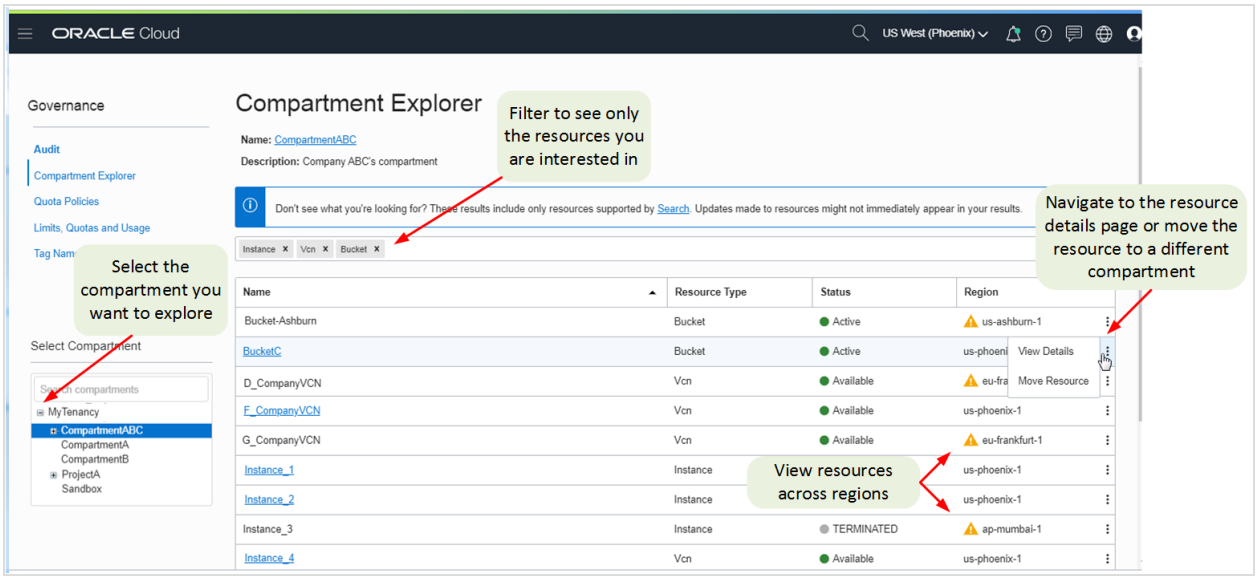
Viewing All Resources in a Compartment

This topic describes how you can use the compartment explorer to get a cross-region view of all resources in a compartment.

Compartment Explorer Overview

The compartment explorer allows you to view all your resources in a specific compartment, across all regions. You can also easily navigate up and down the compartment hierarchy to get the complete view of the resources in a specific compartment tree. From the compartment explorer you can navigate directly to resources, providing an alternative interface to access the resources in each compartment. The compartment explorer also allows you to move a resource to a different compartment.

The following image highlights these features:



When using the compartment explorer, be aware of the following:

- If you recently created a resource, it might not show up in the compartment explorer immediately. Similarly, if you recently updated a resource, your changes might not immediately appear.
- To navigate to the details page of a resource or to move it to another compartment, you must be in the same region as the resource. The compartment explorer displays the resource's region. Use the region selector at the top of the Console to change to the same region as the resource to enable these actions.

Resources Supported by the Compartment Explorer

The compartment explorer is powered by the Search service and supports the same resource types. Most resources are supported.

Supported resources

Service	Resource Type
Block Volume	bootvolume
Block Volume	bootvolumebackup
Block Volume	volume
Block Volume	volumebackup
Compute	autoscalingconfiguration
Compute	consolehistory
Compute	image
Compute	instance
Database	autonomousdatabase
Database	database
Database	dbsystem
Events	eventrule
Functions	functionsapplication
Functions	functionsfunction
IAM	compartment
IAM	group
IAM	identityprovider

Service	Resource Type
IAM	`user`
Key Management	`key`
Key Management	`vault`
Monitoring	`alarm`
Networking	`routetable`
Networking	`securitylist`
Networking	`subnet`
Networking	`vcn`
Notifications	`onssubscription`
Notifications	`onstopic`
Object Storage	`bucket`
Resource Manager	`ormjob`
Resource Manager	`ormstack`
WAF	`waascertificate`
WAF	`waaspolicy`

Required IAM Policy to View Resources in the Compartment Explorer

The resources that you see in the compartment explorer depend on the permissions you have in place for the resource type. You do not necessarily see results for everything in the compartment. For example, if your user account is not associated with a policy that grants you the ability to, at a minimum, `inspect` the `dbsystem` resource type, then you will not be

able to view DB systems in the compartment explorer. (The verb `inspect` lets you list and get resources.) For more information about policies, see How Policies Work. For information about the permissions required for the list API operation for a specific resource type, see the Policy Reference for the appropriate service.

Navigating to the Compartment Explorer and Viewing Resources

Open the navigation menu. Under **Governance and Administration**, go to **Governance** and click **Compartment Explorer**.

When you open the compartment explorer, the list of all resources that you have permission to view is displayed. The compartment explorer opens with a view of the root compartment. The **Name** and **Description** of the compartment you are viewing are displayed at the top of the page.

To navigate to the compartment you are interested in, use the compartment picker on the left of the Console page.

Filtering Displayed Resources

To view only specific resource types, select the resource types you are interested in from the **Filter by resource type** menu. You can select multiple resources to include in the filtered list.

Opening the Resource Details Page

To open the details page for a resource:

1. Locate the resource in the list.
2. Verify that you are in the same region as the resource. The resource's region is listed in the compartment explorer results. If it is not the same as the region you are currently in (shown at the top of the Console), then select the appropriate region from the **Regions** menu.
3. To open the details page, you can either:

- Click the name.
- Click the the Actions icon (three dots) and select **View Details**.

Detail page navigation is not supported for all resource types. If detail page navigation is not supported, the resource name does not display as a link and the option is not available from the Action menu.

Moving a Resource to a Different Compartment

To move a resource to a different compartment:

1. Locate the resource in the list.
2. Verify that you are in the same region as the resource. The resource's region is listed in the compartment explorer results. If it is not the same as the region you are currently in (shown at the top of the Console), then select the appropriate region from the **Regions** menu.
3. Click the the Actions icon (three dots) and select **Move Resource**.
4. In the dialog, choose the destination compartment from the list.
5. Click **Move Resource**.

Important

Ensure that you understand the impact for a resource before you move it. See the resource's service documentation for details.

Not all resources can be moved to a different compartment. If the resource cannot be moved, the option is not available from the Action menu.

Compartment Quotas

This topic describes compartment quotas for Oracle Cloud Infrastructure.

Compartment quotas give tenant and compartment administrators better control over how resources are consumed in Oracle Cloud Infrastructure, enabling administrators to easily allocate resources to compartments using the Console. Along with compartment budgets, compartment quotas create a powerful toolset to manage your spending in Oracle Cloud Infrastructure tenancies.

You can start using compartment quotas from any compartment detail page in the Console.

About Compartment Quotas

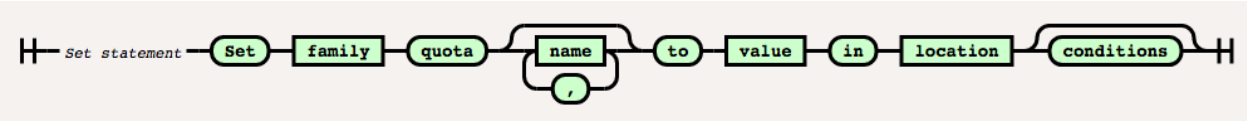
Compartment quotas are similar to Service Limits; the biggest difference is that service limits are set by Oracle, and compartment quotas are set by administrators, using policies that allow them to allocate resources with a high level of flexibility.

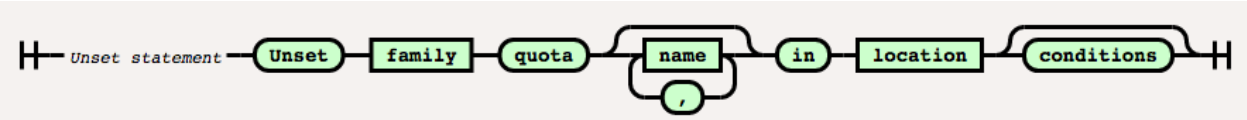
Compartment quotas are set using *policy statements* written in a simple declarative language that is similar to the IAM policy language.

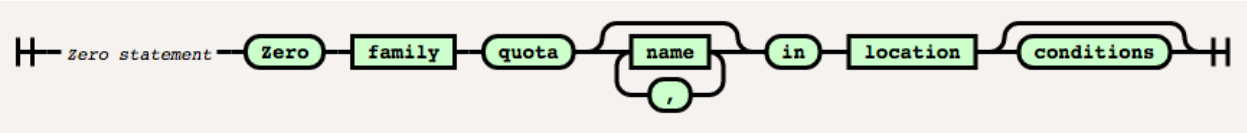
There are three types of quota policy statements:

- `set` - sets the maximum number of a cloud resource that can be used for a compartment
- `unset` - resets quotas back to the default service limits
- `zero` - removes access to a cloud resource for a compartment

The quota policy statements look like this:







The language components for a quota policy statement are:

- The `action` keyword, which corresponds to the type of quota being defined. This can be `set`, `unset`, or `zero`.
- The name of the service family; for example: `compute`.
- The `quota` or `quotas` keyword
- The name of the quota, which varies by service family. For example, a valid quota in the `compute` family is `vm-standard2-16-count`.
    - You can also use wildcards to specify a range of names. For example, `"/vm-*/"` matches all Compute shapes that start with the letters "vm".
- For set statements, the value of the quota.
- The compartment that the quota covers.
- An optional condition. For example `where request.region = 'us-phoenix-1'`. Currently supported conditionals are `request.region` and `request.ad`.

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies. For specific details about writing policies for each of the different services, see Policy Reference.

If you're a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

For common policies used to authorize users, see Common Policies.

To manage quotas in a compartment, you must belong to a group that has the correct permissions. For example:

```
allow group QuotaAdmins to { QUOTA_READ, QUOTA_CREATE, QUOTA_DELETE, QUOTA_UPDATE, QUOTA_INSPECT } in tenancy
```

For in-depth information on granting users permissions for the Quotas service, see Details for the Quotas Service in the IAM policy reference.

Permissions and Nesting

Compartment quotas can be set on the root compartment. An administrator (who must be able to manage quotas on the root compartment) can set quotas on their own compartments and any child compartments. Quotas set on a parent compartment override quotas set on child compartments. This way, an administrator of a parent compartment can create a quota on a child compartment that cannot be overridden by the child.

Scope

Quotas can have different *scopes*, and work at the availability domain, the region, or globally.

There are a few important things to understand about scope when working with compartment quotas:

- When setting a quota at the availability domain (AD) level, the quota is allocated to each AD. So, for example, setting a quota of 2 X7 VMs on a compartment actually sets a limit of 2 VMs per AD. To target a specific AD, use the `request.ad` parameter in the `where` clause.
- Regional quotas apply to each region. For example, if a quota of 10 functions is set on a

compartment, 10 functions will be allocated per region. To target a specific region, use the `request.region` parameter in the `where` clause.

- Usage for sub-compartments counts towards usage for the main compartment.

For more information, see Regions and Availability Domains.

Quota Evaluation and Precedence

The following rules apply when quota statements are evaluated:

- Within a policy, quota statements are evaluated in order, and later statements supersede previous statements that target the same resource.
- In cases where more than one policy is set for the same resource, the most restrictive policy is applied.
- Service limits always take precedence over quotas. Although it is possible to specify a quota for a resource that exceeds the service limit for that resource, the service limit will still be enforced.

Usage Examples

The following example sets the quota for `VM.DenseIO1.16` Compute shapes to 10 in each AD on compartment `MyCompartment` in the US West (Phoenix) region:

```
set compute quota vm-dense-io1-16-count to 10 in compartment MyCompartment
where request.region = us-phoenix-1
```

The next example shows how to make a whitelist, setting every quota in a family to zero and then explicitly allocating resources:

```
zero compute quotas in tenancy
 set compute quota vm-dense-io1-16-count to 10 in tenancy
```

This example shows how to limit creating a bare metal compute resource to only one region:

```
zero compute quotas /*bm*/ in tenancy
set compute quota /*bm*/ to 5 in tenancy where request.region = us-phoenix-1
```

This example policy statement only allows one VM.Standard2.1 Compute instance in a single compartment in a single region:

```
zero compute quotas in tenancy
set compute quota vm-standard2-1-count to 10 in compartment sales_department
where request.region = us-phoenix-1
```

You can clear quotas by using an `unset` statement, which removes the quota for a resource - any limits on this resource will now be enforced by the service limits:

```
zero compute quotas in tenancy
unset compute quota vm-dense-io1-16-count in tenancy
```

Using the Console

To create a quota

1. Open the navigation menu. Under **Governance and Administration**, go to **Governance** and click **Quota Policies**. From the **Quota Policies** screen, click **Create Quota**.
2. Enter the following:
   - Enter a name for your quota in the **Name** field.
   - Enter a description for your quota in the **Description** field.
   - Enter a quota policy string in the **Quota Policy** field.
3. Click **Create Quota Policy**.

Note

New policies can take up to 10 minutes to start working.

To edit a quota

1. From the **Quota Policies** screen, click the quota you want to edit to display the quota policy details page, then click the **Edit Quota** button.
2. Edit the quota.
3. Click **Save Changes**.

To delete a quota

1. There are two ways to delete a quota from the console:
    - From the main **Quota Policies** page, click the context menu to the right of the quota you want to delete, then select **Delete**.
    - Click the quota you want to delete, then from the quota policy detail page click **Delete** .
2. From the **Confirm Delete** dialog, click **Delete** or **Cancel**.

Available Quotas by Service

Analytics Cloud

For Analytics Cloud quotas and examples, see Service Quotas.

Block Volume Quotas

Family name: `block-storage`

Name	Scope	Description
backup-count	Regional	Total number of block and boot volume backups
total-storage-gb	Availability domain	Maximum storage space of block and boot volumes, in GB
volume-count	Availability domain	Total number of block and boot volumes

Example

```
set block-storage quota volume-count to 10 in compartment MyCompartment
```

Compute Quotas

Compute Shapes and Custom Images

Family name: `compute`

Name	Scope	Description
custom-image-count	Regional	Number of custom images
bm-standard1-36-count	Availability domain	Number of BM.Standard1.36 shapes
bm-dense-io1-36-count	Availability domain	Number of BM.DenseIO1.36 shapes

Name	Scope	Description
bm-standard-b1-44-count	Availability domain	Number of BM.Standard.B1.44 shapes
bm-standard2-52-count	Availability domain	Number of BM.Standard2.52 shapes
bm-dense-io2-52-count	Availability domain	Number of BM.DenseIO2.52 shapes
bm-gpu2-2-count	Availability domain	Number of BM.GPU2.2 shapes
bm-gpu3-8-count	Availability domain	Number of BM.GPU3.8 shapes
bm-standard-e2-64-count	Availability domain	Number of BM.Standard.E2.64 shapes
bm-hpc2-36-count	Availability domain	Number of BM.HPC2.36 shapes
vm-standard1-1-count	Availability domain	Number of VM.Standard1.1 shapes
vm-standard1-2-count	Availability domain	Number of VM.Standard1.2 shapes
vm-standard1-4-count	Availability domain	Number of VM.Standard1.4 shapes
vm-standard1-8-count	Availability domain	Number of VM.Standard1.8 shapes

Name	Scope	Description
vm-standard1-16-count	Availability domain	Number of VM.Standard1.16 shapes
vm-dense-io1-4-count	Availability domain	Number of VM.DenseIO1.4 shapes
vm-dense-io1-8-count	Availability domain	Number of VM.DenseIO1.8 shapes
vm-dense-io1-16-count	Availability domain	Number of VM.DenseIO1.16 shapes
vm-standard2-1-count	Availability domain	Number of VM.Standard2.1 shapes
vm-standard2-2-count	Availability domain	Number of VM.Standard2.2 shapes
vm-standard2-4-count	Availability domain	Number of VM.Standard2.4 shapes
vm-standard2-8-count	Availability domain	Number of VM.Standard2.8 shapes
vm-standard2-16-count	Availability domain	Number of VM.Standard2.16 shapes
vm-standard2-24-count	Availability domain	Number of VM.Standard2.24 shapes
vm-standard-e2-1-count	Availability domain	Number of VM.Standard.E2.1 shapes

Name	Scope	Description
vm-standard-e2-2-count	Availability domain	Number of VM.Standard.E2.2 shapes
vm-standard-e2-4-count	Availability domain	Number of VM.Standard.E2.4 shapes
vm-standard-e2-8-count	Availability domain	Number of VM.Standard.E2.8 shapes
vm-dense-io2-8-count	Availability domain	Number of VM.DenseIO2.8 shapes
vm-dense-io2-16-count	Availability domain	Number of VM.DenseIO2.16 shapes
vm-dense-io2-24-count	Availability domain	Number of VM.DenseIO2.24 shapes
vm-gpu2-1-count	Availability domain	Number of VM.GPU2.1 shapes
vm-gpu3-1-count	Availability domain	Number of VM.GPU3.1 shapes
vm-gpu3-2-count	Availability domain	Number of VM.GPU3.2 shapes
vm-gpu3-4-count	Availability domain	Number of VM.GPU3.4 shapes

Example

```
set compute quota vm-dense-io1-4-count to 10 in compartment MyCompartment where request.ad = 'us-phoenix-1-ad-2'
```

Instance Configurations and Instance Pools

Family name: `compute-management`

Name	Scope	Description
config-count	Regional	Number of instance configurations
pool-count	Regional	Number of instance pools

Example

```
set compute-management quota config-count to 10 in compartment MyCompartment
```

Autoscaling

Family name: `auto-scaling`

Name	Scope	Description
config-count	Regional	Number of autoscaling configurations

Example

```
Set auto-scaling quota config-count to 10 in compartment MyCompartment
```

Data Transfer Quotas

Family name: `data-transfer`

Name	Scope	Description
active-appliance-count	Regional	Number of approved transfer appliances
appliance-count	Regional	Number of transfer appliances
job-count	Regional	Number of transfer jobs

Example

```
zero data-transfer quota job-count in tenancy
set data-transfer quota job-count to 1 in compartment Finance
set data-transfer quota appliance-count to 3 in compartment Finance
```

Database Quotas

Family name: `database`

Name	Scope	Description
adw-ocpu-count	Regional	Number of Autonomous Data Warehouse OCPUs
atp-ocpu-count	Regional	Number of Autonomous Transaction Processing OCPUs
adb-free-count	Regional	Number of Always Free Autonomous Databases. Tenancies can have a total of two Always Free Autonomous Databases, and these resources must be provisioned in the home region. For each database, you can choose the workload type (Autonomous Transaction Processing or Autonomous Data Warehouse).

Name	Scope	Description
bm-dense-io1-36-count	Availability domain	Number of BM.DenseIO1.36 DB systems
bm-dense-io2-52-count	Availability domain	Number of BM.DenseIO2.52 DB systems
exadata-base-48-count	Availability domain	Number of Exadata.Base.48 DB systems
exadata-full1-336-x6-count	Availability domain	Number of Exadata.Full1.336 - X6 DB systems
exadata-full2-368-x7-count	Availability domain	Number of Exadata.Full2.368 - X7 DB systems and Autonomous Exadata Infrastructure
exadata-half1-168-x6-count	Availability domain	Number of Exadata.Half1.168 - X6 DB systems
exadata-half2-184-x7-count	Availability domain	Number of Exadata.Half2.184 - X7 DB systems and Autonomous Exadata Infrastructure
exadata-quarter1-84-x6-count	Availability domain	Number of Exadata.Quarter1.84 - X6 DB systems
exadata-quarter2-92-x7-count	Availability domain	Number of Exadata.Quarter2.92 - X7 DB systems and Autonomous Exadata Infrastructure
vm-block-storage-gb	Availability domain	Total size of block storage attachments across all virtual machine DB systems, in GB

Name	Scope	Description
vm-standard1-ocpu-count	Availability domain	Number of VM.Standard1.x OCPUs
vm-standard2-ocpu-count	Availability domain	Number of VM.Standard2.x OCPUs

For information about shapes that are not listed, including non-metered shapes, contact Oracle Support.

Example

The following example shows how to limit the number of Autonomous Data Warehouse resources in a compartment:

```
#Limits the Autonomous Data Warehouse CPU core count to 2 in the MyCompartment compartment
set database quota adw-ocpu-count to 2 in compartment MyCompartment
```

To limit the number of virtual machine DB systems in a compartment, you must set a quota for the number of CPU cores and a separate quota for the block storage:

```
#Sets a quota for virtual machine Standard Edition OCPUs to 2 in the MyCompartment compartment
set database quota vm-standard1-ocpu-count to 2 in compartment MyCompartment

#Sets the virtual machine DB system block storage quota to 1024 GB in the same compartment
set database quota vm-block-storage-gb to 1024 in compartment MyCompartment
```

The following example shows how to prevent the usage of all database resources in the tenancy except for two Exadata full rack X7 resources in a specified compartment:

```
zero database quotas in tenancy
set database quota exadata-full2-368-x7-count to 2 in compartment MyCompartment
```

This example of *nested quotas* shows how to distribute limits for a resource type in a compartment among its subcompartments:

```
#Allows usage of 3 Autonomous Data Warehouse OCPUs in parent compartment Compartment1
set database quota adw-ocpu-count to 3 in compartment Compartment1

#Allows usage of 1 Autonomous Data Warehouse OCPU in child compartment Compartment1.1
set database quota adw-ocpu-count to 1 in compartment Compartment1.1

#Allows usage of 2 Autonomous Data Warehouse OCPUs in child compartment Compartment1.2
set database quota adw-ocpu-count to 2 in compartment Compartment1.2
```

This example shows how to set a quota for Autonomous Exadata Infrastructure quarter rack resources in a compartment:

```
#Limits the usage of Exadata.Quarter2.92 X7 shapes to 1 in the MyCompartment compartment
set database quota exadata-quarter2-92-x7-count to 1 in compartment MyCompartment
```

DNS Quotas

Family name: `dns`

Name	Scope	Description
global-zone-count	Global	Number of public DNS zones
steering-policy-count	Global	Number of traffic management steering policies
steering-policy-attachment-count	Global	Number of traffic management steering policy attachments

Example

```
zero dns quotas in compartment MyCompartment
zero dns quota global-zone-count in compartment MyCompartment
zero dns quota steering-policy-count in compartment MyCompartment
zero dns quota steering-policy-attachment-count in compartment MyCompartment
```

Email Delivery Quotas

Family name: `email-delivery`

Name	Scope	Description
approved-sender-count	Regional	Number of approved senders

Example

```
zero email-delivery quota approved-sender-count in compartment MyCompartment
```

Health Checks Quotas

Family name: `health-checks`

Name	Scope	Description
monitor-basic-count	Regional	Number of basic monitors
monitor-premium-count	Regional	Number of premium monitors

Example

```
zero health-checks quotas monitor-basic-count
```

Key Management Quotas

Family name: `kms`

Name	Scope	Description
virtual-private-vault-count	Regional	Number of virtual private vaults

Example

```
set kms quota virtual-private-vault-count to 10 in compartment MyCompartment
set kms quota virtual-vault-count to 10 in compartment MyCompartment
```

Notifications Quotas

Family name: `notifications`

Name	Scope	Description
topic-count	Regional	Number of topics

Example

```
set notifications quota topic-count to 10 in compartment MyCompartment
```

Resource Manager Quotas

Family name: `resource-manager`

Name	Scope	Description
concurrent-job-count	Regional	Number of concurrent Jobs per compartment
stack-count	Regional	Number of of stacks per compartment

Example

```
set resource-manager quota concurrent-job-count to 1 in compartment MyCompartment
zero resource-manager quota stack-count in compartment MyCompartment
```

Streaming Quotas

Family name: `streaming`

Name	Scope	Description
partition-count	Regional	Number of partitions

Example

```
set streaming quota partition-count to 10 in compartment MyCompartment
```

WAF Quotas

Family name: `waas`

Name	Scope	Description
waas-policy-count	Regional	Number of WAF policies

Example

```
zero waas quota waas-policy-count in compartment MyCompartment
```

Work Requests

This topic describes the work requests feature documented in the Work Requests API. The following Oracle Cloud Infrastructure services are integrated with this API:

- Compute
- Database

> **Note**
>
> Some Oracle Cloud Infrastructure services offer work requests supported by the service API rather than the Work Requests API discussed in this topic. For information about work requests in these services, see the following topics:
>
> - **Load Balancing:** Viewing the State of a Work Request
> - **Object Storage:** Copy Object Work Requests
> - **Identity:** Deleting Compartments and Deleting Tag Key Definitions and Namespace

Work requests allow you to monitor long-running operations such as Database backups or the provisioning of Compute instances. When you launch such an operation, the service spawns a *work request*. A work request is an activity log that enables you to track each step in the operation's progress. Each work request has an OCID that allows you to interact with it programmatically and use it for automation.

If an operation fails, a work request can help you determine which step of the process had an error.

Some operations affect multiple resources. For example, creating an instance pool also affects instances and instance configurations. A work request provides a list of the resources that an operation affects.

For workflows that require sequential operations, you can monitor each operation's work request and confirm that the operation has completed before proceeding to the next operation. For example, say that you want to create an instance pool with autoscaling enabled. To do this, you must first create the instance pool, and then configure autoscaling. You can monitor the work request for creating the instance pool to determine when that workflow is complete, and then configure autoscaling after it is done.

Work requests are retained for 12 hours.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don't have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: Work requests inherit the permissions of the operation that spawns the work request. To enable users to view the work requests, logs, and error messages for an operation, write a policy that grants users permission to do the operation. For example, to let users see the work requests associated with launching instances, write a policy that enables users to launch instances.

To enable users to list all work requests in a tenancy, use the following policy:

```
Allow group SupportTeam to inspect work-requests in tenancy
```

If you're new to policies, see Getting Started with Policies and Common Policies.

Work Request States

Note: Work requests for some services or operations may support only a subset of the following statuses.

ACCEPTED

The request is in the work request queue to be processed.

IN_PROGRESS

A work request record exists for the specified request, but there is no associated WORK_COMPLETED record.

SUCCEEDED

A work request record exists for this request and an associated WORK_COMPLETED record has the state SUCCEEDED.

FAILED

A work request record exists for this request and an associated WORK_COMPLETED record has the state FAILED.

CANCELING

The work request is in the process of canceling.

CANCELED

The work request has been canceled.

Using the Console to View Work Requests

The steps to view a work request are similar for Oracle Cloud Infrastructure services that support work requests.

1. Navigate to resource whose work requests you want to see.
   For example, to see the work requests for a Compute instance: Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
2. If the resource is displayed in a list view, click the resource name to view the resource details.
3. In the **Resources** section of the details page, click **Work Requests**. The status of all work requests appears on the page.
4. To see the log messages, error messages, and resources that are associated with a specific work request, click the operation name. Then, select an option in the **More information** section.
   For associated resources, you can click the the Actions icon (three dots) next to a resource to copy the resource's OCID.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use these API operations to monitor the state of work requests:

- ListWorkRequests
- GetWorkRequest
- ListWorkRequestErrors
- ListWorkRequestLogs

Console Announcements

This topic describes the announcements that Oracle Cloud Infrastructure displays in the Console. Console announcements appear at the top of the page to communicate timely, important information about service status. You can also view a list of past announcements.

Note

- Announcements is not available in Oracle Cloud Infrastructure Government Cloudrealms.
- If you use Oracle Platform Cloud Services or Oracle Cloud Applications and you have announcements about those service entitlements, the Console displays a banner with a link that you can use to access those announcements. For more information about these announcements, including how to set notification preferences, see Monitoring Notifications.

Types of Announcements

There are different categories of announcements. An announcement's prefix helps you understand, at a glance, the type and relative severity of the information and whether there's anything you can or must do. Announcement types currently include the following, in order of most important to least:

- **Required action.** You must take specific action within your environment.
- **Emergency change.** There is a time period during which an unplanned, but urgent, change associated with your environment will take place.
- **Recommended action.** You have specific action to take within your environment, but the action is not required.

- **Planned change.** There is a time period during which a planned change associated with your environment will take place.
- **Planned change extended.** The scheduled change period has extended beyond what was previously communicated.
- **Planned change rescheduled.** The planned change to your environment has been postponed to a later time or date.
- **Production event.** An impactful change to your environment either recently occurred or is actively occurring.
- **Planned change completed.** The planned change to your environment has been completed and regular operations have resumed.
- **Information.** There is information that you might find useful, but is not urgent and does not require action on your part.

For announcements that require action and affect Oracle Cloud Infrastructure Compute instances, you will get 30 days of advance notice. If you need to delay the actions described in the announcement, contact support to request one of the alternate dates listed in the announcement. Critical vulnerabilities might not be eligible for delay.

Required IAM Policy

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

Depending on whether you have access, you might not see any announcements. With access to announcements, you can either see only the summary version of any given announcement or you can also view announcement details.

For administrators: for typical policies that give users access to announcements, see Restrict user access to view only summary announcements and Let users view details of announcements. For more information, see Details for the Announcements Service.

If you're new to policies, see Getting Started with Policies and Common Policies.

Email Delivery

As part of your service agreement, Oracle Cloud Infrastructure also contacts you about service status announcements through email. These emails help alert you to upcoming changes that will impact your tenancy, such as those involving data centers or instances you use, or about required action on your part. Oracle sends these announcements to the tenant administrator email address and you cannot opt out of receiving this operational information. Whenever possible, we try to provide advance notice of impactful events. If you want to change the tenant administrator email address, contact Oracle Support. For more information, see Contacting Support.

Viewing Announcements

This section describes how to view announcements. The Console displays announcements as banners that span the width of the top of your browser window. As long as an announcement remains in effect and you have the access to view announcements, the banner announcement displays each time you sign in to the Console until you mark it as read. You can also view all past announcements. The Announcements icon displays a green dot if you have any unread announcements.

To dismiss a banner announcement

- To close a banner announcement until the next time you sign in to the Console, click the X at the far right edge of the banner. If you want to stop seeing an announcement as a banner altogether, you must mark it as read. For more information, see To mark an announcement as read.

To view the details of an announcement

1. Do one of the following:
    - If you are viewing a banner, click the **Show details** link near the far right edge of the banner.
    - If you are viewing a list of announcements, under the **Summary** column, click the announcement summary.
2. On the **Announcement Details** page, you can view the following information:
    - **Description.** This describes the issue or event in greater detail than the summary text of the announcement.
    - **OCID.** This is the announcement's unique, Oracle-assigned identifier.
    - **Reference Ticket Number.** You can use this number to refer to the issue when talking to Support.
    - **Type.** This is one of several predefined categories that helps to set expectations about the nature and severity of the issue described.
    - **Affected Service.** This indicates the Oracle Cloud Infrastructure services affected by the issue or event.
    - **Region.** This tells you what Oracle Cloud Infrastructure regions are impacted.
    - **Start Time.** This is when the issue or event was first detected.
    - **End Time.** This is when the issue or event was resolved.
    - **Required After.** This is the date after which you must address any required actions described in the announcement.
    - **Created.** This is when the announcement was created.
    - **Updated.** This is when the announcement was updated.
    - **Additional Information.** This includes information such as workarounds or background material.

- **Impacted Resources.** This shows the resources that were affected in some way by the event that prompted the announcement.

3. Optionally, if you want to refer to the list of impacted resources later, click **Download Impacted Resources List**.

To view a list of all announcements

1. Click the Announcements icon (🔔).
2. The **Announcements** page displays all announcements. From this page, you can do the following:
   - **Filter.** You can filter announcements by type or by start or end date.
   - **Sort.** You can sort announcements by summary, type, event start time, or publish time (which indicates when the announcement was last updated).
   - **Mark as read.** You can mark announcements as read if you want stop seeing them as banners in the Console in subsequent sessions.
   - **View announcement details.** You can view the details of an announcement.

To filter a list of announcements

1. Click the Announcements icon (🔔).
2. To filter the list, under **Filters**, do one of the following:
   - Click **Type**, and then click a type from the list.
   - Click **Start Date**, and then choose a date to see only events that started on that date.
   - Click **End Date**, and then choose a date to see only events that ended on that date.
3. To clear a filter on a date, click the X next to the date.

To sort a list of announcements

1. Click the Announcements icon (🔔).
2. By default, the list displays announcements according to the event start time, from most recent to least. To sort the list another way, do one of the following:
   - Click **Summary**. The list sorts alphabetically, according to the summary of the announcement.
   - Click **Type**. The list sorts according to the importance of the announcement.
   - Click **Start Time**. The list sorts according to the start time of the event described in the announcement. If you begin by viewing the default sort order, the sort order will change to show the oldest announcement at the beginning of the list.
   - Click **Publish Time**. The list sorts according to the time that an announcement was last updated. You might find it helpful to sort by this column if you want to track an ongoing issue or if an announcement requires action on your part.
3. To sort the list again, repeat the previous step.

To mark an announcement as read

1. Click the Announcements icon (🔔).
2. Find the announcement that you want to mark as read, click the Actions icon (three dots), and then click **Mark As Read**.

Using the Command Line Interface (CLI)

For information about using the CLI, see Command Line Interface (CLI). For a complete list of flags and options available for CLI commands, see CLI Help.

To view the details of an announcement

Open a command prompt and run `oci announce announcements get` to view detailed information about an announcement:

```
oci announce announcements get --announcement-id <announcement_OCID>
```

For example:

```
oci announce announcements get --announcement-id
ocid1.announcement.region1..examplear73oue4jdywjjvietoc6im3cvb6xae4falm3faux5us3iwra3t6q
```

To view a list of all announcements

Open a command prompt and run `oci announce announcements list` to view a list of all announcements:

```
oci announce announcements list --compartment-id <compartment_OCID>
```

For example:

```
oci announce announcements list --compartment-id
ocid1.tenancy.oc1..exampleati4wjo6cvbxq4iusld5ltpneskcfy7lr4a6wfauxuwrwed5bsdea
```

To filter a list of announcements

Open a command prompt and run `oci announce announcements list` to filter a list of announcements.

To filter a list of announcements by announcement type:

```
oci announce announcements list --compartment-id <compartment_OCID> --announcement-type <announcement_
type>
```

For example:

```
oci announce announcements list --compartment-id
ocid1.tenancy.oc1..exampleati4wjo6cvbxq4iusld5ltpneskcfy7lr4a6wfauxuwrwed5bsdea --announcement-type
ACTION_REQUIRED
```

To sort a list of announcements

Open a command prompt and run `oci announce announcements list` to sort a list of announcements.

To sort a list of announcements in ascending order of time created, from oldest to newest:

```
oci announce announcements list --compartment-id <compartment_OCID> --sort-order ASC
```

For example:

```
oci announce announcements list --compartment-id
ocid1.tenancy.oc1..exampleati4wjo6cvbxq4iusld5ltpneskcfy7lr4a6wfauxuwrwed5bsdea --sort-order ASC
```

To mark an announcement as read

Open a command prompt and run `oci announce user-status update` to mark an announcement as read:

```
oci announce user-status update --announcement-id <announcement_OCID> --user-status-announcement-id
<announcement_OCID> --user-id <user_OCID> --time-acknowledged <date_and_time>
```

For example:

```
oci announce user-status update --announcement-id
ocid1.announcement.region1..examplear73oue4jdywjjvietoc6im3cvb6xae4falm3faux5us3iwra3t6q --user-status-
announcement-id ocid1.announcement.region1..examplear73oue4jdywjjvietoc6im3cvb6xae4falm3faux5us3iwra3t6q
--user-id ocid1.user.region1..exampleaorxz3psplonigcvbzy5oaiwiubh7k7ip6zgklfauxic67kksu4oq --time-
acknowledged 2019-01-06T20:14:00+00:00
```

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the following operations to manage announcements:

- GetAnnouncement
- GetAnnouncementUserStatus
- ListAnnouncements
- UpdateAnnouncementUserStatus

Prerequisites for Oracle Platform Services on Oracle Cloud Infrastructure

This topic describes procedures that are required by some Oracle Platform Services before you can launch them on Oracle Cloud Infrastructure. The information in this topic applies only to the following services:

- Oracle Big Data Cloud
- Oracle Database Cloud Service
- Oracle Data Hub Cloud Service
- Oracle Event Hub Cloud Service
- Oracle Java Cloud Service
- Oracle MySQL Cloud Service
- Oracle SOA Cloud Service

For a list of all services supported on Oracle Cloud Infrastructure, see Information About Supported Platform Services.

Accessing Oracle Cloud Infrastructure

Oracle Cloud Infrastructure has a different interface and credential set than your Oracle Platform Services. You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. For a list of available SDKs, see Software Development Kits and Command Line Interface.

To access the Console, you must use a supported browser (Oracle Cloud Infrastructure supports the latest desktop versions of Google Chrome, Microsoft Edge, Internet Explorer 11, Safari, Firefox, and Firefox ESR. Note that private browsing mode is not supported for Firefox, Internet Explorer, or Edge. Mobile browsers are not supported.

Required Identity and Access Management (IAM) Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

See Common Policies for more information and examples.

Resources Created in Your Tenancy by Oracle

Oracle creates a compartment in your tenancy for Oracle Platform Services. This compartment is specially configured by Oracle for the Oracle Cloud Infrastructure resources that you create through the Platform Services. You can't choose another compartment for Oracle to use.

Along with this compartment, Oracle creates the IAM policies to allow Oracle Platform Services access to the resources.

The compartment that Oracle creates for Oracle Platform Services is named: `ManagedCompartmentForPaaS`.

The polices that Oracle creates for Oracle Platform Services are:

- `PSM-root-policy`

  This policy is attached to the root compartment of your tenancy.
- `PSM-mgd-comp-policy`

  This policy is attached to the `ManagedCompartmentForPaaS` compartment.

Warning

Do not make any changes to these resources. Editing or renaming the policies or the compartment can result in loss of functionality.

Prerequisites for Oracle Platform Services

Before you can create instances of an Oracle Platform Service on Oracle Cloud Infrastructure, you need to have the following resources in your Oracle Cloud Infrastructure tenancy:

- A compartment for your resources
- A virtual cloud network (VCN) with at least one public subnet
- IAM policies to allow Oracle Platform Services to access the VCN
- An Object Storage bucket
- Credentials to use with Object Storage

Some of the Platform Services automatically create some of these resources for you. See details about your service in the following sections.

Setting Up the Prerequisites

Note

To use **Autonomous Data Warehouse Cloud**, you don't need to set up any of the resources listed in this prerequisites section. However, if you optionally choose to use Oracle Cloud Infrastructure Object Storage for data loading, you need to perform these two tasks:

Create a bucket

Create an auth token

Following are two scenarios with procedure sets. If you need to set up all the required resources, follow Scenario 1. If you already have a VCN in your Oracle Cloud Infrastructure tenancy that you want to use for Oracle Platform Services, follow Scenario 2.

To follow a tutorial on how to set up the prerequisites for Scenario 1, see Creating the Infrastructure Resources Required for Oracle Platform Services.

Scenario 1: I need to create all the prerequisite resources

Create a compartment

> **Important**
>
> You cannot use the `ManagedCompartmentForPaaS` for your VCN and bucket.

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Compartments**.
2. A list of the existing compartments in your tenancy is displayed.
3. Click **Create Compartment**.
4. Enter the following:
   - **Name:** For example, PaaSResources. Restrictions for compartment names are: Maximum 100 characters, including letters, numbers, periods, hyphens, and underscores. The name must be unique across all the compartments in your tenancy
   - **Description:** A friendly description.
5. Click **Create Compartment**.

Set up your virtual cloud network

This procedure creates a VCN with these characteristics:

- A VCN with CIDR 10.0.0.0/16.
- Three public subnets (10.0.0.0/24, 10.0.1.0/24, and 10.0.2.0/24) each using the VCN's default security list, default route table, and default DHCP options.
- An internet gateway, with the required route rule in the default route table.

- Use of the Internet and VCN Resolver for DNS, so your instances can use their hostnames instead of their private IP addresses to communicate with each other.

Tip

This Quick VCN procedure is useful for getting started and trying out Oracle Platform Services on Oracle Cloud Infrastructure. For production, use the procedure in VCNs and Subnets. That topic explains features such as how to specify the CIDR ranges for your VCN and subnets, and how to secure your network. When you use the advanced procedure, remember that the VCN that you create must have a public subnet for Oracle Platform Services to use.

1. Open the **Region** menu and select the region in which you want to create the Oracle PaaS service instance.
   Select a region that's within the default data region of your account. For example, if your default data region is EMEA, then select Germany Central (Frankfurt) or UK South (London).
2. From the **Compartment** list, select the compartment you created.
3. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
4. Click **Create Virtual Cloud Network**.
5. In **Create in Compartment**, leave the default value (the compartment you're currently working in).
6. Enter a friendly name for the cloud network, for example: `PaaSVCN`. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API).

7. Select **Create Virtual Cloud Network Plus Related Resources**.
8. Scroll down to the bottom of the dialog box and click **Create Virtual Cloud Network**.

Permit Oracle Platform Services to access resources

1. In the Console, navigate to the root compartment of your tenancy by clicking your tenancy name in the **Compartment** list.
2. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Policies**.
3. Click **Create Policy**.
4. Enter the following:
   - **Name:** A unique name for the policy. The name must be unique across all policies in your tenancy. You cannot change this later.
   - **Description:** A friendly description. You can change this later if you want to.
   - **Policy Versioning:** Select **Keep Policy Current** if you'd like the policy to stay current with any future changes to the service's definitions of verbs and resources. Or if you'd prefer to limit access according to the definitions that were current on a specific date, select **Use Version Date** and enter that date in format YYYY-MM-DD format. For more information, see Policy Language Version.
   - **Statement:** To allow Oracle Platform Services access to use the network in your compartment, enter the following policy statements. Replace *<compartment_name>* with your compartment name. Click **+** after each statement to add another.

     ```
     Allow service PSM  to inspect vcns in compartment <compartment_name>
     ```

     ```
     Allow service PSM  to use subnets in compartment <compartment_name>
     ```

     ```
     Allow service PSM  to use vnics in compartment <compartment_name>
     ```

     ```
     Allow service PSM  to manage security-lists in compartment <compartment_name>
     ```

     For more information about policies, see Policy Basics and also Policy Syntax.

5. (Optional) If you want to enable the use of an Autonomous Transaction Processing or Oracle Cloud Infrastructure Database instance in your compartment as the infrastructure schema database for your Oracle Java Cloud Service instance, then add the following statements:

```
Allow service PSM to inspect autonomous-database in compartment <compartment_name>
```

```
Allow service PSM to inspect database-family in compartment <compartment_name>
```

6. Click **Create**.

Create a bucket

1. Open the **Region** menu and select the region in which you want to create the Oracle PaaS service instance.
   Select a region that's within the default data region of your account. For example, if your default data region is EMEA, then select Germany Central (Frankfurt) or UK South (London).
2. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.
3. Choose the compartment you created.
4. Click **Create Bucket**.
5. In the **Create Bucket** dialog, enter a bucket name, for example: `PaasBucket`.
   Make a note of the name you enter. You will need it when you create an instance for your Oracle Platform Service later.
6. Click **Create Bucket**.

Set up credentials to use with Object Storage

For Big Data Cloud, set up an API signing key:

Set up an API signing key

Follow the instructions in this topic: Required Keys and OCIDs.

For all other services, create an auth token. Note that your service might refer to this credential as a Swift password. Use the auth token wherever you are asked to provide a Swift password.

Create an auth token

1. View the user's details:
   - If you're creating an auth token for yourself: Open the **Profile** menu () and click **User Settings**.
   - If you're an administrator creating an auth token for another user: In the Console, click **Identity**, and then click **Users**. Locate the user in the list, and then click the user's name to view the details.
2. On the left side of the page, click **Auth tokens**.
3. Click **Generate Token**.
4. Enter a friendly description for the token and click **Generate Token**.
   The new token is displayed.
5. Copy the token immediately, because you can't retrieve it again after closing the dialog box. Also, make sure you have this token available when you create your Oracle Platform Services instance.

Scenario 2: I have an existing VCN in Oracle Cloud Infrastructure that I want to use for my Oracle Platform Services instance

You can use an existing VCN. The VCN must have at least one public subnet. Perform these tasks to complete the prerequisites:

Permit Oracle Platform Services to access resources

1. In the Console, navigate to the root compartment of your tenancy by clicking your tenancy name in the **Compartment** list.
2. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Policies**.
3. Click **Create Policy**.
4. Enter the following:
    - **Name:** A unique name for the policy. The name must be unique across all policies in your tenancy. You cannot change this later.
    - **Description:** A friendly description. You can change this later if you want to.
    - **Policy Versioning:** Select **Keep Policy Current** if you'd like the policy to stay current with any future changes to the service's definitions of verbs and resources. Or if you'd prefer to limit access according to the definitions that were current on a specific date, select **Use Version Date** and enter that date in YYYY-MM-DD format. For more information, see Policy Language Version.
    - **Statement:** To allow Oracle Platform Services access to use the network, enter the following policy. Click **+** after each statement to add another. In each statement, replace *<compartment_name>* with the name of the compartment where your VCN resides.

      ```
      Allow service PSM  to inspect vcns in compartment <compartment_name>
      ```

      ```
      Allow service PSM  to use subnets in compartment <compartment_name>
      ```

      ```
      Allow service PSM  to use vnics in compartment <compartment_name>
      ```

      ```
      Allow service PSM  to manage security-lists in compartment <compartment_name>
      ```

      For more information about policies, see Policy Basics and also Policy Syntax.
5. (Optional) If you want to enable the use of an Autonomous Transaction Processing or Oracle Cloud Infrastructure Database instance in your compartment as the infrastructure schema database for your Oracle Java Cloud Service instance, then add the following statements:

```
Allow service PSM to inspect autonomous-database in compartment <compartment_name>

Allow service PSM to inspect database-family in compartment <compartment_name>
```

6. Click **Create**.

Create a bucket

1. Open the **Region** menu and select the region in which you want to create the Oracle PaaS service instance.
   Select a region that's within the default data region of your account. For example, if your default data region is EMEA, then select Germany Central (Frankfurt) or UK South (London).
2. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.
3. Choose the compartment you want to create the bucket in.
4. Click **Create Bucket**.
5. In the **Create Bucket** dialog, enter a bucket name, for example: `PaasBucket`. Make a note of the name you enter. You will need it when you create an instance for your Oracle Platform Service later.
6. Click **Create Bucket**.

Set up credentials to use with Object Storage

For Big Data Cloud, set up an API signing key:

Set up an API signing key

Follow the instructions in this topic: Required Keys and OCIDs.

For all other services, create an auth token. Note that your service might refer to this credential as a Swift password. Use the auth token wherever you are asked to provide a Swift password.

Create an auth token

1. View the user's details:
   - If you're creating an auth token for yourself: Open the **Profile** menu () and click **User Settings**.
   - If you're an administrator creating an auth token for another user: In the Console, click **Identity**, and then click **Users**. Locate the user in the list, and then click the user's name to view the details.
2. On the left side of the page, click **Auth Tokens**.
3. Click **Generate Token**.
4. Enter a friendly description for the token and click **Generate Token**.
   The new token is displayed.
5. Copy the auth token immediately, because you can't retrieve it again after closing the dialog box. Also, make sure you have this token available when you create your Oracle Platform Services instance.

Information About Supported Platform Services

The following table lists the services supported on Oracle Cloud Infrastructure and links to more information about using those services on Oracle Cloud Infrastructure:

Service	More Information
Autonomous Analytics Cloud	About Oracle Autonomous Analytics Cloud
Autonomous API Platform Cloud Service	Using Oracle Autonomous API Platform Cloud Service

Service	More Information
Autonomous Data Warehouse Cloud	About Autonomous Data Warehouse Cloud
Integration Cloud	Oracle Integration Cloud
Autonomous Mobile Cloud Enterprise	About Oracle Autonomous Mobile Cloud Enterprise
NoSQL Database Cloud	Oracle NoSQL Database Cloud
Oracle Visual Builder	Administering Oracle Visual Builder
Big Data Cloud	About Big Data Cloud Clusters in Oracle Cloud Infrastructure
Data Hub Cloud Service	About Oracle Data Hub Cloud Service Clusters in Oracle Cloud Infrastructure
Data Integration Platform Cloud	What is Oracle Data Integration Platform Cloud
Database Cloud Service	About Database Deployments in Oracle Cloud Infrastructure
Developer Cloud Service	About Oracle Developer Cloud Service in Oracle Cloud Infrastructure
Event Hub Cloud Service	About Oracle Event Hub Cloud Service - Dedicated Instances in Oracle Cloud Infrastructure
Java Cloud Service	About Java Cloud Service Instances in Oracle Cloud Infrastructure
MySQL Cloud Service	About MySQL Cloud Service Deployments in Oracle Cloud Infrastructure
Oracle SOA Cloud Service	About SOA Cloud Service Instances in Oracle Cloud Infrastructure Classic and Oracle Cloud Infrastructure

Billing and Payment Tools Overview

Oracle Cloud Infrastructure provides various billing and payment tools that make it easy to manage your service costs.

Budgets

Budgets can be used to set thresholds for your Oracle Cloud Infrastructure spending. You can set alerts on your budget to let you know when you might exceed your budget, and you can view all of your budgets and spending from one single place in the Oracle Cloud Infrastructure console.

See Budgets Overview for more information.

Cost Analysis

Cost Analysis provides easy-to-use visualization tools to help you track and optimize your Oracle Cloud Infrastructure spending. For more information, see Checking Your Balance and Usage.

Usage Reports

A usage report is a comma-separated value (CSV) file that can be used to get a detailed breakdown of resources in Oracle Cloud Infrastructure for audit or invoice reconciliation.

For more information, see Usage Reports Overview.

Invoices

You can view and download invoices for your Oracle Cloud Infrastructure usage. For more information, see Viewing Your Subscription Invoice.

Payment Methods

The Payment Method section of the Oracle Cloud Infrastructure Console allows you to easily manage how you pay for your Oracle Cloud Infrastructure usage.

For more information, see Changing Your Payment Method.

Built 11/26/2019 11:09 AM

Budgets Overview

A budget can be used to set soft limits on your Oracle Cloud Infrastructure spending. You can set alerts on your budget to let you know when you might exceed your budget, and you can view all of your budgets and spending from one single place in the Oracle Cloud Infrastructure console.

How Budgets Work

Budgets are set on cost-tracking tags or on compartments (including the root compartment) to track all spending in that cost-tracking tag or for that compartment and its children.

All budgets alerts are evaluated every 15 minutes. To see the last time a budget was evaluated, open the details for a budget. You will see fields that show the current spend, the forecast and the "Spent in period" field which shows you the time period over which the budget was evaluated. When a budget alert fires, the email recipients configured in the budget alert receive an email.

Budget Concepts

The following concepts are essential to working with budgets:

Budget

A monthly threshold you define for your Oracle Cloud Infrastructure spending. Budgets are set on cost-tracking tags or compartments and track all spending in the cost-tracking tag or compartment and any child compartments. Note: the budget tracks spending in the specified target compartment, but you need to have permissions to manage budgets in the root compartment of the tenancy to create and use budgets.

Alert

You can define email alerts that get sent out for your budget. You can send a customized email message body with these alerts. Alerts are evaluated every 15 minutes, and can be

triggered when your actual or your forecasted spending hits either a percentage of your budget or a specified set amount.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

If you're new to policies, see Getting Started with Policies and Common Policies.

To use budgets, you must be in a group that can use "usage-budgets" in the tenancy (which is the root compartment) or be able to use all resources in the tenancy. All budgets are created in the root compartment, regardless of the compartment they are targeting, so IAM policies that grant budget permissions outside of the root will not be meaningful.

IAM Policy	Description
Allow group accountants to inspect usage-budgets in tenancy	Accountants can inspect budgets including spend.
Allow group accountants to read usage-budgets in tenancy	Accountants can read budgets including spend (same as list).
Allow group accountants to use usage-budgets in tenancy	Accountants can create and edit budgets and alerts rules.
Allow group accountants to manage usage-budgets in tenancy	Accountants can create, edit, and delete budgets and alerts rules.

Tagging Resources

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the desired tags. For general information about applying tags, see Resource Tags.

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies. For specific details about writing policies for each of the different services, see Policy Reference.

If you're a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

Managing Budgets

This topic discusses how to view and manage your budgets.

USING THE CONSOLE

To create a budget

1. Open the navigation menu. Under **Governance and Administration**, go to **Account Management** and click **Budgets**.
2. Click **Create Budget** at the top of the budgets list. The **Create Budget** dialog is displayed.
3. Select either **Compartment** or **Cost-Tracking Tag** to select the type of target for your budget.

4. Select the target for your budget:
    - For budgets targeting a compartment:
        - Select a target compartment for your budget from the **Target Compartment** drop-down list. Note that while the budget tracks spending in the specified target compartment, but you need to have permissions to manage budgets in the root compartment of the tenancy to create and use budgets.
    - For budgets targeting a cost-tracking tag:
        - Select a tag namespace
        - Select a target cost-tracking tag key.
        - Enter a value for the cost-tracking tag.
5. Enter a name for your budget in the **Name** text field. The name can only contain alphanumeric characters, dashes, and the underscore character, and can't begin with a number.
6. Enter a monthly amount for your budget in the **Monthly Budget Amount** field. The minimum allowed value for your monthly budget is 1; the maximum allowed value is 999,999,999,999.
7. You can optionally create an alert for your budget by creating a budget alert rule. In the Budget Alert Rule panel on the Create Budget dialog, configure your alert rule:
    a. Select a threshold for your alert from the **Threshold Metric** drop-down list. There are two possible values:

    Actual Spend will watch the actual amount you spend in your compartment per month;

    Forecast Spend will watch your resource usage and alert you when it appears that you'll exceed your budget. The forecast algorithm is linear extrapolation and requires at least 3 days of consumption to trigger

    b. Select a threshold type from the **Threshold Type** drop-down list. You can select either a percentage of your monthly budget (which must be greater than 0 and no greater than 10,000) or a fixed amount.

c. The label of the next text field changes depending on what type of threshold you selected. Enter either a **Threshold %** or a **Threshold Amount**.

d. In the **Email Recipients** field, enter one or more email addresses to receive the alerts. Multiple addresses can be separated using a comma, semicolon, space, tab, or new line.

e. Enter the body of your email alert in the **Email Message** field. The text of the email message cannot exceed 1000 characters. This message will be included with metadata about your budget, including the budget name, the compartment, and the amount of your monthly budget. You can use this message to for things like providing instructions to the recipient that explain how to request a budget increase or reminding users about corporate policies.

8. **Advanced Options (optional):** Click the **Show Advanced Options** link to add **Tags** to your Budget. Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.
9. Click the **Create** button to create your budget.

To view or edit a budget

1. Open the navigation menu. Under **Governance and Administration**, go to **Account Management** and click **Budgets**.
2. From the list of budgets, click on the budget you want to edit. The budget detail screen will appear.
3. Click the **Edit** button. The **Edit Budget** dialog will appear.
4. You can edit the name of your budget or the budget amount.
5. When you are finished, click **Save Changes**.

To delete a budget

1. From the list of budgets, select **Delete** from the context menu, or click the **Delete** button at the top of budget detail screen. The **Confirm Delete** dialog will appear.
2. Click the **Confirm** button to delete the budget, or cancel by clicking **Cancel**.

To manage tags for a budget

1. Open the navigation menu. Under **Governance and Administration**, go to **Account Management** and click **Budgets**.
2. From the list of budgets, click on the budget you want to tag. The budget detail screen will appear.
3. Click the **Add tag(s)** button to add a tag.
4. Click the the **Tags** tab and then click on the pencil icon next to a tag you want to edit or remove.

USING THE API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the following operation to manage budgets:

- ListBudgets
- GetBudget
- CreateBudget
- DeleteBudget
- UpdateBudget

Managing Budget Alert Rules

You can set email alerts on your budgets. You can set alerts that are based on a percentage of your budget or an absolute amount, and on your actual spending or your forecast spending.

This topic covers how to view and manage your budget alert rules.

REQUIRED IAM POLICY

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

If you're new to policies, see Getting Started with Policies and Common Policies.

USING THE CONSOLE

To create a budget alert rule

1. Click the budget that you want to create an alert for from the budgets list.
2. In the **Budget Alert Rules** panel at the bottom of the screen, click the **Create Budget Alert Rule** button.
3. Configure your alert rule:
    a. Select a threshold for your alert from the **Threshold Metric** drop-down list. There are two possible values:

    Actual Spend will watch the actual amount you spend in your compartment per month;

    Forecast Spend will watch your resource usage and alert you when it appears that you'll exceed your budget. The forecast algorithm is linear extrapolation and requires at least 3 days of consumption to trigger

    b. Select a threshold type from the **Threshold Type** drop-down list. You can select either a percentage of your monthly budget (which must be greater than 0 and no greater than 10,000) or a fixed amount.

    c. The label of the next text field changes depending on what type of threshold you selected. Enter either a **Threshold %** or a **Threshold Amount**.

d. In the **Email Recipients** field, enter one or more email addresses to receive the alerts. Multiple addresses can be separated using a comma, semicolon, space, tab, or new line.

e. Enter the body of your email alert in the **Email Message** field. The text of the email message cannot exceed 1000 characters. This message will be included with metadata about your budget, including the budget name, the compartment, and the amount of your monthly budget. You can use this message for things like providing instructions to the recipient that explain how to request a budget increase or reminding users about corporate policies.

4. Click the **Create** button to create your alert.

To view or edit a budget alert rule

1. In the list of budget alert rules, click the menu icon at the right side of the list and select **View/Edit** from the context menu.
2. Edit your alert rule.
3. Confirm your changes by clicking **Save Changes**, or dismiss the dialog without saving by clicking the **Cancel** button.

To delete a budget alert rule

1. In the list of budget alert rules, click the menu icon at the right side of the list and select **Delete** from the context menu.
2. Confirm or cancel the delete operation in the **Confirm Delete** dialog by clicking either the **Confirm** or **Cancel** button.

USING THE API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the following operation to manage budget alert rules:

- ListAlertRules
- GetAlertRule
- CreateAlertRule
- DeleteAlertRule
- UpdateAlertRule

Usage Reports Overview

A usage report is a comma-separated value (CSV) file that can be used to get a detailed breakdown of resources in Oracle Cloud Infrastructure for audit or invoice reconciliation.

How Usage Reports Work

The usage report is automatically generated daily, and is stored in an Oracle-owned Object Storage bucket. It contains one row per each Oracle Cloud Infrastructure resource (such as instance, Object Storage bucket, VNIC) per hour along with consumption information, metadata, and tags. Usage reports generally contain 24 hours of usage data, although occasionally a usage report may contain late-arriving data that is older than 24 hours.

Usage reports are retained for one year.

The file name for each usage report is appended with an automatically incrementing numerical value.

The report may contain corrections. Corrections are added as new rows to the report, with the `lineItem/iscorrection` column set and the `referenceNo` value of the corrected line populated in the `lineItem/backReference` column.

Usage Report Schema

The following table shows the usage report schema.

Field Name	Description
lineItem/referenceNo	Line identifier. Used for debugging and corrections.
lineItem/TenantId	The identifier (OCID) for the Oracle Cloud Infrastructure tenant.
lineItem/intervalUsageStart	The start time of the usage interval for the resource in UTC.
lineItem/intervalUsageEnd	The end time of the usage interval for the resource in UTC.
product/service	The service that the resource is in.
product/resource	The resource name used by the metering system.
product/compartmentId	The ID of the compartment that contains the resource.
product/compartmentName	The name of the compartment that contains the resource.
product/region	The region that contains the resource.

Field Name	Description
product/availabilityDomain	The availability domain that contains the resource.
product/resourceId	The identifier for the resource.
usage/consumedQuantity	The quantity of the resource that has been consumed over the usage interval.
usage/billedQuantity	The quantity of the resource that has been billed over the usage interval.
usage/consumedQuantityUnits	The unit for the consumed quantity and billed quantity.
usage/consumedQuantityMeasure	The measure for the consumed quantity and billed quantity.

Field Name	Description
`lineItem/backreference`	Data amendments and corrections reference. If a correction to an existing line item is needed, a new row is added with the corrected values and a reference to the original line. Used with the `lineItem/isCorrection` field.
`lineItem/isCorrection`	Used if the current line is a correction. See the `lineitem/backreference` column for a reference to the corrected line item.
`tags/`	The usage report contains one column per tag definition (includes all tag definitions, not just cost tracking tags).

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

If you're new to policies, see Getting Started with Policies and Common Policies.

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies. For specific details about writing policies for each of the different services, see Policy Reference.

If you're a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

Accessing Usage Reports

A usage report is a comma-separate value (CSV) file that is generated daily and stored in an Object Storage bucket. This topic describes how to access usage reports.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don't have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

If you're new to policies, see Getting Started with Policies and Common Policies.

Reports are generated in another tenancy and stored in an Oracle-owned Object Storage bucket. You must set up a cross-tenancy IAM policy to access your usage reports as shown below, changing the group name as appropriate:

```
define tenancy usage-report as
ocid1.tenancy.oc1..aaaaaaaaned4fkpkisbwjlr56u7cj63lf3wffbilvqknstgtvzub7vhqkggq
```

```
endorse group MyGroupName to read objects in tenancy usage-report
```

USING THE CONSOLE

To download a usage report

1. Open the navigation menu. Under **Governance and Administration**, go to **Account Management** and select **Usage Report**.
2. Click the report you want to download from the list, and follow your browser's instructions for downloading.

USING THE API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

To download a usage report, use the Object Storage APIs. The reports are stored in the tenancy's home region. The Object Storage namespace used for the reports is `bling`; the bucket name is the tenancy OCID.

The following example shows how to download a usage report using a Python script:

```
import oci
import os

# This script downloads all of the usage reports for a tenancy (specified in the config file)
#
# Pre-requisites: Create an IAM policy to endorse users in your tenancy to read usage reports from the
OCI tenancy
#
# Example policy:
# define tenancy usage-report as
ocid1.tenancy.oc1..aaaaaaaaned4fkpkisbwjlr56u7cj63lf3wffbilvqknstgtvzub7vhqkggq
# endorse group group_name to read objects in tenancy usage-report
#
# Note - the only value you need to change is group name. Do not change the OCID in the first statement

       usage_report_namespace = 'bling'
```

```
# Update these values
destintation_path = 'downloaded_reports'

# Make a directory to receive reports
if not os.path.exists(destintation_path):
os.mkdir(destintation_path)

# Get the list of usage reports
config = oci.config.from_file('config/config','DEFAULT')
usage_report_bucket = config['tenancy']
object_storage = oci.object_storage.ObjectStorageClient(config)
report_bucket_objects = object_storage.list_objects(usage_report_namespace, usage_report_bucket)

for o in report_bucket_objects.data.objects:
   print('Found file ' + o.name)
   object_details = object_storage.get_object(usage_report_namespace,usage_report_bucket,o.name)
   filename = o.name.rsplit('/', 1)[-1]

with open(destintation_path + '/' + filename, 'wb') as f:
   for chunk in object_details.data.raw.stream(1024 * 1024, decode_content=False):
      f.write(chunk)

print('Finished downloading ' + o.name + '\n')
```

Console Cookies and Local Storage

The Oracle Cloud Infrastructure console uses browser cookies and local storage as detailed below.

Oracle Cloud Infrastructure Console Login Page Cookies

Name	Purpose	Duration	Impact of Disabling
bmc_ tenancy	Tracks the default tenancy for the OCI Console login page	30 days	The last-used tenancy is not tracked, and users are asked to specify a tenancy when logging into the OCI Console

Oracle Cloud Infrastructure Console Local Storage

Name	Purpose	Duration	Impact of Disabling
hg-session-*<userid>*:*<session>*	UI State information, includes selected region, active compartment and other UI state	Never expires	Console UI may not work optimally
recorded-events	Temporary cache of console usage data. Does not include any sensitive information.	Never expires	Console usage not recorded for analysis and product improvement purposes
recorded-metrics	Temporary cache of console metrics (for example, page load time)	Never expires	Console metrics not recorded for analysis and product improvement purposes

Oracle Cloud Infrastructure Console Cookies

Name	Purpose	Duration	Impact of Disabling
s_fid	Adobe Analytics unique visitor information, anonymous	2 years	Cannot track users across different Oracle products (OCI, Cloud Marketplace)
s_nr	Adobe Analytics unique visitor information, anonymous	2 years	Cannot track users across different Oracle products (OCI, Cloud Marketplace)
gpw_e24	Records and saves the previously accessed URL (anonymous)	Never expires	Console metrics not recorded for analysis and product improvement purposes

Oracle Cloud Infrastructure Console Local Storage - Indexed DB

Table	Field	Purpose
duplo - *<tenancy ocid>*	activeCompartmentId	Stores the compartment a user has selected in the UI
duplo - *<tenancy ocid>*	activeRegionId	Stores the region a user has selected in the UI
duplo - *<tenancy ocid>*	selectedLocale	Stores the user's current locale
opc-key-store	key	Signed ID token (carries user identity information) and a signed security token (carries transient user public key as a JSON Web Key) used for signed request calls to API end points. The security token expires after 24 hours, at which point the user will be prompted to log in again.
opc-key-store-v2	key	Signed ID token (carries user identity information) and a signed security token (carries transient user public key as a JSON Web Key) used for Signed Request calls to API end points. The security token expires after 24 hours, at which point the user will be prompted to log in again.

My Services Use Cases

Important

The My Services dashboard and APIs are deprecated.

To interact programmatically with My Services, you can use the Oracle Cloud My Services API. To help you get started, here are some use cases:

- Service Discovery Use Case
- Exadata Use Cases
- Managing Exadata Instances
- Using Access Token Authorization with My Services API

Service Discovery Use Case

This use case shows how you can get the list of your service entitlement IDs.

Important

The My Services dashboard and APIs are deprecated.

Discover Current Service Entitlement IDs

Many of the My Services API operations require you to specify the `serviceEntitlementId`. To get the list of all your service entitlement IDs, use the GET ServiceEntitlements operation. This operation returns information that you can use to make more specific requests using the Oracle Cloud My Services API.

Example:

```
GET /itas/<domain>/myservices/api/v1/serviceEntitlements
```

Note

In the examples, *<domain>* is the identity domain ID. An identity domain ID can be either the *IDCS GUID* that identifies the identity domain for the users within Identity Cloud Service (IDCS) or the *Identity Domain name* for a traditional Cloud Account.

To obtain the IDCS GUID

Go to the Users page in My Services dashboard and click **Identity Console**. The URL in the browser address field displays the IDCS GUID for your identity domain. For example:

```
https://idcs-
105bbbdfe5644611bf7ce04496073adf.identity.oraclecloud.com/ui/v
1/adminconsole/?root=users
```

In the above URL, `idcs-105bbbdfe5644611bf7ce04496073adf` is the IDCS GUID for your identity domain.

Example payload returned for this request:

```
{
     "items": [
         {
             "id": "cesi-511202718",                          // Unique ServiceEntitlementId
             "purchaseEntitlement": {                         // Purchase Entitlement is the entity
bought by a customer
                 "subscriptionId": "511203590",
                 "id": "511203590",
                 "canonicalLink": "/itas/<domain>/myservices/api/v1/purchaseEntitlements/511203590"
             },
             "serviceDefinition": {
                 "canonicalLink": "/itas/<domain>/myservices/api/v1/serviceDefinitions/500089778",
```

```
                "id": "500089778",
                "name": "Storage"                           // The customer is entitled to use the
Storage Service
            },
            "createdOn": "2017-12-20T16:23:23.326Z",
            "createdBy": "paul.smith@oracle.com",

Exadata Use Cases

Important

The My Services dashboard and APIs are deprecated.

The following use case examples can get you started working with the Exadata operations available in the Oracle Cloud My Services API.

Important

These procedures are for use with Oracle Database Exadata Cloud at Customer **ONLY**. For more information, see Administering Oracle Database Exadata Cloud at Customer. These procedures **DO NOT** apply to Oracle Database Exadata Cloud Service available in Oracle Cloud Infrastructure.

Exadata Firewall Whitelisting

To enable access to your Exadata Cloud Service instance, you can configure security rules and associate them with your instance. The security rules define a whitelist of allowed network access points.

The firewall provides a system of rules and groups. By default, the firewall denies network access to the Exadata Cloud Service instance. When you enable a security rule, you enable access to the Exadata Cloud Service instance. To enable access you must:

- Create a security group and create security rules that define specific network access allowances.
- Assign the security group to your Exadata Cloud Service instance.

You can define multiple security groups, and each security group can contain multiple security rules. You can associate multiple security groups with each Exadata Cloud Service instance, and each security group can be associated with multiple Exadata Cloud Service instances. You can dynamically enable and disable security rules by modifying the security groups that are associated with each Exadata Cloud Service instance.

To enable access to an Exadata Cloud Service instance:

Note

In the following examples, *<domain>* is the identity domain ID. An identity domain ID can be either the *IDCS GUID* that identifies the identity domain for the users within Identity Cloud Service (IDCS) or the *Identity Domain name* for a traditional Cloud Account.

To obtain the IDCS GUID

Go to the Users page in My Services dashboard and click **Identity Console**. The URL in the browser address field displays the IDCS GUID for your identity domain. For example:

```
https://idcs-
105bbbdfe5644611bf7ce04496073adf.identity.oraclecloud.com/ui/v
1/adminconsole/?root=users
```

In the above URL, `idcs-105bbbdfe5644611bf7ce04496073adf` is the IDCS GUID for your identity domain.

1. Get the service instance IDs.
   Operation: GET ServiceInstances

Example

Example request:

```
GET
/itas/<domain>/myservices/api/v1/serviceInstances?serviceDefinitionNames=Exadata&statuses=ACTIVE
```

Example payload returned for this request:

```
{
  "items": [
    {
      "id": "csi-585928949",               // Unique ServiceInstanceId
      "serviceEntitlement": {
      "id": "cesi-585927251",
      "canonicalLink": "/itas/<domain>/myservices/api/v1/serviceEntitlements/cesi-585927251"
    },
    "serviceDefinition": {
      "canonicalLink": "/itas/<domain>/myservices/api/v1/serviceDefinitions/502579309",
      "id": "502579309",
      "name": "Exadata"                // The customer is entitled to use the Exadata Service
    },
    "cloudAccount": {
      "canonicalLink": "/itas/<domain>/myservices/api/v1/cloudAccounts/cacct-fd7a122448aaaa",
      "id": "cacct-fd7a122448aaaa",
      "name": "myAccountName"
    },
    ...
    "canonicalLink": "/itas/<domain>/myservices/api/v1/serviceInstances/csi-585928949"
  }
...                                          // More Service Instances could be displayed
  ],
"canonicalLink": "/itas/<domain>/myservices/api/v1/serviceInstances",
"hasMore": false,
"limit": 25,
"offset": 0
}
```

This example payload returns the service instance ID csi-585928949, which is part of the service entitlement ID cesi-585927251.

2. Get the service configuration IDs.
   Operation: GET SIServiceConfigurations

Example

Example request, using the service instance ID csi-585928949:

```
GET /itas/<domain>/myservices/api/v1/serviceInstances/csi-585928949/serviceConfigurations
```

Example payload returned for this request:

```
{
 "canonicalLink": "/itas/<domain>/myservices/api/v1/serviceInstances/csi-
585928949/serviceConfigurations",
 "items": [
   {
     "canonicalLink": "/itas/<domain>/myservices/api/v1/serviceInstances/csi-
585928949/serviceConfigurations/Exadata",
      "exadata": {
      "bursting": {
        "canonicalLink": "/itas/<domain>/myservices/api/v1/serviceInstances/csi-
585928949/serviceConfigurations/Exadata/bursting"
      },
     "id": "Exadata",
     "securityGroupAssignments": {
     "canonicalLink": "/itas/<domain>/myservices/api/v1/serviceInstances/csi-
585928949/serviceConfigurations/Exadata/securityGroupAssignments"
     }
   },
   "id": "Exadata"
   }
 ]
}
```

This example payload shows that /itas/*<domain>*/myservices/api/v1/serviceInstances/csi-585928949/serviceConfigurations/Exadata/securityGroupAssignments is used for Exadata Firewall.

3. Get the current security groups for the service entitlement.
   Operation: GET SEExadataSecurityGroups

Example

Example request, using the service entitlement ID cesi-585927251:

```
GET /itas/<domain>/myservices/api/v1/serviceEntitlements/cesi-
585927251/serviceConfigurations/Exadata/securityGroups
```

Example payload returned for this request:

```
{
  "items": [
    {
      "id": "1",
      "customerId": "585927251",
      "name": "SecGroup 1",
      "description": "My first Security group",
      "version": 10,
      "rules": [
        {
          "direction": "ingress",
          "proto": "tcp",
          "startPort": 1159,
          "endPort": 1159,
          "ipSubnet": "0.0.0.0/0",
          "ruleInterface": "data"
        }
      ],
      "canonicalLink":
"/itas/
<domain>
/myservices/api/v1/serviceEntitlements/585927251/serviceConfigurations/Exadata/securityGroups/1"
    },
    {
      "id": "2",
      "customerId": "585927251",
      "name": " SecGroup 2",
      "description": "My second Security group",
      "version": 3,
      "rules": [
        {
          "direction": "egress",
          "proto": "tcp",
          "startPort": 8123,
          "endPort": 8123,
```

```
          "ipSubnet": "192.168.1.0/28",
          "ruleInterface": "data"
        }
      ],
      "canonicalLink":
"/itas/
<domain>
/myservices/api/v1/serviceEntitlements/585927251/serviceConfigurations/Exadata/securityGroups/2"
    }
  ],
  "canonicalLink":
"/itas/
<domain>
/myservices/api/v1/serviceEntitlements/585927251/serviceConfigurations/Exadata/securityGroups"
}
```

This example payload shows two security groups defined for the specified service entitlement ID.

4. Get the current security group assignments for the service instance
   Operation: GET SIExadataSecurityGroupAssignments

Example

Example request, using the service instance ID csi-585928949:

```
GET /itas/<domain>/myservices/api/v1/serviceInstances/csi-
585928949/serviceConfigurations/Exadata/securityGroupAssignments
```

Example payload returned for this request:

```
{
  "items": [
    {
      "id": "11",
      "securityGroup":
      {
        "id": "1",
        "canonicalLink":
"/itas/
```

```
<domain>
/myservices/api/v1/serviceEntitlements/585927251/serviceConfigurations/Exadata/securityGroups/1"
      },
      "canonicalLink": "/itas/<domain>/myservices/api/v1/serviceInstances/csi-
585928949/serviceConfigurations/Exadata/securityGroupAssignments/11"
    }
  ],
  "canonicalLink": "/itas/<domain>/myservices/api/v1/serviceInstances/csi-
585928949/serviceConfigurations/Exadata/securityGroupAssignments"
}
```

This example payload shows one security group assigned to the service instance csi-585928949.

5. Create a security group with security rules.
   Operation: POST SEExadataSecurityGroups

Example

Example request, using the service entitlement ID cesi-585927251:

```
POST /itas/<domain>/myservices/api/v1/serviceEntitlements/cesi-
585927251/serviceConfigurations/Exadata/securityGroups
{
   "customerId": "585927251",
   "name": "SecGroup 1",
   "description": "My third Security group",
   "version": 1,
   "rules": [
     {
       "direction": "ingress",
       "proto": "tcp",
       "startPort": 30,
       "endPort": 31,
       "ipSubnet": "100.100.100.255",
       "ruleInterface": "admin"
     },
     {
       "direction": "egress",
```

```
      "proto": "tcp",
      "startPort": 32,
      "endPort": 32,
      "ipSubnet": "100.100.255.0/16",
      "ruleInterface": "admin"
    }
  ]
}
```

Attributes:

Name	Description
customerId	Required: Yes String This must be the same as the *<serviceEntitlementId>*
direction	Required: Yes String Allowed values: [ingress | egress] for inbound or outbound.
proto	Required: Yes String Allowed values: [tcp | udp].
startPort	Required: Yes Integer startPort defines the beginning of a range of ports to open/white-list [0 - 65535].

Name	Description
endPort	Required: Yes Integer endPort defines the ending of a range of ports to open/white-list [0 - 65535].
ipSubnet	Required: Yes String Single IP address or range specified in CIDR notation.
ruleInterface	Required: Yes String Allowed values: [admin | client | backup] where: • admin — specifies that the rule applies to network communications over the administration network interface. The administration network is typically used to support administration tasks by using terminal sessions, monitoring agents, and so on. • client — specifies that the rule applies to network communications over the client access network interface, which is typically used by Oracle Net Services connections. • backup — specifies that the rule applies to network communications over the backup network interface, which is typically used to transport backup information to and from network-based storage that is separate from Exadata Cloud Service.

If successful, the POST request will return the unique ID of the newly created security group. For the next step, we'll assume that the newly created security group ID is 3.

Note

A security group can also be modified or deleted.
See Oracle Cloud My Services API.

6. Assign the security group to a service instance.
   Operation: POST SIExadataSecurityGroupAssignments

Example

Example request, using the service instance csi-585928949 and the security group ID 3:

```
POST /itas/<domain>/myservices/api/v1/serviceInstances/csi-
585928949/serviceConfigurations/Exadata/securityGroupAssignments

{
   "securityGroup": {
      "id": "3",
      "customerId": "585927251",
      "canonicalLink":
"/itas/
<domain>
/myservices/api/v1/serviceEntitlements/585927251/serviceConfigurations/Exadata/securityGroups/3"
   }
}
```

Attributes:

Name	Description
customerId	Required: Yes String This must be the same as the serviceEntitlementId.

If successful, the POST request will return the unique Id of the newly created security group assignment.

Note

A security group assignment can also be deleted. See Oracle Cloud My Services API.

You can now verify all your security groups and assignments. See:

- Get the current security groups for the service entitlement.
- Get the current security group assignments for the service instance .

Exadata Scaling with Bursting

You can temporarily modify the capacity of your Exadata environment by configuring bursting. Bursting is a method you can use to scale Exadata Cloud Service non-metered instances within an Exadata system.

To scale up your non-metered instances, increase the number of compute nodes by modifying the `burstOcpu` attribute of the host. When you no longer need the additional nodes, update the `burstOcpu` attribute back to its original setting.

Note

In the following examples, *<domain>* is the identity domain ID. An identity domain ID can be either the *IDCS GUID* that identifies the identity domain for the users within Identity Cloud Service (IDCS) or the *Identity Domain name* for a traditional Cloud Account.

To obtain the IDCS GUID

Go to the Users page in My Services dashboard and click **Identity Console**. The URL in the browser address field displays the IDCS GUID for your identity domain. For example:

```
https://idcs-
105bbbdfe5644611bf7ce04496073adf.identity.oraclecloud.com/ui/v
1/adminconsole/?root=users
```

In the above URL, `idcs-105bbbdfe5644611bf7ce04496073adf` is the IDCS GUID for your identity domain.

1. Get the service instance IDs.
   Operation: GET ServiceInstances

Example

Example request:

```
GET
/itas/<domain>/myservices/api/v1/serviceInstances?serviceDefinitionNames=Exadata&statuses=ACTIVE
```

Example payload returned for this request:

```
{
  "items": [
    {
      "id": "csi-585928949",               // Unique ServiceInstanceId
      "serviceEntitlement": {
      "id": "cesi-585927251",
      "canonicalLink": "/itas/<domain>/myservices/api/v1/serviceEntitlements/cesi-585927251"
    },
    "serviceDefinition": {
      "canonicalLink": "/itas/<domain>/myservices/api/v1/serviceDefinitions/502579309",
      "id": "502579309",
      "name": "Exadata"                // The customer is entitled to use the Exadata Service
    },
    "cloudAccount": {
      "canonicalLink": "/itas/<domain>/myservices/api/v1/cloudAccounts/cacct-fd7a122448aaaa",
      "id": "cacct-fd7a122448aaaa",
      "name": "myAccountName"
    },
    ...
    "canonicalLink": "/itas/<domain>/myservices/api/v1/serviceInstances/csi-585928949"
  }
...                                          // More Service Instances could be displayed
  ],
"canonicalLink": "/itas/<domain>/myservices/api/v1/serviceInstances",
"hasMore": false,
"limit": 25,
"offset": 0
}
```

This example payload returns the service instance ID csi-585928949.

2. Get the service configuration IDs.
   Operation: GET SIServiceConfigurations

Example

Example request, using the service instance ID csi-585928949:

```
GET /itas/<domain>/myservices/api/v1/serviceInstances/csi-585928949/serviceConfigurations
```

Example payload returned for this request:

```
{
 "canonicalLink": "/itas/<domain>/myservices/api/v1/serviceInstances/csi-
585928949/serviceConfigurations",
 "items": [
   {
     "canonicalLink": "/itas/<domain>/myservices/api/v1/serviceInstances/csi-
585928949/serviceConfigurations/Exadata",
      "exadata": {
      "bursting": {
        "canonicalLink": "/itas/<domain>/myservices/api/v1/serviceInstances/csi-
585928949/serviceConfigurations/Exadata/bursting"
      },
     "id": "Exadata",
     "securityGroupAssignments": {
     "canonicalLink": "/itas/<domain>/myservices/api/v1/serviceInstances/csi-
585928949/serviceConfigurations/Exadata/securityGroupAssignments"
     }
   },
   "id": "Exadata"
   }
 ]
}
```

This example payload shows that /itas/*<domain>*/myservices/api/v1/serviceInstances/csi-585928949/serviceConfigurations/Exadata/securityGroupAssignments is used for Bursting.

3. Get the current compute node configuration.
   Operation: GET SIExadataBursting

Example

Example request, using the service instance ID csi-585928949:

```
GET /itas/<domain>/myservices/api/v1/serviceInstances/csi-
585928949/serviceConfigurations/Exadata/bursting
```

Example payload returned for this request:

```
{
   "ocpuOpInProgress": false,
   "exaunitId": 50,
   "ocpuAllocations": [
       {
          "hostName": "host1.oraclecloud.com",
          "subscriptionOcpu": 11,
          "meteredOcpu": 0,
          "burstOcpu": 0,                                  // Current Burst value
          "minOcpu": 11,
          "maxOcpu": 42,
          "maxBurstOcpu": 11,
          "maxSubOcpu": 38,
          "maxMetOcpu": 0
       },
       {
          "hostName": "host2.oraclecloud.com",
          "subscriptionOcpu": 11,
          "meteredOcpu": 0,
          "burstOcpu": 0,                                  // Current Burst value
          "minOcpu": 11,
          "maxOcpu": 42,
          "maxBurstOcpu": 11,
          "maxSubOcpu": 38,
          "maxMetOcpu": 0
       }
       ],
   "status": 200,
   "op": "exaunit_coreinfo",
   "additionalNumOfCores": "0",
   "additionalNumOfCoresHourly": "0",
   "coreBursting": "Y"
}
```

4. Modify the values for `burstOcpu`.
   Operation: PUT SIExadataBursting
   You can modify `burstOcpu` to a value that is up to the value of `maxBurstOcpu`. This example adds two compute nodes to each host.

Example

Example request, using the service instance csi-585928949:

```
PUT /itas/<domain>/myservices/api/v1/serviceInstances/csi-
585928949/serviceConfigurations/Exadata/bursting/
{
   "ocpuOpInProgress": false,
   "exaunitId": 50,
   "ocpuAllocations": [
       {
          "hostName": "host1.oraclecloud.com",
          "subscriptionOcpu": 11,
          "meteredOcpu": 0,
          "burstOcpu": 2,
          "minOcpu": 11,
          "maxOcpu": 42,
          "maxBurstOcpu": 11,
          "maxSubOcpu": 38,
          "maxMetOcpu": 0
       },
       {
          "hostName": "host2.oraclecloud.com",
          "subscriptionOcpu": 11,
          "meteredOcpu": 0,
          "burstOcpu": 2,
          "minOcpu": 11,
          "maxOcpu": 42,
          "maxBurstOcpu": 11,
          "maxSubOcpu": 38,
          "maxMetOcpu": 0
       }
       ]
}
```

Attributes:

Name	Description
burstOcpu	Required: Yes Type: Integer, Minimum Value: 0, Maximum Value: maxBurstOcpu Number of additional cores

Note

This action may take a few minutes to complete.

5. Verify the new compute node configuration.
   Operation: GET SIExadataBursting

Example

Example request, using the service instance ID csi-585928949:

```
GET /itas/<domain>/myservices/api/v1/serviceInstances/csi-
585928949/serviceConfigurations/Exadata/bursting
```

Example payload returned for this request:

```
{
   "ocpuOpInProgress": false,
   "exaunitId": 50,
   "ocpuAllocations": [
       {
          "hostName": "host1.oraclecloud.com",
          "subscriptionOcpu": 11,
          "meteredOcpu": 0,
          "burstOcpu": 2,                    // New Burst value
          "minOcpu": 11,
          "maxOcpu": 42,
          "maxBurstOcpu": 11,
          "maxSubOcpu": 38,
          "maxMetOcpu": 0
```

```
      },
      {
         "hostName": "host2.oraclecloud.com",
         "subscriptionOcpu": 11,
         "meteredOcpu": 0,
         "burstOcpu": 2,                    // New Burst value
         "minOcpu": 11,
         "maxOcpu": 42,
         "maxBurstOcpu": 11,
         "maxSubOcpu": 38,
         "maxMetOcpu": 0
      }
      ],
  "status": 200,
  "op": "exaunit_coreinfo",
  "additionalNumOfCores": "0",
  "additionalNumOfCoresHourly": "0",
  "coreBursting": "Y"
}
```

Managing Exadata Instances

Important

The My Services dashboard and APIs are deprecated.

The following procedures walk you through creating, modifying, and deleting Exadata instances used with the Oracle Cloud My Services API.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Important

These procedures are for use with Oracle Database Exadata Cloud at Customer **ONLY**. For more information, see Administering Oracle Database Exadata Cloud at Customer. These procedures **DO NOT** apply to Oracle Database Exadata Cloud Service available in Oracle Cloud Infrastructure.

Prerequisites

Before you can manage Exadata instances, you need to:

- Subscribe to an Oracle Cloud service
- Obtain account credentials with required roles assigned
- Determine your API endpoint

To subscribe to an Oracle Cloud service

To access Oracle Cloud My Services API, you must request a trial or paid subscription to an Oracle Cloud service.

To obtain account credentials and role assignments

Ask your account administrator for the following items to access Oracle Cloud My Services API:

- Account credentials:
  - User name and password
  - Identity domain ID

An identity domain ID can be either the *IDCS GUID* that identifies the identity domain for the users within Identity Cloud Service (IDCS) or the *Identity Domain name* for a traditional Cloud Account.

- Required roles assigned to above user name

To determine your API endpoint

Insert the identity domain ID provided by the account administrator (*<domain>*) between `/itas/` and `/myservices/`.

Example:

```
https://itra.oraclecloud.com/itas/<domain>/myservices/api/v1/serviceEntitlements
```

Creating Exadata Instances

This section covers how to create a basic Exadata instance, an instance with custom IP network configuration, and an instance with multi-VM support.

To create a basic Exadata instance

Post a request with the required payload to create a new instance for a given service entitlement (Exadata in our case).

In the following example, *<domain>* is the identity domain ID.

```
POST /itas/<domain>/myservices/api/v1/operations
{
  "operationItems": [
    {
      "attributes": [
        {
          "name": "requestPayload.name",
          "value": "newinstanceName"
        },
        {
          "name": "requestPayload.serviceEntitlementId",
```

```
        "value": "500073421"
      },
      {
        "name": "requestPayload.size",
        "value": "CUSTOM"
      },
      {
        "name": "requestPayload.serviceType",
        "value": "Exadata"
      },
      {
        "name": "requestPayload.adminUserName",
        "value": "john.smith@example.com"
      },
      {
        "name": "requestPayload.adminEmail",
        "value": "john.smith@example.com"
      },
      {
        "name": "requestPayload.adminFirstName",
        "value": "John"
      },
      {
        "name": "requestPayload.adminLastName",
        "value": "Smith"
      },
      {
        "name": "requestPayload.invokerAdminUserName",
        "value": "john.smith@example.com"
      },
      {
        "name": "requestPayload.invokerAdminEmail",
        "value": "john.smith@example.com"
      },
      {
        "name": "requestPayload.invokerAdminFirstName",
        "value": "John"
      },
      {
        "name": "requestPayload.invokerAdminLastName",
        "value": "Smith"
```

```
        },
        {
          "name": "requestPayload.customAttributes.ExaUnitName",
          "value": "systemname"
        },
        {
          "name": "requestPayload.customAttributes.CreateSparse",
          "value": "N"
        },
        {
          "name": "requestPayload.customAttributes.BackupToDisk",
          "value": "N"
        },
        {
          "name": "requestPayload.customAttributes.isBYOL",
          "value": "N"
        },
        {
          "name": "requestPayload.customAttributes.PickRackSize",
          "value": "Quarter Rack"
        },
        {
          "name": "requestPayload.customAttributes.SELECTED_DC_ID",
          "value": "US001"
        }
      ],
        "operationItemDefinition": {
        "id": "CIM-Exadata-CUSTOM-PRODUCTION-CREATE"
      }
    }
  ]
}
```

ATTRIBUTES

Name	Description
requestPayload.name	Required: Yes Type: String Name of the Exadata instance. This name: • Must not exceed 25 characters. • Must start with a letter. • Must contain only lower case letters and numbers. • Must not contain spaces or any other special characters. • Must be unique within the identity domain.
requestPayload. serviceEntitlementId	Required: Yes Type: String Service Entitlement for the Exadata instance. See "Exadata Service Entitlement discovery". Note that any "cesi-" or "sub-" prefix should not be included.
requestPayload. customAttributes. ExaUnitName	Required: Yes Type: String A name for your Exadata Database Machine environment. This name is also used as the cluster name for the Oracle Grid Infrastructure installation.

Name	Description
requestPayload. customAttributes. CreateSparse	Required: Yes Type: String "Y" to create a disk group that is based on sparse grid disks, else "N". You must select this option to enable Exadata Cloud Service snapshots. Exadata snapshots enable space-efficient clones of Oracle databases that can be created and destroyed very quickly and easily.
requestPayload. customAttributes. BackupToDisk	Required: Yes Type: String "Y" to use "Database backups on Exadata Storage", else "N". This option configures the Exadata storage to enable local database backups on Exadata storage.
requestPayload. customAttributes. isBYOL	Required: Yes Type: String "Y" to indicate that the Exadata Cloud Service instance uses Oracle Database licenses that are provided by you rather than licenses that are provided are part of the service subscription, else "N". This option only affects the billing that is associated with the service instance. It has no effect on the technical configuration of the Exadata Cloud Service instance.

Name	Description
requestPayload. customAttributes. PickRackSize	Required: Yes Type: String Specify the rack configuration for your service instance. Exact allowed values depend on your purchase. Typical values are like "Full Rack", "Half Rack", "Quarter Rack" or "Eighth Rack".
requestPayload. customAttributes. SELECTED_DC_ID	Required: Yes Type: String Data center that will host your Exadata Cloud Service instance. See "Exadata Service Entitlement discovery" to obtain the Eligible Data Center IDs.

To create an Exadata instance with custom IP network configuration

Post a request with the attributes ClientNetwork and BackupNetwork as part of the payload. The following example includes these optional attributes as well as required attributes.

In the following example, *<domain>* is the identity domain ID.

```
POST /itas/<domain>/myservices/api/v1/operations
{
  "operationItems": [
    {
      "attributes": [
        {
          "name": "requestPayload.name",
          "value": "newinstanceName"
        },
        {
          "name": "requestPayload.serviceEntitlementId",
          "value": "500073421"
        },
```

```
        {
          "name": "requestPayload.size",
          "value": "CUSTOM"
        },
        {
          "name": "requestPayload.serviceType",
          "value": "Exadata"
        },
        {
          "name": "requestPayload.adminUserName",
          "value": "john.smith@example.com"
        },
        {
          "name": "requestPayload.adminEmail",
          "value": "john.smith@example.com"
        },
        {
          "name": "requestPayload.adminFirstName",
          "value": "John"
        },
        {
          "name": "requestPayload.adminLastName",
          "value": "Smith"
        },
        {
          "name": "requestPayload.invokerAdminUserName",
          "value": "john.smith@example.com"
        },
        {
          "name": "requestPayload.invokerAdminEmail",
          "value": "john.smith@example.com"
        },
        {
          "name": "requestPayload.invokerAdminFirstName",
          "value": "John"
        },
        {
          "name": "requestPayload.invokerAdminLastName",
          "value": "Smith"
        },
        {
```

```
          "name": "requestPayload.customAttributes.ExaUnitName",
          "value": "systemname"
        },
        {
          "name": "requestPayload.customAttributes.CreateSparse",
          "value": "N"
        },
        {
          "name": "requestPayload.customAttributes.BackupToDisk",
          "value": "N"
        },
        {
          "name": "requestPayload.customAttributes.isBYOL",
          "value": "N"
        },
        {
          "name": "requestPayload.customAttributes.PickRackSize",
          "value": "Quarter Rack"
        },
        {
          "name": "requestPayload.customAttributes.SELECTED_DC_ID",
          "value": "US001"
        }
        {
          "name": "requestPayload.customAttributes.ClientNetwork",
          "value": "/root/root/1/ipnetwork1"
        },
        {
          "name": "requestPayload.customAttributes.BackupNetwork",
          "value": "/root/root/1/ipnetwork2"
        }
      ],
        "operationItemDefinition": {
        "id": "CIM-Exadata-CUSTOM-PRODUCTION-CREATE"
      }
    }
  ]
}
```

ATTRIBUTES

Name	Description
requestPayload. customAttributes. ClientNetwork	Required: Yes Type: Url IP network definitions for the network that is primarily used for client access to the database servers. Applications typically access databases on Exadata Cloud Service through this network using Oracle Net Services in conjunction with Single Client Access Name (SCAN) and Oracle RAC Virtual IP (VIP) interfaces.
requestPayload. customAttributes. BackupNetwork	Required: Yes Type: Url IP network definitions for the network that is typically used to access the database servers for various purposes, including backups and bulk data transfers.

To create an Exadata instance with multi-VM support

If your Exadata system environment is enabled to support multiple virtual machine (VM) clusters, then you can define up to eight clusters and specify how the overall Exadata system resources are allocated to them.

In a configuration with multiple VM clusters, each VM cluster is allocated a dedicated portion of the overall Exadata system resources, with no over-provisioning or resource sharing. On the compute nodes, a separate VM is defined for each VM cluster, and each VM is allocated a dedicated portion of the available compute node CPU, memory, and local disk resources. Each VM cluster is also allocated a dedicated portion of the overall Exadata storage.

Post a request with the attributes EXAUNIT_ALLOCATIONS and MULTIVM_ENABLED as part of the payload. The following example includes these optional attributes as well as required attributes.

In the following example, *<domain>* is the identity domain ID and *<base64_encoded_string>* is a base64 encoding of the payload following the example.

Example payload for request:

```
POST /itas/<domain>/myservices/api/v1/operations
{
  "operationItems": [
    {
      "attributes": [
        {
          "name": "requestPayload.name",
          "value": "newinstanceName"
        },
        {
          "name": "requestPayload.serviceEntitlementId",
          "value": "500073421"
        },
        {
          "name": "requestPayload.size",
          "value": "CUSTOM"
        },
        {
          "name": "requestPayload.serviceType",
          "value": "Exadata"
        },
        {
          "name": "requestPayload.adminUserName",
          "value": "john.smith@example.com"
        },
        {
          "name": "requestPayload.adminEmail",
          "value": "john.smith@example.com"
        },
        {
          "name": "requestPayload.adminFirstName",
          "value": "John"
```

```
    },
    {
      "name": "requestPayload.adminLastName",
      "value": "Smith"
    },
    {
      "name": "requestPayload.invokerAdminUserName",
      "value": "john.smith@example.com"
    },
    {
      "name": "requestPayload.invokerAdminEmail",
      "value": "john.smith@example.com"
    },
    {
      "name": "requestPayload.invokerAdminFirstName",
      "value": "John"
    },
    {
      "name": "requestPayload.invokerAdminLastName",
      "value": "Smith"
    },
    {
      "name": "requestPayload.customAttributes.ExaUnitName",
      "value": "systemname"
    },
    {
      "name": "requestPayload.customAttributes.CreateSparse",
      "value": "N"
    },
    {
      "name": "requestPayload.customAttributes.BackupToDisk",
      "value": "N"
    },
    {
      "name": "requestPayload.customAttributes.isBYOL",
      "value": "N"
    },
    {
      "name": "requestPayload.customAttributes.PickRackSize",
      "value": "Quarter Rack"
    },
```

```
        {
          "name": "requestPayload.customAttributes.SELECTED_DC_ID",
          "value": "US001"
        }
        {
          "name": "requestPayload.customAttributes.EXAUNIT_ALLOCATIONS",
          "value": "<base64_encoded_string>"
        },
        {
          "name": "requestPayload.customAttributes.MULTIVM_ENABLED",
          "value": "true"
        }
      ],
        "operationItemDefinition": {
        "id": "CIM-Exadata-CUSTOM-PRODUCTION-CREATE"
      }
    }
  ]
}
```

Payload for *<base64_encoded_string>*:

```
{
  ExaunitProperties: [
    {name:requestId, value:27ac0ee3-0c72-4493-b02b-40038f07d2a0},
    {name:Operation, value:AddCluster},
    {name:TotalNumOfCoresForCluster, value:4},
    {name:TotalMemoryInGb, value:30},
    {name:StorageInTb, value:3},
    {name:OracleHomeDiskSizeInGb, value:60},
    {name:ClientNetwork, value:/root/root/1/ipnetwork1},  // Only if Higgs is also required
    {name:BackupNetwork, value:/root/root/1/ipnetwork2},  // Only if Higgs is also required
    {name:ExaUnitName, value:systemname},
    {name:CreateSparse, value:N},
    {name:BackupToDisk, value:N}
  ]
}
```

ATTRIBUTES

Name	Description
requestId	Required: Optional Type: String Unique UUID
TotalNumOfCores ForCluster	Required: Yes Type: String The number of CPU cores that are allocated to the VM cluster. This is the total number of CPU cores that are allocated evenly across all of the compute nodes in the VM cluster. Must be a multiple of numComputes as returned by a call to ecra/endpoint/clustershapes.
TotalMemoryInGb	Required: Yes Type: String The amount of memory (in GB) that is allocated to the VM cluster. This is the total amount of memory that is allocated evenly across all of the compute nodes in the VM cluster. Must be a multiple of numComputes as returned by a call to ecra/endpoint/clustershapes.

Name	Description
StorageInTb	Required: Yes Type: String The total amount of Exadata storage (in TB) that is allocated to the VM cluster. This storage is allocated evenly from all of the Exadata Storage Servers.
OracleHomeDiskSize InGb	Required: Yes Type: String The amount of local disk storage (in GB) that is allocated to each database server in the first VM cluster.

Modifying Exadata Instances

This section covers how to add a cluster to an existing instance, reshape a cluster, and delete a cluster.

To add a cluster to an existing instance

Post a request with the operationItemDefinition of CIM-Exadata-CUSTOM-PRODUCTION-UPDATE and a base64 encoding of a payload that includes the Operation value of AddCluster.

In the following example, *<domain>* is the identity domain ID, *<instanceId>* and *<serviceEntitlementId>* are returned from iTAS serviceInstances, and *<base64_encoded_string>* is a base64 encoding of the payload following the example.

Example payload for request:

```
POST /itas/<domain>/myservices/api/v1/operations HTTP/1.1
{
  "operationItems": [
    {
      "attributes": [
```

```
        {
          "name": "instanceId",
          "value": "<instanceId>"
        },
        {
          "name": "requestPayload.serviceEntitlementId",
          "value": "<serviceEntitlementId>"
        },
        {
          "name": "requestPayload.size",
          "value": "CUSTOM"
        },
        {
          "name": "requestPayload.serviceType",
          "value": "Exadata"
        },
        {
          "name": "requestPayload.customAttributes.EXAUNIT_ALLOCATIONS",
          "value": "<base64_encoded_string>"
        },
        {
          "name": "requestPayload.customAttributes. MULTIVM_ENABLED",
          "value": "true"
        }
      ],
        "operationItemDefinition": {
        "id": "CIM-Exadata-CUSTOM-PRODUCTION-UPDATE"
      }
    }
  ]
}
```

Payload for *<base64_encoded_string>*:

```
{
  ExaunitProperties: [
    {name:requestId, value:27ac0ee3-0c72-4493-b02b-40038f07d2a0},
    {name:Operation, value:AddCluster},
    {name:TotalNumOfCoresForCluster, value:4},
    {name:TotalMemoryInGb, value:30},
    {name:StorageInTb, value:3},
    {name:OracleHomeDiskSizeInGb, value:60},
```

```
    {name:ClientNetwork, value:/root/root/1/ipnetwork1},  // Only if Higgs is also required
    {name:BackupNetwork, value:/root/root/1/ipnetwork2},  // Only if Higgs is also required
    {name:ExaUnitName, value:Cluster2},
    {name:CreateSparse, value:N},
    {name:BackupToDisk, value:N}
  ]
}
```

To reshape a cluster

Post a request with the operationItemDefinition of CIM-Exadata-CUSTOM-PRODUCTION-UPDATE and a base64 encoding of a payload that includes the Operation value of ReshapeCluster.

In the following example, *<domain>* is the identity domain ID and *<base64_encoded_string>* is a base64 encoding of the payload following the example.

Example payload for request:

```
POST /itas/<domain>/myservices/api/v1/operations HTTP/1.1
{
  "operationItems": [
    {
      "attributes": [
        {
          "name": "instanceId",
          "value": "500076173"
        },
        {
          "name": "requestPayload.serviceEntitlementId",
          "value": "500073421"
        },
        {
          "name": "requestPayload.size",
          "value": "CUSTOM"
        },
        {
          "name": "requestPayload.serviceType",
          "value": "Exadata"
        },
```

```
        {
          "name": "requestPayload.customAttributes.EXAUNIT_ALLOCATIONS",
          "value": "<base64_encoded_string>"
        },
        {
          "name": "requestPayload.customAttributes. MULTIVM_ENABLED",
          "value": "true"
        }
      ],
        "operationItemDefinition": {
        "id": "CIM-Exadata-CUSTOM-PRODUCTION-UPDATE"
      }
    }
  ]
}
```

Payload for *<base64_encoded_string>*:

```
{
  ExaunitProperties: [
    {name:requestId, value:27ac0ee3-0c72-4493-b02b-40038f07d2a0},
       {name:ExaunitID, value:1},              // From ecra/endpoint/exaservice/{serviceInstance}/resourceinfo
    {name:Operation, value:ReshapeCluster},
    {name:TotalNumOfCoresForCluster, value:10},
    {name:TotalMemoryInGb, value:10},
    {name:StorageInTb, value:4},
    {name:OhomePartitionInGB, value:100},
    {name:ClientNetwork, value:/root/root/1/ipnetwork1},  // Only if Higgs is also required
    {name:BackupNetwork, value:/root/root/1/ipnetwork2}   // Only if Higgs is also required
  ]
}
```

Important

- Only one attribute can be modified per Reshape request. The payload should contain only the modified attribute. Example:

```
{ExaunitProperties:
[{name:Operation,value:ReshapeCluster},
{name:ExaunitID,value:5},
{name:TotalNumOfCoresForCluster,value:6}]}
```

- When doing a Reshape with the `OracleHomeDiskSizeInGb` attribute, use the name `OhomePartitionInGB`.
- The value for `TotalNumOfCoresForCluster` must be a multiple of `numComputes` as returned by a call to `ecra/endpoint/clustershapes`.
- The value for `TotalMemoryInGb` must be a multiple of `numComputes` as returned by a call to `ecra/endpoint/clustershapes`.

To delete a cluster

Post a request with the operationItemDefinition of CIM-Exadata-CUSTOM-PRODUCTION-UPDATE and a base64 encoding of a payload that includes the Operation value of DeleteCluster.

In the following example, *<domain>* is the identity domain ID and *<base64_encoded_string>* is a base64 encoding of the payload following the example.

Example payload for request:

```
POST /itas/<domain>/myservices/api/v1/operations HTTP/1.1
{
```

```
  "operationItems": [
    {
      "attributes": [
        {
          "name": "instanceId",
          "value": "500076173"
        },
        {
          "name": "requestPayload.serviceEntitlementId",
          "value": "500073421"
        },
        {
          "name": "requestPayload.size",
          "value": "CUSTOM"
        },
        {
          "name": "requestPayload.serviceType",
          "value": "Exadata"
        },
        {
          "name": "requestPayload.customAttributes.EXAUNIT_ALLOCATIONS",
          "value": "<base64_encoded_string>"
        },
        {
          "name": "requestPayload.customAttributes. MULTIVM_ENABLED",
          "value": "true"
        }
      ],
        "operationItemDefinition": {
        "id": "CIM-Exadata-CUSTOM-PRODUCTION-UPDATE"
      }
    }
  ]
}
```

Payload for *<base64_encoded_string>*:

```
{
  ExaunitProperties: [
    {name:requestId, value:27ac0ee3-0c72-4493-b02b-40038f07d202},  // Optional
       {name:ExaunitID, value:2},
    {name:Operation, value:DeleteCluster}
```

```
  ]
}
```

Deleting Exadata Instances

This section covers how to delete Exadata instances.

Important

Delete all existing multi-VM clusters before deleting the Exadata instance. Following this guidance prevents the instance ending up in an invalid state.

To delete an instance

Post a request with the operationItemDefinition of CIM-Exadata-CUSTOM-PRODUCTION-DELETE.

In the following example, *<domain>* is the identity domain ID.

Example payload for request:

```
POST /itas/<domain>/myservices/api/v1/operations HTTP/1.1
{
  "operationItems": [
    {
      "attributes": [
        {
          "name": "instanceId",
          "value": "500076173"
        },
        {
          "name": "requestPayload.serviceEntitlementId",
          "value": "500073421"
        },
        {
          "name": "requestPayload.serviceType",
```

```
          "value": "Exadata"
        }
      ],
        "operationItemDefinition": {
        "id": "CIM-Exadata-CUSTOM-PRODUCTION-DELETE"
      }
    }
  ]
}
```

Discovering Entitlements and Instances

This section describes how to discover service entitlements and service instances.

To discover service entitlements

Send the following request:

```
GET /itas/<domain>/myservices/api/v1/serviceEntitlements?serviceDefinitionNames=Exadata
```

Example payload returned for this request:

```
{
    "items": [
      {
        "id": "cesi-585927251",               // Unique ServiceEntitlementId
        "serviceDefinition": {
          "canonicalLink": "/itas/a517289/myservices/api/v1/serviceDefinitions/502579309",
          "id": "502579309",
          "name": "Exadata"                 // The customer is entitled to use the Exadata Service
        },
        "status": "ACTIVE",
        ...
        "canonicalLink": "/itas/a517289/myservices/api/v1/serviceInstances/csi-585928949"
      }
    ...                                              // More Service Entitlements could be displayed
    ],
  "canonicalLink": "/itas/<domain>/myservices/api/v1/serviceEntitlements",
  "hasMore": false,
  "limit": 25,
```

```
  "offset": 0
}
```

Eligible Data Centers:

Use:

```
/itas/<domain>/myservices/api/v1/serviceEntitlements/
{ServiceEntitlementId}?expands=serviceInstancesEligibleDataCenters
```

where `{ServiceEntitlementId}` is a service entitlement ID such as `cesi-500074601`. This will provide additional information such as:

```
  "serviceInstancesEligibleDataCenters": [
    {
      "id": "US001"
    }
  ],
```

To discover service instances

Send the following request:

```
GET /<domain>/myservices/api/v1/serviceInstances?serviceDefinitionNames=Exadata
```

Example payload returned for this request:

```
{
    "items": [
      {
        "id": "csi-585928949",               // Unique ServiceInstanceId
        "serviceEntitlement": {
          "id": "cesi-585927251",          // Related ServiceEntitlementId
          "canonicalLink": "/itas/a517289/myservices/api/v1/serviceEntitlements/cesi-585927251"
        },
        "serviceDefinition": {
          "canonicalLink": "/itas/a517289/myservices/api/v1/serviceDefinitions/502579309",
          "id": "502579309",
          "name": "Exadata"                 // The customer is entitled to use the Exadata Service
        },
        ...
        "canonicalLink": "/itas/a517289/myservices/api/v1/serviceInstances/csi-585928949"
```

```
      }
    ...                                                  // More Service Entitlements could be displayed
    ],
  "canonicalLink": "/itas/<domain>/myservices/api/v1/serviceEntitlements",
  "hasMore": false,
  "limit": 25,
  "offset": 0
}
```

Using Access Token Authorization with My Services API

Important

The My Services dashboard and APIs are deprecated.

This topic explains how to set up and use access token authorization with the Oracle Cloud My Services API. Access token authorization allows a developer to access programmatic endpoints (APIs) to obtain some information (for example, entitlements, instances, or metering data) for your cloud account.

About Access Tokens

An access token contains the information required to allow a developer to access information on your cloud account. A developer presents the token when making API calls. The allowed actions and endpoints depend on the scopes (permissions) that you select when you generate the token. An access token is valid for about an hour.

A refresh token allows the developer to generate a new access token without having to contact an administrator. A refresh token is valid for about one year.

Process Overview

Setup steps for the Administrator:

1. Create an Identity Cloud Service client application with the specific privileges you want to grant to developers.
2. Generate an access token that contains the required privileges for the intended developer.
3. Provide the access token and required information to the developer.
4. Configure Identity Cloud Service for access token validation.

Steps for developer to use the token:

1. Issue requests against My Services API endpoints. Include the access token for the authorization parameter.
2. When the access token expires, refresh the access token without administrator intervention until the privilege is terminated.

Administrator Tasks to Set Up Token Validation

Perform the following tasks to enable developer access with an access token:

Create the IDCS client application

1. Sign in to Identity Cloud Services as an Administrator and go to the administration console. See How to Access Oracle Identity Cloud Service if you need help signing in.
2. Click the **Applications** tile. A list of the applications is displayed.
3. Click **+ Add** to create a new application.
4. Click **Trusted Application** as the type of application.
5. In the **App Details** section, enter a **Name** and **Description** and then click **Next**.
6. In the **Client** section:

a. Select **Configure this application as a client now**.

b. Under **Authorization**, for **Allowed grant types**, select the following options:

- **JWT Assertion**
- **Refresh Token**

7. Under **Accessing APIs from Other Applications**, from the **Trust Scope** list, select **Allowed scopes**.
8. Under **Allowed Scopes** click **+ Add**.
9. In the **Add Scope** dialog, click the arrow next to **CloudPortalResourceApp** in the list of App.
10. Select the box next to each authorization that you might want to give the developers to whom you will provide an Access Token. (The permissions are assigned in another step.)
11. Click **Add** to close the dialog. Your selections are displayed.
12. Click **Next**.
13. In the **Resources** section, accept the default and click **Next**.
14. In the **Web Tier Policy** section, accept the default and click **Next**.
15. In the **Authorization** section, click **Finish**.
    The **Application Added** notification displays the new Client ID and Client Secret for the application.

Important

Copy and store the Client ID and Client Secret in a safe place and then click **Close**. The Client ID and Client Secret are credentials that are specific to the application that you just created. You will need these credentials later.

16. To complete the creation process, click **Activate** at the top of the page.

Generate an access token

1. Navigate to the IDCS application that you created in the preceding task and select the **Details** tab.
2. Click **Generate Access Token**.
3. On the **Generate Token** dialog, select **Customized Scopes**, then select **Invokes Other APIs**.
4. Select the scopes that you want to give to the developer who will receive this access token.

Note

Oracle recommends that you provide only the minimum required privileges.

5. Select **Include Refresh Token**.
6. Click **Download Token**. Your browser will prompt you to download a token file (.tok). The token file contains an access token and a refresh token.
7. Provide this file to the developer.

Send the access information to a developer

To call API endpoints, the developer needs:

- A token file that you generated.
- The Client ID and Client Secret for the IDCS application used to generate the token file. The Client ID and Secret are required for the developer to generate a new access token from the refresh token.

- The endpoints for the APIs.
    - End points related to the itas:myservices scopes are:
      `https://itra.oraclecloud.com/itas/<tenant-IDCS-ID>/myservices/api/v1`
    - End points related to the itas:metering scopes are:
      `https://itra.oraclecloud.com/metering/api/v1`

Make sure that you send the above information in a secure way. If you think that this information has been compromised, see Revoking a Developer's Ability to Refresh Access Tokens.

Configure Identity Cloud Service for access token validation

To allow clients to access the tenant signing certificate without logging in to Oracle Identity Cloud Service:

1. Sign in to the Oracle Identity Cloud Services admin console. See How to Access Oracle Identity Cloud Service if you need help signing in.
2. Open the navigation menu. Under **Settings** select **Default Settings**.
3. Set the **Access Signing Certificate** toggle button to on.

Using the Access Token

The token file has a .tok extension. The file contains the access token and the refresh token. The content looks like:

```
{"app_access_token":"eyJ4N...aabb...CpNwA","refresh_token":"AQID...9NCA="}
```

To use the token with the My Services API:

1. Open the token file.
2. Issue a request to a valid endpoint, inserting the access token for the `Authorization` parameter.
   For example:

```
curl -X GET  https://itra.oraclecloud.com/itas/<tenant-IDCS-
ID>/myservices/api/v1/serviceEntitlements   -H 'Authorization: Bearer eyJ4N...aabb...CpNwA'
```

REQUESTING A NEW ACCESS TOKEN FROM A REFRESH TOKEN

An access token is valid for about one hour. When the token is no longer valid you will get a 401 response code and an Error Message ("errorMessage") value containing "Expired".

You can generate a new short-lived access token from the refresh token. You'll need the Client ID and Client Secret to generate the new token. You can only generate tokens with the same or lower access (scopes) as your original token.

Example using the curl command:

```
curl -i -H 'Authorization: Basic <base64Encoded clientid:secret>' -H 'Content-Type: application/x-www-
form-urlencoded;charset=UTF-8' --request POST https://<tenant-IDCS-ID>/oauth2/v1/token -d 'grant_
type=refresh_token&refresh_token=<refresh-token>'
```

Using the sample token file from the previous section, the value for *<refresh-token>* would be `AQID...9NCA=`.

Sample response:

```
{ "access_token": "eyJraWQiO....2nqA", "token_type": "Bearer", "expires_in": 3600, "refresh_token":
"AQIDBAUn…VkxNCB7djF9NCA=" }
```

Note

When a developer generates a new access token and refresh token, the previous refresh token becomes invalid.

Revoking a Developer's Ability to Refresh Access Tokens

If you need to revoke a developer's ability to refresh access tokens, you can either invalidate the existing refresh token by generating a new Client Secret for the token; or, you can temporarily revoke access by deactivating the application.

> **Important**
>
> Taking either of these actions will terminate or suspend the ability of all developers using the current Client Secret or application. When generating tokens for multiple developers, consider creating more than one IDCS application to isolate developers from each other.

To terminate a developer's ability to refresh their access token

1. Sign in to Identity Cloud Services as an Administrator and go to the administration console. See How to Access Oracle Identity Cloud Service if you need help signing in.
2. Click the **Applications** tile. A list of the applications is displayed.
3. Click the application used to generate the token to view its details.
4. Click **Configuration**.
5. Under **General Information**, next to **Client Secret**, click **Regenerate** to generate a new Client Secret.

To restore the ability for the developer to generate an access token from a refresh token, generate a new access token. Then provide the token along with the new Client Secret to the developer.

To temporarily suspend a developer's ability to refresh their access token

1. Sign in to Identity Cloud Services as an Administrator and go to the administration console. See How to Access Oracle Identity Cloud Service if you need help signing in.
2. Click the **Applications** tile. A list of the applications is displayed.
3. Click the application used to generate the token to view its details.
4. In the upper right corner of the page, click **Deactivate**.
5. At the prompt, click **Deactivate Application**.

To re-enable developers to use the same tokens, click **Activate**.

CHAPTER 5 Archive Storage

This chapter explains how to upload, manage, and access data using Archive Storage.

Overview of Archive Storage

Oracle Cloud Infrastructure offers two distinct storage class tiers to address the need for both performant, frequently accessed "hot" storage, and less frequently accessed "cold" storage. Storage tiers help you maximize performance where appropriate and minimize costs where possible.

- Use **Archive Storage** for data to which you seldom or rarely access, but that must be retained and preserved for long periods of time. The cost efficiency of the Archive Storage offsets the long lead time required to access the data.
- Use **Object Storage** for data to which you need fast, immediate, and frequent access. Data accessibility and performance justifies a higher price point to store data in the Object Storage. For more information, see Overview of Object Storage.

About Archive Storage

Archive Storage is ideal for storing data that is accessed infrequently and requires long retention periods. Archive Storage is more cost effective than Object Storage for preserving cold data for:

- Compliance and audit mandates
- Retroactively analyzing log data to determine usage pattern or debug problems
- Historical or infrequently accessed content repository data
- Application generated data that requires archival for future analysis or legal purposes

Unlike Object Storage, Archive Storage data retrieval is **not** instantaneous.

Archive Storage is Always Free eligible. For more information about Always Free resources, including additional capabilities and limitations, see Oracle Cloud Infrastructure's Free Tier.

Using Archive Storage

Important

You interact with the data stored in the Archive Storage using the same resources and management interfaces that you use for data stored in Object Storage.

The following summarizes the Object Storage resources you use to store and manage Archive Storage data:

Buckets

Buckets are logical containers for storing objects. A bucket is associated with a single compartment that has policies that determine what actions a user can perform on a bucket and on all the objects in the bucket.

You decide which storage tier (Archive Storage or standard Object Storage) is appropriate for your data when you initially create the bucket container for your data. The storage tier is expressed as a property of the bucket. A bucket's storage tier property sets the initial storage tier of objects added to the bucket. However, objects placed in standard tier buckets can be archived automatically by Object Storage (while remaining in the standard tier bucket) if they meet the criteria of an object lifecycle policy rule in effect for the bucket.

Once set, you cannot change the storage tier property for a bucket:

- An existing Object Storage bucket cannot be downgraded to an Archive Storage bucket.
- An Archive Storage bucket cannot be upgraded to an Object Storage bucket.

In addition to the inability to change the storage tier designation of a bucket, there are other reasons why storage tier selection for buckets requires careful consideration:

- The minimum retention requirement for Archive Storage is 90 days. If you delete objects from Archive Storage before the minimum retention requirements are met, you

are charged a deletion penalty. The deletion penalty is the prorated cost of storing the data for the full 90 days.

- While Archive Storage is more cost effective than Object Storage for cold storage, understand that when you restore objects, you are returning those objects to Object Storage. You are billed for that storage service class while the objects reside in that tier.

You can use object lifecycle policy rules to automatically delete objects in an Archive Storage bucket based on the age of the object.

Important

You *cannot* use object lifecycle policy rules to automatically restore archived objects to the regular Object Storage tier. See Restoring and Downloading Objects for information on restoring objects.

See Managing Buckets for detailed instructions on creating an Archive Storage bucket.

Objects

Any type of data, regardless of content type, is stored as an object. The object is composed of the object itself and metadata about the object. Each object is stored in a bucket.

You upload objects to an Archive Storage bucket the same way you upload objects to a standard Object Storage bucket. The difference is that when you upload an object to an Archive Storage bucket, the object is immediately archived. You must first restore the object before you can download it.

Archived objects are displayed in the object listing of a bucket. You can also display the details of each object.

See Managing Objects for detailed instructions on uploading objects to an Archive Storage bucket.

Restoring and Downloading Objects

To download an object from Archive Storage, you must first restore the object. Restoration takes about four hours from the time an Archive Storage restore request is made, to the time the first byte of data is retrieved. The retrieval time metric is measured by Time To First Byte (TTFB). How long the full restoration takes, depends on the size of the object. You can determine the status of the restoration by looking at the object **Details**. Once the status shows as **Restored**, you can then download the object.

After an object is restored, you have a window of time to download the object. By default, you have 24 hours to download an object, but you can alternatively specify a time from 1 to 240 hours. You can find out how much of the download time is remaining by looking at **Available for Download** in object **Details**. After the allotted download time expires, the object returns to Archive Storage. You always have access to the metadata for an object, regardless of whether the object is in an archived or restored state.

See Managing Objects for detailed instructions on restoring, checking status of, and downloading Archive Storage objects.

Ways to Access Archive Storage

Archive Storage and Object Storage share the *same* management interfaces:

- The Console is an easy-to-use, browser-based interface. To access Archive Storage in the console, do the following:
    - Sign in to the Console.
    - Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**. A list of the buckets in the compartment you're viewing is displayed. If you don’t see the one you're looking for, verify that you’re viewing the correct compartment (select from the list on the left side of the page).
    - Click the name of the Archive Storage tier bucket you want to manage.
- The command line interface (CLI) provides both quick access and full functionality without the need for programming. For more information, see Command Line Interface (CLI).

The syntax for the CLI commands include specifying a service. You will use the Object Storage service designation: `oci os` to manage Archive Storage using the CLI.

- The REST API provides the most functionality, but requires programming expertise. API Reference and Endpoints provides endpoint details and links to the available API reference documents. For general information about using the API, see REST APIs. Archive Storage is accessible with the following APIs:
  - Object Storage Service API
  - Amazon S3 Compatibility API
  - Swift API (for use with Oracle RMAN)
- Oracle Cloud Infrastructure provides SDKs that interact with Archive Storage and Object Storage without you having to create a framework. For general information about using the SDKs, see Software Development Kits and Command Line Interface.

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API). IAM also manages user credentials for things like API signing keys, auth tokens, and customer secret keys for Amazon S3 Compatibility API. See User Credentials for details.

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies. For specific details about writing policies for each of the different services, see the Policy Reference. For specific details about writing policies for Archive Storage, see Details for Object Storage, Archive Storage, and Data Transfer.

If you're a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

For administrators:

- The policy Let Object Storage admins manage buckets and objects lets the specified group do everything with buckets and objects.
- Users that need to restore archived objects require the OBJECT_RESTORE permission.

WORM Compliance

You can achieve WORM compliance with Archive Storage by applying IAM policy permissions so that data once written, cannot be overwritten.

For administrators: There is not a direct way to disallow OBJECT_OVERWRITE. To achieve WORM compliance, you must specifically grant groups OBJECT_CREATE, OBJECT_READ, and OBJECT_INSPECT permissions to keep the data from being overwritten. For example, you can allow groups to inspect objects using a policy like the following:

```
Allow group <group_name> to inspect in compartment <compartment_name>
```

See Details for Object Storage, Archive Storage, and Data Transfer for more information. If you are new to policies, see Getting Started with Policies and Common Policies.

Limits on Archive Storage Resources

See Service Limits for a list of applicable limits and instructions for requesting a limit increase.

Additional limits include:

- Number of namespaces per root compartment: 1
- Maximum object size: 10 TiB
- Maximum object part size in a multipart upload: 50 GiB
- Maximum number of parts in a multipart upload: 10,000
- Maximum size of object metadata: 2 K

CHAPTER 6 Audit

This chapter explains how to work with audit logs.

Overview of Audit

The Oracle Cloud Infrastructure Audit service automatically records calls to all supported Oracle Cloud Infrastructure public application programming interface (API) endpoints as log events. Currently, all services support logging by Audit. Object Storage service supports logging for bucket-related events, but not for object-related events. Log events recorded by the Audit service include API calls made by the Oracle Cloud Infrastructure Console, Command Line Interface (CLI), Software Development Kits (SDK), your own custom clients, or other Oracle Cloud Infrastructure services. Information in the logs includes the following:

- Time the API activity occurred
- Source of the activity
- Target of the activity
- Type of action
- Type of response

Each log event includes a header ID, target resources, timestamp of the recorded event, request parameters, and response parameters. You can view events logged by the Audit service by using the Console, API, or the SDK for Java. Data from events can be used to perform diagnostics, track resource usage, monitor compliance, and collect security-related events.

Version 2 Audit Log Schema

On October 8, 2019, Oracle introduced the Audit version 2 schema, which provides the following benefits:

- Captures state changes of resources
- Better tracking of long running APIs
- Provides troubleshooting information in logs

The new schema is being implemented over time. Oracle continues to provide Audit logs in the version 1 format, but you cannot access version 1 format logs from the Console. The Console displays only the version 2 format logs. However, not all resources are emitting logs using the version 2 schema. For those services that are not emitting in the version 2 format, Oracle converts version 1 logs to version 2 logs, leaving fields blank if information for the version 2 schema cannot be determined.

Ways to Access Oracle Cloud Infrastructure

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. For a list of available SDKs, see Software Development Kits and Command Line Interface.

To access the Console, you must use a supported browser. Oracle Cloud Infrastructure supports the latest desktop versions of Google Chrome, Microsoft Edge, Internet Explorer 11, Safari, Firefox, and Firefox ESR. Note that private browsing mode is not supported for Firefox, Internet Explorer, or Edge. Mobile browsers are not supported.

For general information about using the API, see REST APIs.

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see

Getting Started with Policies. For specific details about writing policies for each of the different services, see Policy Reference.

If you're a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

Administrators: For an example of policy that gives groups access to audit logs, see Required IAM Policy. To modify the Audit log retention period, you must be a member of the Administrators group. See The Administrators Group and Policy.

Contents of an Audit Log Event

The following explains the contents of an Audit log event. Every audit log event includes two main parts:

- Envelopes that act as a container for all event messages
- Payloads that contain data from the resource emitting the event message

Resource Identifiers

Most types of Oracle Cloud Infrastructure resources have a unique, Oracle-assigned identifier called an Oracle Cloud ID (OCID). For information about the OCID format and other ways to identify your resources, see Resource Identifiers.

Event Envelope

These attributes for an event envelope are the same for all events. The structure of the envelope follows the CloudEvents industry standard format hosted by the Cloud Native Computing Foundation (CNCF).

Property	Description
`cloudEventsVersion`	The version of the CloudEvents specification.  **Note** Audit uses version 0.1 specification of the CloudEvents event envelope.
`contentType`	Set to `application/json`. The content type of the data contained in the `data` attribute.
`data`	The payload of the event. Information within `data` comes from the resource emitting the event.
`eventID`	The UUID of the event. This identifier is not an OCID, but just a unique ID for the event.
`eventTime`	The time of the event, expressed in RFC 3339 timestamp format.

Property	Description
`eventType`	The type of event that happened. **Note** The service that produces the event can also add, remove, or change the meaning of a field. A service implementing these type changes would publish a new version of an `eventType` and revise the `eventTypeVersion` field.
`eventTypeVersion`	The version of the event type. This version applies to the payload of the event, not the envelope. Use `cloudEventsVersion` to determine the version of the envelope.
`source`	The resource that produced the event. For example, an Autonomous Database or an Object Storage bucket.

Payload

The data in these fields depends on which service produced the event log and the event type it defines.

Data

The data object contains the following attributes.

Property	Description
`data.additionalDetails`	A container object for attributes unique to the resource emitting the event.
`data.availabilityDomain`	The availability domain where the resource resides.
`data.compartmentId`	The OCID of the compartment of the resource emitting the event.
`data.compartmentName`	The name of the compartment of the resource emitting the event.
`data.definedTags`	Defined tags added to the resource emitting the event.
`data.eventGroupingId`	This value links multiple audit events that are part of the same API operation. For example, a long running API operation that emits an event at the start and the end of the operation.
`data.eventName`	Name of the API operation that generated this event. Example: `LaunchInstance`
`data.freeformTags`	Free-form tags added to the resource emitting the event.
`data.identity`	A container object for identity attributes. See Identity.
`data.request`	A container object for request attributes. See Request.
`data.resourceId`	An OCID or an ID for the resource emitting the event.
`data.resourceName`	The name of the resource emitting the event.
`data.response`	A container object for response attributes. See Response.
`data.stateChange`	A container object for state change attributes. See State Change.

Identity

The identity object contains the following attributes.

Property	Description
`data.identity.authType`	The type of authentication used.
`data.identity.callerId`	The OCID of the caller. The caller that made a request on behalf of the principal.
`data.identity.callerName`	The name of the user or service issuing the request. This value is the friendly name associated with `callerId`.
`data.identity.consoleSessionId`	This value identifies any Console session associated with this request.
`data.identity.credentials`	The credential ID of the user.
`data.identity.ipAddress`	The IP address of the source of the request.
`data.identity.principalId`	The OCID of the principal.
`data.identity.principalName`	The name of the user or service. This value is the friendly name associated with `principalId`.
`data.identity.tenantId`	The OCID of the tenant.
`data.identity.userAgent`	The user agent of the client that made the request.

Request

The request object contains the following attributes.

Property	Description
`data.request.action`	The HTTP method of the request. Example: `GET`
`data.request.headers`	The HTTP header fields and values in the request.
`data.request.id`	The unique identifier of a request.
`data.request.parameters`	All the parameters supplied by the caller during this operation.
`data.request.path`	The full path of the API request. Example: `/20160918/instances/ocid1.instance.oc1.phx.<unique_ID>`

Response

The response object contains the following attributes.

Property	Description
`data.response.headers`	The headers of the response.
`data.response.message`	A friendly description of what happened during the operation.
`data.response.payload`	This value is included for backward compatibility with the Audit version 1 schema, where it contained metadata of interest from the response payload.

Property	Description
`data.response.responseTime`	The time of the response to the audited request, expressed in RFC 3339 timestamp format.
`data.response.status`	The status code of the response.

State Change

The state change object contains the following attributes.

Property	Description
`data.stateChange.current`	Provides the current state of fields that may have changed during an operation. To determine how the current operation changed a resource, compare the information in this attribute to `data.stateChange.previous`.
`data.stateChange.previous`	Provides the previous state of fields that may have changed during an operation. To determine how the current operation changed a resource, compare the information in this attribute to `data.stateChange.current`.

An Example Audit Log

The following is an example an event recorded by the Audit service.

```
{
       "eventType": "com.oraclecloud.ComputeApi.GetInstance",
       "cloudEventsVersion": "0.1",
       "eventTypeVersion": "2.0",
       "source": "ComputeApi",
```

```
      "eventId": "<unique_ID>",
      "eventTime": "2019-09-18T00:10:59.252Z",
      "contentType": "application/json",
      "data": {
              "eventGroupingId": null,
              "eventName": "GetInstance",
              "compartmentId": "ocid1.tenancy.oc1..<unique_ID>",
              "compartmentName": "compartmentA",
              "resourceName": "my_instance",
              "resourceId": "ocid1.instance.oc1.phx.<unique_ID>",

                },
                "stateChange": {
                        "previous": null,
                        "current": null
                },
                "additionalDetails": {
                        "imageId": "ocid1.image.oc1.phx.<unique_ID>",
                        "shape": "VM.Standard1.1",
                        "type": "CustomerVmi"
                }
        }
}
```

Viewing Audit Log Events

Audit provides records of API operations performed against supported services as a list of log events. The service logs events at both the tenant and compartment level. By default, audit logs are maintained for 90 days. You can configure audit log retention for up to 365 days.

When viewing events logged by Audit, you might be interested in specific activities that happened in the tenancy or compartment and who was responsible for the activity. You will need to know that the approximate time and date something happened and the compartment in which it happened to display a list of log events that includes the activity in question. List log events by specifying a time range on the 24-hour clock in Greenwich Mean Time (GMT), calculating the offset for your local time zone, as appropriate. New activity is appended to the existing list, usually within 15 minutes of the API call, though processing time can vary.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: The following policy statement gives the specified group (Auditors) the ability to view all the Audit event logs in the tenancy:

```
Allow group Auditors to read audit-events in tenancy
```

To give the group access to the Audit event logs in a specific compartment only (ProjectA), write a policy like the following:

```
Allow group Auditors to read audit-events in compartment ProjectA
```

If you're new to policies, see Getting Started with Policies and Common Policies. For more details about policies for the Audit, see Details for the Audit Service.

Searching and Filtering in the Console

When you navigate to Audit in the Console, a list of results is generated for the current compartment. Audit logs are organized by compartment, so if you are looking for a particular event, you must know which compartment the event occurred in. You can filter the list in all the following ways:

- Date and time
- Request Action Types (operations)
- Keywords

For example, users begin to report that their attempts to log in are failing. You want to use Audit to research the problem. Adjust the date and time to search for corresponding failures during a window of time that starts a little before the events were reported. Look for corresponding failures and similar operations preceding the failures to correlate a reason for the failures.

Note

The service logs events at the time they are processed. There can be a delay between the time an operation occurs and when it is processed.

You can filter results by request actions to zero in on only the events with operations that interest you. For example, say that you only want to know about instances that were deleted during a specific time frame. Select a delete request action filter to see only the events with delete operations.

You can also filter by keywords. Keyword filters are powerful when combined with the values from audit event fields. For example, say that you know the user name of an account and want a list of all activity by that account in a particulate time frame. Do a search using the user name as a keyword filter.

Every audit event contains the same fields, so search for values from those fields. To get a better understanding of what values are available, see Contents of an Audit Log Event.

Using the Console

To search log events

1. Open the navigation menu. Under **Governance and Administration**, go to **Governance** and click **Audit**.
   The list of events that occurred in the current compartment is displayed.
2. Click one of the compartments under **Compartment**.
   Audit organizes logs by compartment, so if you are looking for a particular event, you must know which compartment the event occurred in.
3. Click in the **Start Date** box to choose the start date and time for the range of results you want to see. You can click the arrows on either side of the month to go backward or forward.
4. (Optional) Specify a time by doing one of the following:
   a. Click **Time** and specify an exact start time in thirty-minute increments.
   b. Type an exact time in the **Start Date** box.
      The service uses a 24-hour clock, so you must provide a number between `0` and `23` for the hour. Also remember to calculate the offset between Greenwich Mean Time (GMT) and your local time.
5. Repeat step 3 and 4 to choose an end date and time.

Note

The age of the results available can be from 90 and 365 days, depending on your tenancy's setting for audit log retention period.

6. (Optional) In **Request Action Types**, specify one or more operations with which to filter results.

- GET
- POST
- PUT
- PATCH
- DELETE

7. (Optional) In the **Keywords** box, type the text you want to find and click **Search**.
   Tip: If you want to find log events with a specific status code, include quotes (") around the code to avoid results that have those numbers embedded in a longer string.

The results are updated to include only log events that were processed within the time range and filters you specified. If an event occurred in the recent past, you might have to wait to see it in the list. The service typically requires up to 15 minutes for processing.

If there are more than 100 results for the specified time range, you can click the right arrow next to the page number at the bottom of the page to advance to the next page of log events.

Tip

If you get fewer than 100 results on the last page of a results list, you might still have more results, which you can access by clicking the right arrow. If there are more results, Audit prompts you.

If you want to view all the key-value pairs in a log event, see To view the details of a log event.

To view the details of a log event

View the details of your event:

- To see only the top-level details, click the down arrow to the right of an event.
- To see lower-level details, click **{ . . . }** to the right of the collapsed parameter.

To copy the details of a log event

The following assumes that you have expanded a row in your results.

- To copy an entire event, click the clipboard icon to the right of the `event` parameter.
- To copy a portion of an event, click the clipboard icon to the right of the nested parameter or value you want to copy.

The log event is copied to your clipboard. The Audit service logs events in JSON format. You can paste the log event details into a text editor to save and review later or to use with standard log analysis tools.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the following operation to list audit log events:

- ListEvents

Note

This API is not intended for bulk-export operations. For bulk export, see Bulk Export of Audit Log Events.

Setting Audit Log Retention Period

By default, Audit logs are retained for 90 days. You can configure log retention for up to 365 days. You can edit the log retention period in the tenancy details page.

Retention period is a tenancy-level setting. The value of the retention period setting affects all regions and all compartments. You can't set different retention periods for different regions or compartments.

Required IAM Policy

To modify the Audit log retention period, you must be a member of the Administrators group. See The Administrators Group and Policy

Using the Console

To modify the Audit log retention period

1. Open the **Profile** menu () and click **Tenancy:** *<your_tenancy_name>*.

   The tenancy details are displayed. The **Audit Retention Period** is displayed under **Tenancy Information**.
2. Click **Edit Audit Retention Policy**. Enter the number of days you want to retain the audit logs for. The minimum you can set the value to is 90 and the maximum is 365. This value is enforced for all regions and all compartments in the tenancy.
3. Click **Submit**.

Note

You don't see the new value immediately

It may take several minutes for the new setting to display in the Console.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the following operations to manage the log retention period configuration:

- GetConfiguration
- UpdateConfiguration

Bulk Export of Audit Log Events

You can request a bulk export of audit logs, and within 3–4 business days Oracle support will begin making copies of the logs and adding them to buckets in your tenancy. The export includes logs for the specified regions, beginning after you make the request and continuing into the future.

Highlights

- Administrators have full control of the buckets and can provide access to others with IAM policy statements.
- Exported logs remain available indefinitely.

Tip

You can automatically manage archiving and deleting logs using Object Storage. See Using Object Lifecycle Management.

- Specify all the regions you want exported in your request. If you only request some regions, then decide later you want to add other regions, you must make another request.

- To disable your bulk export, contact Oracle support. New logs will stop being added to the bucket, and audit logs will only be available through the Console, based on the retention period you have defined.

Required IAM Policy

To access the bucket where Oracle exports the audit logs, you must be a member of the Administrators group. See The Administrators Group and Policy

Requesting an Export of Audit Logs

A member of the Administrators group for your tenancy must create a ticket at My Oracle Support and provide the following information:

- Ticket name: Export Audit Logs - *<your_company_name>*
- Tenancy OCID
- Regions

For example:

- Ticket name: Export Audit Logs - ACME
- Tenancy OCID: ocid1.tenancy.oc1.*<unique_ID>*
- Regions: US East (Ashburn), region identifier= us-ashburn-1; (US West (Phoenix)), region identifier = us-phoenix-1

Note

It can take 3–4 business days before your My Oracle Support ticket is complete and the logs are available to you.

Bucket and Object Details

This section specifies the naming conventions of the bucket and objects you receive.

Bucket Name Format

Oracle support creates buckets for audit log exports using the following naming format:

`oci-logs._audit.`*<compartment_OCID>*

- `oci-logs` identifies that Oracle created this bucket.
- `_audit` identifies that the bucket contains audit events.
- *<compartment_OCID>* identifies the compartment where the audit events were generated.

For example:

```
oci-logs._audit.ocid1compartment.oc1..<unique_ID>
```

Important

If the OCID of the compartment that generated the audit log contains a colon, your bucket name will not match the OCID. To create a bucket, Oracle must substitute colon characters (`:`) from the OCID with dot characters (`.`) in the bucket name.

Object Name Format

Objects use the following naming format:

<region>/*<ad>*/*<YYYY-MM-DDTHH:MMZ>*[_*<seqNum>*].log.gz

- *<region>* identifies the region where the audit events were generated.
- *<ad>* identifies the availability domain where the audit events were generated.
- *<YYYY-MM-DDTHH:MMZ>* identifies the start time of the earliest audit event listed in the object.
- [_*<seqNum>*] identifies a conditional sequence number. If present, this number means that either an event came in late or the object became too large to write. Sequence numbers start at two. Apply multiple sequence numbers to the original object in the order listed.

For example:

```
us-phoenix-1/ad1/2019-03-21T00:00Z.log.gz
us-phoenix-1/ad1/2019-03-21T00:00Z_2.log.gz
```

File Format

Files list a single audit event per line. For more information, see Contents of an Audit Log Event.

Note

Audit introduced a version 2 schema of Audit logs but bulk export is currently only available for version 1 schema logs.

CHAPTER 7 Block Volume

This chapter explains how to create storage volumes and attach them to instances.

Overview of Block Volume

The Oracle Cloud Infrastructure Block Volume service lets you dynamically provision and manage block storage volumes. You can create, attach, connect, and move volumes, as well as change volume performance, as needed, to meet your storage, performance, and application requirements. After you attach and connect a volume to an instance, you can use the volume like a regular hard drive. You can also disconnect a volume and attach it to another instance without the loss of data.

These components are required to create a volume and attach it to an instance:

- **Instance:** A bare metal or virtual machine (VM) host running in the cloud.
- **Volume attachment:** There are two types of volume attachments:
  - iSCSI**:** A TCP/IP-based standard used for communication between a volume and attached instance.
  - Paravirtualized**:** A virtualized attachment available for VMs.
- **Volume:** There are two types of volumes:
  - **Block volume:** A detachable block storage device that allows you to dynamically expand the storage capacity of an instance.
  - **Boot volume:** A detachable boot volume device that contains the image used to boot a Compute instance. See Boot Volumes for more information.

For additional Oracle Cloud Infrastructure terms, see the Glossary.

Block Volume is Always Free eligible. For more information about Always Free resources, including additional capabilities and limitations, see Oracle Cloud Infrastructure's Free Tier.

Typical Block Volume Scenarios

Scenario A: Expanding an Instance's Storage

A common usage of Block Volume is adding storage capacity to an Oracle Cloud Infrastructure instance. After you have launched an instance and set up your cloud network, you can create a block storage volume through the Console or API. Then, you attach the volume to an instance using a volume attachment. After the volume is attached, you connect to the volume from your instance's guest OS using iSCSI. The volume can then be mounted and used by your instance.

Scenario B: Persistent and Durable Storage

A Block Volume volume can be detached from an instance and moved to a different instance without the loss of data. This data persistence enables you to migrate data between instances and ensures that your data is safely stored, even when it is not connected to an instance. Any data remains intact until you reformat or delete the volume.

To move your volume to another instance, unmount the drive from the initial instance, terminate the iSCSI connection, and attach the volume to the second instance. From there, you connect and mount the drive from that instance's guest OS to have access to all of your data.

Additionally, Block Volume volumes offer a high level of data durability compared to standard, attached drives. All volumes are automatically replicated for you, helping to protect against data loss.

Scenario C: Instance Scaling

When you terminate an instance, you can keep the associated boot volume and use it to launch a new instance with a different instance type or shape. This allows you to easily switch from a bare metal instance to a VM instance and vice versa, or scale up or scale down the number of cores for an instance. See Creating an Instance for steps to launch an instance based on a boot volume.

Volume Attachment Types

When you attach a block volume to a VM instance, you have two options for attachment type, iSCSI or paravirtualized. Paravirtualized attachments simplify the process of configuring your block storage by removing the extra commands that are required before connecting to an iSCSI-attached volume. The trade-off is that IOPS performance for iSCSI attachments is greater than that for paravirtualized attachments. You should consider your requirements when selecting a volume's attachment type.

Important

Connecting to Volumes on Linux Instances

When connecting to volumes on Linux instances, if you want to automatically mount these volumes on instance boot, you need to use some specific options in the `/etc/fstab` file, or the instance may fail to launch. See Traditional fstab Options and fstab Options for Block Volumes Using Consistent Device Paths for more information.

iSCSI

iSCSI attachments are the only option when connecting a block volume to any of the following types of instances:

- Bare metal instances
- VM instances based on Windows images that were published before February 2018
- VM instances based on Linux images that were published before December 2017

After the volume is attached, you need to log in to the instance and use the `iscsiadm` command-line tool to configure the iSCSI connection. For more information about the additional configuration steps required for iSCSI attachments, see iSCSI Commands and Information, Connecting to a Volume, and Disconnecting From a Volume.

IOPS performance is better with iSCSI attachments compared to paravirtualized attachments. For more information about iSCSI-attached volume performance, see Block Volume Performance.

Paravirtualized

Paravirtualized attachments are an option when attaching volumes to the following types of VM instances:

- For VM instances launched from Oracle-provided images, you can select this option for Linux-based images published in December 2017 or later, and Windows images published in February 2018 or later.
- For VM instances launched from custom images, the volume attachment type is based on the volume attachment type from the VM the custom image was created from.

After you attach a volume using the paravirtualized attachment type, it is ready to use, and you do not need to run any additional commands. However, because of the overhead of virtualization, this reduces the maximum IOPS performance for larger block volumes. See Block Volume Performance for more information.

Volume Access Types

When you attach a block volume, you can specify one of the following options for access type:

- **Read/write:** This is the default option for volume attachments. With this option, an instance can read and write data to the volume.
- **Read-only:** With this option, an instance can only read data on the volume. It cannot update data on the volume. Specify this option to safeguard data against accidental or malicious modifications.

To change the access type for a block volume, you need to detach the volume and specify the new access type when you reattach the volume. For more information, see Detaching a Volume and Attaching a Volume.

The access type for boot volumes is always read/write. If you want to change the access type, you need to stop the instance and detach the boot volume. You can then reattach it to another

instance as a block volume, with read-only specified as the access type. For more information, see Detaching a Boot Volume and Attaching a Volume.

Device Paths

When you attach a block volume to a compatible Linux-based instance, you can select a device path that remains consistent between instance reboots. This enables you to refer to the volume using a consistent device path. For example, you can use the device path when you set options in the `/etc/fstab` file to automatically mount the volume on instance boot.

Consistent device paths are supported on instances when all of the following things are true:

- The instance was created using an Oracle-provided image.
- The image is a Linux-based image.
- The image was released in November 2018 or later. For specific version numbers, see Oracle-Provided Image Release Notes.
- The instance was launched after January 11, 2019.

For instances launched using the image OCID or an existing boot volume, if the source image supports consistent device paths, the instance supports device paths.

Consistent device paths are not supported on Linux-based partner images or custom images that are created from other sources. This feature does not apply to Windows-based images.

Important

You must select a device path when you attach a volume using the Console, it is required. Specifying a device path is optional when you attach a volume using the CLI, REST APIs, or SDK.

For more information about consistent device paths, see Connecting to Volumes With Consistent Device Paths.

Regions and Availability Domains

Volumes are only accessible to instances in the same availability domain . You cannot move a volume between availability domains or regions, they are only accessible within the region or availability domain they were created in. However volume backups are not limited to the availability domain of the source volume, you can restore them to any availability domain within that region, see Restoring a Backup to a New Volume. You can also copy a volume backup to a new region and restore the backup to a volume in any availability domain in the new region, for more information see Copying a Volume Backup Between Regions.

For more information, see Regions and Availability Domains.

Resource Identifiers

Most types of Oracle Cloud Infrastructure resources have a unique, Oracle-assigned identifier called an Oracle Cloud ID (OCID). For information about the OCID format and other ways to identify your resources, see Resource Identifiers.

Ways to Access Oracle Cloud Infrastructure

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. For a list of available SDKs, see Software Development Kits and Command Line Interface.

To access the Console, you must use a supported browser. Oracle Cloud Infrastructure supports the latest desktop versions of Google Chrome, Microsoft Edge, Internet Explorer 11, Safari, Firefox, and Firefox ESR. Note that private browsing mode is not supported for Firefox, Internet Explorer, or Edge. Mobile browsers are not supported.

For general information about using the API, see REST APIs.

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies. For specific details about writing policies for each of the different services, see Policy Reference.

If you're a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

Monitoring Resources

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications. For more information, see Monitoring Overview and Notifications Overview.

Moving Resources

You can move Block Volume resources such as block volumes, boot volumes, volume backups, volume groups, and volume group backups from one compartment to another. For more information, see Move Block Volume Resources Between Compartments.

Tagging Resources

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the desired tags. For general information about applying tags, see Resource Tags.

Creating Automation with Events

You can create automation based on state changes for your Oracle Cloud Infrastructure resources by using event types, rules, and actions. For more information, see Overview of Events.

The following Block Volume resources emit events:

- Block volumes and block volume backups
- Boot volumes and boot volume backups
- Volume groups and volume group backups

Note

For troubleshooting, see Known Issues - Block Volume for a list of known issues related to Block Volume events.

Block Volume Encryption

The Oracle Cloud Infrastructure Block Volume service always encrypts all block volumes, boot volumes, and volume backups at rest by using the Advanced Encryption Standard (AES) algorithm with 256-bit encryption. By default all volumes and their backups are encrypted using the Oracle-provided encryption keys. Each time a volume is cloned or restored from a backup the volume is assigned a new unique encryption key.

You have the option to encrypt all of your volumes and their backups using the keys that you own and manage using the Key Management service, for more information see Overview of Key Management. If you do not configure a volume to use the Key Management service or you later unassign a key from the volume, the Block Volume service uses the Oracle-provided encryption key instead. This applies to both encryption at-rest and in-transit encryption.

For how to use your own key for new volumes, see Creating a Volume. See To assign a key to an existing Block Volume for how to assign or change the key for an existing volume.

All the data moving between the instance and the block volume is transferred over an internal and highly secure network. If you have specific compliance requirements related to the encryption of the data while it is moving between the instance and the block volume, the Block Volume service provides the option to enable in-transit encryption for paravirtualized volume attachments on virtual machine (VM) instances.

Important

In-transit encryption for boot and block volumes is only available for virtual machine (VM) instances launched from Oracle-provided images, it is not supported on bare metal instances. It is also not supported in most cases for instances launched from custom images imported for "bring your own image" (BYOI) scenarios. To confirm support for certain Linux-based custom images and for more information contact Oracle support, see Contacting Support.

Block Volume Data Eradication

The Oracle Cloud Infrastructure Block Volume service uses eventual-overwrite data eradication, which guarantees that block volumes you delete cannot be accessed by anyone else and that the deleted data is eventually overwritten. When you terminate a volume, its associated data is overwritten in the storage infrastructure before any future volume allocations.

Block Volume Performance

Block Volume performance varies with volume size, see Block Volume Performance for more information.

The Block Volume service's elastic performance feature enables you to dynamically change the volume performance. You can select one of the following volume performance options for your block volumes:

- Balanced
- Higher Performance
- Lower Cost

For more information about this feature and the performance options, see Block Volume Elastic Performance and Changing the Performance of a Volume

Block Volume Capabilities and Limits

Block Volume volumes can be created in sizes ranging from **50 GB** to **32 TB** in **1 GB** increments. By default, Block Volume volumes are **1 TB**.

See Service Limits for a list of applicable limits and instructions for requesting a limit increase. To set compartment-specific limits on a resource or resource family, administrators can use compartment quotas.

Additional limits include:

- **Volumes per instance:** 32
- **Number of backups**
  - Monthly universal credits: 1000
  - Pay-as-you-go: 500

iSCSI Commands and Information

Block volumes attached with the iSCSI attachment type use the iSCSI protocol to connect a volume to an instance. See Volume Attachment Types for more information about volume attachment options.

Once the volume is attached, you need to log on to the instance and use the `iscsiadm` command-line tool to configure the iSCSI connection. After you configure the volume, you can mount it and use it like a normal hard drive.

To enhance security, Oracle enforces an iSCSI security protocol called CHAP that provides authentication between the instance and volume.

Accessing a Volume's iSCSI Information

When you successfully attach a volume to an instance, Block Volume provides a list of iSCSI information. You need the following information from the list when you connect the instance to the volume.

- IP address
- Port
- CHAP user name and password (if enabled)
- IQN

Note

The CHAP credentials are auto-generated by the system and cannot be changed. They are also unique to their assigned volume/instance pair and cannot be used to authenticated another volume/instance pair.

The Console provides this information on the details page of the volume's attached instance. Click the Actions icon (three dots) on your volume's row, and then click **iSCSI Information**. The system also returns this information when the `AttachVolume` API operation completes successfully. You can re-run the operation with the same parameter values to review the information.

See Attaching a Volume and Connecting to a Volume for step-by-step instructions.

Additional Reading

There is a wealth of information on the internet about iSCSI and CHAP. If you need more information on these topics, try the following pages:

- Oracle Linux Administrator's Guide for Release 7 - About iSCSI Storage
- Oracle Linux Administrator's Guide for Release 6 - About iSCSI Storage
- Troubleshooting iSCSI Configuration Problems

Volume Groups

The Oracle Cloud Infrastructure Block Volume service provides you with the capability to group together multiple volumes in a volume group. A volume group can include both types of volumes, boot volumes, which are the system disks for your Compute instances, and block volumes for your data storage. You can use volume groups to create volume group backups and clones that are point-in-time and crash-consistent.

This simplifies the process to create time-consistent backups of running enterprise applications that span multiple storage volumes across multiple instances. You can then restore an entire group of volumes from a volume group backup.

Similarly, you can also clone an entire volume group in a time-consistent and crash-consistent manner. A deep disk-to-disk and fully isolated clone of a volume group, with all the volumes associated in it, becomes available for use within a matter of seconds. This speeds up the process of creating new environments for development, quality assurance, user acceptance testing, and troubleshooting.

For more information about Block Volume-backed system disks, see Boot Volumes. For more information about Block Volume backups see Overview of Block Volume Backups. See Cloning a Volume for more information about Block Volume clones.

This capability is available using the Console, command line interface (CLI), SDKs, or REST APIs.

Volume groups and volume group backups are high-level constructs that allow you to group together multiple volumes. When working with volume groups and volume group backups, keep the following in mind:

- You can only add a volume to a volume group when the volume status is available.
- You can add up to 32 volumes in a volume group, up to a maximum size limit of 128 TB. For example, if you wanted to add 32 volumes of equal size to a volume group, the maximum size for each volume would be 4 TB. Or you could add volumes that vary in size, however the overall combined size of all the block and boot volumes in the volume group must be 128 TB or less. Make sure you account for the size of any boot volumes in your volume group when considering volume group size limits.
- Each volume may only be in one volume group.
- When you clone a volume group, a new group with new volumes are created. For example, if you clone a volume group containing three volumes, once this operation is complete, you will now have two separate volume groups and six different volumes with nothing shared between the volume groups.
- When you update a volume group using the CLI, SDKs, or REST APIs you need to specify all the volumes to include in the volume group each time you use the update operation. If you do not include a volume ID in the update call, that volume will be removed from the volume group.
- When you delete a volume group the individual volumes in the group are not deleted, only the volume group is deleted.
- When you delete a volume that is part of a volume group you must first remove it from the volume group before you can delete it.
- When you delete a volume group backup, all the volume backups in the volume group backup are deleted.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don't have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: The policy in Let volume admins manage block volumes, backups, and volume groups lets the specified group do everything with block volumes, backups, and volume groups.

See the following policy examples for working with volume groups:

- Let users create a volume group lets the specified group create a volume group from a set of volumes.
- Let users clone a volume group lets the specified group clone a volume group from an existing volume group.
- Let users create a volume group backup lets the specified group create a volume group backup.
- Let users restore a volume group backup lets the specified group create a volume group by restoring a volume group backup.

Tip

When users create a backup from a volume or restore a volume from a backup, the volume and backup don't have to be in the same compartment. However, users must have access to both compartments.

If you're new to policies, see Getting Started with Policies and Common Policies. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services.

Tagging Resources

You can apply tags to your resources to help you organize them according to your business needs. You can update the resource later with the desired tags. For general information about applying tags, see Resource Tags.

Using the Console

To create a volume group from existing volumes

1. Open the navigation menu. Under **Core Infrastructure**, go to **Block Storage** and click **Volumes Groups**.
2. Click **Create Volume Group**.
3. Fill in the required volume information:
    - **Name**: A user-friendly name or description.
    - **Compartment**: The compartment for the volume group.
    - **Availability Domain**: The availability domain for the volume group.

- **Volumes**: For each volume you want to add, select the compartment containing the volume and then the volume to add. Click **+ Volume** to add additional volumes.

4. Click **Create Volume Group**.

To view the volumes in a volume group

1. Open the navigation menu. Under **Core Infrastructure**, go to **Block Storage** and click **Volumes Groups**.
2. In the **Volume Groups** list, click the volume group you want to view the volumes for.
3. To view the block volumes for the volume group, in **Resources**, click **Block Volumes**.
4. To view the boot volumes for the volume group, in **Resources**, click **Boot Volumes**.

To add block volumes to an existing volume group

1. Open the navigation menu. Under **Core Infrastructure**, go to **Block Storage** and click **Volumes Groups**.
2. In the **Volume Groups** list, click the volume group you want to add the volume to.
3. In **Resources**, click **Block Volumes**.
4. Click **Add Block Volumes**.
5. For each block volume you want to add, select the compartment containing the volume and then select the volume to add. Click **+ Volume** to add additional volumes.
6. Once you have selected all the block volumes to add to the volume group, click **Add**.

To remove block volumes from an existing volume group

1. Open the navigation menu. Under **Core Infrastructure**, go to **Block Storage** and click **Volumes Groups**.
2. In the **Volume Groups** list, click the volume group you want to add the volume to.

3. In **Resources**, click **Block Volumes**.
4. In **Actions** menu for the block volume you want to remove, click **Remove**.
5. In the **Confirm** dialog, click **Remove**.

Note

When you remove the last volume in a volume group the volume group is terminated.

To add boot volumes to an existing volume group

1. Open the navigation menu. Under **Core Infrastructure**, go to **Block Storage** and click **Volumes Groups**.
2. In the **Volume Groups** list, click the volume group you want to add the volume to.
3. In **Resources**, click **Boot Volumes**.
4. Click **Add Boot Volumes**.
5. For each boot volume you want to add, select the compartment containing the volume and then select the volume to add. Click **+ Volume** to add additional volumes.
6. Once you have selected all the boot volumes to add to the volume group, click **Add**.

To remove boot volumes from an existing volume group

1. Open the navigation menu. Under **Core Infrastructure**, go to **Block Storage** and click **Volumes Groups**.
2. In the **Volume Groups** list, click the volume group you want to add the volume to.
3. In **Resources**, click **Boot Volumes**.
4. In **Actions** menu for the boot volume you want to remove, click **Remove**.
5. In the **Confirm** dialog, click **Remove**.

To create a backup of the volume group

1. Open the navigation menu. Under **Core Infrastructure**, go to **Block Storage** and click **Volumes Groups**.
2. In the **Volume Groups** list, click **Create Volume Group Backup** in the **Actions** menu for the volume group you want to create a backup for.

To create a clone of the volume group

1. Open the navigation menu. Under **Core Infrastructure**, go to **Block Storage** and click **Volumes Groups**.
2. In the **Volume Groups** list, click **Create Volume Group Clone** in the **Actions** menu for the volume group you want to clone.

To delete the volume group

1. Open the navigation menu. Under **Core Infrastructure**, go to **Block Storage** and click **Volumes Groups**.
2. In the **Volume Groups** list, click the volume group you want to delete.
3. On the **Volume Group Details** page, click **Terminate**.
4. On the **Terminate Volume Group** dialog, click **Terminate**.

Note

When you delete a volume group the individual volumes in the group are not deleted, only the volume group is deleted.

To restore a volume group from a volume group backup

1. Open the navigation menu. Under **Core Infrastructure**, go to **Block Storage** and click **Volumes Group Backups**.
2. In the **Volume Group Backups** list, click the volume group backup you want to restore.
3. Click **Create Volume Group**.
4. Fill in the required volume information:
   - **Name**: A user-friendly name or description.
   - **Compartment**: The compartment for the volume group.
   - **Availability Domain**: The availability domain for the volume group.
5. Click **Create Volume Group**.

Using the CLI

For information about using the CLI, see Command Line Interface (CLI).

To retrieve information about the supported operations

Open a command prompt and run the one of the following commands to retrieve the information.

- To retrieve the supported operations for volume groups:

```
oci bv volume-group --help
```

- To retrieve the supported operations for volume group backups:

```
oci bv volume-group-backup --help
```

- To retrieve help for a specific volume group operation:

```
oci bv volume-group <operation_name> --help
```

- To retrieve help for a specific volume group backup operation:

```
oci bv volume-group-backup <operation_name> --help
```

Volume Group Operations

To list the volume groups in a specified compartment

Open a command prompt and run:

```
oci bv volume-group list --compartment-id <compartment_ID>
```

For example:

```
oci bv volume-group list --compartment-id ocid1.compartment.oc1..<unique_ID>
```

To create a volume group from existing volumes

Open a command prompt and run:

```
oci bv volume-group create --compartment-id <compartment_ID> --availability-domain <external_AD> --
source-details <Source_details_JSON>
```

Volume status must be available to add it to a volume group.

For example:

```
oci bv volume-group create --compartment-id ocid1.compartment.oc1..<unique_ID> --availability-domain
ABbv:PHX-AD-1 --source-details '{"type": "volumeIds", "volumeIds":["ocid1.volume.oc1.phx.<unique_ID_1>",
"ocid1.volume.oc1.phx.<unique_ID_2>"]}'
```

To clone a volume group from another volume group

Open a command prompt and run:

```
oci bv volume-group create --compartment-id <compartment_ID> --availability-domain <external_AD> --
source-details <Source_details_JSON>
```

For example:

```
oci bv volume-group create --compartment-id ocid1.compartment.oc1..<unique_ID> --availability-domain
ABbv:PHX-AD-1 --source-details '{"type": "volumeGroupId", "volumeGroupId":
"ocid1.volumegroup.oc1.phx.<unique_ID>"}'
```

To restore a volume group from a volume group backup

Open a command prompt and run:

```
oci bv volume-group create --compartment-id <compartment_ID> --availability-domain <external_AD> --
source-details <Source_details_JSON>
```

For example:

```
oci bv volume-group create --compartment-id ocid1.compartment.oc1..<unique_ID> --availability-domain
ABbv:PHX-AD-1 --source-details '{"type": "volumeGroupBackupId", "volumeGroupBackupId":
"ocid1.volumegroup.oc1.sea.<unique_ID>"}'
```

To retrieve a volume group

Open a command prompt and run:

```
oci bv volume-group get --volume-group-id <volume-group-ID>
```

For example:

```
oci bv volume-group get --volume-group-id ocid1.volumegroup.oc1.phx.<unique_ID>
```

To update display name or add/remove volumes from a volume group

Open a command prompt and run:

```
oci bv volume-group update --volume-group-id <volume-group_ID> --volume-ids <volume_ID_JSON>
```

You can update the volume group display name along with adding or removing volumes from the volume group. The volume group is updated to include only the volumes specified in the update operation. This means that you need to specify the volume IDs for all of the volumes in the volume group each time you update the volume group.

The following example changes the volume group's display name for a volume group with two volumes:

```
oci bv volume-group update --volume-group-id ocid1.volumegroup.oc1.phx.<unique_ID> --volume-ids '
["ocid1.volume.oc1.phx.<unique_ID_1>","ocid1.volume.oc1.phx.<unique_ID_2>"]' --display-name "new display
name"
```

If you specify volumes in the command that are not part of the volume group they are added to the group. Any volumes not specified in the command are removed from the volume group.

To delete a volume group

Open a command prompt and run:

```
oci bv volume-group delete --volume-group-id <volume-group_ID>
```

When you delete a volume group, the individual volumes in the group are not deleted, only the volume group is deleted.

For example:

```
oci bv volume-group delete --volume-group-id ocid1.volumegroup.oc1.phx.<unique_ID>
```

Volume Group Backup Operations

To list volume backup groups

Open a command prompt and run:

```
oci bv volume-group-backup list --compartment-id <compartment_ID>
```

For example:

```
oci bv volume-group-backup list --compartment-id ocid1.compartment.oc1..<unique_ID>
```

To create a volume group backup

Open a command prompt and run:

```
oci bv volume-group-backup create --volume-group-id <volume-group_ID>
```

For example:

```
oci bv volume-group-backup create --volume-group-id ocid1.volumegroup.oc1.phx.<unique_ID>
```

To retrieve a volume group backup

Open a command prompt and run:

```
oci bv volume-group-backup get --volume-group-backup-id <volume-group-backup_ID>
```

For example:

```
oci bv volume-group-backup get --volume-group-backup-id ocid1.volumegroupbackup.oc1.phx.<unique_ID>
```

To update display name for a volume group backup

Open a command prompt and run:

```
oci bv volume-group-backup update --volume-group-backup-id <volume-group-backup_ID> --display-name <new_
display_name>
```

You can only update the display name for the volume group backup.

For example:

```
oci bv volume-group-backup update --volume-group-backup-id ocid1.volumegroupbackup.oc1.phx.<unique_ID> -
-display-name "new display name"
```

To delete a volume group backup

Open a command prompt and run:

```
oci bv volume-group-backup delete --volume-group-backup-id <volume-group-backup_ID>
```

When you delete a volume group backup, all volume backups in the group are deleted.

For example:

```
oci bv volume-group-backup delete --volume-group-backup-id ocid1.volumegroupbackup.oc1.phx.<unique_ID>
```

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the following operations for working with volume groups:

- ListVolumeGroups
- CreateVolumeGroup
- DeleteVolumeGroup
- GetVolumeGroup
- UpdateVolumeGroup

Use the following operations for working with volume group backups:

- ListVolumeGroupBackups
- CreateVolumeGroupBackup
- DeleteVolumeGroupBackup
- GetVolumeGroupBackup
- UpdateVolumeGroupBackup

Creating a Volume

You can create a volume using Block Volume.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: The policy in Let volume admins manage block volumes, backups, and volume groups lets the specified group do everything with block volumes and backups.

If you're new to policies, see Getting Started with Policies and Common Policies. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services.

Monitoring Resources

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications. For more information, see Monitoring Overview and Notifications Overview.

Tagging Resources

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the desired tags. For general information about applying tags, see Resource Tags.

Using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Block Storage** and click **Block Volumes**.
2. Click **Create Block Volume**.

3. Fill in the required volume information:
    - **Name**: A user-friendly name or description.
    - **Domain**: Must be in the same **availability domain** as the instance.
    - **Size**: Must be between **50 GB** and **32 TB**. You can choose in 1 GB increments within this range. The default is 1024 GB. If you choose a size outside of your service limit, you may be prompted to request an increase. For more information, see Service Limits.
    - **Backup Policy**: Optionally, you can select the appropriate backup policy for your requirements. See Policy-Based Backups for more information about backup policies.
    - **Volume Performance**: Optionally, you can select the appropriate performance setting for your requirements. See Block Volume Elastic Performance for more information about volume performance options. The default option is **Balanced**.
    - **Tags:** Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.
    - **Encryption:** Optionally, you can encrypt the data in this volume using your own Key Management encryption key. To use Key Management for your encryption needs, select the **Encrypt using customer-managed keys** radio button. Then, select the **Vault Compartment** and **Vault** that contain the master encryption key you want to use. Also select the **Master Encryption Key Compartment** and **Master Encryption Key**. For more information about encryption, see Overview of Key Management.
4. Click **Create Block Volume**.
   The volume will be ready to attach once its icon no longer lists it as **PROVISIONING** in the volume list. For more information, see Attaching a Volume.

Using the API

To create a volume, use the following operation:

- CreateVolume

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Attaching a Volume

You can attach a volume to an instance in order to expand the available storage on the instance. If you specify iSCSI as the volume attachment type, you must also connect and mount the volume from the instance for the volume to be usable. For more information, see Volume Attachment Types and Connecting to a Volume.

Note

You should only attach Linux volumes to Linux instances and Windows volumes to Windows instances.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: The policy in Let users launch Compute instances includes the ability to attach/detach existing block volumes. The policy in Let volume admins manage block volumes, backups, and volume groups lets the specified group do everything with block volumes and backups, but not launch instances.

If you're new to policies, see Getting Started with Policies and Common Policies. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services.

Using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
2. In the **Instances** list, click the instance that you want to attach a volume to.
3. In the **Resources** section, click **Attached Block Volumes**.
4. Click **Attach Block Volume**.
5. Select the volume attachment type, **iSCSI** or **Paravirtualized**.
   For more information, see Volume Attachment Types.
6. In the **Block Volume Compartment** drop-down list, select the compartment.
7. Specify the volume you want to attach to. To use the volume name, choose **SELECT VOLUME** and then select the volume from the **Block Volume** drop-down list. To specify the volume OCID, choose **ENTER VOLUME OCID** and then enter the OCID into the **Block Volume OCID** field.
8. If the instance supports consistent device paths, and the volume you are attaching is not a boot volume, select a path from the **Device Path** drop-down list when attaching. This is required and enables you to specify a device path for the volume attachment that remains consistent between instance reboots.
   For more information about this feature and the instances that support it, see Connecting to Volumes With Consistent Device Paths

Tip

You must select a device path when you attach a volume from the Console, it is not optional. Specifying a device path is optional when you attach a volume using the CLI, REST APIs, or SDK.

9. Select the access type, **Read/Write** or **Read-only**.
   For more information, see Volume Access Types.
10. For paravirtualized volume attachments on virtual machine (VM) instances, you can optionally encrypt data that is transferred between the instance and the Block Volume service storage servers. To do this, select the **Use in-transit encryption** check box. If you configured the volume to use an encryption key that you manage using the Key Management service, this key is used for in-transit encryption. Otherwise, the Oracle-provided encryption key is used. See Block Volume Encryption for more information.
11. Click **Attach**.
    When the volume's icon no longer lists it as **Attaching**, if the attachment type is Paravirtualized, you can use the volume. If the attachment type is iSCSI, you need to connect to the volume first. For more information, see Connecting to a Volume.
    On Linux-based instances, if you want to automatically mount volumes on instance boot, you need to set some specific options in the `/etc/fstab` file, or the instance may fail to launch. This applies to both iSCSI and paravirtualized attachment types. For volumes using consistent device paths, see fstab Options for Block Volumes Using Consistent Device Paths. For all other volumes, see Traditional fstab Options.

Using the API

To attach a volume to an instance, use the following operation:

- AttachVolume

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Connecting to Volumes With Consistent Device Paths

Oracle Cloud Infrastructure supports consistent device paths for block volumes that are attached to compatible Linux-based instances. When you attach a block volume to an instance, you must select a device path that remains consistent between instance reboots. This enables you to use a consistent device path when you refer to the volume to perform tasks such as:

- Creating partitions.
- Creating file systems.
- Mounting file systems.
- Specifying options in the `/etc/fstab` file to ensure that volumes are mounted properly when automatically mounting volumes on instance boot. For more information, see fstab Options for Block Volumes Using Consistent Device Paths.

When you use consistent device paths on compatible Linux-based instances, the boot volume's device path is:

```
/dev/oracleoci/oraclevda
```

Note

Device paths are not available when you attach a boot volume as a data volume to a second instance.

Images that Support Consistent Device Paths

Consistent device paths are supported on instances when all of the following things are true:

- The instance was created using an Oracle-provided image.
- The image is a Linux-based image.
- The image was released in November 2018 or later. For specific version numbers, see Oracle-Provided Image Release Notes.
- The instance was launched after January 11, 2019.

For instances launched using the image OCID or an existing boot volume, if the source image supports consistent device paths, the instance supports device paths.

Consistent device paths are not supported on Linux-based partner images or custom images that are created from other sources. This feature does not apply to Windows-based images.

> **Important**
>
> You must select a device path when you attach a volume using the Console, it is required. Specifying a device path is optional when you attach a volume using the CLI, REST APIs, or SDK.

Device Paths in the Console

You select a device path when you attach a block volume to an instance.

If you specify a device path, the path appears in the **Attached Block Volumes** list for an instance, in the **Device Path** field. An example is shown in the following screenshot.

Device Paths on the Instance

Use the following sample commands to perform various configuration tasks on the attached volume. Commands are provided for volumes that use consistent device paths and for volumes that don't.

Creating a partition with `fdisk`

- **No device path specified:**

```
fdisk /dev/sdb
```

- **Device path specified:**

```
fdisk /dev/oracleoci/oraclevdb
```

Creating an ext3 file system

- **No device path specified:**

```
/sbin/mkfs.ext3 /dev/sdb1
```

- **Device path specified:**

```
/sbin/mkfs.ext3 /dev/oracleoci/oraclevdb1
```

Updating the `/etc/fstab` file

- **No device path specified:**

```
UUID=84dc162c-43dc-429c-9ac1-b511f3f0e23c /oradiskvdb1 xfs defaults,_netdev,noatime 0 2
```

- **Device path specified:**

```
/dev/oracleoci/oraclevdb1   /oradiskvdb1    ext3    defaults,_netdev,noatime  0  2
```

Mounting the file system

- **No device path specified:**

```
mount /dev/sdb1 /oradiskvdb1
```

- **Device path specified:**

```
mount /dev/oracleoci/oraclevdb1 /oradiskvdb1
```

Connecting to a Volume

For volumes attached with Paravirtualized as the volume attachment type, you do not need to perform any additional steps after Attaching a Volume, the volumes are connected automatically. However, for Linux-based images, if you want to mount these volumes on instance boot, you need to perform additional configuration steps. If you specified a device path when you attached the volume, see fstab Options for Block Volumes Using Consistent Device Paths. If you did not specify a device path or if your instance was created from an image that does not support device paths, see Traditional fstab Options.

For volumes attached with iSCSI as the volume attachment type, you need to connect and mount the volume from the instance for the volume to be usable. For more information about attachment type options, see Volume Attachment Types. In order to connect the volume, you must first attach the volume to the instance, see Attaching a Volume.

Connecting to iSCSI-Attached Volumes

Required IAM Policy

Connecting a volume to an instance does not require a specific IAM policy. However, you may need permission to run the necessary commands on the instance's guest OS. Contact your system administrator for more information.

Prerequisites

You must attach the volume to the instance before you can connect the volume to the instance's guest OS. For details, see Attaching a Volume.

To connect the volume, you need the following information:

- iSCSI IP Address
- iSCSI Port numbers
- CHAP credentials (if you enabled CHAP)
- IQN

The Console provides the commands required to configure, authenticate, and log on to iSCSI.

Connecting to a Volume on a Linux Instance

1. Use the Console to obtain the iSCSI data you need to connect the volume:
    a. Log on to Oracle Cloud Infrastructure.
    b. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
    c. Click the name of the instance to display the instance details.
    d. In the **Resources** section on the **Instance Details** page, click **Attached Block Volumes** to view the attached block volume.
    e. Click the Actions icon (three dots) next to the volume you're interested in, and then click **iSCSI Commands and Information**.
    The **iSCSI Commands and Information** dialog box displays specific identifying information about your volume and the iSCSI commands you'll need. The commands are ready to use with the appropriate information included. You can copy and paste the commands into your instance session window for each of the following steps.
2. Log on to your instance's guest OS.

3. Register the volume with the `iscsiadm` tool.

```
iscsiadm -m node -o new -T <volume IQN> -p <iSCSI IP address>:<iSCSI port>
```

   A successful registration response resembles the following:

```
New iSCSI node [tcp:[hw=,ip=,net_if=,iscsi_if=default] 169.254.0.2,3260,-1 iqn.2015-
12.us.oracle.com:c6acda73-90b4-4bbb-9a75-faux09015418] added
```

4. Configure iSCSI to automatically connect to the authenticated block storage volumes after a reboot:

```
iscsiadm -m node -T <volume IQN> -o update -n node.startup -v automatic
```

   Note: All command arguments are essential. Success returns no response.

5. Skip this step if CHAP is not enabled. If you enabled CHAP when you attached the volume, authenticate the iSCSI connection by providing the volume's CHAP credentials as follows:

```
iscsiadm -m node -T <volume IQN> -p <iSCSI IP address>:<iSCSI port> -o update -n
node.session.auth.authmethod -v CHAP
```

```
iscsiadm -m node -T <volume IQN> -p <iSCSI IP address>:<iSCSI port> -o update -n
node.session.auth.username -v <CHAP user name>
```

```
iscsiadm -m node -T <volume's IQN> -p <iSCSI IP address>:<iSCSI port> -o update -n
node.session.auth.password -v <CHAP password>
```

   Success returns no response.

6. Log in to iSCSI:

```
iscsiadm -m node -T <volume's IQN> -p <iSCSI IP Address>:<iSCSI port> -l
```

   A successful login response resembles the following:

```
Logging in to [iface: default, target: iqn.2015-12.us.oracle.com:c6acda73-90b4-4bbb-9a75-
faux09015418, portal: 169.254.0.2,3260] (multiple)
Login to [iface: default, target: iqn.2015-12.us.oracle.com:c6acda73-90b4-4bbb-9a75-faux09015418,
portal: 169.254.0.2,3260] successful.
```

7. You can now format (if needed) and mount the volume. To get a list of mountable iSCSI devices on the instance, run the following command:

```
fdisk -l
```

The connected volume listing resembles the following:

```
Disk /dev/sdb: 274.9 GB, 274877906944 bytes, 536870912 sectors
Units = sectors of 1 * 512 = 512 bytes
Sector size (logical/physical): 512 bytes / 512 bytes
I/O size (minimum/optimal): 512 bytes / 512 bytes
```

Tip

If you have multiple volumes that do not have CHAP enabled, you can log in to them all at once by using the following commands:

```
iscsiadm -m discovery -t sendtargets -p <iSCSI IP address>:<iSCSI port>
iscsiadm -m node -l
```

Connecting to a Volume on a Windows Instance

Warning

When connecting to a Windows boot volume as a data volume from a second instance, you need to append `-IsMultipathEnabled $True` to the `Connect-IscsiTarget` command. See Attaching a Windows boot volume as a data volume to another instance fails for more information.

1. Use the Console to obtain the iSCSI data you need to connect the volume:
    a. Log on to Oracle Cloud Infrastructure.
    b. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
    c. Click your instance's name to display the instance details.
    d. In the **Resources** section on the **Instance Details** page, click **Attached Block Volumes** to view the attached block volume.
    e. Click the Actions icon (three dots) next to the volume you're interested in, and then click **iSCSI Commands and Information**.
    The **iSCSI Commands and Information** dialog box displays your volume's IP address and port, which you'll need to know later in this procedure.
2. Log in to your instance using a Remote Desktop client.
3. On your Windows instance, open the iSCSI Initiator. The steps to open the iSCSI Initiator may vary depending on the version of Windows.
    For example: Open **Server Manager**, click **Tools**, and then select **iSCSI Initiator**.
4. In the iSCSI Initiator Properties dialog box, click the **Discovery** tab, and then click **Discover Portal**.
5. Enter the block volume **IP Address** and **Port**, and then click **OK**.
6. Click the **Targets** tab.
7. Under **Discovered targets**, select the volume IQN.
8. Click **Connect**.
9. Make sure that the **Add this connection to the list of favorite targets** check box is selected, and then click **OK**.
10. You can now format (if needed) and mount the volume. To view a list of mountable iSCSI devices on your instance, in **Server Manager**, click **File and Storage Services**, and then click **Disks**.
    The disk is displayed in the list.

fstab Options for Block Volumes Using Consistent Device Paths

On Linux instances, if you want to automatically mount volumes on instance boot, you need to set some specific options in the `/etc/fstab` file, or the instance may fail to launch.

Note

These steps are for block volumes that are attached with consistent device paths enabled. If the block volume does not have consistent device paths enabled, use the legacy etc/fstab options instead.

Prerequisites

Before using a consistent device path, you should confirm that the instance supports consistent device paths and is correctly configured.

To verify that the volume is attached to a supported instance, connect to the instance and run the following command:

```
ll /dev/oracleoci/oraclevd*
```

The output will look similar to the following:

```
lrwxrwxrwx. 1 root root 6 Feb  7 21:02 /dev/oracleoci/oraclevda -> ../sda
lrwxrwxrwx. 1 root root 7 Feb  7 21:02 /dev/oracleoci/oraclevda1 -> ../sda1
lrwxrwxrwx. 1 root root 7 Feb  7 21:02 /dev/oracleoci/oraclevda2 -> ../sda2
lrwxrwxrwx. 1 root root 7 Feb  7 21:02 /dev/oracleoci/oraclevda3 -> ../sda3
```

If you don't see this output and instead see the following error message:

```
cannot access /dev/oracleoci/oraclevd*: No such file or directory
```

there may be a problem with the instance configuration for device paths. For assistance with this, contact Support.

Use the _netdev and nofail Options

By default, the `/etc/fstab` file is processed before the initiator starts. To configure the mount process to initiate before the volumes are mounted, specify the `_netdev` option on each line of the `/etc/fstab` file.

When you create a custom image of an instance where the volumes, excluding the root volume, are listed in the `/etc/fstab` file, instances will fail to launch from the custom image. To prevent this issue, specify the `nofail` option in the `/etc/fstab` file.

In the example scenario with three volumes, the `/etc/fstab` file entries for the volumes with the `_netdev` and `nofail` options are as follows:

```
/dev/oracleoci/oraclevdb /mnt/vol1 xfs defaults,_netdev,nofail 0 2
/dev/oracleoci/oraclevdc /mnt/vol2 xfs defaults,_netdev,nofail 0 2
/dev/oracleoci/oraclevdd /mnt/vol3 xfs defaults,_netdev,nofail 0 2
```

After you have updated the `/etc/fstab` file, use the following command to mount the volumes:

```
bash-4.2$ sudo mount -a
```

Reboot the instance to confirm that the volumes are mounted properly on reboot with the following command:

```
bash-4.2$ sudo reboot
```

Troubleshooting Issues with the /etc/fstab File

If the instance fails to reboot after you update the `/etc/fstab` file, you may need to undo the changes to the `/etc/fstab` file. To update the file, first connect to the serial console for the instance. When you have access to the instance using the serial console connection, you can remove, comment out, or fix the changes that you made to the `/etc/fstab` file.

Traditional fstab Options

On Linux instances, if you want to automatically mount volumes on instance boot, you need to set some specific options in the `/etc/fstab` file, or the instance may fail to launch.

Note

These steps are for block volumes that do not have consistent device paths enabled. If consistent device paths are enabled for the block volume, use the /etc/fstab options for block volumes using consistent device paths instead.

Volume UUIDs

On Linux operating systems, the order in which volumes are attached is non-deterministic, so it can change with each reboot. If you refer to a volume using the device name, such as `/dev/sdb`, and you have more than one non-root volume, you can't guarantee that the volume you intend to mount for a specific device name will be the volume mounted.

To prevent this issue, specify the volume UUID in the `/etc/fstab` file instead of the device name. When you use the UUID, the mount process matches the UUID in the superblock with the mount point specified in the `/etc/fstab` file. This process guarantees that the same volume is always mounted to the same mount point.

Determining the UUID for a Volume

1. Follow the steps to attach a volume and connect to the volume.
2. After the volumes are connected, create the file system of your choice on each volume using standard Linux tools.
   The remaining steps assume that three volumes were connected, and that an XFS file system was created on each volume.

3. Run the following command to use the **blkid** utility to get the UUIDs for the volumes:

```
sudo blkid
```

The output will look similar to the following:

```
{{ /dev/sda3: UUID="1701c7e0-7527-4338-ae9f-672fd8d24ec7" TYPE="xfs" PARTUUID="82d2ba4e-4d6e-
4a33-9c4d-ba52db57ea61"}}
{{ /dev/sda1: UUID="5750-10A1" TYPE="vfat" PARTLABEL="EFI System Partition" PARTUUID="082c26fd-
85f5-4db2-9f4e-9288a3f3e784"}}
{{ /dev/sda2: UUID="1aad7aca-689d-4f4f-aff0-e0d46fc1b89f" TYPE="swap" PARTUUID="94ee5675-a805-
49b2-aaf5-2fa15aade8d5"}}
{{ /dev/sdb: UUID="699a776a-3d8d-4c88-8f46-209101f318b6" TYPE="xfs"}}
{{ /dev/sdd: UUID="85566369-7148-4ffc-bf97-50954cae7854" TYPE="xfs"}}
{{ /dev/sdc: UUID="ba0ac1d3-58cf-4ff0-bd28-f2df532f7de9" TYPE="xfs"}}
```

The root volume in this output is `/dev/sda*`. The additional remote volumes are:

- `/dev/sdb`
- `/dev/sdc`
- `/dev/sdd`

4. To automatically attach the volumes at `/mnt/vol1`, `/mnt/vol2`, and `/mnt/vol3` respectively, create the three directories using the following commands:

```
bash-4.2$ sudo mkdir /mnt/vol1
{{ bash-4.2$ sudo mkdir /mnt/vol2}}
{{ bash-4.2$ sudo mkdir /mnt/vol3}}
```

Use the _netdev and nofail Options

By default, the `/etc/fstab` file is processed before the initiator starts. To configure the mount process to initiate before the volumes are mounted, specify the `_netdev` option on each line of the `/etc/fstab` file.

When you create a custom image of an instance where the volumes, excluding the root volume, are listed in the `/etc/fstab` file, instances will fail to launch from the custom image. To prevent this issue, specify the `nofail` option in the `/etc/fstab` file.

In the example scenario with three volumes, the `/etc/fstab` file entries for the volumes with the `_netdev` and `nofail` options are as follows:

```
UUID=699a776a-3d8d-4c88-8f46-209101f318b6 /mnt/vol1 xfs defaults,_netdev,nofail 0 2
UUID=ba0ac1d3-58cf-4ff0-bd28-f2df532f7de9 /mnt/vol2 xfs defaults,_netdev,nofail 0 2
UUID=85566369-7148-4ffc-bf97-50954cae7854 /mnt/vol3 xfs defaults,_netdev,nofail 0 2
```

After you have updated the `/etc/fstab` file, use the following command to mount the volumes:

```
bash-4.2$ sudo mount -a
```

Reboot the instance to confirm that the volumes are mounted properly on reboot with the following command:

```
bash-4.2$ sudo reboot
```

Troubleshooting Issues with the /etc/fstab File

If the instance fails to reboot after you update the `/etc/fstab` file, you may need to undo the changes to the `/etc/fstab` file. To update the file, first connect to the serial console for the instance. When you have access to the instance using the serial console connection, you can remove, comment out, or fix the changes that you made to the `/etc/fstab` file.

Listing Volumes

You can list all Block Volume volumes in a specific compartment, as well as detailed information on a single volume.

Required IAM Service Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: The policy in Let users launch Compute instances includes the ability to list volumes. The policy in Let volume admins manage block volumes, backups, and volume groups lets the specified group do everything with block volumes and backups, but not launch instances.

If you're new to policies, see Getting Started with Policies and Common Policies. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services.

Using the Console

Open the navigation menu. Under **Core Infrastructure**, go to **Block Storage** and click **Block Volumes**. A detailed list of volumes in your current compartment is displayed.

- To view the volumes in a different compartment, change the compartment in the **Compartment** drop-down menu.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

List Volumes:

Get a list of volumes within a compartment.

- ListVolumes

Get a Single Volume:

Get detailed information on a single volume:

- GetVolume

Listing Volume Attachments

You can use the API to list all Block Volume volume attachments in a specific compartment, as well as detailed information on a single volume attachment.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: The policy in Let users launch Compute instances includes the ability to list volume attachments. The policy in Let volume admins manage block volumes, backups, and volume groups lets the specified group do everything with block volumes and backups, but not launch instances.

If you're new to policies, see Getting Started with Policies and Common Policies. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

List Attachments:

Get information on all volume attachments in a specific compartment.

- ListVolumeAttachments

Get a Single Attachment:

Get detailed information on a single attachment.

- GetVolumeAttachment

Listing Boot Volume Attachments

You can use the API to list all the boot volume attachments in a specific compartment. You can also use the API to retrieve detailed information on a single boot volume attachment.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: The policy in Let users launch Compute instances includes the ability to list volume attachments. The policy in Let volume admins manage block volumes, backups, and volume groups lets the specified group do everything with block volumes and backups, but not launch instances.

If you're new to policies, see Getting Started with Policies and Common Policies. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

List Boot Volume Attachments:

Get information on all boot volume attachments in a specific compartment.

- ListBootVolumeAttachments

Get a Single Boot Volume Attachment:

Get detailed information on a single boot volume attachment.

- GetBootVolumeAttachment

Renaming a Volume

You can use the API to change the display name of a Block Volume volume.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: The policy in Let users launch Compute instances includes the ability to rename block volumes. The policy in Let volume admins manage block volumes, backups, and volume groups lets the specified group do everything with block volumes and backups, but not launch instances.

If you're new to policies, see Getting Started with Policies and Common Policies. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services.

Using the API

To update a volume's display name, use the following operation:

- UpdateVolume

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Resizing a Volume

The Oracle Cloud Infrastructure Block Volume service lets you expand the size of block volumes and boot volumes. You have three options to increase the size of your volumes:

- Expand an existing volume in place with offline resizing. See Resizing a Volume Using the Console for the steps to do this.
- Restore from a volume backup to a larger volume. See Restoring a Backup to a New Volume and Restoring a Boot Volume.
- Clone an existing volume to a new, larger volume. See Cloning a Volume and Cloning a Boot Volume.

For more information about the Block Volume service, see the Block Volume FAQ.

You can only increase the size of the volume, you cannot decrease the size. You can attach a volume and start using it as soon as it's resized and becomes available.

This topic describes how to expand your volume in place with offline resizing.

Warning

Before you resize a boot or block volume, you should create a backup of the volume.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: The policy in Let users launch Compute instances includes the ability to attach/detach existing block volumes. The policy in Let volume admins manage block volumes, backups, and volume groups lets the specified group do everything with block volumes and backups, but not launch instances.

If you're new to policies, see Getting Started with Policies and Common Policies. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services.

Considerations When Resizing a Volume

Whenever you detach and re-attach volumes, there are complexities and risks for both Linux-based and Windows-based instances. This applies to both paravirtualized and iSCSI attachment types. You should keep the following in mind when resizing volumes:

- When you re-attach a volume to an instance after resizing, if you are not using consistent device paths, or the instance does not support consistent device paths, device order and path may change. If you are using a tool such as Logical Volume Manager (LVM), you may need to fix the device mappings. For more information about consistent device paths, see Connecting to Volumes With Consistent Device Paths.

- When you detach and then re-attach an iSCSI-attached volume to an instance, the volume's IP address will increment.
- Before you resize a volume, you should create a full backup of the volume.

Resizing a Volume Using the Console

Resizing a Block Volume

1. Detach the block volume, see Detaching a Volume.
2. Open the navigation menu. Under **Core Infrastructure**, go to **Block Storage** and click **Block Volumes**.
3. In the **Block Volumes** list, click the block volume you want to resize.
4. Click **Resize**.
5. Specify the new size and click **Resize**. You must specify a larger value than the block volume's current size.
6. Reattach the block volume, see Attaching a Volume.
7. Extend the partition, see Extending the Partition for a Block Volume.

Resizing a Boot Volume for a Windows Instance

1. Stop the instance, see Stopping and Starting an Instance.
2. Detach the boot volume, see Detaching a Boot Volume.
3. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Boot Volumes**.
4. In the **Boot Volumes** list, click the boot volume you want to resize.
5. Click **Resize**.
6. Specify the new size and click **Resize**. You must specify a larger value than the boot volume's current size.

7. Reattach the boot volume, see Attaching a Boot Volume.
8. Restart the instance, see Stopping and Starting an Instance.
9. Extend the partition, see Extending the System Partition on a Windows-Based Image.

Resizing a Boot Volume for a Linux Instance

1. Stop the instance, see Stopping and Starting an Instance.
2. Detach the boot volume, see Detaching a Boot Volume.
3. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Boot Volumes**.
4. In the **Boot Volumes** list, click the boot volume you want to resize.
5. Click **Resize**.
6. Specify the new size and click **Resize**. You must specify a larger value than the boot volume's current size.
7. Attach the boot volume to a second instance as a data volume. See Attaching a Volume and Connecting to a Volume.
8. Extend the partition and grow the file system, see Extending the Root Partition on a Linux-Based Image.
9. Reattach the boot volume, see Attaching a Boot Volume.
10. Restart the instance, see Stopping and Starting an Instance.

Extending the Partition for a Block Volume

The Oracle Cloud Infrastructure Block Volume service lets you expand the size of block volumes with offline volume resizing. For more information, see Resizing a Volume. In order to take advantage of the larger volume size, you need to extend the partition for the block volume.

Required IAM Policy

Extending a partition on an instance does not require a specific IAM policy. However, you may need permission to run the necessary commands on the instance's guest OS. Contact your system administrator for more information.

Extending a Partition on a Linux-Based Image

On Linux-based images, use the following steps to extend the partition for a block volume.

PREREQUISITES

After you have resized a volume, you need to attach it to an instance before you can extend the partition and grow the file system. See Attaching a Volume and Connecting to a Volume for more information.

EXTENDING THE LINUX PARTITION

Extending a partition

1. To identify the volume that you want to extend the partition for, run the following command to list the attached block volumes:

   ```
   lsblk
   ```

2. Run the following command to edit the volume's partition table with `parted`:

   ```
   parted <volume_id>
   ```

   <volume_id> is the volume identifier, for example `/dev/sdc`.

3. When you run `parted`, you may encounter the following error message:

   ```
   Warning: Not all of the space available to <volume_id> appears to be used,
   you can fix the GPT to use all of the space (an extra volume_size blocks)
   or continue with the current setting?
   ```

   You are then prompted to fix the error or ignore the error and continue with the current setting. Specify the option to fix the error.

4. Run the following command to change the display units to sectors so that you can see the precise start position for the volume:

   ```
   (parted) unit s
   ```

5. Run the following command to display the current partitions in the partition table:

   ```
   (parted) print
   ```

   Make note of the values in the **Number**, **Start**, and **File system** columns for the root partition.

6. Run the following command to remove the existing root partition:

   ```
   (parted) rm <partition_number>
   ```

   <partition_number> is the value from the **Number** column.

7. Run the following command to recreate the partition:

   ```
   (parted) mkpart
   ```

   At the `Start?` prompt, specify the value from the **Start** column. At the `File system type?` prompt, specify the value from the **File system** column. Specify `100%` for the `End?` prompt.

8. Run the following command to exit `parted`:

   ```
   (parted) quit
   ```

   This command forces a rewrite of the partition table with the new partition settings that you specified.

9. To verify that the root partition was extended, run the following command to list the attached block volumes:

   ```
   lsblk
   ```

After you extend the root partition you need to grow the file system. The steps in the following procedure apply only to xfs file systems.

Growing the file system for a partition

1. Before you grow the file system, repair any issues with the file system on the extended partition by running the following command:

   ```
   xfs_repair <partition_id>
   ```

   <partition_id> is the partition identifier, for example `/dev/sdc1`. See Checking and Repairing an XFS File System for more information.

2. After you have confirmed that there are no more issues to repair, you need to create a mount point to run the `xfs_growfs` against. To do this, create a directory and mount the partition to that directory by running the following commands:

   ```
   mkdir <directory_name>
   mount <partition_id> <directory_name> -o nouuid
   ```

   <partition_id> is the partition identifier, for example `/dev/sdc1`, and *<directory_name>* is the directory name, for example `data`.

3. After you have created the mount point run the following command to grow the file system:

   ```
   xfs_growfs -d <directory_name>
   ```

   <directory_name> is the name for the directory you created in the previous step, for example `data`.

4. To verify that the file system size is correct, run the following command to display the file system details:

   ```
   df -lh
   ```

Extending a Partition on a Windows-Based Image

On Windows-based images, you can extend a partition using the Windows interface or from the command line using the DISKPART utility.

Windows Server 2016 and Windows Server 2012

The steps to extend a partition for a block volume attached to an instance running Windows 2012 or Windows 2016 are the same, and are described in the following procedures.

Extending a partition using the Windows interface

1. Open the Disk Management system utility on the instance.
2. Right-click the expanded block volume and select **Extend Volume**.
3. Follow the instructions in the **Extend Volume Wizard**:
    a. Select the disk that you want to extend, enter the size, and then click **Next**.
    b. Confirm that the disk and size settings are correct, and then click **Finish**.
4. Verify that the block volume's disk has been extended in Disk Management.

Extending a partition using the command line with DISKPART

1. Open a command prompt as administrator on the instance.
2. Run the following command to start the DISKPART utility:

    ```
    diskpart
    ```

3. At the `DISKPART` prompt, run the following command to display the instance's volumes:

    ```
    list volume
    ```

4. Run the following command to select the expanded block volume:

    ```
    select volume <volume_number>
    ```

    <volume_number> is the number associated with the block volume that you want to extend the partition for.

5. Run the following command to extend the partition:

```
extend size=<increased_size_in_MB>
```

<increased_size_in_MB> is the size in MB that you want to extend the partition to.

Warning

When using the DISKPART utility, do not overextend the partition beyond the current available space. Overextending the partition could result in data loss.

6. To confirm that the partition was extended, run the following command and verify that the block volume's partition has been extended:

```
list volume
```

WINDOWS SERVER 2008

Use the steps described in the following procedures to extend a partition on instances running Windows 2008.

Extending the system partition using the Windows interface

1. Open the Server Manager on the instance.
2. Expand the **Storage** node in the left navigation pane and click **Disk Management**.
3. Right-click the expanded block volume and select **Extend Volume**.
4. Follow the instructions in the **Extend Volume Wizard**:
   a. Select the disk that you want to extend, enter the size, and then click **Next**.
   b. Confirm that the disk and size settings are correct, and then click **Finish**.
5. Verify that the block volume's disk has been extended in the Server Manager's **Disk Management** node.

Extending a partition using the command line with DISKPART

1. Open a command prompt as administrator on the instance.
2. Run the following command to start the DISKPART utility:

   ```
   diskpart
   ```

3. At the `DISKPART` prompt, run the following command to display the instance's volumes:

   ```
   list volume
   ```

4. Run the following command to select the expanded block volume:

   ```
   select volume <volume_number>
   ```

   <volume_number> is the number associated with the block volume that you want to extend the partition for.

5. Run the following command to extend the partition:

   ```
   extend size=<increased_size_in_MB>
   ```

   <increased_size_in_MB> is the size in MB that you want to extend the partition to.

   Warning

   When using the DISKPART utility, do not overextend the partition beyond the current available space. Overextending the partition could result in data loss.

6. To confirm that the partition was extended, run the following command and verify that the boot volume's partition has been extended:

   ```
   list volume
   ```

Overview of Block Volume Backups

The backups feature of the Oracle Cloud Infrastructure Block Volume service lets you make a point-in-time backup of data on a block volume. These backups can then be restored to new volumes either immediately after a backup or at a later time that you choose.

Backups are encrypted and stored in Oracle Cloud Infrastructure Object Storage, and can be restored as new volumes to any availability domain within the same region they are stored. This capability provides you with a spare copy of a volume and gives you the ability to successfully complete disaster recovery within the same region.

There are two ways you can initiate a backup, either by manually starting the backup, or by assigning a policy which defines a set backup schedule.

Manual Backups

These are on-demand one-off backups that you can launch immediately by following the steps described in Backing Up a Volume. When launching a manual backup, you can specify whether an incremental or a full backup should be performed. See Volume Backup Types for more information about backup types.

Policy-Based Backups

These are automated scheduled backups. Each backup policy has a set backup frequency and retention period. There are three predefined policies, Bronze, Silver, and Gold.

See Policy-Based Backups for more information.

Volume Backup Types

There are two backup types available in the Block Volume service:

- **Incremental:** This backup type includes only the changes since the last backup.
- **Full:** This backup type includes all changes since the volume was created.

Note

Backup Details

Backups are not an identical copy of the volume being backed up. For incremental backups, they are a record of all the changes since the last backup. For full backups, they are a record of all the changes since the volume was created. For example, in a scenario where you create a 16 TB block volume, modify 40 GB on the volume, and then launch a full backup, upon completion the volume backup size is 40 GB.

Planning Your Backup

The primary use of backups is to support business continuity, disaster recovery, and long-term archiving requirements. When determining a backup schedule, your backup plan and goals should consider the following:

- **Frequency:** How often you want to back up your data.
- **Recovery time:** How long you can wait for a backup to be restored and accessible to the applications that use it. The time for a backup to complete varies on several factors, but it will generally take a few minutes or longer, depending on the size of the data being backed up and the amount of data that has changed since your last backup.
- **Number of stored backups:** How many backups you need to keep available and the deletion schedule for those you no longer need. You can only create one backup at a time, so if a backup is underway, it will need to complete before you can create another one. For details about the number of backups you can store, see Block Volume Capabilities and Limits.

The common use cases for using backups are:

- Needing to create multiple copies of the same volume. Backups are highly useful in cases where you need to create many instances with many volumes that need to have the same data formation.
- Taking a snapshot of your work that you can restore to a new volume at a later time.
- Ensuring you have a spare copy of your volume in case something goes wrong with your primary copy.

Copying Block Volume Backups Across Regions

You can copy block volume backups between regions using the Console, command line interface (CLI), SDKs, or REST APIs. For steps, see Copying a Volume Backup Between Regions. This capability enhances the following scenarios:

- **Disaster recovery and business continuity:** By copying block volume backups to another region at regular intervals, it makes it easier for you to rebuild applications and data in the destination region if a region-wide disaster occurs in the source region.
- **Migration and expansion:** You can easily migrate and expand your applications to another region.

To copy volume backups between regions, you must have permission to read and copy volume backups in the source region, and permission to create volume backups in the destination region. For more information see Required IAM Policy.

Once you have copied the volume backup to the new region you can then restore from that backup by creating a new volume from the backup using the steps described in Restoring a Backup to a New Volume.

Volume Backup Encryption

The Oracle Cloud Infrastructure Block Volume service always encrypts all block volumes, boot volumes, and volume backups at rest by using the Advanced Encryption Standard (AES) algorithm with 256-bit encryption.

The Oracle Cloud Infrastructure Key Management service enables you to bring and manage your own keys to use for encrypting volumes and their backups. When you create a volume backup, the encryption key used for the volume is also used for the volume backup. When you restore the backup to create a new volume you configure a new key, see Restoring a Backup to a New Volume. See also Overview of Key Management.

If you do not configure a volume to use the Key Management service, the Block Volume service uses the Oracle-provided encryption key instead. This applies to both encryption at-rest and in-transit encryption.

Best Practices When Creating Block Volume Backups

When creating and restoring from backups, keep in mind the following:

- Before creating a backup, you should ensure that the data is consistent: Sync the file system, unmount the file system if possible, and save your application data. Only the data on the disk will be backed up. When creating a backup, after the backup state changes from REQUEST_RECEIVED to CREATING, you can return to writing data to the volume. While a backup is in progress, the volume that is being backed up cannot be deleted.
- If you want to attach a restored volume that has the original volume attached, be aware that some operating systems do not allow you to restore identical volumes. To resolve this, you should change the partition IDs before restoring the volume. The steps to change an operating system's partition ID vary by operating system. For instructions, see your operating system's documentation.
- You should not delete the original volume until you have verified that the backup you created of it completed successfully.

See Backing Up a Volume and Restoring a Backup to a New Volume for more information.

Differences Between Block Volume Backups and Clones

Consider the following criteria when you decide whether to create a backup or a clone of a volume.

	Volume Backup	**Volume Clone**
Description	Creates a point-in-time backup of data on a volume. You can restore multiple new volumes from the backup later in the future.	Creates a single point-in-time copy of a volume without having to go through the backup and restore process.
Use case	Retain a backup of the data in a volume, so that you can duplicate an environment later or preserve the data for future use. Meet compliance and regulatory requirements, because the data in a backup remains unchanged over time. Support business continuity requirements. Reduce the risk of outages or data mutation over time.	Rapidly duplicate an existing environment. For example, you can use a clone to test configuration changes without impacting your production environment.
Speed	Slower (minutes or hours)	Faster (seconds)
Cost	Lower cost	Higher cost
Storage location	Object Storage	Block Volume

	Volume Backup	Volume Clone
Retention policy	Policy-based backups expire, manual backups do not expire	No expiration
Volume groups	Supported. You can back up a volume group.	Supported. You can clone a volume group.

For background information and steps to clone a block volume, see Cloning a Volume.

Using the CLI or REST APIs to Customize and Manage the Lifecycle of Volume Backups

You can use the CLI, REST APIs, or the SDKs to automate, script, and manage volume backups and their lifecycle.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Using the CLI

This section provides basic sample CLI commands that you can use in a script, such as a cron job run by the cron utility on Linux-based operating systems, to perform automatic backups at specific times. For information about using the CLI, see Command Line Interface (CLI).

To create a manual backup of the specified block volume

Open a command prompt and run:

```
oci bv backup create --volume-id <block_volume_OCID> --display-name <Name> --type <FULL|INCREMENTAL>
```

For example:

```
oci bv backup create --volume-id  ocid1.volume.oc1..<unique_ID> --display-name "backup display name" --
type FULL
```

To delete a block volume backup

Open a command prompt and run:

```
oci bv backup delete --volume-backup-id <volume_backup_OCID>
```

For example:

```
oci bv backup delete --volume-backup-id ocid1.volume.oc1..<unique_ID>
```

To create a manual backup of the specified boot volume

Open a command prompt and run:

```
oci bv boot-volume-backup create --volume-id <boot_volume_OCID> --display-name <Name> --type
<FULL|INCREMENTAL>
```

For example:

```
oci bv boot-volume-backup create --volume-id  ocid1.volume.oc1..<unique_ID> --display-name "backup
display name" --type FULL
```

To delete a boot volume backup

Open a command prompt and run:

```
oci bv backup delete --boot-volume-backup-id <boot_volume__backup_OCID>
```

For example:

```
oci bv backup delete --boot-volume-backup-id ocid1.volume.oc1..<unique_ID>
```

To list the Oracle-defined backup policies

Open a command prompt and run:

```
oci bv volume-backup-policy list
```

To assign an Oracle-defined backup policy to a boot or block volume

Open a command prompt and run:

```
oci bv volume-backup-policy-assignment create --asset-id <volume_OCID> --policy-id <policy_OCID>
```

For example:

```
oci bv volume-backup-policy-assignment create --asset-id  ocid1.volume.oc1..<unique_ID> --policy-id
ocid1.volumebackuppolicy.oc1..<unique_ID>
```

To un-assign an Oracle-defined backup policy from a boot or block volume

Open a command prompt and run:

```
oci bv volume-backup-policy-assignment delete --policy-assignment-id <policy_assignment_OCID>
```

For example:

```
oci bv volume-backup-policy-assignment delete --policy-assignment-id
ocid1.volumebackuppolicyassign.oc1..<unique_ID>
```

To retrieve the backup policy assignment ID for a boot or block volume

Open a command prompt and run:

```
oci bv volume-backup-policy-assignment get-volume-backup-policy-asset-assignment --asset-id <volume_
OCID>
```

For example:

```
oci bv volume-backup-policy-assignment get-volume-backup-policy-asset-assignment --asset-id
ocid1.volume.oc1..<unique_ID>
```

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the following operations for working with block volume backups, boot volume backups, and backup policies.

Block Volume Backups

- CreateVolumeBackup
- DeleteVolumeBackup
- GetVolumeBackup
- ListVolumeBackups
- UpdateVolumeBackup

Boot Volume Backups

- CreateBootVolumeBackup
- DeleteBootVolumeBackup
- GetBootVolumeBackup
- ListBootVolumeBackups
- UpdateBootVolumeBackup

Volume Backup Policies and Policy Assignments

- GetVolumeBackupPolicy
- ListVolumeBackupPolicies
- CreateVolumeBackupPolicyAssignment
- DeleteVolumeBackupPolicyAssignment
- GetVolumeBackupPolicyAssetAssignment
- GetVolumeBackupPolicyAssignment

Backing Up a Volume

You can create a backup of a volume using Block Volume.

For information to help you decide whether to create a backup or a clone of a boot volume, see Differences Between Block Volume Backups and Clones.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: The policy in Let volume admins manage block volumes, backups, and volume groups lets the specified group do everything with block volumes and backups. The policy in Let volume backup admins manage only backups further restricts access to just creating and managing backups.

Tip

When users create a backup from a volume or restore a volume from a backup, the volume and backup don't have to be in the same compartment. However, users must have access to both compartments.

If you're new to policies, see Getting Started with Policies and Common Policies. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services.

Using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Block Storage** and click **Block Volumes**.
2. Click the block volume that you want to create a backup for.
3. Click **Create Manual Backup**.
4. Enter a name for the backup.
5. Select the backup type, either incremental or full. See Volume Backup Types for information about backup types.
6. Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.
7. Click **Create Backup**.
   The backup will be completed once its icon no longer lists it as **CREATING** in the volume list.

Using the API

To back up a volume, use the following operation:

- CreateVolumeBackup

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

For more information about backups, see Overview of Block Volume Backups and Restoring a Backup to a New Volume.

Policy-Based Backups

The Oracle Cloud Infrastructure Block Volume service provides you with the capability to perform volume backups automatically on a schedule and retain them based on the selected backup policy. This allows you to adhere to your data compliance and regulatory requirements.

Warning

Deleting Block Volumes with Policy-Based Backups

All policy-based backups will eventually expire, so if you want to keep a volume backup indefinitely, you need to create a manual backup.

There are two kinds of backup policies:

- **Oracle defined**: Predefined backup policies that have a set backup frequency and retention period. You cannot modify these policies.
- **User defined**: Custom backup policies that you create and configure schedules for.

Oracle Defined Backup Policies

There are three Oracle defined backup policies, Bronze, Silver, and Gold. Each backup policy is comprised of schedules with a set backup frequency and a retention period that you cannot modify. If the backup policy settings for Oracle defined policies don't meet your requirements, you should use User Defined Backup Policies instead. With user defined backup policies you define and control the schedules.

Bronze Policy

The bronze policy includes monthly incremental backups, run on the first day of the month. These backups are retained for twelve months. This policy also includes a full backup, run yearly on January 1st. Full backups are retained for five years.

Silver Policy

The silver policy includes weekly incremental backups that run on Sunday. These backups are retained for four weeks. This policy also includes monthly incremental backups, run on the first day of the month and are retained for twelve months. Also includes a full backup, run yearly on January 1st. Full backups are retained for five years.

Gold Policy

The gold policy includes daily incremental backups. These backups are retained for seven days. This policy also includes weekly incremental backups that run on Sunday and are retained for four weeks. Also includes monthly incremental backups, run on the first day of the month, retained for twelve months, and a full backup, run yearly on January 1st. Full backups are retained for five years.

User Defined Backup Policies

Oracle Cloud Infrastructure enables you to customize your backup schedules with user defined policies. These are backup policies that you define the backup frequency and retention period for. There are two parts to user defined backup policies, the backup policy itself, and then one or more schedules in the policy.

To get started with user defined backup policies, you need to first create the backup policy, see To create a user defined backup policy. After this step, you have an empty backup policy, so the next step is to define and add schedules to the policy.

Schedules

Schedules define the backup frequency and retention period for a user defined backup policy, just like Oracle defined backup policies. The difference is that you can customize the

schedules associated with user defined policies. This gives you control over the backup frequency and retention period.

When defining a schedule for a user defined backup policy, the first thing you configure is the schedule type, this specifies the backup frequency. Oracle Cloud Infrastructure provides the following schedule types:

- **Daily**: Backups are generated daily. You specify the hour of the day for the backup.
- **Weekly**: Backups are generated weekly. You specify the day of the week, and the hour of that day for the backup.
- **Monthly**: Backups are generated monthly. You specify the day of the month, and the hour of that day for the backup.
- **Yearly**: Backups are generated yearly. You specify the month, the day of that month, and the hour of that day for the backup.

In addition to frequency, you also configure the following:

- **Retention time**: The amount of time to keep the backup, in days, weeks, months, or years. The time period is based the schedule type.
- **Backup type** Options are full or incremental, see Volume Backup Types for more information.
- **Timezone** The time zone to use for the backup schedule. Options are UTC or the regional data center time zone.

For more information, see To add a schedule to a user defined backup policy.

You can also edit or remove schedules for a user defined policy at any time, see To edit a schedule for a user defined backup policy and To delete a schedule for a user defined backup policy.

Duplicating Existing Backup Policies

You can create a new backup policy by duplicating any of the existing backup policies.

If one of the Oracle defined policies is close to meeting your volume backup requirements, but with some changes, you can create a new backup policy by duplicating the Oracle defined

policy. This creates a new user defined backup policy with schedules already assigned, enabling you to use the Oracle defined policy's settings as a starting point to save time and simplify the process.

You can also duplicate an existing user defined policy. For more information, see To duplicate a backup policy. You can then add, edit, or delete schedules for the new backup policy.

Working with Backup Policies

There are two types of tasks when working with backup policies:

- Creating and Configuring User Defined Backup Policies
- Managing Backup Policy Assignments to Volumes

The linked sections listed above provide information for working with backup policies using the Console, CLI, and REST APIs.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don't have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

Important

To view or work with backup policies, you need access to the root compartment, which is where the predefined backup policies are located.

For administrators: The policy in Let volume admins manage block volumes, backups, and volume groups lets the specified group do everything with block volumes and backups. The policy in Let volume backup admins manage only backups further restricts access to just creating and managing backups.

Tip

When users create a backup from a volume or restore a volume from a backup, the volume and backup don't have to be in the same compartment. However, users must have access to both compartments.

If you're new to policies, see Getting Started with Policies and Common Policies. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services.

Tagging Resources

You can apply tags to your resources to help you organize them according to your business needs. You can update the resource later with the desired tags. For general information about applying tags, see Resource Tags.

Creating and Configuring User Defined Backup Policies

Using the Console

You can use the Console to create and update user defined backup policies.

To create a user defined backup policy

1. Open the navigation menu. Under **Core Infrastructure**, go to **Block Storage** and click **Backup Policies**.
2. Click **Create Backup Policy**.
3. Specify a name for the backup policy.
4. Select the compartment to create the backup policy in.

While you select a compartment for the backup policy, it is accessible across your tenancy.

5. Click **Create Backup Policy** to create the backup policy.

To add a schedule to a user defined backup policy

1. Open the navigation menu. Under **Core Infrastructure**, go to **Block Storage** and click **Backup Policies**.
2. Click the backup policy you want to add the schedule to.
3. Click **Add Schedule**.
4. Specify the backup frequency by selecting from the **Schedule Type** options: **Daily**, **Weekly**, **Monthly**, or **Yearly**, and then configure the additional schedule options. Depending on the schedule type, the additional schedule options will include one or more of the following:
    - Hour of the day
    - Day of the week
    - Day of the month
    - Month of the year
5. Specify the **Retention Time**, which will be in days, weeks, months, or years, depending on the schedule type you selected in the previous step.
6. Select **Full** or **Incremental** for **Backup Type**.
7. Select the **Timezone**to base the schedule settings on, either **UTC** or **Regional Data Center Time**.
8. Click **Add Schedule**.

To duplicate a backup policy

1. Open the navigation menu. Under **Core Infrastructure**, go to **Block Storage** and

click **Backup Policies**.

2. Click the backup policy that you want to duplicate.Both Oracle defined and user defined backup policies can be duplicated.
3. Click **Duplicate**.
4. Specify a name for the policy.
5. Select the compartment to create the backup policy in. It does not need to be the same compartment as the backup policy you are duplicating.
6. Click **Duplicate Backup Policy**.

To edit a schedule for a user defined backup policy

1. Open the navigation menu. Under **Core Infrastructure**, go to **Block Storage** and click **Backup Policies**.
2. Click the backup policy that you want to edit a schedule for.
3. In **Schedules**, for the schedule you want to edit, click the Actions icon (three dots), and then click **Edit**.
4. After making your changes to the schedule, click **Update**.

To delete a schedule for a user defined backup policy

1. Open the navigation menu. Under **Core Infrastructure**, go to **Block Storage** and click **Backup Policies**.
2. Click the user defined backup policy that you want to delete a schedule for.
3. In **Schedules**, for the schedule you want to delete, click the Actions icon (three dots), and then click **Delete**.
4. Click **Delete** in the confirmation dialog.

To delete a user defined backup policy

1. Open the navigation menu. Under **Core Infrastructure**, go to **Block Storage** and click **Backup Policies**.
2. Click the user defined backup policy you want to delete.
3. Click **Delete**.
4. Enter the name of the backup policy and click **Delete**.

Using the CLI

For information about using the CLI, see Command Line Interface (CLI).

Use the following operations to work with backup policies:

To create a user defined backup policy

Open a command prompt and run:

```
oci bv volume-backup-policy create --compartment-id <compartment_ID> --schedules
file//<path>/<scheduleJSON>.json
```

For example:

```
oci bv volume-backup-policy create --compartment-id ocid1.compartment.oc1..<unique_ID> --schedules
file//~/input.json
```

To list the backup policies in a specified compartment

Open a command prompt and run:

```
oci bv volume-backup-policy list --compartment-id <compartment_ID>
```

For example:

```
oci bv volume-backup-policy list --compartment-id ocid1.compartment.oc1..<unique_ID>
```

To retrieve a specific backup policy

Open a command prompt and run:

```
oci bv volume-backup-policy get --backup-policy-id  <backup-policy-ID>
```

For example:

```
oci bv volume-backup-policy get --backup-policy-id ocid1.volumebackuppolicy.oc1.phx.<unique_ID>
```

To update the display name for a user defined backup policy

Open a command prompt and run:

```
oci bv volume-backup-policy update --backup-policy-id <backup-policy_ID> --display-name <backup-policy_name>
```

For example:

```
oci bv volume-backup-policy update --backup-policy-id ocid1.volumebackuppolicy.oc1.phx.<unique_ID> --display-name "new display name"
```

To update the schedules for a user defined backup policy

Open a command prompt and run:

```
oci bv volume-backup-policy update --backup-policy-id <backup-policy_ID> --schedules file//<path>/<scheduleJSON>.json
```

For example:

```
oci bv volume-backup-policy update --volume-group-id ocid1.volumebackuppolicy.oc1.phx.<unique_ID> --schedules file//~/input.json
```

To delete a user defined backup policy

Open a command prompt and run:

```
oci bv volume-backup-policy delete --backup-policy-id <backup-policy_ID>
```

You can only delete a user defined backup policy if it is not assigned to any volumes. You cannot delete Oracle defined backup policies.

For example:

```
oci bv volume-backup-policy delete --backup-policy-id ocid1.volumebackuppolicy.oc1.phx.<unique_ID>
```

Using the API

Use the following operations to work with backup policies:

- CreateVolumeBackupPolicy
- DeleteVolumeBackupPolicy
- UpdateVolumeBackupPolicy
- ListVolumeBackupPolicies
- GetVolumeBackupPolicy

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

For more information about backups, see Overview of Block Volume Backups and Restoring a Backup to a New Volume.

Managing Backup Policy Assignments to Volumes

Using the Console

You can use the Console to assign, change, or remove both user defined and Oracle defined backup policies for existing volumes.

To assign a backup policy to a volume

1. Open the navigation menu. Under **Core Infrastructure**, go to **Block Storage** and

click **Block Volumes**.

2. Click the volume for which you want to assign a backup policy to.
3. On the **Block Volume Information** tab click **Assign** for **Backup Policy**.
4. Select the compartment containing the backup policies.
5. Select the appropriate backup policy for your requirements.
6. Click **Assign**.

To change a backup policy assigned to a volume

1. Open the navigation menu. Under **Core Infrastructure**, go to **Block Storage** and click **Block Volumes**.
2. Click the volume for which you want to change the backup policy for.
3. On the **Block Volume Information** tab click **Edit** for **Backup Policy**.
4. Select the compartment containing the backup policies.
5. Select the backup policy you want to switch to.
6. Click **Save Changes**.

To remove a backup policy assigned to a volume

1. Open the navigation menu. Under **Core Infrastructure**, go to **Block Storage** and click **Block Volumes**.
2. Click the volume for which you want to remove the backup policy for.
3. On the **Block Volume Information** tab click **Unassign** for **Backup Policy**
4. Click **Unassign** to confirm the backup policy removal.

Using the CLI

For information about using the CLI, see Command Line Interface (CLI).

Use the following operations to work with volume backup policy assignments to volumes:

To assign a backup policy to a volume

Open a command prompt and run:

```
oci bv volume-backup-policy-assignment create --asset-id <volume_ID> --policy-id <policy_ID>
```

For example:

```
oci bv volume-backup-policy-assignment create --asset-id ocid1.volume.oc1..<unique_ID> --policy-id
ocid1.volumebackuppolicy.oc1..<unique_ID>
```

To get the backup policy assigned to a volume

Open a command prompt and run:

```
oci bv volume-backup-policy-assignment get-volume-backup-policy-asset-assignment --asset-id <volume_ID>
```

For example:

```
oci bv volume-backup-policy-assignment get-volume-backup-policy-asset-assignment --asset-id
ocid1.volume.oc1..<unique_ID>
```

To retrieve a specific backup policy assignment

Open a command prompt and run:

```
oci bv volume-backup-policy-assignment get --policy-assignment-id  <backup-policy-ID>
```

For example:

```
oci bv volume-backup-policy-assignment get --policy-assignment-id
ocid1.volumebackuppolicyassignment.oc1.phx.<unique_ID>
```

To delete a backup policy assignment

Open a command prompt and run:

```
oci bv volume-backup-policy-assignment delete ----policy-assignment-id <backup-policy_ID>
```

You can only delete a user defined backup policy if it is not assigned to any volumes. You cannot delete Oracle defined backup policies.

For example:

```
oci bv volume-backup-policy-assignment delete ----policy-assignment-id
ocid1.volumebackuppolicyassignment.oc1.phx.<unique_ID>
```

Using the API

Use the following operations to manage backup policy assignments to volumes:

- CreateVolumeBackupPolicyAssignment
- DeleteVolumeBackupPolicyAssignment
- GetVolumeBackupPolicyAssetAssignment
- GetVolumeBackupPolicyAssignment

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

For more information about backups, see Overview of Block Volume Backups and Restoring a Backup to a New Volume.

Copying a Volume Backup Between Regions

You can copy volume backups from one region to another region using the Oracle Cloud Infrastructure Block Volume service. For more information, see Copying Block Volume Backups Across Regions.

Note

Limitations for Copying Volume Backups Across Regions

Copying boot volume backups across regions is not supported.

When copying block volume backups across regions in your tenancy, you can only copy one backup at a time from a specific source region.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: The first two statements listed in the Let volume admins manage block volumes, backups, and volume groups policy lets the specified group do everything with block volumes and backups with the exception of copying volume backups across regions. The aggregate resource type `volume-family` does not include the `VOLUME_BACKUP_COPY` permission, so to enable copying volume backups across regions you need to ensure that you include the third statement in that policy, which is:

```
Allow group VolumeAdmins to copy volume-backups in tenancy
```

To restrict access to just creating and managing volume backups, including copying volume backups between regions, use the policy in Let volume backup admins manage only backups. The individual resource type `volume-backups` includes the `VOLUME_BACKUP_COPY` permission, so you do not need to specify it explicitly in this policy.

If you are copying volume backups encrypted using Key Management between regions or you want the copied volume backup to use Key Management for encryption in the destination region, you need to use a policy that allows the Block Volume service to perform cryptographic operations with keys in the destination region. For a sample policy showing this, see Let Block Volume, Object Storage, File Storage services encrypt and decrypt volumes, volume backups, buckets, and file systems.

Restricting Access

The specific permissions needed to copy volume backups across regions are:

- **Source region**: `VOLUME_BACKUP_READ`, `VOLUME_BACKUP_COPY`
- **Destination region**: `VOLUME_BACKUP_CREATE`

Sample Policies

To restrict a group to specific source and destination regions for copying volume backups

In this example, the group is restricted to copying volume backups from the UK South (London) region to the Germany Central (Frankfurt) region.

```
Allow group MyTestGroup to read volume-backups in tenancy where all {request.region='lhr'}
Allow group MyTestGroup to use volume-backups in tenancy where all {request.permission='VOLUME_BACKUP_
COPY', request.region = 'lhr',
Allow group MyTestGroup to manage volume-backups in tenancy where all {request.permission='VOLUME_
BACKUP_CREATE', request.region = 'fra'}
```

To restrict some source regions to specific destination regions while enabling all destination regions for other source regions

In this example, the following is enabled for the group:

- Manage volume backups in all regions.
- Copy volume backups from the US West (Phoenix) and US East (Ashburn) regions to any destination regions.
- Copy volume backups from the Germany Central (Frankfurt) and UK South (London) regions only to the Germany Central (Frankfurt) or UK South (London) regions.

```
Allow group MyTestGroup to read volume-backups in tenancy where all {request.region='lhr'}
Allow group MyTestGroup to manage volume-backups in tenancy where any {request.permission!='VOLUME_
BACKUP_COPY'}
Allow group MyTestGroup to use volume-backups in tenancy where all {request.permission='VOLUME_BACKUP_
COPY', any {request.region='lhr', request.region='fra'}, any{target.region='fra', target.region='lhr'}}
Allow group MyTestGroup to use volume-backups in tenancy where all {request.permission='VOLUME_BACKUP_
COPY', any {request.region='phx', request.region='iad'}}
```

If you're new to policies, see Getting Started with Policies and Common Policies. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services.

Using the Console

1. Open the navigation menu. Under **Block Storage**, click **Block Volume Backups**. A list of the block volume backups in the compartment you're viewing is displayed. If you don’t see the one you're looking for, make sure you’re viewing the correct compartment (select from the list on the left side of the page).
2. Click the Actions icon (three dots) for the block volume backup you want to copy to another region.
3. Click **Copy to Another Region**.
4. Enter a name for the backup and choose the region to copy the backup to.
5. In the **Encryption** section select whether you want the volume backup to use the

Oracle-provided encryption key or your own Key Management encryption key. If you select the option to use your own key, paste the OCID for encryption key from the destination region.

6. Click **Copy Block Volume Backup**.
7. Confirm that the source and destination region details are correct in the confirmation dialog and then click **OK**.

Using the API

To copy a volume backup to another region, use the following operation:

- CopyVolumeBackup

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Next Steps

After copying the block volume backup, switch to the destination region in the Console and verify that the copied backup appears in the list of block volume backups for that region. You can then restore the backup by creating a new block volume from it using the steps in Restoring a Backup to a New Volume.

For more information about backups, see Overview of Block Volume Backups.

Restoring a Backup to a New Volume

You can restore a backup of a volume as a new volume using Block Volume.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: The policy in Let volume admins manage block volumes, backups, and volume groups lets the specified group do everything with block volumes and backups.

Tip

When users create a backup from a volume or restore a volume from a backup, the volume and backup don't have to be in the same compartment. However, users must have access to both compartments.

If you're new to policies, see Getting Started with Policies and Common Policies. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services.

Using the Console

1. Open the navigation menu. Under **Block Storage**, click **Block Volume Backups**. A list of the block volume backups in the compartment you're viewing is displayed. If you don't see the one you're looking for, make sure you're viewing the correct compartment (select from the list on the left side of the page).
2. Click the Actions icon (three dots) for the block volume backup you want to restore.
3. Click **Create Block Volume**.
4. Enter a name for the block volume and choose the availability domain in which you want to restore it.
5. You can restore a block volume backup to a larger volume size. To do this, check **Custom Block Volume Size (GB)**, and then specify the new size. You can only increase the size of the volume, you cannot decrease the size. If you restore the block volume backup to a larger size volume, you need to extend the volume's partition, see Extending the Partition for a Block Volume for more information.
6. Optionally, you can select the appropriate backup policy for your requirements. See Policy-Based Backups for more information about backup policies.
7. Optionally, you can encrypt the data in this volume using your own Key Management encryption key. To use Key Management for your encryption needs, select the **Encrypt using Key Management** check box. Then, select the **Vault Compartment** and **Vault** that contain the master encryption key you want to use. Also select the **Master Encryption Key Compartment** and **Master Encryption Key**. For more information about encryption, see Overview of Key Management.
8. Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.
9. Click **Create**.
   The volume will be ready to attach once its icon no longer lists it as **PROVISIONING** in the volume list. For more information, see Attaching a Volume.

Warning

If you want to attach a restored volume that has the original volume attached, be aware that some operating systems do not allow you to restore identical volumes. To resolve this, you should change the partition IDs before restoring the volume. How to change an operating system's partition ID varies by operating system; for instructions, see your operating system's documentation.

Using the API

The API used to restore a backup is CreateVolume. The API has an optional volumeBackupId parameter that you can use to define the backup from which the data should be restored on the newly created volume. For details, see CreateVolumeDetails Reference.

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

For more information about backups, see Overview of Block Volume Backups and Backing Up a Volume.

Cloning a Volume

You can create a clone from a volume using the Block Volume service. Cloning enables you to make a copy of an existing block volume without needing to go through the backup and restore process.

A cloned volume is a point-in-time direct disk-to-disk deep copy of the source volume, so all the data that is in the source volume when the clone is created is copied to the clone volume. Any subsequent changes to the data on the source volume are not copied to the clone. Since

the clone is a copy of the source volume it will be the same size as the source volume unless you specify a larger volume size when you create the clone.

The clone operation occurs immediately, and you can attach and use the cloned volume as a regular volume as soon as the state changes to available. At this point, the volume data is being copied in the background, and can take up to thirty minutes depending on the size of the volume.

There is a single point-in-time reference for a source volume while it is being cloned, so if the source volume is attached when a clone is created, you need to wait for the first clone operation to complete from the source volume before creating additional clones. If the source volume is detached, you can create up to ten clones from the same source volume simultaneously.

You can only create a clone for a volume within the same region, availability domain and tenant. You can create a clone for a volume between compartments as long as you have the required access permissions for the operation.

For more information about the Block Volume service and cloned volumes, see the Block Volume FAQ.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Differences Between Block Volume Clones and Backups

Consider the following criteria when you decide whether to create a backup or a clone of a volume.

	Volume Backup	**Volume Clone**
Description	Creates a point-in-time backup of data on a volume. You can restore multiple new volumes from the backup later in the future.	Creates a single point-in-time copy of a volume without having to go through the backup and restore process.
Use case	Retain a backup of the data in a volume, so that you can duplicate an environment later or preserve the data for future use. Meet compliance and regulatory requirements, because the data in a backup remains unchanged over time. Support business continuity requirements. Reduce the risk of outages or data mutation over time.	Rapidly duplicate an existing environment. For example, you can use a clone to test configuration changes without impacting your production environment.
Speed	Slower (minutes or hours)	Faster (seconds)
Cost	Lower cost	Higher cost
Storage location	Object Storage	Block Volume

	Volume Backup	Volume Clone
Retention policy	Policy-based backups expire, manual backups do not expire	No expiration
Volume groups	Supported. You can back up a volume group.	Supported. You can clone a volume group.

For more information about block volume backups, see Overview of Block Volume Backups and Backing Up a Volume.

Using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Block Storage** and click **Block Volumes**.
2. In the **Block Volumes** list, click the volume that you want to clone.
3. In **Resources**, click **Clones**.
4. Click **Create Clone**.
5. Specify a name for the clone.
6. If you want to clone the block volume to a larger size volume, check **Custom Block Volume Size (GB)** and then specify the new size. You can only increase the size of the volume, you cannot decrease the size. If you clone the block volume to a larger size volume, you need to extend the volume's partition. See Extending the Partition for a Block Volume for more information.
7. If you want to change the elastic performance setting when cloning the volume, check **Custom Block Volume Performance** and select the elastic performance setting you want the volume clone to use. See Block Volume Elastic Performance for more information. You can also change the elastic performance setting after you have cloned the volume, see Block Volume Elastic Performance. If you leave **Custom Block Volume Performance** unchecked, the cloned volume will use the same elastic performance setting as the source volume.
8. Click **Create Clone**.

The volume is ready use when its icon lists it as **AVAILABLE** in the volume list. At this point, you can perform various actions on the volume such as creating a clone from the volume, attaching it to an instance, or deleting the volume.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

To create a clone from a volume, use the CreateVolume operation and specify VolumeSourceFromVolumeDetails for CreateVolumeDetails.

Disconnecting From a Volume

For volumes attached with iSCSI as the volume attachment type you need to disconnect the volume from an instance before you detach the volume. For more information about attachment type options, see Volume Attachment Types.

Required IAM Policy

Disconnecting a volume from an instance does not require a specific IAM policy. Don't confuse this with detaching a volume (see Detaching a Volume).

Disconnecting from a Volume on a Linux Instance

Warning

We recommend that you unmount and disconnect the volume from the instance using `iscsiadm` before you detach the volume. Failure to do so may lead to loss of

data.

1. Log on to your instance's guest OS and unmount the volume.
2. Run the following command to disconnect the instance from the volume:

   ```
   iscsiadm -m node -T <IQN> -p <iSCSI IP ADDRESS>:<iSCSI PORT> -u
   ```

   A successful logout response resembles the following:

   ```
   Logging out of session [sid: 2, target: iqn.2015-12.us.oracle.com:c6acda73-90b4-4bbb-9a75-
   faux09015418, portal: 169.254.0.2,3260]
   Logout of [sid: 2, target: iqn.2015-12.us.oracle.com:c6acda73-90b4-4bbb-9a75-faux09015418,
   portal: 169.254.0.2,3260] successful.
   ```

3. You can now detach the volume without the risk of losing data.

Disconnecting from a Volume on a Windows Instance

1. Use a Remote Desktop client to log on to your Windows instance, and then open **Disk Management**.
2. Right-click the volume you want to disconnect, and then click **Offline**.
3. Open **iSCSI Initiator**, select the target, and then click **Disconnect**.
4. Confirm the session termination. The status should show as **Inactive**.
5. In **iSCSI Initiator**, click the **Favorite Targets** tab, select the target you are disconnecting, and then click **Remove**.
6. Click the **Volumes and Devices** tab, select the volume from the **Volume List**, and then click **Remove**.
7. You can now detach the volume without the risk of losing data.

Detaching a Volume

When an instance no longer needs access to a volume, you can detach the volume from the instance without affecting the volume's data.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: The policy in Let users launch Compute instances includes the ability to attach/detach existing block volumes. The policy in Let volume admins manage block volumes, backups, and volume groups lets the specified group do everything with block volumes and backups, but not launch instances.

If you're new to policies, see Getting Started with Policies and Common Policies. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services.

Using the Console

Warning

For volumes attached using iSCSI, we recommend that you unmount and disconnect the volume from the instance using `iscsiadm` before you detach the volume. Failure to do so may lead to loss of data. See Disconnecting From a Volume for more information.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
2. In the **Instance** list locate the instance. Click its name to display the instance details.
3. In the **Resources** section on the **Instance Details** page, click **Attached Block Volumes**

4. Click **Detach** next to the volume you want to detach and confirm the selection when prompted.

Using the API

To delete an attachment, use the following operation:

- DetachVolume

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Deleting a Volume

You can delete a volume that is no longer needed.

Warning

- You cannot undo this operation. Any data on a volume will be permanently deleted once the volume is deleted.
- All policy-based backups will eventually expire, so if you want to keep a volume backup indefinitely, you need to create a manual backup. See Overview of Block Volume Backups for information about policy-based and manual backups.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK,

CLI, or other tool. If you try to perform an action and get a message that you don't have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: The policy in Let volume admins manage block volumes, backups, and volume groups lets the specified group do everything with block volumes and backups.

If you're new to policies, see Getting Started with Policies and Common Policies. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services.

Using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Block Storage** and click **Block Volumes**.
2. In the **Block Volumes** list, find the volume you want to delete.
3. Click **Terminate** next to the volume you want to delete and confirm the selection when prompted.

Using the API

To delete a volume, use the following operation:

- DeleteVolume

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Move Block Volume Resources Between Compartments

You can move Block Volume resources such as block volumes, boot volumes, volume backups, volume groups, and volume group backups from one compartment to another. When you move a Block Volume resource to a new compartment, associated resources are not moved. After you move the resource to the new compartment, inherent policies apply

immediately and affect access to the resource through the Console. For more information, see Managing Compartments.

Important

When moving Block Volume resources between compartments you need to ensure that the resource users have sufficient access permissions on the compartment the resource is being moved to.

Using the Console

To move a block volume to a new compartment

1. Open the navigation menu. Under **Core Infrastructure**, go to **Block Storage** and click **Block Volumes**.
2. In the **Scope** section, select a compartment.
3. Find the block volume in the list, click the the Actions icon (three dots), and then click **Move Resource**.
4. Choose the destination compartment from the list.
5. Click **Move Resource**.

To move a block volume backup to a new compartment

1. Open the navigation menu. Under **Block Storage**, click **Block Volume Backups**.
2. In the **Scope** section, select a compartment.
3. Find the block volume backup in the list, click the the Actions icon (three dots), and then click **Move Resource**.
4. Choose the destination compartment from the list.

5. Click **Move Resource**.

To move a volume group to a new compartment

1. Open the navigation menu. Under **Core Infrastructure**, go to **Block Storage** and click **Volumes Groups**.
2. In the **Scope** section, select a compartment.
3. Find the volume group in the list, click the the Actions icon (three dots), and then click **Move Resource**.
4. Choose the destination compartment from the list.
5. Click **Move Resource**.

To move a volume group backup to a new compartment

1. Open the navigation menu. Under **Core Infrastructure**, go to **Block Storage** and click **Volumes Group Backups**.
2. In the **Scope** section, select a compartment.
3. Find the volume group backup in the list, click the the Actions icon (three dots), and then click **Move Resource**.
4. Choose the destination compartment from the list.
5. Click **Move Resource**.

To move a boot volume to a new compartment

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Boot Volumes**.
2. In the **Scope** section, select a compartment.
3. Find the boot volume in the list, click the the Actions icon (three dots), and then click **Move Resource**.

4. Choose the destination compartment from the list.
5. Click **Move Resource**.

To move a boot volume backup to a new compartment

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Boot Volume Backups**.
2. In the **Scope** section, select a compartment.
3. Find the boot volume backup in the list, click the the Actions icon (three dots), and then click **Move Resource**.
4. Choose the destination compartment from the list.
5. Click **Move Resource**.

Using the CLI

For information about using the CLI, see Command Line Interface (CLI).

To move a block volume to a new compartment

Open a command prompt and run:

```
oci bv volume change-volume-compartment --volume-id <volume_OCID> --compartment-id <destination_compartment_OCID>
```

To move a block volume backup to a new compartment

Open a command prompt and run:

```
oci bv volume-backup change-volume-backup-compartment --volume-backup-id <volume_backup_OCID> --compartment-id <destination_compartment_OCID>
```

To move a volume group to a new compartment

Open a command prompt and run:

```
oci bv volume-group change-volume-group-compartment --volume-group-id <volume_group_OCID> --compartment-id <destination_compartment_OCID>
```

To move a volume group backup to a new compartment

Open a command prompt and run:

```
oci bv volume-group-backup change-volume-group-backup-compartment --volume-group-backup-id <volume_group_backup_OCID> --compartment-id <destination_compartment_OCID>
```

To move a boot volume to a new compartment

Open a command prompt and run:

```
oci bv boot-volume change-boot-volume-compartment --boot-volume-id <boot_volume_OCID> --compartment-id <destination_compartment_OCID>
```

To move a boot volume backup to a new compartment

Open a command prompt and run:

```
oci bv boot-volume-backup change-boot-volume-backup-compartment --boot-volume-backup-id <boot_volume_backup_OCID> --compartment-id <destination_compartment_OCID>
```

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the following operations for moving Block Volume resources between compartments:

- ChangeVolumeCompartment
- ChangeVolumeBackupCompartment

- ChangeVolumeGroupCompartment
- ChangeVolumeGroupBackupCompartment
- ChangeBootVolumeCompartment
- ChangeBootVolumeBackupCompartment

Block Volume Performance

The content in the sections below apply to **Category 7** and **Section 3.b** of the Oracle PaaS and IaaS Public Cloud Services Pillar documentation.

The Oracle Cloud Infrastructure Block Volume service lets you dynamically provision and manage block storage volumes. You can create, attach, connect and move volumes as needed to meet your storage and application requirements. The Block Volume service uses NVMe-based storage infrastructure, and is designed for consistency. You just need to provision the capacity needed and performance scales with the performance characteristics of the elastic performance option selected up to the service maximums. See Block Volume Elastic Performance for specific details about the elastic performance options.

The Block Volume service supports creating volumes sized from 50 GB to a maximum size of 32 TB, in 1 GB increments. You can attach up to 32 volumes to an instance, with a maximum of 1 PB of attached volumes per instance. Latency performance is independent of the instance shape or volume size, and is always sub-millisecond at the 95th percentile for the **Balanced** and **Higher Performance** elastic performance options.

Note

Block Volume performance may be limited by the network bandwidth of the instance shape, for more information see Compute Shapes.

Higher Performance

The **Higher Performance** elastic performance option is recommended for workloads with the highest I/O requirements, requiring the best possible performance, such as large databases. This option provides the best linear performance scale with 75 IOPS/GB up to a maximum of 35,000 IOPS per volume. Throughput also scales at the highest rate at 600 KBPS/GB up to a maximum of 480 MBPS per volume.

The following table lists the Block Volume service's throughput and IOPS performance numbers based on volume size for this option. IOPS and KPBS performance scales linearly per GB volume size up to the service maximums so you can predictably calculate the performance numbers for a specific volume size. If you're trying to achieve certain performance targets for volumes configured to use the **Higher Performance** elastic performance option you can provision a minimum volume size using this table as a reference.

Volume Size	Max Throughput (1 MB block size)	Max Throughput (8 KB block size)	Max IOPS (4 KB block size)
50 GB	30 MB/s	30 MB/s	3750
100 GB	60 MB/s	60 MB/s	7500
200 GB	120 MB/s	96 MB/s	15,000
300 GB	180 MB/s	180 MB/s	22,500
400 GB	240 MB/s	240 MB/s	30,000
500 GB	300 MB/s	280 MB/s	35,000
800 GB - 32 TB	480 MB/s	280 MB/s	35,000

Balanced Performance

The **Balanced** elastic performance option provides a good balance between performance and cost savings for most workloads, including those that perform random I/O such as boot

volumes. This option provides linear peformance scaling with 60 IOPS/GB up to 25,000 IOPS per volume. Throughtput scales at 480 KBPS/GB up to a maximum of 480 MBPS per volume.

The following table lists the Block Volume service's throughput and IOPS performance numbers based on volume size for this option. IOPS and KPBS performance scales linearly per GB volume size up to the service maximums so you can predictably calculate the performance numbers for a specific volume size. If you're trying to achieve certain performance targets for volumes configured to use the **Balanced** elastic performance option you can provision a minimum volume size using this table as a reference.

Volume Size	Max Throughput (1 MB block size)	Max Throughput (8 KB block size)	Max IOPS (4 KB block size)
50 GB	24 MB/s	24 MB/s	3000
100 GB	48 MB/s	48 MB/s	6000
200 GB	96 MB/s	96 MB/s	12,000
300 GB	144 MB/s	144 MB/s	18,000
400 GB	192 MB/s	192 MB/s	24,000
500 GB	240 MB/s	200 MB/s	25,000
750 GB	360 MB/s	200 MB/s	25,000
1 TB - 32 TB	480 MB/s	200 MB/s	25,000

Lower Cost

The **Lower Cost** elastic performance option is recommended for throughput intensive workloads with large sequential I/O, such as streaming, log processing, and data warehouses. This option gives you linear scaling 2 IOPS/GB upt to a maximum of 3000 IOPS per volume.

The following table lists the Block Volume service's throughput and IOPS performance numbers based on volume size for this option. IOPS and KPBS performance scales linearly per

GB volume size up to the service maximums so you can predictably calculate the performance numbers for a specific volume size. If you're trying to achieve certain performance targets for volumes configured to use the **Lower Cost** elastic performance option you can provision a minimum volume size using this table as a reference.

Volume Size	Max Throughput (1 MB block size)	Max Throughput (8 KB block size)	Max IOPS (4 KB block size)
50 GB	12 MB/s	0.8 MB/s	100
100 GB	24 MB/s	1.6 MB/s	200
200 GB	48 MB/s	3.2 MB/s	400
300 GB	72 MB/s	4.8 MB/s	600
400 GB	96 MB/s	6.4 MB/s	800
500 GB	120 MB/s	8 MB/s	1000
750 GB	180 MB/s	12 MB/s	1500
1 TB	240 MB/s	16 MB/s	2000
1.5 TB - 32 TB	480 MB/s	23 MB/s	3000

For more information about FIO command samples you can use for performance testing see Sample FIO Commands for Block Volume Performance Tests on Linux-based Instances.

See Using Block Volumes Service Metrics to Calculate Block Volume Throughput and IOPS for a walkthrough of a performance testing scenario with FIO that shows how you can use Block Volume metrics to determine the performance characteristics of your block volume.

Limitations and Considerations

- Block Volume performance SLA for IOPS per volume and IOPS per instance applies to the **Balanced** and **Higher Performance** elastic performance settings only, not to the **Lower Cost** setting.
- The throughput performance results are for bare metal Compute instances. Throughput performance on virtual machine (VM) Compute instances is dependent on the network bandwidth that is available to the instance, and further limited by that bandwidth for the volume. For details about the network bandwidth available for VM shapes, see the **Network Bandwidth** column in the VM Shapes table.
- IOPS performance is independent of the instance type or shape, so is applicable to all bare metal and VM shapes, for iSCSI attached volumes. For VM shapes with paravirtualized attached volumes, see Block Volume Performance.
- For the **Lower Cost** option you may not see the same latency performance that you see with the **Balanced** or **Higher Performance** elastic performance options. You may also see a greater variance in latency with the **Lower Cost** option.
- Windows Defender Advanced Threat Protection (Windows Defender ATP) is enabled by default on all Oracle-provided Windows images. This tool has a significant negative impact on disk I/O performance. The IOPS performance characteristics described in this topic are valid for Windows bare metal instances with Windows Defender ATP disabled for disk I/O. Customers must carefully consider the security implications of disabling Windows Defender ATP. See Windows Defender Advanced Threat Protection.
- The IOPS performance characteristics described in this topic are for volumes with iSCSI attachments. Block Volume performance SLA for IOPS per volume and IOPS per instance applies to iSCSI volume attachments only, not to paravirtualized attachments. Paravirtualized attachments simplify the process of configuring your block storage by removing the extra commands needed before accessing a volume. However, due to the overhead of virtualization, this reduces the maximum IOPS performance for larger block volumes. If storage IOPS performance is of paramount importance for your workloads, you can continue to experience the guaranteed performance Oracle Cloud Infrastructure Block Volume offers by using iSCSI attachments.

Testing Methodology and Performance for Balanced Elastic Performance Option

Warning

- Before running any tests, protect your data by making a backup of your data and operating system environment to prevent any data loss.
- Do not run FIO tests directly against a device that is already in use, such as /dev/sdX. If it is in use as a formatted disk and there is data on it, running FIO with a write workload (readwrite, randrw, write, trimwrite) will overwrite the data on the disk, and cause data corruption. Run FIO only on unformatted raw devices that are not in use.

This section describes the setup of the test environments, the methodology, and the observed performance for the Balanced elastic performance configuration option. Some of the sample volume sizes tested were:

- 50 GB volume - 3,000 IOPS @ 4K
- 1 TB volume - 25,000 IOPS @ 4K
- Host maximum, Ashburn (IAD) region, twenty 1 TB volumes - 400,000 IOPS @ 4K

These tests used a wide range of volume sizes and the most common read and write patterns and were generated with the Gartner Cloud Harmony test suite. To show the throughput performance limits, 256k or larger block sizes should be used. For most environments, 4K, 8K, or 16K blocks are common depending on the application workload, and these are used specifically for IOPS measurements.

In the observed performance images in this section, the X axis represents the volume size tested, ranging from 4KB to 1MB. The Y axis represents the IOPS delivered. The Z axis represents the read/write mix tested, ranging from 100% read to 100% write.

Note

Performance Notes for Instance Types

- The throughput performance results are for bare metal instances. Throughput performance on VM instances is dependent on the network bandwidth that is available to the instance, and further limited by that bandwidth for the volume. For details about the network bandwidth available for VM shapes, see the Network Bandwidth column in the VM Shapes table.
- IOPS performance is independent of the instance type or shape, so is applicable to all bare metal and VM shapes, for iSCSI attached volumes. For VM shapes with paravirtualized attached volumes, see Block Volume Performance.

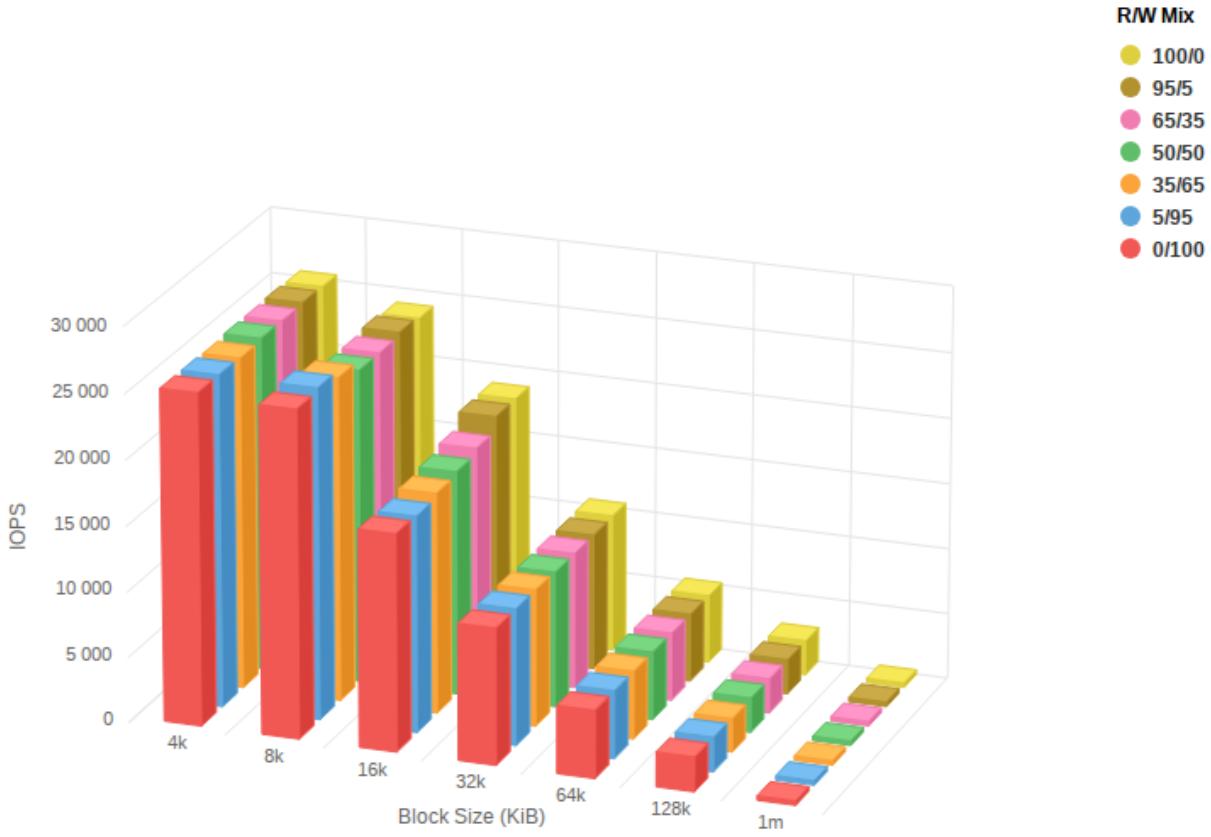
1 TB Block Volume

A 1 TB volume was mounted to a bare metal instance running in the Phoenix region. The instance shape was dense, workload was direct I/O with 10GB working set. The following command was run for the Gartner Cloud Harmony test suite:

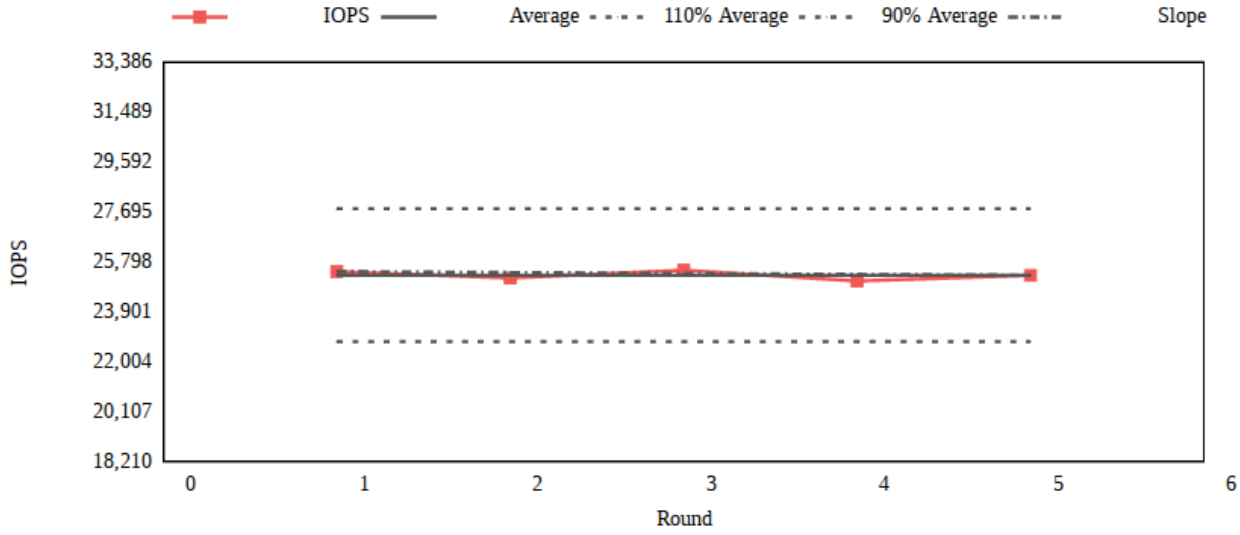
```
~/block-storage/run.sh --nopurge --noprecondition --fio_direct\=1 --fio_size=10g --target /dev/sdb --
test iops --skip_blocksize 512b
```

The results showed that for 1 TB, the bandwidth limit for the larger block size test occurs at 320MBS.

The following images show the observed performance for 1 TB:



Plot A.6 - IOPS -All RW Mix & BS - 3D Columns



Steady State Determination Data

Average IOPS:			25292
Allowed Maximum Data Excursion:	5058.497	Measured Maximum Data Excursion:	410.095321
Allowed Maximum Slope Excursion:	2529.2485	Measured Maximum Slope Excursion:	159.9
Least Squares Linear Fit Formula:			-39.978 * R + 25412.418

Plot A.3 - IOPS Steady State Measurement Window - RND/4KiB

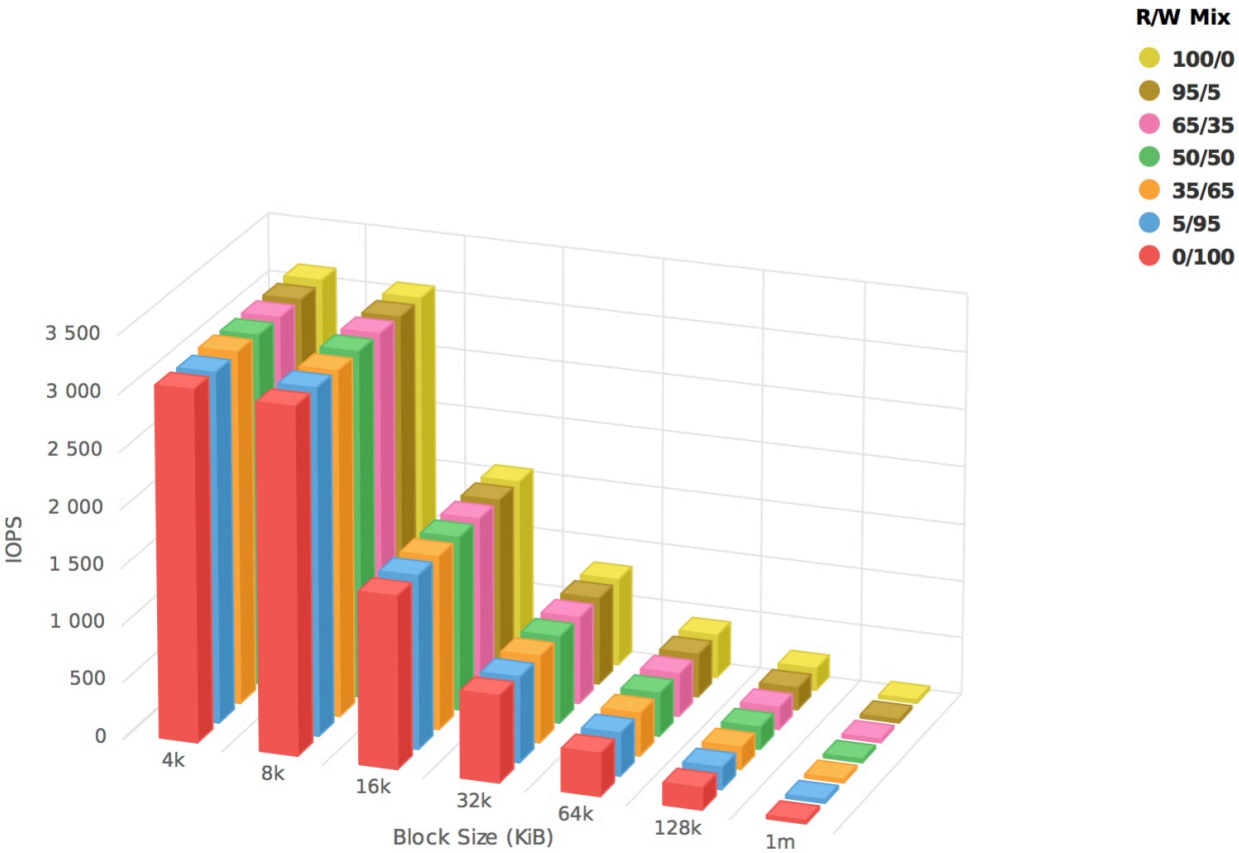
50 GB Block Volume

A 50 GB volume was mounted to a bare metal instance running in the Phoenix region. The instance shape was dense, workload was direct I/O with 10GB working set. The following command was run for the Gartner Cloud Harmony test suite:

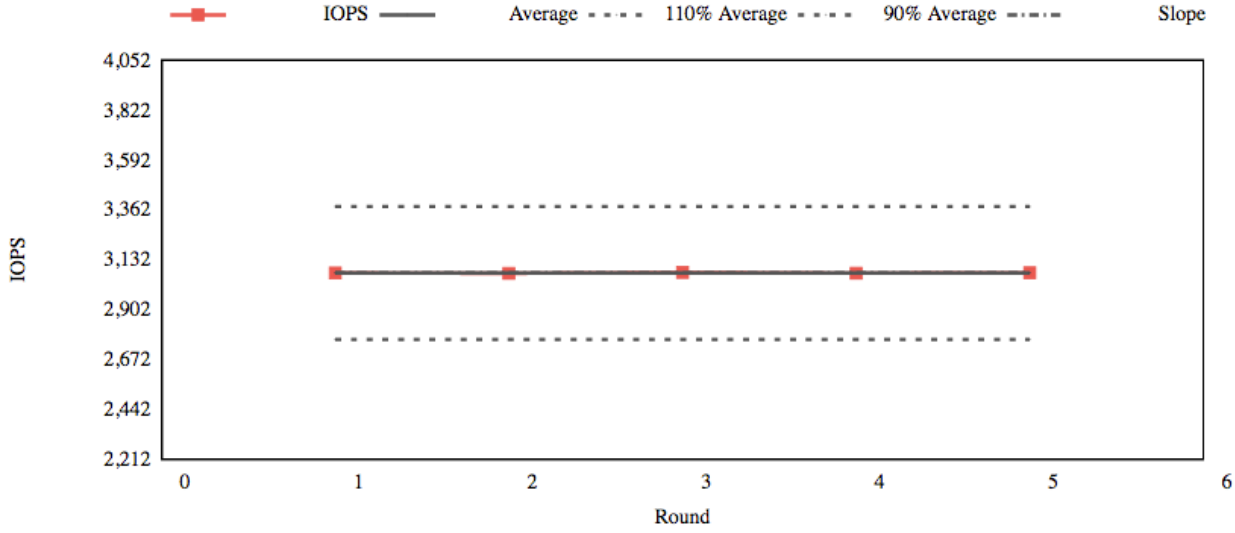
```
~/block-storage/run.sh --nopurge --noprecondition --fio_direct=1 --fio_size=10g --target /dev/sdb --test
iops --skip_blocksize 512b
```

The results showed that for the 50 GB volume, the bandwidth limit is confirmed as 24,000 KBPS for the larger block size tests (256 KB or larger block sizes), and the maximum of 3,000 IOPS at 4K block size is delivered. For small volumes, a 4K block size is common.

The following images show the observed performance for 50 GB:



Plot A.6 - IOPS -All RW Mix & BS - 3D Columns



Steady State Determination Data

Average IOPS:			3073
Allowed Maximum Data Excursion:	614.6282	Measured Maximum Data Excursion:	4.365131
Allowed Maximum Slope Excursion:	307.3141	Measured Maximum Slope Excursion:	1.6
Least Squares Linear Fit Formula:			0.4 * R + 3071.94

Plot A.3 - IOPS Steady State Measurement Window - RND/4KiB

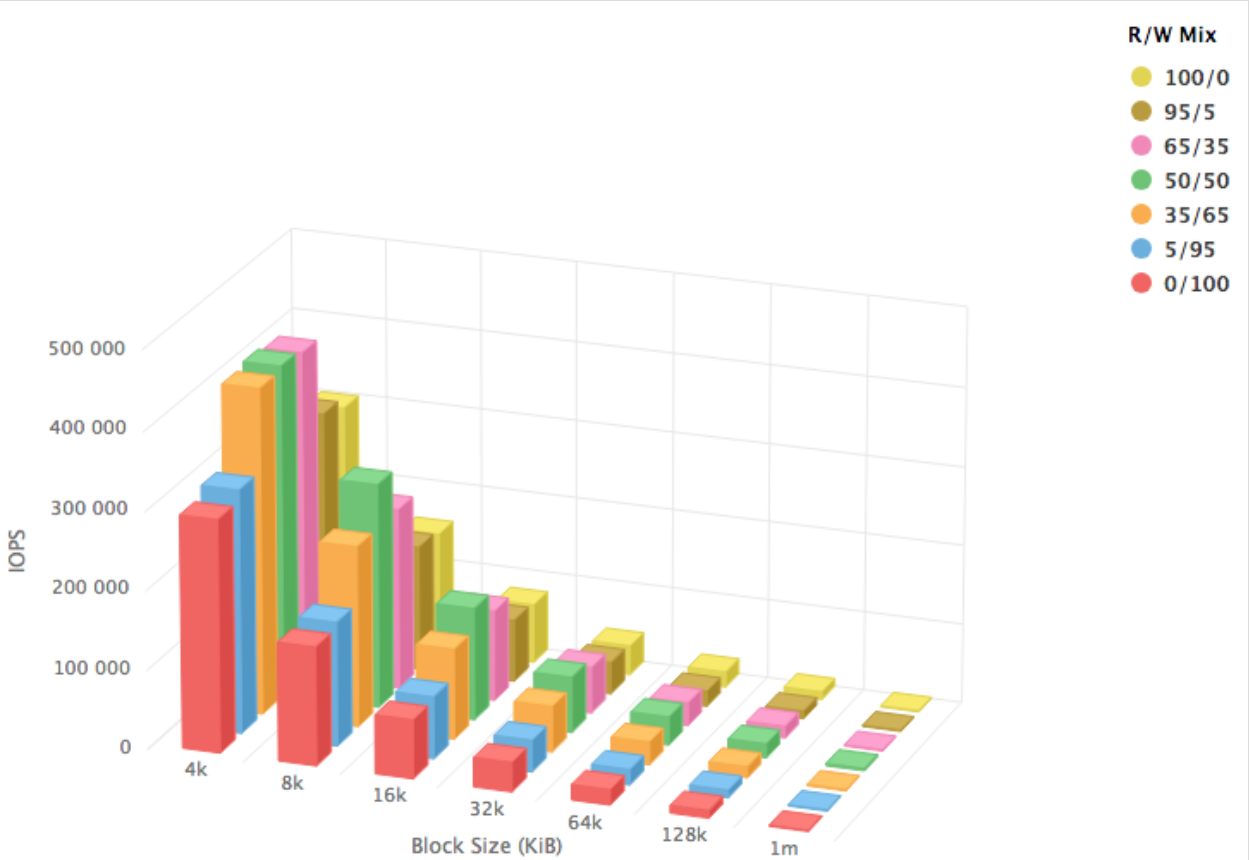
Host Maximum - Twenty 1 TB Volumes

Twenty 1 TB volumes were mounted to a bare metal instance running in the Ashburn region. The instance shape was dense, workload was direct I/O with 10GB working set. The following command was run for the Gartner Cloud Harmony test suite:

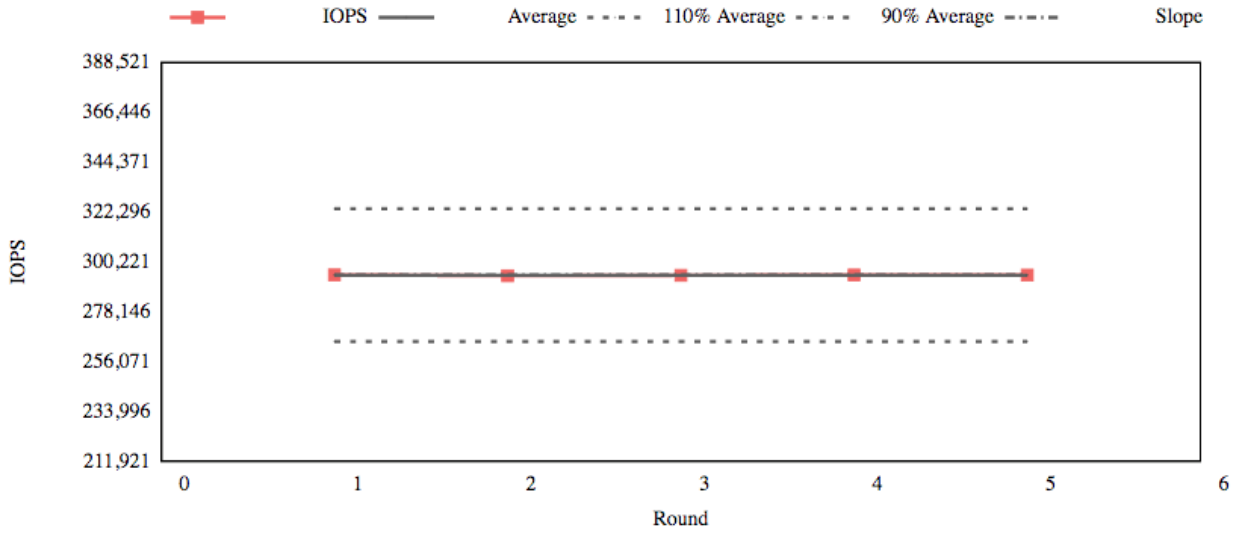
```
~/block-storage/run.sh --nopurge --noprecondition --fio_direct=1 --fio_size=10g --target
/dev/sdb,/dev/sdc,/dev/sdd,/dev/sde,/dev/sdf,/dev/sdg,/dev/sdh,/dev/sdi,/dev/sdj,/dev/sdk,/dev/sdl,/dev
/sdm,/dev/sdn,/dev/sdo,/dev/sdp,/dev/sdq,/dev/sdr,/dev/sds,/dev/sdt,/dev/sdu --test iops --skip_
blocksize 512b
```

The results showed that for the host maximum test of twenty 1 TB volumes, the average is 2.1GBPS, and 400,000 IOPS to the host for the 50/50 read/write pattern.

The following images show the observed performance for 50 GB:



Plot A.6 - IOPS -All RW Mix & BS - 3D Columns



Steady State Determination Data

Average IOPS:			294335
Allowed Maximum Data Excursion:	58867.0562	Measured Maximum Data Excursion:	338.11226299999

Sample FIO Commands for Block Volume Performance Tests on Linux-based Instances

This topic describes sample FIO commands you can use to run performance tests for the Oracle Cloud Infrastructure Block Volume service on instances created from Linux-based images.

Installing FIO

To install and configure FIO on your instances with Linux-based operating systems, run the commands applicable to the operating system version for your instance.

Oracle Linux and CentOS

Run the following command to install and configure FIO for your Oracle Linux CentOS systems:

```
sudo yum install fio -y
```

This applies to Oracle Linux 6.x, Oracle Linux 7.x, CentOS 6.x, and CentOS 7.x.

Ubuntu

Run the following commands to install and configure FIO for your Ubuntu systems:

```
sudo apt-get update && sudo apt-get install fio -y
```

This applies to Ubuntu 16.04, 18.04, and Ubuntu Minimal 16.04, 18.04.

FIO Commands

IOPS Performance Tests

Use the following FIO example commands to test IOPS performance. You can run the commands directly or create a job file with the command and then run the job file.

Test random reads

Run the following command directly to test random reads:

```
sudo fio --filename=device name --direct=1 --rw=randread --bs=4k --ioengine=libaio --iodepth=256 --
runtime=120 --numjobs=4 --time_based --group_reporting --name=iops-test-job --eta-newline=1 --readonly
```

In some cases you might see more consistent results if you use a job file instead of running the command directly. Use the following steps for this approach.

1. Create a job file, fiorandomread.fio, with the following:

   ```
   [global]
   bs=4K
   iodepth=256
   ```

```
direct=1
ioengine=libaio
group_reporting
time_based
runtime=120
numjobs=4
name=raw-randread
rw=randread

[job1]
filename=device name
```

2. Run the job using the following command:

```
fio randomread.fio
```

Test file random read/writes

Run the following command against the mount point to test file read/writes:

```
sudo fio --filename=/custom mount point/file --size=500GB --direct=1 --rw=randrw --bs=4k --
ioengine=libaio --iodepth=256 --runtime=120 --numjobs=4 --time_based --group_reporting --name=iops-test-
job --eta-newline=1
```

Add both the read IOPS and the write IOPS returned.

Test random read/writes

Warning

Do not run FIO tests with a write workload (`readwrite`, `randrw`, `write`, `trimwrite`) directly against a device that is in use.

Run the following command to test random read/writes:

```
sudo fio --filename=device name --direct=1 --rw=randrw --bs=4k --ioengine=libaio --iodepth=256 --
runtime=120 --numjobs=4 --time_based --group_reporting --name=iops-test-job --eta-newline=1
```

Add both the read IOPS and the write IOPS returned.

In some cases you might see more consistent results if you use a job file instead of running the command directly. Use the following steps for this approach.

1. Create a job file, fiorandomreadwrite.fio, with the following:

   ```
   [global]
   bs=4K
   iodepth=256
   direct=1
   ioengine=libaio
   group_reporting
   time_based
   runtime=120
   numjobs=4
   name=raw-randreadwrite
   rw=randrw

   [job1]
   filename=device name
   ```

2. Run the job using the following command:

   ```
   fio randomreadwrite.fio
   ```

Test sequential reads

For workloads that enable you to take advantage of sequential access patterns, such as database workloads, you can confirm performance for this pattern by testing sequential reads.

Run the following command to test sequential reads:

```
sudo fio --filename=device name --direct=1 --rw=read --bs=4k --ioengine=libaio --iodepth=256 --
runtime=120 --numjobs=4 --time_based --group_reporting --name=iops-test-job --eta-newline=1 --readonly
```

In some cases you may see more consistent results if you use a job file instead of running the command directly. Use the following instructions for this approach:

1. Create a job file, fioread.fio, with the following:

```
[global]
bs=4K
iodepth=256
direct=1
ioengine=libaio
group_reporting
time_based
runtime=120
numjobs=4
name=raw-read
rw=read

[job1]
filename=device name
```

2. Run the job using the following command:

```
fio read.fio
```

THROUGHPUT PERFORMANCE TESTS

Use the following FIO example commands to test throughput performance.

Test random reads

Run the following command to test random reads:

```
sudo fio --filename=device name --direct=1 --rw=randread --bs=64k --ioengine=libaio --iodepth=64 --
runtime=120 --numjobs=4 --time_based --group_reporting --name=throughput-test-job --eta-newline=1 --
readonly
```

In some cases you might see more consistent results if you use a job file instead of running the command directly. Use the following steps for this approach.

1. Create a job file, fiorandomread.fio, with the following:

```
[global]
bs=64K
iodepth=64
direct=1
ioengine=libaio
group_reporting
time_based
runtime=120
numjobs=4
name=raw-randread
rw=randread

[job1]
filename=device name
```

2. Run the job using the following command:

```
fio randomread.fio
```

Test file random read/writes

Run the following command against the mount point to test file read/writes:

```
sudo fio --filename=/custom mount point/file --size=500GB --direct=1 --rw=randrw --bs=64k --
ioengine=libaio --iodepth=64 --runtime=120 --numjobs=4 --time_based --group_reporting --name=throughput-
test-job --eta-newline=1
```

Add both the read MBPs and the write MBPs returned.

Test random read/writes

Warning

Do not run FIO tests with a write workload (`readwrite`, `randrw`, `write`, `trimwrite`) directly against a device

that is in use.

Run the following command to test random read/writes:

```
sudo fio --filename=device name --direct=1 --rw=randrw --bs=64k --ioengine=libaio --iodepth=64 --
runtime=120 --numjobs=4 --time_based --group_reporting --name=throughput-test-job --eta-newline=1
```

Add both the read MBPs and the write MBPs returned.

In some cases you might see more consistent results if you use a job file instead of running the command directly. Use the following steps for this approach.

1. Create a job file, fiorandomread.fio, with the following:

```
[global]
bs=64K
iodepth=64
direct=1
ioengine=libaio
group_reporting
time_based
runtime=120
numjobs=4
name=raw-randreadwrite
rw=randrw

[job1]
filename=device name
```

2. Run the job using the following command:

```
fio randomreadwrite.fio
```

Test sequential reads

For workloads that enable you to take advantage of sequential access patterns, such as database workloads, you can confirm performance for this pattern by testing sequential reads.

Run the following command to test sequential reads:

```
sudo fio --filename=device name --direct=1 --rw=read --bs=64k --ioengine=libaio --iodepth=64 --
runtime=120 --numjobs=4 --time_based --group_reporting --name=throughput-test-job --eta-newline=1 --
readonly
```

In some cases you might see more consistent results if you use a job file instead of running the command directly. Use the following steps for this approach.

1. Create a job file, fioread.fio, with the following:

   ```
   [global]
   bs=64K
   iodepth=64
   direct=1
   ioengine=libaio
   group_reporting
   time_based
   runtime=120
   numjobs=4
   name=raw-read
   rw=read

   [job1]
   filename=device name
   ```

2. Run the job using the following command:

   ```
   fio read.fio
   ```

LATENCY PERFORMANCE TESTS

Use the following FIO example commands to test latency performance. You can run the commands directly or create a job file with the command and then run the job file.

Test random reads for latency

Run the following command directly to test random reads for latency:

```
sudo fio --filename=device name --direct=1 --rw=randread --bs=4k --ioengine=libaio --iodepth=1 --
numjobs=1 --time_based --group_reporting --name=readlatency-test-job --runtime=120 --eta-newline=1 --
readonly
```

In some cases you might see more consistent results if you use a job file instead of running the command directly. Use the following steps for this approach.

1. Create a job file, fiorandomreadlatency.fio, with the following:

```
[global]
bs=4K
iodepth=1
direct=1
ioengine=libaio
group_reporting
time_based
runtime=120
numjobs=1
name=readlatency-test-job
rw=randread

[job1]
filename=device name
```

2. Run the job using the following command:

```
fio fiorandomreadlatency.fio
```

Test random read/writes for latency

Warning

Do not run FIO tests with a write workload (`readwrite`, `randrw`, `write`, `trimwrite`) directly against a device that is in use.

Run the following command directly to test random read/writes for latency:

```
sudo fio --filename=device name --direct=1 --rw=randrw --bs=4k --ioengine=libaio --iodepth=1 --numjobs=1
--time_based --group_reporting --name=rwlatency-test-job --runtime=120 --eta-newline=1 --readonly
```

In some cases you might see more consistent results if you use a job file instead of running the command directly. Use the following steps for this approach.

1. Create a job file, fiorandomrwlatency.fio, with the following:

   ```
   [global]
   bs=4K
   iodepth=1
   direct=1
   ioengine=libaio
   group_reporting
   time_based
   runtime=120
   numjobs=1
   name=rwlatency-test-job
   rw=randrw

   [job1]
   filename=device name
   ```

2. Run the job using the following command:

   ```
   fio fioradomrwlatency.fio
   ```

Block Volume Elastic Performance

The elastic performance feature of the Oracle Cloud Infrastructure Block Volume service allows you to dynamically change the volume performance, along with enabling you to pay for the performance characteristics you require independently from the size of your block volumes and boot volumes.

This feature includes the concept of volume performance units (VPUs). You can purchase more VPUs to allocate more resources to a volume, increasing IOPS/GB and throughput per GB. You also have the flexibility to purchase fewer VPUs, which reduces the performance characteristics for a volume, however it can also provide cost savings. You can also choose not to purchase any VPUs which can provide significant cost savings for volumes that don't require the increased performance characteristics.

For specific pricing details, see Oracle Storage Cloud Pricing.

Elastic Performance Configuration Options

There are three elastic performance configuration options, as described below.

- **Balanced**: This is the default setting for new and existing block and boot volumes. It provides a good balance between performance and cost savings for most workloads, including those that perform random I/O such as boot volumes. This option provides linear peformance scaling with 60 IOPS/GB up to 25,000 IOPS per volume. Throughtput scales at 480 KBPS/GB up to a maximum of 480 MBPS per volume. With this option you are purchasing 10 VPUs per GB/month.
- **Higher Performance**: Recommended for workloads with the highest I/O requirements, requiring the best possible performance, such as large databases. This option provides the best linear performance scale with 75 IOPS/GB up to a maximum of 35,000 IOPS per volume. Throughput also scales at the highest rate at 600 KBPS/GB up to a maximum of 480 MBPS per volume. With this option you are purchasing 20 VPUs per GB/month.
- **Lower Cost**: Recommended for throughput intensive workloads with large sequential I/O, such as streaming, log processing, and data warehouses. The cost is only the storage cost, there is no additional VPU cost. This option gives you linear scaling 2 IOPS/GB upt to a maximum of 3000 IOPS per volume. This option is only available for block volumes, it is not available for boot volumes.

The following table lists the performance characteristics for each elastic performance level.

Performance Level	IOPS/GB	Max IOPS/Volume	Throughput/GB	Max Throughput/Volume	VPUs/GB[1]
Lower Cost	2	3000	240	Up to 480	0
Balanced	60	25,000	480	480	10
Higher Performance	75	35,000	600	480	20

See Block Volume Performance for additional performance details for the Block Volume service.

1: Volume performance units, see Oracle Storage Cloud Pricing for specific pricing details.

Configuring Volume Performance

You can configure the volume performance for a block volume when you create a volume, see Creating a Volume. You can also change the volume performance for an existing block volume, see To change the volume performance for an existing block volume.

When you create a Compute instance, the volume performance for the instance's boot volume is set to **Balanced** by default. You can change this setting after the instance has launched, see To change the volume performance for an existing boot volume.

Changing the Performance of a Volume

The Block Volume service's elastic performance feature enables you to dynamically configure the volume performance for block volumes and boot volumes, for more information, see Block Volume Elastic Performance.

Required IAM Service Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: The policy in Let volume admins manage block volumes, backups, and volume groups lets the specified group do everything with block volumes and backups, but not launch instances.

If you're new to policies, see Getting Started with Policies and Common Policies. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services.

LIMITATIONS

- You can only change the elastic performance configuration on three volumes concurrently per tenancy.
- When changing volume performance for boot volumes, you can only select the **Balanced** or **Higher Performance** options.

USING THE CONSOLE

The default elastic performance setting for existing block volumes or when you create a new block volume is **Balanced**. You can change the default setting when you create a new block volume, see Creating a Volume. You can also change the elastic performance setting for an existing block volume using the steps in the following procedure.

To change the volume performance for an existing block volume

1. Open the navigation menu. Under **Core Infrastructure**, go to **Block Storage** and click **Block Volumes**.
2. Click the block volume that you want to change the performance for.
3. Click **Change Performance**.
4. Click the performance option you want to change to.
5. Click **Change Performance**.

When you create an instance, the elastic performance setting for the instance's boot volume is set to **Balanced**. You can change this setting to **Higher Performance** after the instance has been launched.

To change the volume performance for an existing boot volume

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Boot Volumes**.
2. Click the boot volume that you want to change the performance for.
3. Click **Change Performance**.

4. Click the performance option you want to change to.
5. Click **Change Performance**.

USING THE CLI

For information about using the CLI, see Command Line Interface (CLI).

Use the `volume update` operation or the `boot-volume update` operation with `vpus-per-gb` parameter to update a block volume's elastic performance setting. The `vpus-per-gb` parameter is where you specify the volume performance units (VPUs). VPUs represent the elastic performance settings, with the following allowed values:

- `0`: Represents **Lower Cost** setting, applies to block volumes only.
- `10`: Represents **Balanced** setting, applies to both block volumes and boot volumes.
- `20`: Represents **Higher Performance** setting, applies to both block volumes and boot volumes.

For example:

```
oci bv volume update --volume-id <volume_ID> --vpus-per-gb 20
```

USING THE API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

BLOCK VOLUMES

To update a block volume's elastic performance setting, use the following operation:

- UpdateVolume

The elastic performance setting is specified in the `vpusPerGB` attribute of UpdateVolumeDetails. Allowed values are `0`, `10`, and `20`.

BOOT VOLUMES

To update a block volume's elastic performance setting, use the following operation:

- UpdateBootVolume

The elastic performance setting is specified in the `vpusPerGB` attribute of UpdateBootVolumeDetails. Allowed values are `10` and `20`.

Block Volume Metrics

You can monitor the health, capacity, and performance of your block volumes and boot volumes by using metrics, alarms, and notifications.

This topic describes the metrics emitted by the metric namespace `oci_blockstore` (the Block Volume service).

Resources: Block volumes and boot volumes.

See Using Block Volumes Service Metrics to Calculate Block Volume Throughput and IOPS for a walkthrough of a performance testing scenario with FIO that shows how you can use these metrics to determine the performance characteristics of your block volume.

Overview of Metrics for an Instance and Its Storage Devices

If you're not already familiar with the different types of metrics available for an instance and its storage and network devices, see Compute Instance Metrics.

Available Metrics: oci_blockstore

The Block Volume service metrics help you measure volume operations and throughput related to Compute instances.

The metrics listed in the following table are automatically available for any block volume or boot volume, regardless of whether the attached instance has monitoring enabled. You do not need to enable monitoring on the volumes to get these metrics.

You also can use the Monitoring service to create custom queries.

Each metric includes the following dimensions:

ATTACHMENTID

The OCID of the volume attachment.

RESOURCEID

The OCID of the volume.

Metric	Metric Display Name	Unit	Description	Dimensions
`VolumeReadThroughput`*	**Volume Read Throughput**	bytes	Read throughput. Expressed as bytes read per interval.	`attachmentId` `resourceId`
`VolumeWriteThroughput`*	**Volume Write Throughput**	bytes	Write throughput. Expressed as bytes written per interval.	
`VolumeReadOps`*	**Volume Read Operations**	reads	Activity level from I/O reads. Expressed as reads per interval.	
`VolumeWriteOps`*	**Volume Write Operations**	writes	Activity level from I/O writes. Expressed as writes per interval.	

* The Compute service separately reports network-related metrics *as measured on the instance itself and aggregated across all the attached volumes*. Those metrics are available in the `oci_computeagent` metric namespace. For more information, see Compute Instance Metrics.

Using the Console

To view default metric charts for a single volume

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
2. Click the instance to view its details.
3. Click either **Attached Block Volumes** or **Boot Volume** to view the volume you're interested in.
4. Click the volume to view its details.
5. Under **Resources**, click **Metrics**.

For more information about monitoring metrics and using alarms, see Monitoring Overview. For information about notifications for alarms, see Notifications Overview.

To view default metric charts for multiple volumes

1. Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Service Metrics**.
2. For **Compartment**, select the compartment that contains the volumes you're interested in.
3. For **Metric Namespace**, select **oci_blockstore**.
   The **Service Metrics** page dynamically updates the page to show charts for each metric that is emitted by the selected metric namespace.

For more information about monitoring metrics and using alarms, see Monitoring Overview. For information about notifications for alarms, see Notifications Overview.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line

Interface.

Use the following APIs for monitoring:

- Monitoring API for metrics and alarms
- Notifications API for notifications (used with alarms)

CHAPTER 8 Compute

This chapter explains how to launch, access, rename, and terminate compute instances.

Overview of the Compute Service

Oracle Cloud Infrastructure Compute lets you provision and manage compute hosts, known as instances. You can launch instances as needed to meet your compute and application requirements. After you launch an instance, you can access it securely from your computer, restart it, attach and detach volumes, and terminate it when you're done with it. Any changes made to the instance's local drives are lost when you terminate it. Any saved changes to volumes attached to the instance are retained.

Oracle Cloud Infrastructure offers both bare metal and virtual machine instances:

- **Bare Metal:** A bare metal compute instance gives you dedicated physical server access for highest performance and strong isolation.
- **Virtual Machine:** A virtual machine (VM) is an independent computing environment that runs on top of physical bare metal hardware. The virtualization makes it possible to run multiple VMs that are isolated from each other. VMs are ideal for running applications that do not require the performance and resources (CPU, memory, network bandwidth, storage) of an entire physical machine.

  An Oracle Cloud Infrastructure VM compute instance runs on the same hardware as a bare metal instance, leveraging the same cloud-optimized hardware, firmware, software stack, and networking infrastructure.

Be sure to review Best Practices for Your Compute Instance for important information about working with your Oracle Cloud Infrastructure Compute instance.

Oracle Cloud Infrastructure uses Oracle Ksplice to apply important security and other critical kernel updates to the hypervisor hosts without a reboot.

Compute is Always Free eligible. For more information about Always Free resources, including additional capabilities and limitations, see Oracle Cloud Infrastructure's Free Tier.

Instance Types

When you create a Compute instance, you can select the most appropriate type of instance for your applications based on characteristics such as the number of CPUs, amount of memory, and network resources. Oracle Cloud Infrastructure offers a variety of shapes that are designed to meet a range of compute and application requirements:

- **Standard shapes:** Designed for general purpose workloads and suitable for a wide range of applications and use cases. Standard shapes provide a balance of cores, memory, and network resources. Standard shapes are available with Intel or AMD processors.
- **DenseIO shapes:** Designed for large databases, big data workloads, and applications that require high-performance local storage. DenseIO shapes include locally-attached NVMe-based SSDs.
- **GPU shapes:** Designed for hardware-accelerated workloads. GPU shapes include Intel CPUs and NVIDIA graphics processors.
- **High performance computing (HPC) shapes:** Designed for high-performance computing workloads that require high frequency processor cores and cluster networking for massively parallel HPC workloads. HPC shapes are available for bare metal instances only.

For more information about the available bare metal and VM shapes, see Compute Shapes, Bare Metal Instance Types, Virtual Machine Shapes, and Accelerated GPU Instance Types.

Components for Launching Instances

The components required to launch an instance are:

AVAILABILITY DOMAIN

The Oracle Cloud Infrastructure data center within your geographical region that hosts cloud resources, including your instances. You can place instances in the same or different availability domains, depending on your performance and redundancy requirements. For more information, see Regions and Availability Domains.

VIRTUAL CLOUD NETWORK

A virtual version of a traditional network—including subnets, route tables, and gateways—on which your instance runs. At least one cloud network has to be set up before you launch instances. For information about setting up cloud networks, see Overview of Networking.

KEY PAIR (FOR LINUX INSTANCES)

A security mechanism required for Secure Shell (SSH) access to an instance. Before you launch an instance, you'll need at least one key pair. For more information, see Managing Key Pairs on Linux Instances.

TAGS

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the desired tags. For general information about applying tags, see Resource Tags.

PASSWORD (FOR WINDOWS INSTANCES)

A security mechanism required to access an instance that uses an Oracle-provided Windows image. The first time you launch an instance using a Windows image, Oracle Cloud Infrastructure will generate an initial, one-time password that you can retrieve using the console or API. This password must be changed after you initially log on.

IMAGE

A template of a virtual hard drive that determines the operating system and other software for an instance. For details about Oracle Cloud Infrastructure platform images, see Oracle-Provided Images. You can also launch instances from:

- Trusted third-party images published by Oracle partners from the Partner Image catalog. For more information about partner images, see Overview of Marketplace and Working with Listings.
- Pre-built Oracle enterprise images and solutions enabled for Oracle Cloud Infrastructure

- Custom images, including bring your own image scenarios.
- Boot Volumes.

SHAPE

A template that determines the number of CPUs, amount of memory, and other resources allocated to a newly created instance. You choose the most appropriate shape when you launch an instance. See Compute Shapes for a list of available bare metal and VM shapes.

You can optionally attach volumes to an instance. For more information, see Overview of Block Volume.

Creating Automation with Events

You can create automation based on state changes for your Oracle Cloud Infrastructure resources by using event types, rules, and actions. For more information, see Overview of Events.

The following Compute resources emit events:

- Autoscaling configurations and autoscaling policies
- Cluster networks
- Console histories
- Images
- Instances and instance attachments
- Instance configurations
- Instance console connections
- Instance pools

Resource Identifiers

Most types of Oracle Cloud Infrastructure resources have a unique, Oracle-assigned identifier called an Oracle Cloud ID (OCID). For information about the OCID format and other ways to identify your resources, see Resource Identifiers.

Work Requests

Compute is one of the Oracle Cloud Infrastructure services that is integrated with the Work Requests API. For general information on using work requests in Oracle Cloud Infrastructure, see Work Requests in the user guide, and the Work Requests API.

Ways to Access Oracle Cloud Infrastructure

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. For a list of available SDKs, see Software Development Kits and Command Line Interface.

To access the Console, you must use a supported browser. Oracle Cloud Infrastructure supports the latest desktop versions of Google Chrome, Microsoft Edge, Internet Explorer 11, Safari, Firefox, and Firefox ESR. Note that private browsing mode is not supported for Firefox, Internet Explorer, or Edge. Mobile browsers are not supported.

For general information about using the API, see REST APIs.

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies. For specific details about writing policies for each of the different services, see Policy Reference.

If you're a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

Limits on Compute Resources

See Service Limits for a list of applicable limits and instructions for requesting a limit increase. To set compartment-specific limits on a resource or resource family, administrators can use compartment quotas.

Additional limits include:

- To attach a volume to an instance, both the instance and volume must be within the same availability domain.
- Many Compute operations are subject to throttling.

Metadata Key Limits

Custom metadata keys (any key you define that is not `ssh_authorized_keys` or `user_data`) have the following limits:

- Max number of metadata keys: 128
- Max size of key name: 255 characters
- Max size of key value: 255 characters

`ssh_authorized_keys` is a special key that does not have these limits, but its value is validated to conform to a public key in the OpenSSH format.

`user_data` has a maximum size of 16KB. For Linux instances with cloud-init configured, you can populate the `user_data` field with a Base64-encoded string of cloud-init user data. For more information on formats that cloud-init accepts, see cloud-init formats. On Windows instances, the `user_data` field can be provided but isn't used by Oracle-provided images.

Best Practices for Your Compute Instance

Oracle Cloud Infrastructure Compute provides bare metal compute capacity that delivers performance, flexibility, and control without compromise. It is powered by Oracle's next generation, internet-scale infrastructure designed to help you develop and run your most demanding applications and workloads in the cloud.

You can provision compute capacity through an easy-to-use web console or an API. The bare metal compute instance, once provisioned, provides you with access to the host. This gives you complete control of your instance.

While you have full management authority for your instance, Oracle recommends a variety of best practices to ensure system availability and top performance.

IP Addresses Reserved for Use by Oracle

Certain IP addresses are reserved for Oracle Cloud Infrastructure use and may not be used in your address numbering scheme.

169.254.0.0/16

These addresses are used for iSCSI connections to the boot and block volumes, instance metadata, and other services.

Three IP Addresses in Each Subnet

These addresses consist of:

- The first IP address in the CIDR (the network address)
- The last IP address in the CIDR (the broadcast address)
- The first host address in the CIDR (the subnet default gateway address)

For example, in a subnet with CIDR 192.168.0.0/24, these addresses are reserved:

- 192.168.0.0 (the network address)
- 192.168.0.255 (the broadcast address)
- 192.168.0.1 (the subnet default gateway address)

The remaining addresses in the CIDR (192.168.0.2 to 192.168.0.254) are available for use.

Essential Firewall Rules

Warning

Windows 2008 Server R2 images do not support restricting certain firewall rules for local principals, such as "Administrators", so any authenticated user on an instance can make outgoing connections to the iSCSI network endpoints (169.254.0.2:3260, 169.254.2.0/24:3260) that serve the instance's boot and block volumes.

All Oracle-provided images include rules that allow only "root" on Linux instances or "Administrators" on Windows Server 2012 R2 and Windows Server 2016 instances to make outgoing connections to the iSCSI network endpoints (169.254.0.2:3260, 169.254.2.0/24:3260) that serve the instance's boot and block volumes.

- We recommend that you do not reconfigure the firewall on your instance to remove these rules. Removing these rules allows non-root users or non-administrators to access the instance’s boot disk volume.
- We recommend that you do not create custom images without these rules unless you understand the security risks.
- Running Uncomplicated Firewall (UFW) on Ubuntu images might cause issues with these rules. Because of this, we recommend that you do not enable UFW on your instances. See Ubuntu Instance fails to reboot after enabling Uncomplicated Firewall (UFW) for more information.

System Resilience

Oracle Cloud Infrastructure runs on Oracle's high-quality Sun servers. However, any hardware can experience a failure. Follow industry-wide hardware failure best practices to ensure the resilience of your solution. Some best practices include:

- Design your system with redundant compute nodes in different availability domains to support failover capability.
- Create a custom image of your system drive each time you change the image.
- Back up your data drives, or sync to spare drives, regularly.

If you experience a hardware failure and have followed these practices, you can terminate the failed instance, launch your custom image to create a new instance, and then apply the backup data.

Uninterrupted Access to the Instance

Make sure to keep the DHCP client running so you can always access the instance. If you stop the DHCP client manually or disable NetworkManager (which stops the DHCP client on Linux instances), the instance can't renew its DHCP lease and will become inaccessible when the lease expires (typically within 24 hours). Do not disable NetworkManager unless you use another method to ensure renewal of the lease.

Stopping the DHCP client might remove the host route table when the lease expires. Also, loss of network connectivity to your iSCSI connections might result in loss of the boot drive.

User Access

If you created your instance using an Oracle-provided Linux image, you can use SSH to access your instance from a remote host as the `opc` user. After logging in, you can add users on your instance.

If you do not want to share SSH keys, you can create additional SSH-enabled users.

If you created your instance using an Oracle-provided Windows image, you can access your instance using a Remote Desktop client as the `opc` user. After logging in, you can add users on your instance.

For more information about user access, see Adding Users on an Instance.

NTP Service

Oracle Cloud Infrastructure offers a fully managed, secure, and highly available NTP service that you can use to set the date and time of your Compute and Database instances from within your virtual cloud network (VCN). Oracle recommends that you configure your instances to use the Oracle Cloud Infrastructure NTP service. For information about how to configure instances to use this service, see Configuring the Oracle Cloud Infrastructure NTP Service for an Instance.

Fault Domains

A fault domain is a grouping of hardware and infrastructure that is distinct from other fault domains in the same availability domain. Each availability domain has three fault domains. By properly leveraging fault domains you can increase the availability of applications running on Oracle Cloud Infrastructure. See Fault Domains for more information.

Your application's architecture will determine whether you should separate or group instances using fault domains.

Scenario 1: Highly Available Application Architecture

In this scenario you have a highly available application, for example you have two web servers and a clustered database. In this scenario you should group one web server and one database node in one fault domain and the other half of each pair in another fault domain. This ensures that a failure of any one fault domain does not result in an outage for your application.

Scenario 2: Single Web Server and Database Instance Architecture

In this scenario your application architecture is not highly available, for example you have one web server and one database instance. In this scenario both the web server and the database instance must be placed in the same fault domain. This ensures that your application will only be impacted by the failure of that single fault domain.

Customer-Managed Virtual Machine (VM) Maintenance

When an underlying infrastructure component needs to undergo maintenance, we notify you in advance of the planned maintenance downtime. To avoid this planned downtime, you have the options to reboot, or stop and restart your instances prior to the scheduled maintenance. This makes it easy for you to control your instance downtime during the notification period. The reboot, or stop and restart of a VM instance during the notification period is different than a normal reboot. The reboot, or stop and start workflow will stop your instance on the existing VM host that needs maintenance and restart it on a healthy VM host. If you choose not to reboot during the notification period, then Oracle Cloud Infrastructure will reboot your VM instance before proceeding with the planned infrastructure maintenance. For information on rebooting or restarting your instance prior to planned maintenance, see Rebooting Your Virtual Machine (VM) Instance During Planned Maintenance.

Configuring the Oracle Cloud Infrastructure NTP Service for an Instance

Oracle Cloud Infrastructure offers a fully managed, secure, and highly available NTP service that you can use to set the date and time of your Compute and Database instances from within your virtual cloud network (VCN). The Oracle Cloud Infrastructure NTP service uses redundant Stratum 1 devices in every availability domain. The Stratum 1 devices are synchronized to dedicated Stratum 2 devices that every host synchronizes against. The service is available in every region.

This topic describes how to configure your Compute instances to use this NTP service.

You can also choose to configure your instances to use a public NTP service or use FastConnect to leverage an on-premises NTP service.

Oracle Linux 6.x

Use the following steps to configure your Oracle Linux 6.x instances to use the Oracle Cloud Infrastructure NTP service.

1. Configure IPtables to allow connections to the Oracle Cloud Infrastructure NTP service, using the following commands:

```
sudo iptables -I BareMetalInstanceServices 8 -d 169.254.169.254/32 -p udp -m udp --dport 123 -m
comment --comment "Allow access to OCI local NTP service" -j ACCEPT
```

```
sudo service iptables save
```

2. Install the NTP service with the following command:

```
sudo yum install ntp
```

3. Set the date of your instance with the following command:

```
sudo ntpdate 169.254.169.254
```

4. Configure the instance to use the Oracle Cloud Infrastructure NTP service for iburst. To configure, modify the `/etc/ntp.conf` file as follows:

   a. In the `server` section, comment out the lines specifying the RHEL servers:

```
#server 0.rhel.pool.ntp.org iburst
#server 1.rhel.pool.ntp.org iburst
#server 2.rhel.pool.ntp.org iburst
#server 3.rhel.pool.ntp.org iburst
```

   b. Add an entry for the Oracle Cloud Infrastructure NTP server:

```
server 169.254.169.254 iburst
```

   The modified `server` section now contains the following:

```
# Please consider joining the pool (http://www.pool.ntp.org/join.html).
#server 0.rhel.pool.ntp.org iburst
#server 1.rhel.pool.ntp.org iburst
#server 2.rhel.pool.ntp.org iburst
#server 3.rhel.pool.ntp.org iburst
server 169.254.169.254 iburst
```

5. Set the NTP service to launch automatically when the instance boots with the following command:

```
sudo chkconfig ntpd on
```

6. Start the NTP service with the following command:

```
sudo /etc/init.d/ntpd start
```

7. Confirm that the NTP service is configured correctly with the following command:

```
ntpq -p
```

The output will be similar to the following:

```
remote           refid      st t when poll reach   delay   offset  jitter
==============================================================================
169.254.169.254 192.168.32.3     2 u    2   64    1    0.338    0.278   0.187
```

Oracle Linux 7.x

Note

Oracle-provided Oracle 7.x and CentOS 7.x images released after February 2018 include the Chrony service by default, so you do not need to configure the Oracle Cloud Infrastructure NTP service for these instances.

Use the following steps to configure your Oracle Linux 7.x instances to use the Oracle Cloud Infrastructure NTP service.

1. Run commands in this section as root with the following command:

```
sudo su -
```

2. Install the NTP service with the following command:

```
yum -y install ntp
```

3. Change the firewall rules to allow inbound and outbound traffic with the Oracle Cloud Infrastructure NTP server, at 169.254.169.254, on UDP port 123 with the following command:

```
awk -v n=13 -v s=' <passthrough ipv="ipv4">-A OUTPUT -d 169.254.169.254/32 -p udp -m udp --dport
123 -m comment --comment "Allow access to OCI local NTP service" -j ACCEPT </passthrough>' 'NR ==
n {print s} {print}' /etc/firewalld/direct.xml > tmp && mv tmp /etc/firewalld/direct.xml
```

   At the prompt:

```
mv: overwrite '/etc/firewalld/direct.xml'?
```

   enter `y`

4. Restart the firewall with the following command:

```
service firewalld restart
```

5. Set the date of your instance with the following command:

```
ntpdate 169.254.169.254
```

6. Configure the instance to use the Oracle Cloud Infrastructure NTP service for iburst. To configure, modify the `/etc/ntp.conf` file as follows:

   a. In the `server` section comment out the lines specifying the RHEL servers:

```
#server 0.rhel.pool.ntp.org iburst
#server 1.rhel.pool.ntp.org iburst
#server 2.rhel.pool.ntp.org iburst
#server 3.rhel.pool.ntp.org iburst
```

   b. Add an entry for the Oracle Cloud Infrastructure NTP service:

```
server 169.254.169.254 iburst
```

   The modified `server` section should now contain the following:

```
# Please consider joining the pool (http://www.pool.ntp.org/join.html).
#server 0.rhel.pool.ntp.org iburst
#server 1.rhel.pool.ntp.org iburst
#server 2.rhel.pool.ntp.org iburst
#server 3.rhel.pool.ntp.org iburst
server 169.254.169.254 iburst
```

7. Start and enable the NTP service with the following commands:

```
systemctl start ntpd
systemctl enable ntpd
```

   You also need disable the chrony NTP client to ensure that the NTP service starts automatically after a reboot, using the following commands:

```
systemctl stop chronyd
systemctl disable chronyd
```

8. Confirm that the NTP service is configured correctly with the following command:

```
ntpq -p
```

   The output will be similar to the following:

```
     remote           refid      st t when poll reach   delay   offset  jitter
==============================================================================
169.254.169.254 192.168.32.3     2 u    2   64    1    0.338    0.278   0.187
```

Windows Server 2016, Windows Server 2012 R2 and Windows Server 2008 R2

You can configure your Windows Server instances to use the Oracle Cloud Infrastructure NTP service by running the following commands in Windows Powershell as Administrator.

Windows 2012 and Windows 2016:

```
Set-ItemProperty -Path 'HKLM:\System\CurrentControlSet\Services\W32Time\Parameters' -Name 'Type' -Value
NTP -Type String
Set-ItemProperty -Path 'HKLM:\System\CurrentControlSet\Services\W32Time\Config' -Name 'AnnounceFlags' -
Value 5 -Type DWord
Set-ItemProperty -Path 'HKLM:\System\CurrentControlSet\Services\W32Time\TimeProviders\NtpServer' -Name
'Enabled' -Value 1 -Type DWord
Set-ItemProperty -Path 'HKLM:\System\CurrentControlSet\Services\W32Time\Parameters' -Name 'NtpServer' -
Value '169.254.169.254,0x9' -Type String
Set-ItemProperty -Path 'HKLM:\System\CurrentControlSet\Services\W32Time\TimeProviders\NtpClient' -Name
'SpecialPollInterval' -Value 900 -Type DWord
Set-ItemProperty -Path 'HKLM:\System\CurrentControlSet\Services\W32Time\Config' -Name
'MaxPosPhaseCorrection' -Value 1800 -Type DWord
```

```
Set-ItemProperty -Path 'HKLM:\System\CurrentControlSet\Services\W32Time\Config' -Name
'MaxNegPhaseCorrection' -Value 1800 -Type DWord
```

Windows 2008:

```
Set-ItemProperty -Path 'HKLM:\System\CurrentControlSet\Services\W32Time\Parameters' -Name 'Type' -Value
NTP -Type String
Set-ItemProperty -Path 'HKLM:\System\CurrentControlSet\Services\W32Time\Config' -Name 'AnnounceFlags' -
Value 5 -Type DWord
Set-ItemProperty -Path 'HKLM:\System\CurrentControlSet\Services\W32Time\TimeProviders\NtpServer' -Name
'Enabled' -Value 1 -Type DWord
Set-ItemProperty -Path 'HKLM:\System\CurrentControlSet\Services\W32Time\Parameters' -Name 'NtpServer' -
Value '169.254.169.254,0x9' -Type String
Set-ItemProperty -Path 'HKLM:\System\CurrentControlSet\Services\W32Time\TimeProviders\NtpClient' -Name
'SpecialPollInterval' -Value 900 -Type DWord
Set-ItemProperty -Path 'HKLM:\System\CurrentControlSet\Services\W32Time\Config' -Name
'MaxPosPhaseCorrection' -Value 1800 -Type DWord
Set-ItemProperty -Path 'HKLM:\System\CurrentControlSet\Services\W32Time\Config' -Name
'MaxNegPhaseCorrection' -Value 1800 -Type DWord
Set-ItemProperty -Path 'HKLM:\SOFTWARE\Microsoft\Windows\CurrentVersion\DateTime\Servers' -Name 0 -Value
"169.254.169.254"
Set-ItemProperty -Path 'HKLM:\SOFTWARE\Microsoft\Windows\CurrentVersion\DateTime\Servers' -Name "
(Default)" -Value "0"
```

Steps 1 - 7 below walk you though these registry changes, you can use these steps to manually edit the registry instead of using PowerShell. If you use the PowerShell commands, you can skip steps 1 - 7, and proceed with steps 8 and 9 to complete the process of configuring your Windows instance to use the Oracle Cloud Infrastructure NTP service.

1. Change the server type to NTP:
    a. From Registry Editor, navigate to:

        ```
        HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\W32Time\Parameters\
        ```

    b. Click **Type**.
    c. Change the value to `NTP` and click **OK**.
2. Configure the Windows Time service to enable the `Timeserv_Announce_Yes` and `Reliable_Timeserv_Announce_Auto` flags.
    To configure, set the `AnnounceFlags` parameter to 5:

a. From Registry Editor, navigate to:

```
HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\W32Time\Config\
```

b. Click **AnnounceFlags**.

c. Change the value to `5` and click **OK**.

3. Enable the NTP server:

a. From Registry Editor, navigate to:

```
HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\W32Time\TimeProviders\NtpServer\
```

b. Click **Enabled**.

c. Change the value to `1` and click **OK**.

4. Set the time sources:

a. From Registry Editor, navigate to:

```
HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\W32Time\Parameters\
```

b. Click **NtpServer**.

c. Change the value to `169.254.169.254,0x9` and click **OK**.

5. Set the poll interval:

a. From Registry Editor, navigate to:

```
HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\W32Time\TimeProviders\NtpClient\
```

b. Click **SpecialPollInterval**.

c. Set the value to the interval that you want the time service to synchronize on. The value is in seconds. To set it for 15 minutes, set the value to `900`, and click **OK**.

6. Set the phase correction limit settings to restrict the time sample boundaries:

a. From Registry Editor, navigate to:

```
HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\W32Time\Config\
```

b. Click **MaxPosPhaseCorrection**.

c. Set the value to the maximum time offset in the future for time samples. The

value is in seconds. To set it for 30 minutes, set the value to `1800` and click **OK**.

d. Click **MaxNegPhaseCorrection**.

e. Set the value to the maximum time offset in the past for time samples. The value is in seconds. To set it for 30 minutes, set the value to `1800` and click **OK**.

7. For Windows 2008 only, you need to add the Oracle NTP service to the list of available servers and then configure the Oracle NTP service to be the active server:

   a. From Registry Editor, navigate to:

   ```
   HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows\CurrentVersion\DateTime\Servers\
   ```

   b. Right-click **Servers**, and select **New**, **String Value**.

   c. Set the **Name** to `0`.

   d. Set the **Value data** to `169.254.169.254`.

   e. In the same path, find the string value named `(Default)` and double-click it to open the **Edit String** dialog.

   f. Set the **Value data** to `0` and click **OK**.

8. Restart the time service by running the following command from a command prompt:

   ```
   net stop w32time && net start w32time
   ```

9. Test the connection to the NTP service by running the following command from a command prompt:

   ```
   w32tm /query /peers
   ```

   The output will be similar to the following:

   ```
   #Peer: 1

   Peer: 169.254.169.254,0x9
   State: Active
   Time Remaining: 22.1901786s
   Mode: 3 (Client)
   Stratum: 0 (unspecified)
   PeerPoll Interval: 10 (1024s)
   HostPoll Interval: 10 (1024s)
   ```

After the time specified in the poll interval has elapsed, `State` will change from `Pending` to `Active`.

Protecting Data on NVMe Devices

Some instance shapes in Oracle Cloud Infrastructure include locally attached NVMe devices. These devices provide extremely low latency, high performance block storage that is ideal for big data, OLTP, and any other workload that can benefit from high-performance block storage.

Note that these devices are not protected in any way; they are individual devices locally installed on your instance. Oracle Cloud Infrastructure does not take images, back up, or use RAID or any other methods to protect the data on NVMe devices. It is your responsibility to protect and manage the durability the data on these devices.

Oracle Cloud Infrastructure offers high-performance remote block (iSCSI) LUNs that are redundant and can be backed up using an API call. See Overview of Block Volume for more information.

See Compute Shapes for information about which instance types support local NVMe storage.

Finding the NVMe devices on your instance

You can identify the NVMe devices by using the `lsblk` command. The response returns a list. NVMe devices begin with "`nvme`", as shown in the following example for a BM.DenseIO1.36 instance:

```
[opc@somehost ~]$ lsblk
NAME    MAJ:MIN RM  SIZE RO TYPE MOUNTPOINT
sda       8:0    0 46.6G  0 disk
├─sda1    8:1    0  512M  0 part /boot/efi
├─sda2    8:2    0    8G  0 part [SWAP]
└─sda3    8:3    0   38G  0 part /
nvme0n1 259:6    0  2.9T  0 disk
nvme1n1 259:8    0  2.9T  0 disk
nvme2n1 259:0    0  2.9T  0 disk
nvme3n1 259:1    0  2.9T  0 disk
nvme4n1 259:7    0  2.9T  0 disk
nvme5n1 259:4    0  2.9T  0 disk
```

```
nvme6n1 259:5    0  2.9T  0 disk
nvme7n1 259:2    0  2.9T  0 disk
nvme8n1 259:3    0  2.9T  0 disk
[opc@somehost ~]$
```

Failure Modes and How to Protect Against Them

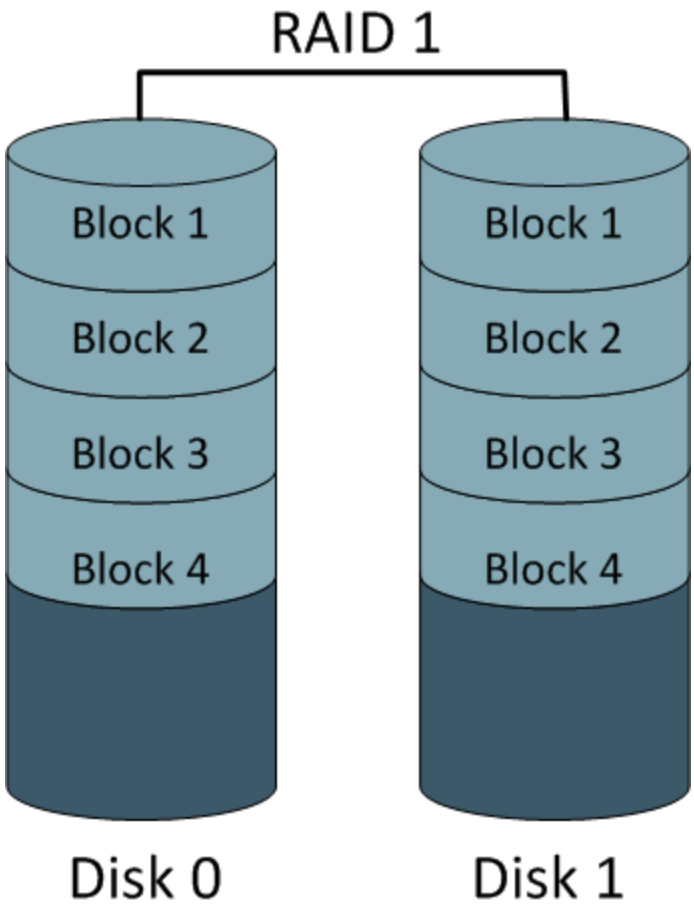
There are three primary failure modes you should plan for:

- Protecting against the failure of an NVMe device
- Protecting Against the Loss of the Instance or Availability Domain
- Protecting Against Data Corruption or Loss from Application or User Error

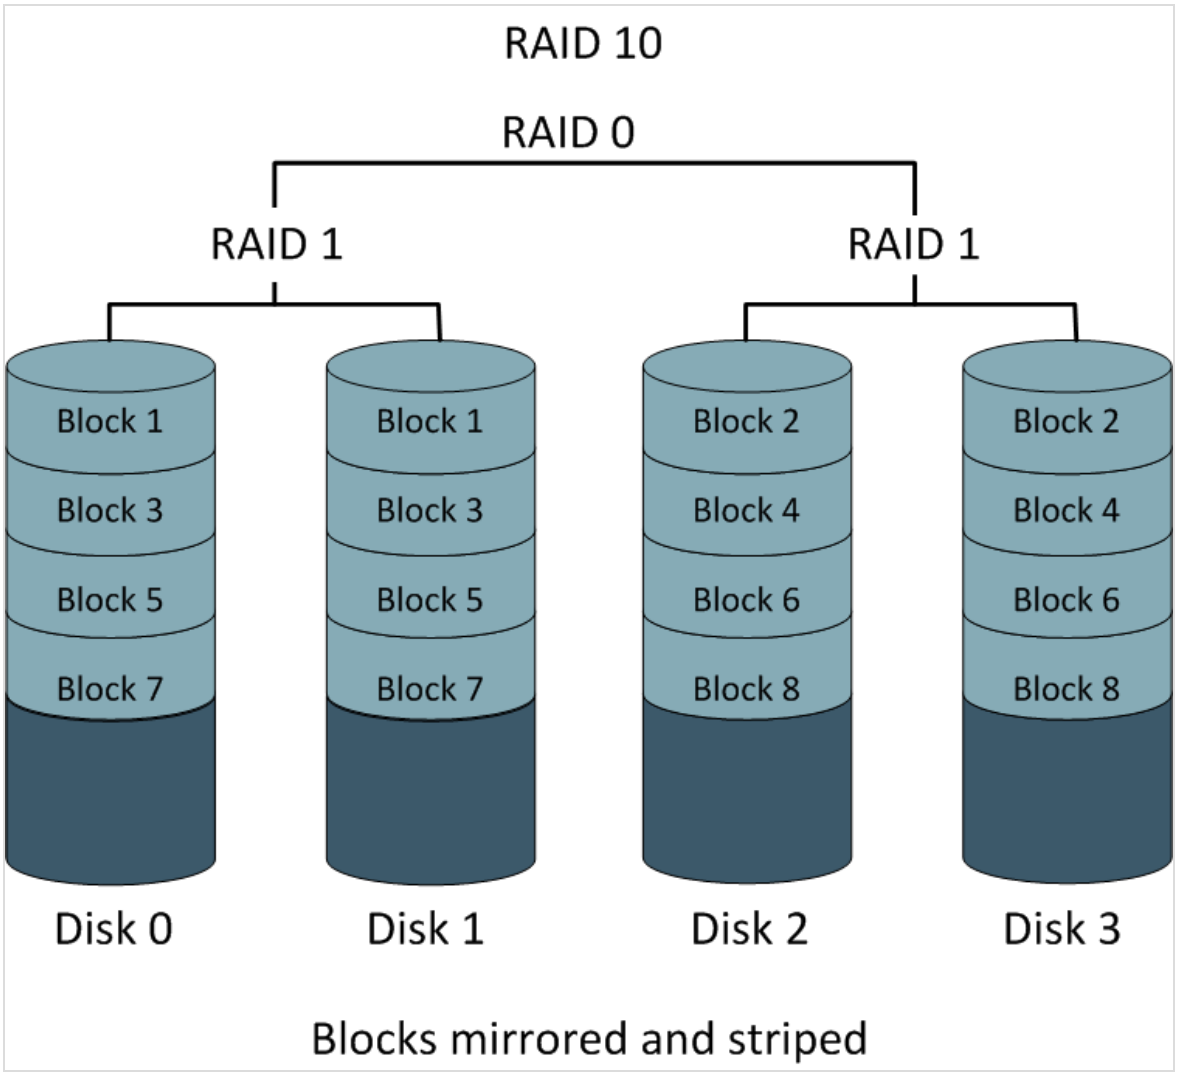
Protecting against the failure of an NVMe device

A protected RAID array is the most recommended way to protect against an NVMe device failure. There are three RAID levels that can be used for the majority of workloads:

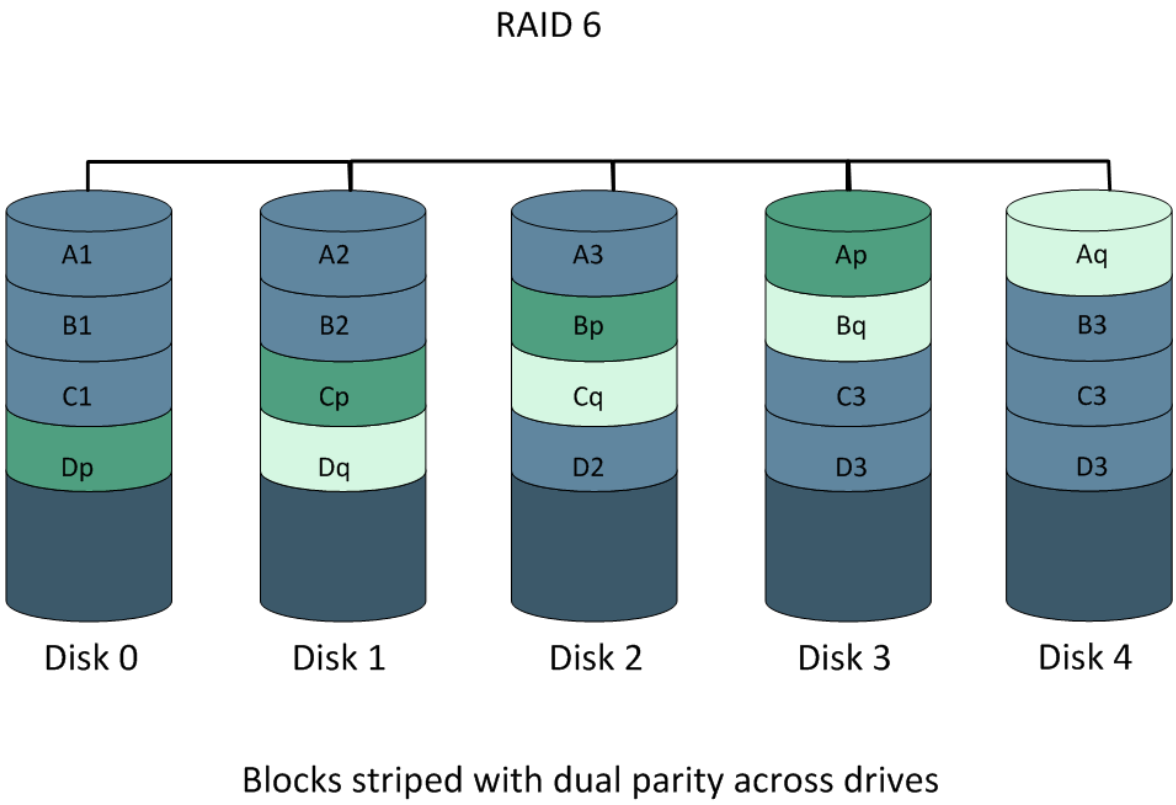
- RAID 1: An exact copy (or mirror) of a set of data on two or more disks; a classic RAID 1 mirrored pair contains two disks, as shown:



- RAID 10: Stripes data across multiple mirrored pairs. As long as one disk in each mirrored pair is functional, data can be retrieved, as shown:



- RAID 6: Block-level striping with two parity blocks distributed across all member disks, as shown.



For more information about RAID and RAID levels, see RAID.

Because the appropriate RAID level is a function of the number of available drives, the number of individual LUNs needed, the amount of space needed, and the performance requirements, there isn't one correct choice. You must understand your workload and design accordingly.

Options for Using a BM.DenseIO1.36 Shape

There are several options for BM.DenseIO1.36 instances with nine NVMe devices:

Create a single RAID 6 device across all nine devices. This array is redundant, performs well, will survive the failure of any two devices, and will be exposed as a single LUN with about 23.8TB of usable space.

Use the following commands to create a single RAID 6 device across all nine devices:

```
$ sudo yum install mdadm -y
```

```
$ sudo mdadm --create /dev/md0 --raid-devices=9 --level=6 /dev/nvme0n1 /dev/nvme1n1 /dev/nvme2n1
/dev/nvme3n1 /dev/nvme4n1 /dev/nvme5n1 /dev/nvme6n1 /dev/nvme7n1 /dev/nvme8n1
```

```
$ sudo mdadm --detail --scan | sudo tee -a /etc/mdadm.conf >> /dev/null
```

Create a four device RAID 10 and a five device RAID 6 array. These arrays would be exposed as two different LUNs to your applications. This is a recommended choice when you need to isolate one type of I/O from another, such as log and data files. In this example, your RAID 10 array would have about 6.4TB of usable space and the RAID 6 array would have about 9.6TB of usable space.

Use the following commands to create a four-device RAID 10 and a five-device RAID 6 array:

```
$ sudo yum install mdadm -y
```

```
$ sudo mdadm --create /dev/md0 --raid-devices=4 --level=10 /dev/nvme5n1 /dev/nvme6n1 /dev/nvme7n1
/dev/nvme8n1
```

```
$ sudo mdadm --create /dev/md1 --raid-devices=5 --level=6 /dev/nvme0n1 /dev/nvme1n1 /dev/nvme2n1
/dev/nvme3n1 /dev/nvme4n1
```

```
$ sudo mdadm --detail --scan | sudo tee -a /etc/mdadm.conf >> /dev/null
```

If you need the best possible performance and can sacrifice some of your available space, then an eight-device RAID 10 array is an option. Because RAID 10 requires an even number of devices, the ninth device is left out of the array and serves as a hot spare in case another device fails. This creates a single LUN with about 12.8 TB of usable space.

Use the following commands to create an eight-device RAID 10 array:

```
$ sudo yum install mdadm -y
```

```
$ sudo mdadm --create /dev/md0 --raid-devices=8 --level=10 /dev/nvme0n1 /dev/nvme1n1 /dev/nvme2n1
/dev/nvme3n1 /dev/nvme4n1 /dev/nvme5n1 /dev/nvme6n1 /dev/nvme7n1
```

The following command adds /dev/nvme8n as a hot spare for the /dev/md0 array:

```
$ sudo mdadm /dev/md0 --add /dev/nvme8n1
```

```
$ sudo mdadm --detail --scan | sudo tee -a /etc/mdadm.conf >> /dev/null
```

For the best possible performance and I/O isolation across LUNs, create two four-device RAID 10 arrays. Because RAID 10 requires an even number of devices, the ninth device is left out of the arrays and serves as a global hot spare in case another device in either array fails. This creates two LUNS, each with about 6.4 TB of usable space.

Use the following commands to create two four-device RAID 10 arrays with a global hot spare:

```
$ sudo yum install mdadm -y
```

```
$ sudo mdadm --create /dev/md0 --raid-devices=4 --level=10 /dev/nvme4n1 /dev/nvme5n1 /dev/nvme6n1
/dev/nvme7n1
```

```
$ sudo mdadm --create /dev/md1 --raid-devices=4 --level=10 /dev/nvme0n1 /dev/nvme1n1 /dev/nvme2n1
/dev/nvme3n1
```

Creating a global hot spare requires the following two steps:

1. Add the spare to either array (it does not matter which one) by running these commands:

   ```
   $ sudo mdadm /dev/md0 --add /dev/nvme8n1
   ```

   ```
   $ sudo mdadm --detail --scan | sudo tee -a /etc/mdadm.conf >> /dev/null
   ```

2. Edit `/etc/mdadm` to put both arrays in the same spare-group. Add `spare-group=global` to the end of the line that starts with `ARRAY`, as follows:

   ```
   $ sudo vi /etc/mdadm.conf
   ```

   ```
   ARRAY /dev/md0 metadata=1.2 spares=1 name=mdadm.localdomain:0
   UUID=43f93ce6:4a19d07b:51762f1b:250e2327 spare-group=global
   ```

   ```
   ARRAY /dev/md1 metadata=1.2 name=mdadm.localdomain:1 UUID=7521e51a:83999f00:99459a19:0c836693
   spare-group=global
   ```

Monitoring Your Array

It's important for you to be notified if a device in one of your arrays fails. Mdadm has built-in tools that can be utilized for monitoring, and there are two options you can use:

- Set the `MAILADDR` option in `/etc/mdadm.conf` and then run the `mdadm` monitor as a daemon
- Run an external script when `mdadm` detects a failure

SET THE MAILADDR OPTION IN /ETC/MDADM.CONF AND RUN THE MDADM MONITOR AS A DAEMON

The simplest method is to set the `MAILADDR` option in `/etc/mdadm.conf`, and then run the mdadm monitor as a daemon, as follows:

1. The `DEVICE partitions` line is required for `MAILADDR` to work; if it is missing, you must add it, as follows:

   ```
   $ sudo vi /etc/mdadm.conf
   ```

   ```
   DEVICE partitions
   ```

   ```
   ARRAY /dev/md0 level=raid1 UUID=1b70e34a:2930b5a6:016we78d:eese14532
   ```

   ```
   MAILADDR <my.name@example.com>
   ```

2. Run the monitor using the following command:

   ```
   $ sudo nohup mdadm --monitor --scan --daemonize &
   ```

3. To verify that the monitor runs at startup, run the following commands:

   ```
   $ sudo chmod +x /etc/rc.d/rc.local
   ```

   ```
   $ sudo vi /etc/rc.local
   ```

   Add the following line to the end of /etc/rc.local:

   ```
   nohup mdadm --monitor --scan --daemonize &
   ```

4. To verify that the email and monitor are both working run the following command:

   ```
   $ sudo mdadm --monitor --scan --test -1
   ```

   Note that these emails will likely be marked as spam. The `PROGRAM` option, described later in this topic, allows for more sophisticated alerting and messaging.

RUN AN EXTERNAL SCRIPT WHEN A FAILURE IS DETECTED

A more advanced option is to create an external script that would run if the `mdadm` monitor detects a failure. You would integrate this type of script with your existing monitoring solution. The following is an example of this type of script:

```
$ sudo vi /etc/mdadm.events

#!/bin/bash
event=$1
device=$2
if [ $event == "Fail" ]
then
  <"do something">
else
 if [ $event == "FailSpare" ]
 then
  <"do something else">
 else
  if [ $event == "DegradedArray" ]
  then
   <"do something else else">
  else
   if [ $event == "TestMessage" ]
    then
    <"do something else else else">
   fi
  fi
 fi
fi

$ sudo chmod +x /etc/mdadm.events
```

Next, add the `PROGRAM` option to `/etc/mdadm.conf`, as shown in the following example:

1. The `DEVICE partitions` line is required for `MAILADDR` to work; if it is missing, you must add it, as follows:

   ```
   $ sudo vi /etc/mdadm.conf
   ```

   ```
   DEVICE partitions
   ```

   ```
   ARRAY /dev/md0 level=raid1 UUID=1b70e34a:2930b5a6:016we78d:eese14532
   ```

   ```
   MAILADDR <my.name@example.com>
   ```

   ```
   PROGRAM /etc/mdadm.events
   ```

2. Run the monitor using the following command:

   ```
   $ sudo nohup mdadm --monitor --scan --daemonize &
   ```

3. To verify that the monitor runs at startup, run the following commands:

```
$ sudo chmod +x /etc/rc.d/rc.local
```

```
$ sudo vi /etc/rc.local
```

Add the following line to the end of /etc/rc.local:

```
nohup mdadm --monitor --scan --daemonize &
```

4. To verify that the email and monitor are both working run the following command:

```
$ sudo mdadm --monitor --scan --test -1
```

Note that these emails will likely be marked as spam. The `PROGRAM` option, described later in this topic, allows for more sophisticated alerting and messaging.

SIMULATE THE FAILURE OF A DEVICE

You can use `mdadm` to manually cause a failure of a device to see whether your RAID array can survive the failure, as well as test the alerts you have set up.

1. Mark a device in the array as failed by running the following command:

```
$ sudo mdadm /dev/md0 --fail /dev/nvme0n1
```

2. Recover the device or your array might not be protected. Use the following command:

```
$ sudo mdadm /dev/md0 --add /dev/nvme0n1
```

Your array will automatically rebuild in order to use the "new" device. Performance will be decreased during this process.

3. You can monitor the rebuild status by running the following command:

```
$ sudo mdadm --detail /dev/md0
```

What To Do When an NVMe Device Fails

Compute resources in the cloud are designed to be temporary and fungible. If an NVMe device fails while the instance is in service, you should start another instance with the same amount of storage or more, and then copy the data onto the new instance, replacing the old instance. There are multiple toolsets for copying large amounts of data, with rsync being the most

popular. Since the connectivity between instances is a full 10Gb/sec, copying data should be quick. Remember that with a failed device, your array may no longer be protected, so you should copy the data off of the impacted instance as quickly as possible.

Using the Linux Logical Volume Manager

The Linux Logical Volume Manager (LVM) provides a rich set of features for managing volumes. If you need these features, we strongly recommend that you use `mdadm` as described in preceding sections of this topic to create the RAID arrays, and then use LVM's `pvcreate`, `vgcreate`, and `lvcreate` commands to create volumes on the `mdadm` LUNs. You should not use LVM directly against your NVMe devices.

Protecting Against the Loss of the Instance or Availability Domain

Once your data is protected against the loss of a NVMe device, you need to protect it against the loss of an instance or the loss of the availability domain. This type of protection is typically done by replicating your data to another availability domain or backing up your data to another location. The method you choose depends on your objectives. For details, see Recovery Time Objective (RTO) and Recovery Point Objective (RPO).

REPLICATION

Replicating your data from one instance in one availability domain to another has the lowest RTO and RPO at a significantly higher cost than backups; for every instance in one availability domain, you must have another instance in a different availability domain.

For Oracle database workloads, you should use the built-in Oracle Data Guard functionality to replicate your databases. Oracle Cloud Infrastructure availability domains are each close enough to each other to support high performance, synchronous replication. Asynchronous replication is also an option.

For general-purpose block replication, DRBD is the recommended option. You can configure DRBD to replicate, synchronously or asynchronously, every write in one availability domain to another availability domain.

BACKUPS

Traditional backups are another way to protect data. All commercial backup products are fully supported on Oracle Cloud Infrastructure. If you use backups, the RTO and RPO are significantly higher than using replication because you must recreate the compute resources that failed and then restore the most recent backup. Costs are significantly lower because you don't need to maintain a second instance. Do not store your backups in the same availability domain as their original instance.

Protecting Against Data Corruption or Loss from Application or User Error

The two recommended ways of protecting against data corruption or loss from application or user error are regularly taking snapshots or creating backups.

SNAPSHOTS

The two easiest ways to maintain snapshots are to either use a file system that supports snapshots, such as ZFS, or use LVM to create and manage the snapshots. Because of the way LVM has implemented copy-on-write (COW), performance may significantly decrease when a snapshot is taken using LVM.

BACKUPS

All commercial backup products are fully supported on Oracle Cloud Infrastructure. Make sure that your backups are not stored in the same availability domain as their original instance.

Boot Volumes

When you launch a virtual machine (VM) or bare metal instance based on an Oracle-provided image or custom image, a new boot volume for the instance is created in the same compartment. That boot volume is associated with that instance until you terminate the instance. When you terminate the instance, you can preserve the boot volume and its data. For more information, see Terminating an Instance. This feature gives you more control and management options for your compute instance boot volumes, and enables:

- **Instance scaling:** When you terminate your instance, you can keep the associated boot volume and use it to launch a new instance using a different instance type or shape. See Creating an Instance for steps to launch an instance based on a boot volume. This allows you to switch easily from a bare metal instance to a VM instance and vice versa, or scale up or down the number of cores for an instance.
- **Troubleshooting and repair:** If you think a boot volume issue is causing a compute instance problem, you can stop the instance and detach the boot volume. Then you can attach it to another instance as a data volume to troubleshoot it. After resolving the issue, you can then reattach it to the original instance or use it to launch a new instance.

Boot volumes are encrypted by default, the same as other block storage volumes. For more information, see Block Volume Encryption.

Important

In-transit encryption for boot and block volumes is only available for virtual machine (VM) instances launched from Oracle-provided images, it is not supported on bare metal instances. It is also not supported in most cases for instances launched from custom images imported for "bring your own image" (BYOI) scenarios. To confirm support for certain Linux-based custom images and for more information contact Oracle support, see Contacting Support.

You can group boot volumes with block volumes into the same volume group, making it easy to create a group volume backup or a clone of your entire instance, including both the system disk and storage disks at the same time. See Volume Groups for more information.

You can move Block Volume resources such as boot volumes and boot volume backups between compartments. For more information, see Move Block Volume Resources Between Compartments.

For more information about the Block Volume service and boot volumes, see the Block Volume FAQ.

Custom Boot Volume Sizes

When you launch an instance, you can specify whether to use the selected image's default boot volume size, or you can specify a custom size up to 32 TB. This capability is available for the following image source options:

- Oracle-provided image
- Custom image
- Image OCID

See Creating an Instance for more information.

The specified size must be larger than the image's default boot volume size or 50 GB, whichever is higher. After you launch the instance, you can't change the boot volume size.

Important

The minimum size for Windows-based image boot volumes is 256 GB.

If you specify a custom boot volume size, you need to extend the volume to take advantage of the larger size. For steps, see Extending the Partition for a Boot Volume.

Boot Volume Performance

Boot volume performance varies with volume size, see Block Volume Performance for more information.

The Block Volume service's elastic performance feature enables you to dynamically change the volume performance for boot volumes. Once an instance has been created, you can

change the volume performance of the boot volume to one of the following performance options:

- Balanced
- Higher Performance

For more information about this feature and the performance options, see Block Volume Elastic Performance and Changing the Performance of a Volume

Required IAM Service Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don't have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: The policy in Let users launch Compute instances includes the ability to list boot volumes. The policy in Let volume admins manage block volumes, backups, and volume groups lets the specified group do everything with block volumes, boot volumes, and backups, but not launch instances.

If you're new to policies, see Getting Started with Policies and Common Policies. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services.

Using the Console

To access the Console, you must use a supported browser.

See the following tasks for managing boot volumes:

- Listing Boot Volumes
- Attaching a Boot Volume
- Detaching a Boot Volume

- Listing Boot Volume Attachments
- Deleting a Boot Volume

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use these API operations to manage boot volumes:

- BootVolume
- ListBootVolumes
- GetBootVolume
- UpdateBootVolume
- DetachBootVolume
- DeleteVolume
- BootVolumeAttachment
- AttachBootVolume
- GetBootVolumeAttachment
- ListBootVolumeAttachments

Extending the Partition for a Boot Volume

When you create a new virtual machine (VM) instance or bare metal instance based on an Oracle-provided image or custom image, you have the option of specifying a custom boot volume size. You can also expand the size of the boot volume for an existing instance; see Resizing a Volume for more information. In order to take advantage of the larger size, you need to extend the partition for the boot volume.

Required IAM Policy

Extending a partition on an instance does not require a specific IAM policy. However, you may need permission to run the necessary commands on the instance's guest OS. Contact your system administrator for more information.

Extending the Root Partition on a Linux-Based Image

For instances running Linux-based images, you need to extend the root partition and then grow the file system.

PREREQUISITES

Before you can extend the partition, you need to detach the boot volume from the instance and attach it to another instance as a data volume. To do this:

1. Stop the instance. For steps, see Stopping and Starting an Instance.
2. After the instance has stopped, detach the boot volume. For steps, see Detaching a Volume.
3. Attach the boot volume to a second instance as a data volume. For steps, see Attaching a Volume and Connecting to a Volume.

EXTENDING THE LINUX PARTITION

After attaching the boot volume as a data volume to the second instance, connect to this instance and perform the following steps to extend the partition.

Extending the root partition

1. To identify the volume you want to extend the partition for, run the following command to list the attached block volumes:

```
lsblk
```

2. Run the following command to edit the volume's partition table with `parted`:

```
parted <volume_id>
```

   <volume_id> is the volume identifier, for example `/dev/sdc`.

3. When you run `parted`, you may encounter the following error message:

```
Warning: Not all of the space available to <volume_id> appears to be used,
you can fix the GPT to use all of the space (an extra volume_size blocks)
or continue with the current setting?
```

   You are then prompted to fix the error or ignore the error and continue with the current setting. Specify the option to fix the error.

4. Run the following command to change the display units to sectors so that you can see the precise start position for the volume:

```
(parted) unit s
```

5. Run the following command to display the current partitions in the partition table:

```
(parted) print
```

   Make note of the values in the **Number**, **Start**, and **File system** columns for the root partition.

6. Run the following command to remove the existing root partition:

```
(parted) rm <partition_number>
```

   <partition_number> is the value from the **Number** column.

7. Run the following command to recreate the partition:

```
(parted) mkpart
```

   At the `Start?` prompt, specify the value from the **Start** column. At the `File system type?` prompt, specify the value from the **File system** column. Specify `100%` for the `End?` prompt.

8. Run the following command to exit `parted`:

   ```
   (parted) quit
   ```

   This command forces a rewrite of the partition table with the new partition settings that you specified.

9. To verify that the root partition was extended, run the following command to list the attached block volumes:

   ```
   lsblk
   ```

After you extend the root partition, you need to grow the file system. The steps in the following procedure apply only to xfs file systems.

Growing the file system for the root partition

1. Before you grow the file system, repair any issues with the file system on the extended partition by running the following command:

   ```
   xfs_repair <partition_id>
   ```

   <partition_id> is the partition identifier, for example `/dev/sdc3`. See Checking and Repairing an XFS File System for more information.

2. After you have confirmed that there are no more issues to repair, you need to create a mount point to run the `xfs_growfs` against. To do this, create a directory and mount the partition to that directory by running the following commands:

   ```
   mkdir <directory_name>
   mount <partition_id> <directory_name> -o nouuid
   ```

   <partition_id> is the partition identifier, for example `/dev/sdc3`, and *<directory_name>* is the directory to create and mount.

3. After you have created the mount point run the following command to grow the file system:

   ```
   xfs_growfs -d <directory_name>
   ```

   <directory_name> is the name for the directory you created in the previous step.

4. To verify that the file system size is correct, run the following command to display the file system details:

   ```
   df -lh
   ```

5. Once you have verified that the file system size is correct, run the following command to unmount the partition:

   ```
   umount <partition_id>
   ```

Next Steps

After you have extended the partition and grown the file system, you can restart the original instance with the boot volume. To do this:

1. Disconnect the volume from the second instance. For steps, see Disconnecting From a Volume.
2. Detach the volume from the second instance. For steps, see Detaching a Volume.
3. Attach the volume to the original instance as a boot volume. For steps, see Attaching a Boot Volume.
4. Restart the instance. For steps, see Stopping and Starting an Instance.

Extending the System Partition on a Windows-Based Image

On Windows-based images, you can extend a partition using the Windows interface or from the command line using the DISKPART utility.

Windows Server 2016 and Windows Server 2012

The steps for extending a system partition on instances running Windows 2012 or Windows 2016 are the same, and are described in the following procedures.

Extending the system partition using the Windows interface

1. Open the Disk Management system utility on the instance.
2. Right-click the boot volume and select **Extend Volume**.
3. Follow the instructions in the **Extend Volume Wizard**:
   a. Select the disk that you want to extend, enter the size, and then click **Next**.
   b. Confirm that the disk and size settings are correct, and then click **Finish**.
4. Verify that the boot volume's system disk has been extended in Disk Management.

Extending the system partition using the command line with DISKPART

1. Open a command prompt as administrator on the instance.
2. Run the following command to start the DISKPART utility:

   ```
   diskpart
   ```

3. At the `DISKPART` prompt, run the following command to display the instance's volumes:

   ```
   list volume
   ```

4. Run the following command to select the boot volume:

   ```
   select volume <volume_number>
   ```

   <volume_number> is the number associated with the boot volume that you want to extend the partition for.

5. Run the following command to extend the partition:

```
extend size=<increased_size_in_MB>
```

<increased_size_in_MB> is the size in MB that you want to extend the partition to.

> **Warning**
>
> When using the DISKPART utility, do not overextend the partition beyond the current available space. Overextending the partition could result in data loss.

6. To confirm that the partition was extended, run the following command and verify that the boot volume's partition has been extended:

```
list volume
```

WINDOWS SERVER 2008

Use the steps described in the following procedures to extend a system partition on instances running Windows 2008.

Extending the system partition using the Windows interface

1. Open the Server Manager on the instance.
2. Expand the **Storage** node in the left navigation pane and click **Disk Management**.
3. Right-click the boot volume and select **Extend Volume**.
4. Follow the instructions in the **Extend Volume Wizard**:
   a. Select the disk that you want to extend, enter the size, and then click **Next**.
   b. Confirm that the disk and size settings are correct, and then click **Finish**.
5. Verify that the boot volume's system disk has been extended in the Server Manager's **Disk Management** node.

Extending the system partition using the command line with DISKPART

1. Open a command prompt as administrator on the instance.
2. Run the following command to start the DISKPART utility:

   ```
   diskpart
   ```

3. At the `DISKPART` prompt, run the following command to display the instance's volumes:

   ```
   list volume
   ```

4. Run the following command to select the boot volume:

   ```
   select volume <volume_number>
   ```

   <volume_number> is the number associated with the boot volume that you want to extend the partition for.

5. Run the following command to extend the partition:

   ```
   extend size=<increased_size_in_MB>
   ```

   <increased_size_in_MB> is the size in MB that you want to extend the partition to.

   Warning

   When using the DISKPART utility, do not overextend the partition beyond the current available space. Overextending the partition could result in data loss.

6. To confirm that the partition was extended, run the following command and verify that the boot volume's partition has been extended:

   ```
   list volume
   ```

Attaching a Boot Volume

If a boot volume has been detached from the associated instance, or if the instance is stopped or terminated, you can attach it to another instance as a data volume. The steps are the same as the steps for attaching a block volume, see Attaching a Volume.

You can also reattach a boot volume to the associated instance. If you want to restart an instance with a detached boot volume, you must reattach the boot volume using the steps described in this topic.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: The policy in Let users launch Compute instances includes the ability to attach/detach existing block volumes. The policy in Let volume admins manage block volumes, backups, and volume groups lets the specified group do everything with block volumes and backups, but not launch instances.

If you're new to policies, see Getting Started with Policies and Common Policies. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services.

Using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
2. In the **Instances** list, select the instance you want to attach the boot volume to.
3. Click the name of the instance to display the instance details.
4. In the **Resources**, click **Boot Volume**.
5. Click the Actions icon (three dots) for the boot volume.

6. Click **Attach** and confirm the selection when prompted.
   You can start the instance once the boot volume's icon no longer lists it as **ATTACHING**. For more information, see Stopping and Starting an Instance.

Using the API

To attach a volume to an instance, use the following operation:

- AttachBootVolume

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Listing Boot Volumes

You can list all boot volumes in a specific compartment, or detailed information on a single boot volume.

Required IAM Service Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don't have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: The policy in Let users launch Compute instances includes the ability to list volumes. The policy in Let volume admins manage block volumes, backups, and volume groups lets the specified group do everything with block volumes and backups, but not launch instances.

If you're new to policies, see Getting Started with Policies and Common Policies. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services.

Using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Boot Volumes**.
2. Choose your **Compartment**.

A detailed list of volumes in the current compartment is displayed. To see detailed information for a specific volume, click the boot volume name.

The instance associated with the boot volume is listed in the **Attached Instance** field. If the value for this field displays:

```
None in this Compartment.
```

the boot volume has been detached from the associated instance, or the instance has been terminated while the boot volume was preserved.

To view the volumes in a different compartment, change the compartment in the **Compartment** drop-down menu.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

List Boot Volumes:

Get a list of boot volumes within a compartment.

- ListBootVolumes

Get a Single Boot Volume:

Get detailed information on a single boot volume:

- GetBootVolume

Overview of Boot Volume Backups

The backups feature of the Oracle Cloud Infrastructure Block Volume service lets you make a point-in-time crash-consistent backup of a boot volume without application interruption or downtime. Boot volume backup capabilities are the same as block volume backup capabilities. See Overview of Block Volume Backups for more information.

There are two ways you can initiate a boot volume backup, the same as block volume backups. You can either manually start the backup, or assign a policy which defines a set backup schedule. See Manual Backups and Policy-Based Backups for more information.

Boot Volume Backup Types

The Block Volume service supports the same backups types for boot volumes as for block volumes:

- **Incremental:** This backup type includes only the changes since the last backup.
- **Full:** This backup type includes all changes since the volume was created.

Backing Up a Boot Volume

You can create boot volume backups using the Console or the REST APIs/command line interface (CLI). See Backing Up a Boot Volume and the BootVolumeBackup API for more information.

Restoring a Boot Volume

Before you can use a boot volume backup, you need to restore it. For steps, see Restoring a Boot Volume.

Making a boot volume backup while an instance is running creates a crash-consistent backup, meaning the data is in the identical state it was in at the time the backup was made. This is the same state it would be in the case of a loss of power or hard crash. In most cases, you can restore a boot volume backup and use it to create an instance. Alternatively you can attach it to an instance as a data volume to repair it or recover data, see Attaching a Volume. To

ensure a bootable image, you should create a custom image from your instance. For information about creating custom images, see Managing Custom Images.

Differences Between Boot Volume Backups and Clones

Consider the following criteria when you decide whether to create a backup or a clone of a volume.

	Volume Backup	Volume Clone
Description	Creates a point-in-time backup of data on a volume. You can restore multiple new volumes from the backup later in the future.	Creates a single point-in-time copy of a volume without having to go through the backup and restore process.
Use case	Retain a backup of the data in a volume, so that you can duplicate an environment later or preserve the data for future use. Meet compliance and regulatory requirements, because the data in a backup remains unchanged over time. Support business continuity requirements. Reduce the risk of outages or data mutation over time.	Rapidly duplicate an existing environment. For example, you can use a clone to test configuration changes without impacting your production environment.
Speed	Slower (minutes or hours)	Faster (seconds)
Cost	Lower cost	Higher cost
Storage location	Object Storage	Block Volume

	Volume Backup	Volume Clone
Retention policy	Policy-based backups expire, manual backups do not expire	No expiration
Volume groups	Supported. You can back up a volume group.	Supported. You can clone a volume group.

Backing Up a Boot Volume

You can create a backup of a boot volume using the Oracle Cloud Infrastructure Block Volume service. This topic describes how to create a manual boot volume backup.

You can also configure a backup policy that creates backups automatically based on a specified schedule and retention policy. This works the same as block volumes. See Policy-Based Backups for more information.

For information to help you decide whether to create a backup or a clone of a boot volume, see Differences Between Boot Volume Backups and Clones.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

Tip

When users create a backup from a volume or restore a volume from a backup, the volume and backup don't have to be in the same compartment. However, users must have access to both compartments.

If you're new to policies, see Getting Started with Policies and Common Policies. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services.

Using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Boot Volumes**.
2. Click the boot volume that you want to create a backup for.
3. Click **Create Manual Backup**.
4. Enter a name for the backup.
5. Select the backup type, either incremental or full. See Boot Volume Backup Types for information about backup types.
6. Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.
7. Click **Create Backup**.
   The backup is completed when its icon no longer lists it as **CREATING** in the **Boot Volume Backup** list.

Using the API

To back up a boot volume, use the following operation:

- CreateBootVolumeBackup

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

For more information about backups, see Overview of Block Volume Backups and Restoring a Backup to a New Volume.

Cloning a Boot Volume

You can create a clone from a boot volume using the Oracle Cloud Infrastructure Block Volume service. Cloning enables you to make a copy of an existing boot volume without needing to go through the backup and restore process. For more information about the Block Volume service, see Overview of Block Volume and the Block Volume FAQ.

A boot volume clone is a point-in-time direct disk-to-disk deep copy of the source boot volume, so all the data that is in the source boot volume when the clone is created is copied to the boot volume clone. Any subsequent changes to the data on the source boot volume are not copied to the boot volume clone. Since the clone is a copy of the source boot volume it will be the same size as the source boot volume unless you specify a larger volume size when you create the clone.

The clone operation occurs immediately and you can use the cloned boot volume as soon as the state changes to available.

There is a single point-in-time reference for a source boot volume while it is being cloned, so if you clone a boot volume while the associated instance is running, you need to wait for the first clone operation to complete from the source before creating additional clones. You also need to wait for any backup operations to complete as well.

You can only create a clone for a boot volume within the same region, availability domain, and tenant. You can create a clone for a boot volume between compartments as long as you have the required access permissions for the operation.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Differences Between Boot Volume Backups and Clones

Consider the following criteria when you decide whether to create a backup or a clone of a volume.

	Volume Backup	Volume Clone
Description	Creates a point-in-time backup of data on a volume. You can restore multiple new volumes from the backup later in the future.	Creates a single point-in-time copy of a volume without having to go through the backup and restore process.
Use case	Retain a backup of the data in a volume, so that you can duplicate an environment later or preserve the data for future use. Meet compliance and regulatory requirements, because the data in a backup remains unchanged over time. Support business continuity requirements. Reduce the risk of outages or data mutation over time.	Rapidly duplicate an existing environment. For example, you can use a clone to test configuration changes without impacting your production environment.

	Volume Backup	Volume Clone
Speed	Slower (minutes or hours)	Faster (seconds)
Cost	Lower cost	Higher cost
Storage location	Object Storage	Block Volume
Retention policy	Policy-based backups expire, manual backups do not expire	No expiration
Volume groups	Supported. You can back up a volume group.	Supported. You can clone a volume group.

For more information about boot volume backups, see Overview of Boot Volume Backups and Backing Up a Boot Volume.

Using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Boot Volumes**.
2. In the **Boot Volumes** list, click the boot volume that you want to clone.
3. In **Resources**, click **Boot Volume Clones**.
4. Click **Create Clone**.
5. Specify a name for the clone.
6. If you want to clone the boot volume to a larger size volume, select **Custom Boot Volume Size (GB)** and then specify the new size. You can only increase the size of the volume, you cannot decrease the size. If you clone the boot volume to a larger size volume, you need to extend the volume's partition. See Extending the Partition for a Boot Volume for more information.
7. Click **Create Clone**.

The boot volume is ready use when its icon lists it as **AVAILABLE** in the **Boot Volumes** list.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

To create a clone from a boot volume, use the CreateBootVolume operation and specify BootVolumeSourceFromBootVolumeDetails for CreateBootVolumeDetails.

Next Steps

After you have cloned a boot volume backup, you can:

- Use the boot volume to create an instance. For more information, see Creating an Instance.
- Attach the boot volume to an instance as a data volume. For more information, see Attaching a Volume.

Making a boot volume clone while an instance is running creates a crash-consistent clone, meaning the data is in the identical state it was in at the time the clone was made. This is the same state it would be in the case of a loss of power or hard crash. In most cases you can use the cloned boot volume to create an instance, however to ensure a bootable image, you should create a custom image from your instance. For information about creating custom images, see Managing Custom Images.

Detaching a Boot Volume

If you think a boot volume issue is causing a compute instance problem, you can stop the instance and detach the boot volume using the steps described in this topic. Then you can attach it to another instance as a data volume to troubleshoot it.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have

permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: The policy in Let users launch Compute instances includes the ability to attach/detach existing block volumes. The policy in Let volume admins manage block volumes, backups, and volume groups lets the specified group do everything with block volumes and backups, but not launch instances.

If you're new to policies, see Getting Started with Policies and Common Policies. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services.

Using the Console

You can only detach a boot volume from an instance when the instance is stopped. See Stopping and Starting an Instance for more information about managing an instance's state.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
2. Choose your **Compartment**.
3. In the **Instances** list, select the instance you want to detach the boot volume from.
4. Click the name of the instance to display the instance details.
5. In the **Resources**, click **Boot Volume**.
6. Click the Actions icon (three dots), for the boot volume.
7. Click **Detach** and confirm the selection when prompted.

You can now attach the boot volume to another instance, for more information see Attaching a Volume.

Using the API

To delete an attachment, use the following operation:

- DetachBootVolume

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Deleting a Boot Volume

When you terminate an instance, you choose to delete or preserve the associated boot volume. For more information, see Terminating an Instance. You can also delete a boot volume if it has been detached from the associated instance. See Detaching a Boot Volume for how to detach a boot volume.

Warning

You cannot undo this operation. Any data on a volume will be permanently deleted once the volume is deleted. You will also not be able to restart the associated instance.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: The policy in Let volume admins manage block volumes, backups, and volume groups lets the specified group do everything with block volumes and backups.

If you're new to policies, see Getting Started with Policies and Common Policies. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services.

Using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Boot Volumes**.
2. Choose your **Compartment**.
3. In the **Boot Volumes** list, find the volume you want to delete.
4. Click the Actions icon (three dots) for the boot volume.
5. Click **Terminate** and confirm the selection when prompted.

Using the API

Use the DeleteBootVolume operation to delete a boot volume.

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Boot Volume Metrics

You can monitor the health, capacity, and performance of your Compute instances by using metrics, alarms, and notifications.

The Block Volume service provides a set of metrics that apply to both boot volumes and block volumes. For more information, see Block Volume Metrics.

Recovering a Corrupted Boot Volume for Linux-Based Instances

If your instance fails to boot successfully or boots with the boot volume set to read-only access, the instance's boot volume may be corrupted. While it is rare, boot volume corruption can occur in the following scenarios:

- When an instance experiences a forced shutdown using the API.
- When an instance experiences a system hang due to an operating system or software error and a graceful reboot or shutdown of the instance times out, and then a forced

shutdown occurs.

- When an error or outage occurs in the underlying infrastructure and there were critical disk writes pending in the system.

Important

In most cases a simple reboot will resolve boot volume corruption issues, so this is the first action you should take when troubleshooting this.

This topic describes how to determine if your Linux-based instance's boot volume is corrupted and what steps to take to troubleshoot and recover the corrupted boot volume. For Windows instances, see Recovering a Corrupted Boot Volume for Windows Instances.

Detecting Boot Volume Corruption

Boot volume corruption can prevent an instance from booting successfully, so you may not be able to connect to the instance using SSH. Instead, you can use the instance console connection feature to connect to the malfunctioning instance. For more information about using this feature, see Instance Console Connections.

This section describes how to use a serial console connection to detect if boot volume corruption has occurred.

Tip

If you have already confirmed your instance's boot volume is corrupted or if you are using an imported custom image, proceed to the Recovering the Boot Volume section, which describes how to use a second instance along with standard file system tools to both detect and repair boot volume corruption.

1. Create a serial console connection for the instance.

   ### To create the serial console connection for an instance

   a. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.

   b. In the list of instances, find the instance you think may have a corrupted boot volume, and then click the instance name.

   c. In the **Resources** section on the **Instance Details** page, click **Console Connections**, and then click **Create Console Connection**.

   d. Specify the public key portion for the SSH key, either by browsing and selecting a public key file, for example id_rsa.pub, or by pasting your public key into the text box, and then click **Create Console Connection**.

2. Connect to the instance through serial console.

   ### To connect to the serial console for an instance using OpenSSH on Mac OS X or Linux

   a. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**. Click the instance you want to connect to.

   b. On the **Instances Details** page, in the **Resources** section, click **Console Connections**.

   c. Click the Actions icon (three dots), and then click **Connect with SSH**.

   d. Select **LINUX/MAC OS** for **PLATFORM**.

   e. Click **Copy** to copy the string to the clipboard.

   f. Paste the connection string copied from the previous step to a terminal window on a Mac OS X or Linux system, and press Enter to connect to the console.

      If you are not using the default SSH key or ssh-agent, you can modify the serial console connection string to include the identity file flag, `-i` to specify the SSH

key to use. You need to specify this for both the SSH connection and the SSH ProxyCommand, as shown in the following line:

```
ssh -i /<path>/<ssh_key> -o ProxyCommand='ssh -i /<path>/<ssh_key> -W %h:%p -p 443...
```

g. Press Enter again to activate the console.

At this point, it's normal for the serial console to appear to hang, as the system may have already crashed.

3. Reboot the instance from the Console, on the **Instances Details page**, click **Reboot**.
4. Once the reboot process starts, switch back to the terminal window, and you should see system messages from the instance start to appear in the window.
5. Monitor the messages that appear as the system is starting up. Most operating systems will set the boot volume to read-only as soon as disk corruption is detected to prevent writes from further corrupting the volume, so look for messages that indicate the boot volume is in read-only mode. Following are some examples:
   - On an instance with iSCSI-attached boot volumes, the `iscsiadm` service will fail to attach a volume because the volume is in read-only mode. This will typically prevent instances from continuing to boot. The serial console may display a message similar to the following:

     ```
     iscsiadm: Maybe you are not root?
     iscsiadm: Could not lock discovery DB: /var/lock/iscsi/lock.write: Read-only file system
     touch: cannot touch `/var/lock/subsys/iscsid': Read-only file system
     touch: cannot touch `/var/lock/subsys/iscsi': Read-only file system
     ```

   - On an instance with paravirtualized-attached boot volumes, the system may continue the boot process, but will be in a degraded state because nothing can be written to the boot drive.The serial console may display error messages similar to the following:

     ```
     [FAILED] Failed to start Create Volatile Files and Directories.
     See 'systemctl status systemd-tmpfiles-setup.service' for details.
     ...
     [   27.160070] cloud-init[819]:     os.chmod(path, real_mode)
     [   27.166027] cloud-init[819]: OSError: [Errno 30] Read-only file system:
     '/var/lib/cloud/data'
     ```

The error messages and system behavior described here are the most commonly seen for boot volume corruption, however depending on the operating system, you may see different error messages and system behavior. If you don't see the ones described here, consult the documentation for your operating system for additional troubleshooting information.

Recovering the Boot Volume

To troubleshoot and recover the corrupted boot volume, you need to detach the boot volume from the instance and then attach the boot volume to a second instance as a data volume.

DETACHING THE BOOT VOLUME

If you have detected that your instance's boot volume is corrupted, you need to detach the boot volume from the instance before you can begin troubleshooting and recovery steps.

1. Stop the instance. For more information, see Stopping and Starting an Instance.

   #### To stop the instance

   a. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.

   b. In the list of instances, find the instance you have detected boot volume corruption for and then click the instance name to display the instance details.

   c. Click **Stop**.

2. Detach the boot volume from the instance. For more information, see Detaching a Boot Volume.

   #### To detach the boot volume from the instance

   a. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.

   b. In the **Instances** list, select the instance you want to detach the boot volume from.

c. Click the name of the instance to display the instance details.

d. In the **Resources**, click **Boot Volume**.

e. Click the Actions icon (three dots), for the boot volume.

f. Click **Detach** and confirm the selection when prompted.

Attaching the Boot Volume as a Data Volume to a Second Instance

For the second instance we recommend that you use an instance running an operating system that most closely matches the operating system for the boot volume's instance. You should only attach boot volumes for Linux-based instances to other Linux-based instances. The second instance must be in the same availability domain and region as the boot volume's instance. If no existing instance is available, create a new Linux instance using the steps described in Creating an Instance. Once you have the second instance, make sure you can log into the instance and that it is functional before proceeding with the recovery steps. For steps to access the instance, see Connecting to a Linux Instance. After you have confirmed that the instance is functional, perform the following steps.

1. Run the `lsblk` command and make note of the drives that are currently on the instance, for example:

```
lsblk
NAME   MAJ:MIN RM  SIZE RO TYPE MOUNTPOINT
sda      8:0    0 46.6G  0 disk
├─sda2   8:2    0    8G  0 part [SWAP]
├─sda3   8:3    0 38.4G  0 part /
└─sda1   8:1    0  200M  0 part /boot/efi
```

2. Attach the boot volume to the second instance as a data volume. For more information, see Attaching a Volume.

To attach the boot volume as a data volume

a. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.

b. In the **Instances** list, click the instance that you want to attach a volume to.

c. In the **Resources** section, click **Attached Block Volumes**.

d. Click **Attach Block Volume**.

e. Select the volume attachment type. If **Paravirtualized** attachments are available for this instance, we recommend that you select this attachment type for this procedure.

If you select **iSCSI** as the volume attachment type, you need to connect to the volume, see Connecting to a Volume for more information.

f. In the **Block Volume Compartment** drop-down list, select the compartment.

g. Choose the **SELECT VOLUME** option and then select the volume from the **Boot Volume** section of the **Block Volume** drop-down list.

h. Select **Read/Write** as the access type.

i. Click **Attach**.

When the volume's icon no longer lists it as **Attaching**, proceed with the next steps.

3. Run the `lsblk` command again to confirm that the boot volume now shows up as a volume attached to the instance. In this sample output for the `lsblk`, the boot volume attached as a data volume shows up as `sdb`:

```
lsblk
NAME   MAJ:MIN RM  SIZE RO TYPE MOUNTPOINT
sdb      8:16   0 46.6G  0 disk
├─sdb2   8:18   0    8G  0 part
├─sdb3   8:19   0 38.4G  0 part
└─sdb1   8:17   0  200M  0 part
sda      8:0    0 46.6G  0 disk
├─sda2   8:2    0    8G  0 part [SWAP]
├─sda3   8:3    0 38.4G  0 part /
└─sda1   8:1    0  200M  0 part /boot/efi
```

4. Run the `fsck` command on the volume's root partition. The root partition is usually the largest partition on the volume.

The following sample for the `fsck` command shows the output when there are no errors or corruption present on the partitions for an Oracle 7.6 instance:

```
sudo fsck -V /dev/sdb1
fsck from util-linux 2.23.2
[/sbin/fsck.vfat (1) -- /boot/efi] fsck.vfat /dev/sdb1
fsck.fat 3.0.20 (12 Jun 2013)
/dev/sdb1: 17 files, 2466/51145 clusters

sudo fsck -V /dev/sdb2
fsck from util-linux 2.23.2

sudo fsck -V /dev/sdb3
fsck from util-linux 2.23.2
[/sbin/fsck.xfs (1) -- /] fsck.xfs /dev/sdb3
If you wish to check the consistency of an XFS filesystem or
repair a damaged filesystem, see xfs_repair(8).
```

If errors are present on a partition, you will usually be prompted to repair the errors. Following is an example of an interactive repair session of a corrupt ext4 boot volume for an Ubuntu instance:

```
sudo fsck -V /dev/sdb1
fsck from util-linux 2.31.1
[/sbin/fsck.ext4 (1) -- /] fsck.ext4 /dev/sdb1
e2fsck 1.44.1 (24-Mar-2018)
One or more block group descriptor checksums are invalid.  Fix<y> yes
Group descriptor 92 checksum is 0xe9a1, should be 0x1f53.  FIXED.
Pass 1: Checking inodes, blocks, and sizes
Pass 2: Checking directory structure

Pass 3: Checking directory connectivity
Pass 4: Checking reference counts
Pass 5: Checking group summary information
Block bitmap differences: Group 92 block bitmap does not match checksum.
FIXED.

cloudimg-rootfs: ***** FILE SYSTEM WAS MODIFIED *****
cloudimg-rootfs: 75336/5999616 files (0.1% non-contiguous), 798678/12181243 blocks
```

Note

XFS file systems will usually auto-repair their contents when the system boots up, fixing any corruption during the boot process. You can use the `xfs_repair` command to force a repair for scenarios where boot volume corruption is preventing the auto-repair functionality from working, as shown in the following example:

```
sudo xfs_repair /dev/sdb3
Phase 1 - find and verify superblock...
Phase 2 - using internal log
- zero log...
- scan filesystem freespace and inode maps...
...
Phase 7 - verify and correct link counts...
done
```

Recovering a Corrupted Boot Volume for Windows Instances

If your instance fails to boot successfully or boots with the boot volume set to read-only access, the instance's boot volume may be corrupted. While it is rare, boot volume corruption can occur in the following scenarios:

- When an instance experiences a forced shutdown using the API.
- When an instance experiences a system hang due to an operating system or software error and a graceful reboot or shutdown of the instance times out, and then a forced shutdown occurs.
- When an error or outage occurs in the underlying infrastructure and there were critical disk writes pending in the system.

Important

In most cases a simple reboot will resolve boot volume corruption issues, so this is the first action you should take when troubleshooting this.

This topic describes how to determine if your Windows instance's boot volume is corrupted and what steps to take to troubleshoot and recover the corrupted boot volume. For Linux-based instances, see Recovering a Corrupted Boot Volume for Linux-Based Instances.

Detecting Boot Volume Corruption

When Windows operating systems detect boot volume corruption, the instance is usually able to recover from it by automatically repairing the file system. You can use a VNC console connection to verify that the instance isn't experiencing a system hang while repairing the file system, or to detect if there are other issues. VNC console connections enable you to see what's displayed through the VGA port, for more information about the VNC console, see Instance Console Connections.

Important

VNC console connections only work for virtual machine (VM) instances launched on October 13, 2017 or later, and bare metal instances launched on February 21, 2019 or later. If your instance does not support VNC console connections, proceed to Recovering the Boot Volume.

1. Create a VNC console connection for the instance.

   ### To create the VNC console connection for an instance

   a. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.

   b. In the list of instances, find the instance you think may have a corrupted boot volume, and then click the instance name.

   c. In the **Resources** section on the **Instance Details** page, click **Console Connections**, and then click **Create Console Connection**.

   d. Specify the public key portion for the SSH key, either by browsing and selecting a public key file, for example id_rsa.pub, or by pasting your public key into the text box, and then click **Create Console Connection**.

2. Connect to the instance through VNC console.

   ### To set up a secure tunnel to the VNC server on the instance using PowerShell on Windows

   a. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**. Click the instance you want to connect to.

   b. On the **Instances Details** page, in the **Resources** section, click **Console Connections**.

   c. Click the Actions icon (three dots), and then click **Connect with VNC**.

   d. Select **WINDOWS** for **PLATFORM**.

   e. Click **Copy** to copy the string to the clipboard.

   f. Paste the connection string copied from the previous step to Windows Powershell and hit enter to set up the secure connection.

   g. Once the connection has been established, open your VNC client and specify `localhost` as the host to connect to and `5900` as the port to use.

Check what is displayed in the VNC console to see if the instance is stuck in the boot process or if it is in the recovery partition.

Tip

For Windows 2012 and Windows 2016 operating systems, if the instance has booted into the recovery partition it may be possible to directly perform the steps to recover the boot volume in the recovery partition .

Detaching the Boot Volume

If you have detected that your instance's boot volume is corrupted, you need to detach the boot volume from the instance before you can begin troubleshooting and recovery steps.

1. Stop the instance. For more information, see Stopping and Starting an Instance.

   To stop the instance

   a. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
   b. In the list of instances, find the instance you have detected boot volume corruption for and then click the instance name to display the instance details.
   c. Click **Stop**.

2. Detach the boot volume from the instance. For more information, see Detaching a Boot Volume.

   To detach the boot volume from the instance

   a. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.

b. In the **Instances** list, select the instance you want to detach the boot volume from.
c. Click the name of the instance to display the instance details.
d. In the **Resources**, click **Boot Volume**.
e. Click the Actions icon (three dots), for the boot volume.
f. Click **Detach** and confirm the selection when prompted.

Recovering the Boot Volume

To troubleshoot and recover the corrupted boot volume, you need to attach the boot volume to a second instance as a data volume. For the second instance we recommend that you use an instance running an operating system that most closely matches the operating system for the boot volume's instance, and you should only attach boot volumes for Windows instances to other Windows instances. The second instance must be in the same availability domain and region as the boot volume's instance. If no existing instance is available create a new Windows instance using the steps described in Creating an Instance.

Once you have the second instance, make sure you can log in to the instance and that it is functional before proceeding with the recovery steps. After you have confirmed that the instance is functional perform the following steps.

1. Attach the boot volume to the second instance as a data volume. For more information, see Attaching a Volume.

To attach the boot volume as a data volume

a. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
b. In the **Instances** list, click the instance that you want to attach a volume to.
c. In the **Resources** section, click **Attached Block Volumes**.
d. Click **Attach Block Volume**.

e. Select **iSCSI** for the volume attachment type.
f. In the **Block Volume Compartment** drop-down list, select the compartment.
g. Choose the **SELECT VOLUME** option and then select the volume from the **Boot Volume** section of the **Block Volume** drop-down list.
h. Select **Read/Write** as the access type.
i. Click **Attach**.
When the volume's icon no longer lists it as **Attaching**, proceed with the next steps.

2. Connect to the second instance, see Connecting to a Windows Instance for more information.
3. Connect to the volume, see Connecting to a Volume on a Windows Instance for more information. Since you are attaching a boot volume as a data volume you must also run the `Connect-IscsiTarget` and set `IsMultiEnabled` to true. For example:

```
Set-Service -Name msiscsi -StartupType Automatic
Start-Service msiscsi
New-IscsiTargetPortal –TargetPortalAddress 169.254.2.4
Connect-IscsiTarget -NodeAddress iqn.2015-02.oracle.boot:uefi -TargetPortalAddress 169.254.2.4 -
IsPersistent $True -IsMultipathEnabled $True
```

4. Open **Computer Management** and navigate to **Storage**, and then **Disk Management**.
5. Select the new disk and mark it **Online**.
6. Click **This PC** and then right-click on the new disk and select **Properties**.
7. Navigate to **Tools**, **Error Checking**, and then **Check**.
8. Select **Scan Drive** and fix issues as they come up.
9. Mark the new disk **Offline**.
10. Open iscsi initiator with administrator privileges.
11. In **Favorite Targets**, remove the iscsi target of the attached volume.

Oracle-Provided Images

An image is a template of a virtual hard drive. The image determines the operating system and other software for an instance. The following table lists the images that are available in Oracle Cloud Infrastructure. For specific image and kernel version details, along with changes between versions, see Oracle-Provided Image Release Notes.

Image	Name	Description
Oracle Linux 7 Unbreakable Enterprise Kernel Release 5	Oracle-Linux-7.*x*-<*date*>-<*number*>	The Unbreakable Enterprise Kernel (UEK) is Oracle's optimized operating system kernel for demanding Oracle workloads. GPU shapes are supported with this image.
Oracle Linux 6 Unbreakable Enterprise Kernel Release 4	Oracle-Linux-6.*x*-<*date*>-<*number*>	The Unbreakable Enterprise Kernel (UEK) is Oracle's optimized operating system kernel for demanding Oracle workloads.
CentOS 7	CentOS-7-<*date*>-<*number*>	CentOS is a free, open-source Linux distribution that is suitable for use in enterprise cloud environments. For more information, see https://www.centos.org/.
CentOS 6	CentOS-6.*x*-<*date*>-<*number*>	CentOS is a free, open-source Linux distribution that is suitable for use in enterprise cloud environments. For more information, see https://www.centos.org/.

Image	Name	Description
Ubuntu 18.04 LTS	Canonical-Ubuntu-18.04-<*date*>-<*number*>	Ubuntu is a free, open-source Linux distribution that is suitable for use in the cloud. For more information, see https://www.ubuntu.com. Minimal Ubuntu is designed for automated use at scale. It uses a smaller boot volume, boots faster, and has a smaller surface for security patches than standard Ubuntu images. For more information, see https://wiki.ubuntu.com/Minimal. GPU shapes are supported with this image. You must install the appropriate GPU drivers from NVIDIA.
Ubuntu 16.04 LTS	Canonical-Ubuntu-16.04-<*date*>-<*number*>	Ubuntu is a free, open-source Linux distribution that is suitable for use in the cloud. For more information, see https://www.ubuntu.com. Minimal Ubuntu is designed for automated use at scale. It uses a smaller boot volume, boots faster, and has a smaller surface for security patches than standard Ubuntu images. For more information, see https://wiki.ubuntu.com/Minimal. GPU shapes are supported with this image. For Minimal Ubuntu, you must install the appropriate GPU drivers from NVIDIA.
Windows Server 2016	Windows-Server-2016-<*edition*>-Gen2.<*date*>-<*number*>	Windows Server 2016 supports running production Windows workloads on Oracle Cloud Infrastructure. GPU shapes are supported with this image. You must install the appropriate GPU drivers from NVIDIA.

Image	Name	Description
Windows Server 2012 R2	Windows-Server-2012-R2-<*edition*>-<*gen*>-<*date*>-<*number*>	Windows Server 2012 R2 supports running production Windows workloads on Oracle Cloud Infrastructure. GPU shapes are supported with this image. You must install the GPU drivers from NVIDIA.
Windows Server 2008 R2 - Virtual Machine (VM)	Windows-Server-2008-R2-Enterprise-Edition-VM-<*date*>-<*number*>	Windows Server 2008 R2 Enterprise Edition supports running production Windows workloads on Oracle Cloud Infrastructure.

You also can create custom images of your boot disk OS and software configuration for launching new instances.

Essential Firewall Rules

Warning

Windows 2008 Server R2 images do not support restricting certain firewall rules for local principals, such as "Administrators", so any authenticated user on an instance can make outgoing connections to the iSCSI network endpoints (169.254.0.2:3260, 169.254.2.0/24:3260) that serve the instance's boot and block volumes.

All Oracle-provided images include rules that allow only "root" on Linux instances or "Administrators" on Windows Server 2012 R2 and Windows Server 2016 instances to make outgoing connections to the iSCSI network endpoints (169.254.0.2:3260, 169.254.2.0/24:3260) that serve the instance's boot and block volumes.

- We recommend that you do not reconfigure the firewall on your instance to remove these rules. Removing these rules allows non-root users or non-administrators to access the instance’s boot disk volume.
- We recommend that you do not create custom images without these rules unless you understand the security risks.
- Running Uncomplicated Firewall (UFW) on Ubuntu images might cause issues with these rules. Because of this, we recommend that you do not enable UFW on your instances. See Ubuntu Instance fails to reboot after enabling Uncomplicated Firewall (UFW) for more information.

User Data

Oracle-provided images give you the ability to run custom scripts or supply custom metadata when the instance launches. To do this, you specify a custom startup script in the **User Data** field when you create the instance. For more information about startup scripts, see cloud-init for Linux-based images and cloudbase-init for Windows-based images.

OS Updates for Linux Images

Oracle Linux and CentOS images are preconfigured to let you install and update packages from the repositories on the Oracle public yum server. The repository configuration file is in the `/etc/yum.repos.d` directory on your instance. You can install, update, and remove packages by using the yum utility.

Note

OS Security Updates for Oracle Linux and CentOS images

After you launch an instance using Oracle Linux or CentOS images, you are responsible for applying the required OS security updates published through the Oracle public yum server. For more information, see Installing and Using the Yum Security Plugin.

The Ubuntu image is preconfigured with suitable repositories to allow you to install, update, and remove packages.

Note

OS Security Updates for the Ubuntu image

After you launch an instance using the Ubuntu image, you are responsible for applying the required OS security updates using the `sudo apt-get upgrade` command.

Linux Kernel Updates

Oracle Linux images on Oracle Cloud Infrastructure include Oracle Linux Premier Support at no extra cost. This gives you all the services included with Premier Support, including Oracle Ksplice. Ksplice enables you to apply important security and other critical kernel updates without a reboot. For more information, see About Oracle Ksplice and Ksplice Overview.

Ksplice is only available for Linux instances launched on or after February 15, 2017. For instances launched before August 25, 2017, you must install Ksplice before running it. See Installing and Running Oracle Ksplice for more information.

Note

Ksplice Support

Oracle Ksplice is not supported for CentOS and Ubuntu images, or on Linux images launched before February 15, 2017.

Configuring Automatic Package Updating on Instance Launch

You can configure your instance to automatically update to the latest package versions when the instance first launches using a cloud-init startup script. To do this, add the following code to the startup script:

```
package_upgrade: true
```

The upgrade process starts when the instance launches and runs in the background until it completes. To verify that it completed successfully, check the cloud-init logs in `/var/log`.

See User Data and Cloud config examples - Run apt or yum upgrade for more information.

Linux Image Details

See Lifetime Support Policy: Coverage for Oracle Linux and Oracle VM for details about the Oracle Linux support policy.

Users

For instances created using Oracle Linux and CentOS images, the user name `opc` is created automatically. The `opc` user has `sudo` privileges and is configured for remote access over the SSH v2 protocol using RSA keys. The SSH public keys that you specify while creating instances are added to the `/home/opc/.ssh/authorized_keys` file.

For instances created using the Ubuntu image, the user name `ubuntu` is created automatically. The `ubuntu` user has `sudo` privileges and is configured for remote access over

the SSH v2 protocol using RSA keys. The SSH public keys that you specify while creating instances are added to the `/home/ubuntu/.ssh/authorized_keys` file.

Note that `root` login is disabled.

Remote Access

Access to the instance is permitted only over the SSH v2 protocol. All other remote access services are disabled.

Firewall Rules

Instances created using Oracle-provided images have a default set of firewall rules that allow only SSH access. Instance owners can modify those rules as needed, but must not restrict link local traffic to address 169.254.0.2 in accordance with the warning at the top of this page.

Be aware that the Networking service uses network security groups and security lists to control packet-level traffic in and out of the instance. When troubleshooting access to an instance, make sure all of the following items are set correctly: the network security groups that the instance is in, the security lists associated with the instance's subnet, and the instance's firewall rules.

Cloud-init Compatibility

Instances created using Oracle-provided images are compatible with cloud-init. When launching an instance with the Core Services API, you can pass cloud-init directives with the metadata parameter. For more information, see LaunchInstance.

OCI Utilities

Instances created using Oracle Linux include a preinstalled set of utilities that are designed to make it easier to work with Oracle Linux images. These utilities consist of a service component and related command line tools.

The following table summarizes the components that are included in the OCI utilities.

Name	Description
`ocid`	The service component of oci-utils. This normally runs as a daemon started via `systemd`. This service scans for changes in the iSCSI and VNIC device configurations and caches the OCI metadata and public IP address of the instance.
`oci-iscsi-config`	Used to display and configure iSCSI devices attached to a compute instance. If no command line options are specified, lists devices that need attention.
`oci-metadata`	Displays metadata for the compute instance. If no command line options are specified, lists all available metadata. Metadata includes the instance OCID, display name, compartment, shape, region, availability domain, creation date, state, image, and any custom metadata that you provide, such as an SSH public key.
`oci-network-config`	Lists or configures virtual network interface cards (VNICs) attached to the Compute instance. When a secondary VNIC is provisioned in the cloud, it must be explicitly configured on the instance using this script or similar commands.
`oci-public-ip`	Displays the public IP address of the current system in either human-readable or JSON format.

For more information, see the OCI Utilities reference.

Windows OS Updates for Windows Images

Windows images include the Windows Update utility, which you can run to get the latest Windows updates from Microsoft. You have to configure the instance's network security group or the security list used by the instance's subnet to allow instances to access Windows update servers.

Windows Image Details

Users

For instances created using Oracle-provided Windows images, the user name `opc` is created automatically. When you launch an instance using the Windows image, Oracle Cloud Infrastructure will generate an initial, one-time password that you can retrieve using the console or API. This password must be changed after you initially log on.

Remote Access

Access to the instance is permitted only through a Remote Desktop connection.

Firewall Rules

Instances created using the Windows image have a default set of firewall rules that allow Remote Desktop protocol or RDP access on port 3389. Instance owners can modify these rules as needed, but must not restrict link local traffic to 169.254.169.253 for the instance to activate with Microsoft Key Management Service (KMS). This is how the instance stays active and licensed.

Be aware that the Networking service uses network security groups and security lists to control packet-level traffic in and out of the instance. When troubleshooting access to an instance, make sure all of the following items are set correctly: the network security groups that the instance is in, the security lists associated with the instance's subnet, and the instance's firewall rules.

User Data on Windows Images

On Windows images custom user data scripts are executed using cloudbase-init, which is the equivalent of cloud-init on Linux-based images. All Oracle-provided Windows images on Oracle Cloud Infrastructure include cloudbase-init installed by default. When an instance launches, cloudbase-init runs PowerShell, batch scripts, or additional user data content. See cloudbase-init Userdata for information about supported content types.

You can use user data scripts to perform various tasks, such as:

- Enable GPU support using a custom script to install the applicable GPU driver.
- Add or update local user accounts.
- Join the instance to a domain controller.
- Install certificates into the certificate store.
- Copy any required application workload files from the Object Storage service directly to the instance.

Warning

Do not include anything in the script that could trigger a reboot, because this could impact the instance launch, causing it to fail. Any actions requiring a reboot should only be performed after the instance state is **RUNNING**.

Windows Remote Management

Windows Remote Management (WinRM) is enabled by default on Oracle-provided Windows images. WinRM provides you with the capability to remotely manage the operating system.

To use WinRM you need to add a stateful ingress security rule for TCP traffic on destination port 5986. You can implement this security rule in either a network security group that the instance belongs to, or a security list that is used by the instance's subnet.

Warning

The following procedure allows WinRM connections from 0.0.0.0/0, which means any IP address, including public IP addresses. To allow access only from instances within the VCN, change the source CIDR value to the VCN's CIDR block. For more information, see Security Recommendations.

To enable WinRM access

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. To add the rule to a network security group that the instance belongs to:
    a. Under **Resources**, click **Network Security Groups**. Then click the network security group that you're interested in.
    b. Click **Add Rules**.
    c. Enter the following values for the rule:
        - **Stateless:** Leave the check box cleared
        - **Source Type:** CIDR
        - **Source CIDR:** 0.0.0.0/0
        - **IP Protocol:** TCP
        - **Source Port Range:** All
        - **Destination Port Range:** 5986
    d. When done, click **Add**.
4. Or, to add the rule to a security list that is used by the instance's subnet:

a. Under **Resources**, click **Security Lists**. Then click the security list you're interested in.
b. Click **Add Ingress Rules**.
c. Enter the following values for the rule:
   - **Stateless:** Leave the check box cleared
   - **Source Type:** CIDR
   - **Source CIDR:** 0.0.0.0/0
   - **IP Protocol:** TCP
   - **Source Port Range:** All
   - **Destination Port Range:** 5986
d. When done, click **Add Ingress Rules**.

To use WinRM on an instance

1. Get the instance's public IP address.
2. Open Windows PowerShell on the Windows client that you're using to connect to the instance.
3. Run the following command:

```
# Get the public IP from your OCI running windows instance
$ComputerName = Public IP Address

# Store your username and password credentials (default username is opc)
$c = Get-Credential

# Options
$opt = New-PSSessionOption -SkipCACheck -SkipCNCheck -SkipRevocationCheck

# Create new PSSession (Pre-requisite: ensure network security group or security list has Ingress
Rule for port 5986)
$PSSession = New-PSSession -ComputerName $ComputerName -UseSSL -SessionOption $opt -
```

```
Authentication Basic -Credential $c

# Connect to Instance PSSession
Enter-PSSession $PSSession

# To close connection use: Exit-PSSession
```

You can now remotely manage the Windows instance from your local PowerShell client.

Operating System Lifecycle and Support Policy

When an operating system reaches the end of its support lifecycle, the OS vendor (such as Microsoft) no longer provides security updates for the OS. You should upgrade to the latest version to remain secure.

Here's what you should expect when an OS version reaches the end of its support lifecycle:

- Oracle Cloud Infrastructure no longer provides new images for the OS version. Images that were previously published are deprecated, and are no longer updated.
- Although you can continue to run instances that use deprecated images, Oracle Cloud Infrastructure does not provide any support for operating systems that have reached the end of the support lifecycle.
- If you have an instance that runs an OS version that will be deprecated, and you want to launch new instances with this OS version after the end of support, you can create a custom image of the instance and then use the custom image to launch new instances in the future. For custom Linux images, you must purchase extended support from the OS vendor. For custom Windows images, Extended Security Updates may not be used on Oracle Cloud Infrastructure. Oracle Cloud Infrastructure does not provide any support for custom images that use end-of-support operating systems.

Be aware of these end-of-support dates:

- **Ubuntu 14.04:** Support ended on April 19, 2019.
- **Windows Server 2008 R2:** Support ends on January 14, 2020.

Using NVIDIA GPU Cloud with Oracle Cloud Infrastructure

NVIDIA GPU Cloud (NGC) is a GPU-accelerated cloud platform optimized for deep learning and scientific computing. This topic provides an overview of how to use NGC with Oracle Cloud Infrastructure.

NVIDIA makes available on Oracle Cloud Infrastructure a customized Compute image optimized for the NVIDIA® Tesla Volta™ and Pascal™ GPUs . Running NGC containers on this instance provides optimum performance for deep learning jobs.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Prerequisites

- An Oracle Cloud Infrastructure tenancy. For more information, see Signing Up for Oracle Cloud Infrastructure.
- A cloud network to launch the instance into. For information about setting up cloud networks, see Using the Console in VCNs and Subnets.
- A key pair, to use for connecting to the instance via SSH. For information about generating a key pair, see Managing Key Pairs on Linux Instances.
- Security group and policy configured for the File Storage service. For more information, see Managing Groups, Getting Started with Policies, and Details for the File Storage Service.
- An NGC API key for authenticating with the NGC service.

To generate your NGC API key

1. Log in to the NGC website.
2. On the NGC Registry page, click **Get API Key**.
3. Click **Generate API Key** and then click **Confirm** to generate the key. If you have an existing API key it will become invalid once you generate a new key.

Launching an instance based on the NGC image

USING THE CONSOLE

1. Open the Console. See Signing In to the Console for steps to do this.
2. Click **Compute**, choose a compartment you have permission to work in, and then click **Create Instance**.
3. In the **Create Instance** dialog box, specify the instance name, and select the availability domain for the instance.
4. Click **Change Image Source**.
5. On the **Oracle Images** tab, check **NVIDIA GPU Cloud Machine Image**, review and accept the **Agreement for Oracle App "NVIDIA GPU Cloud Machine Image"**, and then click **Select Image**.
6. Select **Virtual Machine** or **Bare Metal Machine** for **Instance Type**.
7. Select the shape you want to use for **Shape**.
8. For **SSH Keys**, click **Choose SSH Key File**, navigate to the location where you saved the public key portion (.pub) of the SSH key file you created, select the file and click **Open**.
9. In the **Configure Networking** section, select the virtual cloud network (VCN) compartment, VCN, subnet compartment, and subnet.
10. Click **Create Instance**.

You should now see the NGC instance with the status of **Provisioning**. Once the status has changed to **Running**, you can connect to the instance. For general information about launching Compute instances, see Creating an Instance.

See the following topics for accessing and working with the instance:

- Connecting to an Instance
- Stopping and Starting an Instance
- Terminating an Instance

When you connect to the instance using SSH you will be prompted for the NGC API key. If you supply the API key at the prompt, the instance will automatically log you into the NGC container registry so that you can run containers from the registry. You can choose not to supply the API key at the prompt and still log in to the instance. You can then log in later to the NGC container registry, see Logging in to the NGC Container Registry for more information.

USING THE CLI

Oracle Cloud Infrastructure provides a Command Line Interface (CLI) you can use to complete tasks. For more information, see Quickstart and Configuration. Use the launch command to create an instance, specifying `image` for **sourceType** and the image OCID `ocid1.image.oc1..aaaaaaaaknl6phck7e3iuii4r4axpwhenw5qtnnsk3tqppajdjzb5nhoma3q` in **InstanceSourceDetails** for **LaunchInstanceDetails**.

Using the File Storage Service for Persistent Data Storage

You can use the Overview of File Storage for data storage when working with NGC. See the following tasks for creating and working with the File Storage service:

- Creating File Systems
- Using the Console
- Using the API
- Managing File Systems
- Using the Command Line Interface (CLI)

Using the Block Volume Service for Persistent Data Storage

You can use the Block Volume service for data storage when working with NGC. For more information, see Overview of Block Volume. See the following tasks for creating and working

with the Block Volume service:

- Creating a Volume
- Attaching a Volume
- Connecting to a Volume

You can also use the CLI to manage block volumes, see the volume commands.

Examples of Running Containers

You first need to log into the NGC container registry. You can skip this section if you provided your API key when logging into the instance via SSH. If you did not provide your API key when connecting to your instance, then you must perform this step.

To log into the NGC container registry

1. Run the following Docker command:

```
docker login nvcr.io
```

2. When prompted for a username, enter `$oauthtoken`.
3. When prompted for a password enter your NGC API key.

At this point you can run Docker commands and access the NGC container registry from the instance.

Example: MNIST Training Run Using PyTorch Container

This sample demonstrates running the MNIST example under PyTorch. This example downloads the MNIST dataset from the web.

1. Pull and run the PyTorch container with the following Docker commands:

```
docker pull nvcr.io/nvidia/pytorch:17.10
                                        nvidia-docker run --rm -it nvcr.io/nvidia/pytorch:17.10
```

2. Run the MNIST example with the following commands:

```
cd /opt/pytorch/examples/mnist
                                                python main.py
```

Example: MNIST Training Run Using TensorFlow Container

This sample demonstrates running the MNIST example under TensorFlow. This example downloads the MNIST dataset from the web.

1. Pull and run the TensorFlow container with the following Docker commands:

```
nvcr.io/nvidia/tensorflow:17.10
                                                nvidia-docker run --rm -it nvcr.io/nvidia/tensorflow:17.10
```

2. Run the MNIST_with_summaries example with the following commands:

```
cd /opt/tensorflow/tensorflow/examples/tutorials/mnist
                                                python mnist_with_summaries.py
```

OCI Utilities

Instances created using Oracle-Provided Images based on Oracle Linux include a pre-installed set of utilities that are designed to make it easier to work with Oracle Linux images. These utilities consist of a service component and related command line tools that can help with managing block volumes (attach, remove, and automatic discovery), secondary VNIC configuration, discovering the public IP address of an instance, and retrieving instance metadata.

The following table summarizes the components that are included in the OCI utilities.

Name	Description
`ocid`	The service component of oci-utils. This normally runs as a daemon started via `systemd`. This service scans for changes in the iSCSI and VNIC device configurations and caches the OCI metadata and public IP address of the instance.
`oci-growfs`	Expands the root filesystem of the instance to its configured size.
`oci-iscsi-config`	Used to display and configure iSCSI devices attached to a compute instance. If no command line options are specified, lists devices that need attention.
`oci-metadata`	Displays metadata for the compute instance. If no command line options are specified, lists all available metadata. Metadata includes the instance OCID, display name, compartment, shape, region, availability domain, creation date, state, image, and any custom metadata that you provide, such as an SSH public key.
`oci-network-config`	Lists or configures virtual network interface cards (VNICs) attached to the Compute instance. When a secondary VNIC is provisioned in the cloud, it must be explicitly configured on the instance using this script or similar commands.
`oci-network-inspector`	Displays a detailed report for a given compartment or network.
`oci-public-ip`	Displays the public IP address of the current system in either human-readable or JSON format.

Installing the OCI Utilities

The OCI utilities are automatically included with instances launched with an Oracle Linux image. They are not currently available on other distributions.

Much of the `oci-utils` functionality requires that you have the Oracle Cloud Infrastructure Python SDK and the Oracle Cloud Infrastructure CLI installed and configured.

You can install the Oracle Cloud Infrastructure CLI using `yum`:

```
yum install python-oci-cli
```

For configuration information, see the Oracle Cloud Infrastructure Python SDK documentation and the documentation for configuring the Oracle Cloud Infrastructure CLI.

Updating the OCI Utilities

To update to the latest version of the OCI Utilities:

```
$ sudo yum update oci-utils
```

Using the OCI Utilities

To use the OCI utilities, you first need to start the ocid service:

```
sudo systemctl start ocid.service
```

Example output:

```
Redirecting to /bin/systemctl start ocid.service
```

The ocid Daemon

DESCRIPTION

The `ocid` daemon is the service component of the `oci-utils`. It monitors for changes in the VNIC and iSCSI configuration of the instance and attempts to automatically attach or detach devices as they appear or disappear - for example, when they are created or deleted using the Oracle Cloud Infrastructure Console, the command line interface (CLI), or the API.

CONFIGURATION

The `ocid` daemon requires root privileges. You can configure root privileges for `ocid` using one of the following methods:

- Run the `oci setup config` configuration command as root to create SDK configuration files for the host. For more information, see SDK and Tool Configuration.
- Use instance principals by adding the instance to a dynamic group that was granted access to Oracle Cloud Infrastructure services. For more information, see Managing Dynamic Groups.
- Configure `oci-utils` to allow root to use a non-privileged user's Oracle Cloud Infrastructure configuration files. For more information, see the configuration file located in the `/etc/oci-utils.conf.d` directory of the instance.

USAGE

To start the `ocid` daemon using `systemd`:

```
service ocid start
```

To set `ocid` to start automatically during system boot:

```
sudo systemctl enable ocid.service
```

oci-growfs

DESCRIPTION

Expands the root filesystem of the instance to its configured size. This command must be run as root.

USAGE

```
oci-growfs [-y] [-n] [-h]
```

OPTIONS

-Y

Answer 'yes' to all prompts.

-N

Answer 'no' to all prompts.

-H | --HELP

Displays a summary of the command line options.

EXAMPLE

```
# sudo /usr/libexec/oci-growfs
CHANGE: disk=/dev/sda partition=3: start=17188864 old: size=80486399,end=97675263 new:
size=192526302,end=209715166
Confirm? [y/n]: y
CHANGED: disk=/dev/sda partition=3: start=17188864 old: size=80486399,end=97675263 new:

       meta-data=/dev/sda3              isize=256    agcount=4, agsize=2515200 blks
       =                       sectsz=4096  attr=2, projid32bit=1
       =                       crc=0        finobt=0 spinodes=0
       data     =                       bsize=4096   blocks=10060800, imaxpct=25
       =                       sunit=0      swidth=0 blks
       naming   =version 2              bsize=4096   ascii-ci=0 ftype=1
       log      =internal               bsize=4096   blocks=4912, version=2
       =                       sectsz=4096  sunit=1 blks, lazy-count=1
       realtime =none                   extsz=4096   blocks=0, rtextents=0
       data blocks changed from 10060800 to 24065787
```

oci-iscsi-config

DESCRIPTION

Lists and configures iSCSI devices attached to a Compute instance running in Oracle Cloud Infrastructure. When run without any command line options, `oci-iscsi-config` lists devices that need attention.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

USAGE

```
oci-iscsi-config [-i|--interactive] [-s|--show] [-a | --attach IQN ]
 [-d IQN | --detach IQN  ] [--username username] [--password password]
 [--help] oci-iscsi-config [-s|--show] [-c | --create-volume size]
 [--volume-name name] [--destroy-volume OCID ]
```

OPTIONS

-I | --INTERACTIVE

Run in interactive mode. This option displays devices that need attention and offers to attach and configure them. Requires root privileges.

-S | --SHOW

List all devices. If `ocid` is not running then root privileges are required.

-A | --ATTACH TARGET

Attempt to attach the device with the given IQN (a unique ID assigned to a device) or Oracle Cloud Identifier (OCID). When using an IQN, the volume must already be attached (assigned) to the instance in the Console. The Oracle Cloud Infrastructure Python SDK is required for selecting volumes using their OCID. This option can be used multiple times to attach multiple devices at the same time. Requires root privileges.

-D | --DETACH DEVICE

Detach the device with the given IQN (a unique ID assigned to a device). If the volume (or any partition of the volume) is mounted, this option will attempt to unmount it first. This option can be used multiple times to detach multiple devices at the same time. Requires root privileges.

-C | --CREATE-VOLUME SIZE

Create a new volume of SIZE gigabytes and attach it to the current instance. This option requires the Oracle Cloud Infrastructure Python SDK to be installed and configured.

--DESTROY-VOLUME OCID

Destroy the block storage volume with the given OCID. The volume must not be attached to any instances.

Warning

This action is irreversible.

--VOLUME-NAME NAME

Set the display name for the volume. This is used with the `--create-volume` option.

--USERNAME NAME

Use the specified user name as the CHAP user name when authentication is needed for attaching a device. Not needed when the Oracle Cloud Infrastructure Python SDK is available.

--PASSWORD PASSWORD

Use the supplied password as the CHAP password when authentication is needed for attaching a device. This is not needed when the Oracle Cloud Infrastructure Python SDK is available.

--HELP

Displays a summary of the command line options.

EXAMPLES

DISPLAYING ISCSI CONFIGURATION

The oci-iscsi-config utility works with the ocid daemon to monitor device creation and deletion through the command line, console, or SDK and automatically discover those changes. You can use the `--show` option to display a list of all of the devices attached to an instance:

```
# oci-iscsi-config -s
For full functionality of this utility the ocid service must be running
The administrator can start it using this command:
sudo systemctl start ocid.service
```

```
ocid already running.
Currently attached iSCSI devices:

Target iqn.2015-02.oracle.boot:uefi
Persistent portal:    169.254.0.2:3260
Current portal:    169.254.0.2:3260
State:    running
Attached device:    sda
Size:    46.6G
Partitions:    Device    Size  Filesystem   Mountpoint
sda1      544M        vfat   /boot/efi
sda2        8G        swap   [SWAP]
sda3       38G         xfs   /
```

The following example shows the output of the `--show` option after adding a 50GB block volume using the OCI console:

```
# oci-iscsi-config --show
Currently attached iSCSI devices:

Target iqn.2015-12.com.oracleiaas:abcdefghijklmnopqrstuvwxyz1234567890
Persistent portal:    169.254.2.2:3260
Current portal:    169.254.2.2:3260
State:    running
Attached device:    sdb
Size:    50G
File system type:    Unknown
Mountpoint:    Not mounted

Target iqn.2015-02.oracle.boot:uefi
Persistent portal:    169.254.0.2:3260
Current portal:    169.254.0.2:3260
State:    running
Attached device:    sda
Size:    46.6G
Partitions:    Device    Size  Filesystem   Mountpoint
sda1      544M        vfat   /boot/efi
sda2        8G        swap   [SWAP]
sda3       38G         xfs   /
```

CREATING A VOLUME

The following example shows how to create a volume:

```
# oci-iscsi-config --create-volume 50
For full functionality of this utility the ocid service must be running
The administrator can start it using this command:
sudo systemctl start ocid.service
Creating a new 50 GB volume
Volume abcdefghijklmnopqrstuvwxyz12345678901234567890123456789012345678901234 created
```

DELETING A VOLUME

The following example shows how to destroy a volume:

```
# oci-iscsi-config --destroy-volume
ocid1.volume.oc1.phx.abcdefghijklmnopqrstuvwxyz12345678901234567890123456789012345678901234
```

oci-metadata

DESCRIPTION

Displays metadata for an Oracle Cloud Infrastructure Compute instance.

Note

Instance Metadata

For more information about instance metadata, see Getting Instance Metadata.

USAGE

```
oci-metadata [-h] [-j] [-g key] [--help]
```

OPTIONS

-H | --HUMAN-READABLE

Display human readable output (default).

-J | --JSON

Display output in JSON.

-G | --GET KEY

Retrieve data only for the specified key.

--HELP

Displays a summary of the command line options.

EXAMPLES

GETTING ALL METADATA FOR THE INSTANCE

Running oci-metadata with no options returns all metadata for the instance:

```
# oci-metadata
Instance details:
  Display Name: my-example-instance
  Region: phx - us-phoenix-1 (Phoenix, AZ, USA)
  Canonical Region Name: us-phoenix-1
  Availability Domain: cumS:PHX-AD-1
  Fault domain: FAULT-DOMAIN-3
  OCID: ocid1.instance.oc1.phx.exampleuniqueID
  Compartment OCID: ocid.compartment.oc1..exampleuniqueID
  Instance shape: VM.Standard2.1
  Image ID: ocid1.image.oc1.phx.exampleuniqueID
  Created at: 1569529065596
  state: Running
  agentConfig:
    managementDisabled: False
    monitoringDisabled: False
  Instance Metadata:
    ssh_authorized_keys: ssh-rsa AAAAB3NzaC1yc2EAAAABJQAAAQEApzWsZ0DxxE+jNpsh5C3
    ncc18eZ06MCONWnP5D/8eqdGjUqqBU7lHvgaIqYHy1PH/B4w/pya56k41FLzdXFVAzCy4NGyE4XZjLcS
    SR4jW1As4r3WHY/f61Gc1Vicz39u+bB1XYaHm46zS4WrQEquqU4wbz70iwe50nSIhrGpvM5HWYOK0dsV
    A7/zzw+yW37NUGa/QeM4/bJvCVg3BVjB6VWdmV7dFwRMeCaVJFQH3wKndvuJib78zoHl9sbYm74vzqTY
    Si/bVoIz9YnZ4bA3MS0UqapoK/m2M9T27+UA/lz/ILCKXP3+vNcVcjRplanJT/qlzhLiIiBCRo4RsdGx
    UIw== rsa-key-20181129
Networking details:
  VNIC OCID: ocid1.vnic.oc1.phx.exampleuniqueID
  VLAN Tag: 2392
  Private IP address: 10.0.0.16
  MAC address: 02:00:17:03:D8:FE
```

```
  Subnet CIDR block: 10.0.0.0/24
  Virtual router IP address: 10.0.0.1
```

GETTING ONLY SPECIFIC METADATA

Pass in a key with the `--get` parameter to retrieve only the metadata for that key:

```
# oci-metadata --get state
Instance details:
Instance state: Running
```

oci-network-config

DESCRIPTION

Configures network interfaces for an Oracle Cloud Infrastructure Compute instance.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

USAGE

```
 oci-network-config [-h] [-s] [--create-vnic] [--detach-vnic VNIC] [--add-
private-ip]

 [--del-private-ip ip_address] [--private-ip ip_address] [--subnet subnet] [--
vnic-name name]

 [--assign-public-ip] [--vnic OCID] [-a] [-d] [-e ip_address] [-n format]

 [-r] [-X | --exclude item] [-I | --include item] [--quiet]
```

OPTIONS

-S | --SHOW

Show information on all provisioning and interface configuration. This is the default action if no options are given.

--CREATE-VNIC

Create a new virtual network interface card (VNIC) and attach it to this instance.

--DETACH-VNIC OCID

Detach and delete the VNIC with the given Oracle Cloud Identifier (OCID) or primary IP address. Cannot be the primary VNIC for the instance.

--ADD-PRIVATE-IP OCID

Add a secondary private IP to an existing VNIC.

--DEL-PRIVATE-IP IP_ADDRESS

Delete the secondary private IP address with the given IP address.

--PRIVATE-IP IP_ADDRESS

Assign the given private IP address to the VNIC. Used with the with the `--create-vnic` and `add-private-ip` options,

--SUBNET SUBNET

Used with the with the `--create-vnic` option. Connects the new VNIC to the specified subnet.

--VNIC-NAME NAME

Used with the with the `--create-vnic` option. Display name for the new VNIC.

--ASSIGN-PUBLIC-IP

When used with the `--create-vnic` option, assign a public IP address to the new VNIC.

--VNIC OCID

When used with the `--add-private-ip` option, assign the private IP address to the given VNIC

-A | --AUTO | -C | --CONFIGURE

Add IP configuration for VNICs that are not configured and delete IP configuration for VNICs that are no longer provisioned.

-D | --DECONFIGURE

Deconfigure all VNICs (except the primary). If used with the `-e` option, only the secondary IP addresses are deconfigured.

-E IP_ADDRESS VNIC_OCID

Secondary private IP address to configure or deconfigure. Used with `--configure` and `--deconfigure` options.

-N | -NS FORMAT

When configuring, place interfaces in namespace identified by the given format. Format can include `$nic` and `$vltag` variables.

-R | --SSHD

Start `sshd` in namespace (if `-n` is present).

-X | --EXCLUDE ITEM

Persistently exclude the given item from automatic configuration or deconfiguration. Use the `--include` option to include the item again.

-I | --INCLUDE ITEM

Include an item that was previously excluded using the *--exclude* option in automatic configuration/deconfiguration.

-Q | --QUIET

Do not display information messages.

-H | --HELP

Displays a summary of the command line options.

EXAMPLES

DISPLAYING CURRENT NETWORK CONFIGURATION

Running the oci-network-config command with no options returns the network configuration of the current instance:

```
VNIC configuration for instance my-test-instance-20180622-1222

VNIC 1 (primary): my-test-instance-20180622-1222
Hostname: my-test-instance-20180622-1222
OCID: ocid1.vnic.oc1.phx.abcdefg12345678
MAC address: 00:00:17:00:F4:3F
Public IP address: 129.146.110.62
Subnet: Public Subnet cumS:PHX-AD-1 (10.0.0.0/24)

Operating System level network configuration

CONFIG ADDR            SPREFIX         SBITS VIRTRT          NS         IND IFACE      VLTAG VLAN
STATE MAC               VNIC
-      10.0.0.3        10.0.0.0        24    10.0.0.1        -          0   ens3       -     -
UP    00:00:17:00:f4:3f ocid1.vnic.oc1.phx.abcdefg12345678
```

CREATING A NEW VNIC

This example creates a new VNIC named MY_NEW_VNIC and attaches it to the instance:

```
# sudo oci-network-config --create-vnic --vnic-name MY_NEW_VNIC
Info: creating VNIC: 10.0.0.4
```

Running oci-network-config with the `-s` option shows information for the new VNIC:

```
# sudo oci-network-config -s
VNIC configuration for instance scottb-instance-20180622-1222

VNIC 1 (primary): scottb-instance-20180622-1222
Hostname: scottb-instance-20180622-1222
OCID: ocid1.vnic.oc1.phx.abcdefg12345678
```

```
MAC address: 00:00:17:00:F4:3F
Public IP address: 129.146.110.62
Subnet: Public Subnet cumS:PHX-AD-1 (10.0.0.0/24)

VNIC 2: MY_NEW_VNIC
Hostname: scottb-instance-20180622-1222-mynewvnic
OCID: ocid1.vnic.oc1.phx.abcdefg12345678
MAC address: 00:00:17:00:27:A7
Public IP address: None
Subnet: Public Subnet cumS:PHX-AD-1 (10.0.0.0/24)

Operating System level network configuration

CONFIG ADDR            SPREFIX         SBITS VIRTRT          NS         IND IFACE      VLTAG VLAN
STATE MAC               VNIC
-      10.0.0.3        10.0.0.0        24    10.0.0.1        -          0   ens3       -     -
UP    00:00:17:00:f4:3f ocid1.vnic.oc1.phx.abcdefg12345678
-      10.0.0.4        10.0.0.0        24    10.0.0.1        -          1   ens4       -     -
UP    00:00:17:00:27:a7 ocid1.vnic.oc1.phx.abcdefg12345679
```

DETACHING A VNIC

To detach a VNIC from the instance, use the `--detach-VNIC` option. Note that the given VNIC cannot be the primary VNIC for the instance:

```
sudo oci-network-config --detach-vnic 00:00:17:00:27:A7
```

oci-network-inspector

DESCRIPTION

Displays a detailed report for a given compartment or network.

USAGE

```
oci-network-inspector [-C OCID] [-N OCID] [--help]
```

OPTIONS

-C | --COMPARTMENTOCID

Show report for the specified compartment.

-N | --VCN OCID

Show report for the specified virtual cloud network.

-H | --HELP

Displays a summary of the command line options.

EXAMPLES

DISPLAYING A DETAILED REPORT FOR A SPECIFIED COMPARTMENT

Running the `oci-network-inspector` command and specifying an OCID with the `-C` parameter returns a detailed network report for that compartment:

```
$ oci-network-inspector -C ocid1.compartment.oc1..aaaaaaaabcdefghijklmnopqrstuvwxyz12345678

Compartment: scottb_sandbox (ocid1.compartment.oc1..aaaaaaaabcdefghijklmnopqrstuvwxyz12345678)

  vcn: scottb_vcn
    Security List: Default Security List for scottb_vcn
      Ingress: tcp              0.0.0.0/0:-                       ---:22
      Ingress: icmp             0.0.0.0/0:-                   code-4:type-3

```

oci-public-ip

DESCRIPTION

Displays the public IP address of the current system in either human-readable or JSON format.

If the Oracle Cloud Infrastructure SDK is installed, the `oci-public-ip` utility uses the Oracle Cloud Infrastructure API to discover the IP address.

If the Oracle Cloud Infrastructure SDK is not installed, the `oci-public-ip` utility uses the STUN (Session Traversal Utilities for NAT) protocol to discover IP address. For more information on STUN, see the STUN Wikipedia article.

USAGE

```
oci-public-ip [-h] [-j] [-g] [-s source_IP] [-S STUN_server]
[-L] [--instance-id OCID] [--help]
```

OPTIONS

-H | --HUMAN-READABLE

Display human readable output (default).

-J | --JSON

Display output in JSON.

-G | GET

Print the IP address only.

-S | --SOURCEIP SOURCE_IP

Specify the source IP address to use.

-S | --STUN-SERVER STUN_SERVER

Specify the STUN server to use.

-L | --LIST-SERVERS

Print a list of known STUN servers and exit.

--INSTANCE-ID OCID

Display the public IP address of the given instance instead of the current one. Requires the Oracle Cloud Infrastructure Python SDK to be installed and configured.

--HELP

Displays a summary of the command line options.

EXAMPLES

DISPLAYING CURRENT IP ADDRESS

Running the `oci-public-ip` command with no options returns the IP address of the current instance:

```
                # oci-public-ip
        Public IP address: 128.0.0.1
```

DISPLAYING THE IP ADDRESS OF ANOTHER INSTANCE

You can pass in the OCID of a running instance with the *--instance-id* option to return the IP address for that instance:

```
                # oci-public-ip --instance-id ocid1.instance.oc1.phx.abcdefg12345678
        Public IP address: 128.0.0.4
```

LISTING STUN SERVERS

Use the `--list-servers` option to return a list of STUN servers:

```
                # oci-public-ip --list-servers
                stun.stunprotocol.org
                stun.counterpath.net
                stun.voxgratia.org
                stun.callwithus.com
                stun.ekiga.net
                stun.ideasip.com
                stun.voipbuster.com
                stun.voiparound.com
        stun.voipstunt.com
```

Compute Shapes

A shape is a template that determines the number of CPUs, amount of memory, and other resources allocated to a newly created instance. The following tables provide basic

information about the shapes that are available for bare metal machines, virtual machines (VMs), and dedicated virtual machine hosts.

Note

AMD shapes, X5-based and X6-based shapes, and high performance computing (HPC) shapes are not available in Government Cloud realms.

Bare Metal Shapes

Shape	Instance Type	OCPU	Memory (GB)	Local Disk	Network Bandwidth[1]	Max VNICs Total: Linux	Max VNICS Total: Windows
BM.Standard1.36[2]	X5-based standard compute	36	256	Block storage only	10 Gbps	36	1
BM.Standard.B1.44	X6-based standard compute	44	512	Block storage only	25 Gbps	44	None
BM.Standard2.52	X7-based standard compute: Intel CPUs	52	768	Block storage only	2 x 25 Gbps	52 total (26 per physical NIC)	27 total (1 on the first physical NIC, 26 on the second)

Shape	Instance Type	OCPU	Memory (GB)	Local Disk	Network Bandwidth[1]	Max VNICs Total: Linux	Max VNICS Total: Windows
BM.Standard.E2.64	E2-based standard compute: AMD CPUs	64	512	Block storage only	2 x 25 Gbps	75	76 (1 on the first physical NIC, 75 on the second)
BM.DenseIO1.36[2]	X5-based dense I/O compute	36	512	28.8 TB NVMe SSD (9 drives)	10 Gbps	36	1
BM.DenseIO2.52	X7-based dense I/O compute	52	768	51.2 TB NVMe SSD (8 drives)	2 x 25 Gbps	52 total (26 per physical NIC)	27 total (1 on the first physical NIC, 26 on the second)

Shape	Instance Type	OCPU	Memory (GB)	Local Disk	Network Bandwidth[1]	Max VNICs Total: Linux	Max VNICS Total: Windows
BM.GPU2.2	X7-based GPU compute: 2xP100 NVIDIA GPUs	28	192	Block storage only	2 x 25 Gbps	28	15 (1 on the first physical NIC, 14 on the second)
BM.GPU3.8	X7-based GPU compute: 8xV100 NVIDIA GPUs	52	768	Block storage only	2 x 25 Gbps	52	27 (1 on the first physical NIC, 26 on the second)
BM.HPC2.36	X7-based high frequency compute	36	384	6.7 TB NVMe SSD (1 drive)	1 x 25 Gbps 1 x 100 Gbps RDMA	50	1

1: Network bandwidth is based on expected bandwidth for traffic within a VCN.

2: X5-based shapes availability is limited to monthly universal credit customers existing on or before November 9, 2018, in the US West (Phoenix), US East (Ashburn), and Germany Central (Frankfurt) regions.

VM Shapes

Shape	OCPU	Memory (GB)	Local Disk (TB)	Network Bandwidth [1]	Max VNICs Total: Linux	Max VNICs Total: Windows
VM.Standard1.1[2]	1	7	Block Storage only	Up to 600 Mbps	2	1
VM.Standard1.2[2]	2	14	Block Storage only	Up to 1.2 Gbps	2	1
VM.Standard1.4[2]	4	28	Block Storage only	1.2 Gbps	4	1
VM.Standard1.8[2]	8	56	Block Storage only	2.4 Gbps	8	1
VM.Standard1.16[2]	16	112	Block Storage only	4.8 Gbps	16	1
VM.Standard2.1	1	15	Block Storage only	1 Gbps	2	2
VM.Standard2.2	2	30	Block Storage only	2 Gbps	2	2

Shape	OCPU	Memory (GB)	Local Disk (TB)	Network Bandwidth [1]	Max VNICs Total: Linux	Max VNICs Total: Windows
VM.Standard2.4	4	60	Block Storage only	4.1 Gbps	4	4
VM.Standard2.8	8	120	Block Storage only	8.2 Gbps	8	8
VM.Standard2.16	16	240	Block Storage only	16.4 Gbps	16	16
VM.Standard2.24	24	320	Block Storage only	24.6 Gbps	24	24
VM.Standard.E2.1.Micro	1	1	Block Storage only	480 Mbps	1	-
VM.Standard.E2.1	1	8	Block Storage only	700 Mbps	2	2
VM.Standard.E2.2	2	16	Block Storage only	1.4 Gbps	2	2
VM.Standard.E2.4	4	32	Block Storage only	2.8 Gbps	4	4

Shape	OCPU	Memory (GB)	Local Disk (TB)	Network Bandwidth [1]	Max VNICs Total: Linux	Max VNICs Total: Windows
VM.Standard.E2.8	8	64	Block Storage only	5.6 Gbps	4	4
VM.DenseIO1.4[2]	4	60	3.2 TB NVMe SSD	1.2 Gbps	4	1
VM.DenseIO1.8[2]	8	120	6.4 TB NVMe SSD	2.4 Gbps	8	1
VM.DenseIO1.16[2]	16	240	12.8 TB NVMe SSD	4.8 Gbps	16	1
VM.DenseIO2.8	8	120	6.4 TB NVMe SSD	8.2 Gbps	8	8
VM.DenseIO2.16	16	240	12.8 TB NVMe SSD	16.4 Gbps	16	16
VM.DenseIO2.24	24	320	25.6 TB NVMe SSD	24.6 Gbps	24	24
VM.GPU2.1 (GPU: 1xP100)	12	72	Block Storage only	8 Gbps	12	12

Shape	OCPU	Memory (GB)	Local Disk (TB)	Network Bandwidth [1]	Max VNICs Total: Linux	Max VNICs Total: Windows
VM.GPU3.1 (GPU: 1xV100)	6	90	Block Storage only	4 Gbps	6	6
VM.GPU3.2 (GPU: 2xV100)	12	180	Block Storage only	8 Gbps	12	12
VM.GPU3.4 (GPU: 4xV100)	24	360	Block Storage only	24.6 Gbps	24	24
1: Network bandwidth is based on expected bandwidth for traffic within a VCN. 2: X5-based shapes availability is limited to monthly universal credit customers existing on or before November 9, 2018, in the US West (Phoenix), US East (Ashburn), and Germany Central (Frankfurt) regions.						

Dedicated Virtual Machine Host Shapes

Shape	Instance Type	Billed OCPU	Usable OCPU[1]	Supported Shapes for Hosted VMs
DVH.Standard2.52	X7-based VM host	52	48	VM.Standard2
1: The difference between billed OCPUs and usable OCPUs is due to OCPUs reserved for hypervisor use.				

Installing and Running Oracle Ksplice

Oracle Ksplice enables you to apply important security and other critical kernel updates without a reboot. For more information, see About Oracle Ksplice and Ksplice Overview.

This topic describes how to install and configure Ksplice. Ksplice is only available for Oracle Linux instances launched on or after February 15, 2017. It is installed on instances launched on or after August 25, 2017, so you just need to run it on these instances to install the available Ksplice patches. For instances launched prior to August 25, 2017, you must install it prior to running it.

Installing Ksplice on instances launched prior to August 25 2017

To install Ksplice you need to connect to your Linux instance by using a Secure Shell (SSH). See Connecting to an Instance for more information.

1. Use the following SSH command to access the instance.

   ```
   ssh -l opc@<public-ip-address>
   ```

   <public-ip-address> is your instance IP address that you retrieved from the Console, see Getting the Instance Public IP Address.

2. Run the following SSH commands to sudo to the root:

   ```
   sudo bash
   ```

3. Download the Ksplice installation script with the following SSH command:

   ```
   wget -N https://www.ksplice.com/uptrack/install-uptrack-oc
   ```

4. Once the script is downloaded, use the following SSH command to install Ksplice:

   ```
   sh install-uptrack-oc
   ```

Running Ksplice

To run Ksplice you need to connect to your Linux instance by using a Secure Shell (SSH). See Connecting to an Instance for more information.

1. Use the following SSH command to access the instance.

   ```
   ssh -l opc <public-ip-address>
   ```

   <public-ip-address> is your instance IP address that you retrieved from the Console, see Getting the Instance Public IP Address.

2. Run the following SSH commands to sudo to the root:

   ```
   sudo bash
   cd
   ```

3. To install available Ksplice patches, run the following SSH command:

   ```
   uptrack-upgrade
   ```

Automatic Updates

You can configure automatic updates by setting the value of `autoinstall` to `yes` in `/etc/uptrack/uptrack.conf`.

Note

OS Security Updates for Oracle Linux images

Oracle Linux images are updated regularly with the necessary patches, but after you launch an instance using these images, you are responsible for applying the required OS security updates published through the Oracle public Yum server. For more information, see Installing and Using the Yum Security Plugin.

Managing Custom Images

Oracle Cloud Infrastructure uses images to launch instances. You specify an image to use when you launch an instance.

You can create a custom image of a bare metal instance's boot disk and use it to launch other instances. Instances you launch from your image include the customizations, configuration, and software installed when you created the image.

For details on Windows images, see Creating Windows Custom Images.

Custom images do not include the data from any attached block volumes. For information about backing up volumes, see Backing Up a Volume.

Tip

Oracle Cloud Infrastructure runs on Oracle's high-quality Sun servers. However, any hardware can experience a failure. Follow industry-wide hardware failure best practices to ensure the resilience of your solution. Some best practices include:

- Design your system with redundant compute nodes in different availability domains to support failover capability.
- Create a custom image of your system drive each time you change the image.
- Back up your data drives, or sync to spare drives, regularly.

If you experience a hardware failure and have followed these practices, you can terminate the failed instance, launch your custom image to create a new instance, and then apply the backup data.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don't have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: The policy in Let users launch Compute instances includes the ability to create and manage images. If the specified group doesn't need to launch instances or attach volumes, you could simplify that policy to include only `manage instance-family`, and remove the statements involving `volume-family` and `virtual-network-family`.

Tip

When users create a custom image from an instance or launch an instance from a custom image, the instance and image don't have to be in the same compartment. However, users must have access to both compartments.

If you're new to policies, see Getting Started with Policies and Common Policies. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services.

Limitations and Considerations

- Certain IP addresses are reserved for Oracle Cloud Infrastructure use and may not be used in your address numbering scheme. See IP Addresses Reserved for Use by Oracle for more information.
- Before you create a custom image of an instance, you must disconnect all iSCSI attachments and remove all iscsid node configurations from the instance. For steps, see Disconnecting From a Volume.
- When you create an image of a running instance, the instance shuts down and remains unavailable for several minutes. The instance restarts when the process completes.
- You cannot create additional custom images of an instance while the instance is engaged in the image creation process. When you start to create a custom image, the system implements a 20-minute timeout, during which you cannot create another image of the same instance. You can, however, create images of different instances at the same time.
- Custom images are available to all users authorized for the compartment in which the image was created.
- Custom images inherit the compatible shapes that are set by default from the base image.
- The maximum size for importing a custom image is 400 GB.
- The maximum size for custom exported images is 400 GB.
- You can create a maximum of 25 custom images per region per root compartment.
- You cannot create an image of an Oracle Database instance.
- If you use a custom image and update the OS kernel on your instance, you must also upload the update to the network drive. See OS Kernel Updates for more information.
- Editing custom Windows images is not supported due to hardware differences between shapes.

For information about how to deploy any version of any operating system that is supported by the Oracle Cloud Infrastructure hardware, see Bring Your Own Image (BYOI).

X5 and X7 Compatibility for Custom Images

Oracle X5, X6, and X7 servers have different host hardware. As a result, using an X5 or X6 image on an X7 bare metal or virtual machine (VM) instance may not work without additional modifications. Oracle Cloud Infrastructure recommends for X7 hosts that you use the Oracle-provided images for X7. See Oracle-Provided Image Release Notes for more information about which images support X7. These images have been explicitly created and tested with X7 hardware.

If you attempt to use an existing X5 image on X7 hardware, note the following:

- CentOS 6 and all Windows versions are not cross-compatible.
- Oracle Linux, Ubuntu 16.04, and CentOS 7 are cross-compatible. However, you must update the kernel to the most recent version to install the latest device drivers. To do this, run the following commands from a terminal session:
  - **Oracle Linux**

    ```
    yum update
    ```

  - **CentOS 7**

    ```
    yum update
    ```

  - **Ubuntu 16.04**

    ```
    apt-get update
    apt-get dist-upgrade
    ```

If you attempt to use an X6 image on non-X6 hardware, note the following:

- Oracle Linux 6, all CentOS versions, and all Windows versions are not cross-compatible.
- Oracle Linux 7, Ubuntu 18.04, and Ubuntu 16.04 are cross-compatible. Use the Oracle-provided images for X6.

The primary device drivers that are different between X5, X6, and X7 hosts are:

- Network device drivers
- NVMe drive device drivers

- GPU device drivers

Additional updates may be required depending on how you have customized the image.

Using the Console

To access the Console, you must use a supported browser.

To create a custom image

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
2. Find the instance you want to use as the basis for an image.
3. Click the Actions icon (three dots), and then click **Create Custom Image**.
4. Enter a name for the image, and then click **Create Custom Image**. You can use the API to change the name later, if needed. You cannot use an Oracle-provided image name as a custom image name.
   To track the progress of the operation, you can monitor the associated work request. For more information, see Using the Console to View Work Requests.

Note

Limits

If you see a message indicating that you are at the limit for custom images, you must delete at least one image before you can create another. Or, you can request a service limit increase.

To launch an instance from a custom image

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Custom Images**. Find the custom image you want to use.
2. Click the Actions icon (three dots), and then click **Create Instance**.
3. Provide additional launch options as described in Creating an Instance.

To edit the name or shape of a custom image

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Custom Images**.
2. Click the custom image you're interested in.
3. Click **Edit Details**
4. Edit the name, or add and remove compatible shapes for the custom image.
5. Click **Save**.

To manage tags for a custom image

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Custom Images**.
2. Click the custom image you're interested in.
3. Click the **Tags** tab to view or edit the existing tags. Or click **Apply tag(s)** to add new ones.

For more information, see Resource Tags.

To delete a custom image

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Custom Images**.

2. Find the custom image you want to delete.
3. Click the Actions icon (three dots), and then click **Delete**.
4. Confirm when prompted.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the following operations to manage custom images:

- DeleteImage
- GetImage
- ListImages
- CreateImage
- UpdateImage

Creating Windows Custom Images

You can create a Windows custom image of a bare metal or VM instance's boot disk and use it to launch other instances. Instances you launch from your image include the customizations, configuration, and software installed when you created the image. For information about custom images, see Managing Custom Images. For information about the licensing requirements for Windows images, see Microsoft Licensing on Oracle Cloud Infrastructure.

Windows supports two kinds of images: generalized and specialized. Generalized images are images that have been cleaned of instance-specific information. Specialized images are point-in-time snapshots of the boot disk of a running instance, and are useful for creating backups of an instance. Oracle Cloud Infrastructure supports bare metal and VM instances launched from both generalized and specialized custom Windows images.

Generalized images

A generalized image has a generalized OS disk, cleaned of computer-specific information. The images are generalized using Sysprep. Generalized images can be useful in scenarios such as quickly scaling an environment. Generalized images can be configured to preserve the existing `opc` user's account, including the password, at the time the image is created, or configured to recreate the `opc` user account, including generating a new, random password that you retrieve using the API. For background information, see Sysprep (Generalize) a Windows installation.

Specialized images

A specialized image has an OS disk that is already fully installed, and is essentially a copy of the original bare metal or VM instance. Specialized images are intended to be used for backups so that you can recover from a failure. Specialized images are useful when you are testing a task and may need to roll back to known good configuration. Specialized images are not recommended for cloning multiple identical bare metal instances or VMs in the same network because of issues with multiple computers having the same computer name and ID. When creating a specialized image, you must remember the `opc` user's password; a new password is not generated when the instance launches, and it cannot be retrieved from the console or API.

Creating a Generalized Image

Warning

Creating a generalized image from an instance will render the instance non-functional, so you should first create a custom image from the instance, and then launch a new instance from the custom image. Steps 1 - 2 describe how to do this. This is the instance that you'll generalize. Alternatively, you can make a backup image of the instance that you can use to launch a replacement instance if needed.

Warning

If you upgrade to PowerShell 5.0/WMF 5.0, you may encounter an issue where **Sysprep** fails which will prevent the image generalization process from completing. If this occurs, you may not be able to log into instances launched from the custom image. See Unable to log into instance launched from new Windows custom image for more information and how to work around the issue.

1. Create the new image using To create a custom image.
2. Launch an instance from the new image using To launch an instance from a custom image.
3. Connect to the instance using a Remote Desktop client.
4. Go to Windows Generalized Image Support Files and download to the instance the file matching the Windows version for the instance.
5. Right-click the file, and then click **Run as administrator**.
6. Extract the files to **C:\Windows\Panther**. The following files are extracted into the Panther folder for all Windows Server versions:
   - Generalize.cmd
   - Specialize.cmd
   - unattend.xml
   - Post-Generalize.ps1

   For Windows Server 2008, the following file is also extracted into the Panther folder:
   - Windows2008-SnapshotUtilities.ps1
7. Optional: If you want to preserve the `opc` user account, edit `C:\Program Files\bmcs\imageType.json` and change the `imageType`setting to `custom`. A new password is not created and the password is not retrievable from the console or API.

If you want to configure the generalized image to recreate the `opc` user account when a new instance is launched from the image, leave the `imageType` setting defaulted to `general`. The new account's password can be retrieved through the API using `GetWindowsInstanceInitialCredentials`.

8. Right-click **Generalize.cmd**, and then click **Run as administrator**. Keep in mind the following outcomes of running this command:
   - Your connection to the Remote Desktop client may immediately be turned off and you will be logged out of the instance. If this does not occur, you should log out of the instance yourself.
   - Because `sysprep generalize` turns off Remote Desktop, you won't be able to log in to the instance again.
   - Creating a generalized image essentially destroys the instance's functionality.

   You should wait for a few minutes before proceeding to the following step to ensure the generalization process has completed.
9. Create the new image using To create a custom image.
10. After you create an image from an instance that has been generalized, we recommend that you terminate the instance. Although it may appear to be running, it won't be fully operable.

Creating a Specialized Image

Important

When creating a specialized image, you must remember the `opc` user's password. It cannot be retrieved from the Console or API.

You create a specialized image the same way you create other custom images. For step-by-step instructions, see Managing Custom Images.

Image Import/Export

Oracle Cloud Infrastructure Compute enables you to share custom images across tenancies and regions using image import/export.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Linux-Based Operating Systems

The following Oracle Cloud Infrastructure operating systems support image import/export:

- Oracle Linux 6, Oracle Linux 7
- CentOS 6, CentOS 7
- Ubuntu 16.04

For more information about these images, see Oracle-Provided Images.

Windows-Based Operating Systems

The following Windows versions support image import/export:

- Windows Server 2008 R2* Standard, Enterprise, Datacenter
- Windows Server 2012 Standard, Datacenter
- Windows Server 2012 R2 Standard, Datacenter
- Windows Server 2016 Standard, Datacenter
- Windows Server 2019 Standard, Datacenter

* Windows Server 2008 R2 reaches end of support on January 14, 2020.

For information about the licensing requirements for Windows images, see Microsoft Licensing on Oracle Cloud Infrastructure.

Verify Your Windows Operating System

When importing custom Windows images, ensure that the version you select matches the Windows image that you imported. Failure to provide the correct version and SKU information could be a violation of your Microsoft Licensing Agreement.

WINDOWS SYSTEM TIME ISSUE ON CUSTOM WINDOWS INSTANCES

If you change the time zone from the default setting on Windows VM instances, when the instance reboots or syncs with the hardware clock, the system time will revert back to the time for the default time zone. However, the time zone setting will stay set to the new time zone, so the system clock will be incorrect. You can fix this by setting the `HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\TimeZoneInformation` registry key to 1.

Oracle-provided Windows images already have the `RealTimeIsUniversal` registry key set by default, but you must set this for any custom Windows images that you import.

To fix this issue for custom Windows images:

1. Open the Windows Registry Editor and navigate to the `HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\TimeZoneInformation` registry key.
2. Create a new `DWORD` key named `RealTimeIsUniversal` and set the value to 1.
3. Reboot the instance.
4. Reset the time and time zone manually.

Bring Your Own Image Scenarios

You can also use image import/export to share custom images from Bring Your Own Image (BYOI) scenarios across tenancies and regions, so you don't need to recreate the image manually in each region. You must go through the steps required to manually create the image in one of the regions, but after this is done, you can export the image, making it available for import in additional tenants and regions. The exported image format is `.oci`,

which is a TAR file that contains a QCOW2 file and Oracle Cloud Infrastructure-specific metadata.

Best practices for replicating an image across regions

You can replicate an image from one region to another region using the Console or API. At a high level:

1. Export the image to an Object Storage bucket in the same region as the image. For steps, see Exporting an Image.
2. Copy the image to an Object Storage bucket in the destination region. For steps, see Copying Objects.
3. Obtain the URL path to the image object. For steps, see To view object details.
4. In the destination region, import the image. Use the URL path as the Object Storage URL. For steps, see Importing an Image.

Best practices for sharing an image across tenancies

You can replicate an image from one tenancy to another tenancy using the Console or API. At a high level:

1. Export the image to an Object Storage bucket in the same region as the image. For steps, see Exporting an Image.
2. Create a pre-authenticated request with read-only access for the image in the destination region. For steps, see Working with Pre-Authenticated Requests.
3. In the destination tenancy, import the image. Use the pre-authenticated request URL as the Object Storage URL. For steps, see Importing an Image.

Object Storage Service URLs

When you import or export custom images using the Console, you might need to specify the Object Storage URL pointing to the location that you want to import the image from or export the image to. Object Storage URLs are structured as follows:

```
https://<host_name>/n/<namespace_name>/b/<bucket_name>/o/<object_name>
```

For example:

```
https://objectstorage.us-phoenix-1.oraclecloud.com/n/MyNamespace/b/MyBucket/o/MyCustomImage.qcow2
```

Pre-Authenticated Requests

When using import/export across tenancies, you need to use an Object Storage pre-authenticated request. See Working with Pre-Authenticated Requests for steps to create a pre-authenticated request. When you go through these steps, after you click **Create Pre-Authenticated Request**, the **Pre-Authenticated Request Details** dialog box opens. You must make a copy of the pre-authenticated request URL displayed here, because this is the only time this URL is displayed. This is the Object Storage URL that you specify for import/export.

Note

Pre-authenticated requests for a bucket

With image export, if you create the pre-authenticated request for a bucket, you need to append the object name to the generated URL. For example:

```
/o/MyCustomImage.qcow2
```

Exporting an Image

You can use the Console or API to export images, and the exported images are stored in the Oracle Cloud Infrastructure Object Storage service. To perform an image export, you need write access to the Object Storage bucket for the image. For more information, see Overview of Object Storage and Let users write objects to Object Storage buckets.

To export an image using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Custom Images**.
2. Find the custom image you want to export, click the Actions icon (three dots), and then click **Export Custom Image**.
3. In the **Export Image** dialog box, specify the Object Storage location to export the image to. You have two options here: You can select a compartment and bucket, and then enter a name for the exported image, or you can enter the Object Storage URL.
4. Click **Export Image**.

After you click **Export Image**, the image status changes to **EXPORTING**. You can still launch instances while the image is exporting, but you can't delete the image until the export has finished. To track the progress of the operation, you can monitor the associated work request. For more information, see Using the Console to View Work Requests.

When the export is complete, the image status changes to **AVAILABLE**. If the image status changes to **AVAILABLE**, but you don't see the exported image in the Object Storage location you specified, this means that the export failed, and you will need to go through the steps again to export the image.

Importing an Image

You can use the Console or API to import exported images from Object Storage. To import an image, you need read access to the Object Storage object containing the image. For more information, see Let users download objects from Object Storage buckets.

To import an image using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Custom Images**.
2. Click **Import Image**.
3. Select the compartment that you want to import the image to.

4. Enter a name for the image.
5. Select the **Operating System**:
    - For Linux images, select **Linux**.
    - For Windows images, select **Windows**. Select the **Operating System Version**, and then certify that the selected operating system complies with Microsoft licensing agreements.
6. Specify the **Object Storage URL** where the image is stored. When importing across tenancies, you must specify a pre-authenticated request URL.
7. Select the **Image Type**.
8. Select the **Launch Mode**:
    - For custom images where the image format is `.oci`, Oracle Cloud Infrastructure selects the applicable launch mode based on the launch mode for the source image.
    - For custom images exported from Oracle Cloud Infrastructure where the image type is QCOW2, select **Native Mode**.
    - To import other custom images select **Paravirtualized Mode** or **Emulated Mode**. For more information, see Bring Your Own Image (BYOI).
9. **Tags:** Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.
10. Click **Import Image**.

After you click **Import Image**, you'll see the imported image in the **Custom Images** list for the compartment, with a status of **IMPORTING**. To track the progress of the operation, you can monitor the associated work request. For more information, see Using the Console to View Work Requests.

When the import completes successfully, the status changes to **AVAILABLE**. If the status does not change, or no entry appears in the **Custom Images** list, the import failed. If the

import failed, ensure you have read access to the Object Storage object, and that the object contains a supported image.

Editing Image Details

You can edit the details of custom images, such as the image name and compatible shapes for the image. For more information, see To edit the name or shape of a custom image in Managing Custom Images.

Managing Tags for an Image

You can apply tags to your resources, such as images, to help you organize them according to your business needs. You can apply tags at the time you import an image, or you can update the image later with the desired tags.

To manage tags for an image

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Custom Images**.
2. Click the image you're interested in.
3. Click the **Tags** tab to view or edit the existing tags. Or click **Apply tag(s)** to add new ones.

For more information, see Resource Tags.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the following API operations for custom image import/export:

- ExportImage: Exports a custom image to Object Storage.
- CreateImage: To import an exported image, specify ImageSourceDetails in the request body.
- AddImageShapeCompatibilityEntry: Adds a shape to the compatible shapes list for the image.
- RemoveImageShapeCompatibilityEntry: Removes a shape from the compatible shapes list for the image.

X5 and X7 Compatibility for Image Import/Export

Oracle X5, X6, and X7 servers have different host hardware. As a result, using an X5 or X6 image on an X7 bare metal or virtual machine (VM) instance may not work without additional modifications. Oracle Cloud Infrastructure recommends for X7 hosts that you use the Oracle-provided images for X7. See Oracle-Provided Image Release Notes for more information about which images support X7. These images have been explicitly created and tested with X7 hardware.

If you attempt to use an existing X5 image on X7 hardware, note the following:

- CentOS 6 and all Windows versions are not cross-compatible.
- Oracle Linux, Ubuntu 16.04, and CentOS 7 are cross-compatible. However, you must update the kernel to the most recent version to install the latest device drivers. To do this, run the following commands from a terminal session:
  - **Oracle Linux**

    ```
    yum update
    ```

  - **CentOS 7**

    ```
    yum update
    ```

  - **Ubuntu 16.04**

    ```
    apt-get update
    apt-get dist-upgrade
    ```

If you attempt to use an X6 image on non-X6 hardware, note the following:

- Oracle Linux 6, all CentOS versions, and all Windows versions are not cross-compatible.
- Oracle Linux 7, Ubuntu 18.04, and Ubuntu 16.04 are cross-compatible. Use the Oracle-provided images for X6.

The primary device drivers that are different between X5, X6, and X7 hosts are:

- Network device drivers
- NVMe drive device drivers
- GPU device drivers

Additional updates may be required depending on how you have customized the image.

Bring Your Own Image (BYOI)

The Bring Your Own Image (BYOI) feature enables you to bring your own versions of operating systems to the cloud as long as the underlying hardware supports it. The services do not depend on the OS you run.

The BYOI feature:

- Enables lift-and-shift cloud migration projects.
- Supports both old and new operating systems.
- Encourages experimentation.
- Increases infrastructure flexibility.

Note

Licensing Requirements

You must comply with all licensing requirements when you upload and start instances based on OS images that you supply.

Bringing Your Own Image

A critical part of any lift-and-shift cloud migration project is the migration of on-premises virtual machines (VMs) to the cloud. You can import your on-premises virtualized root volumes to Oracle Cloud Infrastructure using the custom image import feature, and then launch Compute instances using those images.

You can import Windows and Linux-based custom images.

- **Windows images**
  These Windows versions support custom image import:
  - Windows Server 2008 R2* Standard, Enterprise, Datacenter
  - Windows Server 2012 Standard, Datacenter
  - Windows Server 2012 R2 Standard, Datacenter
  - Windows Server 2016 Standard, Datacenter
  - Windows Server 2019 Standard, Datacenter

  * Windows Server 2008 R2 reaches end of support on January 14, 2020.
  For steps to import a Windows image, see Importing Custom Windows Images.
  For information about the licensing requirements for Windows images, see Microsoft Licensing on Oracle Cloud Infrastructure.
- **Linux images**
  These Linux distributions support custom image import:

Linux Distribution	Supported Versions	Preferred Launch Mode
RHEL	7 or later	Paravirtualized
	4.5, 5.5, 5.6, 5.9, 5.11, 6.5, 6.9	Emulated
CentOS	7 or later	Paravirtualized
	4.0, 4.8, 5.11, 6.9	Emulated

Linux Distribution	Supported Versions	Preferred Launch Mode
Oracle Linux	7 or later	Paravirtualized
	4.5, 4.8, 5.8, 5.11, 6.2, 6.5	Emulated
Ubuntu	13.04 or later	Paravirtualized
	12.04	Emulated
FreeBSD	12 or later	Paravirtualized
	8, 9, 10, 11	Emulated
Debian	8 or later	Paravirtualized
	5.0.10, 6.0, 7	Emulated
SUSE	12.2 or later	Paravirtualized
	11, 12.1	Emulated

You might also have success importing other distributions of Linux.
For steps to import a Linux-based image, see Importing Custom Linux Images.

Bringing Your Own Hypervisor

- **Bring your own KVM:** You can bring your own operating system images or older operating systems such as Ubuntu 6.x, RHEL 3.x, CentOS 5.4 using KVM on bare metal instances. For more information, see Getting Started: Oracle Linux KVM Image for Oracle Cloud Infrastructure and Installing and Configuring KVM on Bare Metal Instances with Multi-VNIC.
- **Bring your own Hyper-V:** You can bring your own operating system images or older operating systems such as Windows Server 2003, Windows Server 2008, and older Linux -based operating systems using Hyper-V on bare metal instances. For a full list of supported Hyper-V guests, see Supported Windows guest operating systems for Hyper-

V on Windows Server and Supported Linux and FreeBSD virtual machines for Hyper-V on Windows. See Deploying Hyper-V on Oracle Cloud Infrastructure for more information.

Importing Custom Windows Images

The Compute service enables you to import Windows images that were created outside of Oracle Cloud Infrastructure. For example, you can import images running on your on-premises physical or virtual machines (VMs), or VMs running in Oracle Cloud Infrastructure Classic. You can then launch your imported images on Compute virtual machines.

Note

Imported images are not supported on AMD shapes.

For information about the licensing requirements for Windows images, see Microsoft Licensing on Oracle Cloud Infrastructure.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Supported Operating Systems

These Windows versions support custom image import:

- Windows Server 2008 R2* Standard, Enterprise, Datacenter
- Windows Server 2012 Standard, Datacenter
- Windows Server 2012 R2 Standard, Datacenter

- Windows Server 2016 Standard, Datacenter
- Windows Server 2019 Standard, Datacenter

* Windows Server 2008 R2 reaches end of support on January 14, 2020.

Note

- Oracle Cloud Infrastructure has tested the operating systems listed previously and will support customers in ensuring that instances launched from these images and built according to the guidelines in this topic are accessible using RDP.
- For OS editions not listed previously, Oracle Cloud Infrastructure will provide commercially reasonable support to customers in an effort to get instances that are launched from these images accessible via RDP.
- Support from Oracle Cloud Infrastructure in launching an instance from a custom OS does not ensure that the operating system vendor also supports the instance.
- Oracle Cloud Infrastructure licenses and charges the Windows licensing fee for all instances launched using an imported Windows OS image. This applies whether or not those instances are registered with Oracle Cloud Infrastructure's Microsoft Key Management service.

Windows Source Image Requirements

Custom images must meet the following requirements:

- The maximum image size is 400 GB.
- The image must be set up for BIOS boot.

- Only one disk is supported, and it must be the boot drive with a valid master boot record (MBR) and boot loader. You can migrate additional data volumes after you import the image's boot volume.
- The boot process must not require additional data volumes to be present for a successful boot.
- The disk image cannot be encrypted.
- The disk image must be a VMDK or QCOW2 file.
    - Create the image file by cloning the source volume, not by creating a snapshot.
    - VMDK files must be either the "single growable" (monolithicSparse) type or the "stream optimized" (streamOptimized) type, both of which consist of a single VMDK file. All other VMDK formats, such as those that use multiple files, split volumes, or contain snapshots, are not supported.
- The network interface must use DHCP to discover the network settings. When you import a custom image, existing network interfaces are not recreated. Any existing network interfaces are replaced with a single NIC after the import process is complete. You can attach additional VNICs after you launch the imported instance.
- The network configuration must not hardcode the MAC address for the network interface.

Preparing Windows VMs for Import

Before you can import a custom Windows image, you must prepare the image to ensure that instances launched from the image can boot correctly and that network connections will work.

You can perform the tasks described in this section on the running source system. If you have concerns about modifying the live source system, you can export the image as-is, import it into Oracle Cloud Infrastructure, and then launch an instance based on the custom image. You can then connect to the instance using the VNC console and perform the preparation steps.

Important

The system drive where Windows is installed will be imported to Oracle Cloud Infrastructure. All partitions on the drive will follow through the imported image. Any other drives will not be imported and you must re-create them on the instance after import. You will then need to manually move the data on the non-system drives.

To prepare a Windows VM for import:

1. Follow your organization's security guidelines to ensure that the Windows system is secured. This can include, but is not limited to the following tasks:
   - Install the latest security updates for the operating system and installed applications.
   - Enable the firewall, and configure it so that you only enable the rules which are needed.
   - Disable unnecessary privileged accounts.
   - Use strong passwords for all accounts.
2. Configure Remote Desktop Protocol (RDP) access to the image:
   a. Enable Remote Desktop connections to the image.
   b. Modify the Windows Firewall inbound port rule to allow RDP access for both Private and Public network location types. When you import the image, the Windows Network Location Awareness service will identify the network connection as a Public network type.
3. Determine whether the current Windows license type is a volume license by running the following command in PowerShell:

```
Get-CimInstance -ClassName SoftwareLicensingProduct | where {$_.PartialProductKey} | select
ProductKeyChannel
```

If the license is not a volume license, after you import the image, you will update the license type.

4. If you plan to launch the imported image on more than one VM instance, create a generalized image of the boot disk. A generalized image is cleaned of computer-specific information, such as unique identifiers. When you create instances from a generalized image, the unique identifiers are regenerated. This prevents two instances that are created from the same image from colliding on the same identifiers.
5. Create a backup of the root volume.
6. If the VM has remotely attached storage, such as NFS or block volumes, configure any services that rely on this storage to start manually. Remotely attached storage is not available the first time that an imported instance boots on Oracle Cloud Infrastructure.
7. Ensure that all network interfaces use DHCP, and that the MAC address and IP addresses are not hardcoded. See your system documentation for steps to perform network configuration for your system.
8. Download the Oracle Windows VirtIO drivers:
    a. Log in to the Oracle Software Delivery Cloud site.
    b. In the **All Categories** list, select **Release**.
    c. Type **Oracle Linux 7.6** in the search box and click **Search**.
    d. Add **REL: Oracle Linux 7.6.x** to your cart, and then click **Checkout**.
    e. In the **Platforms/Languages** list, select **x86 64 bit**. Click **Continue**.
    f. Accept the license agreement and then click **Continue**.
    g. Select the check box next to **Oracle VirtIO Drivers Version for Microsoft Windows 1.1.4**. Clear the other check boxes.
    h. Click **Download** and then follow the prompts.

9. Install the Oracle VirtIO drivers for Windows:
    a. Follow the prompts in the installation wizard. On the **Installation Type** page, select **Custom**, as shown in the following screenshot.

    b. Reboot the VM.
10. Stop the VM.
11. Clone the stopped VM as a VMDK or QCOW2 file, and then export the image from your virtualization environment. See the tools documentation for your virtualization environment for steps.

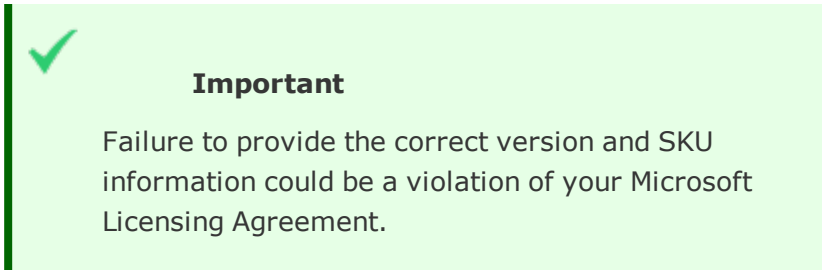
Importing a Windows-Based VM

After you prepare a Windows image for import, follow these steps to import the image:

1. Upload the VMDK or QCOW2 file to Oracle Cloud Infrastructure:
    a. Upload the file to an Object Storage bucket. You can upload the file using the Console or using the command line interface (CLI). If you use the CLI, use the following command:

    ```
    oci os object put -bn <destination_bucket_name> --file <path_to_the_VMDK_or_QCOW2_file>
    ```

    b. Copy the URL of the file that you uploaded: On the **Bucket Details** page, click the the Actions icon (three dots) next to the file, and then click **Details**. Copy the **URL Path (URI)**.
2. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Custom Images**.
3. Click **Import Image**.
4. In the **Create in Compartment** list, select the compartment that you want to import the image to.
5. Enter a name for the image.
6. For the **Operating System**, select **Windows**.
7. In the **Operating System Version** list, select the version of Windows.
8. Confirm that you chose the operating system version that complies with your Microsoft licensing agreement, and then select the compliance check box.

9. In the **Object Storage URL** field, paste the URL of the file that you uploaded.

10. For the **Image Type**, select the file type of the image, either **VMDK** or **QCOW2**.
11. In the **Launch Mode** area, select **Paravirtualized Mode**.
12. **Tags:** Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.
13. Click **Import Image**.
    The imported image appears in the **Custom Images** list for the compartment, with a status of **IMPORTING**. When the import completes successfully, the status changes to **AVAILABLE**.
    If the status doesn't change, or no entry appears in the **Custom Images** list, the import failed. Ensure that you have read access to the Object Storage object, and that the object contains a supported image.
14. Complete the post-import tasks.

Post-Import Tasks for Windows Images

After you import a custom Windows-based image, do the following:

1. Create an instance based on the custom image. For the image source, select **Custom Images**, and then select the image that you imported.
2. Enable Remote Desktop Protocol (RDP) access to the Compute instance.
3. Connect to the instance using RDP.
4. If the instance requires any remotely attached storage, such as block volumes or file storage, create and attach it.
5. Create and attach any required secondary VNICs.
6. Test that all applications are working as expected.
7. Reset any services that were set to start manually.

8. Register the instance with the Oracle-provided Key Management Service (KMS) server:
    a. On the instance, open PowerShell as Administrator.
    b. To set the KMS endpoint, run the following command:

```
slmgr /skms 169.254.169.253:1688
```

    c. If the Windows license type that you noted while preparing the image isn't a volume license, you must update the license type. Run the following command:

```
slmgr /ipk <setup key>
```

    <setup key> is the KMS client setup key that corresponds to the version of Windows that you imported:

Windows Version	KMS Client Setup Key
Windows Server 2008 R2 Standard	YC6KT-GKW9T-YTKYR-T4X34-R7VHC
Windows Server 2008 R2 Enterprise	489J6-VHDMP-X63PK-3K798-CPX3Y
Windows Server 2008 R2 Datacenter	74YFP-3QFB3-KQT8W-PMXWJ-7M648
Windows Server 2012 Standard	XC9B7-NBPP2-83J2H-RHMBY-92BT4
Windows Server 2012 Datacenter	48HP8-DN98B-MYWDG-T2DCC-8W83P
Windows Server 2012 R2 Standard	D2N9P-3P6X9-2R39C-7RTCD-MDVJX
Windows Server 2012 R2 Datacenter	W3GGN-FT8W3-Y4M27-J84CP-Q3VJ9
Windows Server 2016 Standard	WC2BQ-8NRM3-FDDYY-2BFGV-KHKQY
Windows Server 2016 Datacenter	CB7KF-BWN84-R7R2Y-793K2-8XDDG
Windows Server 2019 Standard	N69G4-B89J2-4G8F4-WWYCC-J464C
Windows Server 2019 Datacenter	WMDGN-G9PQG-XVVXX-R3X43-63DFG

d. To activate Windows, run the following command:

```
slmgr /ato
```

e. To verify the license status, run the following command:

```
Get-CimInstance -ClassName SoftwareLicensingProduct | where {$_.PartialProductKey} |
select Description, LicenseStatus
```

If the `LicenseStatus` is `1`, the instance is properly licensed. It might take up to 48 hours for the license status to update.

Importing Custom Linux Images

The Compute service enables you to import Linux-based images that were created outside of Oracle Cloud Infrastructure. For example, you can import images running on your on-premises physical or virtual machines (VMs), or VMs running in Oracle Cloud Infrastructure Classic. You can then launch your imported images on Compute virtual machines.

Note

Imported images are not supported on AMD shapes.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Supported Operating Systems

You can launch imported Linux VMs in either paravirtualized mode or emulated mode.

Paravirtualized mode offers better performance than emulated mode. We recommend that you use paravirtualized mode if your OS supports it. Linux-based operating systems running the kernel version 3.4 or later support paravirtualized drivers. You can verify your system's kernel version using the uname command.

To verify the kernel version using the uname command

Run the following command:

```
uname -a
```

The output should look similar to this sample:

```
Linux ip_bash 4.14.35-1818.2.1.el7uek.x86_64 #2 SMP Mon Aug 27 21:16:31 PDT 2018 x86_64 x86_64 x86_64
GNU/Linux
```

The kernel version is the number at the first part of output string. In the sample output shown previously, the version is 4.14.35.

These Linux distributions support custom image import:

Linux Distribution	Supported Versions	Preferred Launch Mode
RHEL	7 or later	Paravirtualized
	4.5, 5.5, 5.6, 5.9, 5.11, 6.5, 6.9	Emulated
CentOS	7 or later	Paravirtualized
	4.0, 4.8, 5.11, 6.9	Emulated
Oracle Linux	7 or later	Paravirtualized
	4.5, 4.8, 5.8, 5.11, 6.2, 6.5	Emulated
Ubuntu	13.04 or later	Paravirtualized
	12.04	Emulated

Linux Distribution	Supported Versions	Preferred Launch Mode
FreeBSD	12 or later	Paravirtualized
	8, 9, 10, 11	Emulated
Debian	8 or later	Paravirtualized
	5.0.10, 6.0, 7	Emulated
SUSE	12.2 or later	Paravirtualized
	11, 12.1	Emulated

Note

- Oracle Cloud Infrastructure has tested the operating systems listed in the previous table and will support customers in ensuring that instances launched from these images and built according to the guidelines in this topic are accessible using SSH.
- For OS versions not listed in the previous table, Oracle Cloud Infrastructure will provide commercially reasonable support to customers in an effort to get instances that are launched from these images accessible via SSH.
- Support from Oracle Cloud Infrastructure in launching an instance from a custom OS does not ensure that the operating system vendor also supports the instance. Customers running Oracle Linux on Oracle Cloud Infrastructure automatically have access to Oracle Linux Premier Support.

Tip

If your image supports paravirtualized drivers, you can convert your existing emulated mode instances into paravirtualized instances. Create a custom image of your instance, export it to Object Storage, and then reimport it using paravirtualized mode.

Linux Source Image Requirements

Custom images must meet the following requirements:

- The maximum image size is 400 GB.
- The image must be set up for BIOS boot.
- Only one disk is supported, and it must be the boot drive with a valid master boot record (MBR) and boot loader. You can migrate additional data volumes after you import the image's boot volume.
- The boot process must not require additional data volumes to be present for a successful boot.
- The boot loader should use LVM or a UUID to locate the boot volume.
- The disk image cannot be encrypted.
- The disk image must be a VMDK or QCOW2 file.
    - Create the image file by cloning the source volume, not by creating a snapshot.
    - VMDK files must be either the "single growable" (monolithicSparse) type or the "stream optimized" (streamOptimized) type, both of which consist of a single VMDK file. All other VMDK formats, such as those that use multiple files, split volumes, or contain snapshots, are not supported.
- The network interface must use DHCP to discover the network settings. When you import a custom image, existing network interfaces are not recreated. Any existing network interfaces are replaced with a single NIC after the import process is complete.

You can attach additional VNICs after you launch the imported instance.

- The network configuration must not hardcode the MAC address for the network interface.

We recommend that you enable certificate-based SSH, however this is optional. If you want your image to automatically use SSH keys supplied from the **User Data** field when you launch an instance, you can install cloud-init when preparing the image. See Creating an Instance for more information about the **User Data** field.

Preparing Linux VMs for Import

Before you import a custom Linux image, you must prepare the image to ensure that instances launched from the image can boot correctly and that network connections will work. Do the following:

1. Optionally, configure your Linux image to support serial console connections. A console connection can help you remotely troubleshoot malfunctioning instances, such as an imported image that does not complete a successful boot.
2. Create a backup of the root volume.
3. If the VM has remotely attached storage, such as NFS or block volumes, configure any services that rely on this storage to start manually. Remotely attached storage is not available the first time that an imported instance boots on Oracle Cloud Infrastructure.
4. Ensure that all network interfaces use DHCP, and that the MAC address and IP addresses are not hardcoded. See your system documentation for steps to perform network configuration for your system.
5. Stop the VM.
6. Clone the stopped VM as a VMDK or QCOW2 file, and then export the image from your virtualization environment. See the tools documentation for your virtualization environment for steps.

Importing a Linux-Based VM

After you prepare a Linux image for import, follow these steps to import the image:

1. Upload the VMDK or QCOW2 file to Oracle Cloud Infrastructure:
    a. Upload the file to an Object Storage bucket. You can upload the file using the Console or using the command line interface (CLI). If you use the CLI, use the following command:

    ```
    oci os object put -bn <destination_bucket_name> --file <path_to_the_VMDK_or_QCOW2_file>
    ```

    b. Copy the URL of the file that you uploaded: On the **Bucket Details** page, click the the Actions icon (three dots) next to the file, and then click **Details**. Copy the **URL Path (URI)**.
2. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Custom Images**.
3. Click **Import Image**.
4. In the **Create in Compartment** list, select the compartment that you want to import the image to.
5. Enter a name for the image.
6. For the **Operating System**, select **Linux**.
7. In the **Object Storage URL** field, paste the URL of the file that you uploaded.
8. For the **Image Type**, select the file type of the image, either **VMDK** or **QCOW2**.
9. Depending on your image's version of Linux, in the **Launch Mode** area, select **Paravirtualized Mode** or **Emulated Mode**. If your image supports paravirtualized drivers, we recommend that you select paravirtualized mode.
10. **Tags:** Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.

11. Click **Import Image**.
    The imported image appears in the **Custom Images** list for the compartment, with a status of **IMPORTING**. When the import completes successfully, the status changes to **AVAILABLE**.
    If the status doesn't change, or no entry appears in the **Custom Images** list, the import failed. Ensure that you have read access to the Object Storage object, and that the object contains a supported image.
12. Complete the post-import tasks.

Post-Import Tasks for Linux Images

After you import a custom Linux-based image, do the following:

1. Create an instance based on the custom image. For the image source, select **Custom Images**, and then select the image that you imported.
2. Connect to the instance using SSH.
3. If the instance requires any remotely attached storage, such as block volumes or file storage, create and attach it.
4. Create and attach any required secondary VNICs.
5. Test that all applications are working as expected.
6. Reset any services that were set to start manually.
7. If you enabled serial console access to the image, test it by creating a serial console connection to the instance.

See the current issues and workarounds for known issues with imported custom images.

Enabling Serial Console Access for Imported Linux Images

You can configure your custom Linux image to support connections using the serial console feature in the Compute service.

For more information about serial console connections, and steps to troubleshoot if your image has network connectivity issues after it is launched, see Instance Console Connections.

The serial console connection in Oracle Cloud Infrastructure uses the first serial port, ttyS0, on the VM. The boot loader and the operating system should be configured to use ttyS0 as a console terminal for both input and output.

CONFIGURING THE BOOT LOADER

The steps to configure the boot loader to use ttyS0 as a console terminal for both input and output depend on the GRUB version. Run the following command on the operating system to determine the GRUB version:

```
grub install --version
```

If the version number returned is 2.x, use the steps for GRUB 2. For earlier versions, use the steps for GRUB.

To configure GRUB2

1. Run the following command to modify the GRUB configuration file:

   ```
   sudo vi /etc/default/grub
   ```

2. Confirm that the configuration file contains the following:

   ```
   GRUB_SERIAL_COMMAND="serial --unit=0 --speed=115200"
                                                    GRUB_TERMINAL="serial console"
   ```

3. Append the following to the end of the `GRUB_CMDLINE_LINUX` line:

   ```
   console=tty1 console=ttyS0,115200
   ```

   If `GRUB_CMDLINE_LINUX` does not exist, create this line, using `GRUB_CMDLINE_OUTPUT` as a template.

4. Regenerate the GRUB2 configuration using the following command:

   ```
   sudo grub2-mkconfig -o /boot/grub2/grub.cfg
   ```

   If you have a beta version of GRUB 2, use this command instead:

   ```
   sudo grub-mkconfig -o /boot/grub/grub.cfg
   ```

To configure GRUB

1. Run the following command to modify the GRUB configuration file:

```
sudo vi /boot/grub/grub.conf
```

2. Add following after the line containing `timeout`:

```
serial --unit=0 --speed=115200
terminal --timeout=5 serial console
```

3. Append the following to each `kernel` line:

```
console=tty1 console=ttyS0,115200
```

CONFIGURING THE OPERATING SYSTEM

The operating system may already be configured to use ttyS0 as a console terminal for both input and output. To verify, run the following command:

```
sudo vi /etc/securetty
```

Check the file for `ttyS0`. If you don't see it, append `ttyS0` to the end of the file.

VALIDATING SERIAL CONSOLE ACCESS

After completing the steps to enable serial console access to the image, you should validate that serial console access is working by testing the image with serial console in your virtualization environment. Consult the documentation for your virtualization environment for steps to do this. Verify that the boot output displays in the serial console output and that there is interactive input after the image has booted.

TROUBLESHOOTING THE SERIAL CONSOLE

If no output is displayed on the serial console, verify in the configuration for your virtualization environment that the serial console device is attached to the first serial port.

If the serial console displays output, but there is no interactive input available, check that there is a terminal process listening on the ttyS0 port. To do this, run the following command:

```
ps aux | grep ttyS0
```

This command should output a terminal process that is listening on the ttyS0 port. For example, if your system is using getty, you will see the following output:

```
/sbin/getty ttyS0
```

If you don't see this output, it is likely that a login process is not configured for the serial console connection. To resolve this, enable the init settings, so that a terminal process is listening on the ttyS0 at startup.

For example, if your system is using getty, add the following command to the init settings to run on system startup:

```
getty -L 9600 ttyS0 vt102
```

The steps to do this will vary depending on the operating system, so consult the documentation for the image's operating system.

OS Kernel Updates

Note

This topic applies only to Linux instances that were launched before February 15, 2017. Linux instances launched on or after February 15, 2017 boot directly from the image and do not require further action for kernel updates.

Oracle Cloud Infrastructure boots each instance from a network drive. This configuration requires additional actions when you update the OS kernel.

Oracle Cloud Infrastructure uses Unified Extensible Firmware Interface (UEFI) firmware and a Preboot eXecution Environment (PXE) interface on the host server to load iPXE from a Trivial File Transfer Protocol (TFTP) server. The iPXE implementation runs a script to boot Oracle Linux. During the boot process, the system downloads the kernel, the `initrd` file, and the kernel boot parameters from the network. The instance does not use the host's GRUB boot loader.

Normally, the `yum update kernel-uek` command edits the GRUB configuration file, either `grub.cfg` or `grub.conf`, to configure the next boot. Since bare metal instances do not use the GRUB boot loader, changes to the GRUB configuration file are not implemented. When you update the kernel on your instance, you also must upload the update to the network to ensure a successful boot process. The following approaches address this need:

- Instances launched from an Oracle-provided image include an Oracle yum plug-in that seamlessly handles the upload when you run the `yum update kernel-uek` command.
- If you use a custom image based on an Oracle-provided image, the included yum plug-in will continue to work, barring extraordinary changes.
- If you install your own package manager, you must either write your own plug-in or upload the kernel, initrd, and kernel boot parameters manually.

Oracle Yum Plug-in

On instances launched with an Oracle-provided image, you can find the Oracle yum plug-in at:

```
/usr/share/yum-plugins/kernel-update-handler.py
```

The plug-in configuration is at:

```
/etc/yum/pluginconf.d
```

The plug-in looks for two variables in the `/etc/sysconfig/kernel` file, `UPDATEDEFAULT` and `DEFAULTKERNEL`. It picks up the updates only when the first variable is set to "yes" and the `DEFAULTKERNEL` value matches the kernel being updated. For example:

```
# UPDATEDEFAULT specifies if new-kernel-pkg should make
# new kernels the default
UPDATEDEFAULT=yes

# DEFAULTKERNEL specifies the default kernel package type
DEFAULTKERNEL=kernel-uek
```

Oracle-provided images incorporate the Unbreakable Enterprise Kernel (UEK). If you want to switch to a non-UEK kernel, you must update the `DEFAULTKERNEL` value to "kernel" before you run `yum update kernel`.

Manual Updates

Tip

Oracle recommends using the Oracle yum plug-in to update the kernel.

If you manually upload the updates, there are four relevant URLs:

`http://169.254.0.3/kernel`

`http://169.254.0.3/initrd`

`http://169.254.0.3/cmdline`

`http://169.254.0.3/activate`

The first three URLs are for uploading files (HTTP request type PUT). The fourth URL is for activating the uploaded files (HTTP request type POST). The system discards the uploaded files if they are not activated before the host restarts.

The kernel and initrd are simple file uploads. The cmdline upload must contain the kernel boot parameters found in the `grub.cfg` or `grub.conf` file, depending on the Linux version. The following example is an entry from the `/boot/efi/EFI/redhat/grub.cfg` file in Red Hat Linux 7. The highlighted text represents the parameters to upload.

```
kernel /boot/vmlinuz-4.1.12-37.5.1.el6uek.x86_64 ro root=UUID=8079e287-53d7-4b3d-b708-c519cf6829c8 rd_
NO_LUKS  KEYBOARDTYPE=pc KEYTABLE=us netroot=iscsi:@169.254.0.2::3260:iface1:eth0::iqn.2015-
02.oracle.boot:uefi rd_NO_MD SYSFONT=latarcyrheb-sun16 ifname=eth0:90:e2:ba:a2:e3:80 crashkernel=auto
iscsi_initiator=iqn.2015-02. rd_NO_LVM ip=eth0:dhcp rd_NO_DM LANG=en_US.UTF-8 console=tty0
console=ttyS0,9600 iommu=on
```

The following command returns what is being uploaded to the cmdline file.

```
cat /tmp/cmdline
```

A typical response resembles the following.

```
ro root=UUID=8079e287-53d7-4b3d-b708-c519cf6829c8 rd_NO_LUKS  KEYBOARDTYPE=pc KEYTABLE=us
netroot=iscsi:@169.254.0.2::3260:iface1:eth0::iqn.2015-02.oracle.boot:uefi rd_NO_MD SYSFONT=latarcyrheb-
```

```
sun16 ifname=eth0:90:e2:ba:a2:e3:80 crashkernel=auto iscsi_initiator=iqn.2015-02. rd_NO_LVM ip=eth0:dhcp
rd_NO_DM LANG=en_US.UTF-8 console=tty0 console=ttyS0,9600 iommu=on
```

The following commands update the `cmdline` and `initrd` files, and then activate the changes.

```
CKSUM=`md5sum /tmp/cmdline | cut -d ' ' -f 1`
```

```
sudo curl -X PUT --data-binary @/tmp/cmdline -H "Content-MD5: $CKSUM" http://169.254.0.3/cmdline
```

```
CKSUM=`md5sum /boot/initramfs-3.8.13-118.8.1.el7uek.x86_64.img | cut -d ' ' -f 1`
```

```
sudo curl -X PUT --data-binary @/boot/initramfs-3.8.13-118.8.1.el7uek.x86_64.img -H "Content-MD5:
$CKSUM" http://169.254.0.3/initrd
```

```
sudo curl -X POST http://169.254.0.3/activate
```

Managing Key Pairs on Linux Instances

Instances launched using Oracle Linux, CentOS, or Ubuntu images use an SSH key pair instead of a password to authenticate a remote user (see Security Credentials). A key pair consists of a private key and public key. You keep the private key on your computer and provide the public key every time you launch an instance.

When you connect to an instance using SSH, you provide the path to the key pair file in the SSH command. You can have as many key pairs as you want, or you can keep it simple and use one key pair for all or several of your instances.

To create key pairs, you can use a third-party tool such as OpenSSH on UNIX-style systems (including Linux, Solaris, BSD, and OS X) or PuTTY Key Generator on Windows.

Prerequisites

If you're using a UNIX-style system, you probably already have the `ssh-keygen` utility installed. To determine if it's installed, type `ssh-keygen` on the command line. If it's not installed, you can download OpenSSH for UNIX from http://www.openssh.com/portable.html and install it.

If you're using a Windows operating system you will need PuTTY and the PuTTY Key Generator. Download PuTTY and PuTTYgen from http://www.putty.org and install them.

Creating an SSH Key Pair on the Command Line

1. Open a shell or terminal for entering the commands.
2. At the prompt, enter `ssh-keygen` and provide a name and passphrase when prompted. The keys will be created with the default values: RSA keys of 2048 bits.

Alternatively, you can type a complete `ssh-keygen` command, for example:

```
ssh-keygen -t rsa -N "" -b 2048 -C "<key_name>" -f <path/root_name>
```

The command arguments are shown in the following table:

Argument	Description
`-t rsa`	Use the RSA algorithm.
`-N "<passphrase>"`	A passphrase to protect the use of the key (like a password). If you don't want to set a passphrase, don't enter anything between the quotes. A passphrase is not required. You can specify one as a security measure to protect the private key from unauthorized use.
`-b 2048`	Generate a 2048-bit key. You don't have to set this if 2048 is acceptable, as 2048 is the default. A minimum of 2048 bits is recommended for SSH-2 RSA.
`-C "<key_name>"`	A name to identify the key.
`-f <path/root_name>`	The location where the key pair will be saved and the root name for the files.

Creating an SSH Key Pair Using PuTTY Key Generator

1. Find `puttygen.exe` in the PuTTY folder on your computer, for example, `C:\Program Files (x86)\PuTTY`. Double-click `puttygen.exe` to open it.
2. Specify a key type of SSH-2 RSA and a key size of 2048 bits:
   - In the **Key** menu, confirm that the default value of **SSH-2 RSA key** is selected.
   - For the **Type of key to generate**, accept the default key type of **RSA**.
   - Set the **Number of bits in a generated key** to 2048 if it is not already set.
3. Click **Generate**.
4. Move your mouse around the blank area in the PuTTY window to generate random data in the key.
   When the key is generated, it appears under **Public key for pasting into OpenSSH authorized_keys file**.
5. A **Key comment** is generated for you, including the date and time stamp. You can keep the default comment or replace it with your own more descriptive comment.
6. Leave the **Key passphrase** field blank.
7. Click **Save private key**, and then click **Yes** in the prompt about saving the key without a passphrase.
   The key pair is saved in the PuTTY Private Key (PPK) format, which is a proprietary format that works only with the PuTTY tool set.
   You can name the key anything you want, but use the `ppk` file extension. For example, `mykey.ppk`.
8. Select *all* of the generated key that appears under **Public key for pasting into OpenSSH authorized_keys file**, copy it using **Ctrl + C**, paste it into a text file, and then save the file in the same location as the private key.
   (Do not use **Save public key** because it does not save the key in the OpenSSH format.)
   You can name the key anything you want, but for consistency, use the same name as the private key and a file extension of `pub`. For example, `mykey.pub`.

9. Write down the names and location of your public and private key files. You will need the public key when launching an instance. You will need the private key to access the instance via SSH.

Now that you have a key pair, you're ready to launch instances as described in Creating an Instance.

Creating an Instance

You can create an instance using the Console or API. When you create an instance, it is automatically attached to a virtual network interface card (VNIC) in the cloud network's subnet and given a private IP address from the subnet's CIDR. You can either let the IP address be automatically assigned, or specify a particular address of your choice. The private IP address lets instances within the cloud network communicate with each other. They can instead use fully qualified domain names (FQDNs) if you've set up the cloud network for DNS (see DNS in Your Virtual Cloud Network).

If the subnet is public, you can optionally assign the instance a public IP address. A public IP address is required to communicate with the instance over the Internet, and to establish a Secure Shell (SSH) or RDP connection to the instance from outside the cloud network. For more information, see Access to the Internet.

Tip

If this is your first time creating an instance, consider following the Getting Started Tutorial for a guided workflow through the steps required to create an instance.

Note

Partner images and pre-built Oracle enterprise images are not available in Government Cloud realms.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

Tip

When you create an instance, several other resources are involved, such as an image, a cloud network, and a subnet. Those other resources can be in the same compartment with the instance or in other compartments. You must have the required level of access to each of the compartments involved in order to launch the instance. This is also true when you attach a volume to an instance; they don't have to be in the same compartment, but if they're not, you need the required level of access to each of the compartments.

For administrators: The simplest policy to enable users to create instances is listed in Let users launch Compute instances. It gives the specified group general access to managing instances and images, along with the required level of access to attach existing block volumes to the instances. If the group needs to *create* block volumes, they'll need the ability to *manage* block volumes (see Let volume admins manage block volumes, backups, and volume groups).

Partner Image Catalog

If the group needs to create instances based on partner images, they'll need the *manage* permission for app-catalog-listing to create subscriptions to images from the Partner Image catalog. See Let users list and subscribe to images from the Partner Image catalog.

If you're new to policies, see Getting Started with Policies and Common Policies. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services.

Recommended Networking Launch Types

When you launch a virtual machine (VM) instance, by default, Oracle Cloud Infrastructure chooses a recommended networking type for the VNIC based on the instance shape and OS image. The networking interface handles functions such as disk input/output and network communication. The following options are available:

- **Paravirtualized networking:** For general purpose workloads such as enterprise applications, microservices, and small databases. Paravirtualized networking also provides increased flexibility to use the same image across different hardware platforms.
- **Hardware-assisted (SR-IOV) networking:** Single root input/output virtualization. For low-latency workloads such as video streaming, real-time applications, and large or clustered databases. Hardware-assisted (SR-IOV) networking uses the VFIO driver framework.

The following table lists the default and supported networking types for VM shapes.

Shape Type	Default Networking Type	Supported Networking Types
VM.Standard1	SR-IOV	Paravirtualized, SR-IOV
VM.Standard2	Paravirtualized	Paravirtualized, SR-IOV
VM.Standard.E2	Paravirtualized	Paravirtualized only
VM.DenseIO1	SR-IOV	Paravirtualized, SR-IOV
VM.DenseIO2	Paravirtualized	Paravirtualized, SR-IOV
VM.GPU2	SR-IOV	Paravirtualized, SR-IOV
VM.GPU3	SR-IOV	Paravirtualized, SR-IOV

To use paravirtualized networking, you must also use an image that supports paravirtualized networking. Paravirtualized networking is supported on these Oracle-provided images:

- **Oracle Linux 7, Oracle Linux 6:** Images published in March 2019 or later.
- **CentOS 7, CentOS 6:** Images published in July 2019 or later.
- **Ubuntu 18.04, Ubuntu 16.04:** Images published in March 2019 or later.
- **Windows Server 2016:** Images published in August 2019 or later.

SR-IOV networking is supported on all Oracle-provided images.

You can create an instance that uses a specific networking type instead of the default. However, depending on compatibility between the shape and image that you choose, the instance might not launch properly. You can test whether it succeeded by connecting to the instance. If the connection fails, the networking type is not supported. Relaunch the instance using a supported networking type.

Using the Console

To create a Linux instance

Prerequisites

To create a Linux instance, you'll need:

- A virtual cloud network (VCN) to launch the instance in. For information about setting up cloud networks, see Overview of Networking.
- The public key, in OpenSSH format, from the key pair that you plan to use for connecting to the instance via SSH. The following sample public key is abbreviated for readability:

  ```
  ssh-rsa AAAAB3NzaC1yc2EAAAABJQAA....lo/gKMLVM2xzc1xJr/Hc26biw3TXWGEakrK1OQ== rsa-key-20160304
  ```

  For information about generating a key pair, see Managing Key Pairs on Linux Instances.

To create a Linux instance using the Console:

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**. Then, choose a **Compartment** you have permission to work in.
2. Click **Create Instance**.
3. On the **Create Compute Instance** page, you specify the resources to use for your instance. By default, your instance launches in the current compartment, and the resources you choose also come from the current compartment.

   On the **Create Compute Instance** page, you specify the resources to use for the instance. By default, the instance launches in the current compartment, and the resources that you choose also come from the current compartment.

   Specify the following:

   - **Name your instance:** The name for the instance. You can add or change the name later. The name doesn't need to be unique, because an Oracle Cloud Identifier (OCID) uniquely identifies the instance.
   - **Choose an operating system or image source:** The source of the image to use for booting the instance. When you click **Change Image Source**, the **Browse All Images** page opens with the operating system or image source options. The following options are available:
     - **Platform Images:** Pre-built images for Oracle Cloud Infrastructure. See Oracle-Provided Images for a list of these images.
     - **Oracle Images:** Pre-built Oracle enterprise images and solutions enabled for Oracle Cloud Infrastructure.
     - **Partner Images:** Trusted third-party images published by Oracle partners. Click the down arrow in the row for an image to view and change the image build, or to view additional details about the image. For more information, see Overview of Marketplace and Working with Listings.
     - **Custom Images:** Custom images created or imported into your Oracle Cloud Infrastructure environment. See Managing Custom Images for more information.

  - **Boot Volumes:** Boot volumes available for creating a new instance in your Oracle Cloud Infrastructure environment. See Boot Volumes for more information.
  - **Image OCID:** Create an instance using a specific version of an image by providing the image OCID. See Oracle-Provided Image Release Notes to determine the image OCID for Oracle-provided images.
- **Availability Domain:** The availability domain in which you want to run the instance.
- **Instance Type:** Select **Virtual Machine** or **Bare Metal Machine**.
- **Instance Shape:** A template that determines the number of CPUs, amount of memory, and other resources allocated to a newly created instance.

  When you click **Change Shape**, the **Browse All Shapes** dialog box opens with a list of the virtual machine (VM) or bare metal shapes that are available for the instance type that you selected. Incompatible shapes don't appear in the list. See Compute Shapes for more information about bare metal and VM shapes. Choose a shape and then click **Select Shape**.
- **Configure networking:** The network details for the instance. In this section, you configure the following:
  - **Virtual cloud network compartment:** The compartment containing the network in which to create the instance.
  - **Virtual cloud network:** The network in which to create the instance.
  - **Subnet compartment:** The compartment containing a subnet within the cloud network to attach the instance to.
  - **Subnet:** A subnet within the cloud network to attach the instance to. The subnets are either public or private. Private means the instances in that subnet can't have public IP addresses. For more information, see Access to the Internet. Subnets can also be either AD-specific or regional (regional ones have "*regional*" after the name). We recommend using regional subnets. For more information, see About Regional Subnets.

- **Use network security groups to control traffic:** Select this check box to add the instance's primary VNIC to at least one network security group (NSG) of your choice. NSGs have security rules that apply only to the VNICs in that NSG. For more information, see Network Security Groups.
- If the subnet is public, you can optionally assign the instance a public IP address. A public IP address makes the instance accessible from the internet. Select the **Assign a public IP address** option. For more information, see Access to the Internet.

- **Boot volume:** Size and encryption options for the instance's boot volume.
  - To specify a custom size for the boot volume, select the **Custom boot volume size (in GB)** check box. Then, enter a custom size from 50 GB to 32 TB. The specified size must be larger than the default boot volume size for the selected image. See Custom Boot Volume Sizes for more information.
  - For VM instances, you can optionally select the **Use in-transit encryption** check box. See Block Volume Encryption for more information. If you are using your own Key Management encryption key for the boot volume, then this key is also used for in-transit encryption. Otherwise, the Oracle-provided encryption key is used.
  - Boot volumes are encrypted by default, but you can optionally encrypt the data in this volume using your own Key Management encryption key. To use Key Management for your encryption needs, select the **Choose a key from Key Management to encrypt this volume** check box. Then, select the **Vault Compartment** and **Vault** that contain the master encryption key you want to use. Also select the **Master Encryption Key Compartment** and **Master Encryption Key**. For more information about encryption, see Overview of Key Management. If you enable this option, this key is used for both data at rest encryption and in-transit encryption.
  - The Block Volume elastic performance feature enables you to change the volume performance for boot volumes, but this can only be modified after

the instance has been launched. When the instance is created, the boot volume is configured with the default volume performance set to **Balanced**. See Changing the Performance of a Volume for how to modify this setting. See Block Volume Elastic Performance for more information about this feature.

- **Add SSH key:** The public key portion of the key pair that you want to use for SSH access to the instance. You can drag and drop single key files into the box. To provide multiple keys, click **Choose files**, then press and hold down the Command key (on Mac) or the CTRL key (on Windows) while selecting files.
- **Show Advanced Options:** Advanced networking and management options. On the **Management** tab, configure the following:
  - **Choose a compartment for your instance:** The compartment in which you want to launch the instance.
  - **Choose a fault domain:** The fault domain to use for the instance. If you do not specify the fault domain, the system selects one for you. The fault domain cannot be changed after you create the instance. If you want to use a different fault domain, you must terminate the instance and launch a new instance in the preferred fault domain. For more information, see Fault Domains and Best Practices for Your Compute Instance.
  - **User data:** Data to be used by cloud-init to run custom scripts or provide custom cloud-init configuration. Click **Choose File** to select the script file, or paste the script into the text box. The file or script does not need to be base64-encoded, because the Console performs this encoding when the information is submitted. For information about how to take advantage of user data, see the cloud-init documentation.
  - **Enable monitoring:** Select this check box to collect metrics for this instance. When enabled, the OracleCloudAgent software on the instance emits metrics for this instance to the Monitoring service using the oci_computeagent metric namespace.

This option is available for supported images only. Legacy versions of supported images may also require installation of the OracleCloudAgent software. For more information, see Enabling Monitoring for Compute Instances.

- **Tags:** Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.

On the **Networking** tab, configure the following:

- **Private IP Address:** Optional. An available private IP address of your choice from the subnet's CIDR. If you don't specify a value, the private IP address is automatically assigned.
- **Hostname:** Optional. A hostname to be used for DNS within the cloud network. Available only if the VCN and subnet both have DNS labels. For more information, see DNS in Your Virtual Cloud Network.
- **Launch Options:** Optional. The networking launch type. Available only for VMs. For more information, see Recommended Networking Launch Types.

On the **Image** tab, you can optionally change the image build. By default, the latest build of the image is used to create the instance. You can select an older build of the image that is compatible with the shape you selected. Only compatible image builds are displayed in the list. You must select a shape before you can change the image build.

On the **Host** tab, you can optionally choose to launch the instance on a dedicated virtual machine host. This enables you to run the instance in isolation, so that it is not running on shared infrastructure. To do this, select the **Launch the virtual machine on a dedicated host** check box, and then select a dedicated virtual machine host from the drop-down list. Before you can place an instance on a dedicated virtual machine host, you must create a dedicated virtual machine host

in the same availability domain and fault domain as the instance. You can only place an instance on a dedicated virtual machine host at the time that you create the instance. For more information, see Dedicated Virtual Machine Hosts.

4. Click **Create**.
   To track the progress of the operation, you can monitor the associated work request. For more information, see Using the Console to View Work Requests.

After the instance is provisioned, details about it appear in the instance list. To view additional details, including IP addresses, click the instance name.

When the instance is fully provisioned and running, you can connect to it using SSH as described in Connecting to an Instance.

You also can attach a volume to the instance, provided the volume is in the same availability domain. For background information about volumes, see Overview of Block Volume.

To create a Windows instance

Prerequisites

To create a Windows instance, you'll need:

- A virtual cloud network (VCN) to launch the instance in. For information about setting up VCNs, see Overview of Networking.
- A VCN security rule that enables Remote Desktop Protocol (RDP) access so you can connect to your instance. Specifically, you need a stateful ingress rule for TCP traffic on destination port 3389 from source 0.0.0.0/0 and any source port. For more information, see Security Rules. You can implement this security rule in either a network security group that you will add this Windows instance to, or a security list that is used by the instance's subnet.

To enable RDP access

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the cloud network you're interested in.
3. To add the rule to a network security group that the instance belongs to:
    a. Under **Resources**, click **Network Security Groups**. Then click the network security group that you're interested in.
    b. Click **Add Rules**.
    c. Enter the following values for the rule:
        - **Stateless:** Leave the check box unselected
        - **Source Type:** CIDR
        - **Source CIDR:** 0.0.0.0/0
        - **IP Protocol:** RDP (TCP/3389)
        - **Source Port Range:** All
        - **Destination Port Range:** 3389
    d. When done, click **Add**.
4. Or, to add the rule to a security list that is used by the instance's subnet:
    a. Under **Resources**, click **Security Lists**. Then click the security list you're interested in.
    b. Click **Add Ingress Rules**.

c. Enter the following values for the rule:
   - **Stateless:** Leave the check box unselected
   - **Source Type:** CIDR
   - **Source CIDR:** 0.0.0.0/0
   - **IP Protocol:** RDP (TCP/3389)
   - **Source Port Range:** All
   - **Destination Port Range:** 3389

d. When done, click **Add Ingress Rules**.

To create a Windows instance using the Console:

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**. Then, choose a **Compartment** you have permission to work in.
2. Click **Create Instance**.
3. On the **Create Compute Instance** page, you specify the resources to use for the instance. By default, the instance launches in the current compartment, and the resources that you choose also come from the current compartment.
   Specify the following:
   - **Name your instance:** The name for the instance. You can add or change the name later. The name doesn't need to be unique, because an Oracle Cloud Identifier (OCID) uniquely identifies the instance.

Important

Use only these ASCII characters in the instance name: uppercase letters (A-Z), lowercase letters (a-z), numbers (0-9), and hyphens (-). See this known issue for more information.

- **Choose an operating system or image source:** The source of the image to use for booting the instance. When you click **Change Image Source**, the **Browse All Images** page opens with the operating system or image source options. The following options are available:
  - **Platform Images:** Pre-built images for Oracle Cloud Infrastructure. See Oracle-Provided Images for a list of these images.
  - **Oracle Images:** Pre-built Oracle enterprise images and solutions enabled for Oracle Cloud Infrastructure.
  - **Partner Images:** Trusted third-party images published by Oracle partners. Click the down arrow in the row for an image to view and change the image build, or to view additional details about the image. For more information, see Overview of Marketplace and Working with Listings.
  - **Custom Images:**Custom images created or imported into your Oracle Cloud Infrastructure environment. See Managing Custom Images for more information.
  - **Boot Volumes:** Boot volumes available for creating a new instance in your Oracle Cloud Infrastructure environment. See Boot Volumes for more information.
  - **Image OCID:** Create an instance using a specific version of an image by providing the image OCID. See Oracle-Provided Image Release Notes to determine the image OCID for Oracle-provided images.
- **Availability Domain:** The availability domain in which you want to run the instance.
- **Instance Type:** Select **Virtual Machine** or **Bare Metal Machine**.
- **Instance Shape:** A template that determines the number of CPUs, amount of memory, and other resources allocated to a newly created instance.
  When you click **Change Shape**, the **Browse All Shapes** dialog box opens with a list of virtual machine (VM) or bare metal shapes that are available for the instance type that you selected. Incompatible shapes don't appear in the list. See

Compute Shapes for more information about bare metal and VM shapes. Choose a shape and then click **Select Shape**.

- **Configure networking:** The network details for the instance. In this section, you configure the following:
  - **Virtual cloud network compartment:** The compartment containing the network in which to create the instance.
  - **Virtual cloud network:** The network in which to create the instance.
  - **Subnet compartment:** The compartment containing a subnet within the cloud network to attach the instance to.
  - **Subnet:** A subnet within the cloud network to attach the instance to. The subnets are either public or private. Private means the instances in that subnet can't have public IP addresses. For more information, see Access to the Internet. Subnets can also be either AD-specific or regional (regional ones have "*regional*" after the name). We recommend using regional subnets. For more information, see About Regional Subnets.
  - **Use network security groups to control traffic:** Select this check box to add the instance's primary VNIC to at least one network security group (NSG) of your choice. NSGs have security rules that apply only to the VNICs in that NSG. For more information, see Network Security Groups.
  - If the subnet is public, you can optionally assign the instance a public IP address. A public IP address makes the instance accessible from the internet. Select the **Assign a public IP address** option. For more information, see Access to the Internet.
- **Boot volume:** Size and encryption options for the instance's boot volume.
  - To specify a custom size for the boot volume, select the **Custom boot volume size (in GB)** check box. Then, enter a custom size from 50 GB (256 GB for Oracle-provided Windows images) to 32 TB. The specified size must be larger than the selected image's default boot volume size. See Custom Boot Volume Sizes for more information.

- For VM instances, you can optionally select the **Use in-transit encryption** check box. See Block Volume Encryption for more information. If you are using your own Key Management encryption key for the boot volume, then this key is also used for in-transit encryption. Otherwise, the Oracle-provided encryption key is used.
- Boot volumes are encrypted by default, but you can optionally encrypt the data in this volume using your own Key Management encryption key. To use Key Management for your encryption needs, select the **Choose a key from Key Management to encrypt this volume** check box. Then, select the **Vault Compartment** and **Vault** that contain the master encryption key you want to use. Also select the **Master Encryption Key Compartment** and **Master Encryption Key**. For more information about encryption, see Overview of Key Management.
- The Block Volume elastic performance feature enables you to change the volume performance for boot volumes, but this can only be modified after the instance has been launched. When the instance is created, the boot volume is configured with the default volume performance set to **Balanced**. See Changing the Performance of a Volume for how to modify this setting. See Block Volume Elastic Performance for more information about this feature.

- **Add SSH Key:** An SSH key pair is only required for Linux instances. For Windows instances, you connect to the instance using a password. An initial password will be provided when you finish launching the instance.
- **Show Advanced Options:** Advanced networking and management options.
  On the **Management** tab, configure the following:
  - **Choose a compartment for your instance:** The compartment in which you want to launch the instance.
  - **Choose a fault domain:** The fault domain to use for the instance. If you do not specify the fault domain, the system selects one for you. The fault domain cannot be changed after you create the instance. If you want to use

a different fault domain, you must terminate the instance and launch a new instance in the preferred fault domain. For more information, see Fault Domains and Best Practices for Your Compute Instance.

- **User data:** Data to be used by cloudbase-init to run custom scripts or provide custom cloudbase-init configuration. Click **Choose File** to select the script file, or paste the script into the text box. The file or script does not need to be base64-encoded, because the Console performs this encoding when the information is submitted. For information about how to take advantage of user data, see the cloudbase-init documentation.

  Warning

  Do not include anything in the script that could trigger a reboot, because this could impact the instance launch and cause it to fail. Any actions requiring a reboot should only be performed once the instance state is **RUNNING**.

- **Enable monitoring:** Select this check box to collect metrics for this instance. When enabled, the OracleCloudAgent software on the instance emits metrics for this instance to the Monitoring service using the oci_computeagent metric namespace.

  This option is available for supported images only. Legacy versions of supported images may also require installation of the OracleCloudAgent software. For more information, see Enabling Monitoring for Compute Instances.

- **Tags:** Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag

namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.

On the **Networking** tab, configure the following:

- **Private IP address:** Optional. An available private IP address of your choice from the subnet's CIDR. If you don't specify a value, the private IP address is automatically assigned.
- **Hostname:** Optional. A hostname to be used for DNS within the cloud network. Available only if the VCN and subnet both have DNS labels. For more information, see DNS in Your Virtual Cloud Network.
- **Launch Options:** Optional. The networking launch type. Available only for VMs. For more information, see Recommended Networking Launch Types.

On the **Image** tab, you can optionally change the image build. By default, the latest build of the image is used to create the instance. You can select an older build of the image that is compatible with the shape you selected. Only compatible image builds are displayed in the list. You must select a shape before you can change the image build.

On the **Host** tab, you can optionally choose to launch the instance on a dedicated virtual machine host. This enables you to run the instance in isolation, so that it is not running on shared infrastructure. To do this, select the **Launch the virtual machine on a dedicated host** check box, and then select a dedicated virtual machine host from the list. Before you can place an instance on a dedicated virtual machine host, you must create a dedicated virtual machine host in the same availability domain and fault domain as the instance. You can only place an instance on a dedicated virtual machine host at the time you create the instance. For more information, see Dedicated Virtual Machine Hosts.

4. Click **Create**.

   To track the progress of the operation, you can monitor the associated work request. For more information, see Using the Console to View Work Requests.

After the instance is provisioned, details about it appear in the instance list. To view additional details, including IP addresses and the initial Windows password, click the instance name.

When the instance is fully provisioned and running, you can connect to it using Remote Desktop as described in Connecting to an Instance.

You also can attach a volume to the instance, provided the volume is in the same availability domain. For background information about volumes, see Overview of Block Volume.

Managing Tags for an Instance

You can apply tags to your resources, such as instances, to help you organize them according to your business needs. You can apply tags when you create an instance, or you can update the instance later with the tags that you want.

To manage tags for an instance

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
2. Click the instance that you're interested in.
3. Click the **Tags** tab to view or edit the existing tags. Or click **Apply tag(s)** to add new ones.

For more information, see Resource Tags.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use these API operations to manage instances:

- ListInstances
- LaunchInstance
- GetInstance
- UpdateInstance
- TerminateInstance
- GetWindowsInstanceInitialCredentials

Oracle Cloud Infrastructure enables you to launch instances from images published by Oracle partners from the Partner Image catalog. Use these APIs to work with the Partner Image catalog listings:

- AppCatalogListing
- AppCatalogListingResourceVersion
- AppCatalogListingResourceVersionAgreements
- AppCatalogListingResourceVersionSummary
- AppCatalogListingSummary
- AppCatalogSubscription
- AppCatalogSubscription

Managing Compute Instances

You can simplify the management of your Compute instances using resources such as instance configurations and instance pools.

An instance configuration is a template that defines the settings to use when creating Compute instances.

An instance pool is a group of instances within the same region that are created based off of an instance configuration.

Instance Configurations

An instance configuration defines the settings to use when creating Compute instances, including details such as the base image, shape, and metadata. You can also specify the associated resources for the instance, such as block volume attachments and network configuration.

For steps to create an instance configuration, see Creating an Instance Configuration.

To modify an existing instance configuration, create a new instance configuration with the desired settings.

For steps to delete an instance configuration, see Deleting an Instance Configuration.

Use these API operations to work with instance configurations:

- CreateInstanceConfiguration
- DeleteInstanceConfiguration
- GetInstanceConfiguration
- UpdateInstanceConfiguration
- ListInstanceConfigurations

Instance Pools

Instance pools give you the ability to provision and create multiple Compute instances based off of the same instance configuration, within the same region. They also enable integration with other services, such as the Load Balancing service and IAM service, making it easier to manage groups of instances.

You create an instance pool using an existing instance configuration. For steps, see Creating an Instance Pool.

You can automatically adjust the number of instances in an instance pool based on performance metrics such as CPU utilization. To do this, you enable autoscaling for the instance pool. For background information and steps, see Autoscaling.

After you have created an instance pool, you can update the size and attach or detach load balancers from the Console. To update additional settings, you need to use the CLI, API, or SDKs.

If you need to update the instance configuration, create a new instance configuration and then update the instance pool to use the new instance configuration. For more information, see Updating an Instance Pool.

A cluster network is a special kind of instance pool that is designed for massive, high-performance computing jobs. For more information, see Managing Cluster Networks.

For steps to delete an instance pool, see Deleting an Instance Pool.

Warning

When you delete an instance pool all of its resources will be permanently deleted, including associated instances, attached boot volumes, and block volumes.

Instance Pool Lifecycle States

The following list describes the different lifecycle states for instance pools.

- **Provisioning:** When you create an instance pool, this is the first state the instance pool is in. Instances for the instance pool are being configured based on the specified instance configuration.
- **Starting:** The instances are being launched. At this point, the only action you can take is to terminate the instance pool.
- **Running:** The instances are created and running.
- **Stopping:** The instances are in the process of being shut down.
- **Stopped:** The instances are shut down.
- **Scaling:** Once an instance pool has been created, if you update the instance pool size, it will go into this state while creating (for increases in size) or terminating (for decreases

in size) instances. At this point, the only action you can take is to terminate the instance pool.

- **Terminating:** The instances and associated resources are being terminated.
- **Terminated:** The instance pool, all its instances and associated resources are terminated.

When working with instance configurations and instance pools, keep the following in mind:

- You can't delete an instance configuration if it is associated with at least one instance pool.
- You can use the same instance configuration for multiple instance pools. However, an instance pool can only have one instance configuration associated with it.
- If the instance pool has been in the scaling or provisioning state for an extended period of time, it may be because the number of instances requested has exceeded your tenancy's service limits for that shape and availability domain. Check your tenancy's service limits for Compute. If you want to request a limit increase, you need to contact support. For more information, see Service Limits. If this occurs, you need to terminate the instance pool and re-create it.
- If you modify the instance configuration for an instance pool, existing instances that are part of that pool will not change. Any new instances created after the instance configuration change will use the new instance configuration. New instances will not be created unless you have increased the size of the instance pool or terminate existing instances.
- If you decrease the size of an instance pool, the oldest instances will be terminated first.

Use these API operations to manage instance pools:

- CreateInstancePool
- GetInstancePool
- ResetInstancePool
- SoftresetInstancePool

- StartInstancePool
- StopInstancePool
- TerminateInstancePool
- UpdateInstancePool
- ListInstancePools
- ListInstancePoolInstances
- AttachLoadBalancer
- DetachLoadBalancer
- GetInstancePoolLoadBalancerAttachment

Creating an Instance Configuration

Instance configurations allow you to define the settings to use when creating Compute instances.

You use an instance configuration when you want to create one or more instances in an instance pool. For background information about instance pools, see Managing Compute Instances.

You can also use an instance configuration to launch individual instances that are not part of a pool. To do this, use the SDKs, command line interface (CLI), or API.

In the Console, you create an instance configuration using an existing Compute instance as a template. If you want to create an instance configuration by specifying a list of configuration settings, use the SDKs, CLI, or API.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: For a typical policy that gives access to instance pools and instance configurations, see Let users manage Compute instance configurations, instance pools, and cluster networks.

Tagging Resources

You can add tags to your resources to help you organize them according to your business needs. You can add tags at the time you create a resource, or you can update the resource later with the desired tags. For general information about applying tags, see Resource Tags.

Using the Console

To create an instance configuration

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
2. Click the instance that you want to use as a template to create the instance configuration.
3. Click **Actions**, and then click **Create Instance Configuration**.
4. Select the compartment you want to create the instance configuration in.
5. Specify a name for the instance configuration. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API).
6. **Show Tagging Options:** Optionally, you can add tags. If you have permissions to create a resource, you also have permissions to add free-form tags to that resource. To add a defined tag, you must have permissions to use the tag namespace. For more

information about tagging, see Resource Tags. If you are not sure if you should add tags, skip this option (you can add tags later) or ask your administrator.

7. Click **Create Instance Configuration**.

To manage tags for an instance configuration

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instance Configurations**.
2. Click the instance configuration that you're interested in.
3. Click the **Tags** tab to view or edit the existing tags. Or click **Add tags** to add new ones.

For more information, see Resource Tags.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the CreateInstanceConfiguration operation to create an instance configuration.

Creating an Instance Pool

Instance pools give you the ability to provision and create multiple Compute instances based off the same configuration, within the same region. For more information about instance pools and instance configurations, see Managing Compute Instances.

Optionally, you can associate a load balancer with an instance pool. If you do this, when you add an instance to the instance pool, the instance is automatically added to the load balancer's backend set . After the instance reaches a healthy state (the instance is listening on the configured port number), incoming traffic is automatically routed to the new instance. For background information about the Load Balancing service, see Overview of Load Balancing.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don't have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: For a typical policy that gives access to instance pools and instance configurations, see Let users manage Compute instance configurations, instance pools, and cluster networks.

Important

See this known issue for information about the policy statements that are required if the instance configuration or load balancer associated with the instance pool includes defined tags.

Tagging Resources

You can add tags to your resources to help you organize them according to your business needs. You can add tags at the time you create a resource, or you can update the resource later with the desired tags. For general information about applying tags, see Resource Tags.

Distributing Instances Across Fault Domains for High Availability

By default, the instances in a pool are distributed across all fault domains in a best-effort manner based on capacity. If capacity isn't available in one fault domain, the instances are placed in other fault domains to allow the instance pool to launch successfully.

In a high availability scenario, you can require that the instances in a pool are evenly distributed across each of the fault domains that you specify. When sufficient capacity isn't available in one of the fault domains, the instance pool will not launch or scale successfully, and a work request for the instance pool will return an "out of capacity" error. To fix the capacity error, either wait for capacity to become available, or use the UpdateInstancePool operation to update the placement configuration (the availability domain and fault domain) for the instance pool.

Prerequisites

Before you can create an instance pool, you need:

- An instance configuration. An instance configuration is a template that defines the settings to use when creating instances. For more information, see Creating an Instance Configuration.

  Note

  You cannot create an instance pool from an instance configuration where the image source is a boot volume.

- If you want to associate the instance pool with a load balancer, you need a load balancer and backend set. For steps to create a load balancer, see Managing a Load Balancer.

Using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instance Pools**.
2. Click **Create Instance Pool**.
3. In the **Create in Compartment** list, select the compartment that you want to create the instance pool in.
4. Enter a name for the instance pool. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API).
5. Specify the targeted **Number of Instances** for the instance pool.
6. To select the instance configuration that you want to use, enter the following:
   - **Instance Configuration Compartment:** The compartment that the instance configuration is in.
   - **Instance Configuration:** The instance configuration to use.
7. If you want to associate a load balancer with the instance pool, select the **Attach a Load Balancer** check box. Then, enter the following:
   - **Load Balancer Compartment:** The compartment that the load balancer is in.
   - **Load Balancer:** The load balancer to associate with the instance pool.
   - **Backend Set:** The name of the backend set on the load balancer to add instances to.
   - **Port:** The server port on the instances to which the load balancer must direct traffic. This value applies to all instances that use this load balancer attachment.
   - **VNIC:** The VNIC to use when adding the instance to the backend set. Instances that belong to a backend set are also called backend servers. The private IP address is used. This value applies to all instances that use this load balancer attachment.

   For background information about load balancers, see Overview of Load Balancing.

8. Select the location where you want to place the instances:
    a. In the **Availability Domain** list, select the availability domain to launch the instances in.
    b. If you want the instances in the pool to be placed evenly in one or more fault domains, select the **Distribute instances evenly across selected fault domains** check box. Then, select the fault domains to place the instances in. For more information, see Distributing Instances Across Fault Domains for High Availability.
    c. In the **Primary VNIC** section, configure the network details for the instances:
        - **Virtual cloud network compartment:** The compartment containing the network to create the instances in.
        - **Virtual cloud network:** The virtual cloud network (VCN) to create the instances in.
        - **Subnet compartment:** The compartment containing a subnet within the cloud network to attach the instances to.
        - **Subnet:** A subnet within the cloud network to attach the instances to. The subnets are either public or private. Private means the instances in that subnet can't have public IP addresses. For more information, see Access to the Internet. Subnets can also be either AD-specific or regional (regional ones have "*regional*" after the name). We recommend using regional subnets. For more information, see About Regional Subnets.
    d. If secondary VNICs are defined by the instance configuration, a **Secondary VNIC** section appears. Select the compartments, and then select the secondary VCN and subnet for the instance pool.
9. If you want the instance pool to create instances in more than one availability domain, click **+ Additional Selection** and select a different availability domain for the instance pool. Then, repeat the previous step to specify the network information for the second availability domain.
10. **Show Tagging Options:** Optionally, you can add tags. If you have permissions to create a resource, you also have permissions to add free-form tags to that resource. To

add a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should add tags, skip this option (you can add tags later) or ask your administrator.

11. Click **Create Instance Pool**.
    To track the progress of the operation, you can monitor the associated work request. For more information, see Using the Console to View Work Requests.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use these API operations to create and manage instance pools:

- CreateInstancePool
- AttachLoadBalancer
- DetachLoadBalancer
- GetInstancePoolLoadBalancerAttachment

Updating an Instance Pool

You can update the number of instances for an instance pool.

Optionally, you can associate a load balancer with an instance pool. If you do this, when you add an instance to the instance pool, the instance is automatically added to the load balancer's backend set. After the instance reaches a healthy state (the instance is listening on the configured port number), incoming traffic is automatically routed to the new instance. For background information about the Load Balancing service, see Overview of Load Balancing.

To update other settings for an instance pool, use the command line interface (CLI), SDKs, or REST APIs.

You can automatically adjust the number of instances in an instance pool based on performance metrics such as CPU utilization. To do this, you enable autoscaling for the instance pool. For background information and steps, see Autoscaling.

See Managing Compute Instances for more information about instance pools and instance configurations.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don't have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: For a typical policy that gives access to instance pools and instance configurations, see Let users manage Compute instance configurations, instance pools, and cluster networks.

Important

See this known issue for information about the policy statements that are required if the instance configuration or load balancer associated with the instance pool includes defined tags.

Tagging Resources

You can add tags to your resources to help you organize them according to your business needs. You can add tags at the time you create a resource, or you can update the resource later with the desired tags. For general information about applying tags, see Resource Tags.

Using the Console

To update the instance pool size

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click

Instance Pools.

2. Click the name of the instance pool that you're interested in.
3. Click **Edit**.
4. Specify the updated number of instances for the instance pool, and then click **Save Changes**.

When you update the instance pool size, it triggers a scaling event. Keep the following in mind:

- If the instance pool lifecycle state is **RUNNING**, the instance pool will create new instances or terminate existing instances at that time, to match the new size of the instance pool. Instances are terminated in the order that they were created, first-in, first-out.
- If the instance pool lifecycle state is **STOPPED**, for an increase in size, new instances will be configured for the instance pool, but won't be launched. For a decrease in size, the instances will be terminated.

To track the progress of the operation, you can monitor the associated work request. For more information, see Using the Console to View Work Requests.

Important

If the instance pool has been in the scaling or provisioning state for an extended period of time, it may be because the number of instances requested has exceeded your tenancy's service limits for that shape and availability domain. Check your tenancy's service limits for Compute.

To attach a load balancer to an instance pool

You must have a load balancer and backend set to associate with the instance pool. For steps

to create a load balancer, see Managing a Load Balancer.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instance Pools**.
2. Click the name of the instance pool that you're interested in.
3. In the **Resources** section, click **Load Balancers**.
4. Click **Attach a Load Balancer**.
5. Enter the following:
   - **Load Balancer Compartment:** The compartment that the load balancer is in.
   - **Load Balancer:** The load balancer to associate with the instance pool.
   - **Backend Set:** The name of the backend set on the load balancer to add instances to.
   - **Port:** The server port on the instances to which the load balancer must direct traffic. This value applies to all instances that use this load balancer attachment.
   - **VNIC:** The VNIC to use when adding the instance to the backend set. Instances that belong to a backend set are also called backend servers. The private IP address is used. This value applies to all instances that use this load balancer attachment.
6. Click **Attach**.
   To track the progress of the operation, you can monitor the associated work request. For more information, see Using the Console to View Work Requests.

To detach a load balancer from an instance pool

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instance Pools**.
2. Click the name of the instance pool that you're interested in.
3. In the **Resources** section, click **Load Balancers**.
4. Click the Actions icon (three dots) for the load balancer.

5. Click **Detach**, and then click **Detach** to confirm.
   To track the progress of the operation, you can monitor the associated work request. For more information, see Using the Console to View Work Requests.

To manage tags for an instance pool

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instance Pools**.
2. Click the instance pool that you're interested in.
3. Click the **Tags** tab to view or edit the existing tags. Or click **Add tags** to add new ones.

For more information, see Resource Tags.

Using the API

To update other instance pool configuration settings, use the CLI, SDKs, or REST APIs. For information about using the CLI, see Command Line Interface (CLI). For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

For instance pool configuration settings, such as the instance configuration, display name, tags, or availability domain selections, use the UpdateInstancePool operation.

To manage the load balancers that are associated with an instance pool, use the AttachLoadBalancer and DetachLoadBalancer operations.

To update the configuration used by the instance pool when creating instances you can either:

- Create a new instance configuration with the desired settings. You can do this using the Console. For steps, see Creating an Instance Configuration. To do this using the API, use the CreateInstanceConfiguration operation.
- Update the existing instance configuration for the instance pool. You can only update the display name and tags of existing instance configurations. For any other updates, create a new instance configuration with the settings you want to use. To update the display

name or tags, use the UpdateInstanceConfiguration operation. You cannot use the Console to update instance configuration settings.

Stopping and Starting the Instances in an Instance Pool

You can stop and start the instances in an instance pool as needed to update software or resolve error conditions.

Stopping or Restarting an Instance From Within the Instance

In addition to using the API and Console, you can stop and restart instances using the commands available in the operating system when you are logged in to the instance. Stopping an instance using the instance's OS does not stop billing for that instance. If you stop the instances in an instance pool this way, be sure to also stop the instance pool from the Console or API.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: For a typical policy that gives access to instance pools and instance configurations, see Let users manage Compute instance configurations, instance pools, and cluster networks.

If you're new to policies, see Getting Started with Policies and Common Policies. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services.

Resource Billing for Stopped Instances

For both VM and bare metal instances, billing depends on the shape that you use to create the instance:

- **Standard shapes:** Stopping an instance pool pauses billing. However, stopped instances continue to count toward your service limits.
- **Dense I/O shapes:** Billing continues for stopped instance pools because of the attached NVMe storage, and related resources continue to count toward your service limits. To halt billing and remove related resources from your service limits, you must terminate the instance pool.
- **GPU shapes:** Billing continues for stopped instance pools, and related resources continue to count toward your service limits. To halt billing and remove related resources from your service limits, you must terminate the instance pool.
- **HPC shapes:** Billing continues for stopped instance pools because of the attached NVMe storage, and related resources continue to count toward your service limits. To halt billing and remove related resources from your service limits, you must terminate the instance pool.

Stopping an instance using the instance's OS does not stop billing for that instance. If you stop the instances in an instance pool this way, be sure to also stop the instance pool from the Console or API.

For more information about how instances running Microsoft Windows Server are billed when they are stopped, see How am I charged for Windows Server on Oracle Cloud Infrastructure?.

Using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instance Pools**.
2. Click the instance pool that contains the instances that you want to stop or start.

3. Click one of the following actions:
    - **Start:** Starts all instances in the instance pool.
    - **Stop:** Shuts down all instances in the instance pool.
    - **Reboot:** Gracefully reboots all instances in the instance pool by sending a shutdown command to the operating system, and then powers the instances back on.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

To manage the lifecycle state of the instances in an instance pool, use these operations:

- StartInstancePool
- StopInstancePool
- ResetInstancePool
- SoftresetInstancePool

Deleting an Instance Configuration

You can permanently delete instance configurations that you no longer need.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: For a typical policy that gives access to instance pools and instance configurations, see Let users manage Compute instance configurations, instance pools, and cluster networks.

Using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instance Configurations**.
2. Click the instance configuration that you want to delete.
3. Click **Delete**, and then click **Delete Instance Configuration**.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the DeleteInstanceConfiguration operation to delete an instance configuration.

Deleting an Instance Pool

You can permanently delete instance pools that you no longer need.

Warning

When you delete an instance pool all of its resources will be permanently deleted, including associated instances, attached boot volumes, and block volumes.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK,

CLI, or other tool. If you try to perform an action and get a message that you don't have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: For a typical policy that gives access to instance pools and instance configurations, see Let users manage Compute instance configurations, instance pools, and cluster networks.

Using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instance Pools**.
2. Click the instance pool that you want to delete.
3. Click **Actions**, and then click **Terminate**.
4. Enter the name of the instance pool and click **Terminate**.
   To track the progress of the operation, you can monitor the associated work request. For more information, see Using the Console to View Work Requests.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the TerminateInstancePool operation to delete an instance pool.

Autoscaling

Autoscaling enables you to automatically adjust the number of Compute instances in an instance pool based on performance metrics such as CPU utilization. This helps you provide consistent performance for your end users during periods of high demand, and helps you reduce your costs during periods of low demand.

You select a performance metric to monitor, and set thresholds that the performance metric must reach to trigger an autoscaling event. When system usage meets a threshold,

autoscaling dynamically allocates resources in near-real time. As load increases, instances are automatically provisioned: the instance pool *scales out*. As load decreases, instances are automatically removed: the instance pool *scales in*.

When an instance pool scales in, instances are terminated in this order: the number of instances is balanced across availability domains, and then balanced across fault domains. Finally, within a fault domain, the oldest instance is terminated first.

Autoscaling relies on performance metrics that are collected by the Monitoring service. These performance metrics are aggregated into one-minute time periods and then averaged across the instance pool. When three consecutive values (that is, the average metrics for three consecutive minutes) meet the threshold, an autoscaling event is triggered.

A cooldown period between autoscaling events lets the system stabilize at the updated level. The cooldown period starts when the instance pool reaches a steady state. Autoscaling continues to evaluate performance metrics during the cooldown period. When the cooldown period ends, autoscaling adjusts the instance pool's size again if needed.

For background information about the Monitoring service, see Monitoring Overview. For information about the metrics emitted by Compute instances, see Compute Instance Metrics.

Note

Autoscaling is not available in Oracle Cloud Infrastructure Government Cloudrealms.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: For a typical policy that gives access to autoscaling configurations, see Let users manage Compute autoscaling configurations.

Tagging Resources

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the desired tags. For general information about applying tags, see Resource Tags.

Prerequisites

- You have an instance pool. Optionally, you can attach a load balancer to the instance pool. For steps to create an instance pool and attach a load balancer, see Creating an Instance Pool.
- Monitoring is enabled on the instances in the instance pool. For steps to enable monitoring, see Enabling Monitoring for Compute Instances.
- The instance pool supports the maximum number of instances that you want to scale to. This limit is determined by your tenancy's service limits. For more information, see Service Limits.

Using the Console

To create an autoscaling configuration

Each instance pool can have one autoscaling configuration.

You can create an autoscaling configuration from the **Instance Pools** page or the **Autoscaling Configurations** page.

To create an autoscaling configuration from the Instance Pools page

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instance Pools**.
2. Click the instance pool that you want to apply an autoscaling configuration to.
3. Click **Actions**, and then click **Create Autoscaling Configuration**.
4. Select the **Compartment** that you want to create the autoscaling configuration in.
5. Enter a name for the autoscaling configuration.
6. Select the **Instance Pool** to apply the autoscaling configuration to. The current instance pool is selected by default.
7. In the **Cooldown in Seconds** box, enter the minimum amount of time to wait between scaling events. The cooldown period gives the system time to stabilize before rescaling. The minimum value is 300 seconds.
8. In the **Autoscaling Policy** area, define the criteria that trigger autoscaling actions and the actions to take:
    a. Enter a name for the autoscaling policy.
    b. Select the **Performance Metric** that triggers an increase or decrease in the number of instances in the instance pool. For example, CPU utilization or memory utilization.

c. In the **Scaling Limits** area, specify the number of instances in the instance pool:
   - **Minimum Number of Instances:** The minimum number of instances that the instance pool is allowed to decrease to.
   - **Maximum Number of Instances:** The maximum number of instances that the instance pool is allowed to increase to. The maximum number of instances depends on the limits for your tenancy. For more information, see Service Limits.
   - **Initial Number of Instances:** The number of instances to launch in the instance pool immediately after autoscaling is enabled. After autoscaling retrieves performance metrics, the number of instances is automatically adjusted from this initial number to a number that is based on the limits that you set.

d. In the **Scaling Rule** area, specify the thresholds that the performance metric must reach to trigger a scaling event:
   - Select a **Scale-Out Operator** and **Threshold Percentage** at which to increase the number of instances. Then enter the **Number of Instances to Add**. For example, when CPU utilization is greater than 90%, add 10 instances to the instance pool.
   - Select a **Scale-In Operator** and **Threshold Percentage** at which to decrease the number of instances. Then enter the **Number of Instances to Remove**. For example, when CPU utilization is less than 50%, remove 5 instances from the instance pool.

9. **Tags:** Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.

10. Click **Create**.
    Autoscaling runs. The cooldown period starts when the instance pool's status changes from **SCALING** to **RUNNING**.

To create an autoscaling configuration from the Autoscaling Configuration page

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Autoscaling Configurations**.
2. Click **Create Autoscaling Configuration**.
3. Select the **Compartment** that you want to create the autoscaling configuration in.
4. Enter a name for the autoscaling configuration.
5. Select the **Instance Pool** to apply the autoscaling configuration to.
6. In the **Cooldown in Seconds** box, enter the minimum amount of time to wait between scaling events. The cooldown period gives the system time to stabilize before rescaling. The minimum value is 300 seconds.
7. In the **Autoscaling Policy** area, define the criteria that trigger autoscaling actions and the actions to take:
    a. Enter a name for the autoscaling policy.
    b. Select the **Performance Metric** that triggers an increase or decrease in the number of instances in the instance pool. For example, CPU utilization or memory utilization.

c. In the **Scaling Limits** area, specify the number of instances in the instance pool:
   - **Minimum Number of Instances:** The minimum number of instances that the instance pool is allowed to decrease to.
   - **Maximum Number of Instances:** The maximum number of instances that the instance pool is allowed to increase to. The maximum number of instances depends on the limits for your tenancy. For more information, see Service Limits.
   - **Initial Number of Instances:** The number of instances to launch in the instance pool immediately after autoscaling is enabled. After autoscaling retrieves performance metrics, the number of instances is automatically adjusted from this initial number to a number that is based on the limits that you set.

d. In the **Scaling Rule** area, specify the thresholds that the performance metric must reach to trigger a scaling event:
   - Select a **Scale-Out Operator** and **Threshold Percentage** at which to increase the number of instances. Then enter the **Number of Instances to Add**. For example, when CPU utilization is greater than 90%, add 10 instances to the instance pool.
   - Select a **Scale-In Operator** and **Threshold Percentage** at which to decrease the number of instances. Then enter the **Number of Instances to Remove**. For example, when CPU utilization is less than 50%, remove 5 instances from the instance pool.

8. In the **Autoscaling Policy** area, define the criteria that trigger autoscaling actions and the actions to take:
   a. Enter a name for the autoscaling policy.
   b. Select the **Performance Metric** that triggers an increase or decrease in the number of instances in the instance pool. For example, CPU utilization or memory utilization.

c. In the **Scaling Limits** area, specify the number of instances in the instance pool:
   - **Minimum Number of Instances:** The minimum number of instances that the instance pool is allowed to decrease to.
   - **Maximum Number of Instances:** The maximum number of instances that the instance pool is allowed to increase to. The maximum number of instances depends on the limits for your tenancy. For more information, see Service Limits.
   - **Initial Number of Instances:** The number of instances to launch in the instance pool immediately after autoscaling is enabled. After autoscaling retrieves performance metrics, the number of instances is automatically adjusted from this initial number to a number that is based on the limits that you set.

d. In the **Scaling Rule** area, specify the thresholds that the performance metric must reach to trigger a scaling event:
   - Select a **Scale-Out Operator** and **Threshold Percentage** at which to increase the number of instances. Then enter the **Number of Instances to Add**. For example, when CPU utilization is greater than 90%, add 10 instances to the instance pool.
   - Select a **Scale-In Operator** and **Threshold Percentage** at which to decrease the number of instances. Then enter the **Number of Instances to Remove**. For example, when CPU utilization is less than 50%, remove 5 instances from the instance pool.

9. **Tags:** Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.

10. Click **Create**.
    Autoscaling runs. The cooldown period starts when the instance pool's status changes from **SCALING** to **RUNNING**.

To edit an autoscaling configuration

You can change these characteristics of an autoscaling configuration:

- Name
- Cooldown period between autoscaling actions

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Autoscaling Configurations**.
2. Click the autoscaling configuration that you're interested in.
3. Click **Edit**.
4. Update the **Name** or **Cooldown in Seconds**, and then click **Save Changes**.

To edit an autoscaling policy

You can change these characteristics of an autoscaling policy:

- Name
- Which performance metric triggers an autoscaling action
- Scale-out and scale-in operators and thresholds
- The number of instances to add or remove

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Autoscaling Configurations**.
2. Click the autoscaling configuration that you're interested in.

3. In the **Autoscaling Policies** area, click **Edit**.
4. Make your changes, and then click **Save**.

To disable an autoscaling configuration

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Autoscaling Configurations**.
2. Click the autoscaling configuration that you're interested in.
3. Click **Disable**, and then confirm when prompted.

To delete an autoscaling configuration

When you delete an autoscaling configuration, the instance pool remains in its most recent state.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Autoscaling Configurations**.
2. Click the autoscaling configuration that you're interested in.
3. Click **Delete**, and then confirm when prompted.

To manage tags for an autoscaling configuration

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Autoscaling Configurations**.
2. Click the autoscaling configuration that you're interested in.
3. Click the **Tags** tab to view or edit the existing tags. Or click **Apply tag(s)** to add new ones.

For more information, see Resource Tags.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the Autoscaling API to manage autoscaling configurations and policies.

Managing Cluster Networks

A cluster network is a pool of high performance computing (HPC) instances that are connected with a high-bandwidth, ultra low-latency network. Each node in the cluster is a bare metal machine located in close physical proximity to the other nodes. A remote direct memory access (RDMA) network between nodes provides latency as low as single-digit microseconds, comparable to on-premises HPC clusters.

Cluster networks are designed for highly demanding parallel computing workloads. For example:

- Computational fluid dynamics simulations for automotive or aerospace modeling
- Financial modeling and risk analysis
- Biomedical simulations
- Trajectory analysis and design for space exploration
- Artificial intelligence and big data workloads

Cluster networks are built on top of the instance pools feature. Most operations in the instance pool are managed directly by the cluster network, though you can monitor and add tags to the underlying instance pool.

For more information about how to access and store the data that you want to process in your cluster networks, see FastConnect Overview, Overview of File Storage, Overview of Object Storage, and Overview of Block Volume.

Note

Cluster networks are not available in Government Cloud realms.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Supported Regions and Availability Domains for Cluster Networks

Cluster networks are supported in the following regions:

- Germany Central (Frankfurt)
- Japan East (Tokyo)
- UK South (London)
- US East (Ashburn)

The availability domain that you create the cluster network in must have cluster network-capable hardware. Typically, to be able to create the multiple HPC instances that are contained in a cluster network, you must request a service limit increase.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don't have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: For a typical policy that gives access to cluster networks, see Let users manage Compute instance configurations, instance pools, and cluster networks.

Important

See this known issue for information about the policy statements that are required if the instance configuration or load balancer associated with the cluster network includes defined tags.

Tagging Resources

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the desired tags. For general information about applying tags, see Resource Tags.

Prerequisites

Create an instance configuration for the instance pool that is managed by the cluster network. To do this:

a. Create an instance with the following settings:

- **Choose an operating system or image source:** Click **Change Image Source**, and then click **Oracle Images**. Select the Oracle HPC cluster networking image.

- **Instance type:** Select **Bare Metal Machine**.
- **Instance Shape:** Select the **BM.HPC2.36** shape. For more information about this shape, see Compute Shapes.

b. Create an instance configuration using the instance that you created in the previous step as a template.

Optionally, you can delete the instance after you create the instance configuration.

Using the Console

To create a cluster network

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Cluster Networks**.
2. Click **Create Cluster Network**.
3. Select the compartment that you want to create the cluster network in.
4. Specify a name for the cluster network. It doesn't have to be unique, and you can change it later.
5. Select the availability domain to run the cluster network in. Only the availability domains with cluster network-capable hardware can be selected.
6. In the **Configure networking** section, specify the network that you want to use to administer the cluster network. This network is separate from the closed RDMA network between nodes within the cluster. Enter the following information:
   - **Select a virtual cloud network:** The virtual cloud network (VCN) for the cluster network.
   - **Select a subnet:** The subnet for the cluster network.
7. In the **Configure instance pool** section, enter the following:
   - **Instance pool name:** A name for the instance pool that is managed by the cluster network.
   - **Number of instances:** The number of instances in the pool.

- **Select an instance configuration:** Select the instance configuration to use when creating the instances in the cluster network's instance pool, as described in the prerequisites.

8. **Show Advanced Tagging Options:** Optionally, you can add tags. If you have permissions to create a resource, you also have permissions to add free-form tags to that resource. To add a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should add tags, skip this option (you can add tags later) or ask your administrator.
9. Click **Create Cluster Network**.
   To track the progress of the operation, you can monitor the associated work request. For more information, see Using the Console to View Work Requests.
   If the required number of instances is not available or if some instances fail to launch, the cluster network is not created. Wait a few minutes, and then try launching the cluster network again.

To edit the name of a cluster network

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Cluster Networks**.
2. Click the cluster network that you're interested in.
3. Click **Edit Name**.
4. Enter a new name, and then click **Save Changes**.

To manage tags for a cluster network

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Cluster Networks**.
2. Click the cluster network that you're interested in.
3. Click the **Tags** tab to view or edit the existing tags. Or click **Add Tags** to add new ones.

For more information, see Resource Tags.

To delete a cluster network

Warning

When you delete a cluster network, all of its resources are permanently deleted, including associated instances, attached boot volumes, and block volumes.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Cluster Networks**.
2. Click the cluster network that you're interested in.
3. Click **Terminate**, and then confirm when prompted.
   To track the progress of the operation, you can monitor the associated work request. For more information, see Using the Console to View Work Requests.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use these API operations to work with cluster networks:

- CreateClusterNetwork
- GetClusterNetwork
- ListClusterNetworks
- ListClusterNetworkInstances
- UpdateClusterNetwork

- ChangeClusterNetworkCompartment
- TerminateClusterNetwork

Dedicated Virtual Machine Hosts

The Oracle Cloud Infrastructure Compute service's dedicated virtual machine host feature provides you with the ability to run your Compute virtual machine (VM) instances on dedicated servers that are a single tenant and not shared with other customers. This enables scenarios where you have compliance and regulatory requirements for isolation that prevent you from using shared infrastructure.

Support and Limitations

When you create a dedicated virtual machine host, you select a shape for the host, see Dedicated Virtual Machine Host Shapes for the available shapes and shape details for dedicated virtual machine host. Note that there is a difference between the number listed for billed OCPUs compared to available OCPUs, this is because four OCPUs are reserved for virtual machine management.

You are billed for the dedicated virtual machine host as soon as you create it, but you are not billed for any of the individual VM instances you place on it. You will still be billed for image licensing costs if they apply to the image you are using for the VM instances.

For instances launched on a dedicated virtual machine host, all of the VM.Standard2 shapes are supported, for details about these shapes, see VM Shapes. Most of the Compute service features for VM instances are supported for instances running on dedicated virtual machine hosts, however the following features are not supported:

- Instance configurations
- Instance pools
- Autoscaling

Reboot migration is also not supported for dedicated virtual machine hosts, in this scenario, you need to manually migrate the instance. See Moving an Instance with Manual Migration for this process.

You can mix VM instances with different shapes on the same dedicated virtual machine host. This may impact the maximum number of instances you can place on the dedicated virtual machine host, for more information see Optimizing Capacity on your Dedicated Virtual Machine Host.

Managing Dedicated Virtual Machine Hosts

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: The simplest policy to enable users to work with dedicated virtual machine hosts is listed in Let users manage Compute dedicated virtual machine hosts. It gives the specified group general access to launching instances on and managing dedicated virtual machine hosts.

See Let users launch Compute instances on dedicated virtual machine hosts for an example of a policy that allows users to launch instances on dedicated virtual machine hosts without giving them full administrator access to dedicated virtual machine hosts.

Creating a Dedicated Virtual Machine Host

You need to create a dedicated virtual machine host before you can place any instances on it. When creating the dedicated virtual machine host, you select an availability domain and fault domain to launch it in. All the VM instances you place on the host will subsequently be created in this availability domain and fault domain. You also select a compartment when you create the dedicated virtual machine host, but you can move it to a new compartment later without impacting any of the instances placed on it. You can also create the instances in a different compartment than the dedicated virtual machine, or move them to difference compartments after they have been launched.

To create a dedicated virtual machine host using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Dedicated Virtual Machine Hosts**.
2. Click **Create Dedicated Virtual Machine Host**.
3. Fill in the required volume information:
   - **Compartment**: The compartment for the dedicated virtual machine host.
   - **Name**: A user-friendly name or description.
   - **Availability Domain**: The availability domain for the dedicated virtual machine host.
   - **Fault Domain**: The fault domain for the dedicated virtual machine host.
   - **Shape**: The shape to use for the dedicated virtual machine host.
4. Click **Create Dedicated Virtual Machine Host**.

To create a dedicated virtual machine host using the CLI

Open a command prompt and run:

```
oci compute dedicated-vm-host create --dedicated-vm-host-shape DVH.Standard2.52 --wait-for-state ACTIVE
--display-name <display_name> --availability-domain <availability_domain> --compartment-id <compartment_
ID>
```

It can take up to 15 minutes for the dedicated virtual machine host to be fully created. It must be in the `ACTIVE` state before you can launch an instance on it.

To query the current state of a dedicated virtual machine host using the CLI, run the following command:

```
oci compute dedicated-vm-host get --dedicated-vm-host-id <dedicatedVMhost_ID>
```

Deleting a Dedicated Virtual Machine Host

To delete a dedicated virtual machine host using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Dedicated Virtual Machine Hosts**.
2. In the list of dedicated virtual machine hosts, find the dedicated virtual machine hosts you want to delete.
3. Click the name of the dedicated virtual machine host to display the details page.
4. Click **Delete**, and then respond to the confirmation prompt.

If you try to delete a dedicated virtual machine host that still has running instances hosted on it, the delete operation will fail, you need to ensure that all of the instances hosted on it have been terminated. To check if there are any instances still running on the dedicated virtual machine host, go to the **Details** page for the dedicated virtual machine host, and click **Hosted Instances** in the **Resources** section. You need to perform this step for each compartment in your tenancy that may have instances running on your dedicated virtual machine host. To change the compartment for the **Host Instances** list, select a different compartment from the **Table Scope** drop down.

To delete a dedicated virtual machine host using the CLI

Open a command prompt and run:

```
oci compute dedicated-vm-host delete --dedicated-vm-host-id <dedicated_VM_host_ID>
```

Before you can delete a dedicated machine host, all of the instances running on it must be terminated.

To list the instances running on a dedicated virtual machine host using the CLI, run the following command:

```
oci compute dedicated-vm-host list --compartment-id <compartment_ID> --dedicated-vm-host-id
<dedicatedVMhost_ID>
```

You need to run this command for every compartment in your tenancy that may have instances that you placed on the dedicated virtual machine host that you want to delete.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the following operations for working with dedicated virtual machine hosts:

- CreateDedicatedVmHost
- DeleteDedicatedVmHost
- ListDedicatedVmHosts
- ListDedicatedVmHostShapes
- ListDedicatedVmHostInstances
- ListDedicatedVmHostInstanceShapes
- UpdateDedicatedVmHost
- ChangeDedicatedVmHostCompartment

Instances on Dedicated Virtual Machine Hosts

Placing an Instance on a Dedicated Virtual Machine Host

You place an instance on a dedicated virtual machine host at the time that you create the instance. The steps are the same as creating a regular instance, you just need specify that you want to create the instance on a dedicated virtual machine host when you create the instance. See Creating an Instance for the steps to create an instance. Once you get to the **Advanced Options** section of the form, using the following steps to place the instance in a dedicated virtual machine host.

To place an instance on a dedicated virtual machine host using the Console

1. Perform the initial steps to create an instance based on an image and shape type that support placement on a dedicated virtual machine, up to the **Configure networking** section.
2. Click **Show Advanced Options**, and then click the **Host** tab.
3. Check **Launch the virtual machine on a dedicated host**.
4. Select the dedicated virtual machine host you want to place the instance on from the list.
5. Click **Create**.

Note

Only dedicated virtual machine hosts with sufficient capacity to launch an instance based on the shape you have specified will be displayed in the **Dedicated Virtual Machine Host** drop down list. If you have dedicated virtual machine host and it does not appear in the list, you need to do one of the following to place the instance on a dedicated virtual machine host:

- Terminate instances you no longer need on the dedicated virtual machine host to free up capacity.
- Choose another smaller shape for the instance you are trying to place on the dedicated virtual machine host.
- Create a new dedicated virtual machine host to place the instance on.

For more information, see Optimizing Capacity on your Dedicated Virtual Machine Host.

If you're using the CLI or REST API to create the instance, you just need to pass the dedicated virtual machine host OCID in the optional parameter `dedicatedVmHostId` when you use the LaunchInstance operation. If you try to launch an instance with a shape requiring more capacity than what is available on the dedicated virtual machine host you are trying to place it on, the launch operation will fail. To avoid this you can use the ListDedicatedVmHosts operation and pass the shape you want to use when launching the instance in the `InstanceShapeNameQueryParam` parameter. This will return all the dedicated virtual machine hosts that you can place the instance in.

The following example demonstrates how to call this operation in the CLI to return all the dedicated virtual machine hosts with sufficient capacity for you to place an instance launched using the VM.Standard2.16 shape:

```
compute dedicated-vm-host list --compartment-id <compartment_ID> --instance-shape-name VM.Standard2.16
```

Auditing your Dedicated Virtual Machine Host

To fully meet requirements for some compliance scenarios you may be required to validate that your instances are running on a dedicated virtual machine host and not using shared infrastructure. The Oracle Cloud Infrastructure Audit service provides you with the functionality to do this. Use the steps described in the Viewing Audit Log Events to access the log events for the dedicated virtual machine host.

The steps described in the **To search log events** section walk you through how to retrieve the log events with the data you need to verify that your instances are running on a dedicated virtual machine host. For this procedure:

- Ensure that you select the dedicated virtual machine host's compartment and not the compartment for the instances hosted on it.
- Use the dedicated virtual machine host's OCID as the search keyword.

Once you have retrieved the log events for the dedicated virtual machine host, view the log event lower-level details, and check the contents of the `responsePayload` property. This property should contain the OCIDs for the instances running on the dedicated virtual machine host.

Optimizing Capacity on your Dedicated Virtual Machine Host

When you place an instance on a dedicated virtual machine host using the Console, only dedicated virtual machine hosts with sufficient capacity to launch an instance based on the shape you have specified will be displayed in the **Dedicated Virtual Machine Host** drop down list. If you don't see your dedicated virtual machine host in the list, to understand why, it may help to understand how instances are launched in this scenario.

When you place an instance on a dedicated virtual machine host, Oracle Cloud Infrastructure launches them in a manner to optimize performance. For example, a dedicated virtual

machine host created based on the DVH.Standard2.52 shape has two sockets with 24 cores configured per socket. Instances are placed so that each instance will only use resources local to a single physical socket. In scenarios where you are creating and terminating instances with a mix of shapes, this can result in inefficient distribution of resources, meaning that not all OCPUs on a dedicated virtual machine host are available to be used. In this scenario, it may appear that a dedicated virtual machine has enough OCPUs to launch an additional instance on it, but the instance will fail to launch because of their distribution.

In this example, if you are launching instances using a shape with 16 OCPUs on a dedicated virtual machine host, you can only launch a maximum of two instances using that shape, you cannot launch a third instance with 16 OCPUs, even though the remaining number of OCPUs showing for the dedicated virtual machine host is 16. You can launch additional instances using shapes with a smaller number of OCPUs.

When designing your cloud footprint, we recommend that you plan to always launch the largest instance first.

Connecting to an Instance

You can connect to a running instance by using a Secure Shell (SSH) or Remote Desktop connection. Most UNIX-style systems include an SSH client by default. To connect to a Linux instance from a Windows system, you can download a free SSH client called PuTTY from http://www.putty.org.

Required IAM Policy

To connect to a running instance with SSH, you don't need an IAM policy to grant you access. However, to SSH you need the public IP address of the instance (see Prerequisites below). If there's a policy that lets you launch an instance, that policy probably also lets you get the instance's IP address. The simplest policy that does both is listed in Let users launch Compute instances.

For administrators: Here's a more restrictive policy that lets the specified group get the IP address of existing instances and use power actions on the instances (e.g., stop, start, etc.),

but not launch or terminate instances. The policy assumes the instances and the cloud network are together in a single compartment (XYZ):

```
Allow group InstanceUsers to read virtual-network-family in compartment XYZ

Allow group InstanceUsers to use instance-family in compartment XYZ
```

If you're new to policies, see Getting Started with Policies and Common Policies. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services.

Prerequisites

You'll need the following information to connect to the instance:

- For Linux instances: The full path to the key pair that you used when you launched the instance. For information about generating key pairs, see Managing Key Pairs on Linux Instances.
- The default user name for the instance. If you used an Oracle-provided Linux, CentOS, or Windows image to launch the instance, the user name is `opc`. If you used the Ubuntu image to launch the instance, the user name is `ubuntu`.
- The public IP address of the instance. You can get the address from the Instance Details page in the Console. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**. Then, select your instance. Alternatively, you can use the Core Services API `ListVnicAttachments` and `GetVnic` operations.
- For Windows instances: If you're connecting to the instance for the first time, you will need the initial password for the instance. You can get the password from the Instance Details page in the Console.

Connecting to a Linux Instance

Log in to your instance using SSH.

Connecting to Your Linux Instance from a Unix-style System

1. Use the following command to set the file permissions so that only you can read the file:

   ```
   $ chmod 400 <private_key>
   ```

   <private_key> is the full path and name of the file that contains the private key associated with the instance you want to access.

2. Use the following SSH command to access the instance.

   ```
   $ ssh -i <private_key> <username>@<public-ip-address>
   ```

   <private_key> is the full path and name of the file that contains the private key associated with the instance you want to access.
   <username> is the default name for the instance. For Oracle Linux and CentOS images, the default user name is `opc`. For the Ubuntu image, the default name is `ubuntu`.
   <public-ip-address> is your instance IP address that you retrieved from the Console.

Connecting to Your Linux Instance from a Windows System

1. Open `putty.exe`.
2. In the **Category** pane, expand **Window**, and then select **Translation**.
3. In the **Remote character set** drop-down list, select **UTF-8**. The default locale setting on Linux-based instances is UTF-8, and this configures PuTTY to use the same locale.
4. In the **Category** pane, select **Session** and enter the following:
   - **Host Name (or IP address)**:
     <username>@*<public-ip-address>*
     <username> is the default name for the instance. For Oracle Linux and CentOS images, the default user name is `opc`. For the Ubuntu image, the default name is `ubuntu`.
     <public-ip-address> is your instance public IP address that you retrieved from the Console

- **Port:** 22
- **Connection type:** SSH

5. In the **Category** pane, expand **Connection**, expand **SSH**, and then click **Auth**.
6. Click **Browse**, and then select your private key.
7. Click **Open** to start the session.
   If this is your first time connecting to the instance, you might see a message that the server's host key is not cached in the registry. Click **Yes** to continue the connection.

Connecting to a Windows Instance

You can connect to a Windows instance by using a Remote Desktop connection. Most Windows systems include a Remote Desktop client by default.

To enable Remote Desktop Protocol (RDP) access to the Windows instance, you need to add a stateful ingress security rule for TCP traffic on destination port 3389 from source 0.0.0.0/0 and any source port. You can implement this security rule in either a network security group that the Windows instance belongs to, or a security list that is used by the instance's subnet.

To enable RDP access

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the cloud network you're interested in.
3. To add the rule to a network security group that the instance belongs to:
   a. Under **Resources**, click **Network Security Groups**. Then click the network security group that you're interested in.
   b. Click **Add Rules**.
   c. Enter the following values for the rule:

- **Stateless:** Leave the check box unselected
- **Source Type:** CIDR
- **Source CIDR:** 0.0.0.0/0
- **IP Protocol:** RDP (TCP/3389)
- **Source Port Range:** All
- **Destination Port Range:** 3389

d. When done, click **Add**.

4. Or, to add the rule to a security list that is used by the instance's subnet:
   a. Under **Resources**, click **Security Lists**. Then click the security list you're interested in.
   b. Click **Add Ingress Rules**.
   c. Enter the following values for the rule:
      - **Stateless:** Leave the check box unselected
      - **Source Type:** CIDR
      - **Source CIDR:** 0.0.0.0/0
      - **IP Protocol:** RDP (TCP/3389)
      - **Source Port Range:** All
      - **Destination Port Range:** 3389
   d. When done, click **Add Ingress Rules**.

Connecting to Your Windows Instance from a Remote Desktop Client

1. Open the Remote Desktop client.
2. In the **Computer** field, enter the public IP address of the instance you want to connect to. Your public IP is the instance address you get from the Console.

3. The **User name** is **opc**. Depending on the Remote Desktop client you are using, you might have to connect to the instance before you can enter this credential.
4. Click **Connect** to start the session.
5. Accept the certificate if you are prompted to do so.
6. If you are connecting to the instance for the first time, enter the initial password that was provided to you by Oracle Cloud Infrastructure when you launched the instance. You will be prompted to change the password as soon as you log in. Your new password must be at least 12 characters long and must comply with Microsoft's password policy. Otherwise, enter the password that you created. If you are using a custom image, you might need to know the password for the instance that the image was created from. For details about Windows custom images, see Creating Windows Custom Images.
7. Press **Enter**.

Instance Console Connections

The Oracle Cloud Infrastructure Compute service provides console connections that enable you to remotely troubleshoot malfunctioning instances, such as:

- An imported or customized image that does not complete a successful boot.
- A previously working instance that stops responding.

There are two types of instance console connections:

- Serial console connections
- VNC console connections

Creating the Instance Console Connection

Before you can connect to the serial console or VNC console, you need to create the instance console connection.

To create the console connection for an instance

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
2. In the list of instances, find the instance you want to access the serial console for, and then click the instance name.
3. In the **Resources** section, click **Console Connections**.
4. Click **Create Console Connection**.
5. Specify the public key (.pub) portion for the SSH key. You can browse to a public key file on your computer or paste your public key into the text box. Then, click **Create Console Connection**.

When the console connection has been created and is available, the status changes to **ACTIVE**.

Connecting to the Serial Console

After you have created the console connection for the instance, you can then connect to the serial console by using a Secure Shell (SSH) connection. When you are finished with the serial console and have terminated the SSH connection, you should delete the serial console connection. If you do not disconnect from the session, Oracle Cloud Infrastructure terminates the serial console session after 24 hours and you must reauthenticate to connect again.

Note

Serial console connections for VM instances launched before September 2017

Serial console connections only work for VM instances launched in September 2017 or later.

Note

Serial console connections for bare metal instances launched before November 2017

Serial console connections only work for Bare Metal instances launched in November 2017 or later.

Connecting from Mac OS X and Linux Operating Systems

You connect to the serial console by using an SSH client. Mac OS X and most Linux distributions by default include the SSH client OpenSSH.

To connect to the serial console for an instance using OpenSSH on Mac OS X or Linux

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**. Click the instance you want to connect to.
2. On the **Instances Details** page, in the **Resources** section, click **Console Connections**.
3. Click the Actions icon (three dots), and then click **Connect with SSH**.
4. Select **LINUX/MAC OS** for **PLATFORM**.
5. Click **Copy** to copy the string to the clipboard.
6. Paste the connection string copied from the previous step to a terminal window on a Mac OS X or Linux system, and press **Enter** to connect to the console.
   If you are not using the default SSH key or ssh-agent, you can modify the serial console connection string to include the identity file flag, `-i` to specify the SSH key to use. You must specify this for both the SSH connection and the SSH ProxyCommand, as shown in the following line:

   ```
   ssh -i /<path>/<ssh_key> -o ProxyCommand='ssh -i /<path>/<ssh_key> -W %h:%p -p 443...
   ```

7. Press **Enter** again to activate the console.

Connecting from Windows Operating Systems

Windows does not include an SSH client by default, so you need to install one. You can use PuTTY, or there are options that include a version of OpenSSH such as:

- Git for Windows
- Windows Subsystem for Linux

The steps to connect to the serial console from the PuTTY client are different from the steps for OpenSSH.

To connect to the serial console for an instance on Microsoft Windows

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**. Click the instance you want to connect to.
2. On the **Instances Details** page, in the **Resources** section, click **Console Connections**.
3. Click the Actions icon (three dots), and then click **Connect with SSH**.
4. If you are using PuTTY, select **WINDOWS** for **PLATFORM**.
   If you are using OpenSSH, select **LINUX/MAC OS** for **PLATFORM**.
5. Click **Copy** to copy the string to the clipboard.
6. Paste the connection string copied from the previous step to PuTTY or your OpenSSH client and press **Enter** to connect to the console.
7. Press **Enter** again to activate the console.

Connecting to the VNC Console

Warning

The VNC console connection uses SSH port forwarding to create a secure connection from your local system to the VNC server attached to your instance's console. While this is a secure way to use VNC over the internet, owners of multiuser systems should be aware that opening a port on the local system makes it available to all of the users on that system until a VNC client connects. For this reason, we don't recommend using this product on a multiuser system unless you take proper actions to secure the port or you isolate the VNC client by running it in a virtual environment, such as Oracle VM VirtualBox.

After you create the console connection for the instance, you need to set up a secure tunnel to the VNC server on the instance, and then you can connect with a VNC client.

Note

VNC console connections for VM instances launched before October 13, 2017

VNC console connections only work for VM instances launched on October 13, 2017 or later.

Note

VNC console connections for bare metal instances launched before February 21, 2019

VNC console connections only work for bare metal instances launched on February 21, 2019, or later, using one of the following shapes:

- BM.GPU2.2
- BM.HPC2.36
- BM.Standard2.52
- BM.DenseIO2.52
- BM.Standard.B1.44

To set up a secure tunnel to the VNC server on the instance using OpenSSH on Mac OS X or Linux

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**. Click the instance you want to connect to.
2. On the **Instances Details** page, in the **Resources** section, click **Console Connections**.
3. Click the Actions icon (three dots), and then click **Connect with VNC**.
4. Select **LINUX/MAC OS** for **PLATFORM**.
5. Click **Copy** to copy the string to the clipboard.
6. Paste the connection string copied from the previous step to a terminal window on a Mac OS X or Linux system, and press **Enter** to set up the secure connection.
7. After the connection is established, open your VNC client and specify `localhost` as the host to connect to and `5900` as the port to use.

Note

Mac OS X Screen Sharing.app Not Compatible with VNC Console Connections

The Mac OS X built-in VNC client, Screen Sharing.app does not work with VNC console connections in Oracle Cloud Infrastructure. Use another VNC client, such as Real VNC Viewer or Chicken.

To set up a secure tunnel to the VNC server on the instance using PowerShell on Windows

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**. Click the instance you want to connect to.
2. On the **Instances Details** page, in the **Resources** section, click **Console Connections**.
3. Click the Actions icon (three dots), and then click **Connect with VNC**.
4. Select **WINDOWS** for **PLATFORM**.
5. Click **Copy** to copy the string to the clipboard.
6. Paste the connection string copied from the previous step to Windows Powershell and press **Enter** to set up the secure connection.
7. After the connection is established, open your VNC client and specify `localhost` as the host to connect to and `5900` as the port to use.

Note

Secure Connection Warning

When you connect, you may see a warning from the VNC client that the connection is not encrypted. Since you are connecting through SSH, the connection is secure, so this is not an issue.

Troubleshooting Instances from Instance Console Connections

After you are connected with an instance console connection, you can perform various tasks, such as:

- Edit system configuration files.
- Add or reset the SSH keys for the **opc** user.

Both of these tasks require you to boot into a bash shell, in maintenance mode.

Note

The following tasks describe steps specific to instances running Oracle Linux 7, connecting from OpenSSH. Other OS versions and SSH clients may require different steps.

To boot into maintenance mode

1. Reboot the instance from the Console
    - In the Console, on the **Instances Details page**, click **Reboot**.
2. When the reboot process starts, switch back to the terminal window, and you see

Console messages start to appear in the window. As soon as you see the GRUB boot menu appear, use the up/down arrow key to stop the automatic boot process, enabling you to use the boot menu.

3. In the boot menu, highlight the top item in the menu, and type `e` to edit the boot entry.
4. In edit mode, use the down arrow key to scroll down through the entries until you reach the line that starts with either `linuxefi` for instances running Oracle Linux 7.x, or `kernel` for instances running Oracle Linux 6.x.
5. At the end of that line, add the following:

   ```
   init=/bin/bash
   ```

6. Reboot the instance from the terminal window by entering the keyboard shortcut **CTRL+X**.

When the instance has rebooted, you'll see the Bash shell command line prompt, and you can proceed with either of the following procedures.

To edit the system configuration files

1. From the Bash shell, run the following command to load the SELinux policies to preserve the context of the files you are modifying:

   ```
   /usr/sbin/load_policy -i
   ```

2. Run the following command to remount the root partition with read/write permissions:

   ```
   /bin/mount -o remount, rw /
   ```

3. Edit the configuration files as needed to try to recover the instance.
4. After you have finished editing the configuration files, to start the instance from the existing shell, run the following command:

   ```
   exec /usr/lib/systemd/systemd
   ```

   Alternatively, to reboot the instance, run the following command:

   ```
   /usr/sbin/reboot -f
   ```

To add or reset the SSH key for the opc user

1. From the Bash shell, run the following command to load the SELinux policies to preserve the context of the files you are modifying:

   ```
   /usr/sbin/load_policy -i
   ```

2. Run the following command to remount the root partition with read/write permissions:

   ```
   /bin/mount -o remount, rw /
   ```

3. From the Bash shell, run the following command to change to the SSH key directory for the **opc** user:

   ```
   cd ~opc/.ssh
   ```

4. Rename the existing authorized keys file with the following command:

   ```
   mv authorized_keys authorized_keys.old
   ```

5. Replace the contents of the public key file with the new public key file with the following command:

   ```
   echo '<contents of .pub key file>' >> authorized_keys
   ```

6. Restart the instance by running the following command:

   ```
   /usr/sbin/reboot -f
   ```

Exiting the Instance Console Connection

To exit the serial console connection

When using SSH, the ~ character at the beginning of a new line is used as an escape character.

- To exit the serial console, enter:

  ```
  ~.
  ```

- To suspend the SSH session, enter:

  ```
  ~^z
  ```

The ^ character represents the **CTRL** key

- To see all the SSH escape commands, enter:

```
~?
```

To exit the VNC console connection

1. Close the VNC client.
2. In the Terminal or Powershell window, type `CTRL C`

When you are finished using the console connection, delete the connection for the instance.

To delete the console connection for an instance

1. In the Console, on the **Instances Details** page, in the **Resources** section, click **Console Connections**.
2. Click the Actions icon (three dots), click **Delete**, and then click **OK** to confirm.

Adding Users on an Instance

If you created your instance using an Oracle-provided Linux or CentOS image, you can use SSH to access your instance from a remote host as the `opc` user. If you created your instance using the Ubuntu image, you can use SSH to access your instance from a remote host as the `ubuntu` user. After logging in, you can add users on your instance.

If you created your instance using an Oracle-provided Windows image, you can create new users after you log on to the instance through a Remote Desktop client.

Creating Additional SSH-Enabled Users on Linux Instances

If you do not want to share your SSH key, you can create additional SSH-enabled users:

- Generate SSH key pairs for the users offline.
- Add the new users.
- Append a public key to the `~/.ssh/authorized_keys` file for each new user.

Tip

If you re-create an instance from an Oracle-provided image, users and SSH public keys that you added or edited manually (that is, users that weren't defined in the machine image) must be added again.

If you need to edit the `~/.ssh/authorized_keys` file of a user on your instance, start a second SSH session before you make any changes to the file and ensure that it remains connected while you edit the file. If the `~/.ssh/authorized_keys` file becomes corrupted or you inadvertently make changes that lock you out of the instance, you can use the backup SSH session to fix or revert the changes. Before closing the backup SSH session, test all changes you made by logging in with the new or updated SSH key.

The new users then can SSH to the instance using the appropriate private keys.

To create an additional SSH-enabled user:

1. Generate an SSH key pair for the new user. See Managing Key Pairs on Linux Instances.
2. Copy the public key value to a text file for use later in this procedure.

3. Log in to your instance. See Connecting to an Instance.
4. Become the root user:

```
sudo su
```

5. Create the new user:

```
useradd <new_user>
```

6. Create a `.ssh` directory in the new user's home directory:

```
mkdir /home/<new_user>/.ssh
```

7. Copy the SSH public key that you saved to a text file into the `/home/new_user/.ssh/authorized_keys` file:

```
echo <public_key> > /home/<new_user>/.ssh/authorized_keys
```

8. Change the owner and group of the `/home/username/.ssh` directory to the new user:

```
chown -R <new_user>:<group> /home/<new_user>/.ssh
```

9. To enable `sudo` privileges for the new user, run the `visudo` command and edit the `/etc/sudoers` file as follows:
    a. In `/etc/sudoers`, look for:

```
%<username> ALL=(ALL) NOPASSWD: ALL
```

    b. Add the following line immediately after the preceding line:

```
%<group> ALL=(ALL) NOPASSWD: ALL
```

You can now log in as the new user.

Creating Additional Users on a Windows Instance

To create a new user on a Windows Instance:

1. Log in to your instance using a Remote Desktop client.
2. On the **Start** menu, click **Control Panel**.
3. Click **User Accounts**, and then click **User Accounts** again.
4. Click **Manage User Accounts**.
5. Click **Manage Another Account**.
6. Click **Add User Account**.
7. Enter a **User name** and **Password**.
8. Confirm the password, and then create a **Password hint**.
9. Click **Next**.
10. Verify the account, and then click **Finish**.

You can now log in as the new user.

Displaying the Console for an Instance

You can capture and display the serial console data for an instance. The data includes configuration messages that occur when the instance boots, such as kernel and BIOS messages, and is useful for checking the status of the instance or diagnosing problems. Note that the *raw* console data, including multi-byte characters, is captured.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: The policy in Let users launch Compute instances includes the ability to manage console history data. If the specified group doesn't need to launch instances or attach volumes, you could simplify that policy to include only `manage instance-family`, and remove the statements involving `volume-family` and `virtual-network-family`.

Using the API

For information about using the API and signing requests, see REST APIs.

Use these API operations to manage the serial console logs:

- CaptureConsoleHistory
- DeleteConsoleHistory
- GetConsoleHistory
- GetConsoleHistoryContent
- ListConsoleHistories

Getting Instance Metadata

The metadata for an instance includes information such as the instance's OCID, display name, hostname, region, availability domain, fault domain, compartment, shape, image, creation date, state, tags, and any custom metadata that you provide, such as an SSH public key. The instance metadata also includes the region identifier for an instance, such as us-phoenix-1, in the `canonicalRegionName` field.

You can find some of this information in the Console on the **Instance Details** page, or you can get all of it by logging in to the instance and using the metadata service. The service runs on every instance and is an HTTP endpoint listening on 169.254.169.254.

Required IAM Policy

No IAM policy is required if you're logged in to the instance and using cURL to get the metadata.

For administrators: Users can also get instance metadata through the Compute API (for example, with GetInstance). The policy in Let users launch Compute instances covers that ability. If the specified group doesn't need to launch instances or attach volumes, you could simplify that policy to include only `manage instance-family`, and remove the statements involving `volume-family` and `virtual-network-family`.

If you're new to policies, see Getting Started with Policies and Common Policies. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services.

Accessing Instance Metadata on Oracle-Provided Images

You can get instance metadata for Oracle-provided images by using cURL on Linux instances or an internet browser on Windows instances.

Instance metadata is available at the following URLs:

- All of the instance information:

  ```
  http://169.254.169.254/opc/v1/instance/
  ```

- Only the custom metadata:

  ```
  http://169.254.169.254/opc/v1/instance/metadata/
  ```

- The custom metadata only for a specified key name:

  ```
  http://169.254.169.254/opc/v1/instance/metadata/<key-name>
  ```

  <key-name> is `ssh_authorized_keys`, `user_data`, or any custom key name that you provided when you launched the instance. (For information about using the Core Services API to provide `user_data` to cloud-init, see LaunchInstanceDetails.)

- Information about the virtual network interface cards (VNICs) that are attached to the instance:

  ```
  http://169.254.169.254/opc/v1/vnics/
  ```

Here's an example response that shows of all of the information for an instance:

```
{
  "availabilityDomain": "cumS:PHX-AD-1",
  "faultDomain": "FAULT-DOMAIN-2",
  "compartmentId": "ocid.compartment.oc1..exampleuniqueID",
  "displayName": "my-example-instance",
  "hostname": "my-hostname",
  "id": "ocid1.instance.oc1.phx.exampleuniqueID",
  "image": "ocid1.image.oc1.phx.exampleuniqueID",
  "metadata": {
    "ssh_authorized_keys": "ssh-rsa
AAAAB3NzaC1yc2EAAAABJQAAAQEApzWsZ0DxxE+jNpsh5C3ncc18eZ06MCONWnP5D/8eqdGjUqqBU7lHvgaIqYHy1PH/B4w/pya56k4
1FLzdXFVAzCy4NGyE4XZjLcSSR4jW1As4r3WHY/f61Gc1Vicz39u+bB1XYaHm46zS4WrQEquqU4wbz70iwe50nSIhrGpvM5HWYOK0ds
VA7/zzw+yW37NUGa/QeM4/bJvCVg3BVjB6VWdmV7dFwRMeCaVJFQH3wKndvuJib78zoHl9sbYm74vzqTYSi/bVoIz9YnZ4bA3MS0Uqa
poK/m2M9T27+UA/lz/ILCKXP3+vNcVcjRplanJT/qlzhLiIiBCRo4RsdGxUIw== rsa-key-20181129"
  },
  "region": "phx",
  "canonicalRegionName": "us-phoenix-1",
  "shape": "VM.Standard2.1",
  "state": "Running",
  "timeCreated": 1569358494495,
  "agentConfig": {
    "monitoringDisabled": false
  },
  "definedTags": {
    "Operations": {
      "CostCenter": "42"
    }
  },
  "freeformTags": {
    "Department": "Finance"
  }
}
```

For more information about the data that is returned, see Instance.

Here's an example response that shows the VNICs that are attached to an instance:

```
[ {
  "vnicId" : "ocid1.vnic.oc1.phx.exampleuniqueID",
  "privateIp" : "10.0.3.6",
  "vlanTag" : 11,
```

```
  "macAddr" : "02:00:17:00:12:D3",
  "virtualRouterIp" : "10.0.3.1",
  "subnetCidrBlock" : "10.0.3.0/24",
  "nicIndex" : 0
}, {
  "vnicId" : "ocid1.vnic.oc1.phx.exampleuniqueID",
  "privateIp" : "10.0.4.3",
  "vlanTag" : 12,
  "macAddr" : "02:00:17:00:13:13",
  "virtualRouterIp" : "10.0.4.1",
  "subnetCidrBlock" : "10.0.4.0/24",
  "nicIndex" : 0
} ]
```

To use cURL to get Linux instance metadata

1. Connect to a Linux instance using SSH.
2. Use cURL to issue a GET request to the instance metadata URL that you're interested in. For example:

```
curl -L http://169.254.169.254/opc/v1/instance/
```

To use an internet browser to get Windows instance metadata

1. Connect to a Windows instance by using a Remote Desktop connection.
2. Open an internet browser and then navigate to the instance metadata URL that you're interested in.

Updating Instance Metadata

The Oracle Cloud Infrastructure Compute service lets you add and update custom metadata for an instance using the Command Line Interface (CLI) or REST APIs.

When you create an instance using the LaunchInstance operation you can specify custom metadata for the instance in the LaunchInstanceDetails datatype's `metadata` or `extendedMetadata` attributes. To update an instance's metadata, use the UpdateInstance

operation, specifying the custom metadata in the UpdateInstanceDetails datatype's `metadata` or `extendedMetadata` attributes. The `metadata` attribute supports key/value string pairs while the `extendedMetadata` attribute supports nested JSON objects.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: The policy in Let users launch Compute instances includes the ability to rename an instance. If the specified group doesn't need to launch instances or attach volumes, you could simplify that policy to include only `manage instance-family`, and remove the statements involving `volume-family` and `virtual-network-family`.

If you're new to policies, see Getting Started with Policies and Common Policies. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services.

Using the API

When you use the `UpdateInstance` operation, the instance's metadata will be the combination of the values specified in the UpdateInstanceDetails datatype's `metadata` or `extendedMetadata` attributes. Any set of key/value pairs specified for these attributes in the `UpdateInstance` operation will replace the existing values for these attributes, so you need

to include all the metadata values for the instance in each call, not just the ones you want to add. If you leave the attribute empty when calling `UpdateInstance`, the existing metadata values in that attribute will be used. You cannot specify a value for the same metadata key twice, this will cause the `UpdateInstance` operation to fail due to there being duplicate keys.

To understand this, consider the example scenario where you created an instance using the `LaunchInstance` operation and specified the following key/value pair for the `metadata` attribute:

```
"myCustomMetadataKey" : "myCustomMetadataValue"
```

If you then call the `UpdateInstance` operation, and add new metadata by specifying additional key/value pairs in the `extendedMetadata` attribute, but you leave the `metadata` attribute empty, do not include the `myCustomMetadataKey` key/value in the `extendedMetadata` attribute, as this will cause the operation to fail since that key already exists. If you do specify values for the metadata attribute, you need to include the `myCustomMetadataKey` key/value to maintain it in the instance's metadata. In this case, you can specify it in either of the attributes.

There are two reserved keys, `user_data` and `ssh_authorized_keys`, that can only be set for an instance at launch time, they cannot be updated later. If you use the metadata attribute to add or update metadata to an instance, you need to ensure that you include the values specified at launch time for both these keys, otherwise the `UpdateInstance` operation will fail.

Best Practices for Updating an Instance's Metadata

When using the `UpdateInstance` operation, Oracle recommends the following:

- Use the GetInstance operation to retrieve the existing custom metadata for the instance to ensure that you include the values you want to maintain in the appropriate attributes when you call `UpdateInstance`. The metadata values are returned in the `metadata` and `extendedMetadata` attributes for the Instance . For a code example demonstrating this, see the UpdateInstanceExample in the SDK for Java.
- Unless you are updating custom metadata that was added using the `metadata` attribute, use the `extendedMetadata` attribute to add custom metadata. Otherwise you need to include the launch time values for the `user_data` and `ssh_authorized_keys` reserved

keys. If you use the `metadata` attribute to add values and you leave out the values for these reserved keys or specify different values for them, the `UpdateInstance` call will fail.

Renaming an Instance

You can rename an instance without changing its Oracle Cloud Identifier (OCID).

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: The policy in Let users launch Compute instances includes the ability to rename an instance. If the specified group doesn't need to launch instances or attach volumes, you could simplify that policy to include only `manage instance-family`, and remove the statements involving `volume-family` and `virtual-network-family`.

If you're new to policies, see Getting Started with Policies and Common Policies. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the UpdateInstance operation to change the name of an instance.

Moving a Compute Instance to a New Host

This topic covers how to relocate a virtual machine or a bare metal instance by using reboot migration or a manual process.

Note

Dedicated virtual machine hosts do not support reboot migration. To relocate these instances use the process described in Moving an Instance with Manual Migration.

Reboot Migration

For instances with a date in the **Reboot Maintenance** field (available in the Console, CLI, and SDKs), you can reboot your instance to move it to new infrastructure. After you reboot the instance, the **Reboot Maintenance** field is cleared. This change indicates that the instance was moved successfully.

Prerequisites for Reboot Migration

1. Prepare the instance for reboot migration:
    - Ensure that any remote block volumes defined in `/etc/fstab` use the recommended options.
    - Ensure that any File Storage service (NFS) mounts use the `nofail` option.

- If you use the Oracle-provided script to configure secondary VNICs, ensure it runs automatically at startup.

Moving an Instance with Reboot Migration

After you complete the prerequisites:

1. Stop any running applications.
2. Reboot the instance.
3. Confirm that the **Reboot Maintenance** field no longer has a date.
4. Start and test any applications on the instance.

Moving an Instance with Manual Migration

For instances without a date in the **Reboot Maintenance** field (available in the Console, CLI, and SDKs), you must move the instance manually. This method requires that you terminate the instance, and then launch a new instance from the retained boot volume. Instances that have additional VNICs, secondary IP addresses, remote attached block volumes, or that belong to a backend set of a load balancer require additional steps.

Limitations and Warnings for Manual Migration

Be aware of the following limitations and warnings when performing a manual migration:

- Any public IP addresses assigned to your instance from a reserved public pool are retained. Any that were not assigned from a reserved public IP address pool will change. Private IP addresses do not change.
- MAC addresses, CPUIDs, and other unique hardware identifiers do change during the move. If any applications running on the instance use these identifiers for licensing or other purposes, be sure to take note of this information before moving the instance to help you manage the change.

Prerequisites for Manual Migration

1. Before moving the instance, document all critical details:
    - The instance's region, availability domain, and fault domain.
    - The instance's display name.
    - All private IP addresses, names, and subnets. Note that the instance can have multiple VNICs, and each VNIC can have multiple secondary IP addresses.
    - All private DNS names. The instance can have multiple VNICs, and each VNIC can have multiple secondary IP addresses. Each private IP address can have a DNS name.
    - Any public IP addresses assigned from a reserved public pool. Note that the instance can have multiple VNICs, and each VNIC can have multiple secondary private IP addresses. Each VNIC and secondary private IP address can have an attached public IP address.
    - Any remote block volumes attached to the instance.
    - Any tags on the instance or attached resources.
2. Prepare the instance for manual migration:
    - Ensure that any remote block volumes defined in `/etc/fstab` use the recommended options.
    - Ensure that any File Storage service (NFS) mounts use the `nofail` option.
    - If you have statically defined any network interfaces belonging to secondary VNICs using their MAC addresses, such as those defined in `/etc/sysconfig/network-scripts/ifcfg*`, those interfaces will not start due to the change in the MAC address. Remove the static mapping.
    - If you use the Oracle-provided script to configure secondary VNICs, ensure it runs automatically at startup.

Moving an Instance Manually

After you complete the prerequisites:

1. Stop any running applications.
2. Ensure that those applications will not start automatically.

Warning

When the relocated instance starts for the first time, remote block volumes, secondary VNICs, or any resource that relies on them, will not be attached. The absence of these resources can cause application issues.

3. If your instance has local NVMe storage (dense instances), you must back up this data:
   a. Create and attach one or more remote block volumes to the instance.
   b. Copy the data from the NVMe devices to the remote block volumes.
4. Unmount any remote block volumes or File Storage service (NFS) mounts.
5. Back up all remote block volumes. See Overview of Block Volume Backups for more information.
6. Create a backup of the root volume.

Important

Do not generalize or specialize Windows instances.

7. Terminate the instance:

Using the Console

   a. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.

b. In the list of instances, find the instance you want to terminate.
c. Click the highlighted name of the instance to display the instance details.
d. Click **Terminate**, and then respond to the confirmation prompt. Ensure that `Permanently delete the attached Boot Volume` is unchecked to preserve the boot volume associated with the instance.
   Terminated instances temporarily remain in the list of instances with the status **Terminated**.

Using the API

To terminate the instance, use the TerminateInstance operation and pass the `preserveBootVolume` parameter set to `true` in the request.

Using the CLI

To terminate the instance, use the terminate operation and set the `preserve-boot-volume` option to `true`.

8. Create a new instance using the boot volume from the terminated instance.
9. In the launch instance flow, specify the private IP address that was attached to the primary VNIC. If the public IP address was assigned from a reserved IP address pool, be sure to assign the same IP address.
10. When the instance state changes to `RUNNING`, **Stop** the instance.
11. Recreate any secondary VNICs and secondary IP addresses.
12. Attach any remote block volumes.

Note

This step includes any volumes used to back up local NVMe devices. Copy the data onto the NVMe storage on the new instance, and then detach the volumes.

13. Start the instance.
14. Start and test any applications on the instance.
15. Configure the applications to start automatically, as required.
16. Recreate the required tags.
17. (Optional) After you confirm that the instance and applications are healthy, you can delete the volume backups.

Migrating an Instance from a Local to Remote Boot Volume

Oracle Cloud Infrastructure introduced remote boot volumes November 15, 2017. Remote boot volumes include significant improvements over local boot volumes including lower boot times, encryption of data at rest and in-transit, zero downtime snapshots, improved availability, and more. Instances launched before November 15, 2017 use local boot volumes. Local boot volumes are being deprecated, we recommend that you migrate any instances currently using a local boot volume to a remote boot volume. This topic describes that process.

Limitations and Warnings for Manual Migration

Be aware of the following limitations and warnings when performing a manual migration:

- Any public IP addresses assigned to your instance from a reserved public pool are retained. Any that were not assigned from a reserved public IP address pool will

change. Private IP addresses do not change.

- MAC addresses, CPUIDs, and other unique hardware identifiers do change during the move. If any applications running on the instance use these identifiers for licensing or other purposes, be sure to take note of this information before moving the instance to help you manage the change.

Prerequisites for Manual Migration

1. Before moving the instance, document all critical details:
    - The instance's region, availability domain, and fault domain.
    - The instance's display name.
    - All private IP addresses, names, and subnets. Note that the instance can have multiple VNICs, and each VNIC can have multiple secondary IP addresses.
    - All private DNS names. The instance can have multiple VNICs, and each VNIC can have multiple secondary IP addresses. Each private IP address can have a DNS name.
    - Any public IP addresses assigned from a reserved public pool. Note that the instance can have multiple VNICs, and each VNIC can have multiple secondary private IP addresses. Each VNIC and secondary private IP address can have an attached public IP address.
    - Any remote block volumes attached to the instance.
    - Any tags on the instance or attached resources.
2. Prepare the instance for manual migration:
    - Ensure that any remote block volumes defined in `/etc/fstab` use the recommended options.
    - Ensure that any File Storage service (NFS) mounts use the `nofail` option.
    - If you have statically defined any network interfaces belonging to secondary VNICs using their MAC addresses, such as those defined in `/etc/sysconfig/network-scripts/ifcfg*`, those interfaces will not start due to the change in the MAC address. Remove the static mapping.

- If you use the Oracle-provided script to configure secondary VNICs, ensure it runs automatically at startup.

Migrating an Instance Manually

After you complete the prerequisites:

1. Stop any running applications.
2. Ensure that those applications will not start automatically.

Warning

When the relocated instance starts for the first time, remote block volumes, secondary VNICs, or any resource that relies on them, will not be attached. The absence of these resources can cause application issues.

3. If your instance has local NVMe storage (dense instances), you must back up this data:
   a. Create and attach one or more remote block volumes to the instance.
   b. Copy the data from the NVMe devices to the remote block volumes.
4. Unmount any remote block volumes or File Storage service (NFS) mounts.
5. Back up all remote block volumes. See Overview of Block Volume Backups for more information.
6. Create a custom image of the instance using the steps described in the Using the Console or Using the API sections of Managing Custom Images.

Important

Do not generalize or specialize Windows instances.

7. Terminate the instance:

Using the Console

a. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
b. In the list of instances, find the instance you want to terminate.
c. Click the highlighted name of the instance to display the instance details.
d. Click **Terminate**, and then respond to the confirmation prompt. Ensure that the **Permanently delete the attached Boot Volume** check box is cleared to preserve the boot volume associated with the instance.
   Terminated instances temporarily remain in the list of instances with the status **Terminated**.

Using the API

To terminate the instance, use the TerminateInstance operation and pass the `preserveBootVolume` parameter set to `true` in the request.

Using the CLI

To terminate the instance, use the terminate operation and set the `preserve-boot-volume` option to `true`.

8. Create a new instance using the custom image from the terminated instance, see the steps described in the Using the Console or the Using the API sections of Managing Custom Images.
9. In the launch instance flow, specify the private IP address that was attached to the primary VNIC. If the public IP address was assigned from a reserved IP address pool, be sure to assign the same IP address.
10. When the instance state changes to `RUNNING`, **Stop** the instance.

11. Recreate any secondary VNICs and secondary IP addresses.
12. Attach any remote block volumes, see Attaching a Volume for more information.

Note

This step includes any volumes used to back up local NVMe devices. Copy the data onto the NVMe storage on the new instance, and then detach the volumes.

13. Start the instance.
14. Start and test any applications on the instance.
15. Configure the applications to start automatically, as required.
16. Recreate the required tags.
17. (Optional) After you confirm that the instance and applications are healthy, you can delete the volume backups.

Moving Compute Resources to a Different Compartment

You can move Compute resources such as instances, instance pools, and custom images from one compartment to another.

When you move a Compute resource to a new compartment, associated resources such as boot volumes and VNICs are not moved.

After you move the resource to the new compartment, inherent policies apply immediately and affect access to the resource through the Console. For more information, see Managing Compartments.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK,

CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: The following policies allow users to move Compute resources to a different compartment:

```
Allow group ComputeCompartmentMovers to manage instance-family in tenancy
Allow group ComputeCompartmentMovers to manage compute-management-family in tenancy
Allow group ComputeCompartmentMovers to manage auto-scaling-configurations in tenancy
```

If you're new to policies, see Getting Started with Policies and Common Policies.

Using the Console

To move an instance to a different compartment

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
2. In the **List Scope** section, select a compartment.
3. Click the instance that you're interested in.
4. Click **Move Resource**.
5. Choose the destination compartment from the list.
6. Click **Move Resource**.
   To track the progress of the operation, you can monitor the associated work request. For more information, see Using the Console to View Work Requests.
7. If there are alarms monitoring the instance, update the alarms to reference the new compartment. See To update an alarm after moving a resource for more information.
8. Optionally, move the resources that are attached to the instance to the new compartment.

To move an instance configuration to a different compartment

Note

Most of the properties for an existing instance configuration, including the compartment, cannot be modified after you create the instance configuration. Although you can move an instance configuration to a different compartment, you will not be able to use the instance configuration to manage instance pools in the new compartment. If you want to update an instance configuration to point to a different compartment, you should instead create a new instance configuration in the target compartment. For steps, see Creating an Instance Configuration.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instance Configurations**.
2. In the **List Scope** section, select a compartment.
3. Click the instance configuration that you're interested in.
4. Click **Move Resource**.
5. Choose the destination compartment from the list.
6. Click **Move Resource**.

To move an instance pool to a different compartment

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instance Pools**.
2. In the **List Scope** section, select a compartment.
3. Click the instance pool that you're interested in.

4. Click **Move Resource**.
5. Choose the destination compartment from the list.
6. Click **Move Resource**.
7. Optionally, update the instance pool with an instance configuration that points to the new compartment. Do the following:
    a. Create a new instance configuration in the new compartment. You can do this using the Console or the API. For steps, see Creating an Instance Configuration.
    b. Update the instance pool with the new instance configuration. You can do this using the API. For steps, see Updating an Instance Pool.
8. Optionally, move the instances and other resources that are associated with the instance pool to the new compartment.

To move an autoscaling configuration to a different compartment

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Autoscaling Configurations**.
2. In the **List Scope** section, select a compartment.
3. Click the autoscaling configuration that you're interested in.
4. Click **Move Resource**.
5. Choose the destination compartment from the list.
6. Click **Move Resource**.

To move a custom image to a different compartment

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Custom Images**.
2. In the **List Scope** section, select a compartment.
3. Click the custom image that you're interested in.

4. Click **Move Resource**.
5. Choose the destination compartment from the list.
6. Click **Move Resource**.

To move a cluster network to a different compartment

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Cluster Networks**.
2. In the **List Scope** section, select a compartment.
3. Click the cluster network that you're interested in.
4. Click **Move Resource**.
5. Choose the destination compartment from the list.
6. Click **Move Resource**.
7. Optionally, move the instances and other resources that are associated with the cluster network to the new compartment.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use these API operations to move Compute resources to different compartments:

- ChangeInstanceCompartment
- ChangeInstanceConfigurationCompartment
- ChangeInstancePoolCompartment
- ChangeAutoScalingConfigurationCompartment
- ChangeImageCompartment
- ChangeClusterNetworkCompartment

Stopping and Starting an Instance

You can stop and start an instance as needed to update software or resolve error conditions.

For steps to manage the lifecycle state of instances in an instance pool, see Stopping and Starting the Instances in an Instance Pool.

Stopping or Restarting an Instance From Within the Instance

In addition to using the API and Console, you can stop and restart instances using the commands available in the operating system when you are logged in to the instance. Stopping an instance using the instance's OS does not stop billing for that instance. If you stop an instance this way, be sure to also stop it from the Console or API.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: The policy in Let users launch Compute instances includes the ability to stop or start an existing instance. If the specified group doesn't need to launch instances or

attach volumes, you could simplify that policy to include only `manage instance-family`, and remove the statements involving `volume-family` and `virtual-network-family`.

If you're new to policies, see Getting Started with Policies and Common Policies. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services.

Rebooting Your Virtual Machine (VM) Instance During Planned Maintenance

When an underlying Oracle Cloud Infrastructure component needs to undergo maintenance, you are notified before the impact to your VM instances. If your VM instances are scheduled for a maintenance reboot, you can proactively reboot, or stop and start your instances using the Console, API, or CLI at any time before the scheduled reboot. This let you control how and when your applications experience downtime. Customer-managed VM maintenance is supported on standard and GPU instance shapes, including Oracle-provided platform images and custom images imported from outside of Oracle Cloud Infrastructure.

To identify the VM instances that you can proactively reboot, using the Console, check the **Maintenance Reboot** field for the instance. If the instance has a maintenance reboot scheduled and can be proactively rebooted, this field displays the date and start time for the reboot. To check this using the API, use the `timeMaintenanceRebootDue` field for the Instance. For VM instances with a boot volume, additional iSCSI block volume attachments, and a single VNIC, you can proceed to reboot, or stop and start the instance. If you have non-iSCSI (paravirtualized or emulated) block volume attachments or secondary VNICs, you need to first detach these resources before you reboot your instance.

When you reboot, or stop and start the instance, it is migrated to a different physical VM host. Once the **Maintenance Reboot** field is blank, the instance is no longer impacted by the maintenance event. If you choose not to reboot before the scheduled time, then Oracle Cloud Infrastructure will reboot and migrate your instances within a 24-hour period after the scheduled time.

To make it easier to locate and perform these actions on your VM instances, you can use Search with a predefined query to find all instances that have a maintenance reboot scheduled.

To find all the instances scheduled for a maintenance reboot

1. In the Console, append "/a/query" to the end of your base Console URL. For example, https://console.us-ashburn-1.oraclecloud.com/a/query.
2. Click **Select Sample Query**, and then click **Query for all instances which have an upcoming scheduled maintenance**.

Resource Billing for Stopped Instances

For both VM and bare metal instances, billing depends on the shape that you use to create the instance:

- **Standard shapes:** Stopping an instance pauses billing. However, stopped instances continue to count toward your service limits.
- **Dense I/O shapes:** Billing continues for stopped instances because of the attached NVMe storage, and related resources continue to count toward your service limits. To halt billing and remove related resources from your service limits, you must terminate the instance.
- **GPU shapes:** Billing continues for stopped instances, and related resources continue to count toward your service limits. To halt billing and remove related resources from your service limits, you must terminate the instance.
- **HPC shapes:** Billing continues for stopped instances because of the attached NVMe storage, and related resources continue to count toward your service limits. To halt billing and remove related resources from your service limits, you must terminate the instance.

Stopping an instance using the instance's OS does not stop billing for that instance. If you stop an instance this way, be sure to also stop it from the Console or API.

For more information about how instances running Microsoft Windows Server are billed when they are stopped, see How am I charged for Windows Server on Oracle Cloud Infrastructure?.

Hardware Reclamation for Stopped Bare Metal Instances

When a bare metal instance remains in the stopped state for longer than 48 hours, the instance is taken offline and the physical hardware is reclaimed. The next time that you restart the instance, it starts on different physical hardware. There are no changes to the block volumes, boot volumes, and instance metadata, including the ephemeral and public IP addresses.

However, the following properties do change when a bare metal instance restarts on different physical hardware: the MAC addresses and the host serial number. You might also notice changes in the BIOS firmware version, BIOS settings, and CPU microcode. If you want to keep the same physical hardware, do not stop the instance using the Console or the API, SDKs, or CLI. Instead, shut down the instance using the instance's OS. When you want to restart the instance, use the Console or the API, SDKs, or CLI.

This behavior applies to Linux instances that use the following shapes:

- BM.Standard1.36
- BM.Standard.B1.44
- BM.Standard2.52
- BM.Standard.E2.64

Using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
2. Click the instance that you want to stop or start.
3. Click one of the following actions:
    - **Start:** Restarts a stopped instance. After the instance is restarted, the **Stop** action is enabled.
    - **Stop:** Shuts down the instance. After the instance is powered off, the **Start** action is enabled.
    - **Reboot:** Shuts down the instance, and then restarts it.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the InstanceAction operation to restart an instance.

The following actions are only available using the API:

- SOFTSTOP
- SOFTRESET

Terminating an Instance

You can permanently terminate (delete) instances that you no longer need. Any attached VNICs and volumes are automatically detached when the instance terminates. Eventually, the instance's public and private IP addresses are released and become available for other instances. By default, the instance's boot volume is deleted when you terminate the instance, however you can preserve the boot volume associated with the instance, so that you can attach it to a different instance as a data volume, or use it to launch a new instance.

Warning

If your instance has NVMe storage, terminating it securely erases the NVMe drives and the data that was on those drives becomes completely unrecoverable. Make sure you back up important data before terminating an instance. For more information, see Protecting Data on NVMe Devices.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: The policy in Let users launch Compute instances includes the ability to terminate an instance (with or without an attached block volume).

If you're new to policies, see Getting Started with Policies and Common Policies. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services.

Using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
2. In the list of instances, find the instance you want to terminate.
3. Click the name of the instance to display the instance details.
4. Click **Terminate**, and then respond to the confirmation prompt.
   If you want to preserve the boot volume associated with the instance, clear the **Permanently delete the attached Boot Volume** check box.
   Terminated instances temporarily remain in the list of instances with the status **Terminated**.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the TerminateInstance operation to terminate an instance.

Enabling Monitoring for Compute Instances

This topic describes how to enable monitoring for Compute instances that use supported images.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Except for Compute instances, all resources that support the Monitoring service emit metrics by default. A Compute instance using a supported image emits metrics when it has the required instance configuration and OracleCloudAgent software.

Supported Images

Compute instances with Oracle-provided images support the configuration setting to enable monitoring. When this setting is enabled for an instance and the OracleCloudAgent software is installed on the instance, the instance emits metrics.

Note

Because legacy images require installation of the OracleCloudAgent software, we recommend that you select the latest image, which already has the software installed. If you need a legacy image, then select an image dated on or after November 16, 2018 (except Ubuntu, which must be dated after February 28, 2019).

Prerequisites

- Service gateways or public IP addresses: The Compute instances must have either service gateways or public IP addresses to send metrics to the Monitoring service.
- IAM policies: To create and update Compute instances, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don't have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in. For more information, see Creating an Instance.
- SSH: To connect to a Compute instance, you must have an SSH key. For more information, see Connecting to an Instance.

Process Overview: Enabling Monitoring for a New Compute Instance

Following is the process for configuring a new Compute instance to emit metrics.

Task 1: Create a monitoring-enabled instance

Steps depend on the date of the image used to create the instance.

Latest version of supported image

Note

Like the latest version, some recent versions of supported images also have the OracleCloudAgent software installed. Compare to the date listed in Supported Images.

While defining properties for the new instance, set the property that enables the instance for monitoring. For instructions, see Using the Console or Using the API.

Legacy version of supported image

A legacy version of a supported image is one provided before the date listed in Supported Images.

While defining properties for the new instance, set the property that enables the instance for monitoring and do one of the following:

- In the Console: While defining properties for the new instance, provide a script to install the OracleCloudAgent software onto the instance during the instance creation process.
- Complete the instance creation process and then manually install the OracleCloudAgent software.

Task 2: (Optional) Create a service gateway

If your instances do not have public IP addresses, set up a service gateway on the virtual cloud network (VCN). The service gateway allows the instances to send metrics to the Monitoring service without the traffic going over the internet. Here are special notes for setting up the service gateway to access the Monitoring service:

- When creating the service gateway, enable the service label called **All <region> Services in Oracle Services Network**. It includes the Monitoring service.
- When setting up routing for the subnet that contains your instances, set up a route rule with **Target Type** set to **Service Gateway**, and the **Destination Service** set to **All <region> Services in Oracle Services Network**.

For detailed instructions, see Setting Up a Service Gateway in the Console.

Find Out if Monitoring Has Your Metrics

To find out if Monitoring has your metrics

This task involves either querying instance metrics or viewing instance configuration.

- Query metrics to determine if Monitoring is receiving metrics emitted by the instance. For instructions, see Using the Console or Using the API.

Not seeing metrics for your instance?

If you don't see any metric charts, your Compute instance might not be emitting metrics. See the following possible causes and resolutions.

Possible cause	How to check	Resolution
Monitoring is disabled on the instance.	Review the instance configuration.	Enable monitoring.
No OracleCloudAgent software exists on the instance (occurs with older images).	Connect to the instance and look for the software.	Install the software.

Possible cause	How to check	Resolution
The instance cannot access theMonitoring service because its VCN does not use the Internet.	Review the instance's IP address. If it's not public, then a service gateway is needed.	Set up a service gateway.
The instance does not use a supported image.	Review Supported Images.	Create an instance with a supported image.
New instance in a new compartment: The IAM policies required for the instance to publish metrics to Monitoring are not yet initialized. More information: IAM policies are automatically created for new instances and are immediately available, unless the instances are in a new compartment. For a new instance in a new compartment, the policies can take up to 20 minutes to initialize, which delays the emission of metrics.	(not applicable)	Check back after 10 or 20 minutes.

- View the instance configuration to determine if monitoring is enabled. Monitoring-enabled instances may require installation of the OracleCloudAgent software before metrics are emitted. For instructions, see Using the Console or Using the API.

Process Overview: Enabling Monitoring for an Existing Compute Instance

Following is the process for configuring an existing Compute instance to emit metrics.

Task 1: Enable monitoring

Update the instance configuration to enable monitoring. For instructions, see Using the Console or Using the API.

Task 2: Install the OracleCloudAgent software

Choose the operating system corresponding to the instance.

Linux

This section covers CentOS, Linux, and Ubuntu images.

1. Enable monitoring on the instance.
2. Connect to the instance.
   For step-by-step instructions, see Connecting to an Instance.
3. Run the script corresponding to the image used by the instance.

CentOS 6.x, Oracle Linux 6.x

```
#!/bin/sh

cd ~
curl -O https://objectstorage.us-phoenix-1.oraclecloud.com/n/oci-i3/b/agents/o/pool%2F4a97146b-2c7f-4a6c-9d10-7bca4a6b27b3%2Foracle-cloud-agent-0.0.13-196.el6.x86_64.rpm -v
```

CentOS 7.x, Oracle Linux 7.x

```
#!/bin/sh
```

```
cd ~
curl -O https://objectstorage.us-phoenix-1.oraclecloud.com/n/oci-i3/b/agents/o/pool%2Fc2d4e19d-46f2-4331-bd28-aa8b109eec67%2Foracle-cloud-agent-0.0.13-196.el7.x86_64.rpm -v
```

Ubuntu 16.04, 18.04

Note

Installation of the OracleCloudAgent software on instances using Ubuntu images requires Snapcraft. To install Snapcraft, run the following commands, in sequence:

```
sudo apt update
```

```
sudo apt install snapd
```

```
sudo snap install oracle-cloud-agent --classic
```

4. Enter the relevant command to run the OracleCloudAgent software on the instance.

Example 1: CentOS or Oracle Linux image

```
sudo yum install -y <instance-agent-filename>
```

Example 2: Ubuntu image

(Same instructions as noted in the previous step: This command installs and runs the software.)

```
sudo snap install oracle-cloud-agent --classic
```

Metrics are now emitted by the instance.

Windows

1. Enable monitoring on the instance.
2. Download the OracleCloudAgent software from the following URL.
   https://objectstorage.us-phoenix-1.oraclecloud.com/p/RDDCRrNTo5WB19mI52QJTOXCq1whXFZHXCQP74b4ttg/n/imagegen/b/windows_instance_agents/o/OracleCloudAgentSetup.msi
3. Connect to the instance.
   For step-by-step instructions, see Connecting to an Instance.
4. Copy the downloaded OracleCloudAgent software to the instance.
5. As a user with administrative privileges, enter the relevant command to run the OracleCloudAgent software on the instance.

   ```
   msiexec /qb /i <instance-agent-filename>
   ```

   Metrics are now emitted by the instance.

Task 3: (Optional) Create a service gateway

If your instances do not have public IP addresses, set up a service gateway on the virtual cloud network (VCN). The service gateway allows the instances to send metrics to the Monitoring service without the traffic going over the internet. Here are special notes for setting up the service gateway to access the Monitoring service:

- When creating the service gateway, enable the service label called **All <region> Services in Oracle Services Network**. It includes the Monitoring service.
- When setting up routing for the subnet that contains your instances, set up a route rule with **Target Type** set to **Service Gateway**, and the **Destination Service** set to **All <region> Services in Oracle Services Network**.

For detailed instructions, see Setting Up a Service Gateway in the Console.

Updating the OracleCloudAgent Software

We recommend always running the latest version of the OracleCloudAgent software.

If the installed software can access the internet, then no action is needed. The software periodically checks for newer versions and automatically installs the latest version when different from the current version.

If the installed software does not have access to the internet, then a manual update is required. For example, a Compute instance that has no internet gateway or service gateway cannot access the internet. In this situation, the software cannot complete its checks for newer versions.

To find the version of the installed OracleCloudAgent software

Do one of the following:

- For Oracle Linux/CentOS, run the following command:

  ```
  sudo yum info oracle-cloud-agent
  ```

- For Ubuntu, run the following command:

  ```
  snap info oracle-cloud-agent
  ```

- For Windows, do one of the following.
  - In Control Panel, select **Programs and Features** and then find the version number provided for "Oracle Cloud Agent."
  - In PowerShell, run the following command:

    ```
    Get-WmiObject -Class Win32_Product | Where-Object { $_.Name -eq "Oracle Cloud Agent" }
    ```

    Example output:

    ```
    IdentifyingNumber : {exampleuniqueidentifer}
    Name              : Oracle Cloud Agent
    Vendor            : Oracle Corporation
    ```

```
Version           : 0.0.10.0
Caption           : Oracle Cloud Agent
```

To manually update the OracleCloudAgent software on a Compute instance

Do one of the following:

- Temporarily allow the instance to access the internet.
- Redo the installation steps, using the latest version.

OracleCloudAgent software versions

Linux versions

Linux versions include CentOS 6.x, Oracle Linux 6.x, CentOS 7.x, Oracle Linux 7.x, Ubuntu 16.04, and Ubuntu 18.04.

Linux version	Date	Changes
0.0.13	November 4, 2019	Fix a bug in handling monitoring service internal server errors
0.0.11	September 13, 2019	Fix retry strategy for sending metrics and refresh security tokens
0.0.10	July 15, 2019	Fix for correct handling of forced termination of the oracle-cloud-agent-updater

Windows versions

Windows version	Date	Changes
0.0.11.0	November 5, 2019	Fixed: Fix a bug in handling monitoring service internal server errors
0.0.10.0	September 13, 2019	Fixed: • Fix retry strategy for sending metrics and refresh security tokens • Fix for correct handling of forced termination of the oracle-cloud-agent-update
0.0.9.0	June 6, 2019	Fixed: Bug fix where agent restarts when telemetry or auth service returns 5xx

Using the Console

Use the Console to create a Compute instance with monitoring enabled and, for new instances using legacy images, to run the script that installs the required OracleCloudAgent software.

To create a monitoring-enabled instance

Steps depend on the date of the image used to create the instance.

Latest version of supported image

Note

Like the latest version, some recent versions of

supported images also have the OracleCloudAgent software installed. Compare to the date listed in Supported Images.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**. Choose a **Compartment** you have permission to work in, and then click **Create Instance**.
2. In the **Create Instance** dialog box, select the latest version of a supported image. For more information about launching instances, see Creating an Instance.
3. Select **Enable monitoring**.
4. Update other configuration as needed and then click **Create Instance**. The newly created monitoring-enabled instance emits metrics to the Monitoring service.

Legacy version of supported image

A legacy version of a supported image is one provided before the date listed in Supported Images. Legacy images require you to install the OracleCloudAgent software.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**. Choose a **Compartment** you have permission to work in, and then click **Create Instance**.
2. In the **Create Instance** dialog box, select the legacy version of the supported image. For more information about launching instances, see Creating an Instance.
3. Select **Enable monitoring**.
4. Click **Show Advanced Options**.
5. Select **Paste cloud-init script**.
6. Copy and paste the script corresponding to the image used by the instance.

CentOS 6.x, Oracle Linux 6.x

```
#!/bin/sh
curl -O https://objectstorage.us-phoenix-1.oraclecloud.com/n/oci-i3/b/agents/o/pool%2F4a97146b-
2c7f-4a6c-9d10-7bca4a6b27b3%2Foracle-cloud-agent-0.0.13-196.el6.x86_64.rpm
yum install -y ~/oracle-cloud-agent-0.0.13-196.el6.x86_64.rpm -v
```

CentOS 7.x, Oracle Linux 7.x

```
#!/bin/sh
curl -O https://objectstorage.us-phoenix-1.oraclecloud.com/n/oci-i3/b/agents/o/pool%2Fc2d4e19d-
46f2-4331-bd28-aa8b109eec67%2Foracle-cloud-agent-0.0.13-196.el7.x86_64.rpm -v
yum install -y ~/oracle-cloud-agent-0.0.13-196.el7.x86_64.rpm -v
```

Windows Server 2012 R2, 2016

Note

For legacy versions of Windows images, make sure cloudbase-init is supported. See https://docs.cloud.oracle.com/iaas/releasenotes/changes/595afbb7-de0c-4934-8074-5b1ed6be1b56/.

```
#ps1_sysnative
cd \Users\opc\Desktop
Start-BitsTransfer -Source "https://objectstorage.us-phoenix-
1.oraclecloud.com/p/RDDCRrNTo5WB19mI52QJTOXCq1whXFZHXCQP74b4ttg/n/imagegen/b/windows_instance_
agents/o/OracleCloudAgentSetup.msi" -Destination
"c:\Users\opc\Desktop\OracleCloudAgentSetup.msi"
msiexec /i "c:\Users\opc\Desktop\OracleCloudAgentSetup.msi" /quiet /L*V
"c:\Users\opc\Desktop\OracleCloudAgentSetup.log"
```

Windows Server 2008 R2

Download the OracleCloudAgent software from the following URL and manually install it on the instance.

https://objectstorage.us-phoenix-1.oraclecloud.com/p/RDDCRrNTo5WB19mI52QJTOXCq1whXFZHXCQP74b4ttg/n/imagegen/b/windows_instance_agents/o/OracleCloudAgentSetup.msi

Ubuntu 16.04, 18.04

Note

Installation of the OracleCloudAgent software on instances using Ubuntu images requires Snapcraft. To install Snapcraft, run the following commands, in sequence:

```
sudo apt update
```

```
sudo apt install snapd
```

```
sudo snap install oracle-cloud-agent --classic
```

7. Update other configuration as needed and then click **Create Instance**.
   The newly created monitoring-enabled instance emits metrics to the Monitoring service.

To find out if monitoring is enabled or if Monitoring is receiving metrics

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
2. Click the instance you're interested in.

3. On the instance detail page, under **Resources**, click **Metrics**.
   If you see metric charts with data, then the Monitoring service is receiving metrics from this instance. For a list of metrics related to Compute instances, see Compute Instance Metrics.
   If you see a message that monitoring is not enabled, or that the OracleCloudAgent software needs to be installed, then complete those tasks.

To enable monitoring on an existing instance

1. Go to the Metrics page for the instance:
   a. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
   b. Click the instance you're interested in.
   c. On the instance detail page, under **Resources**, click **Metrics**.
      If monitoring is not enabled (and the instance uses a supported image), then a button is available for enabling monitoring.
2. Click **Enable monitoring**.
   If you see metric charts with data, then the Monitoring service is receiving metrics from this instance. For a list of metrics related to Compute instances, see Compute Instance Metrics.
   If you see a message that the OracleCloudAgent software needs to be installed, then see Task 2: Install the OracleCloudAgent software.

Using the API

Use the API to enable monitoring on a new or existing instance. After monitoring is enabled, you can install the OracleCloudAgent software.

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

To create a monitoring-enabled instance

Steps depend on the date of the image used to create the instance.

Latest version of supported image

Note

Like the latest version, some recent versions of supported images also have the OracleCloudAgent software installed. Compare to the date listed in Supported Images.

Use the LaunchInstance API operation, specifying the latest version of a supported image, and include the following parameter setting.

```
{
  "agentConfig":
  {
    "isMonitoringDisabled":false
  }
}
```

Legacy version of supported image

A legacy version of a supported image is one provided before the date listed in Supported Images. Legacy images require you to install the OracleCloudAgent software.

1. Use the LaunchInstance API operation, specifying the legacy version of the supported image, and include the following parameter setting.

   ```
   {
     "agentConfig":
   ```

```
  {
    "isMonitoringDisabled":false
  }
}
```

2. Install the OracleCloudAgent software onto the newly created instance. See Task 2: Install the OracleCloudAgent software.

To find out if monitoring is enabled or if Monitoring is receiving metrics

To query metrics, use the SummarizeMetricsData API operation. Returned metrics indicate that the Monitoring service received metrics from the instance.

To determine instance agent configuration (`isMonitoringDisabled` value), use the GetInstance or ListInstances operation.

To enable monitoring on an existing instance

Use the UpdateInstance API operation and include the following parameter setting.

```
{
  "agentConfig":
  {
    "isMonitoringDisabled":false
  }
}
```

Compute Metrics

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications. For more information, see Monitoring Overview and Notifications Overview.

There are multiple Monitoring service metric namespaces related to Compute resources:

- **oci_computeagent:** Metrics related to the OracleCloudAgent software on Compute instances. See Compute Instance Metrics.
- **oci_compute_infrastructure_health:** Metrics related to the health of bare metal hardware. See Infrastructure Health Metrics.

Compute Instance Metrics

You can monitor the health, capacity, and performance of your Compute instances by using metrics, alarms, and notifications.

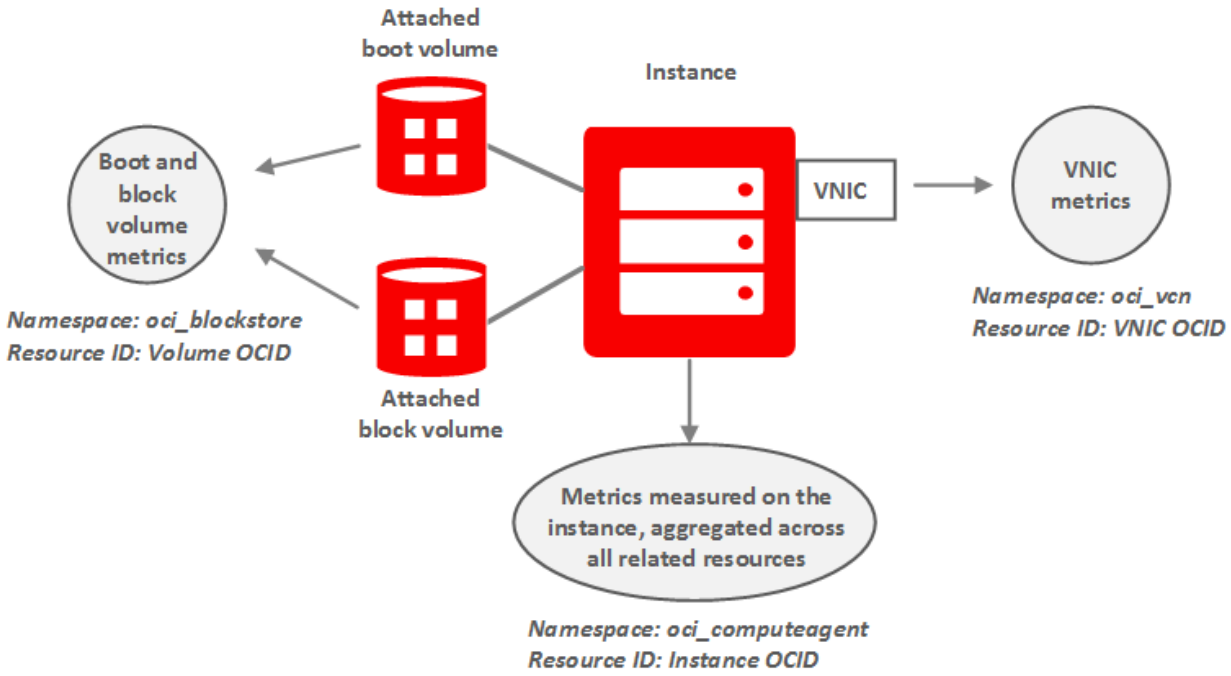
This topic describes the metrics emitted by the metric namespace `oci_computeagent` (the OracleCloudAgent software on Compute instances).

You can view these metrics for individual Compute instances, and for all the instances in an instance pool.

Resources: Monitoring-enabled Compute instances.

Overview of Metrics for an Instance and Related Resources

This section gives an overall picture of the different types of metrics available for an instance and its storage and network devices. See the following diagram and table for a summary.



Attached
boot volume
Instance
Boot and
block
volume
metrics
VNIC
VNIC
metrics
Namespace: oci_blockstore
Resource ID: Volume OCID
Namespace: oci_vcn
Resource ID: VNIC OCID
Attached
block volume
Metrics measured on the
instance, aggregated across
all related resources
Namespace: oci_computeagent
Resource ID: Instance OCID

Metric Namespace	Resource ID	Where Measured	Available Metrics
`oci_computeagent`	Instance OCID	On the instance. The metrics in this namespace are aggregated across all the related resources on the instance. For example, `DiskBytesRead` is aggregated across all the instance's attached storage volumes, and `NetworkBytesIn` is aggregated across all the instance's attached VNICs.	See Available Metrics: oci_computeagent.
`oci_blockstore`	Boot or block volume OCID	By the Block Volume service. The metrics are for an individual volume (either boot volume or block volume).	See Block Volume Metrics.
`oci_vcn`	VNIC OCID	By the Networking service. The metrics are for an individual VNIC.	See VNIC Metrics.

Prerequisites

- IAM policies: To monitor resources, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.
- Metrics exist in Monitoring: The resources that you want to monitor must emit metrics to the Monitoring service.

- Compute instances: To emit metrics, Compute instances must be monitoring-enabled. OracleCloudAgent software installation may also be required. For more information, see Enabling Monitoring for Compute Instances.

Available Metrics: oci_computeagent

The Compute instance metrics help you measure activity level and throughput of Compute instances. The metrics listed in the following table are available for any monitoring-enabled Compute instance. You must enable monitoring on the instances to get these metrics.

The metrics in this namespace are aggregated across all the related resources on the instance. For example, `DiskBytesRead` is aggregated across all the instance's attached storage volumes, and `NetworkBytesIn` is aggregated across all the instance's attached VNICs.

You also can use the Monitoring service to create custom queries.

Each metric includes the following dimensions:

AVAILABILITYDOMAIN

The availability domain where the instance resides.

FAULTDOMAIN

The fault domain where the instance resides.

IMAGEID

The OCID of the image for the instance.

INSTANCEPOOLID

The instance pool that the instance belongs to.

REGION

The region where the instance resides.

RESOURCEDISPLAYNAME

The friendly name of the instance.

RESOURCEID

The OCID of the instance.

SHAPE

The shape of the instance.

Metric	Metric Display Name	Unit	Description	Dimensions
CpuUtilization	**CPU Utilization**	percent	Activity level from CPU. Expressed as a percentage of total time. For instance pools, the value is averaged across all instances in the pool.	availabilityDomain faultDomain imageId instancePoolId region resourceDisplayName resourceId shape
DiskBytesRead[1, 3]	**Disk Read Bytes**	bytes	Read throughput. Expressed as bytes read per interval.	
DiskBytesWritten[1, 3]	**Disk Write Bytes**	bytes	Write throughput. Expressed as bytes written per interval.	

Metric	Metric Display Name	Unit	Description	Dimensions
DiskIopsRead[1, 3]	**Disk Read I/O**	operations	Activity level from I/O reads. Expressed as reads per interval.	
DiskIopsWritten[1, 3]	**Disk Write I/O**	operations	Activity level from I/O writes. Expressed as writes per interval.	

Metric	Metric Display Name	Unit	Description	Dimensions
MemoryUtilization[1]	**Memory Utilization**	percent	Space currently in use. Measured by pages. Expressed as a percentage of used pages. For instance pools, the value is averaged across all instances in the pool.	
NetworksBytesIn[1, 2]	**Network Receive Bytes**	bytes	Network receipt throughput. Expressed as bytes received.	

Metric	Metric Display Name	Unit	Description	Dimensions
NetworksBytesOut [1, 2]	**Network Transmit Bytes**	bytes	Network transmission throughput. Expressed as bytes transmitted.	

[1]This metric is a cumulative counter that shows monotonically increasing behavior for each session of the OracleCloudAgent software, resetting when the operating system is restarted.

[2]The Networking service provides additional metrics (in the `oci_vcn` metric namespace) for each VNIC on the instance. For more information, see Network Metrics.

[3]The Block Volume service provides additional metrics (in the `oci_blockstore` metric namespace) for each volume attached to the instance. For more information, see Block Volume Metrics.

Using the Console

To view default metric charts for a single Compute instance

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
2. Click the instance that you're interested in.
3. Under **Resources**, click **Metrics**. If this is a bare metal instance, in the **Metric Namespace** list, select **oci_computeagent**.
   The Metrics page displays a default set of charts for the current instance.

Not seeing any metric charts for the instance?

If you don't see any metric charts, your Compute instance might not be emitting metrics. See the following possible causes and resolutions.

Possible cause	How to check	Resolution
Monitoring is disabled on the instance.	Review the instance configuration.	Enable monitoring.
No OracleCloudAgent software exists on the instance (occurs with older images).	Connect to the instance and look for the software.	Install the software.
The instance cannot access theMonitoring service because its VCN does not use the Internet.	Review the instance's IP address. If it's not public, then a service gateway is needed.	Set up a service gateway.

Possible cause	How to check	Resolution
The instance does not use a supported image.	Review Supported Images.	Create an instance with a supported image.
New instance in a new compartment: The IAM policies required for the instance to publish metrics to Monitoring are not yet initialized. More information: IAM policies are automatically created for new instances and are immediately available, unless the instances are in a new compartment. For a new instance in a new compartment, the policies can take up to 20 minutes to initialize, which delays the emission of metrics.	(not applicable)	Check back after 10 or 20 minutes.

For more information about monitoring metrics and using alarms, see Monitoring Overview. For information about notifications for alarms, see Notifications Overview.

To view default metric charts for resources related to a Compute instance

- **For an attached block volume:** While viewing the instance's details, click **Attached Block Volumes**, and then click the volume you're interested in. Click **Metrics** to see the volume's charts. For more information about the emitted metrics, see Block Volume Metrics.
- **For the attached boot volume:** While viewing the instance's details, click **Boot Volume**, and then click the volume you're interested in. Click **Metrics** to see the

volume's charts. For more information about the emitted metrics, see Block Volume Metrics.

- **For an attached VNIC:** While viewing the instance's details, click **Attached VNICs**, and then click the VNIC you're interested in. Click **Metrics** to see the charts for the VNIC. For more information about the emitted metrics, see Networking Metrics.

To view default metric charts for all Compute instances in a compartment

1. Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Service Metrics**.
2. Select a compartment.
3. For **Metric Namespace**, select **oci_computeagent**.
   The **Service Metrics** page dynamically updates the page to show charts for each metric that is emitted by the selected metric namespace.

For more information about monitoring metrics and using alarms, see Monitoring Overview. For information about notifications for alarms, see Notifications Overview.

To view default metric charts for the instances in an instance pool

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instance Pools**.
2. Click the instance pool that you're interested in.
3. Under **Resources**, click **Metrics**.
   The Metrics page displays a default set of charts for the current instance pool.

For more information about monitoring metrics and using alarms, see Monitoring Overview. For information about notifications for alarms, see Notifications Overview.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the following APIs for monitoring:

- Monitoring API for metrics and alarms
- Notifications API for notifications (used with alarms)

Infrastructure Health Metrics

You can monitor the health, capacity, and performance of your Compute bare metal instances by using metrics, alarms, and notifications.

This topic describes the metrics emitted by the metric namespace `oci_compute_infrastructure_health`.

Resources: Bare metal Compute instances.

Overview of Metrics: oci_compute_infrastructure_health

The infrastructure health metrics help you monitor the health of the infrastructure for your bare metal instances, including hardware components such as the CPU, motherboard, DIMM, and NVMe drives. You can use the metrics to identify hardware issues, and proactively take action to minimize the impact on your applications.

Required IAM Policy

To monitor resources, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in. For more information on user

authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.

Available Metrics: oci_compute_infrastructure_health

The metric listed in the following table is automatically available for each bare metal instance that you create. You do not need to enable monitoring on the instance to get this metric.

You also can use the Monitoring service to create custom queries.

The metric includes the following dimensions:

FAULTCLASS

The type of hardware issue:

- `CPU`: A fault has been detected in one or more CPUs.
- `MEM-BOOT`: A fault in the memory subsystem was detected during instance launch or a recent reboot.
- `MEM-RUNTIME`: A fault in the memory subsystem was detected.
- `MGMT-CONTROLLER`: A fault in the instance management controller has been detected.
- `PCI`: A fault in the PCI subsystem has been detected.

RESOURCEDISPLAYNAME

The friendly name of the instance.

RESOURCEID

The OCID of the instance.

Metric	Metric Display Name	Unit	Description	Dimensions
`health_status`	**Infrastructure Health Status**	Issues	Number of issues. Any non-zero value indicates a health defect.	`faultClass` `resourceDisplayName` `resourceId`

Using the Console

To view infrastructure health metrics for a single Compute instance

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
2. Click the instance that you're interested in.
3. Under **Resources**, click **Metrics**.
4. In the **Metric Namespace** list, select **oci_compute_infrastructure_health**.
   The Metrics page displays a default set of charts for the current instance.

For more information about monitoring metrics and using alarms, see Monitoring Overview. For information about notifications for alarms, see Notifications Overview.

To view infrastructure health metrics for all Compute instances in a compartment

1. Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Service Metrics**.
2. Select a compartment.
3. For **Metric Namespace**, select **oci_compute_infrastructure_health**.
   The **Service Metrics** page dynamically updates to show charts for each metric that is emitted by the selected metric namespace.

For more information about monitoring metrics and using alarms, see Monitoring Overview. For information about notifications for alarms, see Notifications Overview.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the following APIs for monitoring:

- Monitoring API for metrics and alarms
- Notifications API for notifications (used with alarms)

Compute Performance

The content in the sections below apply to **Category 7** and **Section 3.a** of the Oracle PaaS and IaaS Public Cloud Services Pillar documentation.

Oracle Cloud Infrastructure provides a variety of instance configurations in both bare metal and virtual machine (VM) shapes. Each shape varies on multiple dimensions including memory, CPU cores, network bandwidth, and the option of local NVMe SSD storage found in DenseIO shapes.

Oracle Cloud Infrastructure provides a service-level agreement (SLA) for NVMe performance. Measuring performance is complex and open to variability.

A NVMe drive also has non-uniform drive performance over the period of drive usage. A NVMe drive performs differently when tested brand new compared to when tested in a steady-state after some duration of usage. New drives have not incurred many write/erase cycles and the inline garbage collection has not had a significant impact on IOPS performance. To achieve the goal of reproducibility and reduced variability, our testing focuses on the steady-state duration of the NVMe drive's operation.

Testing Methodology

Warning

Before running any tests, protect your data by making a backup of your data and operating system environment to prevent any data loss. The tests described in this document will overwrite the data on the disk, and cause data corruption.

Summary: To capture the IOPS measure, first provision a shape such as the new BM.DenseIO2.52, and then use the Gartner Cloud Harmony test suite to run tests on an instance running the latest supported Oracle Linux image for each NVMe drive target.

Instructions:

1. Launch an instance based on the latest supported Oracle Linux image and select a shape such as the new BM.DenseIO2.52. For launch instructions, see Creating an Instance.
2. Run the Gartner Cloud Harmony test suite tests on the instance for each NVMe drive target. The following is an example of a command that will work for all shapes and drives on the shape:

```
sudo ./run.sh `ls /dev/nvme[0-9]n1 | sed -e 's/\//\--target=\//'`
--nopurge -noprecondition --fio_direct=1 --fio_size=10g --test=iops
--skip_blocksize=512b --skip_blocksize=8k --skip_blocksize=16k
--skip_blocksize=32k --skip_blocksize=64k --skip_blocksize=128k
--skip_blocksize=1m
```

The SLA for NVMe drive performance is measured against 4k block sizes with 100% random write workload on DenseIO shapes where the drive is in a steady-state of operation.

Performance Benchmarks

The following table lists the minimum IOPS for the specified shape to meet the SLA, given the testing methodology with 4k block sizes for 100% random write tests using the tests described in the previous section.

Shape	Minimum Supported IOPS
VM.DenseIO1.4	200k
VM.DenseIO1.8	250k
VM.DenseIO1.16	400k
BM.DenseIO1.36	2.5MM
VM.DenseIO2.8	250k

Shape	Minimum Supported IOPS
VM.DenseIO2.16	400k
VM.DenseIO2.24	800k
BM.DenseIO2.52	3.0MM

While the NVMe drives are capable of higher IOPS, Oracle Cloud Infrastructure currently guarantee this minimum level of IOPS performance.

Frequently Asked Questions

Q: I suspect a slowdown in my NVMe drive performance. Is there a SLA violation?

A: We test hosts on a regular basis to ensure that are our low-level software updates do not regress performance. In the event you have reproduced the testing methodology and your drive's performance does not meet the terms in the SLA please contact your Oracle sales team.

Q: Why does the testing methodology not represent a diversity of IO workloads such as random reads and writes to reflect real world IO?

A: We focused on reproducibility and we believe the tests provide a significant indicator of overall drive performance.

Q: Will Oracle Cloud Infrastructure change the tests in this document?

A: We will make changes to provide greater customer value through better guarantees and improved reproducibility.

Compute Health Monitoring for Bare Metal Instances

Compute health monitoring for bare metal instances is a feature that provides notifications about hardware issues with your bare metal instances. With the health monitoring feature, you can monitor the health of the hardware for your bare metal instances, including components such as the CPU, motherboard, DIMM, and NVMe drives. You can use the notifications to identify problems, letting you proactively redeploy your instances to improve availability.

Health monitoring notifications are emailed to the tenant administrator within one business day of the error occurring. This warning helps you to take action before any potential hardware failure and redeploy your instances to healthy hardware to minimize the impact on your applications.

You can also use the infrastructure health metrics available in the Monitoring service to create alarms and notifications based on hardware issues.

Error Messages and Troubleshooting

This section contains information about the most common health monitoring error messages and provides troubleshooting suggestions for you to try for your bare metal instance.

A fault has been detected in one or more CPUs

Fault class: `CPU`

Details: This error indicates that a processor or one or more cores have failed in your instance. Your instance might be inaccessible or there might be fewer available cores than expected.

Troubleshooting steps:

- If the instance is inaccessible, you must replace it using the steps in Moving a Compute Instance to a New Host.
- If your instance is available, check for the expected number of cores:

- On Linux-based systems, run the following command:

  ```
  nproc --all
  ```

- On Windows-based systems, open Resource Monitor.

Compare the core count to the expected values documented in Compute Shapes. If the number of cores is less than expected and this reduction impacts your application, we recommend that you replace the instance using the steps in Moving a Compute Instance to a New Host.

A fault in the memory subsystem was detected during instance launch or a recent reboot

Fault class: `MEM-BOOT`

Details: This error indicates that one or more failed DIMMs were detected in your instance while the instance was being launched or rebooted. Any failed DIMMs have been disabled.

Troubleshooting steps: The total amount of memory in the instance will be lower than expected. If this impacts your application, we recommend that you replace the instance using the steps in Moving a Compute Instance to a New Host.

To check for the amount of memory in the instance:

- On Linux-based systems, run the following command:

  ```
  awk '$3=="kB"{$2=$2/1024**2;$3="GB";} 1' /proc/meminfo | column -t | grep MemTotal
  ```

- On Windows-based systems, open Resource Monitor.

The expected values are documented in Compute Shapes.

A fault in the memory subsystem was detected

Fault class: `MEM-RUNTIME`

Details: This error indicates that one or more non-critical errors were detected on a DIMM in your instance. The instance might have unexpectedly rebooted in the last 72 hours.

Troubleshooting steps:

- If the instance has unexpectedly rebooted in the last 72 hours, one or more DIMMs might have been disabled. To check for the total amount of memory in the instance:
    - On Linux-based systems, run the following command:

      ```
      awk '$3=="kB"{$2=$2/1024**2;$3="GB";} 1' /proc/meminfo | column -t | grep MemTotal
      ```

    - On Windows-based systems, open Resource Monitor.

  If the total memory in the instance is lower than expected, then one or more DIMMs have failed. If this impacts your application, we recommend that you replace the instance using the steps in Moving a Compute Instance to a New Host.
- If the instance has not unexpectedly rebooted, it is at increased risk of doing so. During the next reboot, one or more DIMMs might be disabled. We recommend that you replace the instance using the steps in Moving a Compute Instance to a New Host.

A fault in the instance management controller has been detected

Fault class: `MGMT-CONTROLLER`

Details: This error indicates that a device used to manage your instance might have failed. You might not be able to use the Console, CLI, SDKs, or APIs to stop, start, or reboot your instance. This functionality will still be available from within the instance using the standard operating system commands. You also might not be able to create a console connection to your instance. You will still be able to terminate your instance.

Troubleshooting steps: If this loss of control impacts your application, we recommend that you replace the instance using the steps in Moving a Compute Instance to a New Host.

A fault in the PCI subsystem has been detected

Fault class: `PCI`

Details: This error indicates that one or more of the PCI devices in your instance have failed or are not operating at peak performance.

Troubleshooting steps:

- If you cannot connect to the instance over the network, the NIC might have failed. Use the Console or CLI to stop the instance and then start the instance. For steps, see Stopping and Starting an Instance.
  If you're still unable to connect to the instance over the network, you might be able to connect to it using a console connection. Follow the steps in Connecting to the Serial Console or Connecting to the VNC Console to establish a console connection and then reboot the instance. If the instance remains inaccessible, you must replace it using the steps in Moving a Compute Instance to a New Host.
- An NVMe device may have failed.
  On Linux-based systems, run the command `sudo lsblk` to get a list of the attached NVMe devices.
  On Windows-based systems, open Disk Manager. Check the count of NVMe devices against the expected number of devices in Compute Shapes.
  If you determine that an NVMe device is missing from the list of devices for your instance, we recommend that you replace the instance using the steps in Moving a Compute Instance to a New Host.

Microsoft Licensing on Oracle Cloud Infrastructure

This topic provides information about the licensing requirements to use Microsoft products on Oracle Cloud Infrastructure.

Moving Microsoft Licenses to Oracle Cloud Infrastructure: Microsoft License Mobility

Microsoft Volume Licensing customers can move eligible Microsoft server application licenses purchased under a Volume Licensing agreement to Oracle Cloud Infrastructure. To do this, you must enroll in the License Mobility through Microsoft Software Assurance benefit. This

benefit is included with an active Software Assurance contract. You don't need to purchase additional Microsoft software licenses, and there are no associated mobility fees.

For more information about this Microsoft benefit, see Microsoft License Mobility through Software Assurance.

Eligibility Requirements

To enroll in Microsoft License Mobility through Software Assurance, you must be a Microsoft Volume License customer with eligible server application products. The following are key requirements:

- Windows Server operating systems, desktop client operating systems, and desktop applications such as Microsoft Office are not eligible under License Mobility through Software Assurance.
- Active Software Assurance coverage is required on eligible licenses migrated to Oracle Cloud Infrastructure.
- All licenses used to run and access your licensed software, such as server licenses, processor licenses, Client Access Licenses (CALs), External Connector (EC) licenses, and server management licenses, require active Software Assurance coverage. Your rights to run licensed software and manage instances on Oracle Cloud Infrastructure expire with the expiration of the Software Assurance coverage on those licenses.
- Eligible Volume Licensing programs include the Microsoft Enterprise Agreement, Microsoft Enterprise Subscription Agreement, and Microsoft Open Value agreement, where Software Assurance is included, and other Volume Licensing programs where Software Assurance is an option, such as the Microsoft Open License agreement and the Microsoft Select Plus agreement.
- You may move Microsoft licenses from on-premises or another cloud services provider only after more than 90 days have passed since the last license move.
- Eligible Microsoft licenses on Oracle Cloud Infrastructure must be maintained for a minimum period of 90 days in a specific Oracle Cloud Infrastructure region. After the 90-day period, you may move the licensed software to a shared host in another Oracle Cloud Infrastructure region.

- Any Microsoft Server licenses permitted on Oracle Cloud Infrastructure must be eligible according to the latest Microsoft Product Terms. It is your responsibility to verify that the licenses you bring to Oracle Cloud Infrastructure are eligible according to the latest Microsoft Product Terms.

Enrolling in License Mobility through Software Assurance

All customers using License Mobility through Software Assurance must complete a license verification process. Microsoft will verify that you have eligible licenses with active Software Assurance and send confirmation when the verification process is complete.

You can deploy your application server software before completing the verification process, but you must submit the license verification form within 10 days of deployment.

You are responsible for managing true ups and renewals as required under your Volume Licensing agreement.

You must submit a new form each time that you deploy additional licenses, when you renew your agreement, and when you deploy any previously unverified products.

To enroll in License Mobility through Software Assurance:

1. Verify that you are a Microsoft Volume Licensing customer with eligible application server licenses that are covered by active Software Assurance.
2. Download the license verification form:
    a. Go to the Microsoft Product Licensing search page.
    b. In the **Document Type** area, select **License Verification**.
    c. Filter the results by language, region, and business sector. Note that the verification form is not available in the WW (World Wide) region.
    d. Download the **LicenseMobilityVerif** document.

3. Complete the license verification form. To specify Oracle as the Authorized Mobility Partner, provide the following information:
   - **Authorized Mobility Partner Name:** Oracle America, Inc.
   - **Authorized Mobility Partner Website URL:** http://www.oracle.com/
   - **Authorized Mobility Partner Email Address:** microsoftlm_us_grp@oracle.com

   For instructions to complete the form, see the Microsoft License Mobility Verification Guide (PDF).
4. Submit the completed verification form to both Microsoft and Oracle:
   - **Microsoft:** Submit the form through your Microsoft reseller or directly to the email address in the form.
   - **Oracle:** Send the form to microsoftlm_us_grp@oracle.com.

   Microsoft and Oracle verify that the product licenses for the workloads you deploy to Oracle Cloud Infrastructure are eligible according to the terms of your License Mobility through Software Assurance benefit. Microsoft will communicate your verification status to you and to Oracle as an Authorized Mobility Partner.

Using Microsoft Windows on Oracle Cloud Infrastructure: FAQ

Oracle Cloud Infrastructure is licensed to provide Microsoft software offerings, including being a Microsoft Authorized License Mobility Partner.

For the latest Microsoft licensing requirements, refer to the Microsoft Product Terms.

If you can't find the answer to your question here, or you need more assistance running Microsoft products on Oracle Cloud Infrastructure, contact Oracle Support.

General Questions

What OS editions of Microsoft Windows Server are supported?

Oracle-provided images

These Windows versions are available for Oracle-provided images:

- Windows Server 2008 R2* Enterprise
- Windows Server 2012 R2 Standard, Datacenter
- Windows Server 2016 Standard, Datacenter

Bring Your Own Image (BYOI)

These Windows versions support custom image import:

- Windows Server 2008 R2* Standard, Enterprise, Datacenter
- Windows Server 2012 Standard, Datacenter
- Windows Server 2012 R2 Standard, Datacenter
- Windows Server 2016 Standard, Datacenter
- Windows Server 2019 Standard, Datacenter

* Windows Server 2008 R2 reaches end of support on January 14, 2020.

If you don't need to migrate your Windows OS licenses, you can use the Bring Your Own Image process to migrate your Windows image to Oracle Cloud Infrastructure.

Is Windows Server 2019 available as an Oracle-provided image?

No, Windows Server 2019 is currently not available as an Oracle-provided image.

If you're interested in Windows Server 2019, contact Oracle Support.

Is Windows Server 2019 available as a Bring Your Own Image (BYOI) image?

Yes, you can import your own Windows Server 2019 image. For source image requirements and steps to import an image, see Importing Custom Windows Images.

What VM and bare metal options are available for Windows Server operating systems?

The following table shows support for Microsoft Windows Server operating systems on Oracle Cloud Infrastructure.

Use Case	Bare Metal Machines	Virtual Machines (VMs)	License
Use an Oracle-provided Windows Server operating system image for Windows Server 2016, Windows Server 2012 R2, or Windows Server 2008 R2.	Supported	Supported	Volume license issued by Oracle Cloud Infrastructure
Bring your own virtual machine image. You can import your own custom virtual machine Windows Server OS image.	Not supported	Supported	Volume license issued by Oracle Cloud Infrastructure
Bring your own Windows Server ISO image. You can import your own custom Windows Server ISO image. You must use iPXE boot.	Supported	Not supported	Customer-owned license
Bring your own hypervisor. You can use a Windows Server 2016 Datacenter hypervisor host provided by Oracle Cloud Infrastructure and import your own VM images.	Supported	Not supported	Volume license issued by Oracle Cloud Infrastructure

Does Oracle Cloud Infrastructure support Bring Your Own Image (BYOI) for Windows Server?

Yes, you are permitted to import your own generalized custom image of Windows Server.

When you create an instance with an imported image on a VM or a shared bare metal machine, Oracle Cloud Infrastructure licenses the instance. For more information about imported images, see Creating Windows Custom Images.

If you want to use your own license, BYOI is supported only for bare metal machines on a dedicated host.

How am I charged for Windows Server on Oracle Cloud Infrastructure?

The cost of a Microsoft Windows Server license is an additional cost, on top of the underlying Compute instance price. You pay separately for the Compute instance and the Windows Server license. For more information about Microsoft Windows Server pricing, see Compute Pricing.

Billing continues for the Windows Server license when the instance is stopped. To halt billing for the Windows Server license, you must terminate (delete) the instance.

How does Windows Server get updated with the latest patches?

You must update your VCN's security list to enable egress traffic for port 80 (HTTP) and port 443 (HTTPS) to install patches from Microsoft. Oracle Cloud Infrastructure enables automatic updates for Microsoft Windows Server and uses the default settings for applying Windows Server patches.

Can I take a snapshot image after customizing a running Window Server instance?

Yes, there are several options available on both bare metal and virtual machines:

- Create a custom image: Creates a custom image that you can use to launch other instances. Instances that you launch from your image include the customizations, configuration, and software installed when you created the image.
- Clone a boot volume: Makes a copy of an existing boot volume without needing to go through the backup and restore process. A boot volume clone is a point-in-time direct disk-to-disk deep copy of the source boot volume, so all the data that is in the source boot volume when the clone is created is copied to the boot volume clone.
- Back up a block volume: Makes a point-in-time backup of data on a block volume. You can restore a backup to a new volume either immediately after a backup or at a later time that you choose.
- Back up a boot volume: Makes a backup of a boot volume. Boot volume backup capabilities are the same as block volume backup capabilities and are in-region only. Windows boot volume backups cannot be copied across regions.

Can I export a custom Windows Server image?

Yes, exporting custom Windows Server operating system images is supported. For steps, see Image Import/Export.

Licensing - Windows Server

What is BYOL?

BYOL stands for "bring your own license." BYOL enables you use software licenses that you already own to deploy software on Oracle Cloud Infrastructure, without any additional licensing fees. This process uses the License Mobility through Microsoft Software Assurance benefit provided by Microsoft. You must have active Software Assurance with Microsoft to bring your licenses to Oracle Cloud Infrastructure.

What is Microsoft License Mobility?

License Mobility through Software Assurance is a Microsoft benefit that permits you to move your eligible Microsoft licenses to cloud services providers such as Oracle Cloud Infrastructure. Oracle is an Authorized Mobility Partner for License Mobility.

With License Mobility through Software Assurance, you can deploy eligible application servers on bare metal hosts or virtual shared hardware in Oracle Cloud Infrastructure. An example of an application eligible for License Mobility through Software Assurance is Microsoft SQL. Windows Server operating systems are not eligible.

You may move Microsoft licenses from on-premises or another Authorized Mobility Partner only after more than 90 days have passed since the last license move.

For more information about this Microsoft benefit, see Microsoft License Mobility through Software Assurance. For steps to move your Microsoft licenses to Oracle Cloud Infrastructure, see Moving Microsoft Licenses to Oracle Cloud Infrastructure: Microsoft License Mobility.

Is Oracle a Microsoft Authorized Mobility Partner?

Yes, Oracle is an Authorized Mobility Partner for the Microsoft License Mobility through Software Assurance benefit.

Can I bring my own license for Microsoft Windows Server to Oracle Cloud Infrastructure?

Yes. You can bring your own license (BYOL) for Microsoft Windows Server, subject to the Microsoft Product Terms. You are responsible for managing your own licenses to maintain compliance with Microsoft licensing terms.

The following table shows the BYOL requirements for Microsoft licenses on Oracle Cloud Infrastructure.

Microsoft License	Bare Metal Machines and Dedicated Virtual Machine Hosts	Virtual Machines (Multi-Tenant Shared Host)
Windows Server	Supported with restrictions. You can BYOL on a bare metal dedicated host. You must import your own custom ISO image and use the iPXE boot process. BYOL is not supported for Oracle-provided images.	Not supported. Shared hosts must use Oracle-provided images that include the Microsoft license.
SQL Server Subject to the Microsoft Product Terms	Supported. You must have License Mobility through Software Assurance.	Supported. You must have License Mobility through Software Assurance and use an Oracle-provided image.
MSDN	Supported. Non-production use only.	Not supported.
Microsoft Office	Not supported.	Not supported.

Microsoft License	Bare Metal Machines and Dedicated Virtual Machine Hosts	Virtual Machines (Multi-Tenant Shared Host)
Windows 7, Windows 8, and Windows 10	Not supported.	Not supported.
Other Microsoft applications	Supported. Subject to the Microsoft Product Terms.	Supported. You must have License Mobility through Software Assurance and use an Oracle-provided image.

Application licenses require License Mobility through Software Assurance when running on Oracle Cloud Infrastructure VM instances.

Questions about your licensing rights should be directed to Microsoft or your Microsoft reseller.

Can I use virtual machines and bring my own license for Microsoft Windows Server to Oracle Cloud Infrastructure?

You cannot migrate your Windows Server OS licenses when using Oracle Cloud Infrastructure virtual machines.

However, you can bring your own hypervisor (KVM) to run a Windows Server VM with your own Windows Server OS license.

The following restrictions apply:

- You can use VMs with their own license only if you use bring your own hypervisor on a dedicated bare metal host.

- BYOL of Microsoft Windows Server is not supported for VMs running on a shared host. Oracle Cloud Infrastructure-provided VMs offer Windows Server.
    - You can use a bare metal instance under bring your own hypervisor.
    - You must install and manage a hypervisor (KVM or Hyper-V) and launch your own VMs. This will ensure isolation, because all Oracle VMs are running on a dedicated bare metal server. The VMs can run Windows Server if they are licensed through MSDN (development use only).
- BYOL on a dedicated host is only permitted with License Mobility through Active Software Assurance. Follow the license mobility process to move your SQL Server license to Oracle Cloud Infrastructure.

Licensing - Other Microsoft Software

What other Microsoft applications can I bring to Oracle Cloud Infrastructure?

Any Microsoft Server licenses permitted on Oracle Cloud Infrastructure must be eligible according to the latest Microsoft Product Terms. It is your responsibility to verify that the licenses you bring to Oracle Cloud Infrastructure are eligible according to the latest Microsoft Product Terms. All products that are currently eligible for License Mobility and covered by Software Assurance are eligible for BYOL.

Can I bring my own SQL Server license to Oracle Cloud Infrastructure?

Yes, you can bring your own SQL Server license using License Mobility through Active Software Assurance. The following restrictions apply:

- When you move your Microsoft SQL license using the license mobility process, the Microsoft Windows Server license is not included. Microsoft Windows Server licenses are not permitted to be moved under License Mobility. Windows Server operating systems must use the license issued by Oracle Cloud Infrastructure.

- Perpetual licenses can be moved from on-premises or other cloud providers only after more than 90 days have passed since the last license move.
- End-of-support versions are not supported on shared host virtual machines on Oracle Cloud Infrastructure.

Follow the license mobility process to move your SQL Server license to Oracle Cloud Infrastructure.

Can I use my MSDN license on Microsoft Windows Server on Oracle Cloud Infrastructure?

Yes, you can use your MSDN license on Oracle Cloud Infrastructure if you use the Oracle Cloud Infrastructure bare metal offering.

You can use virtual machines with your own MSDN license only if you bring your own hypervisor (KVM). You cannot use your MSDN license when using virtual machines on Oracle Cloud Infrastructure.

Can I buy a MSDN subscription from Oracle Cloud Infrastructure?

No, Oracle does not sell MSDN subscriptions. Contact Microsoft or your Microsoft reseller.

Can I use a MSDN license for a production environment?

No, MSDN subscription licenses are for development, testing, or demonstration purposes only.

How can I remote access to a Windows Server instance on Oracle Cloud Infrastructure?

Follow the steps to connect to a Windows instance. Windows operating systems permit remote access for a maximum of two users using Remote Desktop Services (RDS) for Administration purposes.

RDS Client Access Licenses (CALs) are required for each user or device using Remote Desktop.

Does Oracle Cloud Infrastructure offer additional Remote Desktop Services licenses for applications running on Windows VMs?

No, Oracle Cloud Infrastructure does not offer Microsoft RDS (Remote Desktop Server) Subscriber Access Licenses (SALs). You can bring your own license (BYOL) and use your RDS Client Access Licenses (CALs) on Oracle Cloud Infrastructure bare metal or virtual machines only if you have active Software Assurance coverage and move those licenses using the license mobility process.

Can I bring my own RDS CALs if I want more than two users to access my Windows Server instance?

Yes, you can use your Remote Desktop Services (RDS) Client Access Licenses (CALs) on Oracle Cloud Infrastructure if you use the Oracle Cloud Infrastructure bare metal offering. In addition, you can use virtual machines with their own MSDN license if you bring your own hypervisor (KVM).

You can use your RDS CAL licenses on Oracle Cloud Infrastructure virtual machines only if you have active Software Assurance coverage and move your CALs using the license mobility process.

Other Windows Server Questions

Are there user data capabilities when launching Windows Server images?

Yes, Oracle-provided Windows images include cloudbase-init installed by default. You can use cloudbase-init to run PowerShell scripts, batch scripts, or other user data content on instance launch. Cloudbase-init is the equivalent of cloud-init on Linux-based images.

Can I use Windows Remote Management on Oracle Cloud Infrastructure?

Yes, Microsoft Windows Remote Management (WinRM) is enabled by default on Oracle-provided Windows images. WinRM enables you to remotely manage the operating system.

What is Microsoft end of support?

Microsoft establishes the support lifecycle policy for its products. When a product reaches the end of its support lifecycle, Microsoft no longer provides security updates for the product. You should upgrade to the latest version to remain secure.

What happens when Windows Server 2008 R2 reaches end of support?

Windows Server 2008 R2 reaches the end of its support lifecycle on January 14, 2020. After this date, you can import your own Windows 2008 R2 image and run your existing instances, but are at a higher risk of security issues, incompatibility, or failures. Extended Security Updates may not be used on Oracle Cloud Infrastructure. Oracle does not provide any operating system support for end-of-support operating systems.

Oracle Cloud Infrastructure does not provide platform images after the end of support date. However, you can import your own image and launch it on a shared host VM.

There are no restrictions to running end-of-support operating systems on bare metal machines on a dedicated host. You may bring your own image (BYOI) of a Windows Server 2008 R2 image, but you must import a custom OS image and run the image on a dedicated host.

Updating the Linux iSCSI Service to Restart Automatically

Oracle Cloud Infrastructure supports iSCSI attached remote boot and block volumes to Compute instances. These iSCSI attached volumes are managed by the Linux iSCSI initiator service, `iscsid` . In scenarios where this service is stopped for any reason, such as the service crashes or a system administrator inadvertently stops the service, it's important that this service is automatically restarted immediately.

The following platform images distributed by Oracle Cloud Infrastructure are configured so that the `iscsid` service restarts automatically:

- Oracle Linux 7 images released February 26, 2019 and later. See the release notes for Oracle-Linux-7.6-Gen2-GPU-2019.02.20-0 and Oracle-Linux-7.6-2019.02.20-0.
- Oracle Linux 6 images released February 26, 2019 and later. See the release notes Oracle-Linux-6.10-2019.02.22-0.
- CentOS 7 images released February 25, 2019 and later. See the release notes for CentOS-7-2019.02.23-0.

Instances created from earlier versions of CentOS 7.x and Oracle Linux platform images, or any versions of Oracle Cloud Infrastructure CentOS 6.x and Ubuntu platform images do not have this configuration. You should update these existing instances and custom images created from these images so that the `iscsid` service restarts automatically. You should also check this configuration on your imported paravirtualized custom images and any instances launched from these images and update the configuration as needed.

This topic describes how to update the `iscsid` service on an instance so that it will restart automatically.

Note

Configuring an instance to automatically restart the `iscsid` service does not require a reboot and will increase the stability of your infrastructure.

Oracle Linux 7

Run the following command to update the `iscsid` service on your Oracle 7 Linux instances:

```
sudo yum update -y iscsi-initiator-utils
```

After running this command, the version of the `iscsid` service should be 6.2.0.874 or newer.

Run the following command to check the version:

```
yum info iscsi-initiator-utils
```

This update does not require a system reboot and will not make any changes to your instances beyond configuring `iscsid` to restart automatically.

Oracle Linux 6

Run the following command to update the `iscsid` service on your Oracle 6 Linux instances:

```
sudo yum update -y iscsi-initiator-utils
```

After running this command, the version of the `iscsid` service should be 6.2.0.873 or newer.

Run the following command to check the version:

```
yum info iscsi-initiator-utils
```

This update does not require a system reboot and will not make any changes to your instances beyond configuring `iscsid` to restart automatically.

CentOS 7.x

Important

Do not directly edit the `systemd` **iscsid.service** file. You should instead create an override to ensure that the `restart` option isn't overwritten the next time the `iscsid` service is updated.

On your CentOS 7 instances run the following command to create an override file:

```
sudo systemctl edit iscsid.service
```

Paste and save the following into the file:

```
[Service]
Restart=always
```

Run the following commands to reload `systemd` and restart the `iscsid` service:

```
sudo systemctl daemon-reload
sudo systemctl restart iscsid
```

CentOS 6.x

On your CentOS 6 instances run the following command to install the monit package:

```
sudo yum install monit
```

Create the **/etc/monit/conf.d/iscsid.conf** file and include the following commands:

```
check process iscid with pidfile /run/iscsid.pid
start program = "/etc/init.d/open-iscsi start" with timeout 60 seconds
stop program = "/etc/init.d/open-iscsi stop"
```

Run the following command to start the `monit` service:

```
/etc/init.d/monit start
```

Ubuntu 18

> **Important**
>
> Do not directly edit the `systemd` **iscsid.service** file, instead create an override to ensure that the `restart` option isn't overwritten the next time the `iscsid` service is updated.

On your Ubuntu 18 instances run the following command to create an override file:

```
sudo systemctl edit iscsid.service
```

Paste and save the following into the file:

```
[Service]
Restart=
Restart=always
```

Run the following commands to reload `systemd` and restart the `iscsid` service:

```
sudo systemctl daemon-reload
sudo systemctl restart iscsid
```

Ubuntu 16

Important

Do not directly edit the `systemd` **iscsid.service** file, instead create an override to ensure that the `restart` option isn't overwritten the next time the `iscsid` service is updated.

On your Ubuntu 16 instances run the following command to create an override file:

```
sudo systemctl edit iscsid.service
```

Paste and save the following into the file:

```
[Service]
Restart=
Restart=always
```

Run the following commands to reload `systemd` and restart the `iscsid` service:

```
sudo systemctl daemon-reload
sudo systemctl restart iscsid
```

Ubuntu 14

On your Ubuntu 14 instances run the following command to install the monit package:

```
sudo apt-get install monit
```

Create the **/etc/monit/conf.d/iscsid.conf** file and include the following commands:

```
check process iscid with pidfile /run/iscsid.pid
start program = "/etc/init.d/open-iscsi start" with timeout 60 seconds
stop program = "/etc/init.d/open-iscsi stop"
```

Run the following command to start the `monit` service:

```
/etc/init.d/monit start
```

Testing the `iscsid` Service Update

Perform these steps to verify that the `iscsid` service has been updated successfully, and that it restarts automatically.

Warning

Do not perform these steps on a production instance. If the `iscsid` service fails to restart the instance may become unresponsive.

1. Run the following command to confirm that the `iscsid` service is running:

   ```
   ps -ef | grep iscsid
   ```

2. Run the following command to stop the `iscsid` service:

   ```
   sudo pkill -9 iscsid
   ```

3. Wait 60 seconds and then run the following command to verify that the `iscsid` service has restarted:

   ```
   ps -ef | grep iscsid
   ```

CHAPTER 9 Container Engine for Kubernetes

This chapter explains how to define and create Kubernetes clusters to enable the deployment, scaling, and management of containerized applications.

Overview of Container Engine for Kubernetes

Oracle Cloud Infrastructure Container Engine for Kubernetes is a fully-managed, scalable, and highly available service that you can use to deploy your containerized applications to the cloud. Use Container Engine for Kubernetes (sometimes abbreviated to just OKE) when your development team wants to reliably build, deploy, and manage cloud-native applications. You specify the compute resources that your applications require, and Container Engine for Kubernetes provisions them on Oracle Cloud Infrastructure in an existing OCI tenancy.

Container Engine for Kubernetes uses Kubernetes - the open-source system for automating deployment, scaling, and management of containerized applications across clusters of hosts. Kubernetes groups the containers that make up an application into logical units (called pods) for easy management and discovery. Container Engine for Kubernetes uses versions of Kubernetes certified as conformant by the Cloud Native Computing Foundation (CNCF).

You can access Container Engine for Kubernetes to define and create Kubernetes clusters using the Console and the REST API. You can access the clusters you create using the Kubernetes command line (kubectl), the Kubernetes Dashboard, and the Kubernetes API.

Container Engine for Kubernetes is integrated with Oracle Cloud Infrastructure Identity and Access Management (IAM), which provides easy authentication with native Oracle Cloud Infrastructure identity functionality.

For an introductory tutorial, see Creating a Cluster with Oracle Cloud Infrastructure Container Engine for Kubernetes.

Note

Container Engine for Kubernetes is not available in Oracle Cloud Infrastructure Government Cloudrealms.

Ways to Access Oracle Cloud Infrastructure

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. For a list of available SDKs, see Software Development Kits and Command Line Interface.

To access the Console, you must use a supported browser. Oracle Cloud Infrastructure supports the latest desktop versions of Google Chrome, Microsoft Edge, Internet Explorer 11, Safari, Firefox, and Firefox ESR. Note that private browsing mode is not supported for Firefox, Internet Explorer, or Edge. Mobile browsers are not supported.

For general information about using the API, see REST APIs.

Resource Identifiers

Most types of Oracle Cloud Infrastructure resources have a unique, Oracle-assigned identifier called an Oracle Cloud ID (OCID). For information about the OCID format and other ways to identify your resources, see Resource Identifiers.

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud

network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies. For specific details about writing policies for each of the different services, see Policy Reference.

If you're a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

Note that to perform certain operations on clusters created by Container Engine for Kubernetes, you might require additional permissions granted via a Kubernetes RBAC role or clusterrole. See About Access Control and Container Engine for Kubernetes.

Container Engine for Kubernetes Capabilities and Limits

In each region that is enabled for your tenancy, you can create three clusters (Monthly Universal Credits) or one cluster (Pay-as-You-Go or Promo) by default. Each cluster you create can have a maximum of 1000 nodes. See Service Limits.

Required IAM Service Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don't have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

If you're new to policies, see Getting Started with Policies and Common Policies.

For more details about policies for Container Engine for Kubernetes, see:

- Policy Configuration for Cluster Creation and Deployment
- Details for Container Engine for Kubernetes

Preparing for Container Engine for Kubernetes

Before you can use Container Engine for Kubernetes to create a Kubernetes cluster:

- You must have access to an Oracle Cloud Infrastructure tenancy. The tenancy must be subscribed to one or more of the regions in which Container Engine for Kubernetes is available (see Availability by Region Name and Region Code).
- Your tenancy must have sufficient quota on different types of resource (see Service Limits). More specifically:
    - Compute instance quota: To create a Kubernetes cluster, at least one compute instance (node) must be available in the tenancy. However, you'll probably want more than this minimum. For example, to create a highly available cluster in a region with three availability domains (ADs), at least three compute instances must be available (one in each availability domain).
    - Block volume quota: If you intend to create Kubernetes persistent volumes, sufficient block volume quota must be available in each availability domain to meet the persistent volume claim. Persistent volume claims must request a minimum of 50 gigabytes. See Creating a Persistent Volume Claim.
    - Load balancer quota: If you intend to create a load balancer to distribute traffic between the nodes running a service in a Kubernetes cluster, sufficient load balancer quota must be available in the region. See Creating Load Balancers to Distribute Traffic Between Cluster Nodes.
- Within your tenancy, there must already be a compartment to contain the necessary network resources (such as a VCN, subnets, internet gateway, route table, security lists). If such a compartment does not exist already, you will have to create it. Note that the network resources can reside in the root compartment. However, if you expect multiple teams to create clusters, best practice is to create a separate compartment for each team.
- Within the compartment, network resources (such as a VCN, subnets, internet gateway, route table, security lists) must be appropriately configured in each region in which you want to create and deploy clusters. For example, to create a highly available cluster in a region with three availability domains, the VCN must include:

    - For worker nodes: a regional subnet (recommended), or three AD-specific subnets (one in each of the availability domains).
    - For load balancers: optionally (but usually) an additional regional subnet (recommended), or an additional two AD-specific subnets (each in a different availability domain).

  Best practice is to use regional subnets to make failover across availability domains simpler to implement.

  When creating a new cluster, you can have Container Engine for Kubernetes automatically create and configure new network resources for the new cluster, or you can specify existing network resources. If you specify existing network resources, you or somebody else must have already configured those resources appropriately. See Network Resource Configuration for Cluster Creation and Deployment.

- Within the root compartment of your tenancy, a policy statement (`Allow service OKE to manage all-resources in tenancy`) must be defined to give Container Engine for Kubernetes access to resources in the tenancy. See Create Required Policy for Container Engine for Kubernetes
- To create and/or manage clusters, you must belong to one of the following:
    - The tenancy's Administrators group
    - A group to which a policy grants the appropriate Container Engine for Kubernetes permissions. If you are creating or modifying clusters using the Console, or want Container Engine for Kubernetes to automatically create and configure new network resources for a new cluster, policies must also grant the group the following permissions:
        - VCN_READ and VCN_CREATE
        - SUBNET_READ and SUBNET_CREATE
        - COMPARTMENT_INSPECT
        - INTERNET_GATEWAY_CREATE
        - NAT_GATEWAY_CREATE

        - ROUTE_TABLE_UPDATE
        - SECURITY_LIST_CREATE

      If you want to create a service gateway to enable applications deployed on a cluster to pull images from Oracle Cloud Infrastructure Registry (or to use other Oracle Cloud Infrastructure resources) without exposing data to the public internet, a policy must also grant the group the SERVICE_GATEWAY_CREATE permission.

      See Create Required Policy for Groups.

- To perform operations on a cluster:
    - You must have installed and configured the Kubernetes command line tool kubectl (see the kubectl documentation).
    - You must have downloaded your own copy of the cluster's kubeconfig configuration file (see Downloading a kubeconfig File to Enable Cluster Access). Note that you must download your own kubeconfig file. You cannot access a cluster using a kubeconfig file that a different user downloaded.
    - You must have appropriate permissions to access the cluster (see About Access Control and Container Engine for Kubernetes).

Availability by Region Name and Region Code

Container Engine for Kubernetes is available in the following regions. Note that you have to use the region code in some commands. In some cases, you might have to use shortened versions of availability domain names.

Region Name	Region Code	Shortened Availability Domain Names
US East (Ashburn)	iad	• US-ASHBURN-AD-1 • US-ASHBURN-AD-2 • US-ASHBURN-AD-3
Germany Central (Frankfurt)	fra	• EU-FRANKFURT-1-AD-1 • EU-FRANKFURT-1-AD-2 • EU-FRANKFURT-1-AD-3
UK South (London)	lhr	• UK-LONDON-1-AD-1 • UK-LONDON-1-AD-2 • UK-LONDON-1-AD-3
India West (Mumbai)	bom	• AP-MUMBAI-1-AD-1
US West (Phoenix)	phx	• PHX-AD-1 • PHX-AD-2 • PHX-AD-3
Brazil East (Sao Paulo)	gru	• SA-SAOPAULO-1-AD-1
South Korea Central (Seoul)	icn	• AP-SEOUL-1-AD-1
Australia East (Sydney)	syd	• AP-SYDNEY-1-AD-1
Japan East (Tokyo)	nrt	• AP-TOKYO-1-AD-1
Canada Southeast (Toronto)	yyz	• CA-TORONTO-1-AD-1
Switzerland North (Zurich)	zrh	• EU-ZURICH-1-AD-1

Network Resource Configuration for Cluster Creation and Deployment

Before you can use Container Engine for Kubernetes to create and deploy clusters in the regions in a tenancy:

- The tenancy's root compartment must include a policy to allow Container Engine for Kubernetes to perform operations in the tenancy. See Create Required Policy for Container Engine for Kubernetes.
- Within the tenancy, there must already be a compartment to contain the necessary network resources (such as a VCN, subnets, internet gateway, route table, security lists). If such a compartment does not exist already, you will have to create it. Note that the network resources can reside in the root compartment. However, if you expect multiple teams to create clusters, best practice is to create a separate compartment for each team.
- Within the compartment, network resources (such as a VCN, subnets, internet gateway, route table, security lists) must be appropriately configured in each region in which you want to create and deploy clusters. When creating a new cluster, you can have Container Engine for Kubernetes automatically create and configure new network resources for a new 'quick cluster'. Alternatively, you can explicitly specify the existing network resources to use for a 'custom cluster'. If you specify existing network resources, you or somebody else must have already configured those resources appropriately, as described in this topic.

This topic describes the necessary configuration for each network resource. To see details of a typical configuration, see Example Network Resource Configurations.

For an introductory tutorial, see Creating a Cluster with Oracle Cloud Infrastructure Container Engine for Kubernetes.

Root Compartment Configuration

You have to define a policy for the tenancy's root compartment to enable Container Engine for Kubernetes to perform operations on the tenancy. See Create Required Policy for Container Engine for Kubernetes.

VCN Configuration

The VCN in which you want to create and deploy clusters must be configured as follows:

- The VCN must have a CIDR block defined that is large enough for the number of subnets you specify for the clusters you create. For example, to create a highly available cluster in a region with three availability domains will typically require two regional subnets (recommended) or five AD-specific subnets to support the necessary number of worker nodes and load balancers. However, you can create clusters with fewer subnets. A /16 CIDR block would be large enough for almost all use cases (10.0.0.0/16 for example). The CIDR block you specify for the VCN must not overlap with the CIDR block you specify for pods and for the Kubernetes services (see CIDR Blocks and Container Engine for Kubernetes).
- The VCN must have an appropriate number of subnets defined. For example, to create a highly available cluster in a region with three availability domains, the VCN must include:
    - For worker nodes: a regional subnet (recommended), or three AD-specific subnets (one in each of the availability domains).
    - For load balancers: optionally (but usually) an additional regional subnet (recommended), or an additional two AD-specific subnets (each in a different availability domain).

  However, you can create clusters with fewer worker nodes, and fewer or no load balancers, and therefore require fewer subnets. Best practice is to use regional subnets to make failover across availability domains simpler to implement. See Subnet Configuration.
- The VCN must have security lists defined for worker node subnets and load balancer subnets (if specified). See Security List Configuration.

In addition:

- Oracle recommends DNS Resolution is selected for the VCN.
- If you expect applications deployed on a cluster to require worker nodes to initiate connections to the internet, the VCN must have an internet gateway (if the worker

nodes are in public subnets) or a NAT gateway (if the worker nodes are in private subnets). See Internet Gateway Configuration and NAT Gateway Configuration.

- If you expect applications deployed on a cluster to pull images from Oracle Cloud Infrastructure Registry (or to use other Oracle Cloud Infrastructure resources) and you don't want to expose the data to the public internet, you can define a service gateway in the VCN. See Service Gateway Configuration.
- If the VCN has a NAT gateway, an internet gateway, or a service gateway, it must have a route table with appropriate rules defined. See Route Table Configuration.

See VCNs and Subnets and Example Network Resource Configurations.

Internet Gateway Configuration

If you intend to deploy worker nodes in public subnets, and you expect deployed applications to require the worker nodes to initiate connections to the internet, the VCN must have an internet gateway. The internet gateway must be specified as the target for the destination CIDR block 0.0.0.0/0 in a route rule in a worker node route table.

See VCNs and Subnets and Example Network Resource Configurations.

NAT Gateway Configuration

If you intend to deploy worker nodes in private subnets, and you expect deployed applications to require the worker nodes to initiate connections to the internet, the VCN must have a NAT gateway. The NAT gateway must be specified as the target for the destination CIDR block 0.0.0.0/0 in a route rule in a worker node route table.

See NAT Gateway and Example Network Resource Configurations.

Service Gateway Configuration

If you expect applications deployed on a cluster to pull images from Oracle Cloud Infrastructure Registry (or to use other Oracle Cloud Infrastructure resources) and you want to protect data from the public internet, you can set up a service gateway. Setting up a service gateway enables worker nodes to access other resources in the same region without exposing data to the public internet.

When setting up the service gateway, create it in the same VCN and compartment as the worker nodes, and select the **All <region> Services in Oracle Services Network** option.

Having created the service gateway, it must be specified as the target for **All <region> Services in Oracle Services Network** in a route rule in the worker node route table.

Note that if you expect deployed applications to require access to public endpoints or services not supported by a service gateway (for example, to download updates or patches), configure additional network resources (such as a NAT gateway) to access the internet.

See Access to Oracle Services: Service Gateway and Example Network Resource Configurations.

Route Table Configuration

If you intend to deploy worker nodes in public subnets, and you expect deployed applications to require the worker nodes to initiate connections to the internet, create an internet gateway. Then create a worker node route table with a route rule that specifies the internet gateway as the target for the destination CIDR block 0.0.0.0/0.

If you intend to deploy worker nodes in private subnets, and you expect deployed applications to require the worker nodes to initiate connections to the internet, create a NAT gateway. Then create a worker node route table with a route rule that specifies the NAT gateway as the target for the destination CIDR block 0.0.0.0/0.

If you expect applications deployed on a cluster to pull images from Oracle Cloud Infrastructure Registry (or to use other Oracle Cloud Infrastructure resources) and you don't want to expose the data to the public internet, create a service gateway. Then create a worker node route table with a route rule that specifies the service gateway as the target for **All <region> Services in Oracle Services Network**.

See Internet Gateway, NAT Gateway, Access to Oracle Services: Service Gateway, and Example Network Resource Configurations.

DHCP Options Configuration

The VCN in which you want to create and deploy clusters must have DHCP Options configured. The default value for **DNS Type** of Internet and VCN Resolver is acceptable.

See DHCP Options and Example Network Resource Configurations.

Security List Configuration

The VCN in which you want to create and deploy clusters must have security lists defined for worker node subnets and load balancer subnets (if specified). The security lists for worker node subnets and load balancer subnets must be different. The security list for load balancer subnets must be unique and for their exclusive use.

Worker nodes are created with public or private IP addresses, according to whether you specify public or private subnets when defining the node pools in a cluster. Container Engine for Kubernetes must be able to access worker nodes.

See Security Lists and Example Network Resource Configurations.

Public Worker Node Subnet Security List configuration

When configuring a security list for public worker node subnets, the security list must have:

- stateless ingress and egress rules that allow all traffic between different worker node subnets
- stateless ingress and egress rules that allow all traffic between worker node subnets and load balancer subnets (if specified)
- ingress rules to allow Container Engine for Kubernetes to access worker nodes on port 22 from the following source CIDR blocks:
    - 130.35.0.0/16
    - 134.70.0.0/17
    - 138.1.0.0/16
    - 140.91.0.0/17
    - 147.154.0.0/16
    - 192.29.0.0/16

Optionally, you can include ingress rules for public worker node subnets to:

- explicitly allow SSH access to worker nodes on port 22 (see Connecting to Worker Nodes in Public Subnets Using SSH)
- allow inbound traffic to the worker nodes on the default NodePort range of 30000 to 32767 (see the Kubernetes documentation)

Optionally, you can include an egress rule that allows all outbound traffic to the internet.

Private Worker Node Subnet Security List configuration

When configuring a security list for private worker node subnets, the security list must have:

- stateless ingress and egress rules that allow all traffic between the different worker node subnets
- stateless ingress and egress rules that allow all traffic between worker node subnets and load balancer subnets

Optionally, you can include ingress rules for private worker node subnets to:

- explicitly allow SSH access to worker nodes on port 22 from within the VCN CIDR block (see Connecting to Worker Nodes in Private Subnets Using SSH)
- allow inbound traffic to the worker nodes on the default NodePort range of 30000 to 32767 from within the VCN CIDR block (see the Kubernetes documentation)

Optionally, you can include an egress rule that allows all outbound traffic to the internet.

Subnet Configuration

The characteristics of the cluster you want to create, and the number of availability domains in the region in which you want to deploy the cluster, will determine the number of subnets to configure. For example, to create a highly available cluster in a region with three availability domains will require:

- For worker nodes: a regional subnet (recommended), or three AD-specific subnets (one in each of the availability domains).

- For load balancers: optionally (but usually) an additional regional subnet (recommended), or an additional two AD-specific subnets (each in a different availability domain).

Best practice is to use regional subnets to make failover across availability domains simpler to implement.

The VCN in which you want to create and deploy clusters must have at least one subnet defined in which to deploy worker nodes. Worker node subnets can be either public, or private for additional security (as specified by the **Subnet access** property). The number of worker node subnets to create depends on the region in which you are creating the cluster:

- If you are creating a cluster in a region with multiple availability domains, you can define a single regional subnet (recommended), or multiple AD-specific subnets (one in each of the availability domains).
- If you are creating a cluster in a region with a single availability domain, you can define a single regional subnet (recommended), or a single AD-specific subnet.

You have the option to define and use load balancers in clusters you create. If you want to define and use load balancers, the VCN in which you want to create and deploy clusters must have at least one subnet defined to host the load balancers. Load balancer subnets can be public or private (as specified by the **Subnet access** property). However, load balancers are optional, so you might not define load balancer subnets at all. The number of load balancer subnets to define depends on the region in which you are creating the cluster:

- If you are creating a cluster in a region with three availability domains, you can define:
    - zero or one load balancer regional subnet (recommended)
    - zero or two load balancer AD-specific subnets. If you define two load balancer AD-specific subnets, they must be in different availability domains.
- If you are creating a cluster in a region with a single availability domain, you can define zero or one load balancer subnet:
    - zero or one load balancer regional subnet (recommended)
    - zero or one load balancer AD-specific subnet.

In addition, all subnets must have the following properties set as shown:

- **Route Table:** The name of a route table, if one has been created, that has a route rule specifying an internet gateway (for public worker node subnets) or NAT gateway (for private worker node subnets) as the target for the destination CIDR block 0.0.0.0/0, and/or a route rule specifying a service gateway as the target for **All <region> Services in Oracle Services Network**.
- **DHCP options:** Default.

The CIDR blocks you specify for worker node and load balancer subnets must not overlap with CIDR blocks you specify for pods running in the cluster (see CIDR Blocks and Container Engine for Kubernetes).

Worker node subnets must have different security lists to load balancer subnets.

See VCNs and Subnets and Example Network Resource Configurations.

Example Network Resource Configurations

Before you can use Container Engine for Kubernetes to create and deploy clusters in the regions in a tenancy:

- The tenancy's root compartment must include a policy to allow Container Engine for Kubernetes to perform operations in the tenancy. See Create Required Policy for Container Engine for Kubernetes.
- Within the tenancy, there must already be a compartment to contain the necessary network resources (such as a VCN, subnets, internet gateway, route table, security lists). If such a compartment does not exist already, you will have to create it. Note that the network resources can reside in the root compartment. However, if you expect multiple teams to create clusters, best practice is to create a separate compartment for each team.
- Within the compartment, network resources (such as a VCN, subnets, internet gateway, route table, security lists) must be appropriately configured in each region in which you want to create and deploy clusters. When creating a new cluster, you can have Container Engine for Kubernetes automatically create and configure new network

resources for a new 'quick cluster'. Alternatively, you can explicitly specify the existing network resources to use for a 'custom cluster'. If you specify existing network resources, you or somebody else must have already configured those resources appropriately. See Network Resource Configuration for Cluster Creation and Deployment.

This topic gives examples of how you might configure network resources for highly available 'custom cluster' creation and deployment in a region with three availability domains:

- for public clusters, where you want worker nodes hosted in public AD-specific subnets that can be accessed directly from the internet (see Example 1: Example Network Resource Configuration for a Highly Available Public Cluster in a Region with Three Availability Domains, Using AD-Specific Subnets)
- for private clusters, where you want worker nodes hosted in private AD-specific subnets that can only be accessed from within the VCN (see Example 2: Example Network Resource Configuration for a Highly Available Private Cluster in a Region with Three Availability Domains, Using AD-Specific Subnets)
- for public clusters, where you want worker nodes hosted in a public regional subnet that can be accessed directly from the internet (see Example 3: Example Network Resource Configuration for a Highly Available Public Cluster in a Region with Three Availability Domains, Using a Regional Subnet)

Note that all the examples in this topic include a service gateway to enable worker nodes to access other Oracle Cloud Infrastructure resources in the same region (such as Oracle Cloud Infrastructure Registry) without exposing data to the public internet. However, you might be expecting applications deployed on the cluster to require access to public endpoints or services not supported by a service gateway. For example, to download updates or patches. If so, configure additional network resources (such as a NAT gateway) to access the internet.

For an introductory tutorial, see Creating a Cluster with Oracle Cloud Infrastructure Container Engine for Kubernetes.

Example 1: Example Network Resource Configuration for a Highly Available Public Cluster in a Region with Three Availability Domains, Using AD-Specific Subnets

This example assumes you want worker nodes hosted in three public AD-specific subnets that can be accessed directly from the internet.

EXAMPLE NETWORK RESOURCE CONFIGURATION

Resource	Example
VCN	Created manually, and defined as follows: • **Name:** acme-dev-vcn • **CIDR Block:** 10.0.0.0/16 • **DNS Resolution:** Selected
Internet Gateway	Created manually, and defined as follows: • **Name:** gateway-0
Service Gateway	Created manually, and defined as follows: • **Name:** service-gateway-0 • **Services:** All <region> Services in Oracle Services Network

Resource	Example
Route Table	Two route tables created manually, named, and defined as follows: • **Name:** routetable-0, with a route rule defined as follows: ◦ **Destination CIDR block:** 0.0.0.0/0 ◦ **Target Type:** Internet Gateway ◦ **Target Internet Gateway:** gateway-0 • **Name:** routetable-1, with a route rule defined as follows: ◦ **Destination:** All <region> Services in Oracle Services Network ◦ **Target Type:** Service Gateway ◦ **Target:** service-gateway-0
DHCP Options	Created automatically and defined as follows: • **DNS Type** set to Internet and VCN Resolver

Resource	Example
Security Lists	Two created (in addition to the default security list) manually, named, and defined as follows: • **Security List Name:** workers • **Security List Name:** loadbalancers For details of the ingress rules and egress rules defined for the workers security list and the loadbalancers security list, see Example Security List Configurations for a Highly Available Public Cluster Using AD-Specific Subnets.

Resource	Example
Subnets	Three worker node AD-specific subnets created manually, named, and defined as follows: • **Name:** workers-1 with the following properties: ◦ **Availability Domain:** AD1 ◦ **CIDR Block:** 10.0.10.0/24 ◦ **Route Table:** routetable-1 ◦ **Subnet access:** Public ◦ **DNS Resolution:** Selected ◦ **DHCP Options:** Default ◦ **Security List:** workers • **Name:** workers-2 with the following properties: ◦ **Availability Domain:** AD2 ◦ **CIDR Block:** 10.0.11.0/24 ◦ **Route Table:** routetable-1 ◦ **Subnet access:** Public ◦ **DNS Resolution:** Selected ◦ **DHCP Options:** Default ◦ **Security List:** workers • **Name:** workers-3 with the following properties: ◦ **Availability Domain:** AD3 ◦ **CIDR Block:** 10.0.12.0/24 ◦ **Route Table:** routetable-1 ◦ **Subnet access:** Public ◦ **DNS Resolution:** Selected

Resource	Example
	◦ **DHCP Options:** Default ◦ **Security List:** workers Two load balancer AD-specific subnets created, named, and defined as follows: • **Name:** loadbalancers-1 with the following properties: ◦ **Availability Domain:** AD1 ◦ **CIDR Block:** 10.0.20.0/24 ◦ **Route Table:** routetable-0 ◦ **Subnet access:** Public ◦ **DNS Resolution:** Selected ◦ **DHCP Options:** Default ◦ **Security List:** loadbalancers • **Name:** loadbalancers-2 with the following properties: ◦ **Availability Domain:** AD2 ◦ **CIDR Block:** 10.0.21.0/24 ◦ **Route Table:** routetable-0 ◦ **Subnet access:** Public ◦ **DNS Resolution:** Selected ◦ **DHCP Options:** Default ◦ **Security List:** loadbalancers

EXAMPLE SECURITY LIST CONFIGURATIONS FOR A HIGHLY AVAILABLE PUBLIC CLUSTER USING AD-SPECIFIC SUBNETS

In the example VCN, two security lists have been created (in addition to the default security list) to control access to and from the public worker node AD-specific subnets and the load

balancer AD-specific subnets. The two security lists are named 'workers' and 'loadbalancers' respectively.

The workers security list has the following ingress and egress rules for the public worker node AD-specific subnets:

Example Ingress Rules in a Security List for Public Worker Node AD-Specific Subnets:

#	Type	Source CIDR	IP Protocol	Source Port Range	Dest. Port Range	Type and Code	Allows: and Description:
1	Stateless	10.0.10.0/24	All	n/a	n/a	n/a	**Allows:** All traffic for all ports **Description:** This rule enables intra-VCN traffic.
2	Stateless	10.0.11.0/24	All	n/a	n/a	n/a	**Allows:** All traffic for all ports **Description:** This rule enables intra-VCN traffic.
3	Stateless	10.0.12.0/24	All	n/a	n/a	n/a	**Allows:** All traffic for all ports **Description:** This rule enables intra-VCN traffic.

#	Type	Source CIDR	IP Protocol	Source Port Range	Dest. Port Range	Type and Code	Allows: and Description:
4	Stateful	0.0.0.0/0	ICMP	n/a	n/a	3, 4	**Allows:** ICMP traffic for: 3, 4 Destination Unreachable: Fragmentation Needed and Don't Fragment was Set **Description:** This rule enables worker nodes to receive Path MTU Discovery fragmentation messages.
5	Stateful	130.35.0.0/16	TCP	All	22	n/a	**Allows:** TCP traffic for ports: 22 SSH Remote Login Protocol **Description:** This rule enables Container Engine for Kubernetes to access worker nodes.

#	Type	Source CIDR	IP Protocol	Source Port Range	Dest. Port Range	Type and Code	Allows: and Description:
6	Stateful	134.70.0.0/17	TCP	All	22	n/a	**Allows:** TCP traffic for ports: 22 SSH Remote Login Protocol **Description:** This rule enables Container Engine for Kubernetes to access worker nodes.
7	Stateful	138.1.0.0/16	TCP	All	22	n/a	**Allows:** TCP traffic for ports: 22 SSH Remote Login Protocol **Description:** This rule enables Container Engine for Kubernetes to access worker nodes.

#	Type	Source CIDR	IP Protocol	Source Port Range	Dest. Port Range	Type and Code	Allows: and Description:
8	Stateful	140.91.0.0/17	TCP	All	22	n/a	**Allows:** TCP traffic for ports: 22 SSH Remote Login Protocol **Description:** This rule enables Container Engine for Kubernetes to access worker nodes.
9	Stateful	147.154.0.0/16	TCP	All	22	n/a	**Allows:** TCP traffic for ports: 22 SSH Remote Login Protocol **Description:** This rule enables Container Engine for Kubernetes to access worker nodes.

#	Type	Source CIDR	IP Protocol	Source Port Range	Dest. Port Range	Type and Code	Allows: and Description:
10	Stateful	192.29.0.0/16	TCP	All	22	n/a	**Allows:** TCP traffic for ports: 22 SSH Remote Login Protocol **Description:** This rule enables Container Engine for Kubernetes to access worker nodes.
11	Stateful	0.0.0.0/0	TCP	All	22	n/a	**Allows:** TCP traffic for ports: 22 SSH Remote Login Protocol **Description:** This *optional* rule enables inbound SSH traffic from the internet on port 22 to access worker nodes.

#	Type	Source CIDR	IP Protocol	Source Port Range	Dest. Port Range	Type and Code	Allows: and Description:
12	Stateful	0.0.0.0/0	TCP	All	30000 - 32767	n/a	**Allows:** TCP traffic for ports: 30000 - 32767 **Description:** This *optional* rule enables inbound traffic to the worker nodes on the default NodePort range of 30000-32767 (see the Kubernetes documentation).

Example Egress Rules in a Security List for Public Worker Node AD-Specific Subnets:

#	Type	Dest. CIDR	IP Protocol	Source Port Range	Dest. Port Range	Type and Code	Allows: and Description:
1	Stateless	10.0.10.0/24	All	n/a	n/a	n/a	**Allows:** All traffic for all ports **Description:** This rule enables intra-VCN traffic.
2	Stateless	10.0.11.0/24	All	n/a	n/a	n/a	**Allows:** All traffic for all ports **Description:** This rule enables intra-VCN traffic.
3	Stateless	10.0.12.0/24	All	n/a	n/a	n/a	**Allows:** All traffic for all ports **Description:** This rule enables intra-VCN traffic.
4	Stateful	All <region> Services in Oracle Services Network	All	n/a	n/a	n/a	**Allows:** All traffic for all ports **Description:** This rule enables outbound access to the regional service gateway.

The loadbalancers security list has the following ingress and egress rules for load balancer AD-specific subnets:

Example Ingress Rules in a Security List for Load Balancer AD-Specific Subnets:

#	Type	Source CIDR	IP Protocol	Source Port Range	Dest. Port Range	Type and Code	Allows: and Description:
1	Stateless	0.0.0.0/0	TCP	All	All	n/a	**Allows:** TCP traffic for all ports: all **Description:** This rule enables incoming public traffic to service load balancers.

Example Egress Rules in a Security List for Load Balancer AD-Specific Subnets:

#	Type	Dest. CIDR	IP Protocol	Source Port Range	Dest. Port Range	Type and Code	Allows: and Description:
1	Stateless	0.0.0.0/0	TCP	All	All	n/a	**Allows:** TCP traffic for ports: all **Description:** This rule enables responses from a web application through the service load balancers.

Example 2: Example Network Resource Configuration for a Highly Available Private Cluster in a Region with Three Availability Domains, Using AD-Specific Subnets

This example assumes you want worker nodes hosted in three private AD-specific subnets that can only be accessed from within the VCN.

EXAMPLE NETWORK RESOURCE CONFIGURATION

Resource	Example
VCN	Created manually, and defined as follows: • **Name:** acme-dev-vcn • **CIDR Block:** 10.0.0.0/16 • **DNS Resolution:** Selected
Internet Gateway	Created manually, and defined as follows: • **Name:** gateway-0
NAT Gateway	Created manually, and defined as follows: • **Name:** nat-gateway-0
Service Gateway	Created manually, and defined as follows: • **Name:** service-gateway-0 • **Services:** All <region> Services in Oracle Services Network

Resource	Example
Route Table	Two route tables created manually, named, and defined as follows: • **Name:** routetable-0, with a route rule defined as follows: ◦ **Destination CIDR block:** 0.0.0.0/0 ◦ **Target Type:** Internet Gateway ◦ **Target Internet Gateway:** gateway-0 • **Name:** routetable-1, with two route rules defined as follows: ◦ **Rule 1:** ▪ **Destination CIDR block:** 0.0.0.0/0 ▪ **Target Type:** NAT Gateway ▪ **Target NAT Gateway:** nat-gateway-0 ◦ **Rule 2:** ▪ **Destination:** All <region> Services in Oracle Services Network ▪ **Target Type:** Service Gateway ▪ **Target:** service-gateway-0
DHCP Options	Created automatically and defined as follows: • **DNS Type** set to Internet and VCN Resolver

Resource	Example
Security Lists	Two created (in addition to the default security list) manually, named, and defined as follows: • **Security List Name:** workers • **Security List Name:** loadbalancers For details of the ingress rules and egress rules defined for these security lists, see Example Security List Configurations for a Highly Available Private Cluster Using AD-Specific Subnets.

Resource	Example
Subnets	Three worker node AD-specific subnets created manually, named, and defined as follows: • **Name:** workers-1 with the following properties: ◦ **Availability Domain:** AD1 ◦ **CIDR Block:** 10.0.10.0/24 ◦ **Route Table:** routetable-1 ◦ **Subnet access:** Private ◦ **DNS Resolution:** Selected ◦ **DHCP Options:** Default ◦ **Security List:** workers • **Name:** workers-2 with the following properties: ◦ **Availability Domain:** AD2 ◦ **CIDR Block:** 10.0.11.0/24 ◦ **Route Table:** routetable-1 ◦ **Subnet access:** Private ◦ **DNS Resolution:** Selected ◦ **DHCP Options:** Default ◦ **Security List:** workers • **Name:** workers-3 with the following properties: ◦ **Availability Domain:** AD3 ◦ **CIDR Block:** 10.0.12.0/24 ◦ **Route Table:** routetable-1 ◦ **Subnet access:** Private ◦ **DNS Resolution:** Selected

Resource	Example
	◦ **DHCP Options:** Default ◦ **Security List:** workers Two load balancer AD-specific subnets created, named, and defined as follows: • **Name:** loadbalancers-1 with the following properties: ◦ **Availability Domain:** AD1 ◦ **CIDR Block:** 10.0.20.0/24 ◦ **Route Table:** routetable-0 ◦ **Subnet access:** Public ◦ **DNS Resolution:** Selected ◦ **DHCP Options:** Default ◦ **Security List:** loadbalancers • **Name:** loadbalancers-2 with the following properties: ◦ **Availability Domain:** AD2 ◦ **CIDR Block:** 10.0.21.0/24 ◦ **Route Table:** routetable-0 ◦ **Subnet access:** Public ◦ **DNS Resolution:** Selected ◦ **DHCP Options:** Default ◦ **Security List:** loadbalancers

EXAMPLE SECURITY LIST CONFIGURATIONS FOR A HIGHLY AVAILABLE PRIVATE CLUSTER USING AD-SPECIFIC SUBNETS

In the example VCN, two security lists have been created (in addition to the default security list) to control access to and from the private worker node AD-specific subnets and the load

balancer AD-specific subnets. The two security lists are named 'workers' and 'loadbalancers' respectively.

The workers security list has the following ingress and egress rules for private worker node subnets:

Example Ingress Rules in a Security List for Private Worker Node AD-Specific Subnets:

#	Type	Source CIDR	IP Protocol	Source Port Range	Dest. Port Range	Type and Code	Allows: and Description:
1	Stateless	10.0.10.0/24	All	n/a	n/a	n/a	**Allows:** All traffic for all ports **Description:** This rule enables intra-VCN traffic.
2	Stateless	10.0.11.0/24	All	n/a	n/a	n/a	**Allows:** All traffic for all ports **Description:** This rule enables intra-VCN traffic.

#	Type	Source CIDR	IP Protocol	Source Port Range	Dest. Port Range	Type and Code	Allows: and Description:
3	Stateless	10.0.12.0/24	All	n/a	n/a	n/a	**Allows:** All traffic for all ports **Description:** This rule enables intra-VCN traffic.
4	Stateful	10.0.0.0/16	TCP	All	22	n/a	**Allows:** TCP traffic for ports: 22 SSH Remote Login Protocol **Description:** This *optional* rule enables inbound SSH traffic from the VCN on port 22 to access worker nodes.

Example Egress Rules in a Security List for Private Worker Node AD-Specific Subnets:

#	Type	Dest. CIDR	IP Protocol	Source Port Range	Dest. Port Range	Type and Code	Allows: and Description:
1	Stateless	10.0.10.0/24	All	n/a	n/a	n/a	**Allows:** All traffic for all ports **Description:** This rule enables intra-VCN traffic.
2	Stateless	10.0.11.0/24	All	n/a	n/a	n/a	**Allows:** All traffic for all ports **Description:** This rule enables intra-VCN traffic.
3	Stateless	10.0.12.0/24	All	n/a	n/a	n/a	**Allows:** All traffic for all ports **Description:** This rule enables intra-VCN traffic.
4	Stateful	All <region> Services in Oracle Services Network	All	n/a	n/a	n/a	**Allows:** All traffic for all ports **Description:** This rule enables outbound access to the regional service gateway.

The loadbalancers security list has the following ingress and egress rules for load balancer AD-specific subnets:

Example Ingress Rules in a Security List for a Load Balancer AD-Specific Subnet:

#	Type	Source CIDR	IP Protocol	Source Port Range	Dest. Port Range	Type and Code	Allows: and Description:
1	Stateless	0.0.0.0/0	TCP	All	All	n/a	**Allows:** TCP traffic for all ports: all **Description:** This rule enables incoming public traffic to service load balancers.

Example Egress Rules in a Security List for a Load Balancer AD-Specific Subnet:

#	Type	Dest. CIDR	IP Protocol	Source Port Range	Dest. Port Range	Type and Code	Allows: and Description:
1	Stateless	0.0.0.0/0	TCP	All	All	n/a	**Allows:** TCP traffic for ports: all **Description:** This rule enables responses from a web application through the service load balancers.

Example 3: Example Network Resource Configuration for a Highly Available Public Cluster in a Region with Three Availability Domains, Using a Regional Subnet

This example assumes you want worker nodes hosted in a public regional subnet that can be accessed directly from the internet.

EXAMPLE NETWORK RESOURCE CONFIGURATION

Resource	Example
VCN	Created manually, and defined as follows: • **Name:** acme-dev-vcn • **CIDR Block:** 10.0.0.0/16 • **DNS Resolution:** Selected
Internet Gateway	Created manually, and defined as follows: • **Name:** gateway-0
Service Gateway	Created manually, and defined as follows: • **Name:** service-gateway-0 • **Services:** All <region> Services in Oracle Services Network

Resource	Example
Route Table	Two route tables created manually, named, and defined as follows: • **Name:** routetable-0, with a route rule defined as follows: ◦ **Destination CIDR block:** 0.0.0.0/0 ◦ **Target Type:** Internet Gateway ◦ **Target Internet Gateway:** gateway-0 • **Name:** routetable-1, with a route rule defined as follows: ◦ **Destination:** All <region> Services in Oracle Services Network ◦ **Target Type:** Service Gateway ◦ **Target:** service-gateway-0
DHCP Options	Created automatically and defined as follows: • **DNS Type** set to Internet and VCN Resolver

Resource	Example
Security Lists	Two created (in addition to the default security list) manually, named, and defined as follows: • **Security List Name:** workers • **Security List Name:** loadbalancers For details of the ingress rules and egress rules defined for the workers security list and the loadbalancers security list, see Example Security List Configurations for a Highly Available Public Cluster Using AD-Specific Subnets.
Subnets	One worker node regional subnet created manually, named, and defined as follows: • **Name:** workers-rs with the following properties: ◦ **CIDR Block:** 10.0.10.0/24 ◦ **Route Table:** routetable-1 ◦ **Subnet access:** Public ◦ **DNS Resolution:** Selected ◦ **DHCP Options:** Default ◦ **Security List:** workers One load balancer regional subnet created, named, and defined as follows: • **Name:** loadbalancers-rs with the following properties: ◦ **CIDR Block:** 10.0.20.0/24 ◦ **Route Table:** routetable-0 ◦ **Subnet access:** Public ◦ **DNS Resolution:** Selected ◦ **DHCP Options:** Default ◦ **Security List:** loadbalancers

Example Security List Configurations for a Highly Available Public Cluster using Regional Subnets

In the example VCN, two security lists have been created (in addition to the default security list) to control access to and from a public worker node regional subnet and a load balancer regional subnet. The two security lists are named 'workers' and 'loadbalancers' respectively.

The workers security list has the following ingress and egress rules for the public worker node regional subnet:

Example Ingress Rules in a Security List for a Public Worker Node Regional Subnet:

#	Type	Source CIDR	IP Protocol	Source Port Range	Dest. Port Range	Type and Code	Allows: and Description:
1	Stateless	10.0.10.0/24	All	n/a	n/a	n/a	**Allows:** All traffic for all ports **Description:** This rule enables intra-VCN traffic.
2	Stateful	0.0.0.0/0	ICMP	n/a	n/a	3, 4	**Allows:** ICMP traffic for: 3, 4 Destination Unreachable: Fragmentation Needed and Don't Fragment was Set **Description:** This rule enables worker nodes to receive Path MTU Discovery fragmentation messages.

#	Type	Source CIDR	IP Protocol	Source Port Range	Dest. Port Range	Type and Code	Allows: and Description:
3	Stateful	130.35.0.0/16	TCP	All	22	n/a	**Allows:** TCP traffic for ports: 22 SSH Remote Login Protocol **Description:** This rule enables Container Engine for Kubernetes to access worker nodes.
4	Stateful	134.70.0.0/17	TCP	All	22	n/a	**Allows:** TCP traffic for ports: 22 SSH Remote Login Protocol **Description:** This rule enables Container Engine for Kubernetes to access worker nodes.

#	Type	Source CIDR	IP Protocol	Source Port Range	Dest. Port Range	Type and Code	Allows: and Description:
5	Stateful	138.1.0.0/16	TCP	All	22	n/a	**Allows:** TCP traffic for ports: 22 SSH Remote Login Protocol **Description:** This rule enables Container Engine for Kubernetes to access worker nodes.
6	Stateful	140.91.0.0/17	TCP	All	22	n/a	**Allows:** TCP traffic for ports: 22 SSH Remote Login Protocol **Description:** This rule enables Container Engine for Kubernetes to access worker nodes.

#	Type	Source CIDR	IP Protocol	Source Port Range	Dest. Port Range	Type and Code	Allows: and Description:
7	Stateful	147.154.0.0/16	TCP	All	22	n/a	**Allows:** TCP traffic for ports: 22 SSH Remote Login Protocol **Description:** This rule enables Container Engine for Kubernetes to access worker nodes.
8	Stateful	192.29.0.0/16	TCP	All	22	n/a	**Allows:** TCP traffic for ports: 22 SSH Remote Login Protocol **Description:** This rule enables Container Engine for Kubernetes to access worker nodes.

#	Type	Source CIDR	IP Protocol	Source Port Range	Dest. Port Range	Type and Code	Allows: and Description:
9	Stateful	0.0.0.0/0	TCP	All	22	n/a	**Allows:** TCP traffic for ports: 22 SSH Remote Login Protocol **Description:** This *optional* rule enables inbound SSH traffic from the internet on port 22 to access worker nodes.
10	Stateful	0.0.0.0/0	TCP	All	30000 - 32767	n/a	**Allows:** TCP traffic for ports: 30000 - 32767 **Description:** This *optional* rule enables inbound traffic to the worker nodes on the default NodePort range of 30000-32767 (see the Kubernetes documentation).

Example Egress Rules in a Security List for a Public Worker Node Regional Subnet:

#	Type	Dest. CIDR	IP Protocol	Source Port Range	Dest. Port Range	Type and Code	Allows: and Description:
1	Stateless	10.0.10.0/24	All	n/a	n/a	n/a	**Allows:** All traffic for all ports **Description:** This rule enables intra-VCN traffic.
2	Stateful	All <region> Services in Oracle Services Network	All	n/a	n/a	n/a	**Allows:** All traffic for all ports **Description:** This rule enables outbound access to the regional service gateway.

The loadbalancers security list has the following ingress and egress rules for load balancer regional subnets:

Example Ingress Rules in a Security List for a Load Balancer Regional Subnet:

#	Type	Source CIDR	IP Protocol	Source Port Range	Dest. Port Range	Type and Code	Allows: and Description:
1	Stateless	0.0.0.0/0	TCP	All	All	n/a	**Allows:** TCP traffic for all ports: all **Description:** This rule enables incoming public traffic to service load balancers.

Example Egress Rules in a Security List for a Load Balancer Regional Subnet:

#	Type	Dest. CIDR	IP Protocol	Source Port Range	Dest. Port Range	Type and Code	Allows: and Description:
1	Stateless	0.0.0.0/0	TCP	All	All	n/a	**Allows:** TCP traffic for ports: all **Description:** This rule enables responses from a web application through the service load balancers.

CIDR Blocks and Container Engine for Kubernetes

When configuring the VCN and the worker node and load balancer subnets for use with Container Engine for Kubernetes, you specify CIDR blocks to indicate the network addresses that can be allocated to the resources. See Network Resource Configuration for Cluster Creation and Deployment.

When creating a cluster with Container Engine for Kubernetes, you specify:

- CIDR blocks for the Kubernetes services
- CIDR blocks that can be allocated to pods running in the cluster (see Creating a Kubernetes Cluster)

Note the following:

- The CIDR block you specify for the VCN must not overlap with the CIDR block you specify for the Kubernetes services.
- The CIDR blocks you specify for pods running in the cluster must not overlap with CIDR blocks you specify for worker node and load balancer subnets.

Policy Configuration for Cluster Creation and Deployment

Before you can use Container Engine for Kubernetes to create and deploy clusters in the regions in a tenancy, the tenancy's root compartment must include a policy to allow Container Engine for Kubernetes to perform operations in the tenancy. See Create Required Policy for Container Engine for Kubernetes.

When a tenancy is created, an Administrators group is automatically created for the tenancy. Users that are members of the Administrators group can perform any operation on resources in the tenancy. If all the users that will be working with Container Engine for Kubernetes are already members of the Administrators group, there's no need to create additional policies (aside from the policy to allow Container Engine for Kubernetes to perform operations in the tenancy). However, if you want to enable users that are not members of the Administrators group to use Container Engine for Kubernetes, you must create policies to enable the groups to which those users do belong to perform operations on resources in the tenancy or in

individual compartments. Some policies are required, some are optional. See Create Required Policy for Groups and Create One or More Additional Policies for Groups.

Note that in addition to the above policies managed by IAM, you can also use the Kubernetes RBAC Authorizer to enforce additional fine-grained access control for users on specific clusters via Kubernetes RBAC roles and clusterroles. See About Access Control and Container Engine for Kubernetes.

Create Required Policy for Container Engine for Kubernetes

To create and manage clusters in your tenancy, Container Engine for Kubernetes must have access to all resources in the tenancy. To give Container Engine for Kubernetes the necessary access, create a policy for the service as follows:

1. In the Console, open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Policies**. A list of the policies in the compartment you're viewing is displayed.
2. Select the tenancy's root compartment from the list on the left.
3. Click **Create Policy**.
4. Enter the following:
    - **Name:** A unique name for the policy (for example, `oke-service`). The name must be unique across all policies in your tenancy. You cannot change this later. Avoid entering confidential information.
    - **Description:** A friendly description. You can change this later if you want to. Avoid entering confidential information.
    - **Policy Versioning:** Select **Keep Policy Current** if you'd like the policy to stay current with any future changes to the service's definitions of verbs and resources. Or if you'd prefer to limit access according to the definitions that were current on a specific date, select **Use Version Date** and enter that date in YYYY-MM-DD format. For more information, see Policy Language Version.
    - **Statement:** The following policy statement:

      ```
      Allow service OKE to manage all-resources in tenancy
      ```

- **Tags:** Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.

5. Click **Create**.

Create Required Policy for Groups

To create, update, and delete clusters and node pools, users that are not members of the Administrators group must have permissions to work with cluster-related resources. To give users the necessary access, you must create a policy with a number of required policy statements for the groups to which those users do belong:

1. In the Console, open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Policies**. A list of the policies in the compartment you're viewing is displayed.
2. Select the tenancy's root compartment or an individual compartment containing cluster-related resources from the list on the left.
3. Click **Create Policy**.
4. Enter the following:
   - **Name:** A name for the policy (for example, `acme-dev-team-oke-required-policy`) that is unique within the compartment. If you are creating the policy in the tenancy's root compartment, the name must be unique across all policies in your tenancy. You cannot change this later. Avoid entering confidential information.
   - **Description:** A friendly description. You can change this later if you want to. Avoid entering confidential information.
   - **Policy Versioning:** Select **Keep Policy Current** if you'd like the policy to stay current with any future changes to the service's definitions of verbs and resources. Or if you'd prefer to limit access according to the definitions that were

current on a specific date, select **Use Version Date** and enter that date in YYYY-MM-DD format. For more information, see Policy Language Version.

- **Statement:** The following required policy statements to enable users to use Container Engine for Kubernetes to create, update, and delete clusters and node pools:
  - `Allow group <group-name> to manage instance-family in <location>`
  - `Allow group <group-name> to use subnets in <location>`
  - `Allow group <group-name> to read virtual-network-family in <location>`
  - `Allow group <group-name> to use vnics in <location>`
  - `Allow group <group-name> to inspect compartments in <location>`

  The following required policy statement to enable users to perform any operation on cluster-related resources (this 'catch-all' policy effectively makes all users administrators insofar as cluster-related resources are concerned):
  - `Allow group <group-name> to manage cluster-family in <location>`

  In the above policy statements, replace `<location>` with either `tenancy` (if you are creating the policy in the tenancy's root compartment) or `compartment <compartment-name>` (if you are creating the policy in an individual compartment).
- **Tags:** Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.

5. Click **Create**.

Create One or More Additional Policies for Groups

To enable users that are not members of the Administrators group to use Container Engine for Kubernetes, create additional policies to enable the groups to which those users do belong to perform operations on cluster-related resources as follows:

1. In the Console, open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Policies**. A list of the policies in the compartment you're viewing is displayed.
2. Select the tenancy's root compartment or an individual compartment containing cluster-related resources from the list on the left.
3. Click **Create Policy**.
4. Enter the following:
    - **Name:** A name for the policy (for example, `acme-dev-team-oke-additional-policy`) that is unique within the compartment. If you are creating the policy in the tenancy's root compartment, the name must be unique across all policies in your tenancy. You cannot change this later. Avoid entering confidential information.
    - **Description:** A friendly description. You can change this later if you want to. Avoid entering confidential information.
    - **Policy Versioning:** Select **Keep Policy Current** if you'd like the policy to stay current with any future changes to the service's definitions of verbs and resources. Or if you'd prefer to limit access according to the definitions that were current on a specific date, select **Use Version Date** and enter that date in YYYY-MM-DD format. For more information, see Policy Language Version.
    - **Statement:** A suitable policy statement to allow existing groups to perform operations on cluster-related resources. In the example policy statements below, replace `<location>` with either `tenancy` (if you are creating the policy in the tenancy's root compartment) or `compartment <compartment-name>` (if you are creating the policy in an individual compartment):
        - To enable users in the acme-dev-team group to automatically create and configure associated new network resources when creating new 'quick

clusters', policies must also grant the group:

- the VCN_READ and VCN_CREATE permissions. Enter a policy statement like `Allow group acme-dev-team to manage vcns in <location>`
- the SUBNET_READ and SUBNET_CREATE permissions. Enter a policy statement like `Allow group acme-dev-team to manage subnets in <location>`
- the INTERNET_GATEWAY_CREATE permission. Enter a policy statement like `Allow group acme-dev-team to manage internet-gateways in <location>`
- the NAT_GATEWAY_CREATE permission. Enter a policy statement like `Allow group acme-dev-team to manage nat-gateways in <location>`
- the ROUTE_TABLE_UPDATE permission. Enter a policy statement like `Allow group acme-dev-team to manage route-tables in <location>`
- the SECURITY_LIST_CREATE permission. Enter a policy statement like `Allow group acme-dev-team to manage security-lists in <location>`

◦ To enable users in the acme-dev-team-cluster-viewers group to simply list the clusters, enter a policy statement like `Allow group acme-dev-team-cluster-viewers to inspect clusters in <location>`.

◦ To enable users in the acme-dev-team-pool-admins group to list, create, update, and delete node pools, enter a policy statement like `Allow group acme-dev-team-pool-admins to use cluster-node-pools in <location>`.

◦ To enable users in the acme-dev-team-auditors group to see details of operations performed on clusters, enter a policy statement like `Allow`

`group acme-dev-team-auditors to read cluster-work-requests in <location>`.

- To enable users in the acme-dev-team-sgw group to create a service gateway to enable worker nodes to access other resources in the same region without exposing data to the public internet, enter a policy statement like `Allow group acme-dev-team-sgw to manage service-gateways in <location>`.

- **Tags:** Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.

5. Click **Create**.

About Kubernetes Clusters and Nodes

A Kubernetes cluster is a group of nodes. The nodes are the machines running applications. Each node can be a physical machine or a virtual machine. The node's capacity (its number of CPUs and amount of memory) is defined when the node is created. A cluster can be organized into namespaces, to divide the cluster's resources between multiple uses. A cluster comprises:

- one or more master nodes (for high availability, typically there will be a number of master nodes)
- one or more worker nodes (sometimes known as minions)

The master nodes in a cluster run a number of processes:

- kube-apiserver to support API operations via the Kubernetes command line tool (kubectl) and the REST API, and includes admissions controllers required for advanced Kubernetes operations

- kube-controller-manager to manage different Kubernetes components (for example, replication controller, endpoints controller, namespace controller, and serviceaccounts controller)
- kube-scheduler to control where in the cluster to run jobs
- etcd to store the cluster's configuration data

Each worker node runs two Kubernetes processes:

- kubelet to communicate with the master nodes
- kube-proxy to handle networking

Each worker node also runs the Docker runtime.

The Kubernetes processes running on the master nodes are collectively referred to as the Kubernetes Control Plane. Together, the Control Plane processes monitor and record the state of the cluster and distribute requested operations between the nodes in the cluster.

Where an application running on a worker node comprises multiple containers, Kubernetes groups the containers into a single logical unit called a pod for easy management and discovery. The containers in the pod share the same networking namespace and the same storage space, and can be managed as a single object by the Kubernetes Control Plane. A number of pods providing the same functionality can be grouped into a single logical set known as a service.

A Kubernetes manifest file comprises instructions in a yaml or json file that specify how to deploy an application to the node or nodes in a Kubernetes cluster. The instructions include information about the Kubernetes deployment, the Kubernetes service, and other Kubernetes objects to be created on the cluster. The manifest is commonly also referred to as a pod spec, or as a deployment.yaml file (although other filenames are allowed). The parameters to include in a Kubernetes manifest file are described in the Kubernetes documentation.

A node pool is a subset of machines within a cluster that all have the same configuration. Node pools enable you to create pools of machines within a cluster that have different configurations. For example, you might create one pool of nodes in a cluster as virtual machines, and another pool of nodes as bare metal machines. A cluster must have a minimum of one node pool, but a node pool need not contain any worker nodes.

Creating a Kubernetes Cluster

You can use Container Engine for Kubernetes to create new Kubernetes clusters. To create a cluster, you must either belong to the tenancy's Administrators group, or belong to a group to which a policy grants the CLUSTER_MANAGE permission. In addition, a policy in the root compartment must grant Container Engine for Kubernetes access to all resources in the tenancy. See Policy Configuration for Cluster Creation and Deployment.

You first specify basic details for the new cluster (the cluster name, and the Kubernetes version to install on master nodes). You can then create the cluster in one of two ways:

- Using default settings to create a 'quick cluster' with new network resources as required. This approach is the fastest way to create a new cluster. If you accept all the default values, you can create a new cluster in just a few clicks. New network resources for the 'quick cluster' are created automatically, including one regional subnet for worker nodes, and another regional subnet for load balancers. The regional subnet for load balancers will be public, but you can specify whether the regional subnet for worker nodes will be public or private. Note that if you specify a private regional subnet for worker nodes in the 'quick cluster', a NAT gateway is also created (in addition to an internet gateway). To create a 'quick cluster', you must belong to a group to which a policy grants the necessary permissions to create the new network resources (see Create One or More Additional Policies for Groups).
- Using custom settings to create a 'custom cluster'. This approach gives you the most control over the new cluster. You can explicitly define the new cluster's properties. And you can explicitly specify which existing network resources to use, including the existing public or private subnets in which to create worker nodes and load balancers. The subnets can be regional subnets (recommended) or AD-specific subnets. Note that although you will usually define node pools immediately when defining a new 'custom cluster', you don't have to. You can create a 'custom cluster' with no node pools, and add node pools later.

Regardless of how you create a cluster, Container Engine for Kubernetes gives names to worker nodes in the following format:

```
oke-c<part-of-cluster-OCID>-n<part-of-node-pool-OCID>-s<part-of-subnet-OCID>-
<slot>
```

where:

- `oke` is the standard prefix for all worker nodes created by Container Engine for Kubernetes
- `c<part-of-cluster-OCID>` is a portion of the cluster's OCID, prefixed with the letter `c`
- `n<part-of-node-pool-OCID>` is a portion of the node pool's OCID, prefixed with the letter `n`
- `s<part-of-subnet-OCID>` is a portion of the subnet's OCID, prefixed with the letter `s`
- `<slot>` is an ordinal number of the node in the subnet (for example, `0`, `1`)

For example, if you specified a cluster is to have two nodes in a node pool, the two nodes might be named:

- `oke-cywiqripuyg-nsgagklgnst-st2qczvnmba-0`
- `oke-cywiqripuyg-nsgagklgnst-st2qczvnmba-1`

Do not change the auto-generated names that Container Engine for Kubernetes gives to worker nodes.

To ensure high availability, Container Engine for Kubernetes:

- creates the Kubernetes Control Plane on multiple Oracle-managed master nodes (distributing the master nodes across different availability domains in a region, where supported)
- creates worker nodes in each of the fault domains in an availability domain (distributing the worker nodes as evenly as possible across the fault domains, subject to any other infrastructure restrictions)

Using the Console to create a 'Quick Cluster' with Default Settings

To create a 'quick cluster' with default settings and new network resources using Container Engine for Kubernetes:

1. In the Console, open the navigation menu. Under **Solutions and Platform**, go to **Developer Services** and click **Container Clusters**.
2. Choose a **Compartment** you have permission to work in, and in which you want to create both the new cluster and the associated network resources.
3. On the **Cluster List** page, click **Create Cluster**.
4. Either just accept the default configuration details for the new cluster, or specify alternatives as follows:
    - **Name:** The name of the new cluster. Either accept the default name or enter a name of your choice. Avoid entering confidential information.
    - **Kubernetes Version:** The version of Kubernetes to run on the master nodes and worker nodes of the cluster. Either accept the default version or select a version of your choice. Amongst other things, the Kubernetes version you select determines the default set of admission controllers that are turned on in the created cluster (the set follows the recommendation given in the Kubernetes documentation for that version).
5. Select **Quick Create** to create a new cluster with default settings, along with new network resources for the new cluster.

   The **Create Virtual Cloud Network** panel shows the network resources that will be created for you by default.
6. Select either **Private** or **Public** to specify whether to create a private or a public regional subnet to host worker nodes (note that a public regional subnet is always created to host load balancers in a 'quick cluster', regardless of your selection here):
    - **Private:** Select to create a private regional subnet to host worker nodes (along with the public regional subnet to host load balancers).
    - **Public:** Select to create a public regional subnet to host worker nodes (along with the public regional subnet to host load balancers).

The **Create Node Pool** panel shows the fixed properties of the first node pool in the cluster that will be created for you:

- the name of the node pool (always pool1)
- the compartment in which the node pool will be created (always the same as the one in which the new network resources will reside)
- the version of Kubernetes that will run on each worker node in the node pool (always the same as the version specified for the master nodes)
- the image to use on each node in the node pool

The **Create Node Pool** panel also contains some node pool properties that you can change, but which have been given sensible defaults.

7. Either just accept all the default configuration details and skip ahead to the next step to create the cluster immediately, or specify alternatives as follows:
    a. Either accept the default configuration details for the node pool, or specify alternatives in the **Create Node Pool** panel as follows:
        - **Shape:** The shape to use for each node in the node pool. The shape determines the number of CPUs and the amount of memory allocated to each node. The list shows only those shapes available in your tenancy that are supported by Container Engine for Kubernetes.
        - **Number of Nodes:** The number of worker nodes to create in the node pool, placed in the regional subnet created for the 'quick cluster'. The nodes are distributed as evenly as possible across the availability domains in a region (or in the case of a region with a single availability domain, across the fault domains in that availability domain).
        - **Public SSH Key:** (Optional) The public key portion of the key pair you want to use for SSH access to each node in the node pool. The public key is installed on all worker nodes in the cluster. Note that if you don't specify a public SSH key, Container Engine for Kubernetes will provide one. However, since you won't have the corresponding private key, you will not have SSH access to the worker nodes. Note that if you specify that you want the worker nodes in the 'quick cluster' to be hosted in a private regional subnet,

you cannot use SSH to access them directly (see Connecting to Worker Nodes in Private Subnets Using SSH).

- **Kubernetes Labels:** One or more labels (in addition to a default label) to add to worker nodes in the node pool to enable the targeting of workloads at specific node pools.

b. Either accept the defaults for the remaining cluster details, or specify alternatives in the **Additional Add Ons** panel as follows:

- **Kubernetes Dashboard Enabled:** Select if you want to use the Kubernetes Dashboard to deploy and troubleshoot containerized applications, and to manage Kubernetes resources. See Starting the Kubernetes Dashboard.
- **Tiller (Helm) Enabled:** Select if you want Tiller (the server portion of Helm) to run in the Kubernetes cluster. With Tiller running in the cluster, you can use Helm to manage Kubernetes resources.

c. (Optional) Select **View Detail Page After This Cluster Is Requested** to return to the **Cluster Details** tab (rather than the **Cluster List** page) in the Console at the end of the cluster creation process.

8. Click **Create** to create the new network resources and the new cluster.
Container Engine for Kubernetes starts creating:

- the network resources (such as the VCN, internet gateway, NAT gateway, route tables, security lists, a regional subnet for worker nodes and another regional subnet for load balancers), with auto-generated names in the format `oke-<resource-type>-quick-<cluster-name>-<creation-date>`
- the cluster, with the name you specified
- the node pool, named pool1
- worker nodes, with auto-generated names in the format `oke-c<part-of-cluster-OCID>-n<part-of-node-pool-OCID>-s<part-of-subnet-OCID>-<slot>`

Do not change the resource names that Container Engine for Kubernetes has auto-generated. Note that if the cluster is not created successfully for some reason (for example, if you have insufficient permissions or if you've exceeded the cluster limit for the tenancy), any network resources created during the cluster creation process are not deleted automatically. You will have to manually delete any such unused network resources.

9. Click **Close** to return to the Console.

   If you selected **View Detail Page After This Cluster Is Requested**, you return to the **Cluster Details** tab in the console. If you didn't select **View Detail Page After This Cluster Is Requested**, you return to the **Cluster List** page.

   Initially, the new cluster appears in the Console with a status of Creating. When the cluster has been created, it has a status of Active.

   Container Engine for Kubernetes also creates a Kubernetes kubeconfig configuration file that you use to access the cluster using kubectl and the Kubernetes Dashboard.

Using the Console to create a 'Custom Cluster' with Explicitly Defined Settings

To create a 'custom cluster' with explicitly defined settings and existing network resources using Container Engine for Kubernetes:

1. In the Console, open the navigation menu. Under **Solutions and Platform**, go to **Developer Services** and click **Container Clusters**.
2. Choose a **Compartment** you have permission to work in, and in which you want to create the new cluster.
3. On the **Cluster List** page, click **Create Cluster**.
4. Specify configuration details for the new cluster:
   - **Name:** The name of the new cluster. Either accept the default name or enter a name of your choice. Avoid entering confidential information.

- **Kubernetes Version:** The version of Kubernetes to run on the master nodes of the cluster. Either accept the default version or select a version of your choice. Amongst other things, the Kubernetes version you select determines the default set of admission controllers that are turned on in the created cluster (the set follows the recommendation given in the Kubernetes documentation for that version).

5. Select **Custom Create** to create a new cluster by explicitly defining the new cluster's properties and which existing network resources to use.
6. Specify the existing network resources to use for the new cluster in the **Network Selection** panel:
   - **Network Compartment:** The compartment in which the existing network resources reside.
   - **VCN:** The existing virtual cloud network that has been configured for cluster creation and deployment. See VCN Configuration.
   - **Kubernetes Service LB Subnets:** Optionally, the existing subnets that have been configured to host load balancers. Load balancer subnets must be different from worker node subnets, can be public or private, and can be regional (recommended) or AD-specific. You don't have to specify any load balancer subnets. However, if you do specify load balancer subnets, the number of load balancer subnets to specify depends on the region in which you are creating the cluster and whether the subnets are regional or AD-specific.

     If you are creating a cluster in a region with three availability domains, you can specify:

     - Zero or one load balancer regional subnet (recommended).
     - Zero or two load balancer AD-specific subnets. If you specify two AD-specific subnets, the two subnets must be in different availability domains.

     If you are creating a cluster in a region with a single availability domain, you can specify:

    - Zero or one load balancer regional subnet (recommended).
    - Zero or one load balancer AD-specific subnet.

  See Subnet Configuration.

- **Kubernetes Service CIDR Block:** The available group of network addresses that can be exposed as Kubernetes services (ClusterIPs), expressed as a single, contiguous IPv4 CIDR block. For example, 10.96.0.0/16. The CIDR block you specify must not overlap with the CIDR block for the VCN. See CIDR Blocks and Container Engine for Kubernetes.
- **Pods CIDR Block:** The available group of network addresses that can be allocated to pods running in the cluster, expressed as a single, contiguous IPv4 CIDR block. For example, 10.244.0.0/16. The CIDR block you specify must not overlap with the CIDR blocks for subnets in the VCN, and can be outside the VCN CIDR block. See CIDR Blocks and Container Engine for Kubernetes.

7. Specify whether to encrypt Kubernetes secrets at rest in the etcd key-value store for the cluster using the Key Management service. If you do want to encrypt Kubernetes secrets in the etcd key-value store, select the **Encrypt Using Customer-Managed Keys** option, and select:

   - **Choose a Vault in <compartment-name>:** The vault that contains the master encryption key, from the list of vaults in the specified compartment. By default, <compartment-name> is the compartment in which you are creating the cluster, but you can select a different compartment by clicking **Change Compartment**.
   - **Choose a Key in <compartment-name>:** The name of the master encryption key, from the list of keys in the specified compartment. By default, <compartment-name> is the compartment in which you are creating the cluster, but you can select a different compartment by clicking **Change Compartment**. Note that you cannot change the master encryption key after the cluster has been created.

   Note that if you do want to use encryption, a suitable master encryption key, dynamic group, and policy must already exist before you can create the cluster. For more information, see Encrypting Kubernetes Secrets At Rest in Etcd.

8. Specify remaining details for the cluster in the **Additional Add Ons** panel:
    - **Kubernetes Dashboard Enabled:** Select if you want to use the Kubernetes Dashboard to deploy and troubleshoot containerized applications, and to manage Kubernetes resources. See Starting the Kubernetes Dashboard.
    - **Tiller (Helm) Enabled:** Select if you want Tiller (the server portion of Helm) to run in the Kubernetes cluster. With Tiller running in the cluster, you can use Helm to manage Kubernetes resources.
9. Click **Continue**.
10. (Optional) Specify configuration details for the first node pool in the cluster in the **Node Pool** panel:
    - **Name:** A name of your choice for the new node pool. Avoid entering confidential information.
    - **Version:** The version of Kubernetes to run on each worker node in the node pool. By default, the version of Kubernetes specified for the master nodes is selected. The Kubernetes version on worker nodes must be either the same version as that on the master nodes, or an earlier version that is still compatible. See Kubernetes Versions and Container Engine for Kubernetes.
    - **Image:** The image to use on each node in the node pool. An image is a template of a virtual hard drive that determines the operating system and other software for the node.
    - **Shape:** The shape to use for each node in the node pool. The shape determines the number of CPUs and the amount of memory allocated to each node. The list shows only those shapes available in your tenancy that are supported by Container Engine for Kubernetes.
    - **Number of Nodes:** The number of worker nodes to create in the node pool, placed in the availability domains you select, and in the regional subnet (recommended) or AD-specific subnet you specify for each availability domain.

- **Availability Domain 1:**
  - **Availability Domain:** An availability domain in which to place worker nodes.
  - **Subnet:** A regional subnet (recommended) or AD-specific subnet configured to host worker nodes. If you specified load balancer subnets, the worker node subnets must be different. The subnets you specify can be public or private, and can be regional (recommended) or AD-specific. See Subnet Configuration.

  Optionally click **Add Availability Domain** to select additional domains and subnets in which to place worker nodes.

  When they are created, the worker nodes are distributed as evenly as possible across the availability domains you select (or in the case of a single availability domain, across the fault domains in that availability domain).
- **Public SSH Key:** (Optional) The public key portion of the key pair you want to use for SSH access to each node in the node pool. The public key is installed on all worker nodes in the cluster. Note that if you don't specify a public SSH key, Container Engine for Kubernetes will provide one. However, since you won't have the corresponding private key, you will not have SSH access to the worker nodes. Note that you cannot use SSH to access directly any worker nodes in private subnets (see Connecting to Worker Nodes in Private Subnets Using SSH).
- **Kubernetes Labels:** One or more labels (in addition to a default label) to add to worker nodes in the node pool to enable the targeting of workloads at specific node pools.

11. (Optional) Click **Add node pool** and specify configuration details for a second and subsequent node pools in the cluster.

    If you define multiple node pools in a cluster, you can host all of them on a single AD-specific subnet. However, it's best practice to host different node pools for a cluster on a regional subnet (recommended) or on different AD-specific subnets (one in each availability domain in the region).
12. Click **Review** to confirm the resources that will be used and created.

13. (Optional) Select **View Detail Page After This Cluster Is Requested** to return to the **Cluster Details** tab (rather than the **Cluster List** page) in the Console at the end of the cluster creation process.
14. Click **Create** to create the new cluster.
    Container Engine for Kubernetes starts creating the cluster with the name you specified.
    If you specified details for one or more node pools, Container Engine for Kubernetes creates:
    - node pools with the names you specified
    - worker nodes with auto-generated names in the format `oke-c<part-of-cluster-OCID>-n<part-of-node-pool-OCID>-s<part-of-subnet-OCID>-<slot>`

    Do not change the auto-generated names of worker nodes.
    If you selected **View Detail Page After This Cluster Is Requested**, you return to the **Cluster Details** tab in the console. If you didn't select **View Detail Page After This Cluster Is Requested**, you return to the **Cluster List** page.
15. Initially, the new cluster appears in the Console with a status of Creating. When the cluster has been created, it has a status of Active.
    Container Engine for Kubernetes also creates a Kubernetes kubeconfig configuration file that you use to access the cluster using kubectl and the Kubernetes Dashboard.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the CreateCluster operation to create a cluster.

Downloading a kubeconfig File to Enable Cluster Access

When you create a cluster, you need to download a Kubernetes configuration file (commonly known as a 'kubeconfig' file) for the cluster. The kubeconfig file (by default named `config`

and stored in the `$HOME/.kube` directory) provides the necessary details to access the cluster using kubectl and the Kubernetes Dashboard.

You have to follow a number of steps to download the kubeconfig file. Having completed the steps, you can start using kubectl and the Kubernetes Dashboard to manage the cluster.

To download the kubeconfig file:

Step 1: Generate an API signing key pair

If you already have an API signing key pair, go straight to the next step. If not:

1. Use OpenSSL commands to generate the key pair in the required PEM format. If you're using Windows, you'll need to install Git Bash for Windows and run the commands with that tool. See How to Generate an API Signing Key.
2. Copy the contents of the public key to the clipboard (you'll need to paste the value into the Console later).

Step 2: Upload the public key of the API signing key pair

1. In the top-right corner of the Console, open the **Profile** menu () and then click **User Settings** to view the details.
2. Click **Add Public Key**.
3. Paste the public key's value into the window and click **Add**.
   The key is uploaded and its fingerprint is displayed (for example, d1:b2:32:53:d3:5f:cf:68:2d:6f:8b:5f:77:8f:07:13).

Step 3: Install and configure the Oracle Cloud Infrastructure CLI

1. Install the Oracle Cloud Infrastructure CLI version 2.6.4 (or later). See Quickstart.
2. Configure the Oracle Cloud Infrastructure CLI. See Configuration.

Step 4: Download the kubeconfig file

1. In the Console, open the navigation menu. Under **Solutions and Platform**, go to **Developer Services** and click **Container Clusters**.
2. Choose a **Compartment** you have permission to work in.
3. On the **Cluster List** page, click the name of the cluster you want to access using kubectl and the Kubernetes Dashboard. The **Cluster** page shows details of the cluster.
4. Click the **Access Kubeconfig** button to display the **How to Access Kubeconfig** dialog box.
5. Create a directory to contain the kubeconfig file. By default, the expected directory name is `$HOME/.kube`.

   For example, on Linux, enter the following command (or copy and paste it from the **How to Access Kubeconfig** dialog box):

   ```
   $ mkdir -p $HOME/.kube
   ```

6. Run the Oracle Cloud Infrastructure CLI command to download the kubeconfig file and save it in a location accessible to kubectl and the Kubernetes Dashboard.

   For example, on Linux, enter the following command (or copy and paste it from the **How to Access Kubeconfig** dialog box):

   ```
   $ oci ce cluster create-kubeconfig --cluster-id ocid1.cluster.oc1.phx.aaaaaaaaae... --file
   $HOME/.kube/config  --region us-phoenix-1 --token-version 2.0.0
   ```

   where ocid1.cluster.oc1.phx.aaaaaaaaae... is the OCID of the current cluster. For convenience, the command in the **How to Access Kubeconfig** dialog box already includes the cluster's OCID.

   Note that if a kubeconfig file already exists in the location you specify, details about the cluster will be added as a new context to the existing kubeconfig file. The `current-context:` element in the kubeconfig file will be set to point to the newly-added context.
7. Set the value of the KUBECONFIG environment variable to point to the name and location of the kubeconfig file. For example, on Linux, enter the following command (or copy and paste it from the **How to Access Kubeconfig** dialog box):

```
$ export KUBECONFIG=$HOME/.kube/config
```

Step 5: Verify that kubectl is available

1. Verify that kubectl is available by entering the following command:

   ```
   $ kubectl version
   ```

   The response shows:

   - the version of kubectl installed and running locally
   - the version of Kubernetes (strictly speaking, the version of the kube-apiserver) running on the cluster's master node

   Note that the kubectl version must be within one minor version (older or newer) of the Kubernetes version running on the master node. If kubectl is more than one minor version older or newer, install an appropriate version of kubectl. See Kubernetes version and version skew support policy in the Kubernetes documentation.

2. Verify that kubectl can connect to the cluster by entering the following command:

   ```
   $ kubectl get nodes
   ```

   Information about the nodes in the cluster is shown.

   You can now use kubectl and the Kubernetes Dashboard to perform operations on the cluster.

Notes about kubeconfig Files

Note the following about kubeconfig files:

- A single kubeconfig file can include the details for multiple clusters, as multiple contexts. The cluster on which operations will be performed is specified by the `current-context:` element in the kubeconfig file.
- A kubeconfig file includes an Oracle Cloud Infrastructure CLI command that dynamically generates an authentication token and inserts it when you run a kubectl command. The

Oracle Cloud Infrastructure CLI must be available on your shell's executable path (for example, $PATH on Linux).

- The tokens generated by the Oracle Cloud Infrastructure CLI command in the kubeconfig file are short-lived, cluster-scoped, and specific to individual users. As a result, you cannot share kubeconfig files between users to access Kubernetes clusters.
- The Oracle Cloud Infrastructure CLI command in the kubeconfig file uses your current CLI profile when generating an authentication token. If you have defined multiple profiles in different tenancies in the CLI configuration file (for example, in ~/.oci/config), specify which profile to use when generating the authentication token as follows. In both cases, `<profile-name>` is the name of the profile defined in the CLI configuration file:
    - Add `--profile` to the `args:` section of the kubeconfig file as follows:

```
user:
  exec:
    apiVersion: client.authentication.k8s.io/v1beta1
    args:
    - ce
    - cluster
    - generate-token
    - --cluster-id
    - <cluster ocid>
    - --profile
    - <profile-name>
    command: oci
    env: []
```

    - Set the OCI_CLI_PROFILE environment variable to the name of the profile defined in the CLI configuration file before running kubectl commands. For example:

```
$ export OCI_CLI_PROFILE=<profile-name>
$ kubectl get nodes
```

Upgrading kubeconfig files from Version 1.0.0 to Version 2.0.0

Container Engine for Kubernetes currently supports two versions of kubeconfig file:

- version 1.0.0
- version 2.0.0

Enhancements in kubeconfig version 2.0.0 files provide security improvements for your Kubernetes environment, including short-lived cluster-scoped tokens with automated refreshing, and support for instance principals to access Kubernetes clusters. Additionally, authentication tokens are generated on-demand for each cluster, so kubeconfig version 2.0.0 files cannot be shared between users to access Kubernetes clusters (unlike kubeconfig version 1.0.0 files).

Note that support for kubeconfig version 1.0.0 files will be discontinued on November 15, 2019. Prior to that date, you must upgrade any kubeconfig version 1.0.0 files to version 2.0.0. Follow the instructions below to determine the current version of kubeconfig files, and how to upgrade them to version 2.0.0.

Determine the kubeconfig file version

To determine the version of a cluster's kubeconfig file:

1. In a terminal window, enter the following command to see the format of the kubeconfig file currently pointed at by the KUBECONFIG environment variable:

```
$ kubectl config view
```

2. If the kubeconfig file is version 1.0.0, you see a response in the following format:

```
users:
- name: <username>
  user:
    token: <token-value>
```

If you see a response in the above format, you have to upgrade the kubeconfig file. See Upgrade a kubeconfig version 1.0.0 file to version 2.0.0.

3. If the kubeconfig file is version 2.0.0, you see a response in the following format:

```
user:
  exec:
    apiVersion: client.authentication.k8s.io/v1beta1
    args:
    - ce
```

```
    - cluster
    - generate-token
    - --cluster-id
    - <cluster ocid>
    command: oci
    env: []
```

If you see a response in the above format, no further action is required.

Upgrade a kubeconfig version 1.0.0 file to version 2.0.0

To upgrade a kubeconfig version 1.0.0 file:

1. Confirm the Oracle Cloud Infrastructure CLI version 2.6.4 (or later) is installed by entering:

   ```
   oci -version
   ```

2. If the Oracle Cloud Infrastructure CLI version is earlier than version 2.6.4, upgrade the CLI to a later version. See Upgrading the CLI.
3. Follow the instructions to download the kubeconfig file (see Step 4: Download the kubeconfig file). Running the `oci ce cluster create-kubeconfig` command shown in the **How to Access Kubeconfig** dialog box upgrades the existing kubeconfig version 1.0.0 file. If you change the name or location of the kubeconfig file, set the KUBECONFIG environment variable to point to the new name and location of the file.
4. Confirm the kubeconfig file is now version 2.0.0:
   a. In a terminal window, enter:

      ```
      $ kubectl config view
      ```

   b. Confirm that that the response is in the following format:

      ```
      user:
        exec:
          apiVersion: client.authentication.k8s.io/v1beta1
          args:
          - ce
          - cluster
          - generate-token
          - --cluster-id
      ```

```
- <cluster ocid>
command: oci
env: []
```

Modifying a Kubernetes Cluster

You can use Container Engine for Kubernetes to modify the node pool details of existing Kubernetes clusters.

You can change:

- the name of the node pool
- the number of node pools in a cluster by adding new node pools, or deleting existing node pools
- the number of worker nodes in a node pool, and the availability domains and subnets in which to place them
- the version of Kubernetes to run on new worker nodes

However, note that you cannot change:

- the name of the cluster
- the shape of existing worker nodes
- the operating system running on existing worker nodes
- the version of Kubernetes running on existing worker nodes
- the master encryption key (if specified when the cluster was created)

Also note that you must not change the auto-generated names of resources that Container Engine for Kubernetes has created (such as the names of worker nodes).

Using the Console

To modify an existing Kubernetes cluster:

1. In the Console, open the navigation menu. Under **Solutions and Platform**, go to **Developer Services** and click **Container Clusters**.
2. Choose a **Compartment** you have permission to work in.
3. On the **Cluster List** page, click the name of the cluster you want to modify.
4. Use the buttons across the top of the **Cluster** page as follows:
    - If you want to download the kubeconfig configuration file for the cluster, click the **Access Kubeconfig** button (see Downloading a kubeconfig File to Enable Cluster Access).
    - If you want to add a new node pool to the cluster, click the **Add Node Pool** button and enter details for the new node pool.
    - If you want to delete the cluster along with its master nodes and worker nodes, click the **Delete Cluster** button.
    - If a newer version of Kubernetes is available than the one running on the master nodes in the cluster, the **Upgrade Available** button is enabled. If you want to upgrade the master nodes to a newer version, click **Upgrade Available** (see Upgrading the Version of Kubernetes Running on Master Nodes).
5. Use the **Cluster Details** tab to see information about the cluster, including:
    - The status of the cluster, and of the node pools in the cluster.
    - The cluster's OCID.
    - The Kubernetes version running on the master nodes in the cluster.
    - The address of the Kubernetes endpoint.
6. Use the **Node Pools** tab to:
    - View a summary of each node pool and the worker nodes within it.
    - Change the name of a node pool by selecting **Edit** from the **Actions** menu.

- Change the number and placement of worker nodes in a node pool by selecting **Scale** from the **Actions** menu and specifying a different number of worker nodes, different availability domains, and different regional subnets (recommended) or AD-specific subnets.
- View and edit configuration details of specific worker nodes by selecting **Show Node Details** and clicking the name of the worker node.
- Delete a node pool by selecting **Delete Node Pool** from the **Actions** menu.

7. Use the **Getting Started** tab to:
    - View and copy the commands to start the Kubernetes Dashboard to view the deployed application running on nodes in the cluster (see Starting the Kubernetes Dashboard).
    - View and copy the commands to download and deploy a sample nginx application using the Kubernetes command line tool kubectl from the instructions in a manifest file (see Deploying a Sample Nginx App on a Cluster Using kubectl).

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the Update Cluster and the UpdateNodePool operations to modify an existing Kubernetes cluster.

Deleting a Kubernetes Cluster

You can delete a cluster along with its master nodes, worker nodes, and node pools.

Note the following:

- When you delete a cluster, no other resources created during the cluster creation process or associated with the cluster (such as VCNs, internet gateways, NAT gateways, route tables, security lists, load balancers, and block volumes) are deleted

automatically. If you want to delete these resources, you have to do so manually.

- Container Engine for Kubernetes creates the worker nodes (compute instances) in a cluster with auto-generated names in the format `oke-c<part-of-cluster-OCID>-n<part-of-node-pool-OCID>-s<part-of-subnet-OCID>-<slot>`. Do not change the auto-generated names of worker nodes. If you do change the auto-generated name of a worker node and then delete the cluster, the renamed worker node is not deleted. You would have to delete the renamed worker node manually.

Using the Console

To delete a Kubernetes cluster using Container Engine for Kubernetes:

1. In the Console, open the navigation menu. Under **Solutions and Platform**, go to **Developer Services** and click **Container Clusters**.
2. Choose a **Compartment** you have permission to work in.
3. On the **Cluster List** page, click the Delete icon beside the name of the cluster to delete, and confirm that you want to delete it.

You can also delete a cluster using the **Delete Cluster** button on the **Cluster** page.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the DeleteCluster operation to delete a cluster.

Monitoring Clusters

Having created a cluster, you can monitor the status of the cluster itself, and the nodes and node pools within it.

Using the Console

To monitor a Kubernetes cluster:

1. In the Console, open the navigation menu. Under **Solutions and Platform**, go to **Developer Services** and click **Container Clusters**.
2. Choose a **Compartment** you have permission to work in.
   The **Status** column on the **Cluster List** page shows a summary status for each individual cluster and its master nodes. Clusters can have one of the following statuses:

Cluster Status	Explanation	Possible Reason
Creating	Cluster is in the process of being created.	Application is being deployed.
Active	Cluster is running normally.	Master nodes are running normally.
Failed	Cluster is not running due to an unrecoverable error.	Possible reasons: • a problem setting up load balancers • an error installing cluster add-ons (Tiller, Kubernetes dashboard) • conflicts in networking ranges
Deleting	Cluster is in the process of being deleted. Application no longer required, so resources in the process of being released.	Application no longer required, so resources in the process of being released.

Cluster Status	Explanation	Possible Reason
Deleted	Cluster has been deleted. Application no longer required, so resources have been released.	Application no longer required, so resources have been released.
Updating	Version of Kubernetes on the master nodes is in the process of being upgraded.	A newly supported version of Kubernetes has become available.

Note that the cluster's summary status is not necessarily directly related to the status of node pools and nodes within the cluster.

3. On the **Cluster List** page, click the name of the cluster for which you want to see detailed status.
   The **Cluster Details** tab shows the summary status for the cluster and its master nodes.
4. Use the **Node Pools** tab to see the status of individual nodes within each node pool.
   Nodes can have one of the following statuses:

Node Status	Explanation	Possible Reason
Creating	Node is being created.	Compute instance in the process of being created.
Active	Node is running normally.	Node is running normally.
Updating	Node is in the process of being updated.	Container Engine for Kubernetes is performing an operation on the node.

Node Status	Explanation	Possible Reason
Deleting	Node is in the process of being deleted.	Application no longer required, so resources in the process of being released.
Deleted	Node has been deleted.	Application no longer required, so resources have been released.
Inactive	Node still exists, but is not running.	Compute resource has a status of Stopped, Stopping, or Down For Maintenance.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the GetCluster and GetNodePool operations to monitor the status of Kubernetes clusters.

Monitoring Operations of Container Engine for Kubernetes

You can monitor operations performed by Container Engine for Kubernetes as follows:

- You can monitor and manage operations performed on a particular cluster by Container Engine for Kubernetes using the Work Requests tab of the cluster's Summary page.
- You can view all operations performed by Container Engine for Kubernetes as log events using the Oracle Cloud Infrastructure Audit service.

Using the Console

To monitor and manage operations performed on a particular cluster:

1. In the Console, open the navigation menu. Under **Solutions and Platform**, go to **Developer Services** and click **Container Clusters**.
2. Choose a **Compartment** you have permission to work in.
3. On the **Cluster List** page, click the name of the cluster for which you want to monitor and manage operations.
   The **Cluster** page shows information about the cluster.

To view all operations performed by Container Engine for Kubernetes as log events:

1. In the Console, open the navigation menu. Under **Governance and Administration**, go to **Governance** and click **Policies**.
2. Choose a **Compartment** you have permission to work in.
3. Search and filter to show the operations performed by Container Engine for Kubernetes. See Viewing Audit Log Events.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the GetWorkRequest, DeleteWorkRequest, ListWorkRequestErrors, ListWorkRequestLogs, and ListWorkRequests operations to monitor and manage operations performed by Container Engine for Kubernetes.

Accessing a Cluster Using kubectl

You can use the Kubernetes command line tool kubectl to perform operations on a cluster you've created with Container Engine for Kubernetes. Before you can use kubectl to access a cluster, you need to specify the cluster on which to perform operations by downloading the

cluster's kubeconfig file. Note that a Oracle Cloud Infrastructure CLI command in the kubeconfig file generates authentication tokens that are short-lived, cluster-scoped, and specific to individual users. As a result, you cannot share kubeconfig files between users to access Kubernetes clusters.

To access a cluster using kubectl:

1. If you haven't already done so, install kubectl (see the kubectl documentation).
2. If you haven't already done so, follow the steps to download the cluster's kubeconfig configuration file and set the KUBECONFIG environment variable to point to the file. Note that you must download your own kubeconfig file. You cannot access a cluster using a kubeconfig file that a different user downloaded. See Downloading a kubeconfig File to Enable Cluster Access.
3. In a terminal window, enter `kubectl` followed by the command for the operation you want to perform on the cluster. For a list of available commands and options, see the kubectl documentation.
   Note that you must have the appropriate permissions to run the command you enter. See About Access Control and Container Engine for Kubernetes.

Starting the Kubernetes Dashboard

Kubernetes Dashboard is a web-based user interface that you can use as an alternative to the Kubernetes kubectl command line tool to:

- deploy containerized applications to a Kubernetes cluster
- troubleshoot your containerized applications

You use the Kubernetes Dashboard to get an overview of applications running on a cluster, as well as to create or modify individual Kubernetes resources. The Kubernetes Dashboard also reports the status of Kubernetes resources in the cluster, and any errors that have occurred. Note that to use the Kubernetes Dashboard, it must have been enabled when the cluster was initially created.

In contrast to the Kubernetes Dashboard, Container Engine for Kubernetes enables you to create and delete Kubernetes clusters and node pools, and to manage the associated compute, network, and storage resources.

Before you can use the Kubernetes Dashboard to access a cluster, you need to specify the cluster on which to perform operations by downloading the cluster's kubeconfig file. Note that an Oracle Cloud Infrastructure CLI command in the kubeconfig file generates authentication tokens that are short-lived, cluster-scoped, and specific to individual users. As a result, you cannot share kubeconfig files between users to access Kubernetes clusters.

To start the Kubernetes Dashboard:

1. If you haven't already done so, follow the steps to download the cluster's kubeconfig configuration file and set the KUBECONFIG environment variable to point to the file. Note that you must download your own kubeconfig file. You cannot access a cluster using a kubeconfig file that a different user downloaded. See Downloading a kubeconfig File to Enable Cluster Access.
2. In a text editor, create a file (for example, called oke-admin-service-account.yaml) with the following content:

   ```
   apiVersion: v1
   kind: ServiceAccount
   metadata:
     name: oke-admin
     namespace: kube-system
   ---
   apiVersion: rbac.authorization.k8s.io/v1beta1
   kind: ClusterRoleBinding
   metadata:
     name: oke-admin
   roleRef:
     apiGroup: rbac.authorization.k8s.io
     kind: ClusterRole
     name: cluster-admin
   subjects:
   - kind: ServiceAccount
     name: oke-admin
     namespace: kube-system
   ```

   The file defines an administrator service account and a clusterrolebinding, both called oke-admin.
3. Create the service account and the clusterrolebinding in the cluster by entering:

   ```
   $ kubectl apply -f <filename>
   ```

where <filename> is the name of the file you created earlier. For example:

```
$ kubectl apply -f oke-admin-service-account.yaml
```

The output from the above command confirms the creation of the service account and the clusterrolebinding:

```
serviceaccount "oke-admin" created
clusterrolebinding.rbac.authorization.k8s.io "oke-admin" created
```

You can now use the oke-admin service account to view and control the cluster, and to connect to the Kubernetes dashboard.

4. Obtain an authentication token for the oke-admin service account by entering:

```
$ kubectl -n kube-system describe secret $(kubectl -n kube-system get secret | grep oke-admin |
awk '{print $1}')
```

The output from the above command includes an authentication token (a long alphanumeric string) as the value of the token: element, as shown below:

```
Name:         oke-admin-token-gwbp2
Namespace:    kube-system
Labels:       <none>
Annotations:  kubernetes.io/service-account.name: oke-admin
kubernetes.io/service-account.uid: 3a7fcd8e-e123-11e9-81ca-0a580aed8570
Type:  kubernetes.io/service-account-token
Data
====
ca.crt:     1289 bytes
namespace:  11 bytes
token:      eyJh______px1Q
```

In the example above, eyJh______px1Q (abbreviated for readability) is the authentication token.

5. Copy the value of the token: element from the output. You will use this token to connect to the dashboard.
6. In a terminal window, enter kubectl proxy to start the Kubernetes Dashboard.

7. Open a browser and go to `http://localhost:8001/api/v1/namespaces/kube-system/services/https:kubernetes-dashboard:/proxy/#!/login` to display the Kubernetes Dashboard.
8. In the Kubernetes Dashboard, select **Token** and paste the value of the `token:` element you copied earlier into the **Token** field.
9. In the Kubernetes Dashboard, click **Sign In**, and then click **Overview** to see the applications deployed on the cluster.

Deploying a Sample Nginx App on a Cluster Using kubectl

Having created a Kubernetes cluster using Container Engine for Kubernetes, you'll typically want to try it out by deploying an application on the nodes in the cluster. For convenience, the **Cluster** page includes a **Getting Started** tab that makes it easy to view and copy the commands to:

- download the kubeconfig configuration file for the cluster
- download and deploy a sample Nginx application using the Kubernetes command line tool kubectl from the instructions in a manifest file
- start the Kubernetes Dashboard to view the deployed application running on nodes in the cluster

To deploy the sample nginx application:

1. If you haven't already done so, follow the steps to download the cluster's kubeconfig configuration file and set the KUBECONFIG environment variable to point to the file. Note that you must download your own kubeconfig file. You cannot access a cluster using a kubeconfig file that a different user downloaded. See Downloading a kubeconfig File to Enable Cluster Access.
2. In a terminal window, deploy the sample Nginx application by entering `kubectl create -f https://k8s.io/docs/tasks/run-application/deployment.yaml`

Tip

If the command fails to connect to `https://k8s.io/docs/tasks/run-application/deployment.yaml` , go to the url in a browser and download the manifest file `deployment.yaml` to a local directory. Repeat the `kubectl create` command and specify the local location of the `deployment.yaml` file.

3. Use the Kubernetes Dashboard or kubectl to confirm that the sample application has deployed successfully. For example:
    a. Enter `kubectl proxy` to start the Kubernetes Dashboard.
    b. Open a browser and go to `http://localhost:8001/api/v1/namespaces/kube-system/services/https:kubernetes-dashboard:/proxy/` to display the Kubernetes Dashboard.
    c. Click **Overview** to see the applications deployed on the cluster.

You can see the Nginx sample application has been deployed as two pods, on two nodes in the cluster.

Pulling Images from Registry during Deployment

During the deployment of an application to a Kubernetes cluster, you'll typically want one or more images to be pulled from a Docker registry. In the application's manifest file you specify the images to pull, the registry to pull them from, and the credentials to use when pulling the images. The manifest file is commonly also referred to as a pod spec, or as a deployment.yaml file (although other filenames are allowed).

If you want the application to pull images that reside in Oracle Cloud Infrastructure Registry, you have to perform two steps:

- You have to use kubectl to create a Docker registry secret. The secret contains the Oracle Cloud Infrastructure credentials to use when pulling the image. When creating secrets, Oracle strongly recommends you use the latest version of kubectl (see the kubectl documentation).
- You have to specify the image to pull from Oracle Cloud Infrastructure Registry, including the repository location and the Docker registry secret to use, in the application's manifest file.

To create a Docker registry secret:

1. If you haven't already done so, follow the steps to download the cluster's kubeconfig configuration file and set the KUBECONFIG environment variable to point to the file. Note that you must download your own kubeconfig file. You cannot access a cluster using a kubeconfig file that a different user downloaded. See Downloading a kubeconfig File to Enable Cluster Access.
2. In a terminal window, enter:

   ```
   $ kubectl create secret docker-registry <secret-name> --docker-server=<region-code>.ocir.io --docker-username='<tenancy-namespace>/<oci-username>' --docker-password='<oci-auth-token>' --docker-email='<email-address>'
   ```

   where:

   - `<secret-name>` is a name of your choice, that you will use in the manifest file to refer to the secret . For example, `ocirsecret`
   - `<region-code>` is the code for the Oracle Cloud Infrastructure Registry region you're using. For example, `iad`. See Availability by Region Name and Region Code for the list of region codes.
   - `ocir.io` is the Oracle Cloud Infrastructure Registry name.
   - `<tenancy-namespace>` is the auto-generated Object Storage namespace string of the tenancy containing the repository from which the application is to pull the image (as shown on the **Tenancy Information** page). For example, the namespace of the acme-dev tenancy might be `ansh81vru1zp`. Note that for some

older tenancies, the namespace string might be the same as the tenancy name in all lower-case letters (for example, `acme-dev`).

- `<oci-username>` is the username to use when pulling the image. The username must have access to the tenancy specified by `<tenancy-name>`. For example, `jdoe@acme.com` . If your tenancy is federated with Oracle Identity Cloud Service, use the format `oracleidentitycloudservice/<username>`
- `<oci-auth-token>` is the auth token of the user specified by `<oci-username>`. For example, `k]j64r{1sJSSF-;)K8`
- `<email-address>` is an email address. An email address is required, but it doesn't matter what you specify. For example, `jdoe@acme.com`

Note the use of single quotes around strings containing special characters.

For example, combining the previous examples, you might enter:

```
$ kubectl create secret docker-registry ocirsecret --docker-server=phx.ocir.io --docker-username='ansh81vru1zp/jdoe@acme.com' --docker-password='k]j64r{1sJSSF-;)K8' --docker-email='jdoe@acme.com'
```

Having created the Docker secret, you can now refer to it in the application manifest file.

To specify the image to pull from Oracle Cloud Infrastructure Registry, along with the Docker secret to use, during deployment of an application to a cluster:

1. Open the application's manifest file in a text editor.
2. Add the following sections to the manifest file:
   a. Add a `containers` section that specifies the name and location of the container you want to pull from Oracle Cloud Infrastructure Registry, along with other deployment details.
   b. Add an `imagePullSecrets` section to the manifest file that specifies the name of the Docker secret you created to access the Oracle Cloud Infrastructure Registry.

Here's an example of what the manifest might look like when you've added the `containers` and `imagePullSecrets` sections:

```
apiVersion: v1
kind: Pod
metadata:
  name: ngnix-image
spec:
  containers:
    - name: ngnix
      image: phx.ocir.io/ansh81vru1zp/project01/ngnix-lb:latest
      imagePullPolicy: Always
      ports:
      - name: nginx
        containerPort: 8080
        protocol: TCP
  imagePullSecrets:
    - name: ocirsecret
```

3. Save and close the manifest file.

Encrypting Kubernetes Secrets At Rest in Etcd

The master nodes in a Kubernetes cluster store sensitive configuration data (such as authentication tokens, passwords, and SSH keys) as Kubernetes secret objects in etcd. Etcd is an open source distributed key-value store that Kubernetes uses for cluster coordination and state management. In the Kubernetes clusters created by Container Engine for Kubernetes, etcd writes and reads data to and from block storage volumes in the Oracle Cloud Infrastructure Block Volume service. Although the data in block storage volumes is encrypted, Kubernetes secrets at rest in etcd itself are not encrypted by default.

For additional security, when you create a new cluster you can specify that Kubernetes secrets at rest in etcd are to be encrypted using the Oracle Cloud Infrastructure Key Management service (see Overview of Key Management). Before you can create a cluster where Kubernetes secrets are encrypted in the etcd key-value store, you have to:

- know the name and OCID of a suitable master encryption key in Key Management
- create a dynamic group that includes all clusters in the compartment in which you are going to create the new cluster
- create a policy authorizing the dynamic group to use the master encryption key

Having created the cluster and specified that you want Kubernetes secrets at rest in the etcd key-value store to be encrypted, you can optionally restrict the use of the master encryption key by modifying the dynamic group to include just that cluster.

Note the following:

- You can only select the option to encrypt the Kubernetes secrets in the cluster's etcd key-value store when creating a new 'custom cluster'. You cannot encrypt Kubernetes secrets in the etcd key-value stores of existing 'custom clusters', or in the etcd key-value stores of 'quick clusters'.
- You can only select the option to encrypt Kubernetes secrets in the cluster's etcd key-value store if you specify Kubernetes version 1.13.x or later as the version of Kubernetes to run on the master nodes of the cluster.
- After you've specified a master encryption key for a new cluster and created the cluster, do not subsequently delete the master encryption key in the Key Management service. As soon as you schedule a key for deletion in Key Management, the Kubernetes secrets stored for the cluster in etcd become inaccessible. If you have already scheduled the key for deletion, it might still be in the Pending Deletion state. If that is the case, cancel the scheduled key deletion (see To cancel the deletion of a key) to restore access to the Kubernetes secrets. If you allow the scheduled key deletion operation to complete and the master encryption key to be deleted, the Kubernetes secrets stored for the cluster in etcd are permanently inaccessible. As a result, cluster upgrades will fail. In this situation, you have no choice but to delete and recreate the cluster.

Using the Console

To create a new 'custom cluster' where Kubernetes secrets are encrypted in the cluster's etcd key-value store:

1. Log in to the Console.
2. If you know the OCID of the master encryption key to use to encrypt Kubernetes secrets, go straight to the next step. Otherwise:
   - If a suitable master encryption key already exists in Key Management but you're not sure of its OCID, follow the instructions in To view key details and make a note of the master encryption key's OCID.
   - If a suitable master encryption key does not already exist in Key Management, follow the instructions in To create a new key to create one. Having created a new master encryption key, make a note of its OCID.
3. Create a new dynamic group containing all the clusters in the compartment in which you intend to create the new cluster:
   a. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Dynamic Groups**.
   b. Follow the instructions in To create a dynamic group, and give the dynamic group a name (for example, `acme-oke-kms-dyn-grp`).
   c. Enter a rule that includes all clusters in the compartment in the format:

      ```
      ALL {resource.type = 'cluster', resource.compartment.id = '<compartment-ocid>'}
      ```

      where `<compartment-ocid>` is the OCID of the compartment in which you intend to create the new cluster.
      For example:

      ```
      ALL {resource.type = 'cluster', resource.compartment.id =
      'ocid1.compartment.oc1..aaaaaaaa23_____smwa'}
      ```

   d. Click **Create Dynamic Group**.

Having created a dynamic group that includes all clusters in the compartment, you can now create a policy to give the dynamic group access to the master encryption key in Key Management.

4. Create a new policy to enable use of the master encryption key:
    a. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Policies**.
    b. Follow the instructions in To create a policy, and give the policy a name (for example, `acme-oke-kms-dyn-grp-policy`).
    c. Enter a policy statement to give the dynamic group access to the master encryption key, in the format:

    ```
    Allow dynamic-group <dynamic-group-name> to use keys in compartment <compartment-name>
    where target.key.id = '<key-OCID>'
    ```

    where:

    - `<dynamic-group-name>` is the name of the dynamic group you created earlier.
    - `<compartment-name>` is the name of the compartment containing the master encryption key.
    - `<key-OCID>` is the OCID of the master encryption key in Key Management.

    For example:

    ```
    Allow dynamic-group <acme-oke-kms-dyn-grp> to use keys in compartment acme-kms-key-
    compartment where target.key.id = 'ocid1.key.oc1.iad.annrl______trfg'
    ```

    d. Click **Create** to create the new policy.
5. Follow the instructions to create a new 'custom cluster' in Using the Console to create a 'Custom Cluster' with Explicitly Defined Settings, select the **Encrypt Using Customer-Managed Keys** option, and select:
    - **Choose a Vault in <compartment-name>:** The vault that contains the master encryption key, from the list of vaults in the specified compartment. By default, <compartment-name> is the compartment in which you are creating the cluster, but you can select a different compartment by clicking **Change Compartment**.

- **Choose a Key in <compartment-name>:** The name of the master encryption key, from the list of keys in the specified compartment. By default, <compartment-name> is the compartment in which you are creating the cluster, but you can select a different compartment by clicking **Change Compartment**. Note that you cannot change the master encryption key after the cluster has been created.

6. (Optional) Having created the cluster, for additional security:
    a. Make a note of the OCID of the new cluster you just created.
    b. Restrict the use of the master encryption key by modifying the dynamic group rule you created earlier to explicitly specify the OCID of the new cluster, rather than all clusters in the compartment. For example:

```
resource.id = 'ocid1.cluster.oc1.iad.aaaaaaaaaf______yg5q'
```

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the CreateCluster operation to create a cluster.

Connecting to Worker Nodes Using SSH

If you provided a public SSH key when creating the node pool in a cluster, the public key is installed on all worker nodes in the cluster. On UNIX and UNIX-like platforms (including Solaris and Linux), you can then connect through SSH to the worker nodes using the ssh utility (an SSH client) to perform administrative tasks.

Note the following instructions assume the UNIX machine you use to connect to the worker node:

- Has the ssh utility installed.
- Has access to the SSH private key file paired with the SSH public key that was specified when the cluster was created.

How to connect to worker nodes using SSH depends on whether you specified public or private subnets for the worker nodes when defining the node pools in the cluster.

Connecting to Worker Nodes in Public Subnets Using SSH

Before you can connect to a worker node in a public subnet using SSH, you must define an ingress rule in the subnet's security list to allow SSH access. The ingress rule must allow access to port 22 on worker nodes from source 0.0.0.0/0 and any source port, as follows:

Type	Source CIDR	IP Protocol	Source Port Range	Dest. Port Range	Type and Code	Allows: and Description:
Stateful	0.0.0.0/0	TCP	All	22	n/a	**Allows:** TCP traffic for ports: 22 SSH Remote Login Protocol **Description:** Enables SSH access.

To connect to a worker node in a public subnet through SSH from a UNIX machine using the ssh utility:

1. Find out the IP address of the worker node to which you want to connect. You can do this in a number of ways:
    - Using kubectl. If you haven't already done so, follow the steps to download the cluster's kubeconfig configuration file and set the KUBECONFIG environment variable to point to the file. Note that you must download your own kubeconfig file. You cannot access a cluster using a kubeconfig file that a different user downloaded. See Downloading a kubeconfig File to Enable Cluster Access. Then in a terminal window, enter `kubectl get nodes` to see the public IP addresses of worker nodes in node pools in the cluster.

- Using the Console. In the Console, display the **Cluster List** page and then select the cluster to which the worker node belongs. Click **Node Pools** to see the public IP addresses of worker nodes in every node pool in the cluster.
- Using the REST API. Use the ListNodePools operation to see the public IP addresses of worker nodes in a node pool.

2. In the terminal window, enter `ssh opc@<node_ip_address>` to connect to the worker node, where `<node_ip_address>` is the IP address of the worker node that you made a note of earlier. For example, you might enter `ssh opc@192.0.2.254`.
   Note that if the SSH private key is not stored in the file or in the path that the ssh utility expects (for example, the ssh utility might expect the private key to be stored in ~/.ssh/id_rsa), you must explicitly specify the private key filename and location in one of two ways:
   - Use the `-i` option to specify the filename and location of the private key. For example, `ssh -i ~/.ssh/my_keys/my_host_key_filename opc@192.0.2.254`
   - Add the private key filename and location to an SSH configuration file, either the client configuration file (~/.ssh/config) if it exists, or the system-wide client configuration file (/etc/ssh/ssh_config). For example, you might add the following:

     ```
     Host 192.0.2.254 IdentityFile ~/.ssh/my_keys/my_host_key_filename
     ```

   For more about the ssh utility's configuration file, enter `man ssh_config`
   Note also that permissions on the private key file must allow you read/write/execute access, but prevent other users from accessing the file. For example, to set appropriate permissions, you might enter `chmod 600 ~/.ssh/my_keys/my_host_key_filename`. If permissions are not set correctly and the private key file is accessible to other users, the ssh utility will simply ignore the private key file.

Connecting to Worker Nodes in Private Subnets Using SSH

Worker nodes in private subnets have private IP addresses only (they do not have public IP addresses). They can only be accessed by other resources inside the VCN. Oracle recommends using bastion hosts to control external access (such as SSH) to worker nodes in private subnets. A bastion host is in a public subnet, has a public IP address, and is accessible

from the internet. For more information about bastion hosts, see the white paper Bastion Hosts: Protected Access for Virtual Cloud Networks.

About Access Control and Container Engine for Kubernetes

To perform operations on a Kubernetes cluster, you must have appropriate permissions to access the cluster.

For most operations on Kubernetes clusters created and managed by Container Engine for Kubernetes, Oracle Cloud Infrastructure Identity and Access Management (IAM) provides access control. A user's permissions to access clusters comes from the groups to which they belong. The permissions for a group are defined by policies. Policies define what actions members of a group can perform, and in which compartments. Users can then access clusters and perform operations based on the policies set for the groups they are members of.

IAM provides control over:

- whether a user can create or delete clusters
- whether a user can add, remove, or modify node pools
- which Kubernetes object create/delete/view operations a user can perform on all clusters within a compartment or tenancy

See Policy Configuration for Cluster Creation and Deployment.

In addition to IAM, the Kubernetes RBAC Authorizer can enforce additional fine-grained access control for users on specific clusters via Kubernetes RBAC roles and clusterroles. A Kubernetes RBAC role is a collection of permissions. For example, a role might include read permission on pods and list permission for pods. A Kubernetes RBAC clusterrole is just like a role, but can be used anywhere in the cluster. A Kubernetes RBAC rolebinding maps a role to a user or set of users, granting that role's permissions to those users for resources in that namespace. Similarly, a Kubernetes RBAC clusterrolebinding maps a clusterrole to a user or set of users, granting that clusterrole's permissions to those users across the entire cluster.

IAM and the Kubernetes RBAC Authorizer work together to enable users who have been successfully authorized by at least one of them to complete the requested Kubernetes operation.

When a user attempts to perform any operation on a cluster (except for create role and create clusterrole operations), IAM first determines whether the group to which the user belongs has the appropriate and sufficient permissions. If so, the operation succeeds. If the attempted operation also requires additional permissions granted via a Kubernetes RBAC role or clusterrole, the Kubernetes RBAC Authorizer then determines whether the user has been granted the appropriate Kubernetes role or clusterrole.

Typically, you'll want to define your own Kubernetes RBAC roles and clusterroles when deploying a Kubernetes cluster to provide additional fine-grained control. When you attempt to perform a create role or create clusterrole operation, the Kubernetes RBAC Authorizer first determines whether you have sufficient Kubernetes privileges. Tto create a role or clusterrole, you must have been assigned an existing Kubernetes RBAC role (or clusterrole) that has at least the same or higher privileges as the new role (or clusterrole) you're attempting to create.

By default, users are not assigned any Kubernetes RBAC roles (or clusterroles) by default. So before attempting to create a new role (or clusterrole), you must be assigned an appropriately privileged role (or clusterrole). A number of such roles and clusterroles are always created by default, including the cluster-admin clusterrole (for a full list, see Default Roles and Role Bindings in the Kubernetes documentation). The cluster-admin clusterrole essentially confers super-user privileges. A user granted the cluster-admin clusterrole can perform any operation across all namespaces in a given cluster.

Note that Oracle Cloud Infrastructure tenancy administrators already have sufficient privileges, and do not require the cluster-admin clusterrole.

Example: Granting the Kubernetes RBAC cluster-admin clusterrole

Note

The following instructions assume:

- You have the required access to create Kubernetes RBAC roles and clusterroles, either because you're in the tenancy's Administrators group, or because you have the Kubernetes RBAC cluster-admin clusterrole.
- The user to which you want to grant the RBAC cluster-admin clusterrole is not an OCI tenancy administrator. If they are an OCI tenancy administrator, they do not require the Kubernetes RBAC cluster-admin clusterrole.

Follow these steps to grant a user who is not a tenancy administrator the Kubernetes RBAC cluster-admin clusterrole on a cluster deployed on Oracle Cloud Infrastructure:

1. If you haven't already done so, follow the steps to download the cluster's kubeconfig configuration file and set the KUBECONFIG environment variable to point to the file. Note that you must download your own kubeconfig file. You cannot access a cluster using a kubeconfig file that a different user downloaded. See Downloading a kubeconfig File to Enable Cluster Access.
2. In a terminal window, grant the Kubernetes RBAC cluster-admin clusterrole to the user by entering:

   ```
   $ kubectl create clusterrolebinding <my-cluster-admin-binding> --clusterrole=cluster-admin --user=<user_OCID>
   ```

   where:

   - `<my-cluster-admin-binding>` is a string of your choice to be used as the name for the binding between the user and the Kubernetes RBAC cluster-admin clusterrole. For example, `jdoe_clst_adm`
   - `<user_OCID>` is the user's OCID (obtained from the Console). For example, `ocid1.user.oc1..aaaaa...zutq` (abbreviated for readability).

For example:

```
$ kubectl create clusterrolebinding jdoe_clst_adm --clusterrole=cluster-admin --
user=ocid1.user.oc1..aaaaa...zutq
```

Example: Giving a developer user the ability to read pods in a new cluster

Note

The following instructions assume you're in the tenancy's Administrators group, and therefore have:

- the required permissions to create clusters, and to manage users and groups
- the required access to create Kubernetes RBAC roles and clusterroles

Follow these steps to give a developer the necessary Oracle Cloud Infrastructure and Kubernetes RBAC permissions to use kubectl to view pods running on a cluster deployed on Oracle Cloud Infrastructure:

1. Create a new Oracle Cloud Infrastructure user for the developer to use (for example, called jdoe@acme.com), and make a note of the new user's OCID (for example, `ocid1.user.oc1..aaaaa...tx5a`, abbreviated for readability). See To create a user.
2. Create a new Oracle Cloud Infrastructure group and add the new user to the group (for example, called acme-dev-pod-vwr). See To create a group.
3. Create a new Oracle Cloud Infrastructure policy that grants the new group the CLUSTER_USE permission on clusters, with a policy statement like:

   ```
   Allow group acme-dev-pod-vwr to use clusters in <location>
   ```

   In the above policy statement, replace `<location>` with either `tenancy` (if you are creating the policy in the tenancy's root compartment) or `compartment <compartment-`

name> (if you are creating the policy in an individual compartment).
See To create a policy.

4. Create a new cluster in the Console. See Creating a Kubernetes Cluster.
5. Follow the steps to download the cluster's kubeconfig configuration file and set the KUBECONFIG environment variable to point to the file. Note that you must download your own kubeconfig file. You cannot access a cluster using a kubeconfig file that a different user downloaded. See Downloading a kubeconfig File to Enable Cluster Access.
6. In a text editor, create a file (for example, called role-pod-reader.yaml) with the following content. This file defines a Kubernetes RBAC role that enables users to read pod details.

```
kind: Role
apiVersion: rbac.authorization.k8s.io/v1
metadata:
 namespace: default
 name: pod-reader
rules:
- apiGroups: [""] # "" indicates the core API group
  resources: ["pods"]
  verbs: ["get", "watch", "list"]
```

7. In a terminal window, create the new role in the cluster using kubectl. For example, if you gave the yaml file that defines the new role the name role-pod-reader.yaml, enter the following:

```
$ kubectl create -f role-pod-reader.yaml
```

8. In a terminal window, bind the Kubernetes RBAC role you just created to the Oracle Cloud Infrastructure user account you created earlier by entering the following to create a new rolebinding (in this case, called pod-reader-binding):

```
$ kubectl create rolebinding pod-reader-binding --role=pod-reader --
user=ocid1.user.oc1..aaaaa...tx5a
```

9. Give the developer the credentials of the new Oracle Cloud Infrastructure user you created earlier, and tell the developer they can now see details of pods running on the cluster deployed on Oracle Cloud Infrastructure by:

- Signing in to the Console using the new user's credentials.
- Following the instructions in Downloading a kubeconfig File to Enable Cluster Access to obtain their own copy of the cluster's kubeconfig file. If the file does not have the expected default name and location of `$HOME/.kube/config`, the developer will also have to set the KUBECONFIG environment variable to point to the file. Note that the developer must download their own kubeconfig file. They cannot access a cluster using a kubeconfig file that you (or a different user) downloaded.
- Using kubectl to see details of the pods by entering:

```
$ kubectl get pods
```

Kubernetes Versions and Container Engine for Kubernetes

When you create a new Kubernetes cluster using Container Engine for Kubernetes, you specify:

- The version of Kubernetes to run on the master nodes in the cluster.
- The version of Kubernetes to run on the worker nodes in each node pool. All worker nodes in the same node pool run the same version of Kubernetes. Different node pools in a cluster can run different versions of Kubernetes.

The version of Kubernetes that you specify for the worker nodes in a node pool must be either the same Kubernetes version as that running on the master nodes, or an earlier Kubernetes version that is still compatible. In other words:

- The master nodes in a new cluster must run the same version of Kubernetes as the version running on worker nodes, or must be no more than two versions ahead.
- The worker nodes in a node pool must not run a more recent version of Kubernetes than the associated master nodes.

About Kubernetes Versions

New versions of Kubernetes are released periodically that contain new features and bug fixes.

Kubernetes version numbers have the format `x.y.z` where `x` is a major release, `y` is a minor release, and `z` is a patch release. For example, 1.13.5.

Kubernetes itself is supported for three minor versions at a time (the current release version and two previous versions).

As described in the Kubernetes documentation, a certain amount of version variation is permissible between master nodes and worker nodes in a cluster:

- The Kubernetes version on worker nodes can lag behind the version on the master nodes by up to two versions, but no more. If the version on the worker nodes is more than two versions behind the version on the master nodes, the Kubernetes versions on the worker nodes and the master nodes are incompatible.
- The Kubernetes version on worker nodes must never be more recent than the version on the master nodes.

About Upgrading Clusters to Newer Kubernetes Versions

After a new version of Kubernetes has been released and when Container Engine for Kubernetes supports the new version, you can use Container Engine for Kubernetes to upgrade master nodes running older versions of Kubernetes. Because Container Engine for Kubernetes distributes the Kubernetes Control Plane on multiple Oracle-managed master nodes (distributed across different availability domains in a region where supported) to ensure high availability, you're able to upgrade the Kubernetes version running on master nodes with zero downtime.

Having upgraded master nodes to a new version of Kubernetes, you can subsequently create new node pools running the newer version. Alternatively, you can continue to create new node pools that will run older versions of Kubernetes (providing those older versions are compatible with the Kubernetes version running on the master nodes).

Note that you upgrade master nodes by performing an ‘in-place’ upgrade, but you upgrade worker nodes by performing an ‘out-of-place’ upgrade. To upgrade the version of Kubernetes running on worker nodes in a node pool, you replace the original node pool with a new node pool that has new worker nodes running the appropriate Kubernetes version. Having 'drained'

existing worker nodes in the original node pool to prevent new pods starting and to delete existing pods, you can then delete the original node pool.

Also note the following:

- Container Engine for Kubernetes only upgrades the Kubernetes version running on master nodes when you explicitly initiate the upgrade operation.
- After upgrading master nodes to a newer version of Kubernetes, you cannot downgrade the master nodes to an earlier Kubernetes version.
- Before you upgrade the version of Kubernetes running on the master nodes, it is your responsibility to test that applications deployed on the cluster are compatible with the new Kubernetes version. For example, before upgrading the existing cluster, you might create a new separate cluster with the new Kubernetes version to test your applications.
- The versions of Kubernetes running on the master nodes and the worker nodes must be compatible (that is, the Kubernetes version on the master nodes must be no more than two minor versions ahead of the Kubernetes version on the worker nodes).
- If the version of Kubernetes currently running on the master nodes is more than one version behind the most recent supported version, you are given a choice of versions to upgrade to. If you want to upgrade to a version of Kubernetes that is more than one version ahead of the version currently running on the master nodes, you must upgrade to each intermediate version in sequence without skipping versions.

Kubernetes Versions Supported by Container Engine for Kubernetes

Container Engine for Kubernetes supports the following versions of Kubernetes:

Kubernetes Version	Supported by Container Engine for Kubernetes?	Notes
1.11.x and earlier	No	N/A
1.12.7	Yes	Note that versions of Kubernetes 1.12.x prior to 1.12.7 (for example, 1.12.6) are no longer supported. You cannot: • create clusters running earlier 1.12.x versions • add new node pools to existing clusters running earlier 1.12.x versions If you do have clusters running 1.12.x versions earlier than 1.12.7, Oracle strongly recommends you upgrade those clusters to version 1.12.7.
1.13.5	Yes	N/A

Upgrading the Version of Kubernetes Running on Master Nodes

When Container Engine for Kubernetes supports a newer version of Kubernetes than the version currently running on the master nodes in a cluster, you can upgrade the Kubernetes version running on the master nodes.

Important: After you've upgraded master nodes to a newer version of Kubernetes, you can't downgrade the master nodes to an earlier Kubernetes version. It's therefore important that

before you upgrade the version of Kubernetes running on the master nodes, you test that applications deployed on the cluster are compatible with the new Kubernetes version.

Using the Console

To upgrade the version of Kubernetes running on the master nodes:

1. In the Console, open the navigation menu. Under **Solutions and Platform**, go to **Developer Services** and click **Container Clusters**.
2. Choose a **Compartment** you have permission to work in.
3. On the **Cluster List** page, click the name of the cluster where you want to upgrade the version of Kubernetes running on the master nodes.
   If a newer version of Kubernetes is available than the one running on the master nodes in the cluster, the **Upgrade Available** button is enabled at the top of the **Cluster** page.
4. Click **Upgrade Available** to upgrade the master nodes to a newer version.
5. In the **Upgrade Cluster Master** dialog box, select the version of Kubernetes to which to upgrade the master nodes, and click **Confirm**.

The version of Kubernetes running on the master nodes is upgraded. From now on, the new version of Kubernetes will appear as an option when you're defining new node pools for the cluster.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the UpdateCluster operation to upgrade the version of Kubernetes running on the master nodes.

'Upgrading' the version of Kubernetes running on worker nodes by creating a new node pool

To 'upgrade' the version of Kubernetes running on worker nodes in a node pool, you replace the original node pool with a new node pool that has new worker nodes running the appropriate Kubernetes version. Having 'drained' existing worker nodes in the original node pool to prevent new pods starting and to delete existing pods, you can then delete the original node pool.

To 'upgrade' the version of Kubernetes on worker nodes by creating a new node pool:

1. In the Console, open the navigation menu. Under **Solutions and Platform**, go to **Developer Services** and click **Container Clusters**.
2. Choose a **Compartment** you have permission to work in.
3. On the **Cluster List** page, click the name of the cluster where you want to change the Kubernetes version running on worker nodes.
4. On the **Cluster** page, click **Add Node Pool** to create a new node pool and specify the required version of Kubernetes for its worker nodes.

   The version of Kubernetes you specify must be compatible with the version that is running on the master nodes.
5. If there are labels attached to worker nodes in the original node pool and those labels are used by selectors (for example, to determine the nodes on which to run pods), then use the `kubectl label nodes` command to attach the same labels to the new worker nodes in the new node pool. See Assigning Pods to Nodes in the Kubernetes documentation.
6. For each worker node in the original node pool, prevent new pods from starting and delete existing pods by entering `kubectl drain <node_name>` for each worker node.

   For more information:

   - about using kubectl, see Accessing a Cluster Using kubectl
   - about the drain command, see drain in the Kubernetes documentation

Recommended: Leverage pod disruption budgets as appropriate for your application to ensure that there's a sufficient number of replica pods running throughout the drain operation.

After all the worker nodes have been drained from the original node pool and pods are running on worker nodes in the new node pool, you can delete the original node pool.

7. On the **Cluster** page, display the **Node Pools** tab and select **Delete Node Pool** from the **Actions** menu.

   The original node pool and all its worker nodes are deleted.

'Upgrading' the image running on worker nodes by creating a new node pool

When a node pool is created, the image to use for worker nodes in the node pool is specified. An image is a template of a virtual hard drive that determines the operating system and other software running on the worker nodes.

To 'upgrade' the image running on worker nodes in a node pool (for example, to upgrade to a new version of Oracle Linux), you replace the original node pool with a new node pool that has new worker nodes running the appropriate image. Having 'drained' existing worker nodes in the original node pool to prevent new pods starting and to delete existing pods, you can then delete the original node pool.

To 'upgrade' the image on worker nodes by creating a new node pool:

1. In the Console, open the navigation menu. Under **Solutions and Platform**, go to **Developer Services** and click **Container Clusters**.
2. Choose a **Compartment** you have permission to work in.
3. On the **Cluster List** page, click the name of the cluster where you want to change the image running on worker nodes.
4. On the **Cluster** page, click **Add Node Pool** to create a new node pool and specify the required image for its worker nodes.
5. If there are labels attached to worker nodes in the original node pool and those labels are used by selectors (for example, to determine the nodes on which to run pods), then

use the `kubectl label nodes` command to attach the same labels to the new worker nodes in the new node pool. See Assigning Pods to Nodes in the Kubernetes documentation.

6. For each worker node in the original node pool, prevent new pods from starting and delete existing pods by entering `kubectl drain <node_name>` for each worker node.
   For more information:
   - about using kubectl, see Accessing a Cluster Using kubectl
   - about the `drain` command, see drain in the Kubernetes documentation

   Recommended: Leverage pod disruption budgets as appropriate for your application to ensure that there's a sufficient number of replica pods running throughout the drain operation.
   After all the worker nodes have been drained from the original node pool and pods are running on worker nodes in the new node pool, you can delete the original node pool.
7. On the **Cluster** page, display the **Node Pools** tab and select **Delete Node Pool** from the **Actions** menu.
   The original node pool and all its worker nodes are deleted.

Creating Load Balancers to Distribute Traffic Between Cluster Nodes

When you create a service, you can optionally create a load balancer to distribute service traffic among the nodes assigned to that service. The key fields in the configuration of a load balancer are the **type** of service being created and the **ports** that the load balancer will listen to.

Creating Load Balancers to Distribute HTTP Traffic

Consider the following configuration file, `nginx_lb.yaml`. It defines a deployment (`kind: Deployment`) for the `nginx` app, followed by a service definition with a type of LoadBalancer (`type: LoadBalancer`) that balances http traffic on port 80 for the `nginx` app.

```
apiVersion: apps/v1
kind: Deployment
```

```
metadata:
  name: my-nginx
  labels:
    app: nginx
spec:
  replicas: 3
  selector:
    matchLabels:
      app: nginx
  template:
    metadata:
      labels:
        app: nginx
    spec:
      containers:
      - name: nginx
        image: nginx:1.7.9
        ports:
        - containerPort: 80
---
apiVersion: v1
kind: Service
metadata:
  name: my-nginx-svc
  labels:
    app: nginx
spec:
  type: LoadBalancer
  ports:
  - port: 80
  selector:
    app: nginx
```

The first part of the configuration file defines an Nginx deployment, requesting that it be hosted on 3 pods running the nginx:1.7.9 image, and accept traffic to the containers on port 80.

The second part of the configuration file defines the Nginx service, which uses type LoadBalancer to balance Nginx traffic on port 80 amongst the available pods.

To create the deployment and service defined in `nginx_lb.yaml` while connected to your Kubernetes cluster, enter the command:

```
$ kubectl apply -f nginx_lb.yaml
```

This command outputs the following upon successful creation of the deployment and the load balancer:

```
deployment "my-nginx" created
service "my-nginx-svc" created
```

The load balancer may take a few minutes to go from a pending state to being fully operational. You can view the current state of your cluster by entering `kubectl get all`, where your output looks similar to the following:

```
$ kubectl get all

NAME                                READY     STATUS    RESTARTS   AGE
po/my-nginx-431080787-0m4m8         1/1       Running   0          3m
po/my-nginx-431080787-hqqcr         1/1       Running   0          3m
po/my-nginx-431080787-n8125         1/1       Running   0          3m

NAME               CLUSTER-IP      EXTERNAL-IP      PORT(S)         AGE
svc/kubernetes     203.0.113.1     <NONE>           443/TCP         3d
svc/my-nginx-svc   203.0.113.7     192.0.2.22       80:30269/TCP    3m

NAME                       DESIRED   CURRENT   UP-TO-DATE   AVAILABLE   AGE
deploy/my-nginx            3         3         3            3           3m

NAME                              DESIRED   CURRENT   READY     AGE
rs/my-nginx-431080787             3         3         3         3m
```

The output shows that the `my-nginx` deployment is running on 3 pods (the po/my-nginx entries), that the load balancer is running (svc/my-nginx-svc) and has an external IP (192.0.2.22) that clients can use to connect to the app that's deployed on the pods.

Creating Load Balancers with SSL Support to Distribute HTTPS Traffic

You can create a load balancer with SSL termination, allowing https traffic to an app to be distributed among the nodes in a cluster. This example provides a walkthrough of the configuration and creation of a load balancer with SSL support.

Consider the following configuration file, `nginx-demo-svc-ssl.yaml`, which defines an Nginx deployment and exposes it via a load balancer that serves http on port 80, and https on port 443. This sample creates an Oracle Cloud Infrastructure load balancer, by defining a service with a type of LoadBalancer (`type: LoadBalancer`).

```
apiVersion: apps/v1beta1
kind: Deployment
metadata:
  name: nginx-deployment
spec:
  replicas: 2
  template:
    metadata:
      labels:
        app: nginx
    spec:
      containers:
      - name: nginx
        image: nginx
        ports:
        - containerPort: 80
---
kind: Service
apiVersion: v1
metadata:
  name: nginx-service
  annotations:
    service.beta.kubernetes.io/oci-load-balancer-ssl-ports: "443"
    service.beta.kubernetes.io/oci-load-balancer-tls-secret: ssl-certificate-secret
spec:
  selector:
    app: nginx
  type: LoadBalancer
  ports:
  - name: http
    port: 80
    targetPort: 80
  - name: https
    port: 443
    targetPort: 80
```

The Load Balancer's annotations are of particular importance. The ports on which to support https traffic are defined by the value of **oci-load-balancer-ssl-ports**. You can declare multiple SSL ports by using a comma-separated list for the annotation's value. For example, you could set the annotation's value to "443, 3000" to support SSL on ports 443 and 3000.

The required TLS secret, **ssl-certificate-secret**, needs to be created in Kubernetes. This example creates and uses a self-signed certificate. However, in a production environment, the most common scenario is to use a public certificate that's been signed by a certificate authority.

The following command creates a self-signed certificate, `tls.crt`, with its corresponding key, `tls.key`:

```
$ openssl req -x509 -nodes -days 365 -newkey rsa:2048 -keyout tls.key -out tls.crt -subj
"/CN=nginxsvc/O=nginxsvc"
```

Now that you created the certificate, you need to store both it and its key as a secret in Kubernetes. The name of the secret must match the name from the **oci-load-balancer-tls-secret** annotation of the load balancer's definition. Use the following command to create a TLS secret in Kubernetes, whose key and certificate values are set by `--key` and `--cert`, respectively.

```
$ kubectl create secret tls ssl-certificate-secret --key tls.key --cert tls.crt
```

You must create the Kubernetes secret before you can create the service, since the service references the secret in its definition. Create the service using the following command:

```
$ kubectl create -f manifests/demo/nginx-demo-svc-ssl.yaml
```

Watch the service and wait for a public IP address (EXTERNAL-IP) to be assigned to the Nginx service (nginx-service). This is the load balancer IP to use to connect to the service.

```
$ kubectl get svc --watch

NAME            CLUSTER-IP     EXTERNAL-IP      PORT(S)         AGE
nginx-service   192.0.2.1      198.51.100.1     80:30274/TCP    5m
```

The load balancer is now running, which means the service can now be accessed using either http or https, as demonstrated by the following commands:

```
$ curl http://198.51.100.1
```

```
$ curl --insecure https://198.51.100.1
```

The "`--insecure`" flag is used to access the service using https due to the use of self-signed certificates in this example. Do not use this flag in a production environment where the public certificate was signed by a certificate authority.

Note: When a cluster is deleted, a load balancer that's dynamically created when a service is created will not be removed. Before deleting a cluster, delete the service, which in turn will result in the cloud provider removing the load balancer. The syntax for this command is:

```
$ kubectl delete svc SERVICE_NAME
```

For example, to delete the service from the previous example, enter:

```
$ kubectl delete svc nginx-service
```

Creating Internal Load Balancers in Public and Private Subnets

You can create Oracle Cloud Infrastructure load balancers to control access to services running on a cluster:

- When you create a 'custom' cluster, you select an existing VCN that contains the network resources to be used by the new cluster. If you want to use load balancers to control traffic into the VCN, you select existing public or private subnets in that VCN to host the load balancers.
- When you create a 'quick cluster', the VCN that's automatically created contains a public regional subnet to host a load balancer. If you want to host load balancers in private subnets, you can add private subnets to the VCN later.

Alternatively, you can create an internal load balancer service in a cluster to enable other programs running in the same VCN as the cluster to access services in the cluster. You can host internal load balancers in public subnets and private subnets.

To create an internal load balancer hosted on a public subnet, add the following annotation in the metadata section of the manifest file:

```
service.beta.kubernetes.io/oci-load-balancer-internal: "true"
```

To create an internal load balancer hosted on a private subnet, add both following annotations in the metadata section of the manifest file:

```
service.beta.kubernetes.io/oci-load-balancer-internal: "true"

service.beta.kubernetes.io/oci-load-balancer-subnet1: "ocid1.subnet.oc1..aaaaaa....vdfw"
```

where `ocid1.subnet.oc1..aaaaaa....vdfw` is the OCID of the private subnet.

For example:

```
apiVersion: v1
kind: Service
metadata:
  name: my-nginx-svc
  labels:
    app: nginx
  annotations:
    service.beta.kubernetes.io/oci-load-balancer-internal: "true"
    service.beta.kubernetes.io/oci-load-balancer-subnet1: "ocid1.subnet.oc1..aaaaaa....vdfw"
spec:
  type: LoadBalancer
  ports:
  - port: 8100
  selector:
    app: nginx
```

Specifying Alternative Load Balancer Shapes

The shape of an Oracle Cloud Infrastructure load balancer specifies its maximum total bandwidth (that is, ingress plus egress). By default, load balancers are created with a shape of 100Mbps. Other shapes are available, including 400Mbps and 8000Mbps.

To specify an alternative shape for a load balancer, add the following annotation in the metadata section of the manifest file:

```
service.beta.kubernetes.io/oci-load-balancer-shape: <value>
```

where `value` is the bandwidth of the shape (for example, 100Mbps, 400Mbps, 8000Mbps).

For example:

```
apiVersion: v1
kind: Service
metadata:
  name: my-nginx-svc
  labels:
    app: nginx
  annotations:
    service.beta.kubernetes.io/oci-load-balancer-shape: 400Mbps
spec:
  type: LoadBalancer
  ports:
  - port: 80
  selector:
    app: nginx
```

Note: Sufficient load balancer quota must be available in the region for the shape you specify. Enter the following kubectl command to confirm that load balancer creation did not fail due to lack of quota:

```
$ kubectl describe service <service-name>
```

Specifying Load Balancer Connection Timeout

You can specify the maximum idle time (in seconds) allowed between two successive receive or two successive send operations between the client and backend servers.

To explicitly specify a maximum idle time, add the following annotation in the metadata section of the manifest file:

```
oci-load-balancer-connection-idle-timeout: <value>
```

where `value` is the number of seconds.

For example:

```
apiVersion: v1
kind: Service
metadata:
  name: my-nginx-svc
  labels:
    app: nginx
  annotations:
```

```
    oci-load-balancer-connection-idle-timeout: 100
spec:
  type: LoadBalancer
  ports:
  - port: 80
  selector:
    app: nginx
```

Note that if you don't explicitly specify a maximum idle time, a default value is used. The default value depends on the type of listener:

- for TCP listeners, the default maximum idle time is 300 seconds
- for HTTP listeners, the default maximum idle time is 60 seconds

Specifying Load Balancer Security List Management Options

You can specify how security lists are managed.

To explicitly specify a security list management mode, add the following annotation in the metadata section of the manifest file:

```
oci-load-balancer-security-list-management-mode: <value>
```

where `<value>` is one of:

- `"All"`: All required security list rules for load balancer services are managed.
- `"Frontend"`: Only security list rules for ingress to load balancer services are managed. You have to set up a rule that allows inbound traffic to the appropriate ports for node port ranges, the kube-proxy health port, and the health check port ranges.
- `"None"`: No security list management is enabled. You have to set up a rule that allows inbound traffic to the appropriate ports for node port ranges, the kube-proxy health port, and the health check port ranges. Additionally, you have to set up rules to allow inbound traffic to load balancers.

For example:

```
apiVersion: v1
kind: Service
metadata:
```

```
  name: my-nginx-svc
  labels:
    app: nginx
  annotations:
    oci-load-balancer-security-list-management-mode: "Frontend"
spec:
  type: LoadBalancer
  ports:
  - port: 80
  selector:
    app: nginx
```

Note that if you specify an invalid value for `oci-load-balancer-security-list-management-mode`, the value `"All"` is used instead.

Specifying Load Balancer Listener Protocol

You can define the type of traffic accepted by the load balancer listener by specifying the protocol on which the listener accepts connection requests.

To explicitly specify the load balancer listener protocol, add the following annotation in the metadata section of the manifest file:

```
oci-load-balancer-backend-protocol: <value>
```

where `<value>` is the protocol that defines the type of traffic accepted by the listener. For example, "HTTP". To get a list of valid protocols, use the ListProtocols operation.

For example:

```
apiVersion: v1
kind: Service
metadata:
  name: my-nginx-svc
  labels:
    app: nginx
  annotations:
    oci-load-balancer-backend-protocol: "HTTP"
spec:
  type: LoadBalancer
  ports:
  - port: 80
```

```
  selector:
    app: nginx
```

Note that if you don't explicitly specify a protocol, "TCP" is used as the default value.

Creating a Persistent Volume Claim

Container storage via a container's root file system is ephemeral, and can disappear upon container deletion and creation. To provide a durable location to store data and prevent it from being lost, you can create and use persistent volumes to store data outside of containers.

You can define and apply a persistent volume claim to your cluster, which in turn creates a persistent volume that's bound to the claim. A claim is a block storage volume in the underlying IaaS provider that's durable and offers persistent storage, enabling your data to remain intact, regardless of whether the containers that the storage is connected to are terminated.

With Oracle Cloud Infrastructure as the underlying IaaS provider, you can provision persistent volume claims by attaching volumes from the Block Storage service.

A persistent volume claim (PVC) is a request for storage, similar to how a pod requests compute resources. A PVC provides an abstraction layer to underlying storage. For example, an administrator could create a number of static persistent volumes (PVs) that can later be bound to one or more persistent volume claims. This is analogous to an administrator creating cluster nodes to which pods are later assigned. If none of the static persistent volumes match the user's PVC request, the cluster may attempt to dynamically create a PV that matches the PVC request. This example uses the latter approach, and it assumes that the cluster administrator has not created any suitable PVs that match the PVC request—meaning that the PVCs will dynamically create the PVs for this example.

The minimum amount of persistent storage that a PVC can request is 50 gigabytes. If the request is for less than 50 gigabytes, the request is rounded up to 50 gigabytes.

The following YAML defines two PVCs that each request 50 gigabytes of persistent storage (`storage: 50Gi`). You use names of the PVCs (for example, mysqlclaim) when defining which claims to use as the volumes of a deployment.

```
apiVersion: v1
kind: PersistentVolumeClaim
metadata:
  name: mysqlclaim
spec:
  storageClassName: "oci"
  selector:
    matchLabels:
      failure-domain.beta.kubernetes.io/zone: "US-ASHBURN-AD-1"
  accessModes:
    - ReadWriteOnce
  resources:
    requests:
      storage: 50Gi
---
apiVersion: v1
kind: PersistentVolumeClaim
metadata:
  name: wordpressclaim
spec:
  storageClassName: "oci"
  selector:
    matchLabels:
      failure-domain.beta.kubernetes.io/zone: "US-ASHBURN-AD-2"
  accessModes:
    - ReadWriteOnce
  resources:
    requests:
      storage: 50Gi
```

Note

In the previous example, the PVCs request storage in availability domains in the Ashburn region using `matchLabels:failure-domain.beta.kubernetes.io/zone`. Note that when you specify values for `matchLabels:failure-domain.beta.kubernetes.io/zone`, you must use the shortened versions of availability domain names. For example `US-ASHBURN-AD-1`, `US-ASHBURN-AD-2`. See Availability by Region Name and Region Code for a list of shortened versions of availability domain names.

Enter the following command to create the PVC from the YAML file:

```
$ kubectl create -f https://raw.githubusercontent.com/wercker/oke_examples/master/kubernetes_
examples/persistent_volume_claims.yaml

persistentvolumeclaim "mysqlclaim" created
persistentvolumeclaim "wordpressclaim" created
```

You can verify that the PVCs have been created and bound to persistent volumes by calling `kubectl get pvc`:

```
$ kubectl get pvc

NAME             STATUS    VOLUME                                                    CAPACITY
ACCESSMODES   STORAGECLASS   AGE
mysqlclaim       Bound     abyhqljrerxpanjto7b5zlxjesy4aedghc5c52f5v43xcrymo77ktdl6ibjq   50Gi       RWO
          oci            4m
wordpressclaim   Bound     abyhqljt3rzldcclootxn7yrfgv36s7rnggcobennjohevykqpitzkinspka   50Gi       RWO
          oci            4m
```

You can use these persistent volumes when creating other objects, such as deployments. For example, the following deployment definition instructs the system to use the mysqlclaim PVC as the mysql-persistent-storage volume, which is mounted by pods hosting the deployment as /var/lib/mysql.

```
#MySQL Deployment
apiVersion: extensions/v1beta1
kind: Deployment
metadata:
  name: mysql
  labels:
    app: mysql
spec:
  replicas: 1
  selector:
    matchLabels:
      app: mysql
  template:
    metadata:
      labels:
        app: mysql
    spec:
      containers:
        - image: mysql:5.6
          name: mysql
          env:
            - name: MYSQL_ROOT_PASSWORD
              valueFrom:
                secretKeyRef:
                  name: mysql
                  key: password
          ports:
            - containerPort: 3306
              name: mysql
          volumeMounts:
            - name: mysql-persistent-storage
              mountPath: /var/lib/mysql
      volumes:
        - name: mysql-persistent-storage
          persistentVolumeClaim:
            claimName: mysqlclaim
```

Adding OCI Service Broker for Kubernetes to Clusters

Service brokers offer a catalog of backing services to workloads running on cloud native platforms. The Open Service Broker API is a commonly-used standard for interactions between service brokers and platforms. The Open Service Broker API specification describes a simple set of API endpoints that platforms use to provision, gain access to, and manage service offerings. For more information about the Open Service Broker API, see resources available online including those at openservicebrokerapi.org.

OCI Service Broker for Kubernetes is an implementation of the Open Service Broker API. OCI Service Broker for Kubernetes is specifically for interacting with Oracle Cloud Infrastructure services from Kubernetes clusters. It includes three service broker adapters to bind to the following Oracle Cloud Infrastructure services:

- Object Storage
- Autonomous Transaction Processing
- Autonomous Data Warehouse

You can add OCI Service Broker for Kubernetes to clusters you've created with Oracle Cloud Infrastructure Container Engine for Kubernetes to interact with the Oracle Cloud Infrastructure services listed above. Having added OCI Service Broker for Kubernetes to a cluster, you don't have to manually provision and de-provision the Oracle Cloud Infrastructure services each time you deploy or un-deploy an application on the cluster. Instead, you interact with the Oracle Cloud Infrastructure services by using kubectl to call the Open Service Broker APIs implemented by OCI Service Broker for Kubernetes .

OCI Service Broker for Kubernetes is available as a Helm chart, a Docker container, and as source code from Github.

For more information about OCI Service Broker for Kubernetes, see the OCI Service Broker for Kubernetes documentation in the Github repository.

Adding OCI Service Broker for Kubernetes to a Cluster

To add OCI Service Broker for Kubernetes to a cluster, follow the detailed instructions in the Github repository.

For convenience, here's a high-level summary of the steps involved:

1. Install OCI Service Broker for Kubernetes. During this step, you will typically:
    - Install the Service Catalog.
    - Install the svcat tool.
    - Deploy OCI Service Broker for Kubernetes.
    - Grant RBAC permissions and roles.
    - Register OCI Service Broker for Kubernetes.

    For more information about installation, see the OCI Service Broker for Kubernetes documentation in the Github repository.
2. Secure OCI Service Broker for Kubernetes. During this step, you will typically:
    - Restrict access to Service Catalog resources using RBAC permissions and roles.
    - Configure TLS for OCI Service Broker for Kubernetes.
    - Set up an Oracle Cloud Infrastructure user for use by OCI Service Broker for Kubernetes.
    - Set up appropriate policies to control access to resources (according to the Oracle Cloud Infrastructure services to be used).
    - Limit access to the OCI Service Broker for Kubernetes endpoint using NetworkPolicy.
    - Stand up an etcd cluster for Service Catalog and OCI Service Broker for Kubernetes.
    - Protect sensitive values by creating secrets.

    The security configuration to choose will depend on your particular requirements. For more information, see the OCI Service Broker for Kubernetes documentation in the Github repository.
3. Provision and bind to the required Oracle Cloud Infrastructure services. During this step, you will typically:
    - Provide service provision request parameters.
    - Provide service binding request parameters.

- Provide service binding response credentials.

The details to provide will depend on the Oracle Cloud Infrastructure service to bind to. For more information, see the OCI Service Broker for Kubernetes documentation in the Github repository.

Example: Setting Up an Ingress Controller on a Cluster

You can set up different open source ingress controllers on clusters you have created with Container Engine for Kubernetes.

This topic explains how to set up an example ingress controller along with corresponding access control on an existing cluster. Having set up the ingress controller, this topic describes how to use the ingress controller with an example hello-world backend, and how to verify the ingress controller is working as expected.

Example Components

The example includes an ingress controller and a hello-world backend.

Ingress Controller Components

The ingress controller comprises:

- An ingress controller deployment called `nginx-ingress-controller`. The deployment deploys an image that contains the binary for the ingress controller and Nginx. The binary manipulates and reloads the `/etc/nginx/nginx.conf` configuration file when an ingress is created in Kubernetes. Nginx upstreams point to services that match specified selectors.
- An ingress controller service called `ingress-nginx`. The service exposes the ingress controller deployment as a LoadBalancer type service. Because Container Engine for Kubernetes uses an Oracle Cloud Infrastructure integration/cloud-provider, a load

balancer will be dynamically created with the correct nodes configured as a backend set.

Backend Components

The hello-world backend comprises:

- A backend deployment called `docker-hello-world`. The deployment handles default routes for health checks and 404 responses. This is done by using a stock hello-world image that serves the minimum required routes for a default backend.
- A backend service called `docker-hello-world-svc`.The service exposes the backend deployment for consumption by the ingress controller deployment.

Setting Up the Example Ingress Controller

In this section, you create the access rules for ingress. You then create the example ingress controller components, and confirm they are running.

Creating the Access Rules for the Ingress Controller

1. If you haven't already done so, follow the steps to download the cluster's kubeconfig configuration file and set the KUBECONFIG environment variable to point to the file. Note that you must download your own kubeconfig file. You cannot access a cluster using a kubeconfig file that a different user downloaded. See Downloading a kubeconfig File to Enable Cluster Access.
2. If your Oracle Cloud Infrastructure user is a tenancy administrator, skip the next step and go straight to Creating the Service Account, and the Ingress Controller.
3. If your Oracle Cloud Infrastructure user is not a tenancy administrator, in a terminal window, grant the user the Kubernetes RBAC cluster-admin clusterrole on the cluster by entering:

   ```
   $ kubectl create clusterrolebinding <my-cluster-admin-binding> --clusterrole=cluster-admin --
   user=<user-OCID>
   ```

   where:

- `<my-cluster-admin-binding>` is a string of your choice to be used as the name for the binding between the user and the Kubernetes RBAC cluster-admin clusterrole. For example, `jdoe_clst_adm`
- `<user-OCID>` is the user's OCID (obtained from the Console). For example, `ocid1.user.oc1..aaaaa...zutq` (abbreviated for readability).

For example:

```
$ kubectl create clusterrolebinding jdoe_clst_adm --clusterrole=cluster-admin --
user=ocid1.user.oc1..aaaaa...zutq
```

Creating the Service Account, and the Ingress Controller

1. Run the following command to create the `nginx-ingress-controller` ingress controller deployment, along with the Kubernetes RBAC roles and bindings:

```
$ kubectl apply -f https://raw.githubusercontent.com/kubernetes/ingress-
nginx/master/deploy/static/mandatory.yaml
```

2. Create and save the file `cloud-generic.yaml` containing the following code to define the `ingress-nginx` ingress controller service as a load balancer service:

```
kind: Service
apiVersion: v1
metadata:
  name: ingress-nginx
  namespace: ingress-nginx
  labels:
    app.kubernetes.io/name: ingress-nginx
    app.kubernetes.io/part-of: ingress-nginx
spec:
  type: LoadBalancer
  selector:
    app.kubernetes.io/name: ingress-nginx
    app.kubernetes.io/part-of: ingress-nginx
  ports:
    - name: http
      port: 80
      targetPort: http
    - name: https
```

```
    port: 443
    targetPort: https
```

3. Using the file you just saved, create the `ingress-nginx` ingress controller service by running the following command:

```
$ kubectl apply -f cloud-generic.yaml
```

Verifying the `ingress-nginx` Ingress Controller Service is Running as a Load Balancer Service

1. View the list of running services:

```
$ kubectl get svc -n ingress-nginx

NAME            TYPE           CLUSTER-IP     EXTERNAL-IP     PORT(S)                      AGE
ingress-nginx   LoadBalancer   10.96.229.38   <pending>       80:30756/TCP,443:30118/TCP   1h
```

   The EXTERNAL-IP for the `ingress-nginx` ingress controller service is shown as `<pending>` until the load balancer has been fully created in Oracle Cloud Infrastructure.

2. Repeat the `kubectl get svc` command until an EXTERNAL-IP is shown for the `ingress-nginx` ingress controller service:

```
$ kubectl get svc -n ingress-nginx

NAME            TYPE           CLUSTER-IP     EXTERNAL-IP       PORT(S)                      AGE
ingress-nginx   LoadBalancer   10.96.229.38   129.146.214.219   80:30756/TCP,443:30118/TCP   1h
```

Creating the TLS Secret

A TLS secret is used for SSL termination on the ingress controller. To generate the secret for this example, a self-signed certificate is used. While this is okay for testing, for production, use a certificate signed by a Certificate Authority.

```
$ openssl req -x509 -nodes -days 365 -newkey rsa:2048 -keyout tls.key -out tls.crt -subj
"/CN=nginxsvc/O=nginxsvc"

$ kubectl create secret tls tls-secret --key tls.key --cert tls.crt
```

Note

Under Windows, you may need to replace `"/CN=nginxsvc/O=nginxsvc"` with `"//CN=nginxsvc\O=nginxsvc"` . For example, this is necessary if you run the `openssl` command from a Git Bash shell.

Setting Up the Example Backend

In this section, you define a hello-world backend service and deployment.

Creating the docker-hello-world Service Definition

1. Create the file `hello-world-ingress.yaml` containing the following code. This code uses a publicly available hello-world image from Docker Hub. You can substitute another image of your choice that can be run in a similar manner.

```
apiVersion: apps/v1beta1
kind: Deployment
metadata:
  name: docker-hello-world
  labels:
    app: docker-hello-world
spec:
  replicas: 3
  template:
    metadata:
      labels:
        app: docker-hello-world
    spec:
      containers:
      - name: docker-hello-world
        image: scottsbaldwin/docker-hello-world:latest
        ports:
```

```
        - containerPort: 80
---
apiVersion: v1
kind: Service
metadata:
  name: docker-hello-world-svc
spec:
  selector:
    app: docker-hello-world
  ports:
    - port: 8088
      targetPort: 80
  type: ClusterIP
```

Note the docker-hello-world service's type is ClusterIP, rather than LoadBalancer, because this service will be proxied by the `ingress-nginx` ingress controller service. The docker-hello-world service does not need public access directly to it. Instead, the public access will be routed from the load balancer to the ingress controller, and from the ingress controller to the upstream service.

2. Create the new hello-world deployment and service on nodes in the cluster by running the following command:

```
$ kubectl create -f hello-world-ingress.yaml
```

Using the Example Ingress Controller to Access the Example Backend

In this section you create an ingress to access the backend using the ingress controller.

Creating the Ingress Resource

1. Create the file `ingress.yaml` and populate it with this code:

```
apiVersion: extensions/v1beta1
kind: Ingress
metadata:
  name: hello-world-ing
  annotations:
    kubernetes.io/ingress.class: "nginx"
```

```
spec:
  tls:
  - secretName: tls-secret
  rules:
  - http:
      paths:
      - backend:
          serviceName: docker-hello-world-svc
          servicePort: 8088
```

2. Create the resource:

```
$ kubectl create -f ingress.yaml
```

Verifying that the Example Components are Working as Expected

In this section, you confirm that all of the example components have been successfully created and are operating as expected. The `docker-hello-world-svc` service should be running as a ClusterIP service, and the `ingress-nginx` service should be running as a LoadBalancer service. Requests sent to the ingress controller should be routed to nodes in the cluster.

Obtaining the External IP Address of the Load Balancer

To confirm the `ingress-nginx` service is running as a LoadBalancer service, obtain its external IP address:

```
$ kubectl get svc --all-namespaces

NAMESPACE       NAME                    TYPE           CLUSTER-IP      EXTERNAL-IP      PORT(S)
             AGE
default         docker-hello-world-svc  ClusterIP      10.96.83.247    <none>           8088/TCP
             16s
default         kubernetes              ClusterIP      10.96.0.1       <none>           443/TCP
             1h
ingress-nginx   ingress-nginx           LoadBalancer   10.96.229.38    129.146.214.219
80:30756/TCP,443:30118/TCP   5m
kube-system     kube-dns                ClusterIP      10.96.5.5       <none>           53/UDP,53/TCP
             1h
kube-system     kubernetes-dashboard    ClusterIP      10.96.208.64    <none>           443/TCP
```

```
             1h
kube-system     tiller-deploy            ClusterIP      10.96.28.102    <none>           44134/TCP
             1h
```

Sending cURL Requests to the Load Balancer

1. Use the external IP address of the `ingress-nginx` service (for example, 129.146.214.219) to curl an http request:

   ```
   $ curl -I http://129.146.214.219

   HTTP/1.1 301 Moved Permanently
   Via: 1.1 10.68.69.10 (McAfee Web Gateway 7.6.2.10.0.23236)
   Date: Thu, 07 Sep 2017 15:20:16 GMT
   Server: nginx/1.13.2
   Location: https://129.146.214.219/
   Content-Type: text/html
   Content-Length: 185
   Proxy-Connection: Keep-Alive
   Strict-Transport-Security: max-age=15724800; includeSubDomains;
   ```

   The output shows a 301 redirect and a Location header that suggest that http traffic is being redirected to https.

2. Either cURL against the https url or add the `-L` option to automatically follow the location header. The `-k` option instructs cURL to not verify the SSL certificates.

   ```
   $ curl -ikL http://129.146.214.219

   HTTP/1.1 301 Moved Permanently
   Via: 1.1 10.68.69.10 (McAfee Web Gateway 7.6.2.10.0.23236)
   Date: Thu, 07 Sep 2017 15:22:29 GMT
   Server: nginx/1.13.2
   Location: https://129.146.214.219/
   Content-Type: text/html
   Content-Length: 185
   Proxy-Connection: Keep-Alive
   Strict-Transport-Security: max-age=15724800; includeSubDomains;

   HTTP/1.0 200 Connection established
   ```

```
HTTP/1.1 200 OK
Server: nginx/1.13.2
Date: Thu, 07 Sep 2017 15:22:30 GMT
Content-Type: text/html
Content-Length: 71
Connection: keep-alive
Last-Modified: Thu, 07 Sep 2017 15:17:24 GMT
ETag: "59b16304-47"
Accept-Ranges: bytes
Strict-Transport-Security: max-age=15724800; includeSubDomains;

<h1>Hello webhook world from: docker-hello-world-1732906117-0ztkm</h1>
```

The last line of the output shows the HTML that is returned from the pod whose hostname is `docker-hello-world-1732906117-0ztkm`.

3. Issue the cURL request several times to see the hostname in the HTML output change, demonstrating that load balancing is occurring:

```
$ curl -k https://129.146.214.219

<h1>Hello webhook world from: docker-hello-world-1732906117-6115l</h1>

$ curl -k https://129.146.214.219

<h1>Hello webhook world from: docker-hello-world-1732906117-7r89v</h1>

$ curl -k https://129.146.214.219

<h1>Hello webhook world from: docker-hello-world-1732906117-0ztkm</h1>
```

Inspecting nginx.conf

The `nginx-ingress-controller` ingress controller deployment manipulates the `nginx.conf` file in the pod within which it is running.

1. Find the name of the pod running the `nginx-ingress-controller` ingress controller deployment and use it with a `kubectl exec` command to show the contents of `nginx.conf`.

```
$ kubectl get po -n ingress-nginx

NAME                                        READY     STATUS    RESTARTS   AGE
nginx-ingress-controller-110676328-h86xg   1/1       Running   0          1h

$ kubectl exec -n ingress-nginx -it nginx-ingress-controller-110676328-h86xg -- cat
/etc/nginx/nginx.conf
```

2. Look for `proxy_pass` in the output. There will be one for the default backend and another that looks similar to:

```
proxy_pass http://upstream_balancer;
```

   This shows that Nginx is proxying requests to an upstream called `upstream_balancer`.

3. Locate the upstream definition in the output. It will look similar to:

```
upstream upstream_balancer {
                server 0.0.0.1:1234; # placeholder

                balancer_by_lua_block {
                        tcp_udp_balancer.balance()
                }
        }
```

   The upstream is proxying via Lua.

CHAPTER 10 Data Transfer

This chapter explains how to migrate data to Oracle Cloud Infrastructure using Disk-Based Data Transfer and Data Transfer Appliance.

Overview of Data Transfer Service

Oracle offers offline data transfer solutions that let you migrate data to Oracle Cloud Infrastructure. Moving data over the public internet is not always feasible because of high network costs, unreliable network connectivity, long transfer times, and security concerns. Our transfer solutions address these pain points, are easy to use, and provide faster data upload compared to over-the-wire data transfer.

Note

Data Transfer is not available in Oracle Cloud Infrastructure Government Cloudrealms.

Data transfer is supported in US East (Ashburn), US West (Phoenix), Germany Central (Frankfurt), and UK South (London) regions.

Note

To simplify this Data Transfer documentation, we generically refer to Object Storage to mean that you can transfer data into a bucket in either the Object Storage tier or Archive Storage tier.

DISK-BASED DATA TRANSFER

You send your data as files on encrypted commodity disk to an Oracle transfer site. Operators at the Oracle transfer site upload the files into your designated Object Storage bucket in your tenancy.

This transfer solution requires you to source and purchase the disks used to transfer data to Oracle Cloud Infrastructure. The disks are shipped back to you after the data is successfully uploaded.

See Disk Data Transfer for details.

APPLIANCE-BASED DATA TRANSFER

You send your data as files on secure, high-capacity, Oracle-supplied storage appliances to an Oracle transfer site. Operators at the Oracle transfer site upload the data into your designated Object Storage bucket in your tenancy.

This solution supports data transfer when you are migrating a large volume of data and when using disks is not a practical alternative. You do not need to write any code or purchase any hardware—Oracle supplies the transfer appliance and software required to manage the transfer.

See Appliance Data Transfer for details.

Limits on Data Transfer Service Resources

When you sign up for Oracle Cloud Infrastructure, a set of service limits is configured for your tenancy. The service limit is the quota or allowance set on a resource. Verify that your service limits are set appropriately before you begin the data transfer process.

See Service Limits for a list of applicable limits and instructions for requesting a limit increase. To set compartment-specific limits on a resource or resource family, administrators can use compartment quotas.

Tagging Resources

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the wanted tags. For general information about applying tags, see Resource Tags.

Data Transfer currently supports applying tags to transfer jobs from the command line (Data Transfer Utility or CLSs). Tagging is not supported using the Console.

What's Next

Now you are ready to prepare for your data transfer. See the following pages for more information on each of the data transfer methods:

- Disk Data Transfer
- Appliance Data Transfer

Disk Data Transfer

Disk-Based Data Transfer is one of Oracle's offline data transfer solutions that lets you migrate data to Oracle Cloud Infrastructure. You send your data as files on encrypted disks to an Oracle transfer site. Operators at the Oracle transfer site upload the files into the designated Object Storage bucket in your tenancy. You are then free to move the uploaded data to other Oracle Cloud Infrastructure services as needed.

Disk-Based Data Transfer Concepts

The following concepts are essential to understanding Disk-Based Data Transfer.

DISK

A disk is a user-supplied storage device that is specially prepared to copy and upload data to Oracle Cloud Infrastructure. You copy your data to one or more of these disks and ship

the disks in a parcel to Oracle to upload your data.

The following transfer disks are supported:

- SATA II/III 2.5" or 3.5" hard disk drives
- External USB 2.0/3.0 hard disk drives

Note

Pin-code protected devices and physical-key protected devices are currently not supported.

TRANSFER DISK

A transfer disk is the logical representation of a disk that has been prepared to copy and upload data to Oracle Cloud Infrastructure.

TRANSFER JOB

A transfer job is the logical representation of a data migration to Oracle Cloud Infrastructure. A transfer job consists of one or more transfer packages that each contain one or more transfer disks.

DATA TRANSFER UTILITY

The Data Transfer Utility is the command line software that Oracle provides for you to prepare transfer disks for your data and for shipment to Oracle. In addition, you can use this software to manage transfer jobs and packages.

DATA HOST

The host computer on your site that stores the data you intend to copy to the disk for migration to Oracle Cloud Infrastructure.

TRANSFER PACKAGE

A transfer package is the logical representation of the parcel containing the transfer disks that you ship to Oracle to upload to Oracle Cloud Infrastructure.

BUCKET

The logical container in Oracle Cloud Infrastructure Object Storage where Oracle operators upload your data. A bucket is associated with a single compartment in your tenancy that has policies that determine what actions a user can perform on a bucket and on all the objects in the bucket.

DATA TRANSFER ADMINISTRATOR

A new or existing IAM user that has the authorization and permissions to create and manage transfer jobs. See .

DATA TRANSFER UPLOAD USER

A temporary IAM user that grants Oracle personnel the authorization and permissions to upload the data from your transfer disks to your designated Oracle Cloud Infrastructure Object Storage bucket. Delete this temporary user after your data is uploaded to Oracle Cloud Infrastructure. See .

Roles and Responsibilities

Depending on your organization, the responsibilities of using and managing the data transfer may span multiple roles. Use the following set of roles as a guideline for how you can assign the various tasks associated with the data transfer.

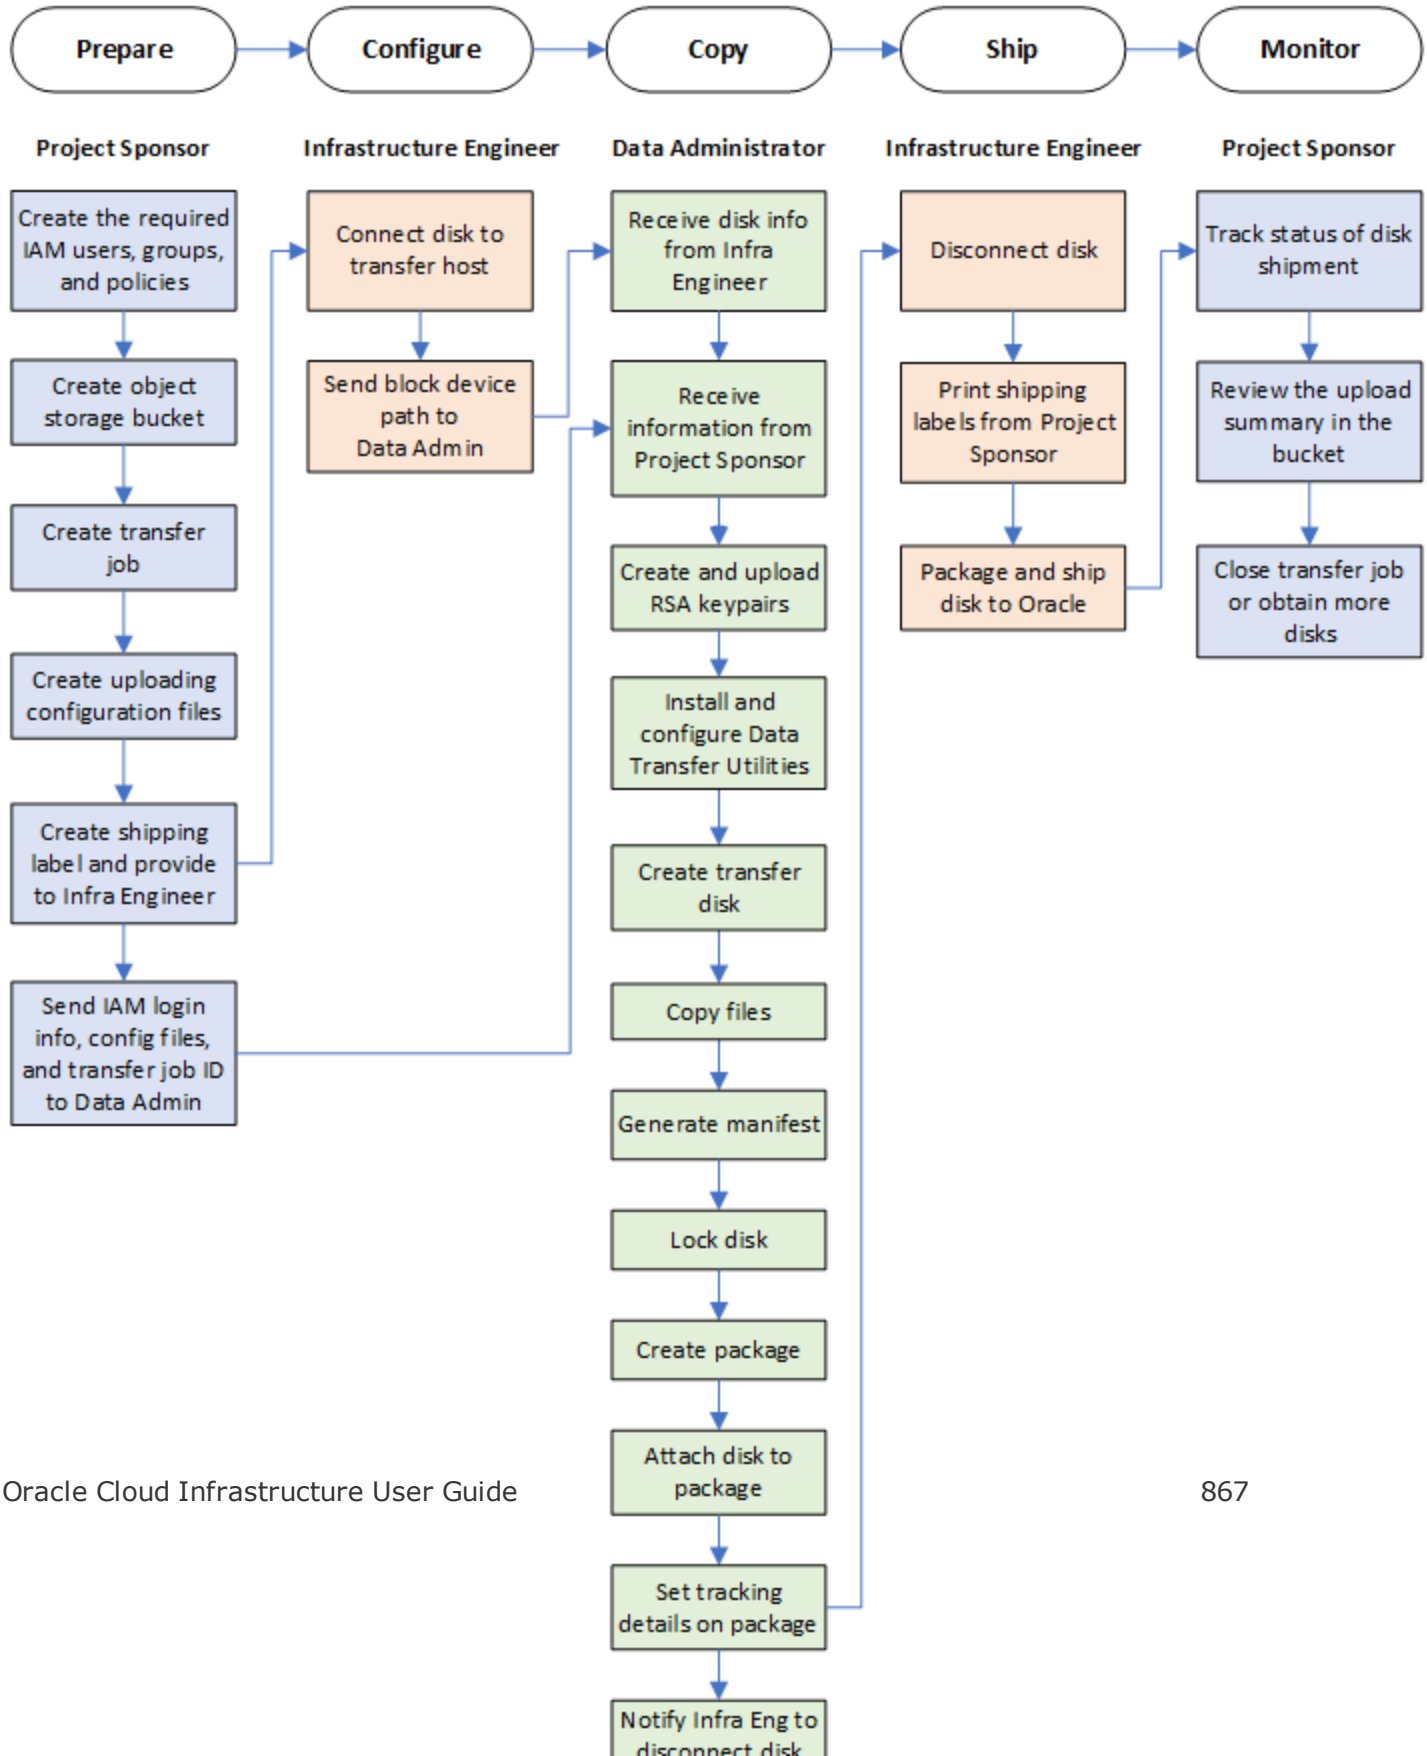
- **Project Sponsor:** Responsible for the overall success of the data transfer. Project Sponsors usually have complete access to their organization's Oracle Cloud Infrastructure tenancy. They coordinate with the other roles in the organization to complete the implementation of data transfer project.
- **Infrastructure Engineer:** Responsible for integrating the transfer appliance into the organization's IT infrastructure from where the data is being transferred. Tasks associated with this role include connecting the transfer appliance to power, placing it within the network, and setting the IP address through a serial console menu using the provided USB-to-Serial adapter.
- **Data Administrator:** Responsible for identifying and preparing the data to be

transferred to Oracle Cloud Infrastructure. This person usually has access to, and expertise with, the data being migrated.

These roles correspond to the various phases of the data transfer described in the following section. A specific role can be responsible for one or more phases.

Task Flow for Disk-Based Data Transfer

Here is a high-level overview of the tasks involved in transferring data to Oracle Cloud Infrastructure using Data Transfer Disk organized by phase. Complete one phase before proceeding to the next one. You can click some of the boxes to get details on how to perform the associated task. Use the roles previously described to distribute the tasks across individuals or groups within your organization.



Prepare
Configure
Copy
Ship
Monitor
Project Sponsor
Infrastructure Engineer
Data Administrator
Infrastructure Engineer
Project Sponsor
Create the required IAM users, groups, and policies
Create object storage bucket
Create transfer job
Create uploading configuration files
Create shipping label and provide to Infra Engineer
Send IAM login info, config files, and transfer job ID to Data Admin
Connect disk to transfer host
Send block device path to Data Admin
Receive disk info from Infra Engineer
Receive information from Project Sponsor
Create and upload RSA keypairs
Install and configure Data Transfer Utilities
Create transfer disk
Copy files
Generate manifest
Lock disk
Create package
Attach disk to package
Set tracking details on package
Notify Infra Eng to disconnect disk
Disconnect disk
Print shipping labels from Project Sponsor
Package and ship disk to Oracle
Track status of disk shipment
Review the upload summary in the bucket
Close transfer job or obtain more disks

Secure Disk Data Transfer to Oracle Cloud Infrastructure

This section highlights the security details of the Data Transfer Service process.

- The Data Transfer Utility uses the standard Linux dm-crypt and LUKS utilities to encrypt block devices.
- The dm-crypt software generates a master AES-256 bit encryption key that is used for all data written to or read from the disk. That key is protected by an encryption passphrase that the user must know to access the encrypted data.
- When the data transfer administrator uses the Data Transfer Utility to create disks, Oracle Cloud Infrastructure creates a strong encryption passphrase that is displayed to the user and passed to dm-crypt. The passphrase is displayed to standard output only once and cannot be retrieved again. Copy this passphrase to a durable, secure location for future reference.
- For extra security, you can also encrypt your own data with your own encryption keys. Before copying your data to the transfer disk, you can encrypt your data with a tool and encryption key of your choosing. After the data has been uploaded, you would need to use the same tool and encryption key to access the data.
- All network communication between the Data Transfer Utility and Oracle Cloud Infrastructure is encrypted in-transit using Transport Layer Security (TLS).
- After copying your data to a transfer disk, generate a manifest file using the Data Transfer Utility. The manifest contains an index of all of the copied files and generated data integrity hashes. The Data Transfer Utility copies the `config_upload_user` configuration file and referenced IAM credentials to the encrypted transfer disk. This configuration file describes the temporary IAM data transfer upload user. Oracle uses the credentials and entries defined in the `config_upload_user` file when processing the transfer disk and uploading files to Oracle Cloud Infrastructure Object Storage.

Note

Data Transfer Service Does Not Support Passphrases on Private Keys

While we recommend encrypting a private key with a passphrase when generating API signing keys, Data Transfer does not support passphrases on the key file required for the `config_upload_user`. If you use a passphrase, Oracle personnel cannot upload your data.

Oracle cannot upload data from a transfer disk without the correct credentials defined in this configuration file. See Data Transfer Utility for more information about the required configuration files.

- When you disconnect or lock a transfer disk using the Data Transfer Utility, the original encryption passphrase is required to once again access the disk. If the encryption passphrase is not known or lost, you cannot access the data on the transfer disk. To reuse a transfer disk, you must reformat the disk. Reformatting a disk removes all the data.
- Oracle retrieves the encryption passphrase for a transfer disk from Oracle Cloud Infrastructure. Oracle uses the passphrase to decrypt, mount the transfer disk, and upload the data to the designated bucket in the tenancy.
- After processing a transfer package, Oracle returns all transfer disks attached to the transfer package using the return shipping label you provide.
- To protect your data, we make the data on the disk unrecoverable before shipping the transfer disks back to you. To comply with customs regulations, we wipe the disks completely before shipping the transfer disks back to international shipping addresses.

Ways to Manage Disk Data Transfers

We provide two ways to manage disk-based data transfers:

- The Data Transfer Utility is a full-featured command line tool for disk-based data transfers only (appliance-based data transfers use a different command line tool). For more information and installation instructions, see Data Transfer Utility.
- The Console is an easy-to-use, partial-featured browser-based interface. For more information, see Signing In to the Console.

> **Note**
>
> You can perform many data transfer tasks using either the Console or the Data Transfer Utility. However, there are some tasks you can **only** perform using the Data Transfer Utility (for example, creating and locking transfer disks). describes the management tasks in detail and guides you to the appropriate management interface to use for each task.

Preparing for Disk Data Transfers

This topic describes the tasks associated with preparing for the Disk-Based Data Transfer. The Project Sponsor role typically performs these tasks. See Roles and Responsibilities.

Creating the Required IAM Users, Groups, and Policies

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization.

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

Access to resources is provided to groups using policies and then inherited by the users that are assigned to those groups. Data transfer requires the creation of two distinct groups:

- Data transfer *administrators* who can create and manage transfer jobs.
- Data transfer *upload users* who can upload data to Object Storage. For your data security, the permissions for upload users allow Oracle personnel to upload standard and multi-part objects on your behalf and inspect bucket and object metadata. The permissions do not allow Oracle personnel to inspect the actual data.

The Data Administrator is responsible for generating the required RSA keys needed for the temporary upload users. These keys should never be shared between users.

For details on creating groups, see Managing Groups.

An administrator creates these groups with the following policies:

- The data transfer administrator group requires an authorization policy that includes the following:

  ```
  Allow group <group_name> to manage data-transfer-jobs in compartment <compartment_name>
  ```

  ```
  Allow group <group_name> to manage buckets in compartment <compartment_name>
  ```

  ```
  Allow group <group_name> to manage objects in compartment <compartment_name>
  ```

  Alternatively, you can consolidate the `manage buckets` and `manage objects` policies into the following:

  ```
  Allow group <group_name> to manage object-family in compartment <compartment_name>
  ```

- The data transfer upload user group requires an authorization policy that includes the following:

```
Allow group <group_name> to manage buckets in compartment <compartment_name> where all {
request.permission='BUCKET_READ' }
```

```
Allow group <group_name> to manage objects in compartment <compartment_name> where any {
request.permission='OBJECT_CREATE' , request.permission='OBJECT_OVERWRITE' ,
request.permission='OBJECT_INSPECT' }
```

Important

For security reasons, we recommend that you create a unique IAM data transfer upload user for each transfer job and then delete that user once your data is uploaded to Oracle Cloud Infrastructure.

The Oracle Cloud Infrastructure administrator then adds a user to each of the data transfer groups created. For details on creating users, see Managing Users.

Creating Object Storage Buckets

The Object Storage service is used to upload your data to Oracle Cloud Infrastructure. Object Storage stores objects in a container called a bucket within a compartment in your tenancy. For details on creating the bucket to store uploaded data, see Managing Buckets.

Creating Transfer Jobs

This section describes how to create a transfer job as part of the preparation for the data transfer. See Transfer Jobs for complete details on all tasks related to transfer jobs.

Tip

You can use the Console or the Data Transfer Utility to create a transfer job.

A transfer job represents the collection of files that you want to transfer and signals the intention to upload those files to Oracle Cloud Infrastructure. A transfer job combines at least

one transfer disk with a transfer package. Identify which compartment and Object Storage bucket that Oracle is to upload your data to. Create the transfer job in the same compartment as the upload bucket and supply a human-readable name for the transfer job. Avoid entering confidential information when providing transfer job names.

Note

It is recommended that you create a compartment for each transfer job to minimize the required access your tenancy.

Creating a transfer job returns a job ID that you specify in other transfer tasks. For example:

```
ocid1.datatransferjob.region1.phx..exampleuniqueID
```

To create a transfer job using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Object Storage** and click **Data Transfer**.
2. Select the designated compartment you are to use for data transfers from the drop-down list.
   A list of transfer jobs that have already been created is displayed.
3. Click **Create Transfer Job**.
4. In the **Create Transfer Job** dialog, enter a **Job Name**, and select the **Upload Bucket** from the drop-down list.
   Avoid entering confidential information in the transfer job name.
5. Select **Disk** for the **Transfer Device Type**.
6. Click **Create Transfer Job**.

To create a transfer job using the Data Transfer Utility

At the command prompt on the Data Host, run `dts job create` to create a transfer job. The

<display_name> is the name of the transfer job. Avoid entering confidential information in the transfer job name.

```
dts job create --bucket <bucket_name> --compartment-id <compartment_id> --display-name <display_name>
--device-type disk
```

Optionally, you can specify one or more free-form or defined tags when you create a transfer job. For more information about tagging, see Resource Tags.

To specify free-form tags when creating a job:

```
dts job create --bucket <bucket_name> --compartment-id <compartment_id> --display-name <display_name>
--device-type disk --freeform-tags '{ "<tag_key>":"<value>" }'
```

To specify defined tags when creating a job:

```
dts job create --bucket <bucket_name> --compartment-id <compartment_id> --display-name <display_name>
--device-type disk --defined-tags '{ "<tag_namespace>": { "<tag_key>":"<value>" }}'
```

Note

Only users with the required permissions can create tag namespaces and tag keys. Create the tag namespaces and keys before you can specify them when creating a job. See Working with Defined Tags for details.

To specify multiple tags, comma separate the JSON-formatted key/value pairs:

```
dts job create --bucket <bucket_name> --compartment-id <compartment_id> --display-name <display_name>
--device-type disk --freeform-tags '{ "<tag_key>":"<value>" }', '{ "<tag_key>":"<value>" }'
```

Preparing Upload Configuration Files

The Project Sponsor is responsible for creating or obtaining configuration files that allow the uploading of user data to the transfer appliance. Send these configuration files to the Data Administrator where they can be placed in the Data Host. The `config` file is for the data transfer administrator, the IAM user with the authorization and permissions to create and manage transfer jobs. The `config_upload_user` file is for the data transfer upload user, the temporary IAM user that Oracle uses to upload your data on your behalf.

Create a base Oracle Cloud Infrastructure directory and two configuration files with the required credentials.

Creating the Data Transfer Directory

Create a Oracle Cloud Infrastructure directory (`.oci`) on the same Data Host where the CLI is installed. For example:

```
mkdir /root/.oci/
```

The two configuration files (`config` and `config_upload_user`) are placed in this directory.

Creating the Data Transfer Administrator Configuration File

Create the data transfer administrator configuration file `/root/.oci/config` with the following structure:

```
[DEFAULT]
user=<The OCID for the data transfer administrator>
fingerprint=<The fingerprint of the above user's public key>
key_file=<The _absolute_ path to the above user's private key file on the host machine>
tenancy=<The OCID for the tenancy that owns the data transfer job and bucket>
region=<The region where the transfer job and bucket should exist. Valid values are:
us-ashburn-1, us-phoenix-1, eu-frankfurt-1, and uk-london-1.>
```

For example:

```
[DEFAULT]
user=ocid1.user.oc1..exampleuniqueID
fingerprint=4c:1a:6f:a1:5b:9e:58:45:f7:53:43:1f:51:0f:d8:45
key_file=/home/user/ocid1.user.oc1..exampleuniqueID.pem
tenancy=ocid1.tenancy.oc1..exampleuniqueID
region=us-phoenix-1
```

For the data transfer administrator, you can create a single configuration file that contains different profile sections with the credentials for multiple users. Then use the `--profile` option to specify which profile to use in the command.

Here is an example of a data transfer administrator configuration file with different profile sections:

```
[DEFAULT]
user=ocid1.user.oc1..exampleuniqueID
fingerprint=4c:1a:6f:a1:5b:9e:58:45:f7:53:43:1f:51:0f:d8:45
key_file=/home/user/ocid1.user.oc1..exampleuniqueID.pem
tenancy=ocid1.tenancy.oc1..exampleuniqueID
```

```
region=us-phoenix-1
[PROFILE1]
user=ocid1.user.oc1..exampleuniqueID
fingerprint=4c:1a:6f:a1:5b:9e:58:45:f7:53:43:1f:51:0f:d8:45
key_file=/home/user/ocid1.user.oc1..exampleuniqueID.pem
tenancy=ocid1.tenancy.oc1..exampleuniqueID
region=us-ashburn-1
```

By default, the `DEFAULT` profile is used for all CLI commands. For example:

```
oci dts job create --compartment-id ocid.compartment.oc1..exampleuniqueID --bucket MyBucket --display-
name MyDisplay --device-type disk
```

Instead, you can issue any CLI command with the `--profile` option to specify a different data transfer administrator profile. For example:

```
oci dts job create --compartment-id ocid.compartment.oc1..exampleuniqueID --bucket MyBucket --display-
name MyDisplay --device-type disk --profile MyProfile
```

Using the example configuration file above, the *<profile_name>* would be `profile1`.

If you created two separate configuration files, use the following command to specify the configuration file to use:

```
oci dts job create --compartment-id <compartment_id> --bucket <bucket_name> --display-name <display_
name>
```

CREATING THE DATA TRANSFER UPLOAD USER CONFIGURATION FILE

The `config_upload_user` configuration file is for the data transfer upload user, the temporary IAM user that Oracle uses to upload your data on your behalf. Create this configuration file with the following structure:

```
[DEFAULT]
user=<The OCID for the data transfer upload user>
fingerprint=<The fingerprint of the above user's public key>
key_file=<The _absolute_ path to the above user's private key file on the host machine>
tenancy=<The OCID for the tenancy that owns the data transfer job and bucket>
region=<The region where the transfer job and bucket should exist. Valid values are:
us-ashburn-1, us-phoenix-1, eu-frankfurt-1, and uk-london-1.>
```

For example:

```
[DEFAULT]
user=ocid1.user.oc1..exampleuniqueID
fingerprint=4c:1a:6f:a1:5b:9e:58:45:f7:53:43:1f:51:0f:d8:45
key_file=/home/user/ocid1.user.oc1..exampleuniqueID.pem
```

```
tenancy=ocid1.tenancy.oc1..exampleuniqueID
region=us-phoenix-1
```

Important

Creating an upload user configuration file with multiple profiles is *not* supported.

CONFIGURATION FILE ENTRIES

The following table lists the basic entries that are required for each configuration file and where to get the information for each entry.

Note

Data Transfer Service does not support passphrases on the key files for both data transfer administrator and data transfer upload user.

Entry	Description and Where to Get the Value	Required?
`user`	OCID of the data transfer administrator or the data transfer upload user, depending on which profile you are creating. To get the value, see Required Keys and OCIDs.	Yes
`fingerprint`	Fingerprint for the key pair being used. To get the value, see Required Keys and OCIDs.	Yes

Entry	Description and Where to Get the Value	Required?
`key_file`	Full path and filename of the private key. **Important:** The key pair must be in PEM format. For instructions on generating a key pair in PEM format, see Required Keys and OCIDs.	Yes
`tenancy`	OCID of your tenancy. To get the value, see Required Keys and OCIDs.	Yes
`region`	An Oracle Cloud Infrastructure region. See Regions and Availability Domains. Data transfer is supported in `US East (Ashburn)`, `US West (Phoenix)`, `Germany Central (Frankfurt)`, and `UK South (London)`.	Yes

You can verify the data transfer upload user credentials using the following command:

```
dts job verify-upload-user-credentials --bucket <bucket_name>
```

Creating Shipping Labels

You can find the shipping address in the transfer package details. Use this information to create a shipping label for the transfer package that is used to send the disk to Oracle.

To get the shipping address for a transfer package using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Object Storage** and click **Data Transfer**.
2. Find the transfer job for which you want to see the details.
3. Click the Actions icon (three dots), and then click **View Details**.

Alternatively, click the hyper-linked name of the transfer job.
A list of transfer packages that have already been created is displayed.

4. Find the transfer package for which you want to see the details.
5. Click the Actions icon (three dots), and then click **View Details**.
   Alternatively, click the hyper-linked name of the transfer job.

To get the shipping address for a transfer package using the Data Transfer Utility

At the command prompt on the Data Host, run `dts package show` to get the shipping address for a transfer package.

```
dts package show --job-id <job_id> --package-label <package_label>
```

Notifying the Data Administrator

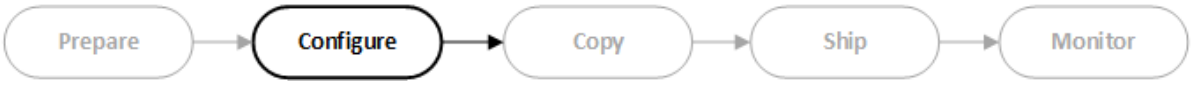
When you have completed all the tasks in this topic, provide the Data Administrator of the following:

- IAM login credentials
- Data Transfer Utility configuration files
- Transfer job ID
- Transfer job label

What's Next

You are now ready to configure your system for the data transfer. See Configuring Disk Data Transfers.

Configuring Disk Data Transfers



This topic describes the tasks associated with configuring the Disk-Based Data Transfer. The Infrastructure Engineer role typically performs these tasks. See Roles and Responsibilities.

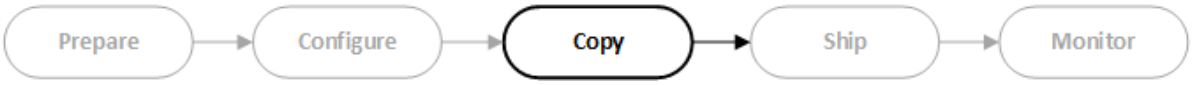
Configuration for the Disk-Based Data Transfer consists of the following tasks:

- Attaching the disk to the Data Host. Remove all partitions and any file systems. To prevent the accidental deletion of data, the Data Transfer Utility does not work with disks that already have partitions or file systems. Disks are visible to the host as block devices and must provide a valid response to the `hdparm -I <device>` Linux command.
- Sending the block device path to the Data Administrator.

What's Next

You are now ready to load your data to the disk. See Copying the Data.

Copying the Data



This topic describes the tasks associated with running the data transfer from the Data Host to the physical disk that has been configured as a transfer disk. The Data Administrator role typically performs these tasks. See Roles and Responsibilities.

Information Prerequisites

Before performing any disk copying tasks, you must obtain the following information:

- Disk block device path. The Infrastructure Engineer typically provides this information.
- IAM login information, Data Transfer Utilityconfiguration files, transfer job ID, and job label. The Project Sponsor typically provides this information.

Generate and Upload RSA Key Pairs

The Data Administrator is responsible for generating and uploading the RSA key pairs. Do not share these generated RSA keys between users. See Creating a Key Pair.

Install and Configure the Data Transfer Utility

The Data Transfer Utility provides a set of command line-based tools for configuring and running disk-based data transfers. Use the Data Transfer Utility as an alternative to running commands from the Console. Sometimes you must use the Data Transfer Utility to complete certain tasks as there is no Console equivalent. See Data Transfer Utility for details on how to install and configure the Data Transfer Utility for use with disk-based data transfers.

Creating the Transfer Disk

The transfer disk is the logical representation of the physical disk that has been configured for use for receiving data as part of the disk-based data transfer. See Transfer Disks for complete details on all tasks related to transfer disks.

Tip

You can only use the Data Transfer Utility to create a transfer disk.

When you create a transfer disk for use with the disk on which you are copying your files, the Data Transfer Utility:

- Sets up the disk for encryption using the passphrase
- Creates a file system on the disk
- Mounts the file system at `/mnt/orcdts_<label>`

For example:

```
/mnt/orcdts_DJZNWK3ET
```

When you register a transfer disk, Oracle Cloud Infrastructure generates a strong encryption passphrase that is used to encrypt the contents on the disk. The encryption passphrase is displayed to standard output to the data transfer administrator user and cannot be retrieved again. Create a local, secure copy of the encryption passphrase, so you can reference the passphrase again.

Creating a transfer disk requires the job ID returned from when you created the transfer job and the path to the attached disk (for example, `/dev/sdb`).

To create a transfer disk using the Data Transfer Utility

At the command prompt on the host, run `dts disk create` to create a transfer disk.

```
dts disk create --job-id <job_id> --block-device <block_device>
```

Copying Files

Attach the disks to the Data Host and copy files to the mount point created by the transfer disk through the Data Transfer Utility.

You can only copy regular files to disks. Special files (links, sockets, pipes, and so forth) cannot be copied directly. To transfer special files, create a tar archive of the files and copy the tar archive to the disk.

Note

Copy all Files Before Disconnecting the Disk

Do not disconnect the disk until you copy all files from the Data Host and generate the manifest file. If you accidentally disconnect the disk before copying all files, you must unlock the disk using the encryption passphrase. The encryption passphrase was generated and displayed when you created the transfer disk. If the generated encryption passphrase is not available, you must delete the transfer disk from the transfer job and re-create the transfer disk. All data previously copied to that disk is lost.

Generating the Manifest

Tip

You can only use the Data Transfer Utility to generate a manifest file.
The amount of time to generate the manifest file depends on the size of the upload files, disk speed, and available processing power.

After copying your data to a transfer disk, generate a manifest file using the Data Transfer Utility. The manifest contains an index of all of the copied files and generated data integrity hashes. The Data Transfer Utility copies the `config_upload_user` configuration file and referenced IAM credentials to the encrypted transfer disk. This configuration file describes the temporary IAM data transfer upload user. Oracle uses the credentials and entries defined in the `config_upload_user` file when processing the transfer disk and uploading files to Oracle Cloud Infrastructure Object Storage.

Note

Data Transfer Service Does Not Support Passphrases on Private Keys

While we recommend encrypting a private key with a passphrase when generating API signing keys, Data Transfer does not support passphrases on the key file required for the `config_upload_user`. If you use a passphrase, Oracle personnel cannot upload your data.

Oracle cannot upload data from a transfer disk without the correct credentials defined in this configuration file. See Data Transfer Utility for more information about the required configuration files.

To create a manifest file using the Data Transfer Utility

At the command prompt on the Data Host, run `dts disk manifest` to create a manifest file.

```
dts disk manifest --job-id <job_id> --disk-label <label>
```

Note

Do You Need to Regenerate the Manifest File?

If you add, remove, or modify any files on the disk after generating the manifest file, you must regenerate the file. If the manifest file does not match the contents of the target bucket, Oracle cannot upload the data.

Locking the Transfer Disk

Tip

You can only use the Data Transfer Utility to lock a transfer disk.

Locking a transfer disk safely unmounts the disk and removes the encryption passphrase from the Data Host.

To lock a transfer disk using the Data Transfer Utility

At the command prompt on the Data Host, run `dts disk lock` to lock a transfer disk.

```
dts disk lock --job-id <job_id> --disk-label <label> --block-device <block_device>
```

If you need to unlock the transfer disk , you are prompted for the encryption passphrase that was generated when you created the transfer disk.

To unlock a transfer disk using the Data Transfer Utility

At the command prompt on the Data Host, run `dts disk unlock` to unlock a transfer disk.

```
dts disk unlock --job-id <job_id> --disk-label <label> --block-device <block_device> --encryption-
passphrase <encryption_passphrase>
```

Creating the Transfer Package

A transfer package is the virtual representation of the physical package of disks that you are shipping to Oracle for upload to Oracle Cloud Infrastructure. See Transfer Packages for complete details on all tasks related to transfer packages.

Tip

You can use the Console or the Data Transfer Utility to create a transfer package.

Creating a transfer package requires the job ID returned from when you created the transfer job. For example:

```
ocid1.datatransferjob.region1.phx..exampleuniqueID
```

To create a transfer package using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Object Storage** and click **Data Transfer**.
2. Find the transfer job for which you want to create a transfer package.
3. Click the Actions icon (three dots), and then click **View Details**.
   Alternatively, click the hyper-linked name of the transfer job.
   A list of transfer packages that have already been created is displayed.
4. Click **Create Transfer Package**.
5. In the **Create Transfer Package** dialog, choose the **Vendor**.
6. Click **Create Transfer Package**.

The Data Transfer Package dialog appears displaying information such as the shipping address, the shipping vendor, and the shipping status.

To create a transfer package using the Data Transfer Utility

At the command prompt on the Data Host, run `dts package create` to create a transfer package.

```
dts package create --job-id <job_id>
```

The following information is returned:

```
Transfer Package :
Label :
TransferSiteShippingAddress :
DeliveryVendor :
DeliveryTrackingNumber :
ReturnDeliveryTrackingNumber :
Status :
Devices :
```

Attaching the Transfer Disk to the Transfer Package

Attach a transfer disk to a transfer package after you have performed the following tasks:

1. Copied your data onto the disk
2. Generated the required manifest file
3. Run and reviewed the dry-run report
4. Locked the transfer disk in preparation for shipment

Tip

You can use the Console or the Data Transfer Utility to attach a transfer disk to a transfer package.

A disk can be attached to one package, detached, and then attached to another package.

To attach a transfer disk to a transfer package using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Object Storage** and click **Data Transfer**.
2. Find the transfer job associated with the transfer package that you want to attach a disk to.

3. Click the Actions icon (three dots), and then click **View Details**.
   A list of transfer packages is displayed.
4. Find the transfer package that you want to attach a disk to.
5. Click the Actions icon (three dots), and then click **View Details**.
   Alternatively, click the hyper-linked name of the transfer package.
   A list of transfer disks is displayed.
6. Click **Attach Transfer Disks**.
7. In the **Attach Transfer Disk** dialog, select the **Transfer Disks** that you want to attach to the transfer package.
8. Click **Attach**.

To attach a transfer disk to a transfer package using the Data Transfer Utility

At the command prompt on the Data Host, run `dts disk attach` to attach a disk to a transfer package.

```
dts disk attach --job-id <job_id> --package-label <package_label> --disk-label <label>
```

You have attached a transfer disk to a transfer package, but have changed your mind about shipping that disk with the transfer package. You can also detach a transfer disk from one transfer package and attach that disk to a different transfer package.

To detach a transfer disk to a transfer package using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Object Storage** and click **Data Transfer**.
2. Find the transfer package for which you want to detach a transfer disk.
3. Click the Actions icon (three dots), and then click **View Details**.
   Alternatively, click the hyper-linked name of the transfer package.
   A list of transfer disks that have already been attached is displayed.
4. Find the transfer disk that you want to detach.

5. Click the Actions icon (three dots), and then click **View Details**.
   Alternatively, click the hyper-linked name of the transfer disk.
6. Click **Detach Transfer Disk**.

To detach a transfer disk to a transfer package using the Data Transfer Utility

At the command prompt on the Data Host, run `dts disk detach` to detach a disk from a transfer package.

```
dts disk detach --job-id <job_id> --package-label <package_label> --disk-label <label>
```

Setting Tracking Details on the Transfer Package

Tip

You can use the Console or the Data Transfer Utility to update the transfer package with tracking information.

After delivering the transfer package to the shipping vendor, update the transfer package with the tracking information.

Important

Oracle cannot process a transfer package until you update the tracking information.

To update the transfer package with tracking information using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Object Storage** and click **Data Transfer**.

2. Find the transfer job for which you want to see the associated transfer packages.
3. Click the Actions icon (three dots), and then click **View Details**.
   A list of transfer packages that have already been created is displayed.
4. Find the transfer package that you want to update.
5. Click the Actions icon (three dots), and then click **View Details**.
6. Click **Edit**.
7. Enter the **Tracking ID** and the **Return Tracking ID**.
8. Click **Edit Transfer Package**.

To update the transfer package with tracking information using the Data Transfer Utility

At the command prompt on the host, run `dts package ship` to update the transfer package tracking information.

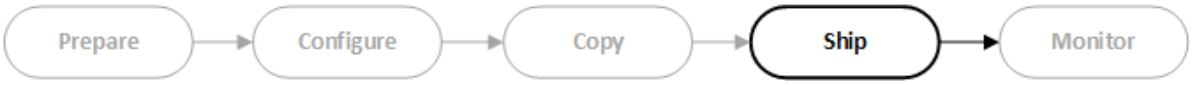
```
dts package ship --job-id <job_id> --package-label <package_label> --package-vendor <vendor_name> --
tracking-number <tracking_number> --return-tracking-number <return_tracking_number>
```

Notifying the Infrastructure Engineer

After completing the tasks listed in this topic, notify the Infrastructure Engineer of the following:

- Disconnect the physical disk from the Data Host
- Package the disk for shipment

Shipping the Disk



This topic describes the tasks associated with shipping the physical disk containing the copied data to Oracle. The Infrastructure Engineer role typically performs these tasks. See Roles and Responsibilities.

Disconnecting the Disk from the Data Host

Do not disconnect the disk until you copy all files from the Data Host and generate the manifest file.

Printing Shipping Labels

You should receive the shipping labels electronically from the Project Sponsor. Print them on the appropriate labels for shipping the disk.

Packaging and Shipping the Disk

GENERAL

Include the required return shipping label in the box when packaging transfer disks for shipment.

Note

Return Shipment Label Requirement

If you do not include the return shipping label inside the box, Oracle cannot process the transfer package.

Ensure that the transfer job and transfer package label are clearly readable on the outside of the box containing the transfer disks.

Important

If you are shipping transfer disks to London or Frankfurt, request that the shipping vendor requires a signature delivery.

SHIPPING TRANSFER DISKS INTERNATIONALLY

Create a commercial invoice when shipping transfer disks internationally. To ensure that packages are not held up in customs, follow these guidelines when creating the commercial invoice:

- Show a unique reference number.
- Show the "bill-to party as follows:
  - For shipments to the European Union (Frankfurt) location:
    ORACLE Deutschland B.V. & Co. KG
    Riesstrasse 25
    Munich, 80992
    GERMANY
  - For shipments to the United States location:
    Oracle America, Inc.
    500 Oracle Parkway
    REDWOOD CITY CA 94065
    UNITED STATES
- Show the "ship-to party" as the address provided in the transfer package details. See Creating Shipping Labels for details.
- State that "The value shown includes the value of software and data recorded onto the hard drive unit."
- State that the "Goods are free of charge - no payment required."
- State that the type of export is "Temporary."

- Ensure that the commodity code shows the correct HS code for a hard drive unit as specified in the source country's HS code list.
- State the description as the manufacture's description of the hard drive unit and include the words "Hard Disk Drive."
- Ensure that the invoice is signed and includes the printed name of the signer.

Monitoring the Disk

This topic describes the tasks to be done after the data transfer is complete the disk has been shipped to Oracle. The Project Sponsor role typically performs these tasks. See Roles and Responsibilities.

Tracking the Disk Shipment

When Oracle has processed the transfer disks associated with a transfer package, the status of the transfer package changes to **Processed**. When Oracle has shipped the transfer disks associated with a transfer package, the status of the transfer package changes to **Returned**.

Tip

You can use the Console or the Data Transfer Utility to check the status of a transfer package.

To check the status of a transfer package using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Object Storage** and click **Data Transfer**.
2. Choose the data transfer package for which you want to display the details.
3. Click the Actions icon (three dots), and then click **View Details**.
4. Look at the **Status**.

To check the status of a transfer package using the Data Transfer Utility

At the command prompt on the Data Host, run `dts package show` to show the status of a transfer package.

```
dts package show --job-id <job_id> --package-label <package_label>
```

Reviewing the Upload Summary

Oracle creates upload summary log files for each uploaded disk. These logs are placed in the bucket where the data was uploaded to Oracle Cloud Infrastructure. The upload summary file compares the disk's manifest file to the contents of the target Oracle Cloud Infrastructure Object Storage bucket after file upload.

The top of the log report summarizes the overall file processing status:

```
P - Present: The file is present in both the disk and the target bucket
M - Missing: The file is present in the disk but not the target bucket. It was likely uploaded and then
deleted by another user before the summary was generated.
C - Name Collision: The file is present in the manifest but a file with the same name but different
contents is present in the target bucket.
U - Unreadable: The file is not readable from the disk
N - Name Too Long: The file name on disk is too long and could not be uploaded
```

Complete file upload details follow the summary.

```
#########################################################################################################################
#####################################  SUMMARY FOR DISK [WDH0B87L] #######################################
Generated    2017-09-08 19:46:36

```

Closing the Transfer Job

Typically, you would close a transfer job when no further transfer job activity is required or possible. Closing a transfer job requires that the status of all associated transfer packages be returned, canceled, or deleted. In addition, the status of all associated transfer disks must be complete, in error, missing, canceled, or deleted.

Tip

You can use the Console or the Data Transfer Utility to close a transfer job.

To close a transfer job using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Object Storage** and click **Data Transfer**.
2. Find the data transfer package for which you want to display the details.
3. Click the Actions icon (three dots), and then click **View Details**.
   Alternatively, click the hyper-linked name of the transfer job.
4. Click **Close Transfer Job**.

To close a transfer job using the Data Transfer Utility

At the command prompt on the host, run `dts job close` to close a transfer job.

```
dts job close --job-id <job_id>
```

What's Next

You have completed the process of setting up, running, and monitoring the disk-based data transfer. After the disk contents is successfully migrated to Oracle Cloud Infrastructure, your physical disk is erased and returned to you.

If you determine that another disk-based data transfer is required, repeat the procedure from the beginning.

Data Transfer Utility

This topic describes how to install and configure the Data Transfer Utility for use in disk-based data transfers. In addition, this topic describes the syntax for the Data Transfer Utility commands.

Important

With this release, the Data Transfer Utility only supports disk-based data transfers. Use of the Data Transfer Utility for appliance-based transfers has been replaced with the Oracle Cloud Infrastructure command line interface (CLI). See for more information.

The Data Transfer Utility is licensed under the Universal Permissive License 1.0 and the Apache License 2.0. Third-party content is separately licensed as described in the code.

Prerequisites

To install and use the Data Transfer Utility, obtain the following:

- An Oracle Cloud Infrastructure account.
- Required Oracle Cloud Infrastructure users and groups with the required IAM policies. See for details.
- A Data Host machine with the following installed:
  - Oracle Linux 6 or greater, Ubuntu 14.04 or greater, or SUSE 11 or greater
  - Java 1.8 or Java 1.11
  - hdparm 9.0 or later
  - Cryptsetup 1.2.0 or greater
- Firewall access: If you have a restrictive firewall in the environment where you are using the Data Transfer Utility, you may need to open your firewall configuration to the following IP address ranges: 140.91.0.0/16.
  You also need to open access to the object storage IP address ranges: 134.70.0.0/17.

Installing the Data Transfer Utility

Download and install the Data Transfer Utility installer that corresponds to your Data Host's operating system.

To install the Data Transfer Utility on Debian or Ubuntu

1. Download the installation .deb file.
2. Issue the `apt install` command as the `root` user that has write permissions to the `/opt` directory.

   ```
   sudo apt install ./dts-X.Y.Z.x86_64.deb
   ```

   `X.Y.Z` represents the version numbers that match the installer you downloaded.
3. Confirm that the Data Transfer Utility installed successfully.

   ```
   sudo dts --version
   ```

   Your Data Transfer Utility version number is returned.

To install the Data Transfer Utility on Oracle Linux or Red Hat Linux

1. Download the installation .rpm file.
2. Issue the `yum install` command as the `root` user that has write permissions to the `/opt` directory.

   ```
   sudo yum localinstall ./dts-X.Y.Z.x86_64.rpm
   ```

   `X.Y.Z` represents the version numbers that match the installer you downloaded.
3. Confirm that the Data Transfer Utility installed successfully.

   ```
   sudo dts --version
   ```

   Your Data Transfer Utility version number is returned.

Configuring the Data Transfer Utility

Before using the Data Transfer Utility, you must create a base Oracle Cloud Infrastructure directory and two configuration files with the required credentials. One configuration file is for the data transfer administrator, the IAM user with the authorization and permissions to create and manage transfer jobs. The other configuration file is for the data transfer upload user, the temporary IAM user that Oracle uses to upload your data on your behalf.

Base Data Transfer Directory

Create a base Oracle Cloud Infrastructure directory:

```
mkdir /root/.oci/
```

Configuration File for the Data Transfer Administrator

Create a data transfer administrator configuration file `/root/.oci/config` with the following structure:

```
[DEFAULT]
user=<The OCID for the data transfer administrator>
fingerprint=<The fingerprint of the above user's public key>
key_file=<The _absolute_ path to the above user's private key file on the host machine>
tenancy=<The OCID for the tenancy that owns the data transfer job and bucket>
region=<The region where the transfer job and bucket should exist. Valid values are:
us-ashburn-1, us-phoenix-1, eu-frankfurt-1, and uk-london-1.>
```

For example:

```
[DEFAULT]
user=ocid1.user.oc1..<unique_ID>
fingerprint=4c:1a:6f:a1:5b:9e:58:45:f7:53:43:1f:51:0f:d8:45
key_file=/home/user/ocid1.user.oc1..<unique_ID>.pem
tenancy=ocid1.tenancy.oc1..<unique_ID>
region=us-phoenix-1
```

For the data transfer administrator, you can create a single configuration file that contains different profile sections with the credentials for multiple users. Then use the `--profile` option to specify which profile to use in the command. Here is an example of a data transfer administrator configuration file with different profile sections:

```
[DEFAULT]
user=ocid1.user.oc1..<unique_ID>
fingerprint=4c:1a:6f:a1:5b:9e:58:45:f7:53:43:1f:51:0f:d8:45
key_file=/home/user/ocid1.user.oc1..<unique_ID>.pem
tenancy=ocid1.tenancy.oc1..<unique_ID>
region=us-phoenix-1
[PROFILE1]
user=ocid1.user.oc1..<unique_ID>
fingerprint=4c:1a:6f:a1:5b:9e:58:45:f7:53:43:1f:51:0f:d8:45
key_file=/home/user/ocid1.user.oc1..<unique_ID>.pem
tenancy=ocid1.tenancy.oc1..<unique_ID>
region=us-ashburn-1
```

By default, the `DEFAULT` profile is used for all Data Transfer Utility commands. For example:

```
dts job create --compartment-id <compartment_id> --bucket <bucket_name> --display-name <display_name>
--device-type <disk>
```

Instead, you can issue any Data Transfer Utility command with the `--profile` option to specify a different data transfer administrator profile. For example:

```
dts job create --compartment-id <compartment_id> --bucket <bucket_name> --display-name <display_name>
--device-type <disk> --profile <profile_name>
```

Using the example configuration file above, the *<profile_name>* would be `profile1`.

Configuration File for the Data Transfer Upload User

Create a data transfer upload user `/root/.oci/config_upload_user` configuration file with the following structure:

```
[DEFAULT]
user=<The OCID for the data transfer upload user>
```

```
fingerprint=<The fingerprint of the above user's public key>
key_file=<The _absolute_ path to the above user's private key file on the host machine>
tenancy=<The OCID for the tenancy that owns the data transfer job and bucket>
region=<The region where the transfer job and bucket should exist. Valid values are:
us-ashburn-1, us-phoenix-1, eu-frankfurt-1, and uk-london-1.>
```

For example:

```
[DEFAULT]
user=ocid1.user.oc1..<unique_ID>
fingerprint=4c:1a:6f:a1:5b:9e:58:45:f7:53:43:1f:51:0f:d8:45
key_file=/home/user/ocid1.user.oc1..<unique_ID>.pem
tenancy=ocid1.tenancy.oc1..<unique_ID>
region=us-phoenix-1
```

Important

Creating an upload user configuration file with multiple profiles is *not* supported.

CONFIGURATION FILE ENTRIES

The following table lists the basic entries that are required for each configuration file and where to get the information for each entry.

Note

Data Transfer Service does not support passphrases on the key files for both data transfer administrator and data transfer upload user.

Entry	Description and Where to Get the Value	Required?
`user`	OCID of the data transfer administrator or the data transfer upload user, depending on which profile you are creating. To get the value, see Required Keys and OCIDs.	Yes
`fingerprint`	Fingerprint for the key pair being used. To get the value, see Required Keys and OCIDs.	Yes
`key_file`	Full path and filename of the private key. **Important:** The key pair must be in PEM format. For instructions on generating a key pair in PEM format, see Required Keys and OCIDs.	Yes
`tenancy`	OCID of your tenancy. To get the value, see Required Keys and OCIDs.	Yes
`region`	An Oracle Cloud Infrastructure region. See Regions and Availability Domains. Data transfer is supported in `US East (Ashburn)`, `US West (Phoenix)`, `Germany Central (Frankfurt)`, and `UK South (London)`.	Yes

You can verify the data transfer upload user credentials using the following command:

```
dts job verify-upload-user-credentials --bucket <bucket_name>
```

CONFIGURATION FILE LOCATION

The location of the configuration files is `/root/.oci/config`.

Using the Data Transfer Utility

This section provides an overview of the syntax for the Data Transfer Utility.

Important

The Data Transfer Utility must be run as the `root` user.

You can specify Data Transfer Utility command options using the following commands:

- `--option` *<value>* *or*
- `--option=`*<value>*

SYNTAX

The basic Data Transfer Utility syntax is:

```
dts <resource> <action> <options>
```

This syntax is applied to the following:

- `dts` is the shortened utility command name
- `job` is an example of a `<resource>`
- `create` is an example of an `<action>`
- Other utility strings are `<options>`

The following commands to create a transfer job shows a typical Data Transfer Utility construct.

```
dts job create --compartment-id ocid1.compartment.oc1..<unique_ID> --display-name "mycompany
transfer1" --bucket mybucket --device-type disk
```

Or:

```
dts job create --compartment-id=ocid1.compartment.oc1..<unique_ID> --display-name="mycompany
transfer1" --bucket=mybucket --device-type=disk
```

Note

In the previous examples, provide a friendly name for the transfer job using the `--display-name` option. Avoid entering confidential information when providing resource names or descriptions.

GETTING HELP WITH COMMANDS

You can get help with the different commands associated with Data Transfer Utility using `dts` by itself. For example:

```
dts
```

FINDING OUT THE INSTALLED VERSION OF THE DATA TRANSFER UTILITY

You can get the installed version of the Data Transfer Utility using `--version` or `-v`. For example:

```
dts --version
```

What's Next

You are now ready to perform disk-based data transfers. See .

Disk Data Transfer Reference

This topic provides complete task details for certain components associated with Disk-Based Data Transfers. Use this topic as a reference to learn and use commands associated with components included in the Disk-Based Data Transfer procedure.

Transfer Jobs

A transfer job represents the collection of files that you want to transfer and signals the intention to upload those files to Oracle Cloud Infrastructure. A transfer job combines at least

one transfer disk with a transfer package. Identify which compartment and Object Storage bucket that Oracle is to upload your data to.

Note

It is recommended that you create a compartment for each transfer job to minimize the required access your tenancy.

Tip

You can use the Console or the Data Transfer Utility to create a transfer job.

CREATING TRANSFER JOBS

Create the transfer job in the same compartment as the upload bucket and supply a human-readable name for the transfer job. Avoid entering confidential information when providing transfer job names.

Creating a transfer job returns a job ID that you specify in other transfer tasks. For example:

```
ocid1.datatransferjob.region1.phx..<unique_ID>
```

To create a transfer job using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Object Storage** and click **Data Transfer**.
2. Select the designated compartment you are to use for data transfers from the drop-down list.

   A list of transfer jobs that have already been created is displayed.

3. Click **Create Transfer Job**.
4. In the **Create Transfer Job** dialog, enter a **Job Name**, and select the **Upload Bucket** from the drop-down list.
   Avoid entering confidential information in the transfer job name.
5. Select **Disk** for the **Transfer Device Type**.
6. Click **Create Transfer Job**.

To create a transfer job using the Data Transfer Utility

At the command prompt on the Data Host, run `dts job create` to create a transfer job. The *<display_name>* is the name of the transfer job. Avoid entering confidential information in the transfer job name.

```
dts job create --bucket <bucket_name> --compartment-id <compartment_id> --display-name <display_name>
--device-type disk
```

Optionally, you can specify one or more free-form or defined tags when you create a transfer job. For more information about tagging, see Resource Tags.

To specify free-form tags when creating a job:

```
dts job create --bucket <bucket_name> --compartment-id <compartment_id> --display-name <display_name>
--device-type disk --freeform-tags '{ "<tag_key>":"<value>" }'
```

To specify defined tags when creating a job:

```
dts job create --bucket <bucket_name> --compartment-id <compartment_id> --display-name <display_name>
--device-type disk --defined-tags '{ "<tag_namespace>": { "<tag_key>":"<value>" }}'
```

Note

Users create tag namespaces and tag keys with the required permissions. These items must exist before you can specify them when creating a job. See Working with Defined Tags for details.

To specify multiple tags, comma separate the JSON-formatted key/value pairs:

```
dts job create --bucket <bucket_name> --compartment-id <compartment_id> --display-name <display_name>
--device-type disk --freeform-tags '{ "<tag_key>":"<value>" }', '{ "<tag_key>":"<value>" }'
```

DISPLAYING TRANSFER JOBS

To display the list of transfer jobs using the Console

Open the navigation menu. Under **Core Infrastructure**, go to **Object Storage** and click **Data Transfer**.

To display the list of transfer jobs using the Data Transfer Utility

At the command prompt on the Data Host, run `dts job list` to display the list of transfer jobs.

```
dts job list --compartment-id <compartment_id>
```

When you use the Data Transfer Utility to list jobs, tagging details are also included in the output if you specified tags.

DISPLAYING TRANSFER JOB DETAILS

To display the details of a transfer job using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Object Storage** and click **Data Transfer**.
2. Find the transfer job for which you want to display the details.
3. Click the Actions icon (three dots), and then click **View Details**.

To display the details of a transfer job using the Data Transfer Utility

At the command prompt on the Data Host, run `dts job show` to display the details of a

transfer job.

```
dts job show --job-id <job_id>
```

When you use the Data Transfer Utility to display the details of a job, tagging details are also included in the output if you specified tags.

EDITING TRANSFER JOBS

To edit the name of a transfer job using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Object Storage** and click **Data Transfer**.
2. Find the data transfer job that you want to edit.
3. Click the Actions icon (three dots), and then click **Edit**.
4. Edit the name of the transfer job.
   Avoid entering confidential information in the transfer job name.
5. Click **Save**.

To edit the name of a transfer job using the Data Transfer Utility

At the command prompt on the Data Host, run `dts job update` to edit the name (`--display-name`) of a transfer job. The *<display_name>* is the new name of the transfer job. Avoid entering confidential information in the transfer job name.

```
dts job update --job-id <job_id> --display-name <display_name>
```

To edit the tags associated with a transfer job using the Data Transfer Utility

At the command prompt on the Data Host, run `dts job update` to edit the tags associated with a transfer job. The Data Transfer Utility **replaces** any existing tags with the new key/value pairs you specify.

To edit free-form tags, provide the replacement key/value pairs:

```
dts job update --job-id <job_id> --freeform-tags '{ "<tag_key>":"<value>" }'
```

To edit defined tags, provide the replacement key value pairs:

```
dts job update --job-id <job_id> --defined-tags '{ "<tag_namespace>": { "<tag_key>":"<value>" }}'
```

To delete the tags associated with a transfer job using the Data Transfer Utility

At the command prompt on the Data Host, run `dts job update` to delete the tags associated with a transfer job. The Data Transfer Utility **replaces** any existing tags with the new key/value pairs you specify. If you want to delete some of the tags, you would specify new tag string that does not contain the key/value pair you want to delete.

Partial tag deletion is handled in the same way as you edit tags:

- To edit free-form tags, provide the replacement key/value pairs:

```
dts job update --job-id <job_id> --freeform-tags '{ "<tag_key>":"<value>" }'
```

- To edit defined tags, provide the replacement key value pairs:

```
dts job update --job-id <job_id> --defined-tags '{ "<tag_namespace>": { "<tag_key>":"<value>" }}'
```

To delete all free-form tags:

```
dts job update --job-id <job_id> --freeform-tags '{}'
```

To delete all defined tags:

```
dts job update --job-id <job_id> --defined-tags '{}'
```

DELETING TRANSFER JOBS

Typically, you would delete a transfer job early in the transfer process and before you create any transfer packages or disks. For example, you initiated the data transfer by creating a transfer job, but changed your mind. If you want to delete a transfer job later in the transfer process, you must first delete all transfer packages and disks associated with the transfer job.

To delete a transfer job using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Object Storage** and click **Data Transfer**.
2. Find the data transfer job that you want to delete.
3. Click the Actions icon (three dots), and then click **Delete**.
   Alternatively, you can delete a transfer job from the **View Details** page.
4. Confirm the deletion when prompted.

To delete a transfer job using the Data Transfer Utility

At the command prompt on the Data Host, run `dts job delete` to delete a transfer job.

```
dts job delete --job-id <job_id>
```

CLOSING TRANSFER JOBS

Tip

You can use the Console or the Data Transfer Utility to close a transfer job.

Typically, you would close a transfer job when no further transfer job activity is required or possible. Closing a transfer job requires that the status of all associated transfer packages be returned, canceled, or deleted. In addition, the status of all associated transfer disks must be complete, in error, missing, canceled, or deleted.

To close a transfer job using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Object Storage** and click **Data Transfer**.
2. Find the data transfer package for which you want to display the details.
3. Click the Actions icon (three dots), and then click **View Details**.
   Alternatively, click the hyper-linked name of the transfer job.
4. Click **Close Transfer Job**.

To close a transfer job using the Data Transfer Utility

At the command prompt on the Data Host, run `dts job close` to close a transfer job.

```
dts job close --job-id <job_id>
```

Transfer Disks

The section describes the creation and management transfer disks.

Important

Before creating a transfer disk from an attached disk, remove all partitions and any file systems. To prevent the accidental deletion of data, the Data Transfer Utility does not work with disks that already have partitions or file systems. Disks are visible to the Data Host as block devices and must provide a valid response to the `hdparm -I <device>` Linux command.

CREATING TRANSFER DISKS

Tip

You can only use the Data Transfer Utility to create a transfer disk.

When you create a transfer disk, the Data Transfer Utility:

- Sets up the disk for encryption using the passphrase
- Creates a file system on the disk
- Mounts the file system at `/mnt/orcdts_<label>`

For example:

```
/mnt/orcdts_DJZNWK3ET
```

When you register a transfer disk, Oracle Cloud Infrastructure generates a strong encryption passphrase that is used to encrypt the transfer disk. The encryption passphrase is displayed to standard output to the data transfer administrator user and cannot be retrieved again. Create a local, secure copy of the encryption passphrase, so you can reference the passphrase again.

Creating a transfer disk requires the job ID returned from when you created the transfer job and the path to the attached disk (for example `/dev/sdb`).

To create a transfer disk using the Data Transfer Utility

At the command prompt on the Data Host, run `dts disk create` to create a transfer disk.

```
dts disk create --job-id <job_id> --block-device <block_device>
```

DELETING TRANSFER DISKS

Tip

You can only use the Data Transfer Utility to delete a transfer disk.

Typically, you would delete a transfer disk during the disk preparation process. You created, attached, and copied data to the transfer disk, but have changed your mind about shipping the disk. If you want to reuse the disk, remove all file systems and create the disk again.

To delete a transfer disk using the Data Transfer Utility

At the command prompt on the Data Host, run `dts disk delete` to delete a transfer disk.

```
dts disk delete --job-id <job_id> --disk-label <label>
```

CANCELING TRANSFER DISKS

Tip

You can only use the Data Transfer Utility to cancel a transfer disk.

If you shipped a disk to Oracle, but have changed your mind about uploading the files, you can cancel the transfer disk. You can cancel a disk in a transfer package, while allowing the file upload from other disks.

Oracle cannot process canceled transfer disks. Oracle returns canceled transfer disks to the sender.

To cancel a transfer disk using the Data Transfer Utility

At the command prompt on the Data Host, run `dts disk cancel` to cancel a transfer disk.

```
dts disk cancel --job-id <job_id> --disk-label <label>
```

LOCKING TRANSFER DISKS

Tip

You can only use the Data Transfer Utility to lock a transfer disk.

Locking a transfer disk safely unmounts the disk and removes the encryption passphrase from the Data Host.

To lock a transfer disk using the Data Transfer Utility

At the command prompt on the Data Host, run `dts disk lock` to lock a transfer disk.

```
dts disk lock --job-id <job_id> --disk-label <label> --block-device <block_device>
```

UNLOCKING TRANSFER DISKS

If you need to unlock the transfer disk, you are prompted for the encryption passphrase that was generated when you created the transfer disk.

To unlock a transfer disk using the Data Transfer Utility

At the command prompt on the Data Host, run `dts disk unlock` to unlock a transfer disk.

```
dts disk unlock --job-id <job_id> --disk-label <label> --block-device <block_device> --encryption-
passphrase <encryption_passphrase>
```

Transfer Packages

A transfer package is the virtual representation of the physical package of disks that you are shipping to Oracle for upload to Oracle Cloud Infrastructure.

Tip

You can use the Console or the Data Transfer Utility to create a transfer package.

CREATING TRANSFER PACKAGES

Creating a transfer package requires the job ID returned from when you created the transfer job. For example:

```
ocid1.datatransferjob.region1.phx..exampleuniqueID
```

To create a transfer package using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Object Storage** and click **Data Transfer**.
2. Find the transfer job for which you want to create a transfer package.
3. Click the Actions icon (three dots), and then click **View Details**.
   Alternatively, click the hyper-linked name of the transfer job.
   A list of transfer packages that have already been created is displayed.
4. Click **Create Transfer Package**.
5. In the **Create Transfer Package** dialog, choose the **Vendor**.
6. Click **Create Transfer Package**.

The Data Transfer Package dialog appears displaying information such as the shipping address, the shipping vendor, and the shipping status.

To create a transfer package using the Data Transfer Utility

At the command prompt on the Data Host, run `dts package create` to create a transfer package.

```
dts package create --job-id <job_id>
```

The following information is returned:

```
Transfer Package :
Label :
TransferSiteShippingAddress :
DeliveryVendor :
DeliveryTrackingNumber :
ReturnDeliveryTrackingNumber :
Status :
Devices :
```

DISPLAYING TRANSFER PACKAGE DETAILS

To display the details of a transfer package using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Object Storage** and click **Data Transfer**.
2. Find the transfer job for which you want to see the details.
3. Click the Actions icon (three dots), and then click **View Details**.
   Alternatively, click the hyper-linked name of the transfer job.
   A list of transfer packages that have already been created is displayed.

To display the details of a transfer package using the Data Transfer Utility

At the command prompt on the Data Host, run `dts package show` to display the details of a transfer package.

```
dts package show --job-id <job_id> --package-label <package_label>
```

The following information is returned:

```
Transfer Package :
Label :
TransferSiteShippingAddress :
DeliveryVendor :
DeliveryTrackingNumber :
```

```
ReturnDeliveryTrackingNumber :
Status :
Devices :
```

EDITING TRANSFER PACKAGES

Edit the transfer package and supply the tracking information when you ship the package.

To edit a transfer package using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Object Storage** and click **Data Transfer**.
2. Find the transfer job for which you want to see the associated transfer packages.
3. Click the Actions icon (three dots), and then click **View Details**.
4. Find the transfer package that you want to edit.
5. Click the Actions icon (three dots), and then click **View Details**.
6. Click **Edit**.
   Change the vendor and supply the tracking information as needed.
7. Click **Edit Transfer Package**.

To edit a transfer package using the Data Transfer Utility

At the command prompt on the Data Host, run `dts package update` to edit the details of a transfer package.

```
dts package update --job-id <job_id> --package-label <package_label> [--package-vendor <vendor_name>]
[--tracking-number <tracking_number>] [--return-tracking-number <return_tracking_number>]
```

DELETING TRANSFER PACKAGES

Typically, you would delete a transfer package early in the transfer process and before you created any transfer disks. You initiated the transfer job and package, but have changed your mind. If you delete a transfer package later in the transfer process, you must first detach all

associated transfer disks. You cannot delete a transfer package once the package has been shipped to Oracle.

To delete a transfer package using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Object Storage** and click **Data Transfer**.
2. Find the transfer job for which you want to see the associated transfer packages.
3. Click the Actions icon (three dots), and then click **View Details**.
4. Find the transfer package that you want to edit.
5. Click the Actions icon (three dots), and then click **View Details**.
6. Click **Edit**.
   Change the vendor and supply the tracking information as needed.
7. Click **Edit Transfer Package**.

To delete a transfer package using the Data Transfer Utility

At the command prompt on the Data Host, run `dts package delete` to delete a transfer package.

```
dts package delete --job-id <job_id> --package-label <package_label>
```

Canceling Transfer Packages

If you shipped a transfer package, but have changed your mind about uploading the data, you can cancel a transfer package. Before canceling a transfer package, you must first cancel all transfer disks associated with that transfer package. Oracle cannot process canceled transfer packages. Oracle returns canceled transfer packages to the sender.

To cancel a transfer package using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Object Storage** and

click **Data Transfer**.

2. Find the transfer job for which you want to see associated transfer packages.
3. Click the Actions icon (three dots), and then click **View Details**.
4. Find the transfer package that you want to cancel.
5. Click the Actions icon (three dots), and then click **View Details**.
6. Click **Cancel Transfer Package**.

To cancel a transfer package using the Data Transfer Utility

At the command prompt on the Data Host, run `dts package cancel` to cancel a transfer package.

```
dts package cancel --job-id <job_id> --package-label <package_label>
```

Attaching Transfer Disks to a Transfer Package

Tip

You can use the Console or the Data Transfer Utility to attach a transfer disk to a transfer package.

Attach a transfer disk to a transfer package after you have done the following tasks in order:

- Copied your data onto the disk
- Generated the required manifest file
- Run and reviewed the dry-run report
- Locked the transfer disk in preparation for shipment

A disk can be attached to one package, detached, and then attached to another package.

To attach a transfer disk to a transfer package using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Object Storage** and click **Data Transfer**.
2. Find the transfer job associated with the transfer package that you want to attach a disk to.
3. Click the Actions icon (three dots), and then click **View Details**.
   A list of transfer packages is displayed.
4. Find the transfer package that you want to attach a disk to.
5. Click the Actions icon (three dots), and then click **View Details**.
   Alternatively, click the hyper-linked name of the transfer package.
   A list of transfer disks is displayed.
6. Click **Attach Transfer Disks**.
7. In the **Attach Transfer Disk** dialog, select the **Transfer Disks** that you want to attach to the transfer package.
8. Click **Attach**.

To attach a transfer disk to a transfer package using the Data Transfer Utility

At the command prompt on the Data Host, run `dts disk attach` to attach a disk to a transfer package.

```
dts disk attach --job-id <job_id> --package-label <package_label> --disk-label <label>
```

You have attached a transfer disk to a transfer package, but have changed your mind about shipping that disk with the transfer package. You can also detach a transfer disk from one transfer package and attach that disk to a different transfer package.

To detach a transfer disk to a transfer package using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Object Storage** and

click **Data Transfer**.

2. Find the transfer package for which you want to detach a transfer disk.
3. Click the Actions icon (three dots), and then click **View Details**.
   Alternatively, click the hyper-linked name of the transfer package.
   A list of transfer disks that have already been attached is displayed.
4. Find the transfer disk that you want to detach.
5. Click the Actions icon (three dots), and then click **View Details**.
   Alternatively, click the hyper-linked name of the transfer disk.
6. Click **Detach Transfer Disk**.

To detach a transfer disk to a transfer package using the Data Transfer Utility

At the command prompt on the host, run `dts disk detach` to detach a disk from a transfer package.

```
dts disk detach --job-id <job_id> --package-label <package_label> --disk-label <label>
```

Appliance Data Transfer

Appliance-Based Data Transfer is one of Oracle's offline data transfer solutions that lets you migrate petabyte-scale datasets to Oracle Cloud Infrastructure. You send your data as files on one or more secure, high-capacity, Oracle-supplied storage appliances to an Oracle transfer site. Operators at the Oracle transfer site upload the files into the designated Object Storage bucket in your tenancy. You are then free to move the uploaded data to other Oracle Cloud Infrastructure services as needed.

Note

Appliance-Based Data Transfer is not available for free trial or Pay As You Go accounts.

Appliance-Based Data Transfer Concepts

The following concepts are essential to understanding Appliance-Based Data Transfer.

TRANSFER JOB

A transfer job is the logical representation of a data migration to Oracle Cloud Infrastructure. A transfer job is associated with one or more appliances.

APPLIANCE

An appliance is high storage capacity device that is specially prepared to copy and upload data to Oracle Cloud Infrastructure. You request an appliance from Oracle, copy your data to the appliance, and then ship the appliance back to Oracle to upload your data.

COMMAND LINE INTERFACE

The command line interface (CLI) is a small footprint tool that you can use on its own or with the Console to complete Oracle Cloud Infrastructure tasks, including Appliance-Based Data Transfer jobs.

Note

You can only run Oracle Cloud Infrastructure CLI commands from a Linux host. This differs from running CLI commands for other Oracle Cloud Infrastructure Services on a variety of host operating systems. Appliance-based commands require validation that is only available on Linux hosts.

HOST

A physical computer on which one or more of the logical hosts (Control, Data, Terminal Emulation) is running. Depending on your computing environment, you can have a separate physical host for each logical host, consolidate all three logical hosts onto a single physical host, or have two logical hosts on one physical host and the thir logical

host on a separate physical host. All physical hosts much be on network used for the data transfer.

CONTROL HOST

The logical representation of the host computer at your site from which you perform Data Transfer Service tasks. Depending on your needs, you may use one or more separate hosts (Control and Data) to run your Appliance-Based Data Transferjob.

DATA HOST

The logical representation of the host computer on your site that stores the data you intend to copy to Oracle Cloud Infrastructure.

TERMINAL EMULATION HOST

The logical representation of the host computer that uses terminal emulation software to communicate with, and allow you to command, the appliance.

BUCKET

The logical container in Oracle Cloud Infrastructure Object Storage where Oracle operators upload your data. A bucket is associated with a single compartment in your tenancy that has policies that determine what actions a user can perform on a bucket and on all the objects in the bucket.

DATA TRANSFER ADMINISTRATOR

A new or existing IAM user that has the authorization and permissions to create and manage transfer jobs.

DATA TRANSFER UPLOAD USER

A temporary IAM user that grants Oracle personnel the authorization and permissions to upload the data from the appliance to your designated Oracle Cloud Infrastructure Object Storage bucket. Delete this temporary user after your data is uploaded to Oracle Cloud Infrastructure.

APPLIANCE MANAGEMENT SERVICE

Software running on the appliance that provides management functions. Users interact with this service though the Oracle Cloud Infrastructure CLI.

Appliance Specifications

Use NFS versions 3, 4, or 4.1 to copy your data onto the appliance. Here are some details about the appliance:

Item Description	Specification
Storage Capacity	150 TB of protected usable space
Network Interfaces	- 10 GbE - RJ45 - 10 GbE - SFP+ You are responsible for providing all network cables. If you want to use SFP+, your transceivers must be compatible with Intel X520 NICs.
Provided Cables	- NEMA 5–15 type B to C13 - C13 - 14 power - USB - DB9 serial
Environmental	- Operational temperature: 50–95°F (10–35°C) - Operational relative humidity: 8–90% non-condensing - Acoustics: < 75 dB @ 73°F (23° C) - Operational altitude: -1,000 ft - 10,000 ft (approx. -300–3048 m))

Item Description	Specification
Power	- Consumption: 554 W - Voltage: 100–240 VAC - Frequency: 47–63 Hz - Conversion efficiency: 89%
Weight	- Unit: 38 lbs (approx. 17 kg) - Unit + Transit Case: 64 lbs (approx. 29 kg)
Height	3.5" (approx. 9 cm) (2U)
Width	17" (approx. 43 cm)
Depth	24" (approx. 61 cm)
Shipping Case	11" x 25" x 28" (approx. 28 x 63.5 x 71 cm)

Roles and Responsibilities

Depending on your organization, the responsibilities of using and managing the data transfer may span multiple roles. Use the following set of roles as a guideline for how you can assign the various tasks associated with the data transfer.

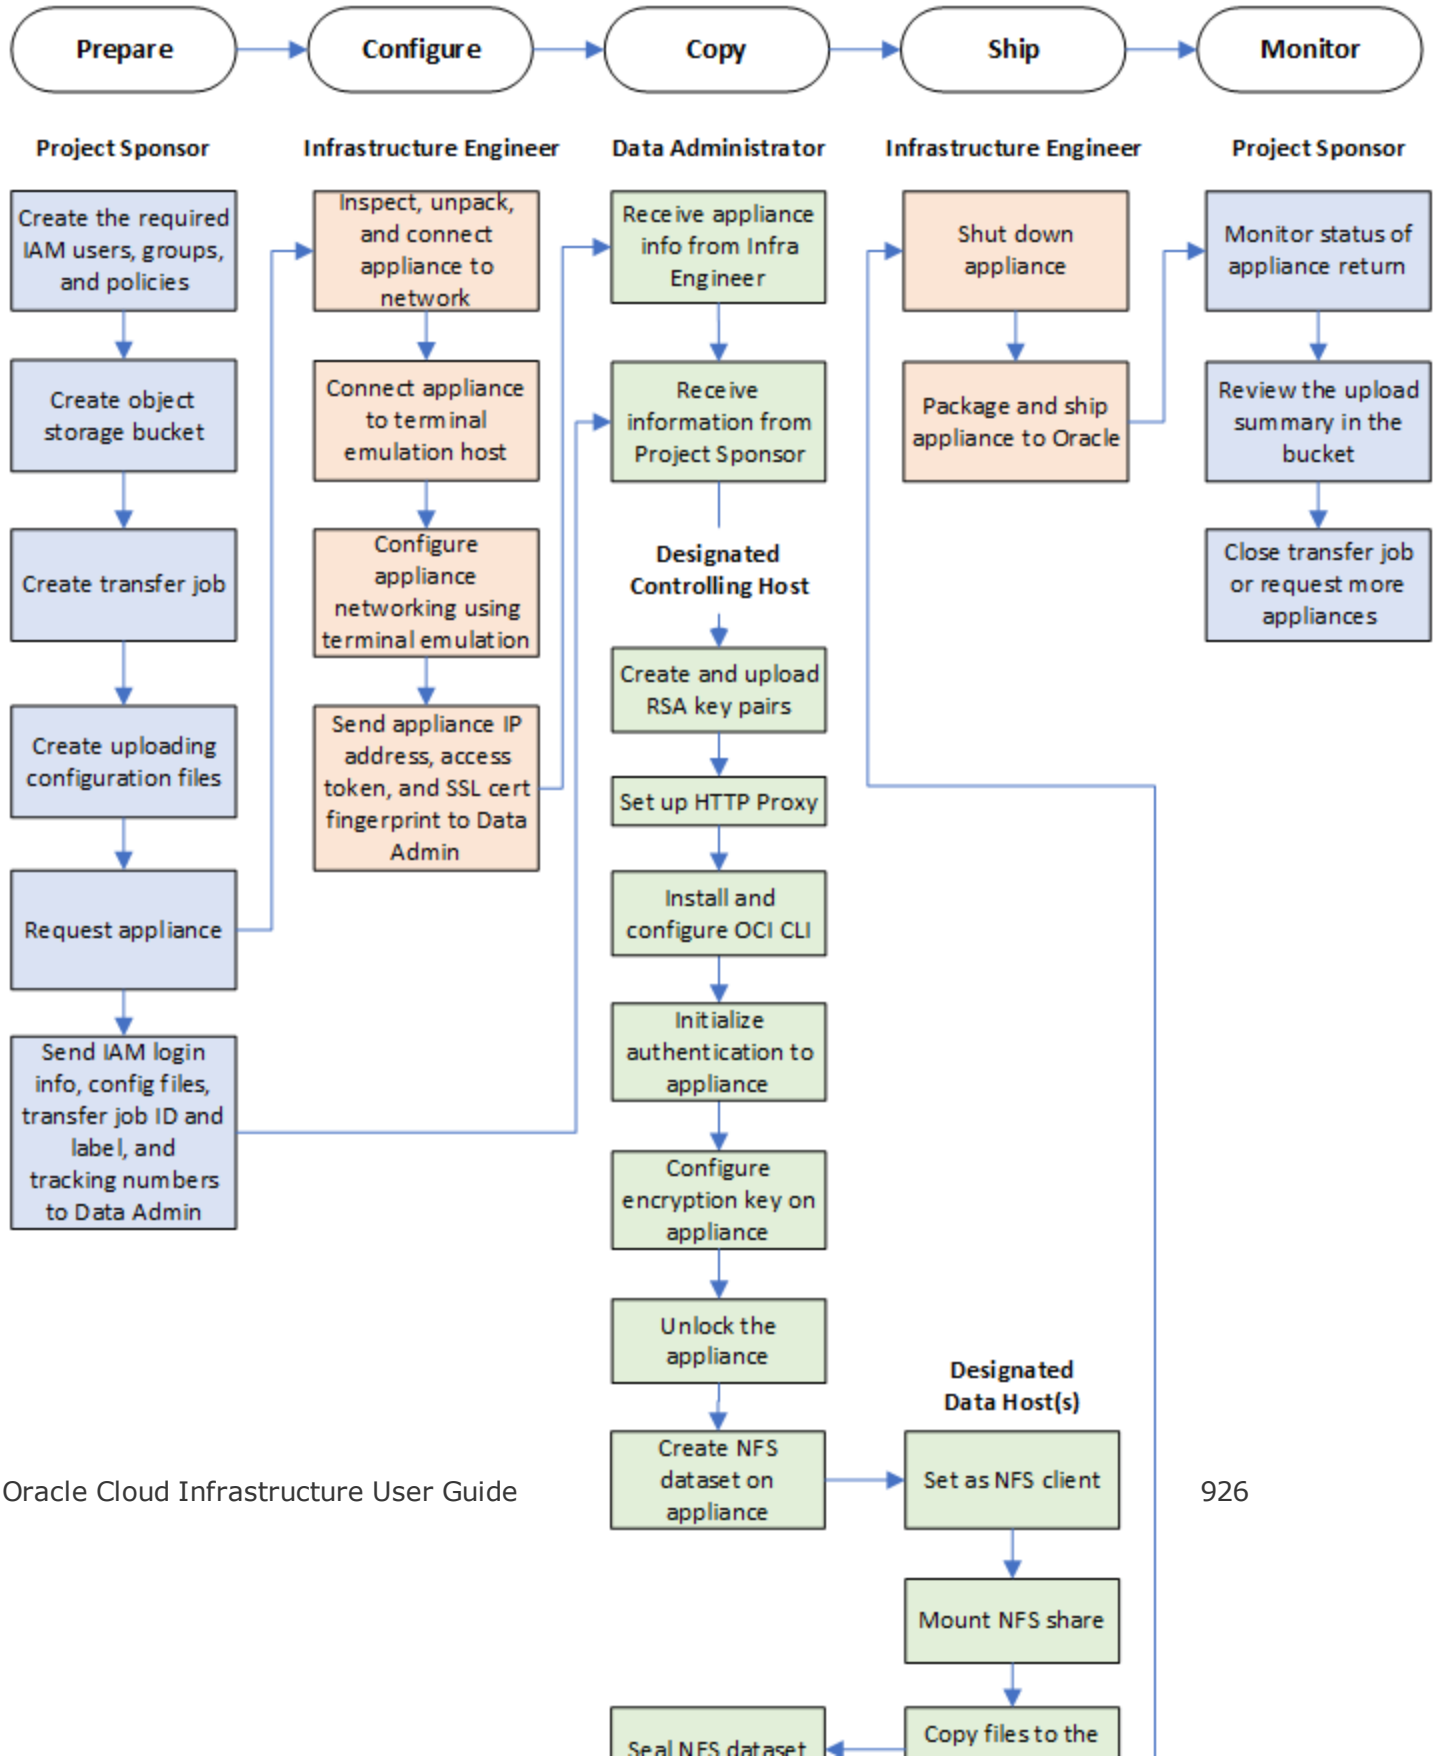
- **Project Sponsor:** Responsible for the overall success of the data transfer. Project Sponsors usually have complete access to their organization's Oracle Cloud Infrastructure tenancy. They coordinate with the other roles in the organization to complete the implementation of data transfer project.
- **Infrastructure Engineer:** Responsible for integrating the transfer appliance into the organization's IT infrastructure from where the data is being transferred. Tasks associated with this role include connecting the transfer appliance to power, placing it within the network, and setting the IP address through a serial console menu using the provided USB-to-Serial adapter.

- **Data Administrator:** Responsible for identifying and preparing the data to be transferred to Oracle Cloud Infrastructure. This person usually has access to, and expertise with, the data being migrated.

These roles correspond to the various phases of the data transfer described in the following section. A specific role can be responsible for one or more phases.

Task Flow for Appliance-Based Data Transfer

Here is a high-level overview of the tasks involved in the Appliance-Based Data Transfer to Oracle Cloud Infrastructure using organized by phase. Complete one phase before proceeding to the next one. Use the roles previously described to distribute the tasks across individuals or groups within your organization.



Prepare
Configure
Copy
Ship
Monitor
Project Sponsor
Infrastructure Engineer
Data Administrator
Infrastructure Engineer
Project Sponsor
Create the required IAM users, groups, and policies
Create object storage bucket
Create transfer job
Create uploading configuration files
Request appliance
Send IAM login info, config files, transfer job ID and label, and tracking numbers to Data Admin
Inspect, unpack, and connect appliance to network
Connect appliance to terminal emulation host
Configure appliance networking using terminal emulation
Send appliance IP address, access token, and SSL cert fingerprint to Data Admin
Receive appliance info from Infra Engineer
Receive information from Project Sponsor
Designated Controlling Host
Create and upload RSA key pairs
Set up HTTP Proxy
Install and configure OCI CLI
Initialize authentication to appliance
Configure encryption key on appliance
Unlock the appliance
Create NFS dataset on appliance
Designated Data Host(s)
Set as NFS client
Mount NFS share
Copy files to the
Seal NFS dataset
Shut down appliance
Package and ship appliance to Oracle
Monitor status of appliance return
Review the upload summary in the bucket
Close transfer job or request more appliances

Secure Appliance Data Transfer to Oracle Cloud Infrastructure

This section highlights the security details of the Data Transfer Appliance process.

- Appliances are shipped from Oracle to you with a tamper-evident security tie on the transit case. A second tamper-evident security tie is included in the appliance transit case for you to secure the case when you ship the case back to Oracle. The number on the physical security ties must match the numbers logged by Oracle in the appliance details.
- When you configure the appliance for the first time:
    - The appliance generates a master AES-256 bit encryption key that is used for all data written to or read from the device. The encryption key never leaves the device.
    - The encryption key is protected by an encryption passphrase that you must know to access the encrypted data. The system securely fetches a provided encryption passphrase from Oracle Cloud Infrastructure and registers that passphrase on the appliance.

Note

The encryption passphrase is never stored on the appliance

- All data is encrypted as the data is copied to an appliance.
- For more security, you can also encrypt your own data with your own encryption keys. Before copying your data to the transfer appliance, you can encrypt your data with a tool and encryption key of your choosing. After the data has been uploaded, you would need to use the same tool and encryption key to access the data.
- All network communication between your appliance-based data transfer environment and Oracle Cloud Infrastructure is encrypted in-transit using Transport Layer Security (TLS).

- After copying your data to a transfer appliance, the data transfer system generates a manifest file. The manifest contains an index of all of the copied files and generated data integrity hashes. The system also encrypts and copies the `config_upload_user` configuration file to the transfer appliance. This configuration file describes the temporary IAM data transfer upload user. Oracle uses the credentials and entries defined in the `config_upload_user` file when processing the transfer appliance and uploading files to Oracle Cloud Infrastructure Object Storage.

  Note

  Data Transfer Service Does Not Support Passphrases on Private Keys

  While we recommend encrypting a private key with a passphrase when generating API signing keys, the Data Transfer Service does not support passphrases on the key file required for the `config_upload_user` configuration file. If you use a passphrase, Oracle personnel cannot upload your data.

  Oracle cannot upload data from a transfer appliance without the correct credentials defined in this configuration file. See Preparing Upload Configuration Files for more information about the required configuration files.

- Oracle erases all of your data from the transfer appliance after it has been processed. The erasure process follows the NIST 800-88 standards.
- Keep possession of the security tie after you have finished unpacking and connecting the appliance. Include it when returning the appliance to Oracle. Failure to include the security tie can result in a delay in the data migration process.

Preparing for Appliance Data Transfers

This topic describes the tasks associated with preparing for the Appliance-Based Data Transfer. The Project Sponsor role typically performs these tasks. See Roles and Responsibilities.

Note

You can only run Oracle Cloud Infrastructure CLI commands from a Linux host. This differs from running CLI commands for other Oracle Cloud Infrastructure Services on a variety of host operating systems. Appliance-based commands require validation that is only available on Linux hosts.

Creating the Required IAM Users, Groups, and Policies

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization.

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

Access to resources is provided to groups using policies and then inherited by the users that are assigned to those groups. Data transfer requires the creation of two distinct groups:

- Data transfer *administrators* who can create and manage transfer jobs.
- Data transfer *upload users* who can upload data to Object Storage. For your data security, the permissions for upload users allow Oracle personnel to upload standard and multi-part objects on your behalf and inspect bucket and object metadata. The permissions do not allow Oracle personnel to inspect the actual data.

The Data Administrator is responsible for generating the required RSA keys needed for the temporary upload users. These keys should never be shared between users.

For details on creating groups, see Managing Groups.

An administrator creates these groups with the following policies:

- The data transfer administrator group requires an authorization policy that includes the following:

```
Allow group <group_name> to manage data-transfer-jobs in compartment <compartment_name>
```

```
Allow group <group_name> to manage buckets in compartment <compartment_name>
```

```
Allow group <group_name> to manage objects in compartment <compartment_name>
```

  Alternatively, you can consolidate the `manage buckets` and `manage objects` policies into the following:

```
Allow group <group_name> to manage object-family in compartment <compartment_name>
```

- The data transfer upload user group requires an authorization policy that includes the following:

```
Allow group <group_name> to manage buckets in compartment <compartment_name> where all {
request.permission='BUCKET_READ' }
```

```
Allow group <group_name> to manage objects in compartment <compartment_name> where any {
request.permission='OBJECT_CREATE' , request.permission='OBJECT_OVERWRITE' ,
request.permission='OBJECT_INSPECT' }
```

Important

For security reasons, we recommend that you create a unique IAM data transfer upload user for each transfer job and then delete that user once your data is uploaded to Oracle Cloud Infrastructure.

The Oracle Cloud Infrastructure administrator then adds a user to each of the data transfer groups created. For details on creating users, see Managing Users.

REQUESTING THE DATA TRANSFER APPLIANCE ENTITLEMENT

If your tenancy has not been entitled to perform Appliance-Based Data Transfers, you are required to request it before creating an appliance-based transfer job. The Data Transfer Appliance Entitlement is a tenancy-wide entitlement that you need to request once for each tenancy.

Use the following policy to enable users in a specific group to request a Data Transfer Appliance Entitlement in your tenancy.

```
Allow group <group_name> to {DTA_ENTITLEMENT_CREATE} in tenancy
```

Creating Object Storage Buckets

The Object Storage service is used to upload your data to Oracle Cloud Infrastructure. Object Storage stores objects in a container called a bucket within a compartment in your tenancy. For details on creating the bucket to store uploaded data, see Managing Buckets.

Creating Transfer Jobs

This section describes how to create a transfer job as part of the preparation for the data transfer. See Transfer Jobs for complete details on all tasks related to transfer jobs.

Tip

You can use the Console or the Oracle Cloud Infrastructure CLI to create a transfer job.

A transfer job represents the collection of files that you want to transfer and signals the intention to upload those files to Oracle Cloud Infrastructure. Identify which compartment and Object Storage bucket that Oracle is to upload your data to. Create the transfer job in the same compartment as the upload bucket and supply a human-readable name for the transfer job. Avoid entering confidential information when providing transfer job names.

Note

It is recommended that you create a compartment for each transfer job to minimize the required access your tenancy.

Creating a transfer job returns a job ID that you specify in other transfer tasks. For example:

```
ocid1.datatransferjob.region1.phx..<unique_ID>
```

To create a transfer job using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Object Storage** and click **Data Transfer**.
2. Select the designated compartment you are to use for data transfers from the drop-down list.
   A list of transfer jobs that have already been created is displayed.
3. Click **Create Transfer Job**.
4. In the **Create Transfer Job** dialog, enter a **Job Name**, and select the **Upload Bucket** from the drop-down list.
   Avoid entering confidential information in the transfer job name.
5. Select **Appliance** for the **Transfer Device Type**.
6. Click **Create Transfer Job**.

To create a transfer job using the CLI

At the command prompt on the Control Host, run `dts job create` to create a transfer job. The *<display_name>* is the name of the transfer job. Avoid entering confidential information in the transfer job name.

```
oci dts job create --bucket <bucket_name> --compartment-id <compartment_id> --display-name <display_
name> --device-type appliance
```

Optionally, you can specify one or more free-form or defined tags when you create a transfer job. For more information about tagging, see Resource Tags.

To specify free-form tags when creating a job:

```
oci dts job create --bucket <bucket_name> --compartment-id <compartment_id> --display-name <display_
name> --device-type appliance --freeform-tags '{ "<tag_key>":"<value>" }'
```

To specify defined tags when creating a job:

```
oci dts job create --bucket <bucket_name> --compartment-id <compartment_id> --display-name <display_
name> --device-type appliance --defined-tags '{ "<tag_namespace>": { "<tag_key>":"<value>" }}'
```

Note

Users with the required permissions create tag namespaces and tag keys. Namespaces and keys must be present before you can specify them when creating a job. See Working with Defined Tags for details.

To specify multiple tags, comma separate the JSON-formatted key/value pairs:

```
oci dts job create --bucket <bucket_name> --compartment-id <compartment_id> --display-name <display_
name> --device-type appliance --freeform-tags '{ "<tag_key>":"<value>", "<tag_key>":"<value>" }'
```

REQUESTING THE DATA TRANSFER APPLIANCE ENTITLEMENT

Tip

You can use the Console or the Oracle Cloud Infrastructure CLI to request the Data Transfer Appliance Entitlement.

If your tenancy is not entitled to use the Data Transfer Appliance, you must request the Data Transfer Appliance Entitlement before creating an appliance-based transfer job.

To request the Data Transfer Appliance Entitlement using the Console

Open the Transfer Job page and click **Request** at the top. Otherwise, you are prompted to request the entitlement when attempting to create your first appliance-based transfer job.

Once requested, the status of your request is visible at the top of the Transfer Job page. It can take a while to get the Data Transfer Appliance Entitlement approved. After Oracle receives your request, a Terms and Conditions Agreement is sent to the account owner via DocuSign to use the appliance. The entitlement request is approved once the signature is received. The Data Transfer Appliance Entitlement is a tenancy-wide entitlement that you need to request once for each tenancy.

To request the Data Transfer Appliance Entitlement using the CLI

```
oci dts appliance request-entitlement --compartment-id <compartment_id> --profile <profile> --name
<your name> --email <your_email>
```

```
oci dts appliance show-entitlement --compartment-id <compartment_id> --profile <profile>
```

Preparing Upload Configuration Files

The Project Sponsor is responsible for creating or obtaining configuration files that allow the uploading of user data to the transfer appliance. Send these configuration files to the Data Administrator where they can be placed in the Control Host (if there are separate Control and Data Hosts).The `config` file is for the data transfer administrator, the IAM user with the authorization and permissions to create and manage transfer jobs. The `config_upload_user` file is for the data transfer upload user, the temporary IAM user that Oracle uses to upload your data on your behalf.

Create a base Oracle Cloud Infrastructure directory and two configuration files with the required credentials.

Creating the Data Transfer Directory

Create a Oracle Cloud Infrastructure directory (`.oci`) on the same Control Host machine where the Oracle Cloud Infrastructure CLI is installed. For example:

```
mkdir /root/.oci/
```

The two configuration files (`config` and `config_upload_user`) are placed in what ever location you choose.

Note

You can store the configuration files anywhere on your Control Host. The `root` directory is only given as an example.

CREATING THE DATA TRANSFER ADMINISTRATOR CONFIGURATION FILE

Create the data transfer administrator configuration file `/root/.oci/config` with the following structure:

```
[DEFAULT]
user=<The OCID for the data transfer administrator>
fingerprint=<The fingerprint of the above user's public key>
key_file=<The _absolute_ path to the above user's private key file on the host machine>
tenancy=<The OCID for the tenancy that owns the data transfer job and bucket>
region=<The region where the transfer job and bucket should exist. Valid values are:
us-ashburn-1, us-phoenix-1, eu-frankfurt-1, and uk-london-1.>
```

For example:

```
[DEFAULT]
user=ocid1.user.oc1..<unique_ID>
fingerprint=4c:1a:6f:a1:5b:9e:58:45:f7:53:43:1f:51:0f:d8:45
key_file=/home/user/ocid1.user.oc1..exampleuniqueID.pem
tenancy=ocid1.tenancy.oc1..<unique_ID>
region=us-phoenix-1
```

For the data transfer administrator, you can create a single configuration file that contains different profile sections with the credentials for multiple users. Then use the `--profile` option to specify which profile to use in the command. Here is an example of a data transfer administrator configuration file with different profile sections:

```
[DEFAULT]
user=ocid1.user.oc1..exampleuniqueID
fingerprint=4c:1a:6f:a1:5b:9e:58:45:f7:53:43:1f:51:0f:d8:45
key_file=/home/user/ocid1.user.oc1..exampleuniqueID.pem
tenancy=ocid1.tenancy.oc1..exampleuniqueID
region=us-phoenix-1
[PROFILE1]
```

```
user=ocid1.user.oc1..exampleuniqueID
fingerprint=4c:1a:6f:a1:5b:9e:58:45:f7:53:43:1f:51:0f:d8:45
key_file=/home/user/ocid1.user.oc1..exampleuniqueID.pem
tenancy=ocid1.tenancy.oc1..exampleuniqueID
region=us-ashburn-1
```

Important

Creating an upload user configuration file with multiple profiles is *not* supported.

By default, the `DEFAULT` profile is used for all CLI commands. For example:

```
oci dts job create --compartment-id ocid.compartment.oc1..exampleuniqueID --bucket MyBucket --display-
name MyDisplay --device-type appliance
```

Instead, you can issue any CLI command with the `--profile` option to specify a different data transfer administrator profile. For example:

```
oci dts job create --compartment-id ocid.compartment.oc1..exampleuniqueID --bucket MyBucket --display-
name MyDisplay --device-type appliance --profile MyProfile
```

Using the example configuration file above, the *<profile_name>* would be `profile1`.

If you created two separate configuration files, use the following command to specify the configuration file to use:

```
oci dts job create --compartment-id <compartment_id> --bucket <bucket_name> --display-name <display_
name>
```

CREATING THE DATA TRANSFER UPLOAD USER CONFIGURATION FILE

The `config_upload_user` configuration file is for the data transfer upload user, the temporary IAM user that Oracle uses to upload your data on your behalf. Create this configuration file with the following structure:

```
[DEFAULT]
user=<The OCID for the data transfer upload user>
fingerprint=<The fingerprint of the above user's public key>
key_file=<The _absolute_ path to the above user's private key file on the host machine>
tenancy=<The OCID for the tenancy that owns the data transfer job and bucket>
region=<The region where the transfer job and bucket should exist. Valid values are:
us-ashburn-1, us-phoenix-1, eu-frankfurt-1, and uk-london-1.>
```

For example:

```
[DEFAULT]
user=ocid1.user.oc1..exampleuniqueID
fingerprint=4c:1a:6f:a1:5b:9e:58:45:f7:53:43:1f:51:0f:d8:45
key_file=/home/user/ocid1.user.oc1..exampleuniqueID.pem
tenancy=ocid1.tenancy.oc1..exampleuniqueID
region=us-phoenix-1
```

CONFIGURATION FILE ENTRIES

The following table lists the basic entries that are required for each configuration file and where to get the information for each entry.

Note

Data Transfer Service does not support passphrases on the key files for both data transfer administrator and data transfer upload user.

Entry	Description and Where to Get the Value	Required?
`user`	OCID of the data transfer administrator or the data transfer upload user, depending on which profile you are creating. To get the value, see Required Keys and OCIDs.	Yes
`fingerprint`	Fingerprint for the key pair being used. To get the value, see Required Keys and OCIDs.	Yes
`key_file`	Full path and filename of the private key. **Important:** The key pair must be in PEM format. For instructions on generating a key pair in PEM format, see Required Keys and OCIDs.	Yes

Entry	Description and Where to Get the Value	Required?
`tenancy`	OCID of your tenancy. To get the value, see Required Keys and OCIDs.	Yes
`region`	An Oracle Cloud Infrastructure region. See Regions and Availability Domains. Data transfer is supported in `US East (Ashburn)`, `US West (Phoenix)`, `Germany Central (Frankfurt)`, and `UK South (London)`.	Yes

You can verify the data transfer upload user credentials using the following command:

```
oci dts job verify-upload-user-credentials --bucket <bucket_name>
```

Requesting the Transfer Appliance

This section describes how to request a transfer appliance from Oracle for copying your data to Oracle Cloud Infrastructure See Appliances for complete details on all tasks related to transfer jobs.

Tip

You can use the Console or the Oracle Cloud Infrastructure CLI to request a transfer appliance.

Oracle Cloud Infrastructure customers can use data transfer appliances to migrate data for free. You are only charged for Object Storage usage once the data is successfully transferred to your designated bucket. All appliance requests still require approval from Oracle.

Tip

We recommend that you identify the data you intend to upload and make data copy preparations before requesting the transfer appliance.

Creating a transfer appliance request returns an Oracle-assigned appliance label. For example:

```
XA8XM27EVH
```

To request a transfer appliance using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Object Storage** and click **Data Transfer**.
   Choose the transfer job that you want to request a transfer appliance for.
2. Under **Transfer Appliances**, click **Request Transfer Appliance**.
3. In the **Request Transfer Appliance** dialog box, provide the shipping address details where you want the appliance sent.
   - **Company Name:** Required. Specify the name of the company that owns the data being migrated to Oracle Cloud Infrastructure.
   - **Recipient Name:** Required. Specify the name of the recipient to send the appliance to.
   - **Recipient Phone Number:** Required. Specify the recipient's phone number.
   - **Recipient Email Address:** Required. Specify the recipient's email address.
   - **Care Of:** Optional intermediary party responsible for transferring the appliance shipment from the delivery vendor to the intended recipient.
   - **Address Line 1:** Required. Specify the street address to send the appliance to.
   - **Address Line 2:** Optional identifying address details like building, suite, unit, or floor information.

- **City/Locality:** Required. Specify the city or locality.
- **State/Province/Region:** Required. Specify the state, province, or region.
- **Zip/Postal Code:** Specify the zip code or postal code.
- **Country:** Required. Select the country.

4. Click **Request Transfer Appliance**.

To request a transfer appliance using the CLI

At the command prompt on the Control Host, run `oci dts appliance request` to request a data transfer appliance.

Here are the minimum requirements for the transfer appliance request:

```
oci dts appliance request --job-id <job_id> --addressee <addressee> --address1 <address_line1> --city-
or-locality <city_or_locality> --state-or-region <state_or_region>--country<country>--zip-code<zip>
```

In addition, you can specify these optional fields in the request:

```
--care-of <care_of>
--address2 <address_line2>, --address3 <address_line3>, and --address4 <address_line4>
--email <email_address>
--phone-number <phone_number>
--profile <profile>
```

When you submit an appliance request, Oracle generates a unique label (name) to identify the transfer appliance and your request is sent to Oracle for approval and processing.

Notifying the Data Administrator

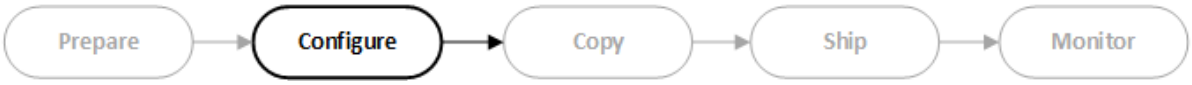
When you have completed all the tasks in this topic, provide the Data Administrator of the following:

- IAM login credentials
- Oracle Cloud Infrastructure CLI configuration files
- Transfer job ID
- Transfer job label

What's Next

You are now ready to configure your system for the data transfer. See Configuring Appliance Data Transfers.

Configuring Appliance Data Transfers



This topic describes the tasks associated with configuring the Appliance-Based Data Transfer. The Infrastructure Engineer role typically performs these tasks. See Roles and Responsibilities.

Unpacking and Connecting the Appliance to the Network

When the shipping vendor delivers your transfer appliance, Oracle updates the status as **Delivered** and provides the date and time the appliance was received in the **Transfer Appliance Details**.

> **Important**
>
> Your transfer appliance arrives in a transit case with a telescoping handle and wheels. The case amenities allow for easy movement to the location where you intend to place the appliance to upload your data.
>
> **Retain all packaging materials!** When shipping the transfer appliance back to Oracle, you must package the appliance in the same manner and packaging in which the appliance was received.

Here are the tasks involved in unpacking and getting your transfer appliance ready to configure.

1. Inspect the tamper-evident security tie on the transit case.
   If the appliance was tampered with during transit, the tamper-evident security tie serves to alert you.

   Warning

   If the security tie is damaged or is missing, do not plug the appliance into your network! Immediately file a Service Request (SR).

2. Remove and compare the number on the security tie with the number logged by Oracle.

To see the security tie number logged by Oracle using the Console

a. Open the navigation menu. Under **Core Infrastructure**, go to **Object Storage** and click **Data Transfer**.
b. Find the transfer job and transfer appliance associated with the removed security tie.
c. Click the **Actions** icon (•••), and then click **View Details**.
d. Look at the contents of the **Send Security Tie ID** field in the **Transfer Appliance Details** and compare that number with the number on the physical tag.

To see the security tie number logged by Oracle using the CLI

At the command prompt on the Control Host, run `oci dts appliance show` to delete a transfer appliance.

```
oci dts appliance show --job-id <job_id> --appliance-label <label>
```

Warning

If the number on the physical security tie does not match the number logged by Oracle, do not plug the appliance into your network! Immediately file a Service Request (SR).

Note

Keep possession of the security tie after you have finished unpacking and connecting the appliance. Include it when returning the appliance to Oracle. Failure to include the security tie can result in a delay in the data migration process.

3. Open the transit case and ensure that the case contains the following items:
    - Appliance unit and power cable (two types of power cables provided: C14 and C13 to 14)
    - USB to DB-9 serial cable
    - Return shipping instructions (retain these instructions)
    - Return shipping label, label sleeve, tie-on tag, and zip tie
    - Return shipment tamper-evident security tie (use this tie to ensure secure transit case back to Oracle)
4. Compare the number on the return shipment security tie with the number logged by Oracle.

To see the security tie number logged by Oracle using the Console

a. Open the navigation menu. Under **Core Infrastructure**, go to **Object Storage** and click **Data Transfer**.

b. Find the transfer job and transfer appliance associated with the return shipment security tie.

c. Click the Actions icon (three dots), and then click **View Details**.

d. Look at the contents of the **Return Security Tie ID** field in the **Transfer Appliance Details** and compare that number with the number on the physical tag.

To see the security tie number logged by Oracle using the CLI

At the command prompt on the Control Host, run `oci dts appliance show` to the security tie number associated with the transfer appliance.

```
oci dts appliance show --job-id <job_id> --appliance-label <label>
```

Warning

If the number on the return security tie does not match the number logged by Oracle, file a Service Request (SR). These security tie numbers must match or Oracle cannot upload data from your returned transfer appliance.

5. Remove the transfer appliance from the case and place the appliance on a solid surface or in a rack.

Warning

We recommend assistance lifting the transfer appliance out of the transit case and placing the appliance in a rack or on a desk top. The total shipping weight is about 64 lbs (29.0299 kg) and appliance weight is 38 lbs (17.2365 kg).

6. Connect the appliance to your local network using one of the following:
   - 10GBase-T: Standard RJ-45
   - SFP+: The transceiver must be compatible with Intel X520 NICs.
7. Attach one of the provided power cords to the appliance and plug the other end into a grounded power source.
8. Turn on the appliance by flipping the power switch on the back of the appliance.

Connecting the Appliance to the Terminal Emulation Host

Connect the appliance to your designated Terminal Emulation Host computer using the provided USB to DB-9 serial cable.

Note

You might need to download the driver for this cable on your Terminal Emulation Host: https://www.cablestogo.com/product/26887/5ft-usb-to-db9-male-serial-rs232-adapter-cable#support

Setting Up Terminal Emulation

Appliance-based transfers require you to set up your host for terminal emulation so you can communicate with the appliance device through the appliance's serial console. This

communication requires installing serial console terminal emulator software. We recommend using the following:

- PuTTY for Windows
- ZOC for OS X
- PuTTY or Minicom for Linux

Configure the following terminal emulator software settings:

- Baud Rate: 115200
- Emulation: VT102
- Handshaking: Disabled/off
- RTS/DTS: Disabled/off

Note

PuTTY does not allow you to configure all of these settings individually. However, you can configure the PuTTY default settings by selecting the **Serial** connection type and specifying "115200" for the **Serial Line** baud speed. This is sufficient to use PuTTY as a terminal emulator for the appliance.

Configuring the Transfer Appliance Networking

When the appliance boots up, an appliance serial console configuration menu is displayed on the Terminal Emulation Host to which the appliance is connected.

```
    Oracle Cloud Data Transfer Appliance
      - For use with minimum dts version: dts-0.4.140
      - See "Help" for determining your dts version

1) Configure Networking
2) Show Networking
3) Reset Authentication
4) Show Authentication
```

```
5) Show Status
6) Collect Appliance Diagnostic Information
7) Generate support bundle
8) Shutdown Appliance
9) Reboot Appliance
10) Help

Select a command:
```

Note

It can take up to 5 minutes for the serial console menu to display. Press **Enter** if you do not see the serial console configuration menu after this amount of time.

The appliance supports a single active network interface on any of the 10-Gbps network ports. If only one interface is cabled and active, that interface is chosen automatically. If multiple interfaces are active, you are given the choice to select the interface to use.

To configure your transfer appliance networking

1. From the Terminal Emulation Host, select **Configure Networking** from the appliance serial console menu.
2. Provide the required networking information when prompted:
   - **IP Address:** IP address of the transfer appliance.
   - **Subnet Mask Length:** The count of leading 1 bit in the subnet mask. For example, if the subnet mask is 255.255.255.0 then the length is 24.
   - **Default Gateway:** Default gateway for network communications.

   For example:

   ```
   Configure Networking:
   ^C to cancel

   Configuring IP address, subnet mask length, gateway
   Example:
   ```

```
IP Address : 10.0.0.2
Subnet Mask Length : 24
Gateway : 10.0.0.1

Address: 10.0.0.1
Subnet Mask Length: 24
Gateway: 10.0.0.1

Configuring IP address 10.0.0.1 netmask 255.255.255.0 default gateway 10.0.0.1
Enabling enp0s3
Now trying to restart the network

Network configuration is complete

New authentication material created.

Client access token                  : 4iH1gw1okPJO
Appliance certificate MD5 fingerprint : BF:C6:49:9B:25:FE:9F:64:06:7E:DF:F5:F9:E5:C6:56
Press ENTER to return...
```

When you configure a network interface, the appliance software generates a new client access token and appliance X.509/SSL certificate. The access token is used to authorize your Control Host to communicate with the Data Transfer Appliance's Management Service. The x.509/SSL certificate is used to encrypt communications with the Data Transfer Appliance's Management Service over the network. Provide the access token and SSL certificate fingerprint values displayed here when you use the CLI commands to initialize authentication on your host machine.

You can change the selected interface, network information, and reset the authentication material at any time by selecting **Configure Networking** again from the appliance serial console menu.

Notify the Data Administrator

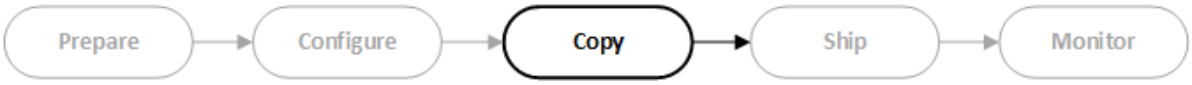
After completing the tasks in this topic, send the following appliance information IP address of the transfer appliance to the Data Administrator:

- Appliance IP address
- Access token
- SSL certificate fingerprint

What's Next

You are now ready to load your data to the disk. See Copying Data to the Appliance.

Copying Data to the Appliance



This topic describes the tasks associated with copying data from the Data Host to the appliance using the Control Host. The Data Administrator role typically performs these tasks. See Roles and Responsibilities.

Note

You can only run Oracle Cloud Infrastructure CLI commands from a Linux host. This differs from running CLI commands for other Oracle Cloud Infrastructure Services on a variety of host operating systems. Appliance-based commands require validation that is only available on Linux hosts.

Information Prerequisites

Before performing any disk copying tasks, you must obtain the following information:

- Appliance IP address - typically is provided by the Infrastructure Engineer.
- IAM login information, Data Transfer Utilityconfiguration files, transfer job ID, and job label - typically is provided by the Project Sponsor.

Generate and Upload RSA Key Pairs

The Data Administrator is responsible for generating and uploading the RSA key pairs. Do not share these generated RSA keys between users. See Creating a Key Pair.

Setting Up an HTTP Proxy Environment

You might need to set up an HTTP proxy environment on the Control Host to allow access to the public internet. This proxy environment allows the Oracle Cloud Infrastructure CLI to communicate with the Data Transfer Appliance Management Service and the appliance over a local network connection. If your environment requires internet-aware applications to use network proxies, configure the Control Host to use your environment's network proxies by setting the standard Linux environment variables on your Control Host.

Assume that your organization has a corporate internet proxy at `http://www-proxy.myorg.com` and that the proxy is an HTTP address at port `80`. You would set the following environment variable:

```
export HTTPS_PROXY=http://www-proxy.myorg.com:80
```

If you configured a proxy on the Control Host and the transfer appliance is directly connected to that host, the Control Host tries unsuccessfully to communicate with the transfer appliance using a proxy. Set a `no_proxy` environment variable for the appliance. For example, if the appliance is on a local network at `10.0.0.1`, you would set the following environment variable:

```
export NO_PROXY=10.0.0.1
```

Install and Using the Oracle Cloud Infrastructure Command Line Interface

The Oracle Cloud Infrastructure Command Line Interface (CLI) provides a set of command line-based tools for configuring and running Appliance-Based Data Transfer. Use the Oracle

Cloud Infrastructure CLI as an alternative to running commands from the Console. Sometimes you must use the CLI to complete certain tasks as there is no Console equivalent.

Installation and configuration of the CLIs is described in detail in Command Line Interface (CLI).

USING THE CLI

The CLI must be run as the `root` user.

You can specify CLI options using the following commands:

- `--option` *<value>* *or*
- `--option=`*<value>*

The basic CLI syntax is:

```
oci dts <resource> <action> <options>
```

This syntax is applied to the following:

- `oci dts` is the shortened CLI command name
- `job` is an example of a `<resource>`
- `create` is an example of an `<action>`
- Other strings are `<options>`

The following command to create a transfer job shows a typical CLI command construct.

```
oci dts job create --compartment-id ocid1.compartment.oc1..exampleuniqueID --bucket MyBucket --device-type appliance --display-name transfer1
```

Note

In the previous examples, provide a friendly name for the transfer job using the `--display-name` option. Avoid entering confidential information as part of the display name.

Firewall Access

If you have a restrictive firewall in the environment where you are using the Oracle Cloud Infrastructure CLI , you may need to open your firewall configuration to the following IP address ranges: 140.91.0.0/16.

Initializing Authentication to the Appliance

Tip

You can only use the Oracle Cloud Infrastructure CLI to initialize authentication.

Initialize authentication to allow the host machine to communicate with the appliance. Use the values returned from the **Configure Networking** command. See Configuring the Transfer Appliance Networking for details.

To initialize authentication using the CLI

Perform this task using CLI commands. There is no Console equivalent.

At the command prompt on the host, run `oci dts physical-appliance initialize-authentication` to initialize authentication.

```
oci dts physical-appliance initialize-authentication --job-id <job-id> --appliance-cert-fingerprint
<fingerprint> --appliance-ip <ip_address> --appliance-label <appliance-label>
```

For example:

```
oci dts physical-appliance initialize-authentication --job-id
ocid1.datatransferjob.region1.phx..exampleuniqueID --appliance-cert-fingerprint
F7:1B:D0:45:DA:04:0C:07:1E:B2:23:82:E1:CA:1A:E9 --appliance-ip 10.0.0.1 --appliance-label XA8XM27EVH
```

When prompted, supply the access token and system. For example:

```
oci dts physical-appliance initialize-authentication --appliance-certfingerprint
86:CA:90:9E:AE:3F:0E:76:E8:B4:E8:41:2F:A4:2C:38 --applianceip 10.0.0.5 --jobid
ocid1.datatransferjob.oc1..exampleuniqueID --appliance-label XAKKJAO9KT
```

```
Retrieving the Appliance serial id from Oracle Cloud Infrastructure.
Access token ('q' to quit):
Found an existing appliance. Is it OK to overwrite it? [y/n]y
Registering and initializing the authentication between the dts CLI and the appliance
Appliance Info :
  encryptionConfigured : false
  lockStatus           : NA
  finalizeStatus       : NA
  totalSpace           : Unknown
  availableSpace       : Unknown
```

The Control Host can now communicate with the appliance.

To show the status of and storage details about the connected appliance using the CLI

At the command prompt on the host, run `oci dts physical-appliance show` to show the status of the connected appliance.

```
oci dts physical-appliance show
```

For example:

```
Appliance Info :
 encryptionConfigured : false
 lockStatus           : NA
 finalizeStatus       : NA
 totalSpace           : Unknown
 availableSpace       : Unknown
```

Configuring Appliance Encryption

Configure the appliance to use encryption. Oracle Cloud Infrastructure creates a strong passphrase for each appliance. The command securely collects the strong passphrase from Oracle Cloud Infrastructure and sends that passphrase to the Data Transfer service.

If your environment requires Internet-aware applications to use network proxies, ensure that you set up the required Linux environment variables. See for more information.

Important

If you are working with multiple appliances at the same time, be sure the job ID and appliance label you specify in this step matches the physical appliance you are currently working with. You can get the serial number associated with the job ID and appliance label using the Console or the Oracle Cloud Infrastructure CLI. You can find the serial number of the physical appliance on the back of the device on the agency label.

Tip

You can only use the Oracle Cloud Infrastructure CLI to configure encryption.

To configure appliance encryption using the CLI

At the command prompt on the host, run `oci dts physical-appliance configure-encryption` to configure appliance encryption.

```
oci dts physical-appliance configure-encryption --job-id <job_id> --appliance-label <label>
```

For example:

```
oci dts physical-appliance configure-encryption --job-id
ocid1.datatransferjob.region1.phx..exampleuniqueID --appliance-label XA8XM27EVH
```

Unlocking the Appliance

Before you can write data to the transfer appliance, you must unlock the appliance. Unlocking the transfer appliance requires the strong passphrase that is created by Oracle Cloud Infrastructure for each appliance. Unlocking can be accomplished in two different ways:

- If you provide the `--job-id` and `--appliance-label` when running the `unlock` command, the data transfer system retrieves the passphrase from Oracle Cloud Infrastructure and sends it to the transfer appliance during the unlock operation.
- You can query Oracle Cloud Infrastructure for the passphrase and provide that passphrase when prompted during the unlock operation.

Important

It can take up to 10 minutes to unlock an appliance the first time. Subsequent unlocks are not as time consuming.

To retrieve the passphrase to unlock the appliance using the CLI

At the command prompt on the host, run `dts physical-appliance unlock` with `--job-id` and `--appliance-label` to unlock the appliance.

```
oci dts physical-appliance unlock --job-id <job_id> --appliance-label <label>
```

For example:

```
oci dts physical-appliance unlock --job-id ocid1.datatransferjob.region1.phx..exampleuniqueID --
appliance-label XA8XM27EVH
```

To query Oracle Cloud Infrastructure for the passphrase to provide to unlock the appliance using the CLI

At the command prompt on the host, run `dts appliance get-passphrase` to obtain the passphrase from the Oracle Cloud Infrastructure.

```
oci dts appliance get-passphrase --job-id <job_id> --appliance-label <label>
```

Then, run `dts physical-appliance unlock` without `--job-id` and `--appliance-label` and supply the passphrase when prompted.

```
oci dts physical-appliance unlock
```

Creating NFS Datasets

A dataset is a collection of files that are treated similarly. You can write up to 100 million files onto the appliance for migration to Oracle Cloud Infrastructure. We currently support one dataset per appliance. Appliance-Based Data Transfer supports NFS versions 3, 4, and 4.1 to write data to the appliance. In preparation for writing data, create and configure a dataset to write to. See Datasets for complete details on all tasks related to datasets.

To create a dataset using the CLI

At the command prompt on the host, run `oci dts nfs-dataset create` to create a dataset.

```
oci dts nfs-dataset create --name <dataset_name>
```

For example:

```
oci dts nfs-dataset create --name nfs-ds-1
```

Activating the Dataset

Activation creates the NFS export, making the dataset accessible to NFS clients.

To activate the dataset

At the command prompt on the host, run `oci dts nfs-dataset activate` to activate the NFS dataset.

```
oci dts nfs-dataset activate --name <dataset_name>
```

For example:

```
oci dts nfs-dataset activate --name nfs-ds-1
```

CONFIGURING EXPORT SETTINGS ON THE DATASET

To configure export settings on a dataset

At the command prompt on the host, run `oci dts nfs-dataset set-export` to configure export settings on an NFS dataset.

```
oci dts nfs-dataset set-export --name <dataset_name> --rw=true --world=true
```

For example:

```
oci dts nfs-dataset set-export --name nfs-ds-1 --rw=true --world=true
```

Here is another example of creating the export to give read/write access to a subnet:

```
oci dts nfs-dataset set-export --name nfs-ds-1 --ip 10.0.0.0 --subnet-mask-length 24 --rw true --world
false
```

Setting Your Data Host as an NFS Client

Set up your Data Host as an NFS client:

- For Debian or Ubuntu, install the `nfs-common` package. For example:

  ```
  sudo apt-get install nfs-common
  ```

- For Oracle Linux or Red Hat Linux, install the `nfs-utils` package. For example:

  ```
  sudo yum install nfs-utils
  ```

Mounting the NFS Share

To mount the NFS share

At the command prompt on the Data Host, use the `mount` command to mount the NFS share.

```
mount -t nfs <appliance_ip>:/data/<dataset_name><mountpoint>
```

For example:

```
mount -t nfs 10.0.0.1:/data/nfs-ds-1 /mnt/nfs-ds-1
```

After the NFS share is mounted, you can write data to the share.

Copying Files to the NFS Share

Copy your file to the appliance using normal file system tools.

Important

You can only copy regular files to transfer appliances. Special files (for example, symbolic links, device special, sockets, and pipes) cannot be copied directly. To transfer special files, create a tar archive of these files and copy the tar archive to the transfer appliance.

Deactivating the Dataset

Note

Deactivating the dataset is only required if you are running appliance commands using the Data Transfer Utility. If you are using the Oracle Cloud Infrastructure CLI to run your Appliance-Based Data Transfer, you can skip this step and proceed to Sealing the Dataset.

After you are done writing data, deactivate the dataset. Deactivation removes the NFS export on the dataset, disallowing any further writes.

To deactivate the dataset

At the command prompt on the host, run `dts nfs-dataset deactivate` to deactivate the NFS dataset.

```
dts nfs-dataset deactivate --name <dataset_name>
```

For example:

```
dts nfs-dataset deactivate --name nfs-ds-1
```

Sealing the Dataset

Sealing a dataset stops all writes to the dataset. Sealing a dataset is a long running process that can take some time to complete. The completion time depends upon the number of files and total amount of data that was copied to the appliance.

If you issue the `seal` command without the `--wait` option, the seal operation is triggered and runs in the background. You are returned to the command prompt and can use the `seal-status` command to monitor the sealing status. If you issue the `seal` command with the `--wait` option, the seal operation is triggered and continues to provide status updates until sealing completion.

Important

You can only copy regular files to transfer appliances. Special files (for example, symbolic links, device special, sockets, and pipes) cannot be copied directly. To transfer special files, create a tar archive of these files and copy the tar archive to the transfer appliance.

The sealing operation generates a manifest across all files in the dataset. The manifest contains an index of the copied files and generated data integrity hashes.

TO SEAL THE DATASET USING THE CLI

At the command prompt on the host, run `oci dts nfs-dataset seal` to seal the NFS dataset.

```
oci dts nfs-dataset seal --name <dataset_name> [--wait]
```

For example:

```
oci dts nfs-dataset seal --name nfs-ds-1
Seal initiated. Please use seal-status command to get progress.
```

TO MONITOR THE DATASET SEALING PROCESS USING THE CLI

At the command prompt on the host, run `oci dts nfs-dataset seal-status` to monitor the dataset sealing process.

```
oci dts nfs-dataset seal-status --name <dataset_name>
```

For example, here is the status that is issued upon sealing completion:

```
oci dts nfs-dataset seal-status --name nfs-ds-1

Seal Status :
 success           : true
 failureReason     : *** none ***
 startTime         : 2018/07/10 18:24:05 EDT
 endTime           : 2018/07/10 18:24:06 EDT
 numFilesToProcess : 2000
 numFilesProcessed : 2000
 bytesToProcess    : 1.95 GB
 bytesProcessed    : 1.95 GB
```

Note

If changes are necessary after sealing a dataset or finalizing an appliance, you must reopen the dataset to modify the contents. See Reopening a Dataset.

DOWNLOADING THE DATASET SEAL MANIFEST

After sealing the dataset, you can optionally download the dataset's seal manifest to a user-specified location. The manifest file contains the checksum details of all the files. The transfer site uploader consults the manifest file to determine the list of files to upload to object storage. For every uploaded file, it validates that the checksum reported by object storage matches the checksum in manifest. This validation ensures that no files got corrupted in transit.

To download the dataset seal manifest file using the CLI

At the command prompt on the host, run `oci dts nfs-dataset get-seal-manifest` to download the seal manifest.

```
oci dts nfs-dataset get-seal-manifest --name <dataset_name> --output-file <file_path>
```

For example:

```
oci dts nfs-dataset get-seal-manifest --name nfs-ds-1 --output-file ~/Downloads/seal-manifest
```

Finalizing the Appliance

Tip

You can only use the CLI commands to finalize the appliance.

Finalizing an appliance tests and copies the following to the appliance:

- Upload user configuration credentials
- Private PEM key details
- Name of the upload bucket

The credentials, API key, and bucket are required for Oracle to be able to upload your data to Oracle Cloud Infrastructure Object Storage. When you finalize an appliance, you can no longer access the appliance for dataset operations unless you unlock the appliance. See Reopening a Dataset if you need to unlock an appliance that was finalized.

Important

If you are working with multiple appliances at the same time, be sure the job ID and appliance label you specify in this step matches the physical appliance you are currently working with. You can get the serial number associated with the job ID and appliance label using the Console or the Oracle Cloud Infrastructure CLI. You can find the serial number of the physical appliance on the back of the device on the agency label.

To finalize the appliance

1. Seal the dataset before finalizing the appliance.
2. At the command prompt on the host, run `oci dts physical-appliance finalize` to finalize an appliance.

```
oci dts physical-appliance finalize --job-id <job_id> --appliance-label <label>
```

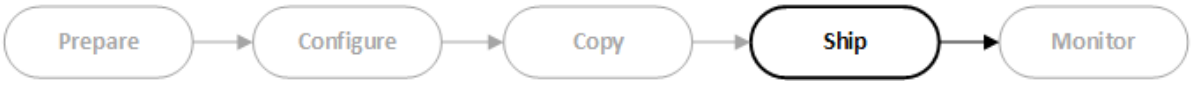
For example:

```
oci dts physical-appliance finalize --job-id ocid1.datatransferjob.region1.phx..exampleuniqueID --
appliance-label XA8XM27EVH
```

Note

If changes are necessary after sealing a dataset or finalizing an appliance, you must reopen the dataset to modify the contents. See Reopening a Dataset.

Shipping the Appliance



This topic describes the tasks associated with shipping the transfer appliance containing the copied data to Oracle. The Infrastructure Engineer role typically performs these tasks. See Roles and Responsibilities.

> **Note**
>
> You can only run Oracle Cloud Infrastructure CLI commands from a Linux host. This differs from running CLI commands for other Oracle Cloud Infrastructure Services on a variety of host operating systems. Appliance-based commands require validation that is only available on Linux hosts.

Shutting Down the Transfer Appliance

Shut down the appliance before packing up and shipping the appliance back to Oracle.

To shut down the appliance

Using the terminal emulator on the host machine, select **Shutdown** from the appliance serial console.

Packing and Shipping Transfer Appliance to Oracle

Return the appliance to Oracle within 30 days. If you need the transfer appliance beyond the standard 30-day window, you can file a Service Request (SR) to ask for an extension of up to 60 days.

> **Important**
>
> Review and follow the instructions that were provided in the transit case with the appliance.

To pack and ship the appliance

1. Unplug the power cord from the power source and detach the other end of the cord from the appliance.
2. Disconnect the appliance from your network.
3. Remove the return shipment tamper-evident security tie from the transit case.
4. Place the transfer appliance, power cord, and serial cable in the transit case.

> **Warning**
>
> We recommend assistance lifting and placing the transfer appliance back into the transit case. The total shipping weight is about 64 lbs (29.0299 kg) and appliance weight is 38 lbs (17.2365 kg).

5. Close and secure the transit case with the return tamper-evident security tie.
6. Loop the top of the plastic tie-on tag with return shipping label through the handle of the transit case. Remove the protective tape from the back of the tie-on tag, exposing the adhesive area on which to secure the tag onto itself. Use the provided zip tie to secure the tie-on tag to the handle.
7. Return the transit case to FedEx by doing one of the following:
   - Drop off the packed, sealed, and labeled transit case to an FedEx Authorized ShipCenter location or a nearby FedEx Office location. *Obtain a receipt from the vendor to certify transfer of custody.*

- Schedule a pickup with FedEx at your location. Ensure that the transit case is packed, sealed, and labeled before FedEx arrives for pickup.

The shipping vendor notifies Oracle when the transfer appliance is shipped back to Oracle for upload to Oracle Cloud Infrastructure Object Storage.

Monitoring the Appliance Return

This topic describes the tasks to be done after the data transfer is complete the transfer appliance has been returned to Oracle. The Project Sponsor role typically performs these tasks. See Roles and Responsibilities.

Note

You can only run Oracle Cloud Infrastructure CLI commands from a Linux host. This differs from running CLI commands for other Oracle Cloud Infrastructure Services on a variety of host operating systems. Appliance-based commands require validation that is only available on Linux hosts.

Monitoring the Status of Your Transfer Appliance Return Shipment

The shipping vendor notifies Oracle when your transfer appliance is picked up and shipped back for upload to Oracle Cloud Infrastructure Object Storage.

To monitor the status of your transfer appliance return shipment using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Object Storage** and click **Data Transfer**.
2. Find the transfer job and transfer appliance that you shipped back to Oracle for data upload.
3. Under **Transfer Appliances**, look at the **Status** field.

To monitor the status of your transfer appliance using the CLI

At the command prompt on the host, run `dts appliance show` to monitor a transfer appliance status.

```
oci dts appliance show --job-id <job_id> -appliance <label>
```

TRANSFER APPLIANCE STATUS VALUES

Here are the transfer appliance status values, listed in alphabetic order:

CANCELED

You can change your mind about uploading your data to Oracle Cloud Infrastructure Object Storage and cancel your transfer appliance. Ship the appliance back to Oracle and then cancel the appliance. Oracle always uses secure wipe tools on the boot and data areas whenever a transfer appliance is returned.

COMPLETE

Oracle completed your transfer appliance data upload. Your data is available in your designated bucket in Oracle Cloud Infrastructure Object Storage.

CUSTOMER LOST

You have not returned a data transfer appliance within the required 90 days.

DELIVERED

Oracle received a delivery confirmation from the shipping vendor that your transfer appliance was delivered. When the appliance is delivered, Oracle provides the date and time the appliance was received in the transfer appliance details. Appliance usage tracking begins.

ERROR

Oracle encountered an unrecoverable error trying to process your transfer appliance. Oracle cannot upload your data from the appliance. To protect your data, Oracle uses secure wipe tools on the boot and data areas any transfer appliance that cannot be processed.
Complete another request for a transfer appliance.

ORACLE PREPARING

Oracle approved your transfer appliance request. The status displays preparing until the transfer appliance is shipped to you.

ORACLE RECEIVED

Oracle received your transfer appliance shipment. The status displays Oracle received until Oracle begins processing and uploading your transfer appliance.

ORACLE RECEIVED CANCELED

You canceled your transfer appliance after you shipped the appliance back to Oracle. Oracle received your canceled transfer appliance. Oracle does *not* upload the appliance data.

PREPARING

You activated your transfer appliance. You can now copy your data onto the transfer appliance. The status displays preparing until you ship the transfer appliance back to Oracle.

PROCESSING

Oracle is processing and uploading the data from your transfer appliance. The status displays the processing status until Oracle completes uploading your data from your transfer appliance.

REJECTED

Oracle denied your transfer appliance request.

Important

If your appliance request is denied and you have questions, contact your Sales Representative or file a Service Request (SR).

REQUESTED

You successfully completed your request for a transfer appliance. The status displays requested until Oracle approves your transfer appliance request.

RETURN SHIPPED

Oracle received confirmation from the shipping vendor that you shipped your transfer appliance back to Oracle. The status displays return shipped until Oracle receives your transfer appliance.

RETURN SHIPPED CANCELED

You canceled your transfer appliance after the appliance was delivered to you or after you shipped the appliance back to Oracle. Oracle received confirmation from the shipping vendor that your canceled transfer appliance is on the way back to Oracle. The status displays return shipped canceled until Oracle receives your transfer appliance.

SHIPPING

Oracle completed the necessary preparations and shipped your transfer appliance. When the appliance is shipped, Oracle provides the serial number of the appliance, the shipping

vendor, and the tracking number in the appliance details. The status displays shipping until the appliance is delivered to you.

Reviewing the Upload Summary

Oracle creates upload summary log files for each uploaded appliance. These log files are placed in the bucket where data was uploaded to Oracle Cloud Infrastructure. The upload summary file compares the appliance's manifest file to the contents of the target Oracle Cloud Infrastructure Object Storage bucket after file upload.

Note

If you chose to upload your data to an Archive Storage bucket, you must first restore the log file object before you can download that file for review.

The top of the log report summarizes the overall file processing status:

```
P - Present: The file is present in both the device and the target bucket
M - Missing: The file is present in the device but not the target bucket. It was likely uploaded and
then deleted by another user before the summary was generated.
C - Name Collision: The file is present in the manifest but a file with the same name but different
contents is present in the target bucket.
U - Unreadable: The file is not readable from the disk
N - Name Too Long: The file name on disk is too long and could not be uploaded
```

Complete file upload details follow the summary.

```
#########################################################################################################################
#####################################  SUMMARY FOR DISK [WDH0B87L] #######################################
Generated    2017-09-08 19:46:36

|    STATUS     |                    NAME                    |        LAST_MODIFIED          |    SIZE(MB)    |          MD5             |                ETag                |
|    present    |                small/01/T6QHX              |  Fri Sep 08 19:04:54 UTC 2017 |     10.00      |  8clkXbwU793H2KMiaF8m6w==  |  58B2F70D1C874AAAE053824310ACAC52  |
|    present    |                small/01/FAFUK              |  Fri Sep 08 19:12:20 UTC 2017 |     10.00      |  8clkXbwU793H2KMiaF8m6w==  |  58B2ECE4616E46D8E053824310AC6DF6  |
|    present    |                small/01/EVPFD              |  Fri Sep 08 19:02:42 UTC 2017 |     10.00      |  8clkXbwU793H2KMiaF8m6w==  |  58B2ECDFA74946D6E053824310AC383A  |
|    present    |                small/01/2UO2W              |  Fri Sep 08 19:13:06 UTC 2017 |     10.00      |  8clkXbwU793H2KMiaF8m6w==  |
```

If you upload more than 100,000 files, the upload details are broken into multiple pages. You can only download the first page from the Console. Download the rest of the pages directly

from the Object Storage bucket. The subsequent pages have the same object name as the first page, but have an enumerated suffix.

Closing a Transfer Job

Tip

You can use the Console or the Oracle Cloud Infrastructure CLI to close a transfer job.

Typically, you would close a transfer job when no further transfer job activity is required or possible. Closing a transfer job requires that the status of all associated transfer appliances be returned, canceled, or deleted.

To close a transfer job using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Object Storage** and click **Data Transfer**.
2. Find the data transfer package for which you want to display the details.
3. Click the Actions icon (three dots), and then click **View Details**.
   Alternatively, click the hyper-linked name of the transfer job.
4. Click **Close Transfer Job**.

To close a transfer job using the CLI

At the command prompt on the host, run `oci dts job close` to close a transfer job.

```
oci dts job close --job-id <job_id>
```

What's Next

You have completed the process of setting up, running, and monitoring the Appliance-Based Data Transfer. If you determine that another appliance-based data transfers is required,

repeat the procedure from the beginning.

Appliance Data Transfer Reference

This topic provides complete task details for certain components associated with Appliance-Based Data Transfers. Use this topic as a reference to learn and use commands associated with components included in the Appliance-Based Data Transfer procedure.

Transfer Jobs

A transfer job represents the collection of files that you want to transfer and signals the intention to upload those files to Oracle Cloud Infrastructure. A transfer job combines at least one transfer disk with a transfer package. Identify which compartment and Object Storage bucket that Oracle is to upload your data to.

Note

It is recommended that you create a compartment for each transfer job to minimize the required access your tenancy.

Tip

You can use the Console or the Oracle Cloud Infrastructure CLI to create a transfer job.

Creating Transfer Jobs

Create the transfer job in the same compartment as the upload bucket and supply a human-readable name for the transfer job. Avoid entering confidential information when providing transfer job names.

Creating a transfer job returns a job ID that you specify in other transfer tasks. For example:

```
ocid1.datatransferjob.region1.phx..<unique_ID>
```

To create a transfer job using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Object Storage** and click **Data Transfer**.
2. Select the designated compartment you are to use for data transfers from the drop-down list.
   A list of transfer jobs that have already been created is displayed.
3. Click **Create Transfer Job**.
4. In the **Create Transfer Job** dialog, enter a **Job Name**, and select the **Upload Bucket** from the drop-down list.
   Avoid entering confidential information in the transfer job name.
5. Select **Disk** for the **Transfer Device Type**.
6. Click **Create Transfer Job**.

To create a transfer job using the CLI

At the command prompt on the host, run `oci dts job create` to create a transfer job. The *<display_name>* is the name of the transfer job. Avoid entering confidential information in the transfer job name.

```
oci dts job create --bucket <bucket_name> --compartment-id <compartment_id> --display-name <display_
name> --device-type disk
```

Optionally, you can specify one or more free-form or defined tags when you create a transfer job. For more information about tagging, see Resource Tags.

To specify free-form tags when creating a job:

```
oci dts job create --bucket <bucket_name> --compartment-id <compartment_id> --display-name <display_
name> --device-type disk --freeform-tags '{ "<tag_key>":"<value>" }'
```

To specify defined tags when creating a job:

```
oci dts job create --bucket <bucket_name> --compartment-id <compartment_id> --display-name <display_
name> --device-type disk --defined-tags '{ "<tag_namespace>": { "<tag_key>":"<value>" }}'
```

Note

Users create tag namespaces and tag keys with the required permissions. These items must exist before you can specify them when creating a job. See Working with Defined Tags for details.

To specify multiple tags, comma separate the JSON-formatted key/value pairs:

```
oci dts job create --bucket <bucket_name> --compartment-id <compartment_id> --display-name <display_
name> --device-type disk --freeform-tags '{ "<tag_key>":"<value>" }', '{ "<tag_key>":"<value>" }'
```

DISPLAYING TRANSFER JOBS

To display the list of transfer jobs using the Console

Open the navigation menu. Under **Core Infrastructure**, go to **Object Storage** and click **Data Transfer**.

To display the list of transfer jobs using the CLI

At the command prompt on the host, run `dts job list` to display the list of transfer jobs.

```
oci dts job list --compartment-id <compartment_id>
```

When you use the CLI command to list jobs, tagging details are also included in the output if you specified tags.

DISPLAYING TRANSFER JOB DETAILS

To display the details of a transfer job using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Object Storage** and click **Data Transfer**.
2. Find the transfer job for which you want to display the details.
3. Click the Actions icon (three dots), and then click **View Details**.

To display the details of a transfer job using the CLI

At the command prompt on the host, run `oci dts job show` to display the details of a transfer job.

```
oci dts job show --job-id <job_id>
```

When you use the CLI command to display the details of a job, tagging details are also included in the output if you specified tags.

EDITING TRANSFER JOBS

To edit the name of a transfer job using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Object Storage** and click **Data Transfer**.
2. Find the data transfer job that you want to edit.
3. Click the Actions icon (three dots), and then click **Edit**.
4. Edit the name of the transfer job.
   Avoid entering confidential information in the transfer job name.
5. Click **Save**.

To edit the name of a transfer job using the CLI

At the command prompt on the host, run `oci dts job update` to edit the name (`--display-name`) of a transfer job. The *<display_name>* is the new name of the transfer job. Avoid entering confidential information in the transfer job name.

```
oci dts job update --job-id <job_id> --display-name <display_name>
```

To edit the tags associated with a transfer job using the CLI

At the command prompt on the host, run `oci dts job update` to edit the tags associated with a transfer job. The CLI command **replaces** any existing tags with the new key/value pairs you specify.

To edit free-form tags, provide the replacement key/value pairs:

```
oci dts job update --job-id <job_id> --freeform-tags '{ "<tag_key>":"<value>" }'
```

To edit defined tags, provide the replacement key value pairs:

```
oci dts job update --job-id <job_id> --defined-tags '{ "<tag_namespace>": { "<tag_key>":"<value>" }}'
```

To delete the tags associated with a transfer job using the CLI

At the command prompt on the host, run `oci dts job update` to delete the tags associated with a transfer job. The CLI command **replaces** any existing tags with the new key/value pairs you specify. If you want to delete some of the tags, you would specify new tag string that does not contain the key/value pair you want to delete.

Partial tag deletion is handled in the same way as you edit tags:

- To edit free-form tags, provide the replacement key/value pairs:

```
oci dts job update --job-id <job_id> --freeform-tags '{ "<tag_key>":"<value>" }'
```

- To edit defined tags, provide the replacement key value pairs:

```
oci dts job update --job-id <job_id> --defined-tags '{ "<tag_namespace>": { "<tag_key>":"<value>" }}'
```

To delete all free-form tags:

```
oci dts job update --job-id <job_id> --freeform-tags '{}'
```

To delete all defined tags:

```
oci dts job update --job-id <job_id> --defined-tags '{}'
```

DELETING TRANSFER JOBS

You can delete transfer jobs when they are in the Initiated, Preparing, and Close states.

To delete a transfer job using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Object Storage** and click **Data Transfer**.
2. Find the data transfer job that you want to delete.
3. Click the Actions icon (three dots), and then click **Delete**.
   Alternatively, you can delete a transfer job from the **View Details** page.
4. Confirm the deletion when prompted.

To delete a transfer job using the CLI

At the command prompt on the host, run `dts job delete` to delete a transfer job.

```
oci dts job delete --job-id <job_id>
```

CLOSING TRANSFER JOBS

Tip

You can use the Console or the Oracle Cloud Infrastructure CLI to close a transfer job.

Typically, you would close a transfer job when no further transfer job activity is required or possible. Closing a transfer job requires that the status of all associated transfer packages be returned, canceled, or deleted. In addition, the status of all associated transfer disks must be complete, in error, missing, canceled, or deleted.

To close a transfer job using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Object Storage** and click **Data Transfer**.
2. Find the data transfer package for which you want to display the details.
3. Click the Actions icon (three dots), and then click **View Details**.
   Alternatively, click the hyper-linked name of the transfer job.
4. Click **Close Transfer Job**.

To close a transfer job using the CLI

At the command prompt on the host, run `dts job close` to close a transfer job.

```
oci dts job close --job-id <job_id>
```

Appliances

This section describes tasks associated with the Oracle-provided appliance.

Tip

You can use the Console or the Oracle Cloud Infrastructure CLIs to request an appliance.

Tip

We recommend that you identify the data you intend to upload and make data copy preparations before requesting the appliance.

Creating an appliance request returns an Oracle-assigned appliance label. For example:

```
XA8XM27EVH
```

To request an appliance using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Object Storage** and click **Data Transfer**.
   Choose the transfer job for which you want to request an appliance.
2. Under **Transfer Appliances**, click **Request Transfer Appliance**.
3. In the **Request Transfer Appliance** dialog box, provide the shipping address details where you want the appliance sent.
   - **Company Name:** Required. Specify the name of the company that owns the data being migrated to Oracle Cloud Infrastructure.
   - **Recipient Name:** Required. Specify the name of the recipient to send the appliance to.

- **Recipient Phone Number:** Required. Specify the recipient's phone number.
- **Recipient Email Address:** Required. Specify the recipient's email address.
- **Care Of:** Optional intermediary party responsible for transferring the appliance shipment from the delivery vendor to the intended recipient.
- **Address Line 1:** Required. Specify the street address to send the appliance to.
- **Address Line 2:** Optional identifying address details like building, suite, unit, or floor information.
- **City/Locality:** Required. Specify the city or locality.
- **State/Province/Region:** Required. Specify the state, province, or region.
- **Zip/Postal Code:** Specify the zip code or postal code.
- **Country:** Required. Select the country.

4. Click **Request Transfer Appliance**.

To request an appliance using the CLIs

At the command prompt on the host, run `oci dts appliance request` to request an appliance.

Here are the minimum requirements for the appliance request:

```
oci dts appliance request --job-id <job_id> --addressee <addressee> --address1 <address_line1> --city-or-locality <city_or_locality> --state-or-region <state_or_region>--country<country>--zip-code<zip>
```

In addition, you can specify these optional fields in the request:

```
--care-of <care_of>
--address2 <address_line2>, --address3 <address_line3>, and --address4 <address_line4>
--email <email_address>
--phone-number <phone_number>
--profile <profile>
```

When you submit an appliance request, Oracle generates a unique label (name) to identify the appliance and your request is sent to Oracle for approval and processing.

MONITORING THE APPLIANCE REQUEST STATUS

The time it takes to approve, prepare, and ship your appliance request varies and depends on various factors, including current available inventory. Oracle provides status updates daily throughout the appliance request and ship process.

To monitor the status of your appliance request using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Object Storage** and click **Data Transfer**.
2. Find and select the transfer job for which you want to monitor associated appliance requests.
3. Under **Transfer Appliances**, find the appliance label Oracle assigned to your appliance request and look at the **Status** field.

Here are the key status values to look for when monitoring your appliance request:

- **Requested**: You successfully completed your request for an appliance. The status displays **Requested** until Oracle approves your appliance request.
- **Rejected**: Oracle denied your appliance request.

> **Important**
>
> If your appliance request is denied and you have questions, contact your Sales Representative or file a Service Request (SR).

- **Oracle Preparing**: Oracle approved your appliance request. The status displays **Oracle Preparing** until the appliance is shipped to you.
- **Shipping**: Oracle completed the necessary preparations and shipped your appliance. When the appliance is shipped, Oracle provides the serial number of the appliance, the shipping vendor, and the tracking number in the **Transfer Appliance Details**. The status displays **Shipping** until the appliance is delivered to you.

- **Delivered**: The shipping vendor delivered your appliance. When the appliance is delivered, Oracle provides the date and time the appliance was received in the **Transfer Appliance Details**. The status displays **Delivered**.

To monitor the status of your appliance request using the CLI

At the command prompt on the host, run `oci dts appliance show` to monitor your appliance request.

```
oci dts appliance show --job-id <job_id> --appliance-label <label>
```

DISPLAYING THE LIST OF APPLIANCES

Tip

You can use the Console to get a list of appliances that are associated with a job.

To display the list of appliances using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Object Storage** and click **Data Transfer**.
2. Choose the transfer job for which you want to display the list of associated appliances. The list of appliances is displayed below the transfer job details.

To display the list of appliances using the CLI commands

At the command prompt on the host, run `oci dts appliance list` to display the list of transfer jobs.

```
oci dts appliance list --job-id <job_id>
```

Displaying the Details of an Appliance

To display the details of an appliance using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Object Storage** and click **Data Transfer**.
2. Find the transfer job for which you want to display the details of an associated appliance.
   The list of appliances is displayed below the transfer job details.
3. Find the appliance for which you want to display the details.
4. Click the Actions icon (three dots), and then click **View Details**.

To display the details of an appliance using the CLI commands

At the command prompt on the host, run `oci dts appliance show` to display the details of an appliance.

```
oci dts appliance show --job-id <job_id> --appliance-label <label>
```

Editing the Appliance Request Shipping Information

You can only edit the shipping information when the status is **Requested**.

To edit the appliance request shipping information using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Object Storage** and click **Data Transfer**.
2. Find the **Requested** appliance that you want to edit the shipping information.
3. Click the Actions icon (three dots), and then click **Edit**.
4. Edit the shipping information for the appliance.

5. Click **Save**.

To edit the appliance request shipping information using the CLI

At the command prompt on the host, run `oci dts appliance update` to edit the shipping information for the appliance.

```
oci dts appliance update-shipping-address --job-id <job_id>--appliance-label<label><changed_fields>
```

The *<changed_fields>* variable represents one or more of the following shipping address fields that you want to update:

```
--addressee <addressee> --careOf <care_of> --address1 <street_address> --city <city> --state
<addressee> --zip <zip> --country <country> --phone <phone>
```

DELETING AN APPLIANCE REQUEST

You can delete an appliance request before Oracle approves the request—the status must be **Requested**. For example, you initiated the transfer by creating a transfer job and requested an appliance, but changed your mind.

To delete an appliance request using the Console

1. Open the navigation menu. Under **Core Infrastructure**, go to **Object Storage** and click **Data Transfer**.
2. Find the data transfer job and appliance request that you want to delete.
3. Click the Actions icon (three dots), and then click **Delete**.
   Alternatively, you can delete an appliance request from the **Transfer Appliance Details** page.
4. Confirm the deletion when prompted.

To delete an appliance request using the CLI commands

At the command prompt on the host, run `oci dts appliance delete` to delete an appliance.

```
oci dts appliance delete --job-id <job_id>--appliance-label<label>
```

Datasets

A dataset is a collection of files that are treated similarly. You can write up to 100 million files onto the appliance for transfer. We currently support one dataset per appliance.

Creating Datasets

Appliance data transfer supports NFSversion 3, 4, and 4.1 to write data to the appliance. In preparation for writing data, create and configure a dataset to write to.

To create a dataset using the CLI

At the command prompt on the host, run `oci dts nfs-dataset create` to create a dataset.

```
oci dts nfs-dataset create --name <dataset_name>
```

For example:

```
oci dts nfs-dataset create --name nfs-ds-1
```

Activating the Dataset

Activation creates the NFS export, making the dataset accessible to NFS clients.

To activate the dataset

At the command prompt on the host, run `oci dts nfs-dataset activate` to activate the NFS dataset.

```
oci dts nfs-dataset activate --name <dataset_name>
```

For example:

```
oci dts nfs-dataset activate --name nfs-ds-1
```

CONFIGURING EXPORT SETTINGS ON THE DATASET

To configure export settings on a dataset

At the command prompt on the host, run `oci dts nfs-dataset set-export` to configure export settings on an NFS dataset.

```
oci dts nfs-dataset set-export --name <dataset_name> --rw=true --world=true
```

For example:

```
oci dts nfs-dataset set-export --name nfs-ds-1 --rw=true --world=true
```

Here is another example of creating the export to give read/write access to a subnet:

```
oci dts nfs-dataset set-export --name nfs-ds-1 --ip=10.0.0.0 --subnet-mask-length=24 --rw=true --
world=false
```

DEACTIVATING THE DATASET

Note

Deactivating the dataset is only required if you are running appliance commands using the Data Transfer Utility. If you are using the Oracle Cloud Infrastructure CLI to run your Appliance-Based Data Transfer, you can skip this step and proceed to Sealing the Dataset.

After you are done writing data, deactivate the dataset. Deactivation removes the NFS export on the dataset, disallowing any further writes.

To deactivate the dataset

At the command prompt on the host, run `dts nfs-dataset deactivate` to deactivate the

NFS dataset.

```
dts nfs-dataset deactivate --name <dataset_name>
```

For example:

```
dts nfs-dataset deactivate --name nfs-ds-1
```

SEALING THE DATASET

Sealing a dataset stops all writes to the dataset. Sealing a dataset is a long running process that can take some time to complete. The completion time depends upon the number of files and total amount of data that was copied to the appliance.

If you issue the `seal` command without the `--wait` option, the seal operation is triggered and runs in the background. You are returned to the command prompt and can use the `seal-status` command to monitor the sealing status. If you issue the `seal` command with the `--wait` option, the seal operation is triggered and continues to provide status updates until sealing completion.

Important

You can only copy regular files to transfer appliances. Special files (for example, symbolic links, device special, sockets, and pipes) cannot be copied directly. To transfer special files, create a tar archive of these files and copy the tar archive to the transfer appliance.

The sealing operation generates a manifest across all files in the dataset. The manifest contains an index of the copied files and generated data integrity hashes.

To seal the dataset using the CLI

At the command prompt on the host, run `oci dts nfs-dataset seal` to seal the NFS dataset.

```
oci dts nfs-dataset seal --name <dataset_name> [--wait]
```

For example:

```
oci dts nfs-dataset seal --name nfs-ds-1
Seal initiated. Please use seal-status command to get progress.
```

To monitor the dataset sealing process using the CLI

At the command prompt on the host, run `oci dts nfs-dataset seal-status` to monitor the dataset sealing process.

```
oci dts nfs-dataset seal-status --name <dataset_name>
```

For example, here is the status that is issued upon sealing completion:

```
oci dts nfs-dataset seal-status --name nfs-ds-1

Seal Status :
 success           : true
 failureReason     : *** none ***
 startTime         : 2018/07/10 18:24:05 EDT
 endTime           : 2018/07/10 18:24:06 EDT
 numFilesToProcess : 2000
 numFilesProcessed : 2000
 bytesToProcess    : 1.95 GB
 bytesProcessed    : 1.95 GB
```

Downloading the Dataset Seal Manifest

After sealing the dataset, you can optionally download the dataset's seal manifest to a user-specified location. The manifest file contains the checksum details of all the files. The transfer site uploader consults the manifest file to determine the list of files to upload to object storage. For every uploaded file, it validates that the checksum reported by object storage matches the checksum in manifest. This validation ensures that no files got corrupted in transit.

To download the dataset seal manifest file using the CLI

At the command prompt on the host, run `oci dts nfs-dataset get-seal-manifest` to download the seal manifest.

```
oci dts nfs-dataset get-seal-manifest --name <dataset_name> --output-file <file_path>
```

For example:

```
oci dts nfs-dataset get-seal-manifest --name nfs-ds-1 --output-file ~/Downloads/seal-manifest
```

REOPENING A DATASET

Tip

You can only use the CLI command to reopen a dataset.

If changes are necessary after sealing a dataset or finalizing an appliance, you must reopen the dataset to modify the contents. Make the required changes and again seal the dataset. Resealing the dataset generates a new manifest.

Note

If an appliance is rebooted or power cycled, follow the instructions in this topic to reopen the dataset.

STEP 1: UNLOCKING THE APPLIANCE

Before you can write data to the transfer appliance, you must unlock the appliance. Unlocking the transfer appliance requires the strong passphrase that is created by Oracle Cloud Infrastructure for each appliance. Unlocking can be accomplished in two different ways:

- If you provide the `--job-id` and `--appliance-label` when running the `unlock` command, the data transfer system retrieves the passphrase from Oracle Cloud Infrastructure and sends it to the transfer appliance during the unlock operation.
- You can query Oracle Cloud Infrastructure for the passphrase and provide that passphrase when prompted during the unlock operation.

To retrieve the passphrase to unlock the appliance

At the command prompt on the host, run `dts physical-appliance unlock` with `--job-id` and `--appliance-label` to unlock the appliance.

```
oci dts physical-appliance unlock --job-id <job_id> --appliance-label <label>
```

For example:

```
oci dts physical-appliance unlock --job-id ocid1.datatransferjob.region1.phx..exampleuniqueID --
appliance-label XA8XM27EVH
```

To query Oracle Cloud Infrastructure for the passphrase to provide to unlock the appliance

At the command prompt on the host, run `dts appliance get-passphrase` to obtain the passphrase from the Oracle Cloud Infrastructure.

```
oci dts appliance get-passphrase --job-id <job_id> --appliance-label <label>
```

Then, run `dts physical-appliance unlock` without `--job-id` and `--appliance-label` and supply the passphrase when prompted.

```
oci dts physical-appliance unlock
```

Step 2: Reopening the Appliance

Reopen the dataset to write data to the appliance again.

To reopen an NFS dataset

At the command prompt on the host, run `oci dts nfs-dataset reopen` to reopen an NFS dataset.

```
oci dts nfs-dataset reopen --name <dataset_name>
```

Step 3: Repeat Steps to Write Data to the Appliance

Repeat the same tasks you performed when you originally wrote data to the appliance beginning with activating the dataset in the Copying Files to the NFS Share section.

Troubleshooting

This topic describes various troubleshooting issues related to the Data Transfer Service.

Troubleshooting the Appliance

You can generate performance information for troubleshooting issues with the appliance through the terminal emulator on the host machine. Select **Collect Appliance Diagnostic Information** from the serial console configuration menu. The diagnostic tool generates system, network, storage, and performance data while the transfer job is running. It then forwards the data to the appliance serial console. Here you can scroll through the terminal to view it.

You can also use the log capture feature of the serial port emulator to capture the output. Serial port emulators often support the ability to copy the session to a file. Refer to the documentation of your serial port emulation package for instructions. Copying to a log file is useful if you need assistance from Oracle or if your emulation session does not allow you to scroll back and see all the output.

For each operation, the display shows exactly what command was executed and all the options.

Here is an example of the diagnostic output:

```
--------------------------------------------------------------------------------
- systemctl -l --type service --state=active                                   -
--------------------------------------------------------------------------------
UNIT LOAD ACTIVE SUB DESCRIPTION
auditd.service loaded active running Security Auditing Service
blk-availability.service loaded active exited Availability of block devices
chronyd.service loaded active running NTP client/server
console-diags@39-3147-1001.service loaded active running Diagnostic Collection Server for the XA (PID
3147/UID 1001)
crond.service loaded active running Command Scheduler
data-transfer-appliance.service loaded active running Data Transfer Appliance
data-transfer-console.service loaded active running Data Transfer Serial Console
```

Any problem with the diagnostic data collection results in the console output being written to the log file of the service. Failure of the commands is indicative of a serious problem, perhaps requiring the return of the appliance. Here is an example of the log:

```
Mar 6 17:55:33 localhost console-diags: {"Module": "main", "Type": "Info", "Message": "Received message
{\"cmd\": \"collect\"}"}
Mar 6 17:55:33 localhost console-diags: {"Module": "main", "Type": "Info", "Message": "Setting up output
file. First to remove all /tmp/xa-diags-results"}
Mar 6 17:55:33 localhost console-diags: {"Module": "main", "Type": "Info", "Message": "Removing /tmp/xa-
diags-results.2019-03-06T17:54:56.000471"}
```

Initializing Appliance Fails Because of IP Address Issues

Initializing the Appliance can fail because of using the incorrect IP address. The IP address for `initialize-auth` can differ from the IP address obtained when running ping or ssl connect. If you experience an initialization failure, ensure that you are using the correct IP address for your Appliance and try initializing again.

Dataset Sealing Process Fails

The dataset sealing process can fail sometimes because there are special files in the dataset:

```
dts nfs-dataset seal-status --name nfs-ds-1

Seal Status :
 success           : false
 failureReason     :
Number of special files : 5
 startTime         : 2019/03/26 11:52:37 PDT
 endTime           : 2019/03/26 11:52:39 PDT
 numFilesToProcess : 0
 numFilesProcessed : 0
 bytesToProcess    : 0.00 KB
 bytesProcessed    : 0.00 KB
 bytesToProcess    : 0.00 KB
```

At the command prompt on the host, reactivate the NFS dataset.

```
oci dts nfs-dataset activate --name <dataset_name>
```

Then run `find` to get the full list of all special files and the specific type of each one.

```
find <mountpoint> \! -type f \! -type d | xargs file
```

For example:

```
$ find /mnt/nfs-ds-1 \! -type f \! -type d | xargs file
/mnt/nfs-ds-1/myfile1: symbolic link to `/home/user1/myfile1'
/mnt/nfs-ds-1/myfile2: symbolic link to `/home/user1/myfile2'
```

Next, review the list and remove all special files from the NFS mount point.

```
find <mountpoint> \! -type f \! -type d | xargs rm
```

Deactivate the NFS dataset.

```
oci dts nfs-dataset deactivate --name <dataset_name>
```

Finally, reseal the dataset.

```
oci dts nfs-dataset seal --name <dataset_name>[--wait]
```

Monitor the seal progress. Wait for it to complete successfully and continue with the subsequent steps.

Initialize Authentication Fails with "connection refused" or "connection timed out"

If you try to configure networking using the appliance serial console but fail with a "connection refused" or "connection timed out" message, follow these troubleshooting steps.

Run the following command at the command prompt on the host:

```
ping <appliance_ip>
```

If a failure occurs, run the following command to verify appliance IP and the path to appliance.

```
ping -I <local_interface> <appliance_ip>
```

To determine expected interface, run `ip route` or an equivalent command. Verify that routing table is sane. Try running `traceroute` if you're not sure to see the network path to the appliance IP.

Run the following command:

```
curl -k https://<appliance_ip>
```

You should receive the response "Not found." This failure can indicate the IP address may be wrong. For example, nothing is listening on port 443.If you receive a failure message, run the following command:

```
openssl s_client -showcerts -connect <appliance_ip>:443
```

You should see a certificate issued for "Oracle Cloud Infrastructure" / "Data Transfer Appliance."

This command is similar to `curl` but does not use HTTPS and so proxies do not affect it. If this command works, and `curl` fails, then verify there are no proxy environmental variables.

Data Transfer Utility Fails with "invalid configuration file"

If you attempt to run Data Transfer commands and receive the error message "invalid configuration file," verify that the following files are present on your host and are correctly set up:

- ~/.oci/config *and*
- ~/.oci/config_upload_user

Both files must have "`[DEFAULT]`" as the first line. Use of the "`~`" character in a path is not valid in the file's contents.

Data Transfer Utility Fails with "Processing exception..." while communicating to Oracle Cloud Infrastructure

Check if your environment has proxies to the internet. If so, update them to the latest version and set "https_proxy." If you are using the appliance, set "no_proxy" environmental variables. See Prerequisites for more information on proxies.

Data Transfer Utility Fails Because of Lack of Exclusive Access to Disk

The Data Transfer Utility requires exclusive access to the disk. If you have any drivers that already claim exclusive access to the disk, then the Data Transfer Utility fails. For example, if you employ a devicemapper multipath driver over all your disk devices, you must first

remove the disk used for the data transfer from the list of devices managed by the multipath driver.

Be sure that access to the disk is not done through any devicemapper or volume manager. During the data transfer, the expectation is that the file system is created on a "raw" device. Any layering or mapping through intermediate drivers or abstraction layers makes it impossible for the disk to be uploaded at the transfer site. The source of these failures can include drivers like multipath, md, striping, logical volume managers, and potentially others as well.

You can confirm that the Data Transfer Utility has exclusive access by attempting to manually format the disk being used for your data transfer. The Data Transfer Utility uses the `cryptsetup` utility to create an encrypted device. You can run `cryptsetup` from the command line (root privileges required):

```
cryptsetup luksFormat -c aes-xts-plain64 -s 512 -h sha512 --iter-time 2000 --use random /dev/<sdXX>
```

<sdXX> is the name of the disk being used for the data transfer.

When prompted, respond that you do want to encrypt the device. You are required to provide a passphrase. Any passphrase is acceptable as the `cryptsetup` utility can run on a disk repeatedly without any problems.

If the command succeeds, then you know that the Data Transfer Utility can gain exclusive ownership of the disk to do the necessary for the data transfer.

CHAPTER 11 Database

This chapter explains how to launch a DB System and manage databases on DB Systems.

Overview of the Database Service

The Database service offers autonomous and user-managed Oracle Database cloud solutions. Autonomous databases are preconfigured, fully-managed environments that are suitable for either transaction processing or for data warehouse workloads. User-managed solutions are bare metal, virtual machine, and Exadata DB systems that you can customize with the resources and settings that meet your needs.

You can quickly provision an autonomous database or user-managed DB system. You have full access to the features and operations available with the database, but Oracle owns and manages the infrastructure.

You can also extend user-managed database services into your data center by using Exadata Cloud at Customer, which applies the combined power of Exadata and Oracle Cloud Infrastructure while enabling you to meet your organization's data-residency requirements.

For details about each offering, start with the following overview topics:

Autonomous Databases

The Database service offers Oracle's Autonomous Database with transaction processing and data warehouse workload types.

User-managed Systems

- Bare Metal and Virtual Machine DB Systems
- Exadata DB Systems
- Exadata Cloud at Customer

License Types and Bring Your Own License (BYOL) Availability

Oracle Cloud Infrastructure supports a licensing model with two license types. With **License included**, the cost of the cloud service includes a license for the Database service. With **Bring Your Own License (BYOL)**, Oracle Database customers can use existing licenses with Oracle Cloud Infrastructure. Note that Oracle Database customers remain responsible for complying with license restrictions applicable to their BYOL licenses, as defined in their program order for those licenses.

You do not need separate on-premises licenses and cloud licenses. BYOL databases support all advanced Database service manageability functionality, including backing up and restoring a DB system, patching, and Oracle Data Guard.

You can choose BYOL when you launch an Oracle Cloud Infrastructure database or DB system. Choosing BYOL impacts how the usage data for the instance is metered and subsequent billing.

Note that on some provisioning dialogs in the Console, the BYOL option is labeled **My Organization Already Owns Oracle Database Software Licenses**.

For additional information about license pricing and features, see Oracle Cloud Database Services.

Always Free Database Resources

The Database service is one of the Oracle Cloud Infrastructure services that provides you with Always Free resources as a part of Oracle's Free Tier. For an introduction to the Free Tier, see Oracle Cloud Infrastructure's Free Tier. For details about the Always Free Autonomous Database, see Always Free Availability in the Autonomous Database overview topic. To provision an Always Free Autonomous Database, see To create an Always Free Autonomous Database.

Moving Database Resources to a Different Compartment

You can move DB systems, Autonomous Database resources, and Exadata Cloud at Customer resources from one compartment to another. When you move a Database resource to a new

compartment, its dependent resources move with it. After you move the resource to the new compartment, inherent policies apply immediately and affect access to that resource and its dependent resources through the Console.

Important

To move resources between compartments, resource users must have sufficient access permissions on the compartment that the resource is being moved to, as well as the current compartment. For more information about permissions for Database resources, see Details for the Database Service.

Dependent Resource Details

Details about dependent resources are as follows:

- **Bare metal, virtual machine, and Exadata DB systems:** Dependent resources that move with these DB systems include Database Homes and databases, as well as the metadata for automatic backups. To verify the compartment of a dependent resource, check the compartment of the DB system.
- **Autonomous Database:** Autonomous Database dependent resources are limited to its automatic backups. Autonomous Exadata Infrastructure instances and Autonomous Container Databases have no dependent resources that move with them. Associated (non-dependent) resources remain in their current compartments.
- **Exadata Cloud at Customer:** Resources that can be moved are Exadata Infrastructure, VM clusters, and backup destinations. VM cluster networks are dependent resources of Exadata Infrastructure instances, so they move with them. VM clusters have the following dependent resources: Database Homes, and databases and their automatic backups. Backup destinations have no dependent resources.

For more information about moving resources to other compartments, see Moving Resources to a Different Compartment.

Monitoring Resources

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications. For more information, see Monitoring Overview and Notifications Overview.

For information about available Database service metrics and how to view them, see Database Metrics.

Creating Automation with Events

You can create automation based on state changes for your Oracle Cloud Infrastructure resources by using event types, rules, and actions. For more information, see Overview of Events.

See Database for details about Database resources that emit events.

Resource Identifiers

Most types of Oracle Cloud Infrastructure resources have a unique, Oracle-assigned identifier called an Oracle Cloud ID (OCID). For information about the OCID format and other ways to identify your resources, see Resource Identifiers.

Ways to Access Oracle Cloud Infrastructure

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. For a list of available SDKs, see Software Development Kits and Command Line Interface.

To access the Console, you must use a supported browser. Oracle Cloud Infrastructure supports the latest desktop versions of Google Chrome, Microsoft Edge, Internet Explorer 11, Safari, Firefox, and Firefox ESR. Note that private browsing mode is not supported for Firefox, Internet Explorer, or Edge. Mobile browsers are not supported.

For more information on tenancies and compartments, see "Key Concepts and Terminology" in the *Oracle Cloud Infrastructure Getting Started Guide*. For general information about using the API, see REST APIs.

If you're new to policies, see Getting Started with Policies and Common Policies. If you want to write policies that provide stricter access to database resources, see Details for the Database Service.

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies. For specific details about writing policies for each of the different services, see Policy Reference.

If you're a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

For common policies used to authorize Oracle Cloud Infrastructure Database users, see Common Policies.

For in-depth information on granting users permissions for the Database service, see Details for the Database Service in the IAM policy reference.

Limits on the Database Service

See Service Limits for a list of applicable limits and instructions for requesting a limit increase. To set compartment-specific limits on a resource or resource family, administrators can use compartment quotas.

Note

Service limits and compartment quotas to not apply to Exadata Cloud at Customer.

Many Database API operations are subject to throttling.

Work Requests Integration

The Database service is integrated with the Oracle Cloud Infrastructure Work Requests API. Work requests allow you to monitor long-running operations such as the provisioning of DB systems. A work request is an activity log that enables you to track each step in the operation's progress. Each work request has an OCID that allows you to interact with it programmatically and use it for automation. For general information on using work requests in Oracle Cloud Infrastructure, see Work Requests and the Work Requests API.

Database service operations that create work requests

The following Database operations result in the creation of a work request:

Autonomous Databases

Note

In the Database service, work requests are currently supported only for the Autonomous Database resources in the list that follows.

- Creating or terminating the following resource types:
  - Autonomous Databases
  - Autonomous Container Databases
  - Autonomous Exadata Infrastructure instances
- Starting or stopping an Autonomous Database instance
- Restoring an Autonomous Database instance
- Cloning an Autonomous Database instance
- Creating or deleting manual backups
- Scaling database storage or CPU
- Updating the database license type
- Updating a database's network access control list (ACL)
- Registering or deregistering an Autonomous Database with Data Safe.

Bare Metal, Virtual Machine, and Exadata Databases

Work requests are not currently available for these products.

Overview of Autonomous Database

Oracle Cloud Infrastructure's Autonomous Database is a fully managed, preconfigured database environment with two workload types available, Autonomous Transaction Processing and Autonomous Data Warehouse. You do not need to configure or manage any hardware, or install any software. After provisioning, you can scale the number of CPU cores or the storage capacity of the database at any time without impacting availability or performance. Autonomous Database handles creating the database, as well as the following maintenance tasks:

- Backing up the database
- Patching the database

- Upgrading the database
- Tuning the database

Always Free Availability

Autonomous Database can be used for free as part of Oracle Cloud Infrastructure's suite of Always Free resources. Users of both paid and free Oracle Cloud Infrastructure accounts have access to two Always Free instances of Autonomous Database. Always Free Autonomous Databases have a fixed 8 GB of memory, 20 GB of storage, 1 OCPU, and can be configured for either Autonomous Transaction Processing or Autonomous Data Warehouse workloads.

For an introduction to the Free Tier, see Oracle Cloud Infrastructure's Free Tier. For details of the Always Free Autonomous Database, see Overview of the Always Free Autonomous Database. To provision an Always Free Autonomous Database, see To create an Always Free Autonomous Database.

Currently, Always Free Autonomous Databases are available in all commercial regions.

Available Workload Types

Autonomous Database offers two workload types:

- The **Autonomous Transaction Processing** workload type configures the database for a transactional workload, with a bias towards high volumes of random data access.
  For a complete product overview of Autonomous Transaction Processing, see Autonomous Transaction Processing. For Autonomous Transaction Processing tutorials, see Quick Start tutorials.
- The **Autonomous Data Warehouse** workload type configures the database for a decision support or data warehouse workload, with a bias towards large data scanning operations.
  For a complete product overview of Autonomous Data Warehouse, see Autonomous Data Warehouse. For Autonomous Data Warehouse tutorials, see Quick Start tutorials.

Deployment Types

Autonomous Databases have the following deployment options:

- **Dedicated deployment.** Using the dedicated deployment option, you have exclusive use of the Exadata infrastructure and hardware. Dedicated deployment offers multitenant database architecture, allowing you to create and manage multiple Autonomous Databases within a single database system. For an overview of Dedicated Deployments, see Overview of Autonomous Database Dedicated Deployments. Both workload types (transaction processing and warehouse) can be provisioned with dedicated deployment.
- **Serverless deployment.** With the serverless deployment option, you provision and manage only the Autonomous Database, while Oracle handles the infrastructure deployment and management tasks. Both workload types (transaction processing and warehouse) can be provisioned with serverless deployment.

CPU Scaling

For serverless deployments, the **auto scaling** feature enables the system to automatically adjust the number of CPU cores as load demand fluctuates, allowing the system to use cores more efficiently. As demand increases, auto scaling gradually increases the number of cores, up to a maximum of three times the assigned number. Likewise, it gradually decreases cores as demand drops. You can also scale the database's assigned number of CPU cores up or down at any time. CPU scaling does not impact Autonomous Database availability or performance. Note the following points regarding the auto scaling feature:

- The maximum number of cores that can be made available to a database remains 128, regardless of whether auto scaling is enabled or not. This means that database with a CPU core count of 64 could auto scale up to two times the assigned number of cores (2 x 64 = 128). A database with 42 cores (or fewer) could auto scale up to three times the assigned number (3 x 42 = 126).
- Auto scaling can be enabled or disabled at any time.

- The auto scaling status for a database (enabled or disabled) is displayed on the database details page.
- You can view hourly snapshots of the database's actual CPU usage over the most recent 8 days. This information is available in the Service Console, in the Overview page graph "Number of OCPUs Allocated". For more information, see To view CPU allocation hourly snapshot data for an Autonomous Database.
- For billing purposes, the Autonomous Database service determines the average CPU utilization per hour.

Storage Scaling

Autonomous Database allows you to scale the storage capacity of the database at any time without impacting availability or performance.

Performance Monitoring Using Oracle Performance Hub

You can monitor and diagnose the performance of an Autonomous Database in the Oracle Cloud Infrastructure Console using the Performance Hub ASH Analytics and SQL Monitoring features. These features provide the same information as the ASH Analytics and SQL Monitoring tools found in Oracle's EM Express, Oracle Management Cloud (OMC), and SQL Developer Web applications. For more information about using these features in the Oracle Cloud Infrastructure Console, see Using Performance Hub to Analyze Database Performance in Oracle Cloud Infrastructure.

Oracle Database Preview Version Availability

Oracle Cloud Infrastructure periodically offers Autonomous Database preview versions of Oracle Database for testing purposes. You can provision an Autonomous Database using preview version software to test applications before the general availability of the software in Autonomous Database. Oracle will notify Autonomous Database customers when preview versions are available. Preview version software is available for a limited time. Databases provisioned with preview version software will display the end date of the preview period at

the top of the database details page in the Console. If you are using the Console, you can also see the end date of the preview period in the Create Database provisioning dialog before the database is created.

Preview version software should not be used for production databases or for databases that need to persist beyond the limited preview period. Note that preview databases and their associated resources (including backups) are terminated automatically at the conclusion of the preview period. Oracle will notify customers prior to the conclusion of the preview period regarding the end date of the preview.

Any existing Autonomous Database (including those provisioned with preview version software) can be cloned using a preview version of Autonomous Database. However, preview version databases cannot be cloned using the regular (general-availability) Autonomous Database software.

See Creating an Autonomous Database for details on provisioning a preview version of Autonomous Database.

Availability

Autonomous Database is currently available in all regions of the commercial realm. Autonomous Database is currently not available in regions within the Government Cloud realm.

Security Considerations

Data Safe Integration

Oracle Data Safe is a cloud service that enables you to monitor the security posture of your Autonomous Databases. Data Safe helps you discover, protect, and mask sensitive and regulated data. It also helps you assess database users and their authentication information for security risks, and provides auditing and reporting features need for compliance.

Autonomous Databases using serverless deployment can be registered with the Data Safe instance in the region containing the Autonomous Database. For information on registering or

deregistering a database, see To register or deregister an Autonomous Database with Data Safe.

For information on creating and using Data Safe instances, see the Data Safe Overview.

Service Gateway

Oracle Autonomous Database is one of the Oracle Cloud services that can be privately accessed through a service gateway within a VCN. This means you do not need a public IP or NAT to access your Autonomous Database instance from any of the cloud services within the Oracle Services Network. For example, if you have a Compute instance that uses a VCN with a service gateway, you can route traffic between your Compute instance and an Autonomous Database in the same region without the traffic going over the internet. For information on setting up a VCN service gateway and configuring it to access all supported Oracle Service Network services (which include Autonomous Database), see Access to Oracle Services: Service Gateway.

Access Control Lists (ACLs) for Serverless Deployments

For Autonomous Databases using serverless deployment, an access control list (ACL) provides additional protection for your Autonomous Database by allowing only specified IP addresses and VCNs in the list to connect to the database. Specified IP addresses can include private IP addresses from your on-premises network that connect to your database using transit routing and allow traffic to move directly from your on-premises network to your Autonomous Database without going over the internet. See Transit Routing: Private Access to Oracle Services for more information on this method of access.

You can add the following to your ACL:

- Public IP addresses (individually, or in CIDR blocks)
- An entire VCN (specified by OCID)
- Private IP addresses within a specified VCN (individually, or in CIDR blocks)
- Private IP addresses within an on-premises network that have access using a transit routing

You can create an ACL during database provisioning, or at any time thereafter. You can also edit an ACL at any time. Removing all entries from the list makes the database accessible to all clients with the applicable credentials. See To manage the access control list of an Autonomous Database with Serverless Deployment to learn how to create, update, or delete an ACL.

Important

If you are using a service gateway and you configure an access control list, you must add the CIDR range 240.0.0.0/4 to the ACL to enable clients accessing the database through the service gateway to connect to it.

Security Tools for Dedicated Deployments

Network security groups (NSGs), an optional Networking feature available with dedicated deployment, act as a virtual firewall for your Autonomous Exadata Infrastructure resources. An NSG consists of a set of ingress and egress security rules that apply only to *a set of VNICs of your choice within a single VCN*. For more information, see the following topics:

- Network Security Groups
- To edit the network security groups (NSGs) for your Autonomous Exadata Infrastructure resource

Development and Administration Tools

Oracle's SQL Developer Web, Application Express (APEX), and Machine Learning applications are available for Autonomous Databases. For information on how to use these applications and access them from the Console, see Autonomous Database Development and Administration Tools.

Using the Oracle Cloud Infrastructure Console to Manage Autonomous Databases

For information on provisioning, managing, and backing up an Autonomous Database in the Oracle Cloud Infrastructure Console, see the following topics:

- Creating an Autonomous Database
- Managing an Autonomous Database
- Connecting to an Autonomous Database
- Backing Up an Autonomous Database Manually
- Restoring an Autonomous Database

Additional Autonomous Database Product Information

Autonomous Transaction Processing

Information for dedicated deployments

For in-depth documentation on using and managing your Autonomous Transaction Processing dedicated deployment, see the following topics:

- Getting Started with Autonomous Transaction Processing
- Connecting to Autonomous Transaction Processing
- Loading Data into Autonomous Transaction Processing
- Starting, Stopping and Scaling Autonomous Transaction Processing
- Managing Database Users
- Managing and Monitoring Performance
- Backing Up and Restoring Autonomous Transaction Processing
- Cloud Object Storage URI Formats
- Using Oracle Database Features in Autonomous Transaction Processing

For information on how application developers connect their applications to Autonomous Transaction Processing databases, see Developer's Guide to Oracle Autonomous Transaction Processing Dedicated Deployments.

For known issues, see Known Issues for Oracle Autonomous Transaction Processing Dedicated Deployments.

Information for serverless deployments

For in-depth documentation on using and managing your Autonomous Transaction Processing database, see the following topics:

- Getting Started with Autonomous Transaction Processing
- Connecting to Autonomous Transaction Processing
- Loading Data with Autonomous Transaction Processing
- Querying External Data with Autonomous Transaction Processing
- Creating Dashboards, Reports, and Notebooks with Autonomous Transaction Processing
- Managing Users on Autonomous Transaction Processing
- Managing and Monitoring Performance of Autonomous Transaction Processing

For information on using a database client to manage your database, see Connect Autonomous Transaction Processing Using a Client Application.

Autonomous Data Warehouse

Information for serverless deployments

For in-depth documentation on using and managing your Autonomous Data Warehouse database, see the following topics:

- Getting Started with Autonomous Data Warehouse Cloud
- Connecting to Autonomous Data Warehouse Cloud

- Loading Data with Autonomous Data Warehouse Cloud
- Migrating Data from Amazon Redshift
- Querying External Data with Autonomous Data Warehouse Cloud
- Creating Dashboards, Reports, and Notebooks with Autonomous Data Warehouse Cloud
- Managing Users on Autonomous Data Warehouse Cloud
- Managing and Monitoring Performance of Autonomous Data Warehouse Cloud

For information on using a database client to manage your database, see the following topic:

- Connect Autonomous Data Warehouse Using a Client Application

Creating an Autonomous Database

This topic describes how to provision a new Autonomous Database using the Oracle Cloud Infrastructure Console or the API. Autonomous Databases can be provisioned using either the dedicated deployment option or the serverless deployment option. Your database can by optimized for either transaction processing or data warehouse workloads.

If you want to provision an Always Free Autonomous Database, see the To create an Always Free Autonomous Database task instructions in this topic. For more information on the Free Tier, see Oracle Cloud Infrastructure's Free Tier.

For *Oracle By Example* tutorials on provisioning Autonomous Databases, see Provisioning Autonomous Transaction Processing and Provisioning Autonomous Data Warehouse Cloud.

Prerequisites

- To create an Autonomous Database, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in. See

Authentication and Authorization for more information on user authorizations for the Oracle Cloud Infrastructure Database service.

Tip

See Let database and fleet administrators manage Autonomous Databases for sample Autonomous Database policies. See Details for the Database Service for detailed information on policy syntax.

- For information on additional prerequisites for provisioning an Autonomous Transaction Processing database, see What Do You Need? Likewise, for information on additional prerequisites for provisioning an Autonomous Data Warehouse, see What Do You Need?
- To create an Autonomous Transaction Processing database with the dedicated deployment option, you must first provision the infrastructure and at least one Autonomous Container Database. For more information, see Creating an Autonomous Exadata Infrastructure Resource and Creating an Autonomous Container Database. Note that Oracle Cloud Infrastructure does not currently offer Autonomous Data Warehouse databases with the dedicated deployment option.

Using the Oracle Cloud Infrastructure Console to Create an Autonomous Database

When provisioning an Autonomous Database using the serverless deployment option, you can choose either the transaction processing or the data warehouse workload types.

For Autonomous Transaction Processing databases, you can choose the dedicated deployment option. Dedicated deployment provides you with exclusive use of the Exadata infrastructure and hardware.

To create an Autonomous Database using the serverless deployment option

1. Open the navigation menu. Under **Database**, click **Autonomous Transaction Processing** or **Autonomous Data Warehouse**.
   In the **Create Autonomous Database** dialog, enter the following:

   Basic Database Information

   - **Display Name:** A user-friendly description or other information that helps you easily identify the resource. The display name does not have to be unique, and you can change it whenever you like. Avoid entering confidential information.
   - **Compartment:** Select the compartment of the Autonomous Database.
   - **Database Name:** The database name must consist of letters and numbers only, starting with a letter. The maximum length is 14 characters. Avoid entering confidential information.

   

   Note

   You cannot use the same database name concurrently for both an Autonomous Data Warehouse and an Autonomous Transaction Processing database.

   Workload Type

   Select the desired workload type. See About Autonomous Transaction Processing and About Autonomous Data Warehouse for information about each workload type.

   Infrastructure Type

   Select **Serverless**.

DATABASE CPU CORE COUNT AND STORAGE CONFIGURATION

- **Always Free:** Use this selector to show only Always Free configuration options if you are provisioning an Always Free Autonomous Database. See Overview of the Always Free Autonomous Database for more information.
- **CPU Core Count:**You can enable up to 128 cores for your Autonomous Transaction Processing database. The actual number of available cores is subject to your tenancy's service limits. Select the number of cores you wish to assign to your database. The total number of number of cores available to all database within the Autonomous Exadata Infrastructure depends on the infrastructure shape being used. For information on the CPU core resources available in the current Oracle Cloud Infrastructure Exadata offerings, see Exadata X7 Shapes.

  Auto Scaling: Auto scaling allows Autonomous Databaseto automatically increase the number of CPU cores by up to three times the assigned CPU core count value, depending on demand for processing. The auto scaling feature reduces the number of CPU cores when additional cores are not needed. For databases with up to 42 assigned cores, you can increase the maximum number of cores available through auto scaling by increasing the CPU core count value.

Note

The maximum number of cores that are available to any Autonomous Database database not using dedicated deployment is 128, regardless of whether auto scaling is enabled or not. This means that database with a CPU core count of 64 could auto scale up to two times the assigned number of cores (2 x 64 = 128). A database with 42 cores (or fewer) could auto scale up to three times the assigned number (3 x 42 = 126). For billing purposes, the database service determines the average number of CPUs used per hour.

- **Storage:** Specify the storage you wish to make available to your Autonomous Database, in terabytes. You can make up to 128 TB available.
- **Enable Preview Version:** *(This option only displays during periods when a preview version of Autonomous Database is available)* Select this option to provision the database with an Autonomous Database preview version. Preview versions of Autonomous Database are made available for limited periods for testing purposes. Do not select this option if you are provisioning a database for production purposes or if you will need the database to persist beyond the limited availability period of the preview version.

ADMINISTRATOR CREDENTIALS

Set the password for the Autonomous Database Admin user by entering a password that meets the following criteria. You use this password when accessing the Autonomous Database service console and when using an SQL client tool.

- Between 12 and 30 characters long
- Contains at least one lowercase letter
- Contains at least one uppercase letter
- Contains at least one number
- Does not contain the double quotation mark (")
- Does not contain the string "admin", regardless of casing

NETWORK ACCESS

Optionally, you can create an Access Control List (ACL) for your database. ACLs provide additional protection for your Autonomous Database by allowing only the public and VCN IP addresses in the list to connect to the database. Click **Configure Access Control Rules** to create an ACL for your database.

You can specify the following types of addresses in your list by using the **Source** drop-down selector:

- **IP Address** allows you to specify one or more individual public IP address. Use commas to separate your addresses in the input field.
- **CIDR Block** allows you to specify one or more ranges of public IP addresses using CIDR notation. Use commas to separate your CIDR block entries in the input field.
- **Virtual Cloud Network** allows you to specify an existing VCN. The drop-down listing in the input field allows you to choose from the VCNs in your current compartment for which you have access permissions. Click the **Change Compartment** link to display the VCNs of a different compartment.
- **Virtual Cloud Network (OCID)** allows you input the OCID of a VCN in a text box. You can use this input method if the VCN you are specifying is in a compartment which you do not have permission to access.

If you add a **Virtual Cloud Network** to your ACL, you can limit further by specifying allowed VCN IP addresses or CIDR ranges. Enter those addresses or CIDR blocks in the

IP Addresses or CIDRs field that is displayed below your **Virtual Cloud Network** choice. Use commas to separate your VCN addresses and CIDR blocks in the input field. You can specify the following types of IP addresses at the VCN level:

- Private IP addresses within your Oracle Cloud Infrastructure VCN
- Private IP addresses within an on-premises network that have access to your Autonomous Database using a transit routing and a private connection via FastConnect or VPN Connect.

Click **+Additional Entry** to add additional access rules to your list.

LICENSE TYPE

Specify the license type setting you want to use. Your choice affects metering for billing. You have the following options:

- **Bring your own license**: Bring my existing database software licenses to the database cloud service.
- **License included**: Subscribe to new database software licenses and the Database cloud service.

ADVANCED OPTIONS

Tags: Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator. Avoid entering confidential information.

2. Click **Create Autonomous Database**.

Note

The following naming restrictions apply to Autonomous Transaction Processing and Autonomous Data Warehouse databases:

- Names associated with databases terminated within the last 60 days cannot be used when creating a new database.
- A database name cannot be used concurrently for both an Autonomous Data Warehouse and an Autonomous Transaction Processing database.

To create an Autonomous Database database using the dedicated deployment option

Note

To provision an Autonomous Database using the dedicated deployment option, you must have already provisioned an Autonomous Exadata Infrastructure resource and at least one container database on that resource. See the following for more information:

- Overview of Autonomous Database Dedicated Deployments
- Creating an Autonomous Exadata Infrastructure Resource
- Creating an Autonomous Container Database

1. Open the navigation menu. Under **Database**, click **Autonomous Transaction Processing** or **Autonomous Data Warehouse**.
   In the **Create Autonomous Database** dialog, enter the following:

   Basic Database Information

   - **Display Name:** A user-friendly description or other information that helps you easily identify the resource. The display name does not have to be unique, and you can change it whenever you like. Avoid entering confidential information.
   - **Compartment:** Select the compartment of the Autonomous Database.
   - **Database Name:** The database name must consist of letters and numbers only, starting with a letter. The maximum length is 14 characters. Avoid entering confidential information.

   Workload Type

   Select the desired workload type. See About Autonomous Transaction Processing and About Autonomous Data Warehouse for information about each workload type.

   Infrastructure Type

   Select **Dedicated**.

   Database CPU Core Count and Storage Configuration

   - **CPU Core Count:** Select the number of cores you wish to assign to your database. The total number of number of cores available to all database within the Autonomous Exadata Infrastructure depends on the infrastructure shape being used. For information on the CPU core resources available in the current Oracle Cloud Infrastructure Exadata offerings, see Exadata X7 Shapes.

Tip

Autonomous Database with dedicated deployment allows for the over-subscription of CPU cores when provisioning databases. This means that for a given infrastructure instance, the sum of all CPU cores provisioned to Autonomous Databases can exceed the number of CPU cores on the Exadata rack. This approach allows for better CPU core utilization. Note that if all databases are heavily loaded at the same time, there will be some contention for CPU resources, and degraded performance.

- **Storage:** Specify the storage you wish to make available to your Autonomous Database, in terabytes. The available storage depends on the infrastructure shape being used. For information on storage available in the current Oracle Cloud Infrastructure Exadata offerings, see Exadata X7 Shapes.

AUTONOMOUS CONTAINER DATABASE

- **Compartment:** Specify the compartment containing the Autonomous Container Database you wish to use.
- **High Availability Database Container:** Specify the Autonomous Container Database you wish to use for your Autonomous Database. This selection determines which Autonomous Exadata Infrastructure the database runs within.

See Creating an Autonomous Container Database for information on provisioning a container database.

ADMINISTRATOR CREDENTIALS

Set the password for the Autonomous Database Admin user by entering a password that meets the following criteria. You use this password when accessing the Autonomous Database service console and when using an SQL client tool.

- Between 12 and 30 characters long
- Contains at least one lowercase letter
- Contains at least one uppercase letter
- Contains at least one number
- Does not contain the double quotation mark (")
- Does not contain the string "admin", regardless of casing

ADVANCED OPTIONS

Tags: Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator. Avoid entering confidential information.

2. Click **Create Autonomous Database**.

Note

The following naming restrictions apply to Autonomous Transaction Processing and Autonomous Data Warehouse databases:

- Names associated with databases terminated within the last 60 days cannot be used when creating a new database.
- A database name cannot be used concurrently for both an Autonomous Data Warehouse and an Autonomous Transaction Processing database.

To create an Always Free Autonomous Database

1. Open the navigation menu. Under **Database**, click **Autonomous Transaction Processing** or **Autonomous Data Warehouse**.
   In the **Create Autonomous Database** dialog, enter the following:

   Basic Database Information

   - **Display Name:** A user-friendly description or other information that helps you easily identify the resource. The display name does not have to be unique, and you can change it whenever you like. Avoid entering confidential information.
   - **Compartment:** Select the compartment of the Autonomous Database.
   - **Database Name:** The database name must consist of letters and numbers only, starting with a letter. The maximum length is 14 characters. Avoid entering confidential information.

Workload Type

Select the desired workload type. See About Autonomous Transaction Processing and About Autonomous Data Warehouse for information about each workload type.

Infrastructure Type

Applies to Autonomous Transaction Processing only.

Select **Serverless**.

Database CPU Core Count and Storage Configuration

- **Always Free:** Move this selector to the right so that the provisioning workflow shows only the Always Free configuration options. Note that the **Core CPU count** and **Storage** configuration fields are disabled when provisioning an Always Free Autonomous Database. Your database will have 1 OCPU, 8 GB of memory, and 20 GB of storage.

Administrator Credentials

Set the password for the Autonomous Database Admin user by entering a password that meets the following criteria:

- Between 12 and 30 characters long
- Contains at least one lowercase letter
- Contains at least one uppercase letter
- Contains at least one number
- Does not contain the double quotation mark (")
- Does not contain the string "admin", regardless of casing

Use this password when accessing the Autonomous Database service console and when using an SQL client tool.

License Type

When you provision an Always Free Autonomous Database, the license type is set to **License included** and cannot be adjusted.

ADVANCED OPTIONS

Tags: Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator. Avoid entering confidential information.

2. Click **Create Autonomous Database**.

Note

The following naming restrictions apply to Autonomous Transaction Processing and Autonomous Data Warehouse databases:

- Names associated with databases terminated within the last 60 days cannot be used when creating a new database.
- A database name cannot be used concurrently for two Autonomous Databases, regardless of workload type.

Using the API

Use the CreateAutonomousDatabase API operation to create Autonomous Databases of either the transaction processing or warehouse workload types.

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Autonomous Transaction Processing

- Using Oracle Autonomous Transaction Processing (the Autonomous Transaction Processing database administrator guide)
- Using Oracle Autonomous Transaction Processing Dedicated Deployments (the Autonomous Transaction Processing Dedicated Deployment database administrator guide)
- Autonomous Transaction Processing: Tutorials (Oracle By Example tutorials)
- Autonomous Transaction Processing: Videos (video tutorials)

Autonomous Data Warehouse

- Using Oracle Autonomous Data Warehouse (the Autonomous Data Warehouse user guide)
- Autonomous Data Warehouse: Tutorials (Oracle By Example tutorials)
- Autonomous Data Warehouse: Videos (video tutorials)

Managing an Autonomous Database

This topic describes the database management tasks for Autonomous Databases that you complete using the Oracle Cloud Infrastructure Console or the API. Note that some database management tasks not covered here are performed using the Autonomous Transaction Processing service console or the Autonomous Data Warehouse service console.

Prerequisites

To perform the management tasks in this topic, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in. See Authentication and Authorization for more information on user authorizations for the Oracle Cloud Infrastructure

Database service. See Let database and fleet administrators manage Autonomous Databases for sample Autonomous Database policies. See Details for the Database Service for detailed information on policy syntax.

Using the Oracle Cloud Infrastructure Console

You can perform basic administrative tasks for Autonomous Databases in the Oracle Cloud Infrastructure Console including stopping, starting, and scaling your databases. You can also use the Console to back up or to restore the database.

To set the Admin password

1. Open the navigation menu. Under **Database**, click **Autonomous Transaction Processing** or **Autonomous Data Warehouse**.
2. Choose your **Compartment**.
3. In the list of Autonomous Databases, click on the display name of the database you wish to administer.
4. Go to **Actions**, and then click **Admin Password**. The Admin Password dialog opens.
5. Enter a password for the Autonomous Database. The password must meet the following criteria:
    - Between 12 and 30 characters long
    - Contains at least one lowercase letter
    - Contains at least one uppercase letter
    - Contains at least one number
    - Does not contain the double quotation mark (")
    - Does not contain the string "admin", regardless of casing
    - Is not one of the last four passwords used for the database
    - Is not a password you previously set within the last 24 hours
6. Enter the password again in the Confirm Password field.

7. Click **Update**.

To scale the CPU core count or storage of an Autonomous Database

1. Open the navigation menu. Under **Database**, click **Autonomous Transaction Processing** or **Autonomous Data Warehouse**.
2. Choose your **Compartment**.
3. In the list of Autonomous Databases, click on the display name of the database you wish to administer.
4. Click **Scale Up/Down**.
5. Enter a new value for **CPU Core Count** or **Storage** between 1 and 128. The number you enter represents the desired total (final) value for your database's CPU core count or storage.

   The number of available cores is subject to your tenancy's service limits. An Autonomous Database database can have a maximum of 128 cores and 128 TB of storage. Scaling the CPU core count affects your CPU billing.
6. Click **Update**.

To enable or disable auto scaling for an Autonomous Database with serverless deployment

Note the following points regarding the auto scaling feature:

- If auto scaling is disabled while more CPU cores are in use than the database's currently assigned number of cores, then Autonomous Database scales the number of CPU cores in use down to the assigned number.
- Enabling auto scaling does not change the concurrency and parallelism settings for the predefined services. See Managing Concurrency and Priorities on Autonomous Data Warehouse and Managing Priorities on Autonomous Transaction Processing for more information.

1. Open the navigation menu. Under **Database**, click **Autonomous Transaction Processing** or **Autonomous Data Warehouse**.
2. Choose your **Compartment**.
3. In the list of Autonomous Databases, click on the display name of the database you wish to administer.
4. Click **Scale Up/Down**.
5. Check **Auto Scaling** to enable the auto scaling feature, or uncheck **Auto Scaling** to disable the feature. Auto scaling allows Autonomous Database to automatically increase the number of CPU cores by up to three times the assigned CPU core count value, depending on demand for processing. The auto scaling feature reduces the number of CPU cores when additional cores are not needed. You can enable or disable auto scaling at any time. For databases with up to 42 assigned cores, you can increase the maximum number of cores available through auto scaling by increasing the CPU core count value.

Note

The maximum number of cores that are available to any Autonomous Database database not using dedicated deployment is 128, regardless of whether auto scaling is enabled or not. This means that database with a CPU core count of 64 could auto scale up to two times the assigned number of cores (2 x 64 = 128). A database with 42 cores (or fewer) could auto scale up to three times the assigned number (3 x 42 = 126). For billing purposes, the database service determines the average number of CPUs used per hour.

6. Click **Update**.

To view CPU allocation hourly snapshot data for an Autonomous Database

1. Open the navigation menu. Under **Database**, click **Autonomous Transaction Processing** or **Autonomous Data Warehouse**.
2. Choose your **Compartment**.
3. In the list of Autonomous Databases, click on the display name of the database for which you wish to view CPU usage data.
4. Click the **Service Console** button. The Service Console opens in a new tab or window.
5. In the Overview screen, the **Number of OCPUs allocated** graph shows hourly snapshot data of CPU allocation over the last eight days. Place your cursor over the graph and move it to the left or right to see data for a specific day and hour.

To move an Autonomous Database to another compartment

Note

To move resources between compartments, resource users must have sufficient access permissions on the compartment that the resource is being moved to, as well as the current compartment. For more information about permissions for Database resources, see Details for the Database Service.

1. Open the navigation menu. Under **Database**, click **Autonomous Transaction Processing** or **Autonomous Data Warehouse**.
2. Choose your **Compartment**.
3. In the list of Autonomous Databases, click on the display name of the database you wish to move.

4. Go to **Actions**, and then click **Move Resource**.
5. Select the new compartment.
6. Click **Move Resource**.
   For information about dependent resources for Database resources, see Moving Database Resources to a Different Compartment.

To stop or start an Autonomous Database

1. Open the navigation menu. Under **Database**, click **Autonomous Transaction Processing** or **Autonomous Data Warehouse**.
2. Choose your **Compartment**.
3. In the list of Autonomous Databases, click on the display name of the database you wish to administer.
4. Go to **Actions**, and then click **Stop** (or **Start**). When you stop your Autonomous Database, billing stops for CPU usage. Billing for storage continues when the database is stopped.
5. Confirm that you wish to stop or start your Autonomous Database in the confirmation dialog.

Note

Stopping your database has the following consequences:

- On-going transactions are rolled back.
- CPU billing is halted based on full-hour cycles of usage.
- You will not be able to connect to your database using database clients or tools.

To terminate an Autonomous Database

Warning

Terminating an Autonomous Database permanently deletes it. The database data, including automatic backups, will be lost when the system is terminated. Manual backups remain in Object Storage and are not automatically deleted when you terminate an Autonomous Database. Oracle recommends that you create a manual backup prior to terminating.

1. Open the navigation menu. Under **Database**, click **Autonomous Transaction Processing** or **Autonomous Data Warehouse**.
2. Choose your **Compartment**.
3. In the list of Autonomous Databases, click on the display name of the database you wish to administer.
4. Go to **Actions**, and then click **Terminate**.
5. Confirm that you wish to terminate your Autonomous Database in the confirmation dialog.

To check the lifecycle state of your Autonomous Database

1. Open the navigation menu. Under **Database**, click **Autonomous Transaction Processing** or **Autonomous Data Warehouse**.
2. Choose your **Compartment**.
3. In the list of Autonomous Databases, click on the display name of the database you wish to administer.

4. In the Information tab, note the value displayed for **Lifecycle State**. For some lifecycle states, an information icon ( ) is displayed to provide additional details regarding the lifecycle state or ongoing operations such as backups, restores, or terminations. The database has one of the following lifecycle states:
    - Available
    - Available needs attention
    - Backup in progress
    - Provisioning
    - Restore in progress
    - Scaling in progress
    - Starting
    - Stopping
    - Stopped
    - Terminating
    - Terminated
    - Unavailable

To view a work request for your Autonomous Database

1. Open the navigation menu. Under **Database**, click **Autonomous Transaction Processing** or **Autonomous Data Warehouse**.
2. Choose your **Compartment**.
3. In the list of Autonomous Databases, click on the display name of the database you wish to administer.
4. In the **Resources** section, click **Work Requests**. The status of all work requests appears on the page.
5. To see the log messages, error messages, and resources that are associated with a

specific work request, click the operation name. Then, select an option in the **More information** section.

For associated resources, you can click the the Actions icon (three dots) next to a resource to copy the resource's OCID.

For more information, see Work Requests.

To manage tags for your Autonomous Database

1. Open the navigation menu. Under **Database**, click **Autonomous Transaction Processing** or **Autonomous Data Warehouse**.
2. Choose your **Compartment**.
3. In the list of Autonomous Databases, click on the display name of the database you wish to administer.
4. Go to **Actions**, and then click **Apply Tag(s)** to add new tags. Or click the **Tags** tab to view or edit the existing tags.

For more information, see Resource Tags.

To access the Autonomous Database service console (serverless deployments only)

1. Open the navigation menu. Under **Database**, click **Autonomous Transaction Processing** or **Autonomous Data Warehouse**.
2. Choose your **Compartment**.
3. In the list of Autonomous Databases, click on the display name of the database you wish to administer.
4. Click **Service Console**.

For information on using the Autonomous Transaction Processing service console features, see Managing and Monitoring Performance of Autonomous Transaction Processing. For

information on using the Autonomous Data Warehouse service console features, see Managing and Monitoring Performance of Autonomous Data Warehouse Cloud.

To change the license type of an Autonomous Database

1. Open the navigation menu. Under **Database**, click **Autonomous Transaction Processing** or **Autonomous Data Warehouse**.
2. Choose your **Compartment**.
3. In the list of Autonomous Databases, click on the display name of the database you wish to administer.
4. Go to **Actions**, and then click **Update License Type**.
   The dialog displays the options with your current license type selected.
5. Select the new license type.
6. Click **Update**.

See Known Issue.

To manage the access control list of an Autonomous Database with Serverless Deployment

An access control list (ACL) provides additional protection for your Autonomous Database by allowing only the IP addresses in the list to connect to the database. An ACL must contain at least one entry representing an IP address or a range of addresses. To create or edit an ACL for an existing serverless Autonomous Database, do the following:

1. Open the navigation menu. Under **Database**, click **Autonomous Transaction Processing** or **Autonomous Data Warehouse**.
2. Choose your **Compartment**.
3. In the list of Autonomous Databases, click on the display name of the database you wish to administer.

4. Under **Network** in the database details, find the **Access Control List** field and click **add** (if no ACL currently exists) or **edit** (to update an existing ACL).
5. In the **Access Control List dialog**, add or modify entries, as applicable.
   You can specify the following types of addresses in your list by using the **Source** drop-down selector:
   - **IP Address** allows you to specify one or more individual public IP address. Use commas to separate your addresses in the input field.
   - **CIDR Block** allows you to specify one or more ranges of public IP addresses using CIDR notation. Use commas to separate your CIDR block entries in the input field.
   - **Virtual Cloud Network** allows you to specify an existing VCN. The drop-down listing in the input field allows you to choose from the VCNs in your current compartment for which you have access permissions. Click the **Change Compartment** link to display the VCNs of a different compartment.
   - **Virtual Cloud Network (OCID)** allows you input the OCID of a VCN in a text box. You can use this input method if the VCN you are specifying is in a compartment which you do not have permission to access.

   If you add a **Virtual Cloud Network** to your ACL, you can limit further by specifying allowed VCN IP addresses or CIDR ranges. Enter those addresses or CIDR blocks in the **IP Addresses or CIDRs** field that is displayed below your **Virtual Cloud Network** choice. Use commas to separate your VCN addresses and CIDR blocks in the input field. You can specify the following types of IP addresses at the VCN level:
   - Private IP addresses within your Oracle Cloud Infrastructure VCN
   - Private IP addresses within an on-premises network that have access to your Autonomous Database using a transit routing and a private connection via FastConnect or VPN Connect.

   Click **+Additional Entry** to add additional access rules to your list.

Important

If you are using a service gateway, ensure that the CIDR range 240.0.0.0/4 is included in the list to allow clients accessing the database through the service gateway to connect to it.

To remove the ACL, simply delete all entries in the list. This action allows all clients to connect to the database.

6. Click **Update**.

For information about access control lists, see Access Control Lists (ACLs) for Serverless Deployments.

To register or deregister an Autonomous Database with Data Safe

1. Open the navigation menu. Under **Database**, click **Autonomous Transaction Processing** or **Autonomous Data Warehouse**.
2. Choose your **Compartment**.
3. In the list of Autonomous Databases, click on the display name of the database you wish to administer.
4. In the Autonomous Database Information tab on the database details page, click the **register** or **deregister** link under **Data Safe**, depending on the operation you are performing.
5. In the confirmation dialog, click **Confirm** to complete the registration or deregistration. You can monitor the progress of the registration or deregistration using the work request created by the system.
   If you are registering your Autonomous Database, you can click the **View Console** link to display the Data Safe user interface for the registered database. For information on using Data Safe, see the Data Safe Overview.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use these API operations to manage Autonomous Databases:

- ListAutonomousDatabases
- GetAutonomousDatabase
- UpdateAutonomousDatabase
- ChangeAutonomousDatabaseCompartment
- StartAutonomousDatabase
- StopAutonomousDatabase
- DeleteAutonomousDatabase

- Autonomous Data Warehouse *(complete user guide)*

Connecting to an Autonomous Database

This topic describes the following actions related to connecting client applications to an Autonomous Database:

- Connecting a client to an Autonomous Database
- Obtaining the credentials and information you need to create a connection
- Rotating the keys and credentials needed for a connection (wallet rotation)
- Obtaining access URLs for Oracle Application Express (APEX) and Oracle SQL Developer Web

About Connecting to Autonomous Databases

Applications and tools connect to Autonomous Databases by using Oracle Net Services (also known as SQL*Net). SQL*Net supports a variety of connection types to Autonomous Databases, including Oracle Call Interface (OCI), ODBC drivers, JDBC OC, and JDBC Thin Driver.

To support connections of any type, you'll need to download the client security credentials and network configuration settings required to access your database. You'll also need to supply the applicable TNS names or connection strings for a connection, depending on the client application or tool, type of connection, and service level. You can view or copy the TNS names and connection strings in the DB Connection dialog for your Autonomous Database. For detailed information about the TNS names, see Predefined Database Service Names for Autonomous Transaction Processing and Predefined Database Service Names for Autonomous Data Warehouse.

Connecting from a VCN

To connect to Autonomous Databases from a VCN, the VCN must be configured with one of the following gateways:

- internet gateway: For access from a public subnet in the VCN
- service gateway: For access from a private subnet in the VCN

Make sure to configure the subnet's route table with a rule that sends the desired traffic to the specific gateway. Also configure the subnet's security lists to allow the desired traffic.

You can also connect to your database from a private IP addresses in your on-premises network by using transit routing with an Oracle Cloud Infrastructure VCN. This allows traffic to move directly from your on-premises network to your Autonomous Databasewithout going over the internet. See Transit Routing: Private Access to Oracle Services for more information on this method of access.

About Downloading Client Credentials

The client credentials .zip that you download contains the following files:

- cwallet.sso - Oracle auto-login wallet
- ewallet.p12 - PKCS #12 wallet file associated with the auto-login wallet
- sqlnet.ora - SQL*Net profile configuration file that includes the wallet location and TNSNAMES naming method
- tnsnames.ora - SQL*Net configuration file that contains network service names mapped to connect descriptors for the local naming method
- Java Key Store (JKS) files - Key store files for use with JDBC Thin Connections

Important

Wallet files, along with the database user ID and password, provide access to data in your Autonomous Database. Store wallet files in a secure location. Share wallet files only with authorized users. If wallet files are transmitted in a way that might be accessed by unauthorized users (for example, over public email), transmit the wallet password separately and securely.

For Autonomous Databases using serverless deployment, you have the choice of downloading an **instance wallet** file or a **regional wallet** file. The instance wallet contains only credentials and keys for a single Autonomous Database. The regional wallet contains credentials and keys for all Autonomous Databases in a specified region. For security purposes, Oracle recommends that regional wallets be used only by database administrators, and that instance wallets be supplied to other users whenever possible.

For Autonomous Databases using dedicated deployment, the wallet file contains only credentials and keys for a single Autonomous Database.

About Rotating Your Autonomous Database Wallet

For Autonomous Databases using serverless deployment, you can rotate an instance or regional wallet for security purposes. When your wallet rotation is complete, you will have a new set of certificate keys and credentials, and the old wallet's keys and credentials will be invalid. Rotating an instance wallet does not invalidate the regional wallet that covers the same database instance. Rotating a regional wallet affects all databases in the specified region. User session termination begins after wallet rotation completes, however this process does not happen immediately.

Important

If you are rotating a wallet to address a security breach and need to reestablish all database connections immediately using the keys and credentials of your newly rotated wallet, stop and restart the database instance.

Before You Begin

The Autonomous Database is preconfigured to support Oracle Net Services (a TNS listener is installed and configured to use secure TCPS and client credentials.) The client computer must be prepared to use Oracle Net Services to connect to the Autonomous Database. Preparing your client includes downloading the client credentials. See the following links for steps you might have to perform before you access the client credentials and connection information for your Autonomous Database

Autonomous Transaction Processing

- Preparing for Oracle Call Interface (OCI), ODBC, and JDBC OCI Connections
- Preparing for JDBC Thin Connections

Autonomous Data Warehouse

- Preparing for Oracle Call Interface (OCI), ODBC, and JDBC OCI Connections
- Preparing for JDBC Thin Connections

Using the Oracle Cloud Infrastructure Console

To download a wallet for an Autonomous Database with serverless deployment

1. Open the navigation menu. Under **Database**, click **Autonomous Transaction Processing** or **Autonomous Data Warehouse**.
2. Choose your **Compartment**.
3. In the list of Autonomous Databases, click on the display name of the database you are interested in.
4. Click **DB Connection**.
5. In the **Download Client Credentials (Wallet)** section, select the **Wallet Type**. You can choose to download an instance wallet or a regional wallet.
6. To obtain the client credentials, click **Download Wallet**.
   You will be prompted to provide a password to encrypt the keys inside the wallet. The password must be at least 8 characters long and must include at least 1 letter and either 1 numeric character or 1 special character.
   Save the client credentials zip file to a secure location. See About Downloading Client Credentials for information about the files included in the download.
7. Take note of or copy the TNS names or connection strings you need for your connection. See About Connecting to Autonomous Databases for information about making connections.

To download a wallet for an Autonomous Database with dedicated deployment

1. Open the navigation menu. Under **Database**, click **Autonomous Transaction Processing** or **Autonomous Data Warehouse**.
2. Choose your **Compartment**.
3. In the list of Autonomous Databases, click on the display name of the database you are interested in.

4. Click **DB Connection**.
5. Select the **DB Connection** option.
6. Click the **DB Connection** tab.
7. To obtain the client credentials, click **Download**.
   You will be prompted to provide a password to encrypt the keys inside the wallet. The password must be at least 8 characters long and must include at least 1 letter and either 1 numeric character or 1 special character.
   Save the client credentials zip file to a secure location. See About Downloading Client Credentials for information about the files included in the download.
8. Take note of or copy the TNS names or connection strings you need for your connection. See About Connecting to Autonomous Databases for information about making connections.

To rotate an Autonomous Database wallet (serverless deployment only)

1. Open the navigation menu. Under **Database**, click **Autonomous Transaction Processing** or **Autonomous Data Warehouse**.
2. Choose your **Compartment**.
3. In the list of Autonomous Databases, click on the display name of the database you are interested in.
4. Click **DB Connection**.
5. In the **Download Client Credentials (Wallet)** section, select the **Wallet Type**. You can choose to rotate an instance wallet or a regional wallet.
6. Click **Rotate Wallet**. A confirmation dialog will prompt you to enter the database name to confirm the rotation.
7. Enter the name of the database, then click **Rotate Wallet**.
   The rotation takes a few minutes to complete.

To obtain access URLs for Oracle Application Express (APEX) and Oracle SQL Developer Web (dedicated deployment only)

1. Open the navigation menu. Under **Database**, click **Autonomous Transaction Processing** or **Autonomous Data Warehouse**.
2. Choose your **Compartment**.
3. In the list of Autonomous Databases, click on the display name of the database you are interested in.
4. Select the **Application Connection** option.
5. Application URLs are displayed in plain text in the **Application URL** field. Copy the URL string using the **Copy** link.
6. Paste the URL into a browser running on a Compute instance that is inside of the VCN of the Autonomous Database. Alternately, you can use the URL with a compute instance that has a direct connection to the VCN of the Autonomous Database.

Using the API

Use the GenerateAutonomousDatabaseWallet API operation to download the client credentials for your Autonomous Database.

Use the UpdateAutonomousDatabaseWalletDetails API operation to rotate the wallet for your Autonomous Database.

Use the AutonomousDatabase API operation to get the access URLs for Application Express (APEX) and SQL Developer Web.

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

What's Next

For information and instructions on making secure connections to your database, see Connecting to Autonomous Transaction Processing and Connecting to Autonomous Data

Warehouse.

Backing Up an Autonomous Database Manually

This topic describes how to create manual backups of Autonomous Databases. You can use the Oracle Cloud Infrastructure Console or the API to perform these tasks.

Oracle Cloud Infrastructure automatically backs up your Autonomous Databases and retains these backups for 60 days. Automatic backups are weekly full backups and daily incremental backups. You can also create manual backups to supplement your automatic backups. Manual backups are stored in an Object Storage bucket that you create, and are retained for 60 days.

Note

During the backup operation, the database remains available. However, lifecycle management operations such as stopping the database, scaling it, or terminating it are disabled.

Prerequisites

- To create or manage Autonomous Database backups, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in. See Authentication and Authorization for more information on user authorizations for the Oracle Cloud Infrastructure Database service. See Let database and fleet administrators manage Autonomous Databases for sample Autonomous Database policies. See Details for the Database Service for detailed information on policy syntax.

- To create a manual backup for an Autonomous Database, you must first configure an Object Storage bucket to serve as a destination for your manual backups. See Setting Up a Bucket to Store Manual Backups for instructions.

Using the Oracle Cloud Infrastructure Console

1. Open the navigation menu. Under **Database**, click **Autonomous Transaction Processing** or **Autonomous Data Warehouse**.
2. Choose your **Compartment**.
3. In the list of Autonomous Databases, find the database that you want to back up.
4. Click the name to display the Autonomous Database details.
5. Click **Create Manual Backup**.

Tip

If this step does not successfully complete, confirm that you have an Object Storage bucket set up and configured to store manual backups. See Setting Up a Bucket to Store Manual Backups for instructions.

6. In the **Create Manual Backup** dialog, enter a name for your backup. Avoid entering confidential information.
7. Click **Create**. Your backup may take several hours to complete, depending on the size of your database.
8. Optionally, you can check the state of your backup in the list of backups on the database details page. For some states, an information icon ( ) is displayed to provide additional details regarding the state or ongoing operations like deletions. The backup has one of the following states:
    - Creating
    - Active

- Deleting
- Deleted
- Failed

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use these API operations to manage Autonomous Database backups:

- ListAutonomousDatabaseBackups
- GetAutonomousDatabaseBackup
- CreateAutonomousDatabaseBackup

Setting Up a Bucket to Store Manual Backups

You must create an Oracle Cloud Infrastructure Object Storage bucket to hold your Autonomous Database manual backups and configure your database to connect to it. This is a one-time operation.

To set up an object store and user credentials for your manual backups

Some of the steps in this procedure require you to connect to the database by using an Oracle Database client such as SQL Developer. See Connecting with Oracle SQL Developer (18.2 or later) for information and instructions on connecting to an Autonomous Transaction Processing database. See Connecting with Oracle SQL Developer (18.2 or later) for information and instructions on connecting to an Autonomous Data Warehouse database.

1. If you have not already done so, generate an auth token for the Oracle Cloud Infrastructure Object Storage user to access the bucket you create in the next step. See To create an auth token to learn how to do this. (You will need this auth token for the

database credential you create in step 4.)

2. In the Oracle Cloud Infrastructure Console, create a bucket in your designated Object Storage Swift compartment to hold the backups. The format of the bucket name is `backup_databasename`, where *databasename* is lowercase.
   For example, if you provision a database named DATABASE1, the bucket name should be `backup_database1`.

   

   Note

   When you create your bucket:

   - Pick **Standard** as the storage tier. Manual backups are only supported with buckets created in the standard storage tier.
   - Ensure that you use the database name, and not the display name, as the bucket name.

3. Using an Oracle Database client, log in to the database as the administrator set the database `default_bucket` property to your Oracle Cloud Infrastructure Object Storage tenancy URL. The format of the tenancy URL is https://swiftobjectstorage.*region*.oraclecloud.com/v1/*object_storage_namespace*.
   For example:

   ```
   ALTER DATABASE PROPERTY SET default_bucket='https://swiftobjectstorage.us-phoenix-
   1.oraclecloud.com/v1/ansh8lvru1zp';
   ```

   In the example, the Object Storage namespace is **ansh8lvru1zp**.

Tip

- To determine the Object Storage namespace string to use, click **View Bucket** in the actions (three dots) menu of the bucket you created in the previous step.
- Do not include the bucket name in the URL.
- Ensure that you follow the format indicated. Do not use a pre-authenticated request URL.

4. With the tenancy user and the auth token referenced in step 1, create the credential for your Oracle Cloud Infrastructure Object Storage account. Use `DBMS_CLOUD.CREATE_CREDENTIAL` to create the credential.

   For example:

   ```
   BEGIN
   DBMS_CLOUD.CREATE_CREDENTIAL(
   credential_name => 'DEF_CRED_NAME',
   username => 'db1_user@oracle.com',
   password => '<auth_token>'
   );
   END;
   /
   ```

   For more information on creating this credential, see CREATE_CREDENTIAL Procedure.

5. Set the database property `default_credential` to the credential you created in the previous step.

   For example:

   ```
   ALTER DATABASE PROPERTY SET default_credential = 'ADMIN.DEF_CRED_NAME';
   ```

To list the current value for the default bucket, run the following command:

```
SELECT PROPERTY_VALUE from database_properties WHERE PROPERTY_NAME='DEFAULT_BUCKET';
```

After completing these steps you can take manual backups any time you want.

Restoring an Autonomous Database

This topic describes how to restore an Autonomous Database from a backup. You can use the Oracle Cloud Infrastructure Console or the API to perform this task.

You can use any existing manual or automatic backup to restore your database, or you can restore and recover your database to any point in time in the 60-day retention period of your automatic backups. For point-in-time restores, you specify a timestamp, and your Autonomous Database decides which backup to use for the fastest restore.

Note

Restoring Autonomous Database puts the database in the unavailable state during the restore operation. You cannot connect to a database in that state. The only lifecycle management operation supported in the unavailable state is terminate.

Prerequisites

To restore Autonomous Databases, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in. See Authentication and Authorization for more information on user authorizations for the Oracle Cloud Infrastructure Database service. See Let database and fleet administrators manage Autonomous Databases for sample Autonomous Database policies. See Details for the Database Service for detailed information on policy syntax.

Using the Oracle Cloud Infrastructure Console

To restore an Autonomous Database from a backup

1. Open the navigation menu. Under **Database**, click **Autonomous Transaction Processing** or **Autonomous Data Warehouse**.
2. Choose your **Compartment**.
3. In the list of Autonomous Databases, find the database that you wish to restore.
4. Click the name of the Autonomous Database to display the database details.
5. Click the **Restore** button to open the restore dialog.
6. Click **Select Backup**.
7. Specify the date range for a list of backups to display.
8. Select the backup.
9. Click **Restore**.

To restore an Autonomous Database using point-in-time restore

1. Open the navigation menu. Under **Database**, click **Autonomous Transaction Processing** or **Autonomous Data Warehouse**.
2. Choose your **Compartment**.
3. In the list of Autonomous Databases, find the database that you wish to restore.
4. Click the name of the Autonomous Database to display the database details.
5. Click the **Restore** button to open the restore dialog.
6. Click **Specify Timestamp**.
7. Enter a timestamp. Your Autonomous Database decides which backup to use for faster recovery. The timestamp input allows you to specify precision to the seconds level (YYYY-MM-DD HH:MM:SS GMT).

8. Click **Restore**.

Using the API

Use the RestoreAutonomousDatabase API operation to restore your Autonomous Database from a backup.

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Cloning an Autonomous Database

This topic describes how to clone an existing Autonomous Database using the Oracle Cloud Infrastructure Console or the API. You may wish to use the cloning feature to create a point-in-time copy of your Autonomous Database for purposes such as testing, development or analytics. If you need to clone only the database schema of your source database, the Console's cloning feature is a quick and easy way to accomplish this task.

Note

Any existing Autonomous Database (including those provisioned with preview version software) can be cloned using a preview version of Autonomous Database. However, preview version databases cannot be cloned using the regular (general-availability) Autonomous Database software.

Clone Types

The clone feature offers the following two types of Autonomous Database clones:

- The full clone option creates a new database that includes all of the source database's metadata and data.
- The metadata clone option creates a new database that includes the source database's metadata, but not the source database's data.

Prerequisites

- To clone an Autonomous Database, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in. See Authentication and Authorization for more information on user authorizations for the Oracle Cloud Infrastructure Database service.

Password Requirement for New Database with Dedicated Deployment

When cloning a database that uses dedicated deployment, the password you set for the target database cannot be one of the three most recently used passwords of the source database.

Using the Oracle Cloud Infrastructure Console

To clone an Autonomous Database with serverless deployment

1. Open the navigation menu. Under **Database**, click **Autonomous Transaction Processing** or **Autonomous Data Warehouse**.
2. Choose your **Compartment**.
3. In the list of Autonomous Databases, click on the display name of the database you wish to clone.
4. Go to **Actions**, and then click **Create Clone**.
   In the **Create Autonomous Database Clone** dialog, enter the following:

   CLONE TYPE

Select the type of clone you wish to create. Choose either **Full Clone** or **Metadata Clone**.

DATABASE INFORMATION

- **Compartment:**Your current compartment is the default selection.
- **Display Name:** A user-friendly description or other information that helps you easily identify the resource. The display name does not have to be unique, and you can change it whenever you like. Avoid entering confidential information.
- **Database Name:** The database name must consist of letters and numbers only, starting with a letter. The maximum length is 14 characters. Avoid entering confidential information.
- **CPU Core Count:** You can enable up to 128 cores for your Autonomous Database. The actual number of available cores is subject to your tenancy's service limits.

  Auto Scaling: allows Autonomous Databaseto automatically increase the number of CPU cores by up to three times the assigned CPU core count value, depending on demand for processing. The auto scaling feature reduces the number of CPU cores when additional cores are not needed. For databases with up to 42 assigned cores, you can increase the maximum number of cores available through auto scaling by increasing the CPU core count value.

Note

The maximum number of cores that are available to any Autonomous Database database not using dedicated deployment is 128, regardless of whether auto scaling is enabled or not. This means that database with a CPU core count of 64 could auto scale up to two times the assigned number of cores (2 x 64 = 128). A database with 42 cores (or fewer) could auto scale up to three times the assigned number (3 x 42 = 126). For billing purposes, the database service determines the average number of CPUs used per hour.

- **Storage:** Specify the storage you wish to make available to your Autonomous Database database, in terabytes. You can make up to 128 TB available. For full clones, the size of the source database determines the minimum amount of storage you can make available.
- **Enable Preview Version:** *(This option only displays during periods when a preview version of Autonomous Database is available)* Select this option to provision the database with an Autonomous Database preview version. Preview versions of Autonomous Database are made available for limited periods for testing purposes. Do not select this option if you are provisioning a database for production purposes or if you will need the database to persist beyond the limited availability period of the preview version.

ADMINISTRATOR CREDENTIAL

Set the password for the Autonomous Database Admin user by entering a password that meets the following criteria. You use this password when accessing the Autonomous

Database service console and when using an SQL client tool.

- Password cannot be one of the three most recently used passwords of the source database
- Between 12 and 30 characters long
- Contains at least one lowercase letter
- Contains at least one uppercase letter
- Contains at least one number
- Does not contain the double quotation mark (")
- Does not contain the string "admin", regardless of casing

LICENSE TYPE

The type of license you want to use for the Autonomous Transaction Processing database. Your choice affects metering for billing. You have the following options:

- **My Organization Already Owns Oracle Database Software Licenses**: This choice is used for the Bring Your Own License (BYOL) license type. If you choose this option, make sure you have proper entitlements to use for new service instances that you create.
- **Subscribe to New Database Software Licenses and the Database Cloud Service**: This is used for the License Included license type. With this choice, the cost of the cloud service includes a license for the Database service.

5. Click **Create Autonomous Database Clone**.

The Console displays the details page for the new clone of your database and the service begins provisioning the Autonomous Database. Note the following:

- The new clone displays the **Provisioning** lifecycle state until the provisioning process completes.
- The source database remains in the **Available** lifecycle state.
- Backups associated with the source database are not cloned for either the full clone or the metadata clone option.

- Oracle recommends that you evaluate the security requirements for the new database and implement them, as applicable. See Security Considerations for details.

To clone an Autonomous Database with dedicated deployment

1. Open the navigation menu. Under **Database**, click **Autonomous Transaction Processing** or **Autonomous Data Warehouse**.
2. Choose your **Compartment**.
3. In the list of Autonomous Databases, click on the display name of the database you wish to clone.
4. Go to **Actions**, and then click **Create Clone**.
   In the **Create Autonomous Database Clone** dialog, enter the following:

   CLONE TYPE

   Select the type of clone you wish to create. Choose either **Full Clone** or **Metadata Clone**.

   DATABASE INFORMATION

   - **Compartment:**Your current compartment is the default selection.
   - **Display Name:** A user-friendly description or other information that helps you easily identify the resource. The display name does not have to be unique, and you can change it whenever you like. Avoid entering confidential information.
   - **Database Name:** The database name must consist of letters and numbers only, starting with a letter. The maximum length is 14 characters. Avoid entering confidential information.
   - **Autonomous Container Database:** *(Read only)* Currently, cloned target databases must be created within the same Autonomous Container Database as the source database.
   - **CPU Core Count:** You can enable up to 92 cores for your target Autonomous

Database.

- **Storage:** Specify the storage you wish to make available to your Autonomous Database database, in terabytes. You can make up to 128 TB available. For full clones, the size of the source database determines the minimum amount of storage you can make available.

ADMINISTRATOR CREDENTIAL

Set the password for the Autonomous Database Admin user by entering a password that meets the following criteria. You use this password when accessing the Autonomous Database service console and when using an SQL client tool.

- Password cannot be one of the three most recently used passwords of the source database
- Between 12 and 30 characters long
- Contains at least one lowercase letter
- Contains at least one uppercase letter
- Contains at least one number
- Does not contain the double quotation mark (")
- Does not contain the string "admin", regardless of casing

5. Click **Create Autonomous Database Clone**.

The Console displays the details page for the new clone of your database and the service begins provisioning the Autonomous Database. Note the following:

- The new clone displays the **Provisioning** lifecycle state until the provisioning process completes.
- The source database remains in the **Available** lifecycle state.
- Backups associated with the source database are not cloned for either the full clone or the metadata clone option.

- Oracle recommends that you evaluate the security requirements for the new database and implement them, as applicable. See Security Tools for Dedicated Deployments for details.

Using the API

Use the CreateAutonomousDatabase API operation to clone an Autonomous Database.

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

For More Information

For information about optimizer statistics, resource management rules and performance data for a cloned database, see the Using Oracle Autonomous Data Warehouse and Using Oracle Autonomous Transaction Processing user guides.

Maintenance Updates for Autonomous Databases with Serverless Deployment

Autonomous Databases perform maintenance updates and database patching for you. Your database remains available throughout the maintenance process. This topic describes Autonomous Database maintenance for serverless deployments.

For information on maintenance for dedicated deployments, see Overview of Dedicated Deployment Maintenance.

Maintenance Duration

For Autonomous Databases with serverless deployments, Oracle performs regular maintenance updates that generally take no more than two hours.

Checking the Scheduling of Maintenance Updates

To see when your next scheduled maintenance update is, navigate to the Autonomous Database details page in the Console for the database you are interested in. The **Next Maintenance** metadata field displays the beginning and ending times of the next database maintenance . You can also use the GetAutonomousDatabase API operation to determine the time of your next maintenance update.

Overview of Autonomous Database Dedicated Deployments

This topic describes the database architecture, features, and user roles of Autonomous Database dedicated deployments. For a general overview of Autonomous Databases that covers the basics common to both deployment options, see Overview of Autonomous Database.

Dedicated Deployment Database Architecture

Autonomous Databases with dedicated deployment have a three-level database architecture model that makes use of Oracle multitenant database architecture.

RESOURCE TYPES

Each level of the architecture model corresponds to one of the following resources types:

- An **Autonomous Exadata Infrastructure** resource, a hardware rack which includes compute nodes and storage servers, tied together by a high-speed, low-latency InfiniBand network and intelligent Exadata software. With dedicated deployment, you have exclusive use of the Exadata infrastructure and hardware on which your Autonomous Transaction Processing databases run.

  For a list of the hardware and Oracle Cloud resource characteristics of Autonomous Exadata Infrastructure resources, see Characteristics of Autonomous Exadata Infrastructure Resources.
- An **Autonomous Container Database**, which provides a container for multiple user databases. This resource is sometimes referred to as a CDB, and is functionally

equivalent to the multitenant container databases found in Oracle 12c and higher databases.

Multitenant architecture offers many advantages over non-CDB architecture. For example, it does the following:

- Allows you to easily manage multiple individual user databases
- Makes more efficient use of database hardware, as individual databases may use only a fraction of the server hardware capacity
- Allows for easier and more rapid movement of data and code
- Allows for easier testing, as development databases can be housed within the same container as production databases
- Allows for the separation of duties between database administrators, who manage only the individual Autonomous Database instances to which they are granted privileges, and fleet managers, who manage infrastructure resources and container databases.

- An **Autonomous Database**. You can create multiple Autonomous Databases within the same container database. This level of the database architecture is analogous to the pluggable databases (PDBs) found in non-Autonomous Exadata systems. Your Autonomous Database can be configured for either transaction processing or data warehouse workloads.

Deployment Order

You must create the dedicated deployment resources in the following order:

1. Autonomous Exadata Infrastructure. See Creating an Autonomous Exadata Infrastructure Resource for more information.
2. Autonomous Container Database. See Creating an Autonomous Container Database for more information.
3. Autonomous Database. See Creating an Autonomous Database for more information.

Related Resources

Related resources and prerequisites include:

- A **Virtual Cloud Network (VCN)** and a **Subnet**, which you create using Oracle Cloud Infrastructure's Networking service. You must have at least one VCN and one subnet available to provision an Autonomous Database with dedicated deployment.
  For more information, see the following topics:
  - Network Isolation (from *Fleet Administrator's Guide to Oracle Autonomous Transaction Processing Dedicated Deployments*)
  - Overview of Networking
  - To create a VCN
  - To create a subnet
- **Autonomous Backups**, created for you automatically by the Autonomous Database service. You do not have to provision storage for your backups. Backups are stored in Object Storage that is managed by Oracle Cloud Infrastructure's Database service. Note that automatic backups incur Object Storage usage costs. By default, backups are stored for 60 days. Using the Console, you can choose to change the retention period to 7, 15, or 30 days.
- **Manual Backups**. Optionally, you can configure Autonomous Database to create on-demand manual backups. See Setting Up a Bucket to Store Manual Backups and Backing Up an Autonomous Database Manually for more information on manual backups. Manual backups are subject to the retention policy you have in place for the Autonomous Container Database. By default, manual backups are stored for 60 days.

User Roles

Your organization may choose to split the administration of the Autonomous Database with dedicated deployment into the following roles:

- **Fleet Administrator.** Fleet administrators create, monitor and manage Autonomous Exadata Infrastructure and Autonomous Container Database resources. A fleet administrator must have permissions for using the networking resources required by the dedicated deployment, and permissions to manage the infrastructure and container database resources.

See Fleet Administrator's Guide to Oracle Autonomous Transaction Processing Dedicated Deployments for a complete overview of the fleet administrator role.

- **Database Administrator.** Database administrators create, monitor and manage Autonomous Databases. They also create and manage users within the database. Database administrators must have permissions for using container databases, for managing Autonomous Transaction Processing databases and backups, and for using the related networking resources. For manual backups, they must have permissions to use the designated Object Storage bucket. At the time of provisioning an Autonomous Database, the administrator provides user credentials for the automatically created ADMIN account, which provides administrative rights to the new database.
  See Using Oracle Autonomous Transaction Processing Dedicated Deployments for a complete overview of the database administrator role.
- **Database User.** Database users are the developers who write applications that connect to and use an Autonomous Database to store and access the data. Database users do not need Oracle Cloud Infrastructure accounts. They gain network connectivity to and connection authorization information for the database from the database administrator.

CPU Provisioning, CPU Scaling, and Storage Scaling

Autonomous Database with dedicated deployment allows for the over-subscription of CPU cores when provisioning databases. This means that for a given infrastructure resource, the sum of all CPU cores provisioned to Autonomous Databases can exceed the number of CPU cores on the Exadata rack. This approach allows for better CPU core utilization. Note that if all databases are heavily loaded at the same time, there will be some contention for CPU resources, and degraded performance.

Additionally, you can scale the CPU count and the storage capacity of the database at any time without impacting availability or performance.

Overview of Dedicated Deployment Maintenance

Autonomous Database dedicated deployment systems have separate regularly scheduled maintenance runs for both Autonomous Exadata Infrastructure resources and Autonomous

Container Databases. You can choose to set the scheduling for your maintenance runs, or let the system handle maintenance scheduling. You can view the maintenance history for infrastructure instances and container databases in the Oracle Cloud Infrastructure Console.

Tip

Oracle recommends that you define the acceptable maintenance times for your Autonomous Exadata Infrastructure resources and Autonomous Container Databases. Doing so will prevent maintenance runs from occurring at times that would be disruptive to regular database operations.

Autonomous Exadata Infrastructure Maintenance

Infrastructure maintenance takes place at least once each quarter and is mandatory. You can schedule the time your infrastructure maintenance will begin. Infrastructure maintenance runs are for infrastructure patching (including patching of the Exadata grid infrastructure code and operating systems updates), and do not include database patching. Oracle will notify you in the weeks leading up to the quarterly infrastructure patching date about the upcoming maintenance. You can also view scheduled maintenance runs in the Oracle Cloud Infrastructure console. The following tasks explain how to view scheduled and past maintenance updates, and to edit the maintenance schedule for an infrastructure instance:

- To configure the automatic maintenance schedule for an Autonomous Exadata Infrastructure resource
- To view the next scheduled maintenance for an Autonomous Exadata Infrastructure resource
- To view the maintenance history of an Autonomous Exadata Infrastructure resource

You can use the GetMaintenanceRun, ListMaintenanceRun, and UpdateAutonomousExadataInfrastructure API operations to view details about scheduled and

past maintenance updates, and to update the maintenance schedule of your infrastructure instance.

Autonomous Container Database Maintenance

Container database maintenance takes place at the time of the quarterly infrastructure maintenance run. Container database maintenance includes Oracle Database software patches. Autonomous Database offers two CDB maintenance type choices:

- Release Update (RU): Autonomous Database installs only the most current release update.
- Release Update Revision (RUR): Autonomous Database installs the release update plus additional fixes.

The following tasks explain how to view and edit maintenance update information for Autonomous Container Databases:

- To view the maintenance history of an Autonomous Container Database
- To skip a scheduled maintenance run for an Autonomous Container Database
- To configure the type of maintenance patching for an Autonomous Container Database

Use the UpdateAutonomousContainerDatabase API operation to change the patching type for an Autonomous Container Database. Use the ListMaintenanceRun API operation to see past maintenance update information. Use the UpdateMaintenanceRun API operations to skip a container database maintenance update. You can skip maintenance runs for up to 2 consecutive quarters if needed.

Using the Oracle Cloud Infrastructure Console to Manage Dedicated Deployments

For information on provisioning, managing, and backing up dedicated deployments in the Oracle Cloud Infrastructure Console, see the following topics:

For Fleet Administrators

- Creating an Autonomous Exadata Infrastructure Resource
- Creating an Autonomous Container Database

- Managing an Autonomous Exadata Infrastructure Resource
- Managing an Autonomous Container Database
- Fleet Administrator's Guide to Oracle Autonomous Transaction Processing Dedicated Deployments *(complete fleet administrator guide)*

FOR DATABASE ADMINISTRATORS

- Creating an Autonomous Database
- Managing an Autonomous Database
- Connecting to an Autonomous Database
- Backing Up an Autonomous Database Manually
- Restoring an Autonomous Database
- Using Oracle Autonomous Transaction Processing Dedicated Deployments *(complete database administrator guide)*

Additional Information

For known issues, see Known Issues for Oracle Autonomous Transaction Processing Dedicated Deployments.

Creating an Autonomous Exadata Infrastructure Resource

This topic describes how to provision an Autonomous Exadata Infrastructure resource for Autonomous Databases with dedicated deployment, using the Oracle Cloud Infrastructure Console or the API. For an overview of the dedicated deployment option, see Overview of Autonomous Database Dedicated Deployments.

The infrastructure resource includes the physical Exadata hardware and intelligent Exadata software. Once you have provisioned an infrastructure instance, you can provision one or more Autonomous Container Databases to run on your infrastructure. To provision an Autonomous Database, you must have both an infrastructure resource and at least one container database available.

Note

This topic is not applicable to Autonomous Databases using the serverless deployment option.

Prerequisites

- To create an Autonomous Exadata Infrastructure resource, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in. See Authentication and Authorization for more information on user authorizations for the Oracle Cloud Infrastructure Database service.

Tip

See Let database and fleet administrators manage Autonomous Databases for sample Autonomous Database policies. See Details for the Database Service for detailed information on policy syntax.

- You will also need a **Virtual Cloud Network** and a **Subnet**, which you create using Oracle Cloud Infrastructure's Networking service. For information on creating and managing these resources, see VCNs and Subnets.

Using the Oracle Cloud Infrastructure Console

To create an Autonomous Exadata Infrastructure resource

1. Open the navigation menu. Under **Database**, click **Autonomous Transaction Processing** or **Autonomous Data Warehouse**.
2. Choose your **Compartment**.
3. Click **Autonomous Exadata Infrastructure**.
4. Click **Create Autonomous Exadata Infrastructure**.
5. In the **Create Autonomous Exadata Infrastructure** dialog, enter the following general information:
    - **Display Name:** A user-friendly description or other information that helps you easily identify the infrastructure resource. The display name does not have to be unique. Avoid entering confidential information.
    - **Compartment:** Specify the compartment in which the Autonomous Exadata Infrastructure will be created.
    - **Availability Domain:** Select an availability domain for the Autonomous Exadata Infrastructure.
    - **Shape:** *Read only.* Oracle Cloud Infrastructure currently offers the Exadata.Quarter2.92 shape for provisioning an Autonomous Exadata Infrastructure resource. This shape has 92 cores, 106 TB storage, and 1440 GB RAM. See Exadata X7 shapes for more information on Exadata shape specifications.
6. Enter the following network information:
    - **Virtual cloud network compartment:** The compartment containing the VCN you wish to use for the Autonomous Exadata Infrastructure. The default value is the user's current compartment. Click **change compartment** to select a VCN in a different compartment.
    - **Virtual cloud network:** The VCN in which to launch the Autonomous Exadata Infrastructure.

- **Subnet compartment:** The compartment containing the subnet you wish to use for the Autonomous Exadata Infrastructure. The default value is the user's current compartment. Click **change compartment** to select a subnet in a different compartment.
- **Subnet:** The subnet to which the Autonomous Exadata Infrastructure should attach. Do not use a subnet that overlaps with 141.144.75.0/24.
- **Use network security groups to control traffic:** *Optional.* You can specify up to five network security groups (NSGs) for your Autonomous Exadata Infrastructure resource by selecting this option. NSGs function as virtual firewalls, allowing you to apply a set of ingress and egress security rules to your infrastructure resource. A maximum of five NSGs can be specified. To add an NSG, select the compartment containing the NSG using the **Network security group compartment** selector, then select the NSG itself using the **Network security group** selector.

  For more information on creating and working with NSGs, see Network Security Groups.

  Note that if you choose a subnet with a security list, the security rules for the infrastructure resource will be a union of the rules in the security list and the NSGs.

7. Optionally, you can specify the date and start time for the Autonomous Exadata Infrastructure quarterly maintenance.

Tip

Oracle recommends that you define the acceptable maintenance times for your Autonomous Exadata Infrastructure resources and Autonomous Container Databases. Doing so will prevent maintenance runs from occurring at times that would be disruptive to regular database operations.

To change the Autonomous Exadata Infrastructure maintenance schedule

a. In the Create Autonomous Exadata Infrastructure dialog, click **Modify Schedule**.

b. In the Automatic Maintenance Schedule dialog, select **Specify a Schedule**

c. In the **Maintenance months** selector, specify at least one month for each quarter during which infrastructure maintenance will take place.

d. For **Week of the Month**, select a week during the month that the maintenance will take place. Weeks start on the 1st, 8th, 15th, and 22nd days of the month, and have a duration of 7 days. Weeks start and end based on calendar dates, not days of the week. For example, to allow maintenance during the 2nd week of the month (from the 8th day to the 14th day of the month), use the value 2. Maintenance cannot be scheduled for the fifth week of months that contain more than 28 days.

e. For **Day of the Week**, select the day of the week that the maintenance will take place.

f. For **Start Hour**, select one of the six start time windows available. The maintenance will begin during the 4 hour time window that you specify and may continue beyond the end of the period chosen. The start time window is specified in universal coordinated time (UTC).

g. Click **Update Maintenance Schedule**.

8. Choose the license type you wish to use. Your choice affects metering for billing. You have the following options:
   - **Bring your own license**: If you choose this option, make sure you have proper entitlements to use for new service instances that you create.
   - **License included**: With this choice, the cost of the cloud service includes a license for the Database service.
9. The following **Advanced Options** are available:

   Tags - Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined

tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.Avoid entering confidential information.

10. Click **Create Autonomous Exadata Infrastructure**.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the LaunchAutonomousExadataInfrastructure API operation to create an Autonomous Exadata Infrastructure resource.

What's Next

After creating an Autonomous Exadata Infrastructure resource, you can create one or more Autonomous Container Databases within your infrastructure. You must have provisioned both an infrastructure resource and at least one container database before you can create your first Autonomous Database in Oracle Cloud Infrastructure.

Managing an Autonomous Exadata Infrastructure Resource

This topic describes the Autonomous Exadata Infrastructure management tasks for Autonomous Databases that you complete using the Oracle Cloud Infrastructure Console or the API. Autonomous Exadata Infrastructure resources are used by Autonomous Databases with dedicated deployment. For an overview of the dedicated deployment option, see Overview of Autonomous Database Dedicated Deployments.

Note

This topic is not applicable to Autonomous Databases using the serverless deployment option.

Using the Oracle Cloud Infrastructure Console

The following management operations can be performed on Autonomous Exadata Infrastructure resources in Oracle Cloud Infrastructure:

- Configuring the automatic maintenance schedule
- Viewing the next scheduled maintenance date and maintenance history
- Copying the Autonomous Exadata Infrastructure endpoint
- Terminating the Autonomous Exadata Infrastructure resource

Tip

Oracle recommends that you define the acceptable maintenance times for your Autonomous Exadata Infrastructure resources and Autonomous Container Databases. Doing so will prevent maintenance runs from occurring at times that would be disruptive to regular database operations.

To configure the automatic maintenance schedule for an Autonomous Exadata Infrastructure resource

1. Open the navigation menu. Under **Database**, click **Autonomous Transaction Processing** or **Autonomous Data Warehouse**.

2. Choose your **Compartment**.
3. Under **Autonomous Database**, click **Autonomous Exadata Infrastructure**.
4. In the list of Autonomous Exadata Infrastructure resources, click on the display name of the resource you are interested in.
5. On the Autonomous Exadata Infrastructure details page, under **Maintenance**, click the **edit** link in the **Maintenance Schedule** field.
6. In the **Automatic Maintenance Schedule** dialog, select **Specify a schedule**.
7. Under **Maintenance months**, specify at least one month for each quarter during which Autonomous Exadata Infrastructure maintenance will take place.
8. Under **Week of the month**, specify which week of the month maintenance will take place. Weeks start on the 1st, 8th, 15th, and 22nd days of the month, and have a duration of 7 days. Weeks start and end based on calendar dates, not days of the week. Maintenance cannot be scheduled for the fifth week of months that contain more than 28 days.
9. Under **Day of the week**, specify the day of the week on which the maintenance will occur.
10. Under **Start hour**, specify the hour during which the maintenance run will begin.
11. Click **Update Maintenance Schedule**.

To view the next scheduled maintenance for an Autonomous Exadata Infrastructure resource

1. Open the navigation menu. Under **Database**, click **Autonomous Transaction Processing** or **Autonomous Data Warehouse**.
2. Choose your **Compartment**.
3. Under **Autonomous Database**, click **Autonomous Exadata Infrastructure**.
4. In the list of Autonomous Exadata Infrastructure resources, click on the display name of the resource you are interested in.

5. On the Autonomous Exadata Infrastructure details page, under **Maintenance**, click the **view** link in the **Next Maintenance** field.
6. On the **Maintenance** page, scheduled maintenance events are listed under the **Regular Autonomous Exadata Infrastructure maintenance** heading.

To view the maintenance history of an Autonomous Exadata Infrastructure resource

1. Open the navigation menu. Under **Database**, click **Autonomous Transaction Processing** or **Autonomous Data Warehouse**.
2. Choose your **Compartment**.
3. Under **Autonomous Database**, click **Autonomous Exadata Infrastructure**.
4. In the list of Autonomous Exadata Infrastructure resources, click on the display name of the resource you are interested in.
5. On the Autonomous Exadata Infrastructure details page, under **Maintenance**, click the **view** link in the **Next Maintenance** field.
6. On the **Maintenance** page, under **Autonomous Database Maintenance**, click **History**. In the list of past maintenance events, you can click on an individual event title to read the details of the maintenance that took place. Maintenance event details include the following:
    - The category of maintenance (quarterly software maintenance, hardware maintenance, or a critical patch)
    - Whether the maintenance was scheduled or unplanned
    - The OCID of the maintenance event. (Go to **Actions**, then choose **Copy OCID**.)
    - The start time and date of the maintenance

To view or copy the Autonomous Exadata Infrastructure endpoint

1. Open the navigation menu. Under **Database**, click **Autonomous Transaction Processing** or **Autonomous Data Warehouse**.
2. Choose your **Compartment**.
3. Under **Autonomous Database**, click **Autonomous Exadata Infrastructure**.
4. In the list of Autonomous Exadata Infrastructure resources, click on the display name of the resource you are interested in.
5. On the Autonomous Exadata Infrastructure Information tab, click **Show** or **Copy** in the DB Infrastructure Endpoint Name field.

To edit the network security groups (NSGs) for your Autonomous Exadata Infrastructure resource

Your Autonomous Exadata Infrastructure instance can use up to five network security groups (NSGs). Note that if you choose a subnet with a security list, the security rules for the infrastructure instance will be a union of the rules in the security list and the NSGs. For more information, see Network Security Groups.

1. Open the navigation menu. Under **Database**, click **Autonomous Transaction Processing**.
2. Choose your **Compartment**.
3. Under **Autonomous Database**, click **Autonomous Exadata Infrastructure**.
4. In the list of Autonomous Exadata Infrastructure resources, click on the display name of the resource you are interested in.
5. In the **Network** details, click the **Edit** link to the right of the **Network Security Groups** field.
6. In the **Edit Network Security Groups** dialog, click **+ Another Network Security Group** to add an NSG to the Autonomous Exadata Infrastructure resource.

To change an assigned NSG, click the drop-down menu displaying the NSG name, then select a different NSG.

To remove an NSG from your DB system, click the **X** icon to the right of the displayed NSG name.

7. Click **Save**.

To move an Autonomous Exadata Infrastructure resource to another compartment

Note

To move resources between compartments, resource users must have sufficient access permissions on the compartment that the resource is being moved to, as well as the current compartment. For more information about permissions for Database resources, see Details for the Database Service.

1. Open the navigation menu. Under **Database**, click **Autonomous Transaction Processing** or **Autonomous Data Warehouse**.
2. Choose your **Compartment**.
3. Under **Autonomous Database**, click **Autonomous Exadata Infrastructure**.
4. In the list of Autonomous Exadata Infrastructure resources, click on the display name of the resource you wish to move.
5. Click **Move Resource**.
6. Select the new compartment.
7. Click **Move Resource**.

For information about dependent resources for Database resources, see Moving Database Resources to a Different Compartment.

To terminate an Autonomous Exadata Infrastructure resource

Warning

Terminating an Autonomous Exadata Infrastructure resource permanently deletes it and removes associated resources such as Autonomous Container Databases, Autonomous Databases, and Autonomous Database backups. You cannot recover a terminated Autonomous Exadata Infrastructure resource.

1. Open the navigation menu. Under **Database**, click **Autonomous Transaction Processing** or **Autonomous Data Warehouse**.
2. Choose your **Compartment**.
3. Under **Autonomous Database**, click **Autonomous Exadata Infrastructure**.
4. In the list of Autonomous Exadata Infrastructure resources, click on the display name of the resource you are interested in.
5. Go to **Actions**, and then click **Terminate**.
6. Confirm that you wish to terminate your Autonomous Exadata Infrastructure in the confirmation dialog.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the UpdateAutonomousExadataInfrastructure API operation to configure the automatic maintenance schedule for your infrastructure resource.

Use the GetMaintenanceRun API to view the details of a maintenance run that is scheduled, in progress, or that has ended.

Use the ListMaintenanceRun API to get a list of maintenance runs in a specified compartment.

Use the ChangeAutonomousExadataInfrastructureCompartment API operation to move an Autonomous Exadata Infrastructure resource to another compartment.

Use the TerminateAutonomousExadataInfrastructure API operation to delete an Autonomous Exadata Infrastructure resource.

For More Information

Create and Manage Autonomous Exadata Infrastructure Resources *(Fleet Administrator's Guide to Oracle Autonomous Transaction Processing Dedicated Deployments)*

Creating an Autonomous Container Database

This topic describes how to provision a new Autonomous Container Database using the Oracle Cloud Infrastructure Console or the API. Container databases are only necessary for Autonomous Databases that use the dedicated deployment option. For a brief overview of the dedicated deployment option, see Overview of Autonomous Database Dedicated Deployments.

Note

This topic is not applicable to Autonomous Databases using the serverless deployment option.

Prerequisites

- To create an Autonomous Container Database, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don't have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in. See Authentication and Authorization for more information on user authorizations for the Oracle Cloud Infrastructure Database service.

Tip

See Let database and fleet administrators manage Autonomous Databases for sample Autonomous Database policies. See Details for the Database Service for detailed information on policy syntax.

- To create an Autonomous Container Database, you must have an available Autonomous Exadata Infrastructure instance. For information on creating an infrastructure instance, see Creating an Autonomous Exadata Infrastructure Resource.

Using the Oracle Cloud Infrastructure Console

To create an Autonomous Container Database

1. Open the navigation menu. Under **Database**, click **Autonomous Transaction Processing** or **Autonomous Data Warehouse**.
2. Click **Autonomous Container Database**.
3. Click **Create Autonomous Container Database**.
4. In the **Create Autonomous Container Database** dialog, enter the following database information:

- **Display Name:** A user-friendly description or other information that helps you easily identify the resource. The display name does not have to be unique. Avoid entering confidential information.
- **Compartment:** Specify the compartment in which the container database will be created.

5. Choose the Autonomous Exadata Infrastructure you wish to use to create your container database:
   - **Compartment:** Specify the compartment containing the Autonomous Exadata Infrastructure you wish to use for your container database.
   - **Autonomous Exadata Infrastructure:** Choose an Autonomous Exadata Infrastructure for your container database. See Creating an Autonomous Exadata Infrastructure Resource for more information.
6. Optionally, you can change the maintenance type for your Autonomous Container Database. The maintenance type choices are Release Update (RU) and Release Update Revision (RUR). The Release Update setting installs only the most current release update, while the Release Update Revision installs the release update plus additional fixes. For more information, see Release Update Introduction and FAQ (Doc ID 2285040.1) in the My Oracle Support online help portal.

   To change the Autonomous Container Database maintenance type

   a. In the Create Autonomous Container Database dialog, click **Modify Schedule**.
   b. In the **Automatic Maintenance Type** dialog, select your desired maintenance type.
   c. Click **Update Automatic Maintenance**.

7. The following **Advanced Options** are available:
   - **Tags -** Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you

should apply tags, skip this option (you can apply tags later) or ask your administrator.Avoid entering confidential information.

- **Management -** Optionally, you can specify the backup retention policy, which controls the length of time you retain backups in the Autonomous Container Database. The choices are 7 days, 15 days, 30 days, and 60 days. The default setting is 60 days.

8. Click **Create Autonomous Container Database**.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the CreateAutonomousContainerDatabase API operation to create an Autonomous container database.

What's Next

After creating an Autonomous Container Database, you can create one or more Autonomous Databases within the container database.

Managing an Autonomous Container Database

This topic describes the database management tasks for Autonomous Container Databases that you complete using the Oracle Cloud InfrastructureConsole or the API. Container databases are used by Autonomous Databases using the dedicated deployment option. For an overview of the dedicated deployment option, see Overview of Autonomous Database Dedicated Deployments.

Note

This topic is not applicable to Autonomous Databases using the serverless deployment option.

The following management operations can be performed on Autonomous Container Databases in Oracle Cloud Infrastructure:

- Edit the backup retention policy. By default, database backups are retained for 60 days. You have the option of retaining backups for 7, 15, 30, or 60 days. The current backup retention policy for an Autonomous Container Database is displayed on the Autonomous Container Database details page.
- Configure the type of database maintenance. You can choose to use Release Update (RU) or Release Update Revision (RUR) updates for your Autonomous Container Database maintenance. For more information, see Release Update Introduction and FAQ (Doc ID 2285040.1) in the My Oracle Support online help portal.
- View the Autonomous Container Database next scheduled maintenance and maintenance history.
- Skip a scheduled maintenance run. For container databases, you can skip maintenance runs for up to 2 consecutive quarters if needed.
- Perform a rolling restart of databases within an Autonomous Container Database. You can perform a "rolling restart" on all the Autonomous Databases in an Autonomous Container Database to ensure that the current memory allocation is optimized. During a rolling restart, each node of an Autonomous Database is restarted separately while the remaining nodes continue to be available. No interruption of service occurs during a rolling restart. You cannot perform a container database restart if a backup is in progress.
- Terminate an Autonomous Container Database. Note that you must terminate all Autonomous Databases within a container database before you can terminate the container database itself.

Using the Oracle Cloud Infrastructure Console

To set the backup retention policy for an Autonomous Container Database

1. Open the navigation menu. Under **Database**, click **Autonomous Transaction Processing** or **Autonomous Data Warehouse**.
2. Choose your **Compartment**.
3. Under **Autonomous Database**, click **Autonomous Container Database**.
4. In the list of Autonomous Container Databases, click on the display name of the container database you are interested in.
5. On the Autonomous Container Database details page, under **Backup**, click the **Edit** link in the **Backup Retention Field**.
6. Specify a backup retention period from the list of choices.
7. Click **Save Changes**.

To configure the type of maintenance patching for an Autonomous Container Database

1. Open the navigation menu. Under **Database**, click **Autonomous Transaction Processing** or **Autonomous Data Warehouse**.
2. Choose your **Compartment**.
3. Under **Autonomous Database**, click **Autonomous Container Database**.
4. In the list of Autonomous Container Databases, click on the display name of the container database you are interested in.
5. On the Autonomous Container Database details page, under **Maintenance**, click the **Edit** link in the **Maintenance Schedule** field.
6. In the **Automatic Maintenance Schedule** dialog, under **Maintenance Type**, select either **Release Update (RU)** or **Release Update Revision (RUR)**.

7. Click **Update Maintenance Schedule**.

To view the maintenance history of an Autonomous Container Database

1. Open the navigation menu. Under **Database**, click **Autonomous Transaction Processing** or **Autonomous Data Warehouse**.
2. Choose your **Compartment**.
3. Under **Autonomous Database**, click **Autonomous Container Database**.
4. In the list of Autonomous Container Databases, click on the display name of the container database you are interested in.
5. On the Autonomous Container Database details page, under **Maintenance**, click the **Edit** link in the **Maintenance Schedule** field.
6. On the **Maintenance** page, under **Autonomous Database Maintenance**, click **History**. In the list of past maintenance events, you can click on an individual event title to read the details of the maintenance that took place. Maintenance event details include the following:
    - The category of maintenance (quarterly software maintenance or a critical patch)
    - Whether the maintenance was scheduled or unplanned
    - The OCID of the maintenance event. (Go to **Actions**, then choose **Copy OCID**.)
    - The start time and date of the maintenance

To skip a scheduled maintenance run for an Autonomous Container Database

1. Open the navigation menu. Under **Database**, click **Autonomous Transaction Processing** or **Autonomous Data Warehouse**.
2. Choose your **Compartment**.
3. Under **Autonomous Database**, click **Autonomous Container Database**.

4. In the list of Autonomous Container Databases, click on the display name of the container database you are interested in.
5. On the Autonomous Container Database details page, under **Maintenance**, click the **View** link in the **Next Maintenance** field.
6. On the **Maintenance** page, any container database maintenance events planned for the next 15 days will appear in the list of maintenance events. To skip a container database maintenance run, click the **Skip Maintenance** button for the scheduled maintenance event.

To perform a rolling restart of databases within an Autonomous Container Database

1. Open the navigation menu. Under **Database**, click **Autonomous Transaction Processing** or **Autonomous Data Warehouse**.
2. Choose your **Compartment**.
3. Under **Autonomous Database**, click **Autonomous Container Database**.
4. In the list of Autonomous Container Databases, click on the display name of the container database you are interested in.
5. On the Autonomous Container Database details page, click **Restart**.
6. In the confirmation dialog, type the name of the Autonomous Container Database.
7. Click **Restart**.

To move an Autonomous Container Database to another compartment

Note

To move resources between compartments, resource users must have sufficient access permissions on the

compartment that the resource is being moved to, as well as the current compartment. For more information about permissions for Database resources, see Details for the Database Service.

1. Open the navigation menu. Under **Database**, click **Autonomous Transaction Processing** or **Autonomous Data Warehouse**.
2. Choose your **Compartment**.
3. Under **Autonomous Database**, click **Autonomous Container Database**.
4. In the list of Autonomous Container Databases, click on the display name of the container database you wish to move.
5. Click **Move Resource**.
6. Select the new compartment.
7. Click **Move Resource**.
   For information about dependent resources for Database resources, see Moving Database Resources to a Different Compartment.

To terminate an Autonomous Container Database

Warning

Terminating an Autonomous Container Database permanently deletes it and removes associated resources such as Autonomous Databases and Autonomous Database backups. You cannot recover a terminated Autonomous Container Database.

1. Open the navigation menu. Under **Database**, click **Autonomous Transaction Processing** or **Autonomous Data Warehouse**.
2. Choose your **Compartment**.
3. Under **Autonomous Database**, click **Autonomous Container Database**.
4. In the list of Autonomous Exadata Infrastructure resources, click on the display name of the infrastructure resource you are interested in.
5. Click **Terminate**.
6. Confirm that you wish to terminate your Autonomous Exadata Infrastructure in the confirmation dialog.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the UpdateAutonomousContainerDatabase API operation to perform the following management actions:

- Set the backup retention period for an Autonomous Container Database.
- Set the maintenance patching type of an Autonomous Container Database.

Use the UpdateMaintenanceRun API operation to skip a container database maintenance run.

Use the ListMaintenanceRun API to get a list of maintenance runs in a specified compartment. Can be used to see maintenance history and scheduled maintenance runs.

Use the RestartAutonomousContainerDatabase API operation to perform a rolling restart on a container database.

Use the ChangeAutonomousContainerDatabaseCompartment API operation to move a container database to another compartment.

Use the TerminateAutonomousContainerDatabase API operation to terminate a container database.

Autonomous Database Development and Administration Tools

This topic describes the Oracle Database tools available for Autonomous Database using the Console and how to access them using the Console. The following tools can be accessed directly from the Oracle Cloud Infrastructure Console:

- Oracle SQL Developer Web
- Oracle Application Express
- Oracle Machine Learning User Administration (available for serverless deployments only)

Tip

Autonomous Database supports a range of other Oracle and third-party tools and applications. See Autonomous Data Warehouse Tools and Application Test Matrix to learn about other tools you can use with your Autonomous Database.

For Autonomous Databases with serverless deployment, additional tools can be accessed through the Service Console.

Oracle SQL Developer Web

Oracle SQL Developer Web in Autonomous Data Warehouse provides a development environment and a data modeler interface for Autonomous Databases. SQL Developer Web is available for both dedicated and serverless Autonomous Database deployments.

The main features of SQL Developer Web are:

- Run SQL statements and scripts in the worksheet
- Export data

- Design Data Modeler diagrams using existing objects

SQL Developer Web is a browser-based interface of Oracle SQL Developer and provides a subset of the features of the desktop version.

For more information, see the Autonomous Transaction Processing and Autonomous Data Warehouse user guides. Each guide contain a section on using SQL Developer Web with Autonomous Databases. Use the following links:

- Using Oracle Autonomous Transaction Processing
- Using Oracle Autonomous Data Warehouse

Complete product information can be found in About Oracle SQL Developer Web.

Oracle Application Express

Oracle Application Express (APEX) is a low-code development platform that enables you to build scalable, secure enterprise applications with world-class features that can be deployed anywhere. APEX provides you with an easy-to-use browser-based environment to load data, manage database objects, develop REST interfaces, and rapidly build applications for both desktop and mobile devices.

Oracle Application Express is available for both dedicated and serverless Autonomous Database deployments.

See Oracle Application Express

For complete information, see the APEX topics in the Autonomous Transaction Processing and the Autonomous Data Warehouse user guides. Use the following links:

- Using Oracle Autonomous Transaction Processing
- Using Oracle Autonomous Data Warehouse

Oracle Machine Learning User Administration

Oracle Machine Learning is a collaborative web-based interface that provides a development environment to create data mining notebooks where you can perform data analytics, data

discovery and data visualizations. Using the Oracle Cloud Infrastructure Console, you can quickly get to the Oracle Machine Learning User Administration interface to create and manage users.

Machine Learning is currently available for serverless Autonomous Database deployments only.

Using the Oracle Cloud Infrastructure Console

FOR AUTONOMOUS DATABASES WITH SERVERLESS DEPLOYMENTS

To access Oracle SQL Developer Web

1. Open the navigation menu. Under **Database**, click **Autonomous Transaction Processing** or **Autonomous Data Warehouse**.
2. Choose your **Compartment**.
3. In the list of Autonomous Databases, click on the display name of the database you wish to work with.
4. Click the **Tools** tab on the Autonomous Database Details page.
5. Click **Open SQL Developer Web**

To access Oracle Application Express (APEX)

1. Open the navigation menu. Under **Database**, click **Autonomous Transaction Processing** or **Autonomous Data Warehouse**.
2. Choose your **Compartment**.
3. In the list of Autonomous Databases, click on the display name of the database you wish to work with.
4. Click the **Tools** tab on the Autonomous Database Details page.
5. Click **Open APEX**

To access Oracle Machine Learning's User Administration Interface

To use Oracle Machine Learning with your Autonomous Database, you must first create a user account within the application. The following steps explain how to navigate to the User Administration interface for Machine Learning from the Autonomous Database details page within the Console.

1. Open the navigation menu. Under **Database**, click **Autonomous Transaction Processing** or **Autonomous Data Warehouse**.
2. Choose your **Compartment**.
3. In the list of Autonomous Databases, click on the display name of the database you wish to work with.
4. Click the **Tools** tab on the Autonomous Database Details page.
5. Click **Open Oracle ML User Administration**

FOR AUTONOMOUS DATABASES WITH DEDICATED DEPLOYMENTS

For dedicated deployments, the Console provides access URLs for Application Express (APEX) and SQL Developer Web that you can use to connect to these applications. The URLs only work from browsers within the same VCN as the Autonomous Database being accessed by the applications. Therefore, to use these URLs, you will need to open a browser running on a computer that meets one of the following conditions:

- The computer is a Compute instance is provisioned in the VCN of the Autonomous Database.
- The computer has a direct connection to the VCN of the Autonomous Database

To access APEX or SQL Developer Web, paste the appropriate access URL into the browser's address field, and then provide the Autonomous Database username and password when prompted. For more information on APEX, see the APEX documentation. For more information on SQL Developer Web, see Oracle SQL Developer Web.

The following tasks explain how to obtain an access URLs for APEX and SQL Developer Web.

To obtain the access URL for Oracle SQL Developer Web for an Autonomous Database with dedicated deployment

1. Open the navigation menu. Under **Database**, click **Autonomous Transaction Processing** or **Autonomous Data Warehouse**.
2. Choose your **Compartment**.
3. In the list of Autonomous Databases, click on the display name of the database you wish to work with.
4. Click the **Tools** tab on the Autonomous Database Details page.
5. Click **Open SQL Developer Web**

To obtain the access URLs for Oracle Application Express (APEX) for an Autonomous Database with dedicated deployment

1. Open the navigation menu. Under **Database**, click **Autonomous Transaction Processing** or **Autonomous Data Warehouse**.
2. Choose your **Compartment**.
3. In the list of Autonomous Databases, click on the display name of the database you wish to work with.
4. Click the **Tools** tab on the Autonomous Database Details page.
5. Click **Open APEX**

Overview of the Always Free Autonomous Database

Oracle Cloud Infrastructure's Always Free Autonomous Database is part of Oracle Cloud Infrastructure's Free Tier of services. You can provision up to two Always Free Autonomous Databases in the home region of your tenancy. These databases are provided free of charge, and they are available to users of both free and paid accounts. You can use these Autonomous Databases for small-scale applications, for development or testing purposes, or for learning about and exploring Oracle Cloud Infrastructure.

Always Free Autonomous Database Specifications

- **Processor:** 1 Oracle CPU processor (cannot be scaled)
- **Memory:** 8 GB RAM
- **Database Storage:** 20 GB storage (cannot be scaled)
- **Workload Type:** Your choice of either the transaction processing or data warehouse workload type
    - The **Autonomous Transaction Processing** workload type configures the database for a transactional workload, with a bias towards high volumes of random data access.

      For a complete product overview of Autonomous Transaction Processing, see Autonomous Transaction Processing. For Autonomous Transaction Processing tutorials, see Quick Start tutorials.
    - The **Autonomous Data Warehouse** workload type configures the database for a decision support or data warehouse workload, with a bias towards large data scanning operations.

      For a complete product overview of Autonomous Data Warehouse, see Autonomous Data Warehouse. For Autonomous Data Warehouse tutorials, see Quick Start tutorials.
- **Deployment Type:** Serverless deployment.
- **Maximum Simultaneous Database Sessions:** 20

Tip

Always Free Autonomous Databases can be upgraded to regular paid instances after provisioning in order to access all Autonomous Database features.

For free accounts, you will need to upgrade your account before upgrading an Always Free Autonomous Database to a paid instance.

Lifecycle for Always Free Autonomous Databases

After provisioning, you can continue using your Always Free Autonomous Database for as long as you want at no charge. You can terminate the database at any time.

If your Always Free Autonomous Database has no activity for a period of 7 consecutive days, the Database service will stop the database automatically. If this happens, you are allowed to restart the database and continue using it. If your Always Free Autonomous Database remains in a stopped state for 3 consecutive months, the resource will be reclaimed by the Database service.

Exadata Cloud at Customer

Exadata Cloud at Customer enables you to apply the combined power of Exadata and Oracle Cloud Infrastructure inside your own data center. You have full access to the features and capabilities of Oracle Database along with the intelligent performance and scalability of Exadata, but with Oracle owning and managing the Exadata infrastructure. You can use the Oracle Cloud Infrastructure console and APIs to manage Exadata Cloud at Customer like any other cloud resource, while maintaining absolute sovereignty over your data.

Each Exadata Cloud at Customer system configuration contains compute nodes (database servers) and Exadata Storage Servers that are interconnected using a high-speed, low-latency InfiniBand network and intelligent Exadata software. Each configuration is equipped with a fixed amount of memory, storage, and network resources.

Exadata Cloud at Customer uses virtual machine (VM) technology to separate the customer-managed and Oracle-managed components on each compute node. You have root privilege for the Exadata compute node VMs, so you can manage the Oracle Database, Oracle Grid Infrastructure, and Exadata system software. However, you do not have administrative access to the physical compute node hardware, which Oracle administers.

Exadata Cloud at Customer uses Exadata Storage Servers for database storage. The storage is allocated to disk groups managed by Oracle Automatic Storage Management (ASM). You have full administrative access to the ASM disk groups, but Oracle administers the Exadata Storage Server hardware and software.

In addition to the compute node hardware and Exadata Storage Servers, Oracle also manages other Exadata Cloud at Customer infrastructure components, including the network switches, power distribution units (PDUs), and integrated lights-out management (ILOM) interfaces.

Subscription to Exadata Cloud at Customer can include all of the required Oracle Database software licenses, or you can choose to bring Oracle Database software licenses that you already own to Exadata Cloud at Customer. If you choose to include Oracle Database software licenses in your Exadata Cloud at Customer subscription, then the included licenses contain all of the features of Oracle Database Enterprise Edition, plus all of the database enterprise management packs, and all of the Enterprise Edition options, such as Oracle Database In-Memory and Oracle Real Application Clusters (RAC). Exadata Cloud at Customer also comes with cloud-specific software tools that assist with administration tasks, such as backup, recovery, and patching.

On each Exadata Cloud at Customer system, you can create one or more databases. Apart from the inherent storage and processing capacity of your Exadata system, there is no set maximum for the number of databases that you can create.

System Configuration

Exadata Cloud at Customer is offered in the following system configurations:

- Base System: Containing two compute nodes and three Exadata Storage Servers. A Base System is an entry-level configuration. Compared to other configurations, a Base System contains Exadata Storage Servers with significantly less storage capacity and

compute nodes with significantly less memory and processing power.

- Quarter Rack: Containing two compute nodes and three Exadata Storage Servers.
- Half Rack: Containing four compute nodes and six Exadata Storage Servers.
- Full Rack: Containing eight compute nodes and 12 Exadata Storage Servers.

Each system configuration is equipped with a fixed amount of memory, storage, and network resources, and all system configurations are based on Oracle Exadata X8 systems.

The following table outlines the technical specifications for each Exadata Cloud at Customer system configuration.

Exadata Cloud at Customer X8 System Specifications

Property	Base System	Quarter Rack	Half Rack	Full Rack
Number of Compute Nodes	2	2	4	8
Total Maximum Number of Enabled CPU Cores	48	100	200	400
Total RAM Capacity	720 GB	1440 GB	2880 GB	5760 GB
Number of Exadata Storage Servers	3	3	6	12
Total Raw Flash Storage Capacity	38.4 TB	76.8 TB	153.6 TB	307.2 TB
Total Raw Disk Storage Capacity	252 TB	504 TB	1008 TB	2016 TB
Total Usable Storage Capacity	74.8 TB	149.7 TB	299.4 TB	598.7 TB

Storage Configuration

As part of configuring each Exadata Cloud at Customer VM cluster, the storage space inside the Exadata Storage Servers is configured for use by Oracle Automatic Storage Management (ASM). By default, the following ASM disk groups are created:

- The DATA disk group is primarily intended for the storage of Oracle Database data files. Also, a small amount of space is allocated from the DATA disk group to support the shared file systems that are used to store software binaries (and patches) and files associated with the cloud-specific tooling. You should not store your own data, including Oracle Database data files, backups, trace files, and so on, inside the system-related ACFS file systems.
- The RECO disk group is primarily used for storing the Fast Recovery Area (FRA), which can be used to provide a local store for files related to backup and recovery. By default, the FRA is used to store archived redo log files and the backup control file. If you configure your VM cluster with the option to allocate storage for local backups, then you can use the FRA as a database backup destination. Finally, if you enable flashback features on a database, then the FRA is used to store the flashback logs.

In addition, you can optionally create the SPARSE disk group. The SPARSE disk group is required to support Exadata snapshot functionality. Exadata snapshots enable space-efficient clones of Oracle databases that can be created and destroyed very quickly and easily. Snapshot clones are often used for development, testing, or other purposes that require a transient database. For more information about Exadata snapshot functionality, see Setting up Oracle Exadata Storage Snapshots in *Oracle Exadata System Software User's Guide*.

Impact of Configuration Settings on Storage

As an input to the VM cluster creation process, you must choose options that determine how storage space in the Exadata Storage Servers is allocated to the ASM disk groups:

- **Allocate Storage for Exadata Snapshots:** If you select this option, the SPARSE disk group is created and less space is allocated to the DATA and RECO disk groups. If you do not select this option, then the SPARSE disk group is not created and you cannot use Exadata snapshot functionality.
- **Allocate Storage for Local Backups:** If you select this option, more space is allocated to the RECO disk group to accommodate local backups to Exadata storage. If

you do not select this option, more space is allocated to the DATA disk group but you cannot use local Exadata storage as a backup destination for any databases in the VM cluster.

Your choices profoundly affect how storage space in the Exadata Storage Servers is allocated to the ASM disk groups. The following table outlines the proportional allocation of storage among the DATA, RECO, and SPARSE disk groups for each possible configuration:

Configuration Settings	DATA Disk Group	RECO Disk Group	SPARSE Disk Group
Allocate Storage for Exadata Snapshots: No **Enable Backups on Local Exadata Storage: No**	80%	20%	0% The SPARSE disk group is not created.
Allocate Storage for Exadata Snapshots: No **Enable Backups on Local Exadata Storage: Yes**	40%	60%	0% The SPARSE disk group is not created.
Allocate Storage for Exadata Snapshots: Yes **Enable Backups on Local Exadata Storage: No**	60%	20%	20%
Allocate Storage for Exadata Snapshots: Yes **Enable Backups on Local Exadata Storage: Yes**	35%	50%	15%

Preparing for Exadata Cloud at Customer

This topic describes the site and network requirements to deploy Exadata Cloud at Customer in a customer data center. Checklists are also provided to help you prepare for Exadata Cloud at Customer.

Site Requirements

The following outlines the site requirements for Exadata Cloud at Customer.

Space

The space requirements for each Exadata Cloud at Customer X8 rack are as follows:

Description	Millimeters (mm)	Inches (”)
Height	2000 mm	78.74”
Width	601 mm	23.66”
Depth	1197 mm	47.13”

Weight

The following table lists the weight of each Exadata Cloud at Customer X8 rack:

Model (X8)	Kilograms (kg)	Pounds (lbs)
Base System	435.9 kg	961.1 lbs
Quarter Rack	449.0 kg	989.8 lbs

Model (X8)	Kilograms (kg)	Pounds (lbs)
Half Rack	591.5 kg	1304.1 lbs
Full Rack	883.9 kg	1948.7 lbs

Receiving, Unpacking, and Access

Before your Exadata Cloud at Customer rack arrives, ensure that the receiving area is large enough for the package.

Use the following package dimensions for each Exadata Cloud at Customer rack:

Description	Millimeters (mm)	Inches (")
Shipping Height	2159 mm	85 inches
Shipping Width	1219 mm	48 inches
Shipping Depth	1575 mm	62 inches

If your loading dock meets the height and ramp requirements for a standard freight carrier truck, then you can use a pallet jack to unload the rack. If the loading dock does not meet the requirements, then you must provide a standard forklift or other means to unload the rack. You can also request that the rack is shipped in a truck with a lift gate.

Use a conditioned space to remove the packaging material to reduce particles before entering the data center. Allow enough space for unpacking it from its shipping cartons.

Use the information in the following table to ensure that there is a clear pathway for moving the Exadata Cloud at Customer rack. Also, the entire access route to the installation site should be free of raised-pattern flooring that can cause vibration.

Access Route Item	With Shipping Pallet	Without Shipping Pallet
Minimum door height	2184 mm (86 inches)	2040 mm (80.32 inches)
Minimum door width	1270 (50 inches)	640 mm (25.19 inches)
Minimum elevator depth	1625.6 mm (64 inches)	1240 mm (48.82 inches)
Maximum incline	6 degrees	6 degrees
Minimum elevator, pallet jack, and floor loading capacity	1134 kg (2500 lbs)	1134 kg (2500 lbs)

Flooring

Oracle recommends that the Exadata Cloud at Customer system is installed on raised flooring. The site floor and the raised flooring must be able to support the total weight of the Exadata Cloud at Customer rack. See Weight.

Electrical Power

Exadata Cloud at Customer can operate effectively over a wide range of voltages and frequencies. However, each rack must have a reliable power source.

Damage may occur if the ranges are exceeded. Electrical disturbances such as the following may damage Exadata Cloud at Customer:

- Fluctuations caused by brownouts
- Wide and rapid variations in input voltage levels or in input power frequency
- Electrical storms
- Faults in the distribution system, such as defective wiring

To protect Exadata Cloud at Customer from such disturbances, you should have a dedicated power distribution system, power-conditioning equipment, and lightning arresters or power cables to protect from electrical storms.

Power Distribution Unit Specifications

Each rack has two pre-installed power distribution units (PDUs). The PDUs accept different power sources. You must choose the type of PDU that is correct for your data center and the Exadata Cloud at Customer rack.

The following table outlines the minimum PDU rating requirement for each rack type:

Model (X8)	Minimum PDU Rating (kVA)
Base System	15 kVA
Quarter Rack	15 kVA
Half Rack	15 kVA
Full Rack	22 kVA

The following list outlines the available PDUs for Exadata Cloud at Customer depending on your region. Follow each of the links to access detailed specifications for each PDU type:

- Americas, Japan, and Taiwan
  - Low-Voltage 15 kVA Single-Phase
  - Low-Voltage 15 kVA Three-Phase

- Low-Voltage 22 kVA Single-Phase
- Low-Voltage 24 kVA Three-Phase

- Europe, the Middle East and Africa (EMEA), and Asia Pacific (APAC), except for Japan and Taiwan
  - High-Voltage 15 kVA Three-Phase
  - High-Voltage 22 kVA Single-Phase
  - High-Voltage 24 kVA Three-Phase

Facility Power Requirements

To prevent catastrophic failures, design the input power sources to ensure that adequate power is provided to the PDUs.

Use dedicated AC breaker panels for all power circuits that supply power to the PDU. When planning for power distribution requirements, balance the power load between available AC supply branch circuits. In the United States of America and Canada, ensure that the overall system AC input current load does not exceed 80 percent of the branch circuit AC current rating.

Note

Electrical work and installations must comply with applicable local, state, or national electrical codes.

PDU power cords are 4 meters (13.12 feet) long, and 1–1.5 meters (3.3–4.9 feet) of the cord is routed within the rack cabinet. The installation site AC power receptacle must be within 2 meters (6.6 feet) of the rack.

Circuit Breaker Requirements

If computer equipment is subjected to repeated power interruptions and fluctuations, then it is susceptible to a higher rate of component failure.

You are responsible for supplying the circuit breakers. One circuit breaker is required for each power cord. In addition to circuit breakers, provide a stable power source, such as an uninterruptible power supply (UPS) to reduce the possibility of component failures.

Use dedicated AC breaker panels for all power circuits that supply power to the server. Servers require grounded electrical circuits.

Note

Electrical work and installations must comply with applicable local, state, or national electrical codes.

ELECTRICAL GROUNDING GUIDELINES

The cabinets for Oracle Exadata Rack are shipped with grounding-type power cords.

- Always connect the cords to grounded power outlets.
- Check the grounding type, because different grounding methods may be used depending on your location.
- Refer to documentation such as IEC documents for the correct grounding method.
- Ensure that the facility administrator or qualified electrical engineer verifies the grounding method for the building, and performs the grounding work.

Temperature and Humidity

Excessive internal temperatures may result in full or partial shutdown of Exadata Cloud at Customer system components.

Note

Studies have shown that temperature increases of 10 degrees Celsius (15 degrees Fahrenheit) above 20 degrees Celsius (70 degrees Fahrenheit) reduce long-term electronics reliability by 50 percent.

The following table lists the temperature, humidity, and altitude requirements for operating and non-operating machines.

Condition	Operating Requirement	Non-operating Requirement	Optimal Requirement
Temperature	5–32 degrees Celsius (59–89.6 degrees Fahrenheit)	-40–70 degrees Celsius (-40–158 degrees Fahrenheit)	21–23 degrees Celsius (70–74 degrees Fahrenheit)
Relative Humidity	10–90 percent relative humidity, non-condensing	Up to 93 percent relative humidity	45–50 percent, non-condensing
Altitude	3048 meters (10000 feet) maximum	12,000 meters (40000 feet) maximum	Maximum ambient temperature is reduced by 1 degree Celsius for every 300 meters of altitude over 900 meters above sea level.

To minimize the chance of downtime because of component failure, set conditions to the optimal temperature and humidity ranges. Maintaining an Exadata Cloud at Customer system for extended periods at or near the operating limits can significantly increase the potential for hardware component failure.

The ambient temperature range of 21–23 degrees Celsius (70–74 degrees Fahrenheit) is optimal for server reliability and operator comfort. Most computer equipment can operate in a wide temperature range, but near 22 degrees Celsius (72 degrees Fahrenheit) is desirable because it is easier to maintain safe humidity levels. Operating in this temperature range provides a safety buffer in case the air conditioning system fails for some time.

The ambient relative humidity range of 45–50 percent is suitable for safe data processing operations. Most computer equipment can operate in a wide range (20–80 percent), but the range of 45–50 percent is recommended for the following reasons:

- The optimal range helps protect computer systems from corrosion problems associated with high humidity levels.
- The optimal range provides the greatest operating time buffer in case the air conditioning system fails for some time.
- The optimal range avoids failures or temporary malfunctions caused by interference from static discharges that may occur when relative humidity is too low. Electrostatic discharge (ESD) is easily generated, and hard to dissipate in areas of low relative humidity, such as below 35 percent. ESD becomes critical when humidity drops below 30 percent.

Ventilation

To allow for proper ventilation, always provide adequate space in front and behind the rack.

Do not obstruct the front or rear of the rack with equipment or objects that might prevent air from flowing through the rack. Each Exadata Cloud at Customer rack draws cool air in through the front of the rack and discharges warm air out the rear of the rack. There is no air flow requirement for the left and right sides because of front-to-back cooling.

Each Exadata Cloud at Customer rack is designed to function while installed in a natural convection air flow. To ensure adequate air flow, allow a minimum clearance of 1219.2 mm (48 inches) at the front of the server, and 914 mm (36 inches) at the rear of the server for ventilation.

Use perforated tiles, approximately 400 CFM/tile, in front of the rack for cold air intake. The tiles can be arranged in any order in front of the rack, as long as cold air from the tiles can flow into the rack. Inadequate cold air flow could result in a higher inlet temperature in the servers because of exhaust air recirculation. The following is the recommended number of floor tiles:

- Four floor tiles for an Exadata Cloud at Customer Full Rack.
- Three floor tiles for an Exadata Cloud at Customer Half Rack.
- One floor tile for an Exadata Cloud at Customer Quarter Rack or Base System.

Network Requirements

Networks and Network Services

NETWORK REQUIREMENTS

Exadata Cloud at Customer utilizes various different networks to provide secure and reliable network connectivity for different application and management functions. The following list outlines the minimum network requirements to install an Exadata Cloud at Customer system:

- Client network

  This network connects the Exadata Cloud at Customer database servers to your existing client network and is used for client access to the database servers. Applications access databases on Exadata Cloud at Customer through this network using Single Client Access Name (SCAN) and Oracle RAC Virtual IP (VIP) interfaces.

  The client access network uses a pair of network interfaces on each database server, which are connected to the customer network.

The database servers support channel bonding to provide higher bandwidth or availability for client connections to Exadata Cloud at Customer. Oracle recommends channel bonding for the client access network. For the connection to your corporate network, you must provide network switches capable of supporting your chosen bonding mode. For example, if mode 4 (IEEE 802.3ad Link Aggregation) is configured, then you must supply and configure network switches capable of supporting this bonding mode.

- Backup network

  This network is similar to the client access network, as it connects the Exadata Cloud at Customer database servers to your existing network. It can be used for access to the database servers for various purposes, including backups and bulk data transfers.

  Like the client network, the backup network uses a pair of network interfaces on each database server, which are connected to the customer network.

  Channel bonding is supported for the backup network to provide higher bandwidth or availability, and Oracle recommends channel bonding for the backup network. For the connection to your corporate network, you must provide network switches capable of supporting your chosen bonding mode. For example, if mode 4 (IEEE 802.3ad Link Aggregation) is configured, then you must supply and configure network switches capable of supporting this bonding mode.

- Control plane network

  This virtual private network (VPN) connects the two control plane servers that are located in the Exadata Cloud at Customer rack to Oracle Cloud Infrastructure. It facilitates customer-initiated operations using the Oracle Cloud Infrastructure Console and APIs. It also facilitates monitoring and administration of the Oracle-managed infrastructure components in Exadata Cloud at Customer.

- Administration network

  This network connects Exadata Cloud at Customer servers and switches to the two control plane servers that are located in the Exadata Cloud at Customer rack. It facilitates customer-initiated operations using the Oracle Cloud Infrastructure Console and APIs. It also facilitates monitoring and administration of the Oracle-managed infrastructure components in Exadata Cloud at Customer.

This network is fully contained within the Exadata Cloud at Customer rack, and does not connect to your corporate network. However, the Exadata infrastructure is indirectly connected to your corporate network through the control plane servers. This connection is required to provide Domain Name System (DNS) and Network Time Protocol (NTP) services to the Exadata infrastructure. Therefore, the IP addresses that are allocated to the administration network must not exist elsewhere in your corporate network.

Each database server and Exadata Storage Server has two network interfaces connected to the administration network. One provides management access to the server through one of the embedded Ethernet ports (NET0). The other provides access to the Integrated Lights-Out Management (ILOM) subsystem through a dedicated ILOM Ethernet port. Exadata Cloud at Customer is delivered with the ILOM and NET0 ports connected to the Ethernet switch in the rack. Cabling or configuration changes to these interfaces are not permitted.

- InfiniBand network

  This network connects the database servers, Exadata Storage Servers, and control plane servers using the InfiniBand switches on the rack. Each server contains two InfiniBand network interfaces (IB0 and IB1) that are connected to separate InfiniBand switches in the rack. Primarily, Oracle Database uses this network for Oracle RAC cluster interconnect traffic and for accessing data on Exadata Storage Servers.

  This non-routable network is fully contained within the Exadata Cloud at Customer rack, and does not connect to your corporate network. However, because the control plane servers are connected to the InfiniBand network and to your corporate network, the IP addresses that are allocated to the InfiniBand network must not exist elsewhere in your corporate network.

DATA CENTER NETWORK SERVICES

Exadata Cloud at Customer requires the following data center network services:

- Domain Name System (DNS)

  As part of the deployment process, you must decide on the host names and IP addresses to be used for various Exadata Cloud at Customer network interfaces. Oracle recommends that you register the host names and IP addresses for the Exadata Cloud

at Customer network interfaces in your corporate DNS. At least one reliable DNS server is required, which must be accessible to the control plane servers and to all of the servers on the client network. Up to three DNS servers can be registered in Exadata Cloud at Customer to ensure coverage in case a server is unavailable.

- Network Time Protocol (NTP) Services
  Exadata Cloud at Customer uses NTP to ensure that all system components are synchronized to the same time. At least one reliable NTP server is required, which must be accessible to the control plane servers and to all of the servers on the client network. Up to three NTP servers can be registered in Exadata Cloud at Customer to ensure coverage in case a server is unavailable.

IP Addresses and Subnets

You must allocate a range of IP addresses to the administration network and another range of IP addresses to the InfiniBand network. No overlap is permitted between the address ranges for the administration network and the InfiniBand network, and all IP addresses should be unique within your corporate network. You must also allocate IP addresses from your corporate network to the control plane servers. These network configuration details are specified when you create the Exadata infrastructure.

When you create the Exadata infrastructure, the Console pre-populates default values for the administration network CIDR block and the InifinBand network CIDR block. You can use the suggested CIDR blocks if there is no overlap with existing IP addresses in your corporate network.

The following table outlines the IP address requirements for each of these networks. The table specifies the maximum and minimum CIDR block prefix length that are allowed for each network. The maximum CIDR block prefix length defines the smallest block of IP addresses that are required for the network. To allow for possible future expansion within Exadata Cloud at Customer, you can choose a smaller CIDR block prefix length, within the allowable range, which reserves more IP addresses for the network.

Network Type	IP Address Requirements
Administration network	Maximum CIDR block prefix length: `/23` Minimum CIDR block prefix length: `/16`
InifinBand network	Maximum CIDR block prefix length: `/22` Minimum CIDR block prefix length: `/19`
Control plane network	2 IP addresses, 1 for each control plane server

To connect to your corporate network, Exadata Cloud at Customer requires several host names and IP addresses for network interfaces on the client network and the backup network. The precise number of IP addresses depends on the Exadata system shape. These network configuration details, including host names and IP addresses, are specified when you create a VM cluster network. All IP addresses must be statically assigned IP addresses, not dynamically assigned (DHCP) addresses. The client network and the backup network require separate subnets.

The following table outlines the IP address requirements for the client and backup networks. The table specifies the maximum and recommended CIDR block prefix length for each network. The maximum CIDR block prefix length defines the smallest block of IP addresses that are required for the network. To allow for possible future expansion within Exadata Cloud at Customer, a smaller CIDR block prefix length is recommended, which reserves more IP addresses for the network.

Network Type	IP Address Requirements for Base System, Quarter Rack, or Half Rack	IP Address Requirements for Full Rack
Client network	Maximum CIDR block prefix length: `/28` Recommended CIDR block prefix length: `/27`	Maximum CIDR block prefix length: `/27` Recommended CIDR block prefix length: `/26`
Backup network	Maximum CIDR block prefix length: `/29` Recommended CIDR block prefix length: `/28`	Maximum CIDR block prefix length: `/28` Recommended CIDR block prefix length: `/27`

Uplinks

Exadata Cloud at Customer has the following uplink requirements:

- Two uplinks are required to connect the control plane servers to your corporate network and the control plane virtual private network (VPN).
- Typically, four uplinks are required for each compute node to connect to your corporate network. Using this configuration, two uplinks support the client network and the other two uplinks support the backup network.

  On Quarter Rack, Half Rack, or Full Rack systems, you can choose to use 10 Gbps RJ45 copper or 10/25 Gbps SFP28 fiber network connections to your corporate network. However, you cannot have a mixture. For example, you cannot use fiber for the client network and copper for the backup network.

  On Base System configurations, the options are more limited because of the physical network interfaces that are available on each compute node. On Base Systems, you can choose to use copper or fiber network connections only for the client network, while the backup network uses a fiber connection.

There is also an option to use shared network interfaces for the client network and the backup network, which reduces the uplink requirement to two uplinks for each compute node. Using shared network interfaces also enables you to use copper network connections to support both the client and backup networks on Base System configurations. However, using shared network interfaces is not generally recommended because it compromises the bandwidth and availability of both networks.

Network Cabling

Every Exadata Cloud at Customer rack is shipped with all of the network equipment and cables that are required to interconnect all hardware in the Exadata Cloud at Customer rack. Oracle also supplies small form-factor pluggable (SFP) network interfaces to enable connectivity to your corporate network. However, you are responsible to provide the required cabling to connect the Exadata compute nodes and control plane servers to your corporate network.

Checklists

System Components Checklist

Use this checklist to ensure that the system component considerations are addressed.

The cells in the second column of the following table are intentionally left blank so that the site survey team can fill in the requested information.

System Components Checklist Items	Customer Response or Comment
How many racks will be installed?	
Will additional equipment be attached to or installed in the rack? If so, ensure that the additional equipment falls within Oracle guidelines and there is sufficient power and cooling.	

Data Center Room Checklist

Use this checklist to ensure that the data center room requirements are addressed.

The cells in the second and subsequent columns of the following table are intentionally left blank so that the site survey team can fill in the requested information.

Data Center Room Checklist Items	Yes	No	Not Applicable	Comment
Has the rack location been allocated and is it vacant?				
Does the floor layout meet the equipment maintenance access requirements?				
Will the rack be positioned so that the exhaust air of one rack does not enter the air inlet of another rack?				

Data Center Room Checklist Items	Yes	No	Not Applicable	Comment
Have cabinet stabilization measures been considered?				
If the data center has a raised floor: • Does the raised floor satisfy the weight requirements for the rack? • Is permission required to remove floor tiles for cabling and servicing below the floor?				
Will the rack location require any non-standard cable lengths?				
Is the floor-to-ceiling height a minimum of 2914 mm (114.72 inches)?				
Is the depth of the raised floor a minimum of 46 cm (18 inches)?				

RELATED TOPICS:

- Space
- Weight
- Flooring
- Ventilation

Data Center Environment Checklist

Use this checklist to ensure that the data center environment requirements are addressed.

The cells in the second and subsequent columns of the following table are intentionally left blank so that the site survey team can fill in the requested information.

Data Center Environment Checklist Items	Yes	No	Not Applicable	Comment
Does the computer room air conditioning meet temperature and humidity requirements?				
Does the installation floor layout satisfy the ventilation requirements?				
If the room cooling is from a raised floor: • Are the perforated floor tiles each rated at 400 CFM or greater? • Can additional perforated floor tiles be obtained if required for additional cooling?				
Does the data center air conditioning provide sufficient front-to-back airflow?				

Data Center Environment Checklist Items	Yes	No	Not Applicable	Comment
Is airflow adequate to prevent hot spots?				
Can the data center continuously satisfy the environmental requirements?				

RELATED TOPICS:

- Temperature and Humidity
- Ventilation

Access Route Checklist

Use this checklist to ensure that the access route requirements are addressed.

The cells in the second and subsequent columns of the following table are intentionally left blank so that the site survey team can fill in the requested information.

Access Route Checklist Items	Yes	No	Not Applicable	Comment
Has the access route been checked for clearance of the rack, including the minimum width and height requirements for all doors on the route?				
Are there any stairs, ramps, or thresholds that are of concern? If yes, then provide details.				
Are all access route incline angles within the permitted range (under 6 degrees)?				
Are all the surfaces acceptable for rolling the new unpacked and packed equipment?				
If a pallet jack is to be used: • Can the pallet jack support the weight of the rack? Are the pallet jack tines compatible with the shipping pallet?				
If there are stairs, is a loading elevator available for the equipment?				

Access Route Checklist Items	Yes	No	Not Applicable	Comment
If an elevator is to be used: • Does the elevator car meet the height, width, and depth requirements for carrying the rack? • Do the elevator doors meet the height and width requirements for moving the rack? • Does the elevator meeting the weight requirements for transporting the rack?				
Can the complete access route support the weight of the rack?				
Is the access route onto the raised floor rated for dynamic loading of the rack?				

RELATED TOPICS:

- Space
- Weight
- Flooring
- Receiving, Unpacking, and Access

Facility Power Checklist

Use this checklist to ensure that the facility power requirements are addressed.

The cells in the second and subsequent columns of the following table are intentionally left blank so that the site survey team can fill in the requested information.

Facility Power Checklist Items	Yes	No	Not Applicable	Comment
Have the operating voltage and electric current requirements been reviewed?				
What type of power supply will be used? • Single-phase or 3-phase. • Low-voltage or High-voltage.				
Are enough power outlets provided within 2 meters for each rack?				
Do the power outlets have appropriate socket receptacles for the planned Power Distribution Units (PDUs)?				
Will optional ground cables be attached to the rack?				
Are the electrical circuits suitable in terms of voltage and current-carrying capacities?				
Does the power frequency meet the equipment specifications?				

Facility Power Checklist Items	Yes	No	Not Applicable	Comment
Are power outlets available for the new equipment at the designated location?				
Will system power be delivered from two separate grids?				
Is there a UPS to power the equipment?				
Are the minimum required power sources available to support the power load (kW or kVA) for the new hardware?				

RELATED TOPICS:

- Electrical Power

Safety Checklist

Use this checklist to ensure that the safety requirements are addressed.

The cells in the second and subsequent columns of the following table are intentionally left blank so that the site survey team can fill in the requested information.

Safety Checklist Items	Yes	No	Not Applicable	Comment
Is there an emergency power shut off?				
Is there a fire protection system in the data center room?				
Is the computer room adequately equipped to extinguish a fire?				
Is antistatic flooring installed?				
Is the area below the raised floor free of obstacles and blockages?				

Logistics Checklist

Use this checklist to ensure that the logistics requirements are addressed.

The cells in the second and subsequent columns of the following table are intentionally left blank so that the site survey team can fill in the requested information.

Logistics Checklist Items	Yes	No	Not Applicable	Comment
Is contact information for the data center personnel available?				
Is there security or access control for the data center?				
Are there any security background checks or security clearances required for Oracle personnel to access the data center? If yes, then provide the process for Oracle to follow.				
How many days in advance must background checks be completed?				
Are there any additional security access issues?				
Is computer room access available for installation personnel?				
Are laptops allowed in the data center?				
Are cell phones allowed in the data center?				

Logistics Checklist Items	Yes	No	Not Applicable	Comment
Are cameras allowed in the data center?				
Does the building have a delivery dock?				
Is there a delivery/ unpacking/ staging area?				
Is inside delivery planned (direct to the final rack location in the data center room)?				
If the delivery is not inside, then is the site prepared for uncrating?				
Is the delivery/ unpacking/ staging area protected from the elements?				
Does the building have adequate receiving space?				
Is the unpacking area air-conditioned to avoid thermal shock for various hardware components?				
Will sufficient moving personnel be available to transport the rack?				

Logistics Checklist Items	Yes	No	Not Applicable	Comment
Is union labor required for any part of the delivery or installation?				
Is the site prepared for uncrating and packaging removal? Package removal should take place outside the data center room.				
Is uncrating of cabinet and packaging removal required?				
Are there any restrictions on delivery truck length, width, or height?				
Is there storage space (cabinet) for the ride along spares? If not, does the customer allow cardboard boxes and other packing material in the computer room, since the spares are packed in cardboard boxes?				
Is there a time constraint on dock access? If yes, provide time constraints.				

Logistics Checklist Items	Yes	No	Not Applicable	Comment
Is a tail or side lift required on the delivery carrier to unload the equipment at the delivery dock?				
Will any special equipment be required to place the rack in the data center room? For example: • Stair walkers • Lifters • Ramps • Steel plates • Floor covers				
Does the delivery carrier require any special equipment, such as non-floor damaging rollers, transport dollies, pallet jacks, or fork lifts?				

RELATED TOPICS:

- Space
- Receiving, Unpacking, and Access

Network Configuration Checklist

Use this checklist to ensure that the network configuration requirements are addressed.

The cells in the second and subsequent columns of the following table are intentionally left blank so that the site survey team can fill in the requested information.

Network Configuration Checklist Items	Yes	No	Not Applicable	Comment
Will the required network cables be laid from the network equipment to the location where the Oracle Exadata Rack will be installed?				
Will the network cables that will connect to the Oracle Exadata Rack be labeled?				
Will the 10 GbE or 25 GbE interfaces be used for the client access network? If so, has the customer ordered the appropriate cables to their switch?				
Will the Cisco Ethernet switch have IP routing disabled (recommended)?				

RELATED TOPICS:

- Network Requirements

Reracking Checklist

Use this checklist to ensure that the reracking requirements are addressed.

Note

- Reracking requires prior approval. Check that reracking has been approved.
- Customer must purchase the Oracle Reracking service.
- Oracle does not provide technical support for customer-supplied equipment.

The cells in the second and subsequent columns of the following table are intentionally left blank so that the site survey team can fill in the requested information.

Reracking Checklist Items	Yes	No	Not Applicable	Comment
Has the customer purchased the Oracle Reracking Service?				
Is there a cart capable of carrying the weight of the servers to move the components and associated cabling from the supplied rack to the customer supplied rack?				
Is the target rack empty?				
Attach pictures of the target rack (inside and outside).				

Reracking Checklist Items	Yes	No	Not Applicable	Comment
Does the target rack meet the following requirements? • Height: 42 RU Width: 600 mm (23.62 inches) Depth: 1112 mm (43.78 inches) without front and rear doors If the rack is less than 42 RU tall, then the rack must be at least 30 RU tall and the customer must provide compatible PDUs to install in the target rack.				
Is the distance between the front and rear mounting planes between the minimum of 610 mm and the maximum 915 mm (24–36 inches)?				
Is the clearance depth in the front of the front mounting plane (distance to the front cabinet door) at least 25.4 mm (1 inch)?				
Does the target rack meet the following minimum load capacity? • 19 kg (41.89 lb) per RU • 785 kg (1730.63 lb) total				

Reracking Checklist Items	Yes	No	Not Applicable	Comment
Is the rack a four-post rack (mounting at both front and rear)?  **Note** Two-post racks are not compatible.				
Does the target rack's horizontal opening and unit vertical pitch conform to ANSI/EIA 310-D-1992 or IEC 60297 standards?				

Reracking Checklist Items	Yes	No	Not Applicable	Comment
Does the target rack have RETMA rail support?				

Reracking Checklist Items	Yes	No	Not Applicable	Comment
 **Note** Oracle Exadata rack requires 19 inches (483 mm) for RETMA rail spacing width. The minimum rack width of 600 mm (23.63 inches) is recommended to accommodate the PDU and cable harnesses on the side. If the rack is less than 600 mm wide, then it must have additional depth to accommodate mounting behind the server cable management arms.				

Reracking Checklist Items	Yes	No	Not Applicable	Comment
Does the target rack support Oracle cable management arms?				
Does the target rack support installation of Oracle vented and solid filler panels?				
Can the target rack provide tie-downs along the left rear side of the rack (as viewed from the front of the rack) to support the lnfiniBand cables?				
Can the target rack provide tie-downs for the Ethernet wiring harness?				
Is there sufficient space for the cable harnesses and the PDUs in the target rack?				
Can a label with the Oracle Exadata Rack serial number be printed and attached to the target rack?				
Does the target rack support installation of standard Oracle PDUs? If not, then complete the following checklist items:				

Reracking Checklist Items	Yes	No	Not Applicable	Comment
• Can the customer provide an equivalent pair of PDUs?				
• Can the customer provide two PDUs, each with a capacity of 10 kVA?				
• Can the customer provide at least 17 x lOA C13 plugs per PDU?				
• Can the customer provide a single PDU and its circuits to support the Oracle Exadata Rack power requirements in case one PDU fails?				
• Can the customer ensure that power loads are evenly distributed across all circuits of a single PDU?				
• Can the customer provide appropriate power drops for the PDUs?				

Provisioning Exadata Cloud at Customer Systems

This topic explains how to provision an Exadata Cloud at Customer system.

Provisioning an Exadata Cloud at Customer system is a collaborative process that involves you and Oracle. The process is outlined as follows:

- You create the Exadata Cloud at Customer infrastructure.
- You generate a file containing the infrastructure configuration details and provide it to Oracle.
- The Exadata Cloud at Customer system is physically installed in your data center.
- Oracle uses the infrastructure configuration file to perform initial system configuration. At the end of this task, Oracle supplies you with an activation file.
- You activate the Exadata Cloud at Customer infrastructure by using the supplied activation file.

Following the provisioning process, the Exadata Cloud at Customer system is ready for you to use. You can then create a virtual machine (VM) cluster and later create some databases.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: The policy in Let database admins manage DB systems lets the specified group do everything with databases and related Database resources.

If you're new to policies, see Getting Started with Policies and Common Policies. If you want to dig deeper into writing policies for databases, see Details for the Database Service.

Prerequisites

- Before you can provision Exadata Cloud at Customer infrastructure, your Oracle Cloud Infrastructure tenancy must be enabled to use Exadata Cloud at Customer. See Welcome to Oracle Cloud Infrastructure. Contact Oracle for further details.
- In preparation for the provisioning process, ensure that your corporate data center and network infrastructure meet the requirements described in Preparing for Exadata Cloud at Customer.

Using the Console

To create Exadata Cloud at Customer infrastructure

1. Open the navigation menu. Under Database, click **Exadata Cloud at Customer**.
2. Choose the **Region** that you want to associate with the Exadata infrastructure.
   The region that is associated with your Exadata infrastructure cannot be changed after the Exadata infrastructure is created. Therefore, ensure that you select the most appropriate region for your Exadata infrastructure. Consider the following factors:
   - Consider any business policies or regulations that preclude the use of a particular region. For example, you may be required to maintain all operations within national boundaries.
   - Consider the physical proximity of the region to your data center. Needless extra physical separation adds unnecessary latency to network communications between Oracle Cloud Infrastructure and your corporate data center.
3. Click **Exadata Infrastructure**.
4. Click **Create Exadata Infrastructure**.

5. Provide the requested information in the **Create Exadata Infrastructure** page:
    - **Oracle Cloud Infrastructure region:** The region that is associated with your Exadata infrastructure cannot be changed after the Exadata infrastructure is created. Therefore, check the displayed region to ensure that you are using the most appropriate region for your Exadata infrastructure.

      See step 2 (earlier in this procedure) for further considerations. To switch regions now, use the Region menu at the top of the Console.
    - **Choose a compartment:** From the list of available compartments, choose the compartment that you want to contain the Exadata infrastructure.

      See also Understanding Compartments.
    - **Provide the display name:** The display name is a user-friendly name that you can use to identify the Exadata infrastructure. The name doesn't need to be unique because an Oracle Cloud Identifier (OCID) uniquely identifies the Exadata infrastructure.
    - **Select the Exadata system model:** From the list, choose the model of the Exadata hardware that is being used.

      The Exadata system model and the Exadata system shape combine to define the amount of CPU, memory, and storage resources that are available in the Exadata infrastructure. For more details, see System Configuration.
    - **Select an Exadata system shape:** Together with the Exadata system model, the Exadata system shape defines the amount of CPU, memory, and storage resources that are available in the Exadata infrastructure.

      ### Exadata system shapes

        - **Base System:** includes two compute nodes and three Exadata Storage Servers. A Base System is an entry-level configuration. Compared to other configurations, a Base System contains Exadata Storage Servers with significantly less storage capacity and compute nodes with significantly less memory and processing power.

- **Quarter Rack:** includes two compute nodes and three Exadata Storage Servers.
- **Half Rack:** includes four compute nodes and six Exadata Storage Servers.
- **Full Rack:** includes eight compute nodes and 12 Exadata Storage Servers.

For more details, see System Configuration.

CONFIGURE THE CLOUD CONTROL PLANE NETWORK

Each Exadata Cloud at Customer system contains two control plane servers, which enable connectivity to Oracle Cloud Infrastructure. The control plane servers are connected to the control plane network, which is a subnet on your corporate network. The following settings define the required network parameters:

- **Control Plane Server 1 IP Address:** Provide the IP address for the first control plane server. This IP address is for the network interface that connects the first control plane server to your corporate network using the control plane network.
- **Control Plane Server 2 IP Address:** Provide the IP address for the second control plane server. This IP is address for the network interface that connects the second control plane server to your corporate network using the control plane network.
- **Netmask:** Specify the IP netmask for the control plane network.
- **Gateway:** Specify the IP address of the control plane network gateway.
- **HTTPS Proxy:** Specify your corporate HTTPS proxy. The expected format is `http://server.domain:port`. For example, `http://proxy.example.com:80`.

CONFIGURE THE EXADATA SYSTEM NETWORKS

Each Exadata Cloud at Customer system contains two system networks, which are not connected to your corporate network. The following settings define IP address allocations for these networks:

- **Administration Network CIDR Block:** Specifies the IP address range for the administration network using CIDR notation. The administration network provides connectivity that enables Oracle to administer the Exadata system components, such as the Exadata compute servers, storage servers, network switches, and power distribution units. You can accept the suggested default, or specify a custom value.

  The maximum CIDR block prefix length is `/23`, which defines the smallest block of IP addresses that are required for the network. To allow for possible future expansion within Exadata Cloud at Customer, a smaller CIDR block prefix length is recommended, which reserves more IP addresses for the network. The minimum CIDR block prefix length is `/16`.

  Ensure that the IP address range does not conflict with other hosts your corporate network, and does not overlap with the InfiniBand network CIDR block.
- **InfiniBand Network CIDR Block:** Specifies the IP address range for the Exadata InfiniBand network using CIDR notation. The Exadata InfiniBand network provides the high-speed low-latency interconnect used by Exadata software for internal communications between various system components. You can accept the suggested default, or specify a custom value.

  The maximum CIDR block prefix length is `/22`, which defines the smallest block of IP addresses that are required for the network. To allow for possible future expansion within Exadata Cloud at Customer, a smaller CIDR block prefix length is recommended, which reserves more IP addresses for the network. The minimum CIDR block prefix length is `/19`.

  Ensure that the IP address range does not conflict with other hosts your corporate network, and does not overlap with the administration network CIDR block.

CONFIGURE DNS AND NTP SERVICES

Each Exadata Cloud at Customer system requires access to Domain Names System (DNS) and Network Time Protocol (NTP) services. The following settings specify the servers that provide these services to the Exadata infrastructure:

- **DNS Servers:** Provide the IP address of a DNS server that is accessible using the control plane network. You may specify up to three DNS servers.
- **NTP Servers:** Provide the IP address of an NTP server that is accessible using the control plane network. You may specify up to three NTP servers.
- **Select the time zone:** Choose the geographic region and time zone for the Exadata infrastructure.

SHOW ADVANCED OPTIONS

- **Tags:** Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.

6. Click **Create Exadata Infrastructure**.
   If all of your inputs are valid, the Infrastructure Details page appears. The page outlines the next steps in the provisioning process. Initially after creation, the state of the Exadata infrastructure is **Requires-Activation**.

To edit Exadata Cloud at Customer infrastructure networking

You can only edit Exadata Cloud at Customer infrastructure networking if the current state of the Exadata infrastructure is **Requires Activation**. Also, ensure that you do not edit the Exadata infrastructure after you download the configuration file and provide it to Oracle.

1. Open the navigation menu. Under Database, click **Exadata Cloud at Customer**.
2. Choose the **Region** and **Compartment** that contains the Exadata infrastructure that you want to edit.
3. Click **Exadata Infrastructure**.
4. Click the name of the Exadata infrastructure that you want to edit.

The Infrastructure Details page displays information about the selected Exadata infrastructure.

5. Click **Edit Infrastructure Networking**.
6. Use the Edit Infrastructure Networking dialog to edit the Exadata infrastructure networking:

CONFIGURE THE CLOUD CONTROL PLANE NETWORK

Each Exadata Cloud at Customer system contains two control plane servers, which enable connectivity to Oracle Cloud Infrastructure. The control plane servers are connected to the control plane network, which is a subnet on your corporate network. The following settings define the required network parameters:

- **Control Plane Server 1 IP Address:** Provide the IP address for the first control plane server. This IP address is for the network interface that connects the first control plane server to your corporate network using the control plane network.
- **Control Plane Server 2 IP Address:** Provide the IP address for the second control plane server. This IP address is for the network interface that connects the second control plane server to your corporate network using the control plane network.
- **Netmask:** Specify the IP netmask for the control plane network.
- **Gateway:** Specify the IP address of the control plane network gateway.
- **HTTPS Proxy:** Specify your corporate HTTPS proxy. The expected format is `http://server.domain:port`. For example, `http://proxy.example.com:80`.

CONFIGURE THE EXADATA SYSTEM NETWORKS

Each Exadata Cloud at Customer system contains two system networks, which are not connected to your corporate network. The following settings define IP address allocations for these networks:

- **Administration Network CIDR Block:** Specifies the IP address range for the administration network using CIDR notation. The administration network provides

connectivity that enables Oracle to administer the Exadata system components, such as the Exadata compute servers, storage servers, network switches, and power distribution units.

The maximum CIDR block prefix length is `/23`, which defines the smallest block of IP addresses that are required for the network. To allow for possible future expansion within Exadata Cloud at Customer, a smaller CIDR block prefix length is recommended, which reserves more IP addresses for the network. The minimum CIDR block prefix length is `/16`.

Ensure that the IP address range does not conflict with other hosts your corporate network, and does not overlap with the InfiniBand network CIDR block.

- **InfiniBand Network CIDR Block:** Specifies the IP address range for the Exadata InfiniBand network using CIDR notation. The Exadata InfiniBand network provides the high-speed low-latency interconnect used by Exadata software for internal communications between various system components.

  The maximum CIDR block prefix length is `/22`, which defines the smallest block of IP addresses that are required for the network. To allow for possible future expansion within Exadata Cloud at Customer, a smaller CIDR block prefix length is recommended, which reserves more IP addresses for the network. The minimum CIDR block prefix length is `/19`.

  Ensure that the IP address range does not conflict with other hosts your corporate network, and does not overlap with the administration network CIDR block.

CONFIGURE DNS AND NTP SERVICES

Each Exadata Cloud at Customer system requires access to Domain Names System (DNS) and Network Time Protocol (NTP) services. The following settings specify the servers that provide these services to the Exadata infrastructure:

- **DNS Servers:** Provide the IP address of a DNS server that is accessible using the control plane network. You may specify up to three DNS servers.
- **NTP Servers:** Provide the IP address of an NTP server that is accessible using the control plane network. You may specify up to three NTP servers.
- **Select the time zone:** Choose the geographic region and time zone for the

Exadata infrastructure.

7. Click **Save Changes**.

To download a file containing the configuration details for Exadata Cloud at Customer infrastructure

1. Open the navigation menu. Under Database, click **Exadata Cloud at Customer**.
2. Choose the **Region** and **Compartment** that contains the Exadata infrastructure for which you want to download a file containing the infrastructure configuration details.
3. Click **Exadata Infrastructure**.
4. Click the name of the Exadata infrastructure for which you want to download a file containing the infrastructure configuration details.
   The Infrastructure Details page displays information about the selected Exadata infrastructure.
5. Click **Download Configuration**.
   Your browser downloads a file containing the infrastructure configuration details.

When you provide the generated infrastructure configuration file to Oracle, ensure that it has not been altered in any way. Also, ensure that you do not edit the Exadata infrastructure after you download the configuration file and provide it to Oracle.

To activate Exadata Cloud at Customer infrastructure

To activate Exadata Cloud at Customer infrastructure, ensure that you that have the activation file. This file is supplied to you by Oracle after installation and initial configuration of your Exadata Cloud at Customer system. You can only activate the Exadata infrastructure if its current state is **Requires Activation**.

1. Download the activation file.
2. Open the navigation menu. Under Database, click **Exadata Cloud at Customer**.

3. Choose the **Region** and **Compartment** that contains the Exadata infrastructure that you want to activate.
4. Click **Exadata Infrastructure**.
5. Click the name of the Exadata infrastructure that you want to activate.
   The Infrastructure Details page displays information about the selected Exadata infrastructure.
6. Click **Activate**.
   The Activate button is only available if the Exadata infrastructure requires activation. You cannot activate Exadata infrastructure multiple times.
7. Use the Activate dialog to upload the activation file and then click **Activate Now**.
   After activation, the state of the Exadata infrastructure changes to **Active**.

To check the status of Exadata Cloud at Customer infrastructure

1. Open the navigation menu. Under Database, click **Exadata Cloud at Customer**.
2. Choose the **Region** and **Compartment** that contains the Exadata infrastructure that you are interested in.
3. Click **Exadata Infrastructure**.
4. Click the name of the Exadata infrastructure that you are interested in.
   The Infrastructure Details page displays information about the selected Exadata infrastructure.
5. Check the icon on the Infrastructure Details page. The color of the icon and the text below it indicates the status of the Exadata infrastructure.
   - **Creating**: Yellow icon. The Exadata infrastructure definition is being created in the control plane.
   - **Requires Activation**: Yellow icon. The Exadata infrastructure is defined in the control plane but it must be provisioned and activated before it can be used.
   - **Active**: Green icon. The Exadata infrastructure is successfully provisioned and activated.

- **Deleting**: Gray icon. The Exadata infrastructure is being deleted by using the Console or API.
- **Deleted**: Gray icon. The Exadata infrastructure is deleted and is no longer available. This state is transitory and is displayed for a short time, after which the Exadata infrastructure is no longer displayed.
- **Activation Failed**: Red icon. An error condition currently prevents the activation of the Exadata infrastructure. Typically, this state is auto-correcting and does not require user intervention.

To move Exadata Cloud at Customer infrastructure to another compartment

You can change the compartment that contains your Exadata Cloud at Customer infrastructure by moving it.

When you move Exadata infrastructure, the compartment change is also applied to the associated VM cluster networks. However, the compartment change does not affect any other associated resources, such as the VM clusters, which remain in their current compartment.

To move Exadata Cloud at Customer infrastructure:

1. Open the navigation menu. Under Database, click **Exadata Cloud at Customer**.
2. Choose the **Region** and **Compartment** that contains the Exadata infrastructure that you want to move.
3. Click **Exadata Infrastructure**.
4. Click the name of the Exadata infrastructure that you want to move.
   The Infrastructure Details page displays information about the selected Exadata infrastructure.
5. Click **Move Resource**.
6. In the resulting dialog, choose the new compartment for the Exadata infrastructure and click **Move Resource**.

To delete Exadata Cloud at Customer infrastructure

Deleting Exadata Cloud at Customer infrastructure removes it from the Cloud Control Plane.

If you are deleting Exadata infrastructure before activation, then if required you can create replacement Exadata infrastructure without any input from Oracle.

In you are deleting active Exadata infrastructure, then to create replacement Exadata infrastructure you must repeat the full provisioning process, including the tasks that Oracle performs.

Before you can delete active Exadata infrastructure, you must:

- Terminate all of the resources that it contains, including the databases, VM cluster, and VM cluster network.
- Lodge a service request (SR) with Oracle indicating your intention to delete the Exadata infrastructure. In response to the SR, Oracle flags the Exadata infrastructure as ready for deletion, which enables you to delete the Exadata infrastructure by using the following process.

To delete Exadata Cloud at Customer infrastructure:

1. Open the navigation menu. Under Database, click **Exadata Cloud at Customer**.
2. Choose the **Region** and **Compartment** that contains the Exadata infrastructure that you want to delete.
3. Click **Exadata Infrastructure**.
4. Click the name of the Exadata infrastructure that you want to delete.
   The Infrastructure Details page displays information about the selected Exadata infrastructure.
5. Click **Delete**.
6. In the resulting dialog, enter the Exadata infrastructure name and click **Delete Exadata Infrastructure** to confirm the action.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use these API operations to manage Exadata Cloud at Customer infrastructure:

- ActivateExadataInfrastructure
- CreateExadataInfrastructure
- DeleteExadataInfrastructure
- DownloadExadataInfrastructureConfigFile
- GenerateRecommendedVmClusterNetwork
- GetExadataInfrastructure
- ListExadataInfrastructure
- UpdateExadataInfrastructure

For the complete list of APIs, see Database Service API.

Managing VM Clusters on Exadata Cloud at Customer

This topic explains how to manage virtual machine (VM) clusters on Exadata Cloud at Customer.

Before you can create any databases on your Exadata Cloud at Customer infrastructure, you must create a VM cluster network and associate it with a VM cluster. Each Exadata Cloud at Customer infrastructure can support one VM cluster network and associated VM cluster.

The VM cluster network specifies network resources, such as IP addresses and host names, that reside in your corporate data center and are allocated to Exadata Cloud at Customer. The VM cluster network includes definitions for the Exadata client network and the Exadata backup network. The client network and backup network contain the network interfaces that you use to connect to the VM cluster compute nodes, and ultimately the databases that reside on those compute nodes.

The VM cluster provides a link between your Exadata Cloud at Customer infrastructure and databases. The VM cluster contains an installation of Oracle Clusterware, which supports the databases in the cluster. In the VM cluster definition, you also specify the number of enabled CPU cores, which determines the amount of CPU resources that are available to your databases.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don't have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: The policy in Let database admins manage DB systems lets the specified group do everything with databases and related Database resources.

If you're new to policies, see Getting Started with Policies and Common Policies. If you want to dig deeper into writing policies for databases, see Details for the Database Service.

Prerequisites

The public key, in OpenSSH format, from the key pair that you plan to use for connecting to the VM cluster compute nodes via SSH. The following shows a sample public key, which is abbreviated for readability.

```
ssh-rsa AAAAB3NzaC1yc2EAAAABJQAA....lo/gKMLVM2xzc1xJr/Hc26biw3TXWGEakrK1OQ== rsa-key-20160304
```

For more information, see Managing Key Pairs on Linux Instances.

Using the Console

To create a VM cluster network

1. Open the navigation menu. Under Database, click **Exadata Cloud at Customer**.
2. Choose the **Region** and **Compartment** that contains the Exadata infrastructure for which you want to create a VM cluster network.
3. Click **Exadata Infrastructure**.
4. Click the name of the Exadata infrastructure for which you want to create a VM cluster network.
   The Infrastructure Details page displays information about the selected Exadata infrastructure.
5. Click **Create VM Cluster Network**.
6. Provide the requested information in the **Data Center Network Details** page:
   - **Provide the display name:** The display name is a user-friendly name that you can use to identify the VM cluster network. The name doesn't need to be unique because an Oracle Cloud Identifier (OCID) uniquely identifies the VM cluster network.

   PROVIDE CLIENT NETWORK DETAILS

   The client network is the primary channel for application connectivity to Exadata Cloud at Customer resources. The following settings define the required network parameters:

   - **VLAN ID:** Provide a virtual LAN identifier (VLAN ID) for the client network.
   - **CIDR Block:** Using CIDR notation, provide the IP address range for the client network.
     The following table specifies the maximum and recommended CIDR block prefix lengths for each Exadata system shape. The maximum CIDR block prefix length defines the smallest block of IP addresses that are required for the network. To allow for possible future expansion within Exadata Cloud at Customer, a smaller

CIDR block prefix length is recommended, which reserves more IP addresses for the network.

Exadata System Shape	Base System, Quarter Rack, or Half Rack	Full Rack
Maximum CIDR block prefix length	/28	/27
Recommended CIDR block prefix length	/27	/26

- **Netmask:** Specify the IP netmask for the client network.
- **Gateway:** Specify the IP address of the client network gateway.
- **Hostname Prefix:** Specify the prefix that is used to generate the hostnames in the client network.
- **Domain Name:** Specify the domain name for the client network.

PROVIDE BACKUP NETWORK DETAILS

The backup network is the secondary channel for connectivity to Exadata Cloud at Customer resources. It is typically used to segregate application connections on the client network from other network traffic. The following settings define the required network parameters:

- **VLAN ID:** Provide a virtual LAN identifier (VLAN ID) for the backup network.
- **CIDR Block:** Using CIDR notation, provide the IP address range for the backup network.

  The following table specifies the maximum and recommended CIDR block prefix lengths for each Exadata system shape. The maximum CIDR block prefix length defines the smallest block of IP addresses that are required for the network. To allow for possible future expansion within Exadata Cloud at Customer, a smaller

CIDR block prefix length is recommended, which reserves more IP addresses for the network.

Exadata System Shape	Base System, Quarter Rack, or Half Rack	Full Rack
Maximum CIDR block prefix length	/29	/28
Recommended CIDR block prefix length	/28	/27

- **Netmask:** Specify the IP netmask for the backup network.
- **Gateway:** Specify the IP address of the backup network gateway.
- **Hostname Prefix:** Specify the prefix that is used to generate the hostnames in the backup network.
- **Domain Name:** Specify the domain name for the backup network.

PROVIDE DNS AND NTP SERVER DETAILS

The VM cluster network requires access to Domain Names System (DNS) and Network Time Protocol (NTP) services. The following settings specify the servers that provide these services:

- **DNS Servers:** Provide the IP address of a DNS server that is accessible using the client network. You may specify up to three DNS servers.
- **NTP Servers:** Provide the IP address of an NTP server that is accessible using the client network. You may specify up to three NTP servers.

SHOW ADVANCED OPTIONS

- **Tags:** Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To

apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.

7. Click **Review Configuration**.
   The Review Configuration page displays detailed information about the VM cluster network, including the hostname and IP address allocations. These allocations are initially system-generated and are based on your inputs to the Specify Parameters page.
8. Optionally, you can adjust the system-generated network definitions on the Review Configuration page.
   a. Click **Edit IP Allocation**.
   b. Use the **Edit** dialog to adjust the system-generated network definitions to meet your requirements.
   c. Click **Save Changes**.
9. Click **Create VM Cluster Network**.
   The VM Cluster Network Details page is now displayed. Initially after creation, the state of the VM cluster network is **Requires Validation**.

To edit a VM cluster network

You can only edit a VM cluster network that is not associated with a VM cluster.

1. Open the navigation menu. Under Database, click **Exadata Cloud at Customer**.
2. Choose the **Region** and **Compartment** that contains the Exadata infrastructure that is associated with the VM cluster network that you want to edit.
3. Click **Exadata Infrastructure**.
4. Click the name of the Exadata infrastructure that is associated with the VM cluster network that you are interested in.

The Infrastructure Details page displays information about the selected Exadata infrastructure.

5. Click the name of the VM cluster network that you want to edit.
   The VM Cluster Network Details page displays information about the selected VM cluster network.
6. Click **Edit VM Cluster Network**.
7. Use the **Edit** dialog to edit the VM cluster network attributes:

   CLIENT NETWORK

   The client network is the primary channel for application connectivity to Exadata Cloud at Customer resources. You can edit the following client network settings:

   - **VLAN ID:** Provide a virtual LAN identifier (VLAN ID) for the client network.
   - **Netmask:** Specify the IP netmask for the client network.
   - **Gateway:** Specify the IP address of the client network gateway.
   - **Hostname:** Specify the hostname for each address in the client network.
   - **IP Address:** Specify the IP address for each address in the client network.

   BACKUP NETWORK

   The backup network is the secondary channel for connectivity to Exadata Cloud at Customer resources. It is typically used to segregate application connections on the client network from other network traffic. You can edit the following backup network settings:

   - **VLAN ID:** Provide a virtual LAN identifier (VLAN ID) for the backup network.
   - **Hostname:** Specify the hostname for each address in the backup network.
   - **IP Address:** Specify the IP address for each address in the backup network.

   CONFIGURE DNS & NTP SERVERS

   The VM cluster network requires access to Domain Names System (DNS) and Network Time Protocol (NTP) services. You can edit the following settings:

- **DNS Servers:** Provide the IP address of a DNS server that is accessible using the client network. You may specify up to three DNS servers.
- **NTP Servers:** Provide the IP address of an NTP server that is accessible using the client network. You may specify up to three NTP servers.

8. Click **Save Changes**.
   After editing, the state of the VM cluster network is **Requires Validation**.

To download a file containing the VM cluster network configuration details

You can download a file containing the VM cluster network configuration details. Your network administrator can use the details to configure your corporate DNS and other network devices to work along with Exadata Cloud at Customer.

1. Open the navigation menu. Under Database, click **Exadata Cloud at Customer**.
2. Choose the **Region** and **Compartment** that contains the Exadata infrastructure that is associated with the VM cluster network that you are interested in.
3. Click **Exadata Infrastructure**.
4. Click the name of the Exadata infrastructure that is associated with the VM cluster network that you are interested in.
   The Infrastructure Details page displays information about the selected Exadata infrastructure.
5. Click the name of the VM cluster network for which you want to download a file containing the VM cluster network configuration details.
   The VM Cluster Network Details page displays information about the selected VM cluster network.
6. Click **Download Network Configuration**.
   Your browser downloads a file containing the VM cluster network configuration details.

To validate a VM cluster network

You can only validate a VM cluster network if its current state is **Requires Validation**, and if

the underlying Exadata infrastructure is activated.

1. Open the navigation menu. Under Database, click **Exadata Cloud at Customer**.
2. Choose the **Region** and **Compartment** that contains the Exadata infrastructure that is associated with the VM cluster network that you want to validate.
3. Click **Exadata Infrastructure**.
4. Click the name of the Exadata infrastructure that is associated with the VM cluster network that you are interested in.
   The Infrastructure Details page displays information about the selected Exadata infrastructure.
5. Click the name of the VM cluster network that you want to validate.
   The VM Cluster Network Details page displays information about the selected VM cluster network.
6. Click **Validate VM Cluster Network**.
   Validation performs a series of automated checks on the VM cluster network. The Validate VM Cluster Network button is only available if the VM cluster network requires validation.
7. In the resulting dialog, click **Validate** to confirm the action.
   After successful validation, the state of the VM cluster network changes to **Validated** and the VM cluster network is ready to use. If validation fails for any reason, examine the error message and resolve the issue before repeating validation.

To terminate a VM cluster network

Terminating a VM cluster network removes it from the Cloud Control Plane. Before you can terminate a VM cluster network, you must first terminate the associated VM cluster, if one exists, and all the databases it contains.

1. Open the navigation menu. Under Database, click **Exadata Cloud at Customer**.
2. Choose the **Region** and **Compartment** that contains the Exadata infrastructure that is associated with the VM cluster network that you want to terminate.

3. Click **Exadata Infrastructure**.
4. Click the name of the Exadata infrastructure that is associated with the VM cluster network that you are interested in.
   The Infrastructure Details page displays information about the selected Exadata infrastructure.
5. Click the name of the VM cluster network that you want to terminate.
   The VM Cluster Network Details page displays information about the selected VM cluster network.
6. Click **Terminate**.
7. In the resulting dialog, enter the name of the VM cluster network and click **Terminate VM Cluster Network** to confirm the action.

To create a VM cluster

To create a VM cluster, ensure that you that have:

- Active Exadata infrastructure available to host the VM cluster.
- A validated VM cluster network available for the VM cluster to use.

1. Open the navigation menu. Under Database, click **Exadata Cloud at Customer**.
2. Choose the **Region** that contains your Exadata infrastructure.
3. Click **VM Clusters**.
4. Click **Create VM Cluster**.
5. Provide the requested information in the **Create VM Cluster** page:
   - **Choose a compartment:** From the list of available compartments, choose the compartment that you want to contain the VM cluster.
   - **Provide the display name:** The display name is a user-friendly name that you can use to identify the VM cluster. The name doesn't need to be unique because an Oracle Cloud Identifier (OCID) uniquely identifies the VM cluster.

- **Select Exadata Cloud at Customer Infrastructure:** From the list, choose the Exadata infrastructure to host the VM cluster. You are not able to create a VM cluster without available and active Exadata infrastructure.
- **Choose the Oracle Grid Infrastructure version:** From the list, choose the version of Oracle Grid Infrastructure to install on the VM cluster.

  The Grid Infrastructure version determines the Oracle Database versions that can be supported on the VM cluster. You cannot run an Oracle Database version that is higher than the version of the Oracle Grid Infrastructure software.
- **Specify the OCPU count:** Specify the total number of CPU cores that are allocated to the VM cluster.

  If you specify a value of zero, then the VM cluster compute nodes are all shut down at the end of the cluster creation process. In this case, you can later start the compute nodes by scaling the CPU resources. See To scale the CPU resources on a VM cluster.

  Otherwise, this value must be a multiple of the number of compute nodes so that every compute node has the same number of CPU cores enabled.
- **Add SSH Key:** Specify the public key portion of an SSH key pair that you want to use to access the VM cluster compute nodes. You can upload a file containing the key, or paste the SSH key string.

  To provide multiple keys, upload multiple key files or paste each key into a separate field. For pasted keys, ensure that each key is on a single, continuous line. The length of the combined keys cannot exceed 10,000 characters.
- **Select a VM Cluster Network:** From the list, choose a VM cluster network definition to use for the VM cluster. You must have an available and validated VM cluster network before you can create a VM cluster.

CONFIGURE THE EXADATA STORAGE

The following settings define how the Exadata storage is configured for use with the VM cluster. These settings cannot be changed after creating the VM cluster. See also Storage Configuration.

- **Allocate Storage for Exadata Snapshots:** Check this option to create a sparse disk group, which is required to support Exadata snapshot functionality. Exadata snapshots enable space-efficient clones of Oracle databases that can be created and destroyed very quickly and easily.
- **Allocate Storage for Local Backups:** Check this option to configure the Exadata storage to enable local database backups. If you select this option, more space is allocated to the RECO disk group to accommodate the backups. If you do not select this option, you cannot use local Exadata storage as a backup destination for any databases in the VM cluster.
- **Choose a license type:** Either:
  - **Bring Your Own License (BYOL):** Select this option if your organization already owns Oracle Database software licenses that you want to use on the VM cluster.
  - **License Included:** Select this option to subscribe to Oracle Database software licenses as part of Exadata Cloud at Customer.

Show Advanced Options

- **Select the time zone:** Choose the geographic region and time zone for the VM cluster. The default time zone is inherited from the time zone setting of the underlying Exadata infrastructure.
- **Tags:** Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.

6. Click **Create VM Cluster**.
   The VM Cluster Details page is now displayed. While the creation process is running, the state of the VM cluster is **Pending**. When the VM cluster creation process completes, the state of the VM cluster changes to **Available**.

To scale the CPU resources on a VM cluster

1. Open the navigation menu. Under Database, click **Exadata Cloud at Customer**.
2. Choose the **Region** and **Compartment** that contains the VM cluster for which you want to scale the CPU resources.
3. Click **VM Clusters**.
4. Click the name of the VM cluster for which you want to scale the CPU resources.
   The VM Cluster Details page displays information about the selected VM cluster.
5. Click **Scale Up/Down**.
6. In the dialog box, adjust the **OCPU Count** and then click **Save Changes**.
   The OCPU Count value must be a multiple of the number of compute nodes so that every compute node has the same number of CPU cores enabled.
   If you set the OCPU Count to zero, then the VM cluster compute nodes are all shut down. If you change from a zero setting, then the VM cluster compute nodes are all started. Otherwise, modifying the number of enabled CPU cores is an online operation, and compute nodes are not rebooted because of this operation. See also System Configuration.

Note

If you have explicitly set the `CPU_COUNT` database initialization parameter, that setting is not affected by modifying the number of CPU cores that are allocated to the VM cluster. Therefore, if you have enabled the Oracle Database instance caging feature, the database instance does not use extra CPU cores until you alter the `CPU_COUNT` setting. If `CPU_COUNT` is set to `0` (the default setting), then Oracle Database continuously monitors the number of CPUs reported by the operating system and uses the current count.

To stop, start, or reboot a VM cluster compute node

1. Open the navigation menu. Under Database, click **Exadata Cloud at Customer**.
2. Choose the **Region** and **Compartment** that is associated with the VM cluster that contains the compute node that you want to stop, start, or reboot.
3. Click **VM Clusters**.
4. Click the name of the VM cluster that contains the compute node that you want to stop, start, or reboot.
   The VM Cluster Details page displays information about the selected VM cluster.
5. In the Resources list, click **Nodes**.
   The list of compute nodes displays.
6. In the list of nodes, click the Actions icon (three dots) for a node and then click one of the following actions:
   - **Start:** Restarts a stopped node. After the node is restarted, the **Stop** action is enabled.

- **Stop:** Shuts down the node. After the node is stopped, the **Start** action is enabled.
- **Reboot:** Shuts down the node, and then restarts it.

To check the status of a VM cluster compute node

1. Open the navigation menu. Under Database, click **Exadata Cloud at Customer**.
2. Choose the **Region** and **Compartment** that is associated with the VM cluster that contains the compute node that you are interested in.
3. Click **VM Clusters**.
4. Click the name of the VM cluster that contains the compute node that you are interested in.
   The VM Cluster Details page displays information about the selected VM cluster.
5. In the Resources list, click **Nodes**.
   The list of compute nodes displays. For each compute node in the VM cluster, the name, state, and client IP address are displayed.
6. In the node list, find the compute node that you are interested in and check its state. The color of the icon and the associated text it indicates its status.
   - **Available:** Green icon. The node is operational.
   - **Starting:** Yellow icon. The node is starting because of a start or reboot action in the Console or API.
   - **Stopping:** Yellow icon. The node is stopping because of a stop or reboot action in the Console or API.
   - **Stopped:** Yellow icon. The node is stopped.
   - **Failed:** Red icon. An error condition prevents the continued operation of the compute node.

To update the license type on a VM cluster

1. Open the navigation menu. Under Database, click **Exadata Cloud at Customer**.

2. Choose the **Region** and **Compartment** that contains the VM cluster for which you want to update the license type.
3. Click **VM Clusters**.
4. Click the name of the VM cluster for which you want to update the license type.
   The VM Cluster Details page displays information about the selected VM cluster.
5. Click **Update License Type**.
6. In the dialog box, choose one of the following license types and then click **Save Changes**.
   - **Bring Your Own License (BYOL):** Select this option if your organization already owns Oracle Database software licenses that you want to use on the VM cluster.
   - **License Included:** Select this option to subscribe to Oracle Database software licenses as part of Exadata Cloud at Customer.

   Updating the license type does not change the functionality or interrupt the operation of the VM cluster.

To move a VM cluster to another compartment

You can change the compartment that contains your VM cluster by moving it.

When you move a VM cluster, the compartment change is also applied to the compute nodes and databases that are associated with the VM cluster. However, the compartment change does not affect any other associated resources, such as the Exadata infrastructure, which remains in its current compartment.

To move a VM cluster:

1. Open the navigation menu. Under Database, click **Exadata Cloud at Customer**.
2. Choose the **Region** and **Compartment** that contains the VM cluster that you want to move.
3. Click **VM Clusters**.

4. Click the name of the VM cluster that you want to move.
   The VM Cluster Details page displays information about the selected VM cluster.
5. Click **Move Resource**.
6. In the resulting dialog, choose the new compartment for the VM cluster and click **Move Resource**.

To terminate a VM cluster

Terminating a VM cluster removes it from the Cloud Control Plane. In the process, the compute node VMs and their contents are destroyed.

Before you can terminate a VM cluster, you must first terminate the databases it contains.

1. Open the navigation menu. Under Database, click **Exadata Cloud at Customer**.
2. Choose the **Region** and **Compartment** that contains the VM cluster that you want to terminate.
3. Click **VM Clusters**.
4. Click the name of the VM cluster that you want to terminate.
   The VM Cluster Details page displays information about the selected VM cluster.
5. Click **Terminate**.
6. In the resulting dialog, enter the name of the VM cluster and click **Terminate VM Cluster** to confirm the action.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use these API operations to manage Exadata Cloud at Customer VM cluster networks and VM clusters:

VM cluster networks:

- GenerateRecommendedVmClusterNetwork
- CreateVmClusterNetwork
- DeleteVmClusterNetwork
- GetVmClusterNetwork
- ListVmClusterNetwork
- UpdateVmClusterNetwork
- ValidateVmClusterNetwork

VM clusters:

- CreateVmCluster
- DeleteVmCluster
- GetVmCluster
- ListVmCluster
- UpdateVmCluster

For the complete list of APIs, see Database Service API.

Managing Backup Destinations for Exadata Cloud at Customer

This topic explains how to manage backup destinations for Exadata Cloud at Customer on Oracle Zero Data Loss Recovery Appliance or Network File System (NFS).

Exadata Cloud at Customer provides a backup facility, which can be individually configured on each database. See Managing Databases on Exadata Cloud at Customer and Managing Database Backup and Recovery on Exadata Cloud at Customer.

However, if you want to store backups on a Recovery Appliance or NFS location that you manage, you must first create a backup destination. Each backup destination defines the properties that are required to connect to the Recovery Appliance or NFS location, and each backup destination must be accessible in your data center from the VM cluster nodes.

The Exadata Cloud at Customer backup facility can also store backups on Oracle Cloud Infrastructure object storage or local Exadata storage on your Exadata Cloud at Customer

system. However, you do not need to create a backup destination for any of these other locations. Instead, applicable options for backup to cloud object storage or local Exadata storage are available directly when you create a database.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: The policy in Let database admins manage DB systems lets the specified group do everything with databases and related Database resources.

If you're new to policies, see Getting Started with Policies and Common Policies. If you want to dig deeper into writing policies for databases, see Details for the Database Service.

Prerequisites

- For a Recovery Appliance backup destination:
  - The Recovery Appliance must be configured with a virtual private catalog (VPC) user, which is used for taking the backups.
  - The Recovery Appliance must be configured with the unique database name of the database being backed up, and a mapping to the VPC user.

    - The Recovery Appliance must be accessible from the Exadata Cloud at Customer system using the Oracle Net Services connection string, which is provided by the Recovery Appliance administrator.
- For an NFS backup destination:
    - You must mount the NFS server location to a local mount point directory on each node in the VM cluster.
    - The local directory path and the NFS server location must each be the same across all of the VM cluster nodes.
    - You must ensure that the NFS mount is maintained continuously on all of the VM cluster nodes.
    - The NFS-mounted file system must be readable and writable by the `oracle` OS user on all of the VM cluster nodes.

Using the Console

To create a backup destination

1. Open the navigation menu. Under Database, click **Exadata Cloud at Customer**.
2. Choose the **Region** that contains your Exadata infrastructure.
3. Click **Backup Destinations**.
4. Click **Create Backup Destination**.
5. Provide the requested information in the **Create Backup Destination** page:
    - **Choose a compartment:** From the list of available compartments, choose the compartment that you want to contain the backup destination.
    - **Name your backup destination:** Specify a user-friendly name that you can use to identify the backup destination. The name doesn't need to be unique because an Oracle Cloud Identifier (OCID) uniquely identifies the backup destination.
    - **Choose the backup destination type:** Select **Recovery Appliance** or **Network Storage (NFS)**.

- If you select **Recovery Appliance**, then you must also specify the following:
  - **Provide the Recovery Appliance connection string:** Specify the Oracle Net Services connection string that connects to the Recovery Appliance. This information is typically provided by the Recovery Appliance administrator.
  - **Provide the Virtual Private Catalog (VPC) Users:** Provide a VPC user name for connecting to the Recovery Appliance. You can specify multiple VPC user names in case you want to use the Recovery Appliance as a backup destination for multiple databases. This information is typically provided by the Recovery Appliance administrator.
- If you select **Network Storage (NFS)**, then you must also specify the following:
  - **Provide the local NFS mount point path:** Specify the local directory path on each VM cluster node where the NFS server location is mounted. The local directory path and the NFS server location must each be the same across all of the VM cluster nodes.

SHOW ADVANCED OPTIONS

- **Tags:** Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.

6. Click **Create Backup Destination**.
   The Backup Destination Details page displays the newly created backup destination.

To edit a backup destination

You can only edit a backup destination if it is not currently associated with database.

1. Open the navigation menu. Under Database, click **Exadata Cloud at Customer**.
2. Choose the **Region** and **Compartment** that contains the backup destination that you want to edit.
3. Click **Backup Destinations**.
4. Click the name of the backup destination that you want to edit.
   The Backup Destination Details page displays information about the selected backup destination.
5. Click **Edit**.
6. Use the **Edit Backup Destination** dialog to edit the backup destination attributes:
   - If you are editing a Recovery Appliance backup destination:
     - **Provide the Recovery Appliance connection string:** Specify the Oracle Net Services connection string that connects to the Recovery Appliance. This information is typically provided by the Recovery Appliance administrator.
     - **Provide the Virtual Private Catalog (VPC) Users:** Provide a VPC user name for connecting to the Recovery Appliance. You can specify multiple VPC user names in case you want to use the Recovery Appliance as a backup destination for multiple databases. This information is typically provided by the Recovery Appliance administrator.
   - If you are editing an NFS backup destination:
     - **Provide the local NFS mount point path:** Specify the local directory path on each VM cluster node where the NFS server location is mounted. The local directory path and the NFS server location must each be the same across all of the VM cluster nodes.
7. Click **Save Changes**.

To move a backup destination to another compartment

You can change the compartment that contains your backup destination by moving it.

When you move a backup destination, the compartment change does not affect other associated resources. These other resources, such as the associated databases, remain in their current compartment.

To move a backup destination:

1. Open the navigation menu. Under Database, click **Exadata Cloud at Customer**.
2. Choose the **Region** and **Compartment** that contains the backup destination that you want to move.
3. Click **Backup Destinations**.
4. Click the name of the backup destination that you want to move.
   The Backup Destination Details page displays information about the selected backup destination.
5. Click **Move Resource**.
6. In the resulting dialog, choose the new compartment for the backup destination and click **Move Resource**.

To terminate a backup destination

Terminating a backup destination removes it from the Cloud Control Plane. Before you can terminate a backup destination, you must ensure that it is not associated with any databases.

1. Open the navigation menu. Under Database, click **Exadata Cloud at Customer**.
2. Choose the **Region** and **Compartment** that contains the backup destination that you want to terminate.
3. Click **Backup Destinations**.
4. Click the name of the backup destination that you want to terminate.
   The Backup Destination Details page displays information about the selected backup destination.

5. Click **Terminate**.
6. In the resulting dialog, enter the backup destination name and click **Terminate Backup Destination** to confirm the action.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use these API operations to manage Exadata Cloud at Customer backup destinations:

- CreateBackupDestination
- DeleteBackupDestination
- GetBackupDestination
- ListBackupDestination
- UpdateBackupDestination

For the complete list of APIs, see Database Service API.

Managing Databases on Exadata Cloud at Customer

This topic explains how to manage Oracle databases on Exadata Cloud at Customer.

Before you can create and use Oracle databases on Exadata Cloud at Customer, you must:

- Provision Exadata Cloud at Customer infrastructure.
- Configure a VM cluster.
- Create any required backup destinations.

You can create one or more databases on each Exadata Cloud at Customer system. Apart from the inherent storage and processing capacity of your Exadata system, there is no set maximum for the number of databases that you can create.

By default, databases on Exadata Cloud at Customer use Oracle Database Enterprise Edition - Extreme Performance. This edition provides all the features of Oracle Database Enterprise Edition, plus all the database enterprise management packs and all the Enterprise Edition options, such as Oracle Database In-Memory and Oracle Real Application Clusters (RAC). If you are using your own Oracle Database licenses, then your ability to use various features is limited by your license holdings.

Exadata Cloud at Customer supports the following Oracle Database software releases:

- Oracle Database 19c
- Oracle Database 18c
- Oracle Database 12c Release 2
- Oracle Database 12c Release 1
- Oracle Database 11g Release 2

When you provision a database, you can associate it with a backup destination and enable automatic backups. For more information, see Managing Backup Destinations for Exadata Cloud at Customer and Managing Database Backup and Recovery on Exadata Cloud at Customer.

Each Oracle database is configured as follows:

- Each database is configured with Oracle RAC database instances running on every node in the VM cluster.
- Each database uses a separate set of Oracle binaries in a separate Oracle home location.
- Each database is configured with default instance parameter settings. While the defaults are reasonable for many cases, you should review the instance parameter settings to ensure that they meet your specific application needs.

  In particular, consider the Oracle Database system global area (SGA) and program global area (PGA) instance parameter settings, especially if your VM cluster supports multiple databases. And, ensure that the sum of all Oracle Database memory allocations never exceeds the available physical memory on each compute node.
- Each database using Oracle Database 12c Release 1, or later, is configured as a

container database (CDB) and one pluggable database (PDB) is created inside the CDB. By default:

- The first PDB is configured with a local PDB administration user account named `PDBADMIN`.
- The `PDBADMIN` user account is initially configured with the same administration password as the CDB `SYS` and `SYSTEM` users.
- The `PDBADMIN` user account is initially configured with basic privileges assigned through two roles; `CONNECT` and `PDB_DBA`. However, for most practical administration purposes you must assign extra privileges to the `PDBADMIN` user account or the `PDB_DBA` role.

You can use native Oracle Database facilities to create extra PDBs and to manage all of your PDBs. The `dbaascli` utility also provides a range of convenient PDB management functions. See Using the dbaascli Utility on Exadata Cloud at Customer.

- Depending on the Oracle Database version in use, each database contains web-based monitoring and management tools provided by Enterprise Manager Database Express (EM Express) or Enterprise Manager Database Control (Database Control). See Using EM Express and Database Control on Exadata Cloud at Customer. The `dbaascli` utility also provides a range of convenient database management functions. See Using the dbaascli Utility on Exadata Cloud at Customer.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK,

CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: The policy in Let database admins manage DB systems lets the specified group do everything with databases and related Database resources.

If you're new to policies, see Getting Started with Policies and Common Policies. If you want to dig deeper into writing policies for databases, see Details for the Database Service.

Using the Console

To create a database

1. Open the navigation menu. Under Database, click **Exadata Cloud at Customer**.
2. Choose the **Region** that contains your Exadata infrastructure.
3. Click **VM Clusters**.
4. Click the name of a VM cluster.
5. In the Resources list of the VM Cluster Details page, click **Databases**.
6. Click **Create Database**.
7. Provide the requested information in the **Create Database** page:
    - **Provide the database name:** Specify a user-friendly name that you can use to identify the database. The name doesn't need to be unique because an Oracle Cloud Identifier (OCID) uniquely identifies the database.
    - **Provide a unique name for the database:** Optionally specify a unique name for the database. This attribute defines the value of the `DB_UNIQUE_NAME` database parameter. The value is case insensitive, it can be up to 30 characters in length, and include alphanumeric characters, underscore (_), number sign (#), and dollar sign ($).

      If you plan to configure the database for backup to a Recovery Appliance backup destination, then the unique database name must match the name that is configured in the Recovery Appliance.

- **Select a VM cluster:** From the list of available VM clusters, choose the VM cluster that you want to host the database. You must have an available VM cluster before you can create a database.
- **Select a database version:** From the list, choose the Oracle Database software version to use for the database.
- **Provide the name of the first PDB:** Optionally specify the name for the first PDB, which is created along with the database.

  To avoid potential service name collisions when using Oracle Net Services to connect to the PDB, ensure that the PDB name is unique across the entire VM cluster. If you do not provide the name of the first PDB, then a system-generated name is used. However, the system-generated name is not guaranteed to be unique across all of the databases in the VM cluster.
- **Provide the administration password:** Provide and confirm the administration password. This password is used for administration accounts and functions in the database, including:
  - The password for the Oracle Database `SYS` and `SYSTEM` users.
  - The Transparent Data Encryption (TDE) keystore password.
  - For databases using Oracle Database 12c Release 1, or later, the password for the PDB administration user in the first PDB (`PDBADMIN`).

  The password must be nine to 30 characters and contain at least two uppercase, two lowercase, two numeric, and two special characters. The special characters must be `_`, `#`, or `-`. In addition, the password must not contain the name of the tenancy or any reserved words, such as `Oracle` or `Table`, regardless of casing.
- **Choose the database workload type:** Select the workload type that best suits your application:
  - **Online Transactional Processing (OLTP)** configures the database for a transactional workload, with a bias toward high volumes of random data access.

- **Decision Support System (DSS)** configures the database for a decision support or data warehouse workload, with a bias toward large data scanning operations.

CONFIGURE BACKUPS

Use the following settings to define the backup configuration for the database:

- **Backup Destination Type:** From the list, choose an option.
  - **None** does not define a backup configuration for the database.
  - **Local** stores backups locally in the Exadata Storage Servers on your Exadata Cloud at Customer system.

    This option is available only if you enabled backups on local Exadata storage in the VM cluster that you want to host the database.
  - **Object Storage** stores backups in an Oracle-managed object storage container on Oracle Cloud Infrastructure.

    To use this option, your Exadata Cloud at Customer system must have egress connectivity to Oracle Cloud Infrastructure Object Storage.
  - **NFS** stores backups in one of your previously defined backup destinations that uses Network File System (NFS) storage. See Managing Backup Destinations for Exadata Cloud at Customer.

    If you select this option, you must also choose from the list of NFS **Backup Destinations**.
  - **Recovery Appliance** stores backups in one of your previously defined backup destinations that uses Oracle Zero Data Loss Recovery Appliance. See Managing Backup Destinations for Exadata Cloud at Customer.

    If you select this option, you must also:
    - Choose from the list of Recovery Appliance **Backup Destinations**.
    - Choose from the **VPC User** list, which contains the list of virtual private catalog (VPC) user names that are defined in the Recovery

Appliance backup destination.

- Provide the **Password** for the VPC user.

Note

If you select a backup destination, you cannot change it after the database is created. However, if you select **None** now, you can select a backup destination after the database is created.

- **Enable automatic backups:** Select this option to enable daily backups using the policy for automatic backups.

  This option is only enabled when you select a **Backup Destination Type** other than **None**. You can change this setting after database creation.

Show Advanced Options

- **Backup retention period:** From the list, you can choose the length of time that automatic backups are retained.

  For backups to local Exadata storage, you can choose a retention period of 7 days or 14 days. The default retention period is 7 days.

  For backups to Oracle Cloud Infrastructure Object Storage or to an NFS backup destination, you can choose one of the following preset retention periods: 7 days, 14 days, 30 days, 45 days, or 60 days. The default retention period is 30 days.

  This option does not apply to Recovery Appliance backup destinations. For backups to a Recovery Appliance, the retention policy that is implemented in the Recovery Appliance controls the retention period.

- **Tags:** Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For

more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.

8. Click **Create Database**.
   The Database Details page is now displayed. While the creation process is running, the state of the database is **Pending**. When the database creation process completes, the state of the database changes to **Active**.

To terminate a database

Terminating a database removes it from the Cloud Control Plane. In the process, all of the associated data files and backups are destroyed.

1. Open the navigation menu. Under Database, click **Exadata Cloud at Customer**.
2. Choose the **Region** and **Compartment** that contains the VM cluster that hosts the database that you want to terminate.
3. Click **VM Clusters**.
4. Click the name of the VM cluster that contains the database that you want to terminate.
5. In the Resources list of the VM Cluster Details page, click **Databases**.
6. Click the name of the database that you want to terminate.
   The Database Details page displays information about the selected database.
7. Click **Terminate**.
8. In the resulting dialog, enter the name of the database and click **Terminate Database** to confirm the action.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use these API operations to manage databases.

Database homes:

- CreateDbHome
- DeleteDbHome
- GetDbHome
- ListDbHomes

Databases:

- GetDatabase
- ListDatabases

Nodes:

- GetDbNode
- ListDbNodes

For the complete list of APIs, see Database Service API.

Managing Database Backup and Recovery on Exadata Cloud at Customer

This topic explains how to work with the backup and recovery facilities provided by Exadata Cloud at Customer.

Exadata Cloud at Customer provides automatic database backup facilities that use Oracle Recovery Manager (RMAN). When you create a database on Exadata Cloud at Customer, you can specify a backup destination and enable automatic backups. See Managing Databases on Exadata Cloud at Customer.

After database creation, you can also:

- View a list of available backups.
- Enable or disable automatic backups.

- Edit backup settings.
- Restore a database.

You can perform these operations by using the Console or the API.

Automatic database backups are configured as follows:

- Automatic backups are scheduled daily. The automatic backup process can run at any time within the daily backup window, which is between midnight and 6:00 AM in the time zone of the VM cluster that hosts the database.
- Automatic backups use a combination of full (RMAN level 0) and incremental (RMAN level 1) database backups:
    - For backups to a Recovery Appliance, after an initial full backup is performed the Recovery Appliance creates and validates virtual full backups from each daily incremental backup.
    - For backups to a Network File System (NFS) backup destination, incremental backups are always performed after an initial full backup is taken. Also, the incremental backups are merged into the full backup when they become older than the retention period.
    - For backups to all other storage types, the default interval between full backups is seven days.
- The retention period defines the period for which automatic backups are maintained:
    - For backups to a Recovery Appliance, the retention policy that is implemented in the Recovery Appliance controls the retention period.
    - For backups to local Exadata storage, you can choose a retention period of 7 days or 14 days. The default retention period is 7 days.
    - For backups to Oracle Cloud Infrastructure Object Storage or to an NFS backup destination, you can choose one of the following preset retention periods: 7 days, 14 days, 30 days, 45 days, or 60 days. The default retention period is 30 days.
- By default, the database runs in `ARCHIVELOG` mode, and archived redo log files are backed up every 60 minutes.
- Regardless of the backup destination, backups of user data are encrypted by default.

While a backup is in progress, Oracle recommends that you avoid performing actions that could interfere with availability, such as restarting compute nodes or applying patches. If an automatic backup operation fails, the backup is deferred until the next day's backup window.

When required, you can restore a database to:

- The latest available restore point.
- A specific point in time by providing a timestamp.
- An Oracle Database System Change Number (SCN).

Note

The backup and recovery facilities described in this topic cater only for database backup and recovery, which includes Oracle Database data files, log files, control files, and the server parameter (SP) file.
You are responsible for backing up other files on your compute nodes.
In particular, Oracle strongly recommends that you back up the Transparent Data Encryption (TDE) keystore (wallet). Without the TDE keystore, the database backups are effectively useless because you cannot read the data contained therein.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don't have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

If you're new to policies, see Getting Started with Policies and Common Policies.

Using the Console

To view a list of available backups

1. Open the navigation menu. Under Database, click **Exadata Cloud at Customer**.
2. Choose the **Region** and **Compartment** that contains the VM cluster that hosts the database that you are interested in.
3. Click **VM Clusters**.
4. Click the name of the VM cluster that hosts the database that you are interested in.
5. In the Resources list of the VM Cluster Details page, click **Databases**.
6. Click the name of the database that you are interested in.
   The Database Details page displays information about the selected database, which includes a list of the available backups.

To edit backup settings

Use the following procedure to change the available backup settings.

1. Open the navigation menu. Under Database, click **Exadata Cloud at Customer**.
2. Choose the **Region** and **Compartment** that contains the VM cluster that hosts the database for which you want to edit backup settings.
3. Click **VM Clusters**.
4. Click the name of the VM cluster that hosts the database for which you want to edit backup settings.
5. In the Resources list of the VM Cluster Details page, click **Databases**.
6. Click the name of the database for which you want to edit backup settings.
   The Database Details page displays information about the selected database.
7. Click **Backup Settings**.
8. Your current backup configuration determines the changes that you can make in the

Backup Settings dialog, as follows:

- If automatic backups are not configured (**Backup Destination Type** is set to **None**), then you can use the following settings to define the backup configuration for the database:
    - **Backup Destination Type:** From the list, choose an option.
        - **None** does not define a backup configuration for the database.
        - **Local** stores backups locally in the Exadata Storage Servers on your Exadata Cloud at Customer system.

          This option is available only if you enabled backups on local Exadata storage in the VM cluster that you want to host the database.
        - **Object Storage** stores backups in an Oracle-managed object storage container on Oracle Cloud Infrastructure.

          To use this option, your Exadata Cloud at Customer system must have egress connectivity to Oracle Cloud Infrastructure Object Storage.
        - **NFS** stores backups in one of your previously defined backup destinations that uses Network File System (NFS) storage. See Managing Backup Destinations for Exadata Cloud at Customer.

          If you select this option, you must also choose from the list of NFS **Backup Destinations**.
        - **Recovery Appliance** stores backups in one of your previously defined backup destinations that uses Oracle Zero Data Loss Recovery Appliance. See Managing Backup Destinations for Exadata Cloud at Customer.

          If you select this option, you must also:
            - Choose from the list of Recovery Appliance **Backup Destinations**.

- Choose from the **VPU User** list, which contains the list of virtual private catalog (VPC) user names that are defined in the Recovery Appliance backup destination.
- Provide the **Password** for the VPC user.

Note

If you select a backup destination (other than **None**), you cannot change it later.

- **Enable automatic backups:** Select this option to enable daily backups using the policy for automatic backups.

  This option is only enabled when you select a **Backup Destination Type** other than **None**. You can change this setting later.
- **Backup retention period:** From the list, you can choose the length of time that automatic backups are retained.

  For backups to local Exadata storage, you can choose a retention period of 7 days or 14 days. The default retention period is 7 days.

  For backups to Oracle Cloud Infrastructure Object Storage or to an NFS backup destination, you can choose one of the following preset retention periods: 7 days, 14 days, 30 days, 45 days, or 60 days. The default retention period is 30 days.

  This option does not apply to Recovery Appliance backup destinations. For backups to a Recovery Appliance, the retention policy that is implemented in the Recovery Appliance controls the retention period.

- If automatic backups were previously configured, then you can make the following changes:
  - For Recovery Appliance backup destinations, you can update the **Password** for the virtual private catalog (VPC) user that is used to access the Recovery Appliance.

- For backup destinations that do not use a Recovery Appliance, you can update the **Backup retention period** for automatic backups:
  - For backups to local Exadata storage, you can choose a retention period of 7 days or 14 days. The default retention period is 7 days.
  - For backups to Oracle Cloud Infrastructure Object Storage or to an NFS backup destination, you can choose one of the following preset retention periods: 7 days, 14 days, 30 days, 45 days, or 60 days. The default retention period is 30 days.
  - For backups to a Recovery Appliance, the retention policy that is implemented in the Recovery Appliance controls the retention period.
- You can set the option to **Enable automatic backups**. Select this option to enable automatic database backups. Deselect this option to suspend automatic database backups.

9. Click **Save Changes**.

To restore a database

1. Open the navigation menu. Under Database, click **Exadata Cloud at Customer**.
2. Choose the **Region** and **Compartment** that contains the VM cluster that hosts the database that you want to restore.
3. Click **VM Clusters**.
4. Click the name of the VM cluster that hosts the database that you want to restore.
5. In the Resources list of the VM Cluster Details page, click **Databases**.
6. Click the name of the database that you want to restore.
   The Database Details page displays information about the selected database.
7. Click **Restore Database**.
8. In the resulting dialog box, select one of the following options, and click **Restore Database**:

- **Restore to latest**: The database is restored and recovered with zero, or least possible, data loss.
- **Restore to a timestamp**: The database is restored and recovered to the specified timestamp.
- **Restore to SCN**: The database is restored and recovered to the specified Oracle Database System Change Number (SCN). The specified SCN must be valid otherwise the operation fails.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use these API operations to manage database backup and recovery:

- GetBackup
- ListBackups
- RestoreDatabase
- UpdateDatabase - To enable and disable automatic backups.

For the complete list of APIs, see Database Service API.

Connecting to an Exadata Cloud at Customer System

This topic explains how to connect to an Exadata Cloud at Customer system using SSH, and how to connect to an Exadata Cloud at Customer database using Oracle Net Services (SQL*Net).

Connecting to a Compute Node with SSH

You can connect to the compute nodes in an Exadata Cloud at Customer system by using a Secure Shell (SSH) connection. Most UNIX-style systems (including Linux, Solaris, BSD, and

OS X) include an SSH client. For Windows, you can download a free SSH client called PuTTY from http://www.putty.org.

PREREQUISITES

To access a compute node in an Exadata Cloud at Customer system by using SSH, you need the following:

- An SSH private key file that corresponds to a public key that is registered in the system. When you create a VM cluster on your Exadata Cloud at Customer system, you must specify the public key portion of one or more SSH key pairs. You can also register extra keys separately after you create the VM cluster. The public keys are stored in the `authorized_keys` file at `~/.ssh/authorized_keys`. Separate `authorized_keys` files are located under the home directories of the `oracle` and `opc` OS users.
- The host name or IP address for the compute node that you want to access. See To check the status of a VM cluster compute node.

To connect from a UNIX-style system

Use the following SSH command to access a compute node:

```
$ ssh -i private-key user@node
```

In the preceding command:

- *`private-key`* is the full path and name of the file that contains the SSH private key that corresponds to a public key that is registered in the system.
- *`user`* is the operating system user you want to connect as:
  - Connect as `oracle` to perform operations as the Oracle Database software owner; this user does not have `root` user access to the compute node.
  - Connect as `opc` to perform operations that require `root` access to the compute node, such as patching. This user can use the `sudo -s` command to gain `root` user access to the compute node.
- *`node`* is the host name or IP address for the compute node that you want to access.

To connect from a Windows system using PuTTY

1. Run the PuTTY program (`putty.exe`).
   The PuTTY Configuration window is displayed, showing the Session panel.
2. In the **Host Name (or IP address)** field, enter the host name or IP address of the compute node that you want to access.
3. Confirm that the **Connection type** option is set to **SSH**.
4. In the Category tree, expand **Connection** if necessary and then click **Data**.
   The Data panel is displayed
5. In the **Auto-login username** field, enter the operating system user you want to connect as:
   - Connect as `oracle` to perform operations as the Oracle Database software owner; this user does not have `root` user access to the compute node.
   - Connect as `opc` to perform operations that require `root` access to the compute node, such as patching. This user can use the `sudo -s` command to gain `root` user access to the compute node.
6. Confirm that the **When username is not specified** option is set to **Prompt**.
7. In the Category tree, expand **SSH** and then click **Auth**.
   The Auth panel is displayed.
8. Click the **Browse** button next to the **Private key file for authentication** field. Then, navigate to and open the private key file that corresponds to a public key that is registered in the system.
9. In the Category tree, click **Session**.
   The Session panel is displayed.
10. In the **Saved Sessions** field, enter a name for the connection configuration. Then, click **Save**.
11. Click **Open** to open the connection.
    The PuTTY Configuration window closes and the PuTTY terminal window displays.

To access a database after you connect to the compute node

After you connect to a compute node, you can use the following series of commands to identify a database and connect to it.

1. Log in as the `oracle` user. For example:

```
$ ssh -i keyfile oracle@node01
[oracle@node01 ~]$
```

2. Use the `srvctl` utility located under the Oracle Grid Infrastructure home directory to list the databases on the system. For example:

```
[oracle@node01 ~]$ /u01/app/12.2.0.1/grid/bin/srvctl config database -v
nc122   /u02/app/oracle/product/12.2.0/dbhome_6 12.2.0.1.0
s12c    /u02/app/oracle/product/12.2.0/dbhome_2 12.2.0.1.0
```

3. Identify the database instances for the database that you want to access. For example:

```
[oracle@node01 ~]$ /u01/app/12.2.0.1/grid/bin/srvctl status database -d s12c
Instance s12c1 is running on node node01
Instance s12c2 is running on node node02
```

4. Configure the environment settings for the database that you want to access. For example:

```
[oracle@node01 ~]$ . oraenv
ORACLE_SID = [oracle] ? s12c
The Oracle base has been set to /u02/app/oracle
[oracle@node01 ~]$ export ORACLE_SID=s12c1
```

5. You can use the `svrctl` command to display more detailed information about the database. For example:

```
[oracle@node01 ~]$ srvctl config database -d s12c
Database unique name: s12c
Database name:
Oracle home: /u02/app/oracle/product/12.2.0/dbhome_2
Oracle user: oracle
Spfile: +DATAC4/s12c/spfiles12c.ora
Password file: +DATAC4/s12c/PASSWORD/passwd
Domain: example.com
```

```
Start options: open
Stop options: immediate
Database role: PRIMARY
Management policy: AUTOMATIC
Server pools:
Disk Groups: DATAC4
Mount point paths:
Services:
Type: RAC
Start concurrency:
Stop concurrency:
OSDBA group: dba
OSOPER group: racoper
Database instances: s12c1,s12c2
Configured nodes: node01,node02
CSS critical: no
CPU count: 0
Memory target: 0
Maximum memory: 0
Default network number for database services:
Database is administrator managed
```

6. You can access the database by using SQL*Plus. For example:

```
[oracle@node01 ~]$ sqlplus / as sysdba

SQL*Plus: Release 12.2.0.1.0 Production ...

Copyright (c) 1982, 2016, Oracle.  All rights reserved.

Connected to:
Oracle Database 12c EE Extreme Perf Release 12.2.0.1.0 - 64bit Production

SQL>
```

Connecting to a Database with Oracle Net Services

Oracle Database Exadata Cloud at Customer supports remote database access by using Oracle Net Services.

Because Exadata Cloud at Customer uses Oracle Grid Infrastructure, you can make Oracle Net Services connections by using Single Client Access Name (SCAN). SCAN is a feature that provides a consistent mechanism for clients to access the Oracle databases running in a cluster.

By default, the SCAN is associated with three virtual IP addresses (VIPs). Each SCAN VIP is also associated with a SCAN listener that provides a connection endpoint for Oracle Database connections using Oracle Net Services. To maximize availability, Oracle Grid Infrastructure distributes the SCAN VIPs and SCAN listeners across the available cluster nodes. In addition, the SCAN VIPs and SCAN listeners are automatically migrated to a surviving node if there is a node shutdown or failure. The aim is to ensure that Oracle Database clients always have a reliable set of connection endpoints that can service all of the databases running in the cluster.

The SCAN listeners are in addition to the Oracle Net Listeners that run on every node in the cluster, which are also known as the node listeners. When an Oracle Net Services connection comes through SCAN, the SCAN listener routes the connection to one of the node listeners and plays no further part in the connection. A combination of factors, including listener availability, database instance placement, and workload distribution, determines which node listener receives each connection.

Note

This section outlines the basic requirements for connecting to your Exadata Cloud at Customer databases by using Oracle Net Services. For more guidance on achieving continuous service during planned maintenance, node failure, or Oracle Database instance failure, see the Continuous Availability white paper.

PREREQUISITES

To connect to an Exadata Cloud at Customer database by using Oracle Net Services, you need the following:

- The IP addresses for your SCAN VIPs, or the hostname or IP address for a compute node that hosts the database that you want to access.
- The database identifier, either the database SID or service name.

To connect using SCAN

To create an Oracle Net Services connection by using the SCAN listeners, you can choose between two approaches. You can:

- Use a connect descriptor that references all of the SCAN VIPs.
  This approach requires you to supply all of the SCAN VIP addresses and allows Oracle Net Services to connect to an available SCAN listener.
  You can use the following template to define a Net Services alias, which is typically used to provide a convenient name for the connect descriptor:

```
alias-name = (DESCRIPTION=
  (ADDRESS_LIST=
    (ADDRESS=(PROTOCOL=tcp)(HOST=SCAN-VIP-1)(PORT=1521))
    (ADDRESS=(PROTOCOL=tcp)(HOST=SCAN-VIP-2)(PORT=1521))
    (ADDRESS=(PROTOCOL=tcp)(HOST=SCAN-VIP-3)(PORT=1521)))
  (CONNECT_DATA=(sid-or-service-entry)))
```

  In the preceding definition:

  - *alias-name* is the name you use to identify the alias.
  - *SCAN-VIP-[1-3]* are the IP addresses for the SCAN VIPs.
  - *sid-or-service-entry* identifies the database SID or service name using one of the following formats:
    - SID=*sid-name*; for example, SID=S12C1.
    - SERVICE_NAME=*service-name*; for example, SERVICE_NAME=PDB1.example.oraclecloudatcust.com.

Note

By default, Oracle Net Services randomly selects one of the addresses in the address list to balance the load between the SCAN listeners.

- Use a connect descriptor that references a custom SCAN name.

  Using this approach, you define a custom SCAN name in your DNS, which resolves to the three SCAN VIPs.

  You can use the following template to define a Net Services alias that references the custom SCAN name:

```
alias-name = (DESCRIPTION=
  (ADDRESS_LIST=(ADDRESS=(PROTOCOL=tcp)(HOST=scan-name)(PORT=1521)))
  (CONNECT_DATA=(sid-or-service-entry)))
```

  Alternatively, you can use the easy connect method to specify a connect descriptor with the following format:

```
scan-name:1521/sid-or-service-entry
```

  For example:

```
exa1scan.example.com:1521/S12C1
```

  or

```
exa1scan.example.com:1521/PDB1.example.oraclecloudatcust.com
```

To connect using a node listener

You can create an Oracle Net Services connection by using a connect descriptor that bypasses the SCAN listeners and routes your connection directly to a node listener.

By using this method, you give up the high-availability and load-balancing provided by SCAN. However, this method may be desirable if you want to direct connections to a specific node or

network interface. For example, you might want to ensure that connections from a program that performs bulk data loading use the backup network.

Using this approach, you direct your connection using the hostname or IP address of the node.

You can use the following template to define a Net Services alias that directly references the node:

```
alias-name = (DESCRIPTION=
  (CONNECT_TIMEOUT=timeout)
  (ADDRESS_LIST=(ADDRESS=(PROTOCOL=tcp)(HOST=node)(PORT=1521)))
  (CONNECT_DATA=(sid-or-service-entry)))
```

In the preceding definition:

- *alias-name* is the name you use to identify the alias.
- *timeout* specifies a timeout period (in seconds), which enables you to terminate a connection attempt without having to wait for a TCP timeout. The `(CONNECT_TIMEOUT=timeout)` parameter is optional.
- *node* is the hostname or IP address for the compute node that you want to use.
- *sid-or-service-entry* identifies the database SID or service name using one of the following formats:
  - `SID=sid-name`; for example, `SID=S12C1`.
  - `SERVICE_NAME=service-name`; for example, `SERVICE_NAME=PDB1.example.oraclecloudatcust.com`.

Alternatively, you can use the easy connect method to specify a connect descriptor with the following format:

```
node:1521/sid-or-service-entry
```

For example:

```
exa1node01.example.com:1521/S12C1
```

or

```
exa1node01.example.com:1521/PDB1.example.oraclecloudatcust.com
```

Patching and Updating an Exadata Cloud at Customer System

This topic describes the responsibilities and procedures for patching and updating various components in Exadata Cloud at Customer.

Note

For more guidance on achieving continuous service during patching operations, see the Continuous Availability white paper.

Patching Performed by Oracle

Oracle performs patches and updates to all of the Oracle-managed system components. This includes the physical compute nodes (Dom0), network switches, power distribution units (PDUs), integrated lights-out management (ILOM) interfaces, and the Exadata Storage Servers.

In all but rare exceptional circumstances, you receive advance communication about these updates to help you plan for them. If there are corresponding recommended updates for your compute node virtual machines (VMs), then Oracle provides notification about them.

Wherever possible, scheduled updates are performed in a manner that preserves service availability throughout the update process. However, there may be some noticeable impact on performance and throughput while individual system components are unavailable during the update process.

For example, Dom0 patching typically requires a reboot. In such cases, wherever possible, the compute nodes are rebooted in a rolling manner, one at a time, to ensure that the service remains available throughout the process. However, each compute node is unavailable for a short time while it reboots, and the overall service capacity diminishes accordingly. Also, if your applications cannot tolerate the reboots, you may need to take mitigating action. For example, you may need to shut down an application while Dom0 patching occurs.

Managing Oracle Database and Oracle Grid Infrastructure Patches

You are responsible for routine patching of the Oracle Database and Oracle Grid Infrastructure software. On Exadata Cloud at Customer, routine patching of the Oracle Database and Oracle Grid Infrastructure software is facilitated by using the `dbaascli` utility. The `dbaascli` utility provides a simple means for applying routine patches, which Oracle periodically loads on to the Cloud Control Plane servers.

The `dbaascli` utility is part of the cloud-specific tooling bundle that is included with Exadata Cloud at Customer. Therefore, before performing the following procedures, ensure that you have the latest version of the cloud-specific tooling on all of the compute nodes in the VM cluster. For more information, see Cloud Tooling Updates.

To list available patches

You can produce a list of available patches by using the `dbaascli` command as follows:

1. Connect to a compute node as the `opc` user and start a command shell as the `root` user.

   For detailed instructions, see Connecting to an Exadata Cloud at Customer System.

2. Execute the `dbaascli patch db list` command:

   ```
   # dbaascli patch db list --oh hostname:oracle_home
   ```

   In the preceding command, `--oh` specifies a compute node and Oracle Home directory for which you want to list the available patches. In this context, an Oracle Home directory may be an Oracle Database home directory or the Oracle Grid Infrastructure home directory.
   For example:

   ```
   # dbaascli patch db list --oh hostname1:/u02/app/oracle/product/12.1.0.2/dbhome_1
   ```

Note

The list of available patches is determined by interrogating the database to establish the patches that have already been applied. When a patch is applied, the corresponding database entry is made as part of the SQL patching operation, which is executed at the end of the patch workflow. Therefore, the list of available patches may include partially applied patches along with patches that are currently being applied.

To check prerequisites before applying a patch

You can perform the prerequisites-checking operation using the `dbaascli` command as follows:

1. Connect to a compute node as the `opc` user and start a command shell as the `root` user.

   For detailed instructions, see Connecting to an Exadata Cloud at Customer System.

2. Execute the `dbaascli patch db prereq` command:

   - On a specific instance:

     ```
     # dbaascli patch db prereq --patchid patchid --instance1 hostname:oracle_home [--dbnames
     dbname[,dbname2 ...]]
     ```

   - By specifying only database names:

     ```
     # dbaascli patch db prereq --patchid patchid --dbnames dbname[,dbname2 ...] [-alldbs]
     ```

   In the preceding commands:

   - *patchid* identifies the patch to be pre-checked. For details about how to find the available patch identifiers, see To list available patches.

- `--instance1` specifies a compute node and Oracle Home directory that is subject to the pre-check operation. In this context, an Oracle Home directory may be an Oracle Database home directory or the Oracle Grid Infrastructure home directory.
- `--dbnames` specifies the database names for the databases that are the target of the pre-check operation.
- `-alldbs` specifies that you want to pre-check all of the databases that share the same Oracle Database binaries (Oracle Home) as the specified databases.

For example:

```
# dbaascli patch db prereq 12345678 --instance1
hostname1:/u02/app/oracle/product/12.1.0.2/dbhome_1
```

To apply a patch

You can apply a patch by using the `dbaascli` command.

The patching operation:

- Can be used to patch some or all of your compute nodes using one command.
- Coordinates multi-node patching in a rolling manner.
- Can execute patch-related SQL after patching all the compute nodes in the cluster.

You can perform a patching operation using the `dbaascli` command as follows:

1. Connect to a compute node as the `opc` user and start a command shell as the `root` user.

   For detailed instructions, see Connecting to an Exadata Cloud at Customer System.
2. Execute the `dbaascli patch db apply` command:
   - On a specific instance:

     ```
     # dbaascli patch db apply --patchid patchid --instance1 hostname:oracle_home [--dbnames
     dbname[,dbname2 ...]] [--run_datasql 1]
     ```

   - By specifying only database names:

```
# dbaascli patch db apply --patchid patchid --dbnames dbname[,dbname2 ...] [--run_datasql
1] [-alldbs]
```

In the preceding commands:

- *patchid* identifies the patch to be applied. For details about how to find the available patch identifiers, see To list available patches.
- `--instance1` specifies a compute node and Oracle Home directory that is subject to the patching operation. In this context, an Oracle Home directory may be an Oracle Database home directory or the Oracle Grid Infrastructure home directory.

  If you use this argument to specify a shared Oracle Home directory and you do not specify the `--dbnames` argument, then all of the databases that share the specified Oracle Home are patched. After the operation, the Oracle Home directory location remains unchanged; however, the patch level information embedded in the Oracle Home name is adjusted to reflect the patching operation.
- `--dbnames` specifies the database names for the databases that are the target of the patching operation.

  If you use this argument to patch a database that uses a shared Oracle Home and you do not specify the `-alldbs` option, then a new Oracle Home containing the patched Oracle Database binaries is created and the database is moved to the new Oracle Home.
- `-alldbs` patches all of the databases that share the same Oracle Database binaries (Oracle Home) as the databases specified in the `--dbnames` argument.

  After the operation, the Oracle Home directory location remains unchanged; however, the patch level information embedded in the Oracle Home name is adjusted to reflect the patching operation.
- `--run_datasql 1` instructs the command to execute patch-related SQL commands.

Note

- Patch-related SQL should only be executed after all of the compute nodes are patched. Take care not to specify this argument if you are patching a node and further nodes remain to be patched.
- This argument can only be specified along with a patching operation on a compute node. If you have patched all of your nodes and you did not specify this argument, you need to manually execute the SQL commands associated with the patch, which typically involves running the `catbundle.sql` script for Oracle Database 11g or the `datapatch` utility for Oracle Database 12c, or later. Refer to the patch documentation for full details.

For example:

```
# dbaascli patch db apply 23456789 --instance1 hostname1:/u02/app/oracle/product/12.1.0.2/dbhome_
1 --run_datasql 1
```

To list applied patches

You can use the `opatch` utility to list the patches that have been applied to an Oracle Database or Grid Infrastructure installation.

To produce a list of applied patches for an Oracle Database installation:

1. Connect to a compute node as the `oracle` user.
   For detailed instructions, see Connecting to an Exadata Cloud at Customer System.
2. Set the `ORACLE_HOME` variable to the location of the Oracle Database installation you want to examine. For example:

```
$ export ORACLE_HOME=/u02/app/oracle/product/12.1.0.2/dbhome_1
```

3. Execute the `opatch` command with the `lspatches` option:

```
$ $ORACLE_HOME/OPatch/opatch lspatches
```

To produce a list of applied patches for Oracle Grid Infrastructure:

1. Connect to a compute node as the `opc` user.
2. Become the `grid` user:

```
$ sudo -s
# su - grid
```

3. Execute the `opatch` command with the `lspatches` option:

```
$ $ORACLE_HOME/OPatch/opatch lspatches
```

To roll back a patch

You can roll back a patch or failed patch attempt by using the `dbaascli` command.

The patch rollback operation:

- Can be used to roll back a patch on some or all of your compute nodes using one command.
- Coordinates multi-node operations in a rolling manner.
- Can execute rollback-related SQL after rolling back the patch on all the compute nodes in the cluster.

You can perform a patch rollback operation using the `dbaascli` command as follows:

1. Connect to a compute node as the `opc` user and start a command shell as the `root` user.

   For detailed instructions, see Connecting to an Exadata Cloud at Customer System.

2. Execute the `dbaascli` command with the `-rollback_async` action:

   - On specific instances:

     ```
     # dbaascli patch db switchback --patchid patchid --instance1 hostname:oracle_home [--
     dbnames dbname[,dbname2 ...]] [--run_datasql 1]
     ```

   - By specifying only database names:

     ```
     # dbaascli patch db switchback --patchid patchid --dbnames dbname[,dbname2 ...] [--run_
     datasql 1] [-alldbs]
     ```

   In the preceding commands:

   - *patchid* identifies the patch to be rolled back.
   - `--instance1` specifies a compute node and Oracle Home directory that is subject to the rollback operation. In this context, an Oracle Home directory may be an Oracle Database home directory or the Oracle Grid Infrastructure home directory. If you use this argument to specify a shared Oracle Home directory and you do not specify the `--dbnames` argument, then all of the databases that share the specified Oracle Home are rolled back.
   - `--dbnames` specifies the database names for the databases that are the target of the rollback operation.
   - `-alldbs` specifies that you want to roll back all of the databases that share the same Oracle Database binaries (Oracle Home) as the databases specified in the `--dbnames` argument.
   - `--run_datasql 1` instructs the command to execute rollback-related SQL commands.

Note

- Rollback-related SQL should only be executed after all of the compute nodes are rolled back. Take care not to specify this argument if you are rolling back a node and further nodes remain to be rolled back.
- This argument can only be specified along with a rollback operation on a compute node. Therefore, if you have rolled back all of your nodes and you did not specify this argument, you need to manually execute the SQL commands associated with the rollback operation. Refer to the patch documentation for full details.

For example:

```
# dbaascli patch db switchback 34567890 --instance1
hostname1:/u02/app/oracle/product/12.1.0.2/dbhome_1 --run_datasql 1
```

MANUALLY PATCHING ORACLE DATABASE AND ORACLE GRID INFRASTRUCTURE SOFTWARE

In general, Oracle recommends that you use the facilities provided by Exadata Cloud at Customer to perform routine patching of Oracle Database and Oracle Grid Infrastructure software. However, you may need to manually patch the Oracle Database or Oracle Grid Infrastructure software in the following circumstances:

- **Oracle Java Virtual Machine (OJVM) Patching:** Because they cannot be applied in a rolling fashion, patches for the Oracle Database OJVM component are not included in the routine patch sets for Exadata Cloud at Customer. If you need to apply patches to the OJVM component of Oracle Database, you must do so manually. See Oracle JavaVM

Component Database PSU and RU (OJVM PSU and OJVM RU) Patches.

- **Daylight Savings Time (DST) Patching:** Because they cannot be applied in a rolling fashion, patches for the Oracle Database DST definitions are not included in the routine patch sets for Exadata Cloud at Customer. If you need to apply patches to the Oracle Database DST definitions, you must do so manually. See Updated DST Transitions and New Time Zones in Oracle RDBMS and OJVM Time Zone File Patches.
- **Non-routine or One-off Patching:** If you encounter a problem that requires a patch which is not included in any routine patch set, work with Oracle Support Services to identify and apply the appropriate patch.

For general information about patching Oracle Database, see "Patch Set Updates and Requirements for Upgrading Oracle Database" in the *Oracle Database Upgrade Guide* for Release 19,18, 12.2, 12.1, or 11.2.

Updating the Compute Node Operating System

You are responsible for managing patches and updates to the operating system environment on the compute node VMs. This section outlines the standard Exadata tools and techniques that you can use to update the operating system components on the Exadata Cloud at Customer compute nodes. For further information, see Updating Exadata Database Servers in the *Oracle Exadata Database Machine Maintenance Guide*.

Preparing for an OS update

- Before you begin an update, review *Exadata Cloud Service Software Versions (Doc ID 2333222.1)* to determine the latest software to use.
- You are able to apply Exadata software release updates to the compute nodes at your convenience. For feature release updates only, Oracle recommends that you lodge a service request with Oracle Support Services to ensure that Oracle is aware of your plans and is primed to assist if there are any difficulties.

  A feature release update is an update that changes any of the first four digits in the Exadata software release identifier. For example, upgrading from Exadata software release 12.1.2.2.0 to release 12.1.2.3.0 would be a feature release update. However,

upgrading from Exadata software release 12.1.2.3.0 to release 12.1.2.3.4 would not be considered a feature release update. You can determine the current Exadata software release by executing the `imageinfo` command on any compute node.

- Some steps in the update process require you to specify a YUM repository. The YUM repository URL is:

  ```
  http://yum.oracle.com/repo/EngineeredSystems/exadata/dbserver/latest-version/base/x86_64.
  ```

  In the preceding URL, *`latest-version`* is the YUM repository version. You can examine the output from the following `curl` command to determine the latest version of the YUM repository:

  ```
  curl -s -X GET http://yum.oracle.com/repo/EngineeredSystems/exadata/dbserver/index.html
  ```

- To apply OS updates, the network hosting your Exadata Cloud at Customer system must be configured to allow access to the YUM repository.

To update the OS on all compute nodes of an Exadata Cloud at Customer system

You update the operating system on the compute node virtual machines by using the `patchmgr` tool. This utility manages the entire update of one or more compute nodes remotely, including the pre-reboot, reboot, and post-reboot steps.

You can run the utility from one of your Exadata Cloud at Customer compute nodes or a non-Exadata server running Oracle Linux. The server on which you run the utility is known as the *driving system*. You cannot use the driving system to update itself. Therefore, if the driving system is one of the compute nodes in a VM cluster that you are updating then you must run the `patchmgr` utility more than once.

The following scenarios describe typical ways of performing the updates:

- **Non-Exadata Driving System**
  The simplest way to run the update the system is to use a separate Oracle Linux server to update all compute nodes in one operation.
- **Exadata Compute Node Driving System**

You can use one compute node to drive the updates for the rest of the compute nodes in the VM cluster. Then, you can use one of the updated nodes to drive the update on the original driving system. For example, consider updating a half rack system with four compute nodes; `node1`, `node2`, `node3`, and `node4`. You could first use `node1` to drive the updates of `node2`, `node3`, and `node4`. Then, you could use `node2` to drive the update of `node1`.

The driving system requires `root` user SSH access to each compute node being updated.

The following procedure is based on an example that assumes the following:

- The system has two compute nodes, `node1` and `node2`.
- The target Exadata software version is `18.1.4.0.0.180125.3`.
- Each node is used as the driving system to update the other node.

1. Gather the environment details.
    a. Using SSH, connect to `node1` as `root` and run the following command to determine the current Exadata software version:

    ```
    [root@node1 ~]# imageinfo -ver
    12.2.1.1.4.171128
    ```

    b. Switch to the grid user, and identify all nodes in the cluster.

    ```
    [root@node1 ~]# su - grid
    [grid@node1 ~]$ olsnodes
    node1
    node2
    ```

2. Configure the driving system.
    a. Switch back to the `root` user on `node1` and check whether an SSH key pair (`id_rsa` and `id_rsa.pub`) exists. If not, then generate it.

    ```
    [root@node1 ~]# ls /root/.ssh/id_rsa*
    ls: cannot access /root/.ssh/id_rsa*: No such file or directory
    [root@node1 ~]# ssh-keygen -t rsa
    Generating public/private rsa key pair.
    Enter file in which to save the key (/root/.ssh/id_rsa):
    ```

```
Enter passphrase (empty for no passphrase):
Enter same passphrase again:
Your identification has been saved in /root/.ssh/id_rsa.
Your public key has been saved in /root/.ssh/id_rsa.pub.
The key fingerprint is:
93:47:b0:83:75:f2:3e:e6:23:b3:0a:06:ed:00:20:a5 root@node1.example.com
The key's randomart image is:
+--[ RSA 2048]----+
|o..     + .      |
|o.     o *       |
|E     . o o      |
| . .     =       |
|  o .   S =      |
|   +     = .     |
|    +   o o      |
|   . .   + .     |
|      ...        |
+-----------------+
```

b. Distribute the public key to the target nodes, and verify this step. In the example, the only target node is `node2`.

```
[root@node1 ~]# scp -i ~root/.ssh/id_rsa.pub opc@node2:/tmp/id_rsa.node1.pub
```

```
[root@node2 ~]# ls -al /tmp/id_rsa.node1.pub
-rw-r--r-- 1 opc opc 442 Feb 28 03:33 /tmp/id_rsa.node1.pub
[root@node2 ~]# date
Wed Feb 28 03:33:45 UTC 2018
```

c. On the target node (`node2` in the example), add the root public key of `node1` to the root `authorized_keys` file.

```
[root@node2 ~]# cat /tmp/id_rsa.node1.pub >> ~root/.ssh/authorized_keys
```

d. Download `patchmgr` into `/root/patch` on the driving system (`node1` in this example).

   You can download the `patchmgr` bundle from Oracle Support by using Patch ID 21634633.

For further information, see also *dbnodeupdate.sh and dbserver.patch.zip: Updating Exadata Database Server Software using the DBNodeUpdate Utility and patchmgr (Doc ID 1553103.1)*.

e. Unzip the `patchmgr` bundle.

The name of your ZIP file may differ depending on the version that you downloaded.

```
[root@node1 ~]# cd /root/patch
[root@node1 patch]# unzip p21634633_181400_Linux-x86-64.zip

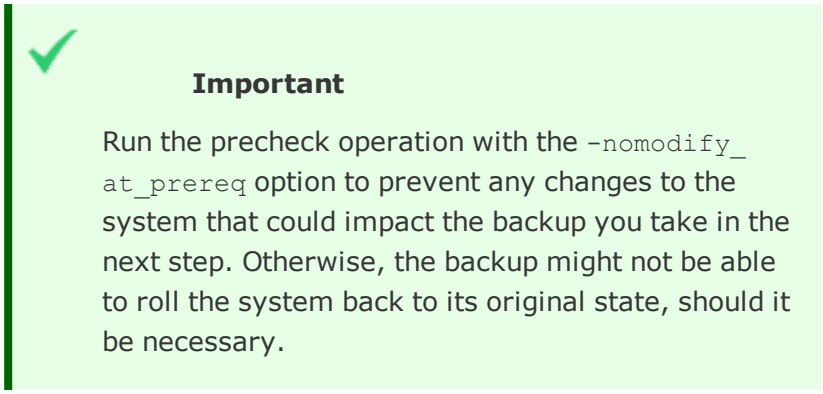
inflating: dbserver_patch_5.180228.2/fwverify
```

f. In the directory that contains the `patchmgr` utility, create the `dbs_group` file, which contains the list of compute nodes to update. Include the nodes listed after running the `olsnodes` command in step 1, except for the driving system. In this example, `dbs_group` only contains `node2`.

```
[root@node1 patch]# cd /root/patch/dbserver_patch_5.180228
[root@node1 dbserver_patch_5.180228]# cat dbs_group
node2
```

3. Run a patching precheck operation.

```
[root@node1 dbserver_patch_5.180228]# ./patchmgr -dbnodes dbs_group -precheck -yum_repo yum-repository -target_version target-version -nomodify_at_prereq
```



The output should look similar to the following example:

```
[root@node1 dbserver_patch_5.180228]# ./patchmgr -dbnodes dbs_group -precheck -yum_repo
http://yum.oracle.com/repo/EngineeredSystems/exadata/dbserver/18.1.4.0.0/base/x86_64 -target_
version 18.1.4.0.180125.3 -nomodify_at_prereq

********************************************************************************************

```

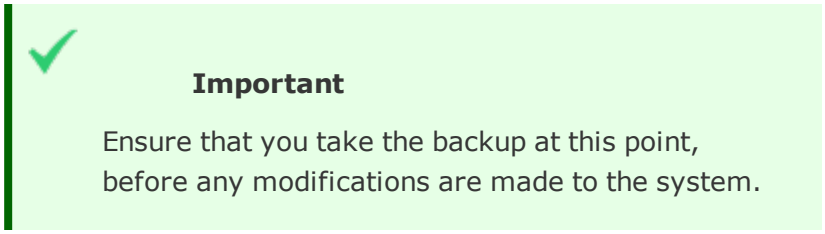
4. Back up the current system.

```
[root@node1 dbserver_patch_5.180228]# ./patchmgr -dbnodes dbs_group -backup -yum_repo yum-
repository -target_version target-version -allow_active_network_mounts
```



The output should look similar to the following example:

```
[root@node1 dbserver_patch_5.180228]# ./patchmgr -dbnodes dbs_group -backup -yum_repo
http://yum.oracle.com/repo/EngineeredSystems/exadata/dbserver/18.1.4.0.0/base/x86_64 -target_
version 18.1.4.0.0.180125.3 -allow_active_network_mounts

********************************************************************************************
***********
NOTE    patchmgr release: 5.180228 (always check MOS 1553103.1 for the latest release of
dbserver.patch.zip)
NOTE
WARNING Do not interrupt the patchmgr session.
WARNING Do not resize the screen. It may disturb the screen layout.
WARNING Do not reboot database nodes during update or rollback.
WARNING Do not open logfiles in write mode and do not try to alter them.

```

5. Remove all custom RPMs from the target compute nodes. Custom RPMs are reported in precheck results. They include RPMs that were manually installed after the system was provisioned.

Note

- If you are updating the system from version 12.1.2.3.4.170111, and the precheck results include `krb5-workstation-1.10.3-57.el6.x86_64`, remove it. This item is considered a custom RPM for this version.
- Do **not** remove `exadata-sun-vm-computenode-exact` or `oracle-ofed-release-guest`. These two RPMs are handled automatically during the update process.

6. Perform the update. Use the `nohup` command to ensure that the update process in not interrupted.

```
[root@node1 dbserver_patch_5.180228]# nohup ./patchmgr -dbnodes dbs_group -upgrade -nobackup -
yum_repo yum-repository -target_version target-version -allow_active_network_mounts &
```

The output should look similar to the following example:

```
[root@node1 dbserver_patch_5.180228]# nohup ./patchmgr -dbnodes dbs_group -upgrade -nobackup -
yum_repo http://yum.oracle.com/repo/EngineeredSystems/exadata/dbserver/18.1.4.0.0/base/x86_64 -
target_version 18.1.4.0.0.180125.3 -allow_active_network_mounts &
```

```

```

```
2018-02-28 21:57:43 +0000        :SUCCESS: DONE: Initiate update on node(s)
```

7. After the update operation completes, verify the version of the Exadata software on the compute node that was updated.

```
[root@node2 ~]# imageinfo -ver
18.1.4.0.0.180125.3
```

8. Repeat steps 2 through 7 of this procedure using the updated compute node as the driving system to update the remaining compute node. In this example update, you would now use `node2` to update `node1`.
9. As `root` On each compute node, run the `uptrack-install` command to install the available `ksplice` updates.

```
[root@node1 ~]# uptrack-install --all -y
```

```
[root@node2 ~]# uptrack-install --all -y
```

INSTALLING ADDITIONAL OS PACKAGES

You are permitted to install and update OS packages on Exadata Cloud at Customer as long as you do not modify the kernel or InfiniBand-specific packages. However, Oracle technical support, including installation, testing, certification and error resolution, does not apply to any non-Oracle software that you install.

Also, adding or updating packages may introduce problems when applying an Exadata software update because the additional software may add new dependencies that may interrupt an Exadata update. For this reason, minimal customization is recommended.

If you install additional packages, it is recommended that you have scripts to automate the removal and reinstallation of those packages. After an Exadata update, verify that the additional packages are still compatible and are still needed, before reinstalling them.

See also Installing, Updating, and Managing Non-Exadata Software in the *Oracle Exadata Database Machine Maintenance Guide*.

Cloud Tooling Updates

You are responsible for updating the cloud-specific tooling included on the Exadata Cloud at Customer compute nodes. You can update the cloud-specific tooling by downloading and

applying a software package containing the updated tools as described in this section.

To check the installed cloud tooling release and check for updates

1. Connect to a compute node as the `opc` user and start a command shell as the `root` user.

   For detailed instructions, see Connecting to an Exadata Cloud at Customer System.
2. Use the following command to display information about the installed cloud tooling and to list the available updates:

   ```
   # dbaascli patch tools list
   ```

   The command output displays:

   - The version of the cloud tooling that is installed on the compute node.
   - The list of available updates.
   - Notification of the cloud tooling version that is installed on the other compute nodes in the VM cluster.

To update the cloud tooling

1. Connect to a compute node as the `opc` user and start a command shell as the `root` user.

   For detailed instructions, see Connecting to an Exadata Cloud at Customer System.
2. Download and apply the cloud tooling update:

   - To update to the latest available cloud tooling, use the following command:

     ```
     # dbaascli patch tools apply --patchid LATEST
     ```

   - To update to a specific cloud tooling release, use the following command:

     ```
     # dbaascli patch tools apply --patchid patchid
     ```

     In the preceding command, *patchid* is a cloud tooling patch identifier, as reported in the output of the `dbaascli patch tools list` command.

The cloud tooling update is applied to all nodes in the VM cluster.

Using EM Express and Database Control on Exadata Cloud at Customer

This topic explains how to access Enterprise Manager Database Express (EM Express) and Enterprise Manager Database Control (Database Control), which are web-based tools for monitoring and managing Oracle Database.

Accessing Enterprise Manager Database Express

Enterprise Manager Database Express is available on Exadata Cloud at Customer databases created using Oracle Database 12c Release 1 (12.1) or later.

How you access EM Express depends on whether you want to manage a CDB or PDB:

- **To manage the CDB.** When a database is created, Exadata Cloud at Customer automatically sets a port for EM Express access to the CDB. You do not need to perform any manual configuration steps. Each database is allocated a unique port number. The allocations use ports in a range starting with 5500, 5501, 5502, and so on.
- **To manage a PDB.** With Oracle Database 12c Release 2 or later, EM Express can be configured to access the CDB and all PDBs on a single port, which is known as the global port. The global port lets you use EM Express to connect to all of the PDBs in the CDB using the HTTPS port for the CDB. You do not need to perform any manual configuration steps. Each database is allocated a unique port number. The allocations use ports in a range starting with 5500, 5501, 5502, and so on.

  For a version 12.1 database, you must manually set a port for each PDB you want to manage using EM Express.

To confirm the port that is in use for a specific database, connect to the database as a database administrator and execute the query shown in the following example:

```
SQL> select dbms_xdb_config.getHttpsPort() from dual;

DBMS_XDB_CONFIG.GETHTTPSPORT()
```

```
------------------------------
                          5502
```

SETTING THE PORT FOR EM EXPRESS TO MANAGE A PDB (ORACLE DATABASE 12.1 ONLY)

In Oracle Database 12c Release 1, a unique HTTPS port must be configured for the root container (CDB) and each PDB that you manage using EM Express.

To configure a HTTPS port so that you can manage a PDB with EM Express:

1. Invoke SQL*Plus and log in to the PDB as the `SYS` user with `SYSDBA` privileges.
2. Execute the `DBMS_XDB_CONFIG.SETHTTPSPORT` procedure.

```
SQL> exec dbms_xdb_config.sethttpsport(port-number)
```

ACCESSING EM EXPRESS

You can access EM Express by directing your browser to the URL:

```
https://node-ip-address:port/em
```

where *node-ip-address* is the client network IP address of the compute node hosting EM Express, and *port* is the EM Express port used by the database.

If your browser displays a warning that your connection is not secure or not private, use the browser's advanced option to ignore the warning and continue. You get this warning because Exadata Cloud at Customer uses a self-signed certificate to provide HTTPS (secure HTTP) connectivity, and such certificates are considered suspicious by many web browsers.

Accessing Enterprise Manager 11g Database Control

Enterprise Manager 11g Database Control is available on Exadata Cloud at Customer databases created using Oracle Database 11g Release 2. Each database is allocated a unique port number in a range starting with 1158, 1159, 1160, and so on.

You can confirm the Database Control port for a database by searching for `REPOSITORY_URL` in the `$ORACLE_HOME/`*host_sid*`/sysman/config/emd.properties` file. In the preceding file name, *host* is the host name of the compute node hosting Database Control, and *sid* is the Oracle Database system identifier (SID).

You can access Database Control by directing your browser to the URL:

```
https://node-ip-address:port/em
```

where *node-ip-address* is the client network IP address of the compute node hosting Database Control, and *port* is the Database Control port used by the database.

If your browser displays a warning that your connection is not secure or not private, use the browser's advanced option to ignore the warning and continue. You get this warning because Exadata Cloud at Customer uses a self-signed certificate to provide HTTPS (secure HTTP) connectivity, and such certificates are considered suspicious by many web browsers.

Using the dbaascli Utility on Exadata Cloud at Customer

This topic describes the facilities provided by the `dbaascli` utility on Exadata Cloud at Customer.

You can use the `dbaascli` utility to perform various database life-cycle and administration operations on Exadata Cloud at Customer such as changing the password of a database user, starting a database, managing pluggable databases (PDBs), and more. The capabilities of the `dbaascli` utility are in addition to, and separate from, the Oracle Cloud Infrastructure Console, API, or CLI.

To use the utility, you must be connected to an Exadata Cloud at Customer compute node. See Connecting to a Compute Node with SSH.

Many `dbaascli` commands can be run as the `oracle` user, but some commands require `root` administrator privileges. The following outlines the specific requirements for each command.

Command Reference

dbaascli database bounce

You can use this command to shut down and restart the specified database:

```
$ dbaascli database bounce --dbname dbname
```

In the command, *dbname* specifies the name of the database that you want to bounce.

The command performs a database shutdown in immediate mode. The database is then restarted and opened. In Oracle Database 12c, or later, all of the PDBs are also opened.

Run the command as the `oracle` user.

dbaascli database changepassword

You can use this command to change the password of a database user:

```
# dbaascli database changepassword --dbname dbname
```

In the command, *dbname* specifies the name of the database that you want to act on.

Enter the database user name and new password when prompted.

Run the command as the `root` user.

dbaascli database move

You can use this command to move a database to another Oracle Home directory location:

```
# dbaascli database move --dbname dbname --ohome oraclehome
```

In the command:

- *dbname* specifies the name of the database that you want to move.
- *oraclehome* specifies the path to an existing Oracle Home directory location, which you want the specified database to use.

Before performing a move operation, ensure that all of the database instances associated with the database are up and running.

Run the command as the `root` user.

dbaascli database start

You can use this command to start the specified database:

```
$ dbaascli database start --dbname dbname
```

In the command, *dbname* specifies the name of the database that you want to start.

The command starts and opens the database. In Oracle Database 12c, or later, all of the PDBs are also opened.

Run the command as the `oracle` user.

dbaascli database status

You can use this command to check the status of the specified database:

```
$ dbaascli database status --dbname dbname
```

In the command, *dbname* specifies the name of the database that you want to check.

Output from the command includes the open mode of the database, the software release and edition of the database, and release version of other software components.

Run the command as the `oracle` user.

dbaascli database stop

You can use this command to stop the specified database:

```
$ dbaascli database stop --dbname dbname
```

In the command, *dbname* specifies the name of the database that you want to stop.

The command performs a database shutdown in immediate mode. No new connections or new transactions are permitted. Active transactions are rolled back and all connected users are disconnected.

Run the command as the `oracle` user.

dbaascli database update

You can use this command to perform the following database configuration changes.

Run the command as the `root` user.

- To modify the globally unique database name (`DB_UNIQUE_NAME`), run the following command:

```
# dbaascli database update --dbname dbname --db_unique_name dbname_uniquename [--precheck]
```

  In the command:

  - *dbname* specifies the name of the database that you want to move.
  - *uniquename* specifies the user configurable portion of the new globally unique database name.

  The command modifies the `DB_UNIQUE_NAME` database parameter and related configuration entries that reference it, including entries in the Oracle Cluster Registry (OCR) and database server parameter file (SPFILE). File locations that reference the globally unique database name are also updated, including the location of the data files and keystore.

  The value for the `--db_unique_name` option must commence with the *dbname* value followed immediately by an underscore character. If this convention is not observed, then the command fails with an error .

  Before performing the update operation, you can use the `--precheck` option to run a series of prerequisite checks to ensure that the update can proceed. No changes are made when using the `--precheck` option.

- To reconfigure the online redo log files, run the following command:

```
# dbaascli database update --dbname dbname --redosize redosize [--groups numgroups] [--precheck]
```

  In the command:

  - *dbname* specifies the name of the database that you want to move.
  - *redosize* specifies the size of each online redo log file in megabytes. The valid range is between `1000m` and `16000m`.
  - *numgroups* optionally specifies the number of online redo log groups to create. The default value is `4`.

Before performing the update operation, you can use the `--precheck` option to run a series of prerequisite checks to ensure that the update can proceed. No changes are made when using the `--precheck` option.

dbaascli dbhome info

You can use this command to view information about Oracle Home directory locations:

```
# dbaascli dbhome info
```

When prompted:

- Press `Enter` to view information about all Oracle Homes registered in the VM cluster.
- Specify an Oracle Home name to view information about that Oracle Home.

Run the command as the `root` user.

dbaascli dbhome purge

You can use this command to delete an unused Oracle Home directory location:

```
# dbaascli dbhome purge
```

When prompted, enter:

- `1` if you want to specify the Oracle Home name for the location being purged.
- `2` if you want to specify the Oracle Home directory path for the location being purged.

When next prompted, enter the Oracle Home name or directory path for the location being purged.

If your entries are valid and the Oracle Home is not associated with a database, then the Oracle binaries are removed from the Oracle Home directory location and the associated metadata is removed from the system.

Run the command as the `root` user.

dbaascli dbimage list

You can use this command to display information about Oracle Database software images that are downloaded to your Exadata Cloud at Customer environment:

```
# dbaascli dbimage list
```

The command displays a list of software images that are downloaded to your Exadata Cloud at Customer environment, including version and bundle patch information.

Run the command as the `root` user.

dbaascli listener bounce

You can use this command to stop and restart the Oracle Net listener that is associated with the specified database:

```
$ dbaascli listener bounce --dbname dbname
```

In the command, *dbname* specifies the name of the database whose listener you want to bounce.

Run the command as the `oracle` user.

dbaascli listener start

You can use this command to start the Oracle Net listener that is associated with the specified database:

```
$ dbaascli listener start --dbname dbname
```

In the command, *dbname* specifies the name of the database whose listener you want to start.

Run the command as the `oracle` user.

dbaascli listener status

You can use this command to check the status of the Oracle Net listener that is associated with

the specified database:

```
$ dbaascli listener start --dbname dbname
```

In the command, *dbname* specifies the name of the database whose listener you want to check.

The command displays status information about the listener, including a summary of the listener configuration settings, listening protocol addresses, and a summary of services that are registered with the listener.

Run the command as the `oracle` user.

dbaascli listener stop

You can use this command to stop the Oracle Net listener that is associated with the specified database:

```
$ dbaascli listener stop --dbname dbname
```

In the command, *dbname* specifies the name of the database whose listener you want to stop.

Run the command as the `oracle` user.

dbaascli patch db apply

You can use this command to apply an Oracle Database or Oracle Grid Infrastructure patch.

- To apply a patch to a specific instance, use the following command:

  ```
  # dbaascli patch db apply --patchid patchid --instance1 hostname:oracle_home [--dbnames dbname
  [,dbname2 ...]] [--run_datasql 1]
  ```

- To apply a patch by specifying only database names, use the following command:

  ```
  # dbaascli patch db apply --patchid patchid --dbnames dbname[,dbname2 ...] [--run_datasql 1] [-
  alldbs]
  ```

In the preceding commands:

- *patchid* identifies the patch to be applied.
- `--instance1` specifies a compute node and Oracle Home directory that is subject to the patching operation. In this context, an Oracle Home directory may be an Oracle Database home directory or the Oracle Grid Infrastructure home directory.

  If you use this argument to specify a shared Oracle Home directory and you do not specify the `--dbnames` argument, then all of the databases that share the specified Oracle Home are patched. After the operation, the Oracle Home directory location remains unchanged; however, the patch level information embedded in the Oracle Home name is adjusted to reflect the patching operation.
- `--dbnames` specifies the database names for the databases that are the target of the patching operation.

  If you use this argument to patch a database that uses a shared Oracle Home and you do not specify the `-alldbs` option, then a new Oracle Home containing the patched Oracle Database binaries is created and the database is moved to the new Oracle Home.
- `-alldbs` patches all of the databases that share the same Oracle Database binaries (Oracle Home) as the databases specified in the `--dbnames` argument.

  After the operation, the Oracle Home directory location remains unchanged; however, the patch level information embedded in the Oracle Home name is adjusted to reflect the patching operation.
- `--run_datasql 1` instructs the command to execute patch-related SQL commands.

Note

- Patch-related SQL should only be executed after all of the compute nodes are patched. Take care not to specify this argument if you are patching a node and further nodes remain to be patched.
- This argument can only be specified along with a patching operation on a compute node. If you have patched all of your nodes and you did not specify this argument, you need to manually execute the SQL commands associated with the patch, which typically involves running the `catbundle.sql` script for Oracle Database 11g or the `datapatch` utility for Oracle Database 12c, or later. Refer to the patch documentation for full details.

Run the command as the `root` user.

dbaascli patch db list

You can use this command to to check whether any Oracle Database or Oracle Grid Infrastructure patches are available:

```
# dbaascli patch db list --oh hostname:oracle_home
```

In the preceding command, `--oh` specifies a compute node and Oracle Home directory for which you want to list the available patches. In this context, an Oracle Home directory may be an Oracle Database home directory or the Oracle Grid Infrastructure home directory.

Note

The list of available patches is determined by interrogating the database to establish the patches that have already been applied. When a patch is applied, the corresponding database entry is made as part of the SQL patching operation, which is executed at the end of the patch workflow. Therefore, the list of available patches may include partially applied patches along with patches that are currently being applied.

Run the command as the `root` user.

dbaascli patch db prereq

You can use this command to check the prerequisites for an Oracle Database or Oracle Grid Infrastructure patch.

- To check patch prerequisites on a specific instance, use the following command:

```
# dbaascli patch db prereq --patchid patchid --instance1 hostname:oracle_home [--dbnames dbname
[,dbname2 ...]]
```

- To check patch prerequisites by specifying only database names, use the following command:

```
# dbaascli patch db prereq --patchid patchid --dbnames dbname[,dbname2 ...] [-alldbs]
```

In the preceding commands:

- *patchid* identifies the patch to be pre-checked.
- `--instance1` specifies a compute node and Oracle Home directory that is subject to the pre-check operation. In this context, an Oracle Home directory may be an Oracle Database home directory or the Oracle Grid Infrastructure home directory.

- `--dbnames` specifies the database names for the databases that are the target of the pre-check operation.
- `-alldbs` specifies that you want to pre-check all of the databases that share the same Oracle Database binaries (Oracle Home) as the specified databases.

Run the command as the `root` user.

dbaascli patch db switchback

You can use this command to roll back an Oracle Database or Oracle Grid Infrastructure patch.

- To roll back a patch on specific instances, use the following command:

```
# dbaascli patch db switchback --patchid patchid --instance1 hostname:oracle_home [--dbnames
dbname[,dbname2 ...]] [--run_datasql 1]
```

- To roll back a patch by specifying only database names, use the following command:

```
# dbaascli patch db switchback --patchid patchid --dbnames dbname[,dbname2 ...] [--run_datasql 1]
[-alldbs]
```

In the preceding commands:

- *`patchid`* identifies the patch to be rolled back.
- `--instance1` specifies a compute node and Oracle Home directory that is subject to the rollback operation. In this context, an Oracle Home directory may be an Oracle Database home directory or the Oracle Grid Infrastructure home directory.

  If you use this argument to specify a shared Oracle Home directory and you do not specify the `--dbnames` argument, then all of the databases that share the specified Oracle Home are rolled back.
- `--dbnames` specifies the database names for the databases that are the target of the rollback operation.

- `-alldbs` specifies that you want to roll back all of the databases that share the same Oracle Database binaries (Oracle Home) as the databases specified in the `--dbnames` argument.
- `--run_datasql 1` instructs the command to execute rollback-related SQL commands.

Note

- Rollback-related SQL should only be executed after all of the compute nodes are rolled back. Take care not to specify this argument if you are rolling back a node and further nodes remain to be rolled back.
- This argument can only be specified along with a rollback operation on a compute node. Therefore, if you have rolled back all of your nodes and you did not specify this argument, you need to manually execute the SQL commands associated with the rollback operation. Refer to the patch documentation for full details.

Run the command as the `root` user.

dbaascli patch tools apply

You can use this command to download and apply a cloud tooling update:

- To update to the latest available cloud tooling, use the following command:

```
# dbaascli patch tools apply --patchid LATEST
```

- To update to a specific cloud tooling release, use the following command:

```
# dbaascli patch tools apply --patchid patchid
```

In the preceding command, *patchid* is a cloud tooling patch identifier, as reported in the output of the dbaascli patch db list command.

The cloud tooling update is applied to all nodes in the VM cluster.

Run the command as the `root` user.

dbaascli patch tools list

You can use this command to display information about the installed cloud tooling and to list the available updates:

```
# dbaascli patch tools list
```

The command output displays:

- The version of the cloud tooling that is installed on the compute node.
- The list of available updates.
- Notification of the cloud tooling version that is installed on the other compute nodes in the VM cluster.

Run the command as the `root` user.

dbaascli pdb checkdb

You can use this command to display information about a container database (CDB):

```
$ dbaascli pdb checkdb --dbname dbname
```

In the command, *dbname* specifies the name of the CDB for which you want display information.

The information returned by this command includes the number of instances and the CPU count that are associated with the CDB.

Run the command as the `oracle` user.

dbaascli pdb checknode

You can use this command to display information about pluggable databases (PDBs) that are associated with a specific container database (CDB) and a specific compute node:

```
$ dbaascli pdb checknode --node nodenum --dbname dbname
```

In the command:

- *nodenum* specifies the node number for a compute node in the Exadata Cloud at Customer environment. You can display a list of compute nodes and corresponding node numbers by using the `olsnodes` command.
- *dbname* specifies the name of the container database that hosts the PDB.

The command displays status information for all PDBs that are associated with the specified compute node and CDB, including the open mode for each PDB.

Run the command as the `oracle` user.

dbaascli pdb checkpdb

You can use this command to display information about a pluggable database (PDB):

```
$ dbaascli pdb checkpdb --pdbname pdbname --dbname dbname
```

In the command:

- *pdbname* specifies the name of the PDB that you want to check.
- *dbname* specifies the name of the container database that hosts the PDB.

The command displays status information for the specified PDB, including the open mode and restricted status.

Run the command as the `oracle` user.

dbaascli pdb close

You can use this command to close a pluggable database (PDB):

```
$ dbaascli pdb close --pdbname pdbname --dbname dbname
```

In the command:

- *pdbname* specifies the name of the PDB that you want to close.
- *dbname* specifies the name of the container database that hosts the PDB.

Upon successful completion, the PDB is closed on all of the container database instances.

Run the command as the `oracle` user.

dbaascli pdb connect_info

You can use this command to retrieve network connection information for a pluggable database (PDB):

```
$ dbaascli pdb connect_info --pdbname pdbname --dbname dbname
```

In the command:

- *pdbname* specifies the name of the PDB for which you want to retrieve connection information.
- *dbname* specifies the name of the container database that hosts the PDB.

The command outputs a zip file that contains `tnsnames.ora`, `sqlnet.ora`, and `ojdbcs` properties for the PDB.

Run the command as the `oracle` user.

dbaascli pdb connect_string

You can use this command to display Oracle Net connect string information for a pluggable database (PDB):

```
$ dbaascli pdb connect_string --pdbname pdbname --dbname dbname
```

In the command:

- *pdbname* specifies the name of the PDB for which you want to display connect string information.
- *dbname* specifies the name of the container database that hosts the PDB.

Run the command as the `oracle` user.

dbaascli pdb create

You can use this command to create a new pluggable database (PDB):

```
$ dbaascli pdb create --pdbname pdbname --dbname dbname [--maxsize maxsize] [--maxcpu maxcpu]
```

In the command:

- *pdbname* specifies the name of the new PDB that you want to create.
- *dbname* specifies the name of the container database that hosts the new PDB.
- *maxsize* optionally specifies the maximum total size of data files and temporary files for tablespaces belonging to the PDB. Setting this option is effectively the same as setting the `MAXSIZE` PDB storage clause in the `CREATE PLUGGABLE DATABASE` SQL command. You can impose a limit by specifying an integer followed by a size unit (`K`, `M`, `G`, or `T`), or you can specify `UNLIMITED` to explicitly enforce no limit.
- *maxcpu* optionally specifies the maximum number of CPUs that are available to the PDB. Setting this option is effectively the same as setting the `CPU_COUNT` parameter in the PDB.

During the PDB creation process, you are prompted to specify the administration password for the new PDB.

Run the command as the `oracle` user.

dbaascli pdb delete

You can use this command to delete a pluggable database (PDB):

```
$ dbaascli pdb delete --pdbname pdbname --dbname dbname
```

In the command:

- *pdbname* specifies the name of the PDB that you want to delete.
- *dbname* specifies the name of the container database that hosts the PDB.

Run the command as the `oracle` user.

dbaascli pdb info

You can use this command to display more detailed information about a pluggable database (PDB):

```
$ dbaascli pdb info [--pdbname pdbname] --dbname dbname [--detailed]
```

In the command:

- *pdbname* optionally specifies the name of the PDB for which you want to display information. If this option is not specified, then the command displays information about all of the PDBs in the specified container database.
- *dbname* specifies the name of the container database that hosts the PDB.

The command displays information such as the CPU count and storage usage that is associated with a PDB. You can add the optional `--detailed` argument to display extra information, including the list of compute nodes where a PDB is open in read/write mode.

Run the command as the `oracle` user.

dbaascli pdb local_clone

You can use this command to create a new pluggable database (PDB) as a clone of an existing PDB in the same container database (CDB):

```
$ dbaascli pdb local_clone --pdbname sourcepdbname --target_pdbname targetpdbname --dbname dbname
```

In the command:

- *sourcepdbname* specifies the name of the PDB that you want to clone.
- *targetpdbname* specifies the name of the new PDB that you want to create.
- *dbname* specifies the name of the container database that hosts the PDBs.

The newly cloned PDB inherits administration passwords from the source PDB.

Run the command as the `oracle` user.

dbaascli pdb open

You can use this command to open a pluggable database (PDB):

```
$ dbaascli pdb open --pdbname pdbname --dbname dbname
```

In the command:

- *pdbname* specifies the name of the PDB that you want to open.
- *dbname* specifies the name of the container database that hosts the PDB.

Upon successful completion, the PDB is opened on all of the container database instances.

Run the command as the `oracle` user.

dbaascli pdb remote_clone

You can use this command to create a new pluggable database (PDB) as a clone of an existing PDB in another container database (CDB):

```
$ dbaascli pdb remote_clone --pdbname sourcepdbname --source_db sourcedbname --source_db_scan
sourcedbscan --dbname dbname
```

In the command:

- *sourcepdbname* specifies the name of the source PDB that you want to clone.
- *sourcedbname* specifies the unique name of the CDB that hosts the source PDB.

- *sourcedbscan* specifies the Single Client Access Name (SCAN) that is used to connect to the source database.
- *dbname* specifies the name of the CDB that hosts the newly cloned PDB.

When promoted, you must supply the `SYS` user password for the source PDB.

The newly cloned PDB inherits administration passwords from the source PDB. The cloned PDB is named using the following format: *dbname_sourcepdbname*.

Run the command as the `oracle` user.

dbaascli pdb rename

You can use this command to change the name of a pluggable database (PDB):

```
$ dbaascli pdb rename --pdbname oldname --newname newname --dbname dbname
```

In the command:

- *oldname* specifies the old name of the PDB that you want to rename.
- *newname* specifies the new name of the PDB that you want to rename.
- *dbname* specifies the name of the container database that hosts the PDB.

Run the command as the `oracle` user.

dbaascli pdb resize

You can use this command to modify the size limits for a pluggable database (PDB):

```
$ dbaascli pdb resize --pdbname pdbname --dbname dbname [--maxsize maxsize] [--maxcpu maxcpu]
```

In the command:

- *pdbname* specifies the name of the new PDB that you want to modify.
- *dbname* specifies the name of the container database that hosts the PDB.

- *maxsize* optionally specifies the maximum total size of data files and temporary files for tablespaces belonging to the PDB. Setting this option is effectively the same as setting the MAXSIZE PDB storage clause in the CREATE PLUGGABLE DATABASE SQL command. You can impose a limit by specifying an integer followed by a size unit (K, M, G, or T), or you can specify UNLIMITED to explicitly enforce no limit.
- *maxcpu* optionally specifies the maximum number of CPUs that are available to the PDB. Setting this option is effectively the same as setting the CPU_COUNT parameter in the PDB.

When you run the command, you must specify at least one of optional attributes, --maxsize or --maxcpu. You can specify both optional attributes in a single command.

Run the command as the oracle user.

dbaascli pdb start_service

You can use this command to start the Oracle Database service that is associated with a pluggable database (PDB):

```
$ dbaascli pdb start_service --pdbname pdbname --dbname dbname
```

In the command:

- *pdbname* specifies the name of the PDB that is associated with the database service that you want to start.
- *dbname* specifies the name of the container database that hosts the PDB.

Run the command as the oracle user.

dbaascli tde rotate masterkey

You can use this command to change (rotate) the master encryption key for the specified database:

```
$ dbaascli tde rotate masterkey --dbname dbname
```

In the command, *dbname* specifies the name of the database that you want to act on.

Enter the keystore password when prompted. The keystore password is initially set to the administration password that you specified when you created the database.

Run the command as the `oracle` user.

dbaascli tde status

You can use this command to display information about the keystore for the specified database:

```
$ dbaascli tde status --dbname dbname
```

In the command, *dbname* specifies the name of the database that you want to check.

Output from the command includes the type of keystore and the status of the keystore.

Run the command as the `oracle` user.

Monitoring and Managing Exadata Storage Servers on Exadata Cloud at Customer

This topic explains how you can use the ExaCLI utility on Exadata Cloud at Customer to perform monitoring and management functions on the Exadata Storage Servers.

ExaCLI is a command-line administration tool that runs on Exadata compute nodes and storage server nodes and enables you to manage other nodes remotely. See Using the ExaCLI Utility.

On Exadata Cloud at Customer, ExaCLI is configured on the compute nodes to support essential Exadata Storage Server monitoring and management functions, which are performed without direct administrative access to the Exadata Storage Servers. The ExaCLI utility is located on each Exadata Cloud at Customer compute node at `/usr/local/sbin/exacli`. To use the ExaCLI utility you require:

- The ExaCLI command, which specifies the operation that you want to perform.
  For Exadata Storage Server targets, ExaCLI supports the same command syntax as CellCLI. See CellCLI Command Reference. However, ExaCLI on Exadata Cloud at Customer supports only a specific set of monitoring and management operations. For a full list, see Supported ExaCLI Commands on Exadata Cloud at Customer.
- The username and password to connect to the Exadata Storage Server.
  On Exadata Cloud at Customer, the preconfigured user is `cloud_user_`*`clustername`*, where *`clustername`* is the name of the Oracle Grid Infrastructure cluster that is being used. You can determine the Oracle Grid Infrastructure cluster name by running the following command as the `grid` user on any cluster node:

  ```
  $ crsctl get cluster name
  ```

  The password for `cloud_user_`*`clustername`* is initially set to a random value, which you can view by running the following command as the `opc` user on any cluster node:

  ```
  $ /opt/exacloud/get_cs_data.py
  ```

- The network address of the Exadata Storage Server that is the target of the operation.
  You can determine the IP addresses for your Exadata Storage Servers by examining the `/etc/oracle/cell/network-config/cellip.ora` file on any Exadata Cloud at Customer compute node.

Supported ExaCLI Commands on Exadata Cloud at Customer

You can use ExaCLI on Exadata Cloud at Customer to view information about the following Exadata Storage Server objects by using the LIST command:

- `activerequest`
- `alertdefinition`
- `alerthistory`
- `cell`
- `celldisk`
- `database`
- `flashcache`

- flashcachecontent
- flashlog
- griddisk
- ibport
- iormprofile
- lun
- metriccurrent
- metricdefinition
- metrichistory
- offloadgroup
- physicaldisk
- pluggabledatabase

You can use ExaCLI on Exadata Cloud at Customer to act on the following Exadata Storage Server objects by using the CREATE, ALTER, DROP, and LIST commands:

- diagpack
- iormplan
- quarantine

You can use ExaCLI on Exadata Cloud at Customer to alter the following Exadata Storage Server cell attributes by using the ALTER CELL command:

- dbPerfDataSuppress
- diagHistoryDays
- events
- metricCollection
- metricHistoryDays
- offloadGroupEvents
- securityCert

- `securityPrivKey`
- `securityPrivKeyPW`
- `securityPubKey`
- `traceLevel`

Exadata DB Systems

Exadata DB systems allow you to leverage the power of Exadata within the Oracle Cloud Infrastructure. An Exadata DB system consists of a base system, quarter rack, half rack, or full rack of compute nodes and storage servers, tied together by a high-speed, low-latency InfiniBand network and intelligent Exadata software. You can configure automatic backups, optimize for different workloads, and scale up the system to meet increased demands.

Note

Exadata DB systems launched on or after March 14, 2019 run Oracle Linux 7 (OL7). Previously launched systems are running Oracle Linux 6 (OL6). See OS Updates for important information about updating existing Exadata DB system operating systems.

Supported Database Edition and Versions

Exadata DB systems require Enterprise Edition - Extreme Performance. This edition provides all the features of Oracle Database Enterprise Edition, plus all the database enterprise management packs and all the Enterprise Edition options, such as Oracle Database In-Memory and Oracle Real Application Clusters (RAC).

Exadata DB systems support the following software releases:

- Oracle Database 19c (19.0)
- Oracle Database 18c (18.0)

- Oracle Database 12c Release 2 (12.2)
- Oracle Database 12c Release 1 (12.1)
- Oracle Database 11g Release 2 (11.2)

Note

If you plan to run Oracle Database 19c on your Exadata DB system, you must specify version 19c when you create the DB system. Earlier database versions are supported on a 19c Exadata DB system and can be created at anytime. Exadata DB systems created with earlier Oracle Database versions will not automatically support Oracle Database 19c. The DB system must be upgraded manually.

Subscription Types

The only subscription type available for Exadata DB systems is the Monthly Flex purchase model under Universal Credit Pricing. See https://www.oracle.com/cloud/bring-your-own-license/faq/universal-credit-pricing.html for more information.

Metering Frequency

For each Exadata DB system you provision, you are billed for the infrastructure for the first month, and then by the hour after that. Each OCPU you add to the system is billed by the hour from the time you add it.

Scaling an Exadata DB System

Two kinds of scaling operations are supported for an Exadata DB system:

- Scaling within an Exadata DB system lets you modify compute node processing power within the system.
- Scaling across Exadata DB system configurations lets you move to a different configuration, for example, from a quarter rack to a half rack.

Scaling Within an Exadata System

If an Exadata DB system requires more compute node processing power, you can scale up the number of enabled CPU cores symmetrically across all the nodes in the system. For a base system or a quarter rack, you can scale in multiples of 2 across the 2 database compute nodes. For a half rack, you can scale in multiples of 4 across the 4 database compute nodes. For a full rack, you can scale in multiples of 8 across the 8 database compute nodes.

For a non-metered Exadata DB system, you can temporarily modify the compute node processing power (bursting) or add compute node processing power on a more permanent basis. For a metered Exadata DB system, you can simply modify the number of enabled CPU cores.

You can provision an X7 Exadata DB system or a base system with zero CPU cores, or scale the DB system down to zero cores after you provision it. With zero cores, you are billed only for the infrastructure until you scale up the system. For detailed information about pricing, see https://www.oracle.com/database/exadata-cloud-service-pricing.html.

For information on CPU cores per configuration, see System Configuration. To learn how to scale a system, see To scale an Exadata DB system.

Scaling Across Exadata DB System Configurations

Scaling across Exadata DB system configurations enables you to move to a different system configuration. This is useful when a database deployment requires:

- Processing power that is beyond the capacity of the current system configuration.
- Storage capacity that is beyond the capacity of the current system configuration.
- A performance boost that can be delivered by increasing the number of available compute nodes.

- A performance boost that can be delivered by increasing the number of available Exadata Storage Servers.

Scaling from a base system or a quarter rack to a half rack, or from a half rack to a full rack, requires that the data associated with your database deployment is backed up and restored on a different Exadata DB system, which requires planning and coordination between you and Oracle. To start the process, submit a service request to Oracle.

System Configuration

Exadata DB systems are offered in base system, quarter rack, half rack or full rack configurations, and each configuration consists of compute nodes and storage servers. The compute nodes are each configured with a Virtual Machine (VM). You have root privilege for the compute node VMs, so you can load and run additional software on them. However, you do not have administrative access to the Exadata infrastructure components, including the physical compute node hardware, network switches, power distribution units (PDUs), integrated lights-out management (ILOM) interfaces, or the Exadata Storage Servers, which are all administered by Oracle.

You have full administrative privileges for your databases, and you can connect to your databases by using Oracle Net Services from outside the Oracle Cloud Infrastructure. You are responsible for database administration tasks such as creating tablespaces and managing database users. You can also customize the default automated maintenance set up, and you control the recovery process in the event of a database failure.

The subsections that follow provide the details for each shape's configuration.

Exadata X7 Shapes

Property	Quarter Rack	Half Rack	Full Rack
Shape Name	Exadata.Quarter2.92	Exadata.Half2.184	Exadata.Full2.368
Number of Compute Nodes	2	4	8

Property	Quarter Rack	Half Rack	Full Rack
Total Minimum Number of Enabled CPU Cores	0	0	0
Total Maximum Number of Enabled CPU Cores	92	184	368
Total RAM Capacity	1440 GB	2880 GB	5760 GB
Number of Exadata Storage Servers	3	6	12
Total Raw Flash Storage Capacity	76.8 TB	153.6 TB	307.2 TB
Total Usable Storage Capacity	106 TB	212 TB	424 TB

Exadata X7 shapes provide 1 TB of user disk space for database homes.

Exadata X6 Shapes

Property	Quarter Rack	Half Rack	Full Rack
Shape Name	Exadata.Quarter1.84	Exadata.Half1.168	Exadata.Full1.336
Number of Compute Nodes	2	4	8
Total Minimum (Default) Number of Enabled CPU Cores	22	44	88

Property	Quarter Rack	Half Rack	Full Rack
Total Maximum Number of Enabled CPU Cores	84	168	336
Total RAM Capacity	1440 GB	2880 GB	5760 GB
Number of Exadata Storage Servers	3	6	12
Total Raw Flash Storage Capacity	38.4 TB	76.8 TB	153.6 TB
Total Usable Storage Capacity	84 TB	168 TB	336 TB

Exadata X6 shapes provide 200 GB of user disk space for database homes.

Exadata Base System

The system configuration of an Exadata base system is similar to a quarter rack with some differences in capacity.

Property	Value
Shape Name	Exadata.Base.48
Number of Compute Nodes	2
Total Minimum Number of Enabled CPU Cores	0
Total Maximum Number of Enabled CPU Cores	48
Total RAM Capacity	720 GB
Number of Exadata Storage Servers	3

Property	Value
Total Raw Flash Storage Capacity	38.4 TB
Total Usable Storage Capacity	74.8 TB

Storage Configuration

When you launch an Exadata DB system, the storage space inside the Exadata storage servers is configured for use by Oracle Automatic Storage Management (ASM). By default, the following ASM disk groups are created:

- The DATA disk group is intended for the storage of Oracle Database data files.
- The RECO disk group is primarily used for storing the Fast Recovery Area (FRA), which is an area of storage where Oracle Database can create and manage various files related to backup and recovery, such as RMAN backups and archived redo log files.
- The DBFS and ACFS disk groups are system disk groups that support various operational purposes. The DBFS disk group is primarily used to store the shared clusterware files (Oracle Cluster Registry and voting disks), while the ACFS disk groups are primarily used to store Oracle Database binaries. Compared to the DATA and RECO disk groups, the system disk groups are so small that they are typically ignored when discussing the overall storage capacity. You should not store Oracle Database data files or backups inside the system disk groups.

The disk group names contain a short identifier string that is associated with your Exadata Database machine environment. For example, the identifier could be C2, in which case the DATA disk group would be named DATAC2, the RECO disk group would be named RECOC2, and so on.

In addition, you can create a SPARSE disk group. A SPARSE disk group is required to support Exadata snapshots. Exadata snapshots enable space-efficient clones of Oracle databases that can be created and destroyed very quickly and easily. Snapshot clones are often used for development, testing, or other purposes that require a transient database.

Note that you cannot change the disk group layout after service creation.

Impact of Configuration Settings on Storage

If you choose to perform database backups to the Exadata storage, or to create a sparse disk group, or to do both, your choices profoundly affect how storage space in the Exadata storage servers is allocated to the ASM and sparse disk groups.

The table that follows shows the approximate percentages of storage allocated for DATA, RECO, and SPARSE disk groups for each possible configuration.

Configuration Settings	DATA Disk Group	RECO Disk Group	SPARSE Disk Group
Database backups on Exadata storage: No **Sparse disk group: No**	80 %	20 %	0 %
Database backups on Exadata storage: Yes **Sparse disk group: No**	40 %	60 %	0 %
Database backups on Exadata storage: No **Sparse disk group: Yes**	60 %	20 %	20 %
Database backups on Exadata storage: Yes **Sparse disk group: Yes**	35 %	50 %	15 %

Best Practices for Exadata DB Systems

Oracle recommends that you follow these best practice guidelines to ensure the manageability of your Exadata DB system:

- Wherever possible, use the Oracle-supplied cloud interfaces such as the Oracle Cloud Infrastructure Console, API, or CLI, or cloud-specific tools such as `dbaascli` and `dbaasapi` to perform lifecycle management and administrative operations on your Exadata DB system. For example, use the `exadbcpatchmulti` command to apply Oracle Database patches instead of manually running `opatch`. In addition, if an operation can be performed by using the Console as well as a command line utility, Oracle recommends that you use the Console. For example, use the Console instead of using `dbaasapi` to create databases.
- Do not change the compute node OS users or manually manipulate SSH key settings associated with your Exadata DB system.
- Apply *only* patches that are available through the Database service. Do *not* apply patches from any other source unless you are directed to do so by Oracle Support.
- Apply the quarterly patches regularly, every quarter if possible.
- Do not change the ports for Oracle Net Listener.

Network Setup for Exadata DB Systems

Before you set up an Exadata DB system, you must set up a virtual cloud network (VCN) and other Networking service components. This topic describes the recommended configuration for the VCN and several related requirements for the Exadata DB system.

VCN and Subnets

To launch an Exadata DB system, you must have:

- A VCN in the region where you want the DB system
- At least two subnets in the VCN. The two subnets are:
  - Client subnet
  - Backup subnet

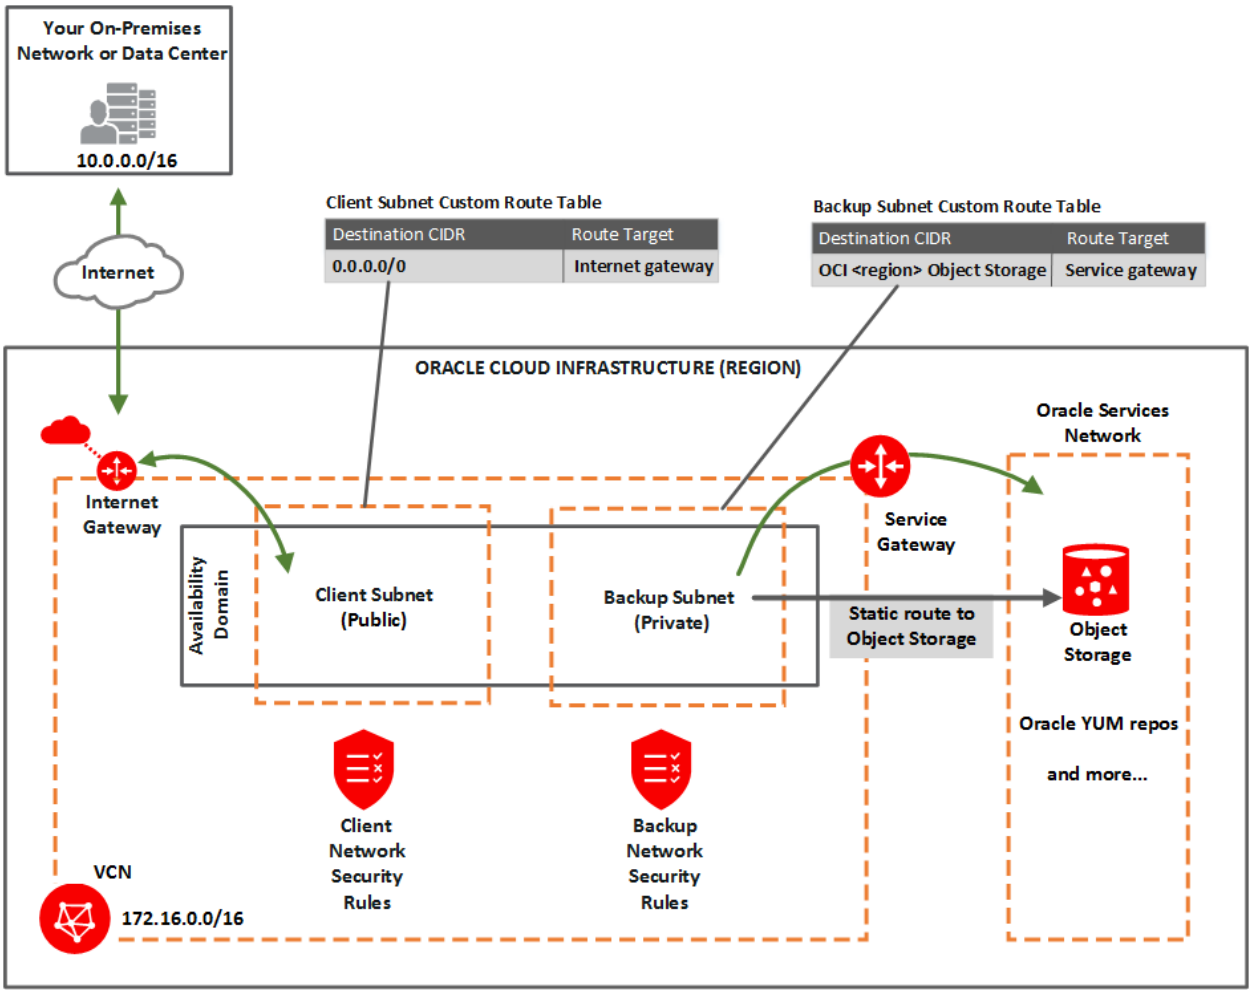
In general, Oracle recommends using regional subnets, which span all availability domains in the region. If you instead use AD-specific subnets, both the client and backup subnets must be in the same availability domain. The important thing to know for your DB system is that the

resources you create in the two subnets must be in the same availability domain. For more information, see About Regional Subnets.

You will create custom route tables for each subnet. You will also create security rules to control traffic to and from the client network and backup network of the Exadata compute notes. More information follows about those items.

Option 1: Public Client Subnet with Internet Gateway

This option can be useful when doing a proof-of-concept or development work. You can use this setup in production if you want to use an internet gateway with the VCN, or if you have services that run only on a public network and need access to the database. See the following diagram and description.



You set up:

- Subnets:
  - *Public* client subnet (*public* means that the resources in the subnet can have public IP addresses at your discretion).

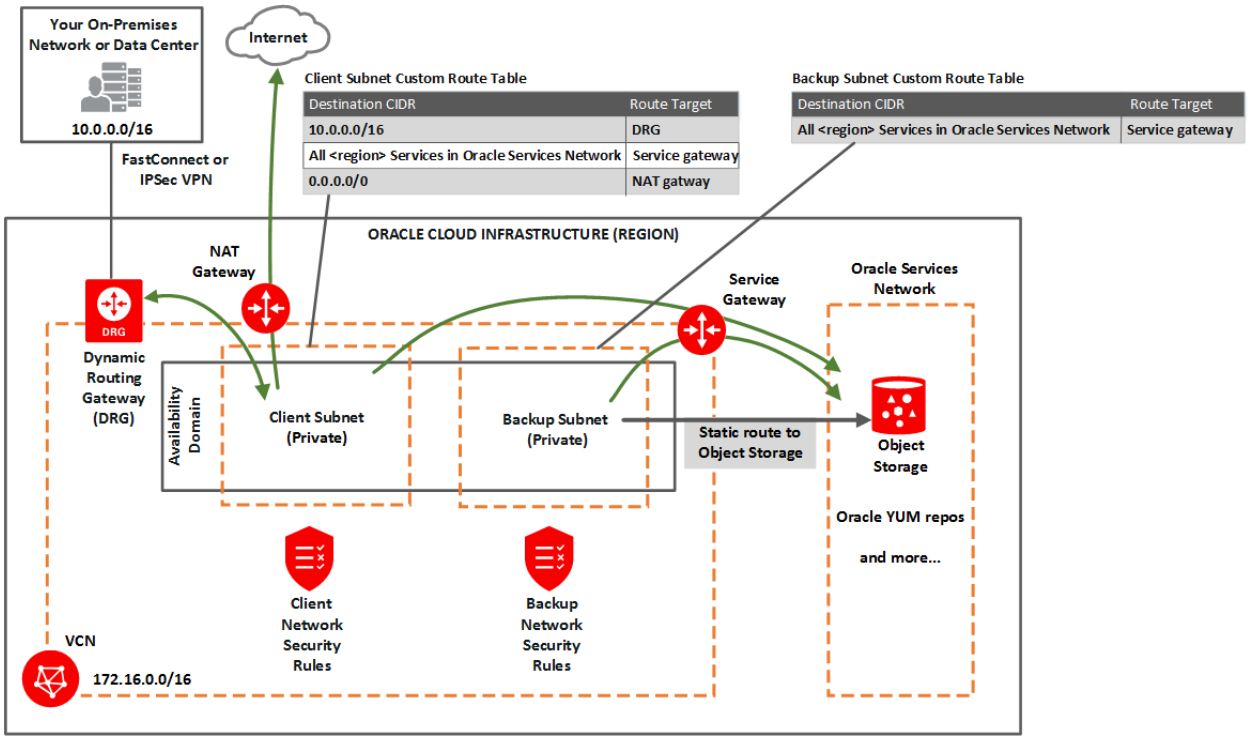
    - Private backup subnet (*private* means that the resources in the subnet cannot have public IP addresses and therefore cannot receive incoming connections from the internet).
- Gateways for the VCN:
    - Internet gateway (for use by the client subnet).
    - Service gateway (for use by the backup subnet). Also see Option 1: Service Gateway Access Only to Object Storage.
- Route tables:
    - Custom route table for the public client subnet, with a route for 0.0.0.0/0, and target = the internet gateway.
    - Separate custom route table for the private backup subnet, with a route rule for the service CIDR label called **OCI *<region>* Object Storage**, and target = the service gateway. Also see Option 1: Service Gateway Access Only to Object Storage.
- Security rules to enable the desired traffic to and from the Exadata nodes. See Security Rules for the Exadata System.
- Static route on the DB system's compute nodes (to enable access to Object Storage by way of the backup subnet).

Important

See this known issue for information about configuring route rules with *service gateway* as the target on route tables associated with public subnets.

Option 2: Private Subnets

Oracle recommends this option for a production system. Both subnets are private and cannot be reached from the internet. See the following diagram and description.



You set up:

- Subnets:
  - *Private* client subnet.
  - Private backup subnet.
- Gateways for the VCN:
  - Dynamic routing gateway (DRG), with a FastConnect or IPSec VPN to your on-premises network (for use by the client subnet).
  - Service gateway (for use by the backup subnet to reach Object Storage, and for use by the client subnet to reach the Oracle YUM repo for OS updates). Also see Option 2: Service Gateway Access to Both Object Storage and YUM Repos.

    - NAT gateway (for use by the client subnet to reach public endpoints not supported by the service gateway).
- Route tables:
    - Custom route table for the private client subnet, with two rules:
        - A rule for the on-premises network's CIDR, and target = DRG.
        - A rule for the service CIDR label called **All *<region>* Services in Oracle Services Network**, and target = the service gateway. The *Oracle Services Network* is a conceptual network in Oracle Cloud Infrastructure that is reserved for Oracle services. The rule enables the client subnet to reach the regional Oracle YUM repo for OS updates. Also see Option 2: Service Gateway Access to Both Object Storage and YUM Repos.
        - A rule for 0.0.0.0/0, and target = NAT gateway.
    - Separate custom route table for the private backup subnet, with one rule:
        - The same rule as for the client subnet: for the service CIDR label called **All *<region>* Services in Oracle Services Network**, and target = the service gateway. This rule enables the backup subnet to reach the regional Object Storage for backups.
- Security rules to enable the desired traffic to and from the Exadata nodes. See Security Rules for the Exadata System.
- Static route on the DB system's compute nodes (to enable access to Object Storage by way of the backup subnet).

Requirements for IP Address Space

If you're setting up Exadata DB systems (and thus VCNs) in more than one region, make sure the IP address space of the VCNs does not overlap. This is important if you want to set up disaster recovery with Oracle Data Guard.

The two subnets you create for the Exadata DB system must not overlap with 192.168.128.0/20.

The following table lists the *minimum* required subnet sizes, depending on the Exadata rack size. For the client subnet, each node requires two IP addresses, and in addition, three

addresses are reserved for Single Client Access Names (SCANs). For the backup subnet, each node requires one address.

Tip

The Networking service reserves three IP addresses in each subnet. Allocating a larger space for the subnet than the minimum required (for example, at least /25 instead of /28) can reduce the relative impact of those reserved addresses on the subnet's available space.

Rack Size	Client Subnet: # Required IP Addresses	Client Subnet: Minimum Size	Backup Subnet: # Required IP Addresses	Backup Subnet: Minimum Size
Base System or Quarter Rack	(2 addresses * 2 nodes) + 3 for SCANs + 3 reserved in subnet = 10	/28 (16 IP addresses)	(1 address * 2 nodes) + 3 reserved in subnet = 5	/29 (8 IP addresses)
Half Rack	(2 * 4 nodes) + 3 + 3 = 14	/28 (16 IP addresses)	(1 * 4 nodes) + 3 = 7	/29 (8 IP addresses)
Full Rack	(2* 8 nodes) + 3 + 3 = 22	/27 (32 IP addresses)	(1 * 8 nodes) + 3 = 11	/28 (16 IP addresses)

VCN Creation Wizard: Not for Production

The Networking section of the Console includes a handy wizard that creates a VCN along with related resources. It can be useful if you just want to try launching an instance. However, the wizard automatically chooses the address ranges and creates public subnets and an internet gateway. You may not want this for your production network, so Oracle recommends you create the VCN and other resources individually yourself instead of using the wizard.

DNS: Short Names for the VCN, Subnets, and DB System

For the nodes to communicate, the VCN must use the Internet and VCN Resolver. It enables hostname assignment to the nodes, and DNS resolution of those hostnames by resources in the VCN. It enables round robin resolution of the database's SCANs. It also enables resolution of important service endpoints required for backing up databases, patching, and updating the cloud tooling on an Exadata DB system. The Internet and VCN Resolver is the VCN's default choice for DNS in the VCN. For more information, see DNS in Your Virtual Cloud Network and also DHCP Options.

When you create the VCN, subnets, and Exadata, you must carefully set the following identifiers, which are related to DNS in the VCN:

- VCN domain label
- Subnet domain label
- Hostname prefix for the Exadata DB system

These values make up the node's fully qualified domain name (FQDN):

`<hostname_prefix>-######.<subnet_domain_label>.<vcn_domain_label>.oraclevcn.com`

For example:

`exacs-abcde1.clientpvtad1.acmevcniad.oraclevcn.com`

In this example, you assign `exacs` as the hostname prefix when you create the Exadata DB system. The Database service automatically appends a hyphen and a five-letter string with the node number at the end. For example:

- Node 1: `exacs-abcde1.clientpvtad1.acmevcniad.oraclevcn.com`
- Node 2: `exacs-abcde2.clientpvtad1.acmevcniad.oraclevcn.com`
- Node 3: `exacs-abcde3.clientpvtad1.acmevcniad.oraclevcn.com`
- And so on

Requirements for the hostname prefix:

- Maximum 12 characters
- Cannot be the string *localhost*

Requirements for the VCN and subnet domain labels:

- Recommended maximum: 14 characters each. The actual underlying requirement is a total of 28 characters *across both domain labels* (excluding the period between the labels). For example, both of these are acceptable: `subnetad1.verylongvcnphx` or `verylongsubnetad1.vcnphx`. For simplicity, the recommendation is 14 characters each.
- No hyphens or underscores.
- Recommended: include the region name in the VCN's domain label, and include the availability domain name in the subnet's domain label.

<12_chars_max>-######.*<14_chars_max>*.*<14_chars_max>*.oraclevcn.com

In general, the FQDN has a maximum total limit of 63 characters.

The preceding maximums are not enforced when you create the VCN and subnets. However, if the labels exceed the maximum, the Exadata deployment fails.

DNS: Between On-Premises Network and VCN

To enable the use of hostnames when on-premises hosts and VCN resources communicate with each other, you have two options:

- Set up an instance in the VCN to be a custom DNS server. For an example of an implementation of this scenario with the Oracle Terraform provider, see Hybrid DNS Configuration.
- Manage hostname resolution yourself manually.

Node Access to Object Storage: Static Route

Access to Oracle Cloud Infrastructure Object Storage is required for backing up databases, patching, and updating the cloud tooling on an Exadata DB system. Regardless of how you set up the VCN with that access (for example, with a service gateway), you must configure a static route to Object Storage on each of the compute nodes in the cluster. This is required

because, by default, all traffic in an Exadata DB system is routed through the data network. You need the traffic destined for Object Storage to be routed instead through the backup interface (BONDETH1).

Important

You must configure a static route for Object Storage access *on each compute node* in an Exadata DB system. Otherwise, attempts to back up databases, patch, or update tooling on the system might fail.

Object Storage IP allocations

Oracle Cloud Infrastructure Object Storage uses the CIDR block IP range 134.70.0.0/17 for all regions. This range was introduced in April and May of 2018.

As of June 1, 2018, Object Storage no longer supports the following discontinued IP ranges. Oracle recommends that you remove these older IP addresses from your access-control lists, firewall rules, and other rules after you have adopted the new IP ranges.

The **discontinued** IP ranges are:

- Germany Central (Frankfurt): 130.61.0.0/16
- UK South (London): 132.145.0.0/16
- US East (Ashburn): 129.213.0.0/16
- US West (Phoenix): 129.146.0.0/16

To configure a static route for Object Storage access

1. SSH to a compute node in the Exadata DB system.

   ```
   ssh -i <private_key_path> opc@<node_ip_address>
   ```

2. Log in as opc and then sudo to the root user. Use `sudo su -` with a hyphen to invoke the

root user's profile.

```
login as: opc

[opc@dbsys ~]$ sudo su -
```

3. Identify the gateway configured for the BONDETH1 interface.

```
[root@dbsys ~]# grep GATEWAY /etc/sysconfig/network-scripts/ifcfg-bondeth1 |awk -F"=" '{print
$2}'

10.0.4.1
```

4. Add the following static rule for BONDETH1 to the `/etc/sysconfig/network-scripts/route-bondeth1` file:

```
10.0.X.0/XX dev bondeth1 table 211
default via <gateway> dev bondeth1 table 211
134.70.0.0/17 via <gateway_from_previous_step> dev bondeth1
```

5. Restart the interface.

```
[root@dbsys ~]# ifdown bondeth1; ifup bondeth1;
```

   The file changes from the previous step take effect immediately after the ifdown and ifup commands run.

6. Repeat the preceding steps on *each* compute node in the Exadata DB system.

Service Gateway for the VCN

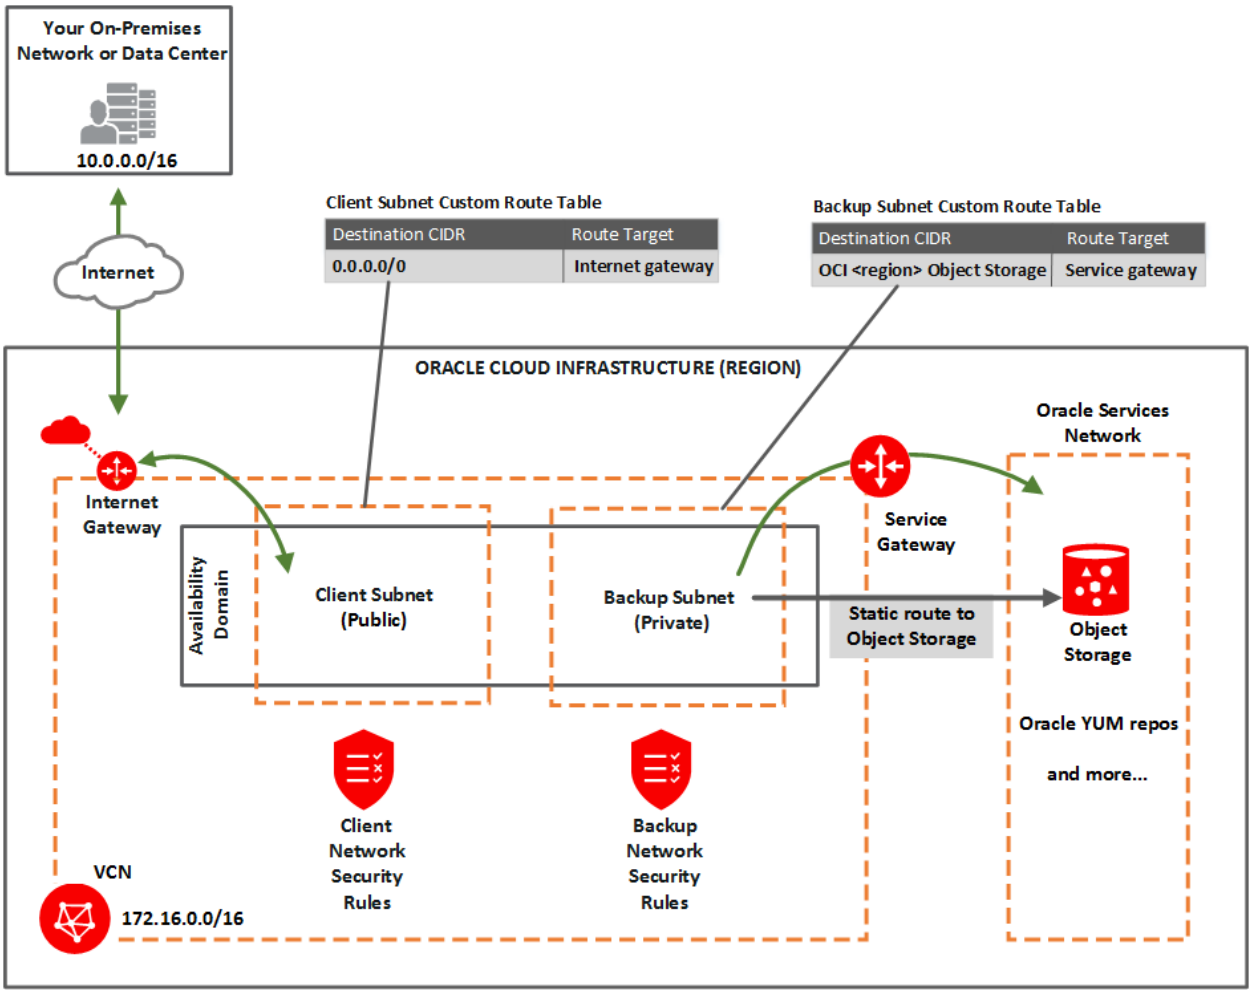
Your VCN needs access to both Object Storage for backups and Oracle YUM repos for OS updates.

Depending on whether you use option 1 or option 2 described previously, you use the service gateway in different ways. See the next two sections.

Option 1: Service Gateway Access Only to Object Storage

You configure the *backup subnet* to use the service gateway for access only to Object Storage.

As a reminder, here's the diagram for option 1:



In general, you must:

- Perform the tasks for setting up a service gateway on a VCN, and specifically enable the service CIDR label called **OCI *<region>* Object Storage**.

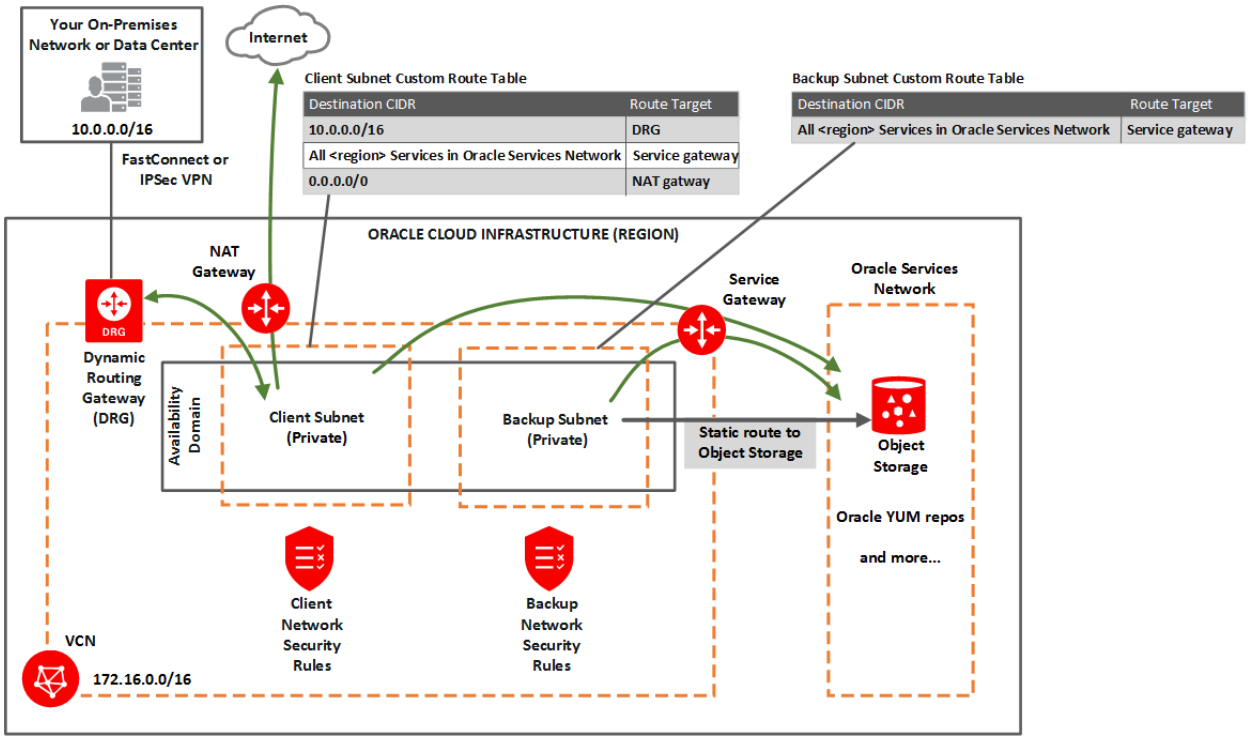
- In the task for updating routing, add a route rule to the *backup* subnet's custom route table. For the destination service, use **OCI *<region>* Object Storage** and target = the service gateway.
- In the task for updating security rules in the subnet, perform the task on the *backup* network's network security group (NSG) or custom security list. Set up a security rule with the destination service set to **OCI *<region>* Object Storage**. See Rule Required Specifically for the Backup Network.

Option 2: Service Gateway Access to Both Object Storage and YUM Repos

You configure *both the client subnet and backup subnet* to use the service gateway for access to the Oracle Services Network, which includes both Object Storage and the Oracle YUM repos.

> **Important**
>
> See this known issue for information about accessing Oracle YUM services through the service gateway.

As a reminder, here's the diagram for option 2:



In general, you must:

- Perform the tasks for setting up a service gateway on a VCN, and specifically enable the service CIDR label called **All *<region>* Services in Oracle Services Network**.
- In the task for updating routing in each subnet, add a rule to each subnet's custom route table. For the destination service, use **All *<region>* Services in Oracle Services Network** and target = the service gateway.
- In the task for updating security rules for the subnet, perform the task on the *backup* network's network security group (NSG) or custom security list. Set up a security rule with the destination service set to **OCI *<region>* Object Storage**. See Rule Required Specifically for the Backup Network. Note that the client subnet already has a broad egress rule that covers access to the YUM repos.

Here are a few additional details about using the service gateway for option 2:

- Both the client subnet and backup subnet use the service gateway, but to access different services. You cannot enable both the **OCI *<region>* Object Storage** service CIDR label and the **All *<region>* Services in Oracle Services Network** for the service gateway. To cover the needs of both subnets, you must enable **All *<region>* Services in Oracle Services Network** for the service gateway. The VCN can have only a single service gateway.
- Any route rule that targets a given service gateway must use an enabled service CIDR label and not a CIDR block as the destination for the rule. That means for option 2, the route tables for both subnets must use **All *<region>* Services in Oracle Services Network** for their service gateway rules.
- Unlike route rules, security rules can use either *any* service CIDR label (whether the VCN has a service gateway or not) or a CIDR block as the source or destination CIDR for the rule. Therefore, although the backup subnet has a route rule that uses **All *<region>* Services in Oracle Services Network**, the subnet can have a security rule that uses **OCI *<region>* Object Storage**. See Rule Required Specifically for the Backup Network.

Security Rules for the Exadata System

This section lists the security rules to use with your Exadata system. Security rules control the types of traffic allowed for the client network and backup network of the Exadata's compute nodes. The rules are divided into three sections.

There are different ways to implement these rules. For more information, see Ways to Implement the Security Rules.

Rules Required for Both the Client Network and Backup Network

This section has several general rules that enable essential connectivity for hosts in the VCN.

If you use security lists to implement your security rules: the following rules are included by default in the default security list.

General ingress rule 1: Allows SSH traffic from anywhere

- **Stateless:** No (all rules must be stateful)
- **Source Type:** CIDR
- **Source CIDR:** 0.0.0.0/0
- **IP Protocol:** TCP
- **Source Port Range:** All
- **Destination Port Range:** 22

General ingress rule 2: Allows Path MTU Discovery fragmentation messages

This rule enables hosts in the VCN to receive Path MTU Discovery fragmentation messages. Without access to these messages, hosts in the VCN can have problems communicating with hosts outside the VCN.

- **Stateless:** No (all rules must be stateful)
- **Source Type:** CIDR
- **Source CIDR:** 0.0.0.0/0
- **IP Protocol:** ICMP
- **Type:** 3
- **Code:** 4

General ingress rule 3: Allows connectivity error messages within the VCN

This rule enables the hosts in the VCN to receive connectivity error messages from each other.

- **Stateless:** No (all rules must be stateful)
- **Source Type:** CIDR
- **Source CIDR:** Your VCN's CIDR

- **IP Protocol:** ICMP
- **Type:** 3
- **Code:** All

General egress rule 1: Allows all egress traffic

- **Stateless:** No (all rules must be stateful)
- **Destination Type:** CIDR
- **Destination CIDR:** 0.0.0.0/0
- **IP Protocol:** All

Rules Required Specifically for the Client Network

The following security rules are important for the client network.

Client ingress rule 1: Allows ONS and FAN traffic from within the client subnet

The first rule is recommended and enables the Oracle Notification Services (ONS) to communicate about Fast Application Notification (FAN) events.

- **Stateless:** No (all rules must be stateful)
- **Source Type:** CIDR
- **Source CIDR:** Client subnet's CIDR
- **IP Protocol:** TCP
- **Source Port Range:** All
- **Destination Port Range:** 6200

Client ingress rule 2: Allows SQL*NET traffic from within the client subnet

This rule is for SQL*NET traffic and is required in these cases:

- If you need to enable client connections to the database
- If you plan to use Oracle Data Guard

- **Stateless:** No (all rules must be stateful)
- **Source Type:** CIDR
- **Source CIDR:** Client subnet's CIDR
- **IP Protocol:** TCP
- **Source Port Range:** All
- **Destination Port Range:** 1521

Important

The two preceding client ingress rules only cover connections initiated from within the client subnet. If you have a client that resides *outside the VCN*, Oracle recommends setting up two *additional* similar rules that instead have the **Source CIDR** set to the public IP address of the client.

The next four rules (two ingress, two egress) allow TCP and ICMP traffic inside the client network and enable the nodes to communicate with each other. If TCP connectivity fails across the nodes, the Exadata DB system fails to provision.

Client ingress rule 3: Allows all TCP traffic inside the client subnet

- **Stateless:** No (all rules must be stateful)
- **Source Type:** CIDR
- **Source CIDR:** Client subnet's CIDR
- **IP Protocol:** TCP

- **Source Port Range:** All
- **Destination Port Range:** All

Client ingress rule 4: Allows all ICMP traffic inside the client subnet

- **Stateless:** No (all rules must be stateful)
- **Source Type:** CIDR
- **Source CIDR:** Client subnet's CIDR
- **IP Protocol:** ICMP
- **Type and Code:** All

Client egress rule 1: Allows all TCP traffic inside the client subnet

- **Stateless:** No (all rules must be stateful)
- **Destination Type:** CIDR
- **Destination CIDR:** Client subnet's CIDR
- **IP Protocol:** TCP
- **Source Port Range:** All
- **Destination Port Range:** All

Client egress rule 2: Allows all ICMP traffic inside the client subnet

- **Stateless:** No (all rules must be stateful)
- **Destination Type:** CIDR
- **Destination CIDR:** Client subnet's CIDR
- **IP Protocol:** ICMP
- **Type and Code:** All

The next egress rule is important because it allows connections to the Oracle YUM repos. It is redundant with the general egress rule in Rules Required for Both the Client Network and Backup Network (and in the default security list). It is optional but recommended in case the general egress rule (or default security list) is inadvertently changed.

Client egress rule 3: Allows all egress traffic

- **Stateless:** No (all rules must be stateful)
- **Destination Type:** CIDR
- **Destination CIDR:** 0.0.0.0/0
- **IP Protocol:** All

Rule Required Specifically for the Backup Network

The following security rule is important for the backup network because it enables the DB system to communicate with Object Storage through the service gateway (and optionally with the Oracle YUM repos if the client network doesn't have access to them). It is redundant with the general egress rule in Rules Required for Both the Client Network and Backup Network (and in the default security list). It is optional but recommended in case the general egress rule (or default security list) is inadvertently changed.

Backup egress rule: Allows access to Object Storage

- **Stateless:** No (all rules must be stateful)
- **Destination Type:** Service
- **Destination Service:**
  - The service CIDR label called **OCI *<region>* Object Storage**
  - If the client network does not have access to the Oracle YUM repos, use the service CIDR label called **All *<region>* Services in Oracle Services Network**
- **IP Protocol:** TCP

- **Source Port Range:** All
- **Destination Port Range:** 443 (HTTPS)

Ways to Implement the Security Rules

The Networking service offers two ways to implement security rules within your VCN:

- Network security groups
- Security lists

For a comparison of the two methods, see Comparison of Security Lists and Network Security Groups.

If you use network security groups

If you choose to use network security groups (NSGs), here is the recommended process:

1. Create an NSG for the client network. Add the following security rules to that NSG:
   - The rules listed in Rules Required for Both the Client Network and Backup Network
   - The rules listed in Rules Required Specifically for the Client Network
2. Create a separate NSG for the backup network. Add the following security rules to that NSG:
   - The rules listed in Rules Required for Both the Client Network and Backup Network
   - The rules listed in Rule Required Specifically for the Backup Network
3. When the database administrator creates the Exadata DB system, they must choose several networking components (for example, which VCN and subnets to use):
   - When they choose the client subnet, they can also choose which NSG or NSGs to use. Make sure they choose the client network's NSG.
   - When they choose the backup subnet, they can also choose which NSG or NSGs to use. Make sure they choose the backup network's NSG.

You could instead create a separate NSG for the general rules. Then when the database administrator chooses which NSGs to use for the client network, make sure they choose both the general NSG and the client network NSG. Similarly for the backup network, they choose both the general NSG and the backup network NSG.

If you use security lists

If you choose to use security lists, here is the recommended process:

1. Configure the client subnet to use the required security rules:
    a. Create a custom security list for the client subnet and add the rules listed in Rules Required Specifically for the Client Network.
    b. Associate the following two security lists with the client subnet:
        - VCN's default security list with all its default rules. This automatically comes with the VCN. By default it contains the rules in Rules Required for Both the Client Network and Backup Network.
        - The new custom security list you created for the client subnet.
2. Configure the backup subnet to use the required security rules:
    a. Create a custom security list for the backup subnet and add the rules listed in Rule Required Specifically for the Backup Network.
    b. Associate the following two security lists with the backup subnet:
        - VCN's default security list with all its default rules. This automatically comes with the VCN. By default it contains the rules in Rules Required for Both the Client Network and Backup Network.
        - The new custom security list you created for the backup subnet.

Later when the database administrator creates the Exadata DB system, they must choose several networking components. When they select the client subnet and backup subnet that you've already created and configured, the security rules are automatically enforced for the nodes created in those subnets.

Warning

Do not remove the default egress rule from the default security list. If you do, make sure to instead include the following replacement egress rule in the client subnet's security list:

- **Stateless:** No (all rules must be stateful)
- **Destination Type:** CIDR
- **Destination CIDR:** 0.0.0.0/0
- **IP Protocol:** All

Creating Exadata DB Systems

This topic explains how to launch an Exadata DB system. It also describes how to configure required access to the Oracle Cloud Infrastructure Object Storage service and set up DNS.

When you launch an Exadata DB system using the Console or the API, the system is provisioned to support Oracle databases. The service creates an initial database based on the options you provide and some default options described later in this topic.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don't have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: The policy in Let database admins manage DB systems lets the specified group do everything with databases and related Database resources.

If you're new to policies, see Getting Started with Policies and Common Policies. If you want to dig deeper into writing policies for databases, see Details for the Database Service.

Prerequisites

- The public key, in OpenSSH format, from the key pair that you plan to use for connecting to the DB System via SSH. A sample public key, abbreviated for readability, is shown below.

  ```
  ssh-rsa AAAAB3NzaC1yc2EAAAABJQAA....lo/gKMLVM2xzc1xJr/Hc26biw3TXWGEakrK1OQ== rsa-key-20160304
  ```

  For more information, see Managing Key Pairs on Linux Instances.
- A correctly configured virtual cloud network (VCN) to launch the DB system in. Its related networking resources (gateways, route tables, security lists, DNS, and so on) must also be configured as necessary for the DB system. For more information, see Network Setup for Exadata DB Systems.

Default Options for the Initial Database

To simplify launching a DB system in the Console and when using the API, the following default options are used for the initial database.

- **Console Enabled:** False
- **Create Container Database:** False for version 11.2.0.4 databases. Otherwise, true.
- **Create Instance Only (for standby and migration):** False
- **Database Home ID:** Creates a database home

- **Database Language:** AMERICAN
- **Database Sizing Template:** odb2
- **Database Storage:** Automatic Storage Management (ASM)
- **Database Territory:** AMERICA
- **Database Unique Name:** The user-specified database name and a system-generated suffix, for example, dbtst_phx1cs.
- **PDB Admin Name:** pdbuser (Not applicable for version 11.2.0.4 databases.)

For a list of the database options that you can set in the Console, see To create an Exadata DB system.

Using the Console

To create an Exadata DB system

1. Open the navigation menu. Under **Database**, click **Bare Metal, VM, and Exadata**.
2. Click **Create DB System**.
3. On the **Create DB System** page, provide the basic information for the DB system:
    - **Select a compartment:** By default, the DB system launches in your current compartment and you can use the network resources in that compartment.
    - **Name your DB system:** A friendly, display name for the DB system. The name doesn't need to be unique. An Oracle Cloud Identifier (OCID) will uniquely identify the DB system.
    - **Select an availability domain:** The availability domain in which the DB system resides.
    - **Select a shape type:** The shape type you select sets the default shape and filters the shape options in the next field.
    - **Select a shape:** The shape determines the type of DB system and the resources allocated to the system. To specify a shape other than the default, click **Change Shape**, and select an available shape from the list.

Exadata shapes

Exadata X7 shapes:

- **Exadata.Quarter2.92:** Provides a 2-node Exadata DB system with up to 92 CPU cores, and 106 TB of usable storage.
- **Exadata.Half2.184:** Provides a 4-node Exadata DB system with up to 184 CPU cores, and 212 TB of usable storage.
- **Exadata.Full2.368:** Provides an 8-node Exadata DB system with up to 368 CPU cores, and 424 TB of usable storage.

Exadata X6 shapes:

- **Exadata.Quarter1.84:** Provides a 2-node Exadata DB system with 22 enabled CPU cores, with up to 62 additional CPU cores, and 84 TB of usable storage.
- **Exadata.Half1.168:** Provides a 4-node Exadata DB system with 44 enabled CPU cores, with up to 124 additional CPU cores, and 168 TB of usable storage.
- **Exadata.Full1.336:** Provides an 8-node Exadata DB system with 88 enabled CPU cores, with up to 248 additional CPU cores, and 336 TB of usable storage.

Exadata base system:

Exadata.Base.48: Provides a 2-node Exadata DB system with up to 48 CPU cores, and 74.8 TB of usable storage.

All Exadata shapes provide 720 GB RAM per node and unlimited I/O, and support only Enterprise Edition - Extreme Performance. For more details about Exadata shapes, see System Configuration.

- **Configure the DB system:** Specify the following:
  - **Total node count:** The number of nodes in the DB system. The number depends on the shape you select.

- **Oracle Database software edition:** The database edition supported by the DB system. Exadata DB systems only support Enterprise Edition - Extreme Performance.
- **CPU core count:** The number of CPU cores for the DB system. The text below the field indicates the acceptable values for that shape. The core count is evenly divided across the nodes.

  You can increase the CPU cores to accommodate increased demand after you launch the DB system.

  For an Exadata X7 DB system or a base system, you can specify zero (0) cores when you launch the system. This will provision the system and immediately stop it. See Scaling Within an Exadata System for information about CPU core scaling and the impact on billing.

- **Configure storage:** Specify the following:
  - **Cluster Name:** *(Optional)* A unique cluster name for a multi-node DB system. The name must begin with a letter and contain only letters (a-z and A-Z), numbers (0-9) and hyphens (-). The cluster name can be no longer than 11 characters and is not case sensitive.
  - **Storage Allocation:** The configuration settings that determine the percentage of storage assigned to DATA, RECO, and optionally, SPARSE disk:
    - **Database Backups on Exadata Storage:** Select this option if you intend to perform database backups to the local Exadata storage within your Exadata DB system environment. If you select this option, more space is allocated to the RECO disk group, which is used to store backups on Exadata storage. If you do not select this option, more space is allocated to the DATA disk group, which enables you to store more information in your databases.
    - **Create Sparse Disk Group:** Select this configuration option if you intend to use snapshot functionality within your Exadata DB system environment. If you select this option, the SPARSE disk group is

created, which enables you to use Exadata DB system snapshot functionality for PDB sparse cloning. If you do not select this option, the SPARSE disk group is not created and Exadata DB system snapshot functionality will not be available on any database deployments that are created in the environment.

Important

Creating a sparse disk group impacts the storage available for the ASM disk groups (DATA and RECO) and you cannot change the storage allocation configuration after you provision your DB system. For information about the percentage of storage that will be assigned to DATA, RECO, and SPARSE disk based on your configuration, see Impact of Configuration Settings on Storage. Similar information will display under the options in the Console dialog.

- **Add public SSH keys:** The public key portion of each key pair you want to use for SSH access to the DB system. You can browse or drag and drop .pub files, or paste in individual public keys. To paste multiple keys, click **+ Another SSH Key**, and supply a single key for each entry.
- **Choose a license type:** The type of license you want to use for the DB system. Your choice affects metering for billing.
    - **License Included** means the cost of the cloud service includes a license for the Database service.

- **Bring Your Own License (BYOL)** means you are an Oracle Database customer with an Unlimited License Agreement or Non-Unlimited License Agreement and want to use your license with Oracle Cloud Infrastructure. This removes the need for separate on-premises licenses and cloud licenses.

4. Specify the network information:
   - **Virtual Cloud Network:** The VCN in which to launch the DB system. Click **Change Compartment** to select a VCN in a different compartment.
   - **Client subnet:** The subnet to which the Exadata DB system should attach. Click **Change Compartment** to select a subnet in a different compartment.

     Do not use a subnet that overlaps with 192.168.16.16/28, which is used by the Oracle Clusterware private interconnect on the database instance. Specifying an overlapping subnet will cause the private interconnect to malfunction.
   - **Backup subnet:** The subnet to use for the backup network, which is typically used to transport backup information to and from Oracle Cloud InfrastructureObject Storage, and for Data Guard replication. Click **Change Compartment** to select a subnet in a different compartment, if applicable.

     Do not use a subnet that overlaps with 192.168.128.0/20. This restriction applies to both the client subnet and backup subnet.

     If you plan to back up databases to Object Storage, see the network prerequisites in Managing Exadata Database Backups.
   - **Network Security Groups:** Optionally, you can specify one or more network security groups (NSGs) for both the client and backup networks. NSGs function as virtual firewalls, allowing you to apply a set of ingress and egress security rules to your DB system. A maximum of five NSGs can be specified. For more information, see Network Security Groups and Network Setup for Exadata DB Systems.

     Note that if you choose a subnet with a security list, the security rules for the DB system will be a union of the rules in the security list and the NSGs.

To use network security groups

a. Check the **Use Network Security Groups to Control Client Traffic** check box. Note that you must have a virtual cloud network selected to be able to assign NSGs to your DB system.

b. Specify the NSG to use with the client network. You might need to use more than one NSG. If you're not sure, contact your network administrator.

c. To use additional NSGs with the client network, click **+ Another Network Security Group**.

d. Check the **Use Network Security Groups to Control Backup Traffic** check box.

e. Specify the NSG to use with the backup network. You might need to use more than one NSG. If you're not sure, contact your network administrator.

f. To use additional NSGs with the backup network, click **+ Another Network Security Group**.

- **Hostname prefix:** Your choice of host name for the Exadata DB system. The host name must begin with an alphabetic character, and can contain only alphanumeric characters and hyphens (-). The maximum number of characters allowed for an Exadata DB system is 12.

Important

The host name must be unique within the subnet. If it is not unique, the DB system will fail to provision.

- **Host domain name:** The domain name for the DB system. If the selected subnet uses the Oracle-provided Internet and VCN Resolver for DNS name resolution, this field displays the domain name for the subnet and it can't be changed. Otherwise, you can provide your choice of a domain name. Hyphens (-) are not

permitted.

If you plan to store database backups in Object Storage, Oracle recommends that you use a VCN Resolver for DNS name resolution for the client subnet because it automatically resolves the Swift endpoints used for backups.

- **Host and domain URL:** Combines the host and domain names to display the fully qualified domain name (FQDN) for the database. The maximum length is 64 characters.

5. Click **Show Advanced Options** to specify advanced options for the DB system:
   - **Disk redundancy:** Exadata DB systems support only high redundancy (3-way mirroring).
   - **Time zone:** The default time zone for the DB system is UTC, but you can specify a different time zone. The time zone options are those supported in both the Java.util.TimeZone class and the Oracle Linux operating system. For more information, see DB System Time Zone.

     Tip

     If you want to set a time zone other than UTC or the browser-detected time zone and if you do not see the time zone you are interested in, try selecting "Miscellaneous" as the time zone prefix.

   - **Tags:** Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.
6. After you completed the network configuration and any advanced options, click **Next**.

7. Provide information for the initial database:
    - **Database name:** The name for the database. The database name must begin with an alphabetic character and can contain a maximum of eight alphanumeric characters. Special characters are not permitted.
    - **Database version:** The version of the initial database created on the DB system when it is launched. After the DB system is active, you can create additional databases on it. You can mix database versions on the DB system.

      Note

      If you plan to run Oracle Database 19c on your Exadata DB system, you must specify version 19c when you create the DB system. Earlier database versions are supported on a 19c Exadata DB system and can be created at anytime. Exadata DB systems created with earlier Oracle Database versions will not automatically support Oracle Database 19c. The DB system must be upgraded manually.
    - **PDB name:***Not applicable to version 11.2.0.4.* The name of the pluggable database. The PDB name must begin with an alphabetic character, and can contain a maximum of 8 alphanumeric characters. The only special character permitted is the underscore (_).
    - **Create administrator credentials:** A database administrator `SYS` user will be created with the password you supply.
        - **Username:** SYS
        - **Password:** Supply the password for this user. The password must meet the following criteria:

A strong password for SYS, SYSTEM, TDE wallet, and PDB Admin. The password must be 9 to 30 characters and contain at least 2 uppercase, 2 lowercase, 2 numeric, and 2 special characters. The special characters must be _, #, or -. The password must not contain the username (SYS, SYSTEM, and so on) or the word "oracle" either in forward or reversed order and regardless of casing.

- **Confirm password:** Re-enter the SYS password you specified.

- **Select workload type:** Choose the workload type that best suits your application:
  - **Online Transactional Processing (OLTP)** configures the database for a transactional workload, with a bias towards high volumes of random data access.
  - **Decision Support System (DSS)** configures the database for a decision support or data warehouse workload, with a bias towards large data scanning operations.
- **Configure database backups:** Specify the settings for backing up the database to Object Storage:
  - **Enable automatic backups:** Check the check box to enable automatic incremental backups for this database.
  - **Backup retention period:** *(Optional)* If you enable automatic backups, you can choose one of the following preset retention periods: 7 days, 15 days, 30 days, 45 days, or 60 days. The default selection is 30 days.
  - **Backup Scheduling:** If you enable automatic backups, you can choose a two-hour scheduling window to control when backup operations begin. If you do not specify a window, the six-hour default window of 00:00 to 06:00 (in the time zone of the DB system's region) is used for your database. See Backup Scheduling for more information.
- Click **Show Advanced Options** to specify advanced options for the initial database:

- **Character set:** The character set for the database. The default is AL32UTF8.
- **National character set:** The national character set for the database. The default is AL16UTF16.

8. Click **Create DB System**.
   The DB system appears in the list with a status of Provisioning. The DB system's icon changes from yellow to green (or red to indicate errors).
   After the DB system's icon turns green, with a status of Available, you can click the highlighted DB system name to see details about the DB system. Note the IP addresses. You'll need the private or public IP address, depending on network configuration, to connect to the DB system.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use these API operations to create DB system components.

DB systems:

- GetDbSystem
- LaunchDbSystem
- ListDbSystems

Database homes:

- CreateDbHome
- GetDbHome
- ListDbHomes

Shapes and database versions:

- ListDbSystemShapes
- ListDbVersions

Configuring a Static Route for Accessing the Object Store

All the traffic in an Exadata DB system is, by default, routed through the data network. To route backup traffic to the backup interface (BONDETH1), you need to configure a static route on *each* of the compute nodes in the cluster. For instructions, see Node Access to Object Storage: Static Route.

Setting Up DNS for a DB System

DNS lets you use hostnames instead of IP addresses to communicate with a DB system. You can use the *Internet and VCN Resolver* (the DNS capability built into the VCN) as described in DNS in Your Virtual Cloud Network. Oracle recommends using a VCN Resolver for DNS name resolution for the client subnet. It automatically resolves the Swift endpoints required for backing up databases, patching, and updating the cloud tooling on an Exadata DB system.

Maintaining an Exadata DB System

Maintaining a secure Exadata DB system in the best working order requires you to perform the following tasks regularly:

- Patching the grid infrastructure and Database software on the compute nodes. See Patching an Exadata DB System for information and instructions.
- Updating the operating system and the tooling on the compute nodes. See Updating an Exadata DB System for information and instructions.

In addition to the maintenance tasks you perform, Oracle manages the patching and updating of all other infrastructure components, including the physical compute nodes (Dom0), network switches, power distribution units (PDUs), integrated lights-out management (ILOM) interfaces, and the Exadata storage servers.

These Oracle updates occur on a quarterly basis, typically in January, April, July, and October. Occasionally, Oracle might need to update your system apart from the regular quarterly

updates to apply time-sensitive changes such as security patches. While you cannot opt out of these infrastructure updates, Oracle alerts you in advance through the Cloud Notification Portal to help you plan for them. For further information about the update policy and details such as the duration and impact on your system's availability and performance, see Oracle Database Cloud Exadata Service Supported Software Versions and Planning for Updates.

Managing Exadata DB Systems

You can start, stop, terminate, scale, manage licenses for, and check the status of, an Exadata DB system by using the Oracle Cloud Infrastructure Console or the API.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: The policy in Let database admins manage DB systems lets the specified group do everything with databases and related Database resources.

If you're new to policies, see Getting Started with Policies and Common Policies. If you want to dig deeper into writing policies for databases, see Details for the Database Service.

Using the Console

To check the status of an Exadata DB system

1. Open the navigation menu. Under **Database**, click **Bare Metal, VM, and Exadata**.
2. Choose your **Compartment**.
   A list of DB systems is displayed.
3. In the list of DB systems, find the system you're interested in and check its icon. The color of the icon and the text next to it indicates the status of the system.
   - **Provisioning:** Yellow icon. Resources are being reserved for the DB system, the system is booting, and the initial database is being created. Provisioning can take several minutes. The system is not ready to use yet.
   - **Available:** Green icon. The DB system was successfully provisioned. A few minutes after the system enters this state, you can SSH to it and begin using it.
   - **Terminating:** Gray icon. The DB system is being deleted by the terminate action in the Console or API.
   - **Terminated:** Gray icon. The DB system has been deleted and is no longer available.
   - **Failed:** Red icon. An error condition prevented the provisioning or continued operation of the DB system.

   To view the status of a database node, under Resources, click **Nodes** to see the list of nodes. In addition to the states listed for a DB system, a node's status can be one of the following:
   - **Starting:** Yellow icon. The database node is being powered on by the start or reboot action in the Console or API.
   - **Stopping:** Yellow icon. The database node is being powered off by the stop or reboot action in the Console or API.
   - **Stopped:** Yellow icon. The database node was powered off by the stop action in the Console or API.

You can also check the status of DB systems and database nodes using the ListDbSystems or ListDbNodes API operations, which return the `lifecycleState` attribute.

To start, stop, or reboot an Exadata DB system

1. Open the navigation menu. Under **Database**, click **Bare Metal, VM, and Exadata**.
2. Choose your **Compartment**.
   A list of DB systems is displayed.
3. In the list of DB systems, find the DB system you want to stop or start, and then click its name to display details about it.
4. In the list of nodes, click the Actions icon (three dots) for a node and then click one of the following actions:
   - **Start:** Restarts a stopped node. After the node is restarted, the **Stop** action is enabled.
   - **Stop:** Shuts down the node. After the node is powered off, the **Start** action is enabled.
   - **Reboot:** Shuts down the node, and then restarts it.

Note

- For billing purposes, the **Stop** state has no effect on the resources you consume. Billing continues for nodes that you stop, and related resources continue to apply against any relevant quotas. You must **Terminate** a DB system to remove its resources from billing and quotas.
- After you restart or reboot a node, the floating IP address might take several minutes to be updated and display in the Console.

To scale an Exadata DB system

If an Exadata DB system requires more compute node processing power, you can scale up (burst) the number of enabled CPU cores (OCPUs) in the system.

You can also scale an X7 Exadata DB system or a base system down to zero CPU cores to temporarily stop the system and be charged only for the hardware infrastructure. For more information about scaling down, see Scaling Within an Exadata System.

CPU cores must be scaled symmetrically across all nodes in the DB system. Use multiples of two for a base system or quarter rack, multiples of four for a half rack, and multiples of eight for a full rack. The total number of CPU cores in a rack must not exceed the maximum limit for that shape.

1. Open the navigation menu. Under **Database**, click **Bare Metal, VM, and Exadata**.
2. Choose your **Compartment**.
   A list of DB systems is displayed.

3. In the list of DB systems, find the system you want to scale and click its highlighted name.
   The system details are displayed.
4. Click **Scale CPU Cores** and then change the number in the **CPU Core Count** field. The text below the field indicates the acceptable values, based on the shape used when the DB system was launched.
5. Click **Update**.

Note

If you scale an X7 Exadata DB system or a base system down to zero CPU cores, the floating IP address of the nodes might take several minutes to be updated and display in the Console.

To move an Exadata DB system to another compartment

Note

To move resources between compartments, resource users must have sufficient access permissions on the compartment that the resource is being moved to, as well as the current compartment. For more information about permissions for Database resources, see Details for the Database Service.

1. Open the navigation menu. Under **Database**, click **Bare Metal, VM, and Exadata**.
2. Choose your **Compartment**.
   A list of DB systems is displayed.

3. In the list of DB systems, find the system you want to move and click its highlighted name.
   The system details are displayed.
4. Click **Move Resource**.
5. Select the new compartment.
6. Click **Move Resource**.
   For information about dependent resources for Database resources, see Moving Database Resources to a Different Compartment.

To terminate an Exadata DB system

Terminating a DB system permanently deletes it and any databases running on it.

Note

The database data is local to the DB system and is lost when the system is terminated. Oracle recommends that you back up any data in the DB system before terminating it.

1. Open the navigation menu. Under **Database**, click **Bare Metal, VM, and Exadata**.
2. Choose your **Compartment**.
   A list of DB systems is displayed.
3. For the DB system you want to terminate, click the Actions icon (three dots), and then click **Terminate**.
4. Confirm when prompted.
   The DB system's icon indicates Terminating.

At this point, you cannot connect to the system and any open connections are terminated.

To edit the network security groups (NSGs) for your client or backup network

Your client and backup networks can each use up to five network security groups (NSGs). Note that if you choose a subnet with a security list, the security rules for the DB system will be a union of the rules in the security list and the NSGs. For more information, see Network Security Groups and Network Setup for Exadata DB Systems.

1. Open the navigation menu. Under **Database**, click **Bare Metal, VM, and Exadata**.
2. Choose your **Compartment**.
   A list of DB systems is displayed.
3. In the list of DB systems, find the system you want to manage and click its highlighted name.
   The system details are displayed.
4. In the **Network** details, click the **Edit** link to the right of the **Client Network Security Groups** or **Backup Network Security Groups** field.
5. In the **Edit Network Security Groups** dialog, click **+ Another Network Security Group** to add an NSG to the network.
   To change an assigned NSG, click the drop-down menu displaying the NSG name, then select a different NSG.
   To remove an NSG from the network, click the **X** icon to the right of the displayed NSG name.
6. Click **Save**.

To manage your BYOL database licenses

If you want to control the number of database licenses that you run at any given time, you can scale up or down the number of OCPUs on the instance. These additional licenses are metered separately.

1. Open the navigation menu. Under **Database**, click **Bare Metal, VM, and Exadata**.
2. Choose your **Compartment**.
   A list of DB systems is displayed.

3. In the list of DB systems, find the system you want to scale and click its highlighted name.
   The system details are displayed.
4. Click **Scale CPU Cores**, and then change the number.

To manage tags for your DB systems and database resources

1. Open the navigation menu. Under **Database**, click **Bare Metal, VM, and Exadata**.
2. Choose your **Compartment**.
   A list of DB systems is displayed.
3. Find the DB system or database resource you're interested in, and click the name.
4. Click the **Tags** tab to view or edit the existing tags. Or click **Apply Tag(s)** to add new tags.

For more information, see Resource Tags.

To view a work request for your DB systems and database resources

1. Open the navigation menu. Under **Database**, click **Bare Metal, VM, and Exadata**.
2. Choose your **Compartment**.
   A list of DB systems is displayed.
3. Find the DB system or database resource you're interested in, and click the name.
4. In the **Resources** section, click **Work Requests**. The status of all work requests appears on the page.
5. To see the log messages, error messages, and resources that are associated with a specific work request, click the operation name. Then, select an option in the **More information** section.
   For associated resources, you can click the Actions icon (three dots) next to a resource to copy the resource's OCID.

For more information, see Work Requests.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use these API operations to manage DB system components.

DB systems:

- GetDbSystem
- ListDbSystems
- ChangeDbSystemCompartment
- TerminateDbSystem
- UpdateDbSystem

Nodes:

- DbNodeAction: Use this operation to power cycle a node in the DB system.
- ListDbNodes
- GetDbNode

Managing Exadata DB System I/O Resources

This topic explains the I/O Resource Management (IORM) feature and how to enable it, modify the IORM settings, and disable it by using the Console or the API.

About IORM

The I/O Resource Management (IORM) feature allows you to manage how multiple databases share the I/O resources of an Oracle Exadata DB system.

On an Exadata DB system, all databases share dedicated storage servers which include flash storage. By default, the databases are given equal priority with respect to these resources. The Exadata storage management software uses a first come, first served approach for query

processing. If a database executes a major query that overloads I/O resources, overall system performance can be slowed down.

IORM allows you to assign priorities to your databases to ensure critical queries are processed first when workloads exceed their resource allocations. You assign priorities by creating directives that specify the number of shares for each database. The number of shares corresponds to a percentage of resources given to that database when I/O resources are stressed.

Directives work together with an overall optimization objective you set for managing the resources. The following objectives are available:

- **Auto** - Recommended. IORM determines the optimization objective and continuously and dynamically determines the optimal settings, based on the workloads observed, and resource plans enabled.
- **Balanced** - For critical OLTP and DSS workloads. This setting balances low disk latency and high throughput. This setting limits disk utilization of large I/Os to a lesser extent than low latency to achieve a balance between good latency and good throughput.
- **High throughput** - For critical DSS workloads that require high throughput.
- **Low latency** - For critical OLTP workloads. This setting provides the lowest possible latency by significantly limiting disk utilization.

For more information about IORM, see Exadata System Software User's Guide.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: The policy in Let database admins manage DB systems lets the specified group do everything with databases and related Database resources.

If you're new to policies, see Getting Started with Policies and Common Policies. If you want to dig deeper into writing policies for databases, see Details for the Database Service.

Using the Console

To enable IORM on your Exadata DB system

Enabling IORM includes specifying an optimization objective and configuring your resource plan directives.

1. Open the navigation menu. Under **Database**, click **Bare Metal, VM, and Exadata**.
2. Choose your **Compartment**.
3. In the list of DB systems, find the Exadata DB system for which you want to enable IORM, and click its highlighted name.
   The system details are displayed, showing the IORM status as "Disabled."
4. Cick **Enable IORM**.
   It might take a minute for the Enable I/O Resource Management dialog to retrieve the DB system information.
5. Select the objective to apply to the resource plan:
   - **Auto** - (Recommended) Dynamically changes the objective based on the resource plan and observed workloads.
   - **Balanced** - Weighs high throughput and low latency evenly.
   - **High throughput** - Provides the best throughput for DSS workloads.
   - **Low latency** - Provides the best latency for critical OLTP workloads.
6. Configure the resource plan default directive by setting the number of shares. This number of shares is assigned to each database not associated with a specific directive.
7. In the Resource Plan Directives section, add a directive for each database you want to assign a greater or lesser number of shares than the default directive.
   To add a directive, click **+ Additional Directive**, then specify the database and the number of shares for that database.

8. When you are done adding directives, click **Enable**.
   While the IORM configuration settings are being applied, the system details page shows the IORM status as "Updating." The update might take several minutes to complete but should have no impact on your ability to perform normal operations on your DB system. After a successful update, the IORM status shows as "Enabled."

To modify the IORM configuration on your Exadata DB system

Use this procedure to change your IORM settings or to disable IORM.

1. Open the navigation menu. Under **Database**, click **Bare Metal, VM, and Exadata**.
2. Choose your **Compartment**.
3. In the list of DB systems, find the Exadata DB system for which you want to modify the IORM configuration, and click its highlighted name.
   The system details are displayed, showing the IORM status as "Enabled."
4. Click **Update IORM**.
5. In the Update I/O Resource Management dialog, take one of the following actions:
   - Change your settings - Specify a new objective and adjust your directives, as applicable, and then click **Update**.
   - Disable IORM - Click **Disable IORM**. Disabling IORM removes all your resource plan directives and restores a basic objective for I/O resource management.

   While the new IORM configuration settings are being applied, the system details page shows the IORM status as "Updating." The update might take several minutes to complete but should have no impact on your ability to perform normal operations on your DB system. After a successful update, the IORM status shows as "Enabled" or "Disabled," depending on the action you took.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use these API operations to manage the I/O resources of your Exadata DB system.

- ListDbSystems
- GetDbSystem
- GetExadataIormConfig
- UpdateExadataIormConfig

Connecting to an Exadata DB System

This topic explains how to connect to an Exadata DB System using SSH or SQL Developer. How you connect depends on how your cloud network is set up. You can find information on various networking scenarios in Overview of Networking, but for specific recommendations on how you should connect to a database in the cloud, contact your network security administrator.

Prerequisites

For SSH access to a compute node in an Exadata DB System, you'll need the following:

- The full path to the file that contains the private key associated with the public key used when the system was launched.
- The public or private IP address of the DB System. Use the private IP address to connect to the DB system from your on-premises network, or from within the virtual cloud network (VCN). This includes connecting from a host located on-premises connecting through a VPN or FastConnect to your VCN, or from another host in the same VCN. Use the DB System's public IP address to connect to the system from outside the cloud (with no VPN). You can find the IP addresses in the Oracle Cloud Infrastructure Console on the **Database** page.

Connecting to a Compute Node with SSH

You can connect to the compute nodes in an Exadata DB System by using a Secure Shell (SSH) connection. Most UNIX-style systems (including Linux, Solaris, BSD, and OS X) include an

SSH client by default. For Windows, you can download a free SSH client called PuTTY from http://www.putty.org.

To connect from a UNIX-style system

Use the following SSH command to access a compute node:

```
$ ssh -i <private key> opc@<DB System IP address>
```

<private key> is the full path and name of the file that contains the private key associated with the Exadata DB System you want to access.

Use the private or public IP address depending on your network configuration. For more information, see Prerequisites.

To connect from a Windows system

1. Open `putty.exe`.
2. In the **Category** pane, select **Session** and enter the following fields:
   - **Host Name (or IP address):** `opc@<ip_address>`
     Use the compute node's private or public IP address depending on your network configuration. For more information, see Prerequisites.
   - **Connection type:** SSH
   - **Port:** 22
3. In the **Category** pane, expand **Connection**, expand **SSH**, and then click **Auth**, and browse to select your private key.
4. Optionally, return to the **Session** category screen and save this session information for reuse later.
5. Click **Open** to start the session.

To access a database after you connect to the compute node

1. Log in as opc and then sudo to the oracle user.

```
login as: opc

[opc@<host_name> ~]$ sudo su - oracle
```

2. Source the database's .env file to set the environment.

```
[oracle@<host_name>]# . <database_name>.env
```

In the following example, the host name is "ed1db01" and the database name is "cdb01".

```
[oracle@ed1db01]# . cdb01.env
```

Connecting to a Database with SQL Developer

You can connect to a database with SQL Developer by using one of the following methods:

- Create a temporary SSH tunnel from your computer to the database. This method provides access only for the duration of the tunnel. (When you are done using the database, be sure to close the SSH tunnel by exiting the SSH session.)
- Open port 1521 for the Oracle default listener by updating the security list used for the DB System. This method provides more durable access to the database. For more information, see Updating the Security List.

After you've created an SSH tunnel or opened port 1521 as described above, you can connect to a Exadata DB System using SCAN IP addresses or public IP addresses, depending on how your network is set up and where you are connecting from. You can find the IP addresses in the Console, in the **Database** details page.

To connect using SCAN IP addresses

You can connect to the database using the SCAN IP addresses if your client is on-premises and you are connecting using a FastConnect or VPN connection. You have the following options:

- Use the private SCAN IP addresses, as shown in the following `tnsnames.ora` example:

```
testdb=
  (DESCRIPTION =
    (ADDRESS_LIST=
      (ADDRESS = (PROTOCOL = TCP)(HOST = <scanIP1>)(PORT = 1521))
      (ADDRESS = (PROTOCOL = TCP)(HOST = <scanIP2>)(PORT = 1521)))
    (CONNECT_DATA =
      (SERVER = DEDICATED)
      (SERVICE_NAME = <dbservice.subnetname.dbvcn.oraclevcn.com>)
    )
  )
```

- Define an external SCAN name in your on-premises DNS server. Your application can resolve this external SCAN name to the DB System's private SCAN IP addresses, and then the application can use a connection string that includes the external SCAN name. In the following `tnsnames.ora` example, `extscanname.example.com` is defined in the on-premises DNS server.

```
testdb =
  (DESCRIPTION =
    (ADDRESS = (PROTOCOL = TCP)(HOST = <extscanname.example.com>)(PORT = 1521))
    (CONNECT_DATA =
      (SERVER = DEDICATED)
      (SERVICE_NAME = <dbservice.subnetname.dbvcn.oraclevcn.com>)
    )
  )
```

To connect using public IP addresses

You can use the node's public IP address to connect to the database if the client and database are in different VCNs, or if the database is on a VCN that has an internet gateway. However, there are important implications to consider:

- When the client uses the public IP address, the client bypasses the SCAN listener and reaches the node listener, so server side load balancing is not available.

- When the client uses the public IP address, it cannot take advantage of the VIP failover feature. If a node becomes unavailable, new connection attempts to the node will hang until a TCP/IP timeout occurs. You can set client side sqlnet parameters to limit the TCP/IP timeout.

The following `tnsnames.ora` example shows a connection string that includes the CONNECT_TIMEOUT parameter to avoid TCP/IP timeouts.

```
test=
  (DESCRIPTION =
    (CONNECT_TIMEOUT=60)
    (ADDRESS_LIST=
      (ADDRESS = (PROTOCOL = TCP)(HOST = <publicIP1>)(PORT = 1521))
      (ADDRESS = (PROTOCOL = TCP)(HOST = <publicIP2>)(PORT = 1521))
    )
    (CONNECT_DATA =
      (SERVER = DEDICATED)
      (SERVICE_NAME = <dbservice.subnetname.dbvcn.oraclevcn.com>)
    )
  )
```

Managing Exadata DB System Software Images

You can control the version of Oracle binaries that is installed when you provision a new database on an Exadata DB system by maintaining the software images on the system. Oracle provides a library of cloud software images that you can view and download onto your Exadata DB system by using the `dbaascli` utility.

When you create a new Exadata DB system database with a new Oracle Home (Database Home) directory location, the Oracle Database binaries are sourced from a software image that is stored on your Exadata DB system. Over time, the software images on your Exadata DB system become outdated if they are not maintained. Using an outdated software image makes it necessary for you to apply patches to newly installed binaries to bring them up to date. Oracle recommends that you maintain your Exadata DB system environment with up-to-date software images to avoid this extra patching step which can be time-consuming and error prone.

Viewing Information About Available Software Images

You can view information about Oracle Database software images that are available to download to your Exadata DB system by using the `cswlib list` subcommand of the `dbaascli` utility.

To view information about available software images

1. Connect to a compute node as the `opc` user.
   For detailed instructions, see Connecting to a Compute Node with SSH.
2. Start a root-user command shell:

   ```
   $ sudo -s
   #
   ```

3. Execute the `dbaascli` command with the `cswlib list` subcommand:

   ```
   # dbaascli cswlib list
   ```

   The command displays a list of available software images, including version and bundle patch information that you can use to download the software image.
4. Exit the root-user command shell:

   ```
   # exit
   $
   ```

Downloading Software Images

You can download available software images onto your Exadata DB system by using the `cswlib download` subcommand of the `dbaascli` utility.

To downloaded a software image

1. Connect to a compute node as the `opc` user.
   For detailed instructions, see Connecting to a Compute Node with SSH.
2. Start a root-user command shell:

```
$ sudo -s
#
```

3. Execute the `dbaascli` command with the `cswlib download` subcommand:

```
# dbaascli cswlib download [--version <software_version>] [--bp <software_bundle_patch>]
```

The command displays a list of software images that are downloaded to your Exadata Cloud Service environment, including version and bundle patch information.

The optional parameters are:

- **version:** specifies an Oracle Database software version. For example, 19000, 18000, or 12201.
- **bp:** identifies a bundle patch release. For example, APR2019, JAN2019, or OCT2018.

If you do not include the optional parameters, the `dbaascli cswlib download` command downloads the latest available software image for all available Oracle Database software versions.

4. Exit the root-user command shell:

```
# exit
$
```

Updating an Exadata DB System

This topic covers how to update the operating system and the tooling on the database server nodes (also known as "compute nodes") of an Exadata DB system. Review all of the information carefully before you begin the updates.

OS Updates

Important

Starting on March 14, 2019, Exadata DB system images run Oracle Linux 7 (OL7). Previously launched systems are running Oracle Linux 6 (OL6). The underlying infrastructure of existing Exadata DB systems will be patched in the April 2019 time frame. This patch will allow you to upgrade the DB system operating system to OL7.

After you receive notification that your infrastructure patch update is complete, follow the instructions in Patching an Exadata DB System to patch the Oracle Grid Infrastructure and the databases, and then update the OS. Review the minimum software requirements and other details in How to update the Exadata System Software (DomU) to 19c on the Exadata Cloud Service in OCI (Doc ID 2521053.1) before you perform the OS update tasks.

You update the operating systems of Exadata compute nodes by using the `patchmgr` tool. This utility manages the entire update of one or more compute nodes remotely, including running pre-reboot, reboot, and post-reboot steps. You can run the utility from either an Exadata compute node or a non-Exadata server running Oracle Linux. The server on which you run the utility is known as the "driving system." You cannot use the driving system to update itself. Therefore, if the driving system is one of the Exadata compute nodes on a system you are updating, you must run a separate operation on a different driving system to update that server.

The following two scenarios describe typical ways of performing the updates:

Scenario 1: Non-Exadata Driving System

The simplest way to run the update the Exadata system is to use a separate Oracle Linux server to update all Exadata compute nodes in the system.

Scenario 2: Exadata Node Driving System

You can use one Exadata compute node to drive the updates for the rest of the compute nodes in the system, and then use one of the updated nodes to drive the update on the original Exadata driver node.

For example: You are updating a half rack Exadata system, which has four compute nodes - node1, node2, node3, and node4. First, use node1 to drive the updates of node2, node3, and node4. Then, use node2 to drive the update of node1.

The driving system requires root user `SSH` access to each compute node the utility will update.

PREPARING FOR THE OS UPDATES

Warning

Do not install NetworkManager on the DB system. Installing this package and rebooting the system results in severe loss of access to the system.

- Before you begin your updates, review *Exadata Cloud Service Software Versions* (Doc ID 2333222.1) to determine the latest software version and target version to use.
- Some steps in the update process require you to specify a YUM repository. The YUM repository URL is:

  ```
  http://yum-<region_key>.oracle.com/repo/EngineeredSystems/exadata/dbserver/<latest_version>/base/x86_64.
  ```

  Region keys are three-letter abbreviations, for example PHX.
  You can run the following `curl` command to determine the latest version of the YUM repository for your DB system region:

  ```
  curl -s -X GET http://yum-<region_key>.oracle.com/repo/EngineeredSystems/exadata/dbserver/index.html |egrep "18.1."
  ```

This example returns the most current version of the YUM repository for the US West (Phoenix):

```
curl -s -X GET http://yum-phx.oracle.com/repo/EngineeredSystems/exadata/dbserver/index.html
|egrep "18.1."
<a href="18.1.4.0.0/">18.1.4.0.0/</a> 01-Mar-2018 03:36 -
```

- To apply OS updates, the DB system's VCN must be configured to allow access to the YUM repository. For more information, see Option 2: Service Gateway Access to Both Object Storage and YUM Repos.

To update the OS on all compute nodes of an Exadata DB system

This example procedure assumes the following:

- The system has two compute nodes, `node1` and `node2`.
- The target version is 18.1.4.0.0.180125.3.
- Each of the two nodes is used as the driving system for the update on the other one.

1. Gather the environment details.
   a. `SSH` to `node1` as `root` and run the following command to determine the version of Exadata:

      ```
      [root@node1]# imageinfo -ver
      12.2.1.1.4.171128
      ```

   b. Switch to the grid user, and identify all computes in the cluster.

      ```
      [root@node1]# su - grid
      [grid@node1]$ olsnodes
      node1
      node1
      ```

2. Configure the driving system.
   a. Switch back to the root user on `node1`, check whether a root ssh key pair (`id_rsa` and `id_rsa.pub`) already exists. If not, then generate it.

```
[root@node1 .ssh]#  ls /root/.ssh/id_rsa*
ls: cannot access /root/.ssh/id_rsa*: No such file or directory
[root@node1 .ssh]# ssh-keygen -t rsa
Generating public/private rsa key pair.
Enter file in which to save the key (/root/.ssh/id_rsa):
Enter passphrase (empty for no passphrase):
Enter same passphrase again:
Your identification has been saved in /root/.ssh/id_rsa.
Your public key has been saved in /root/.ssh/id_rsa.pub.
The key fingerprint is:
93:47:b0:83:75:f2:3e:e6:23:b3:0a:06:ed:00:20:a5
root@node1.fraad1client.exadataclientne.oraclevcn.com
The key's randomart image is:
+--[ RSA 2048]----+
|o..     + .      |
|o.     o *       |
|E     . o o      |
| . .     =       |
|  o .   S =      |
|   +     = .     |
|    +   o o      |
|   . .   + .     |
|      ...        |
+-----------------+
```

b. Distribute the public key to the target nodes, and verify this step. In this example, the only target node is `node2`.

```
[root@node1 .ssh]# scp -i ~opc/.ssh/id_rsa ~root/.ssh/id_rsa.pub opc@node2:/tmp/id_
rsa.node1.pub
id_rsa.pub

[root@node2 ~]# ls -al /tmp/id_rsa.node1.pub
-rw-r--r-- 1 opc opc 442 Feb 28 03:33 /tmp/id_rsa.node1.pub
[root@node2 ~]# date
Wed Feb 28 03:33:45 UTC 2018
```

c. On the target node (`node2`, in this example), add the root public key of `node1` to the root `authorized_keys` file.

```
[root@node2 ~]# cat /tmp/id_rsa.node1.pub >> ~root/.ssh/authorized_keys
```

d. Download `dbserver.patch.zip` as `p21634633_12*_Linux-x86-64.zip` onto the driving system (`node1`, in this example), and unzip it. See *dbnodeupdate.sh and dbserver.patch.zip: Updating Exadata Database Server Software using the DBNodeUpdate Utility and patchmgr* (Doc ID 1553103.1) for information about the files in this .zip.

```
[root@node1 patch]# mkdir /root/patch
[root@node1 patch]# cd /root/patch
[root@node1 patch]# unzip p21634633_181400_Linux-x86-64.zip

```

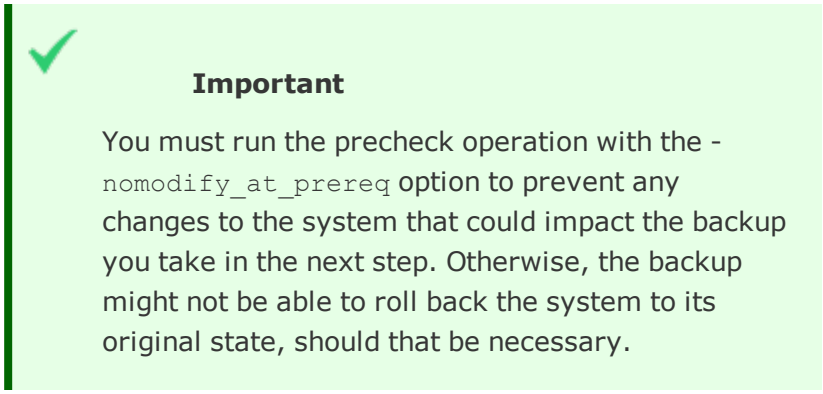
e. Create the `dbs_group` file that contains the list of compute nodes to update. Include the nodes listed after running the `olsnodes` command in step 1 except for the driving system node. In this example, `dbs_group` should include only `node2`.

```
[root@node1 patch]# cd /root/patch/dbserver_patch_5.180228
[root@node1 dbserver_patch_5.180228]# cat dbs_group
node2
```

3. Run a patching precheck operation.

```
patchmgr -dbnodes dbs_group -precheck -yum_repo <yum_repository> -target_version <target_version>
-nomodify_at_prereq
```



The output should look like the following example:

```
[root@node1 dbserver_patch_5.180228]# ./patchmgr -dbnodes dbs_group -precheck -yum_repo
http://yum-phx.oracle.com/repo/EngineeredSystems/exadata/dbserver/18.1.4.0.0/base/x86_64 -target_
version 18.1.4.0.0.180125.3  -nomodify_at_prereq

```

4. Back up the current system.

```
patchmgr -dbnodes dbs_group -backup -yum_repo <yum_repository> -target_version <target_version>
-allow_active_network_mounts
```

Important

This is the proper stage to take the backup, before any modifications are made to the system.

The output should look like the following example:

```
[root@node1 dbserver_patch_5.180228]#  ./patchmgr -dbnodes dbs_group -backup  -yum_repo
http://yum-phx.oracle.com/repo/EngineeredSystems/exadata/dbserver/18.1.4.0.0/base/x86_64 -target_
version 18.1.4.0.0.180125.3 -allow_active_network_mounts

2018-02-28 21:35:50 +0000        :SUCCESS: DONE: Initiate backup on 1 node(s).
```

5. Remove all custom RPMs from the target compute nodes that will be updated. Custom RPMs are reported in precheck results. They include RPMs that were manually installed after the system was provisioned.

Note

- If you are updating the system from version 12.1.2.3.4.170111, and the precheck results include `krb5-workstation-1.10.3-57.el6.x86_64`, remove it. (This item is considered a custom RPM for this version.)
- Do **not** remove `exadata-sun-vm-computenode-exact` or `oracle-ofed-release-guest`. These two RPMs are handled automatically during the update process.

6. Run the `nohup` command to perform the update.

```
nohup patchmgr -dbnodes dbs_group -upgrade -nobackup -yum_repo <yum_repository> -target_version
<target_version> -allow_active_network_mounts &
```

The output should look like the following example:

```
[root@node1 dbserver_patch_5.180228]# nohup ./patchmgr -dbnodes dbs_group -upgrade -nobackup  -
yum_repo  http://yum-phx.oracle.com/repo/EngineeredSystems/exadata/dbserver/18.1.4.0.0/base/x86_
64 -target_version 18.1.4.0.0.180125.3  -allow_active_network_mounts &

********************************************************************************************************

2018-02-28 21:57:43 +0000        :SUCCESS: DONE: Initiate update on node(s)
```

7. After the update operation completes, verify the version of the kernel on the compute node that was updated.

```
[root@node2 ~]# imageinfo -ver
18.1.4.0.0.180125.3
```

8. If the driving system is a compute node that needs to be updated (as in this example), repeat steps 2 through 7 of this procedure using an updated compute node as the driving system to update the remaining compute node. In this example update, you would use `node2` to update `node1`.
9. On each compute node, run the `uptrack-install` command as root to install the available ksplice updates.

```
uptrack-install --all -y
```

Updating Tooling on an Exadata DB System

You can update the cloud-specific tooling included on an Exadata DB system compute node by downloading and applying an RPM file containing the latest version of the tools.

Note

Oracle highly recommends that you maintain the same version of cloud tooling across your Exadata DB system environment. Perform the following procedure on every compute node in the Exadata DB system.

PREREQUISITE

The compute nodes in the Exadata DB system must be configured to access the Oracle Cloud Infrastructure Object Storage service. For more information, see Node Access to Object Storage: Static Route.

UPDATING THE CLOUD TOOLING ON EACH COMPUTE NODE MANUALLY

The method for updating the tooling depends on the tooling release that is currently installed on the compute node.

To check the installed tooling release

1. Connect to the compute node as the opc user.
2. Start a root-user command shell.

```
$ sudo -s
#
```

3. Use the following command to display information about the installed cloud tooling and note the release label, shown in red in the example that follows.

```
# rpm -qa|grep -i dbaastools_exa

dbaastools_exa-1.0-1+18.1.2.1.0_180511.0801.x86_64
```

In this example, the release version is **18.1.2.1.0_180511.0801**.

To update the tooling if the release label is higher than 17430

You use the `patch tools` subcommand of the `dbaascli` utility to update the cloud tooling.

Important

If you are updating the tooling on an Exadata DB system that includes a Data Guard configuration, you must perform these steps on both the primary database's DB system and on the standby database's DB system.

1. Connect as the opc user to the compute node.
2. Start a root-user command shell:

```
$ sudo -s
#
```

3. Check whether any cloud tooling updates are available:

   ```
   # dbaascli patch tools list
   ```

   Example output:

   ```
   [root@exacs-node1 ]# dbaascli patch tools list
   DBAAS CLI version 19.4.1.0.0
   Executing command patch tools list
   Checking tools on all nodes
   Current Patchid on stb-elbdc1: 19.4.1.0.0_190822.1034
   Available Patches
   Patchid : 19.4.1.0.0_190827.1034
   Patchid : 19.4.1.0.0_190912.0440(LATEST)
   Install tools patch using
   dbaascli patch tools apply --patchid 19.4.1.0.0_190912.0440    or
   dbaascli patch tools apply --patchid LATEST
   All Nodes have the same tools version
   ```

4. In the command response, locate the patch ID of the cloud tooling update. The patch ID is listed as the "Patchid" value. If multiple patches are listed, choose the latest one.
5. Apply the patch containing the latest cloud tooling update by using one of the following methods:
   - Specify the patch ID of the latest patch:

     ```
     # dbaascli patch tools apply --patchid <patch_ID>
     ```

   - Specify the patch ID as `LATEST`:

     ```
     # dbaascli patch tools apply --patchid LATEST
     ```

   - Run the update process in the background:

     ```
     # dbaascli patch tools apply --patchid LATEST &
     ```

6. Reset the backup configuration:

   ```
   # /var/opt/oracle/ocde/assistants/bkup/bkup
   ```

7. Exit the root-user command shell and disconnect from the compute node:

```
# exit
$ exit
```

8. If you are updating cloud tooling on a DB system hosting a Data Guard configuration, repeat the preceding steps on the compute node of the peer (primary or standby database's) DB system.

To update the tooling if the release label is 17430 or lower

1. Download the RPM file using the Swift object storage API endpoint URL for your region.

   ```
   wget <swift_API_endpoint>/v1/exadata/patches/dbaas_patch/shome/dbaastools_exa.rpm
   ```

   The following example downloads the RPM file from the US West (Phoenix).

   ```
   wget https://swiftobjectstorage.us-phoenix-1.oraclecloud.com/v1/exadata/patches/dbaas_
   patch/shome/dbaastools_exa.rpm
   ```

   See API Reference and Endpoints for the Swift API endpoint for your region.

2. Apply the RPM file.

   ```
   # rpm -ev dbaastools_exa
   # rpm -ivh dbaastools_exa.rpm
   ```

3. Repeat the previous steps on each compute node in the Exadata DB system.

CONFIGURING AUTOMATIC CLOUD TOOLING UPDATES

You can configure automatic cloud tooling updates for Exadata DB systems. When you configure these updates, an entry is added to the `/etc/crontab` file to regularly check for cloud tooling updates and apply new updates to the compute node when they become available.

Note

These procedures apply only if the release label is higher than 17430.

To check whether automatic cloud tooling updates are enabled for an Exadata DB system

1. Connect to the compute node as the opc user.
2. Start a root-user command shell:

   ```
   $ sudo -s
   #
   ```

3. Use the following command to check whether automatic tooling updates are enabled:

   ```
   # dbaascli patch tools auto status
   ```

   If the command response includes "INFO: auto rpm update is enabled", then automatic updates are enabled. If the response includes "INFO: auto rpm update is disabled", then automatic updates are disabled.
4. Exit the root-user command shell and disconnect from the compute node:

   ```
   # exit
   $ exit
   ```

5. If you are checking the status of automatic cloud tooling updates on a DB system hosting a Data Guard configuration, repeat the preceding steps on the compute node of the peer (primary or standby database's) DB system.

To enable automatic cloud tooling updates for an Exadata DB system

1. Connect to the compute node as the opc user.
2. Start a root-user command shell:

   ```
   $ sudo -s
   #
   ```

3. Use the following command to enable automatic tooling updates:

   ```
   # dbaascli patch tools auto enable
   ```

4. Exit the root-user command shell and disconnect from the compute node:

```
# exit
$ exit
```

5. If you are enabling automatic cloud tooling updates on a DB system hosting a Data Guard configuration, repeat the preceding steps on the compute node of the peer (primary or standby database's) DB system.

To run a tooling update on demand when automatic cloud tooling updates are enabled

You can perform an update at any time between automatic updates by running the `dbaascli patch tools auto enable` subcommand. This command checks whether there is a newer version of the tooling than the version on the compute node and applies the newer version if it finds one.

1. Connect to the compute node as the opc user.
2. Start a root-user command shell:

```
$ sudo -s
#
```

3. Use the following command to check for a newer tooling version and apply it:

```
# dbaascli patch tools auto execute
```

4. Exit the root-user command shell and disconnect from the compute node:

```
# exit
$ exit
```

5. If you are performing the on-demand cloud tooling update on a DB system hosting a Data Guard configuration, repeat the preceding steps on the compute node of the peer (primary or standby database's) DB system.

To disable automatic cloud tooling updates for an Exadata DB system

1. Connect to the compute node as the opc user.

2. Start a root-user command shell:

```
$ sudo -s
#
```

3. Use the following command to disable automatic tooling updates:

```
# dbaascli patch tools auto disable
```

4. Exit the root-user command shell and disconnect from the compute node:

```
# exit
$ exit
```

5. If you are disabling automatic cloud tooling updates on a DB system hosting a Data Guard configuration, repeat the preceding steps on the compute node of the peer (primary or standby database's) DB system.

Patching an Exadata DB System

This topic explains how to use the `dbaascli` utility to perform patching operations for Oracle Grid Infrastructure and Oracle Database on an Exadata DB system. The utility requires root or sudo administration privileges.

Note

You must update the cloud specific tooling on all the compute nodes in your Exadata DB system before performing the following procedures. For more information, see Updating an Exadata DB System.

Prerequisites

Patches are stored in Oracle Cloud Infrastructure Object Storage, so the Exadata DB system requires access to that service. To enable this access, Oracle recommends using a service gateway with the VCN. For more information, see Network Setup for Exadata DB Systems. In

that topic, pay particular attention to:

- Service Gateway for the VCN
- Node Access to Object Storage: Static Route
- Rule Required Specifically for the Backup Network

Managing Patches

To list available patches

You can produce a list of available patches using the `patch db list` subcommand of the `dbaascli` utility:

1. Connect to the compute node as the `opc` user.
   For detailed instructions, see Connecting to an Exadata DB System.
2. Start a root-user command shell:

   ```
   $ sudo -s
   #
   ```

3. Execute the following command:

   ```
   # dbaascli patch db list --oh=<hostname>:<oracle_home>
   ```

   where:

   - `--oh` specifies a compute node and Oracle home directory for which you want to list the available patches. In this context, an Oracle home directory may be an Oracle Database home directory or the Oracle Grid Infrastructure home directory.

   Example (Oracle Database):

   ```
   # dbaascli patch db list --oh exacs-node1:/u02/app/oracle/product/18.0.0.0/dbhome_1
   DBAAS CLI version 18.2.3.2.0
   Executing command patch db list --oh exacs-node1:/u02/app/oracle/product/18.0.0.0/dbhome_1
   INFO : EXACS patching

   Available Patches
   patchid :29708703 (Database Release Update : 18.7.0.0.190716 (Jul 2019))
   ```

```
Install database patch using
dbaascli patch db apply --patchid 29708703 (Database Release Update : 18.7.0.0.190716 (Jul 2019))
--dbnames <>
```

Example (Oracle Grid Infrastructure):

```
# dbaascli patch db list --oh exacs-node1:/u01/app/18.1.0.0/grid
```

Note

The list of available patches is determined by interrogating the database to establish the patches that have already been applied. When a patch is applied, the corresponding database entry is made as part of the SQL patching operation, which is executed at the end of the patch workflow. Therefore, the list of available patches may include partially applied patches along with patches that are currently being applied.

To learn more about the `patch db list` subcommand, including available options, execute the following command:

```
# dbaascli patch db list ?
```

4. Exit the root-user command shell.

```
# exit
$
```

To check prerequisites before applying a patch

You can perform the prerequisites-checking operation using the `patch db prereq` subcommand of the `dbaascli` utility:

1. Connect to the compute node as the `opc` user.
2. Start a root-user command shell:

   ```
   $ sudo -s
   #
   ```

3. Execute the following command:

   ```
   # dbaascli patch db prereq --patchid <patchid> --dbnames <dbname>
   ```

   where:

   - `--patchid` identifies the patch to be pre-checked.
   - `--dbnames` specifies the name of the database you want to pre-check.

   Example (Oracle Database):

   ```
   # dbaascli patch db prereq --patchid 29708703 --dbnames DB18
   ```

   Example (Oracle Grid Infrastructure):

   ```
   # dbaascli patch db prereq --patchid 29708703-GI --dbnames GRID
   ```

   To run the command in the background, append an ampersand (&):

   ```
   # dbaascli patch db prereq --patchid 29708703 --dbnames DB18 &
   ```

   To learn more about the `patch db prereq` subcommand, including available options, execute the following command:

   ```
   # dbaascli patch db prereq ?
   ```

4. Exit the root-user command shell:

   ```
   # exit
   $
   ```

To apply a patch

You can apply a patch by using the `patch db apply` subcommand of the `dbaascli` utility.

The patching operation:

- Can be used to patch some or all of your compute nodes using one command.
- Coordinates multi-node patching in a rolling manner.
- Can execute patch-related SQL after patching all the compute nodes in the cluster.

To perform the patching operation:

1. Connect to the compute node as the `opc` user.
2. Start a root-user command shell:

   ```
   $ sudo -s
   #
   ```

3. Execute the following command:

   ```
   # dbaascli patch db apply --patchid <patchid> --dbnames <dbname> --run_datasql 1
   ```

   where:

   - `--patchid` identifies the patch to be applied.
   - `--dbnames` specifies the name of the database you want to apply the patch to.
   - `--run_datasql 1` instructs the command to execute patch-related SQL commands.

Note

- Patch-related SQL should only be executed after all of the compute nodes are patched. Therefore, take care not to specify this argument if you are patching a subset of nodes and further nodes remain to be patched.
- This argument can only be specified in conjunction with a patching operation on a set of compute nodes. Therefore, if you have patched all of your nodes and you did not specify this argument, you will need to manually execute the SQL commands associated with the patch. Refer to the patch documentation for further details.

Example (Oracle Database):

```
# dbaascli patch db apply --patchid 29708703 --dbnames DB18
```

Example (Oracle Grid Infrastructure):

```
# dbaascli patch db apply --patchid 29708703-GI --dbnames GRID
```

To run the command in the background, append an ampersand (&):

```
# dbaascli patch db apply --patchid 29708703 --dbnames DB18 &
```

To learn more about the `patch db apply` subcommand, including available options, execute the following command:

```
# dbaascli patch db apply ?
```

4. Exit the root-user command shell:

```
# exit
$
```

To list applied patches

You can produce a list of applied patches to determine which patches have been applied.

You can use the `opatch` utility to determine the patches that have been applied to an Oracle Database or Grid Infrastructure installation.

To produce a list of applied patches for an Oracle Database installation:

1. Connect to a compute node as the `oracle` user.
2. Go to the Oracle user's home directory:

   ```
   $ cd
   ```

3. Ensure that you are in the Oracle user's home directory:

   ```
   $ pwd

   /home/oracle
   ```

4. Source the environment file.
   Example (using the environment file for a database named "DB18"):

   ```
   $ . DB18.env
   ```

5. Execute the `opatch` command with the `lspatches` option:

   ```
   $ opatch lspatches
   ```

To produce a list of applied patches for Oracle Grid Infrastructure:

1. Connect to a compute node as the `opc` user.
2. Become the `grid` user:

   ```
   $ sudo -s
   # su - grid
   ```

3. Execute the `opatch` command with the `lspatches` option:

```
$ opatch lspatches
```

To switchback a patch

You can switchback (roll back) a patch by using the `dbaascli` utility.

The patch switchback (roll back) operation:

- Can be used to roll back a patch on some or all of your compute nodes using one command.
- Coordinates multi-node operations in a rolling manner.
- Can execute rollback-related SQL after rolling back the patch on all the compute nodes in the cluster.

To perform a patch switchback (roll back) operation:

1. Connect to the compute node as the `opc` user.
2. Start a root-user command shell:

```
$ sudo -s
#
```

3. Execute the following command:

```
# dbaascli patch db switchback --patchid <patchid> --instance1 <hostname>:<oracle_home> --dbnames
<dbname> --run_datasql 1
```

where:

- `--patchid` identifies the patch to be rolled back.
- `--instanceN` specifies a compute node and one or more Oracle home directories that are subject to the rollback operation. In this context, an Oracle home directory may be an Oracle Database home directory or the Oracle Grid Infrastructure home directory.

- `--dbnames` specifies the name of the database you want to apply the switchback operation to.
- `--run_datasql 1` instructs the command to execute rollback-related SQL commands.

Note

- Rollback-related SQL should only be executed after all of the compute nodes are rolled back. Therefore, take care not to specify this argument if you are rolling back a subset of nodes and further nodes remain to be rolled back.
- This argument can only be specified in conjunction with a rollback operation on a set of compute nodes. Therefore, if you have rolled back all of your nodes and you did not specify this argument, you will need to manually execute the SQL commands associated with the rollback operation. Refer to the patch documentation for further details.

Example (Oracle Database):

```
# dbaascli patch db switchback --patchid 29708703 --dbnames DB18
```

Example (Oracle Grid Infrastructure):

```
# dbaascli patch db switchback --patchid 29708703-GI --dbnames GRID
```

To run the command in the background, append an ampersand (&):

```
# dbaascli patch db switchback --patchid 29708703 --dbnames DB18 &
```

To learn more about the `patch db switchback` subcommand, including available options, execute the following command:

```
# dbaascli patch db switchback ?
```

4. Exit the root-user command shell:

```
# exit
$
```

Monitoring a Database on an Exadata DB System

This topic explains how to access Enterprise Manager Database Express and Enterprise Manager Database Control, which are web-based tools for managing Oracle Database.

Accessing Enterprise Manager Database Express 12c

Enterprise Manager Database Express 12c (EM Express) is available on Exadata DB system database deployments created using Oracle Database 12c Release 1 (12.1) or later.

How you access EM Express depends on whether you want to manage a CDB or PDB.

- **To manage the CDB.** When a database deployment is created, Database automatically sets port 5500 on the deployment's compute nodes for EM Express access to the CDB.
- **To manage a PDB.** For an Oracle Database 12.2 or later deployment, a single port (known as the global port) is automatically set on the deployment's compute nodes. The global port lets you use EM Express to connect to all of the PDBs in the CDB using the HTTPS port for the CDB.

  For an Oracle Database 12.1 deployment, you must manually set a port on the deployment's compute nodes for each PDB you want to manage using EM Express.

For both CDBs and PDBs, you must add the port to a security list as described in Updating the Security List.

To confirm the port that is in use for a specific database, connect to the database as a database administrator and execute the query shown in the following example:

```
SQL> select dbms_xdb_config.getHttpsPort() from dual;

DBMS_XDB_CONFIG.GETHTTPSPORT()
------------------------------
                          5502
```

SETTING THE PORT FOR EM EXPRESS TO MANAGE A PDB (ORACLE DATABASE 12.1 ONLY)

In Oracle Database 12c Release 1, a unique HTTPS port must be configured for the root container (CDB) and each PDB that you manage using EM Express.

To configure a HTTPS port so that you can manage a PDB with EM Express:

1. Invoke SQL*Plus and log in to the PDB as the SYS user with SYSDBA privileges.
2. Execute the `DBMS_XDB_CONFIG.SETHTTPSPORT` procedure.

   ```
   SQL> exec dbms_xdb_config.sethttpsport(port-number)
   ```

ACCESSING EM EXPRESS

Before you access EM Express, add the port to the security list. See Updating the Security List.

After you update the security list, you can access EM Express by directing your browser to the URL `https://<node-ip-address>:<port>/em`, where `node-ip-address` is the public IP address of the compute node hosting EM Express, and `port` is the EM Express port used by the database.

Accessing Enterprise Manager 11g Database Control

Enterprise Manager 11g Database Control (Database Control) is available on Exadata DB system database deployments created using Oracle Database 11g Release 2. Database Control is allocated a unique port number for each database deployment. By default, access to Database Control is provided using port 1158 for the first deployment. Subsequent deployments are allocated ports in a range starting with 5500, 5501, 5502, and so on.

You can confirm the Database Control port for a database by searching for `REPOSITORY_URL` in the `$ORACLE_HOME/host_sid/sysman/config/emd.properties` file.

Before you access Database Control, add the port for the database to the security list associated with the Exadata DB system's client subnet. For more information, see Updating the Security List.

After you update the security list, you can access Database Control by directing your browser to the URL `https://<node-ip-address>:<port>/em`, where `node-ip-address` is the public IP address of the compute node hosting Database Control, and `port` is the Database Control port used by the database.

Updating the Security List

Before you can access EM Express or Database Control, you must add the port for the database to the security list associated with the Exadata DB system's data (client) subnet. To update an existing security list, complete the following steps using the Console:

1. Open the navigation menu. Under **Database**, click **Bare Metal, VM, and Exadata**.
2. Choose your **Compartment**.
   A list of DB systems is displayed.
3. Locate the DB system in the list.
4. Note the DB system's **Client Subnet** name and click its **Virtual Cloud Network**.
5. Locate the subnet in the list, and then click its security list under **Security Lists**.
6. Click **Edit All Rules** and add an ingress rule with source type=CIDR, source CIDR=*<source CIDR>*, protocol=TCP, and port=*<port number or port range>*.
   The source CIDR should be the CIDR block that includes the ports you open for the client connection.

For detailed information about creating or updating a security list, see Security Lists.

Managing Exadata Databases

When you launch an Exadata DB system, an initial database is created in that system. You can create additional databases in that DB system at any time by using the Console or the Oracle Cloud Infrastructure API.

When you add a database to an Exadata DB system, the database versions you can select from depend on the current patch level of that DB system. You might have to patch your DB system to add later database versions. For information about patching the DB system, see Patching an Exadata DB System.

Each new database is created in a separate database home.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

You can also add and remove databases, and perform other management tasks on a database by using command line utilities. For information and instructions on how to use these utilities, see Managing Exadata Databases Manually.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: The policy in Let database admins manage DB systems lets the specified group do everything with databases and related Database resources.

If you're new to policies, see Getting Started with Policies and Common Policies. If you want to dig deeper into writing policies for databases, see Details for the Database Service.

Note

See Known Issues for information about using the Oracle Cloud Infrastructure Console, API, or CLI to manage Exadata DB systems if your system was provisioned before June 15, 2018.

Using the Console

To create a new database in an existing Exadata DB system

Note

If IORM is enabled on the DB system, the default directive will apply to the new database and system performance might be impacted. Oracle recommends that you review the IORM settings and make applicable adjustments to the configuration after the new database is provisioned.

1. Open the navigation menu. Under **Database**, click **Bare Metal, VM, and Exadata**.
2. Choose your **Compartment**.
   A list of DB systems is displayed.
3. In the list of DB systems, find the Exadata DB system in which you want to create the database, and then click its name to display details about it.
4. Click **Create Database**.

5. In the **Create Database** dialog, enter the following:
    - **Database name:** The name for the database. The database name must begin with an alphabetic character and can contain a maximum of eight alphanumeric characters. Special characters are not permitted.
    - **Database version:** The version of the database. You can mix database versions on the Exadata DB system.
    - **PDB name** *(Optional)* For version 12.1.0.2 and later, you can specify the name of the pluggable database. The PDB name must begin with an alphabetic character, and can contain a maximum of 8 alphanumeric characters. The only special character permitted is the underscore (_).
    - **Create administrator credentials:** A database administrator `SYS` user will be created with the password you supply.
        - **Username:** SYS
        - **Password:** Supply the password for this user. The password must meet the following criteria:

          A strong password for SYS, SYSTEM, TDE wallet, and PDB Admin. The password must be 9 to 30 characters and contain at least 2 uppercase, 2 lowercase, 2 numeric, and 2 special characters. The special characters must be _, #, or -. The password must not contain the username (SYS, SYSTEM, and so on) or the word "oracle" either in forward or reversed order and regardless of casing.
        - **Confirm password:** Re-enter the SYS password you specified.
    - **Select workload type:** Choose the workload type that best suits your application:
        - **Online Transactional Processing (OLTP)** configures the database for a transactional workload, with a bias towards high volumes of random data access.

    - **Decision Support System (DSS)** configures the database for a decision support or data warehouse workload, with a bias towards large data scanning operations.
- **Configure database backups:** Specify the settings for backing up the database to Object Storage:
    - **Enable automatic backup:** Check the check box to enable automatic incremental backups for this database.
    - **Backup retention period:** If you enable automatic backups, you can choose one of the following preset retention periods: 7 days, 15 days, 30 days, 45 days, or 60 days. The default selection is 30 days.
    - **Backup Scheduling:** If you enable automatic backups, you can choose a two-hour scheduling window to control when backup operations begin. If you do not specify a window, the six-hour default window of 00:00 to 06:00 (in the time zone of the DB system's region) is used for your database. See Backup Scheduling for more information.

6. Click **Show Advanced Options** to specify advanced options for the database:
    - **Character set:** The character set for the database. The default is AL32UTF8.
    - **National character set:** The national character set for the database. The default is AL16UTF16.
    - Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.
7. Click **Create Database**.

When the database creation is complete, the status changes from Provisioning to Available.

To terminate a database

Oracle recommends that you create a final backup before you terminate any production (non-

test) database. See Managing Exadata Database Backups by Using bkup_api to learn how to back up an Exadata database.

1. Open the navigation menu. Under **Database**, click **Bare Metal, VM, and Exadata**.
2. Choose your **Compartment**.
   A list of DB systems is displayed.
3. In the list of DB Systems, find the DB System that contains the database you want to terminate, and then click its name to display details about it.
4. In the list of databases, find the database you want to terminate, and then click its name to display details about it.
5. Click **Actions**, and then click **Terminate**.
6. In the confirmation dialog, indicate whether you want to back up the database before terminating it, and type the name of the database to confirm the termination.
7. Click **Terminate Database**.
   The database's status indicates Terminating.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use these API operations to manage databases.

Database homes:

- ListDbHomes
- GetDbHome
- CreateDbHome
- DeleteDbHome

Databases:

- ListDatabases
- GetDatabase

For the complete list of APIs for the Database service, see Database Service API.

Changing the Database Passwords

The password that you specify in the Database Admin Password field when you create a new Exadata DB system or database is set as the password for the SYS, SYSTEM, TDE wallet, and PDB Admin credentials. Use the following procedures if you need to change passwords for an existing database.

Note that if you are enabling Data Guard for a database, the SYS password and the TDE wallet password of the primary and standby databases must all be the same.

To change the SYS password for an Exadata DB system database

1. Log onto the DB system host as `opc`.
2. Run the following command:

```
sudo dbaascli database changepassword --dbname <database_name>
```

To change the TDE wallet password for an Exadata DB system database

1. Log onto the DB system host as `opc`.
2. Run the following command:

```
sudo dbaascli tde changepassword --dbname <database_name>
```

Managing Exadata Databases Manually

Exadata DB systems include these command line tools for performing various tasks to manage individual databases:

- `dbaasapi` - For adding and removing databases from the Exadata DB system. See Using dbaasapi.
- `dbaascli` - For a variety of life-cycle and administration operations such as:
    - Starting and stoping a database
    - Starting and stoping the Oracle Net listener
    - Viewing information about Oracle Homes
    - Moving a database to another Oracle Home
    - Deleting an unused Oracle Home
    - Performing database configuration changes
    - Managing Oracle Database software images
    - Managing pluggable databases (PDBs)
    - Performing database recovery
    - Rotating the master encryption key

  For details about how to use this CLI, see The dbaascli Utility.

Using dbaasapi

You can use the `dbaasapi` command line utility to create and delete databases on an Exadata DB system. The utility operates like a REST API. It reads a JSON request body and produces a JSON response body in an output file.

The utility is located in the `/var/opt/oracle/dbaasapi/` directory on the compute nodes and must be run as the root user.

To learn how to add or remove Exadata databases by using the Oracle Cloud Infrastructure Console or API instead, see Managing Exadata Databases.

Note

- Databases that you create by using `dbaasapi` do *not* appear in your Exadata DB system's list of databases that you see in the Console.
- You must update the cloud-specific tooling on all the compute nodes in your Exadata DB system before performing the following procedures. For more information, see Updating an Exadata DB System.
- Only one `dbaasapi` operation can execute at a given time. Oracle recommends that you check the status of an operation to ensure it completed before you run another operation.

Prerequisites

If you plan to create a database and store its backups in the Oracle Cloud Infrastructure Object Storage, refer to the prerequisites in Managing Exadata Database Backups, and ensure that the system meets the networking requirements for backing up to Object Storage. Review the Create Database Parameters and gather the information you'll need to supply in the input file you create for the `dbaasapi` operation.

Warning

Oracle recommends that you avoid specifying parameter values that include confidential information when you use the `dbaasapi` commands.

Creating a Database

The following procedure creates directory called `dbinput`, a sample input file called `myinput.json`, and a sample output file called `createdb.out`.

1. SSH to a compute node in the Exadata DB system.

```
ssh -i <private_key_path> opc@<node_ip_address>
```

2. Log in as opc and then sudo to the root user.

```
login as: opc

[opc@dbsys ~]$ sudo su -
```

3. Make a directory for the input file and change to the directory.

```
[root@dbsys ~]# mkdir -p /home/oracle/dbinput
# cd /home/oracle/dbinput
```

4. Create the input file in the directory. The following sample file will create a database configured to store backups in an existing bucket in Object Storage. For parameter descriptions, see Create Database Parameters.

```
{
  "object": "db",
  "action": "start",
  "operation": "createdb",
  "params": {
    "nodelist":              "",
    "dbname":                "exadb",
    "edition":               "EE_EP",
    "version":               "12.1.0.2",
    "adminPassword":         "<password>",
    "sid":                   "exadb",
    "pdbName":               "PDB1",
    "charset":               "AL32UTF8",
    "ncharset":              "AL16UTF16",
    "backupDestination":     "OSS",
    "cloudStorageContainer": "https://swiftobjectstorage.<region_
name>.oraclecloud.com/v1/mycompany/DBBackups",
    "cloudStorageUser":      "<name@example.com>",
```

```
    "cloudStoragePwd":       "<auth_token>"
  },
  "outputfile": "/home/oracle/createdb.out",
  "FLAGS": ""
}
```

5. Run the utility and specify the input file.

```
[root@dbsys ~]# /var/opt/oracle/dbaasapi/dbaasapi -i myinput.json
```

6. Check the output file and note the ID.

```
[root@dbsys ~]# cat /home/oracle/createdb.out
{
   "msg" : "",
   "object" : "db",
   "status" : "Starting",
   "errmsg" : "",
   "outputfile" : "/home/oracle/createdb.out",
   "action" : "start",
   "id" : "170",
   "operation" : "createdb",
   "logfile" : "/var/opt/oracle/log/gsa1/dbaasapi/db/createdb/1.log"
}
```

7. Create a JSON file to check the database creation status. Note the action of `"status"`. Replace the ID and the dbname with the values from the previous steps.

```
{
  "object": "db",
  "action": "status",
  "operation": "createdb",
  "id": 170,
  "params": {
    "dbname": "exadb"
  },
  "outputfile": "/home/oracle/createdb.out",
  "FLAGS": ""
}
```

8. Run the utility with the status file as input and then check the utility output.

   Rerun the status action regularly until the response indicates that the operation succeeded or failed.

```
[root@dbsys ~]# /var/opt/oracle/dbaasapi/dbaasapi -i db_status.json

[root@dbsys ~]# cat /home/oracle/createdb.out

{

CREATE DATABASE PARAMETERS

Use the following parameters to create a database.

Parameter	Description
object	The value `"db"`.
action	The value `"start"`.

Parameter	Description
operation	The value "createdb".
nodelist	The value "" (an empty string). The database will be created across all nodes in the cluster.
dbname	The database name, in quotes.
edition	The value "EE_EP". (Only Enterprise Edition - Extreme Performance is supported .)
version	The database version as 18.0.0.0, 12.2.0.1, 12.1.0.2, or 11.2.0.4, in quotes.
adminPassword	The administrator (SYS and SYSTEM) password to use for the new database, in quotes. The password must be nine to thirty characters and contain at least two uppercase, two lowercase, two numeric, and two special characters. The special characters must be _, #, or -.
sid	The SID of the database, in quotes.
pdbName	The name of the pluggable database, in quotes.

Parameter	Description
charset	The database character set, in quotes. Allowed values AL32UTF8, AR8ADOS710, AR8ADOS720, AR8APTEC715, AR8ARABICMACS, AR8ASMO8X, AR8ISO8859P6, AR8MSWIN1256, AR8MUSSAD768, AR8NAFITHA711, AR8NAFITHA721, AR8SAKHR706, AR8SAKHR707, AZ8ISO8859P9E, BG8MSWIN, BG8PC437S, BLT8CP921, BLT8ISO8859P13, BLT8MSWIN1257, BLT8PC775, BN8BSCII, CDN8PC863, CEL8ISO8859P14, CL8ISO8859P5, CL8ISOIR111, CL8KOI8R, CL8KOI8U, CL8MACCYRILLICS, CL8MSWIN1251, EE8ISO8859P2, EE8MACCES, EE8MACCROATIANS, EE8MSWIN1250, EE8PC852, EL8DEC, EL8ISO8859P7, EL8MACGREEKS, EL8MSWIN1253, EL8PC437S, EL8PC851, EL8PC869, ET8MSWIN923, HU8ABMOD, HU8CWI2, IN8ISCII, IS8PC861, IW8ISO8859P8, IW8MACHEBREWS, IW8MSWIN1255, IW8PC1507, JA16EUC, JA16EUCTILDE, JA16SJIS, JA16SJISTILDE, JA16VMS, KO16KSCCS, KO16MSWIN949, LA8ISO6937, LA8PASSPORT, LT8MSWIN921, LT8PC772, LT8PC774, LV8PC1117, LV8PC8LR, LV8RST104090, N8PC865, NE8ISO8859P10, NEE8ISO8859P4, RU8BESTA, RU8PC855, RU8PC866, SE8ISO8859P3, TH8MACTHAIS, TH8TISASCII, TR8DEC, TR8MACTURKISHS, TR8MSWIN1254, TR8PC857, US7ASCII, US8PC437, UTF8, VN8MSWIN1258, VN8VN3, WE8DEC, WE8DG, WE8ISO8859P15, WE8ISO8859P9, WE8MACROMAN8S, WE8MSWIN1252, WE8NCR4970, WE8NEXTSTEP, WE8PC850, WE8PC858, WE8PC860, WE8ROMAN8, ZHS16CGB231280, ZHS16GBK, ZHT16BIG5, ZHT16CCDC, ZHT16DBT, ZHT16HKSCS, ZHT16MSWIN950, ZHT32EUC, ZHT32SOPS, ZHT32TRIS

Parameter	Description
ncharset	The database national character set. The value `AL16UTF16` or `UTF8`, in quotes.
backupDestination	The database backup destination, in quotes. You can configure the following backup destinations. `NONE` No backup destination is configured. `DISK` Configure database backups to the local disk Fast Recovery Area. `OSS` Configure database backups to an existing bucket in the Oracle Cloud Infrastructure Object Storage service. You must specify all the `cloudStorage` parameters. `BOTH` Configure database backups to both local disk and an existing bucket in Object Storage. You must specify all the `cloudStorage` parameters. For example: `"backupDestination":"BOTH"`

Parameter	Description
cloudStorageContainer= *<swift_url>*	Required if you specify a backup destination of `OSS` or `BOTH`. The Object Storage URL, your Oracle Cloud Infrastructure tenant, and an existing bucket in the object store to use as the backup destination, in the following format: `https://swiftobjectstorage.<region_name>.oraclecloud.com/v1/<tenant>/<bucket>` See Regions and Availability Domains to look up the region name string. For example: `"cloudStorageContainer":"https://swiftobjectstorage.<region_name>.oraclecloud.com/v1/<company_name>/DBBackups"`
cloudStorageUser= *<user_name>*	Required if you specify a backup destination of `OSS` or `BOTH`. The user name for the Oracle Cloud Infrastructure user account, for example: `"cloudStorageUser":"name@company.com"` This is the user name you use to sign in to the Console. The user name must be a member of the Administrators group, as described in Prerequisites.

Parameter	Description
cloudStoragePwd= *<auth_token>*	Required if you specify a backup destination of `OSS` or `BOTH`. The auth token generated by using the Console or IAM API, in quotes, for example: `"cloudStoragePwd":"<auth_token>"` For more information, see Managing User Credentials. This is **not** the password for the Oracle Cloud Infrastructure user.
outputfile	The absolute path for the output of the request, for example, `"outputfile":"/home/oracle/createdb.out"`.
FLAGS	The value `""` (an empty string).

Deleting a Database

Oracle recommends that you create a final backup before you delete any production (non-test) database. See Managing Exadata Database Backups by Using bkup_api to learn how to back up an Exadata database.

1. SSH to a compute node in the Exadata DB system.

```
ssh -i <private_key_path> opc@<node_ip_address>
```

2. Log in as opc and then sudo to the root user.

```
login as: opc

[opc@dbsys ~]$ sudo su -
```

3. Make a directory for the input file and change to the directory.

```
[root@dbsys ~]# mkdir -p /home/oracle/dbinput

# cd /home/oracle/dbinput
```

4. Create the input file in the directory and specify the database name to delete and an output file. For more information, see Delete Database Parameters .

```
{
  "object":  "db",
  "action":  "start",
  "operation": "deletedb",
  "params": {
    "dbname": "exadb"
  },
   "outputfile":   "/home/oracle/delete_exadb.out",
   "FLAGS": ""
}
```

5. Run the utility and specify the input file.

```
[root@dbsys ~]# /var/opt/oracle/dbaasapi/dbaasapi -i myinput.json
```

6. Check the output file and note the ID.

```
[root@ed1db01 ~]# cat /home/oracle/delete_exadb.out

{
   "msg" : "",
   "object" : "db",
   "status" : "Starting",
   "errmsg" : "",
   "outputfile" : "/home/oracle/deletedb.out",
   "action" : "start",
   "id" : "17",
   "operation" : "deletedb",
   "logfile" : "/var/opt/oracle/log/exadb/dbaasapi/db/deletedb/17.log"
}
```

7. Create a JSON file to check the database deletion status. Note the action of "status" in the sample file below. Replace the ID and the dbname with the values from the previous steps.

```
{
  "object": "db",
  "action": "status",
  "operation": "deletedb",
```

```
  "id": 17,
  "params": {
    "dbname": "exadb"
  },
  "outputfile": "/home/oracle/deletedb.out",
  "FLAGS": ""
}
```

8. Run the utility with the status file as input and then check the utility output.
   Rerun the status action regularly until the response indicates that the operation succeeded.

```
[root@dbsys ~]#  /var/opt/oracle/dbaasapi/dbaasapi -i db_status.json

[root@dbsys ~]# cat /home/oracle/deletedb.out

{
   "msg" : "Using cmd : su - root -c \"/var/opt/oracle/ocde/assistants/dg/dgcc -dbname exadb -
action delete\" \\n\\n##Done executing dg\\nWARN: Could not register elogger_parameters:

nid=\"no\" -dbname=\"exadb\" -action=delete \\n",
   "object" : "db",
   "status" : "InProgress",
   "errmsg" : "",
   "outputfile" : "/home/oracle/deletedb.out",
   "action" : "start",
   "id" : "17",
   "operation" : "deletedb",
   "logfile" : "/var/opt/oracle/log/exadb/dbaasapi/db/deletedb/17.log"
}
```

DELETE DATABASE PARAMETERS

Use the following parameters to delete a database.

Parameter	Description
object	The value "db".
action	The value "start".
operation	The value "deletedb".
dbname	The database name, in quotes.
outputfile	The absolute path for the output of the request, for example, "/home/oracle/deletedb.out".
FLAGS	The value "" (an empty string).

Managing Exadata Database Backups

This topic explains how to work with Exadata database backups managed by Oracle Cloud Infrastructure. You do this by using the Console or the API. (For unmanaged backups, see Managing Exadata Database Backups by Using bkup_api.)

Important

If you previously used `bkup_api` to configure backups and then you switch to using the Console or the API for backups:

- A new backup configuration is created and associated with your database. This means that you can no longer rely on your previously configured unmanaged backups to work.
- `bkup_api` uses cron jobs to schedule backups. These jobs are not automatically removed when you switch to using managed backups.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don't have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

If you're new to policies, see Getting Started with Policies and Common Policies.

Prerequisites

- Review the information and instructions in Configuring a Static Route for Accessing the Object Store and ensure that you configure the static route for the backup subnet on each compute node in the Exadata DB system.
- Your DB system must have connectivity to the applicable Swift endpoint for Object Storage. See https://www.oracle.com/cloud/storage/object-storage-faq.html for information about the Swift endpoints to use.

Important

To avoid backup failures, ensure that the database's archiving mode is set to `ARCHIVELOG` (the default).

Using the Console

You can use the Console to enable automatic incremental backups, create full backups on demand, and view the list of managed backups for a database. The Console also allows you to delete full backups.

Note

The list of backups you see in the Console does not include any unmanaged backups (backups created directly by using `bkup_api`).

All backups are encrypted with the same master key used for Transparent Data Encryption (TDE) wallet encryption.

The database and DB system must be in an "Available" state for a backup operation to run successfully. Oracle recommends that you avoid performing actions that could interfere with availability (such as patching operations) while a backup operation is in progress. If an automatic backup operation fails, the Database service retries the operation during the next day's backup window. If an on-demand full backup fails, you can try the operation again when the DB system and database availability are restored.

AUTOMATIC INCREMENTAL BACKUPS

When you enable the Automatic Backup feature, the service creates daily incremental backups of the database to Object Storage. The first backup created is a level 0 backup. Then, level 1 backups are created every day until the next weekend. Every weekend, the cycle repeats, starting with a new level 0 backup.

BACKUP RETENTION

If you choose to enable automatic backups, you can choose one of the following preset retention periods: 7 days, 15 days, 30 days, 45 days, or 60 days. The system automatically deletes your incremental backups at the end of your chosen retention period.

BACKUP SCHEDULING

The automatic backup process starts at any time during your daily backup window. You can optionally specify a 2-hour scheduling window for your database during which the automatic backup process will begin. There are 12 scheduling windows to choose from, each starting on

an even-numbered hour (for example, one window runs from 4:00-6:00 AM, and the next from 6:00-8:00 AM). Backups jobs do not necessarily complete within the scheduling window

The default backup window of 00:00 to 06:00 in the time zone of the DB system's region is assigned to your database if you do not specify a window. Note that the default backup scheduling window is six hours long, while the windows you specify are two hours long. See note for backup window time zone information.

Note

- **Data Guard** - You can enable the Automatic Backup feature on a database with the standby role in a Data Guard association. However, automatic backups for that database will not be created until it assumes the primary role.
- **Retention Period Changes** - If you shorten your database's automatic backup retention period in the future, existing backups falling outside the updated retention period are deleted by the system.
- **Object Storage Costs** - Automatic backups incur Object Storage usage costs.

On-Demand Full Backups

You can create a full backup of your database at any time.

Standalone Backups

When you terminate a DB system or a database, all of its resources are deleted, along with any automatic backups. Full backups remain in Object Storage as standalone backups. You can use a standalone backup to create a new database.

To configure automatic backups for a database

When you launch a DB system, you can optionally enable automatic backups for the initial database. Use this procedure to enable or disable automatic backups after the database is created.

1. Open the navigation menu. Under **Database**, click **Bare Metal, VM, and Exadata**.
2. Choose your **Compartment**.
   A list of DB systems is displayed.
3. Find the DB system where the database is located, and click the system name to display details about it.
   A list of databases is displayed.
4. Find the database for which you want to enable or disable automatic backups, and click its name to display database details. The details indicate whether automatic backups are enabled.
5. Click **Configure Automatic Backups**.
6. In the **Configure Automatic Backups** dialog, check or uncheck **Enable Automatic Backup**, as applicable. If you are enabling automatic backups, you can choose one of the following preset retention periods: 7 days, 15 days, 30 days, 45 days, or 60 days. The default selection is 30 days.
7. Click **Save Changes**.

To create an on-demand full backup of a database

1. Open the navigation menu. Under **Database**, click **Bare Metal, VM, and Exadata**.
2. Choose your **Compartment**.
   A list of DB systems is displayed.
3. Find the DB system where the database is located, and click the system name to display details about it.
   A list of databases is displayed.

4. Find the database for which you want to create an on-demand full backup and click its name to display database details.
5. Under **Resources**, click **Backups**.
   A list of backups is displayed.
6. Click **Create Backup**.

To delete full backups from Object Storage

Note

You cannot explicitly delete automatic backups. Unless you terminate the database, automatic backups remain in Object Storage for 30 days, after which time they are automatically deleted.

1. Open the navigation menu. Under **Database**, click **Bare Metal, VM, and Exadata**.
2. Choose your **Compartment**.
   A list of DB systems is displayed.
3. Find the DB system where the database is located and click the DB system name to display details.
   A list of databases is displayed.
4. Find the database you are interested in and click its name to display database details.
5. Under **Resources**, click **Backups**.
   A list of backups is displayed.
6. Click the Actions icon (three dots) for the backup you are interested in, and then click **Delete**.
7. Confirm when prompted.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use these API operations to manage database backups:

- ListBackups
- GetBackup
- CreateBackup
- DeleteBackup
- UpdateDatabase - To enable and disable automatic backups.

For the complete list of APIs for the Database service, see Database Service API.

WHAT'S NEXT?

See Recovering an Exadata Database from Object Storage.

Managing Exadata Database Backups by Using bkup_api

You can use Exadata's backup utility, `bkup_api`, to back up databases on an Exadata DB system to an existing bucket in the Oracle Cloud Infrastructure Object Storage service and to the local disk Fast Recovery Area.

For backups managed by Oracle Cloud Infrastructure, see Managing Exadata Database Backups.

This topic explains how to:

- Create a backup configuration file that indicates the backup destination, when the backup should run, and how long backups are retained. If the backup destination is Object Storage, the file also contains the credentials to access the service.
- Associate the backup configuration file with a database. The database will be backed up as scheduled, or you can create an on-demand backup.

Note

You must update the cloud-specific tooling on all the compute nodes in your Exadata DB system before performing the following procedures. For more information, see Updating an Exadata DB System.

Prerequisites

- The Exadata DB system requires access to the Oracle Cloud Infrastructure Object Storage service. Oracle recommends using a service gateway with the VCN to enable this access. For more information, see Network Setup for Exadata DB Systems. In that topic, pay particular attention to:
  - Service Gateway for the VCN
  - Node Access to Object Storage: Static Route
  - Rule Required Specifically for the Backup Network
- An existing Object Storage bucket to use as the backup destination. You can use the Console or the Object Storage API to create the bucket. For more information, see Managing Buckets.
- An auth token generated by Oracle Cloud Infrastructure. You can use the Console or the IAM API to generate the password. For more information, see Working with Auth Tokens.
- The user name specified in the backup configuration file must have tenancy-level access to Object Storage. An easy way to do this is to add the user name to the Administrators group. However, that allows access to *all* of the cloud services. Instead, an administrator should create a policy like the following that limits access to only the required resources in Object Storage for backing up and restoring the database:

```
Allow group <group_name> to manage objects in compartment <compartment_name> where
target.bucket.name = '<bucket_name>'

Allow group <group_name> to read buckets in compartment <compartment_name>
```

For more information about adding a user to a group, see Managing Groups. For more information about policies, see Getting Started with Policies.

Default Backup Configuration

The backup configuration follows a set of Oracle best-practice guidelines:

- Full (level 0) backup of the database followed by rolling incremental (level 1) backups on a seven-day cycle (a 30-day cycle for the Object Storage destination).
- Full backup of selected system files.
- Automatic backups daily at a specific time set during the database deployment creation process.

Retention period:

- Both Object Storage and local storage: 30 days, with the 7 most recent days' backups available on local storage.
- Object Storage only: 30 days.
- Local storage only: Seven days.

Encryption:

- Both Object Storage and local storage: All backups to cloud storage are encrypted.
- Object Storage only: All backups to cloud storage are encrypted.

Managing Backups

To create a backup configuration file

Important

The following procedure must be performed on the first

compute node in the Exadata DB system. To determine the first compute node, connect to any compute node as the `grid` user and execute the following command:

```
$ $ORACLE_HOME/bin/olsnodes -n
```

The first node has the number 1 listed beside the node name.

1. SSH to the first compute node in the Exadata DB system.

```
ssh -i <private_key_path> opc@<node_1_ip_address>
```

2. Log in as opc and then sudo to the root user.

```
login as: opc

[opc@dbsys ~]$ sudo su -
```

3. Create a new backup configuration file in `/var/opt/oracle/ocde/assistants/bkup/` as shown in the sample configuration file below. This example uses the file name `bkup.cfg`, but you can provide your own file name. The following file schedules a backup to both local storage and an existing bucket in Object Storage.
   The parameters are described below this procedure.

```
[root@dbsys ~]# cd /var/opt/oracle/ocde/assistants/bkup/

vi bkup.cfg
bkup_disk=yes
bkup_oss=yes
bkup_oss_url=https://swiftobjectstorage.<region>.oraclecloud.com/v1/companyabc/DBBackups
bkup_oss_user=jsmith@example.com
bkup_oss_passwd=<password>
bkup_oss_recovery_window=7
bkup_daily_time=06:45
```

4. Change the permissions of the file.

```
[root@dbsys bkup]# chmod 600 bkup.cfg
```

5. Use the following command to install the backup configuration, configure the credentials, schedule the backup, and associate the configuration with a database name.

   ```
   [root@dbsys bkup]# ./bkup -cfg bkup.cfg -dbname=<database_name>
   ```

   The backup is scheduled via cron and can be viewed at `/etc/crontab`.

When the scheduled backup runs, you can check its progress with the following command.

```
[root@dbsys bkup]# /var/opt/oracle/bkup_api/bkup_api bkup_status
```

The backup configuration file parameters are described in the following table:

Parameter	Description
bkup_disk=[yes|no]	Whether to back up locally to disk (Fast Recovery Area).
bkup_oss=[yes|no]	Whether to back up to Object Storage. If yes, you must also provide the parameters bkup_oss_url, bkup_oss_user, bkup_oss_passwd, and bkup_oss_recovery_window.

Parameter	Description
bkup_oss_url=*<swift_url>*	Required if bkup_oss=yes. The Object Storage URL including the tenant and bucket you want to use. The URL is: `https://swiftobjectstorage.<region_name>.oraclecloud.com/v1/<tenant>/<bucket>` where *<tenant>* is the *lowercase* tenant name (even if it contains uppercase characters) that you specify when signing in to the Console and *<bucket>* is the name of the existing bucket you want to use for backups.

Parameter	Description
bkup_oss_user=*<oci_user_name>*	Required if bkup_oss=yes. The user name for the Oracle Cloud Infrastructure user account, for example `jsmith@<example>.com`. The user must be a member of the Administrators group, as described in Prerequisites. This is the user name you use to sign in to the Console.
bkup_oss_passwd=*<auth_token>*	Required if bkup_oss=yes. The auth token generated by using the Console or IAM API, as described in Prerequisites. This is **not** the password for the Oracle Cloud Infrastructure user.

Parameter	Description
bkup_oss_recovery_window=*n*	Required if bkup_oss=yes. The number of days for which backups and archived redo logs are maintained in the Object Storage bucket. Specify 1 to 30 days.
bkup_daily_time=*hh:mm*	The time at which the daily backup is scheduled, specified in hours and minutes (hh:mm), in 24-hour format.

To create an on-demand backup

You can use the `bkup_api` utility to create an on-demand backup of a database.

1. SSH to the first compute node in the Exadata DB system.

   ```
   ssh -i <private_key_path> opc@<node_1_ip_address>
   ```

   To determine the first compute node, connect to any compute node as the `grid` user and execute the following command:

   ```
   $ $ORACLE_HOME/bin/olsnodes -n
   ```

   The first node has the number 1 listed beside the node name.

2. Log in as opc and then sudo to the root user.

   ```
   login as: opc

   [opc@dbsys ~]$ sudo su -
   ```

3. You can let the backup follow the current retention policy, or you can create a long-term

backup that persists until you delete it:

- To create a backup that follows the current retention policy, enter the following command:

```
# /var/opt/oracle/bkup_api/bkup_api bkup_start --dbname=<database_name>
```

- To create a long-term backup, enter the following command:

```
# /var/opt/oracle/bkup_api/bkup_api bkup_start --keep --dbname=<database_name>
```

4. Exit the root-user command shell and disconnect from the compute node:

```
# exit
$ exit
```

By default, the backup is given a timestamp-based tag. To specify a custom backup tag, add the `--tag` option to the `bkup_api` command; for example, to create a long-term backup with the tag "monthly", enter the following command:

```
# /var/opt/oracle/bkup_api/bkup_api bkup_start --keep --tag=monthly
```

After you enter a `bkup_api bkup_start` command, the `bkup_api` utility starts the backup process, which runs in the background. To check the progress of the backup process, enter the following command:

```
# /var/opt/oracle/bkup_api/bkup_api bkup_status --dbname=<database_name>
```

To remove the backup configuration

A backup configuration can contain the credentials to access the Object Storage bucket. For this reason, you might want to remove the file after successfully configuring the backup.

```
[root@dbsys bkup]# rm bkup.cfg
```

To delete a local backup

To delete a backup of a database deployment on the Exadata DB system, use the `bkup_api` utility.

1. Connect to the first compute node in your Exadata DB system as the `opc` user.
   To determine the first compute node, connect to any compute node as the `grid` user and execute the following command:

   ```
   $ $ORACLE_HOME/bin/olsnodes -n
   ```

   The first node has the number 1 listed beside the node name.
2. Start a root-user command shell:

   ```
   $ sudo -s#
   ```

3. List the available backups:

   ```
   # >/var/opt/oracle/bkup_api/bkup_api recover_list --dbname=<database_name>
   ```

   where `dbname` is the database name for the database that you want to act on.
   A list of available backups is displayed.
4. Delete the backup you want:

   ```
   # /var/opt/oracle/bkup_api/bkup_api bkup_delete --bkup=<backup-tag> --dbname=<database_name>
   ```

   where `backup-tag` is the tag of the backup you want to delete.
5. Exit the root-user command shell:

   ```
   # exit$
   ```

To delete a backup in Object Storage

Use the RMAN `delete backup` command to delete a backup from the Object Store.

WHAT NEXT?

If you used Object Storage as a backup destination, you can display the backup files in your bucket in the Console on the **Storage** page, by selecting **Object Storage**.

You can manually restore a database backup by using the RMAN utility. For information about using RMAN, see the *Oracle Database Backup and Recovery User's Guide* for Release 18.1, 12.2, 12.1, or 11.2.

Recovering an Exadata Database from Object Storage

This topic explains how to recover an Exadata database from a backup stored in Object Storage by using the Console or the API. The Object Storage service is a secure, scalable, on-demand storage solution in Oracle Cloud Infrastructure. For information on backing up your Exadata DB system to Object Storage, see Managing Exadata Database Backups.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don't have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

If you're new to policies, see Getting Started with Policies and Common Policies.

Using the Console

You can use the Console to restore the database from a backup in the Object Storage that was created by using the Console or the API. You can restore to the last known good state of the database, or you can specify a point in time or an existing System Change Number (SCN).

Note

The list of backups you see in the Console does not include any unmanaged backups (backups created directly by using `bkup_api`).

Restoring an Existing Database

To restore a database

1. Open the navigation menu. Under **Database**, click **Bare Metal, VM, and Exadata**.

2. Choose your **Compartment**.
   A list of DB systems is displayed.
3. Find the DB system where the database is located, and click the system name to display details about it.
   A list of databases is displayed.
4. Find the database you want to restore, and click its name to display details about it.
5. Click **Restore**.
6. Select one of the following options, and click **Restore Database**:
   - **Restore to the latest:** Restores the database to the last known good state with the least possible data loss.
   - **Restore to the timestamp:** Restores the database to the timestamp specified.
   - **Restore to System Change Number (SCN):** Restores the database using the SCN specified. This SCN must be valid.

Tip

You can determine the SCN number to use either by accessing and querying your database host, or by accessing any online or archived logs.

7. Confirm when prompted.
   If the restore operation fails, the database will be in a "Restore Failed" state. You can try restoring again using a different restore option. However, Oracle recommends that you review the `RMAN` logs on the host and fix any issues before reattempting to restore the database. These log files can be found in subdirectories of the `/var/opt/oracle/log` directory.

To restore a database using a specific backup from Object Storage

1. Open the navigation menu. Under **Database**, click **Bare Metal, VM, and Exadata**.
2. Choose your **Compartment**.
   A list of DB systems is displayed.
3. Find the DB system where the database is located, and click the system name to display details about it.
   A list of databases is displayed.
4. Find the database you want to restore, and click its name to display details about it.
5. Under **Resources**, click **Backups**.
   A list of backups is displayed.
6. Click the Actions icon (three dots) for the backup you are interested in, and then click **Restore**.
7. Confirm when prompted.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use these API operations to recover a database:

- ListBackups
- GetBackup
- RestoreDatabase

For the complete list of APIs for the Database service, see Database Service API.

Recovering an Exadata Database by Using RMAN

If you backed up your Exadata database by using `bkup_api`, you can manually restore that database backup by using the Oracle Recovery Manager (RMAN) utility. For information about

using RMAN, see the *Oracle Database Backup and Recovery User's Guide* for Release 18.1, 12.2, 12.1, or 11.2.

To restore an Exadata database from a managed backup, see Recovering an Exadata Database from Object Storage.

Managing Oracle Homes Manually

This topic describes how to manage Oracle Homes using the dbaascli utility. Oracle Homes are also called Database Homes.

An Oracle Home is a directory location on the compute nodes that contains Oracle Database binaries. Exadata DB systems enable multiple database deployments to share a set of Oracle Database binaries in a shared Oracle Home directory location.

Viewing Information About Oracle Homes

You can view information about Oracle Home directory locations by using the dbhome info subcommand of the dbaascli utility as follows.

1. Connect to a compute node as the opc user.
   For detailed instructions, see Connecting to an Exadata DB System.
2. Start a root-user command shell:

```
$ sudo -s
#
```

3. Execute the dbaascli command with the dbhome info subcommand:

```
# dbaascli dbhome info
```

4. When prompted, press **Enter** to view information about all Oracle Homes registered in your Exadata DB system, or specify an Oracle Home name to view information only about that Oracle Home.
5. Exit the root-user command shell:

```
# exit
$
```

Moving a Database to Another Oracle Home

Moving a database to another Oracle Home enables you to consolidate existing Oracle Homes and manage the storage that they consume. You can move a database to another Oracle Home by using the `database move` subcommand of the `dbaascli` utility as follows.

1. Connect to a compute node as the `opc` user.
   For detailed instructions, see Connecting to an Exadata DB System.
2. Start a root-user command shell:

   ```
   $ sudo -s
   #
   ```

3. Ensure that all database instances associated with the database deployment are up and running.

   ```
   # dbaascli database status --dbname <dbname>
   ```

   In the preceding command, *<dbname>* specifies the name of the database that you want to check.
   Restart any database instances that are not running and open.
4. Execute the `dbaascli` command with the `database move` subcommand:

   ```
   # dbaascli database move --dbname <dbname> --ohome <oracle_home>
   ```

   In the preceding command:

   - *<dbname>* — specifies the name of the database that you want to move.
   - *<oracle_home>* — specifies the path to an existing Oracle Home directory location, which you want the specified database to use.

   When performing a move operation to an Oracle Home with a different patch level, if the database is part of an Exadata DB system Data Guard implementation, then ensure that you move the standby database to the new patchset before you move the primary database.
5. Exit the root-user command shell:

   ```
   # exit
   $
   ```

Creating an Oracle Home

You can create an Oracle Home directory location and software installation, without creating a database, by using the `dbhome create` subcommand of the `dbaascli` utility as follows.

1. Connect to a compute node as the `opc` user.
   For detailed instructions, see Connecting to an Exadata DB System.
2. Start a root-user command shell:

   ```
   $ sudo -s
   #
   ```

3. Run the `dbaascli` command with the `dbhome create` subcommand:

   ```
   # dbaascli dbhome create --version <software_version>
   ```

   In the preceding command, *<software_version>* specifies an Oracle Database software version. For example, 19000, 18000, 12201, 12102, or 11204. The latest available bundle patch for the specified software version is automatically used.
   To see information about Oracle Database software images that are available in your Exadata DB system, including software version and bundle patch details, use the `dbaascli dbimage list` command.
   When prompted, type `yes` to confirm that the installation is based on a local software image.
4. Exit the root-user command shell:

   ```
   # exit
   $
   ```

Deleting an Oracle Home

If an Oracle Home directory does not support any databases, you can delete it by using the `dbhome purge` subcommand of the `dbaascli` utility as follows.

1. Connect to a compute node as the `opc` user.
   For detailed instructions, see Connecting to an Exadata DB System.
2. Start a root-user command shell:

```
$ sudo -s
#
```

3. Execute the `dbaascli` command with the `dbhome purge` subcommand:

```
# dbaascli dbhome purge
```

4. When prompted, enter:
   - `1` — if you want to specify the Oracle Home name for the location being purged.
   - `2` — if you want to specify the Oracle Home directory path for the location being purged.
5. When next prompted, enter the Oracle Home name or directory path for the location being purged.

   If your entries are valid and the Oracle Home is not associated with a database, then the Oracle binaries are removed from the Oracle Home directory location and the associated metadata is removed from the system.
6. Exit the root-user command shell:

```
# exit
$
```

Using Oracle Data Guard with Exadata DB Systems

This topic explains how to use the Console or the API to manage Data Guard associations in your Exadata DB system. When you use the Console or the API to enable Data Guard for an Oracle Cloud Infrastructure Exadata DB system database:

- The standby database is a physical standby.
- The peer databases (primary and standby) are in the same compartment, they are the same shape, and their database versions are identical.
- You are limited to one standby database for each primary database.

To configure a Data Guard system across regions or between on-premises and Oracle Cloud Infrastructure DB systems, or to configure your database with multiple standbys, you must access the database host directly and set up Data Guard manually.

For complete information on Oracle Data Guard, see the Data Guard Concepts and Administration documentation on the Oracle Document Portal.

Required IAM Service Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don't have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

If you're new to policies, see Getting Started with Policies and Common Policies.

Prerequisites

An Exadata DB system Data Guard implementation requires two Exadata DB systems, one containing the primary database and one containing the standby database. When you enable Data Guard for an Exadata DB system database, the DB system with the database to be used as the standby must already exist before you enable Data Guard.

Network Requirements

Ensure that your environment meets the following network requirements:

- Peer DB systems in the Data Guard association can use different subnets but they must use the same VCN, and port 1521 must be open.
- **Important!** Properly configure the security list ingress and egress rules for the subnets of both DB systems in the Data Guard association to allow TCP traffic to flow between the applicable ports. Ensure that the rules you create are stateful (the default).
  For example, if the subnet of the primary DB System uses the source CIDR 10.0.0.0/24 and the subnet of the standby DB system uses the source CIDR 10.0.1.0/24, create rules as shown in the following example.

Note

The egress rules in the example show how to enable TCP traffic only for port 1521, which is a minimum requirement for Data Guard to work. If TCP traffic is already enabled on all of your outgoing ports (0.0.0.0/0), then you need not explicitly add these specific egress rules.

Security List for Primary DB System's Subnet

```
Ingress Rules:

Stateless: No
Source: 10.0.1.0/24
IP Protocol: TCP
Source Port Range: All
Destination Port Range: 1521
Allows: TCP traffic for ports: 1521

Egress Rules:

Stateless: No
Destination: 10.0.1.0/24
IP Protocol: TCP
Source Port Range: All
Destination Port Range: 1521
Allows: TCP traffic for ports: 1521
```

Security List for Standby DB System's Subnet

```
Ingress Rules:

Stateless: No
Source: 10.0.0.0/24
IP Protocol: TCP
Source Port Range: All
Destination Port Range: 1521
```

```
Allows: TCP traffic for ports: 1521

Egress Rules:

Stateless: No
Destination: 10.0.0.0/24
IP Protocol: TCP
Source Port Range: All
Destination Port Range: 1521
Allows: TCP traffic for ports: 1521
```

For information about creating and editing rules, see Security Lists.

PASSWORD REQUIREMENTS

For Data Guard operations to work, the SYS password and the TDE wallet password of the primary and standby databases must all be the same. If you change any one of these passwords, you must update the rest of the passwords to match. See Changing the Database Passwords to learn how to change the SYS password or the TDE wallet password.

If you make any change to the TDE wallet (such as adding a master key for a new PDB or changing the wallet password), you must copy the wallet from the primary to the standby so that Data Guard can continue to operate. For Oracle Database versions earlier than 12.2, if you change the SYS password on one of the peers, you need to manually sync the password file between the DB systems.

Availability Domain Considerations for Data Guard

Oracle recommends that the DB system of the standby database be in a different availability domain from the DB system of the primary database to improve availability and disaster recovery.

Working with Data Guard

Oracle Data Guard ensures high availability, data protection, and disaster recovery for enterprise data. The Oracle Cloud Infrastructure Database Data Guard implementation requires two databases, one in a primary role and one in a standby role. The two databases compose a Data Guard association. Most of your applications access the primary database. The standby database is a transactionally consistent copy of the primary database.

Data Guard maintains the standby database by transmitting and applying redo data from the primary database. If the primary database becomes unavailable, you can use Data Guard to switch or fail over the standby database to the primary role.

SWITCHOVER

A switchover reverses the primary and standby database roles. Each database continues to participate in the Data Guard association in its new role. A switchover ensures no data loss. Performing planned maintenance on a DB system with a Data Guard association is typically done by switching the primary to the standby role, performing maintenance on the standby, and then switching it back to the primary role.

FAILOVER

A failover transitions the standby database into the primary role after the existing primary database fails or becomes unreachable. A failover might result in some data loss when you use **Maximum Performance** protection mode.

REINSTATE

Reinstates a database into the standby role in a Data Guard association. You can use the reinstate command to return a failed database into service after correcting the cause of failure.

Note

You can't terminate a primary database that has a Data Guard association with a peer (standby) database. Delete the standby database first. Alternatively, you can switch over the primary database to the standby role, and then terminate it.

You can't terminate a Exadata DB system that includes Data Guard enabled databases. You must first remove the Data Guard association by terminating the standby database.

Using the Console

The Console allows you to enable a Data Guard association between databases, change the role of a database in a Data Guard association using either a *switchover* or a *failover* operation, and *reinstate* a failed database.

When you enable Data Guard, a separate Data Guard association is created for the primary and the standby database.

To enable Data Guard on an Exadata DB system

If you don't already have Exadata DB systems with the databases that will assume the primary and standby roles, create them as described in To create an Exadata DB system. A new DB system includes an initial database.

1. Open the navigation menu. Under **Database**, click **Bare Metal, VM, and Exadata**.
2. Choose the **Compartment** that contains the Exadata DB system with the database for which you want to enable Data Guard.
3. Click the name of the Exadata DB system that contains the database you want to assume the primary role, and then click the name of that database.

Tip

If Data Guard is already enabled, a shield icon appears next to the database name.

4. Under **Resources**, click **Data Guard Associations**.
5. Click **Enable Data Guard**.
6. In the **Enable Data Guard** dialog box, configure your Data Guard association.
   - **Protection Mode:** (Informational) The protection mode used for this Data Guard association. The Console supports only **Maximum Performance**.
   - **Availability Domain:** The availability domain of the peer DB system.

- **Peer DB System:** Select the DB system that contains the peer (standby) database. The peer DB system must be in the same compartment, and must be the same shape.
- **Transport Type:** (Informational) The redo transport type used for this Data Guard association. The Console supports only **Async**.
- **Database Admin Password:** Enter the primary database admin password. The same password is used for the standby database.

Important

The admin password and the TDE password must be the same. If they are not, follow the instructions in Changing the Database Passwords to align them.

7. Click **Enable**.
   When the association is created, a shield icon appears next to the name of this database and its peer, and their respective roles (primary or standby) are displayed.

To perform a database switchover

You initiate a switchover operation by using the Data Guard association of the primary database.

1. Open the navigation menu. Under **Database**, click **Bare Metal, VM, and Exadata**.
2. Choose the **Compartment** that contains the Exadata DB system with the primary database you want to switch over.
3. Click the DB system name, and then click the name of the primary database.
4. Under **Resources**, click **Data Guard Associations**.

5. For the Data Guard association on which you want to perform a switchover, click the Actions icon (three dots), and then click **Switchover**.
6. In the **Switchover Database** dialog box, enter the database admin password, and then click **OK**.
   This database should now assume the role of the standby, and the standby should assume the role of the primary in the Data Guard association.

To perform a database failover

You initiate a failover operation by using the Data Guard association of the standby database.

1. Open the navigation menu. Under **Database**, click **Bare Metal, VM, and Exadata**.
2. Choose the **Compartment** that contains the Exadata DB system with the primary database's peer standby you want to fail over to.
3. Click the DB system name, and then click the name of the standby database.
4. Under **Resources**, click **Data Guard Associations**.
5. For the Data Guard association on which you want to perform a failover, click **Failover**.
6. In the **Failover Database** dialog box, enter the database admin password, and then click **OK**.
   This database should now assume the role of the primary, and the old primary's role should display as **Disabled Standby**.

To reinstate a database

After you fail over a primary database to its standby, the standby assumes the primary role and the old primary is identified as a disabled standby. After you correct the cause of failure, you can reinstate the failed database as a functioning standby for the current primary by using its Data Guard association.

1. Open the navigation menu. Under **Database**, click **Bare Metal, VM, and Exadata**.
2. Choose the **Compartment** that contains the Exadata DB system with the failed database you want to reinstate.
3. Click the DB system name, and then click the database name.
4. Under **Resources**, click **Data Guard Associations**.
5. For the Data Guard association on which you want to reinstate this database, click the Actions icon (three dots), and then click **Reinstate**.
6. In the **Reinstate Database** dialog box, enter the database admin password, and then click **OK**.
   This database should now be reinstated as the standby in the Data Guard association.

To terminate a Data Guard association on an Exadata DB system

On an Exadata DB system, you remove a Data Guard association by terminating the standby database.

1. Open the navigation menu. Under **Database**, click **Bare Metal, VM, and Exadata**.
2. Choose the **Compartment** that contains the Exadata DB system that includes the standby database you want to terminate.
3. Click the DB system name.
4. For the standby database you want to terminate, click the Actions icon (three dots), and then click **Terminate**.
5. In the **Terminate Database** dialog box, enter the name of the database, and then click **OK**.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use these API operations to manage Data Guard associations on an Exadata DB system:

- CreateDataGuardAssociation
- GetDataGuardAssociation
- ListDataGuardAssociations
- SwitchoverDataGuardAssociation
- FailoverDataGuardAssociation
- ReinstateDataGuardAssociation
- DeleteDbHome - To terminate an Exadata DB system Data Guard association, you delete the standby database.

For the complete list of APIs for the Database service, see Database Service API.

Configuring Oracle Database Features for Exadata DB Systems

This topic describes how to configure Oracle Multitenant, tablespace encryption, and Huge Pages for use with your Exadata DB systems.

Using Oracle Multitenant on an Exadata DB system

When you create an Exadata DB system that uses Oracle Database 12c or later, an Oracle Multitenant environment is created.

The multitenant architecture enables an Oracle database to function as a multitenant container database (CDB) that includes zero, one, or many pluggable databases (PDBs). A PDB is a portable collection of schemas, schema objects, and non-schema objects that appears to an Oracle Net Services client as a non-CDB. All Oracle databases using versions earlier than Oracle Database 12c are non-CDBs.

To use Oracle Transparent Data Encryption (TDE) in a pluggable database (PDB), you must create and activate a master encryption key for the PDB.

In a multitenant environment, each PDB has its own master encryption key which is stored in a single keystore used by all containers.

You must export and import the master encryption key for any encrypted PDBs you plug into your Exadata DB system CDB.

If your source PDB is encrypted, you must export the master encryption key and then import it.

You can export and import all of the TDE master encryption keys that belong to the PDB by exporting and importing the TDE master encryption keys from within a PDB. Export and import of TDE master encryption keys support the PDB unplug and plug operations. During a PDB unplug and plug, all of the TDE master encryption keys that belong to a PDB, as well as the metadata, are involved.

See "Exporting and Importing TDE Master Encryption Keys for a PDB" in *Oracle Database Advanced Security Guide* for Release 19, 18, 12.2 or 12.1.

See "ADMINISTER KEY MANAGEMENT" in *Oracle Database SQL Language Reference* for Release 19, 18, 12.2 or 12.1.

To determine if you need to create and activate an encryption key for the PDB

1. Invoke SQL*Plus and log in to the database as the `SYS` user with `SYSDBA` privileges.
2. Set the container to the PDB:

   ```
   SQL> ALTER SESSION SET CONTAINER = pdb;
   ```

3. Query `V$ENCRYPTION_WALLET` as follows:

   ```
   SQL> SELECT wrl_parameter, status, wallet_type FROM v$encryption_wallet;
   ```

   If the `STATUS` column contains a value of `OPEN_NO_MASTER_KEY`, you need to create and activate the master encryption key.

To create and activate the master encryption key in a PDB

1. Set the container to the PDB:

   ```
   SQL> ALTER SESSION SET CONTAINER = pdb;
   ```

2. Create and activate a master encryption key in the PDB by executing the following command:

```
SQL> ADMINISTER KEY MANAGEMENT SET KEY USING TAG 'tag' FORCE KEYSTORE IDENTIFIED BY keystore-
password WITH BACKUP USING 'backup_identifier';
```

In the previous command:

- `keystore-password` is the keystore password. By default, the keystore password is set to the value of the administration password that is specified when the database is created.
- The optional `USING TAG 'tag'` clause can be used to associate a tag with the new master encryption key.
- The `WITH BACKUP` clause, and the optional `USING 'backup_identifier'` clause, can be used to create a backup of the keystore before the new master encryption key is created.

See also `ADMINISTER KEY MANAGEMENT` in *Oracle Database SQL Language Reference for Release*19, 18 or 12.2.

Note

To enable key management operations while the keystore is in use, Oracle Database 12c Release 2, and later, includes the `FORCE KEYSTORE` option to the `ADMINISTER KEY MANAGEMENT` command. This option is also available for Oracle Database 12c Release 1 with the October 2017, or later, bundle patch.

If your Oracle Database 12c Release 1 database does not have the October 2017, or later, bundle patch installed, you can perform the following alternative steps:

a. Close the keystore.

b. Open the password-based keystore.

c. Create and activate a master encryption key in the PDB by using `ADMINISTER KEY MANAGEMENT` without the `FORCE KEYSTORE` option.

d. Update the auto-login keystore by using `ADMINISTER KEY MANAGEMENT` with the `CREATE AUTO_LOGIN KEYSTORE FROM KEYSTORE` option.

3. Query `V$ENCRYPTION_WALLET` again to verify that the `STATUS` column is set to `OPEN`:

```
SQL> SELECT wrl_parameter, status, wallet_type FROM v$encryption_wallet;
```

4. Query `V$INSTANCE` and take note of the value in the `HOST_NAME` column, which identifies the database server that contains the newly updated keystore files:

```
SQL> SELECT host_name FROM v$instance;
```

5. Copy the updated keystore files to all of the other database servers.
   To distribute the updated keystore, you must perform the following actions on each database server that does not contain the updated keystore files:
   a. Connect to the root container and query `V$ENCRYPTION_WALLET`. Take note of the keystore location contained in the `WRL_PARAMETER` column:
      ```
      SQL> SELECT wrl_parameter, status FROM v$encryption_wallet;
      ```
   b. Copy the updated keystore files.
      You must copy all of the updated keystore files from a database server that is already updated. Use the keystore location observed in the `WRL_PARAMETER` column of `V$ENCRYPTION_WALLET`.

   Open the updated keystore:

   ```
   SQL> ADMINISTER KEY MANAGEMENT SET KEYSTORE open FORCE KEYSTORE IDENTIFIED BY keystore-password
   CONTAINER=all;
   ```

Note

To enable key management operations while the keystore is in use, Oracle Database 12c Release 2, and later, includes the `FORCE KEYSTORE` option to the `ADMINISTER KEY MANAGEMENT` command. This option is also available for Oracle Database 12c Release 1 with the October 2017, or later, bundle patch.

If your Oracle Database 12c Release 1 database does not have the October 2017, or later, bundle patch installed, you can perform the following alternative steps:

a. Close the keystore before copying the updated keystore files.

b. Copy the updated keystore files.

c. Open the updated keystore by using `ADMINISTER KEY MANAGEMENT` without the `FORCE KEYSTORE` option.

6. Query `GV$ENCRYPTION_WALLET` to verify that the `STATUS` column is set to `OPEN` across all of the database instances:

```
SQL> SELECT wrl_parameter, status, wallet_type FROM gv$encryption_wallet;
```

To export and import a master encryption key

1. Export the master encryption key.
   a. Invoke SQL*Plus and log in to the PDB.
   b. Execute the following command:

```
SQL> ADMINISTER KEY MANAGEMENT EXPORT ENCRYPTION KEYS WITH SECRET "secret" TO 'filename'
IDENTIFIED BY keystore-password;
```

2. Import the master encryption key.
    a. Invoke SQL*Plus and log in to the PDB.
    b. Execute the following command:

```
SQL> ADMINISTER KEY MANAGEMENT IMPORT ENCRYPTION KEYS WITH SECRET "secret" FROM 'filename'
IDENTIFIED BY keystore-password;
```

Managing Tablespace Encryption

By default, all new tablespaces that you create in an Exadata database are encrypted.

However, the tablespaces that are initially created when the database is created may not be encrypted by default.

- For databases that use Oracle Database 12c Release 2 or later, only the `USERS` tablespaces initially created when the database was created are encrypted. No other tablespaces are encrypted including the non-`USERS` tablespaces in:
    - The root container (`CDB$ROOT`).
    - The seed pluggable database (`PDB$SEED`).
    - The first PDB, which is created when the database is created.
- For databases that use Oracle Database 12c Release 1 or Oracle Database 11g, none of the tablespaces initially created when the database was created are encrypted.

For further information about the implementation of tablespace encryption in Exadata, along with how it impacts various deployment scenarios, see Oracle Database Tablespace Encryption Behavior in Oracle Cloud.

Creating Encrypted Tablespaces

User-created tablespaces are encrypted by default.

By default, any new tablespaces created by using the `SQL CREATE TABLESPACE` command are encrypted with the AES128 encryption algorithm. You do not need to include the `USING 'encrypt_algorithm'` clause to use the default encryption.

You can specify another supported algorithm by including the USING 'encrypt_algorithm' clause in the CREATE TABLESPACE command. Supported algorithms are AES256, AES192, AES128, and 3DES168.

MANAGING TABLESPACE ENCRYPTION

You can manage the software keystore (known as an Oracle wallet in Oracle Database 11g), the master encryption key, and control whether encryption is enabled by default.

MANAGING THE MASTER ENCRYPTION KEY

Tablespace encryption uses a two-tiered, key-based architecture to transparently encrypt (and decrypt) tablespaces. The master encryption key is stored in an external security module (software keystore). This master encryption key is used to encrypt the tablespace encryption key, which in turn is used to encrypt and decrypt data in the tablespace.

When a database is created on an Exadata DB system, a local software keystore is created. The keystore is local to the compute nodes and is protected by the administration password specified during the database creation process. The auto-login software keystore is automatically opened when the database is started.

You can change (rotate) the master encryption key by using the `ADMINISTER KEY MANAGEMENT SQL` statement. For example:

```
SQL> ADMINISTER KEY MANAGEMENT SET ENCRYPTION KEY USING TAG 'tag'
IDENTIFIED BY password WITH BACKUP USING 'backup';
```

```
keystore altered.
```

See "Managing the TDE Master Encryption Key" in *Oracle Database Advanced Security Guide* for Release 19, 18, 12.2 or 12.1 or "Setting and Resetting the Master Encryption Key" in *Oracle Database Advanced Security Administrator's Guide* for Release 11.2.

CONTROLLING DEFAULT TABLESPACE ENCRYPTION

The `ENCRYPT_NEW_TABLESPACES` initialization parameter controls the default encryption of new tablespaces. In Exadata databases, this parameter is set to `CLOUD_ONLY` by default.

Values of this parameter are as follows.

Value	Description
ALWAYS	During creation, tablespaces are transparently encrypted with the AES128 algorithm unless a different algorithm is specified in the ENCRYPTION clause.
CLOUD_ ONLY	Tablespaces created in an Exadata database are transparently encrypted with the AES128 algorithm unless a different algorithm is specified in the ENCRYPTION clause. For non-cloud databases, tablespaces are only encrypted if the ENCRYPTION clause is specified. ENCRYPTION is the default value.
DDL	During creation, tablespaces are not transparently encrypted by default, and are only encrypted if the ENCRYPTION clause is specified.

Note

With Oracle Database 12c Release 2 (12.2), or later, you can no longer create an unencrypted tablespace in an Exadata database. An error message is returned if you set ENCRYPT_NEW_TABLESPACES to DDL and issue a CREATE TABLESPACE command without specifying an ENCRYPTION clause.

Managing Huge Pages

Huge Pages provide considerable performance benefits for Oracle Database on systems with large amounts of memory. Oracle Database on an Exadata DB system hosted in Oracle Cloud Infrastructure provides configuration settings that make use of Huge Pages by default; however, you can make manual adjustments to optimize the configuration of Huge Pages.

Huge Pages is a feature integrated into the Linux kernel 2.6. Enabling Huge Pages makes it possible for the operating system to support large memory pages. Using Huge Pages can improve system performance by reducing the amount of system CPU and memory resources required to manage Linux page tables, which store the mapping between virtual and physical

memory addresses. For Oracle Databases, using Huge Pages can drastically reduce the number of page table entries associated with the System Global Area (SGA).

On Exadata DB systems hosted in Oracle Cloud Infrastructure, a standard page is 4 KB, while a Huge Page is 2 MB by default. Therefore, an Oracle Database on an Exadata DB system with a 50 GB SGA requires 13,107,200 standard pages to house the SGA, compared with only 25,600 Huge Pages. The result is much smaller page tables, which require less memory to store and fewer CPU resources to access and manage.

Adjusting the Configuration of Huge Pages

The configuration of Huge Pages for Oracle Database is a two-step process:

- At the operating system level, the overall amount of memory allocated to Huge Pages is controlled by the vm.nr_hugepages entry in the /etc/sysctl.conf file. This setting is made on each compute node in the environment and it is strongly recommended that the setting is consistent across all of the compute nodes. To alter the Huge Page allocation, you can execute the following command on each compute node as the root user:

  ```
  # sysctl -w vm.nr_hugepages=value
  ```

  where `value` is the number of Huge Pages that you want to allocate.
  On Exadata DB systems hosted in Oracle Cloud Infrastructure, each Huge Page is 2 MB by default. Therefore, to allocate 50 GB of memory to Huge Pages you can execute the following command:

  ```
  # sysctl -w vm.nr_hugepages=25600
  ```

- At the Oracle Database level, the use of Huge Pages is controlled by the `USE_LARGE_PAGES` instance parameter setting. This setting applies to each database instance in a clustered database. Oracle strongly recommends a consistent setting across all of the database instances associated with a database. The following options are available:
  - `TRUE` — specifies that the database instance can use Huge Pages if they are available. For all versions of Oracle Database after 11.2.0.3, Oracle allocates as much of the SGA as it can, using Huge Pages. When the Huge Page allocation is exhausted, standard memory pages are used.

- `FALSE` — specifies that the database instance does not use Huge Pages. This setting is generally not recommended if Huge Pages are available.
- `ONLY` — specifies that the database instance must use Huge Pages. With this setting, the database instance fails to start if the entire SGA cannot be accommodated in Huge Pages.

If you make any adjustments at either the operating system or Oracle Database level, ensure that the overall configuration works.

For more information, see the *Oracle Database Administrator's Reference for Linux and UNIX-Based Operating Systems* for Release 19, 18, 12.1, or 11.2 for a general overview of Huge Pages and more information about configuring Huge Pages. Also, see `USE_LARGE_PAGES` in the *Oracle Database Reference* for Release 12.2, 12.1, or 11.2.

DB System Time Zone

Note

This topic applies only to Exadata DB systems.

The Time Zone field in the Console and in the API allows you to launch an Exadata DB system with a time zone other than UTC (the default). Although UTC is the recommended time zone to use, having a common time zone for your database clients and application hosts can simplify management and troubleshooting for the database administrator.

The time zone that you specify when you create the DB system applies to the host and to the Oracle Grid Infrastructure, and controls the time zone of the database log files. The time zone of the database itself is not affected, however, the database's time zone affects only the timestamp datatype. By default, it is set to UTC and although you can change it manually, Oracle recommends that you keep it as UTC to avoid data conversion and improve performance when data is transferred among databases. This is especially important for distributed databases, replication, and exporting and importing.

Time Zone Options

Whether you use the Console or the API, the time zone options you can select from are represented in the named region format, for example, *America/Los_Angeles*. The Console allows you to select UTC, the time zone detected in your browser (if your browser supports time zone detection), or an alternate time zone.

To specify an alternate time zone (the **Select Another Time Zone** option), you first select a value in the Time Zone Prefix field to narrow the list of time zones from which to select in the Time Zone Suffix field. In the *America/Los_Angeles* example, *America* is the time zone prefix and *Los_Angeles* is the time zone suffix. The items you see in the Time Zone Prefix and Time Zone Suffix fields roughly correlate with the time zones supported in both the Java.util.TimeZone class and on the Linux operating system. If you do not see the time zone you are looking for, try selecting "Miscellaneous" as the time zone prefix.

Tip

If you are using the API and would like to see a list of supported time zones, you can examine the time zone options in the Console. These options appear in the **Launch DB System** dialog when you show advanced options after you select an Exadata DB system shape.

Changing Time Zones After Provisioning

Follow these steps if you need to change the time zone of the Exadata DB system, Oracle Grid Infrastructure, or database, after you launch the DB system:

To change the time zone of the DB system host

1. Log on to the host system as `root`.
2. Stop the CRS stack on all of the Exadata compute nodes.

```
#Grid_Home/bin/crsctl stop crs
```

3. Run the following commands to check the current time zone and to change it to the time zone you choose:

```
$ cat /etc/sysconfig/clock
ZONE="America/New_York"
$ cp -p /etc/sysconfig/clock /etc/sysconfig/clock.20160629

$ vi /etc/sysconfig/clock
ZONE="Europe/Berlin"

$ date
Wed Jun 29 10:35:17 EDT 2016
$ ln -sf /usr/share/zoneinfo/Europe/Berlin /etc/localtime
$ date
Wed Jun 29 16:35:27 CEST 2016
```

   In this example, the time zone was changed from *America/New_York* to *Europe/Berlin*.

Tip

To see a list of valid time zones on the host, you can run the `ls -l /usr/share/zoneinfo` command.

4. (Optional) Verify that `/opt/oracle.cellos/cell.conf` indicates the correct time zone. Using our example, the time zone entry in this file would be `<Timezone>Europe/Berlin</Timezone>`.
5. Restart the CRS stack on all of the Exadata compute nodes.

```
#Grid_Home/bin/crsctl start crs
```

To change the time zone of the Oracle Grid Infrastructure

The time zone of the Oracle Grid Infrastructure determines the time zone of the database log files. You can change this time zone by updating the `TZ` property in the `GRID_HOME/crs/install/s_crsconfig_`*`<node_name>`*`_env.txt` configuration file.

1. Ensure that you are logged onto the host as `root` and that the CRS stack is stopped on all of the Exadata compute nodes. See To change the time zone of the DB system host.
2. Inspect the current time zone value in the `GRID_HOME/crs/install/s_crsconfig_<node_name>_env.txt` file.

```
$ cat /u01/app/12.1.0.2/grid/crs/install/s_crsconfig_node1_env.txt
################################################################################
#This file can be used to set values for the NLS_LANG and TZ environment
#variables and to set resource limits for Oracle Clusterware and
#Database processes.
#1. The NLS_LANG environment variable determines the language and
#   characterset used for messages. For example, a new value can be
#   configured by setting NLS_LANG=JAPANESE_JAPAN.UTF8
#2. The Time zone setting can be changed by setting the TZ entry to
#   the appropriate time zone name. For example, TZ=America/New_York
#3. Resource limits for stack size, open files and number of processes
#   can be specified by modifying the appropriate entries.
#
#Do not modify this file except as documented above or under the
#direction of Oracle Support Services.
################################################################################
TZ=UTC
NLS_LANG=AMERICAN_AMERICA.WE8ISO8859P1
CRS_LIMIT_STACK=2048
CRS_LIMIT_OPENFILE=65536
CRS_LIMIT_NPROC=16384
TNS_ADMIN=
```

   In this example, the time zone is set to UTC.
3. Modify the time zone value, as applicable. Perform this task for all nodes in the cluster.
4. Restart the CRS stack on all of the Exadata compute nodes.

```
#Grid_Home/bin/crsctl start crs
```

For more information about changing the time zone of the Grid Infrastructure, see How To Change Timezone for Grid Infrastructure (Doc ID 1209444.1).

To change the time zone of a database

Use the `ALTER DATABASE SET TIME_ZONE` command to change the time zone of a database. This command takes either a named region such as America/Los_Angeles or an absolute offset from UTC.

This example sets the time zone to UTC:

```
ALTER DATABASE SET TIME_ZONE = '+00:00';
```

You must restart the database for the change to take effect. For more information, see Setting the Database Time Zone.

Bare Metal and Virtual Machine DB Systems

Oracle Cloud Infrastructure offers 1-node DB systems on either bare metal or virtual machines, and 2-node RAC DB systems on virtual machines. If you need to quickly spin up a DB system for development or testing purposes, a special fast provisioning 1-node VM system is available.

You can manage these systems by using the Console, the API, the Oracle Cloud Infrastructure CLI, the Database CLI (DBCLI), Enterprise Manager, Enterprise Manager Express, or SQL Developer.

Note

This documentation is intended for Oracle database administrators and assumes familiarity with Oracle databases and tools. If you need additional information, see the product documentation available at http://docs.oracle.com/en/database/.

Supported Database Editions and Versions

All 1- node RAC DB systems support the following Oracle Database editions:

- Standard Edition
- Enterprise Edition
- Enterprise Edition - High Performance
- Enterprise Edition - Extreme Performance

2-node RAC DB systems require Oracle Enterprise Edition - Extreme Performance.

For standard provisioning of DB systems (using Oracle Automatic Storage Management (ASM) as your storage management software), the supported database versions are:

- Oracle Database 19c (19.0) *(available for virtual machine DB systems only)*
- Oracle Database 18c (18.0)
- Oracle Database 12c Release 2 (12.2)
- Oracle Database 12c Release 1 (12.1)
- Oracle Database 11g Release 2 (11.2)

For fast provisioning of 1-node Virtual Machine DB systems (using Logical Volume Manager as your storage management software), the supported database versions are:

- Oracle Database 19c (19.0) *(available for virtual machine DB systems only)*
- Oracle Database 18c (18.0)

Tip

Your DB system's operating system will periodically need to be updated, just as your Oracle Database software will need to be updated. Before attempting an OS update, be sure to read the information in Updating a DB System and back up your DB system's databases.

Availability of Older Database Versions for Virtual Machine DB Systems

For virtual machine DB systems, Oracle Cloud Infrastructure also supports the creation of DB systems using older database versions. For each shape, the latest version and the two prior versions of the release are available at provisioning.

Warning

If you need to launch your DB system with an older database version, see Critical Patch Updates for information on known security issues with your chosen database version. You will also need to analyze and patch known security issues for the operating system included with the older database version. See Securing Database for information on security best practices for databases in Oracle Cloud Infrastructure.

Bare Metal DB Systems

Bare metal DB systems consist of a single bare metal server running Oracle Linux 6.8, with locally attached NVMe storage. If the node fails, you can simply launch another system and restore the databases from current backups.

When you launch a bare metal DB system, you select a single Oracle Database Edition that applies to all the databases on that DB system. The selected edition cannot be changed. Each DB system can have multiple database homes, which can be different versions. Each database home can have only one database, which is the same version as the database home.

Shapes for Bare Metal DB Systems

When you launch a DB system, you choose a *shape*, which determines the resources allocated to the DB system. The available shapes for a bare metal DB system are:

- **BM.DenseIO2.52:** Provides a 1-node DB system (one bare metal server), with up to 52 CPU cores, 768 GB memory, and eight 6.4 TB locally attached NVMe drives (51.2 TB total) to the DB system.
- **BM.DenseIO1.36:** *Limited availability.* Provides a 1-node DB system (one bare metal server), with up to 36 CPU cores, 512 GB memory, and nine 3.2 TB locally attached NVMe drives (28.8 TB total) to the DB system.

  Note: BM.DenseO1.36 is available only to monthly universal credit customers existing on or before November 9th, 2018. This shape is available only in the US West (Phoenix), US East (Ashburn), and Germany Central (Frankfurt) regions.

Storage Considerations

The shape you choose for a bare metal DB system determines its total raw storage, but other options, like 2- or 3-way mirroring and the space allocated for data files, affect the amount of usable storage on the system. The following table shows how various configurations affect the usable storage for bare metal DB systems.

Shape	Raw Storage	Usable Storage with Normal Redundancy (2-way Mirroring)	Usable Storage with High Redundancy (3-way Mirroring)
BM.DenseIO2.52	51.2 TB NVMe	DATA 16 TB RECO 4 TB	DATA 9 TB RECO 2.3 TB
BM.DenseIO1.36 see note	28.8 TB NVMe	DATA 9.4 TB RECO 1.7 TB	DATA 5.4 TB RECO 1 TB

Note: BM.DenseIO1.36 availability is limited to monthly universal credit customers existing on or before November 9th, 2018, in the us-phoenix-1, us-ashburn-1, and eu-frankfurt-1 regions.

Virtual Machine DB Systems

There are two types of DB systems on virtual machines:

- A 1-node virtual machine DB system consists of one virtual machine.
- A 2-node virtual machine DB system consists of two virtual machines.

When you launch a virtual machine DB system, you select the Oracle Database Edition that applies to the database on that DB system. The selected edition cannot be changed. Unlike a bare metal DB system, a virtual machine DB system can have only a single database home, which in turn can have only a single database. The database can be a container database (CDB) with multiple pluggable databases (PDBs), if the edition is High Performance or Extreme Performance. The database will be the same version as the database home.

Virtual machine DB systems also differ from bare metal DB systems in the following ways:

- A virtual machine DB system database uses Oracle Cloud Infrastructure block storage instead of local storage. You specify a storage size when you launch the DB system, and you can scale up the storage as needed at any time.
- The number of CPU cores on an existing virtual machine DB system cannot be changed.

Fast Provisioning Option for 1-node Virtual Machine DB Systems

For 1-node virtual machine DB systems, Oracle Cloud Infrastructure provides have a "fast provisioning" option that allows you to create your DB system using Logical Volume Manager as your storage management software. The alternative ("standard provisioning") is to provision with Oracle Automatic Storage Management (ASM).

Note

- When using the fast provisioning option, the number and size of the block volumes specified during provisioning determines the maximum total storage available through scaling. See Storage Scaling Considerations for Virtual Machine Databases Using Fast Provisioning for details.
- Multi-node Virtual Machine DB systems require Oracle Automatic Storage Management and cannot be created using the fast-provisioning option.

Fault Domain Considerations for 2-node Virtual Machine DB Systems

When you provision a 2-node RAC DB systems, the system assigns each node to a different fault domain by default. Using the **Advanced Options** link in the provisioning dialog, you can select the fault domain(s) to be used for your 2-node RAC DB systems and the system will assign the nodes to your selected fault domains. Oracle recommends that you place each node of a 2-node RAC DB system in a different fault domain. For more information on fault domains, see Fault Domains.

Shapes for Virtual Machine DB Systems

When you launch a DB system, you choose a *shape*, which determines the resources allocated to the DB system.

The following table shows the available shapes for a virtual machine DB system on X7.

Shape	CPU Cores	Memory
VM.Standard2.1	1	15 GB
VM.Standard2.2	2	30 GB

Shape	CPU Cores	Memory
VM.Standard2.4	4	60 GB
VM.Standard2.8	8	120 GB
VM.Standard2.16	16	240 GB
VM.Standard2.24	24	320 GB

The following table shows the available shapes for a virtual machine DB system on X5.[see note]

Shape	CPU Cores	Memory
VM.Standard1.1[see note]	1	7 GB
VM.Standard1.2[see note]	2	14 GB
VM.Standard1.4[see note]	4	28 GB
VM.Standard1.8[see note]	8	56 GB
VM.Standard1.16[see note]	16	112 GB

Note: X5-based shapes availability is limited to monthly universal credit customers existing on or before November 9th, 2018, in the us-phoenix-1, us-ashburn-1, and eu-frankfurt-1 regions.

Storage Options for Virtual Machine DB Systems

Virtual machine DB systems use Oracle Cloud Infrastructure block storage. The following table shows details of the storage options for a virtual machine DB system. Total storage includes available storage plus recovery logs.

Available Storage (GB)	Total Storage (GB)
256	712
512	968
1024	1480
2048	2656
4096	5116
6144	7572
8192	10032
10240	12488
12288	14944
14336	17404
16384	19860
18432	22320
20480	24776
22528	27232
24576	29692
26624	32148
28672	34608
30720	37064
32768	39520

Available Storage (GB)	Total Storage (GB)
34816	41980
36864	44436
38912	46896
40960	49352

For 2-node RAC virtual machine DB systems, storage capacity is shared between the nodes.

Database Backups

See Backing Up a Database for information about the backup options you have for your cloud databases. See Backing Up a Database to Oracle Cloud Infrastructure Object Storage for information about managed automatic backups in Oracle Cloud Infrastructure.

Network Setup for DB Systems

Note

This topic is not applicable to Exadata DB systems. For information on the network setup for an Exadata DB system, see Network Setup for Exadata DB Systems.

Before you set up a bare metal or virtual machine DB system, you must set up a virtual cloud network (VCN) and other Networking service components. This topic describes the recommended configuration for the VCN.

VCN and Subnets

To launch a DB system, you must have:

- A VCN in the region where you want the DB system
- At least one subnet in the VCN (either a public subnet or a private subnet)

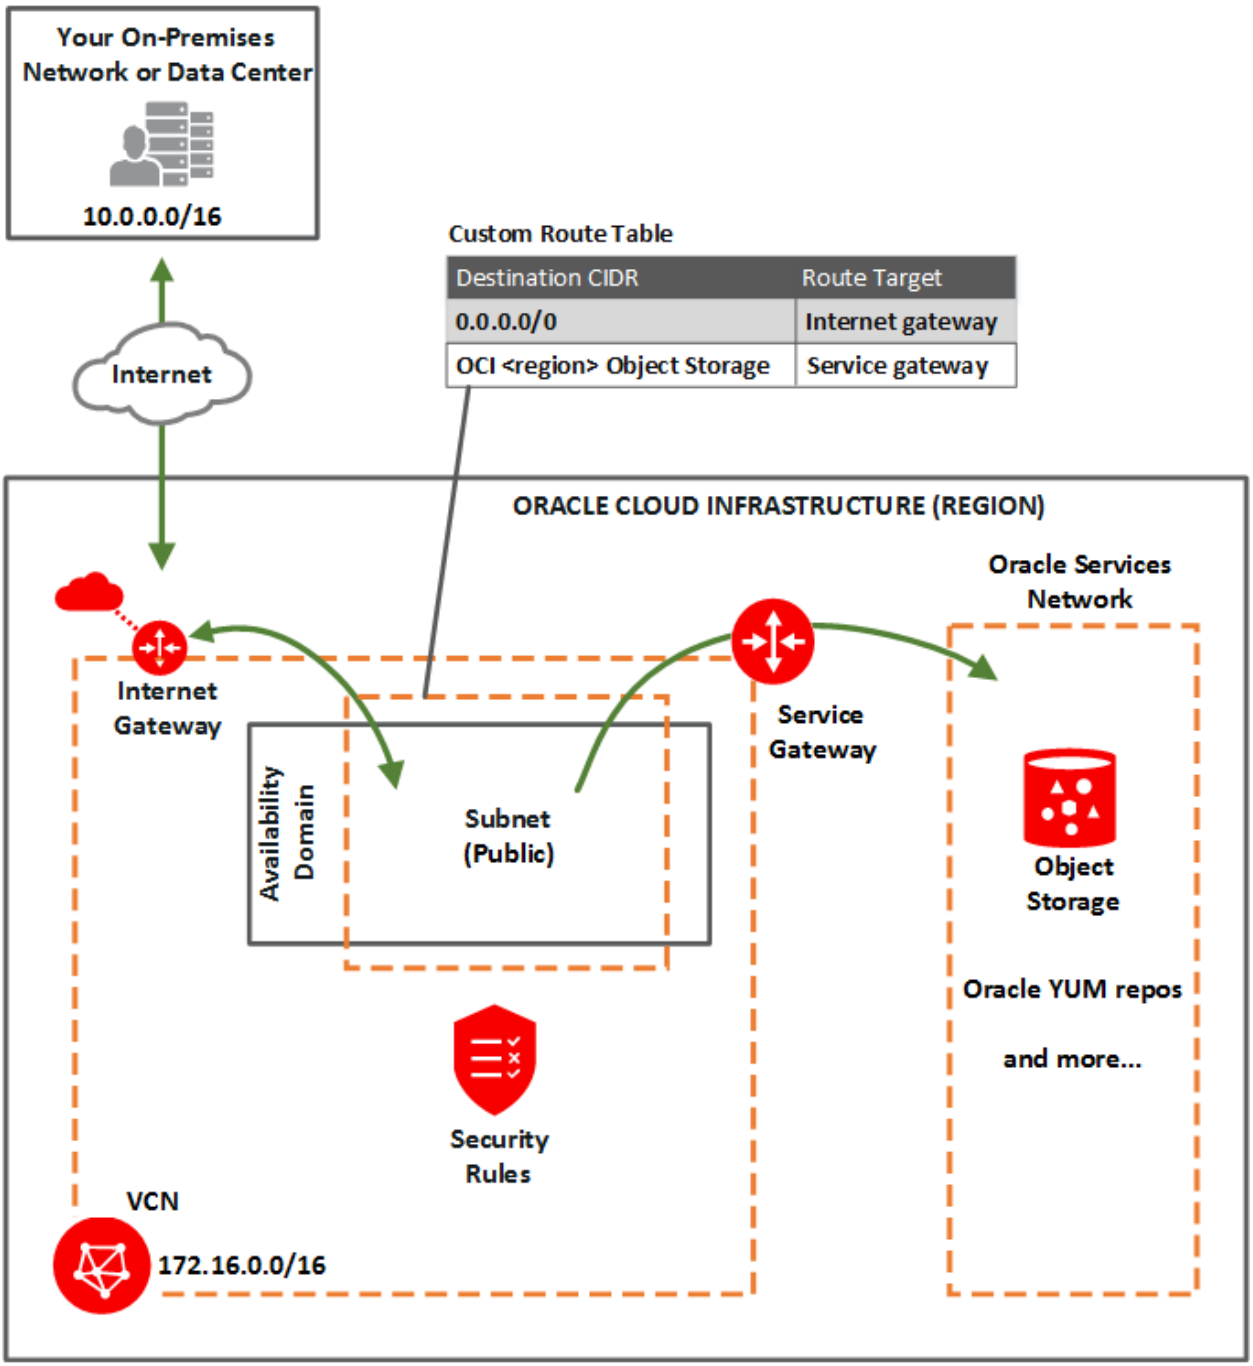
In general, Oracle recommends using regional subnets, which span all availability domains in the region. For a bare metal or virtual machine DB system, either a regional subnet or AD-specific subnet works. For more information, see About Regional Subnets.

You will create a custom route table. You will also create security rules to control traffic to and from the DB system's compute notes. More information follows about that.

Certain details of the VCN and subnet configuration depend on your choice for DNS resolution within the VCN. For more information, see DNS for the DB System.

Option 1: Public Subnet with Internet Gateway

This option can be useful when doing a proof-of-concept or development work. You can use this setup in production if you want to use an internet gateway with the VCN, or if you have services that run only on a public network and need access to the database. See the following diagram and description.



Your On-Premises Network or Data Center
10.0.0.0/16
Internet
Custom Route Table
Destination CIDR
Route Target
0.0.0.0/0
Internet gateway
OCI <region> Object Storage
Service gateway
ORACLE CLOUD INFRASTRUCTURE (REGION)
Oracle Services Network
Internet Gateway
Service Gateway
Availability Domain
Subnet (Public)
Object Storage
Oracle YUM repos
and more...
Security Rules
VCN
172.16.0.0/16

You set up:

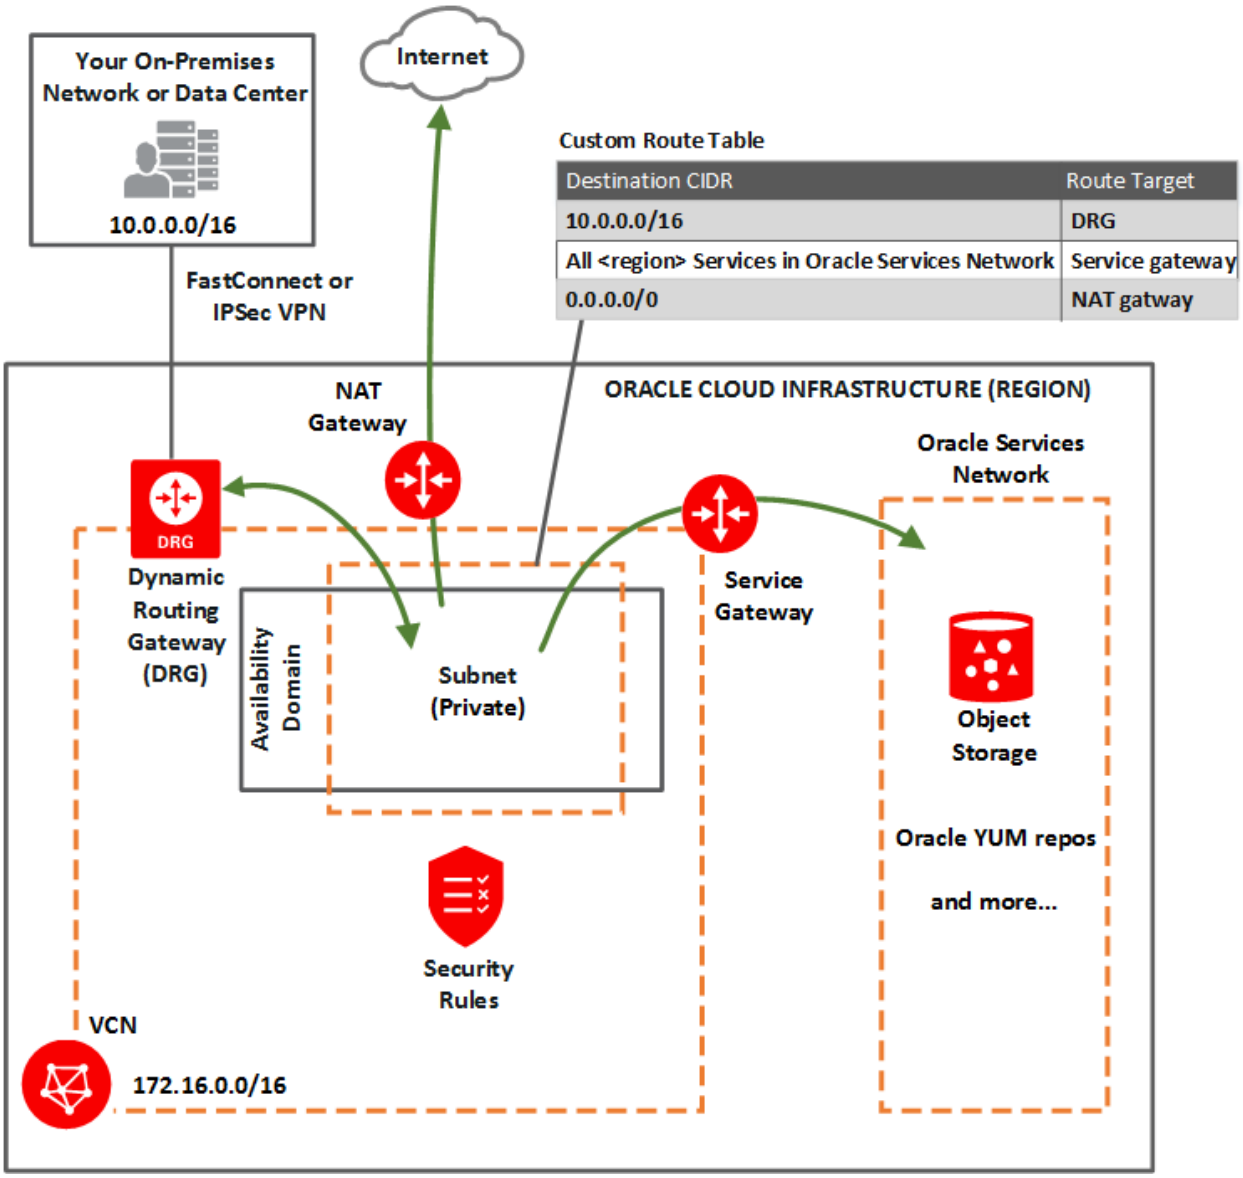
- Public subnet.
- Internet gateway.
- Service gateway to reach Object Storage for database backups and patching. Also see Option 1: Service Gateway Access Only to Object Storage.
- Route table: A custom route table for the subnet, with two rules:
  - A rule for 0.0.0.0/0, and target = internet gateway.
  - A rule for the service CIDR label called **OCI *<region>* Object Storage**, and target = the service gateway. Also see Option 1: Service Gateway Access Only to Object Storage.
- Security rules to enable the desired traffic to and from the DB system nodes. See Security Rules for the DB System.

Important

See this known issue for information about configuring route rules with *service gateway* as the target on route tables associated with public subnets.

OPTION 2: PRIVATE SUBNET

Oracle recommends this option for a production system. The subnet is private and cannot be reached from the internet. See the following diagram and description.



Your On-Premises Network or Data Center
10.0.0.0/16
Internet
FastConnect or IPSec VPN
Custom Route Table
Destination CIDR
Route Target
10.0.0.0/16
DRG
All <region> Services in Oracle Services Network
Service gateway
0.0.0.0/0
NAT gatway

Dynamic Routing Gateway (DRG)
Service Gateway
Availability Domain
Subnet (Private)
Object Storage
Oracle YUM repos
and more...
Security Rules
VCN
172.16.0.0/16

You set up:

- Private subnet.
- Gateways for the VCN:
  - Dynamic routing gateway (DRG), with a FastConnect or IPSec VPN to your on-premises network.
  - Service gateway to reach Object Storage for database backups and patching, and to reach Oracle YUM repos for OS updates. Also see Option 2: Service Gateway Access to Both Object Storage and YUM Repos.
  - NAT gateway (to reach public endpoints not supported by the service gateway).
- Route table: A custom route table for the subnet, with these rules:
  - A route for the on-premises network's CIDR, and target = DRG.
  - A rule for the service CIDR label called **All *<region>* Services in Oracle Services Network**, and target = the service gateway. Also see Option 2: Service Gateway Access to Both Object Storage and YUM Repos.
  - If you want to access the Oracle YUM repos through the NAT gateway, add a route rule for the regional YUM repo's public IP address, and target = the NAT gateway. If you just use the next rule only, the traffic to the YUM repo would still be routed to the service gateway, because the service gateway route is more specific than 0.0.0.0/0.
  - A rule for 0.0.0.0/0, and target = NAT gateway.
- Security rules to enable the desired traffic to and from the DB system nodes. See Security Rules for the DB System.

Requirements for IP Address Space

If you are setting up DB systems (and thus VCNs) in more than one region, make sure the IP address space of the VCNs does not overlap.

The subnet you create for a bare metal or virtual machine DB system cannot overlap with 192.168.16.16/28, which is used by the Oracle Clusterware private interconnect on the database instance.

The following table lists the *minimum* required subnet size.

Tip

The Networking service reserves three IP addresses in each subnet. Allocating a larger space for the subnet than the minimum required (for example, at least /25 instead of /28) can reduce the relative impact of those reserved addresses on the subnet's available space.

DB System Type	# Required IP Addresses	Minimum Subnet Size
1-node bare metal or virtual machine	1 + 3 reserved in subnet = 4	/30 (4 IP addresses)
2-node RAC virtual machine	(2 addresses * 2 nodes) + 3 for SCANs + 3 reserved in subnet = 10	/28 (16 IP addresses)

VCN Creation Wizard: Not for Production

The Networking section of the Console includes a handy wizard that creates a VCN along with related resources. It can be useful if you just want to try launching an instance. However, the wizard automatically chooses the address ranges and creates public subnets and an internet gateway. You may not want this for your production network, so Oracle recommends you create the VCN and other resources individually yourself instead of using the wizard.

DNS for the DB System

There are two choices for DNS and hostname resolution for the DB system:

- Recommended: Use the default DNS functionality in the VCN (called the *Internet and VCN Resolver*)
- Use a custom DNS resolver of your choice

The following table shows which choices are supported with each type of DB system, and the endpoints that need to be resolved for the DB system to function.

DB System Type	Supported DNS Choices	Endpoints to Be Resolved
1-node bare metal or virtual machine	• Recommended: Default (Internet and VCN Resolver) • Custom DNS resolver of your choice	• Object Storage endpoints (includes both the Object Storage endpoints and Swift endpoints) • Oracle YUM repo endpoints
2-node RAC virtual machine	• Default (Internet and VCN Resolver)	• Object Storage endpoints (includes both the Object Storage endpoints and Swift endpoints) • Oracle YUM repo endpoints • Single Client Access Names (SCANs)

The following sections give more details about the DNS choices.

Default (Internet and VCN Resolver)

See the preceding table for the types of DB systems that support the Internet and VCN Resolver.

Oracle recommends using the Internet and VCN Resolver for DNS. It's the default, built-in DNS functionality that comes with each VCN. It enables hosts in a VCN to resolve these items:

- Hostnames of other hosts in the same VCN
- Hostnames that are publicly published on the Internet

For general information about the Internet and VCN Resolver, see DNS in Your Virtual Cloud Network.

For a DB system, the Internet and VCN Resolver handles resolution of all necessary endpoints: Object Storage endpoints (includes both the Object Storage endpoints and Swift endpoints), YUM repos, and SCANs (SCANs are used only with 2-node RAC systems).

By default, each VCN is configured to use the Internet and VCN Resolver. If you plan to use a custom DNS resolver, you must configure the VCN in a different way. For more information, see Custom DNS Resolver.

To use the Internet and VCN Resolver with your DB System

As part of the overall network setup, perform these tasks:

1. Create the VCN with the required DNS settings:
   - When creating the VCN, select the check box for **Use DNS Hostnames in this VCN**.
   - Specify a DNS label for the VCN. See the restrictions in Hostname restrictions for using the Internet and VCN Resolver.
   - Notice that you cannot change these VCN DNS settings after you create the VCN.
2. Create each subnet with the required DNS settings:
   - When creating a subnet in the VCN, select the check box for **Use DNS Hostnames in this Subnet**.
   - Specify a DNS label for the subnet. See the restrictions in Hostname restrictions for using the Internet and VCN Resolver.
   - Notice that you cannot change these subnet DNS settings after you create the subnet.
3. Use the default set of DHCP options that come with the VCN:
   - When creating each subnet, configure it to use the VCN's default set of DHCP options.
   - By default, the default set of DHCP options is configured to use the Internet and VCN Resolver.
4. Create the DB system with a hostname prefix:

- Later, when creating the DB system, specify a value in the **Hostname Prefix** field. See the restrictions in Hostname restrictions for using the Internet and VCN Resolver.
- Notice that the DB system's **Host Domain Name** value is automatically assigned based on the VCN and subnet DNS labels.

The resulting DB system has a fully qualified domain name (FQDN) based on the hostname prefix, VCN label, and subnet label you specify.

Hostname restrictions for using the Internet and VCN Resolver

When you create the VCN, subnet, and DB system, you must carefully set the following identifiers, which are related to DNS in the VCN:

- VCN DNS label
- Subnet DNS label
- Hostname prefix for the DB system

These values make up the node's fully qualified domain name (FQDN):

`<hostname_prefix><RAC_node_#>.<subnet_DNS_label>.<VCN_DNS_label>.oraclevcn.com`

For RAC systems only, the Database service automatically appends a node number after the hostname prefix.

For example:

- Node 1: `dbsys1.ad1.acmevcniad.oraclevcn.com`
- Node 2: `dbsys2.ad1.acmevcniad.oraclevcn.com`

Requirement for the DB system's hostname prefix:

- Maximum 16 characters, otherwise the DB system deployment will fail.
- Cannot be the string *localhost*.

Requirements for the VCN and subnet DNS labels:

- Recommended maximum: 15 characters.
- No hyphens or underscores.
- Recommended: Include the region name in the VCN's name, and include the availability domain name in the subnet's name.
- The FQDN has a maximum total limit of 63 characters, so set the VCN and subnet DNS labels short enough to meet that requirement. Here is a safe general rule:
  <16_chars_max>#.*<15_chars_max>*.*<15_chars_max>*.oraclevcn.com
- The recommended maximums are not enforced when you create the VCN and subnets. However, the DB system deployment fails if the FQDN has more than 63 characters.

CUSTOM DNS RESOLVER

See the preceding table for the types of DB systems that support the use of a custom DNS resolver.

A custom DNS resolver is a DNS server that you set up in your on-premises network and maintain yourself. It must resolve the endpoints required by the DB system.

By default, the VCN is configured to use the Internet and VCN Resolver. Therefore, if you instead want to use a custom DNS resolver, you must configure the VCN and DHCP options in a different way. See the following process.

To use a custom DNS resolver with your DB system

As part of the overall network setup, perform these tasks:

1. Create the VCN with the recommended DNS settings:
   - When creating the VCN, Oracle recommends that you select the check box for **Use DNS Hostnames in this VCN** and then specify a DNS label for the VCN. See the restrictions listed in Hostname restrictions when using a custom DNS resolver.
   - Notice that you cannot change the preceding VCN DNS settings after you create the VCN. They are optional for a custom DNS server, but required if you use the

Internet and VCN Resolver. Therefore, Oracle recommends that you configure them now in case you later want to use the Internet and VCN Resolver.

2. Create each subnet with the recommended DNS settings:
    - When creating a subnet in the VCN, Oracle recommends that you select select the check box for **Use DNS Hostnames in this Subnet** and then specify a DNS label for the subnet. See the restrictions listed in Hostname restrictions when using a custom DNS resolver.
    - Notice that you cannot change the preceding subnet DNS settings after you create the subnet. They are optional for a custom DNS server, but required if you use the Internet and VCN Resolver. Therefore, Oracle recommends that you configure them now in case you later want to use the Internet and VCN Resolver.
3. Edit the default set of DHCP options to use a custom resolver:
    - When creating each subnet, configure it to use the VCN's default set of DHCP options.
    - Edit the default set of DHCP options so that **DNS Type** is set to **Custom Resolver**. Provide the IP address for at least one DNS server (maximum three). Optionally provide a single search domain (which will automatically be added to the host's `/etc/resolv.conf` file).
4. Create the DB system with required DNS entries:
    - Later, when creating the DB system, specify a **Hostname Prefix**.
    - For the **Host Domain Name**: If you selected the check box for **Use DNS Hostnames** in the preceding steps, the **Host Domain Name** is automatically generated from the VCN and subnet DNS labels. Otherwise, you must provide a value for the **Host Domain Name**. See the restrictions listed in Hostname restrictions when using a custom DNS resolver.
    - Notice that when launching the DB system, the Database service automatically assigns an IP address from the VCN's CIDR block and resolves the address locally based on the host's `/etc/hosts` file. Your custom DNS resolver does not need to resolve the hostname in advance for the DB system launch to succeed.

Hostname restrictions when using a custom DNS resolver

Requirement for the DB system's hostname prefix:

- Maximum 16 characters, otherwise the DB system deployment will fail.
- Cannot be the string *localhost*.

Requirements for the VCN and subnet DNS labels:

- You can provide a value for the DNS labels only if you select the check box for **Use DNS Hostnames** when creating the VCN and subnets. The resulting FQDN for the DB system follows this format:
  <hostname_prefix>.*<subnet_DNS_label>*.*<VCN_DNS_label>*.oraclevcn.com
- Recommended maximum for each DNS label: 15 characters.
- No hyphens or underscores.
- Recommended: Include the region name in the VCN's name, and include the availability domain name in the subnet's name.
- The FQDN has a maximum total limit of 63 characters, so set the VCN and subnet DNS labels short enough to meet that requirement. Here is a safe general rule:
  <16_chars_max>.*<15_chars_max>*.*<15_chars_max>*.oraclevcn.com
- The recommended maximums are not enforced when you create the VCN and subnets. However, the DB system deployment fails if the FQDN has more than 63 characters.

Requirements for the DB system's host domain name:

- You can provide a value in the **Host Domain Name** field only if you did not select the check box for **Use DNS Hostnames** when creating the VCN and subnets.
- No hyphens or underscores.
- Ensure that the value results in an FQDN that is no longer than 63 characters. Otherwise the DB system deployment will fail.

DNS: Between On-Premises Network and VCN

If you are using the Internet and VCN Resolver and want to enable the use of hostnames when on-premises hosts and VCN resources communicate with each other, you can set up an instance in the VCN to be a custom DNS server. For an example of an implementation of this scenario with the Oracle Terraform provider, see Hybrid DNS Configuration.

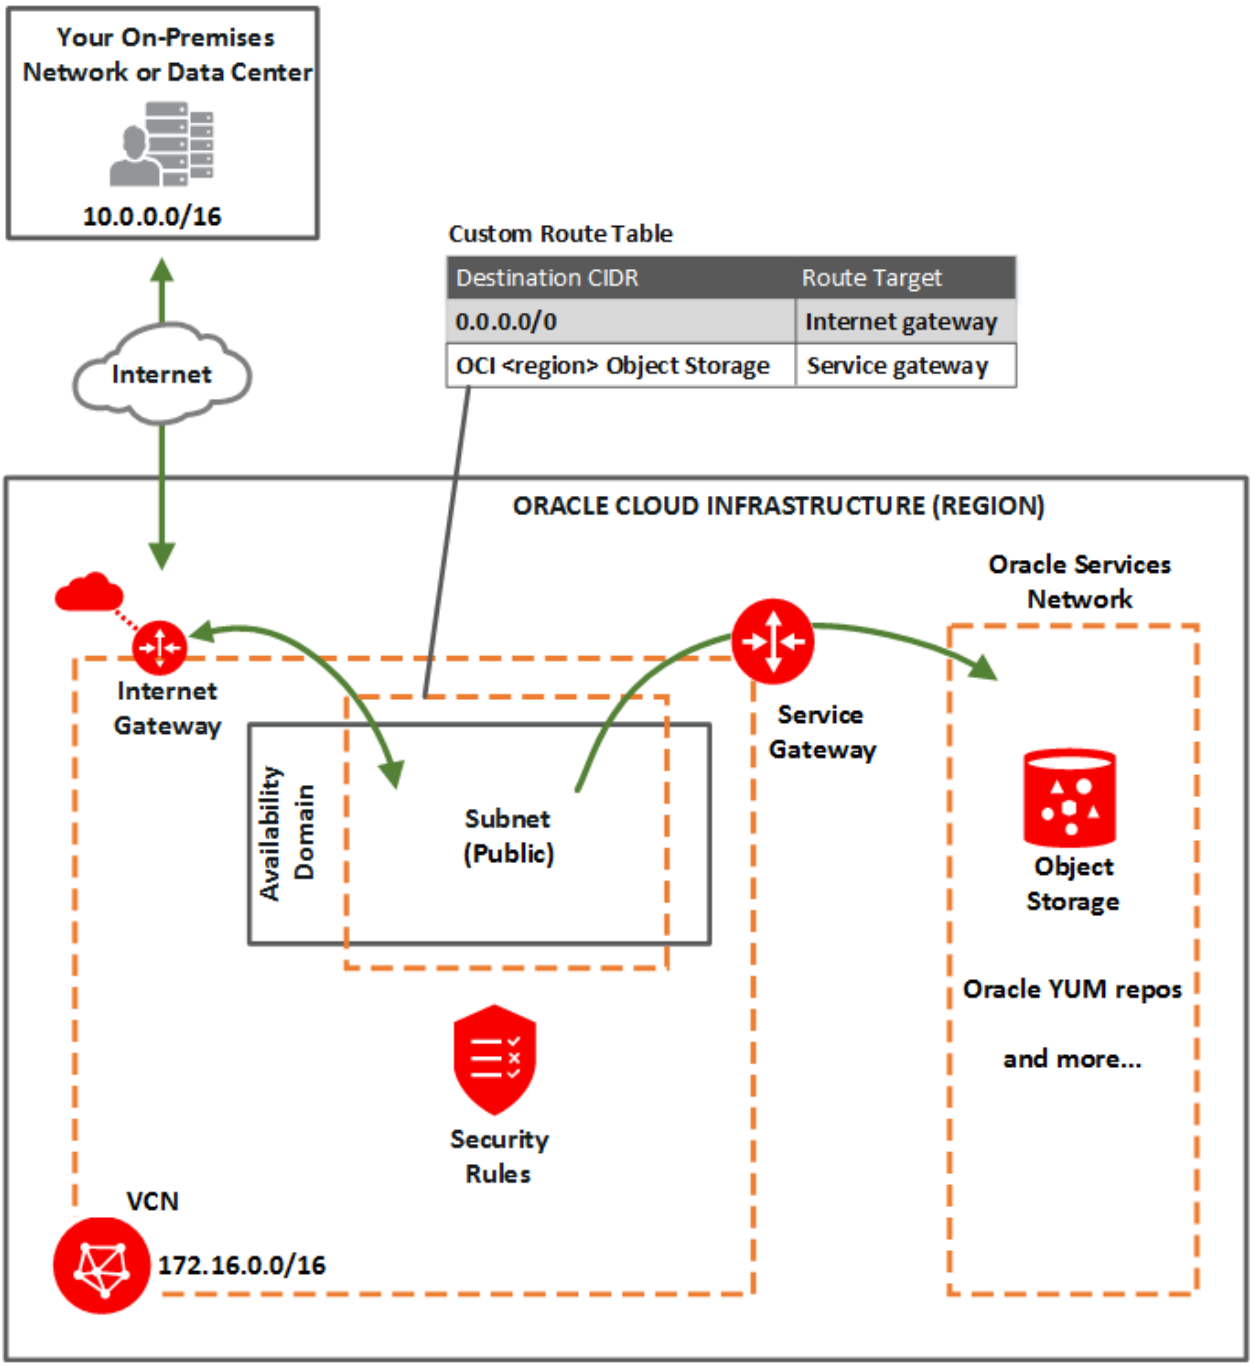
Service Gateway for the VCN

Your VCN needs access to both Object Storage (for backing up databases, patching, and updating the cloud tooling on a DB system) and Oracle YUM repos for OS updates.

Depending on whether you use option 1 or option 2 described previously, you use the service gateway in different ways. See the next two sections.

Option 1: Service Gateway Access Only to Object Storage

You configure the subnet to use the service gateway for access only to Object Storage. As a reminder, here's the diagram for option 1:



Your On-Premises Network or Data Center
10.0.0.0/16
Internet
Custom Route Table
Destination CIDR
Route Target
0.0.0.0/0
Internet gateway
OCI <region> Object Storage
Service gateway
ORACLE CLOUD INFRASTRUCTURE (REGION)
Oracle Services Network
Internet Gateway
Service Gateway
Availability Domain
Subnet (Public)
Object Storage
Oracle YUM repos
and more...
Security Rules
VCN
172.16.0.0/16

In general, you must:

- Perform the tasks for setting up a service gateway on a VCN, and specifically enable the service CIDR label called **OCI *<region>* Object Storage**.
- In the task for updating routing, add a route rule to the subnet's custom route table. For the destination service, use **OCI *<region>* Object Storage** and target = the service gateway.
- In the task for updating security rules for the subnet, perform the task on the DB system's custom network security group (NSG) or security list. Here you set up a security rule with the destination service set to **OCI *<region>* Object Storage**. See Custom Security Rules.

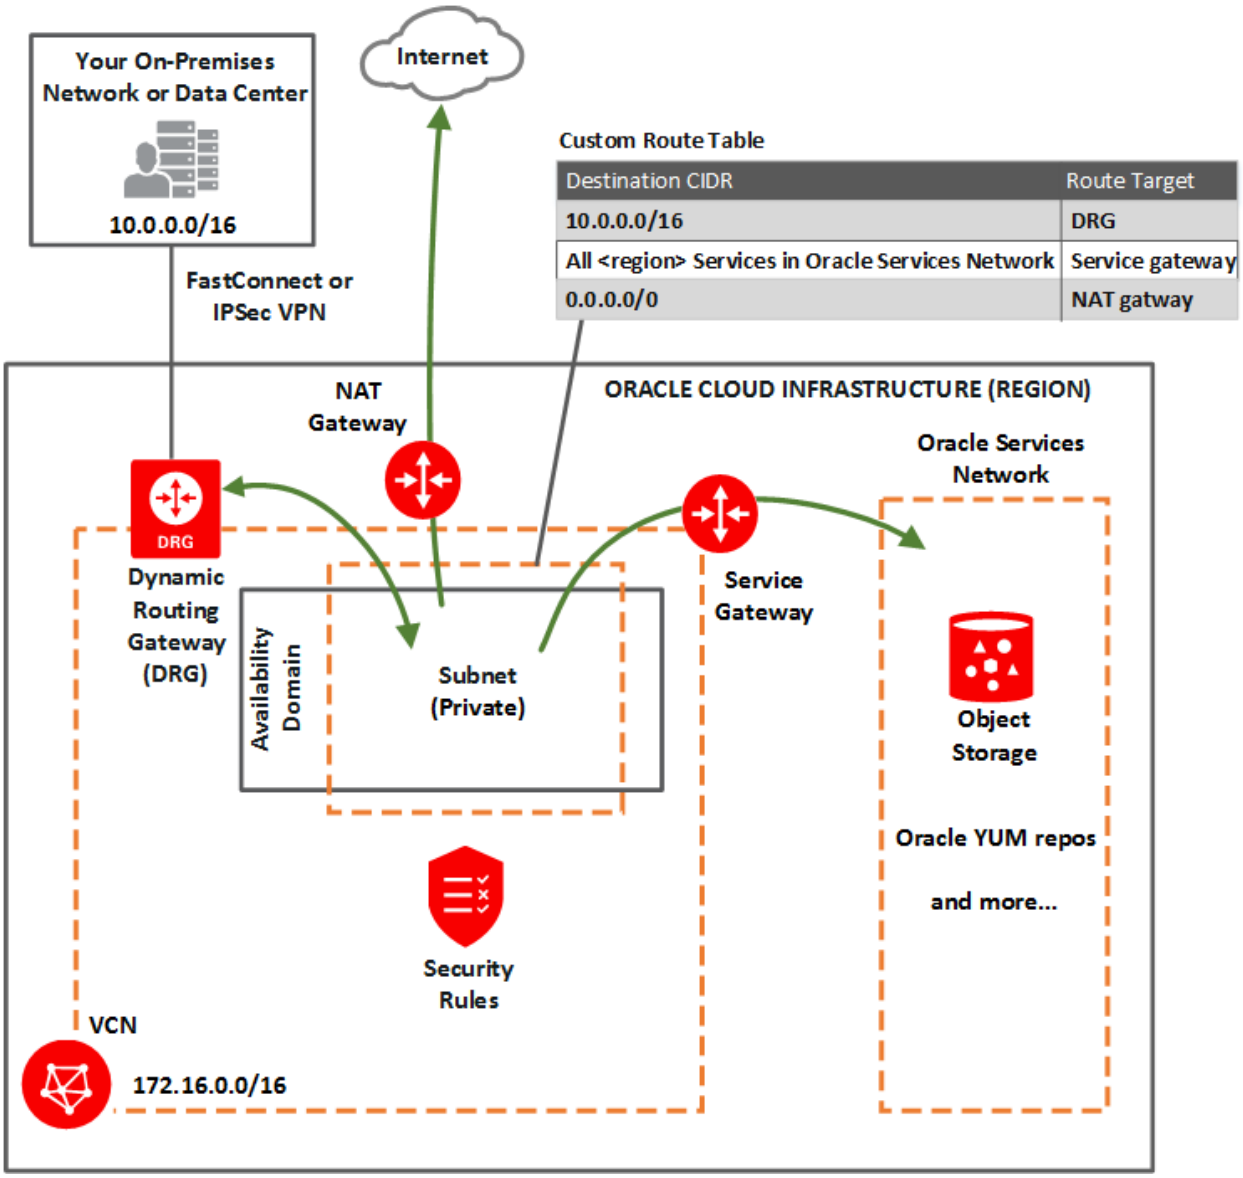
Option 2: Service Gateway Access to Both Object Storage and YUM Repos

You configure the subnet to use the service gateway for access to the Oracle Services Network, which includes both Object Storage and the Oracle YUM repos.

Important

See this known issue for information about accessing Oracle YUM services through the service gateway.

As a reminder, here's the diagram for option 2:



In general, you must:

- Perform the tasks for setting up a service gateway on a VCN, and specifically enable the service CIDR label called **All *<region>* Services in Oracle Services Network**.
- In the task for updating routing in the subnet, add a rule to the subnet's custom route table. For the destination service, use **All *<region>* Services in Oracle Services Network** and target = the service gateway.
- In the task for updating security rules for the subnet, perform the task on the subnet's custom network security group (NSG) or security list. Here you set up a security rule with the destination service set to **All *<region>* Services in Oracle Services Network**. See Custom Security Rules.

Security Rules for the DB System

This section lists the security rules to use with your DB system. Security rules control the types of traffic allowed in and out of the DB system's compute nodes. The rules are divided into two sections.

There are different ways to implement these rules. For more information, see Ways to Implement the Security Rules.

Important

Your instances running Oracle-provided DB system images also have firewall rules that control access to the instance. Make sure that both the instance's security rules and firewall rules are set correctly. Also see Opening Ports on the DB System.

General Rules Required for Basic Connectivity

This section has several general rules that enable essential connectivity for hosts in the VCN.

If you use security lists to implement your security rules: the following rules are included by default in the default security list.

General ingress rule 1: Allows SSH traffic from anywhere

- **Stateless:** No (all rules must be stateful)
- **Source Type:** CIDR
- **Source CIDR:** 0.0.0.0/0
- **IP Protocol:** TCP
- **Source Port Range:** All
- **Destination Port Range:** 22

General ingress rule 2: Allows Path MTU Discovery fragmentation messages

This rule enables hosts in the VCN to receive Path MTU Discovery fragmentation messages. Without access to these messages, hosts in the VCN can have problems communicating with hosts outside the VCN.

- **Stateless:** No (all rules must be stateful)
- **Source Type:** CIDR
- **Source CIDR:** 0.0.0.0/0
- **IP Protocol:** ICMP
- **Type:** 3
- **Code:** 4

General ingress rule 3: Allows connectivity error messages within the VCN

This rule enables the hosts in the VCN to receive connectivity error messages from each other.

- **Stateless:** No (all rules must be stateful)
- **Source Type:** CIDR
- **Source CIDR:** Your VCN's CIDR

- **IP Protocol:** ICMP
- **Type:** 3
- **Code:** All

General egress rule 1: Allows all egress traffic

- **Stateless:** No (all rules must be stateful)
- **Destination Type:** CIDR
- **Destination CIDR:** 0.0.0.0/0
- **IP Protocol:** All

CUSTOM SECURITY RULES

The following rules are necessary for the DB system's functionality.

Custom ingress rule 1: Allows ONS and FAN traffic from within the VCN

This rule is recommended and enables the Oracle Notification Services (ONS) to communicate about Fast Application Notification (FAN) events.

- **Stateless:** No (all rules must be stateful)
- **Source Type:** CIDR
- **Source CIDR:** VCN's CIDR
- **IP Protocol:** TCP
- **Source Port Range:** All
- **Destination Port Range:** 6200

Custom ingress rule 2: Allows SQL*NET traffic from within the VCN

This rule is for SQL*NET traffic and is required only if you need to enable client connections to

the database.

- **Stateless:** No (all rules must be stateful)
- **Source Type:** CIDR
- **Source CIDR:** VCN's CIDR
- **IP Protocol:** TCP
- **Source Port Range:** All
- **Destination Port Range:** 1521

Important

The preceding custom ingress rules 1 and 2 only cover connections initiated from within the VCN. If you have a client that resides *outside the VCN*, Oracle recommends setting up two *additional* similar rules that instead have the **Source CIDR** set to the public IP address of the client.

Custom egress rule 1: Allows outbound SSH access

This rule enables SSH access between nodes in a 2-node DB system. It is redundant with the general egress rule in General Rules Required for Basic Connectivity (and in the default security list). It is optional but recommended in case the general rule (or default security list) is inadvertently changed.

- **Stateless:** No (all rules must be stateful)
- **Destination Type:** CIDR
- **Destination CIDR:** 0.0.0.0/0
- **IP Protocol:** TCP

- **Source Port Range:** All
- **Destination Port Range:** 22

Custom egress rule 2: Allows access to Object Storage and YUM repos

This rule enables the DB system to communicate with Object Storage alone (for option 1), or with the Oracle Services Network, which includes both Object Storage and the Oracle YUM repos (for option 2). It is redundant with the general egress rule in General Rules Required for Basic Connectivity (and in the default security list). It is optional but recommended in case the general rule (or default security list) is inadvertently changed.

- **Stateless:** No (all rules must be stateful)
- **Destination Type:** Service
- **Destination Service:**
  - For option 1, use the service CIDR label called **OCI *<region>* Object Storage**
  - For option 2, use the service CIDR label called **All *<region>* Services in Oracle Services Network**
- **IP Protocol:** TCP
- **Source Port Range:** All
- **Destination Port Range:** 443 (HTTPS)

Ways to Implement the Security Rules

The Networking service offers two ways to implement security rules within your VCN:

- Network security groups
- Security lists

For a comparison of the two methods, see Comparison of Security Lists and Network Security Groups.

If you use network security groups

If you choose to use network security groups (NSGs), here is the recommended process:

1. Create a network security group for DB systems. Add the following security rules to that NSG:
    - The rules listed in General Rules Required for Basic Connectivity
    - The rules listed in Custom Security Rules
2. When the database administrator creates the DB system, they must choose several networking components (for example, which VCN and subnet to use). They can also choose which NSG or NSGs to use. Make sure they choose the NSG you created.

You could instead create one NSG for the general rules and a separate NSG for the custom rules. Then when the database administrator chooses which NSGs to use for the DB system, make sure they choose both NSGs.

If you use security lists

If you choose to use security lists, here is the recommended process:

1. Configure the subnet to use the required security rules:
    a. Create a custom security list for the subnet and add the rules listed in Custom Security Rules.
    b. Associate the following two security lists with the subnet:
        - VCN's default security list with all its default rules. This automatically comes with the VCN.
        - The new custom security list you created for the subnet
2. Later when the database administrator creates the DB system, they must choose several networking components. When they select the subnet that you have already created and configured, the security rules are automatically enforced for the compute nodes created in the subnet.

Warning

Do not remove the default egress rule from the default security list. If you do, instead make sure to include the following replacement egress rule in the subnet's custom security list:

- **Stateless:** No (all rules must be stateful)
- **Destination Type:** CIDR
- **Destination CIDR:** 0.0.0.0/0
- **IP Protocol:** All

Managing Bare Metal and Virtual Machine DB Systems

This topic explains how to launch, start, stop, terminate, scale, manage licenses for, and check the status of a bare metal and virtual machine DB system, and set up DNS for a 1-node or 2-node RAC DB system.

When you launch a DB system using the Console, the API, or the CLI, the system is provisioned to support Oracle databases and an initial database is created based on the options you provide and some default options described later in this topic.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don't have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: The policy in Let database admins manage DB systems lets the specified group do everything with databases and related Database resources.

If you're new to policies, see Getting Started with Policies and Common Policies. If you want to dig deeper into writing policies for databases, see Details for the Database Service.

Prerequisites

You'll need the following items to launch any DB system.

- The public key, in OpenSSH format, from the key pair that you plan to use for connecting to the DB System via SSH. A sample public key, abbreviated for readability, is shown below.

  ```
  ssh-rsa AAAAB3NzaC1yc2EAAAABJQAA....lo/gKMLVM2xzc1xJr/Hc26biw3TXWGEakrK1OQ== rsa-key-20160304
  ```

  For more information, see Managing Key Pairs on Linux Instances.
- A correctly configured virtual cloud network (VCN) to launch the DB system in. Its related networking resources (gateways, route tables, security lists, DNS, and so on) must also be configured as necessary for the DB system. For more information, see Network Setup for DB Systems.
- If you plan to back up your DB system to Object Storage or to use the managed patching feature, Oracle recommends using a service gateway to enable access to Object Storage.
- For a 2-node RAC DB system, ensure that port 22 is open for both ingress and egress on the subnet, and that the security rules you create are stateful (the default), otherwise, the DB system might fail to provision successfully.

Default Options for the Initial Database

To simplify launching a DB system in the Console and when using the API, the following default options are used for the initial database and for any additional databases that you create. (Several advanced options such as Time Zone can be set when you can use the `dbcli` command line interface to create databases.)

- **Console Enabled:** False
- **Create Container Database:** False for version 11.2.0.4 databases. Otherwise, true.
- **Create Instance Only (for standby and migration):** False
- **Database Home ID:** Creates a new database home
- **Database Language:** AMERICAN
- **Database Sizing Template:** odb2
- **Database Storage:** ACFS for version 11.2.0.4 databases. Otherwise, ASM.
- **Database Territory:** AMERICA
- **Database Unique Name:** The user-specified database name and a system-generated suffix, for example, dbtst_phx1cs.
- **PDB Admin Name:** pdbuser (Not applicable for version 11.2.0.4 databases.)

For a list of the database options that you can set, see To launch a DB system.

Using the Console

To launch a DB system

1. Open the navigation menu. Under **Database**, click **Bare Metal, VM, and Exadata**.
2. Choose your **Compartment**.
3. Click **Launch DB System**.
4. In the **Launch DB System** dialog, enter the following:

   DB System Information

- **Compartment:** By default, the DB system launches in your current compartment and you can use the network resources in that compartment. Click the **click here** link in the dialog box if you want to enable compartment selection for the DB system, network, and subnet resources.
- **Display Name:** A friendly, display name for the DB system. The name doesn't need to be unique. An Oracle Cloud Identifier (OCID) will uniquely identify the DB system.
- **Availability Domain:** The availability domain in which the DB system resides.
- **Shape Type:** The type of shape to use to launch the DB system. The shape type filters the list of available shapes to select from.
- **Shape:** The shape to use to launch the DB system. The shape determines the type of DB system and the resources allocated to the system.

Bare metal shapes

- **BM.DenseIO2.52:** Provides a 1-node DB system (one bare metal server), with up to 52 CPU cores, 768 GB memory, and eight 6.4 TB locally attached NVMe drives (51.2 TB total) to the DB system.
- **BM.DenseIO1.36:** *Limited availability.* Provides a 1-node DB system (one bare metal server), with up to 36 CPU cores, 512 GB memory, and nine 3.2 TB locally attached NVMe drives (28.8 TB total) to the DB system.
  Note: BM.DenseO1.36 is available only to monthly universal credit customers existing on or before November 9th, 2018. This shape is available only in the US West (Phoenix), US East (Ashburn), and Germany Central (Frankfurt) regions.

Virtual machine shapes

Virtual machine X7 shapes:

- **VM.Standard2.1:** Provides a 1-node DB system with 1 core.
- **VM.Standard2.2:** Provides a 1- or 2-node DB system with 2 cores.
- **VM.Standard2.4:** Provides a 1- or 2-node DB system with 4 cores.
- **VM.Standard2.8:** Provides a 1- or 2-node DB system with 8 cores.
- **VM.Standard2.16:** Provides a 1- or 2-node DB system with 16 cores.
- **VM.Standard2.24:** Provides a 1- or 2-node DB system with 24 cores.

Virtual machine X5 shapes:

- **VM.Standard1.1:** Provides a 1-node DB system with 1 core.
- **VM.Standard1.2:** Provides a 1- or 2-node DB system with 2 cores.
- **VM.Standard1.4:** Provides a 1- or 2-node DB system with 4 cores.
- **VM.Standard1.8:** Provides a 1- or 2-node DB system with 8 cores.
- **VM.Standard1.16:** Provides a 1- or 2-node DB system with 16 cores.

Note

- X5-based shapes availability is limited to monthly universal credit customers existing on or before November 9th, 2018, in the US West (Phoenix), US East (Ashburn), and Germany Central (Frankfurt) regions.
- VM.Standard1.1 and VM.Standard2.1 shapes cannot be used for 2-node RAC clusters.

- **Cluster Name:** A unique cluster name for a multi-node DB system. The name must begin with a letter and contain only letters (a-z and A-Z), numbers (0-9) and

hyphens (-). The cluster name can be no longer than 11 characters and is not case sensitive.

- **Total Node Count:** *Virtual machine DB systems only.* The number of nodes in the DB system. The number depends on the shape you select. You can specify 1 or 2 nodes for virtual machine DB systems, except for VM.Standard2.1 and VM.Standard1.1, which are single-node DB systems.
- **Oracle Database Software Edition:** The database edition supported by the DB system. For bare metal systems, you can mix supported database releases on the DB system to include older database versions, but not editions. The database edition cannot be changed and applies to all the databases in this DB system. Virtual machine systems support only one database.
- **Available Storage Size:** *Virtual machine DB systems only.* The amount of Block Storage you wish to allocate to the virtual machine DB system.
- **Cluster Name:** A unique cluster name for a multi-node DB system. The name must begin with a letter and contain only letters (a-z and A-Z), numbers (0-9) and hyphens (-). The cluster name can be no longer than 11 characters and is not case sensitive.
- **CPU Core Count:** The number of CPU cores for the DB system. Displays only if you select a shape that allows you to configure the number of cores. The text below the field indicates the acceptable values for that shape. For a multi-node DB system, the core count is evenly divided across the nodes.

  Except for virtual machine DB systems, you can increase the CPU cores to accommodate increased demand after you launch the DB system.
- **License Type:** The type of license you want to use for the DB system. Your choice affects metering for billing.
  - **License included** means the cost of this Oracle Cloud Infrastructure Database service resource will include both the Oracle Database software licenses and the service.

    - **Bring Your Own License (BYOL)** means you will use your organization's Oracle Database software licenses for this Oracle Cloud Infrastructure Database service resource. See Bring Your Own License for more information.
- **SSH Public Key:** The public key portion of the key pair you want to use for SSH access to the DB system. To provide multiple keys, paste each key on a new line. Make sure each key is on a single, continuous line. The length of the combined keys cannot exceed 10,000 characters.
- **Data Storage Percentage:** *For bare metal DB systems only.* The percentage (40% or 80%) assigned to DATA storage (user data and database files). The remaining percentage is assigned to RECO storage (database redo logs, archive logs, and recovery manager backups).
- **Available Storage Size:** *For virtual machine DB systems only.* The amount of block storage to allocate to the virtual machine DB system. Available storage can be scaled up or down as needed after provisioning your DB system.
- **Advanced Options**: *For bare metal DB systems only.*
    - **Disk Redundancy:** *For bare metal systems only.* The type of redundancy configured for the DB system.
        - **Normal** is 2-way mirroring, recommended for test and development systems.
        - **High** is 3-way mirroring, recommended for production systems.

NETWORK INFORMATION

- **Virtual Cloud Network Compartment:** The compartment containing the network in which to launch the DB system.
- **Virtual Cloud Network:** The VCN in which to launch the DB system.
- **Subnet Compartment:** The compartment containing a subnet within the cloud network to attach the DB system to.
- **Client Subnet:** The subnet to which the bare metal or virtual machine DB system

should attach.

For 1- and 2-node RAC DB systems: Do not use a subnet that overlaps with 192.168.16.16/28, which is used by the Oracle Clusterware private interconnect on the database instance. Specifying an overlapping subnet will cause the private interconnect to malfunction.

- **Hostname Prefix:** Your choice of host name for the bare metal or virtual machine DB system. The host name must begin with an alphabetic character, and can contain only alphanumeric characters and hyphens (-). The maximum number of characters allowed for bare metal and virtual machine DB systems is 16.

Important

The host name must be unique within the subnet. If it is not unique, the DB system will fail to provision.

- **Host Domain Name:** The domain name for the DB system. If the selected subnet uses the Oracle-provided Internet and VCN Resolver for DNS name resolution, this field displays the domain name for the subnet and it can't be changed. Otherwise, you can provide your choice of a domain name. Hyphens (-) are not permitted.
- **Host and Domain URL:** Combines the host and domain names to display the fully qualified domain name (FQDN) for the database. The maximum length is 64 characters.

DATABASE INFORMATION

- **Database Name:** The name for the database. The database name must begin with an alphabetic character and can contain a maximum of eight alphanumeric characters. Special characters are not permitted.
- **Database Version:** The version of the initial database created on the DB system

when it is launched. After the DB system is active, you can create additional databases on it. You can mix database versions on the DB system, but not editions.

If you are launching a DB system with a virtual machine shape, you have option of selecting an older database version. Check **Display all database versions** to include older database versions in the drop-down list of database version choices. See Availability of Older Database Versions for Virtual Machine DB Systems for more information.

Note

When you display all database versions in the drop-down list, the latest database version of each release is represented twice in the list, as follows:

- Once using four numeric segments and the notation "(latest)" . For example: 12.2.0.1 (latest)
- Once using five numeric segments, without the "(latest)" notation. For example: 12.2.0.1.180417

- **PDB Name:** *Not applicable to version 11.2.0.4.* The name of the pluggable database. The PDB name must begin with an alphabetic character, and can contain a maximum of 8 alphanumeric characters. The only special character permitted is the underscore (_).
- **Database Admin Password:**
  A strong password for SYS, SYSTEM, TDE wallet, and PDB Admin. The password must be 9 to 30 characters and contain at least 2 uppercase, 2 lowercase, 2

numeric, and 2 special characters. The special characters must be _, #, or -. The password must not contain the username (SYS, SYSTEM, and so on) or the word "oracle" either in forward or reversed order and regardless of casing.

- **Confirm Database Admin Password:** Re-enter the Database Admin Password you specified.
- **Automatic Backup:** (Optional) If you enable automatic backups, you can choose one of the following preset retention periods: 7 days, 15 days, 30 days, 45 days, or 60 days. The default selection is 30 days.
- **Database Workload:**
  Select the workload type that best suits your application.
  - **Online Transactional Processing (OLTP)** configures the database for a transactional workload, with a bias towards high volumes of random data access.
  - **Decision Support System (DSS)** configures the database for a decision support or data warehouse workload, with a bias towards large data scanning operations.
- **Character Set:** The character set for the database. The default is AL32UTF8.
  Advanced Options:
  - **Character Set:** The character set for the database. The default is AL32UTF8.
  - **National Character Set:** The national character set for the database. The default is AL16UTF16.
  - **Fault Domain:** The fault domain(s) in which the DB system resides. You can choose which fault domain to use for your DB system. For 2-node RAC DB systems, you can specify which two fault domains are to be used. Oracle recommends that you place each node of a 2-node RAC DB system in a different fault domain. For more information on fault domains, see Fault Domains.
- **Tags:** Optionally, you can apply tags. If you have permissions to create a

resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.

5. Click **Launch DB System**.
   The DB system appears in the list with a status of Provisioning. The DB system's icon changes from yellow to green (or red to indicate errors).
6. Wait for the DB system's icon to turn green, with a status of Available, and then click the highlighted DB system name.
   Details about the DB system are displayed.
7. Note the IP addresses; you'll need the private or public IP address, depending on network configuration, to connect to the DB system.

To launch a new DB system from a backup

Before you begin, note the following:

- When you launch a new DB system from a backup, the availability domain will be the same as where the backup is hosted.
- The shape you specify must be the same type as the database from which the backup was taken. For example, if you are using a backup of a 1-node database, then the DB system you select as your target must also be a 1-node DB system.
- The Oracle database software edition you specify must be an equal or greater edition than that of the backed up database.
- If you specify a virtual machine DB system shape, the Available Storage Size will default to the data size of the backup, rounded up to the closest storage size option. However, you can specify a larger storage size.
- If you are creating a database from an automatic backup, you may choose any level 0 weekly backup, or a level 1 incremental backup created after the most recent level 0

backup. For more information on automatic backups, see Automatic Incremental Backups

1. Open the navigation menu. Under **Database**, click **Bare Metal, VM, and Exadata**.
2. Choose your **Compartment**.
   A list of DB systems is displayed.
3. Navigate to the backup you wish to use to create a new database. You can select a backup from a database details page, or select a backup that appears in your compartment's list of standalone backups.

   ### To navigate to a database's list of backups

   a. Find the DB system where the database is located, and click the system name to display details about it.
      A list of databases is displayed.
   b. Find the database associated with the backup you wish to use, and click its name to display details about it.
      A list of backups is displayed in the default view of the database details. You can also access the list of backups for a database by clicking on **Backups** under **Resources**.

   ### To navigate to the list of standalone backups for your current compartment

   a. Click **Standalone Backups** under **Bare Metal, VM, and Exadata**.
   b. In the list of standalone backups, find the backup you want to use to create the database.

4. Click the Actions icon (three dots) for the backup you are interested in, and then click **Create Database**.

5. In the **Create Database from Backup** dialog, enter the following:

   DB System Information

   - **DB System Information:** Select **Launch New DB System**.
   - **Display Name:** A friendly, display name for the DB system. The name doesn't need to be unique. An Oracle Cloud Identifier (OCID) will uniquely identify the DB system.
   - **Shape:** The shape to use to launch the DB system. The shape determines the type of DB system and the resources allocated to the system.

     The selected shape must support the same number of nodes as the DB system from which the backup was created.

     ### Bare metal shapes

     - **BM.DenseIO2.52:** Provides a 1-node DB system (one bare metal server), with up to 52 CPU cores, 768 GB memory, and eight 6.4 TB locally attached NVMe drives (51.2 TB total) to the DB system.
     - **BM.DenseIO1.36:** *Limited availability.* Provides a 1-node DB system (one bare metal server), with up to 36 CPU cores, 512 GB memory, and nine 3.2 TB locally attached NVMe drives (28.8 TB total) to the DB system.

       Note: BM.DenseO1.36 is available only to monthly universal credit customers existing on or before November 9th, 2018. This shape is available only in the US West (Phoenix), US East (Ashburn), and Germany Central (Frankfurt) regions.

     ### Virtual machine shapes)

     Virtual machine X7 shapes:

     - **VM.Standard2.1:** Provides a 1-node DB system with 1 core.
     - **VM.Standard2.2:** Provides a 1- or 2-node DB system with 2 cores.

- **VM.Standard2.4:** Provides a 1- or 2-node DB system with 4 cores.
- **VM.Standard2.8:** Provides a 1- or 2-node DB system with 8 cores.
- **VM.Standard2.16:** Provides a 1- or 2-node DB system with 16 cores.
- **VM.Standard2.24:** Provides a 1- or 2-node DB system with 24 cores.

Virtual machine X5 shapes:

- **VM.Standard1.1:** Provides a 1-node DB system with 1 core.
- **VM.Standard1.2:** Provides a 1- or 2-node DB system with 2 cores.
- **VM.Standard1.4:** Provides a 1- or 2-node DB system with 4 cores.
- **VM.Standard1.8:** Provides a 1- or 2-node DB system with 8 cores.
- **VM.Standard1.16:** Provides a 1- or 2-node DB system with 16 cores.

Note

- X5-based shapes availability is limited to monthly universal credit customers existing on or before November 9th, 2018, in the US West (Phoenix), US East (Ashburn), and Germany Central (Frankfurt) regions.
- VM.Standard1.1 and VM.Standard2.1 shapes cannot be used for 2-node RAC clusters.

- **Total Node Count:** *Virtual machine DB systems only.* The number of nodes in the DB system. The number depends on the shape you select. You can specify 1 or 2 nodes for virtual machine DB systems, except for VM.Standard2.1 and VM.Standard1.1, which are single-node DB systems.
- **Oracle Database Software Edition:** The database edition supported by the DB

system. For bare metal systems, you can mix supported database releases on the DB system to include older database versions, but not editions. The database edition cannot be changed and applies to all the databases in this DB system. Virtual machine systems support only one database.

- **Available Storage Size:** *Virtual machine DB systems only.* The amount of Block Storage you wish to allocate to the virtual machine DB system.
- **Cluster Name:** A unique cluster name for a multi-node DB system. The name must begin with a letter and contain only letters (a-z and A-Z), numbers (0-9) and hyphens (-). The cluster name can be no longer than 11 characters and is not case sensitive.
- **License Type:** The type of license you want to use for the DB system. Your choice affects metering for billing.
    - **License included** means the cost of this Oracle Cloud Infrastructure Database service resource will include both the Oracle Database software licenses and the service.
    - **Bring Your Own License (BYOL)** means you will use your organization's Oracle Database software licenses for this Oracle Cloud Infrastructure Database service resource. See Bring Your Own License for more information.
- **SSH Public Key:** The public key portion of the key pair you want to use for SSH access to the DB system. To provide multiple keys, paste each key on a new line. Make sure each key is on a single, continuous line. The length of the combined keys cannot exceed 10,000 characters.
- **Data Storage Percentage:** *For bare metal DB systems only.* The percentage (40% or 80%) assigned to DATA storage (user data and database files). The remaining percentage is assigned to RECO storage (database redo logs, archive logs, and recovery manager backups).
- **Available Storage Size:** *For virtual machine DB systems only.* The amount of block storage to allocate to the virtual machine DB system. Available storage can be scaled up or down as needed after provisioning your DB system.

If you are creating a DB system from a backup, the minimum value for available storage is determined by the size of the backup.

- **Advanced Options:**
  - **Disk Redundancy:** *For bare metal systems only.* The type of redundancy configured for the DB system.
    - **Normal** is 2-way mirroring, recommended for test and development systems.
    - **High** is 3-way mirroring, recommended for production systems.
  - **Fault Domain:** The fault domain(s) in which the DB system resides. You can choose which fault domain to use for your DB system. For 2-node RAC DB systems, you can specify which two fault domains are to be used. Oracle recommends that you place each node of a 2-node RAC DB system in a different fault domain. For more information on fault domains, see Fault Domains.

Network Information

- **Virtual Cloud Network:** The VCN in which to launch the DB system.
- **Client Subnet:** The subnet to which the bare metal or virtual machine DB system should attach.
  For 1- and 2-node RAC DB systems: Do not use a subnet that overlaps with 192.168.16.16/28, which is used by the Oracle Clusterware private interconnect on the database instance. Specifying an overlapping subnet will cause the private interconnect to malfunction.
- **Hostname Prefix:** Your choice of host name for the bare metal or virtual machine DB system. The host name must begin with an alphabetic character, and can contain only alphanumeric characters and hyphens (-). The maximum number of characters allowed for bare metal and virtual machine DB systems is 16.

Important

The host name must be unique within the subnet. If it is not unique, the DB system will fail to provision.

DATABASE INFORMATION

- **Database Name:** The name for the database. The database name must begin with an alphabetic character and can contain a maximum of eight alphanumeric characters. Special characters are not permitted.
- **Database Admin Password:**
  A strong password for SYS, SYSTEM, TDE wallet, and PDB Admin. The password must be 9 to 30 characters and contain at least 2 uppercase, 2 lowercase, 2 numeric, and 2 special characters. The special characters must be _, #, or -. The password must not contain the username (SYS, SYSTEM, and so on) or the word "oracle" either in forward or reversed order and regardless of casing.
- **Confirm Database Admin Password:** Re-enter the Database Admin Password you specified.
- **Password for Transparent Data Encryption (TDE) Wallet or RMAN Encryption:**
  Enter either the TDE wallet password or the RMAN encryption password for the backup, whichever is applicable. The TDE wallet password is the SYS password provided when the database was created by using the Oracle Cloud Infrastructure Console, API, or CLI. The RMAN encryption password is typically required instead if the password was subsequently changed manually.

6. Click **Create Database**.
7. Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging,

see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.

To check the status of a DB system

1. Open the navigation menu. Under **Database**, click **Bare Metal, VM, and Exadata**.
2. Choose your **Compartment**.
   A list of DB systems is displayed.
3. In the list of DB systems, find the system you're interested in and check its icon. The color of the icon and the text below it indicates the status of the system.
   - **Provisioning:** Yellow icon. Resources are being reserved for the DB system, the system is booting, and the initial database is being created. Provisioning can take several minutes. The system is not ready to use yet.
   - **Available:** Green icon. The DB system was successfully provisioned. A few minutes after the system enters this state, you can SSH to it and begin using it.
   - **Terminating:** Gray icon. The DB system is being deleted by the terminate action in the Console or API.
   - **Terminated:** Gray icon. The DB system has been deleted and is no longer available.
   - **Failed:** Red icon. An error condition prevented the provisioning or continued operation of the DB system.

   To view the status of a database node, under Resources, click **Nodes** to see the list of nodes. In addition to the states listed for a DB system, a node's status can be one of the following:
   - **Starting:** Yellow icon. The database node is being powered on by the start or reboot action in the Console or API.
   - **Stopping:** Yellow icon. The database node is being powered off by the stop or reboot action in the Console or API.

- **Stopped:** Yellow icon. The database node was powered off by the stop action in the Console or API.

You can also check the status of DB systems and database nodes by using the ListDbSystems or ListDbNodes API operations, which return the `lifecycleState` attribute.

To start, stop, or reboot a DB system

Tip

Oracle recommends that you run a Network Time Protocol (NTP) daemon to keep system clocks stable during rebooting. If you need information about an NTP daemon, see Setting Up "NTP (Network Time Protocol) Server" in RHEL/CentOS 7.

1. Open the navigation menu. Under **Database**, click **Bare Metal, VM, and Exadata**.
2. Choose your **Compartment**.
   A list of DB systems is displayed.
3. In the list of DB systems, find the DB system you want to stop or start, and then click its name to display details about it.
4. In the list of nodes, click the Actions icon (three dots) for a node and then click one of the following actions:
   - **Start:** Restarts a stopped node. After the node is restarted, the **Stop** action is enabled.
   - **Stop:** Shuts down the node. After the node is powered off, the **Start** action is enabled.
   - **Reboot:** Shuts down the node, and then restarts it.

Note

- Resource billing differs between bare metal and virtual machine DB systems as follows:
  - **Bare metal DB systems** - The **Stop** state has no effect on the resources you consume. Billing continues for nodes that you stop, and related resources continue to apply against any relevant quotas. You must **Terminate** a DB system to remove its resources from billing and quotas.
  - **Virtual machine DB systems** - Stopping a node stops billing for all OCPUs associated with that node. Billing resumes if you restart the node.
- After you restart or reboot a node, the floating IP address might take several minutes to be updated and display in the Console.

To scale the CPU cores for a bare metal DB system

If a multi-node DB system requires more compute node processing power, you can scale up (burst) the number of enabled CPU cores in the system.

Note

You cannot change the number of CPU cores for a virtual machine DB system.

1. Open the navigation menu. Under **Database**, click **Bare Metal, VM, and Exadata**.
2. Choose your **Compartment**.
   A list of DB systems is displayed.
3. In the list of DB systems, find the system you want to scale and click its highlighted name.
   The system details are displayed.
4. Click **Scale Up/Down** and then change the number in **Total CPU Core Count**. The text below the field indicates the acceptable values, based on the shape used when the DB system was launched.
5. Click **Scale Up/Down DB System**.

To scale up the storage for a virtual machine DB system

If a virtual machine DB system requires more block storage, you can increase the storage at any time without impacting the system.

Note

This procedure does not apply to bare metal DB systems.

1. Open the navigation menu. Under **Database**, click **Bare Metal, VM, and Exadata**.
2. Choose your **Compartment**.

A list of DB systems is displayed.

3. In the list of DB systems, find the system you want to scale up and click its highlighted name.
   The system details are displayed.
4. Click **Scale Storage Up**, and then select the new storage size from the drop-down list.
5. Click **Scale Storage Up**.

To terminate a DB system

Terminating a DB system permanently deletes it and any databases running on it.

Note

The database data is local to the DB system and will be lost when the system is terminated. Oracle recommends that you back up any data in the DB system prior to terminating it.

Terminating a DB system removes all automatic incremental backups of all databases in the DB system from Oracle Cloud Infrastructure Object Storage. Full backups remain in Object Storage as standalone backups which you can use to create a new database. See Recovering a Database from Object Storage.

1. Open the navigation menu. Under **Database**, click **Bare Metal, VM, and Exadata**.
2. Choose your **Compartment**.
   A list of DB systems is displayed.
3. For the DB system you want to terminate, click the Actions icon (three dots) and then click **Terminate**.

4. Confirm when prompted. .
   The DB system's icon indicates Terminating.

At this point, you cannot connect to the system and any open connections will be terminated.

To manage your BYOL database licenses

If you want to control the number of database licenses that you run at any given time, you can scale up or down the number of OCPUs on the instance. These additional licenses are metered separately.

1. Open the navigation menu. Under **Database**, click **Bare Metal, VM, and Exadata**.
2. Choose your **Compartment**.
   A list of DB systems is displayed.
3. In the list of DB systems, find the system you want to scale and click its highlighted name.
   The system details are displayed.
4. Click **Scale Up/Down OCPU**, and then change the number.

To manage tags for your DB systems and database resources

1. Open the navigation menu. Under **Database**, click **Bare Metal, VM, and Exadata**.
2. Choose your **Compartment**.
3. Find the DB system or database resource you're interested in, and click the name.
4. Click the **Tags** tab to view or edit the existing tags. Or click **Apply Tag(s)** to add new ones.

For more information, see Resource Tags.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use these API operations to manage DB system components.

DB systems:

- ListDbSystems
- GetDbSystem
- LaunchDbSystem
- TerminateDbSystem

Database homes:

- ListDbHomes
- GetDbHome
- CreateDbHome
- DeleteDbHome

Databases:

- ListDatabases
- GetDatabase

Nodes:

- DbNodeAction: Use this operation to power cycle a node in the DB system.
- ListDbNodes
- GetDbNode

Shapes and database versions:

- ListDbSystemShapes
- ListDbVersions

For the complete list of APIs for the Database service, see Database Service API.

Setting up DNS for a DB System

DNS lets you use host names instead of IP addresses to communicate with a DB system. You can use the *Internet and VCN Resolver* (the DNS capability built into the VCN) as described in DNS in Your Virtual Cloud Network.

Alternatively, you can use your choice of DNS server. You associate the host name and domain name to the public or private IP address of the DB system. You can find the host and domain names and IP addresses for the DB system in the Oracle Cloud Infrastructure Console on the **Database** page.

To associate the host name to the DB system's public or private IP address, contact your DNS administrator and request a custom DNS record for the DB system's IP address. For example, if your domain is example.com and you want to use clouddb1 as the host name, you would request a DNS record that associates clouddb1.example.com to your DB system's IP address.

If you provide the public IP address to your DNS administrator as described above, you should also associate a custom domain name to the DB system's public IP address:

1. Register your domain name through a third-party domain registration vendor, such as register.com.
2. Resolve your domain name to the DB system's public IP address, using the third-party domain registration vendor console. For more information, refer to the third-party domain registration documentation.

Connecting to a DB System

This topic explains how to connect to an active DB system. How you connect depends on the client tool or protocol you use, the purpose of the connection, and how your cloud network is set up. You can find information on various networking scenarios in Overview of Networking,

but for specific recommendations on how you should connect to a database in the cloud, contact your network security administrator.

Prerequisites

This section describes prerequisites you'll need to perform various tasks in this topic.

- To use the Console or the API to get the default administration service connection strings, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don't have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in. See Authentication and Authorization for more information on user authorizations for the Oracle Cloud Infrastructure Database service.
- To connect to the database, you'll need the public or private IP address of the DB system. Use the private IP address to connect to the DB system from your on-premises network, or from within the virtual cloud network (VCN). This includes connecting from a host located on-premises connecting through a VPN or FastConnect to your VCN, or from another host in the same VCN. Use the DB System's public IP address to connect to the system from outside the cloud (with no VPN). You can find the IP addresses in the Oracle Cloud Infrastructure Console on the **Database** page.
- For Secure Shell (SSH) access to the DB system, you'll need the full path to the file that contains the private key associated with the public key used when the DB system was launched.

If you have problems connecting, see Troubleshooting Connection Issues.

Database Services and Connection Strings

Database services allow you to control client access to a database instance depending on the functionality needed. For example, you might need to access the database for administration purposes only or you might need to connect an application to the database. Connection strings are specific to a database service.

When you provision a DB system, a default database administration service is automatically created. For 12c and later Oracle Databases, this service is for administrating the database at the CDB level. Because this service provides limited functionality, it is not suitable for connecting an application. Oracle recommends that you create a default application service for the initial database after you create your DB system. For 12c and later Oracle Databases, application services connect at the PDB level. Here are some important functions an application service can provide:

- Workload identification
- Load balancing
- Application continuity and Transaction Guard
- Fast Application Notification
- Resource assignment based on the service name

For details about these and other High Availability capabilities, see Client Failover Best Practices for Highly Available Oracle Databases.

CREATING AN APPLICATION SERVICE

You use the `srvctl` utility to create an application service. Before you can connect to the service, you must start it.

To create an application service for a PDB or an 11g Oracle database

1. Log in to the DB system host as `opc`.
2. Switch to the oracle user, and set your environment to the Oracle Database you want to administer.

```
$ sudo su - oracle
$ . oraenv
ORACLE_SID = [oracle] ? <database_name>
The Oracle base has been set to /u01/app/oracle
```

3. Create the application service for the database. Include the `pdb` option only if you are creating an application service for a PDB.

```
$ srvctl add service
-db <DB_unique_name>
-pdb <PDB_name>
-service <app_service_name>
-role PRIMARY
-notification TRUE
-session_state dynamic
-failovertype transaction
-failovermethod basic
-commit_outcome TRUE
-failoverretry 30
-failoverdelay 10
-replay_init_time 900
-clbgoal SHORT
-rlbgoal SERVICE_TIME
-preferred <rac_node1>,<rac_node2>
-retention 3600
```

Note that the preferred option is required only for multi-node databases to specify the hostname of the node in the RAC.

4. Start the application service.

```
$ srvctl start service -db <DB_unique_name> -s <app_service_name>
```

For more information about services for a PDB, see Managing Services for PDBs.

Database Connection Strings

You must use the appropriate connection string to access a database administration or application service. You can use the Console or the API to get the string for connecting to the default administration service from within a VCN. For 12c and later Oracle Databases, this service is for administrating the database at the CDB level. The string is provided in both the Easy Connect and in the full connect descriptor (long) format. Use the long format for the connection if hostname resolution is not available. You can also use the long format to create an alias in the tnsnames.ora file.

For accessing a database service within the VCN, the connection string for a Real Application Cluster (RAC) DB system uses the Single Client Access Name (SCAN) while the connection string for single instance DB system uses the hostname instead.

The private SCAN name is a Round Robin DNS entry created when you launch a 2-node RAC DB system. The private SCAN name is resolvable only within the VCN. If the client and the database are in the same VCN, the connection mechanism is the same as an on-premises RAC database; all the features provided by VIPs and SCAN VIPs, such as server side load balancing and VIP failover, are available.

Note

If you manually change the DB_UNIQUE_NAME, DB_DOMAIN, or listener port on the DB system, the connection strings you see in the Console or API will not reflect your changes. Ensure that you use the actual values of these parameters when you make a connection.

To get the connection strings for the default administration service

1. Open the navigation menu. Under **Database**, click **Bare Metal, VM, and Exadata**.
2. Choose your **Compartment**.
3. Find the DB system you're interested in, and click the name.
4. Click **DB Connection**.
5. Click the applicable link to view or copy the connection string.

You can derive the connection strings for other database services by replacing part of the default application service connection string with the applicable values.

To derive the connection string for a PDB administration service or an application service

1. Follow the procedure to get the Easy Connect string for the default administration service. That string should have the following format:

```
<hostname|SCAN>:1521/<DB_unique_name>.<DB_domain>
```

2. Make the appropriate substitution:
   - For the PDB administration service, replace `DB_unique_name` with the PDB name.

     ```
     <hostname|SCAN>:1521/<PDB_name>.<DB_domain>
     ```

   - For an application service, replace `DB_UNIQUE_NAME` with the name of the application service.

     ```
     <hostname|SCAN>:1521/<app_service_name>.<DB_domain>
     ```

Connecting to a Database Service by Using SQL*Net

This section describes how to connect to a database service from a computer that has a SQL*Net client installed. Port 1521 must be open to support the SQL*Net protocol.

Connecting from Within the VCN

For security reasons, Oracle recommends that you connect to your database services from within the VCN. You can use this method whether you are connecting to an administration service or to an application service.

To connect using SQL*Plus, you run the following command using the applicable connection string:

```
sqlplus system/<password>@<connection_string>
```

Consider the following:

- If your system is not using the VCN Resolver, ensure that the DB system's hostname (for single-node systems) or SCAN name (for multi-node systems) can be resolved. See DNS in Your Virtual Cloud Network for information about DNS name resolution.
- For connecting to the administration service of a PDB, ensure that the PDB is open or the service will not be available.
- For connecting to an application service, ensure that the service is started. For Fast Application Notification to work, ensure that port 6200 can be reached. See Client Failover Best Practices for Highly Available Oracle Databases for information about Fast Application Notification.

CONNECTING FROM THE INTERNET

Although Oracle does not recommend connecting to your database from the Internet, you can connect to a database service by using a public IP address if port 1521 is open to the public for ingress.

To use this method, you run the following command using the public IP address instead of the hostname or SCAN in the connection string:

```
sqlplus system/<password>@<public_IP>:1521/<service_name>.<DB_domain>
```

Consider the following:

- SCANs and hostnames are not resolvable on the Internet, therefore load balancing and failover for multi-node DB systems, which rely on these names, cannot work.
- For multi-node DB systems, which normally use SCANs, you must specify the IP address of one of the RAC hosts to access the database.

Important

Do not use this method to connect to the database from within the VCN. Doing so negatively impacts performance because traffic to the database is routed out of the VCN and back in through the public IP address.

EXAMPLE: CONNECTING IN SQL DEVELOPER USING SQL*NET

Prerequisites:

- Ensure that port 1521 is open for the Oracle default listener. (You can do this by checking the DB system's security list.)
- If port 1521 is open only to hosts in the VCN, then you must run your SQL Developer client from a machine that has direct access to the VCN. If you are connecting to the database from the Internet instead, then the public IP address of your computer must be granted access to port 1521 in the security list. (Alternatively, the security list can

grant full access to port 1521, however, this is not recommended for security reasons.) You must use the public IP address of the host because connecting from the Internet does not support SCAN name resolution.

To connect from within the VCN

After the prerequisites are met, start SQL Developer and create a connection by supplying the following connection details:

- **Username:** sys as sysdba
- **Password:** The **Database Admin Password** that was specified in the **Launch DB System** dialog in the Console.
- **Hostname:** The hostname as it appears in the Easy Connect format of the connection string. (See Database Connection Strings for help with getting the connection string and identifying the hostname.)
- **Port:** 1521
- **Service name:** The concatenated name of the service and host domain name, for example, db1_phx1tv.example.com. You can identify this value as the last part of the Easy Connect string, *<service_name>.<DB_domain>*.

To connect from The Internet by using public IP addresses

You can use the node's public IP address to connect to the database if the database is in a VCN that has an internet gateway. However, there are important implications to consider:

- When the client uses the public IP address, the client bypasses the SCAN listener and reaches the node listener, so server side load balancing is not available.
- When the client uses the public IP address, it cannot take advantage of the VIP failover feature. If a node becomes unavailable, new connection attempts to the node will hang until a TCP/IP timeout occurs. You can set client side SQL*Net parameters to limit the TCP/IP timeout.

The following `tnsnames.ora` example shows a connection string that includes the CONNECT_TIMEOUT parameter. This parameter controls the TCP timeout for connecting to a node.

```
test=
  (DESCRIPTION =
    (CONNECT_TIMEOUT=3)
    (ADDRESS_LIST=
      (ADDRESS = (PROTOCOL = TCP)(HOST = <public_IP1>)(PORT = 1521))
      (ADDRESS = (PROTOCOL = TCP)(HOST = <public_IP2>)(PORT = 1521))
    )
    (CONNECT_DATA =
      (SERVER = DEDICATED)
      (SERVICE_NAME = <dbservice.subnetname.dbvcn.oraclevcn.com>)
    )
  )
```

For more information about using the CONNECT_TIMEOUT parameter, see Client Failover Best Practices for Highly Available Oracle Databases.

Connecting to a Database with a Public IP by Using SSH Tunneling

You can access the services of DB system databases with public IP addresses by using SSH tunneling. The main advantage of this method is that port 1521 does not need to be opened to the public internet. However, just like accessing the database with a public IP using a SQL*Net client, load balancing and failover for multi-node DB systems cannot work because they rely on SCANs and hostnames.

Oracle SQL Developer and Oracle SQLcL and are two tools that facilitate the use of tunneling for Oracle Database access.

To open a tunnel, and then connect to a database service by using SQLcL, you run commands like the following:

```
SQL> sshtunnel opc@<public_IP> -i <private_key> -L <local_port>:<private_IP>:1521
Using port:22
SSH Tunnel connected
SQL> connect system/<password>@localhost:<local_port>/<service_name>.<DB_domain>
```

See Oracle SQL Developer and Oracle SQLcL for information about these tools.

Connecting to a Database by Using SSH and the Bequeath Protocol

This method allows you to connect to the database without using the network listener. It should be used to connect only for administration purposes.

When connecting to a multi-node DB system, you'll SSH to each individual node in the cluster.

To connect from a UNIX-style system

Use the following SSH command to access the DB system:
`$ ssh -i <private_key> opc@<DB_system_IP_address>`

<private_key> is the full path and name of the file that contains the private key associated with the DB system you want to access.

Use the DB system's private or public IP address depending on your network configuration. For more information, see Prerequisites.

To connect from a Windows system

1. Open `putty.exe`.
2. In the **Category** pane, select **Session** and enter the following fields:
   - **Host Name (or IP address):** `opc@<DB_system_IP_address>`
     Use the DB system's private or public IP address depending on your network configuration. For more information, see Prerequisites.
   - **Connection type:** SSH
   - **Port:** 22
3. In the **Category** pane, expand **Connection**, expand **SSH**, and then click **Auth**, and browse to select your private key.
4. Optionally, return to the **Session** category screen and save this session information for reuse later.
5. Click **Open** to start the session.

To access a database after you connect

1. Log in as opc and then sudo to the grid user.

```
login as: opc

[opc@ed1db01 ~]$ sudo su - grid
```

2. List all the databases on the system.

```
root@ed1db01 ]# srvctl config database -v

cdbm01 /u02/app/oracle/product/12.1.0/dbhome_2 12.1.0.2.0
exadb /u02/app/oracle/product/11.2.0/dbhome_2 11.2.0.4.0
mmdb /u02/app/oracle/product/12.1.0/dbhome_3 12.1.0.2.0
```

3. Connect as the oracle user and get the details about one of the databases by using the `srvctl` command.

```
[root@ed1db01 ~]# su - oracle
[oracle@ed1db01 ~]$ . oraenv
ORACLE_SID = [oracle] ? cdbm01
The Oracle base has been set to /u02/app/oracle
[oracle@ed1db01 ~]$ srvctl config database -d cdbm01
Database unique name: cdbm01 <<== DB unique name
Database name:
Oracle home: /u02/app/oracle/product/12.1.0/dbhome_2
Oracle user: oracle
Spfile: +DATAC1/cdbm01/spfilecdbm01.ora
Password file: +DATAC1/cdbm01/PASSWORD/passwd
Domain: data.customer1.oraclevcn.com
Start options: open
Stop options: immediate
Database role: PRIMARY
Management policy: AUTOMATIC
Server pools:
Disk Groups: DATAC1,RECOC1
Mount point paths:
Services:
Type: RAC
Start concurrency:
```

```
Stop concurrency:
OSDBA group: dba
OSOPER group: racoper
Database instances: cdbm011,cdbm012 <<== SID
Configured nodes: ed1db01,ed1db02
Database is administrator managed
```

4. Set the ORACLE_SID and ORACLE_UNIQUE_NAME using the values from the previous step.

```
[oracle@ed1db01 ~]$ export ORACLE_UNIQUE_NAME=cdbm01
[oracle@ed1db01 ~]$ export ORACLE_SID=cdbm011
[oracle@ed1db01 ~]$ sqlplus / as sysdba

SQL*Plus: Release 12.1.0.2.0 Production on Wed Apr 19 04:10:12 2017

Connected to:
Oracle Database 12c EE Extreme Perf Release 12.1.0.2.0 - 64bit Production
With the Partitioning, Real Application Clusters, Automatic Storage Management, Oracle Label
Security,
OLAP, Advanced Analytics and Real Application Testing options
```

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the GetDatabase API operation to get the default administration service connection strings.

Troubleshooting Connection Issues

The following issues might occur when connecting to a DB system or database.

ORA-28365: Wallet is Not Open Error

For a 1-node DB system or 2-node RAC DB system, regardless of how you connect to the DB system, *before* you use OS authentication to connect to a database (for example, `sqlplus / as sysdba`) be sure to set the ORACLE_UNQNAME variable. Otherwise, commands that require the TDE wallet will result in the error `ORA-28365: wallet is not open`.

Note that this is not an issue when using a TNS connection because ORACLE_UNQNAME is automatically set in the database CRS resource.

SSH Access Stops Working

If the DB system's root volume becomes full, you might lose the ability to SSH to the system (the SSH command will fail with permission denied errors). Before you copy a large amount of data to the root volume, for example, to migrate a database, use the `dbcli create-dbstorage` command to set up storage on the system's NVMe drives and then copy the database files to that storage. For more information, see Setting Up Storage on the DB System.

What Next?

Before you begin updating your DB system, review the information in Updating a DB System.

For information about setting up an Enterprise Manager console to monitor your databases, see Monitoring a Database.

Updating a DB System

Note

This topic is not applicable to Exadata DB systems. For information on how to update an Exadata DB system, see Updating an Exadata DB System

This topic includes information and instructions on how to update the OS of a bare metal or virtual machine DB system.

Warning

- Review all of the information before you begin updating the system. Updating the operating system through methods not described on this page can cause permanent loss of access.
- Always back up your databases prior to updating your DB system's operating system.

Bash Profile Updates

Do not add interactive commands such as `oraenv`, or commands that might return an error or warning message, to the `.bash_profile` file for the grid or oracle users. Adding such commands can prevent Database service operations from functioning properly.

Essential Firewall Rules

For a 1-node DB system or 2-node RAC DB system, do not remove or modify the following firewall rules in `/etc/sysconfig/iptables`:

- The firewall rules for ports 1521, 7070, and 7060 allow the Database service to manage the DB system. Removing or modifying them can result in the Database Service no longer operating properly.
- The firewall rules for 169.254.0.2:3260 and 169.254.0.3:80 prevent non-root users from escalating privileges and tampering with the system’s boot volume and boot process. Removing or modifying these rules can allow non-root users to modify the system's boot volume.

OS Updates

Before you update the OS, review the following important guidelines and information:

- Back up your DB system's databases prior to attempting an OS update.
- Do not remove packages from a DB system. However, you might have to remove custom RPMs (packages that were installed after the system was provisioned) for the update to complete successfully.

Warning

Do not install NetworkManager on the DB system. Installing this package and rebooting the system results in severe loss of access to the system.

- Oracle recommends that you test any updates thoroughly before updating a production system.
- The image used to launch a DB system is updated regularly with the necessary patches. After you launch a DB system, you are responsible for applying the required OS security updates published through the Oracle public YUM server.
- To apply OS updates, the DB system's VCN must be configured to allow access to the YUM repository. For more information, see Network Setup for DB Systems.

To update an OL7 OS on a DB system host

You can update the OS on 2-node RAC virtual machine DB systems in a rolling fashion.

Note

Ensure the Oracle Clusterware (CRS) is completely shut down before performing the OS kernel updates.

1. Log on to the DB system host as `opc`, and then sudo to the `root` user.

```
login as: opc
[opc@dbsys ~]$ sudo su -
```

2. If your DB system uses an image with the kernel version 4.1.12-124.27.1.el7uek (used with older images), then change the bootefi label before updating the OS.

To check the kernel version

Run the following command.

```
$ uname -r
```

Example response indicating kernel version 4.1.12-124.27.1.el7uek:

```
4.1.12-124.27.1.el7uek.x86_64
```

If you have kernel version 4.1.12-124.27.1.el7uek, then proceed to change the bootefi label.

To change the bootefi label (each node)

a. Edit /etc/fstab: Change the label `bootefi` to `BOOTEFI` (uppercase).
   Example:

```
LABEL=BOOTEFI             /boot/efi             vfat    defaults        1 2
```

b. Restart the DB node.

c. Run the following command to ensure that the required link is created.

```
$ sudo ls -lrt /etc/grub2-efi.cfg
```

   Example response indicating that the required link exists:

```
lrwxrwxrwx 1 root root 31 Sep  4 11:49 /etc/grub2-efi.cfg ->
../boot/efi/EFI/redhat/grub.cfg
```

3. Identify the host region by running the following command:

```
# curl -s http://169.254.169.254/opc/v1/instance/ |grep region
```

4. With the region you noted from the previous step, determine the region name, and perform the following two steps.
   See Regions and Availability Domains to look up the region name.
   a. Download the repo.

```
# wget https://swiftobjectstorage.<region_
name>.oraclecloud.com/v1/dbaaspatchstore/DBaaSOSPatches/oci_dbaas_ol7repo -O /tmp/oci_
dbaas_ol7repo
```

   This example output assumes the region is us-phoenix-1 (PHX).

```
# wget https://swiftobjectstorage.us-phoenix-
1.oraclecloud.com/v1/dbaaspatchstore/DBaaSOSPatches/oci_dbaas_ol7repo -O /tmp/oci_dbaas_
ol7repo
--2019-07-16 10:40:42-- https://swiftobjectstorage.us-phoenix-

100%
[==========================================================================================
==========================================================================================
==================================================>] 15,769 --.-K/s in 0.1s

2019-07-16 10:41:39 (123 KB/s) - `/tmp/versionlock.list' saved [15769/15769]
```

5. Copy the repo file to the `/etc/yum.repos.d` directory.

```
cp /tmp/oci_dbaas_ol7repo /etc/yum.repos.d/ol7.repo
```

6. Copy and overwrite the existing version lock file.

```
cp /etc/yum/pluginconf.d/versionlock.list /etc/yum/pluginconf.d/versionlock.list-`date +%Y%m%d`
cp /tmp/versionlock.list /etc/yum/pluginconf.d/versionlock.list
```

   The initial version lock file should be empty. However, it is a good practice to back it up in case it is not and you need to refer to it later.

7. Run the update command.

```
        |  18 MB     00:00
# yum update

  Updating   : libtalloc-2.1.13-1.el7.x86_64
                                2/6
  Updating   : pytalloc-2.1.13-1.el7.x86_64
                                3/6
  Installing : kernel-uek-4.1.12-124.28.5.el7uek.x86_64
                                4/6
  Cleanup    : pytalloc-2.1.10-1.el7.x86_64
                                5/6
  Cleanup    : libtalloc-2.1.10-1.el7.x86_64
                                6/6
```

Note

- Ignore the error activating message that results from running the update.
- An update will occur only if a versionlock file has a valid update available to apply to the DB system.

8. Restart the system.

```
$ sudo su -
# reboot
```

9. Run the following command to validate the update:

```
# uname -r
 4.1.12-124.28.5
```

In this example, then new kernel version is 4.1.12-124.28.5.

To update an OL6 OS on a DB system host

You can update the OS on 2-node RAC virtual machine DB systems in a rolling fashion.

Note

Ensure the Oracle Clusterware (CRS) is completely shut down before performing the OS kernel updates.

1. Log on to the DB system host as `opc`, and then sudo to the `root` user.

```
login as: opc
[opc@dbsys ~]$ sudo su -
```

2. Identify the host region by running the following command:

```
# curl -s http://169.254.169.254/opc/v1/instance/ |grep region
```

3. With the region you noted from the previous step, determine the region name, and perform the following two steps.
   See Regions and Availability Domains to look up the region name.

   a. Download the repo.

   ```
   # wget https://swiftobjectstorage.<region_
   name>.oraclecloud.com/v1/dbaaspatchstore/DBaaSOSPatches/oci_dbaas_ol6repo -O /tmp/oci_
   dbaas_ol6repo
   ```

   This example output assumes the region is us-phoenix-1 (PHX).

   ```
   # wget https://swiftobjectstorage.us-phoenix-

  Installing : yum-plugin-versionlock-1.1.30-40.0.1.el6.noarch
                                                        1/1
  Verifying  : yum-plugin-versionlock-1.1.30-40.0.1.el6.noarch
                                                        1/1

Installed:
  yum-plugin-versionlock.noarch 0:1.1.30-40.0.1.el6

Complete!
```

Note

Ignore the `RPMDB` warning messages that refer to `oda-hw-mgmt`.

6. Copy and overwrite the existing version lock file.

```
cp /etc/yum/pluginconf.d/versionlock.list /etc/yum/pluginconf.d/versionlock.list-`date +%Y%m%d`
cp /tmp/versionlock.list /etc/yum/pluginconf.d/versionlock.list
```

   The initial version lock file should be empty. However, it is a good practice to back it up in case it is not and you need to refer to it later.

7. Run the update command.

```
# yum update

Uploading /boot/initramfs-4.1.12-112.14.13.el6uek.x86_64.img to http://169.254.0.3/initrd
Uploading /tmp/tmp5HjrRUcmdline to http://169.254.0.3/cmdline

Error activating kernel/initrd/cmdline: 502 - <html>
<head><title>502 Bad Gateway</title></head>
<body bgcolor="white">
<center><h1>502 Bad Gateway</h1></center>
</body>
</html>
```

Note

- Ignore the error activating message that results from running the update.
- An update will occur only if a versionlock file has a valid update available to apply to the DB system.

8. Restart the system.

```
$ sudo su -
# reboot
```

9. Run the following command to validate the update:

```
# uname -r
 4.1.12-112.14.13
```

In this example, then new kernel version is 4.1.12-112.14.13.

For information about applying Oracle database patches to a DB system, see Patching a DB System.

Configuring a DB System

This topic provides information to help you configure your DB system.

Network Time Protocol

Oracle recommends that you run a Network Time Protocol (NTP) daemon on your 1-node DB systems to keep system clocks stable during rebooting. If you need information about an NTP daemon, see Setting Up "NTP (Network Time Protocol) Server" in RHEL/CentOS 7.

Oracle recommends that you configure NTP on both nodes in a 2-node RAC DB system to synchronize time across the nodes. If you do not configure NTP, then Oracle Clusterware configures and uses the Cluster Time Synchronization Service (CTSS), and the cluster time might be out-of-sync with applications that use NTP for time synchronization.

For information about configuring NTP on a version 12c database, see Setting Network Time Protocol for Cluster Time Synchronization. For a version 11g database, see Network Time Protocol Setting.

Transparent Data Encryption

All user-created tablespaces in a DB system database are encrypted by default, using Transparent Data Encryption (TDE).

- For version 12c databases, if you don't want your tablespaces encrypted, you can set the `ENCRYPT_NEW_TABLESPACES` database initialization parameter to `DDL`.
- On a 1- or 2-node RAC DB system, you can use the dbcli update-tdekey command to update the master encryption key for a database.

- You must create and activate a master encryption key for any PDBs that you create. After creating or plugging in a new PDB on a 1- or 2-node RAC DB System, use the `dbcli update-tdekey` command to create and activate a master encryption key for the PDB. Otherwise, you might encounter the error `ORA-28374: typed master key not found in wallet` when attempting to create tablespaces in the PDB. In a multitenant environment, each PDB has its own master encryption key which is stored in a single keystore used by all containers. For more information, see "Overview of Managing a Multitenant Environment" in the Oracle Database Administrator's Guide.
- For information about encryption on Exadata DB systems, see Using Tablespace Encryption in Exadata Cloud Service.

For detailed information about database encryption, see the Oracle Database Security White Papers.

Patching a DB System

Note

This topic is not applicable to Exadata DB systems.

This topic explains how to perform patching operations on bare metal and virtual machine DB systems and database homes by using the Console, API, or the database CLI (DBCLI).

Currently, the following patches are available:

Version	DB System Patch	Database Patch
19.0.0.0	October 2019	October 2019, July 2019, April 2019, January 2019
18.0.0.0	October 2019	October 2019, July 2019, April 2019, January 2019
12.2.0.1	October 2019	October 2019, July 2019, April 2019, January 2019

Version	DB System Patch	Database Patch
12.1.0.2	October 2019	October 2019, July 2019, April 2019, January 2019
11.2.0.4	Not applicable	October 2019, July 2019, April 2019, January 2019

For information about operating system updates, see OS Updates.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don't have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: The policy in Let database admins manage DB systems lets the specified group do everything with databases and related Database resources.

If you're new to policies, see Getting Started with Policies and Common Policies. If you want to dig deeper into writing policies for databases, see Details for the Database Service.

About Patching DB Systems

Because patching a system requires a reboot, plan to run the operations at a time when they will have minimal impact on users. To avoid system interruption, consider implementing a high availability strategy such as Oracle Data Guard. For more information, see Using Oracle Data Guard with the Database CLI.

Oracle recommends that you back up your database and test the patch on a test system before you apply the patch. For information about backing up the databases, see Backing Up a Database.

You must patch a DB system before you patch the databases within that system.

Prerequisites

The DB system requires access to the Oracle Cloud Infrastructure Object Storage service, including connectivity to the applicable Swift endpoint for Object Storage. Oracle recommends using a service gateway with the VCN to enable this access. For more information, see these topics:

- Network Setup for DB Systems: For information about setting up your VCN for the DB system, including the service gateway.
- https://cloud.oracle.com/infrastructure/storage/object-storage/faq: For information about the Swift endpoints to use.

Important

In addition to the prerequisites listed, ensure that the following conditions are met to avoid patching failures:

- The `/u01` directory on the database host file system has at least 15 GB of free space for the execution of patching processes.
- The Oracle Clusterware is up and running on the DB system.
- All nodes of the DB system are up and running.

See Patching Failures on Bare Metal and Virtual Machine DB Systems for details on problems that can result from not following these guidelines.

Using the Console

You can use the Console to view the history of patch operations on a DB system or an individual database, apply patches, and monitor the status of an operation.

Oracle recommends that you use the pre-check action to ensure your DB system or database home has met the requirements for the patch you want to apply.

PERFORMING PATCH OPERATIONS

To perform a patch operation on a DB system

1. Open the navigation menu. Under **Database**, click **Bare Metal, VM, and Exadata**.
2. Choose your **Compartment**.
   A list of DB systems is displayed.
3. Find the DB system on which you want to perform a patch operation, and click its name to display details about it.
4. Under **Resources**, click **Patches**.
5. Review the list of patches.
6. Click the Actions icon (three dots) for the patch you are interested in, and then click one of the following actions:
   - **Pre-check:** Check for any prerequisites to make sure that the patch can be successfully applied.
   - **Apply:** Performs the pre-check, and then applies the patch.
7. Confirm when prompted.
8. In the list of patches, click the patch name to display its patch request and monitor the progress of the patch operation.
   While a patch is being applied, the patch's status displays as **Applying** and the DB system's status displays as **Updating**. If the operation completes successfully, the patch's status changes to **Applied** and the DB system's status changes to **Available**.

To perform a patch operation on a database

Before you perform this procedure, ensure that the latest patch was successfully applied to the DB system.

1. Open the navigation menu. Under **Database**, click **Bare Metal, VM, and Exadata**.
2. Choose your **Compartment**.
   A list of DB systems is displayed.
3. Find the DB system where the database is located, and click the system name to display details about it.
   A list of databases is displayed.
4. Find the database on which you want to perform the patch operation, and click its name to display details about it.
5. Under **Resources**, click **Patches**.
6. Review the list of patches.
7. Click the Actions icon (three dots) for the patch you are interested in, and then click one of the following actions:
   - **Pre-check:** Check for any prerequisites to make sure that the patch can be successfully applied.
   - **Apply:** Performs the pre-check, and then applies the patch.
8. Confirm when prompted.
9. In the list of patches, click the patch name to display its patch request and monitor the progress of the patch operation.
   While a patch is being applied, the patch's status displays as **Applying** and the database's status displays as **Updating**. If the operation completes successfully, the patch's status changes to **Applied** and the database's status changes to **Available**.

VIEWING PATCH HISTORY

Each patch history entry represents an attempted patch operation and indicates whether the operation was successful or failed. You can retry a failed patch operation. Repeating an operation results in a new patch history entry.

Patch history views in the Console do not show patches that were applied by using command line tools like DBCLI or the Opatch utility.

To view the patch history of a DB system

1. Open the navigation menu. Under **Database**, click **Bare Metal, VM, and Exadata**.
2. Choose your **Compartment**.
   A list of DB systems is displayed.
3. Find the DB system you are interested in, and click the system name to display details about it.
4. Under **Resources**, click **Patch History**.
   The history of patch operations for that DB system is displayed.

To view the patch history of a database

1. Open the navigation menu. Under **Database**, click **Bare Metal, VM, and Exadata**.
2. Choose your **Compartment**.
   A list of DB systems is displayed.
3. Find the DB system where the database is located, and click the system name to display details about it.
   A list of databases is displayed.
4. Find the database you are interested in, and click its name to display details about it.
5. Under **Resources**, click **Patch History**.
   The history of patch operations for that database is displayed.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use these API operations to manage patching DB systems and databases.

DB systems:

- ListDbSystemPatches
- ListDbSystemPatchHistoryEntries
- GetDbSystemPatch
- GetDbSystemPatchHistoryEntry
- UpdateDbSystem

Databases:

- ListDbHomePatches
- ListDbHomePatchHistoryEntries
- GetDbHomePatch
- GetDbHomePatchHistoryEntry
- UpdateDbHome

For the complete list of APIs for the Database service, see Database Service API.

Using the Database CLI

This topic explains how to use the command line interface on the DB system to patch a DB system. Patches are available from the Oracle Cloud Infrastructure Object Storage service. You'll use the `dbcli` commands to download and apply patches to some or all of the components in your system.

PREREQUISITES

For connecting to the DB system via SSH, you'll need the path to private key associated with the public key used when the DB system was launched.

You also need the public or private IP address of the DB system. Use the private IP address to connect to the DB system from your on-premises network, or from within the virtual cloud network (VCN). This includes connecting from a host located on-premises connecting through a VPN or FastConnect to your VCN, or from another host in the same VCN. Use the DB System's public IP address to connect to the system from outside the cloud (with no VPN).

You can find the IP addresses in the Oracle Cloud Infrastructure Console on the **Database** page.

To update the CLI with the latest commands

Update the CLI to ensure you have the latest patching commands (older DB systems might not include them).

1. SSH to the DB System.

```
ssh -i <private_key_path> opc@<db_system_ip_address>
```

2. Log in as opc and then sudo to the root user. Use `sudo su -` with a hyphen to invoke the root user's profile, which will set the PATH to the dbcli directory (`/opt/oracle/dcs/bin`).

```
login as: opc

[opc@dbsys ~]$ sudo su -
```

3. Update the CLI by using the cliadm update-dbcli command.

```
[root@dbsys ~]# cliadm update-dbcli
{
  "jobId" : "dc9ce73d-ed71-4473-99cd-9663b9d79bfd",
  "status" : "Created",
  "message" : "Dcs cli will be updated",
  "reports" : [ ],
  "createTimestamp" : "January 18, 2017 10:19:34 AM PST",
  "resourceList" : [ ],
  "description" : "dbcli patching",
  "updatedTime" : "January 18, 2017 10:19:34 AM PST"
}
```

4. Wait for the update job to complete successfully. Check the status of the job by using the dbcli list-jobs command.

```
[root@dbsys ~]# dbcli list-jobs

ID                                       Description                    Created
          Status
---------------------------------------- ------------------------------ --------------------------
```

```
---------- ----------
dc9ce73d-ed71-4473-99cd-9663b9d79bfd     dbcli patching               January 18, 2017 10:19:34
AM PST    Success
```

To check for installed and available patches

1. SSH to the DB System.

```
ssh -i <private_key_path> opc@<db_system_ip_address>
```

2. Log in as opc and then sudo to the root user. Use `sudo su -` with a hyphen to invoke the root user's profile, which will set the PATH to the dbcli directory (`/opt/oracle/dcs/bin`).

```
login as: opc

[opc@dbsys ~]$ sudo su -
```

3. Display the installed patch versions by using the dbcli describe-component command. If the **Available Version** column indicates a version number for a component, you should update the component.

```
[root@dbsys ~]# dbcli describe-component
System Version
---------------
12.1.2.10.0

Component Name                             Installed Version    Available Version
------------------------------------------ -------------------- --------------------
OAK                                        12.1.2.10.0          up-to-date
GI                                         12.1.0.2.161018      up-to-date
ORADB12102_HOME1                           12.1.0.2.160719      12.1.0.2.161018
```

4. Display the latest patch versions available in Object Storage by using the dbcli describe-latestpatch command.

```
[root@dbsys ~]# dbcli describe-latestpatch

componentType   availableVersion
--------------- --------------------
gi              12.1.0.2.161018
```

```
db              11.2.0.4.161018
db              12.1.0.2.161018
oak             12.1.2.10.0
```

To patch server components

You can patch the Grid Infrastructure (GI) and storage management kit (OAK) server components.

1. SSH to the DB System.

   ```
   ssh -i <private_key_path> opc@<db_system_ip_address>
   ```

2. Log in as opc and then sudo to the root user. Use `sudo su -` with a hyphen to invoke the root user's profile, which will set the PATH to the dbcli directory (`/opt/oracle/dcs/bin`).

   ```
   login as: opc

   [opc@dbsys ~]$ sudo su -
   ```

3. Update the server components by using the dbcli update-server command.

   ```
   [root@dbsys ~]# dbcli update-server
   {
     "jobId" : "9a02d111-e902-4e94-bc6b-9b820ddf6ed8",
     "status" : "Created",
     "reports" : [ ],
     "createTimestamp" : "January 19, 2017 09:37:11 AM PST",
     "resourceList" : [ ],
     "description" : "Server Patching",
     "updatedTime" : "January 19, 2017 09:37:11 AM PST"
   }
   ```

   Note the job ID above.

4. Check the job output by using the dbcli describe-job command with the job ID.

   ```
   [root@dbsys ~]# dbcli describe-job -i 9a02d111-e902-4e94-bc6b-9b820ddf6ed8

   Job details
   ----------------------------------------------------------------
   ```

```
                     ID:  9a02d111-e902-4e94-bc6b-9b820ddf6ed8

```

5. Verify that the server components were updated successfully by using the dbcli describe-component command. The **Available Version** column should indicate `update-to-date`.

To patch database home components

1. SSH to the DB System.

```
ssh -i <private_key_path> opc@<db_system_ip_address>
```

2. Log in as opc and then sudo to the root user. Use `sudo su -` with a hyphen to invoke the

root user's profile, which will set the PATH to the dbcli directory (`/opt/oracle/dcs/bin`).

```
login as: opc

[opc@dbsys ~]$ sudo su -
```

3. Get the ID of the database home by using the dbcli list-dbhomes command.

```
[root@dbsys ~]# dbcli list-dbhomes
ID                                   Name                DB Version Home Location
------------------------------------ ------------------  ---------- ------------------------------
------------
b727bf80-c99e-4846-ac1f-28a81a725df6 OraDB12102_home1   12.1.0.2
/u01/app/orauser/product/12.1.0.2/dbhome_1
```

4. Update the database home components by using the dbcli update-dbhome command and providing the ID from the previous step.

```
[root@dbsys ~]# dbcli update-dbhome -i b727bf80-c99e-4846-ac1f-28a81a725df6
{
  "jobId" : "31b38f67-f993-4f2e-b7eb-5bccda9901ae",
  "status" : "Created",
  "message" : null,
  "reports" : [ ],
  "createTimestamp" : "January 20, 2017 10:08:48 AM PST",
  "resourceList" : [ ],
  "description" : "DB Home Patching: Home Id is 52e2e799-946a-4339-964b-c203dee35328",
  "updatedTime" : "January 20, 2017 10:08:48 AM PST"
}
```

Note the job ID above.

5. Check the job output by using the dbcli describe-job command with the job ID.

```
[root@dbsys ~]# dbcli describe-job -i 31b38f67-f993-4f2e-b7eb-5bccda9901ae

```

6. Verify that the database home components were updated successfully by using the dbcli describe-component command. The **Available Version** column should indicate `update-to-date`.

Applying Interim Patches

Note

This topic applies only to database homes in 1-node and 2-node RAC DB systems.

If you are required to apply an interim patch (previously known as a "one-off" patch) to fix a specific defect, follow the procedure in this section. You use the Opatch utility to apply an interim patch to a database home.

In the procedure example, the database home directory is **/u02/app/oracle/product/12.1.0.2/dbhome_1** and the patch number is **26543344**.

To apply an interim patch to a database home

1. Obtain the applicable interim patch from My Oracle Support.
2. Review the information in the patch README.txt file. This file might contain additional and/or custom instructions to follow to apply the patch successfully.
3. Use SCP or SFTP to place the patch on your target database.
4. Shut down each database that is running in the database home.

   ```
   srvctl stop database -db <db name> -stopoption immediate -verbose
   ```

5. Set the Oracle home environment variable to point to the target Oracle home.

   ```
   sudo su - oracle
   export ORACLE_HOME=/u02/app/oracle/product/12.1.0.2/dbhome_1
   ```

6. Change to the directory where you placed the patch, and unzip the patch.

   ```
   cd <work_dir_where_opatch_is stored>
   unzip p26543344_122010_Linux-x86-64.zip
   ```

7. Change to the directory with the unzipped patch, and check for conflicts.

   ```
   cd 26543344
   $ORACLE_HOME/OPatch/opatch prereq CheckConflictAgainstOHWithDetail -ph ./
   ```

8. Apply the patch.

   ```
   $ORACLE_HOME/OPatch/opatch apply
   ```

9. Verify the patch was applied successfully.

   ```
   $ORACLE_HOME/OPatch/opatch lsinventory -detail -oh $ORACLE_HOME
   ```

10. If the database home contains databases, restart them.

    ```
    $ORACLE_HOME/bin/srvctl start database -db <db_name>
    ```

    Otherwise, run the following command as root user.

    ```
    # /u01/app/<db_version>/grid/bin/setasmgidwrap o=/u01/app/oracle/product/<db_version>/dbhome_
    1/bin/oracle
    ```

11. If the readme indicates that the patch has a sqlpatch component, run the datapatch command against each database.
    Before you run datapatch, ensure that all pluggable databases (PDBs) are open. To open a PDB, you can use SQL*Plus to execute `ALTER PLUGGABLE DATABASE <pdb_name> OPEN READ WRITE;` against the PDB.

```
$ORACLE_HOME/OPatch/datapatch
```

Creating a Database

Note

This topic is not applicable to virtual machine DB systems.

When you launch a bare metal DB system, an initial database is created in that system. You can create additional databases in that DB system at any time by using the Console or the API. You can create an empty database or reproduce a database by using a backup. Note that if you are creating a database from an automatic backup, you can choose any level 0 weekly backup, or a level 1 incremental backup created after the most recent level 0 backup. For more information on automatic backups, see Automatic Incremental Backups.

The database edition will be the edition of the DB system in which the database is created, and each new database is created in a separate database home.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don't have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: The policy in Let database admins manage DB systems lets the specified group do everything with databases and related Database resources.

If you're new to policies, see Getting Started with Policies and Common Policies. If you want to dig deeper into writing policies for databases, see Details for the Database Service.

Using the Console

To create a new database in an existing DB system

Note

The database that you create will be the same edition as the initial database in the DB system.

1. Open the navigation menu. Under **Database**, click **Bare Metal, VM, and Exadata**.
2. Choose your **Compartment**.
   A list of DB systems is displayed.
3. In the list of DB systems, find the DB system in which you want to create the database, and then click its name to display details about it.
4. Click **Create Database**.

5. In the **Create Database** dialog, enter the following:
    - **Database name:** The name for the database. The database name must begin with an alphabetic character and can contain a maximum of eight alphanumeric characters. Special characters are not permitted.
