   - **Dimension Name**: A qualifier specified in the metric definition. For example, the dimension `resourceId` is specified in the metric definition for `CpuUtilization`.

     Note

     Long lists of dimensions are trimmed.

     - To view dimensions by name, type one or more characters in the box. A refreshed (trimmed) list shows matching dimension names.
     - To retrieve all dimensions for a given metric, use the following API operation: ListMetrics

   - **Dimension Value**: The value you want to use for the specified dimension. For example, the resource identifier for your instance of interest.
   - **+ Additional dimension**: Adds another name-value pair for a dimension.

4. Click **Done**.
   The default charts show the filtered results of your query.

To select different resources

1. View the default metric charts: Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Service Metrics**.
2. To select resources on a different compartment, select the **Compartment**.
   The default charts update to show results for the selected compartment.
3. To select a specific resource within the selected compartment, filter results by a resource-specific dimension, such as **resourceDisplayName**:
   a. To the right of **Dimensions**, click **Add**.
   b. For **Dimension Name**, select **resourceDisplayName** or other resource-specific dimension.

Note

Long lists of dimensions are trimmed.

- To view dimensions by name, type one or more characters in the box. A refreshed (trimmed) list shows matching dimension names.
- To retrieve all dimensions for a given metric, use the following API operation: ListMetrics

   c. For **Dimension Value**, select the value corresponding to the resource you want.
   d. Click **Done**.
   The default charts update to show filtered results.

To aggregate data from all metric streams

Aggregate all metric streams to view the average. For example, aggregate all metric streams

for CPU Utilization to view the average data across all resources. By default, a chart represents each metric stream with a line, which results in multiple lines per chart. When you aggregate metric streams, a chart represents all metric streams with a single line, which results in just one line per chart.

1. View the default metric charts: Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Service Metrics**.
2. Select **Aggregate Metric Streams**.

To change the time range

For metric queries, the interval you select drives the default resolution of the request, which determines the maximum time range of data returned.

Maximum time range returned for a query

The maximum time range returned for a metric query depends on the resolution. By default, for metric queries, the resolution is the same as the query interval. The maximum time range is calculated using the current time, regardless of any specified end time. Following are the maximum time ranges returned for each interval selection available in the Console.

Interval	Default resolution (metric queries)	Maximum time range returned
1h	1 hour	90 days
5m	5 minutes	30 days
1m	1 minute	7 days

See examples of returned data

Example 1: One-minute interval and resolution up to the current time, sent at 10:00 on

January 8th. No resolution or end time is specified, so the resolution defaults to the interval value of `1m`, and the end time defaults to the current time (`2019-01-08T10:00:00.789Z`). This request returns a maximum of 7 days of metric data points. The earliest data point possible within this seven-day period would be 10:00 on January 1st (`2019-01-01T10:00:00.789Z`).

Example 2: Five-minute interval with one-minute resolution up to two days ago, sent at 10:00 on January 8th. Because the resolution drives the maximum time range, a maximum of 7 days of metric data points is returned. While the end time specified was 10:00 on January 6th (`2019-01-06T10:00:00.789Z`), the earliest data point possible within this seven-day period would be 10:00 on January 1st (`2019-01-01T10:00:00.789Z`). Therefore, only 5 days of metric data points can be returned in this example.

For more information about the resolution parameter as used in metric queries, see SummarizeMetricsData.

1. View the default metric charts: Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Service Metrics**.
2. To select a period of time, such as **Last hour**, click **Start Time** or **End Time**.
3. To enter a time value, click in **Start Time** or **End Time** and then type a value.

To change a chart interval or statistic

For metric queries, the interval you select drives the default resolution of the request, which determines the maximum time range of data returned.

Maximum time range returned for a query

The maximum time range returned for a metric query depends on the resolution. By default, for metric queries, the resolution is the same as the query interval. The maximum time range is calculated using the current time, regardless of any specified end time. Following are the maximum time ranges returned for each interval selection available in the Console.

Interval	Default resolution (metric queries)	Maximum time range returned
1h	1 hour	90 days
5m	5 minutes	30 days
1m	1 minute	7 days

See examples of returned data

Example 1: One-minute interval and resolution up to the current time, sent at 10:00 on January 8th. No resolution or end time is specified, so the resolution defaults to the interval value of `1m`, and the end time defaults to the current time (`2019-01-08T10:00:00.789Z`). This request returns a maximum of 7 days of metric data points. The earliest data point possible within this seven-day period would be 10:00 on January 1st (`2019-01-01T10:00:00.789Z`).

Example 2: Five-minute interval with one-minute resolution up to two days ago, sent at 10:00 on January 8th. Because the resolution drives the maximum time range, a maximum of 7 days of metric data points is returned. While the end time specified was 10:00 on January 6th (`2019-01-06T10:00:00.789Z`), the earliest data point possible within this seven-day period would be 10:00 on January 1st (`2019-01-01T10:00:00.789Z`). Therefore, only 5 days of metric data points can be returned in this example.

For more information about the resolution parameter as used in metric queries, see SummarizeMetricsData.

1. View the default metric charts: Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Service Metrics**.
2. At the top of the chart you want, select an **Interval** or **Statistic**.
   For supported values, see Monitoring Query Language (MQL) Reference.

To go back to the default charts

1. View the default metric charts: Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Service Metrics**.
2. On the upper right, click **Reset charts**.

To view chart details

Chart details include the query as a Monitoring Query Language (MQL) expression and the names and OCIDs of represented resources.

1. View the default metric charts: Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Service Metrics**.
2. Click the chart you want.
3. To view a list of resources represented in the chart, click the arrow to the left of the query displayed under the chart.

   You can copy the OCID for a resource by clicking **Copy** to the right of the resource OCID.

To share a chart

Note

The person you share the chart with must have the required IAM policies for access to metrics.

On the upper right of the chart you want, go to **Options**, and then click **Copy Chart URL**.

To view a query in Metrics Explorer

On the upper right of the chart you want, go to **Options**, and then click **View Query in**

Metrics Explorer.

To copy a query (MQL expression)

On the upper right of the chart you want, go to **Options**, and then click **Copy Query (MQL)**.

To view default metric charts for a single resource

On the page for the resource of interest, under **Resources**, click **Metrics**.

For example, to view metric data for a Compute instance:

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
2. Click the instance you're interested in.
3. On the instance detail page, under **Resources**, click **Metrics**.
   A chart is shown for each metric. For a list of metrics related to Compute instances, see Compute Instance Metrics.

The Console displays the last hour of metric data for the selected resource. A chart is shown for each metric emitted by the selected resource.

For a list of metrics emitted by your resource, see Supported Services.

To create an alarm from a chart query

Follow the instructions for the page on which the query appears: Service Metrics or Metrics Explorer.

Service Metrics page

To create an alarm from a chart query (Service Metrics)

1. View the **Service Metrics** page: Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Service Metrics**.
2. At the top of the chart you're interested in, go to Options, and then select **Create an Alarm on this Query**.
3. On the **Create Alarm** page, under **Define alarm**, add the trigger, and fill in or update other alarm settings as needed:

Alarm settings

Basic Mode (default)

By default, this page uses **Basic Mode**, which separates the metric from its dimensions and its trigger rule.

- **Alarm Name**: User-friendly name for the new alarm. This name is sent as the title for notifications related to this alarm.

Rendering of the title by protocol

Protocol	Rendering of the title
Email	Subject line of the email message.
HTTPS (Custom URL)	Not rendered.
PagerDuty	Title field of the published message.
Slack	Not rendered.

- **Alarm Severity**: The perceived type of response required when the alarm is in the firing state.

- **Alarm Body**: The human-readable content of the notification delivered. Oracle recommends providing guidance to operators for resolving the alarm condition. Consider adding links to standard runbook practices. Example: "High CPU usage alert. Follow runbook instructions for resolution."
- **Tags (optional):** Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.
- **Metric description**: The metric to evaluate for the alarm condition.
    - **Compartment**: The compartment containing the resources that emit the metrics evaluated by the alarm. The selected compartment is also the storage location of the alarm. By default, the first accessible compartment is selected.
    - **Metric Namespace**: The service or application emitting metrics for the resources that you want to monitor.
    - **Resource Group** (optional): The group that the metric belongs to. A resource group is a custom string provided with a custom metric. Not applicable to service metrics.
    - **Metric Name**: The name of the metric. Only one metric can be specified. Example: **CpuUtilization**

- **Interval**: The aggregation window, or the frequency at which data points are aggregated.

  Interval values

  - **1m** - 1 minute
  - **5m** - 5 minutes
  - **1h** - 1 hour

  Note

  For alarm queries, the specified interval has no effect on the resolution of the request. The only valid value of the resolution for an alarm query request is `1m`. For more information about the resolution parameter as used in alarm queries, see Alarm.

- **Statistic**: The aggregation function.

  Statistic values

  - **COUNT**- The number of observations received in the specified time period.
  - **MAX** - The highest value observed during the specified time period.

- **MEAN** - The value of Sum divided by Count during the specified time period.
- **MIN** - The lowest value observed during the specified time period.
- **P50** - The value of the 50th percentile.
- **P90** - The value of the 90th percentile.
- **P95** - The value of the 95th percentile.
- **P99** - The value of the 99th percentile.
- **P99.5** - The value of the 99.5th percentile.
- **RATE** - The per-interval average rate of change.
- **SUM** - All values added together.

- **Metric dimensions**: Optional filters to narrow the metric data evaluated.

  Dimension fields

  - **Dimension Name**: A qualifier specified in the metric definition. For example, the dimension `resourceId` is specified in the metric definition for `CpuUtilization`.

    Note

    Long lists of dimensions are trimmed.

    - To view dimensions by name, type one or more characters in the box. A refreshed (trimmed) list shows matching dimension names.
    - To retrieve all dimensions for a given metric, use the following API operation: ListMetrics

  - **Dimension Value**: The value you want to use for the specified dimension. For example, the resource identifier for your instance of interest.
  - **+ Additional dimension**: Adds another name-value pair for a dimension.

- **Trigger rule**: The condition that must be satisfied for the alarm to be in the firing state. The condition can specify a threshold, such as 90% for CPU Utilization, or an absence.

- **Operator**: The operator used in the condition threshold.

  Operator values

  - **greater than**
  - **greater than or equal to**
  - **equal to**
  - **less than**
  - **less than or equal to**
  - **between** (inclusive of specified values)
  - **outside** (inclusive of specified values)
  - **absent**

- **Value**: The value to use for the condition threshold.
- **Trigger Delay Minutes**: The number of minutes that the condition must be maintained before the alarm is in firing state.

Advanced Mode

Click **Advanced Mode** or **Switch to Advanced Mode** to view the alarm query as a Monitoring Query Language (MQL) expression. Edit your query using MQL syntax to aggregate results by group or for additional parameter values. See Monitoring Query Language (MQL) Reference.

- **Alarm Name**: User-friendly name for the new alarm. This name is sent as the title for notifications related to this alarm.

Rendering of the title by protocol

Protocol	Rendering of the title
Email	Subject line of the email message.
HTTPS (Custom URL)	Not rendered.
PagerDuty	Title field of the published message.
Slack	Not rendered.

- **Alarm Severity**: The perceived type of response required when the alarm is in the firing state.
- **Alarm Body**: The human-readable content of the notification delivered. Oracle recommends providing guidance to operators for resolving the alarm condition. Consider adding links to standard runbook practices. Example: "High CPU usage alert. Follow runbook instructions for resolution."
- **Tags (optional):** Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.
- **Metric description, dimensions, and trigger rule**: The metric to evaluate for the alarm condition, including dimensions and the trigger rule.
    - **Compartment**: The compartment containing the resources that emit the metrics evaluated by the alarm. The selected compartment is also the

storage location of the alarm. By default, the first accessible compartment is selected.

- **Metric Namespace**: The service or application emitting metrics for the resources that you want to monitor.
- **Resource Group** (optional): The group that the metric belongs to. A resource group is a custom string provided with a custom metric. Not applicable to service metrics.
- **Query Code Editor** box: The alarm query as a Monitoring Query Language (MQL) expression.
  Example alarm query:

  ```
  CpuUtilization[1m]{availabilityDomain=AD1}.groupBy(poolId).percentile(0.9) > 85
  ```

  For query syntax and examples, see Working with Metric Queries.
- **Trigger Delay Minutes**: The number of minutes that the condition must be maintained before the alarm is in firing state.

The chart below the **Define alarm** section dynamically displays the last six hours of emitted metrics according to currently selected fields for the query. Very small or large values are indicated by International System of Units (SI units), such as M for mega (10 to the sixth power).

4. Under **Notifications**, select or create at least one notification destination:

Notifications settings

- **Destinations**:
  - **Destination Service**: The provider of the destination to use for notifications.

Available options:

- **Notifications Service**.

- **Compartment**: The compartment storing the topic to be used for notifications. Can be a different compartment from the alarm and metric. By default, the first accessible compartment is selected.
- **Topic**: The topic to use for notifications. Each topic supports a subscription protocol, such as PagerDuty.
- **Create a topic**: Sets up a topic and subscription protocol in the selected compartment, using the specified destination service.
  - **Topic Name**: User-friendly name for the new topic. Example: "Operations Team " for a topic used to notify operations staff of firing alarms.
  - **Topic Description**: Description of the new topic.
  - **Subscription Protocol**: Medium of communication to use for the new topic. Configure your subscription for the protocol you want:

    ### Email subscription

    Sends an email message when you publish a message to the subscription's parent topic.

    - **Subscription Protocol**: Select **Email**.
    - **Subscription Email**: Type an email address.

HTTPS (Custom URL) subscription

Sends specified information when you publish a message to the subscription's parent topic.

Endpoint format (URL using HTTPS protocol):

```
https://<anyvalidURL>
```

Basic access authentication is supported, allowing you to specify a username and password in the URL, as in `https://user:password@domain.com` or `https://user@domain.com`. The username and password are encrypted over the SSL connection established when using HTTPS. For more information about Basic Access Authentication, see RFC-2617.

Query parameters are not allowed in URLs.

- **Subscription Protocol**: Select **HTTPS (Custom URL)**.
- **Subscription URL**: Type (or copy and paste) the URL you want to use as the endpoint.

PagerDuty subscription

Creates a PagerDuty incident by default when you publish a message to the subscription's parent topic.

Endpoint format (URL):

```
https://events.pagerduty.com/integration/<integrationkey>/enqueue
```

Query parameters are not allowed in URLs.

To create an endpoint for a PagerDuty subscription (set up and retrieve an integration key), see the PagerDuty documentation.

- **Subscription Protocol**: Select **PagerDuty**.
- **Subscription URL**: Type (or copy and paste) the *integration key* portion of the URL for your PagerDuty subscription. (The other portions of the URL are hard-coded.)

Slack subscription

Note

See the following known issue for up-to-date information about creating Slack subscriptions.

Sends a message to the specified Slack channel by default when you publish a message to the subscription's parent topic.

Endpoint format (URL):

```
https://hooks.slack.com/services/<webhook-token>
```

The *<webhook-token>* portion of the URL contains two slashes (/).

Query parameters are not allowed in URLs.

To create an endpoint for a Slack subscription (using a webhook for your Slack channel), see the Slack documentation.

        - **Subscription Protocol**: Select **Slack**.
        - **Subscription URL**: Type (or copy and paste) the Slack endpoint, including your webhook token.

    - **+ Additional destination service**: Adds another destination service and topic to use for notifications.

> **Note**
>
> Each alarm is limited to one destination per supported destination service.

- **Repeat Notification?**: While the alarm is in the firing state, resends notifications at the specified interval.
- **Notification Interval**: The period of time to wait before resending the notification.
- **Suppress Notifications**: Sets up a suppression time window during which to suspend evaluations and notifications. Useful for avoiding alarm notifications during system maintenance periods.
    - **Suppression Description**
    - **Start Time**
    - **End Time**

5. If you want to disable the new alarm, clear **Enable This Alarm?**.
6. Click **Save alarm**.
   The new alarm is listed on the **Alarm Definitions** page.
   For more information about alarms, see Alarms Feature Overview.

Metrics Explorer page

To create an alarm from a chart query (Metrics Explorer)

1. View the **Metrics Explorer** page: Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Metrics Explorer**.
2. If necessary, open the query for editing: Click the **Edit query** icon.
3. Click **Create Alarm**.
4. On the **Create Alarm** page, under **Define alarm**, add the trigger, and fill in or update other alarm settings as needed:

Alarm settings

Basic Mode (default)

By default, this page uses **Basic Mode**, which separates the metric from its dimensions and its trigger rule.

- **Alarm Name**: User-friendly name for the new alarm. This name is sent as the title for notifications related to this alarm.

Rendering of the title by protocol

Protocol	Rendering of the title
Email	Subject line of the email message.
HTTPS (Custom URL)	Not rendered.
PagerDuty	Title field of the published message.
Slack	Not rendered.

- **Alarm Severity**: The perceived type of response required when the alarm is in the firing state.
- **Alarm Body**: The human-readable content of the notification delivered. Oracle recommends providing guidance to operators for resolving the alarm condition. Consider adding links to standard runbook practices. Example: "High CPU usage alert. Follow runbook instructions for resolution."
- **Tags (optional):** Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.
- **Metric description**: The metric to evaluate for the alarm condition.
    - **Compartment**: The compartment containing the resources that emit the metrics evaluated by the alarm. The selected compartment is also the storage location of the alarm. By default, the first accessible compartment is selected.
    - **Metric Namespace**: The service or application emitting metrics for the resources that you want to monitor.
    - **Resource Group** (optional): The group that the metric belongs to. A resource group is a custom string provided with a custom metric. Not applicable to service metrics.
    - **Metric Name**: The name of the metric. Only one metric can be specified. Example: **CpuUtilization**

- **Interval**: The aggregation window, or the frequency at which data points are aggregated.

  ### Interval values

  - **1m** - 1 minute
  - **5m** - 5 minutes
  - **1h** - 1 hour

  Note

  For alarm queries, the specified interval has no effect on the resolution of the request. The only valid value of the resolution for an alarm query request is `1m`. For more information about the resolution parameter as used in alarm queries, see Alarm.

- **Statistic**: The aggregation function.

  ### Statistic values

  - **COUNT**- The number of observations received in the specified time period.
  - **MAX** - The highest value observed during the specified time period.

- **MEAN** - The value of Sum divided by Count during the specified time period.
- **MIN** - The lowest value observed during the specified time period.
- **P50** - The value of the 50th percentile.
- **P90** - The value of the 90th percentile.
- **P95** - The value of the 95th percentile.
- **P99** - The value of the 99th percentile.
- **P99.5** - The value of the 99.5th percentile.
- **RATE** - The per-interval average rate of change.
- **SUM** - All values added together.

- **Metric dimensions**: Optional filters to narrow the metric data evaluated.

  Dimension fields

  - **Dimension Name**: A qualifier specified in the metric definition. For example, the dimension `resourceId` is specified in the metric definition for `CpuUtilization`.

    Note

    Long lists of dimensions are trimmed.

    - To view dimensions by name, type one or more characters in the box. A refreshed (trimmed) list shows matching dimension names.
    - To retrieve all dimensions for a given metric, use the following API operation: ListMetrics

  - **Dimension Value**: The value you want to use for the specified dimension. For example, the resource identifier for your instance of interest.
  - **+ Additional dimension**: Adds another name-value pair for a dimension.

- **Trigger rule**: The condition that must be satisfied for the alarm to be in the firing state. The condition can specify a threshold, such as 90% for CPU Utilization, or an absence.

- **Operator**: The operator used in the condition threshold.

  Operator values

  - **greater than**
  - **greater than or equal to**
  - **equal to**
  - **less than**
  - **less than or equal to**
  - **between** (inclusive of specified values)
  - **outside** (inclusive of specified values)
  - **absent**

- **Value**: The value to use for the condition threshold.
- **Trigger Delay Minutes**: The number of minutes that the condition must be maintained before the alarm is in firing state.

Advanced Mode

Click **Advanced Mode** or **Switch to Advanced Mode** to view the alarm query as a Monitoring Query Language (MQL) expression. Edit your query using MQL syntax to aggregate results by group or for additional parameter values. See Monitoring Query Language (MQL) Reference.

- **Alarm Name**: User-friendly name for the new alarm. This name is sent as the title for notifications related to this alarm.

Rendering of the title by protocol

Protocol	Rendering of the title
Email	Subject line of the email message.
HTTPS (Custom URL)	Not rendered.
PagerDuty	Title field of the published message.
Slack	Not rendered.

- **Alarm Severity**: The perceived type of response required when the alarm is in the firing state.
- **Alarm Body**: The human-readable content of the notification delivered. Oracle recommends providing guidance to operators for resolving the alarm condition. Consider adding links to standard runbook practices. Example: "High CPU usage alert. Follow runbook instructions for resolution."
- **Tags (optional):** Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.
- **Metric description, dimensions, and trigger rule**: The metric to evaluate for the alarm condition, including dimensions and the trigger rule.
    - **Compartment**: The compartment containing the resources that emit the metrics evaluated by the alarm. The selected compartment is also the

storage location of the alarm. By default, the first accessible compartment is selected.

- **Metric Namespace**: The service or application emitting metrics for the resources that you want to monitor.
- **Resource Group** (optional): The group that the metric belongs to. A resource group is a custom string provided with a custom metric. Not applicable to service metrics.
- **Query Code Editor** box: The alarm query as a Monitoring Query Language (MQL) expression.
  Example alarm query:

  ```
  CpuUtilization[1m]{availabilityDomain=AD1}.groupBy(poolId).percentile(0.9) > 85
  ```

  For query syntax and examples, see Working with Metric Queries.
- **Trigger Delay Minutes**: The number of minutes that the condition must be maintained before the alarm is in firing state.

The chart below the **Define alarm** section dynamically displays the last six hours of emitted metrics according to currently selected fields for the query. Very small or large values are indicated by International System of Units (SI units), such as M for mega (10 to the sixth power).

5. Under **Notifications**, select or create at least one notification destination:

Notifications settings

- **Destinations**:
  - **Destination Service**: The provider of the destination to use for notifications.

Available options:

- **Notifications Service**.

- **Compartment**: The compartment storing the topic to be used for notifications. Can be a different compartment from the alarm and metric. By default, the first accessible compartment is selected.
- **Topic**: The topic to use for notifications. Each topic supports a subscription protocol, such as PagerDuty.
- **Create a topic**: Sets up a topic and subscription protocol in the selected compartment, using the specified destination service.
  - **Topic Name**: User-friendly name for the new topic. Example: "Operations Team " for a topic used to notify operations staff of firing alarms.
  - **Topic Description**: Description of the new topic.
  - **Subscription Protocol**: Medium of communication to use for the new topic. Configure your subscription for the protocol you want:

    ### Email subscription

    Sends an email message when you publish a message to the subscription's parent topic.

    - **Subscription Protocol**: Select **Email**.
    - **Subscription Email**: Type an email address.

HTTPS (Custom URL) subscription

Sends specified information when you publish a message to the subscription's parent topic.

Endpoint format (URL using HTTPS protocol):

```
https://<anyvalidURL>
```

Basic access authentication is supported, allowing you to specify a username and password in the URL, as in `https://user:password@domain.com` or `https://user@domain.com`. The username and password are encrypted over the SSL connection established when using HTTPS. For more information about Basic Access Authentication, see RFC-2617.

Query parameters are not allowed in URLs.

- **Subscription Protocol**: Select **HTTPS (Custom URL)**.
- **Subscription URL**: Type (or copy and paste) the URL you want to use as the endpoint.

PagerDuty subscription

Creates a PagerDuty incident by default when you publish a message to the subscription's parent topic.

Endpoint format (URL):

```
https://events.pagerduty.com/integration/<integrationkey>/enqueue
```

Query parameters are not allowed in URLs.

To create an endpoint for a PagerDuty subscription (set up and retrieve an integration key), see the PagerDuty documentation.

- **Subscription Protocol**: Select **PagerDuty**.
- **Subscription URL**: Type (or copy and paste) the *integration key* portion of the URL for your PagerDuty subscription. (The other portions of the URL are hard-coded.)

Slack subscription

Note

See the following known issue for up-to-date information about creating Slack subscriptions.

Sends a message to the specified Slack channel by default when you publish a message to the subscription's parent topic.

Endpoint format (URL):

```
https://hooks.slack.com/services/<webhook-token>
```

The *<webhook-token>* portion of the URL contains two slashes (/).

Query parameters are not allowed in URLs.

To create an endpoint for a Slack subscription (using a webhook for your Slack channel), see the Slack documentation.

        - **Subscription Protocol**: Select **Slack**.
        - **Subscription URL**: Type (or copy and paste) the Slack endpoint, including your webhook token.
    - **+ Additional destination service**: Adds another destination service and topic to use for notifications.

> **Note**
>
> Each alarm is limited to one destination per supported destination service.

- **Repeat Notification?**: While the alarm is in the firing state, resends notifications at the specified interval.
- **Notification Interval**: The period of time to wait before resending the notification.
- **Suppress Notifications**: Sets up a suppression time window during which to suspend evaluations and notifications. Useful for avoiding alarm notifications during system maintenance periods.
    - **Suppression Description**
    - **Start Time**
    - **End Time**

6. If you want to disable the new alarm, clear **Enable This Alarm?**.
7. Click **Save alarm**.
   The new alarm is listed on the **Alarm Definitions** page.
   For more information about alarms, see Alarms Feature Overview.

resource page

Examples of resource pages are Compute instance detail pages and Block Volume volume detail pages. Alarms are available from these pages for resources that emit metrics.

To create an alarm from a chart query (resource page)

1. To view charts: On the resource page, under **Resources**, click **Metrics**.
2. At the top of the chart you're interested in, go to **Options**, and then select **Create an Alarm on this Query**.
3. On the **Create Alarm** page, under **Define alarm**, add the trigger, and fill in or update other alarm settings as needed:

Alarm settings

Basic Mode (default)

By default, this page uses **Basic Mode**, which separates the metric from its dimensions and its trigger rule.

- **Alarm Name**: User-friendly name for the new alarm. This name is sent as the title for notifications related to this alarm.

Rendering of the title by protocol

Protocol	Rendering of the title
Email	Subject line of the email message.
HTTPS (Custom URL)	Not rendered.

Protocol	Rendering of the title
PagerDuty	Title field of the published message.
Slack	Not rendered.

- **Alarm Severity**: The perceived type of response required when the alarm is in the firing state.
- **Alarm Body**: The human-readable content of the notification delivered. Oracle recommends providing guidance to operators for resolving the alarm condition. Consider adding links to standard runbook practices. Example: "High CPU usage alert. Follow runbook instructions for resolution."
- **Tags (optional):** Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.
- **Metric description**: The metric to evaluate for the alarm condition.
    - **Compartment**: The compartment containing the resources that emit the metrics evaluated by the alarm. The selected compartment is also the storage location of the alarm. By default, the first accessible compartment is selected.
    - **Metric Namespace**: The service or application emitting metrics for the resources that you want to monitor.

- **Resource Group** (optional): The group that the metric belongs to. A resource group is a custom string provided with a custom metric. Not applicable to service metrics.
- **Metric Name**: The name of the metric. Only one metric can be specified. Example: **CpuUtilization**
- **Interval**: The aggregation window, or the frequency at which data points are aggregated.

  Interval values

  - **1m** - 1 minute
  - **5m** - 5 minutes
  - **1h** - 1 hour

  Note

  For alarm queries, the specified interval has no effect on the resolution of the request. The only valid value of the resolution for an alarm query request is `1m`. For more information about the resolution parameter as used in alarm queries, see Alarm.

- **Statistic**: The aggregation function.

Statistic values

- **COUNT**- The number of observations received in the specified time period.
- **MAX** - The highest value observed during the specified time period.
- **MEAN** - The value of Sum divided by Count during the specified time period.
- **MIN** - The lowest value observed during the specified time period.
- **P50** - The value of the 50th percentile.
- **P90** - The value of the 90th percentile.
- **P95** - The value of the 95th percentile.
- **P99** - The value of the 99th percentile.
- **P99.5** - The value of the 99.5th percentile.
- **RATE** - The per-interval average rate of change.
- **SUM** - All values added together.

- **Metric dimensions**: Optional filters to narrow the metric data evaluated.

  Dimension fields

  - **Dimension Name**: A qualifier specified in the metric definition. For example, the dimension `resourceId` is specified in the metric definition for `CpuUtilization`.

    Note

    Long lists of dimensions are trimmed.

    - To view dimensions by name, type one or more characters in the box. A refreshed (trimmed) list shows matching dimension names.
    - To retrieve all dimensions for a given metric, use the following API operation: ListMetrics

  - **Dimension Value**: The value you want to use for the specified dimension. For example, the resource identifier for your instance of interest.
  - **+ Additional dimension**: Adds another name-value pair for a dimension.

- **Trigger rule**: The condition that must be satisfied for the alarm to be in the firing state. The condition can specify a threshold, such as 90% for CPU Utilization, or an absence.

- **Operator**: The operator used in the condition threshold.

  Operator values

  - **greater than**
  - **greater than or equal to**
  - **equal to**
  - **less than**
  - **less than or equal to**
  - **between** (inclusive of specified values)
  - **outside** (inclusive of specified values)
  - **absent**

- **Value**: The value to use for the condition threshold.
- **Trigger Delay Minutes**: The number of minutes that the condition must be maintained before the alarm is in firing state.

Advanced Mode

Click **Advanced Mode** or **Switch to Advanced Mode** to view the alarm query as a Monitoring Query Language (MQL) expression. Edit your query using MQL syntax to aggregate results by group or for additional parameter values. See Monitoring Query Language (MQL) Reference.

- **Alarm Name**: User-friendly name for the new alarm. This name is sent as the title for notifications related to this alarm.

Rendering of the title by protocol

Protocol	Rendering of the title
Email	Subject line of the email message.
HTTPS (Custom URL)	Not rendered.
PagerDuty	Title field of the published message.
Slack	Not rendered.

- **Alarm Severity**: The perceived type of response required when the alarm is in the firing state.
- **Alarm Body**: The human-readable content of the notification delivered. Oracle recommends providing guidance to operators for resolving the alarm condition. Consider adding links to standard runbook practices. Example: "High CPU usage alert. Follow runbook instructions for resolution."
- **Tags (optional):** Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.
- **Metric description, dimensions, and trigger rule**: The metric to evaluate for the alarm condition, including dimensions and the trigger rule.
    - **Compartment**: The compartment containing the resources that emit the metrics evaluated by the alarm. The selected compartment is also the

storage location of the alarm. By default, the first accessible compartment is selected.

- **Metric Namespace**: The service or application emitting metrics for the resources that you want to monitor.
- **Resource Group** (optional): The group that the metric belongs to. A resource group is a custom string provided with a custom metric. Not applicable to service metrics.
- **Query Code Editor** box: The alarm query as a Monitoring Query Language (MQL) expression.
  Example alarm query:

  ```
  CpuUtilization[1m]{availabilityDomain=AD1}.groupBy(poolId).percentile(0.9) > 85
  ```

  For query syntax and examples, see Working with Metric Queries.
- **Trigger Delay Minutes**: The number of minutes that the condition must be maintained before the alarm is in firing state.

The chart below the **Define alarm** section dynamically displays the last six hours of emitted metrics according to currently selected fields for the query. Very small or large values are indicated by International System of Units (SI units), such as M for mega (10 to the sixth power).

4. Under **Notifications**, select or create at least one notification destination:

Notifications settings

- **Destinations**:
  - **Destination Service**: The provider of the destination to use for notifications.

Available options:

- **Notifications Service**.

- **Compartment**: The compartment storing the topic to be used for notifications. Can be a different compartment from the alarm and metric. By default, the first accessible compartment is selected.
- **Topic**: The topic to use for notifications. Each topic supports a subscription protocol, such as PagerDuty.
- **Create a topic**: Sets up a topic and subscription protocol in the selected compartment, using the specified destination service.
  - **Topic Name**: User-friendly name for the new topic. Example: "Operations Team " for a topic used to notify operations staff of firing alarms.
  - **Topic Description**: Description of the new topic.
  - **Subscription Protocol**: Medium of communication to use for the new topic. Configure your subscription for the protocol you want:

    ### Email subscription

    Sends an email message when you publish a message to the subscription's parent topic.

    - **Subscription Protocol**: Select **Email**.
    - **Subscription Email**: Type an email address.

HTTPS (Custom URL) subscription

Sends specified information when you publish a message to the subscription's parent topic.

Endpoint format (URL using HTTPS protocol):

```
https://<anyvalidURL>
```

Basic access authentication is supported, allowing you to specify a username and password in the URL, as in `https://user:password@domain.com` or `https://user@domain.com`. The username and password are encrypted over the SSL connection established when using HTTPS. For more information about Basic Access Authentication, see RFC-2617.

Query parameters are not allowed in URLs.

- **Subscription Protocol**: Select **HTTPS (Custom URL)**.
- **Subscription URL**: Type (or copy and paste) the URL you want to use as the endpoint.

PagerDuty subscription

Creates a PagerDuty incident by default when you publish a message to the subscription's parent topic.

Endpoint format (URL):

```
https://events.pagerduty.com/integration/<integrationkey>/enqueue
```

Query parameters are not allowed in URLs.

To create an endpoint for a PagerDuty subscription (set up and retrieve an integration key), see the PagerDuty documentation.

- **Subscription Protocol**: Select **PagerDuty**.
- **Subscription URL**: Type (or copy and paste) the *integration key* portion of the URL for your PagerDuty subscription. (The other portions of the URL are hard-coded.)

Slack subscription

Note

See the following known issue for up-to-date information about creating Slack subscriptions.

Sends a message to the specified Slack channel by default when you publish a message to the subscription's parent topic.

Endpoint format (URL):

```
https://hooks.slack.com/services/<webhook-token>
```

The *<webhook-token>* portion of the URL contains two slashes (/).

Query parameters are not allowed in URLs.

To create an endpoint for a Slack subscription (using a webhook for your Slack channel), see the Slack documentation.

- **Subscription Protocol**: Select **Slack**.
- **Subscription URL**: Type (or copy and paste) the Slack endpoint, including your webhook token.

◦ **+ Additional destination service**: Adds another destination service and topic to use for notifications.

Note

Each alarm is limited to one destination per supported destination service.

- **Repeat Notification?**: While the alarm is in the firing state, resends notifications at the specified interval.
- **Notification Interval**: The period of time to wait before resending the notification.
- **Suppress Notifications**: Sets up a suppression time window during which to suspend evaluations and notifications. Useful for avoiding alarm notifications during system maintenance periods.
  - **Suppression Description**
  - **Start Time**
  - **End Time**

5. If you want to disable the new alarm, clear **Enable This Alarm?**.
6. Click **Save alarm**.
   The new alarm is listed on the **Alarm Definitions** page.
   For more information about alarms, see Alarms Feature Overview.

Building Metric Queries

This topic describes how to query metrics for resources of interest, create alarms from a given query, and share Console charts.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Prerequisites

- IAM policies: Querying metrics is part of monitoring. To monitor resources, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.
- Metrics exist in Monitoring: The resources that you want to monitor must emit metrics to the Monitoring service.
- Compute instances: To emit metrics, Compute instances must be monitoring-enabled. OracleCloudAgent software installation may also be required. For more information, see Enabling Monitoring for Compute Instances.

Working with Metric Queries

This section shows MQL syntax of metric and alarm queries.

Use metric queries to actively and passively monitor your cloud resources. Actively monitor with metric queries that you generate spontaneously, on demand. In the Console, update a chart to show data from multiple queries. Store queries you want to reuse. Passively monitor with alarms that add a condition, or trigger rule, to a metric query.

Metric query syntax (boldface elements are required):

`metric[interval]``{dimensionname=dimensionvalue}.groupingfunction.`**`statistic`**

Threshold Alarm query syntax (boldface elements are required):

`metric[interval]``{dimensionname=dimensionvalue}.groupingfunction.`**`statistic alarmoperator alarmvalue`**

For supported parameter values, see Monitoring Query Language (MQL) Reference.

Example queries

Simple metric query

Maximum CPU Utilization at a one-minute interval.

Number of lines displayed in the metric chart (Console): 1 per resource.

```
CpuUtilization[1m].max()
```

Filtered metric query

Maximum CPU Utilization at a one-minute interval, filtered to a single resource.

Number of lines displayed in the metric chart (Console): 1.

```
CpuUtilization[1m]{resourceId="ocid1.instance.oc1.phx.exampleuniqueID"}.max()
```

Aggregated metric query

All IopsRead at a one-minute interval, filtered to a compartment, aggregated for the maximum.

Number of lines displayed in the metric chart (Console): 1.

```
IopsRead[1m]
{compartmentId="ocid1.compartment.oc1.phx..exampleuniqueID"}.grouping().max()
```

Group-aggregated metric query

Aggregated average of CPU Utilization by availability domain and pool ID, filtered to Compute instances that use the specified shape.

Number of lines displayed in the metric chart (Console): 1 per pool and 1 per availability domain.

```
CPUUtilization[1m]{shape="VM.Standard2.8"}.groupBy
(availabilityDomain,poolId).mean()
```

Alarm query (threshold)

Triggered when the 90th percentile of CPU Utilization, aggregated by pool ID, and filtered to the specified availability domain, exceeds 85.

Number of lines displayed in the metric chart (Console): 1 per pool.

```
CpuUtilization[1m]{availabilityDomain="VeBZ:PHX-AD-1"}.groupBy
(poolId).percentile(0.9) > 85
```

Grouped count of resources (alarm query or metric query)

Note

Nested alarm queries are not currently supported in the Console. Use the API to create alarms with nested queries.

An example of a nested query is a grouped count of hosts with up time greater than zero, where the alarm query to identify these hosts is defined within parentheses:

```
(metric[1h].groupBy(host).min() > 0).grouping().count()
```

You can use such a query to either define an alarm or query a metric.

For background information on metrics in Oracle Cloud Infrastructure, see Metrics Feature Overview.

Using the Console

To create a query

1. Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Metrics Explorer**.
   The **Metrics Explorer** page displays an empty chart with fields to build a query.
2. Fill in the fields for a new query.
   - **Compartment**: The compartment containing the resources that you want to monitor. By default, the first accessible compartment is selected.
   - **Metric Namespace**: The service or application emitting metrics for the resources that you want to monitor.
   - **Resource Group** (optional): The group that the metric belongs to. A resource group is a custom string provided with a custom metric. Not applicable to service metrics.
   - **Metric Name**: The name of the metric. Only one metric can be specified. Metric selections depend on the selected compartment and metric namespace.
     Example: **CpuUtilization**
   - **Interval**: The aggregation window.

Interval values

- **1m** - 1 minute
- **5m** - 5 minutes
- **1h** - 1 hour

Note

For metric queries, the interval you select drives the default resolution of the request, which determines the maximum time range of data returned.

Maximum time range returned for a query

The maximum time range returned for a metric query depends on the resolution. By default, for metric queries, the resolution is the same as the query interval. The maximum time range is calculated using the current time, regardless of any specified end time. Following are the maximum time ranges returned for each interval selection available in the Console.

Interval	Default resolution (metric queries)	Maximum time range returned
1h	1 hour	90 days
5m	5 minutes	30 days
1m	1 minute	7 days

See examples of returned data

Example 1: One-minute interval and resolution up to the current time, sent at 10:00 on January 8th. No resolution or end time is specified, so the resolution defaults to the interval value of `1m`, and the end time defaults to the current time (`2019-01-08T10:00:00.789Z`). This request returns a maximum of 7 days of metric data points. The earliest data point possible within this seven-day period would be 10:00 on January 1st (`2019-01-01T10:00:00.789Z`).

Example 2: Five-minute interval with one-minute resolution up to two days ago, sent at 10:00 on January 8th. Because the resolution drives the maximum time range, a maximum of 7 days of metric data points is returned. While the end time specified was 10:00 on January 6th (`2019-01-06T10:00:00.789Z`), the earliest data point possible within this seven-day period would be 10:00 on January 1st (`2019-01-01T10:00:00.789Z`). Therefore, only 5 days of metric data points can be returned in this example.

For more information about the resolution parameter as used in metric queries, see SummarizeMetricsData.

- **Statistic**: The aggregation function.

Statistic values

- **COUNT**- The number of observations received in the specified time period.
- **MAX** - The highest value observed during the specified time period.
- **MEAN** - The value of Sum divided by Count during the specified time period.
- **MIN** - The lowest value observed during the specified time period.
- **P50** - The value of the 50th percentile.
- **P90** - The value of the 90th percentile.
- **P95** - The value of the 95th percentile.
- **P99** - The value of the 99th percentile.
- **P99.5** - The value of the 99.5th percentile.
- **RATE** - The per-interval average rate of change.
- **SUM** - All values added together.

- **Metric dimensions**: Optional filters to narrow the metric data evaluated.

  Dimension fields

  - **Dimension Name**: A qualifier specified in the metric definition. For example, the dimension `resourceId` is specified in the metric definition for `CpuUtilization`.

    Note

    Long lists of dimensions are trimmed.

    - To view dimensions by name, type one or more characters in the box. A refreshed (trimmed) list shows matching dimension names.
    - To retrieve all dimensions for a given metric, use the following API operation: ListMetrics

  - **Dimension Value**: The value you want to use for the specified dimension. For example, the resource identifier for your instance of interest.
  - **+ Additional dimension**: Adds another name-value pair for a dimension.

- **Aggregate Metric Streams**: Aggregates all results to plot a single aggregated average for all metric streams. This average is plotted as a single line on the metric chart. This operation is helpful when you want to plot a metric as one line for all resources.

3. Click **Update Chart**.
   The chart shows the results of your new query. Very small or large values are indicated by International System of Units (SI units), such as M for mega (10 to the sixth power). Units correspond to the selected metric and do not change by statistic.

   ### Troubleshooting Errors and Query Limits

   If you see an error that the query has exceeded the maximum number of metric streams, then update the query to evaluate a number of metric streams that is within the limit. For example, you can reduce the metric streams by specifying dimensions. You can continue to evaluate all metric streams that were in the original query by spreading the metric streams across multiple queries (or alarms).
   Limits information for returned data includes the 100,000 data point maximum and time range maximums (determined by resolution, which relates to interval). See MetricData Reference.

4. To customize the y-axis label or range, type the label you want into **Y-Axis Label** or type the minimum and maximum values you want into **Y-Axis Min Value** and **Y-Axis Max Value**.
   Only numeric characters are allowed for custom ranges. Custom labels and ranges are not persisted in shared queries (MQL).
5. To view the query as a Monitoring Query Language (MQL) expression, click **Advanced Mode**.
   Advanced Mode is located on the right, under the chart.
   Use Advanced Mode to edit your query using MQL syntax to aggregate results by group. The MQL syntax also supports additional parameter values. For more information about query parameters in Basic Mode and Advanced Mode, see Monitoring Query Language (MQL) Reference.
6. To create another query, click **Add Query** below the chart.

To change the time range

For metric queries, the interval you select drives the default resolution of the request, which determines the maximum time range of data returned.

Maximum time range returned for a query

The maximum time range returned for a metric query depends on the resolution. By default, for metric queries, the resolution is the same as the query interval. The maximum time range is calculated using the current time, regardless of any specified end time. Following are the maximum time ranges returned for each interval selection available in the Console.

Interval	Default resolution (metric queries)	Maximum time range returned
1h	1 hour	90 days
5m	5 minutes	30 days
1m	1 minute	7 days

See examples of returned data

Example 1: One-minute interval and resolution up to the current time, sent at 10:00 on January 8th. No resolution or end time is specified, so the resolution defaults to the interval value of `1m`, and the end time defaults to the current time (`2019-01-08T10:00:00.789Z`). This request returns a maximum of 7 days of metric data points. The earliest data point possible within this seven-day period would be 10:00 on January 1st (`2019-01-01T10:00:00.789Z`).

Example 2: Five-minute interval with one-minute resolution up to two days ago, sent at 10:00 on January 8th. Because the resolution drives the maximum time range, a maximum of 7 days of metric data points is returned. While the end time specified was 10:00 on January 6th (`2019-01-06T10:00:00.789Z`), the earliest data point possible within this seven-day period

would be 10:00 on January 1st (`2019-01-01T10:00:00.789Z`). Therefore, only 5 days of metric data points can be returned in this example.

For more information about the resolution parameter as used in metric queries, see SummarizeMetricsData.

1. View the **Metrics Explorer** page: Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Metrics Explorer**.
2. To select a period of time, such as **Last hour**, click **Start Time** or **End Time**.
3. To enter a time value, click in **Start Time** or **End Time** and then type a value.

To filter results

Filter results to limit the data plotted on the metric chart. For example, filter results to a resource or pool of interest.

Filtering is done through selected dimensions; available dimensions vary by metric.You can also filter by resource groups when provided with the metric.

To filter by dimensions

1. View the **Metrics Explorer** page: Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Metrics Explorer**.
2. If necessary, open the query for editing: Click the **Edit query** icon.
3. Under **Metric dimensions**, select a **Dimension Name** and **Dimension Value**.

Dimension fields

- **Dimension Name**: A qualifier specified in the metric definition. For example, the dimension `resourceId` is specified in the metric definition for `CpuUtilization`.

Note

Long lists of dimensions are trimmed.

- To view dimensions by name, type one or more characters in the box. A refreshed (trimmed) list shows matching dimension names.
- To retrieve all dimensions for a given metric, use the following API operation: ListMetrics

- **Dimension Value**: The value you want to use for the specified dimension. For example, the resource identifier for your instance of interest.
- **+ Additional dimension**: Adds another name-value pair for a dimension.

4. To add a dimension name-value pair, click **+ Additional dimension**.
5. Click **Update Chart**.
   The chart shows the filtered results of your query.

Troubleshooting Errors and Query Limits

If you see an error that the query has exceeded the maximum number of metric streams, then update the query to evaluate a number of metric streams that is within the limit. For example, you can reduce the metric streams by specifying dimensions. You can continue to evaluate all metric streams that were in the original query by spreading the metric streams across multiple queries (or alarms).

Limits information for returned data includes the 100,000 data point maximum and time range maximums (determined by resolution, which relates to interval). See MetricData Reference.

6. To view the query as a Monitoring Query Language (MQL) expression, click **Advanced Mode**.
   The dimension name-value fragment appears after the metric-interval fragment.
   In the following example query, the dimension name-value fragment is `{resourceId="ocid1.instance.oc1.phx.exampleuniqueID"}`, which filters results by the specified resource identifier.
   ```
   CpuUtilization[1m]
   {resourceId="ocid1.instance.oc1.phx.exampleuniqueID"}.max()
   ```
   The MQL syntax supports more parameter values. See Monitoring Query Language (MQL) Reference.

To filter by a resource group

1. View the **Metrics Explorer** page: Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Metrics Explorer**.
2. If necessary, open the query for editing: Click the **Edit query** icon.
3. Select the **Resource Group** you want to use as a filter.
4. Click **Update Chart**.
   The chart shows the filtered results of your query.

Troubleshooting Errors and Query Limits

If you see an error that the query has exceeded the maximum number of metric streams, then update the query to evaluate a number of metric streams that is within the limit. For example, you can reduce the metric streams by specifying dimensions. You can continue to evaluate all metric streams that were in the original query by spreading the metric streams across multiple queries (or alarms).

Limits information for returned data includes the 100,000 data point maximum and time range maximums (determined by resolution, which relates to interval). See MetricData Reference.

To aggregate all results

Aggregate all results to plot a single aggregated average for all metric streams. This average is plotted as a single line on the metric chart. This operation is helpful when you want to plot a metric as one line for all resources.

1. View the **Metrics Explorer** page: Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Metrics Explorer**.
2. If necessary, open the query for editing: Click the **Edit query** icon.
3. Click **Aggregate Metric Streams**.
4. Click **Update Chart**.
   The chart shows the results of your query.

   ### Troubleshooting Errors and Query Limits

   If you see an error that the query has exceeded the maximum number of metric streams, then update the query to evaluate a number of metric streams that is within the limit. For example, you can reduce the metric streams by specifying dimensions. You can continue to evaluate all metric streams that were in the original query by spreading the metric streams across multiple queries (or alarms).
   Limits information for returned data includes the 100,000 data point maximum and time range maximums (determined by resolution, which relates to interval). See MetricData Reference.

5. To view the query as a Monitoring Query Language (MQL) expression, click **Advanced Mode**.
   The `grouping()` function appears before the statistic. For example, the following query returns the maximum (`max()`) IopsRead metric data at a one-minute interval, filtered to a compartment, with all results aggregated.
   ```
   IopsRead[1m]{compartmentID = "<compartment_OCID>"}.grouping().max()
   ```
   Edit your query in MQL to aggregate results by group. The MQL syntax also supports more parameter values. See Monitoring Query Language (MQL) Reference.

To aggregate results by group

Note

Aggregating query results by group requires the `groupBy()` function, which is available in **Advanced Mode** only.

Aggregate query results by group to plot group-specific aggregated averages. Each group's average is plotted as a single line on the metric chart. This operation is helpful when you want to identify trends by group rather than individual resource.

For example, the following query returns the average (`mean()`) CPU Utilization metric data at a one-minute interval. Results are filtered to the specified shape and grouped by availability domain. If you have Compute instances of this shape sending metrics across three availability domains, then three lines are plotted on the metric chart.

```
CPUUtilization[1m]{shape="VM.Standard1.1"}.groupBy(availabilityDomain).mean()
```

You can also aggregate by resource groups when provided with the metric (`groupBy(resourceGroup)`).

1. View the **Metrics Explorer** page: Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Metrics Explorer**.
2. If necessary, open the query for editing: Click the **Edit query** icon.
3. Select **Advanced Mode** below the chart on the right.

4. In the **Query Code Editor** box, insert the `groupBy({dimension})` function between the metric-interval fragment and the statistic, where {dimension} is the name of a dimension provided in the definition of the indicated metric.
   For example, insert the following fragment to group by availability domain, assuming that the dimension is available for the selected metric.
   ```
   groupBy(availabilityDomain)
   ```
   The MQL syntax supports more parameter values. See Monitoring Query Language (MQL) Reference.
5. Click **Update Chart**.
   The chart is updated to show a single line for each grouped result.

Troubleshooting Errors and Query Limits

If you see an error that the query has exceeded the maximum number of metric streams, then update the query to evaluate a number of metric streams that is within the limit. For example, you can reduce the metric streams by specifying dimensions. You can continue to evaluate all metric streams that were in the original query by spreading the metric streams across multiple queries (or alarms).

Limits information for returned data includes the 100,000 data point maximum and time range maximums (determined by resolution, which relates to interval). See MetricData Reference.

To edit a query using MQL syntax

Edit your query using MQL syntax to aggregate results by group or for more parameter values. See Monitoring Query Language (MQL) Reference.

1. View the **Metrics Explorer** page: Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Metrics Explorer**.
2. If necessary, open the query for editing: Click the **Edit Query** icon.

3. Click **Advanced Mode**.
   The query is displayed as a Monitoring Query Language (MQL) expression.
4. In the **Query Code Editor** box, edit the query as needed.
5. Click **Update Chart**.
   The chart is updated.

Troubleshooting Errors and Query Limits

If you see an error that the query has exceeded the maximum number of metric streams, then update the query to evaluate a number of metric streams that is within the limit. For example, you can reduce the metric streams by specifying dimensions. You can continue to evaluate all metric streams that were in the original query by spreading the metric streams across multiple queries (or alarms).

Limits information for returned data includes the 100,000 data point maximum and time range maximums (determined by resolution, which relates to interval). See MetricData Reference.

To create an alarm from a query

Create an alarm to passively monitor for a condition in results from metric queries. Creating an alarm from a query involves adding a trigger rule to the query and setting up notifications.

1. View the **Metrics Explorer** page: Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Metrics Explorer**.
2. If necessary, open the query for editing: Click the **Edit Query** icon.
3. Click **Create Alarm**.
4. On the **Create Alarm** page, under **Define alarm**, add the trigger, and fill in or update other alarm settings as needed:

Alarm settings

Basic Mode (default)

By default, this page uses **Basic Mode**, which separates the metric from its dimensions and its trigger rule.

- **Alarm Name**: User-friendly name for the new alarm. This name is sent as the title for notifications related to this alarm.

  #### Rendering of the title by protocol

Protocol	Rendering of the title
Email	Subject line of the email message.
HTTPS (Custom URL)	Not rendered.
PagerDuty	Title field of the published message.
Slack	Not rendered.

- **Alarm Severity**: The perceived type of response required when the alarm is in the firing state.
- **Alarm Body**: The human-readable content of the notification delivered. Oracle recommends providing guidance to operators for resolving the alarm condition. Consider adding links to standard runbook practices. Example: "High CPU usage alert. Follow runbook instructions for resolution."
- **Tags (optional):** Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are

not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.

- **Metric description**: The metric to evaluate for the alarm condition.
  - **Compartment**: The compartment containing the resources that emit the metrics evaluated by the alarm. The selected compartment is also the storage location of the alarm. By default, the first accessible compartment is selected.
  - **Metric Namespace**: The service or application emitting metrics for the resources that you want to monitor.
  - **Resource Group** (optional): The group that the metric belongs to. A resource group is a custom string provided with a custom metric. Not applicable to service metrics.
  - **Metric Name**: The name of the metric. Only one metric can be specified. Example: **CpuUtilization**

- **Interval**: The aggregation window, or the frequency at which data points are aggregated.

  ### Interval values

  - **1m** - 1 minute
  - **5m** - 5 minutes
  - **1h** - 1 hour

  Note

  For alarm queries, the specified interval has no effect on the resolution of the request. The only valid value of the resolution for an alarm query request is `1m`. For more information about the resolution parameter as used in alarm queries, see Alarm.

- **Statistic**: The aggregation function.

  ### Statistic values

  - **COUNT**- The number of observations received in the specified time period.
  - **MAX** - The highest value observed during the specified time period.
  - **MEAN** - The value of Sum divided by Count during the specified time period.

- **MIN** - The lowest value observed during the specified time period.
- **P50** - The value of the 50th percentile.
- **P90** - The value of the 90th percentile.
- **P95** - The value of the 95th percentile.
- **P99** - The value of the 99th percentile.
- **P99.5** - The value of the 99.5th percentile.
- **RATE** - The per-interval average rate of change.
- **SUM** - All values added together.

- **Metric dimensions**: Optional filters to narrow the metric data evaluated.

  Dimension fields

  - **Dimension Name**: A qualifier specified in the metric definition. For example, the dimension `resourceId` is specified in the metric definition for `CpuUtilization`.

    Note

    Long lists of dimensions are trimmed.

    - To view dimensions by name, type one or more characters in the box. A refreshed (trimmed) list shows matching dimension names.
    - To retrieve all dimensions for a given metric, use the following API operation: ListMetrics

  - **Dimension Value**: The value you want to use for the specified dimension. For example, the resource identifier for your instance of interest.
  - **+ Additional dimension**: Adds another name-value pair for a dimension.

- **Trigger rule**: The condition that must be satisfied for the alarm to be in the firing state. The condition can specify a threshold, such as 90% for CPU Utilization, or an absence.

- **Operator**: The operator used in the condition threshold.

  Operator values

  - **greater than**
  - **greater than or equal to**
  - **equal to**
  - **less than**
  - **less than or equal to**
  - **between** (inclusive of specified values)
  - **outside** (inclusive of specified values)
  - **absent**

- **Value**: The value to use for the condition threshold.
- **Trigger Delay Minutes**: The number of minutes that the condition must be maintained before the alarm is in firing state.

Advanced Mode

Click **Advanced Mode** or **Switch to Advanced Mode** to view the alarm query as a Monitoring Query Language (MQL) expression. Edit your query using MQL syntax to aggregate results by group or for additional parameter values. See Monitoring Query Language (MQL) Reference.

- **Alarm Name**: User-friendly name for the new alarm. This name is sent as the title for notifications related to this alarm.

Rendering of the title by protocol

Protocol	Rendering of the title
Email	Subject line of the email message.
HTTPS (Custom URL)	Not rendered.
PagerDuty	Title field of the published message.
Slack	Not rendered.

- **Alarm Severity**: The perceived type of response required when the alarm is in the firing state.
- **Alarm Body**: The human-readable content of the notification delivered. Oracle recommends providing guidance to operators for resolving the alarm condition. Consider adding links to standard runbook practices. Example: "High CPU usage alert. Follow runbook instructions for resolution."
- **Tags (optional):** Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.
- **Metric description, dimensions, and trigger rule**: The metric to evaluate for the alarm condition, including dimensions and the trigger rule.
    - **Compartment**: The compartment containing the resources that emit the metrics evaluated by the alarm. The selected compartment is also the storage location of the alarm. By default, the first accessible compartment is selected.

- **Metric Namespace**: The service or application emitting metrics for the resources that you want to monitor.
- **Resource Group** (optional): The group that the metric belongs to. A resource group is a custom string provided with a custom metric. Not applicable to service metrics.
- **Query Code Editor** box: The alarm query as a Monitoring Query Language (MQL) expression.

  Example alarm query:

  ```
  CpuUtilization[1m]{availabilityDomain=AD1}.groupBy(poolId).percentile(0.9) > 85
  ```

  For query syntax and examples, see Working with Metric Queries.
- **Trigger Delay Minutes**: The number of minutes that the condition must be maintained before the alarm is in firing state.

The chart below the **Define alarm** section dynamically displays the last six hours of emitted metrics according to currently selected fields for the query. Very small or large values are indicated by International System of Units (SI units), such as M for mega (10 to the sixth power).

5. Under **Notifications**, select or create at least one notification destination:

   Notifications settings

   - **Destinations**:
     - **Destination Service**: The provider of the destination to use for notifications.

       Available options:

       - **Notifications Service**.
     - **Compartment**: The compartment storing the topic to be used for

notifications. Can be a different compartment from the alarm and metric. By default, the first accessible compartment is selected.

- **Topic**: The topic to use for notifications. Each topic supports a subscription protocol, such as PagerDuty.
- **Create a topic**: Sets up a topic and subscription protocol in the selected compartment, using the specified destination service.
  - **Topic Name**: User-friendly name for the new topic. Example: "Operations Team " for a topic used to notify operations staff of firing alarms.
  - **Topic Description**: Description of the new topic.
  - **Subscription Protocol**: Medium of communication to use for the new topic. Configure your subscription for the protocol you want:

Email subscription

Sends an email message when you publish a message to the subscription's parent topic.

- **Subscription Protocol**: Select **Email**.
- **Subscription Email**: Type an email address.

HTTPS (Custom URL) subscription

Sends specified information when you publish a message to the subscription's parent topic.

Endpoint format (URL using HTTPS protocol):

```
https://<anyvalidURL>
```

Basic access authentication is supported, allowing you to specify a username and password in the URL, as in `https://user:password@domain.com` or `https://user@domain.com`. The username and password are encrypted over the SSL connection established when using HTTPS. For more information about Basic Access Authentication, see RFC-2617.

Query parameters are not allowed in URLs.

- **Subscription Protocol**: Select **HTTPS (Custom URL)**.
- **Subscription URL**: Type (or copy and paste) the URL you want to use as the endpoint.

PagerDuty subscription

Creates a PagerDuty incident by default when you publish a message to the subscription's parent topic.

Endpoint format (URL):

```
https://events.pagerduty.com/integration/<integrationkey>/enqueue
```

Query parameters are not allowed in URLs.

To create an endpoint for a PagerDuty subscription (set up and retrieve an integration key), see the PagerDuty documentation.

- **Subscription Protocol**: Select **PagerDuty**.
- **Subscription URL**: Type (or copy and paste) the *integration key* portion of the URL for your PagerDuty subscription. (The other portions of the URL are hard-coded.)

Slack subscription

> **Note**
>
> See the following known issue for up-to-date information about creating Slack subscriptions.

Sends a message to the specified Slack channel by default when you publish a message to the subscription's parent topic.
Endpoint format (URL):

```
https://hooks.slack.com/services/<webhook-token>
```

The *<webhook-token>* portion of the URL contains two slashes (/).
Query parameters are not allowed in URLs.
To create an endpoint for a Slack subscription (using a webhook for your Slack channel), see the Slack documentation.

- **Subscription Protocol**: Select **Slack**.
- **Subscription URL**: Type (or copy and paste) the Slack endpoint, including your webhook token.

- **+ Additional destination service**: Adds another destination service and topic to use for notifications.

> **Note**
>
> Each alarm is limited to one destination per supported destination service.

- **Repeat Notification?**: While the alarm is in the firing state, resends notifications at the specified interval.
- **Notification Interval**: The period of time to wait before resending the notification.
- **Suppress Notifications**: Sets up a suppression time window during which to suspend evaluations and notifications. Useful for avoiding alarm notifications during system maintenance periods.
  - **Suppression Description**
  - **Start Time**
  - **End Time**

6. If you want to disable the new alarm, clear **Enable This Alarm?**.
7. Click **Save alarm**.
   The new alarm is listed on the **Alarm Definitions** page.
   For more information about alarms, see Alarms Feature Overview.

To hide a query from the chart

1. View the **Metrics Explorer** page: Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Metrics Explorer**.
2. Click the **Toggle query on chart** icon for the query that you want to hide.

To share a query

1. View the **Metrics Explorer** page: Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Metrics Explorer**.
2. If necessary, open the query for editing: Click the **Edit query** icon.
3. Click **Advanced Mode**.
4. In the **Query Code Editor** box, copy the query.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use this API operation to find metric names and dimensions (view metric definitions):

ListMetrics

Use this API operation to query metrics by name (and optionally filter by dimension):

SummarizeMetricsData

Publishing Custom Metrics

This topic describes how to publish your own custom metrics to the Monitoring service.

You can publish your own metrics to Monitoring using the API. You can view charts of your published metrics using the Console , query metrics using the API, and set up alarms using the Console or API.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Prerequisites

IAM policies: To publish custom metrics, you must be given the required type of access in a policy written by an administrator. This requirement applies whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, check with your administrator. You may not have the

required type of access in the current compartment. Administrators: For a related common policy, see Let users publish custom metrics.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Note

When defining your custom metrics, note the following:

- Ensure that your custom metrics do not exceed limits. For example, note the valid range of dimensions and maximum number of streams for custom metrics. See PostMetricData.
- Define your metrics with aggregation in mind. While custom metrics can be posted as frequently as every second (minimum frequency of one second), the minimum aggregation interval is one minute.
- Define your metrics with return limits in mind. Limits information for returned data includes the 100,000 data point maximum and time range maximums (determined by resolution, which relates to interval). See MetricData Reference.

Use this API operation to publish custom metrics:

PostMetricData

Note

Oracle recommends the following:

- Send batched requests to maximize metric streams per request. A batched request contains multiple metrics or metric namespaces. Note limits. See PostMetricData.
- Publish metrics only when relevant contexts require monitoring; that is, when data points need to be collected. If you want to publish metrics during inactive periods when no observations exist, then you can manually create "0" values for publishing.

Example of a batched request

This example shows a single request containing data points for metrics across two metric namespaces.

```
[
   {
      "namespace":"myFirstNamespace",
      "compartmentId":"ocid1.compartment.oc1..exampleuniqueID",
      "resourceGroup":"myFirstResourceGroup",
      "name":"successRate",
      "dimensions":{
         "resourceId":"ocid1.exampleresource.region1.phx.exampleuniqueID",
         "appName":"myAppA"
      },
      "metadata":{
         "unit":"percent",
         "displayName":"MyAppA Success Rate"
      },
      "datapoints":[
```

```
        {
           "timestamp":"2019-03-10T22:19:20Z",
           "value":83.0
        },
        {
           "timestamp":"2019-03-10T22:19:40Z",
           "value":90.1
        }
     ]
  },
  {
     "namespace":"myFirstNamespace",
     "compartmentId":"ocid1.compartment.oc1..exampleuniqueID",
     "resourceGroup":"mySecondResourceGroup",
     "name":"successRate",
     "dimensions":{
        "resourceId":"ocid1.exampleresource.region1.phx.differentuniqId",
        "appName":"myAppA"
     },
     "metadata":{
        "unit":"percent",
        "displayName":"MyAppA Success Rate"
     },
     "datapoints":[
        {
           "timestamp":"2019-03-10T22:19:10Z",
           "value":100.0
        },
        {
           "timestamp":"2019-03-10T22:19:30Z",
           "value":100.0
        }
     ]
  },
  {
     "namespace":"mySecondNamespace",
     "compartmentId":"ocid1.compartment.oc1..exampleuniqueID",
     "name":"deliveryRate",
     "dimensions":{
        "resourceId":"ocid1.exampleresource.region1.phx.exampleuniqueID",
        "appName":"myAppB"
```

```
      },
      "metadata":{
         "unit":"bytes",
         "displayName":"MyAppB Delivery Rate"
      },
      "datapoints":[
         {
            "timestamp":"2019-03-10T22:19:00Z",
            "value":87.0,
            "count":60
         },
         {
            "timestamp":"2019-03-10T22:19:00Z",
            "value":96.0,
            "count":30
         }
      ]
   }
]
```

You can access your published custom metrics the same way you access any other metrics stored by the Monitoring service. View charts from queries using the Console, query metrics using the CLI or API, and set up alarms using the Console, CLI, or API.

Managing Alarms

This topic describes how to create, update, suppress, and delete alarms, as well as how to retrieve alarm history. See also Best Practices for your Alarms.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Prerequisites

- IAM policies: Managing alarms is part of monitoring. To monitor resources, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.
- Metrics exist in Monitoring: The resources that you want to monitor must emit metrics to the Monitoring service.
- Compute instances: To emit metrics, Compute instances must be monitoring-enabled. OracleCloudAgent software installation may also be required. For more information, see Enabling Monitoring for Compute Instances.

Tagging Resources

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the desired tags. For general information about applying tags, see Resource Tags.

Using the Console

To see all firing alarms

Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Alarm Status**.

You can suppress alarms during a given time range. You can also disable and delete alarms.

To create an alarm

This section includes steps to create example alarms as well as any kind of alarm.

To create an example threshold alarm

This procedure walks through creation of an example threshold alarm to detect Compute instances operating at non-optimal thresholds. A *threshold alarm* is an alarm that checks for metric values outside a given range or value. The procedure uses options as displayed in Basic Mode.

1. Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Alarm Definitions**.
2. Click **Create alarm**.
3. On the **Create Alarm** page, under **Define alarm**, fill in or update the alarm settings:
    - **Alarm Name**: Non-Optimal Alarm
    - **Alarm Severity**: Warning
    - **Alarm Body**: Non-optimal utilization detected. An application or process may be consuming more CPU than usual.
    - **Metric description**:
        - **Compartment**: (select your compartment)
        - **Metric Namespace**: **oci_computeagent**
        - **Metric Name**: **CpuUtilization**
        - **Interval**: **1m**
        - **Statistic**: **Count**
    - **Trigger rule**:
        - **Operator**: **between**
        - **Value**: 60

    - **Value**: 80
    - **Trigger Delay Minutes**: 10
4. Set up an email notification under **Notifications**, **Destinations**:
    - **Destination Service**: **Notifications Service**
    - **Compartment**: (select your compartment)
    - **Topic**: Click **Create a topic**
        - **Topic Name**: Operations Team
        - **Topic Description**: Resource Monitoring Channel
        - **Subscription Protocol**: **Email**
        - **Email Addresses**: (type an email address for the operations team here)
5. Repeat notifications every day:
    - **Repeat Notification?**: (select this option)
    - **Notification Interval**: 24 hours
6. Click **Save alarm**.

To create an example absence alarm

This procedure walks through creation of an example absence alarm to detect resources that may be down or unreachable. An *absence alarm* is an alarm that checks for absent metrics (using the absent operator). The procedure uses options as displayed in Basic Mode.

1. Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Alarm Definitions**.
2. Click **Create alarm**.
3. On the **Create Alarm** page, under **Define alarm**, fill in or update the alarm settings:
    - **Alarm Name**: Up/Down Resource Alarm
    - **Alarm Severity**: Critical

- **Alarm Body**: Resource may be down. Please investigate. Move workloads to another available resource.
- **Metric description**:
  - **Compartment**: (select your compartment)
  - **Metric Namespace**: **oci_computeagent**
  - **Metric Name**: **CpuUtilization**
  - **Interval**: **1m**
  - **Statistic**: **Count**
- **Trigger rule**:
  - **Operator**: **absent**
  - **Trigger Delay Minutes**: 5

4. Set up an email notification under **Notifications**, **Destinations**:
   - **Destination Service**: **Notifications Service**
   - **Compartment**: (select your compartment)
   - **Topic**: Click **Create a topic**
     - **Topic Name**: Operations Team
     - **Topic Description**: Resource Up/Down Channel
     - **Subscription Protocol**: **Email**
     - **Email Addresses**: (type an email address for the operations team here)

Note

To add a notification (subscription) for another protocol, such as PagerDuty, create a copy of this alarm and choose the corresponding protocol. For more information about subscription protocols, see To create a subscription.

5. Repeat notifications every minute:
    - **Repeat Notification?**: (select this option)
    - **Notification Interval**: 1 minute
6. Click **Save alarm**.

To create an alarm (any kind)

1. Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Alarm Definitions**.
2. Click **Create alarm**.

Note

You can also create an alarm from a predefined query on the **Service Metrics** page. Expand **Options** and click **Create an Alarm on this Query**. For more information about service metrics, see Viewing Default Metric Charts.

3. On the **Create Alarm** page, under **Define alarm**, fill in or update the alarm settings:

Note

To toggle between Basic Mode and Advanced Mode, click **Switch to Advanced Mode** or **Switch to Basic Mode** (to the right of **Define Alarm**).

Basic Mode (default)

By default, this page uses **Basic Mode**, which separates the metric from its dimensions and its trigger rule.

- **Alarm Name**: User-friendly name for the new alarm. This name is sent as the title for notifications related to this alarm.

Rendering of the title by protocol

Protocol	Rendering of the title
Email	Subject line of the email message.
HTTPS (Custom URL)	Not rendered.
PagerDuty	Title field of the published message.
Slack	Not rendered.

- **Alarm Severity**: The perceived type of response required when the alarm is in the firing state.
- **Alarm Body**: The human-readable content of the notification delivered. Oracle recommends providing guidance to operators for resolving the alarm condition.

Consider adding links to standard runbook practices. Example: "High CPU usage alert. Follow runbook instructions for resolution."

- **Tags (optional):** Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.
- **Metric description**: The metric to evaluate for the alarm condition.
    - **Compartment**: The compartment containing the resources that emit the metrics evaluated by the alarm. The selected compartment is also the storage location of the alarm. By default, the first accessible compartment is selected.
    - **Metric Namespace**: The service or application emitting metrics for the resources that you want to monitor.
    - **Resource Group** (optional): The group that the metric belongs to. A resource group is a custom string provided with a custom metric. Not applicable to service metrics.
    - **Metric Name**: The name of the metric. Only one metric can be specified. Example: **CpuUtilization**

- **Interval**: The aggregation window, or the frequency at which data points are aggregated.

  ### Interval values

  - **1m** - 1 minute
  - **5m** - 5 minutes
  - **1h** - 1 hour

  Note

  For alarm queries, the specified interval has no effect on the resolution of the request. The only valid value of the resolution for an alarm query request is `1m`. For more information about the resolution parameter as used in alarm queries, see Alarm.

- **Statistic**: The aggregation function.

  ### Statistic values

  - **COUNT**- The number of observations received in the specified time period.
  - **MAX** - The highest value observed during the specified time period.
  - **MEAN** - The value of Sum divided by Count during the specified time period.

- **MIN** - The lowest value observed during the specified time period.
- **P50** - The value of the 50th percentile.
- **P90** - The value of the 90th percentile.
- **P95** - The value of the 95th percentile.
- **P99** - The value of the 99th percentile.
- **P99.5** - The value of the 99.5th percentile.
- **RATE** - The per-interval average rate of change.
- **SUM** - All values added together.

- **Metric dimensions**: Optional filters to narrow the metric data evaluated.

  Dimension fields

  - **Dimension Name**: A qualifier specified in the metric definition. For example, the dimension `resourceId` is specified in the metric definition for `CpuUtilization`.

    Note

    Long lists of dimensions are trimmed.

    - To view dimensions by name, type one or more characters in the box. A refreshed (trimmed) list shows matching dimension names.
    - To retrieve all dimensions for a given metric, use the following API operation: ListMetrics

  - **Dimension Value**: The value you want to use for the specified dimension. For example, the resource identifier for your instance of interest.
  - **+ Additional dimension**: Adds another name-value pair for a dimension.

- **Trigger rule**: The condition that must be satisfied for the alarm to be in the firing state. The condition can specify a threshold, such as 90% for CPU Utilization, or an absence.

- **Operator**: The operator used in the condition threshold.

  Operator values

  - **greater than**
  - **greater than or equal to**
  - **equal to**
  - **less than**
  - **less than or equal to**
  - **between** (inclusive of specified values)
  - **outside** (inclusive of specified values)
  - **absent**

- **Value**: The value to use for the condition threshold.
- **Trigger Delay Minutes**: The number of minutes that the condition must be maintained before the alarm is in firing state.

Advanced Mode

Click **Advanced Mode** or **Switch to Advanced Mode** to view the alarm query as a Monitoring Query Language (MQL) expression. Edit your query using MQL syntax to aggregate results by group or for additional parameter values. See Monitoring Query Language (MQL) Reference.

- **Alarm Name**: User-friendly name for the new alarm. This name is sent as the title for notifications related to this alarm.

Rendering of the title by protocol

Protocol	Rendering of the title
Email	Subject line of the email message.
HTTPS (Custom URL)	Not rendered.
PagerDuty	Title field of the published message.
Slack	Not rendered.

- **Alarm Severity**: The perceived type of response required when the alarm is in the firing state.
- **Alarm Body**: The human-readable content of the notification delivered. Oracle recommends providing guidance to operators for resolving the alarm condition. Consider adding links to standard runbook practices. Example: "High CPU usage alert. Follow runbook instructions for resolution."
- **Tags (optional):** Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.
- **Metric description, dimensions, and trigger rule**: The metric to evaluate for the alarm condition, including dimensions and the trigger rule.
    - **Compartment**: The compartment containing the resources that emit the metrics evaluated by the alarm. The selected compartment is also the storage location of the alarm. By default, the first accessible compartment is selected.

- **Metric Namespace**: The service or application emitting metrics for the resources that you want to monitor.
- **Resource Group** (optional): The group that the metric belongs to. A resource group is a custom string provided with a custom metric. Not applicable to service metrics.
- **Query Code Editor** box: The alarm query as a Monitoring Query Language (MQL) expression.

  Example alarm query:

  ```
  CpuUtilization[1m]{availabilityDomain=AD1}.groupBy(poolId).percentile(0.9) > 85
  ```

  For query syntax and examples, see Working with Metric Queries.
- **Trigger Delay Minutes**: The number of minutes that the condition must be maintained before the alarm is in firing state.

The chart below the **Define alarm** section dynamically displays the last six hours of emitted metrics according to currently selected fields for the query. Very small or large values are indicated by International System of Units (SI units), such as M for mega (10 to the sixth power).

4. Set up notifications: Under **Notifications**, fill in the fields.

   - **Destinations**:
     - **Destination Service**: The provider of the destination to use for notifications.

       Available options:

       - **Notifications Service**.
     - **Compartment**: The compartment storing the topic to be used for notifications. Can be a different compartment from the alarm and metric. By default, the first accessible compartment is selected.

- **Topic**: The topic to use for notifications. Each topic supports a subscription protocol, such as PagerDuty.
- **Create a topic**: Sets up a topic and subscription protocol in the selected compartment, using the specified destination service.
  - **Topic Name**: User-friendly name for the new topic. Example: "Operations Team " for a topic used to notify operations staff of firing alarms.
  - **Topic Description**: Description of the new topic.
  - **Subscription Protocol**: Medium of communication to use for the new topic. Configure your subscription for the protocol you want:

Email subscription

Sends an email message when you publish a message to the subscription's parent topic.

- **Subscription Protocol**: Select **Email**.
- **Subscription Email**: Type an email address.

HTTPS (Custom URL) subscription

Sends specified information when you publish a message to the subscription's parent topic.

Endpoint format (URL using HTTPS protocol):

```
https://<anyvalidURL>
```

Basic access authentication is supported, allowing you to specify a username and password in the URL, as in `https://user:password@domain.com` or

`https://user@domain.com`. The username and password are encrypted over the SSL connection established when using HTTPS. For more information about Basic Access Authentication, see RFC-2617.

Query parameters are not allowed in URLs.

- **Subscription Protocol**: Select **HTTPS (Custom URL)**.
- **Subscription URL**: Type (or copy and paste) the URL you want to use as the endpoint.

PagerDuty subscription

Creates a PagerDuty incident by default when you publish a message to the subscription's parent topic.

Endpoint format (URL):

```
https://events.pagerduty.com/integration/<integrationkey>/enqueue
```

Query parameters are not allowed in URLs.

To create an endpoint for a PagerDuty subscription (set up and retrieve an integration key), see the PagerDuty documentation.

- **Subscription Protocol**: Select **PagerDuty**.
- **Subscription URL**: Type (or copy and paste) the *integration key* portion of the URL for your PagerDuty subscription. (The other portions of the URL are hard-coded.)

Slack subscription

> **Note**
>
> See the following known issue for up-to-date information about creating Slack subscriptions.

Sends a message to the specified Slack channel by default when you publish a message to the subscription's parent topic.

Endpoint format (URL):

```
https://hooks.slack.com/services/<webhook-token>
```

The *<webhook-token>* portion of the URL contains two slashes (/).

Query parameters are not allowed in URLs.

To create an endpoint for a Slack subscription (using a webhook for your Slack channel), see the Slack documentation.

- **Subscription Protocol**: Select **Slack**.
- **Subscription URL**: Type (or copy and paste) the Slack endpoint, including your webhook token.

- **+ Additional destination service**: Adds another destination service and topic to use for notifications.

> **Note**
>
> Each alarm is limited to one destination per supported destination service.

- **Repeat Notification?**: While the alarm is in the firing state, resends notifications at the specified interval.
- **Notification Interval**: The period of time to wait before resending the notification.
- **Suppress Notifications**: Sets up a suppression time window during which to suspend evaluations and notifications. Useful for avoiding alarm notifications during system maintenance periods.
  - **Suppression Description**
  - **Start Time**
  - **End Time**

5. If you want to disable the new alarm, clear **Enable This Alarm?**.
6. Click **Save alarm**.
   The new alarm is listed on the **Alarm Definitions** page.

To disable or enable an alarm

1. Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Alarm Definitions**.
2. Click the alarm that you want to disable or enable.
3. On the alarm detail page, select or clear **Alarm is Enabled**.

> **Note**
>
> You can also disable and enable alarms when creating or editing an alarm.

To move an alarm to a different compartment

Associated metrics remain in their current compartments. For more information, see Moving Alarms to a Different Compartment .

Note

To move resources between compartments, resource users must have sufficient access permissions on the compartment that the resource is being moved to, as well as the current compartment. For more information about permissions for Monitoring resources, see Details for Monitoring.

1. Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Alarm Definitions**.
2. In the **List Scope** section, select a compartment.
3. Click the alarm that you want to move.
4. On the alarm detail page, click **Move Resource**.
5. Choose the destination compartment from the list.
6. Click **Move Resource**.

To update an alarm

1. Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Alarm Definitions**.
2. Click the alarm that you want to update.
3. Go to **Actions** on the right, and then click **Edit Alarm**.
4. On the **Edit Alarm** page, under **Define alarm**, update alarm settings as needed:

Basic Mode (default)

By default, this page uses **Basic Mode**, which separates the metric from its dimensions and its trigger rule.

- **Alarm Name**: User-friendly name for the new alarm. This name is sent as the title for notifications related to this alarm.

  #### Rendering of the title by protocol

Protocol	Rendering of the title
Email	Subject line of the email message.
HTTPS (Custom URL)	Not rendered.
PagerDuty	Title field of the published message.
Slack	Not rendered.

- **Alarm Severity**: The perceived type of response required when the alarm is in the firing state.
- **Alarm Body**: The human-readable content of the notification delivered. Oracle recommends providing guidance to operators for resolving the alarm condition. Consider adding links to standard runbook practices. Example: "High CPU usage alert. Follow runbook instructions for resolution."
- **Tags (optional):** Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.

- **Metric description**: The metric to evaluate for the alarm condition.
    - **Compartment**: The compartment containing the resources that emit the metrics evaluated by the alarm. The selected compartment is also the storage location of the alarm. By default, the first accessible compartment is selected.
    - **Metric Namespace**: The service or application emitting metrics for the resources that you want to monitor.
    - **Resource Group** (optional): The group that the metric belongs to. A resource group is a custom string provided with a custom metric. Not applicable to service metrics.
    - **Metric Name**: The name of the metric. Only one metric can be specified. Example: **CpuUtilization**

- **Interval**: The aggregation window, or the frequency at which data points are aggregated.

  ### Interval values

  - **1m** - 1 minute
  - **5m** - 5 minutes
  - **1h** - 1 hour

  Note

  For alarm queries, the specified interval has no effect on the resolution of the request. The only valid value of the resolution for an alarm query request is `1m`. For more information about the resolution parameter as used in alarm queries, see Alarm.

- **Statistic**: The aggregation function.

  ### Statistic values

  - **COUNT**- The number of observations received in the specified time period.
  - **MAX** - The highest value observed during the specified time period.
  - **MEAN** - The value of Sum divided by Count during the specified time period.
  - **MIN** - The lowest value observed during the specified time period.

- **P50** - The value of the 50th percentile.
- **P90** - The value of the 90th percentile.
- **P95** - The value of the 95th percentile.
- **P99** - The value of the 99th percentile.
- **P99.5** - The value of the 99.5th percentile.
- **RATE** - The per-interval average rate of change.
- **SUM** - All values added together.

- **Metric dimensions**: Optional filters to narrow the metric data evaluated.

  Dimension fields

  - **Dimension Name**: A qualifier specified in the metric definition. For example, the dimension `resourceId` is specified in the metric definition for `CpuUtilization`.

    Note

    Long lists of dimensions are trimmed.

    - To view dimensions by name, type one or more characters in the box. A refreshed (trimmed) list shows matching dimension names.
    - To retrieve all dimensions for a given metric, use the following API operation: ListMetrics

  - **Dimension Value**: The value you want to use for the specified dimension. For example, the resource identifier for your instance of interest.
  - **+ Additional dimension**: Adds another name-value pair for a dimension.

- **Trigger rule**: The condition that must be satisfied for the alarm to be in the firing state. The condition can specify a threshold, such as 90% for CPU Utilization, or an absence.

- **Operator**: The operator used in the condition threshold.

  Operator values

  - **greater than**
  - **greater than or equal to**
  - **equal to**
  - **less than**
  - **less than or equal to**
  - **between** (inclusive of specified values)
  - **outside** (inclusive of specified values)
  - **absent**

- **Value**: The value to use for the condition threshold.
- **Trigger Delay Minutes**: The number of minutes that the condition must be maintained before the alarm is in firing state.

Advanced Mode

Click **Advanced Mode** or **Switch to Advanced Mode** to view the alarm query as a Monitoring Query Language (MQL) expression. Edit your query using MQL syntax to aggregate results by group or for additional parameter values. See Monitoring Query Language (MQL) Reference.

- **Alarm Name**: User-friendly name for the new alarm. This name is sent as the title for notifications related to this alarm.

Rendering of the title by protocol

Protocol	Rendering of the title
Email	Subject line of the email message.
HTTPS (Custom URL)	Not rendered.
PagerDuty	Title field of the published message.
Slack	Not rendered.

- **Alarm Severity**: The perceived type of response required when the alarm is in the firing state.
- **Alarm Body**: The human-readable content of the notification delivered. Oracle recommends providing guidance to operators for resolving the alarm condition. Consider adding links to standard runbook practices. Example: "High CPU usage alert. Follow runbook instructions for resolution."
- **Tags (optional):** Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.
- **Metric description, dimensions, and trigger rule**: The metric to evaluate for the alarm condition, including dimensions and the trigger rule.
    - **Compartment**: The compartment containing the resources that emit the metrics evaluated by the alarm. The selected compartment is also the storage location of the alarm. By default, the first accessible compartment is selected.

- **Metric Namespace**: The service or application emitting metrics for the resources that you want to monitor.
- **Resource Group** (optional): The group that the metric belongs to. A resource group is a custom string provided with a custom metric. Not applicable to service metrics.
- **Query Code Editor** box: The alarm query as a Monitoring Query Language (MQL) expression.

  Example alarm query:

  ```
  CpuUtilization[1m]{availabilityDomain=AD1}.groupBy(poolId).percentile(0.9) > 85
  ```

  For query syntax and examples, see Working with Metric Queries.
- **Trigger Delay Minutes**: The number of minutes that the condition must be maintained before the alarm is in firing state.

The chart below the **Define alarm** section dynamically displays the last six hours of emitted metrics according to currently selected fields for the query. Very small or large values are indicated by International System of Units (SI units), such as M for mega (10 to the sixth power).

5. Under **Notifications**, update settings as needed:

   - **Destinations**:
     - **Destination Service**: The provider of the destination to use for notifications.

       Available options:

       - **Notifications Service**.
     - **Compartment**: The compartment storing the topic to be used for notifications. Can be a different compartment from the alarm and metric. By default, the first accessible compartment is selected.
     - **Topic**: The topic to use for notifications. Each topic supports a subscription protocol, such as PagerDuty.

- **Create a topic**: Sets up a topic and subscription protocol in the selected compartment, using the specified destination service.
  - **Topic Name**: User-friendly name for the new topic. Example: "Operations Team " for a topic used to notify operations staff of firing alarms.
  - **Topic Description**: Description of the new topic.
  - **Subscription Protocol**: Medium of communication to use for the new topic. Configure your subscription for the protocol you want:

    ### Email subscription

    Sends an email message when you publish a message to the subscription's parent topic.

    - **Subscription Protocol**: Select **Email**.
    - **Subscription Email**: Type an email address.

    ### HTTPS (Custom URL) subscription

    Sends specified information when you publish a message to the subscription's parent topic.
    Endpoint format (URL using HTTPS protocol):

    ```
    https://<anyvalidURL>
    ```

    Basic access authentication is supported, allowing you to specify a username and password in the URL, as in `https://user:password@domain.com` or `https://user@domain.com`. The username and password are encrypted over the SSL connection established when using HTTPS. For more information about Basic Access Authentication, see RFC-2617.

Query parameters are not allowed in URLs.

- **Subscription Protocol**: Select **HTTPS (Custom URL)**.
- **Subscription URL**: Type (or copy and paste) the URL you want to use as the endpoint.

PagerDuty subscription

Creates a PagerDuty incident by default when you publish a message to the subscription's parent topic.

Endpoint format (URL):

```
https://events.pagerduty.com/integration/<integrationkey>/enqueue
```

Query parameters are not allowed in URLs.

To create an endpoint for a PagerDuty subscription (set up and retrieve an integration key), see the PagerDuty documentation.

- **Subscription Protocol**: Select **PagerDuty**.
- **Subscription URL**: Type (or copy and paste) the *integration key* portion of the URL for your PagerDuty subscription. (The other portions of the URL are hard-coded.)

Slack subscription

Note

See the following known issue for up-to-date information about creating

Slack subscriptions.

Sends a message to the specified Slack channel by default when you publish a message to the subscription's parent topic.

Endpoint format (URL):

```
https://hooks.slack.com/services/<webhook-token>
```

The *<webhook-token>* portion of the URL contains two slashes (/).

Query parameters are not allowed in URLs.

To create an endpoint for a Slack subscription (using a webhook for your Slack channel), see the Slack documentation.

- **Subscription Protocol**: Select **Slack**.
- **Subscription URL**: Type (or copy and paste) the Slack endpoint, including your webhook token.

- **+ Additional destination service**: Adds another destination service and topic to use for notifications.

Note

Each alarm is limited to one destination per supported destination service.

- **Repeat Notification?**: While the alarm is in the firing state, resends notifications at the specified interval.
- **Notification Interval**: The period of time to wait before resending the notification.

- **Suppress Notifications**: Sets up a suppression time window during which to suspend evaluations and notifications. Useful for avoiding alarm notifications during system maintenance periods.
    - **Suppression Description**
    - **Start Time**
    - **End Time**

6. Select or clear **Enable this alarm?**.
7. Click **Save alarm**.
   The updated alarm settings are listed on the **Alarm Definitions** page.

To update an alarm after moving a resource

This section shows how to update the metric compartment of an alarm after you move a resource that is emitting metrics monitored by the alarm. For example, if you move a block volume to another compartment, then the alarm must be updated if you want to continue monitoring metrics from the moved block volume.

1. Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Alarm Definitions**.
2. Click the alarm that you want to update.
3. Go to **Actions** on the right, and then click **Edit Alarm**.
4. Update the metric compartment: On the **Edit Alarm** page, under **Metric description** (or **Metric description, dimensions, and trigger rule** for Advanced mode), change the **Compartment** to the compartment where the resource has been moved.
   The chart below the **Define alarm** section dynamically updates according to the selected compartment, displaying the last six hours of emitted metrics. Very small or large values are indicated by International System of Units (SI units), such as M for mega (10 to the sixth power).
   If the chart is not showing the expected data, then the old compartment might be specified in the query (MQL), as in the following example:

```
IopsRead[1m]{compartmentId="ocid1.compartment.oc1.phx..oldcompartmentexampleuniqueID"}.grouping
().max()
```

5. If the old compartment is specified in the query, then update the query to reference the new compartment:
   a. Click **Advanced Mode** or **Switch to Advanced Mode** to view the alarm query as a Monitoring Query Language (MQL) expression.
   b. In **Query Code Editor**, update the query to reference the new compartment.

      View example

      Original query:

      ```
      IopsRead[1m]
      {compartmentId="ocid1.compartment.oc1.phx..oldcompartmentexampleuniqueID"}.grouping().max
      ()
      ```

      Updated query:

      ```
      Read[1m]
      {compartmentId="ocid1.compartment.oc1.phx..newcompartmentexampleuniqueID"}.grouping().max
      ()
      ```

      For more information about query syntax and more examples, see Working with Metric Queries.

      The chart below the **Define alarm** section dynamically updates according to the updated query, displaying the last six hours of emitted metrics. Very small or large values are indicated by International System of Units (SI units), such as M for mega (10 to the sixth power).
      If the chart is not showing the expected data, then confirm that every compartment reference (**Compartment**, **Query Code Editor**) points to the new compartment.
6. Click **Save alarm**.
   The alarm now monitors metrics from the new compartment.

To suppress alarms

Important

Only one suppression can be configured per alarm. Any existing suppression for the alarm is overwritten when you apply a new suppression.

1. Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Alarm Definitions**.
2. On the **Alarm Definitions** page, select the check boxes for the alarms you want to suppress.

Note

You can also suppress alarms from the Alarm Status page or when creating or editing an alarm.

3. Go to **Actions** and select **Add Suppressions**.
4. In the **Suppress alarms** dialog box, select a **Start Time** and **End Time** and then optionally fill in a **Suppression Description**.
5. Click **Apply suppressions**.
   A suppression is created for each selected alarm. The updated alarm settings are listed on the **Alarm Definitions** page.

To delete alarms

1. Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Alarm Definitions**.

2. On the **Alarm Definitions** page, select the check boxes for the alarms you want to delete.

Note

You can also delete an alarm from its detail page.

3. Go to **Actions** and select **Delete Alarms**.
   The deleted alarms are removed from the compartment and are no longer displayed on the **Alarm definitions** page.

To view alarm history

1. Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Alarm Definitions**.
2. On the **Alarm Definitions** page, click the alarm that you want to view history for.
   The alarm detail page displays a chart showing data for the indicated time range and a list of timestamped transitions, such as Firing to OK.
   Alarm history is retained for 30 days.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use these API operations to manage alarms:

- ListAlarms
- GetAlarm
- CreateAlarm
- ChangeAlarmCompartment

- UpdateAlarm
- DeleteAlarm
- ListAlarmsStatus
- RemoveAlarmSuppression
- GetAlarmHistory

Best Practices for your Alarms

This topic describes best practices for working with your alarms.

Create a Set of Alarms for Each Metric

For each metric emitted by your resources, create alarms that define the following resource behaviors:

- At risk. The resource is at risk of becoming inoperable, as indicated by metric values.
- Non-optimal. The resource is performing at non-optimal levels, as indicated by metric values.
- Resource is up or down. The resource is either not reachable or not operating.

The following examples use the CpuUtilization metric emitted by the oci_computeagent metric namespace. This metric monitors the utilization of the Compute instance and the activity level of any services and applications running on the instance. CpuUtilization is a key performance metric for a cloud service because it indicates CPU usage for the Compute instance and it can be used to investigate performance issues. To learn more about CPU usage, see the following URL: https://en.wikipedia.org/wiki/CPU_time.

At-Risk Example

A typical at-risk threshold for the CpuUtilization metric is any value greater than 80 percent. A Compute instance breaching this threshold is at risk of becoming inoperable. Often the cause of this behavior is one or more applications consuming a high percentage of the CPU.

In this example, you decide to notify the operations team immediately, setting the severity of the alarm as "Critical" because repair is required to bring the instances back to optimal operational levels. You configure alarm notifications to the responsible team by both PagerDuty and email, requesting an investigation and appropriate fixes before the instances go into an inoperable state. You set repeat notifications every minute. When someone responds to the alarm notifications, you temporarily stop notifications using the best practice of suppressing the alarm. Once metrics return to optimal values, you remove the suppression.

Non-Optimal Example

A typical non-optimal threshold for the CpuUtilization metric is from 60 to 80 percent. When the metric values for a Compute instance are within this range, the instance is above the optimal operational range.

In this example, you decide to notify the appropriate individual or team that an application or process is consuming more CPU than usual. You configure a threshold alarm to notify the appropriate contacts, setting the severity of the alarm as "Warning," as no immediate actions are required to investigate and reduce the CPU. You set notification to email only, directed to the appropriate developer or team, with repeat notifications every 24 hours to reduce email notification noise.

Resource is Up or Down Example

A typical indicator of resource availability is a five-minute absence of the CpuUtilization metric. A Compute instance breaching this threshold is either not reachable or not operating. The resource may have stopped responding, or it might have become unavailable because of connectivity issues.

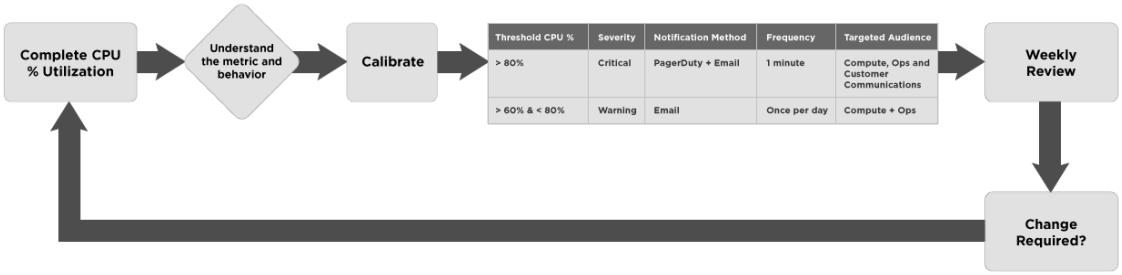
In this example, you decide to notify the operations team immediately, setting the severity of your absence alarm as "Critical" because repair is required to bring the instances online. You configure alarm notifications to the responsible team by both PagerDuty and email, requesting an investigation and a move of the workloads to another available resource. You set repeat notifications every minute. When someone responds to the alarm notifications, you temporarily stop notifications using the best practice of suppressing the alarm. When the CpuUtilization metric is once again detected from the resource, you remove the suppression.

Suppress Alarms During Investigations

Once a team member responds to an alarm, suppress notifications during the effort to investigate or mitigate the issue. Temporarily stopping notifications helps to avoid distractions during the investigation and mitigation. Remove the suppression when the issue has been resolved. For instructions, see To suppress alarms.

Routinely Tune Your Alarms

On a regular basis, such as weekly, review your alarms to ensure optimal configuration. Calibrate each alarm's threshold, severity, and notification details, including method, frequency, and targeted audience.



Optimal alarm configuration addresses the following factors:

- Criticality of the resource.
- Appropriate resource behavior. Assess behavior singly and within the context of the service ecosystem. Review metric value fluctuations for a given period of time and then adjust thresholds as needed.
- Acceptable notification noise. Assess the notification method (for example, email or PagerDuty), the appropriate recipients, and the frequency of repeated notifications.

For instructions, see To update an alarm.

Monitoring Query Language (MQL) Reference

This topic describes the components that appear in Monitoring Query Language (MQL) expressions, the order that they appear in, and valid values.

MQL syntax governs expressions for querying metrics that are published to the Monitoring service. In the Console, MQL expressions appear in **Advanced Mode**. If you don't need to aggregate results by group or to use other advanced query functionality, then you can create simpler versions of metric queries using **Basic Mode** in the Console.

Components in an MQL Expression

An MQL expression includes the following components:

- metric
- interval
- dimensions, as one or more name-value pairs (optional)
- grouping function (optional)
- statistic
- comparison operation (optional). Useful for defining alarms.

The query components appear in the following order (boldface components are required):

`metric[interval]``{dimensionname="dimensionvalue"}.groupingfunction.`**`statistic`**

Comparison operation queries used for alarms can take the following formats (boldface components are required):

- **`metric[interval]`** `{dimensionname="dimensionvalue"}.groupingfunction.`**`statistic`** (where the statistic is `absent()`)
- **`metric[interval]`** `{dimensionname="dimensionvalue"}.groupingfunction.`**`statistic operator value`**

- **`metric[interval]`**`{dimensionname="dimensionvalue"}.groupingfunction.`**`statistic operator (value1, value2)`**

You can nest alarm queries and metric queries.

Note

Nested alarm queries are not currently supported in the Console. Use the API to create alarms with nested queries.

When nesting queries, the query components appear in the following order (boldface components are required):

`(metric[interval]``{dimensionname="dimensionvalue"}.groupingfunction.`**`statistic)`**`.groupingfunction.`**`statistic`**

An example of a nested query is a grouped count of hosts with up time greater than zero, where the alarm query to identify these hosts is defined within parentheses:

```
(metric[1h].groupBy(host).min() > 0).grouping().count()
```

Metric Query Component

The *metric* component of the query appears before the interval.

`metric``[interval]{dimensionname="dimensionvalue"}.groupingfunction.statistic`

Valid values for *metric* depend on the resource. An example of a metric is `CpuUtilization`, sent by Compute instances. For a list of supported resources with links to their metric references, see Supported Services. You can also use the ListMetrics operation to find metrics sent by a particular service, such as the Compute service. This operation returns metric definitions.

Interval Query Component

The *interval* component of the query appears between the metric and statistic (before the optional dimension name-value pair and grouping function).

```
metric[interval]{dimensionname="dimensionvalue"}.groupingfunction.statistic
```

The Monitoring Query Language (MQL) syntax (**Advanced Mode** in the Console) supports the following range of values for *interval*:

`1m`-`60m` (also, `1h`)

The **Interval** option in the Console (**Basic Mode**) supports the following range of values:

- **1m** - 1 minute
- **5m** - 5 minutes
- **1h** - 1 hour

Note

For metric queries, the interval you select drives the default resolution of the request, which determines the maximum time range of data returned.

Maximum time range returned for a query

The maximum time range returned for a metric query depends on the resolution. By default, for metric queries, the resolution is the same as the query interval. The maximum time range is calculated using the current time, regardless of any specified end time. Following are the maximum time ranges returned for each interval selection available in the Console.

Interval	Default resolution (metric queries)	Maximum time range returned
1h	1 hour	90 days
5m	5 minutes	30 days
1m	1 minute	7 days

See examples of returned data

Example 1: One-minute interval and resolution up to the current time, sent at 10:00 on January 8th. No resolution or end time is specified, so the resolution

defaults to the interval value of `1m`, and the end time defaults to the current time (`2019-01-08T10:00:00.789Z`). This request returns a maximum of 7 days of metric data points. The earliest data point possible within this seven-day period would be 10:00 on January 1st (`2019-01-01T10:00:00.789Z`).

Example 2: Five-minute interval with one-minute resolution up to two days ago, sent at 10:00 on January 8th. Because the resolution drives the maximum time range, a maximum of 7 days of metric data points is returned. While the end time specified was 10:00 on January 6th (`2019-01-06T10:00:00.789Z`), the earliest data point possible within this seven-day period would be 10:00 on January 1st (`2019-01-01T10:00:00.789Z`). Therefore, only 5 days of metric data points can be returned in this example.

For more information about the resolution parameter as used in metric queries, see SummarizeMetricsData.

For alarm queries, the specified interval has no effect on the resolution of the request. The only valid value of the resolution for an alarm query request is `1m`. For more information about the resolution parameter as used in alarm queries, see Alarm.

Dimension Query Component

The *dimensionname="dimensionvalue"* component of the query appears between the interval and statistic (before the optional grouping function).

```
metric[interval]{dimensionname="dimensionvalue"}.groupingfunction.statistic
```

Surround the dimension value with double quotes. Example dimension name-value pair for filtering by availability domain: `availabilityDomain = "VeBZ:PHX-AD-1"`

You can specify multiple dimension name-value pairs. Place each pair within the brackets and separate the pairs with commas.

Valid values for *dimensionname* depend on the *metric*. An example of a dimension name is `resourceDisplayName`, included with the `CpuUtilization` metric sent by Compute instances. For a list of supported resources with links to their metric references, including dimensions, see Supported Services. You can also use the ListMetrics operation to find metrics (and their dimensions) sent by a particular application or service, such as the Compute service.

Grouping Function Query Component

The *groupingfunction* component of the query appears between the interval and statistic (after the optional dimension name-value pair).

`metric[interval]{dimensionname="dimensionvalue"}.`*`groupingfunction`*`.statistic`

Valid grouping functions are as follows.

Grouping function (MQL expression; Advanced Mode in the Console)	**Grouping function option (Basic Mode in the Console)**	**Description**
`groupBy()`	(not available)	Aggregates query results by group (dimension or resource group). For example, `groupBy (availabilityDomain)` groups results by availability domain so that results from each availability domain are together.
`grouping()`	**Aggregate Metric Streams**	Aggregates all query results.

Statistic Query Component

The *statistic* component of the query appears after the interval and optional dimension name-value pair and grouping function.

`metric[interval]{dimensionname="dimensionvalue"}.groupingfunction.statistic`

Valid statistics are as follows.

Statistic (MQL expression; Advanced Mode in the Console)	Statistic option (Basic Mode in the Console)	Description
`absent()`	(see absent)	Sets the trigger condition as absence of the specified metric. (Applies to comparison operation queries only. Useful for defining alarms.)
`avg()`	(not available)	Returns the value of Sum divided by Count during the specified time period. Identical to `mean()`.
`count()`	**COUNT**	Returns the number of observations received in the specified time period.
`increment()`	(not available)	Returns the per-interval change.
`max()`	**MAX**	Returns the highest value observed during the specified time period.
`mean()`	**MEAN**	Returns the value of Sum divided by Count during the specified time period.
`min()`	**MIN**	Returns the lowest value observed during the specified time period.

Statistic (MQL expression; Advanced Mode in the Console)	Statistic option (Basic Mode in the Console)	Description
`percentile()`	**P50** **P90** **P95** **P99** **P99.9**	Returns the estimated value of the specified percentile. Valid values are greater than 0.0 and less than 1.0. For example, `percentile(0.8)` returns the value of the 80th percentile.
`rate()`	**RATE**	Returns the per-interval average rate of change. The unit is per-second.
`sum()`	**SUM**	Returns all values added together.

Operator and Value Query Component

The *operator value* component of the query appears after the statistic in threshold alarm queries. Either one or two values are needed, depending on the operator:

- `metric[interval]{dimensionname="dimensionvalue"}.groupingfunction.statistic` *`operator value`*
- `metric[interval]{dimensionname="dimensionvalue"}.groupingfunction.statistic` *`operator (value1, value2)`*

Valid operators are as follows.

Operator (MQL expression; Advanced Mode in the Console)	Operator option (Basic Mode in the Console)	Number of values
`>`	**greater than**	1
`>=`	**greater than or equal to**	1
`==`	**equal to**	1
`!=` (not equal to)	(not available)	1
`<`	**less than**	1
`<=`	**less than or equal to**	1
`in` (inclusive of specified values)	**between** (inclusive of specified values)	2
`not in` (inclusive of specified values)	**outside** (inclusive of specified values)	2
Not applicable. See absent().	**absent**	0

CHAPTER 23 Networking

This chapter explains how to set up cloud networks.

Overview of Networking

When you work with Oracle Cloud Infrastructure, one of the first steps is to set up a virtual cloud network (VCN) for your cloud resources. This topic gives you an overview of Oracle Cloud Infrastructure Networking components and typical scenarios for using a VCN.

Networking Components

The Networking service uses virtual versions of traditional network components you might already be familiar with:

VIRTUAL CLOUD NETWORK (VCN)

A virtual, private network that you set up in Oracle data centers. It closely resembles a traditional network, with firewall rules and specific types of communication gateways that you can choose to use. A VCN resides in a single Oracle Cloud Infrastructure region and covers a single, contiguous IPv4 CIDR block of your choice. See Allowed VCN Size and Address Ranges. The terms *virtual cloud network*, *VCN, and cloud network* are used interchangeably in this documentation. For more information, see VCNs and Subnets.

SUBNETS

Subdivisions you define in a VCN (for example, 10.0.0.0/24 and 10.0.1.0/24). Subnets contain virtual network interface cards (VNICs), which attach to instances. Each subnet consists of a contiguous range of IP addresses that do not overlap with other subnets in the VCN. You can designate a subnet to exist either in a single availability domain or across an entire region (regional subnets are recommended). Subnets act as a unit of configuration within the VCN: All VNICs in a given subnet use the same route table, security lists, and DHCP options (see the definitions that follow). You can designate a subnet as either public or private when you create it. Private means VNICs in the subnet

can't have public IP addresses. Public means VNICs in the subnet can have public IP addresses at your discretion. See Access to the Internet.

VNIC

A virtual network interface card (VNIC), which attaches to an instance and resides in a subnet to enable a connection to the subnet's VCN. The VNIC determines how the instance connects with endpoints inside and outside the VCN. Each instance has a primary VNIC that's created during instance launch and cannot be removed. You can add secondary VNICs to an existing instance (in the same availability domain as the primary VNIC), and remove them as you like. Each secondary VNIC can be in a subnet in the same VCN as the primary VNIC, or in a different subnet that is either in the same VCN or a different one. However, all the VNICs must be in the same availability domain as the instance. For more information, see Virtual Network Interface Cards (VNICs).

PRIVATE IP

A private IPv4 address and related information for addressing an instance (for example, a hostname for DNS). Each VNIC has a primary private IP, and you can add and remove secondary private IPs. The primary private IP address on an instance doesn't change during the instance's lifetime and cannot be removed from the instance. For more information, see Private IP Addresses.

PUBLIC IP

A public IPv4 address and related information. You can optionally assign a public IP to your instances or other resources that have a private IP. Public IPs can be either *ephemeral* or *reserved*. For more information, see Public IP Addresses.

IPv6

An IPv6 address and related information. IPv6 is currently supported only in the Government Cloud. For more information, see IPv6 Addresses.

DYNAMIC ROUTING GATEWAY (DRG)

An optional virtual router that you can add to your VCN. It provides a path for *private* network traffic between your VCN and on-premises network. You can use it with other

Networking components and a router in your on-premises network to establish a connection by way of IPSec VPN or Oracle Cloud Infrastructure FastConnect. It can also provide a path for private network traffic between your VCN and another VCN in a different region. For more information, see Access to Your On-Premises Network, Dynamic Routing Gateways (DRGs), and Remote VCN Peering (Across Regions).

INTERNET GATEWAY

Another optional virtual router that you can add to your VCN for direct internet access. For more information, see Access to the Internet and also Scenario A: Public Subnet.

NETWORK ADDRESS TRANSLATION (NAT) GATEWAY

Another optional virtual router that you can add to your VCN. It gives cloud resources without public IP addresses access to the internet without exposing those resources to incoming internet connections. For more information, see Access to the Internet and also NAT Gateway.

SERVICE GATEWAY

Another optional virtual router that you can add to your VCN. It provides a path for *private* network traffic between your VCN and supported services in the Oracle Services Network (examples: Oracle Cloud Infrastructure Object Storage and Autonomous Database). For example, DB Systems in a private subnet in your VCN can back up data to Object Storage without needing public IP addresses or access to the internet. For more information, see Access to Oracle Services: Service Gateway.

LOCAL PEERING GATEWAY (LPG)

Another optional virtual router that you can add to your VCN. It lets you peer one VCN with another VCN in the same region. *Peering* means the VCNs communicate using private IP addresses, without the traffic traversing the internet or routing through your on-premises network. A given VCN must have a separate LPG for each peering it establishes. For more information, see Local VCN Peering (Within Region).

REMOTE PEERING CONNECTION (RPC)

A component that you can add to a DRG. It lets you peer one VCN with another VCN in a *different* region. For more information, see Remote VCN Peering (Across Regions).

ROUTE TABLES

Virtual route tables for your VCN. They have rules to route traffic from subnets to destinations outside the VCN by way of gateways or specially configured instances. Your VCN comes with an empty default route table, and you can add custom route tables of your own. For more information, see Route Tables.

SECURITY RULES

Virtual firewall rules for your VCN. They are ingress and egress rules that specify the types of traffic (protocol and port) allowed in and out of the instances. You can choose whether a given rule is stateful or stateless. For example, you can allow incoming SSH traffic from anywhere to a set of instances by setting up a stateful ingress rule with source CIDR 0.0.0.0/0, and destination TCP port 22. To implement security rules, you can use *network security groups* or *security lists*. A network security group consists of a set of security rules that apply only to the resources in that group. Contrast this with a security list, where the rules apply to all the resources in any subnet that uses the list. Your VCN comes with a default security list with default security rules. For more information, see Security Rules.

DHCP OPTIONS

Configuration information that is automatically provided to the instances when they boot up. For more information, see DHCP Options.

Allowed VCN Size and Address Ranges

A VCN covers a single, contiguous IPv4 CIDR block of your choice. The allowable VCN size range is /16 to /30. Example: 10.0.0.0/16. The Networking service reserves the first two IP addresses and the last one in each subnet's CIDR. After you've created a VCN or subnet, you can't change its size, so it's important to think about the size of VCN and subnets you need before creating them.

For your VCN, Oracle recommends using one of the private IP address ranges specified in RFC 1918 (10.0.0.0/8, 172.16/12, and 192.168/16). However, you can use a publicly routable range. Regardless, this documentation uses the term *private IP address* when referring to IP addresses in your VCN's CIDR.

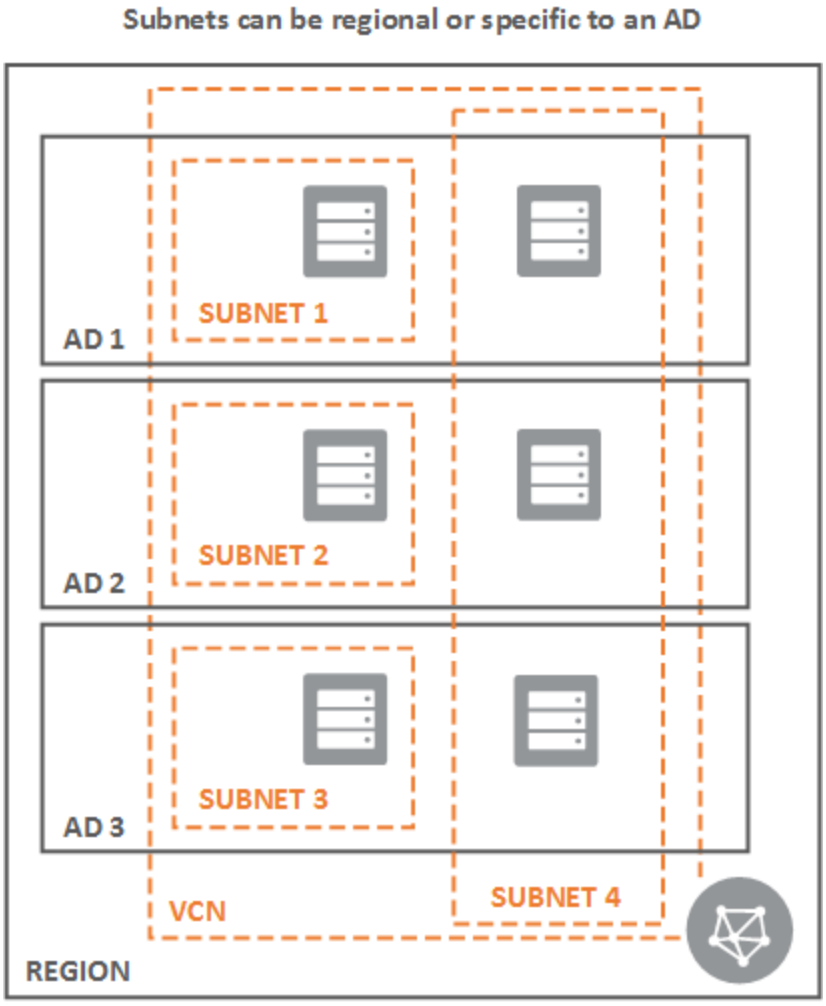
The VCN's CIDR must not overlap with your on-premises network or another VCN you peer with. The subnets in a given VCN must not overlap with each other. For reference, here's a CIDR calculator.

IPv6 addressing is currently supported only in the US Government Cloud. For more information, see IPv6 Addresses.

Availability Domains and Your VCN

Your VCN resides in a single Oracle Cloud Infrastructure region. A region can have multiple availability domains to provide isolation and redundancy. For more information, see Regions and Availability Domains.

Originally subnets were designed to cover only one availability domain (AD) in a region. They were all *AD-specific*, which means the subnet's resources were required to reside in a particular availability domain. Now subnets can be either AD-specific or *regional*. You choose the type when you create the subnet. Both types of subnets can co-exist in the same VCN. In the following diagram, subnets 1-3 are AD-specific, and subnet 4 is regional.



Aside from the removal of the AD constraint, regional subnets behave the same as AD-specific subnets. **Oracle recommends using regional subnets** because they're more flexible. They make it easier to efficiently divide your VCN into subnets while also designing for availability domain failure.

When you create a resource such as a Compute instance, you choose which availability domain the resource will be in. From a virtual networking standpoint, you must also choose

which VCN and subnet the instance will be in. You can either choose a regional subnet, or choose an AD-specific subnet that matches the AD you chose for the instance.

Default Components that Come With Your VCN

Your VCN automatically comes with these *default* components:

- Default route table, with no route rules
- Default security list, with default security rules
- Default set of DHCP options, with default values

You can't delete these default components. However, you can change their contents (for example, the rules in the default security list). And you can create your own custom versions of each kind of component in your VCN. There are limits to how many you can create and the maximum number of rules. For more information, see Service Limits.

Each subnet always has these components associated with it:

- One route table
- One or more security lists (for the maximum number, see Service Limits)
- One set of DHCP options

During subnet creation, you can choose which route table, security list, and set of DHCP options the subnet uses. If you don't specify a particular component, the subnet automatically uses the VCN's default component. You can change which components the subnet uses at any time.

Tip

Security lists are one way to control traffic in and out of the VCN's resources. You can also use network security groups, which let you apply a set of security rules to a set of resources that all have the same security posture.

Connectivity Choices

You can control whether subnets are public or private, and whether instances get public IP addresses. You can set up your VCN to have access to the internet if you like. You can also privately connect your VCN to public Oracle Cloud Infrastructure services such as Object Storage, to your on-premises network, or to another VCN.

Public vs. Private Subnets

When you create a subnet, by default it's considered public, which means instances in that subnet are allowed to have public IP addresses. Whoever launches the instance chooses whether it will have a public IP address. You can override that behavior when creating the subnet and request that it be private, which means instances launched in the subnet are prohibited from having public IP addresses. Network administrators can therefore ensure that instances in the subnet have no internet access, even if the VCN has a working internet gateway, and security rules and firewall rules allow the traffic.

How IP Addresses Are Assigned

Each instance has a primary VNIC that's created during instance launch and cannot be removed. You can add secondary VNICs to an existing instance (in the same availability domain as the primary VNIC) and remove them as you like.

Every VNIC has a private IP address from the associated subnet's CIDR. You can choose the particular IP address (during instance launch or secondary VNIC creation), or Oracle can choose it for you. The private IP address does not change during the lifetime of the instance and cannot be removed. You can also add secondary private IPs to a VNIC.

If the VNIC is in a public subnet, then each private IP on that VNIC can have a public IP assigned to it at your discretion. Oracle chooses the particular IP address. There are two types of public IPs: *ephemeral* and *reserved*. An ephemeral public IP exists only for the lifetime of the private IP it's assigned to. In contrast, a reserved public IP exists as long as you want it to. You maintain a pool of reserved public IPs and allocate them to your instances at your discretion. You can move them from resource to resource in a region as you need to.

Access to the Internet

There are two optional gateways (virtual routers) that you can add to your VCN depending on the type of internet access you need:

- **Internet gateway:** For resources with public IP addresses that need to be reached from the internet (example: a web server) or need to initiate connections to the internet.
- **NAT gateway:** For resources without public IP addresses that need to initiate connections to the internet (example: for software updates) but need to be protected from inbound connections from the internet.

Just having an internet gateway alone does not expose the instances in the VCN's subnets directly to the internet. The following requirements must also be met:

- The internet gateway must be enabled (by default, the internet gateway is enabled upon creation).
- The subnet must be public.
- The subnet must have a route rule that directs traffic to the internet gateway.
- The subnet must have security list rules that allow the traffic (and each instance's firewall must allow the traffic).
- The instance must have a public IP address.

Tip

To access public services such as Object Storage from your VCN without the traffic going over the internet, use a service gateway.

Also, be aware that when an internet gateway receives traffic from your VCN destined for a public IP address *that is part of Oracle Cloud Infrastructure* (such as Object Storage), the internet gateway routes the traffic to the destination without sending the traffic over the internet.

You can also give a subnet *indirect* access to the internet by setting up an internet proxy in your on-premises network and then connecting that network to your VCN by way of a DRG. For more information, see Access to Your On-Premises Network.

Access to Public Oracle Cloud Infrastructure Services

You can use a service gateway with your VCN to enable private access to public Oracle Cloud Infrastructure services such as Object Storage. For example, DB Systems in a private subnet in your VCN can back up data to Object Storage without needing public IP addresses or access to the internet. No internet gateway or NAT is required. For more information, see Access to Oracle Services: Service Gateway.

Access to Your On-Premises Network

There are two ways to connect your on-premises network to Oracle Cloud Infrastructure:

- VPN Connect: Offers multiple IPSec tunnels between your existing network's edge and your VCN, by way of a DRG that you create and attach to your VCN.
- Oracle Cloud Infrastructure FastConnect: Offers a private connection between your existing network's edge and Oracle Cloud Infrastructure. Traffic does not traverse the internet. Both private peering and public peering are supported. That means your on-

premises hosts can access private IPv4 addresses in your VCN as well as regional public IPv4 addresses in Oracle Cloud Infrastructure (for example, Object Storage or public load balancers in your VCN).

You can use one or both types of the preceding connections. If you use both, you can use them simultaneously, or in a redundant configuration. These connections come to your VCN by way of a single DRG that you create and attach to your VCN. Without that DRG attachment and a route rule for the DRG, traffic does not flow between your VCN and on-premises network. At any time, you can detach the DRG from your VCN but maintain all the remaining components that form the rest of the connection. You could then reattach the DRG again, or attach it to another VCN.

Access to Another VCN

You can connect your VCN to another VCN over a private connection that doesn't require the traffic to traverse the internet. In general, this type of connection is referred to as *VCN peering*. Each VCN must have specific components to enable peering. The VCNs must also have specific IAM policies, route rules, and security rules that permit the connection to be made and the desired network traffic to flow over the connection. For more information, see Access to Other VCNs: Peering.

Connection to Oracle Cloud Infrastructure Classic

You can set up a connection between your Oracle Cloud Infrastructure environment and Oracle Cloud Infrastructure Classic environment. This connection can facilitate hybrid deployments between the two environments, or migration from Oracle Cloud Infrastructure Classic to Oracle Cloud Infrastructure. For more information, see Access to Oracle Cloud Infrastructure Classic.

Connection to Microsoft Azure

Oracle and Microsoft have created a cross-cloud connection between Oracle Cloud Infrastructure and Microsoft Azure in certain regions. This connection lets you set up cross-cloud workloads without the traffic between the clouds going over the internet. For more information, see Access to Microsoft Azure.

Connection to Other Clouds with Libreswan

You can connect your VCN to another cloud provider by using an IPSec VPN with a Libreswan VM as the customer-premises equipment (CPE). For more information, see Access to Other Clouds with Libreswan.

Networking Scenarios

This documentation includes a few basic networking scenarios to help you understand the Networking service and generally how the components work together. See these topics:

- Scenario A: Public Subnet
- Scenario B: Private Subnet with a VPN
- Scenario C: Public and Private Subnets with a VPN

Transit Routing

Scenarios A–C show your on-premises network connected to a VCN by way of FastConnect or VPN Connect, and accessing only the resources in that VCN.

The following advanced routing scenarios give your on-premises network additional access beyond the resources in the connected VCN. Traffic travels from your on-premises network to the VCN, and then *transits through* the VCN to its destination. See these topics:

- Transit Routing: Access to Multiple VCNs in the Same Region: Your on-premises network has access to *multiple* VCNs in the same region over a single FastConnect private virtual circuit or VPN Connect. The VCNs are in a hub-and-spoke layout, with the on-premises network connected to the VCN that acts as the hub. The spoke VCNs are peered with the hub VCN.
- Transit Routing: Private Access to Oracle Services: Your on-premises network has *private access* to Oracle services in the Oracle Services Network by way of the connected VCN and the VCN's service gateway. The traffic does not go over the internet.

Regions and Availability Domains

Your VCN resides in a single Oracle Cloud Infrastructure region. Each subnet resides in a single availability domain (AD). Availability domains are designed to provide isolation and redundancy in your VCN, as illustrated in Scenario B and C earlier. For example, you could set up your primary set of subnets in a single AD, and then set up a duplicate set of subnets in a secondary AD. The two ADs are isolated from each other in the Oracle data centers, so if one fails, you can easily switch over to the other AD. For more information, see Regions and Availability Domains.

Public IP Address Ranges

For a list of Oracle Cloud Infrastructure public IP ranges, see IP Address Ranges.

IP Addresses Reserved for Use by Oracle

Certain IP addresses are reserved for Oracle Cloud Infrastructure use and may not be used in your address numbering scheme.

169.254.0.0/16

These addresses are used for iSCSI connections to the boot and block volumes, instance metadata, and other services.

Three IP Addresses in Each Subnet

These addresses consist of:

- The first IP address in the CIDR (the network address)
- The last IP address in the CIDR (the broadcast address)
- The first host address in the CIDR (the subnet default gateway address)

For example, in a subnet with CIDR 192.168.0.0/24, these addresses are reserved:

- 192.168.0.0 (the network address)
- 192.168.0.255 (the broadcast address)
- 192.168.0.1 (the subnet default gateway address)

The remaining addresses in the CIDR (192.168.0.2 to 192.168.0.254) are available for use.

Creating Automation with Events

You can create automation based on state changes for your Oracle Cloud Infrastructure resources by using event types, rules, and actions. For more information, see Overview of Events.

Resource Identifiers

Most types of Oracle Cloud Infrastructure resources have a unique, Oracle-assigned identifier called an Oracle Cloud ID (OCID). For information about the OCID format and other ways to identify your resources, see Resource Identifiers.

Ways to Access Oracle Cloud Infrastructure

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. For a list of available SDKs, see Software Development Kits and Command Line Interface.

To access the Console, you must use a supported browser. Oracle Cloud Infrastructure supports the latest desktop versions of Google Chrome, Microsoft Edge, Internet Explorer 11, Safari, Firefox, and Firefox ESR. Note that private browsing mode is not supported for Firefox, Internet Explorer, or Edge. Mobile browsers are not supported.

For general information about using the API, see REST APIs.

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies. For specific details about writing policies for each of the different services, see Policy Reference.

If you're a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

Limits on Your Networking Components

See Service Limits for a list of applicable limits and instructions for requesting a limit increase.

Scenario A: Public Subnet

This topic explains how to set up Scenario A, which consists of a virtual cloud network (VCN) and a regional public subnet. There are public servers in separate availability domains for redundancy. The VCN is directly connected to the internet by way of an internet gateway. The gateway is also used for connectivity to your on-premises network. Any resource in the on-premises network that needs to communicate with resources in the VCN must have a public IP address and access to the internet.

The subnet uses the default security list, which has default rules that are designed to make it easy to get started with Oracle Cloud Infrastructure. The rules enable typical required access (for example, inbound SSH connections and any type of outbound connections). Remember

that security list rules only *allow* traffic. Any traffic not explicitly covered by a security list rule is implicitly denied.

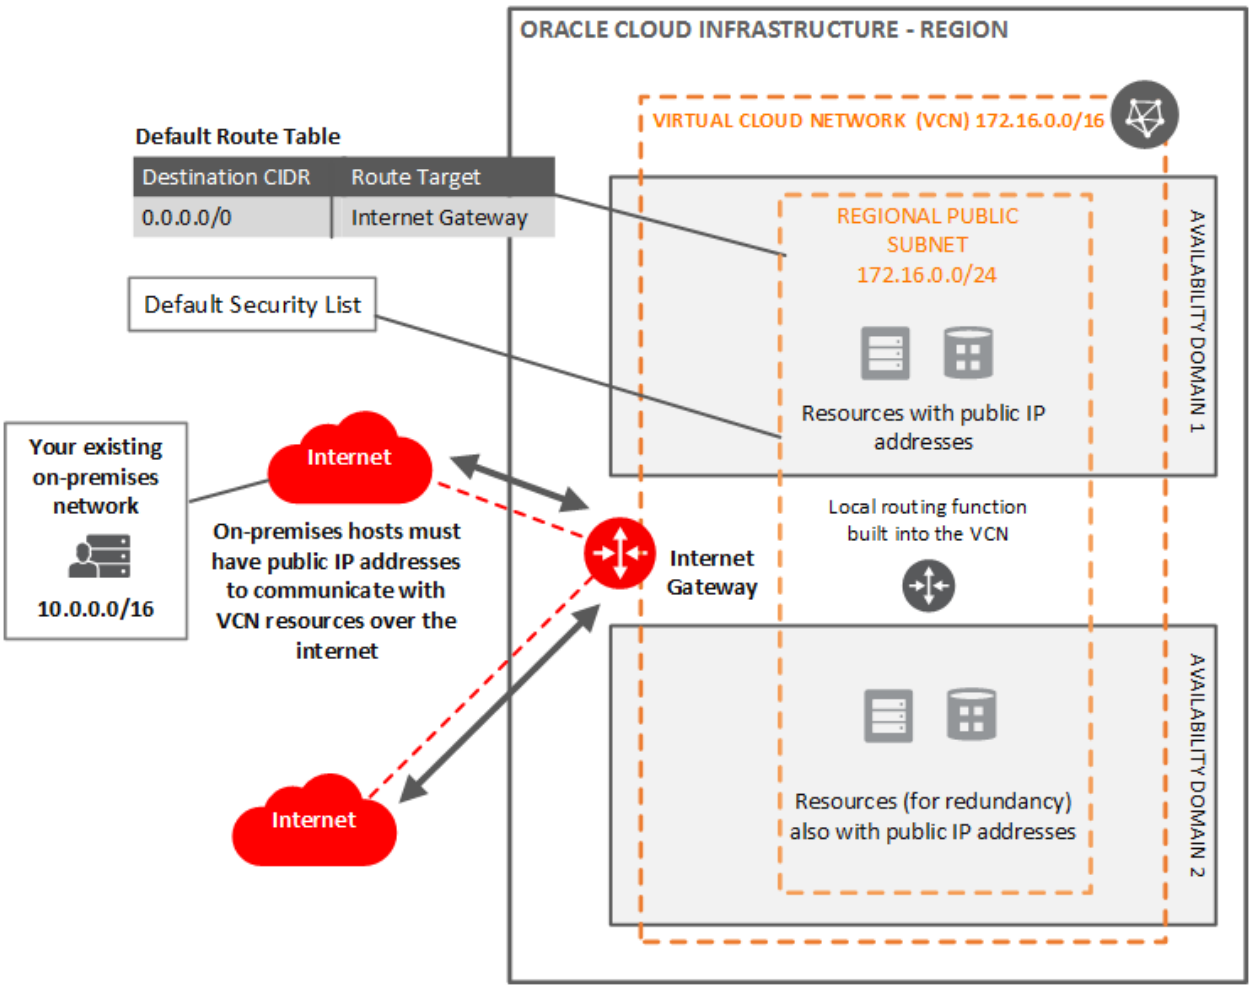
In this scenario, you add additional rules to the default security list. You could instead create a custom security list for those rules. You would then set up the subnet to use both the default security list and the custom security list.

Tip

Security lists are one way to control traffic in and out of the VCN's resources. You can also use network security groups, which let you apply a set of security rules to a set of resources that all have the same security posture.

The subnet uses the default route table, which starts out with no rules when the VCN is created. In this scenario, the table has only a single rule for the internet gateway.

See the following figure.



Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

If you're a member of the Administrators group, you already have the required access to execute Scenario A. Otherwise, you need access to Networking, and you need the ability to launch instances. See IAM Policies for Networking.

Setting Up Scenario A in the Console

Setup is easy in the Console.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Task 1: Create the VCN

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator. For more information, see Access Control.
3. Click **Create Virtual Cloud Network**.
4. Enter the following:
   - **Name:** A friendly name for the VCN. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
   - **Create in Compartment:** Leave as is.

- **Create Virtual Cloud Network Only:** Make sure this radio button is selected (the default).
- **Enable IPv6 Address Assignment:** This option is available only if the VCN is in the Government Cloud. For more information, see IPv6 Addresses.
- **CIDR Block:** A single, contiguous CIDR block for the VCN. For example: 172.16.0.0/16. You *cannot* change this value later. See Allowed VCN Size and Address Ranges. For reference, here's a CIDR calculator.
- **Use DNS Hostnames in this VCN:** Required for assignment of DNS hostnames to hosts in the VCN, and required if you plan to use the VCN's default DNS feature (called the *Internet and VCN Resolver*). If the check box is selected, you can specify a DNS label for the VCN, or the Console will generate one for you. The dialog box automatically displays the corresponding **DNS Domain Name** for the VCN (`<VCN DNS label>.oraclevcn.com`). For more information, see DNS in Your Virtual Cloud Network.
- **Tags:** Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.

5. Click **Create Virtual Cloud Network**.
   The VCN is then created and displayed on the **Virtual Cloud Networks** page in the compartment you chose.

Task 2: Create the regional public subnet

1. While still viewing the VCN, click **Create Subnet**.
2. Enter the following:
   - **Name:** A friendly name for the subnet (for example, Regional Public Subnet). It doesn't have to be unique, and it cannot be changed later in the Console (but you

can change it with the API). Avoid entering confidential information.

- **Regional or Availability Domain-Specific:** Select **Regional** (recommended), which means the subnet spans all availability domains in the region. Later when you launch an instance, you can create it in any availability domain in the region. For more information, see About Regional Subnets.
- **CIDR Block:** A single, contiguous CIDR block within the VCN's CIDR block. For example: 172.16.0.0/24. You *cannot* change this value later. For reference, here's a CIDR calculator.
- **Enable IPv6 Address Assignment:** This option is available only if the VCN is in the US Government Cloud. For more information, see IPv6 Addresses.
- **Route Table:** Select the default route table.
- **Private or public subnet**: Select **Public Subnet**, which means instances in the subnet can optionally have public IP addresses. For more information, see Access to the Internet.
- **Use DNS Hostnames in this Subnet:**This option is available only if you provided a DNS label for the VCN during creation. The option is required for assignment of DNS hostnames to hosts in the subnet, and required if you plan to use the VCN's default DNS feature (called the *Internet and VCN Resolver*). If the check box is selected, you can specify a DNS label for the subnet, or the Console will generate one for you. The dialog box automatically displays the corresponding **DNS Domain Name** for the subnet (*<subnet_DNS_label>*.*<VCN_DNS_label>*.oraclevcn.com). For more information, see DNS in Your Virtual Cloud Network.
- **DHCP Options:** Select the default set of DHCP options.
- **Security Lists:** Make sure the default security list is selected (the default).
- **Tags:** Leave as is. You can add tags later if you want. For more information, see Resource Tags.

3. Click **Create Subnet**.
   The subnet is then created and displayed on the **Subnets** page.

Task 3: Create the internet gateway

1. Under **Resources**, click **Internet Gateways**.
2. Click **Create Internet Gateway**.
3. Enter the following:
   - **Name:** A friendly name for the internet gateway. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
   - **Create in Compartment:** Leave as is.
   - **Tags:** Leave as is. You can add tags later if you want. For more information, see Resource Tags.
4. Click **Create Internet Gateway**.
   Your internet gateway is created and displayed on the **Internet Gateways** page. It's already enabled, but you must add a route rule that allows traffic to flow to the gateway.

Task 4: Update the default route table to use the internet gateway

The default route table starts out with no rules. Here you add a rule that routes all traffic destined for addresses outside the VCN to the internet gateway. The existence of this rule also enables inbound connections to come from the internet to the subnet, through the internet gateway. You use security list rules to control the *types of traffic* that are allowed in and out of the instances in the subnet (see the next task).

No route rule is required in order to route traffic within the VCN itself.

1. Under **Resources**, click **Route Tables**.
2. Click the default route table to view its details.
3. Click **Add Route Rule**.
4. Enter the following:

- **Target Type:** Internet Gateway
- **Destination CIDR block:** 0.0.0.0/0 (which means that all non-intra-VCN traffic that is not already covered by other rules in the route table goes to the target specified in this rule)
- **Compartment:** The compartment where the internet gateway is located.
- **Target:** The internet gateway you created.

5. Click **Add Route Rule**.

The default route table now has a rule for the internet gateway. Because the subnet was set up to use the default route table, the resources in the subnet can now use the internet gateway. The next step is to specify the types of traffic you want to allow in and out of the instances you later create in the subnet.

Task 5: Update the default security list

Earlier you set up the subnet to use the VCN's default security list. Now you add security list rules that allow the types of connections that the instances in the VCN will need.

For example: This is a public subnet with an internet gateway, so the instances your launch might need to receive inbound HTTPS connections from the internet (if they're web servers). Here's how to add another rule to the default security list to enable that traffic:

1. Under **Resources**, click **Security Lists.**
2. Click the default security list to view its details. By default, you land on the **Ingress Rules** page.
3. Click **Add Ingress Rule**.
4. To enable inbound connections for HTTPS (TCP port 443), enter the following:
   - **Stateless**: Unselected (this is a stateful rule)
   - **Source Type:** CIDR
   - **Source CIDR:** 0.0.0.0/0

- **IP Protocol:** TCP
- **Source Port Range:** All
- **Destination Port Range**: 443

5. Click **Add Ingress Rule**.

> **Important**
>
> *Security List Rule for Windows Instances*
>
> If you're going to launch Windows instances, you need to add a security list rule to enable Remote Desktop Protocol (RDP) access. Specifically, you need a stateful ingress rule for TCP traffic on destination port 3389 from source 0.0.0.0/0 and any source port. For more information, see Security Lists.

For a production VCN, you typically set up one or more *custom* security lists for each subnet. If you like, you can edit the subnet to use different security lists. If you choose not to use the default security list, do so only after carefully assessing which of its default rules you want to duplicate in your custom security list. For example: the default ICMP rules in the default security list are important for receiving connectivity messages.

Task 6: Create instances in separate availability domains

Your next step is to create one or more instances in the subnet. The scenario's diagram shows instances in two different availability domains. When you create the instance, you choose the AD, which VCN and subnet to use, and several other characteristics.

Each instance automatically gets a private IP address. When you create an instance in a *public subnet*, you choose whether the instance gets a public IP address. With this network setup in Scenario A, you *must* give each instance a public IP address, or else you can't access them

through the internet gateway. The default (for a public subnet) is for the instance to get a public IP address.

After creating an instance in this scenario, you can connect to it over the internet with SSH or RDP from your on-premises network or other location on the internet. For more information and instructions, see Launching an Instance.

Setting Up Scenario A with the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the following operations:

1. CreateVcn: Make sure to include a DNS label for the VCN if you want the instances to have hostnames (see DNS in Your Virtual Cloud Network).
2. CreateSubnet: Create one regional public subnet. Include a DNS label for the subnet if you want the instances to have hostnames. Use the default route table, default security list, and default set of DHCP options.
3. CreateInternetGateway
4. UpdateRouteTable: To enable communication with the internet gateway, update the default route table to include a route rule with destination = 0.0.0.0/0, and destination target = the internet gateway. This rule routes all traffic destined for addresses outside the VCN to the internet gateway. No route rule is required in order to route traffic within the VCN itself.
5. UpdateSecurityList: To allow specific types of connections to and from the instances in the subnet.

Important

Security List Rule for Windows Instances

If you're going to launch Windows instances, you need to add a security list rule to enable Remote Desktop Protocol (RDP) access. Specifically, you need a stateful ingress rule for TCP traffic on destination port 3389 from source 0.0.0.0/0 and any source port. For more information, see Security Lists.

Your next step is to create one or more instances in the subnet. The scenario's diagram shows instances in two different availability domains. When you create the instance, you choose the AD, which VCN and subnet to use, and several other characteristics.

Each instance automatically gets a private IP address. When you create an instance in a *public subnet*, you choose whether the instance gets a public IP address. With this network setup in Scenario A, you *must* give each instance a public IP address, or else you can't access them through the internet gateway. The default (for a public subnet) is for the instance to get a public IP address.

After creating an instance in this scenario, you can connect to it over the internet with SSH or RDP from your on-premises network or other location on the internet. For more information and instructions, see Launching an Instance.

Scenario B: Private Subnet with a VPN

This topic explains how to set up Scenario B, which consists of a virtual cloud network (VCN) with a regional private subnet. There are servers in separate availability domains for redundancy. The VCN has a dynamic routing gateway (DRG) and IPSec VPN for connectivity to your on-premises network. The VCN has no direct connection to the internet. Any connection to the internet would need to come indirectly by way of the on-premises network.

The subnet uses the default security list, which has default rules that are designed to make it easy to get started with Oracle Cloud Infrastructure. The rules enable typical required access

(for example, inbound SSH connections and any type of outbound connections). Remember that security list rules only *allow* traffic. Any traffic not explicitly covered by a security list rule is denied.

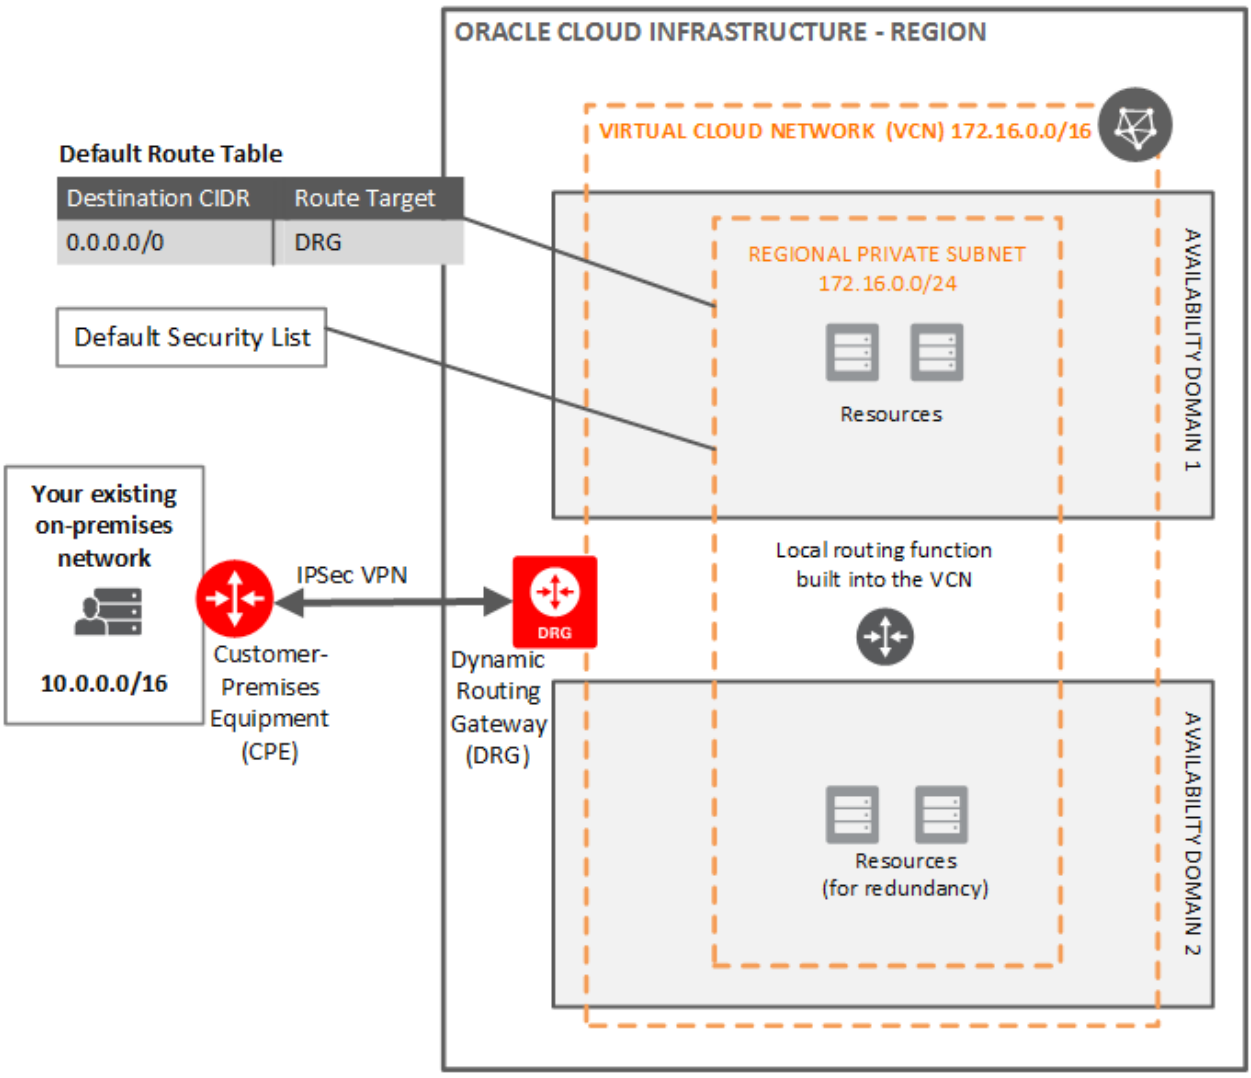
In this scenario, you add additional rules to the default security list. You could instead create a custom security list for those rules. You would then set up the subnet to use both the default security list and the custom security list.

Tip

Security lists are one way to control traffic in and out of the VCN's resources. You can also use network security groups, which let you apply a set of security rules to a set of resources that all have the same security posture.

The subnet uses the default route table, which starts out with no rules when the VCN is created. In this scenario, the table has only a single rule for the DRG. No route rule is required in order to route traffic within the VCN itself.

See the following figure.



ORACLE CLOUD INFRASTRUCTURE - REGION
VIRTUAL CLOUD NETWORK (VCN) 172.16.0.0/16
Default Route Table
Destination CIDR
Route Target
0.0.0.0/0
DRG
Default Security List
REGIONAL PRIVATE SUBNET
172.16.0.0/24
Resources
AVAILABILITY DOMAIN 1
Your existing on-premises network
10.0.0.0/16
IPSec VPN
Customer-Premises Equipment (CPE)
DRG
Dynamic Routing Gateway (DRG)
Local routing function built into the VCN
Resources
(for redundancy)
AVAILABILITY DOMAIN 2

Tip

The scenario uses an IPSec VPN for connectivity. However, you could instead use Oracle Cloud Infrastructure FastConnect.

Prerequisites

To set up the VPN in this scenario, you need to get the following information from a network administrator:

- Public IP address of the customer-premises equipment (CPE) at your end of the VPN
- Static routes for your on-premises network (this scenario uses static routing for the VPN tunnels, but you could instead use BGP dynamic routing)

You will provide Oracle this information and in return receive the information your network administrator must have to configure the CPE at your end of the VPN.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

If you're a member of the Administrators group, you already have the required access to execute Scenario B. Otherwise, you need access to Networking, and you need the ability to launch instances. See IAM Policies for Networking.

Setting Up Scenario B

Setup is easy in the Console. Alternatively, you can use the Oracle Cloud Infrastructure API, which lets you execute the individual operations yourself.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Important

Most of this process involves working with the Console or API (whichever you choose) for a short period to set up the desired Networking components. But there's also a critical step that requires a network administrator in your organization to take information you receive from setting up the components and use it to configure the CPE at your end of the VPN. Therefore you can't complete this process in one short session. You'll need to break for an unknown period of time while the network administrator completes the configuration and then return afterward to confirm communication with your instances over the VPN.

Using the Console

Task 1: Set up the VCN and subnet

1. Create the VCN:
    a. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
    b. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator. For more information, see Access Control.
    c. Click **Create Virtual Cloud Network**.
    d. Enter the following:
        - **Name:** A friendly name for the VCN. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
        - **Create in Compartment:** Leave as is.
        - **Create Virtual Cloud Network Only:** Make sure this radio button is selected (the default).
        - **CIDR Block:** A single, contiguous CIDR block for the VCN. For example: 172.16.0.0/16. You *cannot* change this value later. See Allowed VCN Size and Address Ranges. For reference, here's a CIDR calculator.
        - **Enable IPv6 Address Assignment:** This option is available only if the VCN is in the US Government Cloud. For more information, see IPv6 Addresses.
        - **Use DNS Hostnames in this VCN:** Required for assignment of DNS hostnames to hosts in the VCN, and required if you plan to use the VCN's default DNS feature (called the *Internet and VCN Resolver*). If the check box is selected, you can specify a DNS label for the VCN, or the Console will

generate one for you. The dialog box automatically displays the corresponding **DNS Domain Name** for the VCN (`<VCN DNS label>.oraclevcn.com`). For more information, see DNS in Your Virtual Cloud Network.

- **Tags:** Leave as is. You can add tags later if you want. For more information, see Resource Tags.

e. Click **Create Virtual Cloud Network**.
The VCN is then created and displayed on the **Virtual Cloud Networks** page in the compartment you chose.

2. Create the regional private subnet:
   a. While still viewing the VCN, click **Create Subnet**.
   b. Enter the following:
      - **Name:** A friendly name for the subnet (for example, *Regional Private Subnet*). It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
      - **Regional or Availability Domain-Specific:** Select **Regional** (recommended), which means the subnet spans all availability domains in the region. Later when you launch an instance, you can create it any availability domain in the region. For more information, see About Regional Subnets.
      - **CIDR Block:** A single, contiguous CIDR block within the VCN's CIDR block. For example: 172.16.0.0/24. You *cannot* change this value later. For reference, here's a CIDR calculator.
      - **Enable IPv6 Address Assignment:** This option is available only if the VCN is in the US Government Cloud. For more information, see IPv6 Addresses.
      - **Route Table:** Select the default route table.

- **Private or public subnet**: Select **Private Subnet**, which means instances in the subnet cannot have public IP addresses. For more information, see Access to the Internet.
- **Use DNS Hostnames in this Subnet:**This option is available only if you provided a DNS label for the VCN during creation. The option is required for assignment of DNS hostnames to hosts in the subnet, and required if you plan to use the VCN's default DNS feature (called the *Internet and VCN Resolver*). If the check box is selected, you can specify a DNS label for the subnet, or the Console will generate one for you. The dialog box automatically displays the corresponding **DNS Domain Name** for the subnet (*<subnet_DNS_label>*.*<VCN_DNS_label>*.oraclevcn.com). For more information, see DNS in Your Virtual Cloud Network.
- **DHCP Options:** Select the default set of DHCP options.
- **Security Lists:** Select the default security list.
- **Tags:** Leave as is. You can add tags later if you want. For more information, see Resource Tags.

c. Click **Create Subnet**.

The subnet is then created and displayed on the **Subnets** page.

3. Update the default security list to include rules to allow the types of connections that your instances in the VCN will need:

a. While still on the page displaying your VCN's subnets, click **Security Lists**, and then click the default security list.

b. Under **Resources**, click either **Ingress Rules** or **Egress Rules** depending on the type of rule you want to work with. You can add one rule at a time by clicking either **Add Ingress Rule** or **Add Egress Rule**.

c. Add your desired rules. Here are suggested ones to add to the default ones already in the default security list:

Example: Ingress HTTP access

- **Type:** Ingress
- **Stateless**: Unselected (this is a stateful rule)
- **Source Type:** CIDR
- **Source CIDR:** 0.0.0.0/0
- **IP Protocol:** TCP
- **Source Port Range:** All
- **Destination Port Range**: 80

Example: Ingress HTTPS access

- **Type:** Ingress
- **Stateless**: Unselected (this is a stateful rule)
- **Source Type:** CIDR
- **Source CIDR:** 0.0.0.0/0
- **IP Protocol:** TCP
- **Source Port Range:** All
- **Destination Port Range**: 443

Example: Ingress SQL*Net access for Oracle databases

- **Type:** Ingress
- **Stateless**: Unselected (this is a stateful rule)
- **Source Type:** CIDR
- **Source CIDR:** 0.0.0.0/0

- **IP Protocol:** TCP
- **Source Port Range:** All
- **Destination Port Range**: 1521

Example: Ingress RDP access required for Windows instances

- **Type:** Ingress
- **Stateless**: Unselected (this is a stateful rule)
- **Source Type:** CIDR
- **Source CIDR:** 0.0.0.0/0
- **IP Protocol:** TCP
- **Source Port Range:** All
- **Destination Port Range**: 3389

Tip

For additional security, you could modify all the stateful ingress rules to allow traffic only from within your VCN and your on-premises network. You would need to create separate rules for each, one with the VCN's CIDR as the source, and one with the on-premises network's CIDR as the source.

For a production VCN, you typically set up one or more *custom* security lists for each subnet. You can edit the subnet to use different security lists if you like. If you choose not to use the default security list, do so only after carefully assessing which of its default rules you want to duplicate in your custom security list. For example: the default ICMP rules in the default security list are important for receiving connectivity messages.

Task 2: Create instances in separate availability domains

You can now create one or more instances in the subnet (see Launching an Instance). The scenario's diagram shows instances in two different availability domains. When you create the instance, you choose the AD, which VCN and subnet to use, and several other characteristics.

However, you can't yet communicate with the instances because there's no gateway connecting the VCN to your on-premises network. The next procedure walks you through creating an IPSec VPN connection to enable that communication.

Task 3: Add an IPSec VPN to your VCN

1. Create a customer-premises equipment (CPE) object:
    a. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Customer-Premises Equipment**.
    b. Click **Create Customer-Premises Equipment**.
    c. Enter the following:
        - **Create in Compartment:** Leave the default value (the compartment you're currently working in).
        - **Name:** A friendly name for the customer-premises equipment object. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
        - **IP Address:** The public IP address of the CPE at your end of the VPN (see Prerequisites).
    d. Click **Create**.

    The CPE object will be in the "Provisioning" state for a short period.
2. Create a dynamic routing gateway (DRG):
    a. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Dynamic Routing Gateways**.

b. Click **Create Dynamic Routing Gateway**.

c. For **Create in Compartment:** Leave the default value (the compartment you're currently working in).

d. Enter a friendly name for the DRG. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.

e. Click **Create**.

The DRG will be in the "Provisioning" state for a short period. Make sure it is done being provisioned before continuing.

3. Attach the DRG to your VCN:

a. Click the DRG that you just created.

b. Under **Resources**, click **Virtual Cloud Networks**.

c. Click **Attach to Virtual Cloud Network**.

d. Select the VCN. Ignore the section for advanced options, which is only for an advanced routing scenario called *transit routing*, which is not relevant here.

e. Click **Attach**.

The attachment will be in the "Attaching" state for a short period before it's ready.

4. Update the default route table (which has no rules yet):

a. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.

b. Click your VCN.

c. Under **Resources**, click **Route Tables**, and then click the default route table.

d. Click **Add Route Rule**.

e. Enter the following:

- **Target Type:** Dynamic Routing Gateway. The VCN's attached DRG is automatically selected as the target, and you don't have to specify the

target yourself.

- **Destination CIDR Block:** 0.0.0.0/0 (which means that all non-intra-VCN traffic that is not already covered by other rules in the route table will go to the target specified in this rule).

f. Click **Add Route Rule**.

The VCN's default route table now directs outbound traffic to the DRG and ultimately to your on-premises network.

5. Create an IPSec Connection:

a. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **IPSec Connections**.

b. Click **Create IPSec Connection**.

c. Enter the following:

- **Create in Compartment:** Leave the default value (the compartment you're currently working in).
- **Name:** Enter a friendly name for the IPSec connection. It doesn't have to be unique. Avoid entering confidential information.
- **Customer-Premises Equipment Compartment:** Leave as is (the VCN's compartment).
- **Customer-Premises Equipment:** Select the CPE object you created earlier.
- **Dynamic Routing Gateway Compartment:** Leave as is (the VCN's compartment).
- **Dynamic Routing Gateway:** Select the DRG that you created earlier.
- **Static Route CIDR:** Enter at least one static route CIDR (see Prerequisites). If you need to add another, click **Add Static Route**. You can enter up to 10 static routes, and you can change the static routes later if you like.

d. Click **Show Advanced Options** and optionally provide the following items:
   - **CPE IKE Identifier:** Oracle defaults to using the public IP address of the CPE. But if your CPE is behind a NAT device, you might need to enter a different value. You can either enter the new value here, or change the value later.
   - **Tunnel 1** and **Tunnel 2**: Leave as is. Later if you want to use BGP dynamic routing instead of static routing for the VPN tunnels, see Changing from Static Routing to BGP Dynamic Routing.
   - **Tags:** Leave as is. You can add tags later if you want. For more information, see Resource Tags.

e. Click **Create IPSec Connection**.
   The IPSec connection is created and displayed on the page. It will be in the Provisioning state for a short period.
   The displayed tunnel information includes the IP address of the VPN headend and the tunnel's IPSec status (possible values are Up, Down, and Down for Maintenance). At this point, the status is Down. To view the tunnel's shared secret, click the Actions icon (three dots), and then click **View Shared Secret**.

f. Copy the Oracle VPN IP address and shared secret for each of the tunnels to an email or other location so you can deliver it to the network engineer who will configure the on-premises router.
   For more information, see CPE Configuration. You can view this tunnel information here in the Console at any time.

You have now created all the components required for the IPSec VPN. But your network administrator must configure the CPE before network traffic can flow between your on-premises network and VCN.

Task 4: Configure your CPE

These instructions are for the network administrator.

1. Make sure you have the tunnel configuration information that Oracle provided during IPSec VPN setup. See Task 3: Add an IPSec VPN to your VCN.
2. Configure your CPE according to the information in CPE Configuration.

If there are already instances in the subnet, you can confirm the IPSec connection is up and running by connecting to the instances from your on-premises network.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the following operations:

1. CreateVcn: Make sure to include a DNS label for the VCN if you want the instances to have hostnames (see DNS in Your Virtual Cloud Network).
2. CreateSubnet: Create one regional private subnet. Include a DNS label for the subnet if you want the instances to have hostnames. Use the default route table, default security list, and default set of DHCP options.
3. CreateDrg: This creates a new dynamic routing gateway (DRG)
4. CreateDrgAttachment: This attaches the DRG to the VCN.
5. CreateCpe: Here you'll provide the public IP address of the CPE at your end of the VPN (see Prerequisites).
6. CreateIPSecConnection: Here you'll provide the static routes for your on-premises network (see Prerequisites). In return, you'll receive the configuration information that your network administrator needs in order to configure your CPE. If you need that information later, you can get it with GetIPSecConnectionDeviceConfig. For more information about the configuration, see CPE Configuration.
7. UpdateRouteTable: To enable communication via the VPN, update the default route table to include this route: a route rule with destination = 0.0.0.0/0, and destination target = the DRG you created earlier.

8. First call GetSecurityList to get the default security list, and then call UpdateSecurityList to add rules for the types of connections that your instances in the VCN will need. Be aware that `UpdateSecurityList` overwrites the entire set of rules. Here are some suggested rules to add:
    - Stateful ingress: Source type=CIDR, source CIDR=0.0.0.0/0, protocol=TCP, source port = all, destination port=80 (for HTTP).
    - Stateful ingress: Source type=CIDR, source CIDR=0.0.0.0/0, protocol=TCP, source port = all, destination port=443 (for HTTPS).
    - Stateful ingress: Source type=CIDR, source CIDR=0.0.0.0/0, protocol=TCP, source port = all, destination port=1521 (for SQL*Net access to Oracle databases).
    - Stateful ingress: Source type=CIDR, source CIDR=0.0.0.0/0, protocol=TCP, source port=all, destination port=3389 (for RDP; required only if using Windows instances).

    Tip

    For additional security, you could modify all the stateful ingress rules to allow traffic only from within your VCN and your on-premises network. You would need to create separate rules for each, one with the VCN's CIDR as the source, and one with the on-premises network's CIDR as the source.

9. LaunchInstance: Create one or more instances in the subnet. The scenario's diagram shows instances in two different availability domains. When you create the instance, you choose the AD, which VCN and subnet to use, and several other characteristics. For more information, see Launching an Instance.

Important

Although you can create instances in the subnet, you won't be able to communicate with them from your on-premises network until your network administrator configures your CPE (see CPE Configuration). After that, your IPSec connection should be up and running. You can confirm its status by using GetIPSecConnectionDeviceStatus. You can also confirm the IPSec connection is up by connecting to the instances from your on-premises network.

Scenario C: Public and Private Subnets with a VPN

This topic explains how to set up Scenario C, which is a simple example of a multi-tier setup. It consists of a virtual cloud network (VCN) with a regional public subnet to hold public servers (such as web servers), and a regional private subnet to hold private servers (such as database servers). There are servers in separate availability domains for redundancy.

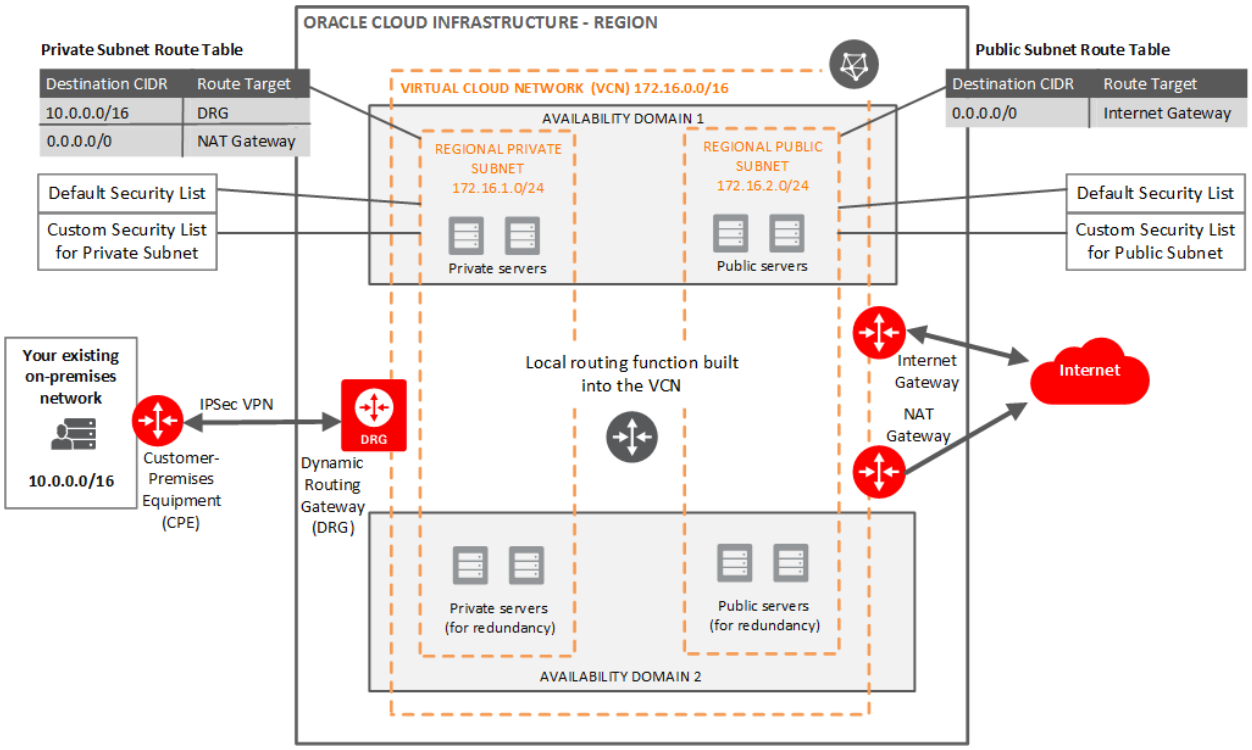
The VCN has a dynamic routing gateway (DRG) and IPSec VPN for connectivity to your on-premises network. Instances in the public subnet have direct access to the internet by way of an internet gateway. Instances in the private subnet can initiate connections to the internet by way of a NAT gateway (for example, to get software updates), but cannot receive inbound connections from the internet through that gateway.

Each subnet uses the default security list, which has default rules that are designed to make it easy to get started with Oracle Cloud Infrastructure. The rules enable typical required access (for example, inbound SSH connections and any type of outbound connections). Remember that security list rules only *allow* traffic. Any traffic not explicitly covered by a security list rule is denied.

> **Tip**
>
> Security lists are one way to control traffic in and out of the VCN's resources. You can also use network security groups, which let you apply a set of security rules to a set of resources that all have the same security posture.

Each subnet also has its own custom security list and custom route table with rules specific to the needs of the subnet's instances. In this scenario, the VCN's default route table (which is always empty to start with) is not used.

See the following figure.



Tip

The scenario uses an IPSec VPN for connectivity. However, you could instead use Oracle Cloud Infrastructure FastConnect.

Prerequisites

To set up the VPN in this scenario, you need to get the following information from a network administrator:

- Public IP address of the customer-premises equipment (CPE) at your end of the VPN
- Static routes for your on-premises network (this scenario uses static routing for the VPN tunnels, but you could instead use BGP dynamic routing)

You will provide Oracle this information and in return receive the information your network administrator needs in order to configure the on-premises router at your end of the VPN.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

If you're a member of the Administrators group, you already have the required access to execute Scenario C. Otherwise, you need access to Networking, and you need the ability to launch instances. See IAM Policies for Networking.

Setting Up Scenario C

Setup is easy in the Console. Alternatively, you can use the Oracle Cloud Infrastructure API, which lets you execute the individual operations yourself.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Important

Most of this process involves working with the Console or API (whichever you choose) for a short period to set up the desired Networking components. But there's also a critical step that requires a network administrator in your organization to take information you receive from setting up the components and use it to configure the on-premises router at your end of the VPN. Therefore you can't complete this process in one short session. You'll need to break for an unknown period of time while the network administrator completes the configuration and then return afterward to confirm communication with your instances over the VPN.

Using the Console

Task 1: Set up the VCN and subnets

1. Create the VCN:
    a. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
    b. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator. For more information, see Access Control.
    c. Click **Create Virtual Cloud Network**.
    d. Enter the following:
        - **Name:** A friendly name for the VCN. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
        - **Create in Compartment:** Leave as is.
        - **Create Virtual Cloud Network Only:** Make sure this radio button is selected (the default).
        - **CIDR Block:** A single, contiguous CIDR block for the VCN. For example: 172.16.0.0/16. You *cannot* change this value later. See Allowed VCN Size and Address Ranges. For reference, here's a CIDR calculator.
        - **Enable IPv6 Address Assignment:** This option is available only if the VCN is in the US Government Cloud. For more information, see IPv6 Addresses.
        - **Use DNS Hostnames in this VCN:** Required for assignment of DNS hostnames to hosts in the VCN, and required if you plan to use the VCN's default DNS feature (called the *Internet and VCN Resolver*). If the check box is selected, you can specify a DNS label for the VCN, or the Console will generate one for you. The dialog box automatically displays the

corresponding **DNS Domain Name** for the VCN (*<VCN DNS label>*.oraclevcn.com). For more information, see DNS in Your Virtual Cloud Network.

- **Tags:** Leave as is. You can add tags later if you want. For more information, see Resource Tags.

e. Click **Create Virtual Cloud Network**.
The VCN is then created and displayed on the **Virtual Cloud Networks** page in the compartment you chose.

2. Create an internet gateway for your VCN:
   a. Under **Resources**, click **Internet Gateways**.
   b. Click **Create Internet Gateway**.
   c. Enter the following:
      - **Name:** A friendly name for the internet gateway. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
      - **Create in Compartment:** Leave as is.
      - **Tags:** Leave as is. You can add tags later if you want. For more information, see Resource Tags.
   d. Click **Create Internet Gateway**.
   The internet gateway is then created and listed on the page.
3. Create a NAT gateway for your VCN:
   a. Under **Resources**, click **NAT Gateways**.
   b. Click **Create NAT Gateway**.
   c. Enter the following:
      - **Name:** A friendly name for the NAT gateway. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.

- **Create in Compartment:** Leave as is.
- **Tags:** Leave as is. You can add tags later if you want. For more information, see Resource Tags.

d. Click **Create NAT Gateway**.
The NAT gateway is then created and listed on the page.

4. Create the custom route table for the public subnet (which you will create later):
   a. Under **Resources**, click **Route Tables**.
   b. Click **Create Route Table**.
   c. Enter the following:
      - **Name:** A friendly name for the route table (for example, *Public Subnet Route Table*). It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
      - **Create in Compartment:** Leave the default value (the compartment you're currently working in).
      - Click **+ Additional Route Rule** and enter the following:
        - **Target Type:** Internet Gateway.
        - **Destination CIDR Block:** 0.0.0.0/0 (which means that all non-intra-VCN traffic that is not already covered by other rules in the route table will go to the target specified in this rule).
        - **Compartment:** Leave as is.
        - **Target:** The internet gateway you just created.
   d. **Tags:** Leave as is. You can add tags later if you want. For more information, see Resource Tags.
   e. Click **Create Route Table**.
   The route table is then created and listed on the page.
5. Create the custom route table for the private subnet (which you will create later):

a. Click **Create Route Table**.

b. Enter the following:

- **Name:** A friendly name for the route table (for example, *Private Subnet Route Table*). It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
- **Create in Compartment:** Leave the default value (the compartment you're currently working in).
- Click **+ Additional Route Rule** and enter the following:
  - **Target Type:** NAT Gateway.
  - **Destination CIDR Block:** 0.0.0.0/0 (which means that all non-intra-VCN traffic that is not already covered by other rules in the route table will go to the target specified in this rule).
  - **Compartment:** Leave as is.
  - **Target:** The NAT gateway you just created.

c. **Tags:** Leave as is. You can add tags later if you want. For more information, see Resource Tags.

d. Click **Create Route Table**.

The route table is then created and listed on the page. Later on after you've set up the IPSec VPN, you will update the Private Subnet Route Table so it routes traffic from the private subnet to the on-premises network by way of the DRG.

6. Update the default security list to include rules to allow the types of connections that your instances in the VCN will need:

a. Under **Resources**, click **Security Lists**.

b. Click the default security list to view its details. By default, you land on the **Ingress Rules** page.

c. Edit each of the existing stateful ingress rules so that the **Source CIDR** is the CIDR for your on-premises network (10.0.0.0/16 in this example) and not

0.0.0.0/0. To edit an existing rule, click the Actions icon (three dots) for the rule, and then click **Edit**.

d. If you plan to launch Windows instances, add a rule to enable RDP access:

Example: Ingress RDP access required for Windows instances

- **Type:** Ingress
- **Stateless**: Unselected (this is a stateful rule)
- **Source Type:** CIDR
- **Source CIDR:** Your on-premises network (10.0.0.0/16 in this example)
- **IP Protocol:** TCP
- **Source Port Range:** All
- **Destination Port Range**: 3389

7. Create a custom security list for the public subnet:
   a. Return to the **Security Lists** page for the VCN.
   b. Click **Create Security List**.
   c. Enter the following:
      - **Name:** Enter a friendly name for the list (for example, *Public Subnet Security List)*. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
      - **Create in Compartment:** Leave the default value (the compartment you're currently working in).
   d. Add the following ingress rules:

Example: Ingress HTTP access

- **Type:** Ingress

- **Stateless**: Unselected (this is a stateful rule)
- **Source Type:** CIDR
- **Source CIDR:** 0.0.0.0/0
- **IP Protocol:** TCP
- **Source Port Range:** All
- **Destination Port Range**: 80

Example: Ingress HTTPS access

- **Type:** Ingress
- **Stateless**: Unselected (this is a stateful rule)
- **Source Type:** CIDR
- **Source CIDR:** 0.0.0.0/0
- **IP Protocol:** TCP
- **Source Port Range:** All
- **Destination Port Range**: 443

e. Add the following egress rule:

Example: Egress SQL*Net access to Oracle databases

- **Type:** Egress
- **Stateless**: Unselected (this is a stateful rule)
- **Destination Type:** CIDR
- **Destination CIDR:** CIDR for the private subnet (172.16.1.0/24 in this example)
- **IP Protocol:** TCP

- **Source Port Range:** All
- **Destination Port Range**: 1521

f. Click **Create Security List**.
The custom security list for the public subnet is then created and listed on the page.

8. Create a custom security list for the *private* subnet:
   a. Click **Create Security List**.
   b. Enter the following:
      - **Name:** Enter a friendly name for the list (for example, *Private Subnet Security List)*. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
      - **Create in Compartment:** Leave the default value (the compartment you're currently working in).
   c. Add the following ingress rules:

Example: Ingress SQL*Net access from clients in the public subnet

- **Type:** Ingress
- **Stateless**: Unselected (this is a stateful rule)
- **Source Type:** CIDR
- **Source CIDR:** CIDR for the public subnet (172.16.2.0/24 in this example)
- **IP Protocol:** TCP
- **Source Port Range:** All
- **Destination Port Range**: 1521

Example: Ingress SQL*Net access from clients in the private subnet

- **Type:** Ingress
- **Stateless**: Unselected (this is a stateful rule)
- **Source Type:** CIDR
- **Source CIDR:** CIDR for the private subnet (172.16.2.1/24 in this example)
- **IP Protocol:** TCP
- **Source Port Range:** All
- **Destination Port Range**: 1521

d. Add the following egress rules:

Example: Egress SQL*Net access to instances in the private subnet

- **Type:** Egress
- **Stateless**: Unselected (this is a stateful rule)
- **Destination Type:** CIDR
- **Destination CIDR:** CIDR for the private subnet (172.16.1.0/24 in this example)
- **IP Protocol:** TCP
- **Source Port Range:** All
- **Destination Port Range**: 1521

e. Click **Create Security List**.
The custom security list for the private subnet is then created and listed on the page.

9. Create the subnets in the VCN:
   a. Under **Resources**, click **Subnets**.
   b. Click **Create Subnet**.

c. Enter the following:

- **Name:** A friendly name for the regional public subnet (for example, *Regional Private Subnet*). It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
- **Regional or Availability Domain-Specific:** Select **Regional** (recommended), which means the subnet spans all availability domains in the region. Later when you launch an instance, you can create it any availability domain in the region. For more information, see About Regional Subnets.
- **CIDR Block:** A single, contiguous CIDR block within the VCN's CIDR block. For example: 172.16.1.0/24. You *cannot* change this value later. For reference, here's a CIDR calculator.
- **Enable IPv6 Address Assignment:** This option is available only if the VCN is in the US Government Cloud. For more information, see IPv6 Addresses.
- **Route Table:** Select the Private Subnet Route Table you created earlier.
- **Private or public subnet**: Select **Private Subnet**, which means VNICs in the subnet are not allowed to have public IP addresses. For more information, see Access to the Internet.
- **Use DNS Hostnames in this Subnet:**This option is available only if you provided a DNS label for the VCN during creation. The option is required for assignment of DNS hostnames to hosts in the subnet, and required if you plan to use the VCN's default DNS feature (called the *Internet and VCN Resolver*). If the check box is selected, you can specify a DNS label for the subnet, or the Console will generate one for you. The dialog box automatically displays the corresponding **DNS Domain Name** for the subnet (`<subnet_DNS_label>.<VCN_DNS_label>.oraclevcn.com`). For more information, see DNS in Your Virtual Cloud Network.

- **DHCP Options:** Select the default set of DHCP options.
- **Security Lists:** Select two security lists: Both the default security list and the Private Subnet Security List you created earlier.

d. Click **Create Subnet**.
   The private subnet is then created and displayed on the **Subnets** page.

e. Repeat the preceding steps a-d to create the *regional public subnet*. Instead use a name such as *Regional Public Subnet*, select **Public Subnet** instead of **Private Subnet**, use the Public Subnet Route Table, and use both the default security list and Public Subnet Security List you created earlier.

Task 2: Create instances in separate availability domains

You can now create one or more instances in the subnet (see Launching an Instance). The scenario's diagram shows instances in two different availability domains. When you create the instance, you choose the AD, which VCN and subnet to use, and several other characteristics.

For each instance in the public subnet, make sure to assign the instance a public IP address. Otherwise, you won't be able to reach the instance from your on-premises network.

You can't yet reach the instances in the private subnet because there's no gateway connecting the VCN to your on-premises network. The next procedure walks you through creating an IPSec VPN connection to enable that communication.

Task 3: Add an IPSec VPN to your VCN

1. Create a customer-premises equipment object:
   a. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Customer-Premises Equipment**.
   b. Click **Create Customer-Premises Equipment**.
   c. Enter the following:

- **Create in Compartment:** Leave the default value (the compartment you're currently working in).
- **Name:** A friendly name for the customer-premises equipment object. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
- **IP Address:** The IP address of the on-premises router at your end of the VPN (see Prerequisites).

d. Click **Create**.

The CPE object is in the "Provisioning" state for a short period.

2. Create a dynamic routing gateway (DRG):
   a. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Dynamic Routing Gateways**.
   b. Click **Create Dynamic Routing Gateway**.
   c. For **Create in Compartment:** Leave the default value (the compartment you're currently working in).
   d. Enter a friendly name for the DRG. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
   e. Click **Create**.

   The DRG will be in the "Provisioning" state for a short period. Make sure it is done being provisioned before continuing.
3. Attach the DRG to your VCN:
   a. Click the DRG that you just created.
   b. Under **Resources**, click **Virtual Cloud Networks**.
   c. Click **Attach to Virtual Cloud Network**.

d. Select the VCN. Ignore the section for advanced options, which is only for an advanced routing scenario called *transit routing*, which is not relevant here.

e. Click **Attach**.

The attachment will be in the "Attaching" state for a short period before it's ready.

4. Update the private subnet's route table (which already has one rule for the NAT gateway):

   a. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.

   b. Click your VCN.

   c. Click **Route Tables**, and then click the Private Subnet Route Table you created earlier.

   d. Click **Add Route Rule**.

   e. Enter the following:

      - **Target Type:** Dynamic Routing Gateway. The VCN's attached DRG is automatically selected as the target, and you don't have to specify the target yourself.
      - **Destination CIDR Block:** 0.0.0.0/0 (which means that all non-intra-VCN traffic that is not already covered by other rules in the route table will go to the target specified in this rule).

   f. Click **Add Route Rule**.

   The table is updated to route any traffic destined for your on-premises network to the DRG. The original rule for 0.0.0.0/0 routes any remaining traffic leaving the subnet to the NAT gateway.

5. Create an IPSec Connection:

   a. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **IPSec Connections**.

   b. Click **Create IPSec Connection**.

c. Enter the following:

- **Create in Compartment:** Leave the default value (the compartment you're currently working in).
- **Name:** Enter a friendly name for the IPSec connection. It doesn't have to be unique. Avoid entering confidential information.
- **Customer-Premises Equipment Compartment:** Leave as is (the VCN's compartment).
- **Customer-Premises Equipment:** Select the CPE object you created earlier.
- **Dynamic Routing Gateway Compartment:** Leave as is (the VCN's compartment).
- **Dynamic Routing Gateway:** Select the DRG that you created earlier.
- **Static Route CIDR:** Enter at least one static route CIDR (see Prerequisites). If you need to add another, click **Add Static Route**. You can enter up to 10 static routes, and you can change the static routes later if you like.

d. Click **Show Advanced Options** and optionally provide the following items:

- **CPE IKE Identifier:** Oracle defaults to using the public IP address of the CPE. But if your CPE is behind a NAT device, you might need to enter a different value. You can either enter the new value here, or change the value later.
- **Tunnel 1** and **Tunnel 2**: Leave as is. Later if you want to use BGP dynamic routing instead of static routing for the VPN tunnels, see Changing from Static Routing to BGP Dynamic Routing.
- **Tags:** Leave as is. You can add tags later if you want. For more information, see Resource Tags.

e. Click **Create IPSec Connection**.

The IPSec connection is created and displayed on the page. It will be in the Provisioning state for a short period.

The displayed tunnel information includes the IP address of the VPN headend and the tunnel's IPSec status (possible values are Up, Down, and Down for Maintenance). At this point, the status is Down. To view the tunnel's shared secret, click the Actions icon (three dots), and then click **View Shared Secret**.

f. Copy the Oracle VPN IP address and shared secret for each of the tunnels to an email or other location so you can deliver it to the network engineer who will configure the on-premises router.

For more information, see CPE Configuration. You can view this tunnel information here in the Console at any time.

You have now created all the components required for the IPSec VPN. But your network administrator must configure the on-premises router before network traffic can flow between your on-premises network and VCN.

Task 4: Configure your on-premises router (CPE)

These instructions are for the network administrator.

1. Make sure you have the tunnel configuration information that Oracle provided during VPN setup. See Task 3: Add an IPSec VPN to your VCN.
2. Configure your on-premises router according to the information in CPE Configuration.

If there are already instances in one of the subnets, you can confirm the IPSec connection is up and running by connecting to the instances from your on-premises network. To connect to instances in the public subnet, you must connect to the instance's public IP address.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the following operations:

1. CreateVcn: Make sure to include a DNS label if you want the VCN to use the VCN Resolver (see DNS in Your Virtual Cloud Network).
2. CreateInternetGateway
3. CreateNatGateway
4. CreateRouteTable: Call it to create the Public Subnet Route Table. To enable communication by way of the internet gateway, add a route rule with destination = 0.0.0.0/0, and destination target = the internet gateway you created earlier.
5. CreateRouteTable: Call it again to create the Private Subnet Route Table. To enable communication by way of the NAT gateway, add a route rule with destination = 0.0.0.0/0, and destination target = the NAT gateway you created earlier.
6. First call GetSecurityList to get the default security list, and then call UpdateSecurityList:
    - Change the existing stateful ingress rules to use your on-premises network's CIDR as the source CIDR, instead of 0.0.0.0/0.
    - If you plan to launch Windows instances, add this stateful ingress rule: Source type = CIDR, source CIDR = your on-premises network on TCP, source port = all, destination port = 3389 (for RDP).
7. CreateSecurityList: Call it to create the Public Subnet Security List with these rules:
    - Stateful ingress: Source type = CIDR, source 0.0.0.0/0 on TCP, source port = all, destination port = 80 (HTTP)
    - Stateful ingress: Source type = CIDR, source 0.0.0.0/0 on TCP, source port = all, destination port = 443 (HTTPS)
    - Stateful egress: Destination type = CIDR, destination CIDR blocks of private subnets on TCP, source port = all, destination port = 1521 (for Oracle databases)
8. CreateSecurityList: Call it again to create the Private Subnet Security List with these rules:
    - Stateful ingress: Source type = CIDR, source CIDR blocks of public subnets on TCP, source port = all, destination port = 1521 (for Oracle databases)

- Stateful ingress: Source type = CIDR, source CIDR blocks of private subnets on TCP, source port = all, destination port = 1521 (for Oracle databases)
- Stateful egress: Destination type = CIDR, destination CIDR blocks of private subnets on TCP, source port = all, destination port = 1521 (for Oracle databases)

9. CreateSubnet: Call it to create regional public subnet. Include a DNS label for the subnet if you want the VCN Resolver to resolve hostnames for VNICs in the subnet. Use the Public Subnet Route Table you created earlier. Use both the default security list and the Public Subnet Security List that you created earlier. Use the default set of DHCP options.
10. CreateSubnet: Call it again to create regional private subnet. Include a DNS label for the subnet if you want the VCN Resolver to resolve hostnames for VNICs in the subnet. Use the Private Subnet Route Table you created earlier. Use both the default security list and the Private Subnet Security List that you created earlier. Use the default set of DHCP options.
11. CreateDrg: This creates a new dynamic routing gateway (DRG).
12. CreateDrgAttachment: This attaches the DRG to the VCN.
13. CreateCpe: Here you provide the IP address of the router at your end of the VPN (see Prerequisites).
14. CreateIPSecConnection: Here you provide the static routes for your on-premises network (see Prerequisites). In return, you receive the configuration information your network administrator needs in order to configure your router. If you need that information later, you can get it with GetIPSecConnectionDeviceConfig. For more information about the configuration, see CPE Configuration.
15. First call GetRouteTable to get the Private Subnet Route Table. Then call UpdateRouteTable to add a route rule with destination = the on-premises network CIDR (10.0.0.0/16 in this example), and destination target = the DRG you created earlier.
16. LaunchInstance: Launch at least one instance in each subnet. By default, the instances in the public subnets are assigned public IP addresses. For more information, see Launching an Instance.

You can now communicate from your on-premises network with the instances in the public subnet over the internet gateway.

Important

Although you can launch instances into the private subnets, you can't communicate with them from your on-premises network until your network administrator configures your on-premises router (see CPE Configuration). After that, your IPSec connection should be up and running. You can confirm its status by using GetIPSecConnectionDeviceStatus. You can also confirm the IPSec connection is up by connecting to the instances from your on-premises network.

Transit Routing: Access to Multiple VCNs in the Same Region

Transit routing refers to a network setup in which your on-premises network uses a connected virtual cloud network (VCN) to reach Oracle resources or services beyond that VCN. You connect the on-premises network to the VCN with FastConnect or VPN Connect, and then configure the VCN routing so that traffic *transits through the VCN* to its destination beyond the VCN.

There are two primary transit routing scenarios:

- **Access to multiple VCNs in the same region:** The scenario covered in this topic. This scenario enables communication between your on-premises network and multiple VCNs in the same region over a single FastConnect private virtual circuit or VPN Connect.
- **Private access to Oracle services:** This scenario gives your on-premises network *private access* to Oracle services, so that your on-premises hosts can use their private

IP addresses and the traffic does not go over the internet. See Transit Routing: Private Access to Oracle Services.

Highlights

- You can use a single FastConnect or IPSec VPN to connect your on-premises network with *multiple* VCNs in the same region, in a *hub-and-spoke* layout.
- The VCNs must be in the same region but can be in different tenancies. For accurate routing, the CIDR blocks of the various subnets of interest in the on-premises network and VCNs must not overlap.
- The VCN that acts as the *hub* uses a dynamic routing gateway (DRG) to communicate with the on-premises network. This *hub* VCN peers with each VCN that is acting as a spoke (referred to as *spoke* VCNs in this topic). The hub and spoke VCNs use local peering gateways (LPGs) to communicate.
- To enable the desired traffic from the on-premises network through the hub VCN to a peered spoke VCN, you implement route rules for the hub VCN's DRG attachment and LPG, and for the spoke VCN's subnets.
- If you like, you can set up transit routing *through a private IP in the hub VCN*. For example, you might want to filter or inspect the traffic between the on-premises network and a spoke VCN. In that case, you route the traffic to a private IP on an instance in the hub VCN for inspection, and the resulting traffic continues to its destination. This topic covers both situations: transit routing directly between gateways on the hub VCN, and transit routing through a private IP.
- By configuring route tables that reside in the hub VCN, you can control whether a particular subnet in a peered spoke VCN is advertised to the on-premises network, and whether a particular subnet in the on-premises network is advertised to a peered spoke VCN.

Tip

There's another scenario that lets you connect your on-premises network to multiple VCNs. Instead of using a single DRG and hub-and-spoke layout, you set up a separate DRG for each VCN and a separate private virtual circuit over a single FastConnect. However, the scenario can be used only with FastConnect through a third-party provider or through colocation with Oracle. The VCNs must be in the same region and same tenancy. For more information, see FastConnect with Multiple DRGs and VCNs.

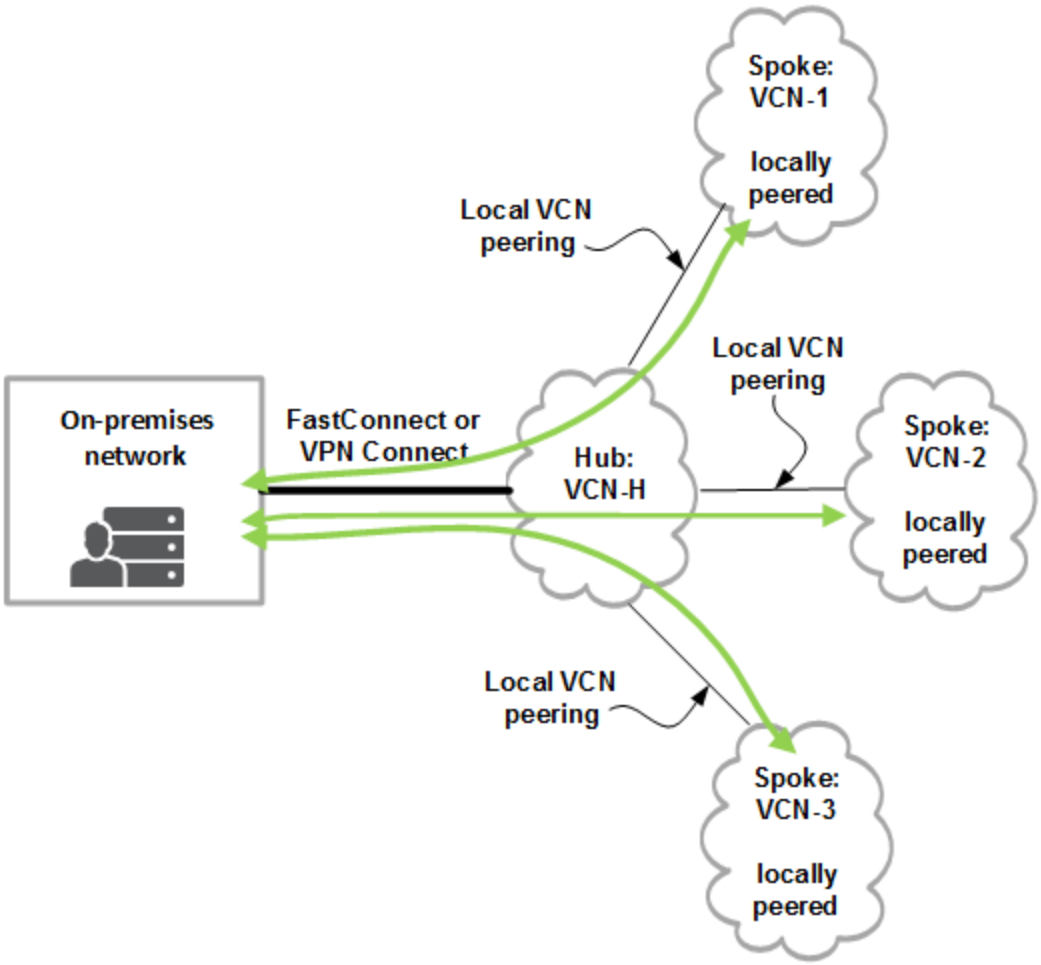
Overview of Transit Routing

A basic networking scenario involves connecting your on-premises network to a VCN with either Oracle Cloud Infrastructure FastConnect or an IPSec VPN. These two basic scenarios illustrate that layout: Scenario B: Private Subnet with a VPN and Scenario C: Public and Private Subnets with a VPN.

There's an advanced networking scenario that lets you use your single FastConnect or IPSec VPN to communication with *multiple VCNs* from your on-premises network. The VCNs must be in the same region but can be in different tenancies.

Here's a basic example of why you might use transit routing: you have a large organization with different departments, each with their own VCN. Your on-premises network needs access to the different VCNs, but you don't want the administration overhead of maintaining a secure connection from each VCN to the on-premises network. Instead you want to use a single FastConnect or IPSec VPN.

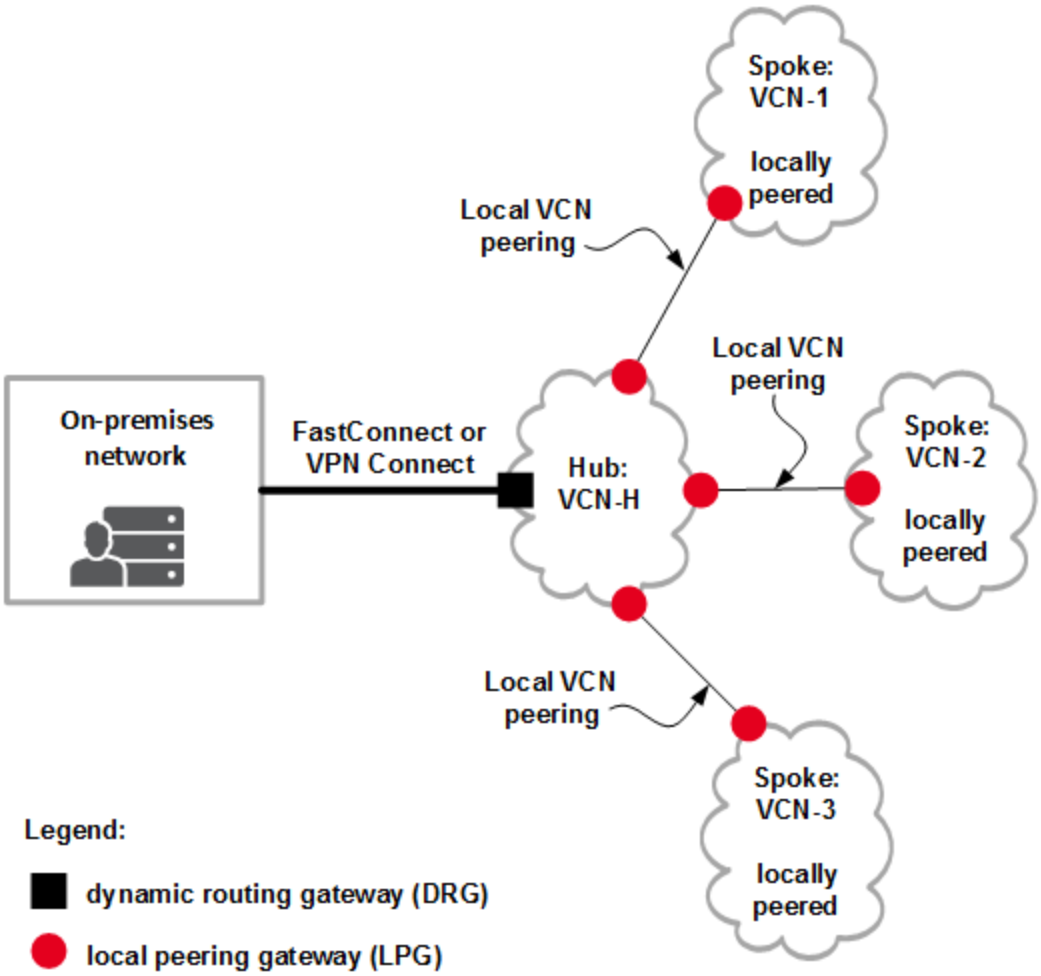
The scenario uses a *hub-and-spoke* layout, as illustrated in the following diagram. The term *hub VCN* here means only that a VCN is acting as the hub in this hub-and-spoke design.



One of the VCNs acts as the hub (VCN-H) and connects to your on-premises network by way of FastConnect or an IPSec VPN. The other VCNs are locally peered with the hub VCN. The traffic between the on-premises network and the peered VCNs transits through the hub VCN. The VCNs must be in the same region but can be in different tenancies.

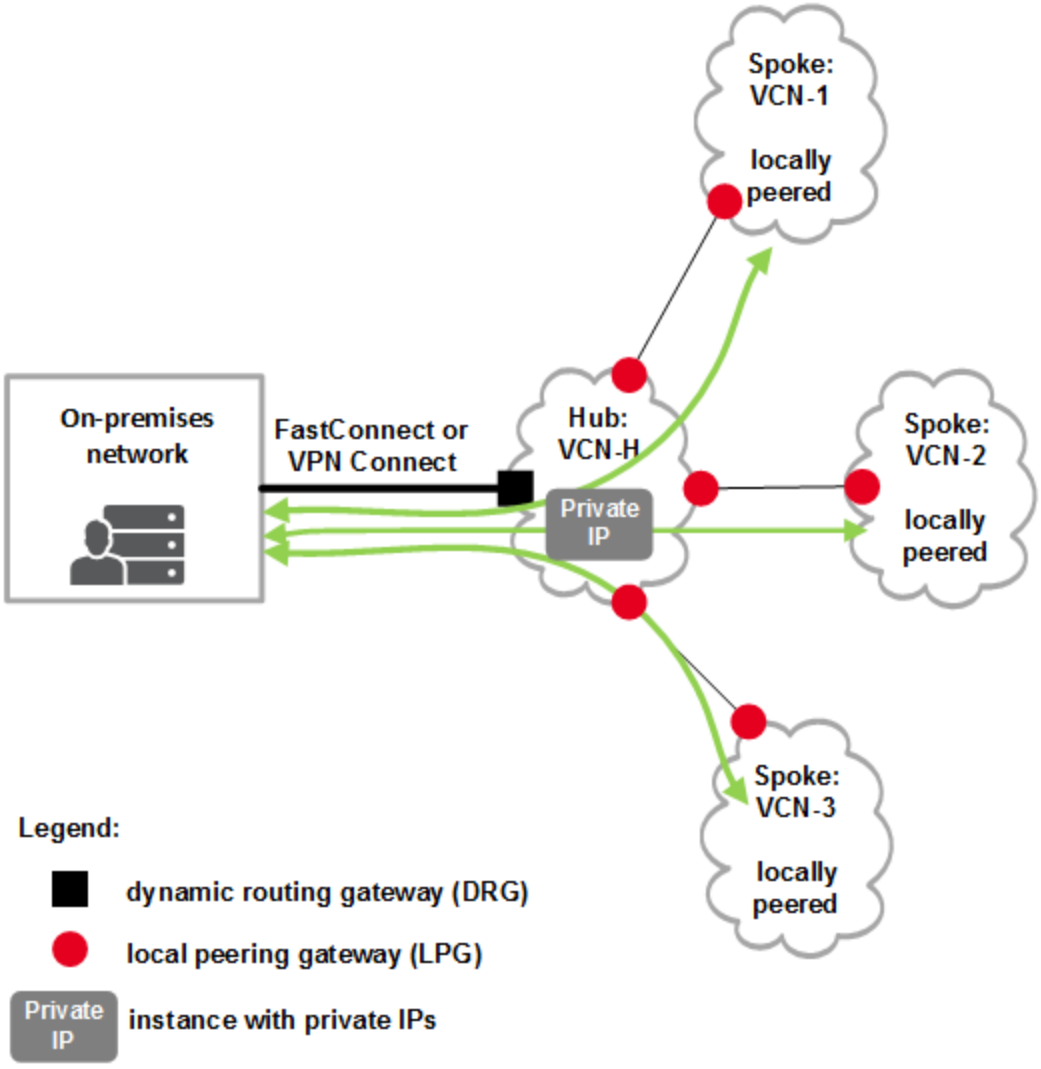
Gateways Involved in Transit Routing

The next diagram shows the gateways on the VCNs. The hub VCN has a dynamic routing gateway (DRG), which is the communication path with the on-premises network. For each locally peered spoke VCN, there's a pair of local peering gateways (LPGs) that anchor the peering connection. One LPG is on the hub VCN, and the other is on the spoke VCN.



Transit Routing Through a Private IP in the Hub VCN

If you want, you can route all the traffic through a private IP on an instance in the hub VCN. For example, you could set up a firewall or intrusion detection system on the instance in the hub VCN to filter or inspect the traffic between the on-premises network and spoke VCNs. Then you would configure the hub VCN's routing so that the transit traffic is routed to a private IP on that instance. You must disable the source/destination check for the private IP's VNIC. The resulting traffic would then travel on to its destination in either the spoke VCN or on-premises network. The following diagram illustrates the idea. Regardless of whether you choose to route through a private IP or not, the same gateways are required. However, you configure the hub VCN's routing a little differently.



Summary of New Concepts for Experienced Networking Service Users

If you're already familiar with the Networking service and local VCN peering, these are the most important new concepts to understand:

- For each spoke VCN subnet that needs to communicate with the on-premises network, you must update the subnet's route table with a rule that sets the target (the next hop) as the spoke VCN's LPG for all traffic destined for the on-premises network.
- You must add a route table to the hub VCN, associate it with *the DRG attachment*, and add a route rule with a target that depends on your situation:
    - **Transit routing directly through gateways:** Set the target (the next hop) to the **hub VCN's LPG (for that spoke)** for all traffic destined for that spoke VCN (or a specific subnet in that VCN).
    - **Transit routing through a private IP:** Set the target (the next hop) to a private IP on the instance, for all traffic destined for that spoke VCN (or a specific subnet in that VCN). Make sure to disable the source/destination check for the private IP's VNIC.
- You must add another route table to the hub VCN, associate it with *the hub VCN's LPG* (for that spoke), and add a route rule with a target that depends on your situation:
    - **Transit routing directly through gateways:** Set the target (the next hop) as the **DRG** for all traffic destined for the on-premises network (or a specific subnet in that network).
    - **Transit routing through a private IP:** Set the target (the next hop) to *another***private IP** on that instance, for all traffic destined for the on-premises network (or a specific subnet in that network). Again, make sure to disable the source/destination check for the private IP's VNIC. In the example presented here, the private IP is on a *secondary VNIC* on the instance, in a different subnet. In the subsequent diagrams, the subnets are referred to as the *frontend* subnet and *backend* subnet.

For transit routing directly through gateways, see these specific tasks for more information:

- Task 5: Add a route rule to the spoke VCN's subnet
- Task 6: Set up ingress routing for the DRG and LPG on the hub VCN

For transit routing through a private IP: see these specific tasks for more information:

- Task 5: Add a route rule to the spoke VCN's subnet
- Task 6: Set up the private IPs on an instance in the hub VCN
- Task 7: Set up ingress routing for the DRG and LPG on the hub VCN

Example: Components and Routing for a Hub and Single Spoke

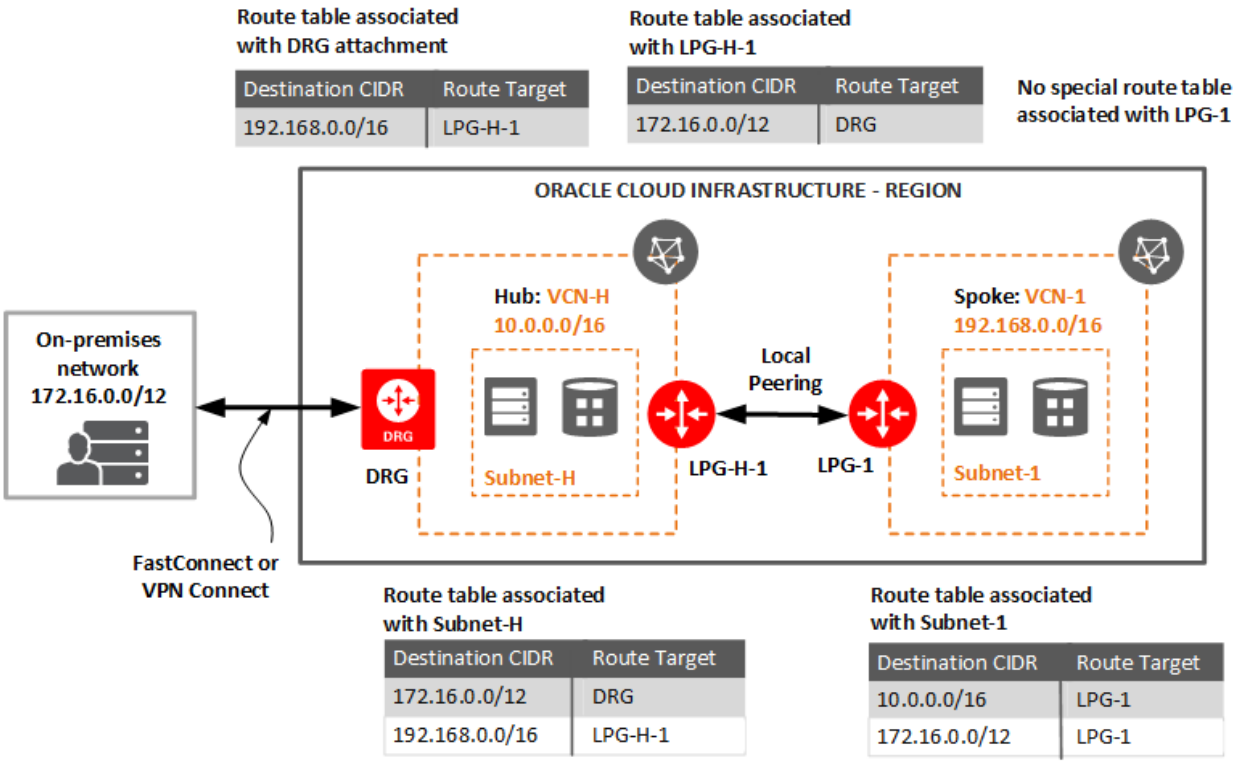
The examples in this section show a VCN acting as a hub and only a single spoke VCN for simplicity.

Note

In a hub-and-spoke model, the hub VCN can have multiple spokes and therefore multiple LPGs (one per spoke). This topic uses the phrase *the hub VCN's LPG*, which could therefore be ambiguous. When the phrase is used here, it means the hub LPG for the *particular spoke of interest.* In the following diagrams, it's LPG-H-1. Additional spokes would involve creation of an LPG-H-2, LPG-H-3, and so on.

For transit routing directly through gateways

The following diagram shows the required Networking service route tables and route rules for transit routing directly through gateways. Although the hub VCN does not require a subnet to make transit routing work, the example presented here includes a subnet called Subnet-H.



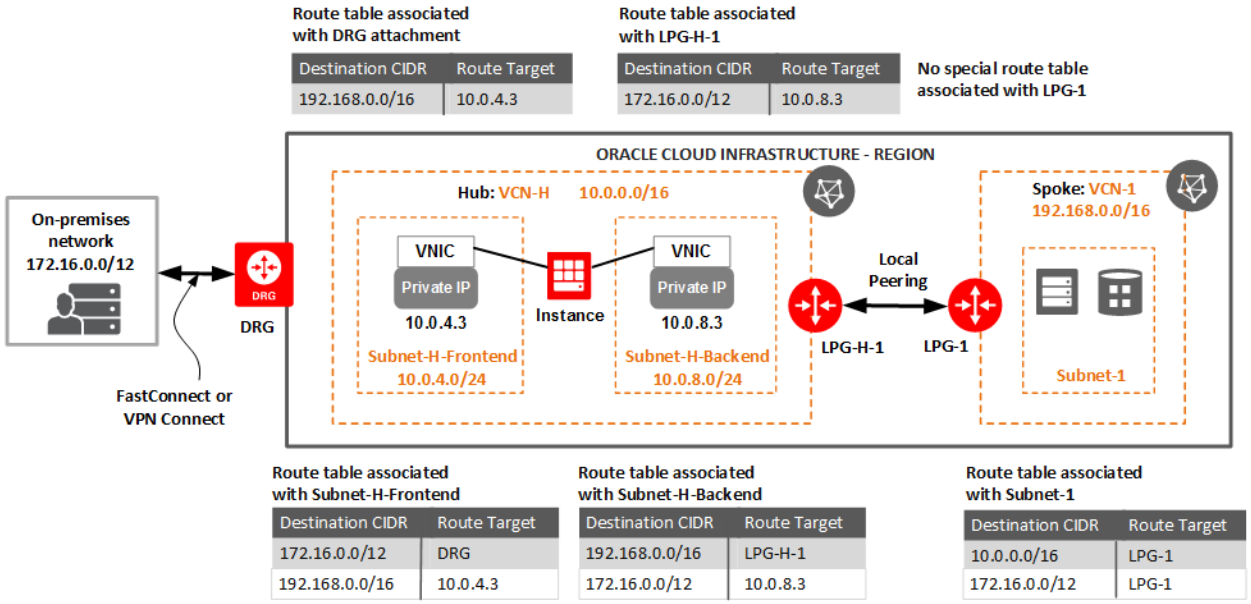
The diagram shows four route tables, each associated with a different resource:

- **DRG attachment:**
  - The route table belongs to the hub VCN and is associated with the DRG *attachment*. Why the attachment and not the DRG itself? Because the DRG is a standalone resource that you can attach to any VCN in the same region and tenancy as the DRG. The attachment itself identifies which VCN.
  - The route table routes the inbound traffic that is from the on-premises network and destined for the spoke VCN (VCN-1). You configure the rule to send that traffic to LPG-H-1.
- **LPG-H-1:**

    - This route table belongs to the hub VCN and is associated with LPG-H-1.
    - The route table routes inbound traffic that is from VCN-1 and destined for the on-premises network. You configure the rule to send that traffic to the DRG.
- **Subnet-H:**
    - This route table belongs to the hub VCN and is associated with Subnet-H.
    - This route table has a rule to route traffic that is destined for the on-premises network to the DRG. It has another rule to route traffic that is destined for the spoke VCN to LPG-H-1.
- **Subnet-1:**
    - This route table belongs to the spoke VCN and is associated with Subnet-1.
    - This route table has rules to route traffic that is destined for the hub VCN or the on-premises network to LPG-1.

For transit routing through a private IP

The following diagram shows the required Networking service route tables and route rules for transit routing through a private IP on an instance in the hub VCN. You can choose to implement this scenario with either a single VNIC or multiple VNICs. The diagram and example here shows two VNICs: one in a subnet called Subnet-H-Frontend, and another in a subnet called Subnet-H-Backend. The frontend VNIC has private IP 10.0.4.3, and the backend VNIC has private IP 10.0.8.3.



The diagram shows five route tables, each associated with a different resource:

- **DRG attachment:**
  - The route table belongs to the hub VCN and is associated with the DRG *attachment*. Why the attachment and not the DRG itself? Because the DRG is a standalone resource that you can attach to any VCN in the same region and tenancy as the DRG. The attachment itself identifies which VCN.
  - The route table routes the inbound traffic that is from the on-premises network and destined for the spoke VCN (VCN-1). You configure the rule to send the traffic to the private IP in the frontend subnet.
- **LPG-H-1:**
  - This route table belongs to the hub VCN and is associated with LPG-H-1.
  - The route table routes inbound traffic that is from VCN-1 and destined for the on-premises network. You configure the rule to send that traffic to the private IP in the backend subnet.

- **Subnet-H-Frontend:**
  - This route table belongs to the hub VCN and is associated with Subnet-H-Frontend.
  - This route table has a rule to route traffic that is destined for the on-premises network to the DRG.
  - Although Oracle does not recommend putting workloads in the hub VCN's subnets, the diagram also shows a route rule to route traffic that is destined for the spoke VCN to the private IP in the frontend subnet (10.0.4.3) for filtering by the instance. The second rule is shown here to give a more complete picture of routing for this example.
- **Subnet-H-Backend:**
  - This route table belongs to the hub VCN and is associated with Subnet-H-Backend.
  - This route table has a rule to route traffic that is destined for the spoke VCN (VCN-1) to LPG-H-1.
  - Although Oracle does not recommend putting workloads in the hub VCN's subnets, the diagram also shows a route rule to route traffic that is destined for the on-premises network to the private IP in the backend subnet (10.0.8.3) for filtering by the instance. The second rule is shown here to give a more complete picture of routing for this example.
- **Subnet-1:**
  - This route table belongs to the spoke VCN and is associated with Subnet-1.
  - This route table has rules to route traffic that is destined for the hub VCN or the on-premises network to LPG-1.

Important Transit Routing Restrictions to Understand

This section includes some additional important details about routing:

- **Route table for the DRG attachment:**
  - A route table that is associated with a DRG attachment can have only rules that target an LPG or a private IP.
  - A DRG attachment can exist without a route table associated with it. However, after you associate a route table with a DRG attachment, there must always be a route table associated with it. But, you can associate a *different* route table. You can also edit the table's rules, or delete some or all of the rules.
- **Route table for an LPG:**
  - A route table that is associated with an LPG can have only rules that target a DRG or a private IP.
  - An LPG can exist without a route table associated with it. However, after you associate a route table with an LPG, there must always be a route table associated with it. But, you can associate a different route table. You can also edit the table's rules, or delete some or all of the rules.
- **Traffic *through* the hub VCN:** The route tables discussed here are intended only for moving traffic *through* the hub VCN between locations in the on-premises network and locations in the spoke VCN. If you're using a private IP in the hub, you configure those route tables so that the private IP is placed in that traffic path going *through* the hub.
- **Inbound traffic to the hub VCN:** Even though the preceding statement is true (about traffic *through* the hub), inbound traffic to subnets *within the hub VCN* is always allowed. You do not need to set up explicit rules for this inbound traffic in the DRG attachment's route table or hub LPG's route table. When this kind of inbound traffic reaches the DRG or the hub LPG, the traffic is automatically routed to its destination in the hub VCN by the *VCN local routing*. Because of VCN local routing, for any route table belonging to a given VCN, you can't create a rule that lists that VCN's CIDR (or a sub-section) as the rule's destination.
- **Hub VCN traffic when transit routing through a private IP:** The immediately preceding statement about VCN local routing means that you should use the hub VCN only for *transit* between the on-premises network and spoke VCNs. **Do not set up workloads in the hub VCN itself.** More explicitly, if you set up transit routing through a private IP in the hub VCN, you can't also route the *hub VCN's* traffic through

that private IP. For example, in the preceding diagram, if you were to change the route rule in the LPG-H-1 route table so that the destination CIDR is 0.0.0.0/0 instead of 172.16.0.0/12, only traffic coming from VCN-1 and destined for addresses *outside* the hub VCN's CIDR block would be routed through the private IP. Because of VCN local routing, any traffic destined for addresses within the VCN is automatically routed directly to the destination IP address. The VCN local routing takes precedence over the LPG-H-1 route table (in general, over *any* of the VCN's route tables).

About CIDR Overlap

In this example, the various networks do not have overlapping CIDR blocks (172.16.0.0/12 versus 10.0.0.0/16 versus 192.168.0.0/16). The Networking service does not allow local VCN peering between two VCNs with overlapping CIDRs. That means each spoke must not overlap with the hub.

However, the Networking service does not validate whether the spoke VCNs themselves overlap with each other, or if any of the VCNs overlap with the on-premises network. You must ensure that CIDRs for all the subnets that need to communicate with each other don't overlap. Otherwise, traffic may be dropped.

A Networking service route table cannot contain two rules with the exact same destination CIDR. However, if two rules in the same route table have overlapping destination CIDRs, the most specific rule in the table is used to route the traffic (that is, the rule with the longest prefix match).

Route Advertisement to the On-Premises Network and Spoke VCNs

From a security standpoint, you can control route advertisement so that only specific subnets in the on-premises network are advertised to the spoke VCNs. Similarly, you can control which subnets in the spoke VCNs are advertised to the on-premises network.

The routes advertised to the on-premises network consist of:

- The rules listed in the route table associated with the DRG attachment (192.168.0.0/16 in the preceding diagram)
- The individual subnets in the hub VCN

The routes advertised to the spoke VCN consist of:

- The individual subnets in the hub VCN
- The rules listed in the route table associated with the hub VCN's LPG for the spoke (172.16.0.0/12 in the preceding diagram)

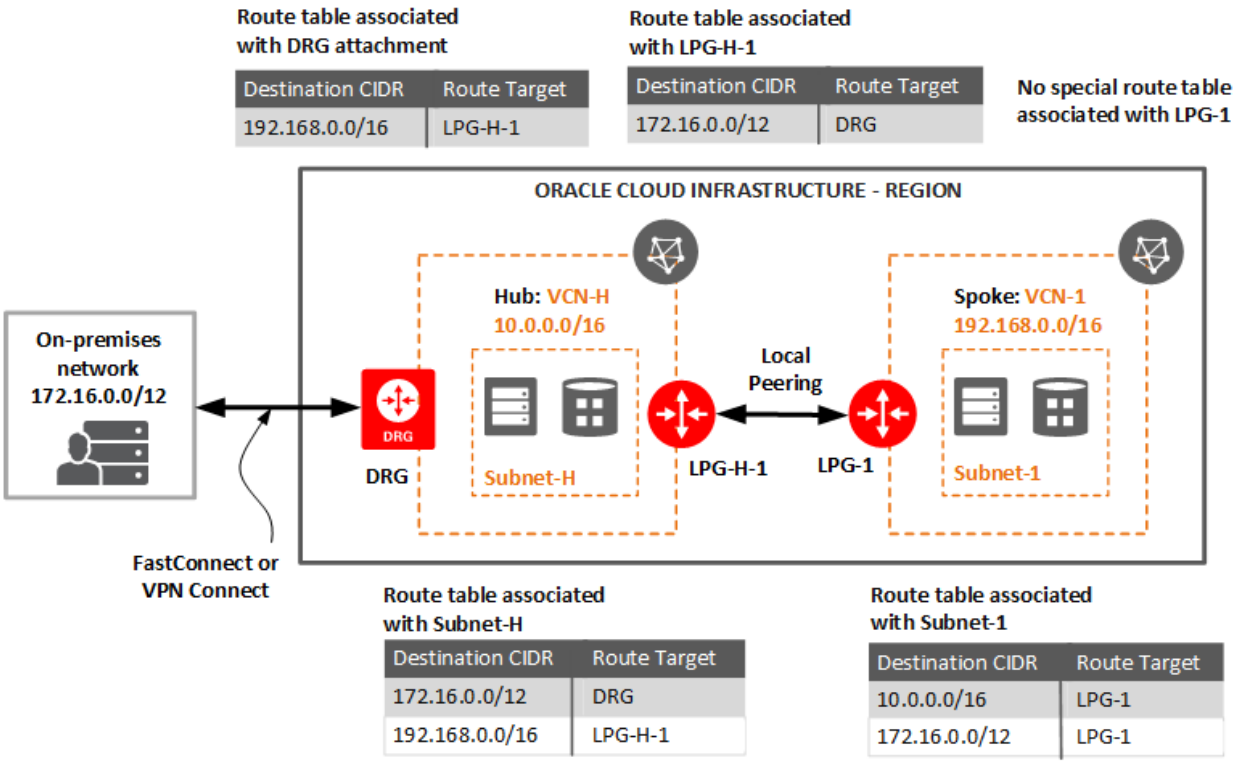
Therefore, the administrator *of the hub VCN* alone can control which routes are advertised to the on-premises network and spoke VCNs.

In the preceding example, the relevant routes use the full CIDR block of the on-premises network and spoke VCN as the destination (172.16.0.0/12 and 192.168.0.0/16, respectively), but they could instead use a subnet of those networks to restrict routing to specific subnets.

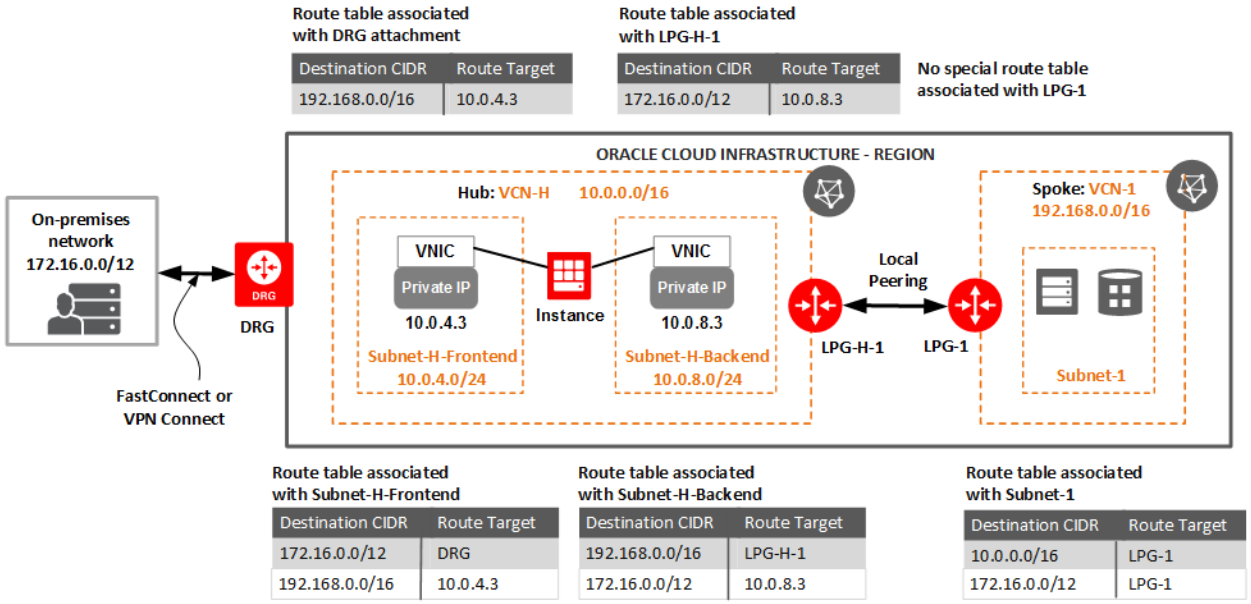
Details About Routing for Different Traffic Paths

To further illustrate how routing takes place in the preceding example, let's look more closely at different paths of traffic. Here are the same diagrams again.

First, if you are transit routing directly through gateways on the hub VCN:



Second, if you are transit routing through a private IP in the hub VCN:



Traffic from the on-premises network to the spoke VCN

1. Traffic leaves the on-premises network and reaches the DRG. The traffic's destination is in Subnet-1 (for example, 192.168.0.5).
2. The DRG attachment's associated route table has a rule for 192.168.0.0/16. It matches the destination and sends the traffic to the route target:
   - **Transit routing directly through gateways:** The rule's target is LPG-H-1.
   - **Transit routing through a private IP:** The rule's target is the private IP 10.0.4.3. The instance receives and processes the traffic and sends any resulting traffic out of the backend subnet's VNIC. The backend subnet's route table sends that traffic to LPG-H-1.

   Remember that you can use the rules in the DRG attachment's route table to control which subnets in the spoke VCN are advertised to the on-premises network. You could instead set up the rule to list only a subnet of the spoke VCN.

3. LPG-H-1 receives the traffic.
4. Egress traffic leaving a VCN through an LPG is automatically routed to the LPG's peered LPG, which is LPG-1 in this situation. That routing occurs automatically because of the peering connection between the two LPGs.
5. LPG-1 receives the traffic.
6. Traffic coming in to a VCN through the LPG is automatically routed to the destination within the VCN because of VCN local routing. No explicit route rules are required.

Traffic from the spoke VCN to the on-premises network

1. Traffic comes from an instance in Subnet-1 in the spoke VCN. The traffic's destination is in the on-premises network (for example, 172.16.0.3).
2. Subnet-1's associated route table has a rule for 172.16.0.0/12. It matches the destination and sends the traffic to the route target, LPG-1.
3. LPG-1 receives the traffic.
4. Egress traffic leaving a VCN through an LPG is automatically routed to the LPG's peered LPG, which is LPG-H-1 in this situation. That routing occurs automatically because of the peering connection between the two LPGs.
5. LPG-H-1 receives the traffic.
6. LPG-H-1's associated route table has a rule for 172.16.0.0/12. It matches the destination and sends the traffic to the route target:
   - **Transit routing directly through gateways:** The rule's target is the DRG.
   - **Transit routing through a private IP:** The rule's target is the private IP 10.0.8.3. The instance receives and processes the traffic and sends any resulting traffic out of the frontend subnet's VNIC. The frontend subnet's route table sends that to the DRG.

   Remember that you can use the rules in the LPG's route table to control which subnets in the on-premises network are advertised to the spoke VCN. You could instead set up the rule to list only a subnet of the on-premises network.

7. The DRG receives the traffic.
8. Egress traffic leaving the VCN through the DRG is routed based on the IPSec VPN and FastConnect configuration. No explicit rules in the DRG attachment's route table are required.

Notice that Subnet-1 in the spoke VCN and LPG-H-1 both have route rules with 172.16.0.0/12 as the destination CIDR. Those rules don't have to use the exact same CIDR block. However, make sure both rules cover the traffic you want to route from the spoke to the on-premises network. The rule in Subnet-1's route table controls which traffic is routed from Subnet-1 to LPG-H-1. The rule in LPG-H-1's route table controls which traffic is routed from the spoke VCN to the on-premises network. If LPG-H-1's route rule is more restrictive than Subnet-1's route rule, some traffic leaving the subnet could ultimately be dropped and not reach the DRG.

Traffic from the spoke VCN to a subnet in the hub VCN (routing directly between gateways only)

Depending on your situation, you might want to enable traffic between instances in the hub VCN and a spoke VCN, and not just traffic between the on-premises network and a spoke VCN. You can do this if you're routing directly between gateways. **You can't route the traffic from a spoke VCN *through the private IP* and on to other instances in the hub VCN.** The note at the end of this section explains why.

Here's how traffic would flow from the spoke VCN to a destination with an address in the hub VCN:

1. Traffic comes from an instance in Subnet-1 in the spoke VCN. The traffic's destination is in a subnet in the hub VCN (for example, 10.0.0.3).
2. Subnet-1's associated route table has a rule for 10.0.0.0/16. It matches the destination and sends the traffic to the route target, LPG-1.
3. LPG-1 receives the traffic.
4. Egress traffic leaving a VCN through an LPG is automatically routed to the LPG's peered LPG, which is LPG-H-1 in this situation. That routing occurs automatically because of the peering connection between the two LPGs.

5. LPG-H-1 receives the traffic.
6. Traffic coming in to a VCN through an LPG and destined for an address in the VCN is automatically routed to the destination by VCN local routing. No explicit route rules are required.

A similar series of routing steps occurs for traffic going from Subnet-H to Subnet-1, but in the reverse direction. Subnet-H's route table has a rule that matches the spoke VCN's CIDR (192.168.0.0/16) and sends the traffic to LPG-H-1, which forwards it on to LPG-1.

Note

If you set up transit routing through a private IP in the hub VCN, remember that the LPG-H-1 route table only controls routing of traffic that is destined for addresses *outside the hub VCN*. Traffic destined for addresses within the VCN is instead handled by the hub VCN local routing, which takes precedence and always routes the traffic directly to the packet's destination address. This means that you cannot route traffic that is destined for addresses inside the hub VCN *through the private IP* that is being used for the transit traffic through the hub. Even if the LPG-H-1 route rule uses a destination = 0.0.0.0/0 and target = 10.0.8.3, the hub VCN local routing takes precedence and routes the traffic directly to the destination in the hub VCN instead of the private IP.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have

permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

If you're a member of the Administrators group, you already have the required access to set up transit routing. Otherwise, you need access to the Networking service, and you need the ability to launch instances. See IAM Policies for Networking.

Setting Up VCN Transit Routing in the Console

This section shows how to use the Console to set up transit routing with a VCN to give your on-premises network access to multiple VCNs in the same region.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

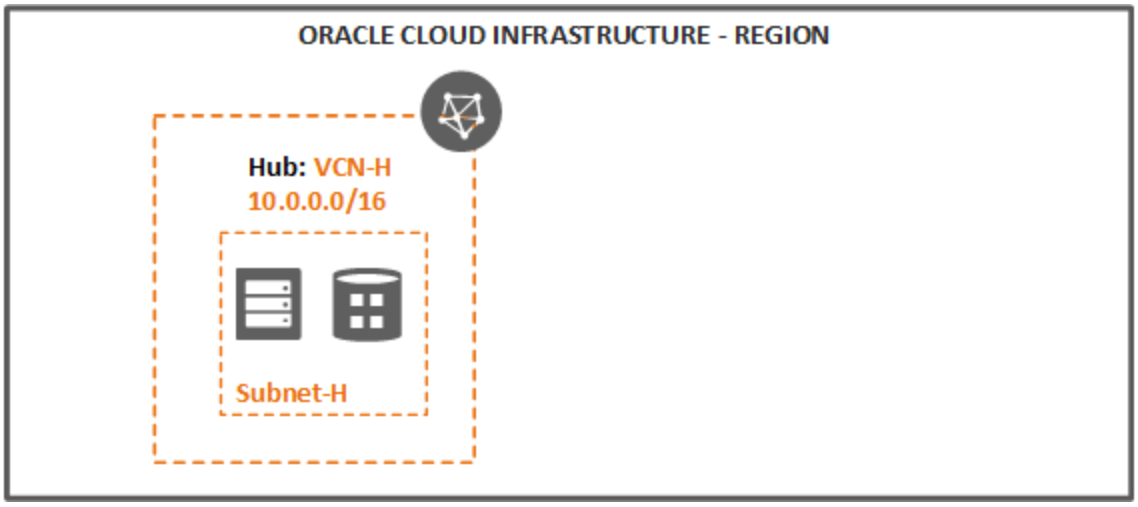
For routing directly between gateways

Tip

You might already have many of the necessary Networking components and connections in this advanced scenario already set up. So you might be able to skip some of the following tasks. **If you already have a network layout with a hub VCN connected to your on-premises network, and spoke VCNs locally peered with the hub VCN, then Task 5 and Task 6 are the most important.** They enable traffic

to be routed between your on-premises network and the spoke VCN.

Task 1: Set up the hub VCN

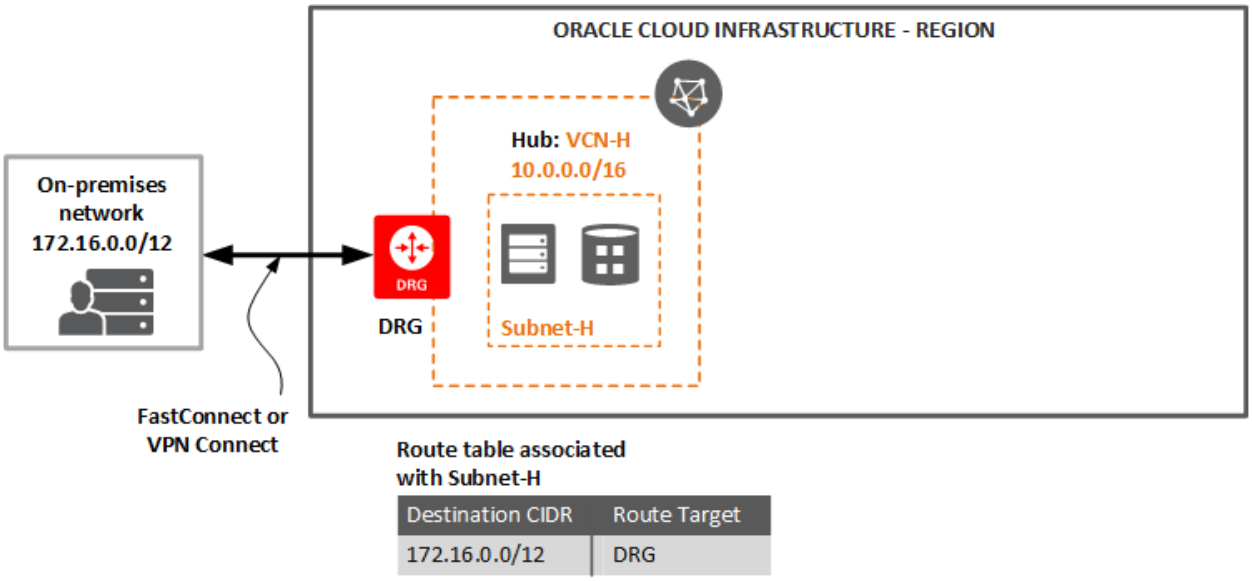


In this task, you set up the hub VCN. A subnet in the hub VCN is optional. However, this example includes one. The subnet can contain cloud resources that your on-premises network or the spoke VCN need to use.

For more information and instructions:

- VCNs and Subnets

Task 2: Connect the hub VCN with your on-premises network



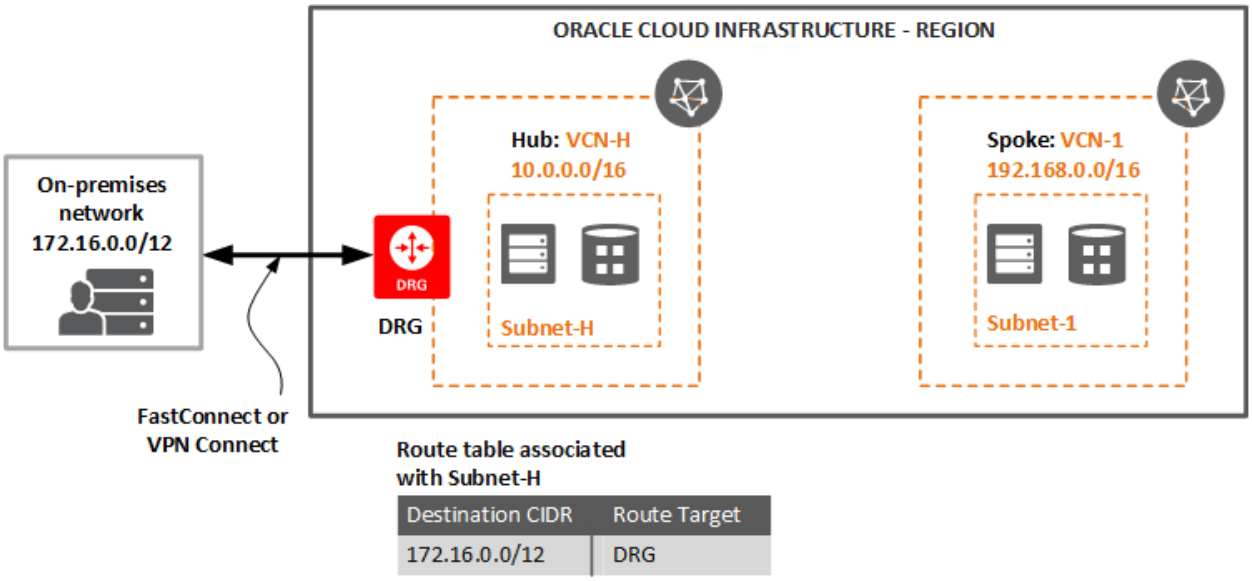
In this task, you set up either FastConnect or VPN Connect between your hub VCN and your on-premises network. As part of this process, you attach a DRG to the hub VCN and set up routing between the hub VCN and your on-premises network.

Notice that you do not yet create the route table that will be associated with the DRG attachment. That comes in a later step.

For more information and instructions:

- FastConnect
- VPN Connect
- Dynamic Routing Gateways (DRGs)

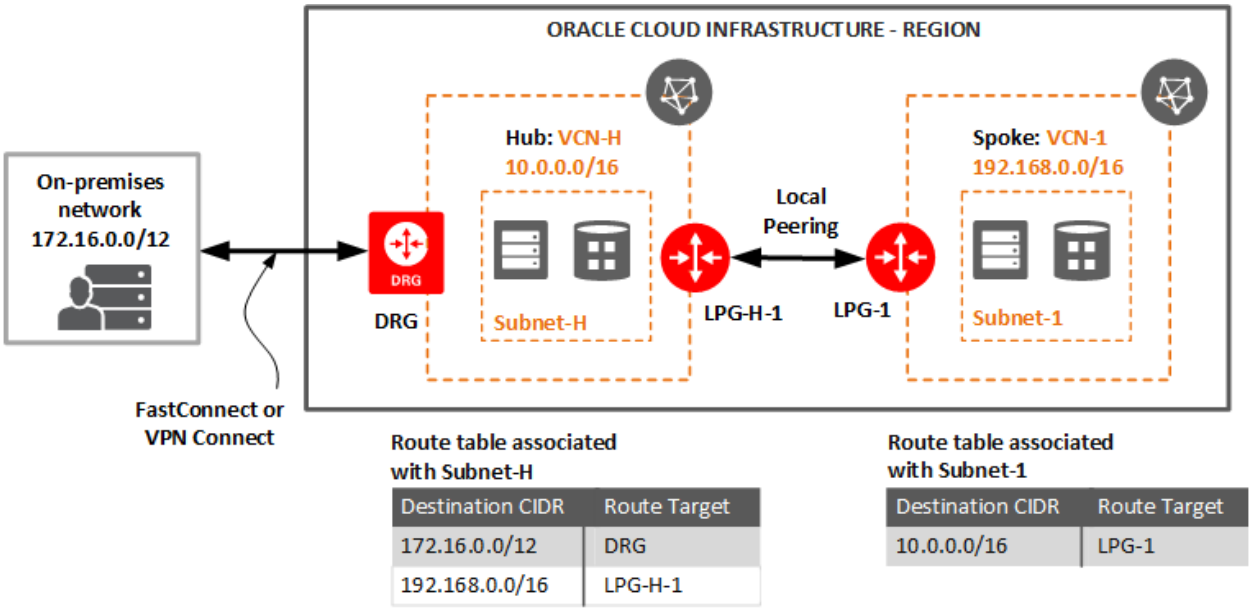
Task 3: Set up a spoke VCN with at least one subnet



In this task, you set up the spoke VCN with at least one subnet. For more information and instructions:

- VCNs and Subnets

Task 4: Set up a local peering between the hub VCN and the spoke VCN



In this task, you add an LPG to each VCN, establish a connection between the LPGs, and set up routing that enables resources in one VCN to communicate with resources in the other.

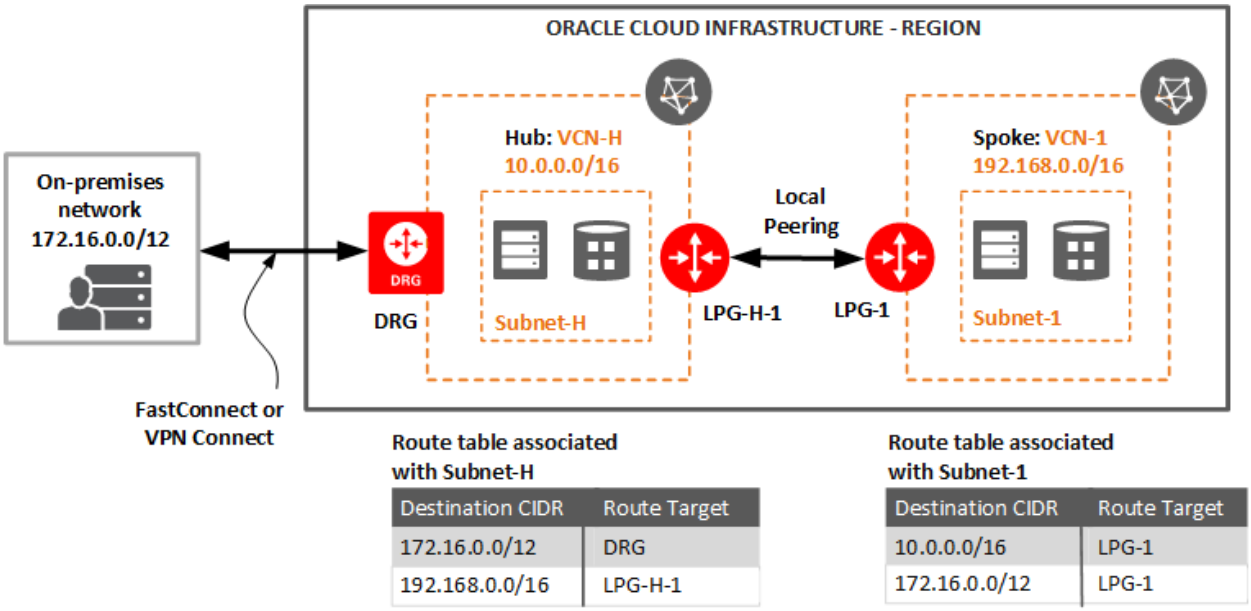
> **Important**
>
> When setting up local peering between two VCNs, make sure to establish the connection between the LPGs. It can be easy to overlook that part of the process.

Notice that you do not yet create the route table that will be associated with the LPG on the hub VCN (LPG-H-1). That comes in a later step.

For more information and instructions:

- Setting Up a Local Peering

Task 5: Add a route rule to the spoke VCN's subnet

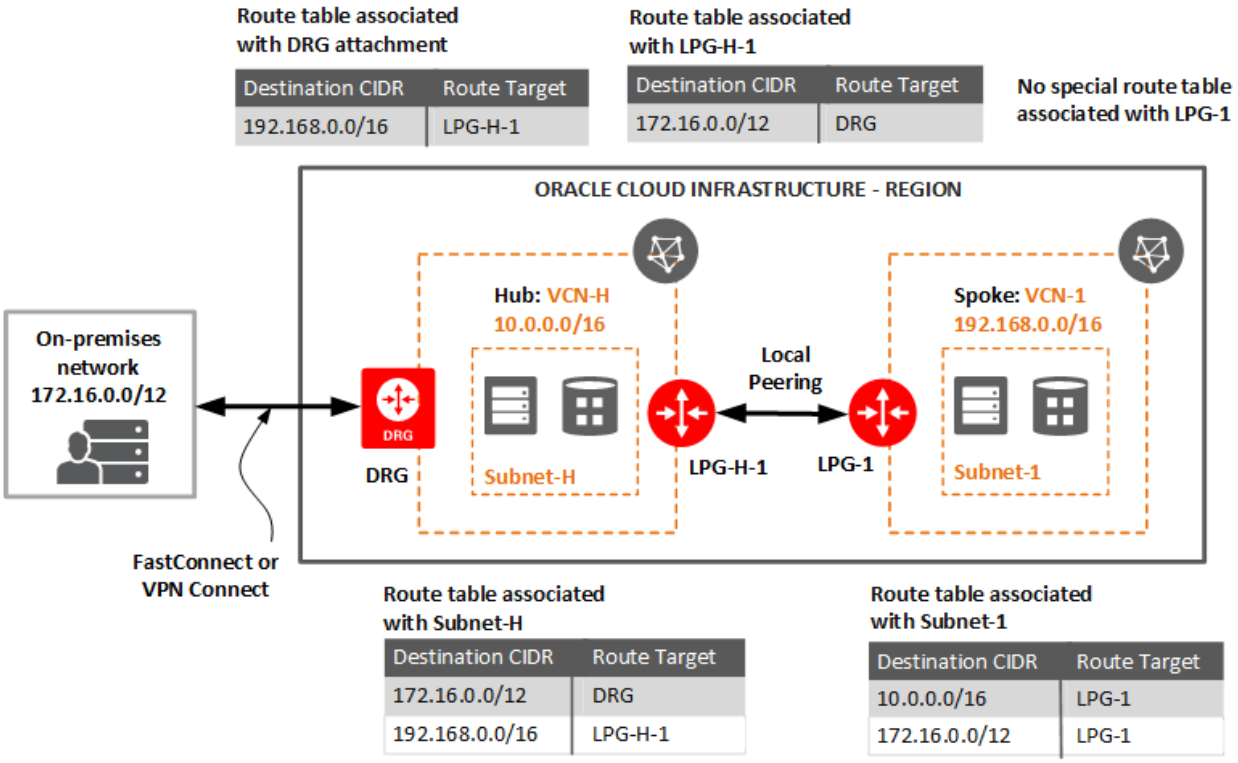


In this task, you add a rule to the route table associated with the spoke VCN's subnet. This rule routes traffic that is destined for the on-premises network to the spoke VCN's LPG (LPG-1 in the diagram).

Prerequisites: You already have an LPG for the spoke VCN, and a route table associated with the subnet (on the spoke VCN) that needs to communicate with the on-premises network.

1. For the spoke VCN, view the list of subnets.
2. For the subnet of interest, look at its details and click the link for its associated route table.
3. Edit the route table to include a rule that sends traffic to the on-premises network:
    a. Click **Add Route Rules**.
    b. Enter this information for the route rule:
        - **Target Type:** Local Peering Gateway.
        - **Destination CIDR Block**: The on-premises network's CIDR (172.16.0.0/12 in the earlier example).
        - **Compartment:** The compartment where the spoke VCN's LPG is located.
        - **Target Local Peering Gateway:** The spoke VCN's LPG.
    c. Click **Add Route Rules**.

Task 6: Set up ingress routing for the DRG and LPG on the hub VCN



In this task, you set up the route tables for the DRG attachment and hub VCN's LPG for the spoke of interest (LPG-H-1).

Prerequisites:

- You already have a DRG attached to the hub VCN.
- You already have a hub VCN LPG for the spoke of interest.

1. Create a route table for the DRG attachment:
    a. In the Console, view the hub VCN's details.
    b. Under **Resources**, click **Route Tables** to view the VCN's route tables.
    c. Click **Create Route Table**.
    d. Enter the following:
        - **Name:** A descriptive name for the route table. Example: DRG Route Table. Avoid entering confidential information.
        - **Create in Compartment:** Leave as is.
    e. Click **+ Additional Route Rule**, and enter this information for the route rule:
        - **Target Type:** Local Peering Gateway.
        - **Destination CIDR Block**: This spoke VCN's CIDR (192.168.0.0/16 in the earlier example). Remember that you can use the routes in this table to control which subnets in the spoke VCN are advertised to the on-premises network. You could instead set up the rule to list only a particular subnet of the spoke VCN that the on-premises network.
        - **Compartment:** The compartment where the hub VCN's LPG is located.
        - **Target:** The hub VCN's LPG.
    f. Click **Create Route Table**.
    The route table is created and displayed in the list.
2. Associate the route table (called *DRG Route Table* in this example) with the hub VCN's DRG attachment:
    a. While still viewing the hub VCN's details, click **Dynamic Routing Gateways** to view the attached DRG.
    b. Click the Actions icon (three dots), and then click **Associate Route Table**.
    c. Select the route table.

d. Click **Associate Route Table**.
   The route table is associated with the DRG attachment.

3. Create a route table for the hub VCN's LPG for this spoke:
   a. While still viewing the hub VCN's details, click **Route Tables**.
   b. Click **Create Route Table**.
   c. Enter the following:
      - **Create in Compartment:** Leave as is.
      - **Name:** A descriptive name for the route table. Example: `Hub LPG-# Route Table` (where # indicates which spoke). Avoid entering confidential information.
   d. Click **+ Additional Route Rule**, and enter this information for the route rule:
      - **Target Type:** Dynamic Routing Gateway. The VCN's attached DRG is automatically selected as the target, and you don't have to specify the target yourself.
      - **Destination CIDR Block**: The on-premises network's CIDR (172.16.0.0/12 in the earlier example). Remember that you can use the routes in this table to control which subnets in the on-premises network are advertised to this spoke VCN. You could instead set up the rule to list only a subnet of the on-premises network that needs to communicate with this spoke.
   e. Click **Create Route Table**.
      The route table is created and displayed in the list.
4. Associate the route table (called *Hub LPG-# Route Table* in this example) with the hub VCN's LPG for the spoke of interest:
   a. While still viewing the hub VCN's details, click **Local Peering Gateways** to view the hub VCN's LPG for this spoke.

b. For the LPG you're interested in, click the Actions icon (three dots), and then click **Associate With Route Table**.

c. Enter the following:

- **Route Table Compartment:** Select the compartment of the route table for the LPG.
- **Route Table:** Select the route table for the LPG.

d. Click **Associate**.
The route table is associated with the LPG.

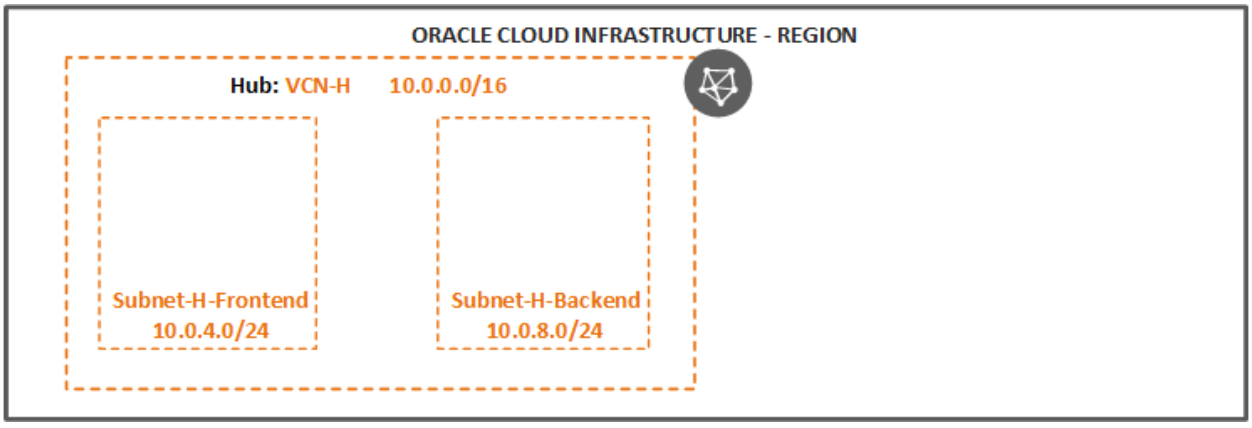
Later if you need more spoke VCNs

1. Repeat Tasks 3-5 for the new spoke VCN.
2. Repeat Task 6 with these changes:
   - For Step 1: Instead of creating a new route table for the DRG attachment, update the existing route table to include a new rule for the new spoke VCN. The destination CIDR is the spoke VCN's CIDR (or a subnet within). The target is the hub VCN's LPG for the new spoke.
   - For Step 2: Skip this step entirely because the DRG attachment is already associated with its route table.
   - For Step 3: Repeat as is. Name the new route table according to which spoke the route table is for (for example, `Hub LPG-2 Route Table` for the second spoke).
   - For Step 4: Repeat as is. Associate the new route table you created in Step 3 with the hub VCN's LPG for the new spoke.

For routing through a private IP

> **Tip**
>
> You might already have many of the necessary Networking components and connections in this advanced scenario already set up. So you might be able to skip some of the following tasks. **If you already have a network layout with a hub VCN connected to your on-premises network, and spoke VCNs locally peered with the hub VCN, then Tasks 5 through 7 are the most important.** They enable traffic to be routed between your on-premises network and the spoke VCN.

Task 1: Set up the hub VCN

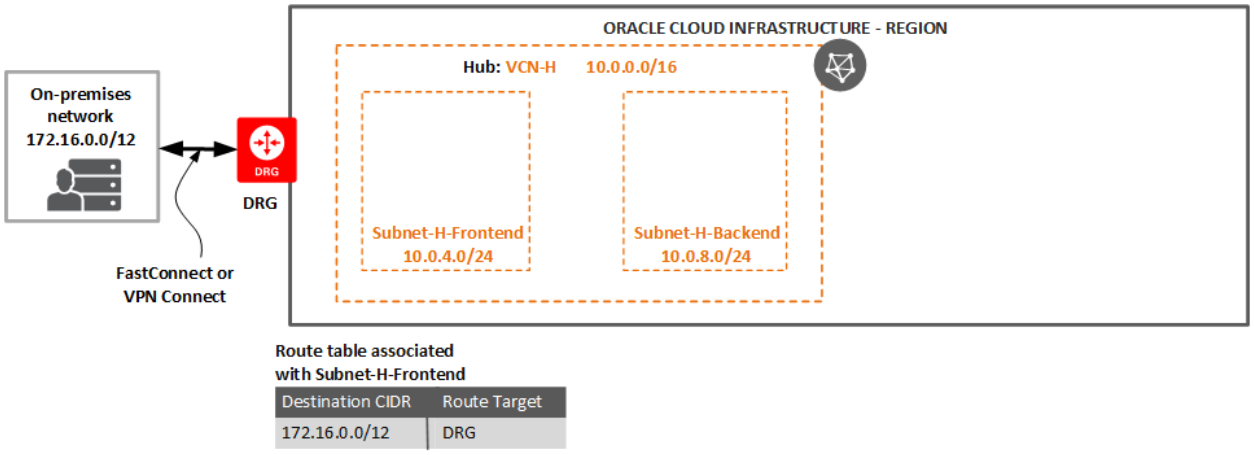


In this task, you set up the hub VCN. The hub VCN must have two subnets: one for the frontend VNIC on the instance, and one for the backend VNIC on the instance. Oracle recommends using regional *private* subnets, unless there will be resources in the frontend subnet that need internet access.

For more information and instructions:

- VCNs and Subnets

Task 2: Connect the hub VCN with your on-premises network



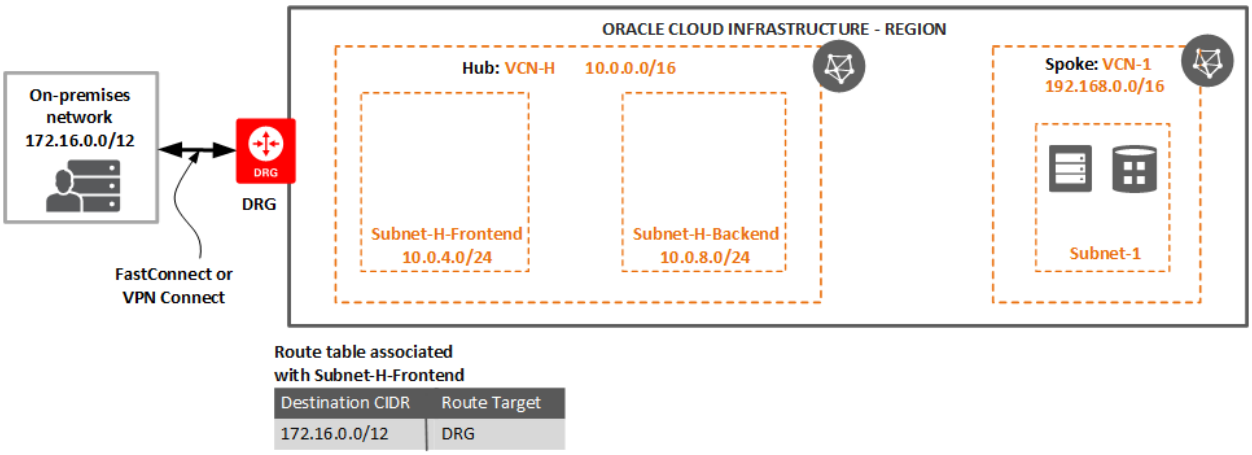
In this task, you set up either FastConnect or VPN Connect between your hub VCN and your on-premises network. As part of this process, you attach a DRG to the hub VCN and set up routing between the hub VCN and your on-premises network.

Notice that you do not yet create the route table that will be associated with the DRG attachment. That comes in a later step.

For more information and instructions:

- FastConnect
- VPN Connect
- Dynamic Routing Gateways (DRGs)

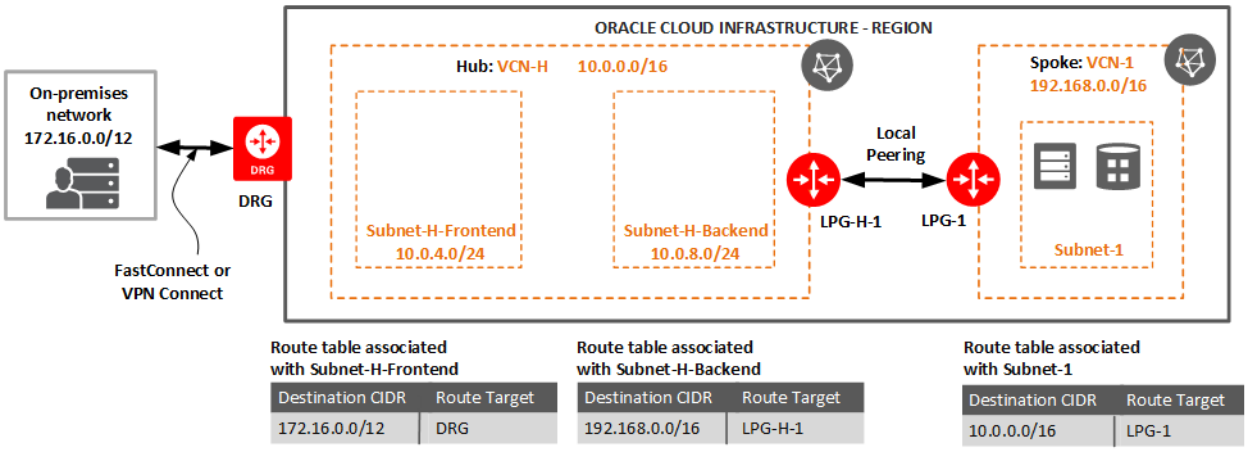
Task 3: Set up a spoke VCN with at least one subnet



In this task, you set up the spoke VCN with at least one subnet. For more information and instructions:

- VCNs and Subnets

Task 4: Set up a local peering between the hub VCN and the spoke VCN



In this task, you add an LPG to each VCN, establish a connection between the LPGs, and set up routing that enables resources in one VCN to communicate with resources in the other.

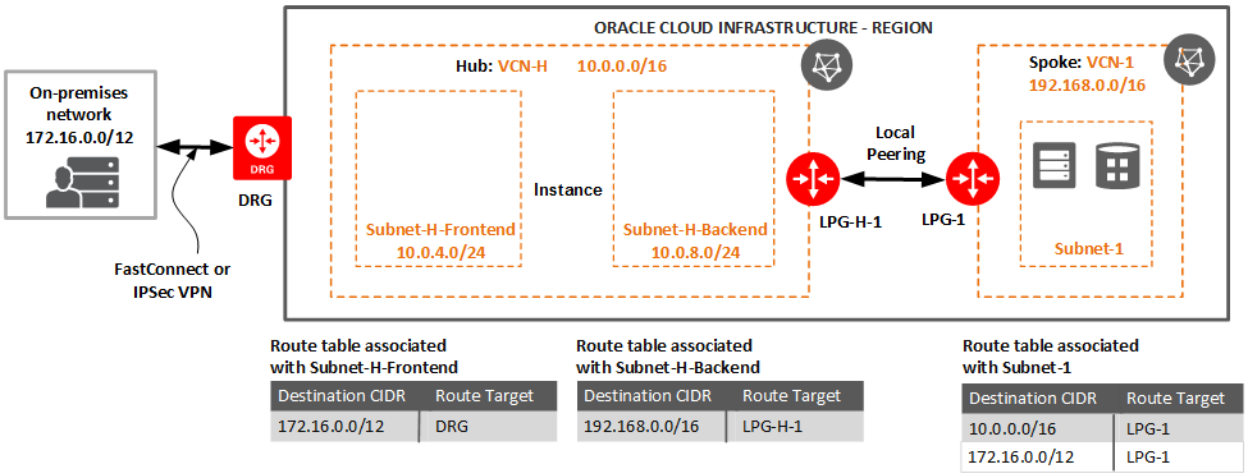
> **Important**
>
> When setting up local peering between two VCNs, make sure to establish the connection between the LPGs. It can be easy to overlook that part of the process.

Notice that you do not yet create the route table that will be associated with the LPG on the hub VCN (LPG-H-1). That comes in a later step.

For more information and instructions:

- Setting Up a Local Peering

Task 5: Add a route rule to the spoke VCN's subnet



In this task, you add a rule to the route table associated with the spoke VCN's subnet. This rule routes traffic that is destined for the on-premises network to the spoke VCN's LPG (LPG-1 in the diagram).

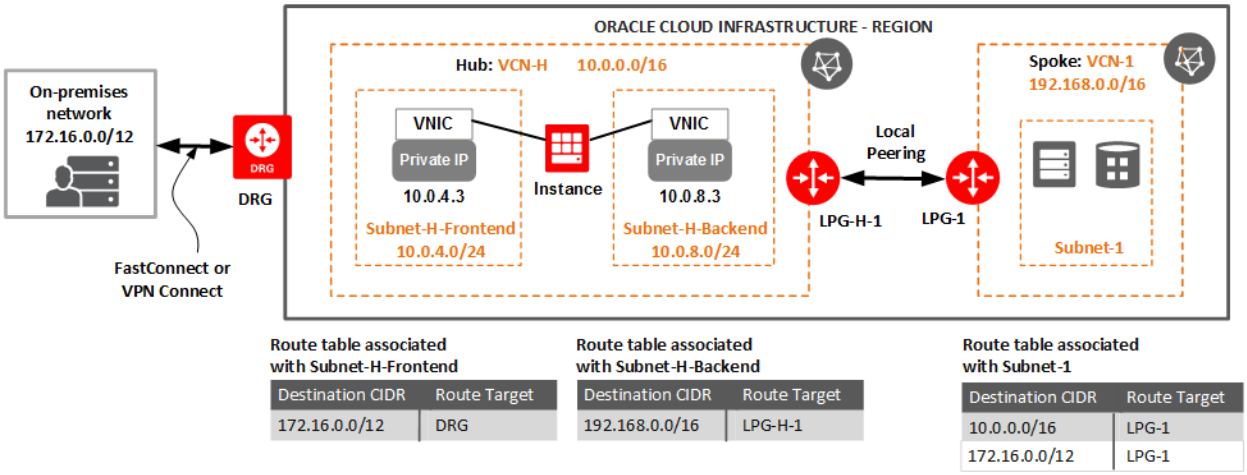
Prerequisites: You already have an LPG for the spoke VCN, and a route table associated with the subnet (on the spoke VCN) that needs to communicate with the on-premises network.

1. For the spoke VCN, view the list of subnets.
2. For the subnet of interest, look at its details and click the link for its associated route table.
3. Edit the route table to include a rule that sends traffic to the on-premises network:
    a. Click **Add Route Rules**.
    b. Enter this information for the route rule:

- **Target Type:** Local Peering Gateway.
- **Destination CIDR Block**: The on-premises network's CIDR (172.16.0.0/12 in the earlier example).
- **Compartment:** The compartment where the spoke VCN's LPG is located.
- **Target Local Peering Gateway:** The spoke VCN's LPG.

c. Click **Add Route Rules**.

Task 6: Set up the private IPs on an instance in the hub VCN



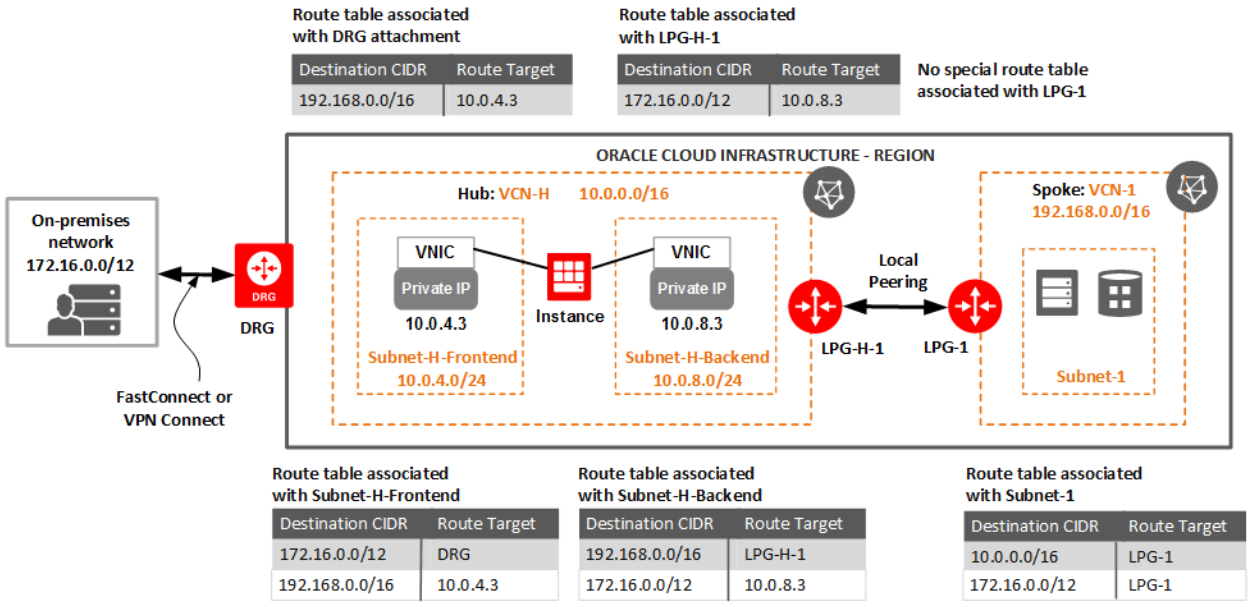
In this task, you set up the instance to have 2 private IPs.

Prerequisites:

- You already have a hub VCN with a subnet.
- Review this information: Using a Private IP as a Route Target.

1. If you haven't already, create the instance in the hub VCN. See Creating an Instance. The primary VNIC is created in the subnet you specify.
2. Create a secondary VNIC for the other subnet and configure the OS to use it. See To create and attach a secondary VNIC.
3. Disable the source/destination check on each of the VNICs. See Source/Destination Check.
4. For each VNIC, determine which private IP you want to use as the routing target. If you want to use a secondary private IP instead of the VNIC's primary private IP, assign that secondary private IP and configure the OS to use it. See To assign a new secondary private IP to a VNIC.
5. For each of the private IPs you created, record the private IP address (for example: 10.0.4.3).
6. Configure the instance as necessary for the job it will perform (for example, configure the firewall or intrusion detection system on the instance).

Task 7: Set up ingress routing for the DRG and LPG on the hub VCN



In this task, you set up the route tables for the DRG attachment and hub VCN's LPG for the spoke of interest (LPG-H-1).

Prerequisites:

- You already have a DRG attached to the hub VCN.
- You already have a hub VCN LPG for the spoke of interest.
- You already have the two private IPs to use as the routing targets (see the preceding task).

1. Create a route table for the DRG attachment:
    a. In the Console, view the hub VCN's details.
    b. Under **Resources**, click **Route Tables** to view the VCN's route tables.
    c. Click **Create Route Table**.
    d. Enter the following:
        - **Name:** A descriptive name for the route table. Example: DRG Route Table. Avoid entering confidential information.
        - **Create in Compartment:** Leave as is.
    e. Click **+ Additional Route Rule**, and enter this information for the route rule:
        - **Target Type:** Private IP.
        - **Destination CIDR Block**: This spoke VCN's CIDR (192.168.0.0/16 in the earlier example). Remember that you can use the routes in this table to control which subnets in the spoke VCN are advertised to the on-premises network. You could instead set up the rule to list only a particular subnet of the spoke VCN that the on-premises network.
        - **Compartment:** The compartment where the frontend subnet's private IP is located.
        - **Target:** The frontend subnet's private IP, which you recorded in the previous task (10.0.4.3 in the example).
    f. Click **Create Route Table**.
    The route table is created and displayed in the list.
2. Associate the route table (called *DRG Route Table* in this example) with the hub VCN's DRG attachment:
    a. While still viewing the hub VCN's details, click **Dynamic Routing Gateways** to view the attached DRG.
    b. Click the Actions icon (three dots), and then click **Associate With Route Table**.
    c. Enter the following:

- **Route Table Compartment:** Select the compartment of the route table for the DRG attachment.
- **Route Table:** Select the route table for the DRG attachment.

d. Click **Associate**.
The route table is associated with the DRG attachment.

3. Create a route table for the hub VCN's LPG for this spoke:
   a. While still viewing the hub VCN's details, click **Route Tables**.
   b. Click **Create Route Table**.
   c. Enter the following:
      - **Create in Compartment:** Leave as is.
      - **Name:** A descriptive name for the route table. Example: Hub LPG-# Route Table (where # indicates which spoke). Avoid entering confidential information.
   d. Click **+ Additional Route Rule**, and enter this information for the route rule:
      - **Target Type:** Private IP.
      - **Destination CIDR Block**: The on-premises network's CIDR (172.16.0.0/12 in the earlier example). Remember that you can use the routes in this table to control which subnets in the on-premises network are advertised to this spoke VCN. You could instead set up the rule to list only a subnet of the on-premises network that needs to communicate with this spoke.
      - **Compartment:** The compartment where the private IP is located.
      - **Target:** The backend subnet's private IP, which you recorded in the previous task (10.0.8.3 in the example).
   e. Click **Create Route Table**.
   The route table is created and displayed in the list.
4. Associate the route table (called *Hub LPG-# Route Table* in this example) with the hub

VCN's LPG for the spoke of interest:

a. While still viewing the hub VCN's details, click **Local Peering Gateways** to view the hub VCN's LPG for this spoke.
b. For the LPG you're interested in, click the Actions icon (three dots), and then click **Associate With Route Table**.
c. Enter the following:
   - **Route Table Compartment:** Select the compartment of the route table for the LPG.
   - **Route Table:** Select the route table for the LPG.
d. Click **Associate**.
   The route table is associated with the LPG.

Although Oracle does not recommend putting workloads in the hub VCN's subnets, to give you a more complete picture of routing in the example, the diagram shows two additional route rules in the hub VCN's subnet route tables. For the frontend subnet, there's a route rule to route traffic that is destined for the spoke VCN to the private IP in the frontend subnet (10.0.4.3) for filtering by the instance. For the backend subnet, there's a route rule to route traffic that is destined for the on-premises network to the private IP in the backend subnet (10.0.8.3) for filtering by the instance. The following procedure adds those two route rules.

1. For the spoke VCN, view the list of subnets.
2. For the frontend subnet, look at its details and click the link for its associated route table.
3. Edit the frontend subnet's route table to include a rule that sends traffic destined for the spoke VCN to the private IP in the frontend subnet:
   a. Click **Add Route Rules**.
   b. Enter this information for the route rule:

- **Target Type:** Private IP.
- **Destination CIDR Block**: This spoke VCN's CIDR (192.168.0.0/16 in the earlier example).
- **Compartment:** The compartment where the frontend subnet's private IP is located.
- **Target:** The frontend subnet's private IP, which you recorded in the previous task (10.0.4.3 in the example).

c. Click **Add Route Rules**.

4. For the backend subnet, look at its details and click the link for its associated route table.
5. Edit the backend subnet's route table to include a rule that sends traffic destined for the on-premises network to the private IP in the backend subnet:
   a. Click **Add Route Rules**.
   b. Enter this information for the route rule:
      - **Target Type:** Private IP.
      - **Destination CIDR Block**: The on-premises network's CIDR (172.16.0.0/12 in the earlier example).
      - **Compartment:** The compartment where the backend subnet's private IP is located.
      - **Target:** The backend subnet's private IP, which you recorded in the previous task (10.0.8.3 in the example).
   c. Click **Add Route Rules**.

Later if you need more spoke VCNs

1. Repeat Tasks 3-5 for the new spoke VCN.
2. Repeat task 7 with these changes:

- For Step 1: Instead of creating a new route table for the DRG attachment, update the existing route table to include a new rule for the new spoke VCN. The destination CIDR is the spoke VCN's CIDR (or a subnet within). The target is the frontend subnet private IP 10.0.4.3.
- For Step 2: Skip this step entirely because the DRG attachment is already associated with its route table.
- For Step 3: Repeat as is. Name the new route table according to which spoke the route table is for (for example, `Hub LPG-2 Route Table` for the second spoke).
- For Step 4: Repeat as is. Associate the new route table you created in Step 3 with the hub VCN's LPG for the new spoke.

Turning Off Transit Routing

To turn off transit routing, remove the rules from:

- The route table associated with the DRG attachment.
- The route table associated with each LPG on the hub VCN.

A route table can be associated with a resource but have no rules. Without at least one rule, a route table does nothing.

A DRG attachment or LPG can exist without a route table associated with it. However, after you associate a route table with a DRG attachment or LPG, there must always be a route table associated with it. But, you can associate a *different* route table. You can also edit the table's rules, or delete some or all of the rules.

Changes to the API

For information about changes to the Networking service API to support transit routing, see the transit routing release notes.

Transit Routing: Private Access to Oracle Services

Transit routing refers to a network setup in which your on-premises network uses a connected virtual cloud network (VCN) to reach Oracle resources or services beyond that VCN. You connect the on-premises network to the VCN with FastConnect or VPN Connect, and then configure the VCN routing so that traffic *transits through the VCN* to its destination beyond the VCN.

There are two primary transit routing scenarios:

- **Private access to Oracle services:** The scenario covered in this topic. This scenario gives your on-premises network *private access* to Oracle services, so that your on-premises hosts can use their private IP addresses and the traffic does not go over the public internet. Instead, the traffic travels over a FastConnect private virtual circuit or VPN Connect, transits through a virtual cloud network (VCN), and then through a service gateway to the Oracle service of interest.
- **Access to multiple VCNs in the same region:** This scenario enables communication between an on-premises network and multiple VCNs in the same region over a single FastConnect private virtual circuit or VPN Connect. See Transit Routing: Access to Multiple VCNs in the Same Region.

Highlights

- You can set up a VCN so that your on-premises network has *private access* to Oracle services in the Oracle Services Network by way of the VCN. The hosts in your on-premises network communicate with their private IP addresses.
- The VCN uses a dynamic routing gateway (DRG) to communicate with the on-premises network. Access to Oracle services is through a service gateway on the VCN. The traffic from the VCN to the Oracle service travels over the Oracle network fabric and never traverses the public internet.
- The service gateway is regional and enables access only to supported Oracle services *in the same region* as the VCN.

- The supported Oracle services are Oracle Cloud Infrastructure Object Storage and others in the Oracle Services Network. For a list, see Service Gateway: Supported Cloud Services in Oracle Services Network.
- The service gateway uses the concept of a *service CIDR label*, which is a string that represents all the regional public IP address ranges for the service or group of services of interest (for example, *OCI PHX Object Storage* is the string for Object Storage in US West (Phoenix)). You use that service CIDR label when you configure the service gateway and related route rules to control traffic to the service. You can optionally use it when configuring security rules. If the service's public IP addresses change in the future, you don't have to adjust those rules.
- To enable the desired traffic from the on-premises network through the VCN to Oracle services, you implement route rules for the VCN's DRG attachment and service gateway.
- If you want, you can set up transit routing *through a private IP in the VCN*. For example, you might want to filter or inspect the traffic between the on-premises network and the Oracle service. In that case, you route the traffic to a private IP on an instance in the VCN for inspection, and the resulting traffic continues to its destination. This topic covers both situations: transit routing directly between gateways on the VCN, and transit routing through a private IP.

Overview of the Oracle Services Network

The *Oracle Services Network* is a conceptual network in Oracle Cloud Infrastructure that is reserved for Oracle services. These services have public IP addresses that you typically reach over the public internet. However, you can access the Oracle Services Network *without the traffic going over the public internet*. There are different ways, depending on which of your hosts need the access:

- **Hosts in your on-premises network:**
  - Private access through a VCN with FastConnect private peering or VPN Connect: This is the scenario covered in this topic. The on-premises hosts use private IP addresses and reach the Oracle Services Network by way of the VCN and the

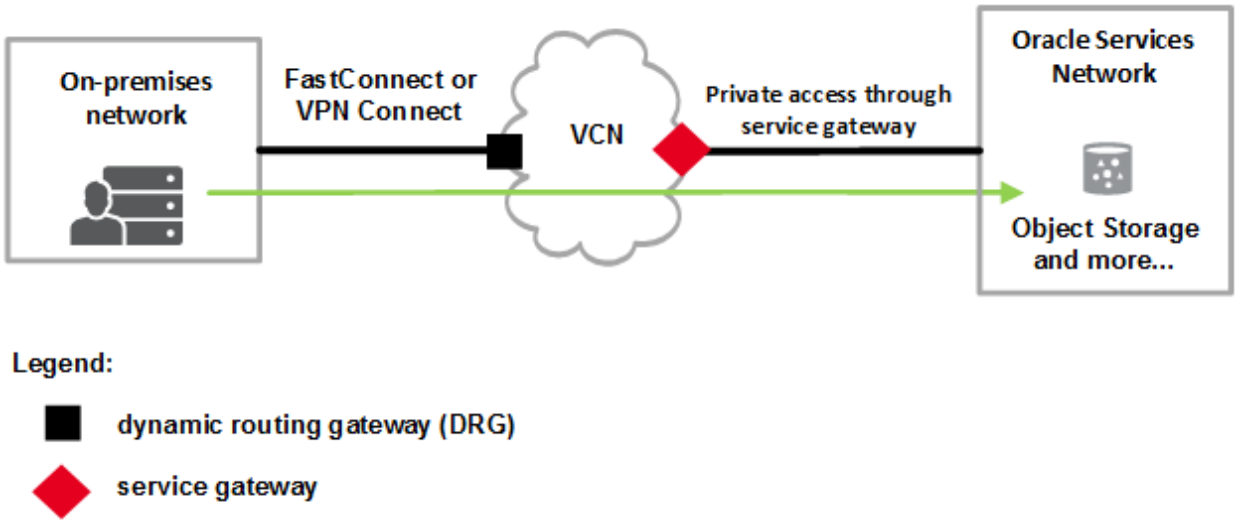
VCN's service gateway.

- Public access with FastConnect public peering: The on-premises hosts use public IP addresses.

- **Hosts in your VCN:**
  - Private access through a service gateway: The VCN's hosts use private IP addresses.

Overview of On-Premises Network Private Access to Oracle Services

The following diagram illustrates the basic layout for giving your on-premises network private access to Oracle services.



Your on-premises network connects to the VCN by way of a FastConnect private virtual circuit or VPN Connect. Each of these types of connections terminates on a dynamic routing gateway (DRG) that is attached to the VCN. The VCN also has a service gateway, which gives the VCN access to the Oracle Services Network. The traffic from your on-premises network transits through the VCN, through the service gateway, and to the Oracle service of interest. The responses return through the service gateway and VCN to your on-premises network.

When you set up a service gateway, you enable a *service CIDR label*, which is a string that represents all the regional public IP address ranges for the service or group of services that you want to access through the service gateway. For example, *All PHX Services in Oracle Services Network* is the service CIDR label for the Oracle services available in US West (Phoenix) through a service gateway. Oracle uses Border Gateway Protocol (BGP) on the DRG to advertise those regional public IP address ranges to the edge device (also called the customer-premises equipment or CPE) in your on-premises network. For a list of those ranges available through the service gateway, see Public IP Addresses for VCNs and the Oracle Services Network.

Multiple Connection Paths to Oracle Services

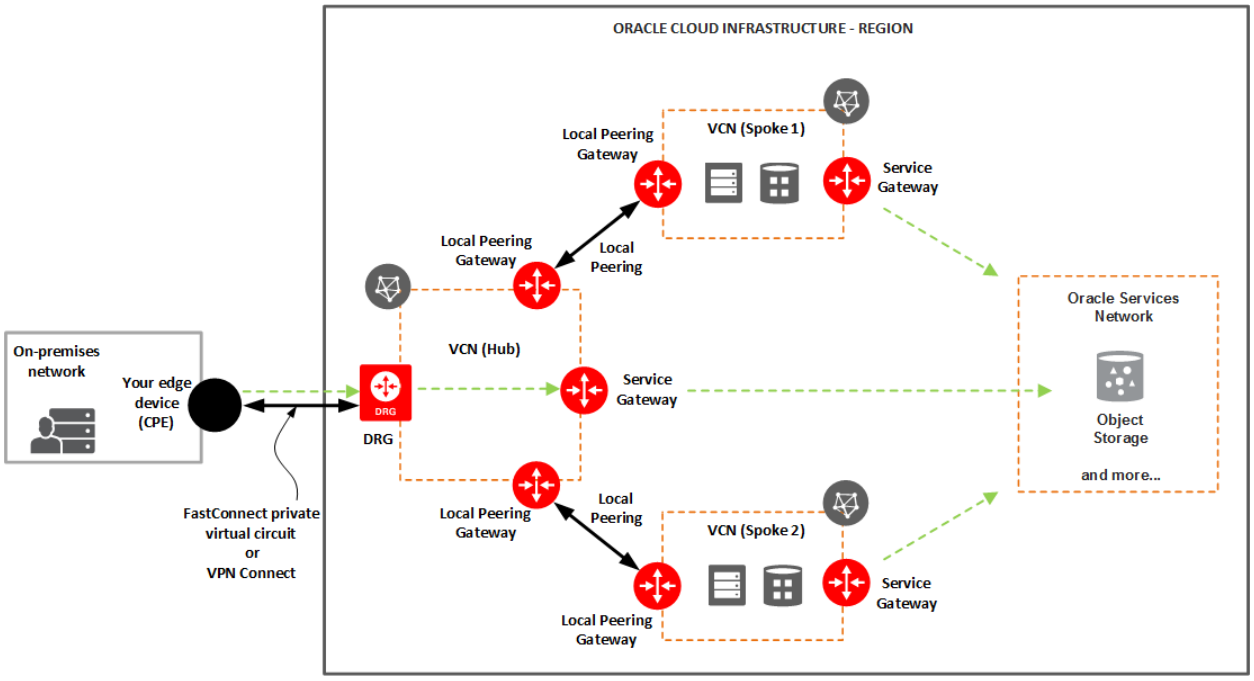
You can configure your on-premises network with multiple connection paths to Oracle Cloud Infrastructure and Oracle services for redundancy or other reasons. For example, you could use both FastConnect public peering and FastConnect private peering. If you have multiple paths, your edge device receives route advertisement of the Oracle services public IP address ranges over multiple paths. For important information about configuring your edge device correctly, see Routing Details for Connections to Your On-Premises Network.

Multiple VCNs with Private Access to Oracle Services

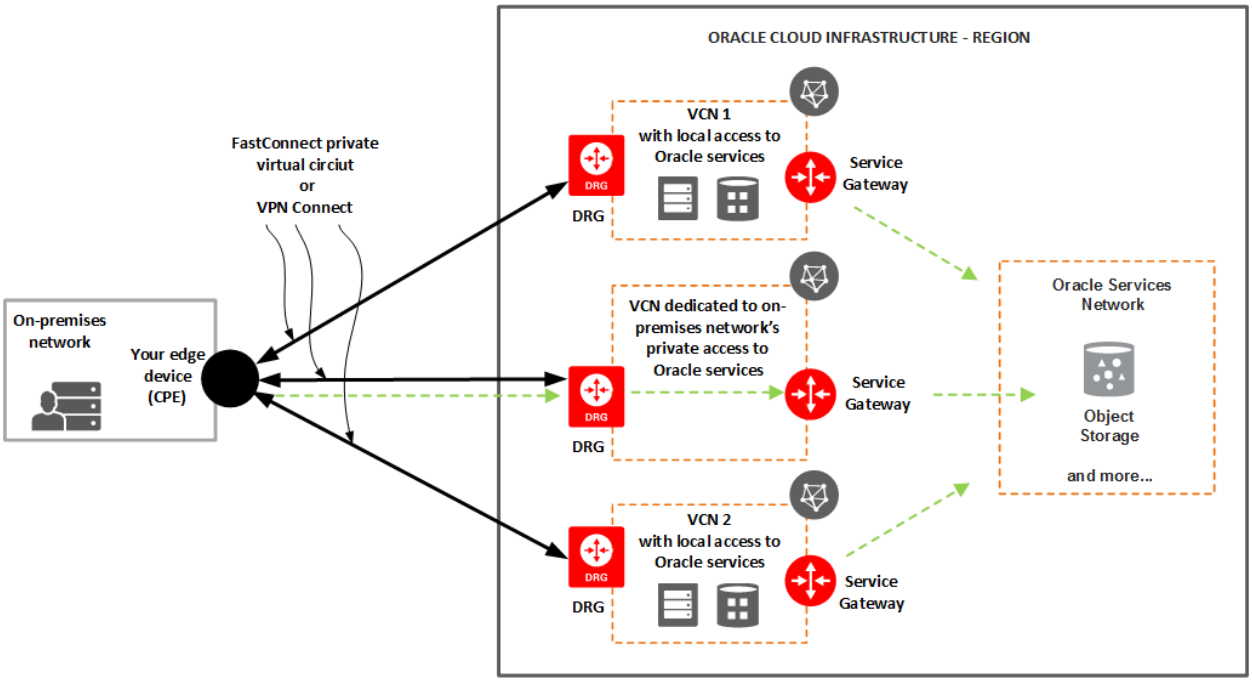
Your organization might choose to use multiple VCNs, each with a service gateway to give the VCN's resources access to Oracle services. For example, you might have a different VCN for each department in your organization.

If you *also* want to set up your on-premises network with private access to Oracle services through a VCN with a service gateway, this section describes two different network layouts you could use.

In the first layout, you set up a *single* DRG, with the VCNs in a hub-and-spoke layout as shown in the next diagram. The VCN that acts as the hub is dedicated to providing the on-premises network with private access to Oracle services. The other VCNs are locally peered with the hub VCN. You configure only the hub VCN according to instructions in Setting Up Private Access to Oracle Services. This hub-and-spoke layout is recommended and described further in Transit Routing: Access to Multiple VCNs in the Same Region.



In the second layout, there's a separate DRG for each VCN, with a separate FastConnect private virtual circuit or VPN Connect from your on-premises network to each DRG. You dedicate one DRG and VCN to providing your on-premises network with private access to Oracle services. In the next diagram, it's the VCN in the center. To configure that VCN, follow the instructions in Setting Up Private Access to Oracle Services.



Notice that in both of these layouts, the on-premises network can reach the Oracle services only through a single VCN's service gateway (the one dedicated for this purpose) and not through the service gateways of the other VCNs. For those other VCNs, only the resources *inside* those VCNs can reach Oracle services through their VCN's service gateway.

Regardless of which layout you choose, you can write an IAM policy to restrict access to an Object Storage bucket so that *only requests that come through a specific VCN's service gateway* are allowed for that bucket. With either of these layouts, you might want to write the policy to allow requests from *multiple* VCNs. The following example policy lets resources in the example ObjectBackup group write objects to an existing bucket called db-backup that resides in a compartment called ABC. When writing a policy like this one, you can specify one or more VCN OCIDs. This example shows three.

```
Allow group ObjectBackup to read buckets in compartment ABC

Allow group ObjectBackup to manage objects in compartment ABC where
   all {target.bucket.name='db-backup',
```

```
        any {request.vcn.id='<hub_VCN_OCID>', request.vcn.id='<spoke_1_VCN_OCID>',
request.vcn.id='<spoke_2_VCN_OCID>'},
        any {request.permission='OBJECT_CREATE', request.permission='OBJECT_INSPECT'}}
```

For more information, see Task 4: (Optional) Update IAM Policies to Restrict Object Storage Bucket Access in the procedure for setting up a service gateway.

Requests from Oracle Services to Your Clients

The service gateway does not allow incoming connection requests to the VCN or your on-premises network. Any connection requests coming from an Oracle service to your on-premises network must come over a public path such as the internet or FastConnect public peering.

If you use Oracle Analytics Cloud so that it initiates connection requests to clients, and you *also* want to set up private access to Oracle services for your on-premises network, see this known issue.

Transit Routing Options for Private Access to Oracle Services

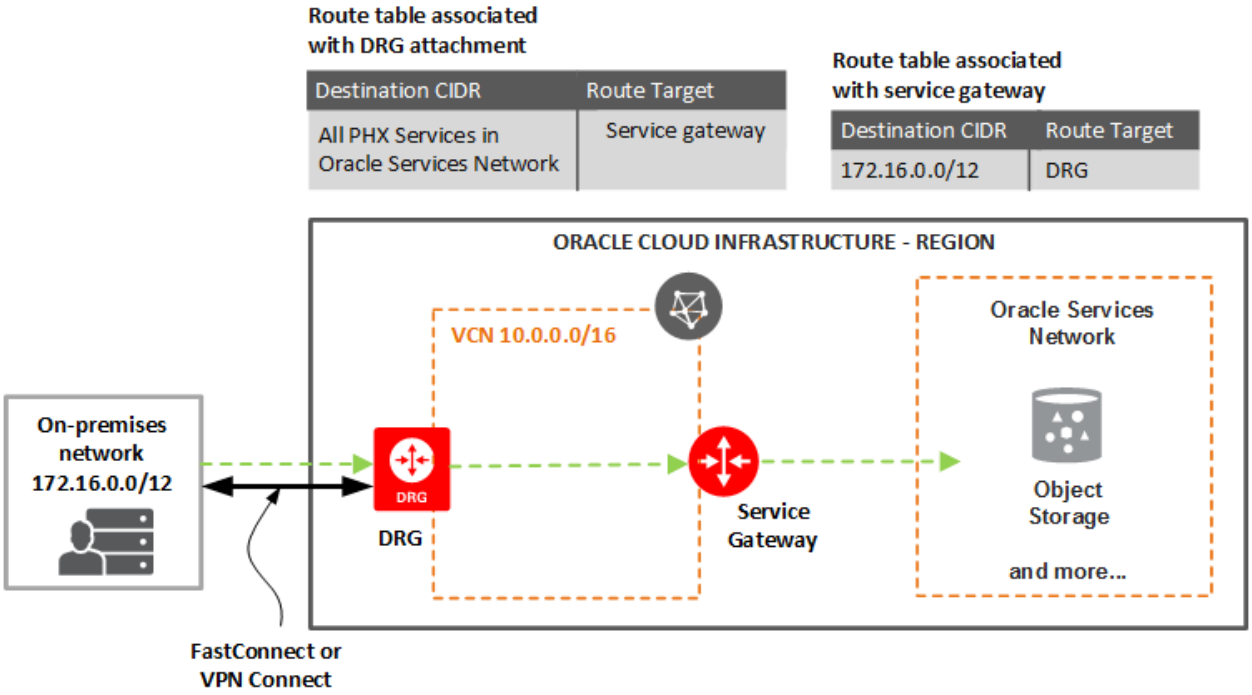
There are two options for routing through the VCN for private access to Oracle services:

- **Transit routing directly through gateways:** You route the traffic directly through the VCN, from one gateway to the other.
- **Transit routing through a private IP:** You set up an instance in the VCN to filter or inspect the traffic between the on-premises network and Oracle Services Network, and route traffic through a private IP on the instance.

The examples shown in the following sections assume that the VCN contains no workloads that need to access the on-premises network or Oracle Services Network. The VCN is being used only for transit routing of traffic *through the VCN*.

Transit routing directly through gateways

In this example, you route directly through the two gateways on the VCN: the dynamic routing gateway (DRG) and the service gateway. See the following diagram.



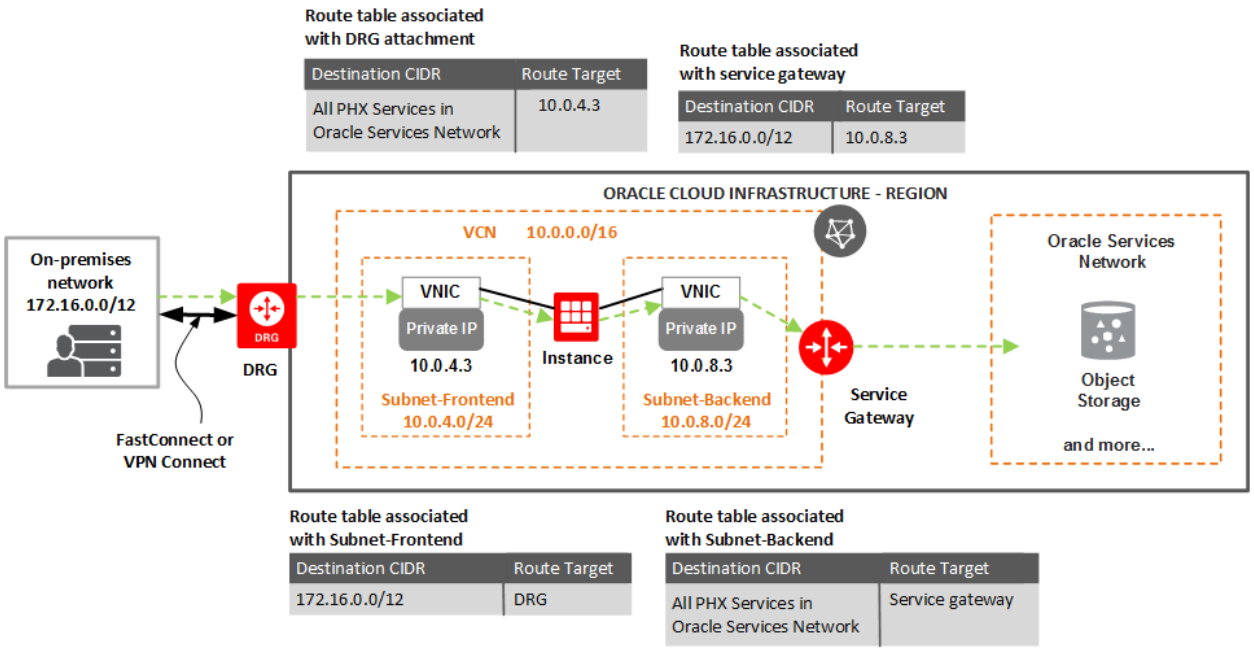
The diagram shows two route tables, each associated with a different resource:

- **DRG attachment:**
  - The route table belongs to the VCN and is associated with the DRG *attachment*. Why the attachment and not the DRG itself? Because the DRG is a standalone resource that you can attach to any VCN in the same region and tenancy as the DRG. The attachment itself identifies which VCN.
  - The route table routes the inbound traffic that is from the on-premises network and destined for a supported Oracle service. You configure the rule to send that traffic to the service gateway.
- **Service gateway:**

- This route table belongs to the VCN and is associated with the service gateway.
- The route table routes response traffic that is from a supported Oracle service and destined for the on-premises network. You configure the rule to send that traffic to the DRG.

Transit routing through a private IP in the VCN

In this example, you set up an instance in the VCN to act as a firewall or intrusion detection system to filter or inspect the traffic between the on-premises network and Oracle Services Network. See the following diagram.



The instance has two VNICs, each with a private IP. One of the VNICs is in a subnet that faces the on-premises network (referred to here as the *frontend subnet*). The other VNIC is in a

subnet that faces the Oracle Services Network (referred to here as the *backend subnet*). The frontend VNIC has private IP 10.0.4.3, and the backend VNIC has private IP 10.0.8.3.

The diagram shows four route tables, each associated with a different resource:

- **DRG attachment:**
  - The route table belongs to the VCN and is associated with the DRG *attachment*. Why the attachment and not the DRG itself? Because the DRG is a standalone resource that you can attach to any VCN in the same region and tenancy as the DRG. The attachment itself identifies which VCN.
  - The route table routes the inbound traffic that is from the on-premises network and destined for a supported Oracle service. You configure the rule to send the traffic to the private IP in the frontend subnet.
- **Service gateway:**
  - This route table belongs to the VCN and is associated with the service gateway.
  - The route table routes response traffic that is from a supported Oracle service and destined for the on-premises network. You configure the rule to send that traffic to the private IP in the backend subnet.
- **Subnet-frontend:**
  - This route table belongs to the VCN and is associated with Subnet-frontend.
  - It includes a rule to enable traffic with the on-premises network.
- **Subnet-backend:**
  - This route table belongs to the VCN and is associated with Subnet-backend.
  - It includes a rule to enable traffic with the regional Oracle Services Network.

Important Transit Routing Restrictions to Understand

This section includes some additional important details about routing:

- **Route table for the DRG attachment:**
  - A route table that is associated with a DRG attachment can only have rules that target a service gateway, a private IP, or a local peering gateway.
  - A DRG attachment can exist without a route table associated with it. However, after you associate a route table with a DRG attachment, there must always be a route table associated with it. But, you can associate a *different* route table. You can also edit the table's rules, or delete some or all of the rules.
- **Route table for a service gateway:**
  - A route table that is associated with a service gateway can only have rules that target a DRG or a private IP.
  - A service gateway can exist without a route table associated with it. However, after you associate a route table with a service gateway, there must always be a route table associated with it. But, you can associate a different route table. You can also edit the table's rules, or delete some or all of the rules.
- **Traffic *transiting through* the VCN:** The route tables discussed here are intended only for moving traffic *through* the VCN between locations in the on-premises network and the Oracle Services Network. If you're using a private IP in the VCN, you configure the route tables so that the private IP is placed in that traffic path going *through* the VCN.
- **Inbound traffic to the VCN:** Even though the preceding statement is true (about traffic *through* the VCN), inbound traffic to subnets *within the VCN* is always allowed. You do not need to set up explicit rules for this inbound traffic in the DRG attachment's route table or service gateway's route table. When this kind of inbound traffic reaches the DRG or the service gateway, the traffic is automatically routed to its destination in the VCN by the *VCN local routing*. Because of VCN local routing, for any route table belonging to a given VCN, you can't create a rule that lists that VCN's CIDR (or a subsection) as the rule's destination.
- **VCN traffic when transit routing through a private IP:** The immediately preceding statement about VCN local routing means that you should use the VCN only for *transit* between the on-premises network and spoke VCNs. **You should not set up workloads in the VCN itself.** More explicitly, if you set up transit routing through a

private IP in the VCN, you can't also route the *VCN's* traffic through that private IP. For example, in the preceding diagram, if you were to change the route rule in the service gateway's route table so that the destination CIDR is 0.0.0.0/0 instead of 172.16.0.0/12, only traffic coming from the Oracle Services Network and destined for addresses *outside* the VCN's CIDR block would be routed through the private IP. Because of VCN local routing, any traffic destined for addresses within the VCN is automatically routed directly to the destination IP address. The VCN local routing takes precedence over the service gateway's route table (in general, over *any* of the VCN's route tables).

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

If you're a member of the Administrators group, you already have the required access to set up transit routing. Otherwise, you need access to the Networking service, and you need the ability to launch instances. See IAM Policies for Networking.

Setting Up Private Access to Oracle Services

This section shows how to use the Console to set up transit routing with a VCN to give your on-premises network private access to Oracle services.

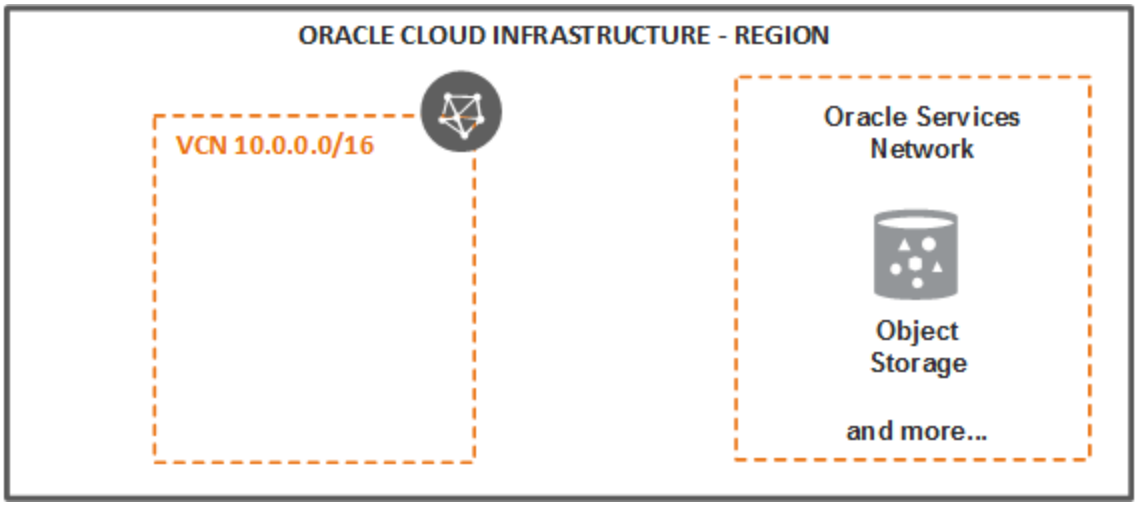
Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

For routing directly between gateways

> **Tip**
>
> You might already have many of the necessary Networking components and connections in this advanced scenario already set up. So you might be able to skip some of the following tasks. **If you already have a network layout with a VCN connected to your on-premises network, and a service gateway for that VCN, then Task 4 is the most important.** It enables traffic to be routed between your on-premises network and the Oracle Services Network.

Task 1: Set up the VCN

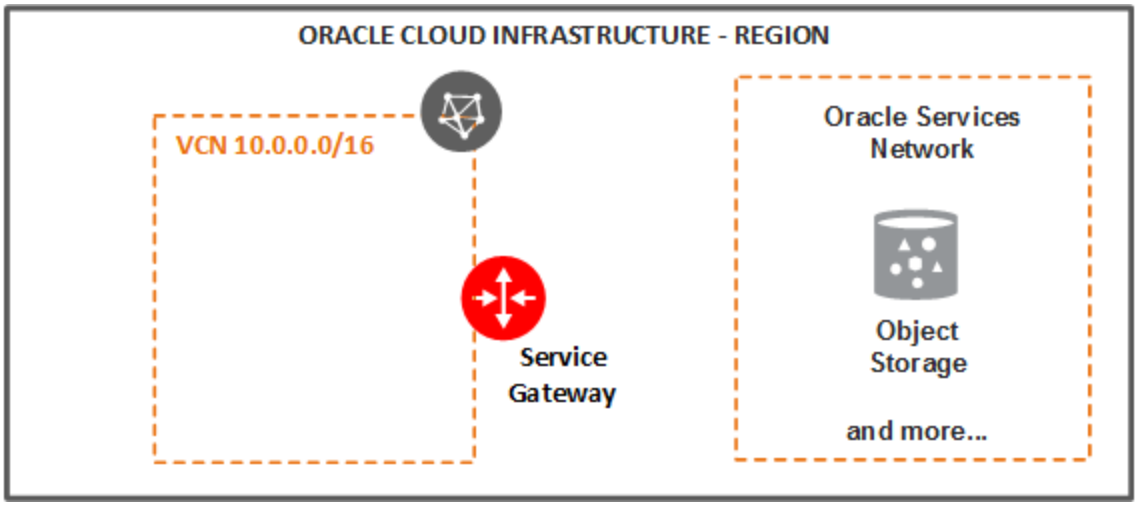


In this task, you set up the VCN. For this example, no subnet is required.

For more information and instructions:

- VCNs and Subnets

Task 2: Add a service gateway to the VCN



In this task, you add a service gateway to the VCN and enable the gateway for the regional Oracle Services Network.

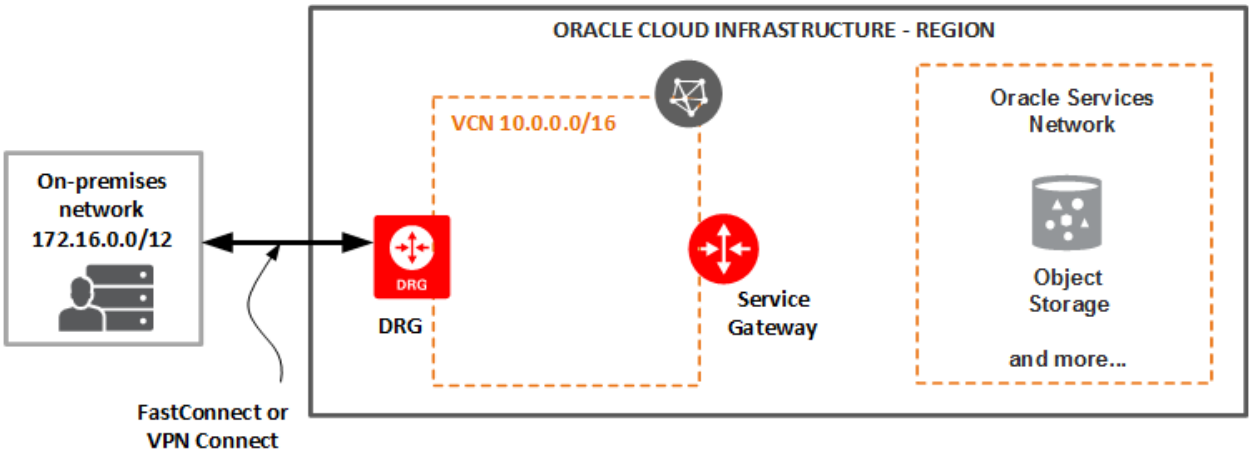
Notice that you do not yet create the route table that will be associated with the service gateway. That comes in a later task.

1. In the Console, view the VCN's details.
2. Under **Resources**, click **Service Gateways**.
3. Click **Create Service Gateway**.
4. Enter the following values:

- **Name:** A descriptive name for the service gateway. It doesn't have to be unique. Avoid entering confidential information.
- **Create in compartment**: The compartment where you want to create the service gateway, if different from the compartment you're currently working in.
- **Services:** All *<region>* Services in Oracle Services Network.

5. Click **Create Service Gateway**.
   The service gateway is then created and displayed on the **Service Gateways** page in the compartment you chose.

Task 3: Connect the VCN to your on-premises network



In this task, you set up either FastConnect or VPN Connect between your VCN and your on-premises network. As part of this process, you attach a DRG to the VCN and set up routing between the VCN and your on-premises network.

Notice that you do not yet create the route table that will be associated with the DRG attachment. That comes in a later task.

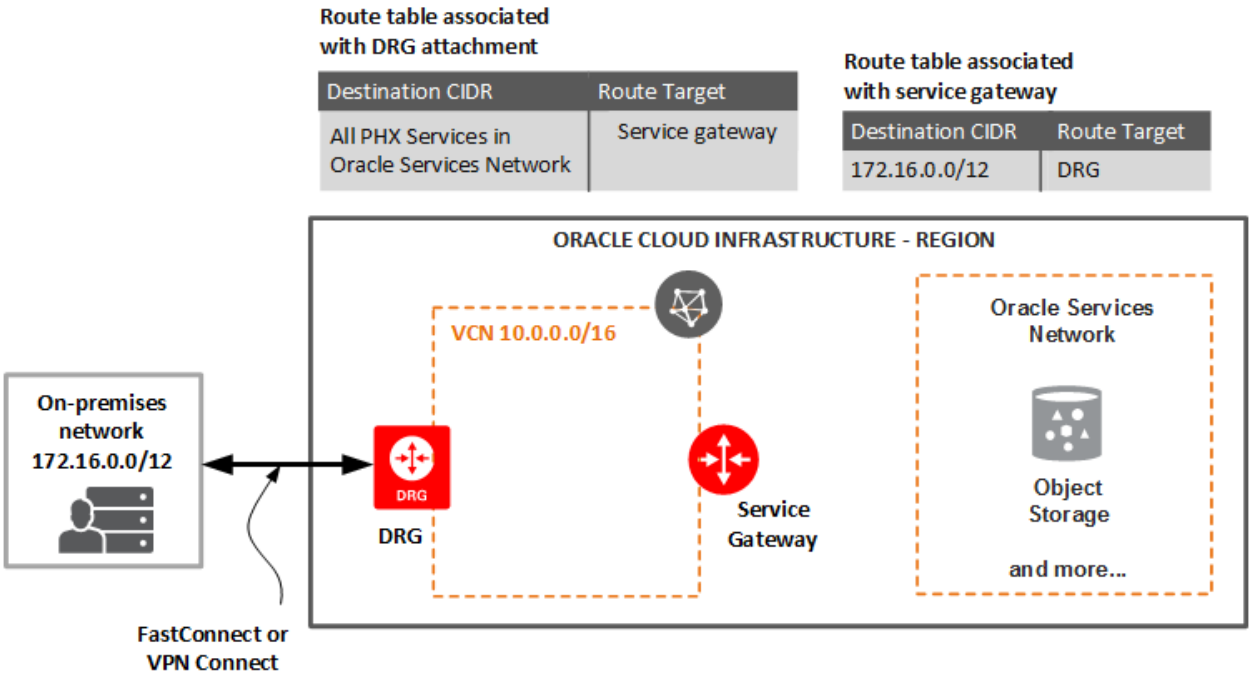
For more information and instructions:

- FastConnect
- VPN Connect
- Dynamic Routing Gateways (DRGs)

Important

If you're using VPN Connect with static routing, and you've configured the VCN to give your on-premises network private access to Oracle services, you must configure your edge device with the routes for the Oracle Services Network public IP ranges that are advertised by the DRG over the private path (through the service gateway). For a list of those ranges, see Public IP Addresses for VCNs and the Oracle Services Network

Task 4: Set up ingress routing for the DRG and service gateway



In this task, you set up the route tables for the DRG attachment and the service gateway.

Prerequisites:

- You already have a DRG attached to the VCN.
- You already have a service gateway.

1. Create a route table for the DRG attachment:
    a. In the Console, view the VCN's details.
    b. Under **Resources**, click **Route Tables** to view the VCN's route tables.

c. Click **Create Route Table**.

d. Enter the following:

- **Name:** A descriptive name for the route table. Example: DRG Route Table. Avoid entering confidential information.
- **Create in Compartment:** Leave as is.

e. Click **+ Additional Route Rule**, and enter this information for the route rule:

- **Target Type:** Service gateway.
- **Destination Service**: All *<region>* Services in Oracle Services Network.
- **Compartment:** The compartment where the service gateway is located.
- **Target:** The service gateway.

f. Click **Create Route Table**.
The route table is created and displayed in the list.

2. Associate the route table (called *DRG Route Table* in this example) with the VCN's DRG attachment:

a. While still viewing the VCN's details, click **Dynamic Routing Gateways** to view the attached DRG.

b. Click the Actions icon (three dots), and then click **Associate With Route Table**.

c. Enter the following:

- **Route Table Compartment:** Select the compartment of the route table for the DRG attachment.
- **Route Table:** Select the route table for the DRG attachment.

d. Click **Associate**.
The route table is associated with the DRG attachment.

3. Create a route table for the service gateway:

a. While still viewing the VCN's details, click **Route Tables**.

b. Click **Create Route Table**.

c. Enter the following:
   - **Create in Compartment:** Leave as is.
   - **Name:** A descriptive name for the route table. Example: Service Gateway Route Table. Avoid entering confidential information.

d. Click **+ Additional Route Rule**, and enter this information for the route rule:
   - **Target Type:** Dynamic Routing Gateway. The VCN's attached DRG is automatically selected as the target, and you don't have to specify the target yourself.
   - **Destination CIDR Block**: The on-premises network's CIDR (172.16.0.0/12 in the earlier example).

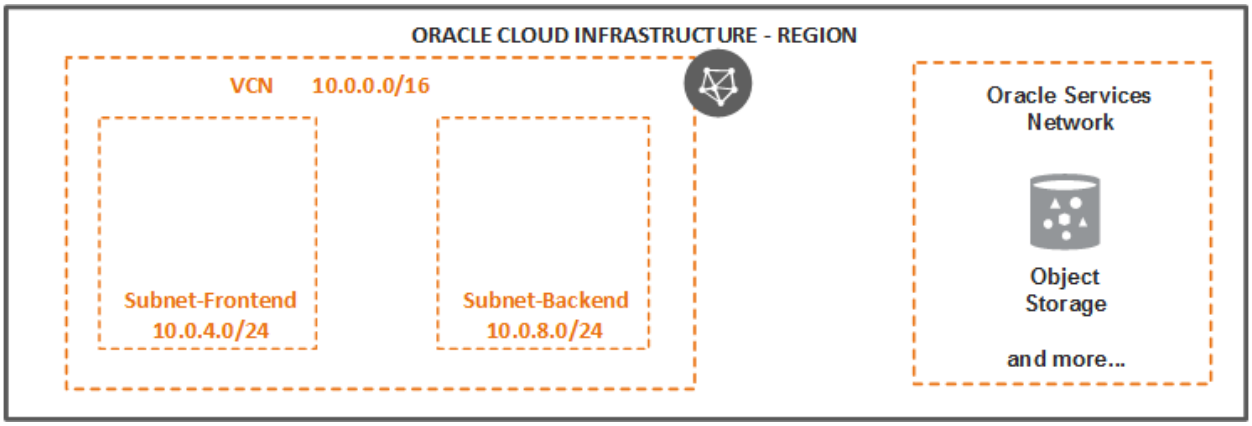
e. Click **Create Route Table**.
   The route table is created and displayed in the list.

4. Associate the route table (called *Service Gateway Route Table* in this example) with the service gateway:
   a. While still viewing the VCN's details, click **Service Gateways**.
   b. For the service gateway, click the Actions icon (three dots), and then click **Associate With Route Table**.
   c. Enter the following:
      - **Route Table Compartment:** Select the compartment of the route table for the service gateway.
      - **Route Table:** Select the route table for the service gateway.
   d. Click **Associate**.
      The route table is associated with the service gateway.

For routing through a private IP

> **Tip**
>
> You might already have many of the necessary Networking components and connections in this advanced scenario already set up. So you might be able to skip some of the following tasks. **If you already have a network layout with a VCN connected to your on-premises network, and a service gateway for that VCN, then Tasks 4 and 5 are the most important.** They enable traffic to be routed between your on-premises network and the spoke VCN.

Task 1: Set up the VCN

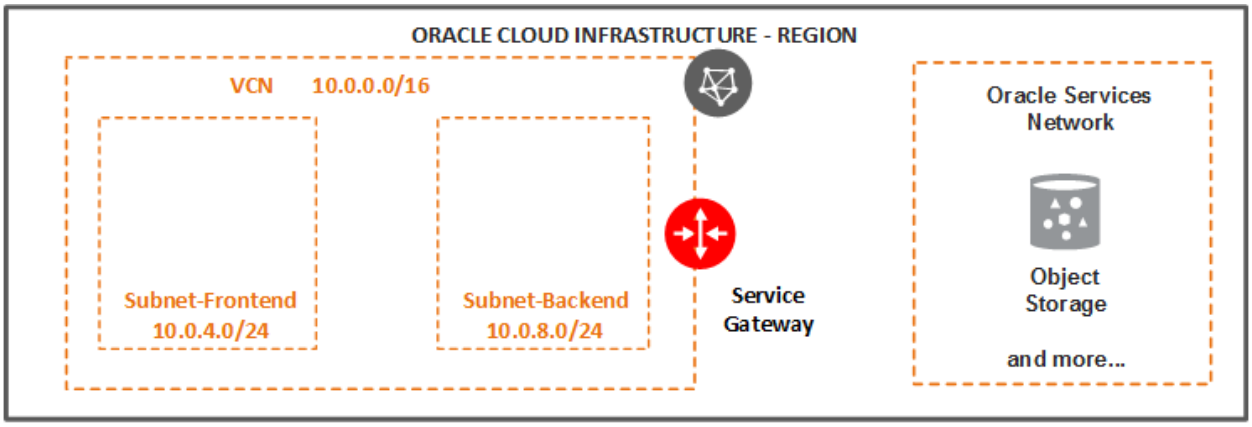


In this task, you set up the VCN. This example also has two subnets: one for the frontend VNIC on the instance, and one for the backend VNIC on the instance. Oracle recommends using regional *private* subnets.

For more information and instructions:

- VCNs and Subnets

Task 2: Add a service gateway to the VCN



Route table associated with Subnet-Backend

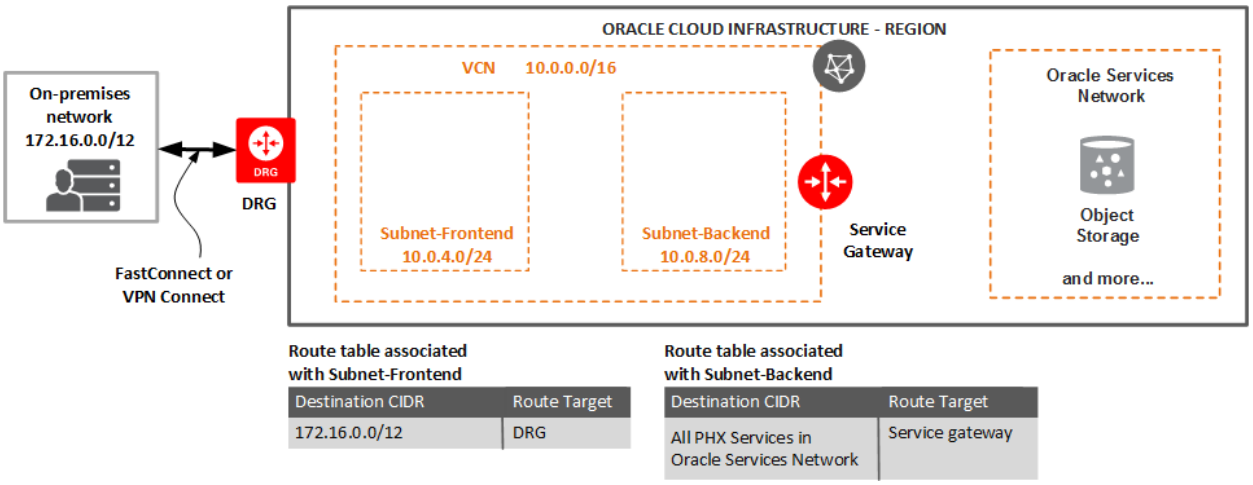
Destination CIDR	Route Target
All PHX Services in Oracle Services Network	Service gateway

In this task, you add a service gateway to the VCN and enable the gateway for the regional Oracle Services Network.

Notice that you do not yet create the route table that will be associated with the service gateway. That comes in a later task.

1. In the Console, view the VCN's details.
2. Under **Resources**, click **Service Gateways**.
3. Click **Create Service Gateway**.
4. Enter the following values:
   - **Name:** A descriptive name for the service gateway. It doesn't have to be unique. Avoid entering confidential information.
   - **Create in compartment**: The compartment where you want to create the service gateway, if different from the compartment you're currently working in.
   - **Services:** All *<region>* Services in Oracle Services Network.
5. Click **Create Service Gateway**.
   The service gateway is then created and displayed on the **Service Gateways** page in the compartment you chose.

Task 3: Connect the VCN to your on-premises network



In this task, you set up either FastConnect or VPN Connect between your hub VCN and your on-premises network. As part of this process, you attach a DRG to the hub VCN and set up routing between the hub VCN and your on-premises network.

Notice that you do not yet create the route table that will be associated with the DRG attachment. That comes in a later step.

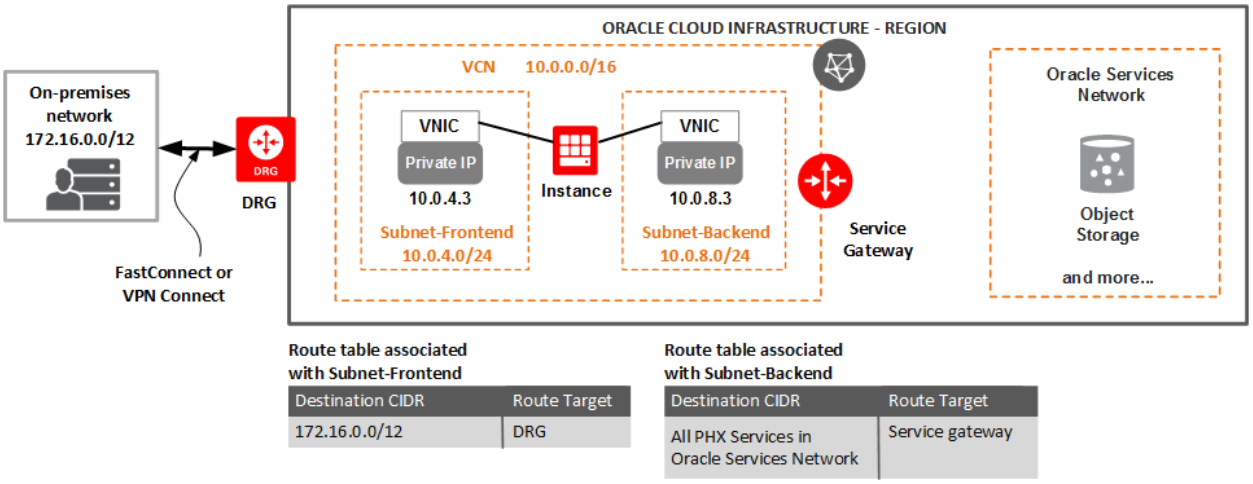
For more information and instructions:

- FastConnect
- VPN Connect
- Dynamic Routing Gateways (DRGs)

Important

If you're using VPN Connect with static routing, and you've configured the VCN to give your on-premises network private access to Oracle services, you must configure your edge device with the routes for the Oracle Services Network public IP ranges that are advertised by the DRG over the private path (through the service gateway). For a list of those ranges, see Public IP Addresses for VCNs and the Oracle Services Network

Task 4: Set up the private IPs on an instance in the VCN



In this task, you set up the instance to have 2 private IPs.

Prerequisites:

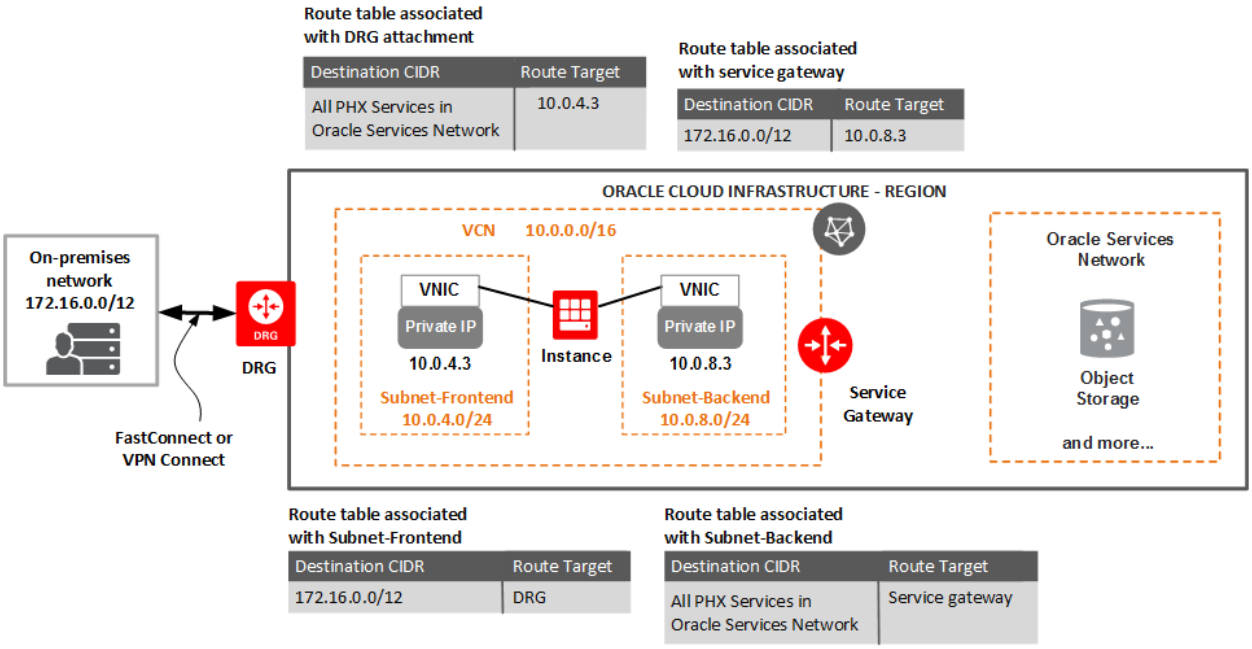
- You already have a VCN with two subnets.
- Review this information: Using a Private IP as a Route Target.

1. If you haven't already, create the instance in the VCN. See Creating an Instance. The primary VNIC is created in the subnet you specify.
2. Create a secondary VNIC for the other subnet and configure the OS to use it. See To create and attach a secondary VNIC.
3. Disable the source/destination check on each of the VNICs. See Source/Destination Check.
4. For each VNIC, determine which private IP you want to use as the routing target. If you want to use a secondary private IP instead of the VNIC's primary private IP, assign that

secondary private IP and configure the OS to use it. See To assign a new secondary private IP to a VNIC.

5. For each of the private IPs you created, record the private IP address (for example: 10.0.4.3).
6. Configure the instance as necessary for the job it will perform (for example, configure the firewall or intrusion detection system on the instance).

Task 5: Set up ingress routing for the DRG and service gateway



In this task, you set up the route tables for the DRG attachment and service gateway.

Prerequisites:

- You already have a DRG attached to the VCN.
- You already have a service gateway.
- You already have the 2 private IPs to use as the routing targets (see the preceding task).

1. Create a route table for the DRG attachment:
    a. In the Console, view the VCN's details.
    b. Under **Resources**, click **Route Tables** to view the VCN's route tables.
    c. Click **Create Route Table**.
    d. Enter the following:
        - **Name:** A descriptive name for the route table. Example: DRG Route Table. Avoid entering confidential information.
        - **Create in Compartment:** Leave as is.
    e. Click **+ Additional Route Rule**, and enter this information for the route rule:
        - **Target Type:** Private IP.
        - **Destination:** Service.
        - **Destination Service**: All *<region>* Services in Oracle Services Network
        - **Compartment:** The compartment where the frontend subnet's private IP is located.
        - **Target:** The frontend subnet's private IP, which you recorded in the previous task (10.0.4.3 in the example).
    f. Click **Create Route Table**.
    The route table is created and displayed in the list.
2. Associate the route table (called *DRG Route Table* in this example) with the VCN's DRG attachment:
    a. While still viewing the VCN's details, click **Dynamic Routing Gateways** to view the attached DRG.

b. Click the Actions icon (three dots), and then click **Associate Route Table**.
c. Select the route table.
d. Click **Associate Route Table**.
The route table is associated with the DRG attachment.

3. Create a route table for the service gateway:
a. While still viewing the VCN's details, click **Route Tables**.
b. Click **Create Route Table**.
c. Enter the following:
- **Create in Compartment:** Leave as is.
- **Name:** A descriptive name for the route table. Example: Service Gateway Route Table. Avoid entering confidential information.

d. Click **+ Additional Route Rule**, and enter this information for the route rule:
- **Target Type:** Private IP.
- **Destination:** CIDR Block.
- **Destination CIDR Block**: The on-premises network's CIDR (172.16.0.0/12 in the earlier example).
- **Compartment:** The compartment where the private IP is located.
- **Target:** The backend subnet's private IP, which you recorded in the previous task (10.0.8.3 in the example).

e. Click **Create Route Table**.
The route table is created and displayed in the list.

4. Associate the route table (called *Service Gateway Route Table* in this example) with the service gateway:
a. While still viewing the VCN's details, click **Service Gateways**.
b. For the service gateway, click the Actions icon (three dots), and then click **Associate With Route Table**.

c. Enter the following:
   - **Route Table Compartment:** Select the compartment of the route table for the service gateway.
   - **Route Table:** Select the route table for the service gateway.

d. Click **Associate**.
   The route table is associated with the service gateway.

Turning Off Transit Routing

To turn off transit routing, remove the rules from:

- The route table associated with the DRG attachment.
- The route table associated with service gateway.

A route table can be associated with a resource but have no rules. Without at least one rule, a route table does nothing.

A DRG attachment or service gateway can exist without a route table associated with it. However, after you associate a route table with a DRG attachment or service gateway, there must always be a route table associated with it. But, you can associate a *different* route table. You can also edit the table's rules, or delete some or all of the rules.

FastConnect with Multiple DRGs and VCNs

This topic summarizes an advanced networking scenario that enables communication between an on-premises network and multiple virtual cloud networks (VCNs) over a single Oracle Cloud Infrastructure FastConnect. **Each VCN has its own dynamic routing gateway (DRG), and you set up a separate FastConnect private virtual circuit to each DRG.**

This scenario is supported for only certain FastConnect setups:

- Supported:
  - Using a third-party provider
  - Colocation with Oracle in a FastConnect location
- Not supported:
  - Using an Oracle provider

There's a scenario called *transit routing* that also involves using multiple VCNs, but only a single DRG. It can be used with VPN Connect or FastConnect. It involves setting up the VCNs in a hub-and-spoke layout and using the hub VCN for transit routing of traffic to the other VCNs. You might use this scenario if you need multiple VCNs for different parts of your organization, but you want to use one VCN for centralized services that all parts of the organization need. For more information, see Transit Routing: Access to Multiple VCNs in the Same Region.

Highlights

- You can use a single FastConnect to connect your on-premises network with *multiple* VCNs in the same region. The scenario is supported only for FastConnect through a third-party provider or through colocation with Oracle. You need at least one physical connection (cross-connect) in your connection.
- The VCNs must be in the same region and same tenancy. The VCNs can be in the same compartment or different ones in the tenancy. For accurate routing, the CIDR blocks of the various subnets of interest in the on-premises network and VCNs must not overlap.
- Each VCN has its own dynamic routing gateway (DRG) and private virtual circuit. You must use a different VLAN and different set of BGP IP addresses for each private virtual circuit.
- You can also use FastConnect public peering to give your on-premises network access to public endpoints of Oracle services. In this case, you set up a single public virtual circuit, which covers all the VCNs. With public peering, make sure to configure your edge device (also known as your *customer-premises equipment* or *CPE*) to prefer FastConnect over your ISP for the Oracle Cloud Infrastructure public IP prefixes. Or, if you plan to also set up private access to Oracle services through one of the VCNs, see

the important routing details in Routing Details for Connections to Your On-Premises Network.

Overview of the Scenario

In this scenario, you have a single FastConnect that connects your existing on-premises network to Oracle Cloud Infrastructure. That FastConnect has at least one physical connection, or cross-connect.

In Oracle Cloud Infrastructure, you have multiple VCNs, all in the same region. Each VCN has its own DRG. For each VCN, there's a private virtual circuit that runs on the FastConnect and terminates at your CPE on one end, and on the VCN's DRG on the other end. The private virtual circuit enables communication that uses private IP addresses between the VCN and the on-premises network. See the following diagram.

location
Oracle edge
Legend: Private virtual circuit

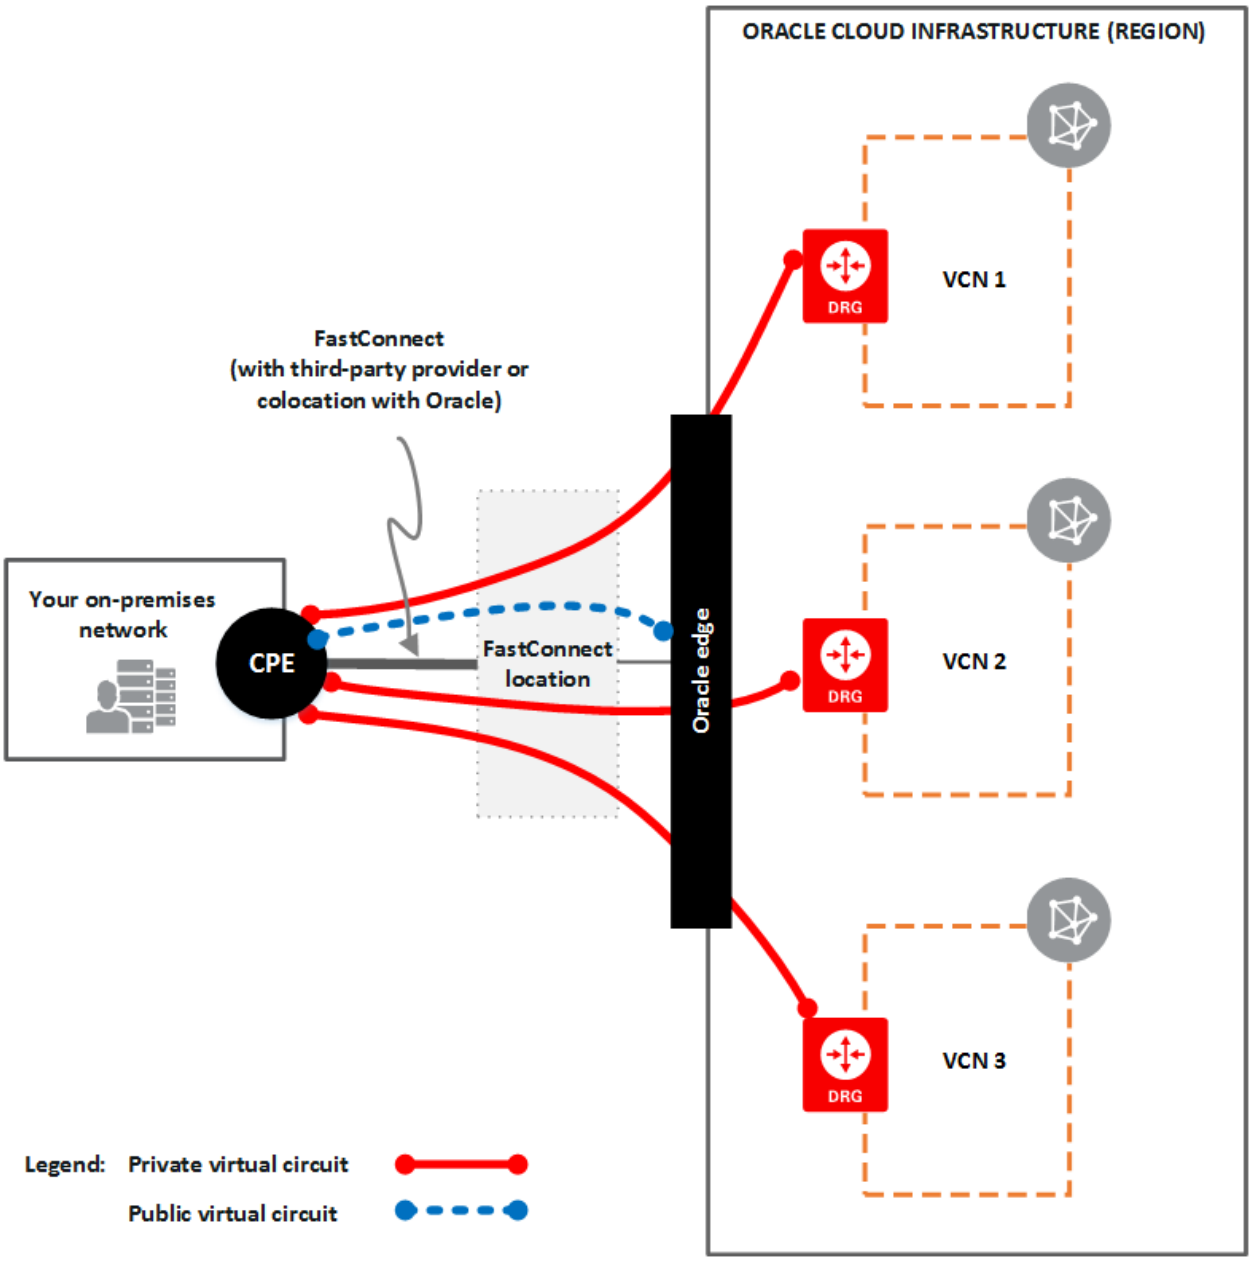
For example, imagine that each department in your organization has its own subnet in your on-premises network and a corresponding departmental VCN in Oracle Cloud Infrastructure. You want to enable private communication between each department's subnet and VCN over the FastConnect.

Or, perhaps all the departments need to communicate with all the VCNs. For example, instead perhaps the VCNs are for separate development, test, and production environments, and each department needs access to all three VCNs.

The FastConnect and virtual circuits give you the general private connection where none of the traffic traverses the internet. You can separately control which on-premises subnets and VCNs can communicate by configuring route rules in your on-premises network and VCN route tables. You can optionally configure VCN security rules and other firewalls that you maintain to allow only certain types of traffic (such as SSH) between your on-premises network and VCN.

Public Peering

You can also set up public peering on that same FastConnect by creating a public virtual circuit. In the following diagram, the public virtual circuit is shown separate from the private virtual circuits. It terminates at Oracle's edge. The public virtual circuit enables communication *that uses public IP addresses* but does not traverse the internet. If a given VCN happens to also have an internet gateway, Oracle's edge prefers the FastConnect route over the VCN's internet gateway. For other important details about how you can control route preferences when you have multiple connections between your on-premises network and Oracle, see Routing Details for Connections to Your On-Premises Network.



ORACLE CLOUD INFRASTRUCTURE (REGION)

CPE
FastConnect
location
Oracle edge
Legend:
Private virtual circuit
Public virtual circuit

When you set up public peering for your FastConnect, the public IP prefixes that you designate for the public virtual circuit are advertised to *all* the VCNs in your tenancy. The routes advertised to your on-premises network are all the Oracle Cloud Infrastructure public IP addresses (including the CIDRs for each of the VCNs in the tenancy).

Important

Your network will receive Oracle's public IP addresses through both FastConnect and your Internet Service Provider (ISP). When configuring your edge, make sure to give higher preference to FastConnect over your ISP, or you will not receive the benefits of FastConnect. If you plan to also set up private access to Oracle services through one of the VCNs, see the important routing details in Routing Details for Connections to Your On-Premises Network.

For more information, see Logical Connection: Public Virtual Circuit.

General Setup Process

The setup process and instructions are in these topics, based on your particular FastConnect setup:

- FastConnect: With a Third-Party Provider
- FastConnect: Colocation with Oracle

However, remember that:

- You set up a separate DRG for each VCN. A DRG can be attached to only a single VCN, and each VCN can be attached to only a single DRG.
- You set up a separate private virtual circuit for each DRG.

- For each private virtual circuit, **you must specify a different VLAN and a different set of BGP IP addresses**.
- When you configure your CPE, you can advertise the same on-premises routes to each VCN, or different ones, based on your own requirements.

VCNs and Subnets

This topic describes how to manage virtual cloud networks (VCNs) and the subnets in them. This topic uses the terms *virtual cloud network*, *VCN*, and *cloud network* interchangeably. The Console uses the term *Virtual Cloud Network*, whereas for brevity the API uses *VCN*.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Overview of VCNs and Subnets

A VCN is a software-defined network that you set up in the Oracle Cloud Infrastructure data centers in a particular region. A subnet is a subdivision of a VCN. For an overview of VCNs, allowed size, default VCN components, and scenarios for using a VCN, see Overview of Networking.

You can privately connect a VCN to another VCN so that the traffic does not traverse the internet. The CIDRs for the two VCNs must not overlap. For more information, see Access to Other VCNs: Peering. For an example of an advanced routing scenario that involves the peering of multiple VCNs, see Transit Routing: Access to Multiple VCNs in the Same Region.

Each subnet in a VCN consists of a contiguous range of IPv4 addresses that do not overlap with other subnets in the VCN. Example: 172.16.1.0/24. The first two IPv4 addresses and the last in the subnet's CIDR are reserved by the Networking service. You can't change the size of

the subnet after creation, so it's important to think about the size of subnets you need before creating them.

Subnets act as a unit of configuration: all instances in a given subnet use the same route table, security lists, and DHCP options. For more information, see Default Components that Come With Your VCN.

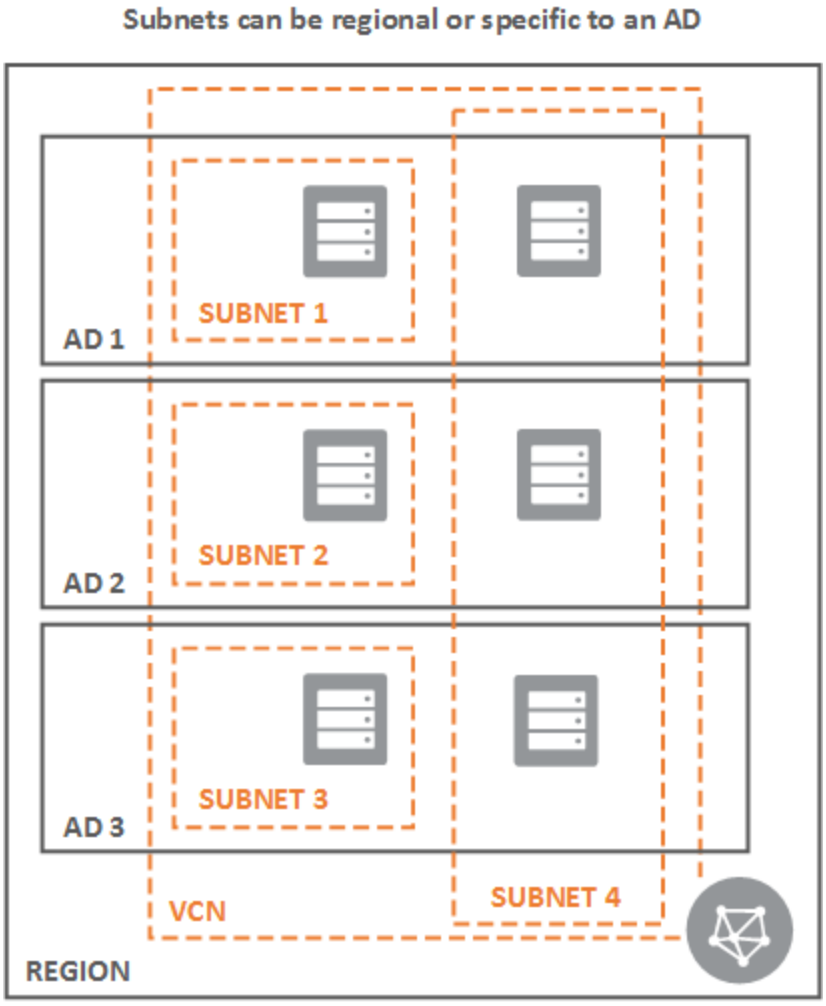
Subnets can be either public or private (see Public vs. Private Subnets). You choose this during subnet creation, and you can't change it later.

You can think of each Compute instance as residing in a subnet. But to be precise, each instance is actually attached to a virtual network interface card (VNIC), which in turn resides in the subnet and enables a network connection for that instance.

IPv6 addressing is currently supported only in the US Government Cloud. For more information, see IPv6 Addresses.

About Regional Subnets

Originally subnets were designed to cover only one availability domain (AD) in a region. They were all *AD-specific*, which means the subnet's resources were required to reside in a particular availability domain. Now subnets can be either AD-specific or *regional*. You choose the type when you create the subnet. Both types of subnets can co-exist in the same VCN. In the following diagram, subnets 1-3 are AD-specific, and subnet 4 is regional.



Aside from the removal of the AD constraint, regional subnets behave the same as AD-specific subnets. **Oracle recommends using regional subnets** because they're more flexible. They make it easier to efficiently divide your VCN into subnets while also designing for availability domain failure.

When you create a resource such as a Compute instance, you choose which availability domain the resource will be in. From a virtual networking standpoint, you must also choose

which VCN and subnet the instance will be in. You can either choose a regional subnet, or choose an AD-specific subnet that matches the AD you chose for the instance.

Warning

If anyone in your organization implements a regional subnet, be aware that you **may need to update any client code that works with Networking service subnets and private IPs**. There are possible breaking API changes. For more information, see the regional subnet release note.

Working with VCNs and Subnets

One of the first things you do when working with Oracle Cloud Infrastructure resources is create a VCN with one or more subnets. You can easily get started in the Console with a simple VCN and some related resources that enable you to launch and connect to an instance. See Tutorial - Launching Your First Linux Instance or Tutorial - Launching Your First Windows Instance.

For the purposes of access control, when you create a VCN or subnet, you must specify the compartment where you want the resource to reside. Consult an administrator in your organization if you're not sure which compartment to use.

You may optionally assign friendly names to the VCN and its subnets. The names don't have to be unique, and you can change them later. Oracle automatically assigns each resource a unique identifier called an Oracle Cloud ID (OCID). For more information, see Resource Identifiers.

You can also add a DNS label for the VCN and each subnet, which are required if you want the instances to use the *Internet and VCN Resolver* feature for DNS in the VCN. For more information, see DNS in Your Virtual Cloud Network.

When you create a subnet, you may optionally specify a route table for the subnet to use. If you don't, the subnet uses the cloud network's default route table. You can change which route table the subnet uses at any time.

Also, you may optionally specify one or more security lists for the subnet to use (up to five). If you don't specify any, the subnet uses the cloud network's default security list. You can change which security list the subnet uses at any time. Remember that the security rules are enforced at the instance level, even though the list is associated at the subnet level. Network security groups are an alternative to security lists and let you apply a set of security rules to a set of resources that all *have the same security posture*, instead of all the resources in a particular subnet.

You may optionally specify a set of DHCP options for the subnet to use. All instances in the subnet will receive the configuration specified in that set of DHCP options. If you don't specify a set, the subnet uses the cloud network's default set of DHCP options. You can change which set of DHCP options the subnet uses at any time.

To delete a subnet, it must contain no resources (no instances, load balancers, DB systems, and orphaned mount targets). For more details, see Subnet or VCN Deletion.

To delete a VCN, its subnets must contain no resources. Also, the VCN must have no attached gateways. If you're using the Console, there's a "Delete All" process you can use after first ensuring the subnets are empty. See To delete a VCN.

For information about the number of VCNs and subnets you can have, see Service Limits.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: see IAM Policies for Networking.

Using the Console

To create a VCN

Note

The following procedure creates a VCN without any subnets or gateways for access. You must manually create the subnets and other resources before you can use the VCN. For a quick procedure that creates a VCN that you can try out immediately (that is, with subnets and an internet gateway), see Scenario A: Public Subnet.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator. For more information, see Access Control.
3. Click **Create Virtual Cloud Network**.
4. Enter the following:
   - **Name:** A friendly name for the VCN. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
   - **Create in Compartment:** Leave as is.
   - **Create Virtual Cloud Network Only:** Make sure this radio button is selected (the default).

- **Enable IPv6 Address Assignment:** This option is available only if the VCN is in the Government Cloud. For more information, see IPv6 Addresses.
- **CIDR Block:** A single, contiguous CIDR block for the VCN. For example: 172.16.0.0/16. You *cannot* change this value later. See Allowed VCN Size and Address Ranges. For reference, here's a CIDR calculator.
- **Use DNS Hostnames in this VCN:** Required for assignment of DNS hostnames to hosts in the VCN, and required if you plan to use the VCN's default DNS feature (called the *Internet and VCN Resolver*). If the check box is selected, you can specify a DNS label for the VCN, or the Console will generate one for you. The dialog box automatically displays the corresponding **DNS Domain Name** for the VCN (`<VCN DNS label>.oraclevcn.com`). For more information, see DNS in Your Virtual Cloud Network.
- **Tags:** Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.

5. Click **Create Virtual Cloud Network**.
   The VCN is then created and displayed on the **Virtual Cloud Networks** page in the compartment you chose.

Next you'll typically want to create one or more subnets in the cloud network.

To create a subnet

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Click **Create Subnet**.
4. In the **Create Subnet** dialog box, you specify the resources to associate with the

subnet (for example, a route table, and so on). By default, the subnet will be created in the current compartment, and you'll choose the resources from the same compartment. Click the **click here** link in the dialog box if you want to enable compartment selection for the subnet and each of those resources.

Enter the following:

- **Create in Compartment:** If you've enabled compartment selection, specify the compartment where you want to put the subnet.
- **Name:** A friendly name for the subnet. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
- **Regional or AD-specific subnet:** Oracle recommends creating only regional subnets, which means that the subnet can contain resources in any of the region's availability domains. If you instead choose **Availability Domain-Specific** (the only kind of subnet that Oracle originally offered), you must also specify an availability domain. This choice means that any instances or other resources later created in this subnet must also be in that availability domain.
- **CIDR Block:** A single, contiguous CIDR block for the subnet (for example, 172.16.0.0/24). Make sure it's within the cloud network's CIDR block and doesn't overlap with any other subnets. You *cannot* change this value later. See Allowed VCN Size and Address Ranges. For reference, here's a CIDR calculator.
- **Enable IPv6 Address Assignment:** This option is available only if the VCN is in the US Government Cloud. For more information, see IPv6 Addresses.
- **Route Table:** The route table to associate with the subnet. If you've enabled compartment selection, under **Route Table Compartment**, you must specify the compartment that contains the route table.
- **Private or public subnet:** This controls whether VNICs in the subnet can have public IP addresses. For more information, see Access to the Internet.
- **Use DNS Hostnames in this Subnet:** This option is available only if you provided a DNS label for the VCN during creation. The option is required for

assignment of DNS hostnames to hosts in the subnet, and required if you plan to use the VCN's default DNS feature (called the *Internet and VCN Resolver*). If the check box is selected, you can specify a DNS label for the subnet, or the Console will generate one for you. The dialog box automatically displays the corresponding **DNS Domain Name** for the subnet (*<subnet_DNS_label>*.*<VCN_DNS_label>*.oraclevcn.com). For more information, see DNS in Your Virtual Cloud Network.

- **DHCP Options:** The set of DHCP options to associate with the subnet. If you've enabled compartment selection, under **DHCP Options Compartment**, you must specify the compartment that contains the set of DHCP options.
- **Security Lists:** One or more security lists to associate with the subnet. If you've enabled compartment selection, you must specify the compartment that contains the security list.
- **Tags:** Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.

5. Click **Create**.
   The subnet is then created and displayed on the **Subnets** page in the compartment you chose.

To edit a subnet

You can change these characteristics of a subnet:

- Name
- Which set of DHCP options the subnet uses
- Which route table the subnet uses
- Which security lists the subnet uses

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Click **Subnets**.
4. Click the subnet you're interested in.
5. Click **Edit**.
6. Make your changes.
7. Click **Save Changes**.
   The changes take effect within a few seconds.

To delete a subnet

Prerequisite: The subnet must have no instances, load balancers, DB systems, and orphaned mount targets in it. For more information, see Subnet or VCN Deletion.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Click **Subnets**.
4. Click the subnet you're interested in.
5. Click **Terminate**.
6. Confirm when prompted.

If the subnet is empty, its state changes to TERMINATING briefly and then TERMINATED. If the subnet is not empty, you get an error indicating that there are still instances or other resources in it that you must delete first.

To delete a VCN

Important

The Console has an easy "Delete all" process that deletes a VCN and its related Networking resources (subnets, route tables, security lists, sets of DHCP options, internet gateway, and so on). If the VCN is attached to a dynamic routing gateway (DRG), the attachment is deleted, but the DRG remains.

The "Delete All" process deletes one resource at a time and takes a minute or two. A progress report is displayed to show you what's been deleted so far.

Before using the "Delete All" process, make sure there are no instances, load balancers, DB systems, or orphaned mount targets in any of the subnets. For more information, see Subnet or VCN Deletion.

If there are still resources in any subnet, or if you don't have permission to delete a particular Networking resource, the "Delete All" process stops and an error message is displayed. Any resources deleted up to that point cannot be restored. You might need to contact your tenancy administrator to help you delete any remaining resources.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Click **Terminate**.

The resulting dialog box displays a list of the resources to be deleted. The list doesn't include the default components that come with the VCN, but they will be deleted along with the VCN.

4. Click **Delete All**.
   The process begins. The progress is displayed as each resource is deleted.
5. When the process is complete, click **Close**.

To manage tags for a VCN

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Click the **Tags** tab to view or edit the existing tags. Or click **Apply tag(s)** to add new ones.

For more information, see Resource Tags.

To manage tags for a subnet

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Click the subnet you're interested in.
4. Click the **Tags** tab to view or edit the existing tags. Or click **Apply tag(s)** to add new ones.

For more information, see Resource Tags.

To move a VCN to a different compartment

You can move a VCN from one compartment to another. When you move a VCN, its associated

VNICs, private IPs, and ephemeral IPs move with it to the new compartment. For more information, see Moving Resources to a Different Compartment.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Find the VCN in the list, click the the Actions icon (three dots), and then click **Move Resource**.
3. Choose the destination compartment from the list.
4. Click **Move Resource**.
5. If there are alarms monitoring the VCN, update the alarms to reference the new compartment. See To update an alarm after moving a resource for more information.

To move a subnet to a different compartment

You can move a subnet from one compartment to another. For more information, see Moving Resources to a Different Compartment.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Find the subnet in the list, click the the Actions icon (three dots), and then click **Move Resource**.
4. Choose the destination compartment from the list.
5. Click **Move Resource**.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

To manage your VCNs, use these operations:

- ListVcns
- CreateVcn
- GetVcn
- UpdateVcn
- DeleteVcn: Deletes only the VCN and not its related resources. For more information, see Subnet or VCN Deletion. Note that the Console offers a "Delete All" process that makes it easy to delete the VCN and its related resources. See To delete a VCN.
- ChangeVcnCompartment

To manage a VCN's subnets, use these operations:

- ListSubnets
- CreateSubnet
- GetSubnet
- UpdateSubnet
- DeleteSubnet
- ChangeSubnetCompartment

Ways to Secure Your Network

There are several ways you can control security for your cloud network and compute instances:

- **Public versus private subnets:** You can designate a subnet to be private, which means instances in the subnet cannot have public IP addresses. For more information, see Public vs. Private Subnets.
- **Security rules:** To control packet-level traffic in and out of an instance. You configure security rules in the Oracle Cloud Infrastructure API or Console. To implement security rules, you can use network security groups or security lists. For more information, see Security Rules.

- **Firewall rules:** To control packet-level traffic in/out of an instance. You configure firewall rules directly on the instance itself. Notice that Oracle Cloud Infrastructure images that run Oracle Linux automatically include default rules that allow ingress on TCP port 22 for SSH traffic. Also, the Windows images include default rules that allow ingress on TCP port 3389 for Remote Desktop access. For more information, see Oracle-Provided Images.

Important

Firewall rules and security rules both operate at the instance level. However, you configure security lists at the subnet level, which means all resources in a given subnet have the same set of security list rules. Also, the security rules in a network security group apply only to the resources in the group. When troubleshooting access to an instance, make sure all of the following items are set correctly: the network security groups that the instance is in, the security lists associated with the instance's subnet, and the instance's firewall rules.

If your instance is running Oracle Linux 7, you need to use firewalld to interact with the iptables rules. For your reference, here are commands for opening a port (1521 in this example):

```
sudo firewall-cmd --zone=public --permanent --add-
port=1521/tcp

sudo firewall-cmd --reload
```

For instances with an iSCSI boot volume, the preceding `--reload` command can cause problems. For details and a workaround, see Instances experience system hang after running firewall-cmd --reload.

- **Gateways and route tables:** To control general traffic flow from your cloud network to outside destinations (the internet, your on-premises network, or another VCN). You configure your cloud network's gateways and route tables in the Oracle Cloud

Infrastructure API or Console. For more information about the gateways, see Networking Components. For more information about route tables, see Route Tables.

- **IAM policies:** To control who has access to the Oracle Cloud Infrastructure API or Console itself. You can control the type of access, and which cloud resources can be accessed. For example, you can control who can set up your network and subnets, or who can update route tables, network security groups, or security lists. You configure policies in the Oracle Cloud Infrastructure API or Console. For more information, see Access Control.

Access Control

This topic gives basic information about using compartments and IAM policies to control access to your cloud network.

Compartments and Your Cloud Network

Anytime you create a cloud resource such as a virtual cloud network (VCN) or compute instance, you must specify which IAM *compartment* you want the resource in. A compartment is a collection of related resources that can be accessed only by certain groups that have been given permission by an administrator in your organization. The administrator will create compartments and corresponding IAM policies to control which users in your organization have access to which compartments. Ultimately, the goal is to ensure that each person has access to only the resources they need.

If your company is starting to try out Oracle Cloud Infrastructure, only a few people need to create and manage the VCN and its components, launch instances into the VCN, and attach block storage volumes to those instances. Those few people need access to *all* these resources, so all those resources could be in the same compartment.

In an enterprise production environment with a VCN, your company will want to use multiple compartments to make it easier to control access to certain types of resources. For example, your administrator could create Compartment_A for your VCN and other networking components. The administrator could then create Compartment_B for all the compute instances and block storage volumes that the HR organization uses, and Compartment_C for

all the instances and block storage volumes that the Marketing organization uses. The administrator would then create IAM policies that give users only the level of access they need in each compartment. For example, the HR instance administrator is not entitled to modify the existing cloud network. So they would have full permissions for Compartment_B, but limited access to Compartment_A (just what's required to launch instances into the network). If they tried to modify other resources in Compartment_A, the request would be denied.

Network resources such as VCNs, subnets, route tables, security lists, service gateways, NAT gateways, VPNs, and FastConnect connections can be moved from one compartment to another. When you move a resource to a new compartment, inherent policies apply immediately.

For more information about compartments and how to control access to your cloud resources, see "Setting Up Your Tenancy" in the *Oracle Cloud Infrastructure Getting Started Guide* and Overview of Oracle Cloud Infrastructure Identity and Access Management.

IAM Policies for Networking

The simplest approach to granting access to Networking is the policy listed in Let network admins manage a cloud network. It covers the cloud network and all the other Networking components (subnets, security lists, route tables, gateways, and so on). To also give network admins the ability to launch instances (to test network connectivity), see Let users launch Compute instances.

If you're new to policies, see Getting Started with Policies and Common Policies.

For reference material for writing more detailed policies for Networking, see Details for the Core Services.

Individual Resource-Types

If you'd like, you can write policies that focus on individual resource-types (for example, just security lists) instead of the broader `virtual-network-family`. Be aware that the `instance-family` resource-type also includes several permissions for VNICs, which reside in a subnet

but attach to an instance. For more information, see For instance-family Resource Types and Virtual Network Interface Cards (VNICs).

There's a resource-type called `local-peering-gateways` that is included within `virtual-network-family` and includes two other resource-types related to local VCN peering (within region):

- `local-peering-from`
- `local-peering-to`

The `local-peering-gateways` resource-type covers all permissions related to local peering gateways (LPGs). The `local-peering-from` and `local-peering-to` resource-types are for granting permission to *connect* two LPGs and form a peering relationship within a single region. For more information, see Local VCN Peering (Within Region).

Similarly, there's a resource-type called `remote-peering-connections` that is included within `virtual-network-family` and includes two other resource-types related to remote VCN peering (across regions):

- `remote-peering-from`
- `remote-peering-to`

The `remote-peering-connections` resource-type covers all permissions related to remote peering connections (RPCs). The `remote-peering-from` and `remote-peering-to` resource-types are for granting permission to *connect* two RPCs and form a peering relationship across regions. For more information, see Remote VCN Peering (Across Regions).

Nuances of Different Verbs

If you'd like, you can write policies that limit the level of access by using a different policy verb (`manage` versus `use`, and so on). If you do, there are some nuances to understand about the policy verbs for Networking.

Be aware that the `inspect` verb not only returns general information about the cloud network's components (for example, the name and OCID of a security list, or of a route table). It also includes the contents of the component (for example, the actual rules in the security list, the routes in the route table, and so on).

Also, the following types of abilities are available only with the `manage` verb, not the `use` verb:

- Update (enable/disable) `internet-gateways`
- Update `security-lists`
- Update `route-tables`
- Update `dhcp-options`
- Attach a dynamic routing gateway (DRG) to a virtual cloud network (VCN)
- Create an IPSec connection between a DRG and customer-premises equipment (CPE)
- Peer VCNs

Important

Each VCN has various components that directly affect the behavior of the network (route tables, security lists, DHCP options, Internet Gateway, and so on). When you create one of these components, you establish a relationship between that component and the VCN, which means you must be allowed in a policy to both create the component and manage the VCN itself. However, the ability to *update* that component (to change the route rules, security list rules, and so on) does NOT require permission to manage the VCN itself, even though changing that component can directly affect the behavior of the network. This discrepancy is designed to give you flexibility in granting least privilege to users, and not require you to grant excessive access to the VCN just so the user can manage other components of the network. Be aware that by giving someone the ability to update a particular type of component, you're implicitly trusting them with controlling the network's behavior.

For more information about policy verbs, see Verbs.

Security Rules

The Networking service offers two virtual firewall features that both use *security rules* to control traffic at the packet level. The two features are:

- **Security lists:** The original virtual firewall feature from the Networking service.
- **Network security groups (NSGs):** A subsequent feature designed for application components that have different security postures. NSGs are supported only for specific services.

These two features offer different ways to apply security rules to a set of virtual network interface cards (VNICs) in the virtual cloud network (VCN).

This topic summarizes basic differences between the two features. It also explains important security rule concepts that you need to understand. How you create, manage, and apply security rules varies between security lists and network security groups. For implementation details, see these related topics:

- Security Lists
- Network Security Groups

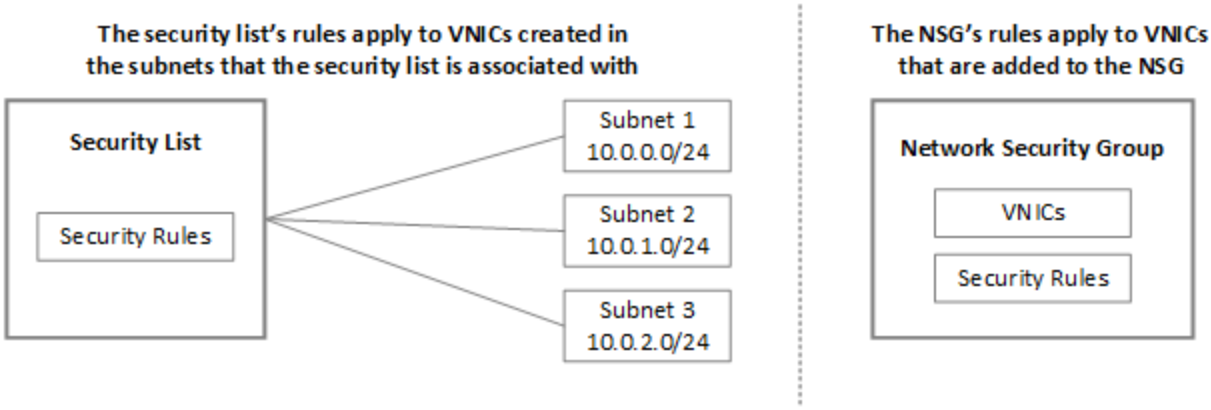
Comparison of Security Lists and Network Security Groups

Security lists let you define a set of security rules that applies to all the VNICs in an entire *subnet*. To use a given security list with a particular subnet, you *associate* the security list with the subnet either during subnet creation or later. A subnet can be associated with a maximum of five security lists. Any VNICs that are created in that subnet are subject to the security lists associated with the subnet.

Network security groups (NSGs) let you define a set of security rules that applies to a *group of VNICs of your choice* (or the VNICs' parent resources such as load balancers or DB systems). For example: the VNICs that belong to a set of Compute instances that all have the same security posture. To use a given NSG, you add the VNICs of interest to the group. Any VNICs

added to that group are subject to that group's security rules. A VNIC can be added to a maximum of five NSGs.

The following diagram illustrates the concept.



Oracle recommends using NSGs instead of security lists because NSGs let you separate the VCN's subnet architecture from your application security requirements.

However, you can use both security lists and NSGs together if you want. For more information, see If You Use Both Security Lists and Network Security Groups.

About VNICs and Parent Resources

A VNIC is a Networking service component that enables a networked resource such as a Compute instance to connect to a virtual cloud network (VCN). The VNIC determines how the instance connects with endpoints inside and outside the VCN. Each VNIC resides in a subnet in a VCN.

When you create a Compute instance, a VNIC is automatically created for the instance in the instance's subnet. The instance is considered to be the *parent resource* for the VNIC. You can add additional (secondary) VNICs to a Compute instance. For this reason, an instance's VNICs are displayed prominently as part of a Compute instance's related resources in the Console.

There are other types of parent resources that you can create that also result in a VNIC automatically being created. For example: when you create a load balancer, the Load Balancing service automatically creates VNICs for balancing traffic across the backend set. Also, when you create a DB system, the Database service automatically creates VNICs as DB system nodes. Those services create and manage those VNICs for you. For this reason, those VNICs are not readily apparent in the Console the same way VNICs are for Compute instances.

To use an NSG, you put VNICs of your choice into the group. However, you typically work *with the parent resource* when you add a VNIC to the group, not the VNIC itself. For example, when you create a Compute instance, you can optionally specify an NSG for the instance. Although you conceptually put the instance in the group, you're actually putting the instance's *primary VNIC* in the network security group. The group's security rules apply to that VNIC, not the instance. Also, if you add a secondary VNIC to the instance, you can optionally specify an NSG for that VNIC, and the rules apply to that VNIC, not the instance. Note that all the VNICs in a given NSG must be in the VCN that the NSG belongs to.

Likewise, when you put a load balancer in a network security group, you conceptually put the load balancer in the group. But you're actually putting VNICs managed by the Load Balancing service into the network security group.

You manage the VNIC membership of an NSG *at the parent resource*, and not at the NSG itself. In other words, to add a parent resource to an NSG, you execute the action on the *parent resource* (by specifying which NSGs the parent resource should be added to). You do not execute the action on the NSG (by specifying which VNICs or parent resources should be added to the NSG). Similarly, to remove a VNIC from an NSG, you execute that action by updating the parent resource, not the NSG. For example, to add an existing Compute instance's VNIC to an NSG, you update that VNIC's properties and specify the NSG. For example, with the REST API, you call `UpdateVnic`. In the Console, you view the instance and then the VNIC of interest, and then edit the VNIC's properties there.

For a list of parent resources that support the use of NSGs, see Support for Network Security Groups.

Network Security Group as Source or Destination of a Rule

There's an important difference in how you can write security rules for NSGs compared to security lists.

When writing rules for an NSG, you can specify an *NSG* as the source of traffic (for ingress rules) or the traffic's destination (for egress rules). Contrast this with security list rules, where you specify a *CIDR* as the source or destination.

The ability to specify an NSG means that you can easily write rules to control traffic between two different NSGs. The NSGs must be in the same VCN.

Also, if you want to control traffic between *VNICs in a specific NSG*, you can write rules that specify the *rule's own NSG* as the source (for ingress rules) or destination (for egress rules).

For more information, see Overview of Network Security Groups.

REST API Differences

There are a few basic differences in the REST API model for NSGs compared to security lists. For more information, see Using the API.

Default Rules

Your VCN automatically comes with a default security list that contains several default security rules to help you get started using the Networking service. When you create a subnet, the default security list is associated with the subnet unless you specify a custom security list that you've already created in the VCN. For comparison, the VCN does NOT have a default network security group.

Limits

The two features have different limits.

Security List Limits

Resource	Scope	Monthly Universal Credits	Pay-as-You-Go or Promo
Security lists	VCN	300	300
Security lists	Subnet	5*	5*
Security rules	Security list	200 ingress rules* and 200 egress rules*	200 ingress rules* and 200 egress rules*
* Limit for this resource cannot be increased			

Network Security Group Limits

Resource	Scope	Monthly Universal Credits	Pay-as-You-Go or Promo
Network security groups	VCN	1000	1000
VNICs	Network security group	A given network security group can have as many VNICs as are in the VCN. A given VNIC can belong to a maximum of 5 network security groups.*	A given network security group can have as many VNICs as are in the VCN. A given VNIC can belong to a maximum of 5 network security groups.*

Resource	Scope	Monthly Universal Credits	Pay-as-You-Go or Promo
Security rules	Network security group	120 (total ingress plus egress)	120 (total ingress plus egress)
* Limit for this resource cannot be increased			

Best Practices for Security Rules

Use Network Security Groups

Oracle recommends using NSGs for components that all have the same security posture. For example, in a multi-tier architecture, you would have a separate NSG for each tier. A given tier's VNICs would all belong to that tier's NSG. Within a given tier, you might have a particular subset of the tier's VNICs that have additional, special security requirements. Therefore you would create another NSG for those additional rules, and place that subset of VNICs into both the tier's NSG and the additional NSG.

Oracle also recommends using NSGs because Oracle will prioritize NSGs over security lists when implementing future enhancements.

Get Familiar with the Default Security List Rules

Your VCN automatically comes with a default security list that contains several default security rules to help you get started using the Networking service. Those rules exist because they enable basic connectivity. Even if you choose not to use security lists or the default security list, get familiar with the rules so you better understand the types of traffic that your networked cloud resources require. You might want to use those rules in your NSGs or any custom security lists that you set up.

The default security list does not include rules to enable ping. If you need to use ping, see Rules to Enable Ping.

Don't Delete Default Security Rules Indiscriminately

Your VCN might have subnets that use the default security list by default. Do not delete any of the list's default security rules unless you've first confirmed that resources in your VCN do not require them. Otherwise, you might disrupt your VCN's connectivity.

Confirm That Your OS Firewall Rules Align with Your Security Rules

Your instances running Oracle-provided Linux images or Windows images also have OS firewall rules that control access to the instance. When troubleshooting access to an instance, make sure that all of the following items are set correctly:

- The rules in the network security groups that the instance is in
- The rules in the security lists associated with the instance's subnet
- The instance's OS firewall rules

For more information, see Oracle-Provided Images.

If your instance is running Oracle Linux 7, you need to use firewalld to interact with the iptables rules. For your reference, here are commands for opening a port (1521 in this example):

```
sudo firewall-cmd --zone=public --permanent --add-port=1521/tcp

sudo firewall-cmd --reload
```

For instances with an iSCSI boot volume, the preceding `--reload` command can cause problems. For details and a workaround, see Instances experience system hang after running firewall-cmd --reload.

Use VNIC Metrics to Troubleshoot Packets Dropped Because of Security Rules

The Networking service offers metrics for VNICs, which show the levels of VNIC traffic (packets and bytes). Two of the metrics are for ingress and egress packets that violate security rules and are therefore dropped. You can use these metrics to help you troubleshoot issues related to security rules and whether your VNICs are receiving the desired traffic.

If You Use Both Security Lists and Network Security Groups

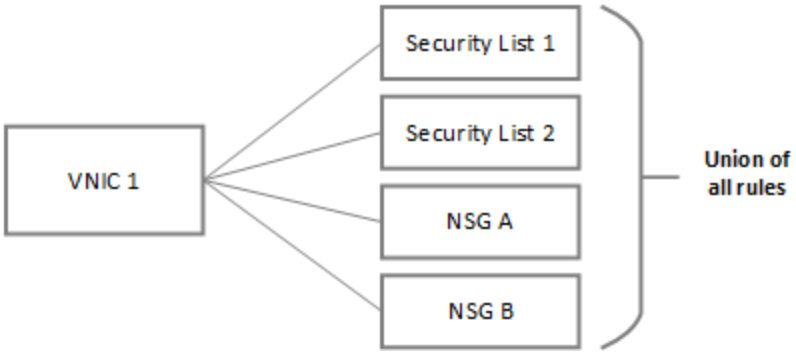
You can use security lists alone, network security groups alone, or both together. It depends on your particular security needs.

If you have security rules that you want to enforce for *all VNICs in a VCN*: the easiest solution is to put the rules in one security list, and then associate that security list with all subnets in the VCN. This way you can ensure that the rules are applied, regardless of who in your organization creates a VNIC in the VCN. If you like, you can use the VCN's default security list, which automatically comes with the VCN and contains a set of essential rules by default.

If you choose to use *both* security lists and network security groups, the set of rules that applies to a given VNIC is the union of these items:

- The security rules in the security lists associated with the VNIC's subnet
- The security rules in all NSGs that the VNIC is in

The following diagram is a simple illustration of the idea.



A packet in question is allowed if *any rule in any of the relevant lists and groups* allows the traffic (or if the traffic is part of an existing connection being tracked). There's a caveat if the lists happen to contain both stateful and stateless rules that cover the same traffic. For more information, see Stateful Versus Stateless Rules.

Parts of a Security Rule

A security rule **allows** a particular type of traffic in or out of a VNIC. For example, a commonly used security rule allows ingress TCP port 22 traffic for establishing SSH connections to the instance (more specifically to the instance's VNICs). Without security rules, no traffic is allowed in and out of VNICs in the VCN.

Note

Security rules are not enforced for traffic involving the 169.254.0.0/16 CIDR block, which includes services such as iSCSI and instance metadata.

Each security rule specifies the following items:

- **Direction (ingress or egress):** Ingress is inbound traffic to the VNIC, and egress is outbound traffic from the VNIC. The REST API model for security lists is different from network security groups. With security lists, there is an `IngressSecurityRule` object and a separate `EgressSecurityRule` object. With network security groups, there is only a `SecurityRule` object, and the object's `direction` attribute determines whether the rule is for ingress or egress traffic.
- **Stateful or stateless:** If stateful, connection tracking is used for traffic matching the rule. If stateless, no connection tracking is used. See Stateful Versus Stateless Rules.
- **Source type and source (ingress rules only):** The source you provide for an ingress rule depends on the source type you choose.

Allowed source types

Source Type	Allowed Source
CIDR	The CIDR block where the traffic originates from. Use 0.0.0.0/0 to indicate all IP addresses. The prefix is required (for example, include the /32 if specifying an individual IP address).
Network Security Group	An NSG that is in the same VCN as this rule's NSG. This source type is available only if the rule belongs to an NSG and not a security list.
Service	Only for packets coming from an Oracle service through a service gateway. The source service is the service CIDR label that you're interested in.

- **Destination type and destination (egress rules only):** The destination you provide for an egress rule depends on the destination type you choose.

Allowed destination types

Destination Type	Allowed Destination
CIDR	The CIDR block where the traffic is destined to. Use 0.0.0.0/0 to indicate all IP addresses. The prefix is required (for example, include the /32 if specifying an individual IP address).
Network Security Group	An NSG that is in the same VCN as this rule's NSG. This destination type is available only if the rule belongs to an NSG and not a security list.
Service	Only for packets going to an Oracle service through a service gateway. The destination service is the service CIDR label that you're interested in.

- **IP Protocol:** Either a single IPv4 protocol or "all" to cover all protocols.
- **Source port:** The port where the traffic originates from. For TCP or UDP, you can specify all source ports, or optionally specify a single source port number, or a range.
- **Destination port:** The port where the traffic is destined to. For TCP or UDP, you can specify all destination ports, or optionally specify a single destination port number, or a range.
- **ICMP type and code:** For ICMP, you can specify all types and codes, or optionally specify a single type with an optional code. If the type has multiple codes, create a separate rule for each code you want to allow.
- **Description** (NSG rules only): NSG security rules include an optional attribute where you can provide a friendly description of the rule. This is currently not supported for security list rules.

For examples of security rules, see Networking Scenarios.

For the limit on the number of rules you can have, see Limits.

Note

If you're using NSGs, and two VNICs that are in the same VCN need to communicate *using their public IP addresses*, you must use the VNIC's public IP address and not the VNIC's NSG as the source (for ingress) or destination (for egress) in the relevant security rules. The packet is routed to the VCN's internet gateway, and at that point, the VNIC's NSG information is not available. Therefore a security rule that specifies the NSG as the source or destination will be ineffective in allowing that specific type of traffic.

Stateful Versus Stateless Rules

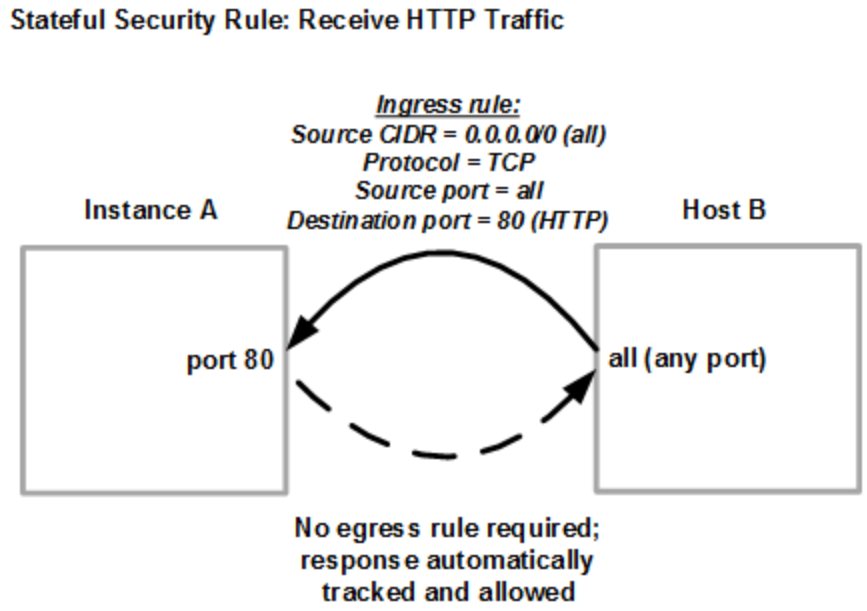
When you create a security rule, you choose whether it's *stateful* or *stateless*. The difference is described in the next sections. The default is stateful. Stateless rules are recommended if you have a high-volume internet-facing website (for the HTTP/HTTPS traffic).

This section refers specifically to Compute instances and their traffic. However, the discussion is applicable to all types of resources with VNICs. See About VNICs and Parent Resources.

Stateful Rules

Marking a security rule as stateful indicates that you want to use connection tracking for any traffic that matches that rule. This means that when an instance receives traffic matching the stateful ingress rule, the response is tracked and automatically allowed back to the originating host, regardless of any egress rules applicable to the instance. And when an instance sends traffic that matches a stateful egress rule, the incoming response is automatically allowed, regardless of any ingress rules. For more details, see Connection Tracking Details for Stateful Rules.

The figure below illustrates a stateful ingress rule for an instance that needs to receive and respond to HTTP traffic. Instance A and Host B are communicating (Host B could be any host, whether an instance or not). The stateful ingress rule allows traffic from any source IP address (0.0.0.0/0) to destination port 80 only (TCP protocol). No egress rule is required to allow the response traffic.

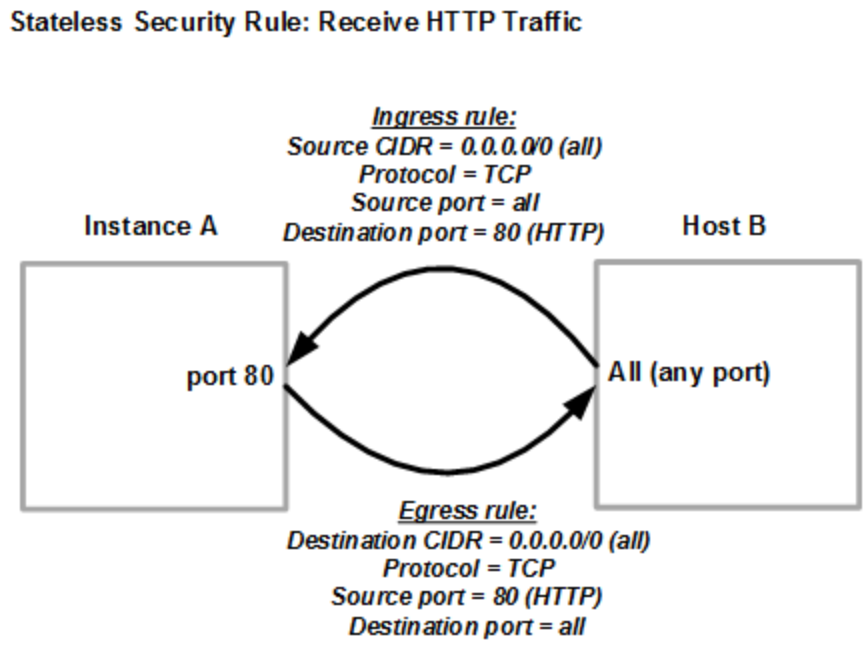


Stateless Rules

Marking a security rule as stateless indicates that you do NOT want to use connection tracking for any traffic that matches that rule. This means that response traffic is not automatically allowed. To allow the response traffic for a stateless ingress rule, you must create a corresponding stateless egress rule.

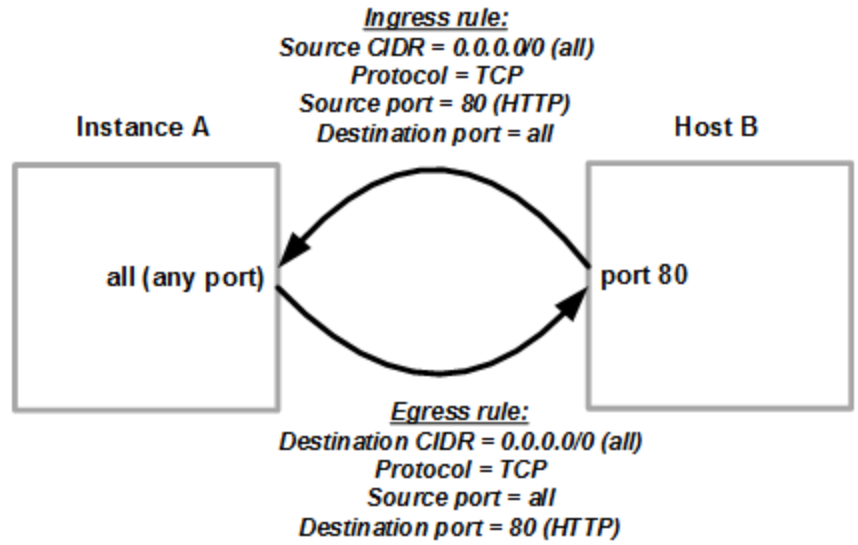
The next figure shows Instance A and Host B as before, but now with stateless security rules. As with the stateful rule in the preceding section, the stateless ingress rule allows traffic from all IP addresses and any ports, on destination port 80 only (using the TCP protocol). To allow the response traffic, there needs to be a corresponding stateless egress rule that allows traffic

to any destination IP address (0.0.0.0/0) and any ports, from source port 80 only (using the TCP protocol).



If Instance A needs instead to *initiate* HTTP traffic and get the response, then a different set of stateless rules are required. As the next figure shows, the egress rule would have source port = all and destination port = 80 (HTTP). The ingress rule would then have source port 80 and destination port = all.

Stateless Security Rule: Initiate HTTP Traffic



If you were to use port binding on Instance A to specify exactly which port the HTTP traffic would come from, you could specify that as the source port in the egress rule and the destination port in the ingress rule.

Note

If for some reason you use both stateful and stateless rules, and there's traffic that matches both a stateful and stateless rule in a particular direction (for example, ingress), the stateless rule takes precedence and the connection is not tracked. You would need a corresponding rule in the other direction (for example, egress, either stateless or stateful) for the response traffic to be allowed.

Connection Tracking Details for Stateful Rules

Oracle uses connection tracking to allow responses for traffic that matches stateful rules (see Stateful Versus Stateless Rules). Each instance has a maximum number of concurrent connections that can be tracked, based on the instance's shape.

To determine response traffic for TCP, UDP, and ICMP, Oracle performs connection tracking on these items for the packet:

- Protocol
- Source and destination IP addresses
- Source and destination ports (for TCP and UDP only)

Note

For other protocols, Oracle tracks only the protocol and IP addresses, and not the ports. This means that when an instance initiates traffic to another host and that traffic is allowed by egress security rules, any traffic that the instance subsequently receives from that host for a period is considered response traffic and is allowed.

Enabling Path MTU Discovery Messages for Stateless Rules

If you decide to use stateless security rules to allow traffic to/from endpoints outside the VCN, it's important to add a security rule that allows ingress ICMP traffic type 3 code 4 from source 0.0.0.0/0 and any source port. This rule enables your instances to receive Path MTU Discovery fragmentation messages. This rule is critical for establishing a connection to your instances. Without it, you can experience connectivity issues. For more information, see Hanging Connection.

Rules to Enable Ping

The VCN's default security list contains several default rules, but not one to allow ping requests. If you want to ping an instance, make sure the instance's applicable security lists or NSGs include an *additional* stateful ingress rule to specifically allow ICMP traffic type 8 from the source network you plan to ping from. To allow ping access from the internet, use 0.0.0.0/0 for the source. Note that this rule for pinging is separate from the default ICMP-related rules in the default security list. Do not remove those rules.

Rules to Handle Fragmented UDP Packets

Instances can send or receive UDP traffic. If a UDP packet is too large for the connection, it is fragmented. However, only the first fragment from the packet contains the protocol and port

information. If the security rules that allow this ingress or egress traffic specify a particular port number (source or destination), the fragments after the first one are dropped. If you expect your instances to send or receive large UDP packets, set both the source and destination ports for the applicable security rules to ALL (instead of a particular port number).

Network Security Groups

The Networking service offers two virtual firewall features to control traffic at the packet level:

- **Network security groups:** Covered in this topic. Network security groups are supported only for specific services.
- **Security lists:** The original type of virtual firewall offered by the Networking service. See Security Lists.

Both of these features use *security rules*. For important information about how security rules work, and a general comparison of security lists and network security groups, see Security Rules.

Highlights

- Network security groups (NSGs) act as a virtual firewall for your Compute instances and other kinds of resources. An NSG consists of a set of ingress and egress security rules that apply only to *a set of VNICs of your choice in a single VCN* (for example: all the Compute instances that act as web servers in the web tier of a multi-tier application in your VCN).
- Compared to security lists, NSGs let you separate your VCN's subnet architecture from your application security requirements. See Comparison of Security Lists and Network Security Groups.
- At this time, you can use NSGs with Compute instances, load balancers, and DB systems. For more information, see Support for Network Security Groups.
- NSG security rules function the same as security list rules. However, for an NSG security rule's source (for ingress rules) or destination (for egress rules), you can

specify an NSG instead of a CIDR. This means you can easily write security rules to control traffic between two NSGs *in the same VCN*, or traffic within a single NSG. See Parts of a Security Rule.

- Unlike with security lists, the VCN does not have a default NSG. Also, each NSG you create is initially empty. It has no default security rules.
- Network security groups have separate and different limits compared to security lists. See Limits.

Support for Network Security Groups

NSGs are available for you to create and use. However, they are not yet supported by all the relevant Oracle Cloud Infrastructure services.

Currently, the following types of parent resources support the use of NSGs:

- **Compute instances:** When you create an instance, you can specify one or more NSGs for the instance's primary VNIC. If you add a secondary VNIC to an instance, you can specify one or more NSGs for that VNIC. You can also update existing VNICs on an instance so that they are in one or more NSGs.
- **Load balancers:** When you create a load balancer, you can specify one or more NSGs for the load balancer (not the backend set). You can also update an existing load balancer to use one or more NSGs.
- **DB systems:** When you create a DB system, you can specify one or more NSGs. You can also update an existing DB system to use one or more NSGs.
- **Autonomous Databases:** When you create an Autonomous Database using the dedicated deployment option, you can specify one or more NSGs. You can also update an existing dedicated deployment to use NSGs.

For resource types that do not yet support NSGs, continue to use security lists to control traffic in and out of those parent resources.

Overview of Network Security Groups

A network security group (NSG) provides a virtual firewall for a set of cloud resources that all have the same security posture. For example: a group of Compute instances that all perform the same tasks and thus all need to use the same set of ports.

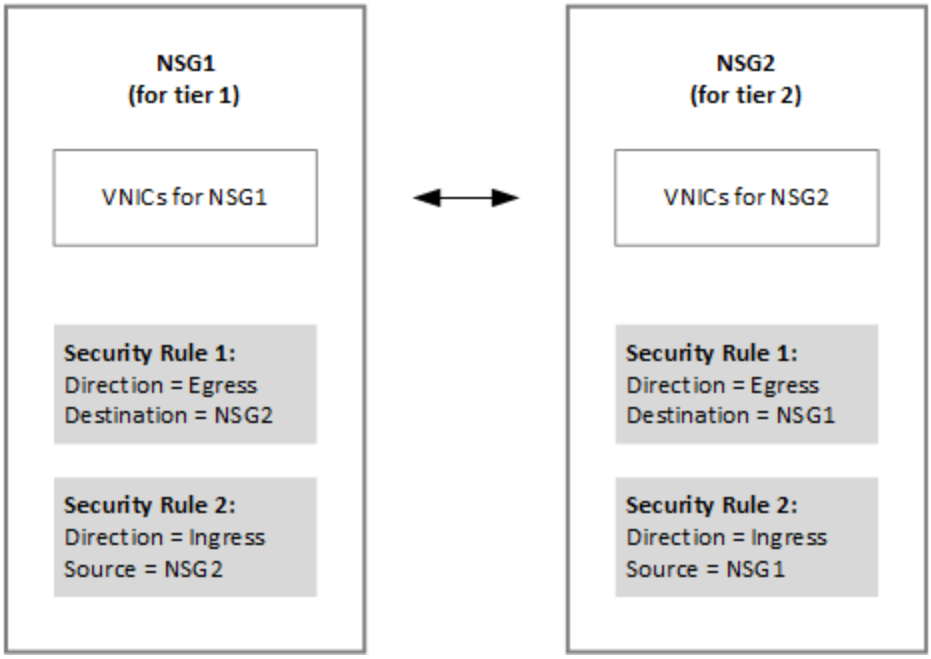
An NSG consists of two types of items (as illustrated in the following diagram):

- **VNICs:** One or more VNICs (for example, the VNICs attached to the set of Compute instances that all have the same security posture). All the VNICs must be in the VCN that the NSG belongs to. Also see About VNICs and Parent Resources.
- **Security rules:** Security rules that define the types of traffic allowed in and out of the VNICs in the group. For example: ingress TCP port 22 SSH traffic from a particular source.

If you have resources with different security postures *in the same VCN*, you can write NSG security rules to control traffic between the resources with one posture versus another. For example, in the following diagram, NSG1 has VNICs running in one tier of a multi-tier architecture application. NSG2 has VNICs running in a second tier. Both NSGs must belong to the same VCN. The assumption is that both NSGs need to initiate connections to the other NSG.

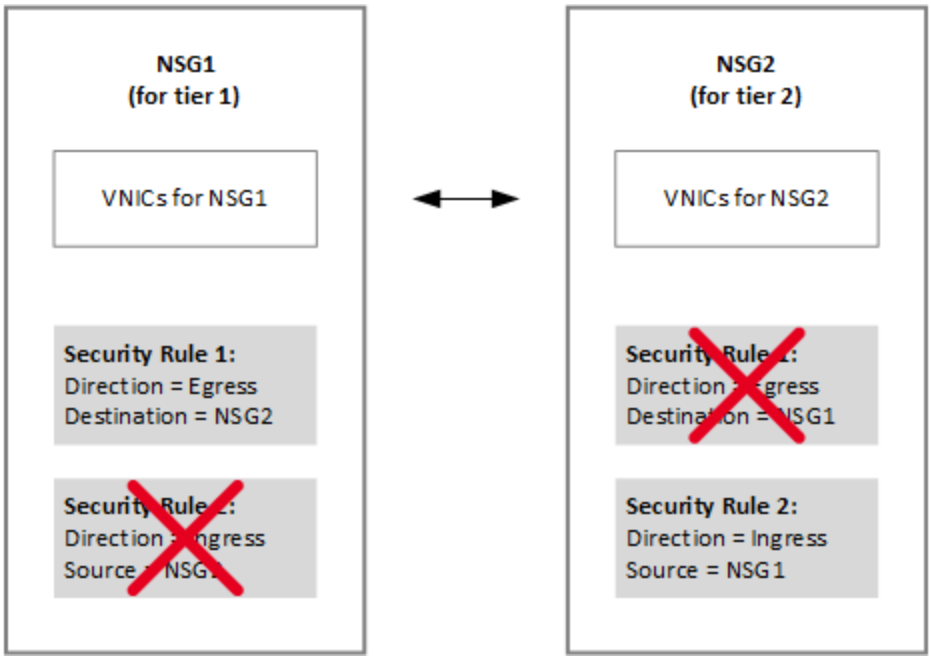
For NSG1, you set up egress security rules that specify NSG2 as the destination, and ingress security rules that specify NSG2 as the source. Likewise for NSG2, you set up egress security

rules that specify NSG1 as the destination, and ingress security rules that specify NSG1 as the source. The rules are assumed to be stateful in this example.

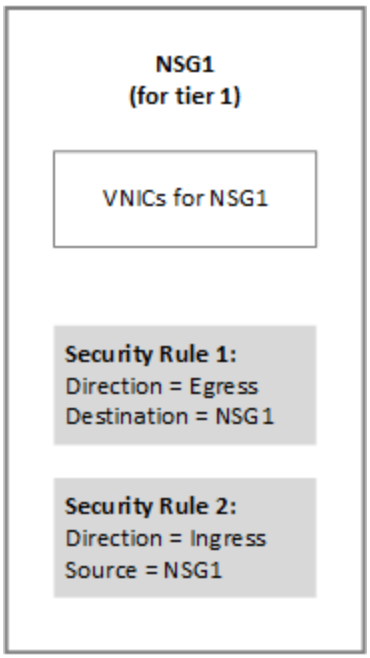


The preceding diagram assumes that each NSG needs to initiate connections to the other NSG.

The next diagram assumes that you instead want to only allow connections initiated from NSG1 to NSG2. To do that, remove the ingress rule from NSG1 and the egress rule from NSG2. The remaining rules do not allow connections initiated from NSG2 to NSG1.



The next diagram assumes that you want to control traffic between VNICs *in the same NSG*. To do that, set the rule's source (for ingress) or destination (for egress) as the rule's own NSG.



A VNIC can be in a maximum of five NSGs. A packet in question is allowed if *any rule in any of the VNIC's NSGs* allows the traffic (or if the traffic is part of an existing connection being tracked). There's a caveat if the lists happen to contain both stateful and stateless security rules that cover the same traffic. For more information, see Stateful Versus Stateless Rules.

Network security groups are regional entities. For limits related to network security groups, see Limits.

Security Rules

If you're not yet familiar with the basics of NSG security rules, see these sections in the security rules topic:

- Parts of a Security Rule
- Stateful Versus Stateless Rules

Working with Network Security Groups

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

General Process for Working with NSGs

1. Create an NSG.
2. Add security rules to the NSG.
3. Add parent resources (or more specifically, VNICs) to the NSG. You can do this when you create the parent resource, or you can update the parent resource and add it to one or more NSGs. When you create a Compute instance and add it to an NSG, the instance's primary VNIC is added to the NSG. Separately, you can create secondary VNICs and optionally add them to NSGs.

Before deleting an NSG, you must remove all VNICs from it.

See the next sections for more details.

Creating NSGs

Each VCN comes with a default security list that has default security rules in it to enable basic connectivity. However, there is no default NSG in the VCN.

When you create an NSG, it is initially empty, without any security rules or VNICs. If you're using the Console, you can add security rules to the NSG during creation.

You may optionally assign a friendly name to the NSG during creation. It doesn't have to be unique, and you can change it later. Oracle automatically assigns the NSG a unique identifier called an Oracle Cloud ID (OCID). For more information, see Resource Identifiers.

For the purposes of access control, you must specify the compartment where you want the NSG to reside. Consult an administrator in your organization if you're not sure which compartment to use. For more information, see Access Control.

Updating Security Rules and Group Membership

After the NSG is created, you can add or remove security rules to allow the types of ingress and egress traffic that the VNICs in the group require.

If you're familiar with security lists and use the REST API, note that the model for *updating* existing security rules is different between security lists and NSGs. With NSGs, each rule in a given group has a unique Oracle-assigned identifier (example: 04ABEC). When you call `UpdateNetworkSecurityGroupSecurityRules`, you provide the IDs of the specific rules that you want to update. For comparison, with security lists, the rules have no unique identifier. When you call `UpdateSecurityList`, you must pass in the *entire* list of rules, including rules that are not being updated in the call.

When you manage an NSG's VNIC membership, you do it as part of working with the parent resource, not the NSG itself. For more information, see About VNICs and Parent Resources.

Specifying an NSG in a Security Rule

As mentioned earlier in Overview of Network Security Groups, you can specify an NSG as the source (for ingress rules) or destination (for egress rules) in a given NSG's security rule. The two NSGs must be in the same VCN. For example, if both NSG1 and NSG2 belong to the same VCN, you could add an ingress rule to NSG1 that lists NSG2 as the source. If someone deletes NSG2, the rule becomes invalid. The REST API uses an `isValid` Boolean in the `SecurityRule` object to convey that status.

Deleting NSGs

To delete an NSG, it must not contain any VNICs or parent resources. When a parent resource (or a Compute instance VNIC) is deleted, it is automatically removed from the NSGs it was in. You might not have permission to delete a particular parent resource. Contact your administrator to determine who owns a given resource.

The Console displays a list of parent resources that are in an NSG, with a link to each parent resource. If the parent resource is a Compute instance, the Console also displays the instance's VNIC or VNICs that are in the NSG.

To remove a parent resource from its NSGs without deleting the resource, first view the parent resource's details in the Console. There you can see a list of the NSGs that the resource belongs to. From there, you can click **Edit** and remove the resource from all NSGs. If you're instead working with a Compute instance, view the details of the specific VNIC that you want to remove from the NSGs.

If you're using the REST API: the `ListNetworkSecurityGroupVnics` lists the parent resources and VNICs in an NSG. Use the resource's Update operation to remove the resource from NSGs. For example, for a Compute instance, use the `UpdateVnic` operation . For a load balancer, use the `UpdateNetworkSecurityGroups` operation, and so on.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: The policy in Let network admins manage a cloud network covers management of all Networking components, including NSGs.

If you have security admins who need to manage NSGs but not other components in the Networking service, you could write a more restrictive policy:

```
Allow group NSGAdmins to manage network-security-groups in tenancy

Allow group NSGAdmins to manage vcns in tenancy

Allow group NSGAdmins to use VNICs in tenancy
```

The first statement lets the NSGAdmins group create and manage NSGs and their security rules.

The second statement is required because the creation of an NSG affects the VCN that the NSG is in. The scope of the second statement *also* allows the NSGAdmins group to create VCNs. However, the group can't create subnets or manage any other components related to any of those VCNs (except for the NSGs), because additional permissions would be required for those resources. The NSGAdmins group also can't delete any existing VCNs that already have subnets in them, because that action would require permissions related to subnets.

The third statement is required if the NSGAdmins need to put VNICs into an NSG. Whoever creates the parent resource of the VNIC (for example, a Compute instance) must already have this level of permission to create the parent resource.

For more information, see IAM Policies for Networking.

Using the Console

To view the security rules and resources in an NSG

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Under **Resources**, click **Network Security Groups.**
4. Click the NSG you're interested in to view its details.
   The NSG's security rules are displayed on the page. From there you can add, edit, or remove rules.
5. Under **Resources**, click **VNICs** to see the parent resources that belong to the NSG.
   If the parent resource is a Compute instance, the corresponding VNICs from that instance are also listed on the page.
   For other types of parent resources, the relevant service manages the VNICs on your behalf. Therefore only the parent resource (and not its corresponding VNICs) is listed on the page.

To create an NSG

Prerequisite: Become familiar with the parts of security rules.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Under **Resources**, click **Network Security Groups**.
4. Click **Create Network Security Group**.
5. Enter the following:
    a. **Name:** A descriptive name for the network security group. The name doesn't have to be unique, and you can change it later. Avoid entering confidential information.
    b. **Create in Compartment:** The compartment where you want to create the network security group, if different from the compartment you're currently working in.
    c. **Show Tagging Options:** Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.
6. Click **Next**.
   If you want to create the NSG without any rules yet, click **Create** and you're done. Otherwise proceed to the next step.
7. For the first security rule, enter the following items (for examples of rules, see Networking Scenarios):
    - **Stateful or stateless:** If stateful, connection tracking is used for traffic matching the rule. If stateless, no connection tracking is used. By default, rules

are stateful unless you specify otherwise. See Stateful Versus Stateless Rules.

- **Direction (ingress or egress):** Ingress is inbound traffic to the VNIC, and egress is outbound traffic from the VNIC.
- **Source Type** and **Source** (for ingress rules only):

Allowed source types

Source Type	Allowed Source
CIDR	The CIDR block where the traffic originates from. Use 0.0.0.0/0 to indicate all IP addresses. The prefix is required (for example, include the /32 if specifying an individual IP address).
Service	Only for packets coming from an Oracle service through a service gateway. The source service is the service CIDR label that you're interested in.
Network Security Group	An NSG that is in the same VCN as this rule's NSG.

- **Destination Type** and **Destination** (for egress rules only):

Allowed destination types

Destination Type	Allowed Destination
CIDR	The CIDR block where the traffic is destined to. Use 0.0.0.0/0 to indicate all IP addresses. The prefix is required (for example, include the /32 if specifying an individual IP address).
Service	Only for packets going to an Oracle service through a service gateway. The destination service is the service CIDR label that you're interested in.
Network Security Group	An NSG that is in the same VCN as this rule's NSG.

- **IP Protocol:** Either a single IPv4 protocol (for example, TCP or ICMP) or "all" to cover all protocols.
- **Source port range:** The port where the traffic originates from. For TCP or UDP, you can specify all source ports, or optionally specify a single source port number, or a range.
- **Destination port range:** The port where the traffic is destined to. For TCP or UDP, you can specify all destination ports, or optionally specify a single destination port number, or a range.
- **ICMP type and code:** For ICMP, you can specify all types and codes, or optionally specify a single type with an optional code. If the type has multiple codes, create a separate rule for each code you want to allow.

8. To add another security rule, click **+ Another Rule** and enter the rule's information. Repeat for each rule you want to add.

9. When you're done, click **Create**.

The NSG is created and then displayed on the **Network Security Group** page in the compartment you chose. You can now specify this NSG when creating or managing instances or other types of parent resources.

When you view all the security rules in an NSG, you can filter the list by ingress or egress.

To add or remove a resource from an NSG

In general, you manage the resource membership of an NSG *at the parent resource*, and not at the NSG itself. In other words, to add a parent resource to an NSG, you execute the action on the *parent resource* (by specifying which NSGs the parent resource should be added to). You do not execute the action on the NSG (by specifying which VNICs or parent resources should be added to the NSG). Similarly, to remove a VNIC from an NSG, you execute that action by updating the parent resource, not the NSG. For a list of the parent resources that support the use of NSG, see Support for Network Security Groups.

Example: Compute instances

- **When creating an instance:** In the **Configure networking** section, select the check box for **Use network security groups to control traffic**, and then specify one or more NSGs. The instance's primary VNIC is added to the NSGs. See the procedure in Creating an Instance.
- **For an existing instance:** Adding an existing instance to an NSG means adding its *primary VNIC* to the NSG. You can also add a secondary VNIC to an NSG. See To add or remove a VNIC from a network security group.

Example: Exadata DB systems

- **When creating an Exadata DB system:** In the **Network Information** section, you set up the client network and backup network. For each network, select the check box

for **Use network security groups to control traffic**, and then specify one or more NSGs for the specific network. See To create an Exadata DB system. Also see Network Setup for Exadata DB Systems.

- **For an existing Exadata DB system:** An Exadata's details include a list of the NSGs that the client network belongs to (if any), and a list of the NSGs that the backup network belongs to (if any). Next to the relevant **Network Security Groups**, click **Edit** to change that list. See To edit the network security groups (NSGs) for your client or backup network.

To delete an NSG

Prerequisite: To delete a security list, it must not be associated with a subnet . You can't delete the default security list in a VCN.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Under **Resources**, click **Security Lists**.
4. For the security list you want to delete, click the Actions icon (three dots), and then click **Terminate**.
5. Confirm when prompted.

To manage security rules for an NSG

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Under **Resources**, click **Network Security Groups.**
4. Click the NSG you're interested in to view its details.

The NSG's security rules are displayed on the page. From there you can add, edit, or remove rules.

To manage tags for an NSG

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Under **Resources**, click **Network Security Groups**.
4. Click the NSG you're interested in.
5. Click the **Tags** tab to view or edit the existing tags. Or click **Add tags** to add new ones.

For more information, see Resource Tags.

To move an NSG to a different compartment

You can move an NSG from one compartment to another. When you move an NSG to a new compartment, inherent policies apply immediately.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Under **Resources**, click **Network Security Groups**.
4. Click the the Actions icon (three dots) for the NSG, and then click **Move Resource**.
5. Choose the destination compartment from the list.
6. Click **Move Resource**.

For more information about using compartments and policies to control access to your cloud network, see Access Control. For general information about compartments, see Managing Compartments.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

To manage a VCN's network security groups, use these operations:

- ListNetworkSecurityGroups
- GetNetworkSecurityGroup
- UpdateNetworkSecurityGroup
- CreateNetworkSecurityGroup
- DeleteNetworkSecurityGroup
- ChangeNetworkSecurityGroupCompartment
- ListNetworkSecurityGroupVnics
- ListNetworkSecurityGroupSecurityRules
- AddNetworkSecurityGroupSecurityRules
- RemoveNetworkSecurityGroupSecurityRules
- UpdateNetworkSecurityGroupSecurityRules

There are some differences in the REST API model for NSGs compared to security lists:

- With security lists, there is an `IngressSecurityRule` object and a separate `EgressSecurityRule` object. With network security groups, there is only a `SecurityRule` object, and the object's `direction` attribute determines whether the rule is for ingress or egress traffic.
- With security lists, the rules are part of the `SecurityList` object, and you work with the rules by calling the security list operations (such as `UpdateSecurityList`). With NSGs, the rules are not part of the `NetworkSecurityGroup` object. Instead you use separate operations to work with the rules for a given NSG (example: `UpdateNetworkSecurityGroupSecurityRules`).

- The model for *updating* existing security rules is different between security lists and NSGs. With NSGs, each rule in a given group has a unique Oracle-assigned identifier (example: 04ABEC). When you call `UpdateNetworkSecurityGroupSecurityRules`, you provide the IDs of the specific rules that you want to update. For comparison, with security lists, the rules have no unique identifier. When you call `UpdateSecurityList`, you must pass in the *entire* list of rules, including rules that are not being updated in the call.
- There is a limit of 25 rules when calling the operations to add, remove, or update security rules.

Security Lists

The Networking service offers two virtual firewall features to control traffic at the packet level:

- **Security lists:** Covered in this topic. This is the original type of virtual firewall offered by the Networking service.
- **Network security groups:** Another type of virtual firewall that Oracle recommends over security lists. See Network Security Groups.

Both of these features use *security rules*. For important information about how security rules work, and a general comparison of security lists and network security groups, see Security Rules.

Highlights

- Security lists act as virtual firewalls for your Compute instances and other kinds of resources. A security list consists of a set of ingress and egress security rules that apply to all the VNICs *in any subnet that the security list is associated with*. This means that all the VNICs in a given subnet are subject to the same set of security lists. See Comparison of Security Lists and Network Security Groups.
- Security list rules function the same as network security group rules. For a discussion of rule parameters, see Parts of a Security Rule.

- Each VCN comes with a default security list that has several default rules for essential traffic. If you don't specify a custom security list for a subnet, the default security list is automatically used with that subnet. You can add and remove rules from the default security list.
- Security lists have separate and different limits compared to network security groups. See Limits.

Overview of Security Lists

A security list acts as a virtual firewall for an instance, with ingress and egress rules that specify the types of traffic allowed in and out. Each security list is enforced at the VNIC level. However, you configure your security lists *at the subnet level*, which means that all VNICs in a given subnet are subject to the same set of security lists. The security lists apply to a given VNIC whether it's communicating with another instance in the VCN or a host outside the VCN.

Each subnet can have multiple security lists associated with it, and each list can have multiple rules (for the maximum number, see Limits). A packet in question is allowed if *any rule in any of the lists* allows the traffic (or if the traffic is part of an existing connection being tracked). There's a caveat if the lists happen to contain both stateful and stateless rules that cover the same traffic. For more information, see Stateful Versus Stateless Rules.

Security lists are regional entities. For limits related to security lists, see Limits.

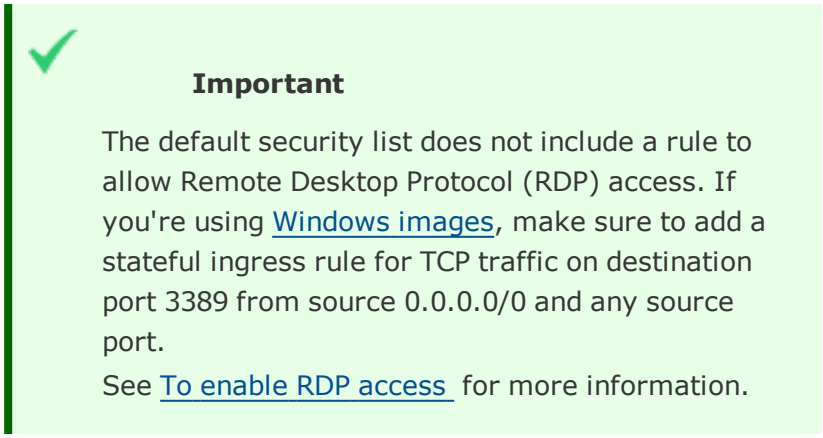
Security lists can control both IPv4 and IPv6 traffic. However, IPv6 addressing and related security list rules are currently supported only in the US Government Cloud. For more information, see IPv6 Addresses.

Default Security List

Each cloud network has a *default security list*. You can also create other security lists for the VCN. A given subnet automatically has the default security list associated with it if you don't specify one or more other security lists during subnet creation. At any time after you create a subnet, you can change which security lists are associated with it. And you can change the rules in the lists.

Unlike other security lists, the default security list comes with an initial set of stateful rules, which you can change:

- **Stateful ingress:** Allow TCP traffic on destination port 22 (SSH) from source 0.0.0.0/0 and any source port. This rule makes it easy for you to create a new cloud network and public subnet, launch a Linux instance, and then immediately use SSH to connect to that instance without needing to write any security list rules yourself.

- **Stateful ingress:** Allow ICMP traffic type 3 code 4 from source 0.0.0.0/0. This rule enables your instances to receive Path MTU Discovery fragmentation messages.
- **Stateful ingress:** Allow ICMP traffic type 3 (all codes) from source = your VCN's CIDR. This rule makes it easy for your instances to receive connectivity error messages from other instances within the VCN.
- **Stateful egress:** Allow all traffic. This allows instances to initiate traffic of any kind to any destination. Notice that this means the instances with public IP addresses can talk to any internet IP address if the VCN has a configured internet gateway. And because stateful security rules use connection tracking, the response traffic is automatically allowed regardless of any ingress rules. For more information, see Connection Tracking Details for Stateful Rules.

The default security list comes with no stateless rules. However, you can add or remove rules from the default security list as you like.

If your VCN is enabled for IPv6 addressing (which is currently supported in only the Government Cloud), the default security list contains some default rules for IPv6 traffic. For more information, see IPv6 Addresses.

Enabling Ping

The default security list does not include a rule to allow ping requests. If you plan to ping an instance, see Rules to Enable Ping.

Security Rules

If you're not yet familiar with the basics of security rules, see these sections in the security rules topic:

- Parts of a Security Rule
- Stateful Versus Stateless Rules

Working with Security Lists

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

General Process for Working with Security Lists

1. Create a security list.
2. Add security rules to the security list.
3. Associate the security list with one or more subnets.

4. Create resources in the subnet (for example, create Compute instances in the subnet). The security rules apply to all the VNICs in that subnet. See About VNICs and Parent Resources.

Additional Details

When you create a subnet, you must associate at least one security list with it. It can be either the VCN's default security list or one or more other security lists that you've already created (for the maximum number, see Service Limits). You can change which security lists the subnet uses at any time.

You may optionally assign a friendly name to the security list during creation. It doesn't have to be unique, and you can change it later. Oracle automatically assigns the security list a unique identifier called an Oracle Cloud ID (OCID). For more information, see Resource Identifiers.

For the purposes of access control, you must specify the compartment where you want the security list to reside. Consult an administrator in your organization if you're not sure which compartment to use. For more information, see Access Control.

You can move security lists from one compartment to another. Moving a security list doesn’t affect its attachment to a subnet. When you move a security list to a new compartment, inherent policies apply immediately and affect access to the security list. For more information, see Managing Compartments.

You can add and remove rules from the security list. A security list can have no rules. Notice that when you update a security list in the API, the new set of rules replaces the entire existing set of rules.

To delete a security list, it must not be associated with a subnet. You can't delete a VCN's default security list.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have

permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: The policy in Let network admins manage a cloud network covers management of all Networking components, including security lists.

If you have security admins who need to manage security lists but not other components in Networking, you could write a more restrictive policy:

```
Allow group SecListAdmins to manage security-lists in tenancy

Allow group SecListAdmins to manage vcns in tenancy
```

Both statements are needed because the creation of a security list affects the VCN the security list is in. The scope of the second statement *also* allows the SecListAdmins group to create VCNs. However, the group can't create subnets or manage any other components related to any of those VCNs (except for the security lists), because additional permissions would be required for those resources. The group also can't delete any existing VCNs that already have subnets in them, because that action would require permissions related to subnets.

For more information, see IAM Policies for Networking.

Using the Console

To view a VCN's default security list

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Under **Resources**, click **Security Lists.**
4. Click the default security list to view its details.
   Under **Resources**, you can click **Ingress Rules** or **Egress Rules** to switch between the different types of rules.

To update rules in an existing security list

Important

When updating the default security list, be aware of the default rules, the purpose each serves, and the consequences of deleting them. For example, deleting the default stateful egress rule can cause problems if the instances need to initiate connections.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Under **Resources**, click **Security Lists**.
4. Click the security list you're interested in.
5. Under **Resources**, click either **Ingress Rules** or **Egress Rules** depending on the type of rule you want to work with.
6. If you want to add a rule, click **Add Ingress Rule** (or **Add Egress Rule**). See details of adding a rule in To create a security list.
7. If you want to delete an existing rule, click the Actions icon (three dots), and then click **Remove**.
8. If you wanted to edit an existing rule, click the Actions icon (three dots), and then click **Edit**.

To create a security list

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.

3. Under **Resources**, click **Security Lists**.
4. Click **Create Security List**.
5. Enter the following:
    a. **Name:** A descriptive name for the security list. The name doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
    b. **Create in Compartment:** The compartment where you want to create the security list, if different from the compartment you're currently working in.
6. Add either an ingress rule or egress rule (for examples of rules, see Networking Scenarios):
    a. Click either **Add Ingress Rule** or **Add Egress Rule**.
    b. Choose whether it's a stateful or stateless rule (see Stateful Versus Stateless Rules). By default, rules are stateful unless you specify otherwise.
    c. Enter either the source CIDR (for ingress) or destination CIDR (for egress). For example, use 0.0.0.0/0 to indicate all IP addresses. Other typical CIDRs you might specify in a rule are the CIDR block for your on-premises network, or for a particular subnet. If you're setting up a security list rule to allow traffic with a service gateway, instead see Task 3: (Optional) Update security rules.
    d. Select the IP protocol (for example, TCP, UDP, ICMP, "All protocols", and so on).
    e. Enter further details depending on the protocol:
        - If you chose TCP or UDP, enter a source port range and destination port range. You can enter "All" to cover all ports. If you want to allow a specific port, enter the port number (for example, 22 for SSH or 3389 for RDP) or a port range (for example, 20–22).
        - If you chose ICMP, you can enter "All" to cover all types and codes. If you want to allow a specific ICMP type, enter the type and an optional code separated by a comma (for example, 3,4). If the type has multiple codes you want to allow, create a separate rule for each code.

7. Repeat the preceding step for each rule you want to add to the list.
8. **Tags:** Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.
9. When you're done, click **Create Security List**.

The security list is created and then displayed on the **Security Lists** page in the compartment you chose. You can now specify this security list when creating or updating a subnet.

When you view all the rules in a security list, notice that any stateless rules in the list are shown above any stateful rules. Stateless rules in the list take precedence over stateful rules. In other words: If there's traffic that matches both a stateless rule and a stateful rule across all the security lists associated with the subnet, the stateless rule takes precedence and the connection is not tracked.

To change which security lists a subnet uses

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Click **Subnets**.
4. Click the subnet you're interested in.
5. Under **Resources**, click **Security Lists**.
6. If you want to add a security list, click **Add Security List**, and select the new security list you want the subnet to use.
7. If you want to remove a security list, click the Actions icon (three dots), and then click **Remove**. Remember that a subnet must always have at least one security list associated with it.

   The changes take effect within a few seconds.

To move a security list to a different compartment

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Under **Resources**, click **Security Lists**.
4. Find the security list , click the the Actions icon (three dots), and then click **Move Resource**.
5. Choose the destination compartment from the list.
6. Click **Move Resource**.

To delete a security list

Prerequisite: To delete a security list, it must not be associated with a subnet . You can't delete the default security list in a VCN.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Under **Resources**, click **Security Lists**.
4. For the security list you want to delete, click the Actions icon (three dots), and then click **Terminate**.
5. Confirm when prompted.

To manage tags for a security list

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Under **Resources**, click **Security Lists**.

4. Click the security list you're interested in.
5. Click the **Tags** tab to view or edit the existing tags. Or click **Add tags** to add new ones.

For more information, see Resource Tags.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

To manage a VCN's security lists, use these operations:

- ListSecurityLists
- GetSecurityList
- UpdateSecurityList
- CreateSecurityList
- DeleteSecurityList
- ChangeSecurityListCompartment

Virtual Network Interface Cards (VNICs)

This topic describes how to manage the virtual network interface cards (VNICs) in a virtual cloud network (VCN).

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Overview of VNICs and Physical NICs

The servers in Oracle Cloud Infrastructure data centers have physical network interface cards (NICs). When you launch an instance on one of these servers, the instance communicates using Networking service *virtual* NICs (VNICs) associated with the physical NICs. The next sections talk about VNICs and NICs, and how they're related.

About VNICs

A VNIC enables an instance to connect to a VCN and determines how the instance connects with endpoints inside and outside the VCN. Each VNIC resides in a subnet in a VCN and includes these items:

- One *primary* private IPv4 address from the subnet the VNIC is in, chosen by either you or Oracle.
- Up to 31 optional *secondary* private IPv4 addresses from the same subnet the VNIC is in, chosen by either you or Oracle.
- An optional public IPv4 address for each private IP, chosen by Oracle but assigned by you at your discretion.
- An optional hostname for DNS for each private IP address (see DNS in Your Virtual Cloud Network).
- A MAC address.
- A VLAN tag assigned by Oracle and available when attachment of the VNIC to the instance is complete (relevant only for bare metal instances).
- A flag to enable or disable the source/destination check on the VNIC's network traffic (see Source/Destination Check).
- Optional membership in one or more network security groups (NSGs) of your choice. NSGs have security rules that apply only to the VNICs in that NSG.
- Up to 32 optional IPv6 addresses. IPv6 addressing is currently supported only in the US Government Cloud. For more information, see IPv6 Addresses.

Each VNIC also has a friendly name you can assign, and an Oracle-assigned OCID (see Resource Identifiers).

Each instance has a *primary VNIC* that is automatically created and attached during launch. That VNIC resides in the subnet you specify during launch. The primary VNIC cannot be removed from the instance.

How VNICs and Physical NICs Are Related

This section is relevant to bare metal instances.

The OS on a bare metal instance recognizes two physical network devices and configures them as two physical NICs, 0 and 1. Whether they're both active depends on the underlying hardware:

- **Oracle X5 servers (also called *first-generation*):** Only NIC 0 is active.
- **Oracle X6 servers:** Only NIC 0 is active.
- **Oracle X7 servers (also called *second-generation*):** Both NIC 0 and NIC 1 are active. Each physical NIC has 25 Gbps bandwidth.

NIC 0 is automatically configured with the primary VNIC's IP configuration (the IP addresses, DNS hostname, and so on).

If you add a *secondary VNIC* to a second-generation instance, you must specify which physical NIC the secondary VNIC should use. You must also configure the OS so that the physical NIC has the secondary VNIC's IP configuration. For Linux instances, see Linux: Configuring the OS for Secondary VNICs. For Windows instances, see Windows: Configuring the OS for Secondary VNICs.

About Secondary VNICs

You can add secondary VNICs to an instance after it's launched. Each secondary VNIC can be in a subnet in the same VCN as the primary VNIC, or in a different subnet that is either in the same VCN or a different one. However, all the VNICs must be in the same availability domain as the instance.

Here are some reasons why you might use secondary VNICs:

- **Use your own hypervisor on a bare metal instance:** The virtual machines on the bare metal instance each have their own secondary VNIC, giving direct connectivity to other instances and services in the VNIC's VCN. For more information, see Installing and Configuring KVM on Bare Metal Instances with Multi-VNIC.
- **Connect an instance to subnets in multiple VCNs:** For example, you might set up your own firewall to protect traffic between VCNs, so the instance needs to connect to subnets in different VCNs.

Here are more details about secondary VNICs:

- They're supported for these types of instances:
  - **Linux:** Both VM and bare metal instances. Also see Linux: Configuring the OS for Secondary VNICs.
  - **Windows:** Both VM and bare metal instances, but only on X7/second-generation shapes (shapes with "2" in the name, such as VM.Standard 2.16 and BM.Standard2.52). For bare metal, secondary VNICs are supported only on the second physical NIC. Remember that the first physical NIC is NIC 0, and the second is NIC 1. Also see Windows: Configuring the OS for Secondary VNICs.
- There's a limit to how many VNICs can be attached to an instance, and it varies by shape. For those limits, see Compute Shapes.
- They can be added only after the instance is launched.
- They must always be attached to an instance and cannot be moved. The process of creating a secondary VNIC automatically attaches it to the instance. The process of detaching a secondary VNIC automatically deletes it.
- They are automatically detached and deleted when you terminate the instance.
- The instance's bandwidth is fixed regardless of the number of VNICs attached. You can't specify a bandwidth limit for a particular VNIC on an instance.
- Attaching multiple VNICs from the same subnet CIDR block to an instance can introduce asymmetric routing, especially on instances using a variant of Linux. If you need this

type of configuration, Oracle recommends assigning multiple private IP addresses to one VNIC, or using policy-based routing as shown in the script later in this topic.

Source/Destination Check

By default, every VNIC performs the source/destination check on its network traffic. The VNIC looks at the source and destination listed in the header of each network packet. If the VNIC is not the source or destination, then the packet is dropped.

If the VNIC needs to forward traffic (for example, if it needs to perform Network Address Translation (NAT)), you must disable the source/destination check on the VNIC. For instructions, see To update an existing VNIC. For information about the general scenario, see Using a Private IP as a Route Target.

VNIC Information in the Instance Metadata

The instance metadata includes information about the VNICs at this URL:

```
http://169.254.169.254/opc/v1/vnics/
```

Here's an example response that shows the VNICs that are attached to an instance:

```
[ {
  "vnicId" : "ocid1.vnic.oc1.phx.exampleuniqueID",
  "privateIp" : "10.0.3.6",
  "vlanTag" : 11,
  "macAddr" : "02:00:17:00:12:D3",
  "virtualRouterIp" : "10.0.3.1",
  "subnetCidrBlock" : "10.0.3.0/24",
  "nicIndex" : 0
}, {
  "vnicId" : "ocid1.vnic.oc1.phx.exampleuniqueID",
  "privateIp" : "10.0.4.3",
  "vlanTag" : 12,
  "macAddr" : "02:00:17:00:13:13",
  "virtualRouterIp" : "10.0.4.1",
  "subnetCidrBlock" : "10.0.4.0/24",
  "nicIndex" : 0
} ]
```

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

VNICs reside in a subnet but attach to an instance. The VNIC's *attachment to the instance* is a separate object from the VNIC or the instance itself. Be aware that the VNIC and subnet always exist together in the same compartment, but the VNIC's *attachment to the instance* always exists in the instance's compartment. This distinction isn't important if you have a simple access control scenario where all the cloud resources are in the same compartment (for example, for a proof-of-concept). When you move to a production implementation, you might decide to have network administrators manage the network, and other personnel administer instances. That means you might put instances in a different compartment than the subnet.

For administrators: see IAM Policies for Networking.

Monitoring VNICs

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications. For more information, see Monitoring Overview and Notifications Overview.

For information about monitoring the traffic coming in and out of VNICs, see VNIC Metrics.

Using the Console

To view an instance's VNICs

1. Confirm you're viewing the compartment that contains the instance you're interested in.
2. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.

3. Click the instance to view its details.
4. Under **Resources**, click **Attached VNICs**.
   The primary VNIC and any secondary VNICs attached to the instance are displayed. If the instance has two active physical NICs, the VNICs are grouped by NIC 0 and NIC 1.

To create and attach a secondary VNIC

1. Confirm you're viewing the compartment that contains the instance you're interested in.
2. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
3. Click the instance to view its details.
4. Under **Resources**, click **Attached VNICs**.
   The primary VNIC and any secondary VNICs attached to the instance are displayed.
5. Click **Create VNIC**.
6. In the **Create VNIC** dialog box, you specify which VCN and subnet to put the VNIC in. By default, the VNIC will be created in the current compartment, and you'll choose the VCN and subnet from the same compartment. Click the **click here** link in the dialog box if you want to enable compartment selection and choose a VCN or subnet in a different compartment.
   Enter the following:
   - **Name:** A friendly name for the secondary VNIC. The name doesn't have to be unique, and you can change it later. Avoid entering confidential information.
   - **Virtual Cloud Network Compartment:** The compartment that contains the VCN that in turn contains the subnet of interest.
   - **Virtual Cloud Network:** The VCN that contains the subnet of interest.
   - **Subnet Compartment:** The compartment that contains the subnet of interest.
   - **Subnet:** The subnet of interest. The secondary VNIC must be in the same availability domain as the instance's primary VNIC, so the subnet list includes any

regional subnets or AD-specific subnets in the primary VNIC's availability domain.

- **Physical NIC:** Only relevant if this is a bare metal instance with two active physical NICs. Select which one you want the secondary VNIC to use. When you later view the instance's details and the list of VNICs attached to the instance, they'll be grouped by NIC 0 and NIC 1.
- **Use network security groups to control traffic:** Select this check box to add the secondary VNIC to at least one network security group (NSG) of your choice. NSGs have security rules that apply only to the VNICs in that NSG.
- **Skip Source/Destination Check:** By default, this check box is NOT selected, which means the VNIC performs the source/destination check. Only select this check box if you want the VNIC to be able to forward traffic. See Source/Destination Check.
- **Private IP Address:** Optional. An available private IP address of your choice from the subnet's CIDR (otherwise the private IP address is automatically assigned).
- **Assign public IP address:** Whether to assign an ephemeral public IP address to the VNIC's primary private IP. Available only if the subnet is public. For more information, see Public IP Addresses.
- **Hostname:** Optional. A hostname to be used for DNS within the cloud network. Available only if the VCN and subnet both have DNS labels. For more information, see DNS in Your Virtual Cloud Network.
- **Tags:** Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.

7. Click **Create VNIC**.
   The secondary VNIC is created and then displayed on the **Attached VNICs** page for the instance. It can take several seconds before the secondary VNIC appears on the page.
8. Configure the OS to use the VNIC. See Linux: Configuring the OS for Secondary VNICs or Windows: Configuring the OS for Secondary VNICs.

To update an existing VNIC

You can update the VNIC's friendly name or hostname, or whether the VNIC performs the source/destination check.

1. Confirm you're viewing the compartment that contains the instance you're interested in.
2. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
3. Click the instance to view its details.
4. Under **Resources**, click **Attached VNICs**.
   The primary VNIC and any secondary VNICs attached to the instance are displayed.
5. For the VNIC you want to edit, click the Actions icon (three dots), and then click **Edit VNIC**.
6. Make your changes and click **Update VNIC**.

To add or remove a VNIC from a network security group

You can change which network security groups (NSGs) a VNIC belongs to, or remove a VNIC from all NSGs.

1. Confirm you're viewing the compartment that contains the instance you're interested in.
2. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
3. Click the instance to view its details.
4. Under **Resources**, click **Attached VNICs**.

The primary VNIC and any secondary VNICs attached to the instance are displayed. Each VNIC's details include a list of the NSGs that the VNIC belongs to (if any).

5. For the VNIC you want to edit, next to **Network Security Groups** in the VNIC's details, click **Edit**.
6. Make your changes and click **Save**.

To delete a secondary VNIC

Warning

If the VNIC has a private IP that is the target of a route rule, deleting the VNIC causes the route rule to blackhole and traffic will be dropped.

1. Confirm you're viewing the compartment that contains the instance you're interested in.
2. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
3. Click the instance to view its details.
4. Under **Resources**, click **Attached VNICs**.
   The primary VNIC and any secondary VNICs attached to the instance are displayed.
5. For the VNIC you want to delete, click the Actions icon (three dots), and then click **Delete**.
6. Confirm when prompted.

It takes typically a few seconds before the VNIC is deleted.

If the secondary VNIC is on a Linux instance: If you then run the provided script in Linux: Configuring the OS for Secondary VNICs, it removes the secondary VNIC from the OS configuration.

To manage tags for a VNIC

1. Confirm you're viewing the compartment that contains the instance you're interested in.
2. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
3. Click the instance to view its details.
4. Under **Resources**, click **Attached VNICs**.
   The primary VNIC and any secondary VNICs attached to the instance are displayed.
5. Click the VNIC you're interested in.
6. Click the **Tags** tab to view or edit the existing tags. Or click **Apply tag(s)** to add new ones.

For more information, see Resource Tags.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

To manage VNICs on an instance, use these operations:

- ListVnicAttachments: Use this to list the VNICs attached to an instance.
- GetVnicAttachment: Use this to get the VNIC's VLAN tag and other properties.
- GetVnic: Use this to get the VNIC's private IP address, MAC address, optional public IP address, optional DNS hostname, and other properties.
- AttachVnic
- DetachVnic
- UpdateVnic

Linux: Configuring the OS for Secondary VNICs

This section gives details about OS configuration that is required for secondary VNICs on instances that run a variant of Linux.

At the end of the section is a script that you can use to configure secondary VNICs on either VM instances or bare metal instances.

Linux VM Instances

When you add a secondary VNIC to a Linux VM instance, a new interface (that is, an Ethernet device) is added to the instance and automatically recognized by the OS. However, DHCP is not active for the secondary VNIC, and you must configure the interface with the static IP address and default route. The script provided here handles that configuration for you.

Linux Bare Metal Instances

When you add a secondary VNIC to a Linux bare metal instance, the OS does not automatically recognize the secondary VNIC, so you must configure it in the OS. Depending on your requirements, you can configure it as either:

- An SR-IOV virtual function (see Installing and Configuring KVM on Bare Metal Instances with Multi-VNIC).
- A VLAN-tagged interface (see the script in the following section).

Configuration Script for Either Linux VM Instances or Linux Bare Metal Instances

The following script works for both VM instances and bare metal instances. It looks at the secondary VNIC information in the instance metadata and configures the OS accordingly. You could run the script periodically to bring the OS configuration up to date with the instance metadata.

For VM instances in particular, the OS automatically recognizes the secondary VNIC's interface, and the script just needs to configure the static IP address and default route.

For bare metal instances in particular, the script creates the interface for the secondary VNIC and configures it with the relevant information. If the instance has two active physical NICs

(an X7/second-generation shape with NIC 0 and NIC 1), the script configures the secondary VNIC to use whichever physical NIC you chose when you added the VNIC to the instance. Note that for NIC 1, if a secondary VNIC has VLAN tag 0, it uses the NIC's interface. The script doesn't create an interface for that secondary VNIC.

Here are some additional notes about how the script works for both VM instances and bare metal instances:

- **Default namespace and policy-based routing:** By default, this script configures the secondary VNIC in the default namespace and with policy-based routing so applications can communicate through the VNIC with hosts outside the VNIC's subnet. **This policy-based routing has effect only if the packets are sourced from the IP address of the secondary VNIC.** The ability to bind to a specific source IP address or source interface exists in most tools (such as ssh, ping, and wget) and libraries that initiate connections. For example, the `ssh -b` option lets you bind to the private IP address of the secondary VNIC:

  ```
  ssh -b <secondary_VNIC_IP_address> <destination_IP_address>
  ```

  Be aware that if traffic comes in to a service on the instance through a secondary VNIC's interface and the service replies, the reply packets automatically have the VNIC's interface IP address as the source IP address. Policy-based routing is required for that reply to go back out on the same interface and find the correct default gateway.
- **A separate namespace:** If you're familiar with namespaces, you can instead configure the secondary VNIC in another namespace of your choice by running the script with the `-n` option. A separate namespace is required when an instance has secondary VNICs that are attached to subnets in different VCNs, and those subnets have overlapping CIDR blocks.
- **Secondary private IPs:** The instance metadata does not include information about any secondary private IPs assigned to the instance. To include that as part of the script's OS configuration, you must provide the secondary private IP address and OCID at the command line when you run the script.
- **Removal of a secondary VNIC:** After deleting a secondary VNIC from an instance, running the script removes the VNIC's information from the OS configuration.

Important

The script uses a simple configuration process that does not persist if you reboot the instance. If you use the script, make sure to rerun it after each reboot.

Here are basic examples of how to run the script:

- *<script_name>* `-c`: Configure (adds or deletes) secondary VNIC host IP configuration
- *<script_name>* `-c -n`: Same but uses separate namespaces
- *<script_name>* `-d`: Force removes all secondary VNIC host IP configuration

See the script's help for more information.

Tip

Download the script from the online version of this user guide at https://docs.cloud.oracle.com/iaas/Content/Network/Tasks/managingVNICs.htm#linux.

Windows: Configuring the OS for Secondary VNICs

Secondary VNICs are supported on VM and bare metal instances, **but only on X7/second-generation shapes** (shapes with "2" in the name, such as VM.Standard2.16 and BM.Standard2.52). For bare metal, secondary VNICs are supported **only on the second physical NIC**.

Tip

The first physical NIC is NIC 0, and the second is NIC 1.

You must configure the secondary VNIC within the OS. There's an Oracle-provided PowerShell script that performs configuration. When running the script, you can optionally provide the secondary VNIC's OCID (which you can get from the instance's VNIC metadata):

```
.\secondary_vnic_windows_configure.ps1 "<secondary_VNIC_OCID>"
```

Otherwise, the script shows a list of the secondary VNICs on the instance and asks you to choose the one you want to configure. Here's generally what the script does:

1. The script checks if the network interface has an IP address and a default route.
2. To enable the OS to recognize the secondary VNIC, the **script must overwrite the IP address and default route with static settings (which effectively disables DHCP).** The script prompts you with a choice: to overwrite with the static settings, or exit.

Tip

Download the script from the online version of this user guide at https://docs.cloud.oracle.com/iaas/Content/Network/Tasks/managingVNICs.htm#windows.

The overall process for configuration varies slightly depending on the type of instance (VM or bare metal) and how many secondary VNICs you add to the instance.

Windows VM instances

Here's the overall process:

1. Add one or more secondary VNICs to the instance. Keep each VNIC's OCID handy so you can provide it later when you run the configuration script. You can also get the OCID from the instance's VNIC metadata.
2. Connect to the instance with Remote Desktop.

3. Run the script:
    a. Open PowerShell as an administrator.
    b. Run the script with the secondary VNIC's OCID:

```
.\secondary_vnic_windows_configure.ps1 "<secondary_VNIC_OCID>"
```

4. Repeat the preceding step for each additional secondary VNIC.

Windows bare metal instances: adding the first secondary VNIC

If you're adding only a single secondary VNIC to the bare metal instance, here's the overall process:

1. Add the secondary VNIC to your instance. Keep the VNIC's OCID handy so you can provide it when later running the configuration script. You can also get the OCID from the instance's VNIC metadata.
2. Connect to the instance with Remote Desktop.
3. Enable the second physical NIC on the instance:
    a. Open the Device Manager, and then click **Network adapters**.
    b. Right-click the adapter that corresponds to the instance's second physical NIC, and click **Enable**.
4. Run the script:
    a. Open PowerShell as an administrator.
    b. Run the script with the secondary VNIC's OCID:

```
.\secondary_vnic_windows_configure.ps1 "<secondary_VNIC_OCID>"
```

    c. When the script prompts you to overwrite the network interface's settings, say yes.

Windows bare metal instances: adding additional secondary VNICs

If you have one secondary VNIC on the second physical NIC of a bare metal instance, and you

want to one or more additional VNICs, here's the overall process. It includes a task for setting up NIC teaming, which is required if the instance has more than one VNIC on the second physical NIC.

Note

If you increase the number of secondary VNICs on the second physical NIC from one to two or more, you must enable *NIC teaming* for the second physical NIC (see instructions that follow). In your NIC "team," you create a separate interface for *each* secondary VNIC on that physical NIC, including the initial one. This means that the original interface for that first secondary VNIC will no longer work, and any subsequent configuration you want to do for that VNIC must be done instead on the VNIC's new interface that's part of the "team".

1. Add one or more additional secondary VNICs to your instance. Keep each VNIC's OCID and VLAN tag handy so you can provide them when later running the configuration script. You can also get the values from the instance's VNIC metadata.
2. Connect to the instance with Remote Desktop.
3. Set up NIC teaming on the instance:
    a. Open the Server manager, and then click **Local Server**.
    b. In the list of properties, locate **NIC Teaming**, and then click **Disabled** to enable and set up NIC teaming.
    c. In the **Teams** section on the lower-left side of the screen, click **Tasks**, and then click **New Team**.
    d. Enter a name for the team, select the check box for the second physical NIC on the instance, and click **OK**.
    The new team is created and appears in the list of teams in the **Teams** section.

e. Click the new team so it's selected, and then in the **Adapters and Interfaces** section on the right side of the screen, click the **Team Interfaces** tab.

f. Click **Tasks**, and then click **Add Interface** (you will create a separate interface for each secondary VNIC on the second physical NIC).

g. Click the radio button for **Specific VLAN**, and then enter the Oracle-assigned VLAN tag number for the VLAN (for example, 1). You can get the VLAN tag from the Console or the instance's VNIC metadata.

h. Click **OK**.

i. Repeat the four preceding steps (e-h) for each of the other secondary VNICs. You create a separate interface for each secondary VNIC.

4. Run the script:

a. Open PowerShell as an administrator.

b. For the first secondary VNIC, run the script with the secondary VNIC's OCID:

```
.\secondary_vnic_windows_configure.ps1 "<secondary_VNIC_OCID>"
```

c. When the script prompts you to overwrite the network interface's settings, say yes.

d. Repeat the preceding two steps (b and c) for each of the additional secondary VNICs.

VNIC Metrics

You can monitor the health, capacity, and performance of your Networking service VNICs by using metrics, alarms, and notifications.

This topic describes the metrics emitted by the metric namespace `oci_vcn` (the Networking service).

Resources: virtual network interface cards (VNICs).

Overview of Metrics for an Instance and Its Network Devices

If you're not already familiar with the different types of metrics available for an instance and its storage and network devices, see Compute Instance Metrics.

Overview of Metrics: oci_vcn

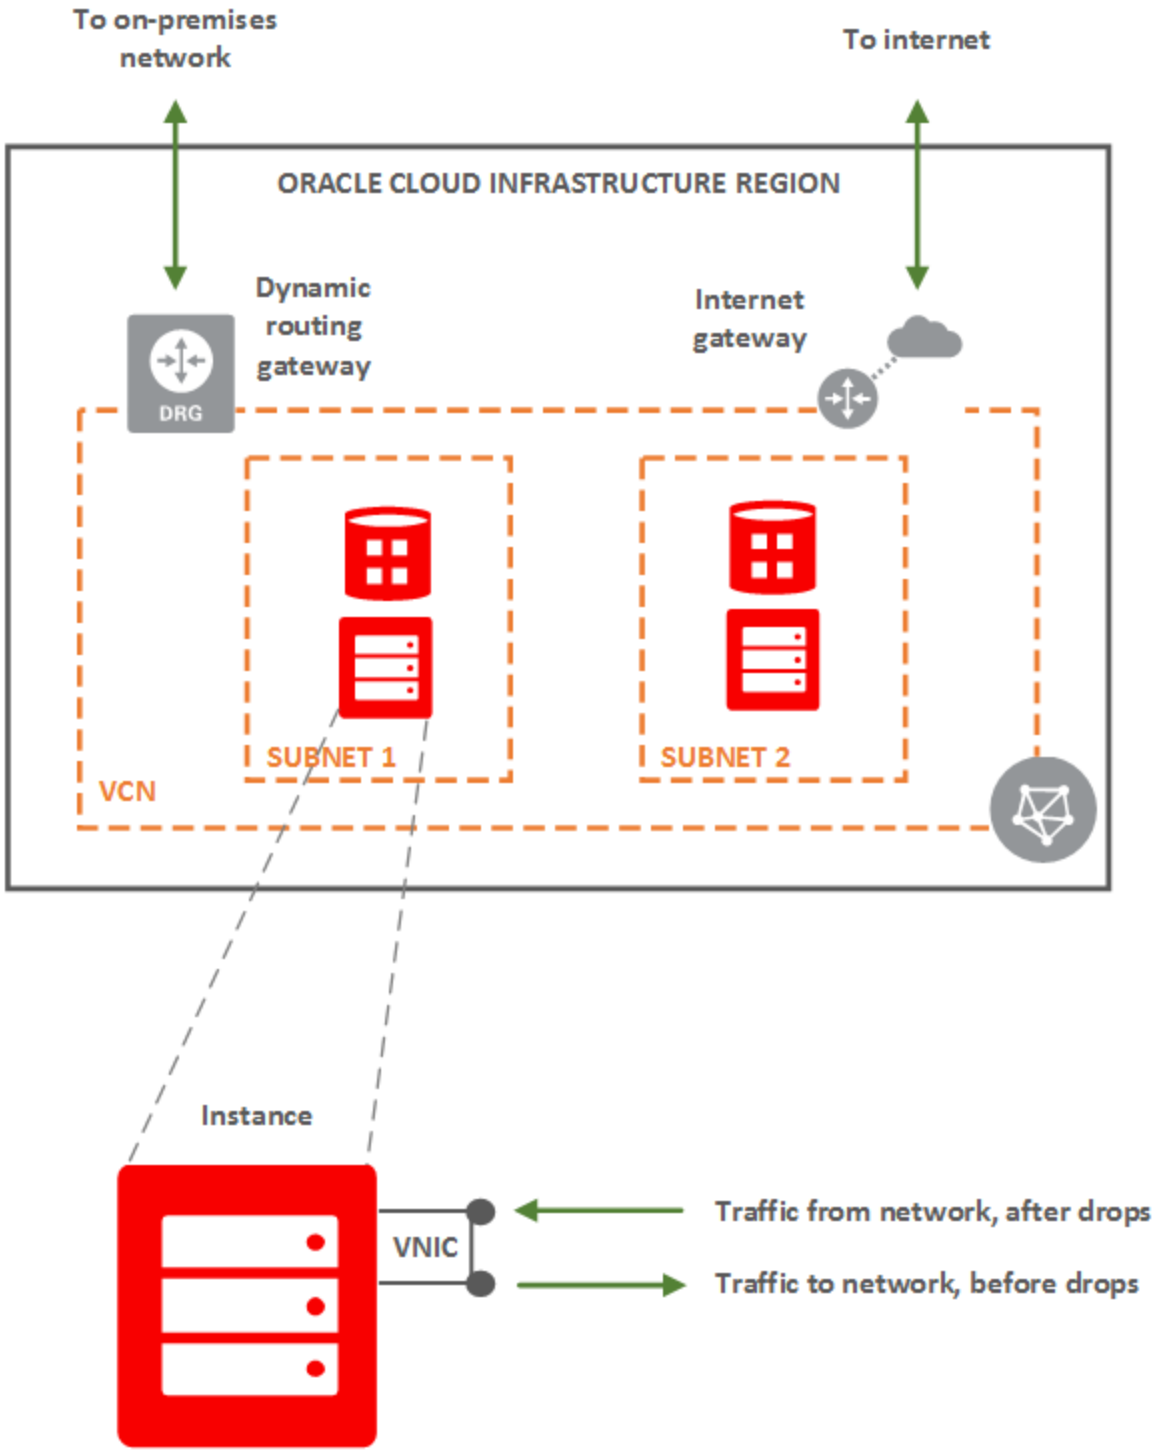
Each Compute instance has one or more Networking service VNICs. A VNIC connects the instance to a subnet in a virtual cloud network (VCN). A given VNIC controls how the instance communicates with endpoints inside the VCN (other instances) and endpoints outside the VCN (hosts on the internet, in your on-premises network, in another VCN, and so on).

With the Networking service metrics (in metric namespace `oci_vcn`), you can get this information for a VNIC:

- **Traffic to and from the network:** Per-VNIC traffic levels (packets and bytes), which can help you identify meaningful increases or decreases in traffic coming in and out of your instances
- **Packets dropped due to security list violations:** Per-VNIC *drops* (dropped packets), which can help you identify changes in traffic caused by security list changes

The following diagram illustrates the general concept. A given instance resides in a subnet within a VCN that has one or more gateways to communicate with other networks. The instance is enlarged to show its VNIC, which the instance uses to communicate with the network. In this context, the term *network* means both the other instances in the VCN and hosts outside the VCN available through the gateways.

The VNIC receives traffic from the network and sends traffic to the network. The Networking service drops packets according to security list rules you set up for the instance's subnet. Traffic coming to the VNIC from the network is measured *after* the Networking service drops the packets that violate the subnet's security list rules. Traffic leaving the VNIC is measured *before* the Networking service drops the packets that violate the subnet's security list rules.



To on-premises network
To internet
ORACLE CLOUD INFRASTRUCTURE REGION
Dynamic routing gateway
DRG
Internet gateway
SUBNET 1
SUBNET 2
VCN
Instance
VNIC
Traffic from network, after drops
Traffic to network, before drops

The Compute service separately reports network-related metrics *as measured on the instance itself and aggregated across all the attached VNICs*. Those metrics are available in the `oci_computeagent` metric namespace. For more information, see Compute Instance Metrics.

Raw Data Point Frequency

For every 1-minute interval, the Networking service posts one raw data point to the Monitoring service. The Monitoring service charts show data points at 1-minute, 5-minute, and 60-minute intervals. The available statistics are calculated by using the count of 1-minute data points in the select interval. For example, for a given metric:

- The mean for each 5-minute interval is calculated over 5 raw data points.
- The mean for each 60-minute interval is calculated over 60 raw data points.

Required IAM Policy

When writing an IAM policy for viewing VNIC metrics, it's important to remember that:

- The VNIC and the VNIC's metrics (emitted by the `oci_vcn` metric namespace) reside in the *subnet's compartment*, and not the instance's compartment.
- The *VNIC attachment* (which is an object different from the VNIC itself) resides in the *instance's compartment*.

If the instance and subnet are in the same compartment, these details aren't so important when you write the IAM policy.

Minimum required policy for getting VNIC metrics

The following policy contains the one statement required to get VNIC metrics, which are part of the `oci_vcn` metric namespace.

If you're using the Console, this policy lets you go to the **Monitoring** tab in the Console and view the metrics for one or more VNICs in the specified compartment. The policy uses an example group called VnicMetricReaders. The condition at the end (`where`

`target.metrics.namespace='oci_vcn'`) allows the group to view only the metrics in the `oci_vcn` metric namespace.

```
Allow group VnicMetricReaders to read metrics in compartment <subnet_compartment> where
target.metrics.namespace='oci_vcn'
```

Policy for viewing a VNIC's details and metrics in the Console

The following policy lets you view an instance in the Console, click through to a specific VNIC, and then view that VNIC's details and metrics.

```
Allow group VnicMetricReaders to read metrics in compartment <subnet_compartment> where
target.metrics.namespace='oci_vcn'

Allow group VnicMetricReaders to read instance-family in compartment <instance_compartment>

Allow group VnicMetricReaders to inspect virtual-network-family in compartment <subnet_compartment>
```

The second and third statements let you view the instance's details and the VNIC's details, respectively.

Available Metrics: oci_vcn

The metrics listed in the following table are automatically available for any VNIC on any instance you create. You do not need to enable monitoring on the instance to get these metrics for the VNIC or VNICs on the instance.

You also can use the Monitoring service to create custom queries.

Each metric includes the following dimension:

RESOURCEID

The OCID of the VNIC.

Metric	Metric Display Name	Unit	Description	Dimensions
VnicEgressDropsSecurityList	**Egress Packets Dropped by Security List**	packets	Packets sent by the VNIC, destined for the network, dropped due to security rule violations.	resourceId
VnicIngressDropsSecurityList	**Ingress Packets Dropped by Security List**	packets	Packets received from the network, destined for the VNIC, dropped due to security rule violations.	
VnicFromNetworkBytes*	**Bytes from Network**	bytes	Bytes received at the VNIC from the network, after drops.	
VnicFromNetworkPackets*	**Packets from Network**	packets	Packets received at the VNIC from the network, after drops.	

Metric	Metric Display Name	Unit	Description	Dimensions
`VnicToNetworkBytes`*	**Bytes to Network**	bytes	Bytes sent from the VNIC to the network, before drops.	
`VnicToNetworkPackets`*	**Packets to Network**	packets	Packets sent from the VNIC to the network, before drops.	

* The Compute service separately reports network-related metrics *as measured on the instance itself and aggregated across all the attached VNICs*. Those metrics are available in the `oci_computeagent` metric namespace. For more information, see Compute Instance Metrics.

Tips for Working with VNIC Metrics

Here are some tips to help you use VNIC metrics.

Default Metric Charts for One VNIC Versus Multiple VNICs

The default charts for VNIC metrics use these default settings:

- Time range = the last hour
- Interval = 1 minute
- Statistic displayed: Sum
- Aggregation of metric streams = not selected (which means each VNIC is displayed as a separate line on the chart)

You can view the default charts with *data for only a single VNIC* by viewing the VNIC's details in the Console. When looking at a single VNIC, these statistics are the most useful: sum, mean, max, and min.

You can view the default charts with *data for multiple VNICs* by going to the **Service Metrics** page in the Console. Make sure to select the desired compartment and metric namespace (`oci_vcn`) at the top of the page. For all the charts, you can either show each VNIC as a separate line, or show a single line that aggregates the data for all the VNICs in your selected compartment. To aggregate the data, select the check box for **Aggregate Metric Streams**.

When viewing aggregated data, you can use the P90 - P99.9 statistics to help identify typical behavior of your instance fleet and outliers. To view these statistics over an even larger number of data points, expand the chart's start and end time (for example, view the last 7 days instead of the last hour), and set the interval to 1 hour.

For general information about how to work with and modify the default metric charts, see Using the Console in the Monitoring documentation.

Alarms for VNIC Metrics

You can set up alarms for a given metric. For VNICs, an alarm makes the most sense for the egress security list drops metric (`VnicEgressDropsSecurityList`). In a normal situation, you shouldn't have egress security list drops. If you do, it most likely means that one or both of these is true:

- An application is behaving in an unexpected manner
- Your security list is configured incorrectly

In either case, an alarm is warranted.

Using the Console

To view default metric charts for a single VNIC

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
2. Click the instance to view its details.
3. Click **Attached VNICs**.
4. Click the VNIC to view its details.
5. Under **Resources**, click **Metrics**.

For more information about monitoring metrics and using alarms, see Monitoring Overview. For information about notifications for alarms, see Notifications Overview.

To view default metric charts for multiple VNICs

1. Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Service Metrics**.
2. For **Compartment**, select the compartment that contains the VNICs you're interested in. Remember that a given VNIC resides in its *subnet's* compartment.
3. For **Metric Namespace**, select **oci_vcn**.
   The **Service Metrics** page dynamically updates the page to show charts for each metric that is emitted by the selected metric namespace.

Tip

If there are multiple VNICs in the compartment, the charts default to show a separate line for each VNIC. You can instead show a single line aggregated across all the VNICs by selecting the check box for **Aggregate Metric Streams** on the right side of the page.

For more information about monitoring metrics and using alarms, see Monitoring Overview. For information about notifications for alarms, see Notifications Overview.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the following APIs for monitoring:

- Monitoring API for metrics and alarms
- Notifications API for notifications (used with alarms)

Private IP Addresses

This topic describes how to manage the IPv4 addresses assigned to an instance in a virtual cloud network (VCN).

IPv6 addressing is currently supported only in the US Government Cloud. For more information, see IPv6 Addresses.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Overview of IP Addresses

Instances use IP addresses for communication. Each instance has at least one private IP address and optionally one or more public IP addresses. A private IP address enables the instance to communicate with other instances inside the VCN, or with hosts in your on-premises network (via an IPSec VPN or Oracle Cloud Infrastructure FastConnect). A public IP address enables the instance to communicate with hosts on the internet. For more information, see these related topics:

- Public vs. Private Subnets
- How IP Addresses Are Assigned
- Public IP Addresses

About the Private IP Object

The Networking service defines an object called a *private IP*, which consists of:

- Private IPv4 address, assigned by either you or Oracle.
- Optional hostname for DNS (see DNS in Your Virtual Cloud Network).

Each private IP object has an Oracle-assigned OCID (see Resource Identifiers). If you're using the API, you can also assign each private IP object a friendly name.

Each instance receives a *primary private IP* object during launch. The Networking service uses the Dynamic Host Configuration Protocol (DHCP) to pass the object's private IP address to the instance. This address does not change during the instance's lifetime and cannot be

removed from the instance. The private IP object is terminated when the instance is terminated.

If an instance has any secondary VNICs attached, each of those VNICs also has a primary private IP.

A private IP can have a public IP assigned to it at your discretion.

A private IP can be the target of a route rule in your VCN. For more information, see Using a Private IP as a Route Target.

About Secondary Private IP Addresses

You can add a *secondary private IP* to an instance after it's launched. You can add it to either the primary VNIC or a secondary VNIC on the instance. The secondary private IP address must come from the CIDR of the VNIC's subnet. You can move a secondary private IP from a VNIC on one instance to a VNIC on another instance if both VNICs belong to the same subnet.

Here are a few reasons why you might use secondary private IPs:

- **Instance failover:** You assign a secondary private IP to an instance. Then if the instance has problems, you can easily reassign that secondary private IP to a standby instance in the same subnet. If the secondary private IP has a public IP assigned to it, that public IP moves along with the private IP.
- **Running multiple services or endpoints on a single instance:** For example, you could have multiple container pods running on a single instance, and each uses an IP address from the VCN's CIDR. The containers have direct connectivity to other instances and services in the VCN. Another example: you could run multiple SSL websites with each one using its own IP address.

Here are more details about secondary private IP addresses:

- They're supported for all shapes and OS types, for both bare metal and VM instances.
- A VNIC can have a maximum of 31 secondary private IPs.
- They can be assigned only after the instance is launched (or the secondary VNIC is created/attached).

- A secondary private IP that is assigned to a VNIC in a regional subnet has a null availability domain attribute. Compare this with the VNIC's *primary* private IP, which always has its availability domain attribute set to the instance's availability domain, regardless of whether the instance's subnet is regional or AD-specific.
- Deleting a secondary private IP from a VNIC returns the address to the pool of available addresses in the subnet.
- They are automatically deleted when you terminate the instance (or detach/delete the secondary VNIC).
- The instance's bandwidth is fixed regardless of the number of private IP addresses attached. You can't specify a bandwidth limit for a particular IP address on an instance.
- A secondary private IP can have a reserved public IP assigned to it at your discretion.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: see IAM Policies for Networking.

Using the Console

To view an instance's private IPs

1. Confirm you're viewing the compartment that contains the instance you're interested in.
2. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
3. Click the instance to view its details.
4. Under **Resources**, click **Attached VNICs**.

The primary VNIC and any secondary VNICs assigned to the instance are displayed.

5. Click the VNIC you're interested in.
6. Under **Resources**, click **IP Addresses**.
   The VNIC's primary private IP and any secondary private IPs are displayed.

To assign a new secondary private IP to a VNIC

1. Confirm you're viewing the compartment that contains the instance you're interested in.
2. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
3. Click the instance to view its details.
4. Under **Resources**, click **Attached VNICs**.
   The primary VNIC and any secondary VNICs attached to the instance are displayed.
5. Click the VNIC you're interested in.
6. Under **Resources**, click **IP Addresses**.
   The VNIC's primary private IP and any secondary private IPs are displayed.
7. Click **Assign Private IP Address**.
8. Enter the following:
   - **Private IP Address:** Optional. An available private IP address of your choice from the subnet's CIDR (otherwise the private IP address is automatically assigned).
   - **Unassign if already assigned to another VNIC:** Select this check box to force reassignment of the IP address if it's already assigned to another VNIC in the subnet. Relevant only if you specify a private IP address in the preceding field.
   - **Hostname:** Optional. A hostname to be used for DNS within the cloud network. Available only if the VCN and subnet both have DNS labels. See DNS in Your Virtual Cloud Network.

- **Tags:** Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.
- **Public IP address:** Whether to assign a public IP address. Available only if the VNIC is in a public subnet. See Public IP Addresses.

9. Click **Assign**.
   The secondary private IP is created and then displayed on the **IP Addresses** page for the VNIC.
10. Configure the IP address:
    - For instances running a variant of Linux, see Linux: Details about Secondary IP Addresses.
    - For Windows instances, see Windows: Details about Secondary IP Addresses.

To move a secondary private IP to another VNIC in the same subnet

1. Confirm you're viewing the compartment that contains the instance you're interested in.
2. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
3. Click the instance to view its details.
4. Under **Resources**, click **Attached VNICs**.
   The primary VNIC and any secondary VNICs attached to the instance are displayed.
5. Click the VNIC you're interested in.
6. Under **Resources**, click **IP Addresses**.
   The VNIC's primary private IP and any secondary private IPs are displayed.
7. Click **Assign Private IP Address**.

8. Enter the following:
    - **Private IP Address:** The secondary private IP address you want to move.
    - **Unassign if already assigned to another VNIC:** Select this check box to move the secondary IP address from the VNIC it's currently assigned to.
    - **Hostname:** Optional. The hostname to be used for DNS within the cloud network. Available only if the VCN and subnet both have DNS labels. See DNS in Your Virtual Cloud Network.
    - **Tags:** Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.
    - **Public IP address:** Whether to assign a public IP address. Available only if the VNIC is in a public subnet. See Public IP Addresses.
9. Click **Assign**.

The private IP address is moved from the original VNIC to the new VNIC.

To update the hostname for an existing private IP

1. Confirm you're viewing the compartment that contains the instance you're interested in.
2. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
3. Click the instance to view its details.
4. Under **Resources**, click **Attached VNICs**.
   The primary VNIC and any secondary VNICs attached to the instance are displayed.
5. Click the VNIC you're interested in.
6. Under **Resources**, click **IP Addresses**.

The VNIC's primary private IP and any secondary private IPs are displayed.

7. For the IP address you're interested in, click the Actions icon (three dots), and then click **Edit**.
8. Make your changes and click **Update**.

To delete a secondary private IP from a VNIC

Warning

If the private IP is the target of a route rule, deleting it from the VNIC causes the route rule to blackhole and the traffic will be dropped.

Prerequisite: Oracle recommends removing the IP address from the OS configuration before deleting it from the VNIC. See Linux: Details about Secondary IP Addresses or Windows: Details about Secondary IP Addresses.

1. Confirm you're viewing the compartment that contains the instance you're interested in.
2. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
3. Click the instance to view its details.
4. Under **Resources**, click **Attached VNICs**.
   The primary VNIC and any secondary VNICs attached to the instance are displayed.
5. Click the VNIC you're interested in.
6. Under **Resources**, click **IP Addresses**.
   The VNIC's primary private IP and any secondary private IPs are displayed.
7. For the private IP you want to delete, click the Actions icon (three dots), and then click **Delete Private IP**.
8. Confirm when prompted.

The private IP address is returned to the pool of available addresses in the subnet.

To manage tags for a private IP

1. Confirm you're viewing the compartment that contains the instance you're interested in.
2. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
3. Click the instance to view its details.
4. Under **Resources**, click **Attached VNICs**.
   The primary VNIC and any secondary VNICs attached to the instance are displayed.
5. Click the VNIC you're interested in.
6. Under **Resources**, click **IP Addresses**.
   The VNIC's primary private IP and any secondary private IPs are displayed.
7. For the private IP you're interested in, click the Actions icon (three dots), and then click **View Tags**. From there you can view the existing tags, edit them, and apply new ones.

For more information, see Resource Tags.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

To manage private IPs on a VNIC, use these operations:

- GetPrivateIp: Use this to get a single `privateIp` object by specifying its OCID.
- ListPrivateIps: Use this to get a single `privateIp` object by specifying the private IP address (for example, 10.0.3.3) and the subnet's OCID. Or you can list all the `privateIp` objects in a given subnet, or just the ones assigned to a given VNIC.
- CreatePrivateIp: Use this to assign a new secondary private IP to a VNIC.

- UpdatePrivateIp: Use this to reassign a secondary private IP to a different VNIC in the same subnet, or to update the hostname or display name of a secondary private IP.
- DeletePrivateIp: Use this to delete a secondary private IP from a VNIC. The private IP address is returned to the subnet's pool of available addresses.

Linux: Details about Secondary IP Addresses

After assigning a secondary private IP to a VNIC, you must configure the OS to use it.

Basic Commands (Not Persistent Through a Reboot)

On the instance, run the following command. It works on all variants of Linux, for both bare metal and VM instances:

```
ip addr add <address>/<subnet_prefix_len> dev <phys_dev> label <phys_dev>:<addr_seq_num>
```

where:

- <address>: The secondary private IP address.
- <subnet_prefix_len>: The subnet's prefix length. For example, if the subnet is 192.168.20.0/24, the subnet prefix length is 24.
- <phys_dev>: The interface to add the address to (for example, ens2f0).
- <addr_seq_num>: The sequential number in the stack of addresses on the device (for example, 0).

For example:

```
ip addr add 192.168.20.50/24 dev ens2f0 label ens2f0:0
```

Later if you want to delete the address, you can use:

```
ip addr del 192.168.20.50/24 dev ens2f0:0
```

Also make sure to delete the secondary IP from the VNIC. You can do that before or after executing the above command to delete the address from the OS configuration.

Note

If you've assigned a secondary IP to a secondary VNIC, and you're using policy-based routing for the secondary VNIC, make sure to configure the route rules to look up the same route table for the secondary IP address.

Configuration File (Persistent Through a Reboot)

You can make the configuration persistent through a reboot by adding the information to a configuration file.

For Oracle Linux and CentOS

Create an `ifcfg` file named `/etc/sysconfig/network-scripts/ifcfg-<phys_dev>:<addr_seq_num>`. To continue with the preceding example, the file name would be `/etc/sysconfig/network-scripts/ifcfg-ens2f0:0`, and the contents would be:

```
DEVICE="ens2f0:0"
BOOTPROTO=static
IPADDR=192.168.20.50
NETMASK=255.255.255.0
ONBOOT=yes
```

Note

If you've assigned a secondary IP to a secondary VNIC, and you're using policy-based routing for the secondary VNIC, make sure to configure the route rules to look up the same route table for the secondary IP address.

For Ubuntu

Add the following information to the end of the `/etc/network/interfaces` file:

```
auto <phys_dev>:<addr_seq_num>
iface <phys_dev>:<addr_seq_num> inet static
       address <address>
       netmask <address_netmask>
```

Where the netmask is not the prefix but the 255.255.x.x. address.

To continue with the earlier example:

```
auto ens2f0:0
iface ens2f0:0 inet static
       address 192.168.20.50
       netmask 255.255.255.0
```

Note

If you've assigned a secondary IP to a secondary VNIC, and you're using policy-based routing for the secondary VNIC, make sure to configure the route rules to look up the same route table for the secondary IP address.

Windows: Details about Secondary IP Addresses

After assigning a secondary private IP to a VNIC, you must configure the OS to use it. Here are instructions for using a PowerShell script or the Network and Sharing Center UI.

Using a PowerShell Script

You must run PowerShell as an administrator. The script configures two things: static IP addressing on the instance and the secondary private IP. The configuration persists through a

reboot of the instance.

1. In your browser, go to the Console, and note the secondary private IP address that you want to configure on the instance.
2. Connect to the instance, and run the following command at a command prompt:

   ```
   ipconfig /all
   ```

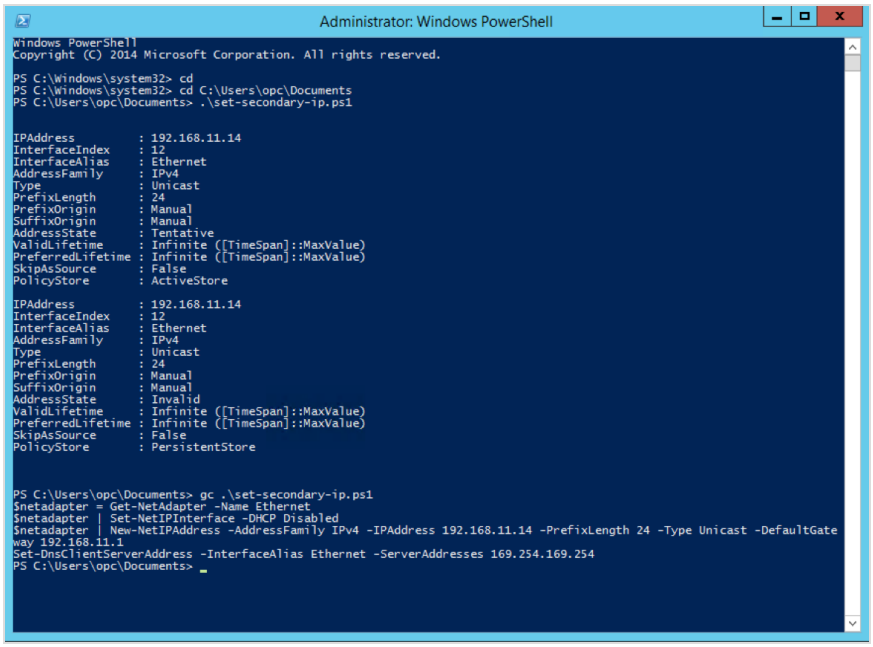
3. Note the values for the following items so you can enter them into the script in the next step:
   - Default Gateway
   - DNS Servers
4. Replace the variables in the following PowerShell script with your own values:

   ```
   netadapter = Get-NetAdapter -Name Ethernet
   $netadapter | Set-NetIPInterface -DHCP Disabled
   $netadapter | New-NetIPAddress -AddressFamily IPv4 -IPAddress <secondary_IP_address> -
   PrefixLength <subnet_prefix_length> -Type Unicast -DefaultGateway <default_gateway>
   Set-DnsClientServerAddress -InterfaceAlias Ethernet -ServerAddresses <DNS_server>
   ```

   For example:

   ```
   netadapter = Get-NetAdapter -Name Ethernet
   $netadapter | Set-NetIPInterface -DHCP Disabled
   $netadapter | New-NetIPAddress -AddressFamily IPv4 -IPAddress 192.168.11.14 -PrefixLength 24 -
   Type Unicast -DefaultGateway 192.168.11.1
   Set-DnsClientServerAddress -InterfaceAlias Ethernet -ServerAddresses 169.254.169.254
   ```

5. Save the script with the name of your choice and a `.ps1` extension, and run it on the instance.



If you run `ipconfig /all` again, you'll see that DHCP has been disabled and the secondary private IP address is included in the list of IP addresses.

Later if you want to delete the address, you can use this command:

```
Remove-NetIPAddress -IPAddress 192.168.11.14 -InterfaceAlias Ethernet
```

Also make sure to delete the secondary IP from the VNIC. You can do that before or after executing the above command to delete the address from the OS configuration.

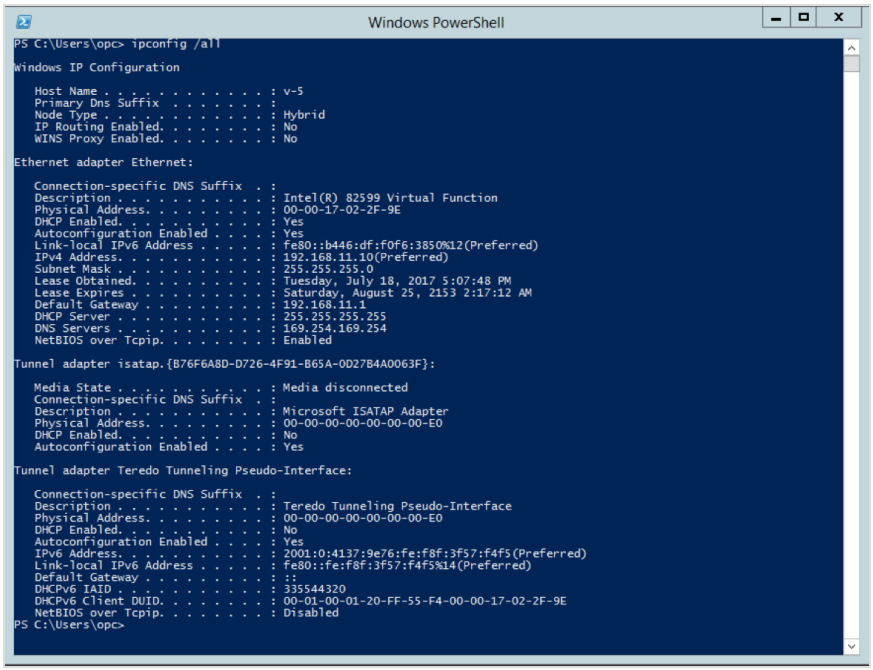
Using the Network and Sharing Center UI

The following instructions configure two things: static IP addressing on the instance and the secondary private IP. The configuration persists through a reboot of the instance.

1. In your browser, go to the Console, and note the secondary private IP address that you want to configure on the instance.

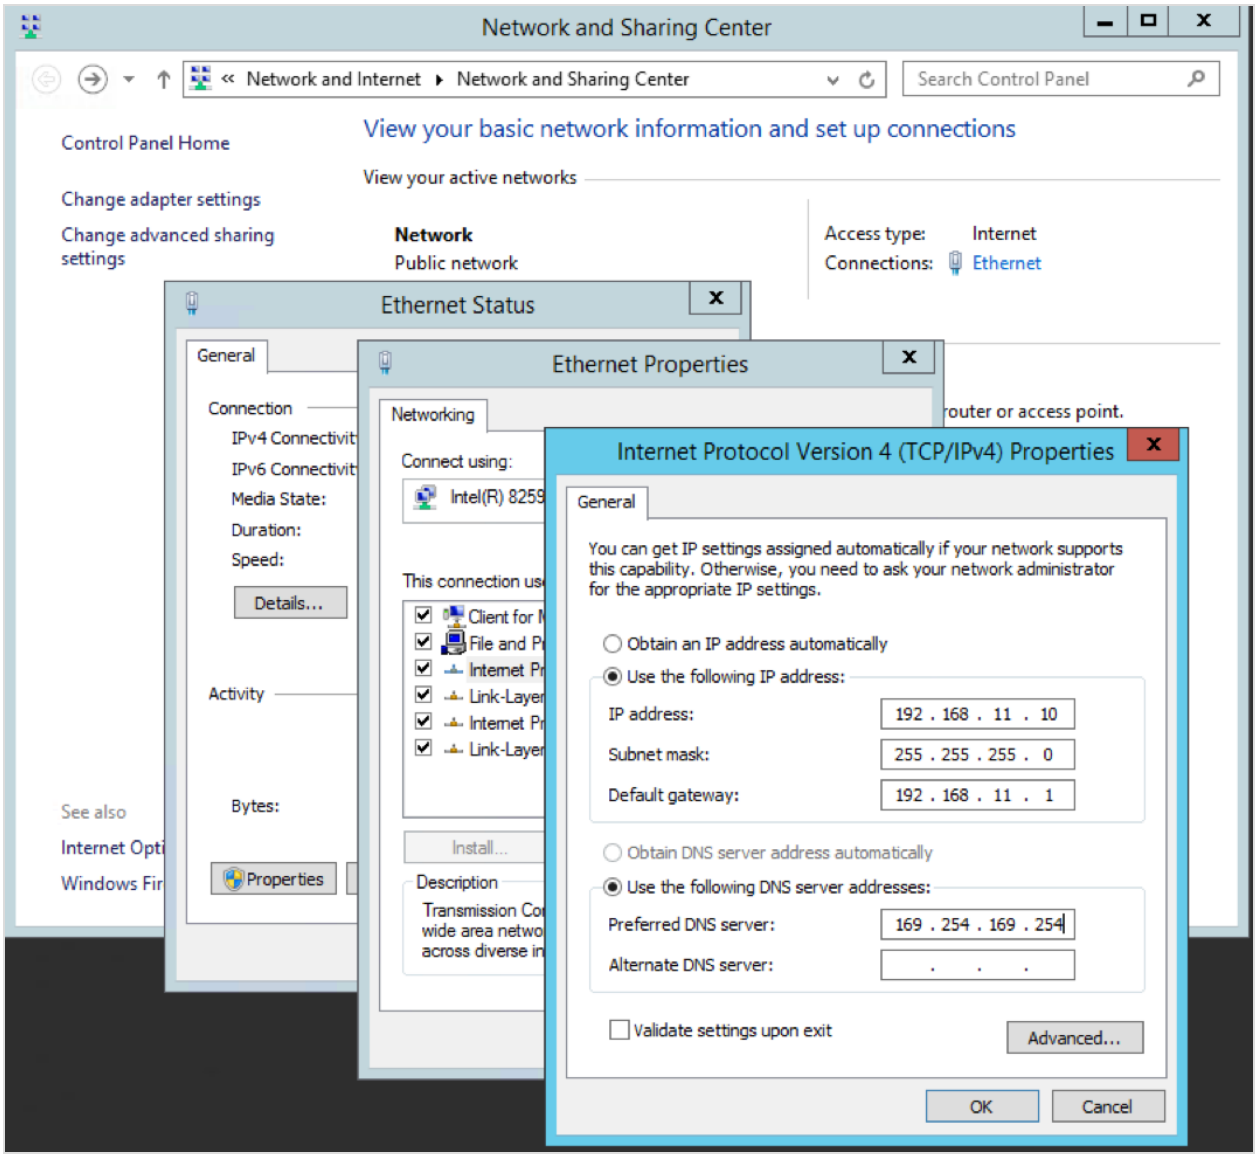
2. Connect to the instance, and run the following command at a command prompt:

```
ipconfig /all
```



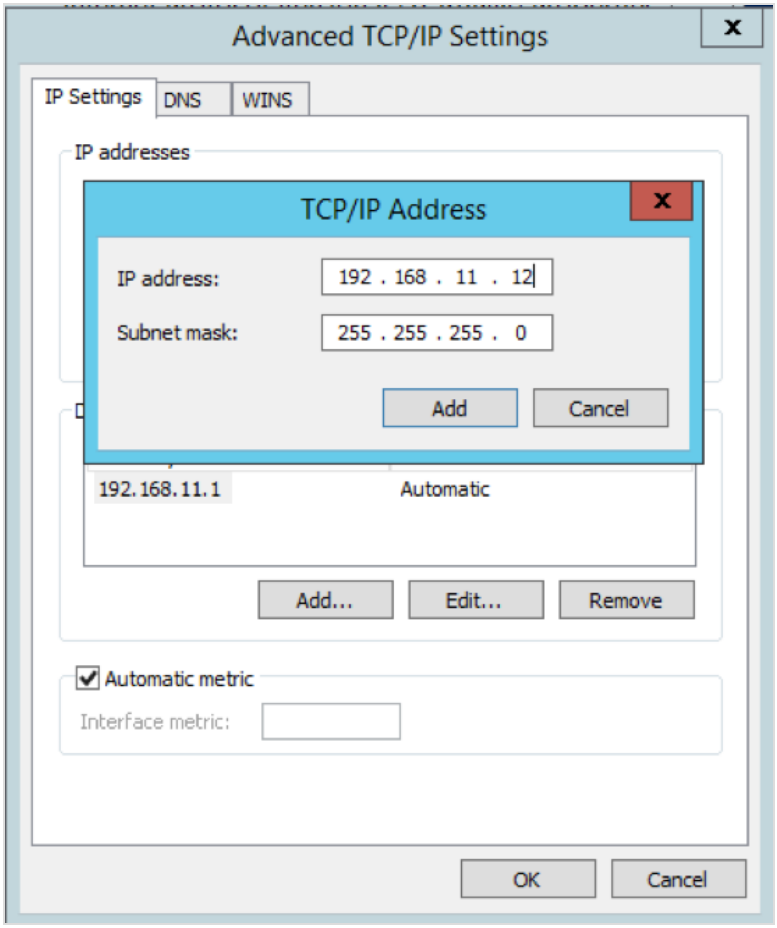
3. Note the values for the following items so you can enter them elsewhere in a later step:
    - IPv4 Address
    - Subnet Mask
    - Default Gateway
    - DNS Servers
4. In the instance's **Control Panel**, open the **Network and Sharing Center** (see the image below for the set of dialog boxes you'll see in these steps).
5. For the active networks, click the connection (**Ethernet**).

6. Click **Properties**.
7. Click **Internet Protocol Version 4 (TCP/IPv4)**, and then click **Properties**.
8. Select the radio button for **Use the following IP address**, and then enter the values you noted earlier for the IP address, subnet mask, default gateway, and DNS servers.



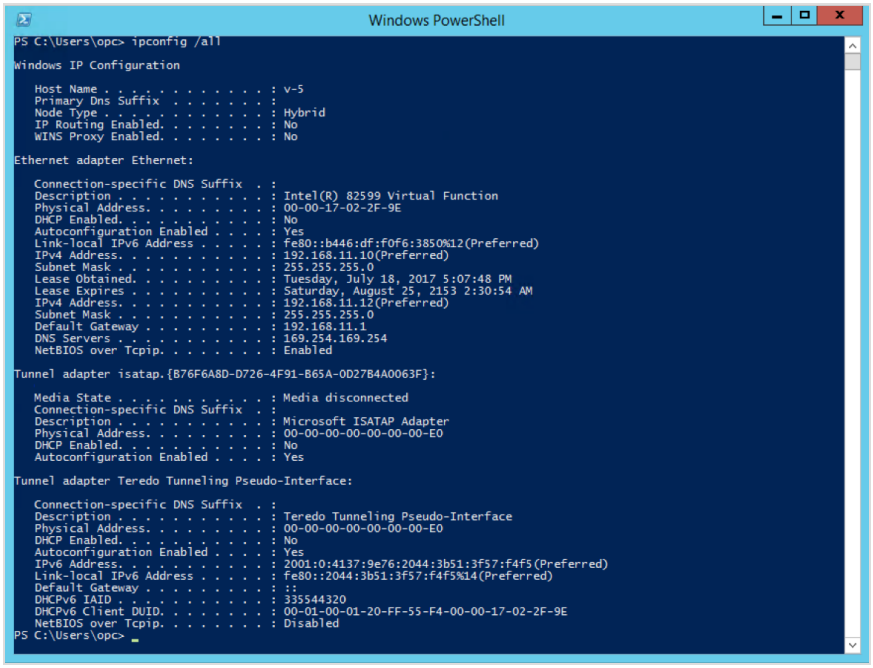
9. Click **Advanced...**.
10. Under **IP addresses**, click **Add...**.

11. Enter the secondary private IP address and the subnet mask you used earlier and click **Add**.



12. Click **OK** until the Network and Sharing Center is closed.
13. Verify the changes by returning to the command prompt and running `ipconfig /all`.

You should now see that DHCP is disabled (static IP addressing is enabled), and the secondary private IP address is in the list of addresses displayed. The address is now configured on the instance and available to use.



Note

You might not see the primary private IP address when you again view the properties for Internet Protocol Version 4 (TCP/IPv4) in the Network and Sharing Center UI. The best way to confirm your changes is to use `ipconfig /all` at the command line.

Public IP Addresses

This topic describes how to manage public IPv4 addresses on instances in a virtual cloud network (VCN).

IPv6 addressing is currently supported only in the US Government Cloud. For more information, see IPv6 Addresses.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Overview of Public IP Addresses

A public IP address is an IPv4 address that is reachable from the internet. If a resource in your tenancy needs to be directly reachable from the internet, it must have a public IP address. Depending on the type of resource, there might be other requirements.

Certain types of resources in your tenancy are designed to be directly reachable from the internet and therefore automatically come with a public IP address. For example: a NAT gateway or a public load balancer. Other types of resources are directly reachable only if you configure them to be. For example: instances in your VCN.

This topic focuses on these subjects:

- The types of public IP addresses and their characteristics
- How to control whether an instance has a public IP address

For more information about resources that automatically get a public IP address, see Resources That Always Get a Public IP.

Instances and Public IP Addresses

You can assign a public IP address to an instance to enable communication with the internet. The instance is assigned a public IP address from the Oracle Cloud Infrastructure address pool.

The assignment is actually to a private IP object on the instance. The VNIC that the private IP is assigned to must be in a public subnet. A given instance can have multiple secondary VNICs, and a given VNIC can have multiple secondary private IPs. So you can assign a given instance multiple public IPs across one or more VNICs if you like.

For an instance to communicate directly with the internet, all of the following are required:

- The instance must be in a public subnet.
- The instance must have a public IP address.
- The instance's VCN must have an internet gateway.
- The public subnet must have route tables and security lists configured accordingly.

Tip

Oracle Cloud Infrastructure FastConnect public peering lets your on-premises network access the public IP addresses of resources in Oracle Cloud Infrastructure *without the traffic traversing the internet*. For more information, see FastConnect.

The Public IP Object

The Networking service defines an object called a *public IP*, which consists of these items:

- Public IPv4 address (chosen by Oracle)
- Properties that further define the public IP's type and behavior

Each public IP object has an Oracle-assigned OCID (see Resource Identifiers). If you're using the API, you can also assign each public IP object a friendly name.

Types of Public IPs

There are two types of public IPs:

- **Ephemeral:** Think of it as temporary and existing for the lifetime of the instance.
- **Reserved:** Think of it as persistent and existing beyond the lifetime of the instance it's assigned to. You can unassign it and then reassign it to another instance whenever you like. Exception: reserved public IPs on public load balancers. See Resources That Always Get a Public IP.

The following table summarizes the differences between the two types.

Characteristic	Ephemeral Public IPs	Reserved Public IPs
Allowed assignment	To a VNIC's primary private IP only Limits: • One per VNIC • Two per VM instance, and 16 per bare metal instance	To either a primary or secondary private IP Limit: 32 per VNIC
Creation	Optionally created and assigned during instance launch or secondary VNIC creation. You can create and assign one later if the VNIC doesn't already have one.	You create one at any time. You can then assign it when you like. Limit: You can create 50 per region

Characteristic	Ephemeral Public IPs	Reserved Public IPs
Unassignment	You can unassign it at any time, which deletes it. You might do this if whoever launched the instance included a public IP, but you don't want the instance to have one. When you stop an instance, its ephemeral public IPs remain assigned to the instance.	You can unassign it at any time, which returns it to your tenancy's pool of reserved public IPs.
Moving to a different resource	You cannot move an ephemeral public IP to a different private IP.	If assigned to a secondary private IP: If you move the private IP to a different VNIC (must be in the same subnet), the reserved public IP goes with it. You can move it (unassign and then reassign it) at any time to another private IP in the same region. Can be in a different VCN or availability domain.
Automatic deletion	Its lifetime is tied to the private IP's lifetime. Automatically unassigned and deleted when: • Its private IP is deleted • Its VNIC is detached or terminated • Its instance is terminated	Never. Exists until you delete it.

Characteristic	Ephemeral Public IPs	Reserved Public IPs
Scope	Availability domain	Regional (can be assigned to a private IP in any availability domain in the region)
Compartment and availability domain	Same as the private IP's	Can be different from the private IP's

When you launch an instance in a public subnet, by default, the instance gets a public IP unless you say otherwise. See To choose whether an ephemeral public IP is assigned when launching an instance.

After you create a given public IP, you can't change which type it is. For example, if you launch an instance that is assigned an ephemeral public IP with address 129.146.1.9, you can't convert the ephemeral public IP to a reserved public IP with address 129.146.1.9.

The preceding table notes the public IP limits per VNIC and instance. If you try to perform any operation that assigns or moves a public IP to a VNIC or instance that has already reached its public IP limit, an error is returned. The operations include:

- Assigning a public IP
- Creating a new secondary VNIC with a public IP
- Moving a private IP with a public IP to another VNIC
- Moving a public IP to another private IP

Resources That Always Get a Public IP

As mentioned earlier, certain types of resources are designed to be directly reachable from the internet. Examples: a NAT gateway or a public load balancer. These resources automatically get a public IP address upon creation. Oracle chooses the public IP address from the Oracle pool. You can't remove or change the address.

For public load balancers, the address is a regional reserved public IP that is assigned to a private IP on the load balancer. This public IP appears in the list of your tenancy's reserved public IPs, which you can view in the Console. However, unlike other reserved public IPs that you create, you have no control over this public IP. You can't edit it or unassign it from the load balancer yourself. It's automatically unassigned and deleted from your tenancy when you terminate the load balancer.

For NAT gateways, the address is a regional ephemeral public IP that is assigned to the NAT gateway. Like other ephemeral public IPs, it's automatically unassigned and deleted when you terminate its assigned resource (the NAT gateway). However, unlike other ephemeral public IPs, you can't edit it or unassign it yourself.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: see IAM Policies for Networking.

Ephemeral Public IPs: Using the Console

To choose whether an ephemeral public IP is assigned when launching an instance

When you launch an instance into a public subnet, there's an **Assign public IP address** check box in the **Launch Instance** dialog box (in the **Advanced Options**, on the **Networking** tab). By default, the check box is selected, which means the instance gets an ephemeral public IP.

If you do NOT want an ephemeral public IP assigned, you can either:

- Clear the **Assign public IP address** check box
- Delete the ephemeral public IP after instance launch

To assign an ephemeral public IP when creating a secondary VNIC

When you add a secondary VNIC to an instance, you choose whether the primary private IP on the new VNIC gets an ephemeral public IP. This choice is available only if the secondary VNIC is in a public subnet.

In the **Create VNIC** dialog box, there's an **Assign public IP address** check box. By default, the check box is NOT selected, which means the secondary VNIC does not get an ephemeral public IP. You must select the check box.

For instructions, see To create and attach a secondary VNIC.

To assign an ephemeral public IP to an existing primary private IP

Prerequisite: The primary private IP must not have a reserved or ephemeral public IP already assigned to it. If it does, first delete the ephemeral public IP, or unassign the reserved public IP.

1. Confirm you're viewing the compartment that contains the instance you're interested in.
2. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
3. Click the instance to view its details.
4. Under **Resources**, click **Attached VNICs**.
   The primary VNIC and any secondary VNICs attached to the instance are displayed.
5. Click the VNIC you're interested in.
6. Under **Resources**, click **IP Addresses**.
   The VNIC's primary private IP and any secondary private IPs are displayed.
7. For the VNIC's primary private IP, click the Actions icon (three dots), and then click **Edit**.

8. In the **Public IP Address** section, for **Public IP type**, select the radio button for **Ephemeral Public IP**.
9. In the **Ephemeral Public IP Name** field, enter an optional friendly name for the public IP. The name doesn't have to be unique, and you can change it later. Avoid entering confidential information.
10. Click **Update**.

To delete an ephemeral public IP from an instance

Deleting an ephemeral public IP automatically unassigns it from its private IP.

1. Confirm you're viewing the compartment that contains the instance you're interested in.
2. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
3. Click the instance to view its details.
4. Under **Resources**, click **Attached VNICs**.
   The primary VNIC and any secondary VNICs attached to the instance are displayed.
5. Click the VNIC you're interested in.
6. Under **Resources**, click **IP Addresses**.
   The VNIC's primary private IP and any secondary private IPs are displayed.
7. For the VNIC's primary private IP, click the Actions icon (three dots), and then click **Edit**.
8. In the **Public IP Address** section, for **Public IP Type**, select the radio button for **No Public IP**.
9. Click **Update**.

To change the display name for an ephemeral public IP

1. Confirm you're viewing the compartment that contains the instance you're interested in.

2. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
3. Click the instance to view its details.
4. Under **Resources**, click **Attached VNICs**.
   The primary VNIC and any secondary VNICs attached to the instance are displayed.
5. Click the VNIC you're interested in.
6. Under **Resources**, click **IP Addresses**.
   The VNIC's primary private IP and any secondary private IPs are displayed.
7. For the VNIC's primary private IP, click the Actions icon (three dots), and then click **Edit**.
8. In the **Public IP Address** section, edit the **Ephemeral Public IP Name**. The name doesn't have to be unique, and you can change it later. Avoid entering confidential information.
9. Click **Update**.

Reserved Public IPs: Using the Console

To view your reserved public IPs

1. Confirm you're viewing the region and compartment you're interested in.
2. Open the navigation menu. Under Core Infrastructure, go to **Networking** and click **Public IPs**.

The details of the reserved public IPs in the selected region and compartment are displayed. If the reserved public IP is assigned, there's a link to the relevant VNIC.

To create a new reserved public IP in your pool

1. Confirm you're viewing the region and compartment where you want to create the

reserved public IP.

2. Open the navigation menu. Under Core Infrastructure, go to **Networking** and click **Public IPs**.
3. Click **Create Reserved Public IP**.
4. Enter the following:
   - **Name**: An optional friendly name for the reserved public IP. The name doesn't have to be unique, and you can change it later. Avoid entering confidential information.
   - **Compartment:** Leave as is.
   - **Tags:**Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.
5. Click **Create Reserved Public IP**.

The new reserved public IP is created and displayed on the page. You can now assign it to an existing private IP if you like.

To delete a reserved public IP from your pool

The reserved public IP can be in the "Assigned" state. Deleting a reserved public IP automatically unassigns it from its private IP.

1. Confirm you're viewing the region and compartment that contains the reserved public IP.
2. Open the navigation menu. Under Core Infrastructure, go to **Networking** and click **Public IPs**.

3. For the reserved public IP you want to delete, click the Actions icon (three dots), and then click **Terminate**.
4. Confirm when prompted.

After a few seconds, the reserved public IP is unassigned (if it was assigned) and deleted from your pool.

To assign a reserved public IP to a private IP

Prerequisite: The private IP must not have an ephemeral or reserved public IP already assigned to it. If it does, first delete the ephemeral public IP, or unassign the reserved public IP.

1. Confirm you're viewing the compartment that contains the instance with the private IP you're interested in.
2. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
3. Click the instance to view its details.
4. Under **Resources**, click **Attached VNICs**.
   The primary VNIC and any secondary VNICs attached to the instance are displayed.
5. Click the VNIC you're interested in.
6. Under **Resources**, click **IP Addresses**.
   The VNIC's primary private IP and any secondary private IPs are displayed.
7. For the private IP you're interested in, click the Actions icon (three dots), and then click **Edit**.
8. In the **Public IP Address** section, for **Public IP Type**, select the radio button for **Reserved Public IP**.
9. Enter the following:
   - **Compartment:** The compartment that contains the reserved public IP you want to assign.

- **Reserved Public IP:** The reserved public IP you want to assign. You have three choices:
  - Create a new reserved public IP. You may optionally provide a friendly name for it. The name doesn't have to be unique, and you can change it later. Avoid entering confidential information.
  - Assign a reserved public IP that is currently unassigned.
  - Move a reserved public IP from another private IP.

10. Click **Update**.

To unassign a reserved public IP and return it to the pool

1. Confirm you're viewing the compartment that contains the instance with the reserved public IP you're interested in.
2. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
3. Click the instance to view its details.
4. Under **Resources**, click **Attached VNICs**.
   The primary VNIC and any secondary VNICs attached to the instance are displayed.
5. Click the VNIC you're interested in.
6. Under **Resources**, click **IP Addresses**.
   The VNIC's primary private IP and any secondary private IPs are displayed.
7. For the private IP you're interested in, click the Actions icon (three dots), and then click **Edit**.
8. In the **Public IP Address** section, for **Public IP Type**, select the radio button for **No Public IP**.
9. Click **Update**.

The reserved public IP is unassigned and returned to your pool.

To move a reserved public IP from one private IP to another

Let's say you want to move a reserved public IP from private IP 1 to private IP 2. In summary: Make sure private IP 2 doesn't have a public IP already assigned to it. Then assign the reserved public IP to private IP 2. It will be automatically unassigned from private IP 1 first. Detailed instructions:

1. Confirm you're viewing the compartment that contains the instance with private IP 2.
2. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
3. Click the instance to view its details.
4. Under **Resources**, click **Attached VNICs**.
   The primary VNIC and any secondary VNICs attached to the instance are displayed.
5. Click the VNIC you're interested in.
6. Under **Resources**, click **IP Addresses**.
   The VNIC's primary private IP and any secondary private IPs are displayed.
7. For private IP 2, click the Actions icon (three dots), and then click **Edit**.
8. If private IP 2 already has a public IP assigned to it:
   a. In the **Public IP Address** section, select the radio button for **No Public IP**.
   b. Click **Update**.
   c. Again for private IP 2, click the Actions icon (three dots), and then click **Edit**.
9. In the **Public IP Address** section, select the radio button for **Reserved Public IP**.
10. Enter the following:
    - **Compartment:** The compartment that contains the reserved public IP you want to assign.
    - **Reserved Public IP:** The reserved public IP you want to assign. It will be moved from the public IP it's currently assigned to.
11. Click **Update**.

To change the display name for a reserved public IP

1. Confirm you're viewing the region and compartment that contains the reserved public IP.
2. Open the navigation menu. Under Core Infrastructure, go to **Networking** and click **Public IPs**.
3. For the reserved public IP you want to edit, click the Actions icon (three dots), and then click **Edit**.
4. Make your changes to the friendly name. The name doesn't have to be unique, and you can change it later. Avoid entering confidential information.
5. Click **Save**.

To manage tags for a reserved public IP

1. Confirm you're viewing the region and compartment that contains the reserved public IP.
2. Open the navigation menu. Under Core Infrastructure, go to **Networking** and click **Public IPs**.
3. For the reserved public IP you're interested in, click the Actions icon (three dots), and then click **View Tags**. From there you can view the existing tags, edit them, and apply new ones.

For more information, see Resource Tags.

To move a reserved public IP to a different compartment

You can move a reserved public IP from one compartment to another. When you move a reserved public IP to a new compartment, inherent policies apply immediately.

1. Open the navigation menu. Under Core Infrastructure, go to **Networking** and click **Public IPs**.

2. For the reserved public IP you're interested in, click the Actions icon (three dots), and then click **Move Resource**.
3. Choose the destination compartment from the list.
4. Click **Move Resource**.

For more information about using compartments and policies to control access to your cloud network, see Access Control. For general information about compartments, see Managing Compartments.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

To manage public IPs, use these operations:

- GetPublicIp: Use this to get a `publicIp` object by specifying its OCID.
- GetPublicIpByIpAddress: Use this to get a `publicIp` object by specifying its public IP address.
- GetPublicIpByPrivateIpId: Use this to get a `publicIp` object by specifying the OCID of the private IP it's assigned to.
- ListPublicIps: Use this to list either your ephemeral or reserved `publicIp` objects.
- CreatePublicIp: Use this to create a new reserved public IP in your pool.
- UpdatePublicIp: Use this to assign, reassign, or unassign a reserved public IP, or to update the display name of an ephemeral or reserved public IP. You can also update a reserved public IP's tags.
- DeletePublicIp: Use this to delete an ephemeral public IP from its private IP, or delete a reserved public IP from your pool. The operation first unassigns the public IP.

- ChangePublicIpCompartment: Use this to move a reserved public IP from one compartment to another. This operation applies only to reserved public IPs. Ephemeral public IPs always belong to the same compartment as their VNIC and move accordingly.

IPv6 Addresses

This topic describes support for IPv6 addressing in your VCN.

Highlights

- IPv6 addressing is currently supported only in the US Government Cloud. See For All Government Cloud Customers.
- During VCN creation, you choose whether the VCN is enabled for IPv6. You also choose whether each subnet in an IPv6-enabled VCN is enabled for IPv6. **You cannot change whether a VCN or subnet is IPv6-enabled after creation.**
- IPv6-enabled VCNs use a /48 IPv6 CIDR block. Oracle assigns a /48 *public* IPv6 CIDR block to the VCN for internet communication. You can either let the *private* IPv6 CIDR block be the same as the public CIDR, or provide your own value (in which case it's referred to as a *custom* IPv6 CIDR). All subnets are /64.
- You also choose whether a given VNIC in an IPv6-enabled subnet has IPv6 addresses (up to 32 maximum per VNIC), and whether each address can be used for internet communication.
- You can choose which particular IPv6 address in the subnet is assigned to a VNIC. This means you can plan how the VCN's private and public address space is allocated within your organization.
- Only these Networking gateways support IPv6 traffic: dynamic routing gateway (DRG) and internet gateway.
- Both inbound- and outbound-initiated IPv6 connections are supported between your VCN and the internet, and between your VCN and your on-premises network.
- Private IPv6 traffic between resources within a region (intra- and inter-VCN) is not yet supported. See other important details in Routing for IPv6 Traffic.

- Both FastConnect and IPSec VPN support IPv6 traffic between your VCN and on-premises network. You must configure the FastConnect or IPSec VPN for IPv6.

Overview of IPv6 Addresses

Oracle supports dual-stack IPv4/IPv6 addressing for VCNs. Every VCN always supports IPv4, and you can optionally enable IPv6 during VCN creation. Enabling IPv6 for the VCN means that when you create a subnet, you can optionally enable it to also have IPv6 addresses. Therefore a VCN can have a mix of IPv4-only subnets and IPv6-enabled subnets.

After you create a Compute instance, you may optionally add an *IPv6* to the VNIC. You can add up to 32 IPv6s to a given VNIC. You can remove an IPv6 from a VNIC at any time.

CIDRs Assigned to an IPv6-Enabled VCN

An IPv6-enabled VCN has 3 CIDR blocks assigned to it. The following table summarizes them.

IPv4 or IPv6	Use and Size	Who Assigns the CIDR Block	Allowed Values
Private IPv4 CIDR	Private communication /16 to /30	You	Typically RFC 1918 range
Private IPv6 CIDR *	On-premises communication Only /48	Optionally, you can assign it. If you do, it's referred to in this documentation as a *custom IPv6 CIDR*. Or, you can let Oracle assign it. **Important:** You must assign this value if you want instances in the same VCN to communicate with each other using public IPv6 addresses. For more information, see Routing for IPv6 Traffic.	If you assign it, see Allowed Custom IPv6 CIDR Ranges.

IPv4 or IPv6	Use and Size	Who Assigns the CIDR Block	Allowed Values
Public IPv6 CIDR	Internet communication Only /48	Oracle	If you assign the VCN's private IPv6 CIDR, it will be different from the *public* IPv6 CIDR that Oracle assigns. But if you let Oracle assign the VCN's private IPv6 CIDR, Oracle uses the *same* CIDR for both the private and public IPv6 CIDRs. That means the private address and public address for a given IPv6 *are the same*.
* Oracle assigns IPv6 CIDR blocks that are NOT in the IPv6 unique local address (ULA) range. This range is analogous to the IPv4 RFC 1918 private ranges. Therefore, all Oracle-assigned IPv6 CIDRs can be considered *public* ranges by this definition.			

Allowed Custom IPv6 CIDR Ranges

Your custom IPv6 CIDR block can be in these general ranges:

- Global unicast: 2000::/3
- ULA: fc00::/7

But it cannot be in these IANA special registry ranges:

- IETF protocol assignments: 2001::/23
- Documentation: 2001:db8::/32
- 6to4: 2002::/16
- Direct Delegation AS112 Service: 2620:4f:8000::/48

Internet Communication

Regardless of whether you or Oracle assigns the VCN's private IPv6 CIDR, Oracle also assigns the VCN an IPv6 CIDR block for the *public* IP address space (the *public IPv6 CIDR*). These addresses are used for internet communication. If you do not assign a custom CIDR, Oracle uses the same Oracle-assigned public IPv6 CIDR for the private address space. **This means that a given VNIC might use the same IPv6 IP address for both private and internet communication.**

You control whether a given IPv6 address can be used for internet communication. If the IPv6 is in a private subnet, it can never be used for internet communication. If it's in a public subnet, you can enable or disable internet access for that IPv6 at any time. If internet access is enabled, the IPv6 uses its public IPv6 address for communication.

Assignment of IPv6 Addresses to a VNIC

To enable IPv6 for a given VNIC, you assign an IPv6 to the VNIC. You can assign up to 32 IPv6s to a VNIC.

As with IPv4, when assigning an IPv6, you can specify the particular address you want to use, or let Oracle choose one for you. By choosing the IPv6 addresses yourself, you can plan how the VCN's private and public address space is allocated within your organization.

You also choose whether the IPv6 has internet access enabled (it is enabled by default if the VNIC is in a public subnet). A VNIC with an internet-enabled IPv6 is not required to have a public IPv4 address.

You can move an IPv6 address from one VNIC to another in the same subnet.

After adding an IPv6 to a VNIC, you must configure the instance's OS to use the IPv6.

Format of IPv6 Addresses

IPv6 addresses have 128 bits.

An IPv6 CIDR block for a VCN must be /48 in size. The left 48 bits identify the VCN portion of the address. For example:

2001:0db8:0123::/48

An IPv6 CIDR block for a subnet must be /64 in size. The right 16 bits in a subnet's CIDR identify the subnet portion of the address. In the following example, the *1111* is the unique portion for the subnet:

2001:0db8:0123:*1111*::/64

The right-most 64 bits of an IPv6 address identify the unique portion specific to the particular IPv6 address. For example:

2001:0db8:0123:1111:*abcd:ef01:2345:6789*

For a given IPv6, those right-most 64 bits **are identical for both the private and public address for an IPv6**. When you assign an IPv6 to a VNIC, you can specify which specific IPv6 address to use (those 64 bits). Therefore you can control how the private and public address space is allocated within your organization.

Example 1: You assign a custom CIDR

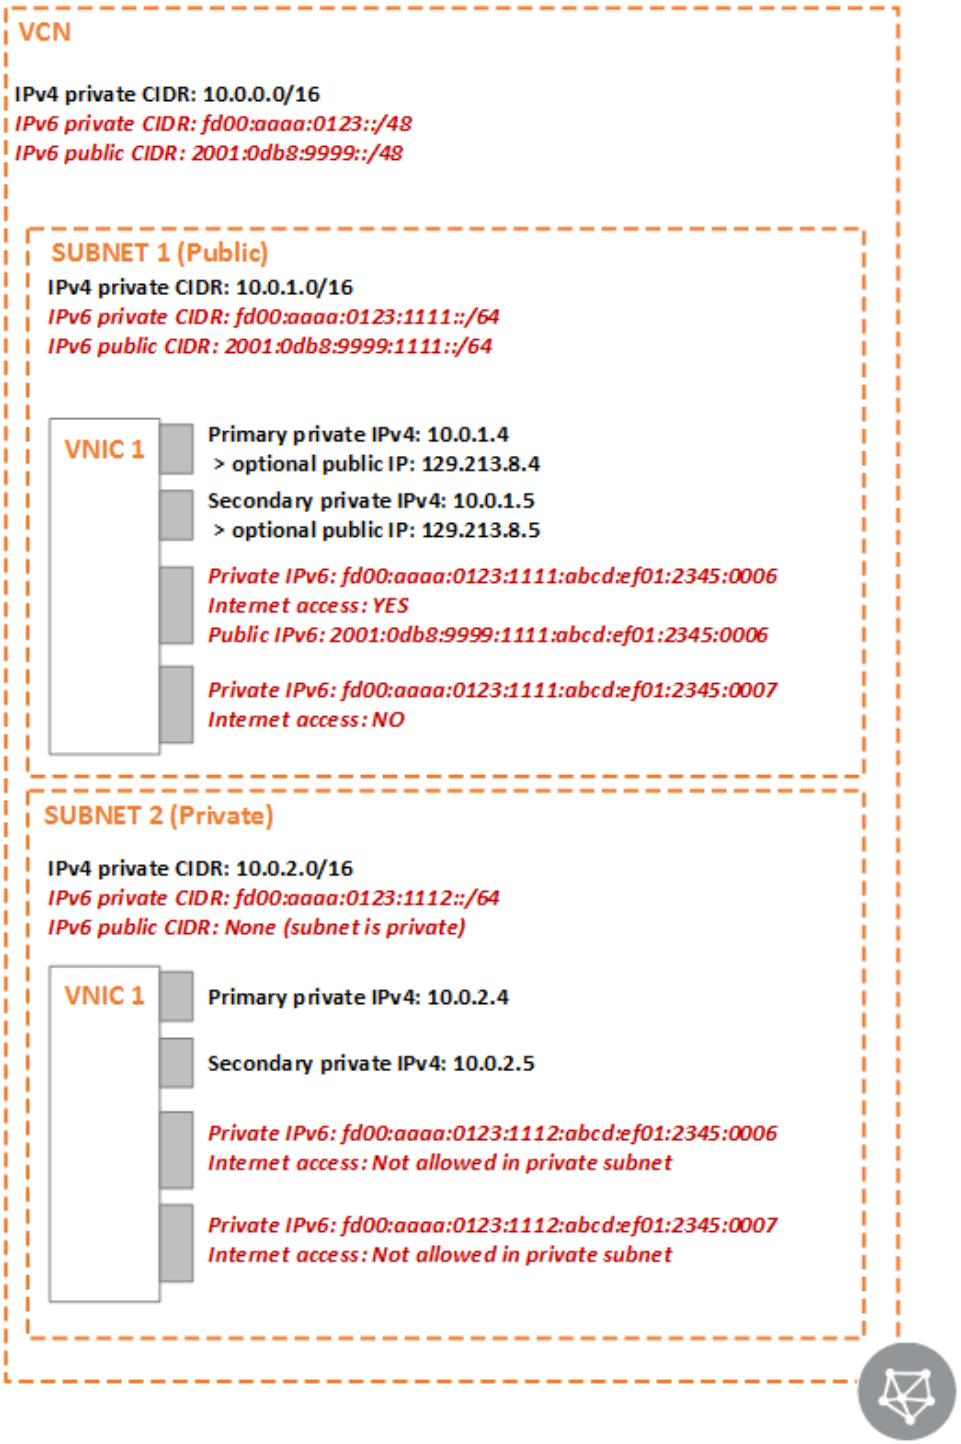
Important

Oracle recommends this option if you want instances within the same IPv6-enabled VCN to communicate with each other using public IPv6 addresses. For more information, see Routing for IPv6 Traffic.

Let's say you provide this custom IPv6 CIDR: *fd00:aaaa:0123*::/48.

Oracle assigns a separate CIDR block for the VCN's public CIDR: *2001:0db8:9999*::/48.

The following diagram illustrates the VCN and includes two subnets: public subnet 1111 and private subnet 1112.



VCN
IPv4 private CIDR: 10.0.0.0/16
IPv6 private CIDR: fd00:aaaa:0123::/48
IPv6 public CIDR: 2001:0db8:9999::/48
SUBNET 1 (Public)
IPv4 private CIDR: 10.0.1.0/16
IPv6 private CIDR: fd00:aaaa:0123:1111::/64
IPv6 public CIDR: 2001:0db8:9999:1111::/64
VNIC 1
Primary private IPv4: 10.0.1.4
> optional public IP: 129.213.8.4
Secondary private IPv4: 10.0.1.5
> optional public IP: 129.213.8.5
Private IPv6: fd00:aaaa:0123:1111:abcd:ef01:2345:0006
Internet access: YES
Public IPv6: 2001:0db8:9999:1111:abcd:ef01:2345:0006
Private IPv6: fd00:aaaa:0123:1111:abcd:ef01:2345:0007
Internet access: NO
SUBNET 2 (Private)
IPv4 private CIDR: 10.0.2.0/16
IPv6 private CIDR: fd00:aaaa:0123:1112::/64
IPv6 public CIDR: None (subnet is private)
VNIC 1
Primary private IPv4: 10.0.2.4
Secondary private IPv4: 10.0.2.5
Private IPv6: fd00:aaaa:0123:1112:abcd:ef01:2345:0006
Internet access: Not allowed in private subnet
Private IPv6: fd00:aaaa:0123:1112:abcd:ef01:2345:0007
Internet access: Not allowed in private subnet

The VNIC in the public subnet has a primary private IPv4 (10.0.1.4) with an optional public IP address assigned. The VNIC has a secondary private IPv4 (10.0.1.5), also with an optional public IP address assigned.

The VNIC also has two IPv6s. The first one has internet access enabled and therefore has both private and public IPv6 addresses, which are the following:

- Private IPv6 address: fd00:aaaa:0123:1111:abcd:ef01:2345:0006
- Public IPv6 address: 2001:0db8:9999:1111:abcd:ef01:2345:0006

Notice that the right-most 64 bits are the same for both the private and public IP address, as are the subnet's 16 bits. Only the left 48-most bits differ.

The second IPv6 in the public subnet does not have internet access enabled and therefore has only a private IP address, which is fd00:aaaa:0123:1111:abcd:ef01:2345:0007.

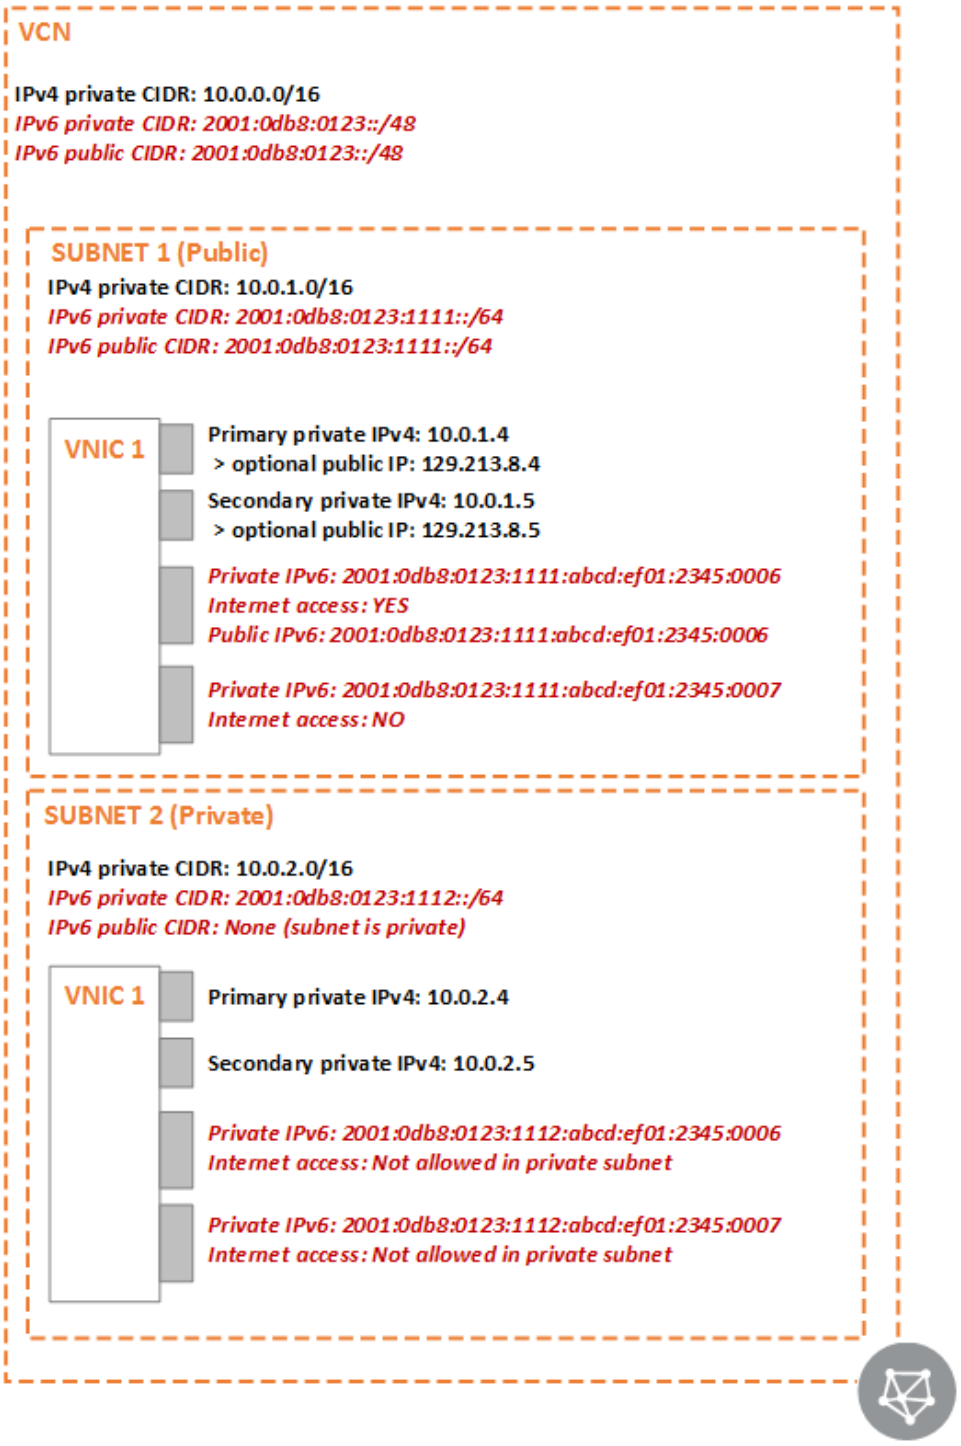
The second subnet is private, which means the VNICs can never have public IPv4 or IPv6 addresses. In this case, there's one VNIC that has a primary and secondary IPv4 with addresses 10.0.2.4 and 10.0.2.5, respectively.

The VNIC also has two IPv6s. The first has private address fd00:aaaa:0123:1112:abcd:ef01:2345:0006, and the second IPv6 has private address fd00:aaaa:0123:1112:abcd:ef01:2345:0007.

Example 2: You let Oracle assign the VCN's CIDR

You do not assign a custom CIDR, and Oracle assigns this CIDR: *2001:0db8:0123*::/48. Oracle uses this same CIDR for both the private and public IP addresses.

The following diagram illustrates the VCN and includes two subnets: public subnet 1111 and private subnet 1112.



VCN
IPv4 private CIDR: 10.0.0.0/16
IPv6 private CIDR: 2001:0db8:0123::/48
IPv6 public CIDR: 2001:0db8:0123::/48
SUBNET 1 (Public)
IPv4 private CIDR: 10.0.1.0/16
IPv6 private CIDR: 2001:0db8:0123:1111::/64
IPv6 public CIDR: 2001:0db8:0123:1111::/64
VNIC 1
Primary private IPv4: 10.0.1.4
> optional public IP: 129.213.8.4
Secondary private IPv4: 10.0.1.5
> optional public IP: 129.213.8.5
Private IPv6: 2001:0db8:0123:1111:abcd:ef01:2345:0006
Internet access: YES
Public IPv6: 2001:0db8:0123:1111:abcd:ef01:2345:0006
Private IPv6: 2001:0db8:0123:1111:abcd:ef01:2345:0007
Internet access: NO
SUBNET 2 (Private)
IPv4 private CIDR: 10.0.2.0/16
IPv6 private CIDR: 2001:0db8:0123:1112::/64
IPv6 public CIDR: None (subnet is private)
VNIC 1
Primary private IPv4: 10.0.2.4
Secondary private IPv4: 10.0.2.5
Private IPv6: 2001:0db8:0123:1112:abcd:ef01:2345:0006
Internet access: Not allowed in private subnet
Private IPv6: 2001:0db8:0123:1112:abcd:ef01:2345:0007
Internet access: Not allowed in private subnet

The VNIC in the public subnet has a primary private IPv4 (10.0.1.4) with an optional public IP address assigned. The VNIC has a secondary private IPv4 (10.0.1.5), also with an optional public IP address assigned.

The VNIC also has two IPv6s. The first one has internet access enabled and therefore has both private and public IPv6 addresses, which are the following:

- Private IPv6 address: 2001:0db8:0123:1111:abcd:ef01:2345:0006
- Public IPv6 address: 2001:0db8:0123:1111:abcd:ef01:2345:0006

Notice that the two addresses are the same.

The second IPv6 does not have internet access enabled and therefore has only a private IP address, which is 2001:0db8:0123:1111:abcd:ef01:2345:0007.

The second subnet is private, which means the VNICs can never have public addresses, IPv4 or IPv6. In this case, there's one VNIC that has a primary and secondary IPv4 with addresses 10.0.2.4 and 10.0.2.5, respectively.

The VNIC also has two IPv6s. The first has private address 2001:0db8:0123:1112:abcd:ef01:2345:0006, and the second IPv6 has private address 2001:0db8:0123:1112:abcd:ef01:2345:0007.

Routing for IPv6 Traffic

Both inbound- and outbound-initiated IPv6 connections are supported between your VCN and the internet, and between your VCN and your on-premises network.

Here are other important details about routing of IPv6 traffic:

- Currently IPv6 traffic is supported only through these gateways:
    - Dynamic routing gateway (DRG): For access to your on-premises network or other networks outside the region. Both Oracle Cloud Infrastructure FastConnect and IPSec VPN support IPv6 traffic. For more details about IPv6 configuration,

see the upcoming sections.

- Internet gateway: For access to the internet.

- Traffic between instances on their public IPv6 addresses is supported and must traverse the VCN's internet gateway. Exception: if the given IPv6 uses the same address for both private and public communication, traffic between instances on their public IPv6 address is not supported. **Therefore, if you want instances in the same VCN to communicate with each other using public IPv6 addresses, specify your own private IPv6 CIDR when creating the VCN.** This means the private address for an IPv6 in the VCN will be different than its public address. For more information, see CIDRs Assigned to an IPv6-Enabled VCN.
- Private IPv6 traffic between resources within a region (intra- and inter-VCN) is not yet supported.

VCN Route Tables and IPv6

The VCN's route tables support both IPv4 rules and IPv6 rules that use a DRG or internet gateway as the target. For example, the route table for a given subnet could have these rules:

- Rule to route traffic that matches a certain IPv4 CIDR to the VCN's attached DRG
- Rule to route traffic that matches a certain IPv4 CIDR to the VCN's service gateway
- Rule to route traffic that matches a certain IPv4 CIDR to the VCN's NAT gateway
- Rule to route traffic that matches a certain **IPv6** CIDR to the VCN's attached DRG
- Rule to route traffic that matches a certain **IPv6** CIDR to the VCN's attached internet gateway

Security Rules for IPv6 Traffic

Like route tables, the VCN's network security groups and security lists support both IPv4 and IPv6 rules. For example, a network security group or security list could have these security rules:

- Rule to allow SSH traffic from the on-premises network's IPv4 CIDR
- Rule to allow ping traffic from the on-premises network's IPv4 CIDR
- Rule to allow SSH traffic from the on-premises network's **IPv6** CIDR
- Rule to allow ping traffic from the on-premises network's **IPv6** CIDR

The default security list in an IPv6-enabled VCN includes default IPv4 rules and the following default IPv6 rules:

- **Stateful ingress:** Allow IPv6 TCP traffic on destination port 22 (SSH) from source ::/0 and any source port. This rule makes it easy for you to create a new VCN with a public subnet and internet gateway, create a Linux instance, add an internet-access-enabled IPv6, and then immediately connect with SSH to that instance without needing to write any security rules yourself.

  Important

  The default security list does not include a rule to allow Remote Desktop Protocol (RDP) access. If you're using Windows images, make sure to add a stateful ingress rule for TCP traffic on destination port 3389 from source ::/0 and any source port. See To enable RDP access for more information.

- **Stateful ingress:** Allow ICMPv6 traffic type 2 code 0 (Packet Too Big) from source ::/0 and any source port. This rule enables your instances to receive Path MTU Discovery fragmentation messages.
- **Stateful egress:** Allow all IPv6 traffic. This allows instances to initiate IPv6 traffic of any kind to any destination. Notice that this means the instances with an internet-access-enabled IPv6 can talk to any internet IPv6 address if the VCN has a configured internet gateway. And because stateful security rules use connection tracking, the response traffic is automatically allowed regardless of any ingress rules. For more information, see Connection Tracking Details for Stateful Rules.

FastConnect and IPv6

If you use FastConnect, you can configure it so that on-premises hosts with IPv6 addresses can communicate with an IPv6-enabled VCN. In general, you must ensure that the FastConnect virtual circuit has IPv6 BGP addresses, and update the VCN's routing and security rules for IPv6 traffic.

About the IPv6 BGP Addresses

A FastConnect virtual circuit always requires IPv4 BGP addresses, but IPv6 BGP addresses are optional and only required for IPv6 traffic. Depending on how you're using FastConnect, you might be asked to provide all of the virtual circuit's BGP addresses yourself (both IPv4 and IPv6).

The addresses consist of a pair: one for your end of the BGP session, and another for the Oracle end of the BGP session.

When you specify a BGP address pair, you must include a subnet mask that contains both of the addresses. Specifically for IPv6, the allowed subnet masks are:

- /64
- /96
- /126
- /127

For example, you could specify 2001:db8::6/127 for the address at your end of the BGP session, and 2001:db8::7/127 for the Oracle end.

Process to Enable IPv6

In general, here's how to enable IPv6 for a FastConnect virtual circuit:

- **Virtual circuit BGP:** Ensure the FastConnect virtual circuit has IPv6 BGP addresses. If you're responsible for providing the BGP IP addresses, when you set up a new virtual circuit or edit an existing one, there's a place for the two IPv4 BGP addresses. There's a

separate check box for **Enable IPv6 Address Assignment** and a place to provide the two IPv6 addresses. Be aware that if you're editing an existing virtual circuit to add support for IPv6, it will go down while it's being reprovisioned to use the new BGP information.

- **VCN route tables:** For each IPv6-enabled subnet in the VCN, update its route table to include rules that route the IPv6 traffic from the VCN to the desired IPv6 subnets in your on-premises network. For example, the **Destination CIDR Block** for a route rule would be an IPv6 subnet in your on-premises network, and the **Target** would be the dynamic routing gateway (DRG) attached to the IPv6-enabled VCN.
- **VCN security rules:** For each IPv6-enabled subnet in the VCN, update its security lists or relevant network security groups to allow the desired IPv6 traffic between the VCN and your on-premises network. See Security Rules for IPv6 Traffic.

If you do not yet have a FastConnect connection, see these topics to get started:

- FastConnect Overview
- FastConnect Requirements

VPN Connect and IPv6

If you use VPN Connect, you can configure it so that on-premises hosts with IPv6 addresses can communicate with an IPv6-enabled VCN. Here's how to enable IPv6 for the connection:

- **IPSec connection static routes:** Configure the IPSec connection with the IPv6 static routes of your on-premises network. Currently the Oracle IPSec VPN does not support BGP dynamic routing.
- **VCN route tables:** For each IPv6-enabled subnet in the VCN, update its route table to include rules that route the IPv6 traffic from the VCN to the desired IPv6 subnets in your on-premises network. For example, the **Destination CIDR Block** for a route rule would be an IPv6 static route for your on-premises network, and the **Target** would be the dynamic routing gateway (DRG) attached to the IPv6-enabled VCN.

- **VCN security rules:** For each IPv6-enabled subnet in the VCN, update its security lists or relevant network security groups to allow the desired IPv6 traffic between the VCN and your on-premises network. See Security Rules for IPv6 Traffic.

If you have an existing IPSec VPN that uses static routing, you can update the list of static routes to include ones for IPv6. Be aware that changing the list of static routes causes the IPSec VPN to go down while it's being reprovisioned. See Changing the Static Routes.

If you do not yet have an IPSec VPN, see these topics to get started:

- VPN Connect Overview
- Setting Up VPN Connect
- Working with VPN Connect

DHCP

Currently DHCPv6 auto-configuration of IP addresses is not supported.

DNS

The VCN's Internet Resolver supports IPv6, which means resources in your VCN can resolve IPv6 addresses of hosts outside the VCN. IPv6 traffic between resources within the VCN is not yet supported, and assignment of a hostname to an IPv6 address is not supported.

Load Balancers

When you create a load balancer, you can optionally choose to have an IPv4/IPv6 dual-stack configuration. When you choose the IPv6 option, the Load Balancing service assigns both an IPv4 and an IPv6 address to the load balancer. The load balancer receives client traffic sent to the assigned IPv6 address. The load balancer uses only IPv4 addresses to communicate with backend servers. There is no IPv6 communication between the load balancer and the backend servers.

IPv6 address assignment occurs only at load balancer creation. You cannot assign an IPv6 address to an existing load balancer.

Comparison of IPv4 and IPv6 for Your VCN

The following table summarizes the differences between IPv4 and IPv6 addressing in a VCN.

Characteristic	IPv4	IPv6
Addressing type supported	IPv4 addressing is always required, regardless of whether IPv6 is enabled.	IPv6 addressing is optional per VCN, optional per subnet in an IPv6-enabled VCN, and optional per VNIC in an IPv6-enabled subnet.
Supported traffic types	IPv4 traffic is supported for all gateways. IPv4 traffic between instances within the VCN is supported (east/west traffic).	IPv6 traffic is supported only with these gateways: internet gateway and DRG. Both inbound- and outbound-initiated IPv6 connections are supported between your VCN and the internet, and between your VCN and your on-premises network. Private IPv6 traffic between resources within a region (intra- and inter-VCN) is not yet supported (east/west traffic). Also see the caveats in Routing for IPv6 Traffic.
VCN size	/16 to /30	/48 only
Subnet size	/16 to /30, with 3 addresses reserved in each subnet by Oracle (first 2 and last 1).	/64 only, with 8 addresses in the subnet reserved by Oracle (first 4 and last 4).

Characteristic	IPv4	IPv6
Private and public IP address space	Private: A VCN's private IPv4 CIDR can be from an RFC 1918 range or a publicly routable range (in which case, it's treated as private). You must specify the range, unless you use the Console's VCN creation wizard, which always uses 10.0.0.0/16. Public: The VCN does not have a dedicated public IPv4 address space. Any public addresses in your VCN are always chosen by Oracle.	You can specify a /48 from the list of supported ranges for the private IPv6 CIDR (see CIDRs Assigned to an IPv6-Enabled VCN). If you don't specify a range, Oracle assigns a /48 CIDR that is used for both the private and public IP address space. **Important:** You must assign this value if you want instances in the same VCN to communicate with each other using public IPv6 addresses. For more information, see Routing for IPv6 Traffic. Unlike with IPv4, your VCN has a *dedicated* public IPv6 address space, which is always /48 in size. When you assign an IPv6 to a VNIC, you can choose the address, or you can let Oracle chose it.

Characteristic	IPv4	IPv6
IP address assignment	Private: Each VNIC gets a private IPv4 address. You can choose the address or let Oracle choose it. Public: You determine whether the private IPv4 address has a public IP address associated with it (assuming the VNIC is in a public subnet). Oracle chooses the public IP address. From an API standpoint: the `PrivateIp` object is separate from the `PublicIp` object. You can remove the public IP address from the private IPv4 address at any time.	You decide whether a VNIC in an IPv6-enabled subnet gets an IPv6. You can choose the private IPv6 address or let Oracle choose it. You also decide whether that IPv6 has internet access enabled (assuming the VNIC is in a public subnet). You can remove the internet access for that IPv6 at any time. When an IPv6 is internet enabled, it has a public IPv6 address. The public IPv6 address always has the same right-most 64 bits as the private IPv6 address. Recall that if Oracle assigns the VCN's private IPv6 CIDR, then the private and public CIDRs for the VCN are the same. In that case, each IPv6 uses the same address (all 128 bits) for both its private IP address and public IP address. From an API standpoint: both the private and public IP addresses are included in the `Ipv6` object and always exist together.
Internet access	You control whether a subnet is public or private. You add or remove a public IP address from a private IPv4 address on a VNIC (assuming the VNIC is in a public subnet).	You control whether a subnet is public or private. You do not add or remove a public IP address to or from the VNIC as you do with IPv4. Instead you enable or disable the internet access for a given IPv6 that you've added to a VNIC (assuming the VNIC is in a public subnet).

Characteristic	IPv4	IPv6
Primary and secondary labels	Each VNIC automatically has a primary private IP address, and you can assign up to 31 secondary private IPs per VNIC.	You choose to add an IPv6 to a VNIC. There is no *primary* or *secondary* label for it. You can assign up to 32 IPv6s per VNIC.
Hostnames	You can assign hostnames to IPv4 addresses.	You cannot assign hostnames to IPv6 addresses.
Route rule limits	See Service Limits.	IPv4 and IPv6 route rules can reside together in the same route table. IPv6 route rules can target only an internet gateway or DRG. Limit on number of IPv6 route rules in a route table: 8.
Security rule limits	See Service Limits.	IPv4 and IPv6 security rules can reside together in same network security group or security list. IPv6 security rules can use only IPv6 CIDR ranges for source or destination, and not a service CIDR label used for a service gateway. Limit on number of IPv6 security rules in a security list: 8 ingress and 8 egress. Limit on number of IPv6 security rules in a network security group: 16 total.

Characteristic	IPv4	IPv6
Reserved public IP addresses	Supported.	Not supported.
Regional or AD-specific	Primary private IPv4 addresses are AD-specific. Secondary private IPv4 addresses are AD-specific unless assigned to a VNIC in a regional subnet. Public IP addresses can be AD-specific or regional depending on the type (ephemeral or reserved). See Public IP Addresses.	IPv6 addresses are regional.

Setting Up an IPv6-Enabled VCN with Internet Access

Use the following process if you want to set up an IPv6-enabled VCN with internet access so you can easily launch an instance and connect to it by using its public IPv6 address.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Task 1: Create the IPv6-enabled VCN

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator. For more information, see Access Control.
3. Click **Create Virtual Cloud Network**.
4. Enter the following:
    - **Name:** A descriptive name for the VCN. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
    - **Create in Compartment:** Leave as is.
    - **Create Virtual Cloud Network Only:** Make sure this radio button is selected (the default).
    - **CIDR Block:** A single, contiguous IPv4 CIDR block for the VCN. For example: 172.16.0.0/16. You *cannot* change this value later. See Allowed VCN Size and Address Ranges. For reference, here's a CIDR calculator.
    - **Enable IPv6 Address Assignment:** Select the check box and optionally provide the private IPv6 CIDR in the field labeled **Private IPv6 CIDR Block**. You must provide the value **if you want the instances in this IPv6-enabled VCN to communicate with each other using their public IP addresses**. Leave the field blank if you want Oracle to assign the private IPv6 CIDR for you. You *cannot* later disable IPv6 for the VCN or change the CIDR. All IPv6-enabled VCNs are always /48 in size.
    - **Use DNS Hostnames in this VCN** (supported for IPv4 only): Required for assignment of DNS hostnames to hosts in the VCN, and required if you plan to use the VCN's default DNS feature (called the *Internet and VCN Resolver*). If the

check box is selected, you can specify a DNS label for the VCN, or the Console will generate one for you. The dialog box automatically displays the corresponding **DNS Domain Name** for the VCN (*<VCN DNS label>*.oraclevcn.com). For more information, see DNS in Your Virtual Cloud Network.

- **Tags:** Leave as is. You can add tags later if you want. For more information, see Resource Tags.

5. Click **Create Virtual Cloud Network**.
   The VCN is then created and displayed on the **Virtual Cloud Networks** page in the compartment you chose.

Task 2: Create a regional IPv6-enabled public subnet

1. While still viewing the VCN, click **Create Subnet**.
2. Enter the following:
   - **Name:** A descriptive name for the subnet (for example, Regional Public Subnet). It doesn't have to be unique, and you can change it later. Avoid entering confidential information.
   - **Regional or Availability Domain-specific subnet:** Oracle recommends creating only regional subnets, which means that the subnet can contain resources in any of the region's availability domains. If you instead choose **Availability Domain-Specific** (the only kind of subnet that Oracle originally offered), you must also specify an availability domain. This choice means that any instances or other resources later created in this subnet must also be in that availability domain.
   - **CIDR Block:** A single, contiguous IPv4 CIDR block for the subnet (for example, 172.16.0.0/24). Make sure it's within the VCN's IPv4 CIDR block and doesn't overlap with any other subnets. You *cannot* change this value later. See Allowed VCN Size and Address Ranges. For reference, here's a CIDR calculator.
   - **Enable IPv6 Address Assignment:** Select the check box and provide your choice of 16 bits for the subnet (example: 1111). You *cannot* later disable IPv6 for

the subnet or change the CIDR. All IPv6-enabled subnets are always /64 in size. For more information about IPv6 address format, see Format of IPv6 Addresses.

- **Route Table:** Select the default route table.
- **Private or public subnet**: Select **Public Subnet**, which means instances in the subnet can optionally have public IP addresses. For more information, see Access to the Internet.
- **Use DNS Hostnames in this Subnet** (supported for IPv4 only): This option is available only if you provided a DNS label for the VCN during creation. The option is required for assignment of DNS hostnames to hosts in the subnet, and required if you plan to use the VCN's default DNS feature (called the *Internet and VCN Resolver*). If the check box is selected, you can specify a DNS label for the subnet, or the Console will generate one for you. The dialog box automatically displays the corresponding **DNS Domain Name** for the subnet (*<subnet_DNS_label>*.*<VCN_DNS_label>*.oraclevcn.com). For more information, see DNS in Your Virtual Cloud Network.
- **DHCP Options:** Select the default set of DHCP options.
- **Security Lists:** Make sure the default security list is selected (the default).
- **Tags:** Leave as is. You can add tags later if you want. For more information, see Resource Tags.

3. Click **Create Subnet**.
   The subnet is then created and displayed on the **Subnets** page.

Task 3: Create the internet gateway

1. Under **Resources**, click **Internet Gateways**.
2. Click **Create Internet Gateway**.
3. Enter the following:
   - **Name:** A descriptive name for the internet gateway. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API).

Avoid entering confidential information.

- **Create in Compartment:** Leave as is.
- **Tags:** Leave as is. You can add tags later if you want. For more information, see Resource Tags.

4. Click **Create Internet Gateway**.
   Your internet gateway is created and displayed on the **Internet Gateways** page. It's already enabled, but you must add route rules that allow IPv4 and IPv6 traffic to flow to the gateway.

Task 4: Update the default route table to use the internet gateway

The default route table starts out with no rules. Here you add rules that route all IPv4 and IPv6 traffic destined for addresses outside the VCN to the internet gateway. The existence of these rules also enables inbound connections to come from the internet to the subnet, through the internet gateway. You use security rules to control the *types of traffic* that are allowed in and out of the instances in the subnet (see the next task).

No route rule is required in order to route traffic within the VCN itself.

1. Under **Resources**, click **Route Tables**.
2. Click the default route table to view its details.
3. Click **Add Route Rules**.
4. Enter the following:
   - **Target Type:** Internet Gateway
   - **Destination CIDR block:** `0.0.0.0/0` (which means that all IPv4 non-intra-VCN traffic that is not already covered by other rules in the route table goes to the target specified in this rule).
   - **Compartment:** The compartment where the internet gateway is located.
   - **Target:** The internet gateway you created.
5. Click **+ Additional Route Rule**.

6. Enter the following:
    - **Target Type:** Internet Gateway
    - **Destination CIDR block:** `::/0` (for the IPv6 traffic).
    - **Compartment:** The compartment where the internet gateway is located.
    - **Target:** The internet gateway you created.
7. Click **Add Route Rules**.

The default route table now has two rules for the internet gateway, one for IPv4 traffic and one for IPv6 traffic. Because the subnet was set up to use the default route table, the resources in the subnet can now use the internet gateway. The next step is to specify the types of traffic you want to allow in and out of the instances you later create in the subnet.

Task 5: Update the default security list (optional)

Note

This task is about configuring security rules to allow the desired traffic to and from your instances. Although this task uses a security list to implement those rules, you can also use network security groups to implement security rules.

Earlier you set up the subnet to use the VCN's default security list. This list already includes basic rules that allow essential IPv4 and IPv6 traffic. In this task, you add any *additional* security rules that allow the types of connections that the instances in the VCN will need.

For example: This is a public subnet with an internet gateway, so the instances you create might need to receive inbound HTTPS connections from the internet (if they're web servers). Here's how to add another rule to the default security list to enable that traffic:

1. Under **Resources**, click **Security Lists.**
2. Click the default security list to view its details. By default, you land on the **Ingress Rules** page.
3. Click **Add Ingress Rule**.
4. To enable inbound connections for HTTPS (TCP port 443), enter the following:
   - **Stateless**: Unselected (this is a stateful rule)
   - **Source Type:** CIDR
   - **Source CIDR:** 0.0.0.0/0 (or ::/0 if you want to enable IPv6 traffic with this rule)
   - **IP Protocol:** TCP
   - **Source Port Range:** All
   - **Destination Port Range**: 443
5. Click **Add Ingress Rule**.

> **Important**
>
> *Security List Rule for Windows Instances*
>
> If you're going to create Windows instances, you need to add a security rule to enable Remote Desktop Protocol (RDP) access. Specifically, you need a stateful ingress rule for TCP traffic on destination port 3389 from source 0.0.0.0/0 (and a separate rule with ::/0 for IPv6 traffic) and any source port. For more information, see Security Rules.

For a production VCN, you typically set up one or more *custom* security lists for each subnet. If you like, you can edit the subnet to use different security lists. If you choose not to use the default security list, do so only after carefully assessing which of its default rules you want to duplicate in your custom security list. For example: the default ICMP rules in the default security list are important for receiving connectivity messages for IPv4.

Task 6: Create an instance

Your next step is to create an instance in the subnet. When you create the instance, you choose the availability domain, which VCN and subnet to use, and several other characteristics.

Each instance automatically gets a private IPv4 address. When you create an instance in a *public subnet*, you choose whether the instance gets a public IP address. A public IPv4 address is NOT required for public IPv6 traffic. But if you want to connect to the instance from an IPv4 host, you *must* give the instance a public IP address, or else you can't access them through the internet gateway. The default (for a public subnet) is for the instance to get a public IP address.

For more information and instructions, see Launching an Instance.

Task 7: Add an internet-enabled IPv6 to the instance

1. While viewing the instance you just created, click **Attached VNICs**.
2. Click the VNIC.
3. Under **Resources**, click **IPv6 Addresses**.
4. Click **Assign Private IPv6 Address**.
5. Enter the following:
    - **Private IPv6 Address:** Optional. An available private IPv6 address of your choice from the subnet's private IPv6 CIDR (otherwise the private IP address is automatically assigned).
    - **Unassign if already assigned to another VNIC:** Leave this check box as is (cleared). Use this only to force reassignment of an IPv6 address if it's already assigned to another VNIC in the subnet. Relevant only if you specify a private IP address in the preceding field.
    - **Enable Internet Access:** Select this check box. This enables internet access and assigns the IPv6 a public address (if it's in a public subnet, which is the case here). See Internet Communication.

- **Tags:** Leave as is. You can add tags later if you want. For more information, see Resource Tags.

6. Click **Assign**.
   The IPv6 is created and then displayed on the **IPv6 Addresses** page for the VNIC. Notice that it has both a private and public IPv6 address.

Task 8: Configure the instance's OS to use the IPv6

You must configure the instance's OS to use the IPv6. For more information, see Configuring the OS to Use an IPv6.

After performing this task, you can connect to the instance over the internet with SSH or RDP from your on-premises network or a location on the internet. The host connecting to the instance must be using a public IPv6 address.

Managing IPv6s in the Console

This section includes basic tasks for working with IPv6-related resources.

To create an IPv6-enabled VCN

Important

You can't enable IPv6 for an existing VCN. You can only enable IPv6 when creating a VCN. After enabling IPv6 for a VCN, you cannot disable it.

Summary: When creating a VCN, you choose between these two options:

- Creating *only* a VCN
- Creating a VCN plus related resources

The following table summarizes the difference between the two options. Regardless of which option you select, make sure to select the check box for **Enable IPv6 Address Assignment** when you create the VCN. Further instructions follow the table.

Choice for creating the VCN	What Is Created	Notes
VCN only	VCN only You must manually create and configure other components required so you can create instances in the VCN and connect to them. For instructions, see Setting Up an IPv6-Enabled VCN with Internet Access.	**Recommended choice if you want the instances in the same IPv6-enabled VCN to communicate with each other using their public IP addresses.** This type of communication is supported only if the private address for an IPv6 in the VCN is different than its public address. That means you must specify the value for the VCN's private IPv6 CIDR and NOT let Oracle choose it (Oracle uses the same IPV6 CIDR for both private and public address space). For more information, see CIDRs Assigned to an IPv6-Enabled VCN and also Routing for IPv6 Traffic.
VCN plus related resources	VCN One public subnet per availability domain Internet gateway Default route table with IPv4 rule and IPv6 rule for internet gateway traffic Default security list with rules for essential IPv4 traffic and IPv6 traffic	Oracle automatically chooses the IPv6 CIDR for the VCN and uses that same CIDR for the private and public IPv6 address space. For more information, see CIDRs Assigned to an IPv6-Enabled VCN.

Instructions to create an IPv6-enabled VCN only

See the instructions in Task 1: Create the IPv6-enabled VCN.

Instructions to create an IPv6-enabled VCN plus related resources

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator. For more information, see Access Control.
3. Click **Create Virtual Cloud Network**.
4. Enter the following:
    - **Name:** A descriptive name for the VCN. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
    - **Create in Compartment:** Leave as is.
    - **Create Virtual Cloud Network Plus Related Resources:** Make sure this radio button is selected.
    - **Enable IPv6 Address Assignment:** Select the check box. Oracle chooses the private IPv6 CIDR and uses the same value for the public IPv6 CIDR. For more information, see CIDRs Assigned to an IPv6-Enabled VCN.
    - **Use DNS Hostnames in this VCN** (supported for IPv4 only): Required for assignment of DNS hostnames to hosts in the VCN, and required if you plan to use the VCN's default DNS feature (called the *Internet and VCN Resolver*). If the check box is selected, you can specify a DNS label for the VCN, or the Console will generate one for you. The dialog box automatically displays the corresponding **DNS Domain Name** for the VCN (`<VCN DNS label>.oraclevcn.com`). For more information, see DNS in Your Virtual Cloud Network.

- **Tags:** Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.

5. Click **Create Virtual Cloud Network**.
   The VCN is then created and displayed on the **Virtual Cloud Networks** page in the compartment you chose. The VCN has one public subnet per availability domain, an internet gateway, routing set up to use the internet gateway, and basic security rules in the default security list.

To create an IPv6-enabled subnet

Important

After enabling IPv6 for a subnet, you cannot disable it.

Summary: Creating an IPv6-enabled subnet is similar to creating an IPv4 subnet. The only difference is that you must select the check box for **Enable IPv6 Address Assignment** and provide 16 bits for the subnet's portion of the IPv6 CIDR. See Format of IPv6 Addresses.

For general instructions, see Task 2: Create a regional IPv6-enabled public subnet. If you want a private subnet, make sure to select the radio button for **Private Subnet** when creating the subnet.

To assign an IPv6 to a VNIC

Summary: The process for adding an IPv6 to a VNIC is similar to adding a secondary private IPv4 address. You can specify the particular IPv6 address to use or let Oracle choose it from the subnet. You can enable internet access if you like. The resulting public IPv6 address uses

the same right-most 64 bits as the private IPv6 address. In certain situations, the entire IPv6 address is the same. For more information, see Format of IPv6 Addresses. After assigning the IPv6 to the VNIC, you must configure the OS to use the IPv6.

Instructions

1. Assign the IPv6. For general instructions, see Task 7: Add an internet-enabled IPv6 to the instance. If you want an IPv6 without internet access, do not select the check box for **Enable Internet Access** when assigning the IPv6.
2. Configure the OS to use the IPv6 address. For more information, see Configuring the OS to Use an IPv6.

To move an IPv6 to another VNIC in the subnet

Summary: The process is similar to moving a secondary private IPv4 address from one VNIC to another (let's call them the *original VNIC* and the *new VNIC*). You assign the IPv6 to the new VNIC, specify the private IPv6 address, and select the check box for **Unassign if already assigned to another VNIC**. Oracle automatically unassigns it from original VNIC and assigns it to the new VNIC. The public address for the IPv6 stays the same regardless of which VNIC the IPv6 is assigned to.

Instructions

1. Confirm you're viewing the compartment that contains the instance you're interested in.
2. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
3. Click the instance to view its details.
4. Under **Resources**, click **Attached VNICs**.
   The primary VNIC and any secondary VNICs attached to the instance are displayed.
5. Click the VNIC you're interested in.

6. Under **Resources**, click **IPv6 Addresses**.
7. Click **Assign Private IP Address**.
8. Enter the following:
   - **Private IPv6 Address:** The private IPv6 address that you want to move.
   - **Unassign if already assigned to another VNIC:** Select this check box to move the IPv6 address from the VNIC it's currently assigned to.
   - **Enable Internet Access:** Whether to assign a public IPv6 address. Available only if the VNIC is in a public subnet. See Internet Communication.
   - **Tags:** Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.
9. Click **Assign**.

The private IP address is moved from the original VNIC to the new VNIC.

To delete an IPv6 from a VNIC

1. Confirm you're viewing the compartment that contains the instance you're interested in.
2. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
3. Click the instance to view its details.
4. Under **Resources**, click **Attached VNICs**.
   The primary VNIC and any secondary VNICs attached to the instance are displayed.
5. Click the VNIC you're interested in.
6. Under **Resources**, click **IPv6 Addresses**.

7. For the IPv6 you want to delete, click the Actions icon (three dots), and then click **Delete IPv6**.
8. Confirm when prompted.

The IPv6 address is returned to the pool of available addresses in the subnet.

To enable or disable internet access for an IPv6

Summary: Internet access for an IPv6 is controlled by the IPv6's **Enable Internet Access** check box. When you enable internet access, the IPv6 is assigned a public IPv6 address. That address's right-most 64 bits are the same as the private IPv6 address. In certain situations, the entire IPv6 address is the same. For more information, see Format of IPv6 Addresses.

Instructions

1. Confirm you're viewing the compartment that contains the instance you're interested in.
2. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
3. Click the instance to view its details.
4. Under **Resources**, click **Attached VNICs**.
   The primary VNIC and any secondary VNICs attached to the instance are displayed.
5. Click the VNIC you're interested in.
6. Under **Resources**, click **IPv6 Addresses**.
7. For the IPv6 you're interested in, click the Actions icon (three dots), and then click **Edit**.
8. Either select or clear the check box for **Enable Internet Access**.
9. Click **Update**.

When you disable internet access, the public IPv6 address becomes null. If you re-enable internet access, the public IPv6 address is again assigned to the IPv6.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

For IPv6 addressing, there's an Ipv6 object with the following operations:

- ListIpv6s
- GetIpv6
- UpdateIpv6
- CreateIpv6
- DeleteIpv6

Configuring the OS to Use an IPv6

After assigning an IPv6 to a VNIC, you must configure the OS to use the IPv6.

Getting the IPv6 Virtual Router IP (Default Gateway)

You need the *IPv6 virtual router IP* (called the *default gateway* in Windows), which is included in the instance metadata available at the following URL:

```
http://169.254.169.254/opc/v1/vnics/
```

Here's an example response:

```
[ {
  "vnicId" : "ocid1.vnic.oc1.phx.examplevq7kncmdtfr23dznohdkd2cywjcem33eg3dxa",
  "privateIp" : "10.0.3.7",
  "vlanTag" : 3396,
  "macAddr" : "00:00:17:01:14:0C",
  "virtualRouterIp" : "10.0.3.1",
  "subnetCidrBlock" : "10.0.3.0/24",
  "ipv6SubnetCidrBlock" : "2001:0db8:95f4::/64",
  "ipv6VirtualRouterIp" : "2001:0db8::200:17ff:fee3:c491"
} ]
```

Oracle Linux 7 Configuration

The following commands are for Oracle Linux 7. They are NOT persistent through a reboot. You need the IPv6 virtual router IP from the instance metadata (see the previous section).

```
sysctl net.ipv6.conf.all.disable_ipv6=0
ip -6 addr add <private_IPv6_address>/64 dev <interface_name>
ip -6 route add default via <IPv6_virtual_router_IP> dev <interface_name>
```

For example:

```
sysctl net.ipv6.conf.all.disable_ipv6=0
ip -6 addr add 2001:0db8:95f4::abcd:1234/64 dev ens3
ip -6 route add default via 2001:0db8::200:17ff:fee3:c491 dev ens3
```

If you haven't yet, make sure the VCN's route table and security rules are configured for the desired IPv6 traffic. See Routing for IPv6 Traffic and Security Rules for IPv6 Traffic.

Windows Configuration

You can use a command line or the Network Connections UI.

Command Line

If you use PowerShell, you must run it as an administrator. The following configuration persists through a reboot of the instance.

1. In your browser, go to the Console, and note the private IPv6 address that you want to configure on the instance.
2. Connect to the instance, and run the following command at a command prompt:

   ```
   http://169.254.169.254/opc/v1/vnics/
   ```

3. Note the value for the `ipv6VirtualRouterIp`, which is the *<default_gateway>* to use in the next step.
4. Run the following 2 commands:

```
netsh interface ipv6 add address interface="Ethernet" address=<private_IPv6_address>/64
netsh interface ipv6 add route prefix=::/0 interface="Ethernet" nexthop=<default_gateway>
publish=Yes
```

For example:

```
netsh interface ipv6 add address interface="Ethernet" address=2001:0db8:95f4::abcd:1234/64
netsh interface ipv6 add route prefix=::/0 interface="Ethernet"
nexthop=2001:0db8::200:17ff:fee3:c491 publish=Yes
```

If you haven't yet, make sure the VCN's route table and security rules are configured for the desired IPv6 traffic. See Routing for IPv6 Traffic and Security Rules for IPv6 Traffic.

You can run the following command to see that the IPv6 address has been configured for the interface:

```
netsh interface ipv6 show addresses
```

Later if you want to delete the address, you can use this command:

```
netsh interface ipv6 delete address interface="Ethernet" address=<private_IPv6_address>
```

For example:

```
netsh interface ipv6 delete address interface="Ethernet" address=2001:0db8:95f4::abcd:1234
```

Also make sure to delete the IPv6 from the VNIC. You can do that before or after executing the earlier command to delete the address from the OS configuration.

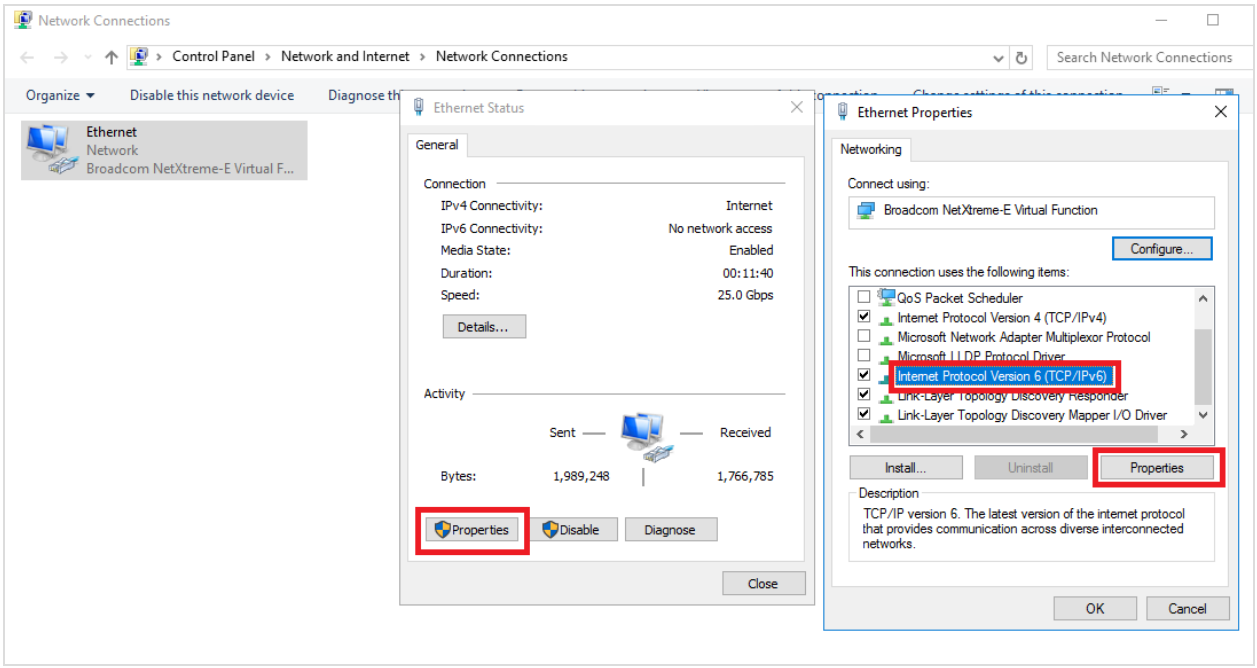
Network Connections UI

The following configuration persists through a reboot of the instance.

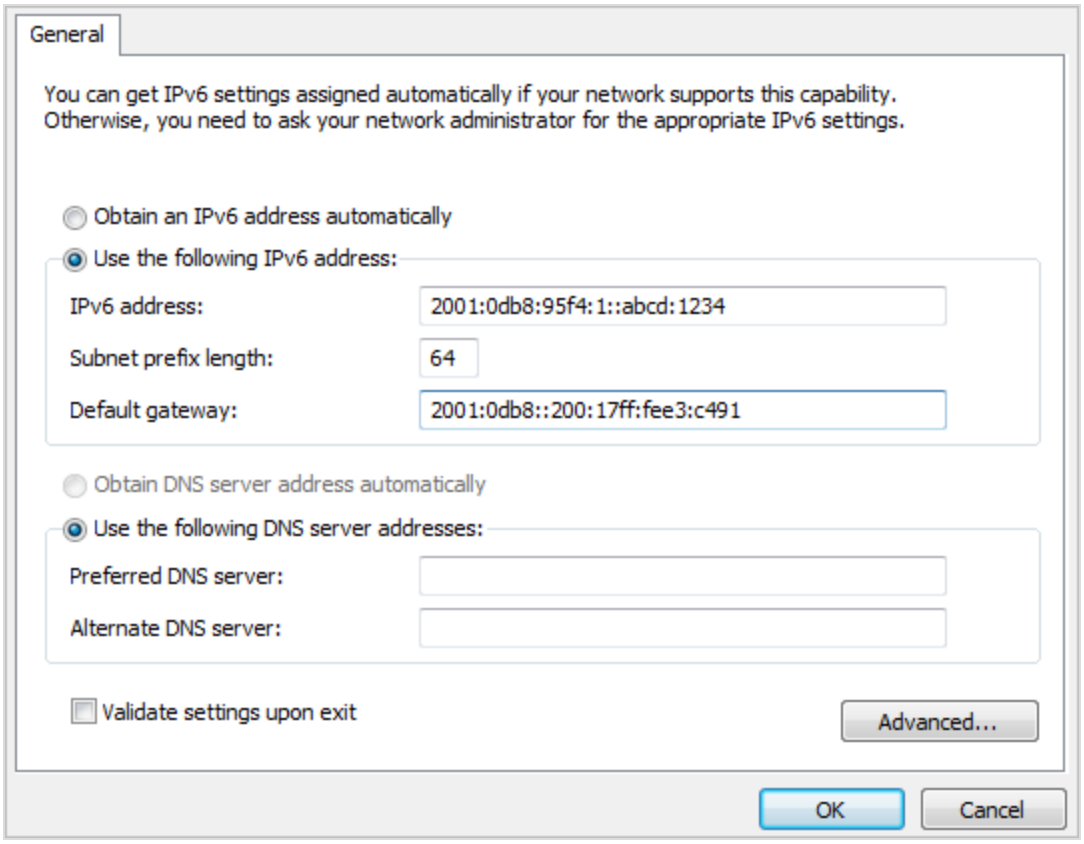
1. In your browser, go to the Console, and note the private IPv6 address that you want to configure on the instance.
2. Connect to the instance, and run the following command at a command prompt:

```
http://169.254.169.254/opc/v1/vnics/
```

3. Note the value for the `ipv6VirtualRouterIp`, which is the default gateway to use in a later step.
4. In the instance's **Control Panel**, go to **Network and Internet**, and view your network connections (see the image that follows for the set of dialog boxes you see in these steps).
5. For the active networks, click the connection (**Ethernet**).
6. Click **Properties**.
7. Click **Internet Protocol Version 6 (TCP/IPv6)**, and then click **Properties**.



8. Select the radio button for **Use the following IP address**, and then enter the values you noted earlier for the private IPv6 address and default gateway. Use 64 for the subnet prefix length.



9. Click **OK** until the dialog boxes are closed.

If you haven't yet, make sure the VCN's route table and security rules are configured for the desired IPv6 traffic. See Routing for IPv6 Traffic and Security Rules for IPv6 Traffic.

DNS in Your Virtual Cloud Network

The Domain Name System (DNS) lets computers use hostnames instead of IP addresses to communicate with each other.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Choices for DNS in Your VCN

Following are the choices for DNS name resolution for the instances in your VCN. You make this choice for *each subnet* in the VCN, using the subnet's set of DHCP options. This is similar to how you configure which route table and security lists are associated with each subnet. For more information, see DHCP Options.

Note

You use the Domain Name Server DHCP option to specify the DNS Type for the associated subnet. If you change the option's value, either restart the DHCP client on the instance or reboot the instance. Otherwise, the change does not get picked up until the DHCP client refreshes the lease (within 24 hours).

DEFAULT CHOICE: INTERNET AND VCN RESOLVER

This is an Oracle-provided option that includes two parts:

- **Internet Resolver:** Lets instances resolve hostnames that are publicly published on the internet. The instances do not need to have internet access by way of either an internet gateway or a connection to your on-premises network (such as an IPSec VPN connection through a DRG).

- **VCN Resolver:** Lets instances resolve hostnames (which you can assign) of other instances in the same VCN. For more information, see About the DNS Domains and Hostnames.

By default, new VCNs you create use the Internet and VCN Resolver. If you're using the Networking API, this choice refers to the `VcnLocalPlusInternet` enum in the DhcpDnsOption object.

Note

The Internet and VCN Resolver does not let instances resolve the hostnames of hosts in your on-premises network connected to your VCN by IPSec VPN connection or FastConnect. Use your own custom DNS resolver to enable that.

CUSTOM RESOLVER

Use DNS servers of your choice for resolution (maximum three). They could be DNS servers that are:

- Available through the internet. For example, 216.146.35.35 for Dyn's Internet Guide.
- In your VCN.
- In your on-premises network, which is connected to your VCN by way of an IPSec VPN connection or FastConnect (through a DRG).

About the DNS Domains and Hostnames

When you initially create a VCN and subnets, you may specify DNS labels for each. The labels, along with the parent domain of `oraclevcn.com` form the VCN domain name and subnet domain name:

- **VCN domain name:** *<VCN DNS label>*.oraclevcn.com
- **Subnet domain name:** *<subnet DNS label>*.*<VCN DNS label>*.oraclevcn.com

When you then launch an instance, you may assign a hostname. It's assigned to the VNIC that's automatically created during instance launch (that is, the *primary VNIC*). Along with the subnet domain name, the hostname forms the instance's fully qualified domain name (FQDN):

- **Instance FQDN:** `<hostname>.<subnet DNS label>.<VCN DNS label>.oraclevcn.com`

For example: `database1.privatesubnet1.abccorpvcn1.oraclevcn.com`.

The FQDN resolves to the instance's private IP address. The Internet and VCN Resolver also enables reverse DNS lookup, which lets you determine the hostname corresponding to the private IP address.

If you add a secondary VNIC to the instance, you can specify a hostname. The resulting FQDN resolves to the VNIC's private IP address (that is, the *primary private IP*).

If you add a secondary private IP to a VNIC, you can specify a hostname. The resulting FQDN resolves to that private IP address.

Requirements for DNS Labels and Hostnames

- VCN and subnet labels: Max 15 alphanumeric characters and must start with a letter. **Notice that hyphens and underscores are NOT allowed.** The value cannot be changed later.
- Hostnames: Max 63 characters and must be compliant with RFCs 952 and 1123. The value can be changed later.

Important

The Networking service allows hostnames up to 63 characters. However, some older operating systems enforce shorter hostnames. In Linux, here's how to determine the maximum allowed hostname length:

```
getconf HOST_NAME_MAX
```

If an instance has a hostname longer than the OS-specific maximum, the instance's FQDN is not resolvable within the VCN. You can use the Networking service to update the VNIC and change the hostname to a shorter value.

Uniqueness:

- VCN DNS label should be unique across your VCNs (not required, but a best practice)
- Subnet DNS labels must be unique within the VCN
- Hostnames must be unique within the subnet

Tip

Don't confuse the DNS label or hostname with the friendly name you can assign to the object (that is, the *display name*), which doesn't have to be unique.

Validation and Generation of the Hostname

If you've set DNS labels for the VCN and subnets, Oracle validates the hostname for DNS compliance and uniqueness during instance launch. If either of these requirements isn't met, the launch request fails.

If you don't specify a hostname during instance launch, Oracle tries to use the instance's display name as the hostname. If the display name does not pass the validation, Oracle automatically generates a DNS-compliant hostname that's unique across the subnet. You can see the generated hostname on the instance's page in the Console. In the API, the hostname is part of the VNIC object.

If you don't provide a hostname or display name during instance launch, Oracle automatically generates a display name but NOT a hostname. This means the instance won't be resolvable using the Internet and VCN Resolver.

Note

The Linux OS hostname on the instance is automatically set to the hostname you set during instance launch (or the one generated by Oracle). If you change the hostname directly on the instance, the FQDN of the instance does not get updated.

If you add a secondary VNIC to an instance, or add a secondary private IP to a VNIC, Oracle never tries to generate a hostname. Provide a valid hostname if you want the private IP address to be resolvable using the Internet and VCN Resolver.

DHCP Options for DNS

There are two DHCP options related to DNS in your VCN:

- **Domain Name Server:** To specify your choice for DNS type (either Internet and VCN Resolver, or Custom Resolver).
  - **Default value in the default set of DHCP options:** Internet and VCN Resolver

- **Search Domain:** To specify a single search domain. When resolving a DNS query, the OS appends this search domain to the value being queried. You can specify only one search domain for the set of DHCP options.
    - **Default value in the default set of DHCP options:** The VCN domain name (*<VCN DNS label>*.oraclevcn.com), if you specified a DNS label for the VCN during creation but did not specify a search domain value. If you specified a search domain value, then that value is used for the Search Domain option. If you did NOT specify a DNS label, the default set of DHCP options does not include a Search Domain option.

The default set of DHCP options that you can associate with all the subnets in the VCN automatically uses the default values. This means you can simply use the *<hostname>*.*<subnet DNS label>* to communicate with any of the instances in the VCN. If the VCN uses a set of DHCP options that does not contain a Search Domain option, the instances must use the entire FQDN to communicate.

Important

In general, when *any* set of DHCP options is initially created (the default set or a custom set you create), the Networking service automatically adds the Search Domain option and sets it to the VCN domain name (*<VCN DNS label>*.oraclevcn.com) *if all of these are true*:

- The VCN has a DNS label
- DNS Type = Internet and VCN Resolver
- You did NOT specify a search domain of your choice during creation of the set of DHCP options

After the set of DHCP options is created, you can always remove the Search Domain option or set it to a different value.

How to Enable DNS Hostnames in Your VCN

Only new VCNs created after the release of the Internet and VCN Resolver feature have automatic access to it. How to enable DNS hostnames for a new VCN depends on which interface you're using.

If you create a new VCN and subnets with the Console

1. When creating the VCN:
    - Check the checkbox for **Use DNS Hostnames in this VCN**
    - Specify a DNS label of your choice for the VCN. If you check the checkbox but don't specify a DNS label, the Console assumes that you want to use the Internet and VCN Resolver in your VCN and automatically generates a DNS label for the VCN. The Console takes the VCN name you provided, removes non-alphanumeric characters, ensures that the first character is a letter, and truncates the label to 15 characters. The Console displays the result, and if you don't like it, you can instead enter your own value in the **DNS Label** field. See Requirements for DNS Labels and Hostnames.
2. When creating the subnets:
    - Again, check the checkbox for **Use DNS Hostnames in this Subnet**
    - Specify a DNS label of your choice for each subnet. If you check the checkbox but don't specify the DNS label for a given subnet, the Console assumes you want to use the Internet and VCN Resolver for the subnet and automatically generates a DNS label for the subnet. The Console takes the subnet name you provided, removes non-alphanumeric characters, ensures that the first character is a letter, and truncates the label to 15 characters. The Console displays the result, and if you don't like it, you can instead enter your own value in the **DNS Label** field. See Requirements for DNS Labels and Hostnames.
    - Associate any set of DHCP options that has DNS type = Internet and VCN Resolver. The default set of DHCP options in the VCN uses the Internet and VCN Resolver by default.

3. When launching instances:
    - Specify a hostname (or at least a display name) for each instance. For more information, see Validation and Generation of the Hostname.

If you don't check the checkbox for **Use DNS Hostnames in this VCN** when creating the VCN, you can't set the DNS label for the VCN or subnets, and you can't specify a hostname during instance launch.

Note

The above procedure assumes you create the VCN and subnets one at a time in the Console. The Console has a feature that automatically creates a VCN with subnets and an internet gateway all at the same time. If you use that feature to create the VCN and subnets, the Console automatically generates DNS labels for them.

If you create a new VCN and subnets with the API

1. When creating the VCN:
    - Specify a DNS label for the VCN. See Requirements for DNS Labels and Hostnames. If you don't set a value (if it's null), Oracle assumes you don't want to use the Internet and VCN Resolver, even if the DHCP options have DhcpDnsOption `serverType` = `VcnLocalPlusInternet`.
2. When creating the subnets:
    - Specify a DNS label for each subnet. See Requirements for DNS Labels and Hostnames. If you specified a DNS label for the VCN, but you don't specify a DNS label for the subnet, Oracle assumes you don't want the instances in the subnet to use the Internet and VCN Resolver. They will not be able to use hostnames to communicate with instances in the VCN.

- Associate any set of DHCP options that has DhcpDnsOption`serverType` = `VcnLocalPlusInternet`. The default set of DHCP options in the VCN uses this by default.

3. When launching instances:
    - Specify a hostname (or at least a display name) for each instance. For more information, see Validation and Generation of the Hostname.

If you don't specify a DNS label when creating the VCN, you can't set the DNS label for the subnets (the `CreateSubnet` call will fail), nor specify a hostname during instance launch (the `LaunchInstance` call will fail). You also cannot assign a hostname to a secondary VNIC or a secondary private IP.

Scenario 1: Use Internet and VCN Resolver with DNS Hostnames Across the VCN

The typical scenario is to enable the Internet and VCN Resolver *across your entire VCN*. This means all instances in the VCN can communicate with each other without knowing their IP addresses. To do that, follow the instructions for creating a new VCN in How to Enable DNS Hostnames in Your VCN, and make sure to assign a DNS label to the VCN and every subnet. Then make sure to assign every instance a hostname (or at least a display name) at launch. If you add a secondary VNIC or secondary private IP, also assign it a hostname. The instances can then communicate with each other using FQDNs instead of IP addresses. If you also set the Search Domain DHCP option to the VCN domain name (*`<VCN DNS label>`*`.oraclevcn.com`), the instances can then communicate with each other using just *`<hostname>`*`.`*`<subnet DNS label>` instead of the FQDN.

Scenario 2: Use Custom DNS Servers to Resolve DNS Hostnames

You can set up an instance to be a custom DNS server within your VCN and configure it to resolve the hostnames that you set when launching the instances. You must configure the servers to use 169.254.169.254 as the forwarder for the VCN domain (that is, *`<VCN DNS label>`*`.oraclevcn.com`).

Note

The custom DNS servers must be located in a subnet that uses Internet and VCN Resolver for DNS.

For an example of an implementation of this scenario with the Oracle Terraform provider, see Hybrid DNS Configuration.

Scenario 3: Use Different DHCP Options Per Subnet

Scenario 1 assumes you want to use the Internet and VCN Resolver the same way across all subnets, and thus all instances in the VCN. You could, however, configure different DNS settings *for each subnet*, because the DHCP options are configured *at the subnet level*. The important thing to understand is this: the subnet where you want to generate the DNS query is where you need to configure the corresponding Internet and VCN Resolver settings.

For example, if you want instance A in subnet A to resolve the hostname of instance B in subnet B, you must configure subnet A to use the Internet and VCN Resolver. Conversely, if you want instance B to resolve the hostname of instance A, you must configure subnet B to use the Internet and VCN Resolver.

You can configure a different set of DHCP options for each subnet. For example, you could set subnet A's Search Domain to `subneta.vcn1.oraclevcn.com`, which means all instances in subnet A could use just hostnames to communicate with each other. You could similarly set subnet B's Search domain to `subnetb.vcn1.oraclevcn.com` to enable Subnet B's instances to communicate with each other with just hostnames. But that means any instances in a given subnet would need to use FQDNs to communicate with instances in other subnets.

DHCP Options

This topic describes how to manage the Dynamic Host Configuration Protocol (DHCP) options in a virtual cloud network (VCN).

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Overview of DHCP Options

The Networking service uses DHCP to automatically provide configuration information to instances when they boot up. Although DHCP lets you change some settings dynamically, others are static and never change. For example, when you launch an instance, either you or Oracle specifies the instance's private IP address. Each time the instance boots up or you restart the instance's DHCP client, DHCP passes that same private IP address to the instance. The address never changes during the instance's lifetime.

The Networking service provides *DHCP options* to let you control certain types of configuration on the instances in your VCN. You can change the values of these options at your discretion, unlike the static information that DHCP provides to the instance. The changes take effect the next time you restart a given instance's DHCP client or reboot the instance. For more details, see Important Notes about Your Instances and DHCP Options.

Each subnet in a VCN can have a single set of DHCP options associated with it. That set of options applies to all instances in the subnet. Each VCN comes with a *default set of DHCP options* with initial values that you can change. If you don't specify otherwise, every subnet uses the VCN's default set of DHCP options.

The following table summarizes the available DHCP options you can configure.

DHCP Option	Possible Values	Initial Value in the Default DHCP Options	Notes
Domain Name Server	DNS Type: • Internet and VCN Resolver • Custom Resolver	DNS Type = Internet and VCN resolver. For more information, see Choices for DNS in Your VCN.	If you set DNS Type = Custom Resolver, you can specify up to three DNS servers of your choice. For more information, see Choices for DNS in Your VCN.

DHCP Option	Possible Values	Initial Value in the Default DHCP Options	Notes
Search Domain	A single search domain	If you've set up your VCN with a DNS label, the default value for the Search Domain option is the VCN domain name (*<VCN DNS label>*.oraclevcn.com). Otherwise, the Search Domain option is not present in the default set of DHCP options.	In general, when *any* set of DHCP options is initially created (the default set or a custom set you create), the Networking service automatically adds the Search Domain option and sets it to the VCN domain name (*<VCN DNS label>*.oraclevcn.com) *if all of these are true*: • The VCN has a DNS label • DNS Type = Internet and VCN Resolver • You did NOT specify a search domain of your choice during creation of the set of DHCP options After the set of DHCP options is created, you can always remove the Search Domain option or set it to a different value. You can specify only a single search domain in a set of DHCP options.

Working with DHCP Options

When you create a subnet, you specify which set of DHCP options to associate with the subnet. If you don't, the default set of DHCP options for the VCN is used. You can change which set of

DHCP options the subnet uses at any time.

When creating a new set of DHCP options, you may optionally assign it a friendly name. It doesn't have to be unique, and you can change it later. Oracle automatically assigns the set of options a unique identifier called an Oracle Cloud ID (OCID). For more information, see Resource Identifiers.

You can change the values of an individual DHCP option in a set, but notice that when you use the REST API to update a single option in a set, the new set of options replaces the entire existing set.

To delete a set of DHCP options, it must not be associated with a subnet yet. You can't delete a VCN's default set of DHCP options.

For information about the maximum number of DHCP options allowed, see Service Limits.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: see IAM Policies for Networking.

Important Notes about Your Instances and DHCP Options

Whenever you change the value of one of the DHCP options, you must do one of the following for the change to take effect on existing instances in the subnets associated with that set of DHCP options: either restart the DHCP client on the instance, or reboot the instance.

Make sure to keep the DHCP client running so you can always access the instance. If you stop the DHCP client manually or disable NetworkManager (which stops the DHCP client on Linux instances), the instance can't renew its DHCP lease and will become inaccessible when the lease expires (typically within 24 hours). Do not disable NetworkManager unless you use another method to ensure renewal of the lease.

Stopping the DHCP client might remove the host route table when the lease expires. Also, loss of network connectivity to your iSCSI connections might result in loss of the boot drive.

Any changes you make to the `/etc/resolv.conf` file are overwritten whenever the DHCP lease is renewed or the instance is rebooted.

Changes you make to the `/etc/hosts` file are overwritten whenever the DHCP lease is renewed or the instance is rebooted. To persist your changes to the `/etc/hosts` file, add the following line to `/etc/oci-hostname.conf`:

```
PRESERVE_HOSTINFO=2
```

If the `/etc/oci-hostname.conf` file does not exist, create it.

Using the Console

To view a VCN's set of default DHCP options

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Under **Resources**, click **DHCP Options**.
   The default set and its details are displayed in the list.

To update options in an existing set of DHCP options

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Under **Resources**, click **DHCP Options**.
4. For the set you're interested in, click the Actions icon (three dots), and then click **Edit:**

- For **DNS Type**: If want instances in the subnet to resolve internet hostnames and hostnames of instances in the VCN, select **Internet and VCN Resolver**. Or to use a DNS server of your choice, select **Custom Resolver** and then enter the server's IP address (three servers maximum). For more information, see DNS in Your Virtual Cloud Network.
- For **Search Domain**: If you want instances in the subnet to append a particular search domain when resolving DNS queries, enter it here. If the Search Domain option is already set to the VCN domain name and you're not sure why, see the details in Overview of DHCP Options.

5. When you're done, click **Save Changes**.
6. If you have any existing instances in a subnet that uses this set of DHCP options, make sure to restart the DHCP client on each affected instance, or reboot the instance itself so that it picks up the new setting.

To create a new set of DHCP options

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Under **Resources**, click **DHCP Options**.
4. Click **Create DHCP Options**.
5. Enter the following:
   - **Name**: A friendly name for the set of options. It doesn't have to be unique, and you can change it later. Avoid entering confidential information.
   - **Create in Compartment:** The compartment where you want to create the set of DHCP options, if different from the compartment you're currently working in.
   - **DNS Type**: If want instances in the subnet to resolve internet hostnames and hostnames of instances in the VCN, select **Internet and VCN Resolver**. Or to use a DNS server of your choice, select **Custom Resolver** and then enter the

server's IP address (three servers maximum). For more information, see DNS in Your Virtual Cloud Network.

- **Search Domain**: If you want instances in the subnet to append a particular search domain when resolving DNS queries, enter it here. Be aware that the Networking service automatically sets the Search Domain option in certain situations. See the details in Overview of DHCP Options.
- **Tags:** Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.

6. When you're done, click **Create DHCP Options**.

The set of options is created and then displayed on the **DHCP Options** page of the compartment you chose. You can now specify this set of options when creating or updating a subnet.

To change which set of DHCP options a subnet uses

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Click **Subnets**.
4. Click the subnet you're interested in.
5. Click **Edit**.
6. In the **DHCP Options** section, select the new set of DHCP options you want the subnet to use.
7. Click **Save Changes**.
   The changes take effect within a few seconds.

To delete a set of DHCP options

Prerequisite: To delete a set of DHCP options, it must not be associated with a subnet yet. You can't delete the default set of DHCP options in a VCN.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Under **Resources**, click **DHCP Options**.
4. For the set you want to delete, click the Actions icon (three dots), and then click **Terminate**.
5. Confirm when prompted.

To manage tags for a set of DHCP options

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Under **Resources**, click **DHCP Options**.
4. For the set you're interested in, click the Actions icon (three dots), and then click **View Tags**. From there you can view the existing tags, edit them, and apply new ones.

For more information, see Resource Tags.

To move a set of DHCP options to a different compartment

You can move a set of DHCP options from one compartment to another. When you move a set of DHCP options to a new compartment, inherent policies apply immediately.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.

3. Under **Resources**, click **DHCP Options**.
4. For the set you're interested in, click the Actions icon (three dots), and then click **Move Resource**.
5. Choose the destination compartment from the list.
6. Click **Move Resource**.

For more information about using compartments and policies to control access to your cloud network, see Access Control. For general information about compartments, see Managing Compartments.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

To manage a VCN's DHCP options, use these operations:

- ListDhcpOptions
- GetDhcpOptions
- UpdateDhcpOptions
- CreateDhcpOptions
- DeleteDhcpOptions
- ChangeDhcpOptionsCompartment

Route Tables

This topic describes how to manage the route tables in a virtual cloud network (VCN).

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Overview of Routing for Your VCN

Your VCN uses virtual route tables to send traffic out of the VCN (for example, to the internet, to your on-premises network, or to a peered VCN). These virtual route tables have rules that look and act like traditional network route rules you might already be familiar with. Each rule specifies a destination CIDR block and the target (the next hop) for any traffic that matches that CIDR.

Here are basics about routing in your VCN:

- The primary routing scenario is for sending a subnet's traffic to destinations outside the VCN. A subnet has a single route table of your choice associated with it. All VNICs in that subnet are subject to the rules in the route table. The rules govern how the traffic leaving the subnet is routed.
- Traffic within the VCN is automatically handled by the VCN *local routing*. No route rules are required to enable that traffic. And in general: for any route table that belongs to a given VCN, you can't create a rule that lists that VCN's CIDR (or a sub-section) as the rule's destination. Oracle uses a subnet's route table *only* if the destination IP address is not within the VCN's CIDR block.
- If a route table has overlapping rules, Oracle uses the most specific rule in the table to route the traffic (that is, the rule with the longest prefix match).
- If there is no route rule that matches the network traffic you intend to route outside the VCN, the traffic is dropped (blackholed).
- IPv6 addressing and routing is currently supported only in the US Government Cloud. For more information, see IPv6 Addresses.

For important details about routing between your VCN and on-premises network, see Routing Details for Connections to Your On-Premises Network.

Working with Route Tables and Route Rules

Each VCN automatically comes with a default route table that has no rules. If you don't specify otherwise, every subnet uses the VCN's default route table. When you add route rules to your VCN, you can simply add them to the default table if that suits your needs. However, if you need both a public subnet and a private subnet (for example, see Scenario C: Public and Private Subnets with a VPN), you instead create a separate (custom) route table for each subnet.

Each subnet in a VCN uses a single route table. When you create the subnet, you specify which one to use. You can change which route table the subnet uses at any time. You can also edit a route table's rules, or remove all the rules from the table.

You may optionally assign a descriptive name to a custom route table during creation. It doesn't have to be unique, and you can change it later. Oracle automatically assigns the route table a unique identifier called an Oracle Cloud ID (OCID). For more information, see Resource Identifiers.

A route rule specifies a destination CIDR block and the target (the next hop) for any traffic that matches that CIDR. Here are the allowed types of targets for a route rule:

- dynamic routing gateway (DRG): For subnets that need private access to networks connected to your VCN (for example, your on-premises network connected with an IPSec VPN or FastConnect, or a peered VCN in another region).
- internet gateway: For public subnets that need direct access to the internet.
- NAT gateway: For subnets with instances that do not have public IP addresses but need outbound access to the internet.
- service gateway: For subnets that need private access to Oracle services such as Object Storage.
- local peering gateway (LPG): For subnets that need private access to a peered VCN in the same region.

- private IP: For subnets that need to route traffic to an instance in the VCN. For more information, see Using a Private IP as a Route Target. Also see Advanced Scenarios: Transit Routing.

Note

You can't delete a particular resource if it's the target in a route rule. For example, you can't delete an internet gateway that has traffic routed to it. You must first delete all rules (in all route tables) with that internet gateway as the target.

When adding a route rule to a route table, you provide the destination CIDR block and target (plus the compartment where the target resides). Exception: if the target is a service gateway, instead of a destination CIDR block, you specify an Oracle-provided string that represents the public endpoints for the service of interest. That way you don't need to know all the service's CIDR blocks, which might change over time.

If you misconfigure a rule (for example, enter the wrong destination CIDR block), the network traffic you intended to route might be dropped (blackholed) or sent to an unintended target.

You can move route tables from one compartment to another. Moving a route table doesn't affect its attachment to VCNs or subnets. When you move a route table to a new compartment, inherent policies apply immediately and affect access to the route table. For more information, see Access Control.

You can't delete a VCN's default route table. To delete a custom route table, it must not be associated with a subnet yet. Or, in the advanced scenario of transit routing, it must not be associated with a DRG attachment or LPG in the VCN.

For information about the maximum number of route tables and route rules, see Service Limits.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don't have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: see IAM Policies for Networking.

Advanced Scenarios: Transit Routing

This documentation includes a few basic networking scenarios to help you understand the Networking service and generally how the components work together. See scenarios A, B, and C in Networking Scenarios.

Scenarios A–C show your on-premises network connected to a VCN by way of FastConnect or VPN Connect, and accessing only the resources in that VCN.

The following advanced routing scenarios give your on-premises network additional access beyond the resources in the connected VCN. Traffic travels from your on-premises network to the VCN, and then *transits through* the VCN to its destination. See these topics:

- Transit Routing: Access to Multiple VCNs in the Same Region: Your on-premises network has access to *multiple* VCNs in the same region over a single FastConnect private virtual circuit or VPN Connect. The VCNs are in a hub-and-spoke layout, with the on-premises network connected to the VCN that acts as the hub. The spoke VCNs are peered with the hub VCN.
- Transit Routing: Private Access to Oracle Services: Your on-premises network has *private access* to Oracle services in the Oracle Services Network by way of the connected VCN and the VCN's service gateway. The traffic does not go over the internet.

Both of the transit routing scenarios involve creating route tables that you associate *with a gateway instead of a subnet*.

For example:

- For Transit Routing: Access to Multiple VCNs in the Same Region, you create a route table for a DRG attachment, and then multiple route tables, each for different LPGs.
- For Transit Routing: Private Access to Oracle Services, you create a route table for a DRG attachment and a route table for a service gateway.

The Networking service imposes restrictions on how the route tables can be used:

- DRG attachment: If you associate a route table with the DRG attachment on a VCN, the route table can contain only rules that use an LPG on the VCN, a service gateway on the VCN, or a private IP in the VCN as the target.
- LPG or service gateway: If you associate a route table with an LPG or a service gateway, the route table can contain only rules that use the VCN's attached DRG or a private IP in the VCN as the target.

A DRG attachment or LPG can exist without a route table associated with it. However, after you associate a route table with a DRG attachment or LPG, there must always be a route table associated with it. But, you can associate a *different* route table. You can also edit the table's rules, or delete some or all of the rules.

Using a Private IP as a Route Target

If you're not familiar with the definition of a private IP, see Private IP Addresses. In short: a private IP is an object that contains a private IP address and related properties and has its own OCID.

General Use Cases

As mentioned earlier, Oracle uses a given subnet's route table *only* for traffic with a destination IP address outside the VCN. Typically you set up one or more rules to route that traffic to a gateway on the VCN (for example, a DRG connected to your on-premises network, or an internet gateway connected to the internet). However, you might want to route that traffic (going to destinations outside the VCN) through an instance in the VCN first. In that case, you can use a private IP in the VCN as the target instead of a gateway on the VCN. Here are a few reasons you might do this:

- To implement a virtual network appliance (NVA) such as a firewall or intrusion detection that filters outgoing traffic from instances.
- To manage an overlay network on the VCN, which lets you run container orchestration workloads.
- To implement Network Address Translation (NAT) in the VCN. Note that Oracle instead recommends using a NAT gateway with your VCN. In general, NAT enables outbound internet access for instances that don't have direct internet connectivity.

To implement these use cases, there's more to do than simply route traffic to the instance. There's also configuration required on the instance itself.

Tip

You can enable high availability of the private IP route target by using a secondary private IP address. In the event of a failure, you can move the secondary private IP from an existing VNIC to another VNIC in the same subnet. See To move a secondary private IP to another VNIC in the same subnet (Console instructions) and UpdatePrivateIp (API instructions).

Requirements for Using a Private IP as a Target

- The private IP must be in the same VCN as the route table.
- The private IP's VNIC must be configured to skip the source/destination check so that the VNIC can forward traffic. By default, VNICs are configured to perform the check. For more information, see Source/Destination Check.
- You must configure the instance itself to forward packets. For more information, see NAT Instance Configuration.
- The route rule must specify the OCID of the private IP as the target, and not the IP address itself. Exception: If you use the Console, you can instead specify the private IP address itself as the target, and the Console determines and uses the corresponding OCID in the rule.

Important

A route rule with a private IP target can result in blackholing in these cases:

- The instance the private IP is assigned to is stopped or terminated
- The VNIC the private IP is assigned to is updated to enable the source/destination check or is deleted
- The private IP is unassigned from the VNIC

When a target private IP is terminated, in the Console, the route rule displays a note that the target OCID no longer exists.

For failover: If your target instance is terminated before you can move the secondary private IP to a standby, you must update the route rule to use the OCID of the new target private IP on the standby. The rule uses the target's OCID and not the private IP address itself.

General Setup Process

1. Determine which instance will receive and forward the traffic (the NAT instance, for example).
2. Choose a private IP on the instance (can be on the instance's primary VNIC or a secondary VNIC). If you want to implement failover, set up a secondary private IP on one of the VNICs on the instance.
3. Disable the source/destination check on the private IP's VNIC. See Source/Destination Check.

4. Get the OCID for the private IP. If you're using the Console, you can get either the OCID or the private IP address itself, along with the name of the private IP's compartment.
5. For the subnet that needs to route traffic to the private IP, view the subnet's route table. If the table already has a rule with the same destination CIDR but a different target, delete that rule.
6. Add a route rule with the following:
    - **Destination CIDR block**: If all traffic leaving the subnet needs to go to the private IP, use 0.0.0.0/0.
    - **Target type:** Private IP.
    - **Compartment:** The compartment of the private IP.
    - **Target:** The OCID of the private IP. If you're using the Console and instead enter the private IP address itself, the Console determines the corresponding OCID and uses it as the target for the route rule.

As mentioned earlier, you must configure the instance itself to forward packets. For more information, see NAT Instance Configuration.

Using the Console

To view a VCN's default route table

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Under **Resources**, click **Route Tables.**
   The default route table is displayed in the list of tables.
4. Click the default route table to view its details.

To update rules in an existing route table

You can add, edit, or delete rules.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Under **Resources**, click **Route Tables**.
4. Click the route table you're interested in.
5. If you want to create a new route rule, click **Add Route Rule** and enter the following:
    - **Target Type:** See the list of target types in Route Tables. If the target type is a DRG, the VCN's attached DRG is automatically selected as the target, and you don't have to specify the target yourself. If the target is a private IP, make sure you've first disabled the source/destination check on the private IP's VNIC. For more information, see Using a Private IP as a Route Target.
    - **Destination CIDR Block**: Only if the target is not a service gateway. The value is the destination CIDR block for the traffic. A value of 0.0.0.0/0 means that all non-intra-VCN traffic that is not already covered by other rules in the route table will go to the target specified in this rule.
    - **Destination Service:** Only if the target is a service gateway. The value is the service CIDR label that you're interested in.
    - **Compartment:** The compartment where the target is located.
    - **Target:** The target. If the target is a private IP, enter its OCID. Or you can enter the private IP address itself, in which case the Console determines the corresponding OCID and uses it as the target for the route rule.
6. If you want to delete an existing rule, click the Actions icon (three dots), and then click **Remove**.
7. If you wanted to edit an existing rule, click the Actions icon (three dots), and then click **Edit**.

To create a route table

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Under **Resources**, click **Route Tables**.
4. Click **Create Route Table**.
5. Enter the following:
   - **Name:** A friendly name for the route table. The name doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
   - **Create in Compartment:** The compartment where you want to create the route table, if different from the compartment you're currently working in.
6. Optionally, click **+Additional Route Rule** to add one or more route rules, each with the following information (remember, a route table can exist with no rules until you're ready to add them):
   - **Target Type:** See the list of target types in Route Tables. If the target type is a DRG, the VCN's attached DRG is automatically selected as the target, and you don't have to specify the target yourself. If the target is a private IP, make sure you've first disabled the source/destination check on the private IP's VNIC. For more information, see Using a Private IP as a Route Target.
   - **Destination CIDR Block**: Only if the target is not a service gateway. The value is the destination CIDR block for the traffic. A value of 0.0.0.0/0 means that all non-intra-VCN traffic that is not already covered by other rules in the route table will go to the target specified in this rule.
   - **Destination Service:** Only if the target is a service gateway. The value is the service CIDR label that you're interested in.
   - **Compartment:** The compartment where the target is located.

- **Target:** The target. If the target is a private IP, enter its OCID. Or you can enter the private IP address itself, in which case the Console determines the corresponding OCID and uses it as the target for the route rule.

7. **Tags:** Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.
8. Click **Create Route Table**.
   The route table is created and then displayed on the **Route Tables** page in the compartment you chose. You can now specify this route table when creating or updating a subnet.

To change which route table a subnet uses

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Click **Subnets**.
4. Click the subnet you're interested in
5. Click **Edit**.
6. In the **Route Table** section, select the new route table you want the subnet to use.
7. Click **Save Changes**.
   The changes take effect within a few seconds.

To move a route table to a different compartment

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.

2. Click the VCN you're interested in.
3. Click **Route Tables**.
4. Find the route table in the list, click the the Actions icon (three dots), and then click **Move Resource**.
5. Choose the destination compartment from the list.
6. Click **Move Resource**.

To delete a route table

Prerequisite: To delete a route table, it must not be associated with a subnet yet. You can't delete the default route table in a VCN.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Under **Resources**, click **Route Tables**.
4. Click the route table you're interested in.
5. Click **Terminate**.
6. Confirm when prompted.

To manage tags for a route table

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Under **Resources**, click **Route Tables**.
4. Click the route table you're interested in.

5. Click the **Tags** tab to view or edit the existing tags. Or click **Apply tag(s)** to add new ones.

For more information, see Resource Tags.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

To manage a VCN's route tables, use these operations:

- ListRouteTables
- GetRouteTable
- UpdateRouteTable
- CreateRouteTable
- DeleteRouteTable
- ChangeRouteTableCompartment

Dynamic Routing Gateways (DRGs)

This topic describes how to manage a dynamic routing gateway (DRG). This topic uses the terms *dynamic routing gateway* and *DRG* interchangeably. The Console uses the term *Dynamic Routing Gateway*, whereas for brevity the API uses *DRG*.

You use a DRG when connecting your existing on-premises network to your virtual cloud network (VCN) with one (or both) of these:

- IPSec VPN
- Oracle Cloud Infrastructure FastConnect

You also use a DRG when peering a VCN with a VCN in a different region:

- Remote VCN Peering (Across Regions)

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Overview of Dynamic Routing Gateways

You can think of a DRG as a virtual router that provides a path for private traffic (that is, traffic that uses private IPv4 addresses) between your VCN and networks outside the VCN's region.

For example, if you use an IPSec VPN or Oracle Cloud Infrastructure FastConnect (or both) to connect your on-premises network to your VCN, that private IPv4 address traffic goes through a DRG that you create and attach to your VCN. For scenarios for using a DRG to connect a VCN to your on-premises network, see Networking Scenarios. For important details about routing to your on-premises network, see Routing Details for Connections to Your On-Premises Network.

Also, if you decide to peer your VCN with a VCN in another region, your VCN's DRG routes traffic to the other VCN over a private backbone that connects the regions (without traffic traversing the internet). For information about connecting VCNs in different regions, see Remote VCN Peering (Across Regions).

Working with DRGs and DRG Attachments

For the purposes of access control, when creating a DRG, you must specify the compartment where you want the DRG to reside. If you're not sure which compartment to use, put the DRG in the same compartment as the VCN. For more information, see Access Control.

You may optionally assign a friendly name to the DRG. It doesn't have to be unique, and you can change it later. Oracle automatically assigns the DRG a unique identifier called an Oracle Cloud ID (OCID). For more information, see Resource Identifiers.

A DRG is a standalone object. To use it, you must attach it to a VCN. A VCN can be attached to only one DRG at a time, and a DRG can be attached to only one VCN at a time. You can detach a DRG and reattach it at any time. In the API, the process of attaching creates a `DrgAttachment` object with its own OCID. To detach the DRG, you delete that attachment object.

After attaching a DRG, you must update the routing in the VCN to use the DRG. Otherwise, traffic from the VCN will not flow to the DRG. See To route a subnet's traffic to a DRG.

To delete a DRG, it must not be attached to a VCN or connected to another network by way of IPSec VPN, Oracle Cloud Infrastructure FastConnect, or remote VCN peering. Also, there must not be a route rule that lists that DRG as a target.

For information about the number of DRGs you can have, see Service Limits.

Routing a Subnet's Traffic to a DRG

The basic routing scenario sends traffic from a subnet in the VCN to the DRG. For example, if you're sending traffic from the subnet to your on-premises network, you set up a rule in the subnet's route table. The rule's destination CIDR is the CIDR for the on-premises network (or a subnet within), and the rule's target is the DRG. For more information, see Route Tables.

Advanced Scenarios: Transit Routing

This documentation includes a few basic networking scenarios to help you understand the Networking service and generally how the components work together. See scenarios A, B, and C in Networking Scenarios.

Scenarios A–C show your on-premises network connected to a VCN by way of FastConnect or VPN Connect, and accessing only the resources in that VCN.

The following advanced routing scenarios give your on-premises network additional access beyond the resources in the connected VCN. Traffic travels from your on-premises network to the VCN, and then *transits through* the VCN to its destination. See these topics:

- Transit Routing: Access to Multiple VCNs in the Same Region: Your on-premises network has access to *multiple* VCNs in the same region over a single FastConnect private virtual circuit or VPN Connect. The VCNs are in a hub-and-spoke layout, with the on-premises network connected to the VCN that acts as the hub. The spoke VCNs are peered with the hub VCN.
- Transit Routing: Private Access to Oracle Services: Your on-premises network has *private access* to Oracle services in the Oracle Services Network by way of the connected VCN and the VCN's service gateway. The traffic does not go over the internet.

In the transit routing scenarios, the VCN has a route table *associated with its DRG attachment* (typically route tables are associated with a VCN's subnets). That route table lets you manage routing of traffic *through the VCN* that is connected to the on-premises network.

When you attach a DRG to a VCN, you can optionally associate a route table with the attachment. Or if you already have a DRG attachment, you can associate a route table with it. The route table must belong to the attached VCN. A route table associated with a DRG attachment can contain only rules that use one of the following as a target:

- A local peering gateway (LPG) on the attached VCN
- A service gateway on the attached VCN
- A private IP in the attached VCN

A DRG attachment can exist without a route table associated with it. However, after you associate a route table with a DRG attachment, there must always be a route table associated with it. But, you can associate a *different* route table. You can also edit the table's rules, or delete some or all of the rules.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: see IAM Policies for Networking.

Using the Console

In general, to use a DRG, you must complete these steps:

1. Create the DRG.
2. Attach the DRG to your VCN.
3. Route subnet traffic to the DRG. This involves updating the route table associated with each subnet that must send traffic to the DRG. If all the subnets use the VCN's default route table, you must only update that one table.

To create a DRG

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Dynamic Routing Gateways**.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator. For more information, see Access Control.
3. Click **Create Dynamic Routing Gateway**.
4. Enter the following items:
    - **Create in Compartment:** The compartment where you want to create the DRG, if different from the compartment you're currently working in.
    - **Name:** A descriptive name for the DRG. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
    - **Tags:** Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.

5. Click **Create Dynamic Routing Gateway**.

The resource is created and then displayed on the **Dynamic Routing Gateways** page of the compartment you chose. It will be in the "Provisioning" state for a short period. You can connect it to other parts of your network only after provisioning is complete.

To update a DRG's name

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Dynamic Routing Gateways**.
2. Click the DRG you're interested in.
3. Click **Edit**.
4. Edit the name and click **Save Changes**.

To attach a DRG to a VCN

Note: A VCN can be attached to only one DRG at a time, and a DRG can be attached to only one VCN at a time. The attachment is automatically created in the compartment that holds the VCN.

The following instructions have you navigate to the DRG and then choose which VCN to attach. You could instead navigate to the VCN and then choose which DRG to attach.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Dynamic Routing Gateways**.
2. Click the DRG you want to attach.
3. Under **Resources**, click **Virtual Cloud Networks**. If you want to attach the DRG to a VCN in a different compartment than the one you're working in, choose that compartment from the list on the left side of the page.
4. Click **Attach to Virtual Cloud Network**.
5. Select the VCN.

6. (Optional) Only if you're setting up an advanced scenario for transit routing, you can associate a route table with the DRG attachment (you can do this later if you want to):
    a. Click **Show Advanced Options**.
    b. Select the route table that you want to associate with the DRG attachment.
7. Click **Attach to Virtual Cloud Network**.

The attachment will be in the "Attaching" state for a short period before it's ready.

After it's ready, make sure to create a route rule that directs subnet traffic to this DRG. See To route a subnet's traffic to a DRG.

To route a subnet's traffic to a DRG

For each subnet that must send traffic to the DRG, you must add a route rule to the route table associated with that subnet. If all the subnets in the VCN use the default route table, you must add a rule to only that one table.

If all non-intra-VCN traffic that's not covered by another rule in the table must be routed to the DRG, then this is the new rule to add:

- **Target Type:** Dynamic Routing Gateway. The VCN's attached DRG is automatically selected as the target, and you don't have to specify the target yourself.
- **Destination CIDR Block** = 0.0.0.0/0. If you want to limit the rule to a specific network (for example, your on-premises network), then use that network's CIDR instead of 0.0.0.0/0.

For step-by-step instructions, see To update rules in an existing route table.

To associate a route table with an existing DRG attachment

Important

Perform this task only if you're setting up an advanced scenario for transit routing. See Transit Routing: Access to Multiple VCNs in the Same Region and Transit Routing: Private Access to Oracle Services.

A DRG attachment can exist without a route table associated with it. However, after you associate a route table with a DRG attachment, there must always be a route table associated with it. But, you can associate a *different* route table. You can also edit the table's rules, or delete some or all of the rules.

Prerequisites: The route table must exist and belong to the VCN that the DRG is already attached to.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Dynamic Routing Gateways**.
2. Click the DRG that is attached to the VCN that has the route table.
3. Click the Actions icon (three dots), and then click either:
   - **Associate Route Table:** If the DRG attachment has no route table associated with it yet.
   - **Associate Different Route Table:** If you're changing which route table is associated with the DRG attachment.
4. Select the route table.
5. Click **Associate Route Table**.

The route table is associated with the DRG attachment.

To detach a DRG from a VCN

Note: You do not need to remove the route rule that routes traffic to the DRG before you detach the DRG from the VCN.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Dynamic Routing Gateways**.
2. Click the DRG you want to detach.
3. Under **Resources**, click **Virtual Cloud Networks** to see the VCN the DRG is attached to. If the VCN is in a different compartment than the one you're working in, choose that compartment from the list on the left side of the page.
4. Click the Actions icon (three dots), and then click **Detach**.
5. Confirm when prompted.

The attachment will be in the "Detaching" state for a short period.

To delete a DRG

Prerequisites:

- The DRG must not be attached to a VCN.
- The DRG must not be connected to another network by way of an IPSec VPN, FastConnect, or remote VCN peering.
- There must not be a route rule that lists the DRG as a target.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Dynamic Routing Gateways**.
2. Click the DRG you're interested in.
3. Click **Terminate**.
4. Confirm when prompted.

The DRG will be in the "Terminating" state for a short period while it's being deleted.

To manage tags for a DRG

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Dynamic Routing Gateways**.
2. Click the DRG you're interested in.
3. Click the **Tags** tab to view or edit the existing tags. Or click **Add Tags** to add new ones.

For more information, see Resource Tags.

To move a dynamic routing gateway to a different compartment

You can move a dynamic routing gateway from one compartment to another. When you move a dynamic routing gateway to a new compartment, inherent policies apply immediately.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Dynamic Routing Gateways**.
2. Click the DRG you're interested in.
3. Find the DRG in the list, click the the Actions icon (three dots), and then click **Move Resource**.
4. Choose the destination compartment from the list.
5. Click **Move Resource**.

For more information about using compartments and policies to control access to your cloud network, see Access Control. For general information about compartments, see Managing Compartments.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

To manage your DRGs, use these operations:

- ListDrgs
- CreateDrg
- GetDrg
- UpdateDrg
- DeleteDrg
- ChangeDrgCompartment
- ListDrgAttachments
- CreateDrgAttachment: This attaches a DRG to a VCN and results in a `DrgAttachment` object with its own OCID. You may optionally specify a route table if you're setting up the advanced routing scenario called transit routing.
- GetDrgAttachment
- UpdateDrgAttachment: Among other things, this associates a route table with an existing DRG attachment for transit routing.
- DeleteDrgAttachment: This detaches a DRG from a VCN by deleting the `DrgAttachment`.

For information about route table operations, see Route Tables.

Routing Details for Connections to Your On-Premises Network

You might use multiple connections between your on-premises network and virtual cloud network (VCN) for redundancy or other reasons.

For example, you might use both FastConnect private peering and VPN Connect to the dynamic routing gateway (DRG) attached to your VCN. Or perhaps you use redundant VPN Connect connections to the DRG (for an example scenario, see Example Layout with Multiple Geographic Areas). Or perhaps you use FastConnect public peering, FastConnect private peering, and VPN Connect.

This topic covers important details about route advertisement and path preferences when you have multiple connections.

DRG Route Advertisements to Your On-Premises Network

FastConnect private peering and VPN Connect provide your on-premises network with private access to a VCN. Both types of connections terminate on a single DRG that is attached to the VCN. Remember that VPN Connect can use either Border Gateway Protocol (BGP) or static routing, or a combination. FastConnect always uses BGP for route advertisements.

The DRG advertises the routes for the individual subnets in the DRG's attached VCN. A DRG can be attached to only a single VCN, and a VCN can be attached to only a single DRG.

If you set up transit routing to multiple VCNs for your on-premises network, the DRG advertises additional routes. Transit routing is an advanced routing scenario that involves a single FastConnect or VPN Connect and multiple *peered* VCNs in a hub-and-spoke layout. With transit routing, the DRG also advertises routes for the VCNs that are peered with the DRG's attached VCN (the hub).

If you set up your on-premises network with private access to Oracle services through the VCN's service gateway, the DRG advertises more routes. They are routes for the Oracle Services Network, which is available with the service gateway. For a list of those ranges, Public IP Addresses for VCNs and the Oracle Services Network.

Important

If you're using VPN Connect with static routing, and you've configured the VCN to give your on-premises network private access to Oracle services, you must configure your edge device with the routes for the Oracle Services Network public IP ranges that are advertised by the DRG over the private path (through the service gateway). For a list of those ranges, see Public IP Addresses for VCNs and the Oracle Services Network

Routing Preferences for Traffic from Oracle to Your On-Premises Network

This section describes how Oracle chooses which path to use when sending traffic to your on-premises network. The traffic can be for responding to a request or initiating new connections.

In general, routers use the most specific route (the one with the longest prefix match).

However, if the routes for the different paths are the same, **Oracle uses the shortest AS path** when sending traffic to your on-premises network, regardless of which path was used to initiate the connection to Oracle. **This means asymmetric routing is allowed.** *Asymmetric routing* here means that Oracle's response to a request can follow a different path than the request. For example, depending on how your edge device (also called your *customer-premises equipment*, or CPE) is configured, you could send a request over VPN Connect, but the Oracle response could come back over FastConnect. If you want to force routing to be symmetric, Oracle recommends using BGP and AS path prepending with your routes to influence which path Oracle uses when responding to and initiating connections.

Oracle implements AS path prepending to determine which path to use if your edge device advertises the same route over multiple connections between your on-premises network and VCN. The details are summarized in the following table. Assuming that you're not influencing routing in some way, when the same route is advertised over multiple paths to the DRG at the Oracle end of the connections, Oracle prefers the paths in the following order:

Oracle preference	Path	Details of how Oracle prefers the path	Resulting AS path for the route
1	FastConnect	Oracle prepends no ASNs to the routes that your edge device advertises.	Your ASN
2	VPN Connect with BGP routing	Oracle prepends a single private ASN on all the routes that your edge device advertises over VPN Connect with BGP.	Private ASN, Your ASN
3	VPN Connect with static routing	Oracle prepends 3 private ASNs on the static routes that you've provided (Oracle advertises those routes to the dynamic routing gateway (DRG) at the Oracle end of the IPSec VPN) .	Private ASN, Private ASN, Private ASN

If you have two connections of the same type (for example, two IPSec VPNs that both use BGP), and you advertise the *same* routes across both connections, **Oracle prefers the oldest established route** when responding to requests or initiating connections.

Routing Preferences for Traffic from Your On-Premises Network to Oracle

You can configure your edge device to prefer a specific path when sending traffic from your on-premises network to Oracle. This section describes a particular situation where you *must* do that to ensure a consistent traffic path if your on-premises hosts use Oracle services.

Your on-premises network can access Oracle services such as Object Storage over multiple paths. You can use public paths, such as the internet or FastConnect public peering. With these public paths, the on-premises hosts communicate with Oracle services by using public IP addresses.

You can also set up your on-premises network with private access to Oracle services through the VCN's service gateway. You might do this if hosts in your on-premises network use any of the services listed in Service Gateway: Supported Cloud Services in Oracle Services Network. This implementation lets your on-premises hosts communicate with those Oracle services from your private IP addresses.

If you've configured your on-premises network with *multiple* connection paths to Oracle services, your edge device may receive route advertisement of the Oracle services' public IP address routes over multiple paths. Here are the possible paths you can use with your on-premises network:

- Public access paths:
  - Internet service provider (ISP)
  - FastConnect public peering
- Private access paths by way of the VCN's DRG and service gateway:
  - FastConnect private peering
  - VPN Connect

Your edge device receives route advertisements from the DRG and possibly from routers over public paths. Most of the routes for Oracle services that the DRG advertises have a longer prefix (they are more specific) than the routes for Oracle services that are advertised over the public access paths. Therefore, if you set up your network with both public access and private access to Oracle services, **you must configure your edge device to prefer the private access path to the DRG** for traffic traveling from the on-premises network to Oracle services. This ensures a consistent path for all your access to Oracle services.

For a list of the public IP ranges advertised over FastConnect public peering, see FastConnect Public Peering Advertised Routes.

For a list of the regional public IP ranges advertised over the private paths (for a VCN with a service gateway), see Public IP Addresses for VCNs and the Oracle Services Network.

VPN Connect Overview

One way to connect your on-premises network and your virtual cloud network (VCN) is to use VPN Connect, which is an IPSec VPN. IPSec stands for *Internet Protocol Security* or *IP Security*. IPSec is a protocol suite that encrypts the entire IP traffic before the packets are transferred from the source to the destination.

This topic gives an overview of an IPSec VPN for your VCN. For scenarios that include an IPSec VPN, see Scenario B: Private Subnet with a VPN and Scenario C: Public and Private Subnets with a VPN.

Required Personnel and Knowledge

Typically the following types of personnel are involved in setting up an IPSec VPN with Oracle Cloud Infrastructure:

- **Dev Ops team member** (or similar function) who uses the Oracle Cloud InfrastructureConsole to set up the cloud components required for the virtual network and IPSec VPN.

- **Network engineer** (or similar function) who configures the customer-premises equipment (CPE) device with information provided by the Dev Ops team member.

Tip

The Dev Ops team member must have the required permission to create and manage the cloud components. If the person is the default administrator for your Oracle Cloud Infrastructure tenancy or a member of the Administrators group, then they have the required permission. For information about restricting access to your networking components, see Access Control.

The personnel should be familiar with the following concepts and definitions:

- The fundamentals of Oracle Cloud Infrastructure
- The basic Networking service components
- General IPSec VPN tunnel functionality

CLOUD RESOURCES

Anything you provision on a cloud platform. For example, with Oracle Cloud Infrastructure, a cloud resource can refer to a VCN, compute instance, user, compartment, load balancer, or any other service component on the platform.

ON-PREMISES

A widely used term in cloud technologies that refers to your traditional data center environments. On-premises can refer to a colocation scenario, a dedicated floor space, a dedicated data center building, or a desktop running under your desk.

ORACLE CLOUD IDENTIFIER (OCID)

A unique identifier assigned to each resource that you provision on Oracle Cloud Infrastructure. The OCID is a long string that Oracle automatically generates. You can't

choose the value for an OCID or change a resource's OCID. For more information, see Resource Identifiers.

About the Oracle IPSec VPN

In general, IPSec can be configured in the following modes:

- **Transport mode:** IPSec encrypts and authenticates only the actual payload of the packet, and the header information stays intact.
- **Tunnel mode (supported by Oracle):** IPSec encrypts and authenticates the entire packet. After encryption, the packet is then encapsulated to form a new IP packet that has different header information.

Oracle Cloud Infrastructure supports only the tunnel mode for IPSec VPNs.

Each Oracle IPSec VPN consists of multiple redundant IPSec tunnels. For a given tunnel, you can use either Border Gateway Protocol (BGP) dynamic routing or static routing to route that tunnel's traffic. More details about routing follow.

IPSec VPN site-to-site tunnels offer the following advantages:

- Public internet lines are used to transmit data, so dedicated, expensive lease lines from one site to another aren't necessary.
- The internal IP addresses of the participating networks and nodes are hidden from external users.
- The entire communication between the source and destination sites is encrypted, significantly lowering the chances of information theft.

Note

IPv6 addressing is currently supported only in the US Government Cloud. For more information, see IPv6 Addresses.

Routing for the Oracle IPSec VPN

When you create an IPSec VPN, it has two redundant IPSec tunnels. Oracle encourages you to configure your CPE device to use both tunnels (if your device supports it). Note that in the past, Oracle created IPSec VPNs that had up to four IPSec tunnels.

The following two routing types are available, and you choose the routing type separately *for each tunnel* in the IPSec VPN:

- **BGP dynamic routing:** The available routes are learned dynamically through BGP. The DRG dynamically learns the routes from your on-premises network. On the Oracle side, the DRG advertises the VCN's subnets.
- **Static routing:** When you set up the IPSec connection to the DRG, you specify the particular routes to your on-premises network that you want the VCN to know about. You also must configure your CPE device with static routes to the VCN's subnets. These routes are not learned dynamically.

Important Routing Details for an Oracle IPSec VPN

Here are important details to understand about routing for your IPSec VPN:

- **Routing choices:**
  - Originally, the Oracle IPSec VPN supported only static routing, and you were required to provide at least one static route for the overall IPSec connection.
  - Now two different types of routing are available (BGP and static routing), and you configure the routing type *per tunnel*. *Only one type of routing at a time is supported for a given tunnel*.
  - In general, Oracle encourages you to use the same routing type for all tunnels in your IPSec connection. Exception: if you're in the process of transitioning between static routing and BGP, then one tunnel might temporarily still use static routing while the other has already been switched to BGP.
  - When you create an IPSec connection, static routing is the default type of routing for all tunnels *unless you explicitly configure each tunnel to use BGP*.
- **Routing information required:**

- If you choose BGP, for each tunnel you must provide two IP addresses (one for each of the two BGP speakers in the tunnel's BGP session). The addresses must be in the encryption domain for the IPSec connection. You must also provide the BGP autonomous system number (BGP ASN) for your network.
- If you choose static routing, you must provide at least one static route (maximum 10). The static routes are configured with the *overall IPSec connection*, so the same set of static routes are used for *all* tunnels in the IPSec connection that are configured to use static routing. You can change the static routes at any time after creating the IPSec connection. If you're doing PAT between your CPE device and VCN, the static route for the IPSec connection is the PAT IP address. See Example Layout with PAT.
- If you choose static routing, you may optionally provide an IP address for each end of the tunnel for the purposes of tunnel troubleshooting or monitoring.
- If the tunnel is configured to use BGP, the IPSec connection's static routes are ignored. Any static routes associated with the IPSec connection are used for routing a given tunnel's traffic *only if that tunnel is configured to use static routing*. This is especially relevant if you have an IPSec VPN that uses static routing, but want to switch to using BGP.

- **Changing the routing:**
  - If you want to change a tunnel from BGP to static routing, you must first ensure that the IPSec connection itself has at least one static route associated with it.
  - You can change an existing tunnel's routing type at any time (unless the tunnel is currently being provisioned by Oracle). While you change the routing, the tunnel remains up (its IPSec status does not change). However, traffic flowing through the tunnel is disrupted temporarily during reprovisioning and while you reconfigure your CPE device. For information about making changes to an existing IPSec VPN, see Working with VPN Connect.
  - Because you configure the routing type separately for each tunnel, if you want to switch your IPSec VPN from static routing to BGP, you can do it one tunnel at a time. This avoids the entire IPSec VPN being down. For instructions, see Changing from Static Routing to BGP Dynamic Routing.

Route Advertisements and Path Preferences When You Have Multiple Connections

When you use BGP, the DRG attached to your VCN advertises routes to your CPE.

If you set up multiple connections between your on-premises network and VCN, you must understand what routes the DRG advertises and how to set path preferences to use your desired connection.

For important information, see Routing Details for Connections to Your On-Premises Network.

Preferring a Specific Tunnel in the IPSec VPN

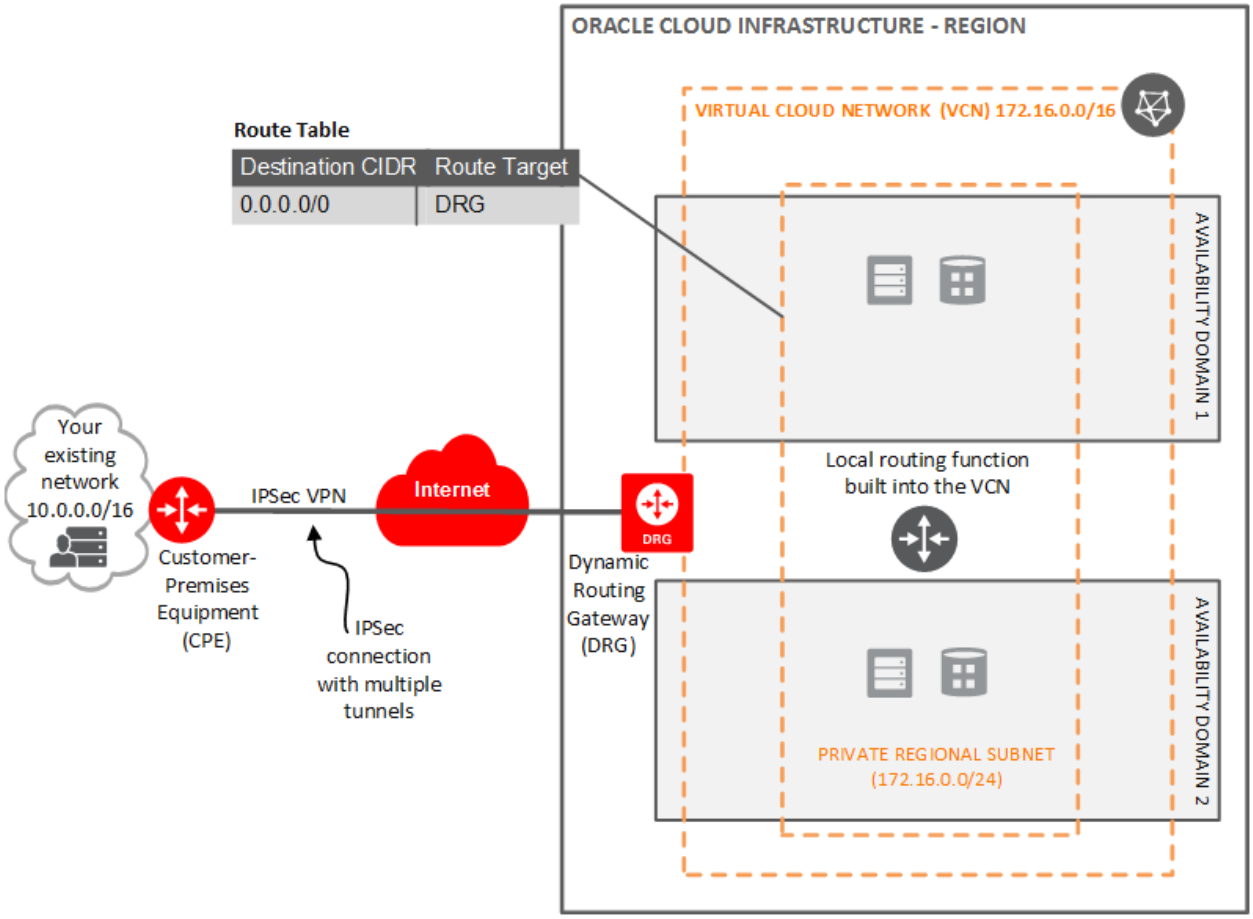
Within an IPSec VPN, you can influence *which tunnel* is preferred. Here are items you can configure:

- **Your CPE's BGP local preference:** If you use BGP, you can configure the BGP local preference attribute on your CPE device to control which tunnel is preferred for connections initiated from your on-premises network to your VCN. Because Oracle generally uses asymmetric routing, you must configure other attributes if you want Oracle to respond on that same tunnel. See the next two items.
- **More specific routes on the preferred tunnel:** You can configure your CPE to advertise more specific routes for the tunnel that you want to prefer. Oracle uses the route with the longest prefix match when responding to or initiating connections.
- **AS path prepending:** BGP prefers the shortest AS path, so if you use BGP, you can use AS path prepending to control which tunnel has the shortest path for a given route. Oracle uses the shortest AS path when responding to or initiating connections.

Overview of the IPSec VPN Components

If you're not already familiar with the basic Networking service components, see Overview of Networking before proceeding.

When you set up an IPSec VPN for your VCN, you must create several Networking components. You can create the components with either the Console or the API. See the following diagram and description of the components.



CPE OBJECT

At your end of the IPSec VPN is the actual device in your on-premises network (whether hardware or software). The term *customer-premises equipment (CPE)* is commonly used in some industries to refer to this type of on-premises equipment. When setting up the

VPN, you must create a *virtual representation* of the device. Oracle calls the virtual representation a CPE, but this documentation typically uses the term *CPE object* to help distinguish the virtual representation from the actual CPE device. The CPE object contains basic information about your device that Oracle needs.

DYNAMIC ROUTING GATEWAY (DRG)

At Oracle's end of the IPSec VPN is a virtual router called a dynamic routing gateway, which is the gateway into your VCN from your on-premises network. Whether you're using an IPSec VPN or Oracle Cloud Infrastructure FastConnect private virtual circuits to connect your on-premises network and VCN, the traffic goes through the DRG. For more information, see Dynamic Routing Gateways (DRGs).

A network engineer might think of the DRG as the *VPN headend*. After creating a DRG, you must *attach* it to your VCN, using either the Console or API. You must also add one or more route rules that route traffic from the VCN to the DRG. Without that DRG attachment and the route rules, traffic does not flow between your VCN and on-premises network. At any time, you can detach the DRG from your VCN but maintain all the remaining VPN components. You can then reattach the DRG, or attach it to another VCN.

IPSEC CONNECTION

After creating the CPE object and DRG, you connect them by creating an IPSec connection, which you can think of as a parent object that represents the overall IPSec VPN. The IPSec connection has its own OCID. When you create this component, you configure the type of routing to use for each tunnel, and you provide any related routing information.

TUNNEL

An IPSec tunnel is used to encrypt traffic between secure IPSec endpoints. Oracle creates two tunnels in each IPSec connection for redundancy. Each tunnel has its own OCID. Oracle recommends that you configure your CPE device to support both tunnels in case one fails or Oracle takes one offline for maintenance. Each tunnel has configuration information that your network engineer needs when configuring your CPE device. This information includes an IP address and shared secret, as well as ISAKMP and IPSec parameters. For more information, see Supported IPSec Parameters and Verified CPE Devices.

Access Control for the Components

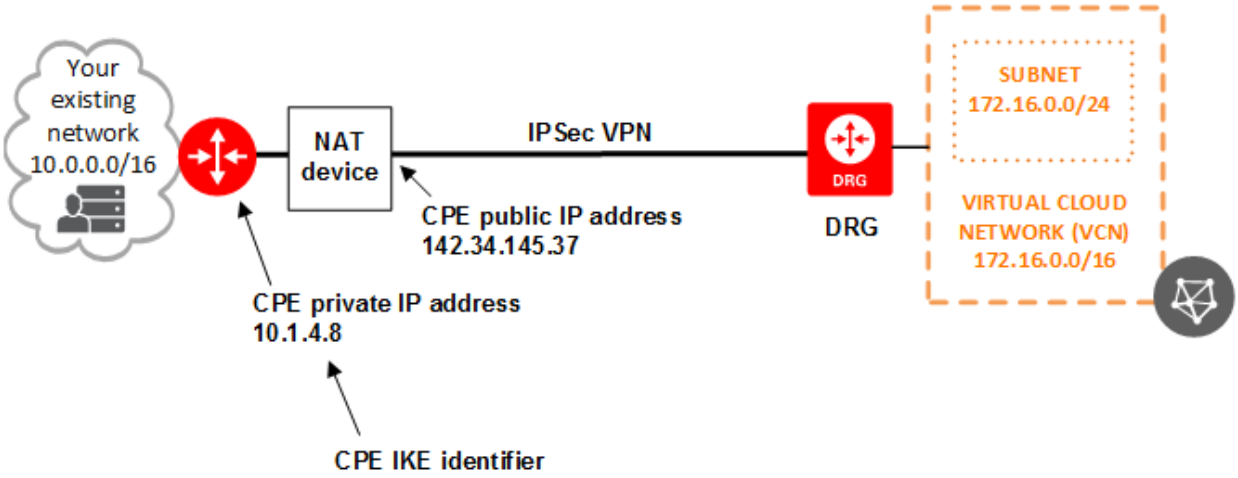
For the purposes of access control, when you set up the IPSec VPN, you must specify the compartment where you want each of the components to reside. If you're not sure which compartment to use, put all the components in the same compartment as the VCN. Note that the IPSec tunnels always reside in the same compartment as the parent IPSec connection. For information about compartments and restricting access to your networking components, see Access Control.

Component Names and Identifiers

You can optionally assign a descriptive name to each of the components when you create them. These names don't have to be unique, although it's a best practice to use unique names across your tenancy. Avoid including confidential information in the names. Oracle automatically assigns each component an OCID. For more information, see Resource Identifiers.

If Your CPE Is Behind a NAT Device

In general, the CPE IKE identifier configured on your end of the connection must match the CPE IKE identifier that Oracle is using. By default, Oracle uses the CPE's *public* IP address, which you provide when you create the CPE object in the Oracle Console. However, if your CPE is behind a NAT device, the CPE IKE identifier configured on your end might be the CPE's *private* IP address, as show in the following diagram.



Note

Some CPE platforms do not allow you to change the local IKE identifier. If you cannot, you must change the remote IKE ID in the Oracle Console to match your CPE's local IKE ID. You can provide the value either when you set up the IPSec connection, or later, by editing the IPSec connection. Oracle expects the value to be either an IP address or a fully qualified domain name (FQDN) such as *cpe.example.com*. For instructions, see Changing the CPE IKE Identifier That Oracle Uses.

About the Tunnel Shared Secret

Each tunnel has a shared secret. By default, Oracle assigns the shared secret to the tunnel unless you provide a shared secret yourself. You can provide a shared secret for each tunnel when you create the IPSec connection, or later after the tunnels are created. For the shared

secret, only letters, numbers, and spaces are allowed. If you change an existing tunnel's shared secret, the tunnel goes down while it is being reprovisioned.

For instructions, see Changing the Shared Secret That an IPSec Tunnel Uses

Monitoring Your Connection

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications. For more information, see Monitoring Overview and Notifications Overview.

For information about monitoring your connection, VPN Connect Metrics.

VPN Connect Quickstart

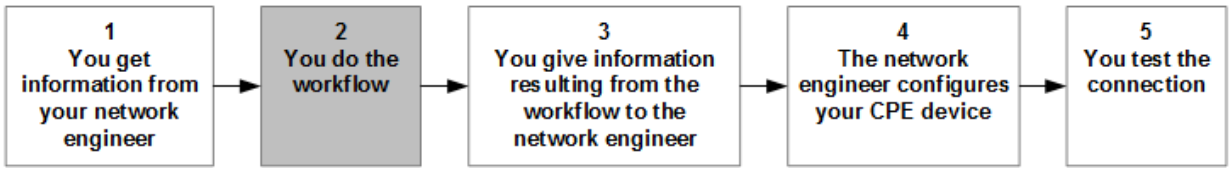
Using the VPN Connect workflow is the quickest way to set up an IPSec VPN between your on-premises network and your virtual cloud network (VCN). The workflow is a guided, step-by-step process in the Console that sets up the IPSec VPN plus related Networking service components.

Purpose of the Workflow

VPN Connect involves setting up and configuring several Networking service components. The purpose of the workflow is to set up those components for you. In general, the workflow does the following:

- Uses a template with assumptions that will help you get started.
- Asks you for some basic network information.
- Sets up the Networking service components for you.

The workflow is a task within the overall process of setting up VPN Connect, which is illustrated in the following diagram. The workflow is the shaded box.



Notice that the overall process includes work by a network engineer in your organization. That engineer provides information that you, in turn, must supply during the workflow. The workflow returns information that the network engineer needs when configuring your CPE device.

The following short sections summarize each task.

Task 1: Information to get from your network engineer

- CPE device's public IP address.
- If the CPE is behind a NAT device, get the CPE IKE identifier. For more information, see If Your CPE Is Behind a NAT Device.
- On-premises network routes.

- If you use BGP dynamic routing with the VPN:
    - Your network's BGP ASN
    - For each of the two IPSec tunnels that will be created, the pair of BGP IP addresses (with subnet mask) that you want to use for the inside tunnel interfaces at the ends of each tunnel. For example:
        - Tunnel 1: Inside tunnel interface - CPE: 10.0.0.8/31
        - Tunnel 1: Inside tunnel interface - Oracle: 10.0.0.9/31
        - Tunnel 2: Inside tunnel interface - CPE: 10.0.0.16/31
        - Tunnel 2: Inside tunnel interface - Oracle: 10.0.0.17/31
- The CIDR to use for the VCN. For the workflow, the allowed VCN size is /16 to /24. The CIDR must not overlap with your on-premises network.

Task 2: Workflow

You walk through the workflow in the Console. For more information, see these sections:

- Where to Access the Workflow
- What the Workflow Creates for You

Task 3: Information to give to your network engineer

- For each IPSec tunnel, the Oracle VPN IP address and shared secret.
- The supported IPSec parameter values.
- CPE-specific configuration information.

Task 4: CPE configuration

Your network engineer takes the information you provide and configures your CPE device.

Task 5: Testing

You and the network engineer test the connection and confirm that traffic is flowing.

Workflow Assumptions

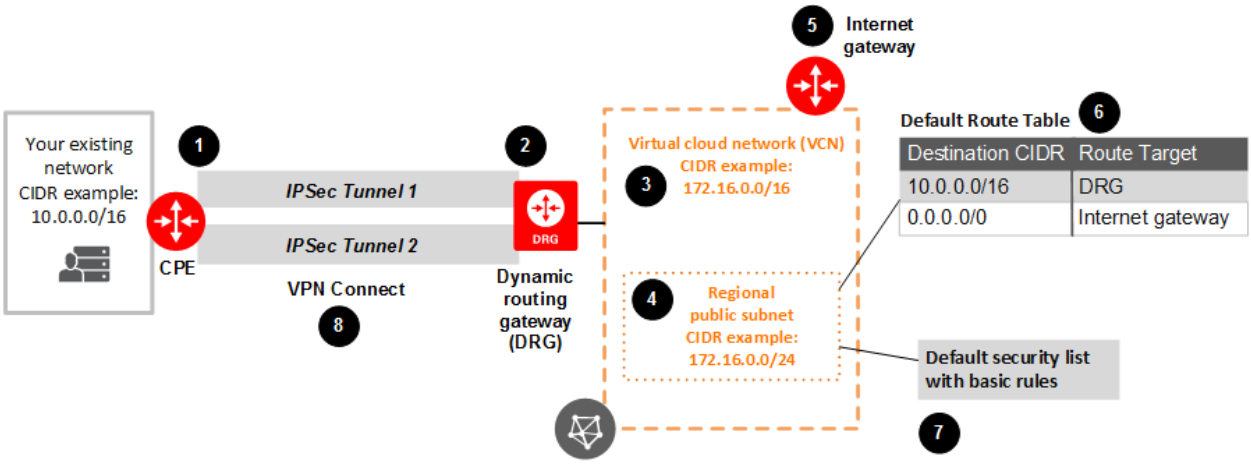
- **You do not already have a VCN:** The workflow automatically creates a VCN for you, along with related resources. If you instead have an existing VCN that you want to set up VPN Connect for, you can follow the step-by-step instructions in Setting Up VPN Connect.
- **You want an internet gateway for easy initial access to the VCN:** The workflow automatically adds an internet gateway to make it easy for you to quickly create an instance in the VCN and connect to it over the internet. You can delete this internet gateway later if you don't want it.

Alternative to the Workflow

If the workflow does not meet your specific needs (for example, if you already have a VCN), you can manually set up VPN Connect yourself. For step-by-step instructions, see Setting Up VPN Connect.

What the Workflow Creates for You

The workflow assumes that you start with only on-premises network and a CPE device. The workflow creates the numbered components in the diagram for you. The table describes each component.



5

Number	Component	Description	Can Use Existing One or Create New One?
1	CPE	A CPE is a *virtual representation* of your actual CPE device. This virtual representation contains basic information such as the CPE device's public IP address.	Yes, you can either use an existing CPE or the workflow creates a new one.
2	Dynamic routing gateway (DRG)	A DRG is a *virtual representation* of the actual router at the Oracle end of your VPN Connect.	Yes. If you use an existing one, it must not already be attached to a VCN.
3	VCN	A VCN is the extension of your on-premises network into the cloud. You can later add Compute instances and other cloud resources to your VCN.	No. The workflow automatically creates a new VCN.
4	Subnet	A subnet is a subdivision within the VCN. The workflow creates a regional public subnet. You can later add more subnets later if you like.	No. The workflow automatically creates the subnet in the new VCN.

Number	Component	Description	Can Use Existing One or Create New One?
5	Internet gateway	An internet gateway is a *virtual representation* of the actual router that gives your VCN access to the internet. Although this gateway is not necessary for VPN Connect, the workflow creates it to make it easy for you to quickly access any instances or other cloud resources you later create in the VCN. You can delete the internet gateway later if you like.	No. The workflow automatically creates an internet gateway for the new VCN.
6	Default route table with rules	The VCN automatically comes with a default route table. The workflow configures the subnet to use this route table and adds two types of rules: • One or more rules to route the desired VCN traffic to your on-premises network by way of the DRG. There's one rule per on-premises network route that you provide in the workflow. • One rule to route the remaining VCN traffic to the internet by way of the internet gateway. You can edit the rules or add more later if you want.	No. The new VCN automatically comes with this component.

Number	Component	Description	Can Use Existing One or Create New One?
7	Default security list with rules	The VCN automatically comes with a default security list. The workflow configures the subnet to use this security list, which automatically comes with default rules to enable basic traffic flow. The workflow also adds one or more rules to allow all types of traffic from your on-premises network. There's one rule per on-premises network route that you provide in the workflow. Notice that the security list does not include rules to allow ping.	No. The new VCN automatically comes with this component.
8	VPN Connect IPSec tunnels	The workflow creates two IPSec tunnels, each with specific configuration information that you must provide to your network engineer. **Note:** The workflow uses IKEv1 for the tunnels. If you want to use IKEv2 instead, after creating the IPSec connection, edit each tunnel in the Oracle Console to use IKEv2. Then configure your CPE to use only IKEv2 and related IKEv2 encryption parameters that your CPE supports. For more information, see Using IKEv2.	No. The workflow automatically creates the tunnels.

Where to Access the Workflow

1. In the Console, click the **Oracle Cloud** icon at the top of the page to go to the Console home page.

The page has a **Quick Actions** section to take you directly to common tasks.

2. Click the quick action for **Networking Solutions: Create an IPSec VPN connection**.
   The workflow starts.

- Using the API for VPN Connect

Supported IPSec Parameters

This topic lists the supported phase 1 (ISAKMP) and phase 2 (IPSec) configuration parameters for VPN Connect. Oracle chose these values to maximize security and to cover a wide range of CPE devices. If your CPE device is not on the list of verified devices, use the information here to configure your device.

Important

Oracle uses asymmetric routing across the multiple tunnels that make up the IPSec VPN connection. Even if you configure one tunnel as primary and another as backup, traffic from your VCN to your on-premises network can use any tunnel that is "up" on your device. Configure your firewalls accordingly. Otherwise, ping tests or application traffic across the connection will not reliably work.

Supported Encryption Domain or Proxy ID

The values for the encryption domain (also known as a proxy ID, security parameter index (SPI), or traffic selector) depend on whether your CPE supports route-based tunnels or policy-based tunnels. For more information about the correct encryption domain values to use, see Supported Encryption Domain or Proxy ID.

Supported Parameters for the Commercial Cloud

This section lists the supported parameters if your VPN Connect is for the commercial cloud. For a list of the commercial cloud regions, see Regions and Availability Domains.

For some parameters, Oracle supports multiple values, and the recommended one is highlighted in *red italics*.

Oracle supports the following parameters for IKEv1 or IKEv2. Check the documentation for your particular CPE to confirm which parameters the CPE supports for IKEv1 or IKEv2.

Phase 1 (ISAKMP)

Parameter	Options
ISAKMP Protocol	Version 1
Exchange type	Main mode
Authentication method	Pre-shared keys
Encryption algorithm	*AES-256-cbc* AES-192-cbc AES-128-cbc
Authentication algorithm	*SHA-2 384* SHA-2 256 SHA-1 (also called SHA or SHA1-96)
Diffie-Hellman group	group 1 (MODP 768) group 2 (MODP 1024) group 5 (MODP 1536) group 14 (MODP 2048) group 19 (ECP 256 *group 20 (ECP 384) **
IKE session key lifetime	28800 seconds (8 hours)
* Group 20 will be supported in all Oracle Cloud Infrastructure regions very soon.	

Phase 2 (IPSec)

Parameter	Options
IPSec Protocol	ESP, tunnel mode
Encryption algorithm	*AES-256-gcm* AES-192-gcm AES-128-gcm AES-256-cbc AES-192-cbc AES-128-cbc
Authentication algorithm	If using GCM (Galois/Counter Mode), no authentication algorithm is required because authentication is included with GCM encryption. If not using GCM, these are supported: *HMAC-SHA-256-128* HMAC-SHA-196
IPSec session key lifetime	3600 seconds (1 hour)
Perfect Forward Secrecy (PFS)	enabled, group 5

Supported Parameters for the Government Cloud

This section lists the supported parameters if your VPN Connect is for the Government Cloud. For more information, see For All Government Cloud Customers.

For some parameters, Oracle supports multiple values, and the recommended one is highlighted in *red italics*.

Oracle supports the following parameters for IKEv1 or IKEv2. Check the documentation for your particular CPE to confirm which parameters the CPE supports for IKEv1 or IKEv2.

Phase 1 (ISAKMP)

Parameter	Options
ISAKMP protocol	Version 1
Exchange type	Main mode
Authentication method	Pre-shared keys
Encryption algorithm	*AES-256-cbc* AES-192-cbc AES-128-cbc
Authentication algorithm	*SHA-2 384* SHA-2 256 SHA-1 (also called SHA or SHA1-96)
Diffie-Hellman group	group 14 (MODP 2048) group 19 (ECP 256) *group 20 (ECP 384) **
IKE session key lifetime	28800 seconds (8 hours)
* Group 20 will be supported in all Oracle Cloud Infrastructure regions very soon.	

Phase 2 (IPSec)

Parameter	Options
IPSec protocol	ESP, tunnel mode
Encryption algorithm	*AES-256-gcm* AES-192-gcm AES-128-gcm AES-256-cbc AES-192-cbc AES-128-cbc
Authentication algorithm	If using GCM (Galois/Counter Mode), no authentication algorithm is required because authentication is included with GCM encryption. If not using GCM, use HMAC-SHA-256-128.
IPSec session key lifetime	3600 seconds (1 hour)
Perfect Forward Secrecy (PFS)	enabled, group 14

Supported Encryption Domain or Proxy ID

The IPSec protocol uses Security Associations (SAs) to determine how to encrypt packets. Within each SA, you define encryption domains to map a packet's source and destination IP address and protocol type to an entry in the SA database to define how to encrypt or decrypt a packet.

Note

Other vendors or industry documentation might use the term *proxy ID, security parameter index (SPI)*, or *traffic selector* when referring to SAs or encryption domains.

There are two general methods for implementing IPSec tunnels:

- **Route-based tunnels:** Also called *next-hop-based tunnels*. A route table lookup is performed on a packet's destination IP address. If that route's egress interface is an IPSec tunnel, the packet is encrypted and sent to the other end of the tunnel.
- **Policy-based tunnels:** The packet's source and destination IP address and protocol are matched against a list of policy statements. If a match is found, the packet is encrypted based on the rules in that policy statement.

The Oracle VPN headends use route-based tunnels but can work with policy-based tunnels with some caveats listed in the following sections.

Important

The Oracle VPN headend supports only a single encryption domain. If your policy includes multiple entries, the tunnel will flap or there will be connectivity problems in which only a single policy works at any one time.

Encryption domain for route-based tunnels

If your CPE supports route-based tunnels, use that method to configure the tunnel. It's the simplest configuration with the most interoperability with the Oracle VPN headend.

Route-based IPSec uses an encryption domain with the following values:

- **Source IP address:** Any (0.0.0.0/0)
- **Destination IP address:** Any (0.0.0.0/0)
- **Protocol:** IPv4

If you need to be more specific, you can use a single summary route for your encryption domain values instead of a default route.

Encryption domain for policy-based tunnels

If your CPE supports only policy-based tunnels, there are restrictions on the policy that you can use on the CPE.

When you use policy-based tunnels, every policy entry that you define generates a pair of IPSec SAs. This pair is referred to as an *encryption domain*.

Important

The Oracle VPN headend supports only a single encryption domain. If your policy includes multiple entries, the tunnel will flap or there will be connectivity problems in which only a single policy works at any one time.

If you use policy-based IPSec, Oracle recommends using a *single encryption domain* with the following values:

- **Source IP address:** Any (0.0.0.0/0)
- **Destination IP address:** VCN CIDR (example: 10.120.0.0/20)
- **Protocol:** IPv4

Make sure the single encryption domain matches any traffic that needs to go from your on-premises network across the IPSec tunnel to the VCN. The VCN CIDR must not overlap with your on-premises network.

Setting Up VPN Connect

This topic gives instructions for setting up VPN Connect for your VCN. For general information about IPSec VPNs, see VPN Connect Overview.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Before You Get Started

To prepare, do these things first:

- Read this section: Routing for the Oracle IPSec VPN
- Answer these questions:

Question	Answer
What is your VCN's CIDR?	
What is the public IP address of your CPE device? If you have multiple devices for redundancy, get the IP address for each. **Note:** If your CPE device is behind a NAT device, see If Your CPE Is Behind a NAT Device and also Information About Your CPE Device.	
Will you be doing port address translation (PAT) between each CPE device and your VCN?	
What type of routing do you plan to use? If it's BGP dynamic routing, what are the BGP session IP addresses to use and the ASN of your network? The IP addresses must be part of the IPSec VPN's encryption domain. If static routing, what are the static routes for your on-premises network? See Routing for the Oracle IPSec VPN.	
Do you want to provide each tunnel's shared secret or let Oracle assign them? See About the Tunnel Shared Secret.	

- Draw a diagram of your network layout (for examples, see the first task in Example: Setting Up a Proof of Concept IPSec VPN). Think about which parts of your on-premises network need to communicate with your VCN, and the reverse. Map out the routing and security rules that you need for your VCN.

Tip

If you have an existing Oracle IPSec VPN that uses static routing, you can change the tunnels to instead use BGP dynamic routing.

Overall Process

Here's the overall process for setting up an IPSec VPN:

1. **Complete the tasks listed in** Before You Get Started**.**
2. **Set up the IPSec VPN components** (instructions in Example: Setting Up a Proof of Concept IPSec VPN):
    a. Create your VCN.
    b. Create a DRG.
    c. Attach the DRG to your VCN.
    d. Create a route table and route rule for the DRG.
    e. Create a security list and required rules.
    f. Create a subnet in the VCN.
    g. Create a CPE object and provide your CPE device's public IP address.
    h. Create an IPSec connection to the CPE object and provide required routing information.
3. **Have your network engineer configure your CPE device:** Your network engineer must configure your CPE device with information that Oracle provides during the previous steps. There is general information about the VCN, and specific information for each IPSec tunnel. This is the only part of the setup that you can't execute by using the Console or API. Without this configuration, traffic will not flow between your VCN and on-premises network. For more information, see CPE Configuration.
4. **Validate connectivity.**

Example: Setting Up a Proof of Concept IPSec VPN

Tip

Oracle offers a quickstart workflow to make it easier to set up VPN Connect. For more information, see VPN Connect Quickstart.

This example scenario shows how to set up a single IPSec VPN with a simple layout that you might use for a proof of concept (POC). It follows tasks 1 and 2 in Overall Process and shows each component in the layout being created. For each task, there's a corresponding screenshot from the Console to help you understand what information is needed. For more complex layouts, see Example Layout with Multiple Geographic Areas or Example Layout with PAT.

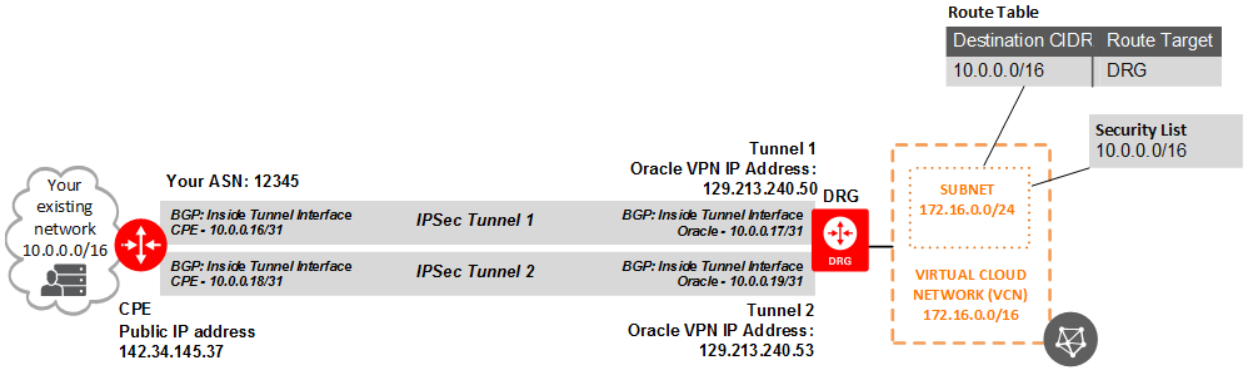
Task 1: Gather information

Question	Answer
What is your VCN's CIDR?	172.16.0.0/16
What is the public IP address of your CPE device? If you have multiple devices for redundancy, get the IP address for each. **Note:** If your CPE device is behind a NAT device, see If Your CPE Is Behind a NAT Device and also Information About Your CPE Device.	142.34.145.37
Will you be doing port address translation (PAT) between each CPE device and your VCN?	No

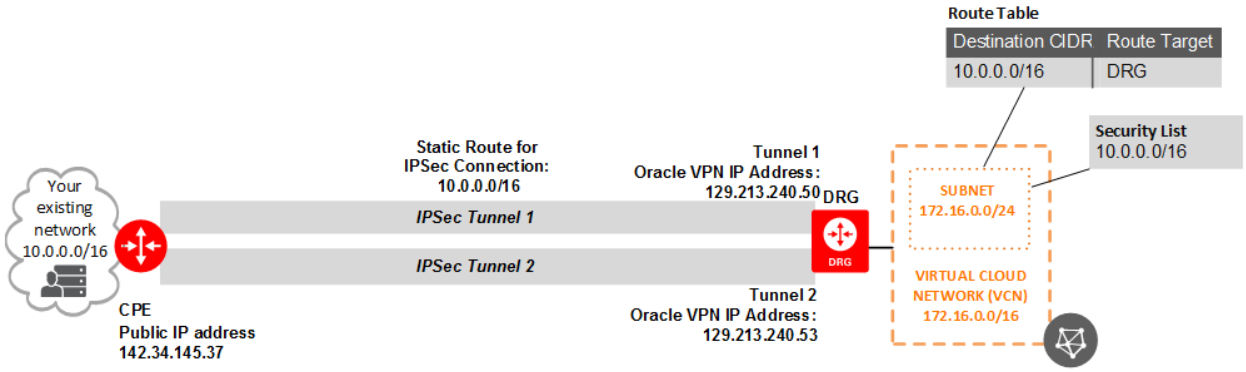
Question	Answer
What type of routing do you plan to use? If it's BGP dynamic routing, what are the BGP session IP addresses to use and the ASN of your network? If static routing, what are the static routes for your on-premises network? See Routing for the Oracle IPSec VPN.	**BGP dynamic routing example:** Tunnel 1: • BGP Inside tunnel interface - CPE: 10.0.0.16/31 • BGP Inside tunnel interface - Oracle: 10.0.0.17/31 Tunnel 2: • BGP Inside tunnel interface - CPE: 10.0.0.18/31 • BGP Inside tunnel interface - Oracle: 10.0.0.19/31 Network ASN:

Question	Answer
	12345 **Static routing example:** Use 10.0.0.0/16 for the static route for a simple POC.
Do you want to provide each tunnel's shared secret or let Oracle assign them? See About the Tunnel Shared Secret.	Let Oracle assign

Here's an example diagram for task 1 if you plan to use BGP dynamic routing:



Here's an example diagram for task 1 if you plan to use static routing:

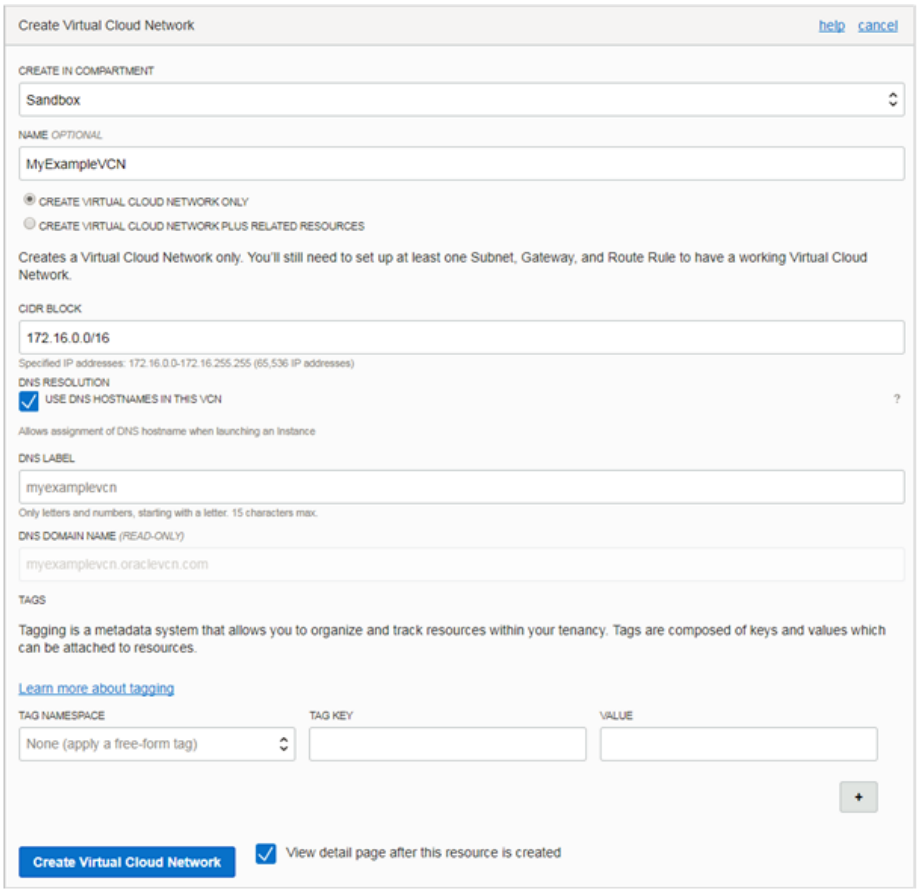


Task 2a: Create the VCN

If you already have a VCN, skip to the next task.

Tip

When you use the Console to create a VCN, you can create only the VCN, or you can create the VCN with several related resources. This task creates only the VCN, and the subsequent tasks create the other required resources.



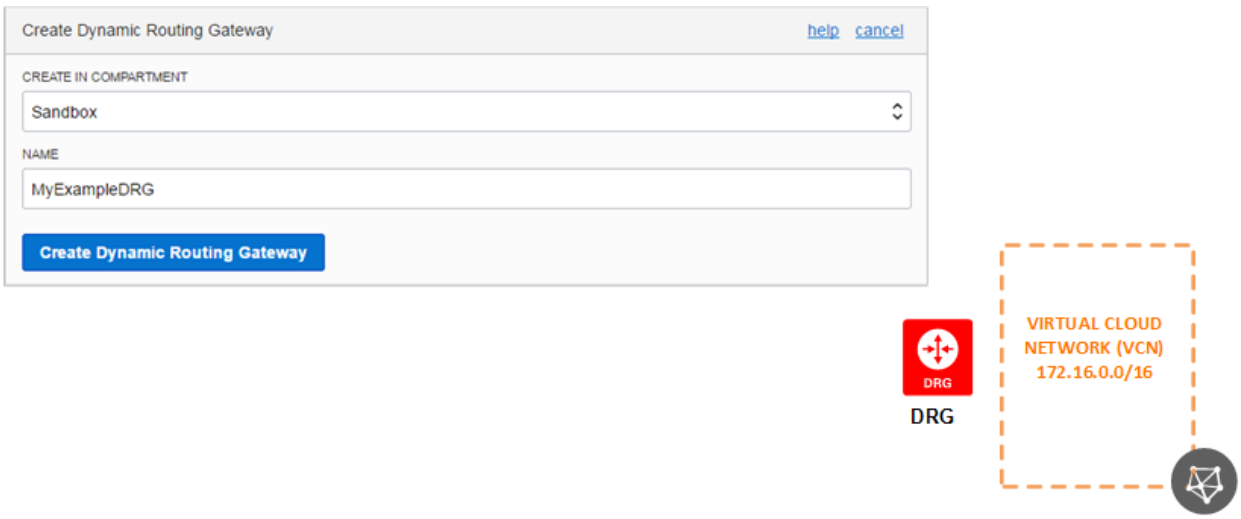
1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator. For more information, see Access Control.
3. Click **Create Virtual Cloud Network**.
4. Enter the following values:

- **Create in Compartment:** Leave as is.
- **Name:** A descriptive name for the cloud network. It doesn't have to be unique, and it can't be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
- **Create Virtual Cloud Network Only:** Select this option.
- **CIDR Block:** A single, contiguous CIDR block for the cloud network (for example, 172.16.0.0/16). You *can't* change this value later. See Allowed VCN Size and Address Ranges. For reference, use a CIDR calculator.
- **Enable IPv6 Address Assignment:** This option is available only if the VCN is in the US Government Cloud. For more information, see IPv6 Addresses.

5. You can provide values for the rest of the options, or you can ignore them:
   - **DNS Resolution:** Required for assignment of DNS hostnames to hosts in the VCN, and required if you plan to use the VCN's default DNS feature (called the *Internet and VCN Resolver*). If the check box is selected, you can specify a DNS label for the VCN, or the Console will generate one for you. The dialog box automatically displays the corresponding **DNS Domain Name** for the VCN (`<VCN DNS label>.oraclevcn.com`). For more information, see DNS in Your Virtual Cloud Network.
   - **Tags:** Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.
6. Click **Create Virtual Cloud Network**.

The VCN is created and displayed on the page. Ensure that it's done being provisioned before continuing.

Task 2b: Create the DRG

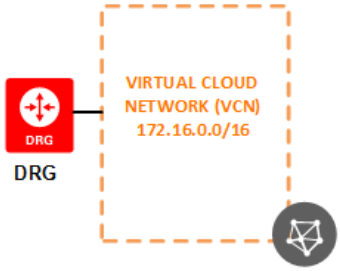


1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Dynamic Routing Gateways**.
2. Click **Create Dynamic Routing Gateway**.
3. Enter the following values:
   - **Create in Compartment:** Leave as is (the VCN's compartment).
   - **Name:** A descriptive name for the DRG. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
   - **Tags:** Leave as is. You can add tags later if you want. For more information, see Resource Tags.
4. Click **Create Dynamic Routing Gateway**.

The DRG is created and displayed on the page. Ensure that it's done being provisioned before continuing.

> **Tip**
>
> You could also use this DRG as the gateway for Oracle Cloud Infrastructure FastConnect, which is an alternative way to connect your on-premises network to your VCN.

Task 2c: Attach the DRG to the VCN



1. Click the name of the DRG that you just created.
2. Under **Resources**, click **Virtual Cloud Networks**.
3. Click **Attach to Virtual Cloud Network**.
4. Select the VCN. Ignore the section for advanced options, which is only for an advanced

routing scenario called transit routing, which is not relevant here.

5. Click **Attach**.

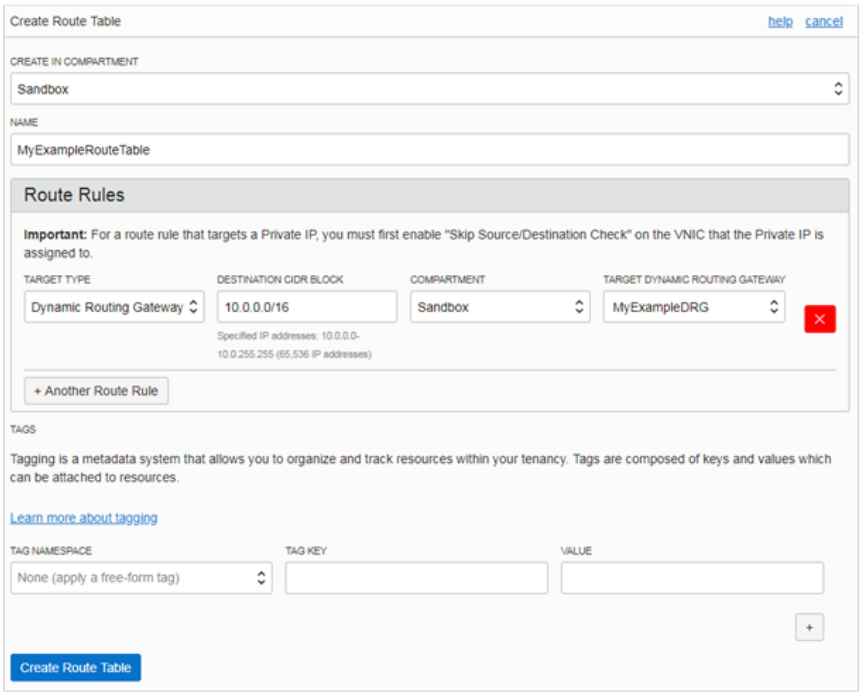
The attachment will be in the Attaching state for a short period before it's ready.

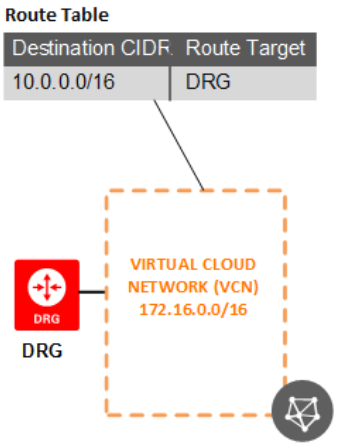
Task 2d: Create a route table and route rule for the DRG

Although the VCN comes with a default route table (without any rules), in this task you create a custom route table with a route rule for the DRG. In this example, your on-premises network is 10.0.0.0/16. You create a route rule that takes any traffic destined for 10.0.0.0/16 and routes it to the DRG. When you create a subnet in task 2f, you associate this custom route table with the subnet.

Tip

If you already have an existing VCN with a subnet, you don't need to create a route table or subnet. Instead you can update the existing subnet's route table to include the route rule for the DRG.





1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click your VCN.
3. Click **Route Tables** to see your VCN's route tables.
4. Click **Create Route Table**.
5. Enter the following values:
    - **Name:** A descriptive name for the route table (for example, MyExampleRouteTable). The name doesn't have to be unique, and it can't be changed later in the Console (but you can change it in the API). Avoid entering confidential information.
    - **Create in compartment:** Leave as is.
    - Click **+ Additional Route Rule**, and enter the following:

- **Target Type:** Dynamic Routing Gateway. The VCN's attached DRG is automatically selected as the target, and you don't have to specify the target yourself.
- **Destination CIDR Block:** The CIDR for your on-premises network (10.0.0.0/16 in this example).

- **Tags:** Leave the tag information as is.

6. Click **Create Route Table**.

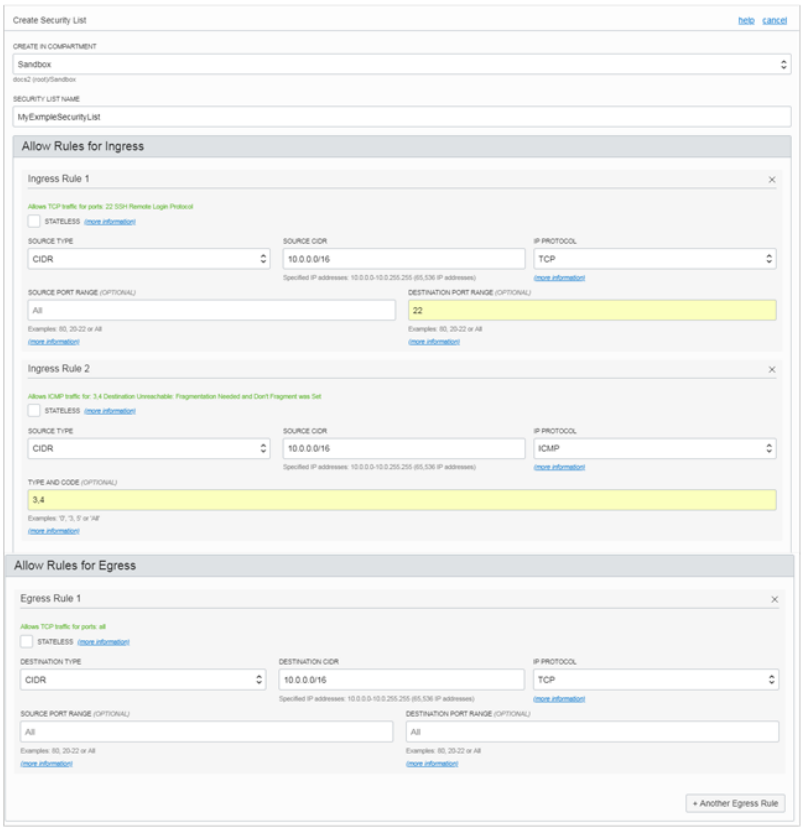
The route table is created and displayed on the page. However, the route table doesn't do anything unless you associate it with a subnet during subnet creation (see task 2f).

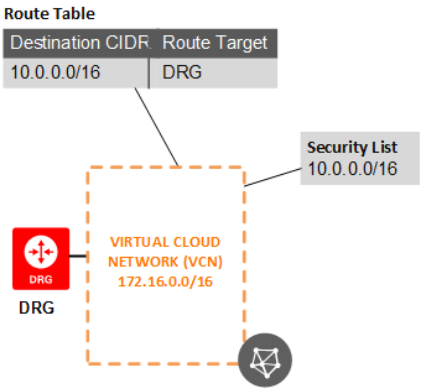
Task 2e: Create a security list

By default, incoming traffic to the instances in your VCN is set to DENY on all ports and all protocols. In this task, you set up two ingress rules and one egress rule to allow basic required network traffic. Your VCN comes with a default security list with a set of default rules. However, in this task you create a separate security list with a more restrictive set of rules focused on traffic with your on-premises network. When you create a subnet in task 2f, you associate this security list with the subnet.

Tip

Security lists are one way to control traffic in and out of the VCN's resources. You can also use network security groups, which let you apply a set of security rules to a set of resources that all have the same security posture.





Important

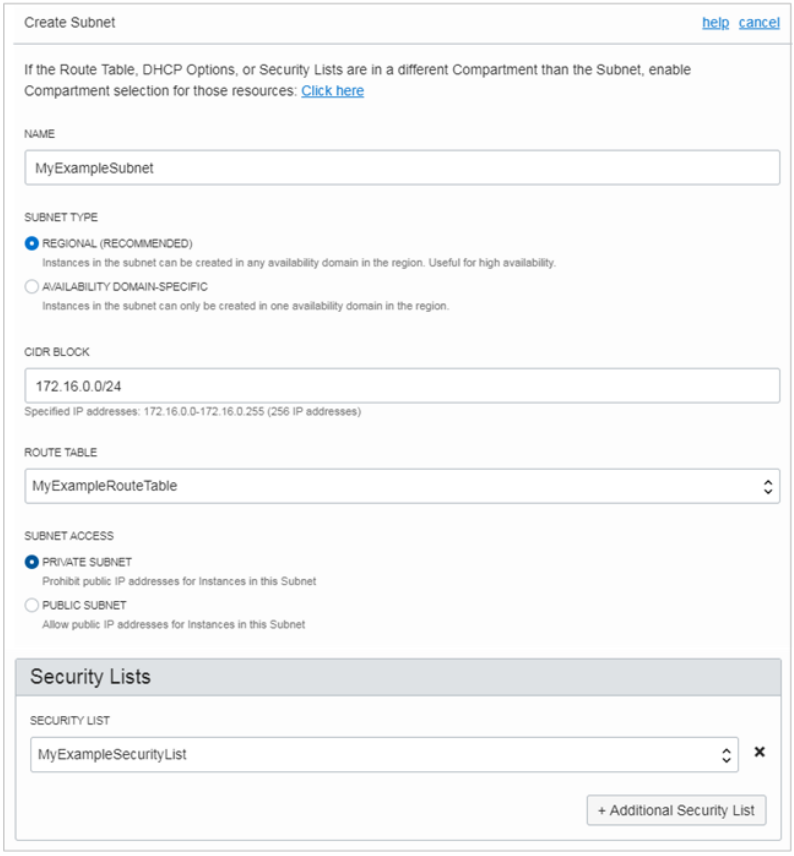
In the following procedure, ensure that the on-premises CIDR that you specify in the security list rules is the same (or smaller) than the CIDR that you specified in the route rule in the preceding task. Otherwise, traffic will be blocked by the security lists.

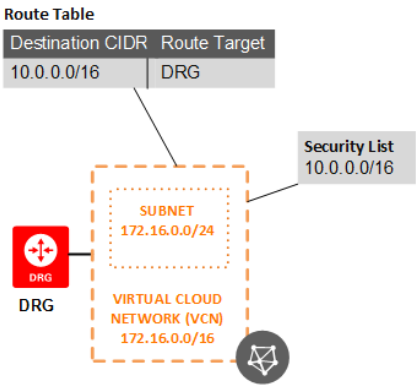
1. While still viewing your VCN, click **Security Lists** on the left side of the page.
2. Click **Create Security List**.
3. Enter the following values:
    - **Name:** A descriptive name for the security list. The name doesn't have to be unique, and it cannot be changed later in the Console (but you can change it in the API). Avoid entering confidential information.
    - **Create in compartment:** Leave as is.
4. In the **Allow Rules for Ingress** section, click **Add Ingress Rule** and enter the following values for the ingress rule, which allows incoming SSH on TCP port 22 from your on-premises network:
    - **Source Type:** CIDR
    - **Source CIDR:** The CIDR for your on-premises network (10.0.0.0/16 in this example)
    - **IP Protocol:** TCP.
    - **Source Port Range:** Leave as is (the default All).
    - **Destination Port Range:** 22 (for SSH traffic).
5. In the **Allow Rules for Egress** section, click **Add Egress Rule** enter the following values for the egress rule, which allows outgoing TCP traffic on all ports to your on-premises network:
    - **Destination Type:** CIDR
    - **Destination CIDR:** The CIDR for your on-premises network (10.0.0.0/16 in this example).
    - **IP Protocol:** TCP.
    - **Source Port Range:** Leave as is (the default All).
    - **Destination Port Range:** Leave as is (the default All).
6. Leave the tag information as is.
7. Click **Create Security List**.

The security list is created and displayed on the page. However, the security list doesn't do anything unless you associate it with a subnet during subnet creation (see task 2f).

Task 2f: Create a subnet

In this task, you create a subnet in the VCN. Typically a subnet has a CIDR block smaller than the VCN's CIDR. Any instances that you create in this subnet have access to your on-premises network. Oracle recommends using regional subnets. Here you create a regional private subnet.



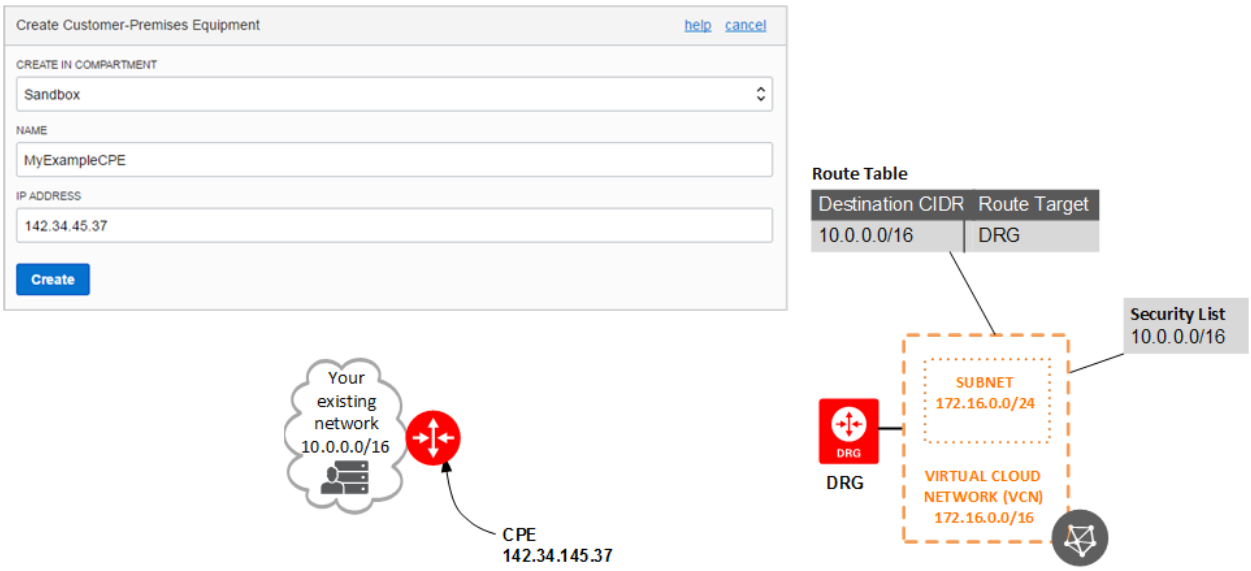


1. While still viewing your VCN, click **Subnets** on the left side of the page.
2. Click **Create Subnet**.
3. Enter the following values:
    - **Name:** A descriptive name for the subnet. It doesn't have to be unique, and it can't be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
    - **Regional or AD-specific subnet:** Select the radio button for **Regional**. Oracle recommends using regional subnets.
    - **CIDR Block:** A single, contiguous CIDR block for the subnet (for example, 172.16.0.0/24). It must be within the cloud network's CIDR block and can't overlap with any other subnets. You *can't* change this value later. See Allowed VCN Size and Address Ranges. For reference, use a CIDR calculator.
    - **Enable IPv6 Address Assignment:** This option is available only if the VCN is in the US Government Cloud. For more information, see IPv6 Addresses.
    - **Route Table:** The route table that you created earlier.
    - **Private Subnet**: Select this option. For more information, see Access to the Internet.
    - **Use DNS Hostnames in this Subnet:** Leave as is (selected).
    - **DHCP Options:** The set of DHCP options to associate with the subnet. Select the default set of DHCP options for the VCN.
    - **Security Lists:** The security list that you created earlier.
    - **Tags:** Leave as is. You can add tags later if you want. For more information, see Resource Tags.
4. Click **Create Subnet**.

The subnet is created and displayed on the page. The basic VCN in this example is now set up, and you're ready to create the remaining components for the IPSec VPN.

Task 2g: Create a CPE object and provide your CPE device's public IP address

In this task, you create the CPE object, which is a virtual representation of your CPE device.



1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Customer-Premises Equipment**.
2. Click **Create Customer-Premises Equipment**.
3. Enter the following values:
   - **Create in Compartment:** Leave as is (the VCN's compartment).
   - **Name:** A descriptive name for the CPE object. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
   - **IP Address:** The public IP address of the CPE device at your end of the VPN (see the list of information to gather in Before You Get Started).

- **Tags:** Leave as is. You can add tags later if you want. For more information, see Resource Tags.

4. Click **Create**.

The CPE object is created and displayed on the page.

Task 2h: Create an IPSec connection to the CPE object

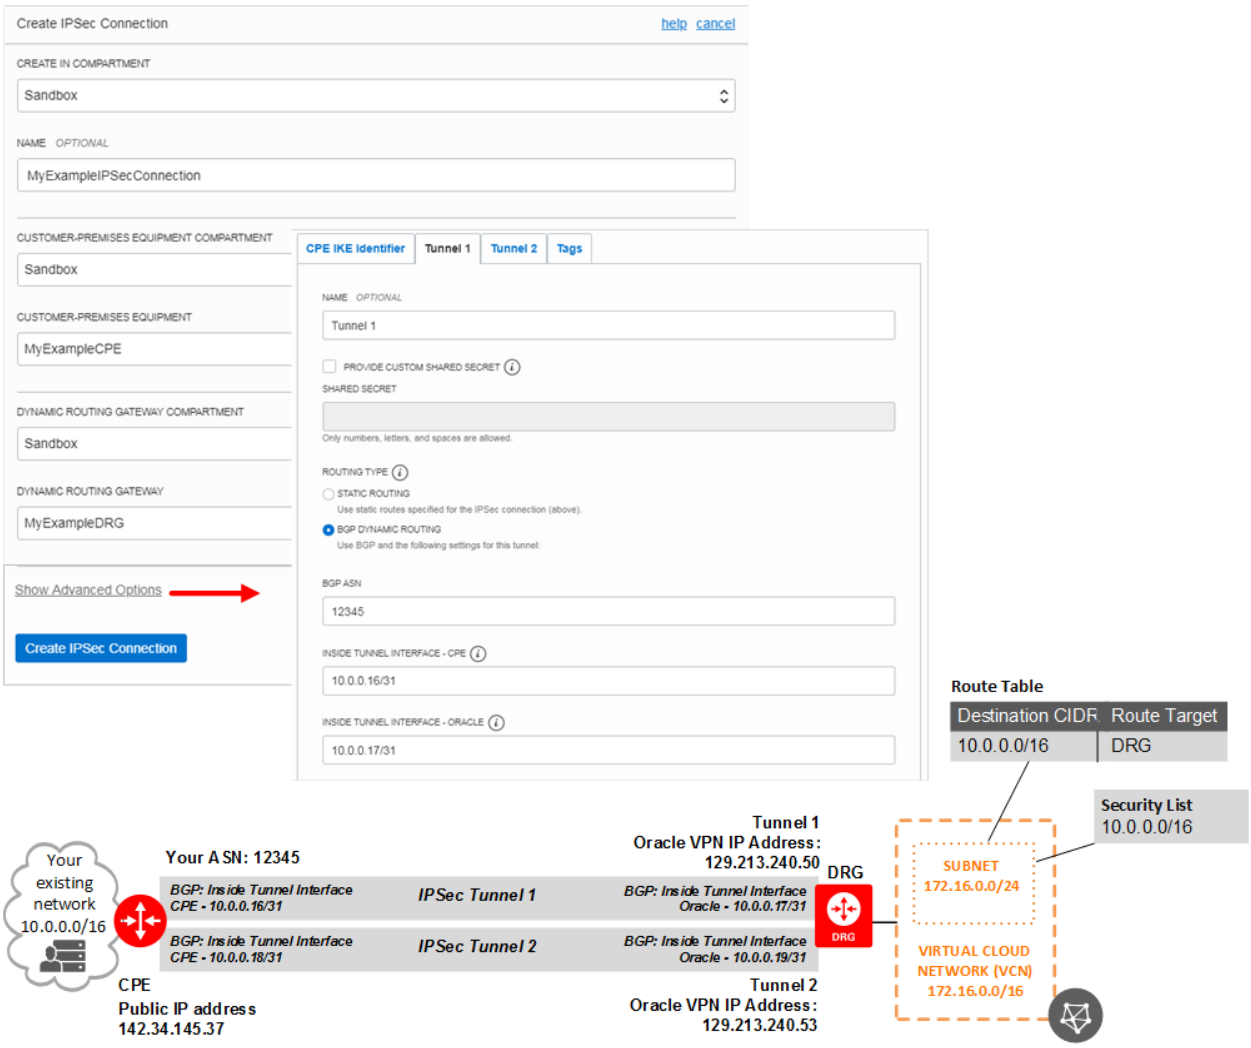
In this task, you create the IPSec tunnels and configure the type of routing for them (BGP dynamic routing or static routing).

Tip

If you have an existing Oracle IPSec VPN that uses static routing, you can change the tunnels to instead use BGP dynamic routing.

For BGP dynamic routing

In this example, you configure both tunnels to use BGP dynamic routing.



1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **IPSec Connections**.
2. Click **Create IPSec Connection**.
3. Enter the following values:

- **Create in Compartment:** Leave as is (the VCN's compartment).
- **Name:** Enter a descriptive name for the IPSec connection. It doesn't have to be unique, and you can change it later if you like. Avoid entering confidential information.
- **Customer-Premises Equipment Compartment:** Leave as is (the VCN's compartment).
- **Customer-Premises Equipment:** Select the CPE object that you created earlier.
- **Dynamic Routing Gateway Compartment:** Leave as is (the VCN's compartment).
- **Dynamic Routing Gateway:** Select the DRG that you created earlier.
- **Static Route CIDR:** Leave empty because this IPSec connection uses BGP dynamic routing. You configure the two tunnels to use BGP in subsequent steps.

4. Click **Show Advanced Options**.
5. On the **CPE IKE Identifier** tab (optional): Oracle defaults to using the public IP address of the CPE. But if your CPE is behind a NAT device, you might need to enter a different value. You can either enter the new value here, or change the value later.
6. On the **Tunnel 1** tab (required):
   - **Name:** Enter a descriptive name for the tunnel. It doesn't have to be unique, and you can change it later if you like. Avoid entering confidential information.
   - **Provide custom shared secret** (optional): By default, Oracle provides the shared secret for the tunnel. If you want to provide it instead, select this check box and enter the shared secret. You can change the shared secret later.
   - **IKE Version:** The Internet Key Exchange (IKE) version to use for this tunnel. Only select IKEv2 if your CPE supports it. You must also then configure the CPE to use only IKEv2 for this tunnel.
   - **Routing Type:** Select the radio button for **BGP Dynamic Routing**.

- **BGP ASN:** Enter your network's ASN.
- **Inside Tunnel Interface - CPE:** Enter the BGP IP address with subnet mask (either /30 or /31) for the CPE end of the tunnel. For example: 10.0.0.16/31. The IP address must be part of the IPSec VPN's encryption domain.
- **Inside Tunnel Interface - Oracle:** Enter the BGP IP address with subnet mask (either /30 or /31) for the Oracle end of the tunnel. For example: 10.0.0.17/31. The IP address must be part of the IPSec VPN's encryption domain.

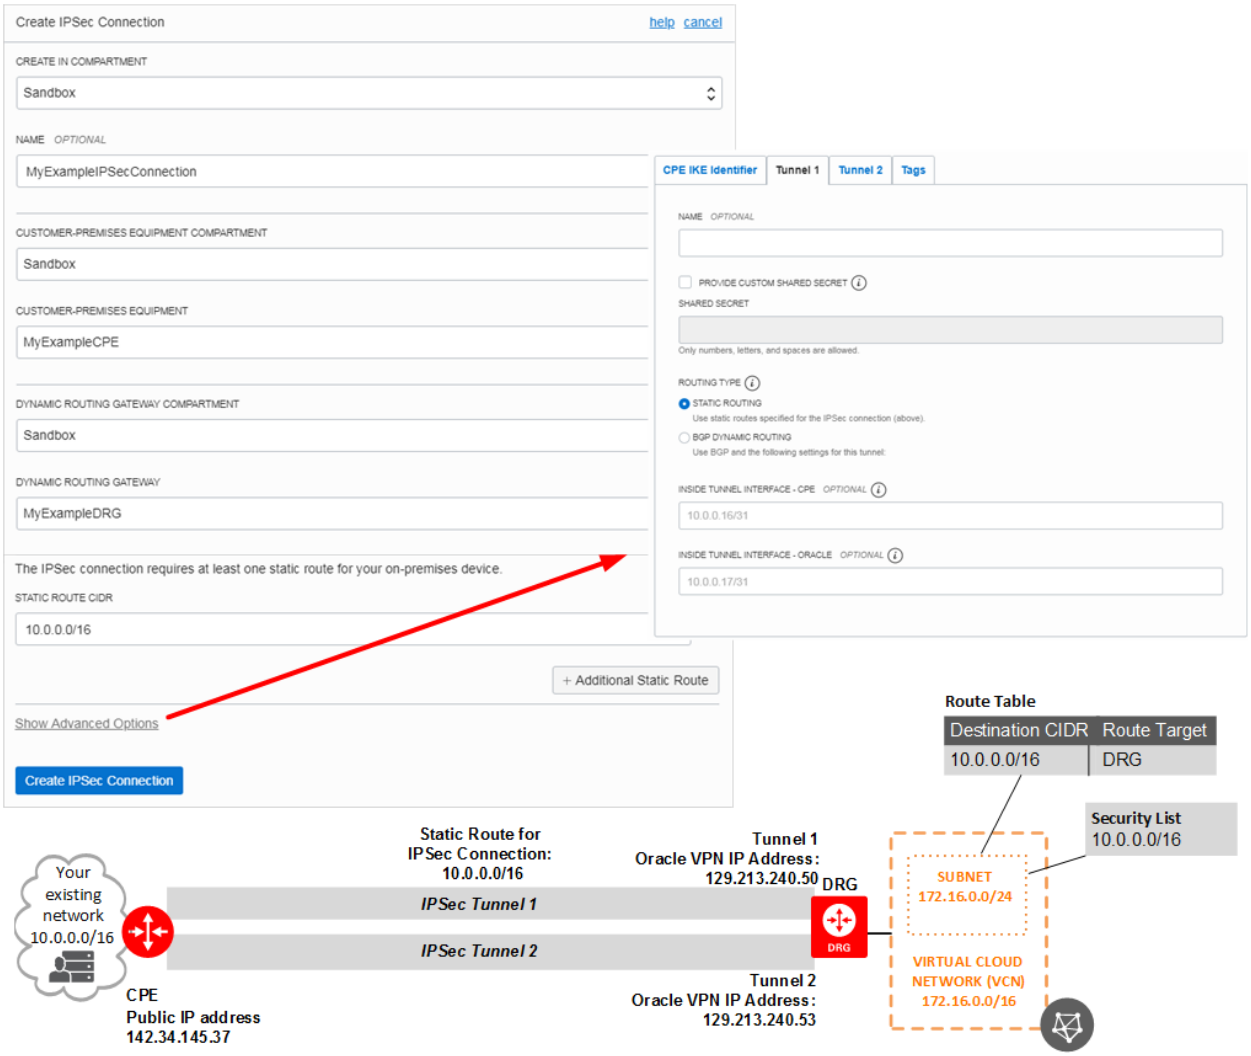
7. On the **Tunnel 2** tab (required):
   - **Name:** Enter a descriptive name for the tunnel. It doesn't have to be unique, and you can change it later if you like. Avoid entering confidential information.
   - **Provide custom shared secret** (optional): By default, Oracle provides the shared secret for the tunnel. If you want to provide it instead, select this check box and enter the shared secret. You can change the shared secret later.
   - **IKE Version:** The Internet Key Exchange (IKE) version to use for this tunnel. Only select IKEv2 if your CPE supports it. You must also then configure the CPE to use only IKEv2 for this tunnel.
   - **Routing Type:** Select the radio button for **BGP Dynamic Routing**.
   - **BGP ASN:** Enter your network's ASN.
   - **Inside Tunnel Interface - CPE:** Enter the BGP IP address with subnet mask (either /30 or /31) for the CPE end of the tunnel. Use a different IP address than for tunnel 1. For example: 10.0.0.18/31. The IP address must be part of the IPSec VPN's encryption domain.
   - **Inside Tunnel Interface - Oracle:** Enter the BGP IP address with subnet mask (either /30 or /31) for the Oracle end of the tunnel. Use a different IP address than for tunnel 1. For example: 10.0.0.19/31. The IP address must be part of the IPSec VPN's encryption domain.
8. On the **Tags** tab (optional): Leave as is. You can add tags later if you want. For more information, see Resource Tags.

9. Click **Create IPSec Connection**.
   The IPSec connection is created and displayed on the page. It will be in the Provisioning state for a short period.
   The displayed tunnel information includes:
   - The Oracle VPN IP address (for the Oracle VPN headend).
   - The tunnel's IPSec status (possible values are Up, Down, and Down for Maintenance). At this point, the status is Down. Your network engineer still must configure your CPE device.
   - The tunnel's BGP status. At this point, the status is Down. Your network engineer still must configure your CPE device.

   To view the tunnel's shared secret, click the tunnel to view its details, and then click **Show** next to **Shared Secret**.
10. Copy the Oracle VPN IP address and shared secret for each of the tunnels to an email or other location so you can deliver it to the network engineer who will configure your CPE device.
    You can view this tunnel information here in the Console at any time.

You have now created all the components required for the IPSec VPN. But your network engineer must configure your CPE device before network traffic can flow between your on-premises network and VCN.

For static routing



1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **IPSec Connections**.

2. Click **Create IPSec Connection**.
3. Enter the following values:
    - **Create in Compartment:** Leave as is (the VCN's compartment).
    - **Name:** Enter a descriptive name for the IPSec connection. It doesn't have to be unique, and you can change it later if you like. Avoid entering confidential information.
    - **Customer-Premises Equipment Compartment:** Leave as is (the VCN's compartment).
    - **Customer-Premises Equipment:** Select the CPE object that you created earlier.
    - **Dynamic Routing Gateway Compartment:** Leave as is (the VCN's compartment).
    - **Dynamic Routing Gateway:** Select the DRG that you created earlier.
    - **Static Route CIDR:** Enter at least one static route CIDR (see the list of information to gather in Before You Get Started). For this example, enter 10.0.0.0/16. You can enter up to 10 static routes, and you can change the static routes later if you like.
4. Click **Show Advanced Options**.
5. On the **CPE IKE Identifier** tab (optional): Oracle defaults to using the public IP address of the CPE. But if your CPE is behind a NAT device, you might need to enter a different value. You can either enter the new value here, or change the value later.
6. On the **Tunnel 1** tab (optional):
    - **Tunnel Name:** Enter a descriptive name for the tunnel. It doesn't have to be unique, and you can change it later if you like. Avoid entering confidential information.
    - **Provide custom shared secret** (optional): By default, Oracle provides the shared secret for the tunnel. If you want to provide it instead, select this check box and enter the shared secret. You can change the shared secret later.

- **IKE Version:** The Internet Key Exchange (IKE) version to use for this tunnel. Only select IKEv2 if your CPE supports it. You must also then configure the CPE to use only IKEv2 for this tunnel.
- **Routing Type:** Leave the radio button for **Static Routing** selected.
- **Inside Tunnel Interface - CPE** (optional): You can provide an IP address with subnet mask (either /30 or /31) for the CPE end of the tunnel for the purposes of tunnel troubleshooting or monitoring. For example: 10.0.0.16/31. The IP address must be part of the IPSec VPN's encryption domain.
- **Inside Tunnel Interface - Oracle** (optional): You can provide an IP address with subnet mask (either /30 or /31) for the Oracle end of the tunnel for the purposes of tunnel troubleshooting or monitoring. For example: 10.0.0.17/31. The IP address must be part of the IPSec VPN's encryption domain.

7. On the **Tunnel 2** tab (optional):
   - **Tunnel Name:** Enter a descriptive name for the tunnel. It doesn't have to be unique, and you can change it later if you like. Avoid entering confidential information.
   - **Provide custom shared secret** (optional): By default, Oracle provides the shared secret for the tunnel. If you want to provide it instead, select this check box and enter the shared secret. You can change the shared secret later.
   - **IKE Version:** The Internet Key Exchange (IKE) version to use for this tunnel. Only select IKEv2 if your CPE supports it. You must also then configure the CPE to use only IKEv2 for this tunnel.
   - **Routing Type:** Leave the radio button for **Static Routing** selected.
   - **Inside Tunnel Interface - CPE** (optional): You can provide an IP address with subnet mask (either /30 or /31) for the CPE end of the tunnel for the purposes of tunnel troubleshooting or monitoring. Use a different IP address than for tunnel 1. For example: 10.0.0.18/31. The IP address must be part of the IPSec VPN's encryption domain.

- **Inside Tunnel Interface - Oracle** (optional): You can provide an IP address with subnet mask (either /30 or /31) for the Oracle end of the tunnel for the purposes of tunnel troubleshooting or monitoring. Use a different IP address than for tunnel 1. For example: 10.0.0.19/31. The IP address must be part of the IPSec VPN's encryption domain.

8. **Tags:** Leave as is. You can add tags later if you want. For more information, see Resource Tags.
9. Click **Create IPSec Connection**.
   The IPSec connection is created and displayed on the page. It will be in the Provisioning state for a short period.
   The displayed tunnel information includes:
   - The Oracle VPN IP address (for the Oracle VPN headend).
   - The tunnel's IPSec status (possible values are Up, Down, and Down for Maintenance). At this point, the status is Down. Your network engineer still must configure your CPE device.

   To view the tunnel's shared secret, click the tunnel to view its details, and then click **Show** next to **Shared Secret**.
10. Copy the Oracle VPN IP address and shared secret for each of the tunnels to an email or other location so you can deliver it to the network engineer who will configure the CPE device.
    You can view this tunnel information here in the Console at any time.

You have now created all the components required for the IPSec VPN. But your network engineer must configure the CPE device before network traffic can flow between your on-premises network and VCN.

For more information, see CPE Configuration.

Task 3: Have your network engineer configure your CPE

Provide your network engineer with the following information:

- The VCN's OCID.
- The VCN's CIDR and subnet mask.
- The shared secret and Oracle VPN IP address for each tunnel (from task 2h).
- If using BGP: the BGP session information for each tunnel, which includes the IP addresses and Oracle BGP ASN. Oracle's BGP ASN for the commercial cloud is 31898. For the Government Cloud, see Oracle's BGP ASN.
- The information required to configure your particular CPE device, which is listed in the topic for each verified type of CPE device.
- The general IPSec parameters that Oracle supports.
- A link to this topic: CPE Configuration.

Important

Be sure to have your network engineer configure your CPE device to support both of the tunnels in case one fails or Oracle takes one down for maintenance. If you're using BGP, see Important Routing Details for an Oracle IPSec VPN.

Task 4: Validate connectivity

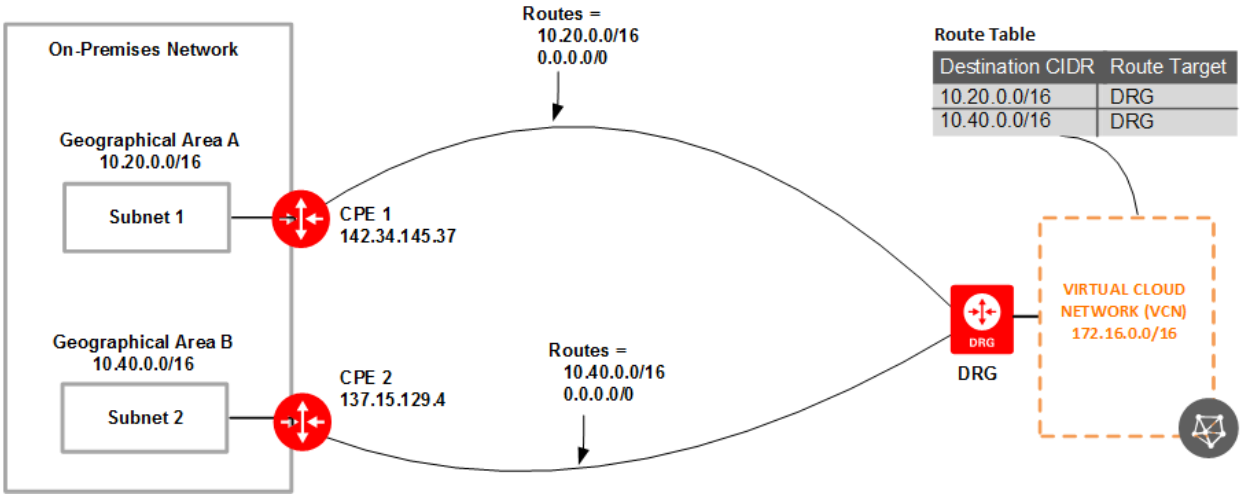
After the network engineer configures your CPE device, you can confirm that the tunnel's IPSec status is Up and green. Next, you can create a Linux instance in the subnet in your VCN. You should then be able to use SSH to connect to the instance's private IP address from a host in your on-premises network. For more information, see Creating an Instance.

Example Layout with Multiple Geographic Areas

The following diagram shows an example with this configuration:

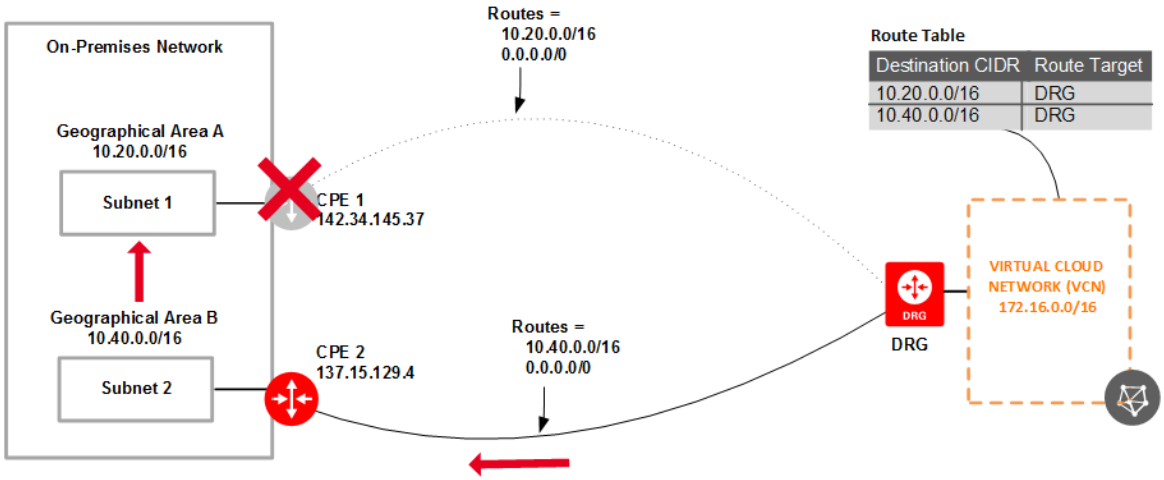
- Two networks in separate geographical areas that each connect to your VCN
- A single CPE device in each area
- Two IPSec VPNs (one for each CPE device)

Notice that each IPSec VPN has two routes associated with it: one for the particular geographical area's subnet, and a default 0.0.0.0/0 route. Oracle learns about the available routes for each tunnel either through BGP (if the tunnels use BGP), or because you've set them as static routes for the IPSec connection (if the tunnels use static routing).

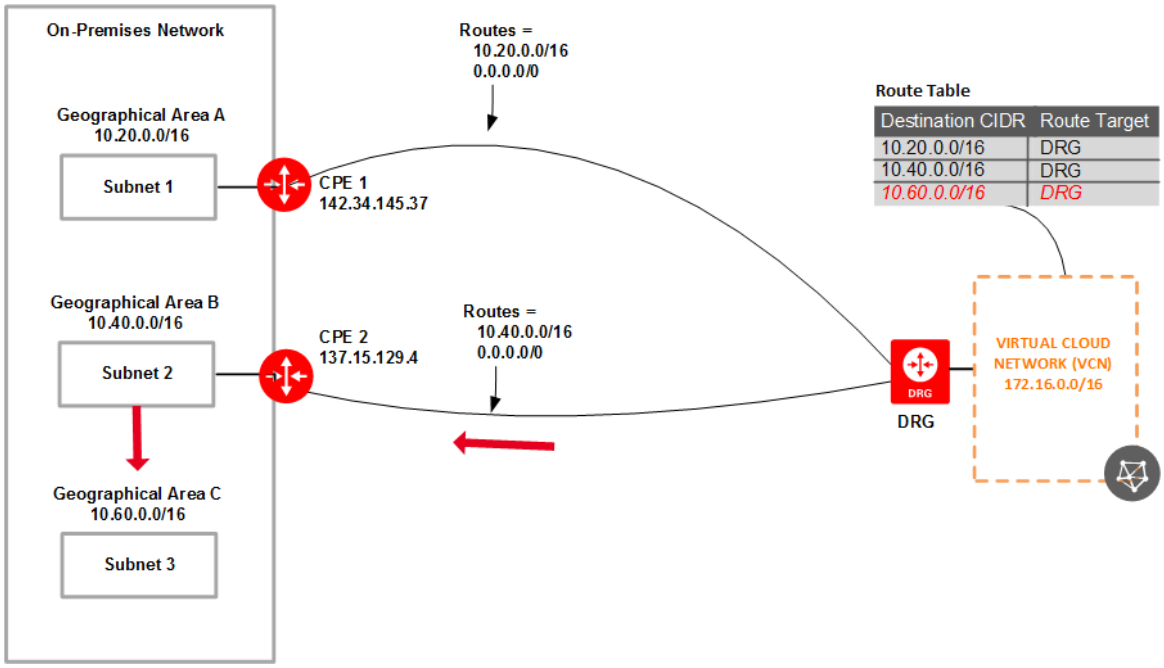


Following are some examples of situations in which the 0.0.0.0/0 route can provide flexibility:

- Assume that the CPE 1 device goes down (see the next diagram). If Subnet 1 and Subnet 2 can communicate with each other, your VCN could still reach the systems in Subnet 1 because of the 0.0.0.0/0 route that goes to CPE 2.



- Assume that your organization adds a new geographical area with Subnet 3 and initially just connects it to Subnet 2 (see the next diagram). If you added a route rule to your VCN's route table for Subnet 3, the VCN could reach systems in Subnet 3 because of the 0.0.0.0/0 route that goes to CPE 2.



Example Layout with PAT

The following diagram shows an example with this configuration:

- Two networks in separate geographical areas that each connect to your VCN
- Redundant CPE devices (two in each geographical area)
- Four IPSec VPNs (one for each CPE device)
- Port address translation (PAT) for each CPE device

For each of the four IPSec connections, the route that Oracle needs to know about is the PAT IP address for the specific CPE device. Oracle learns about the PAT IP address route for each tunnel either through BGP (if the tunnels use BGP), or because you've set the relevant address as a static route for the IPSec connection (if the tunnels use static routing).

When you set up the route rules for the VCN, you specify a rule for each PAT IP address (or an aggregate CIDR that covers them all) with your DRG as the rule's target.

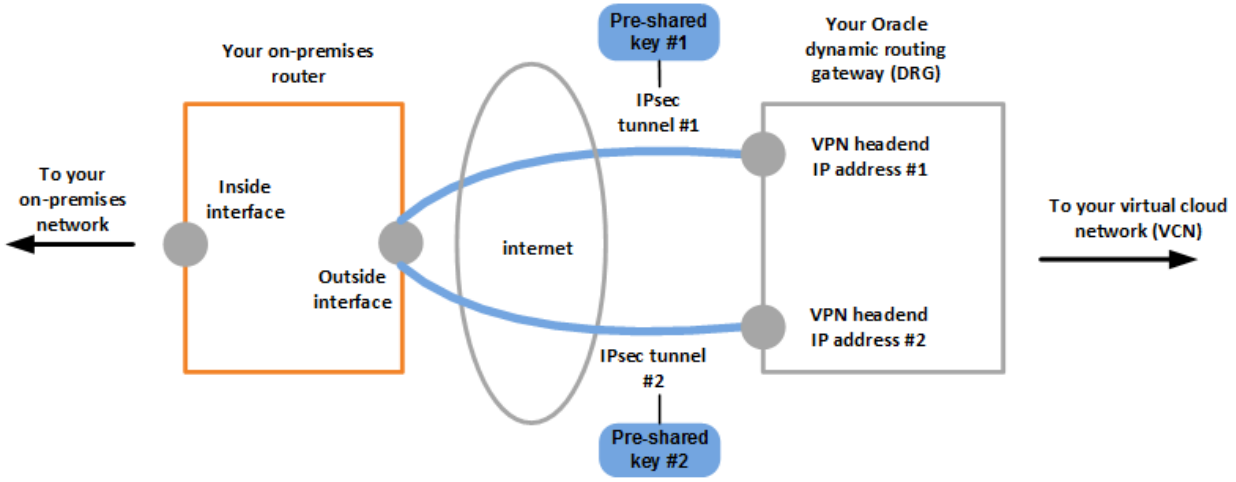
CPE Configuration

This topic is for network engineers. It explains how to configure the on-premises device (the customer-premises equipment, or CPE) at your end of the IPSec VPN so traffic can flow between your on-premises network and virtual cloud network (VCN). See these related topics:

- Overview of Networking: For general information about the parts of a VCN
- VPN Connect: For various topics about IPSec VPNs
- Verified CPE Devices: For a list of CPE devices Oracle has verified

The following figure shows the basic layout of the IPSec VPN connection.



Requirements and Prerequisites

There are several requirements and prerequisites to be aware of before moving forward.

Routing Considerations

For important details about routing for your IPSec VPN see Routing for the Oracle IPSec VPN.

Oracle uses asymmetric routing across the multiple tunnels that make up the IPSec VPN connection. Even if you configure one tunnel as primary and another as backup, traffic from your VCN to your on-premises network can use any tunnel that is "up" on your device. Configure your firewalls accordingly. Otherwise, ping tests or application traffic across the connection will not reliably work.

If you use BGP dynamic routing with your IPSec VPN, you can configure routing so that Oracle prefers one tunnel over the other.

Note that the Cisco ASA policy-based configuration uses a single tunnel.

Creation of Cloud Network Components

You or someone in your organization must have already used the Oracle Console to create a VCN and an IPSec connection, which consists of multiple IPSec tunnels for redundancy. You must gather the following information about those components:

- VCN OCID: The VCN OCID is a unique Oracle Cloud Infrastructure identifier that has a UUID at the end. You can use this UUID or any other string that helps you identify this VCN in the device configuration and doesn't conflict with other object-group or access-list names.
- VCN CIDR
- VCN CIDR subnet mask
- For each IPSec tunnel:
    - The IP address of the Oracle IPSec tunnel endpoint (the VPN headend)
    - The shared secret

Information About Your CPE Device

You also need some basic information about the inside and outside interfaces of your on-premises device (your CPE). For a list of the required information for your particular CPE, see the links in this list: Verified CPE Devices.

Oracle recommends that you disable NAT-T at your CPE when establishing IPSec tunnels with Oracle Cloud Infrastructure. Unless you have multiple CPEs sharing the same NAT IP, NAT-T is not required.

If your CPE is behind a NAT device, you can provide Oracle with your CPE's IKE identifier. For more information, see If Your CPE Is Behind a NAT Device.

Route-Based Versus Policy-Based IPSec

The Oracle VPN headends use route-based tunnels, but can work with policy-based tunnels with some caveats listed in the following section.

Oracle supports only a single encryption domain (also known as a proxy ID, security parameter index (SPI), or traffic selector).

For more information, see Supported Encryption Domain or Proxy ID.

IPSec VPN Best Practices

- **Configure all tunnels for every IPSec connection:** Oracle deploys multiple IPSec headends for all your connections to provide high availability for your mission-critical workloads. Configuring all the available tunnels is a key part of the "Design for Failure" philosophy. (Exception: Cisco ASA policy-based configuration, which uses a single tunnel.)
- **Have redundant CPEs in your on-premises locations:** Each of your sites that connects with IPSec to Oracle Cloud Infrastructure should have redundant CPE devices. You add each CPE to the Oracle Cloud Infrastructure Console and create a separate IPSec connection between your dynamic routing gateway (DRG) and each CPE. For each IPSec connection, Oracle provisions two tunnels on geographically redundant IPSec headends. Oracle may use any tunnel that is "up" to send traffic back to your on-premises network. For more information, see Routing for the Oracle IPSec VPN.
- **Consider backup aggregate routes:** If you have multiple sites connected via IPSec VPNs to Oracle Cloud Infrastructure, and those sites are connected to your on-premises backbone routers, consider configuring your IPSec connection routes with both the local site aggregate route as well as a default route.

  Note that the DRG routes learned from the IPSec connections are only used by traffic you route from your VCN to your DRG. The default route will only be used by traffic sent to your DRG whose destination IP address does not match the more specific routes of any of your tunnels.

Confirming the Status of the Connection

After you configure the IPSec connection, you can test the connection by launching an instance into the VCN and then pinging it from your on-premises network. For information about launching an instance, see Launching an Instance. To ping the instance, the VCN's security rules must allow ping traffic.

You can get the status of the IPSec tunnels in the API or Console. For instructions, see To view the status and configuration information for the IPSec tunnels.

Device Configurations

For links to the specific configuration information for each verified CPE device, see Verified CPE Devices.

Verified CPE Devices

The following devices or software have been verified for use with VPN Connect.

Note

Oracle provides configuration instructions for the vendors and devices in the following table. Make sure to use the configuration instructions for the correct vendor.

If the device or software version that Oracle used to verify the configuration does not exactly match your device or software, the configuration might still work for you. Consult your vendor's documentation and make any necessary adjustments.

If your device is for a vendor not in the following table, or if you're already familiar with configuring your device for IPSec, see the list of supported IPSec parameters and consult your vendor's documentation for assistance.

Vendor	Device	Minimum Software Version	Configuration
Check Point	2200 or Open Server	R80.20	Check Point Configuration Options
Cisco	ASA	9.7.1 (recommended)	Cisco ASA Configuration Options
Cisco	2921	IOS version 15.4(3)M3	Cisco IOS
FortiGate	FortiGate-VM	6.0.4	FortiGate
Juniper	MX 240	JunOS 15.1	Juniper MX
Juniper	SRX 240	JunOS 11.0	Juniper SRX
Libreswan (or Openswan)		3.18	Libreswan
NEC	IX3315	10.1.16	NEC IX Series
NEC	IX2106	10.1.16	NEC IX Series
Palo Alto	PA-500	PanOS version 8.0.0	Palo Alto
WatchGuard	Firebox	Fireware v12	WatchGuard
Yamaha	RTX1210	Firmware Rev.14.01.28	Yamaha RTX Series
Yamaha	RTX830	Firmware Rev.15.02.03	Yamaha RTX Series

Check Point Configuration Options

Choose the configuration that suits your situation:

- Check Point: Route-Based
- Check Point: Policy-Based

Check Point: Route-Based

This topic provides a route-based configuration for Check Point CloudGuard. The instructions were validated with Check Point CloudGuard version R80.20.

This topic is for route-based (VTI-based) configuration. If you instead want policy-based configuration, see Check Point: Policy-Based.

Check Point experience is required. This topic does not include how to add Check Point CloudGuard Security Gateway to Check Point CloudGuard Security Manager. For more information about using Check Point products, see the Check Point documentation.

Important

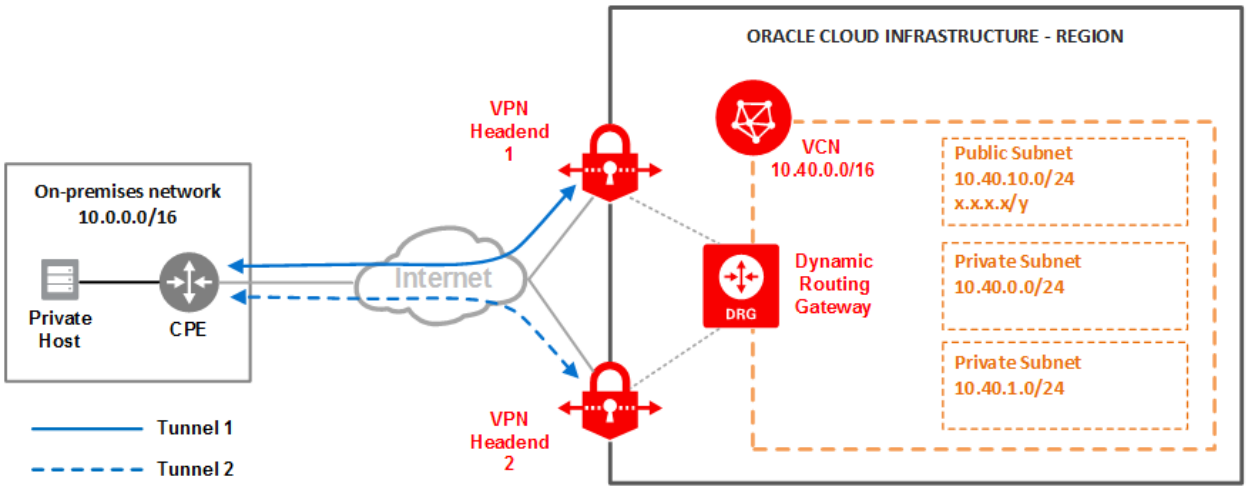
Oracle provides configuration instructions for a set of vendors and devices. Make sure to use the configuration for the correct vendor.

If the device or software version that Oracle used to verify the configuration does not exactly match your device or software, the configuration might still work for you. Consult your vendor's documentation and make any necessary adjustments.

If your device is for a vendor not in the list of verified vendors and devices, or if you're already familiar with configuring your device for IPSec, see the list of supported IPSec parameters and consult your vendor's documentation for assistance.

VPN Connect is the IPSec VPN that Oracle Cloud Infrastructure offers for connecting your on-premises network to a virtual cloud network (VCN).

The following diagram shows a basic IPSec connection to Oracle Cloud Infrastructure with redundant tunnels. IP addresses used in this diagram are for example purposes only.



Best Practices

This section covers general best practices and considerations for using VPN Connect.

Configure All Tunnels for Every IPSec Connection

Oracle deploys two IPSec headends for each of your connections to provide high availability for your mission-critical workloads. On the Oracle side, these two headends are on different routers for redundancy purposes. Oracle recommends configuring all available tunnels for maximum redundancy. This is a key part of the "Design for Failure" philosophy.

Have Redundant CPEs in Your On-Premises Network Locations

Each of your sites that connects with IPSec to Oracle Cloud Infrastructure should have redundant edge devices (also known as customer-premises equipment (CPE)). You add each CPE to the Oracle Console and create a separate IPSec connection between your dynamic routing gateway (DRG) and each CPE. For each IPSec connection, Oracle provisions two

tunnels on geographically redundant IPSec headends. For more information, see the Connectivity Redundancy Guide (PDF).

Routing Protocol Considerations

When you create an IPSec VPN, it has two redundant IPSec tunnels. Oracle encourages you to configure your CPE to use both tunnels (if your CPE supports it). Note that in the past, Oracle created IPSec VPNs that had up to four IPSec tunnels.

The following two routing types are available, and you choose the routing type separately for each tunnel in the IPSec VPN:

- **BGP dynamic routing:** The available routes are learned dynamically through BGP. The DRG dynamically learns the routes from your on-premises network. On the Oracle side, the DRG advertises the VCN's subnets.
- **Static routing:** When you set up the IPSec connection to the DRG, you specify the particular routes to your on-premises network that you want the VCN to know about. You also must configure your CPE device with static routes to the VCN's subnets. These routes are not learned dynamically.

For more information about routing with VPN Connect, including Oracle recommendations on how to manipulate the BGP best path selection algorithm, see Routing for the Oracle IPSec VPN.

Other Important CPE Configurations

Ensure access lists on your CPE are configured correctly to not block necessary traffic from or to Oracle Cloud Infrastructure.

If you have multiple tunnels up simultaneously, ensure that your CPE is configured to handle traffic coming from your VCN on any of the tunnels. For example, you need to disable ICMP inspection, configure TCP state bypass, and so on. For more details about the appropriate configuration, contact your CPE vendor's support.

Caveats and Limitations

This section covers general important characteristics and limitations of VPN Connect to be aware of.

Asymmetric Routing

Oracle uses asymmetric routing across the multiple tunnels that make up the IPSec connection. Configure your firewalls accordingly. Otherwise, ping tests or application traffic across the connection will not reliably work.

When you use multiple tunnels to Oracle Cloud Infrastructure, Oracle recommends that you configure your routing to deterministically route traffic through the preferred tunnel. If you want to use one IPSec tunnel as primary and another as backup, configure more-specific routes for the primary tunnel (BGP) and less-specific routes (summary or default route) for the backup tunnel (BGP/static). Otherwise, if you advertise the same route (for example, a default route) through all tunnels, return traffic from your VCN to your on-premises network will route to any of the available tunnels (because Oracle uses asymmetric routing).

For specific Oracle routing recommendations about how to force symmetric routing, see Preferring a Specific Tunnel in the IPSec VPN.

Route-Based or Policy-Based IPSec VPN

The IPSec protocol uses Security Associations (SAs) to determine how to encrypt packets. Within each SA, you define encryption domains to map a packet's source and destination IP address and protocol type to an entry in the SA database to define how to encrypt or decrypt a packet.

Note

Other vendors or industry documentation might use the term *proxy ID, security parameter index (SPI)*, or *traffic selector* when referring to SAs or encryption domains.

There are two general methods for implementing IPSec tunnels:

- **Route-based tunnels:** Also called *next-hop-based tunnels*. A route table lookup is performed on a packet's destination IP address. If that route's egress interface is an

IPSec tunnel, the packet is encrypted and sent to the other end of the tunnel.

- **Policy-based tunnels:** The packet's source and destination IP address and protocol are matched against a list of policy statements. If a match is found, the packet is encrypted based on the rules in that policy statement.

The Oracle VPN headends use route-based tunnels but can work with policy-based tunnels with some caveats listed in the following sections.

Important

The Oracle VPN headend supports only a single encryption domain. If your policy includes multiple entries, the tunnel will flap or there will be connectivity problems in which only a single policy works at any one time.

Encryption domain for route-based tunnels

If your CPE supports route-based tunnels, use that method to configure the tunnel. It's the simplest configuration with the most interoperability with the Oracle VPN headend.

Route-based IPSec uses an encryption domain with the following values:

- **Source IP address:** Any (0.0.0.0/0)
- **Destination IP address:** Any (0.0.0.0/0)
- **Protocol:** IPv4

If you need to be more specific, you can use a single summary route for your encryption domain values instead of a default route.

Encryption domain for policy-based tunnels

If your CPE supports only policy-based tunnels, there are restrictions on the policy that you

can use on the CPE.

When you use policy-based tunnels, every policy entry that you define generates a pair of IPSec SAs. This pair is referred to as an *encryption domain*.

Important

The Oracle VPN headend supports only a single encryption domain. If your policy includes multiple entries, the tunnel will flap or there will be connectivity problems in which only a single policy works at any one time.

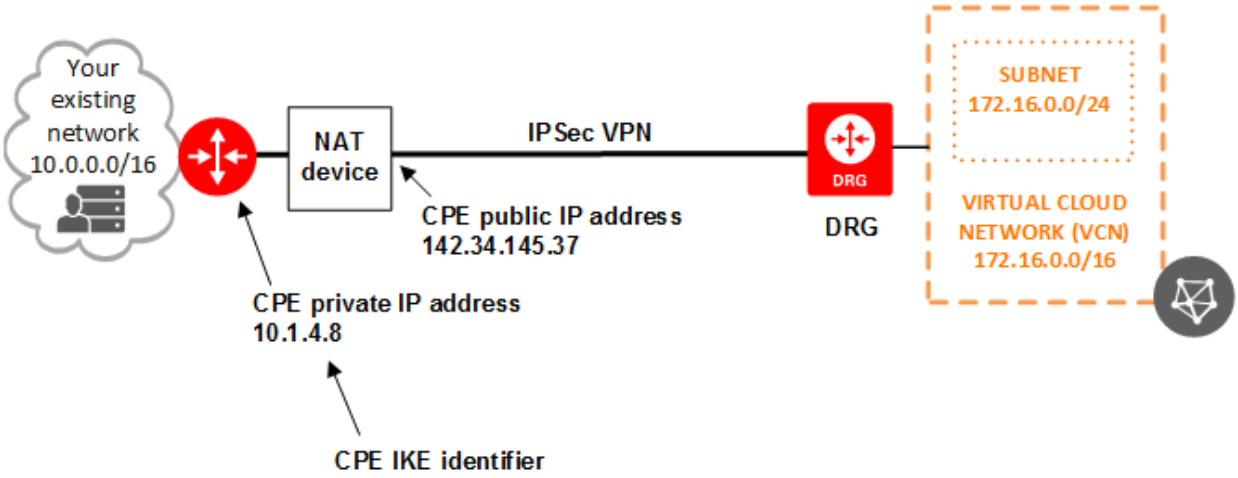
If you use policy-based IPSec, Oracle recommends using a *single encryption domain* with the following values:

- **Source IP address:** Any (0.0.0.0/0)
- **Destination IP address:** VCN CIDR (example: 10.120.0.0/20)
- **Protocol:** IPv4

Make sure the single encryption domain matches any traffic that needs to go from your on-premises network across the IPSec tunnel to the VCN. The VCN CIDR must not overlap with your on-premises network.

If Your CPE Is Behind a NAT Device

In general, the CPE IKE identifier configured on your end of the connection must match the CPE IKE identifier that Oracle is using. By default, Oracle uses the CPE's *public* IP address, which you provide when you create the CPE object in the Oracle Console. However, if your CPE is behind a NAT device, the CPE IKE identifier configured on your end might be the CPE's *private* IP address, as show in the following diagram.



Note

Some CPE platforms do not allow you to change the local IKE identifier. If you cannot, you must change the remote IKE ID in the Oracle Console to match your CPE's local IKE ID. You can provide the value either when you set up the IPSec connection, or later, by editing the IPSec connection. Oracle expects the value to be either an IP address or a fully qualified domain name (FQDN) such as *cpe.example.com*. For instructions, see Changing the CPE IKE Identifier That Oracle Uses.

Supported IPSec Parameters

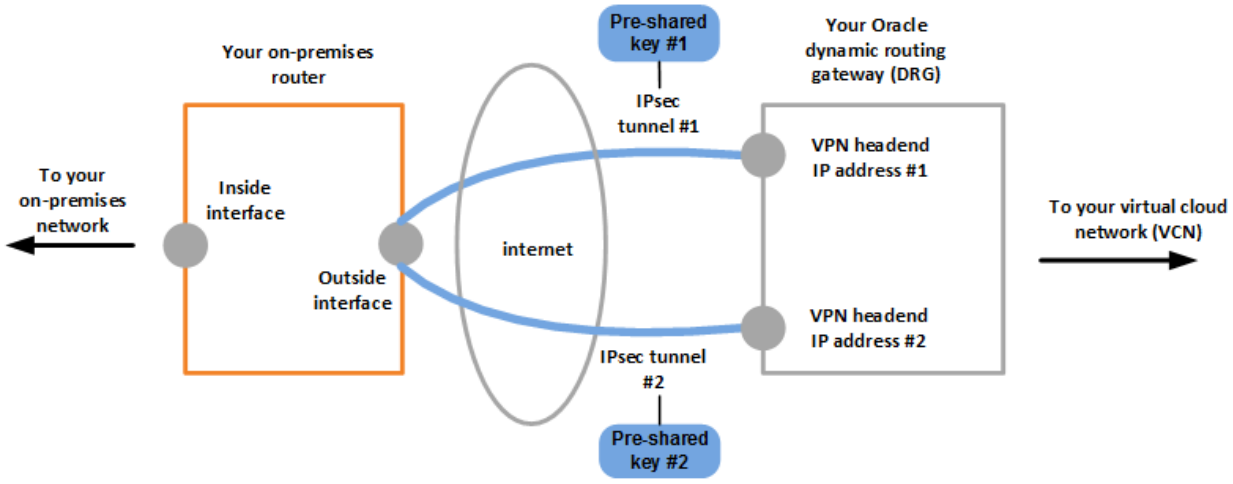
For a vendor-neutral list of supported IPSec parameters for all regions, see Supported IPSec Parameters.

The Oracle BGP ASN for the commercial cloud is 31898. If you're configuring VPN Connect for the Government Cloud, see Required VPN Connect Parameters for Government Cloud and also Oracle's BGP ASN.

CPE Configuration (Route-Based)

> **Important**
>
> The configuration instructions in this section are provided by Oracle Cloud Infrastructure for your CPE. If you need support or further assistance, contact your CPE vendor's support directly.

The following figure shows the basic layout of the IPSec connection.



About Using IKEv2

Oracle supports Internet Key Exchange version 1 (IKEv1) and version 2 (IKEv2). If you configure the IPSec connection in the Console to use IKEv2, you must configure your CPE to

use only IKEv2 and related IKEv2 encryption parameters that your CPE supports. For a list of parameters that Oracle supports for IKEv1 or IKEv2, see Supported IPSec Parameters.

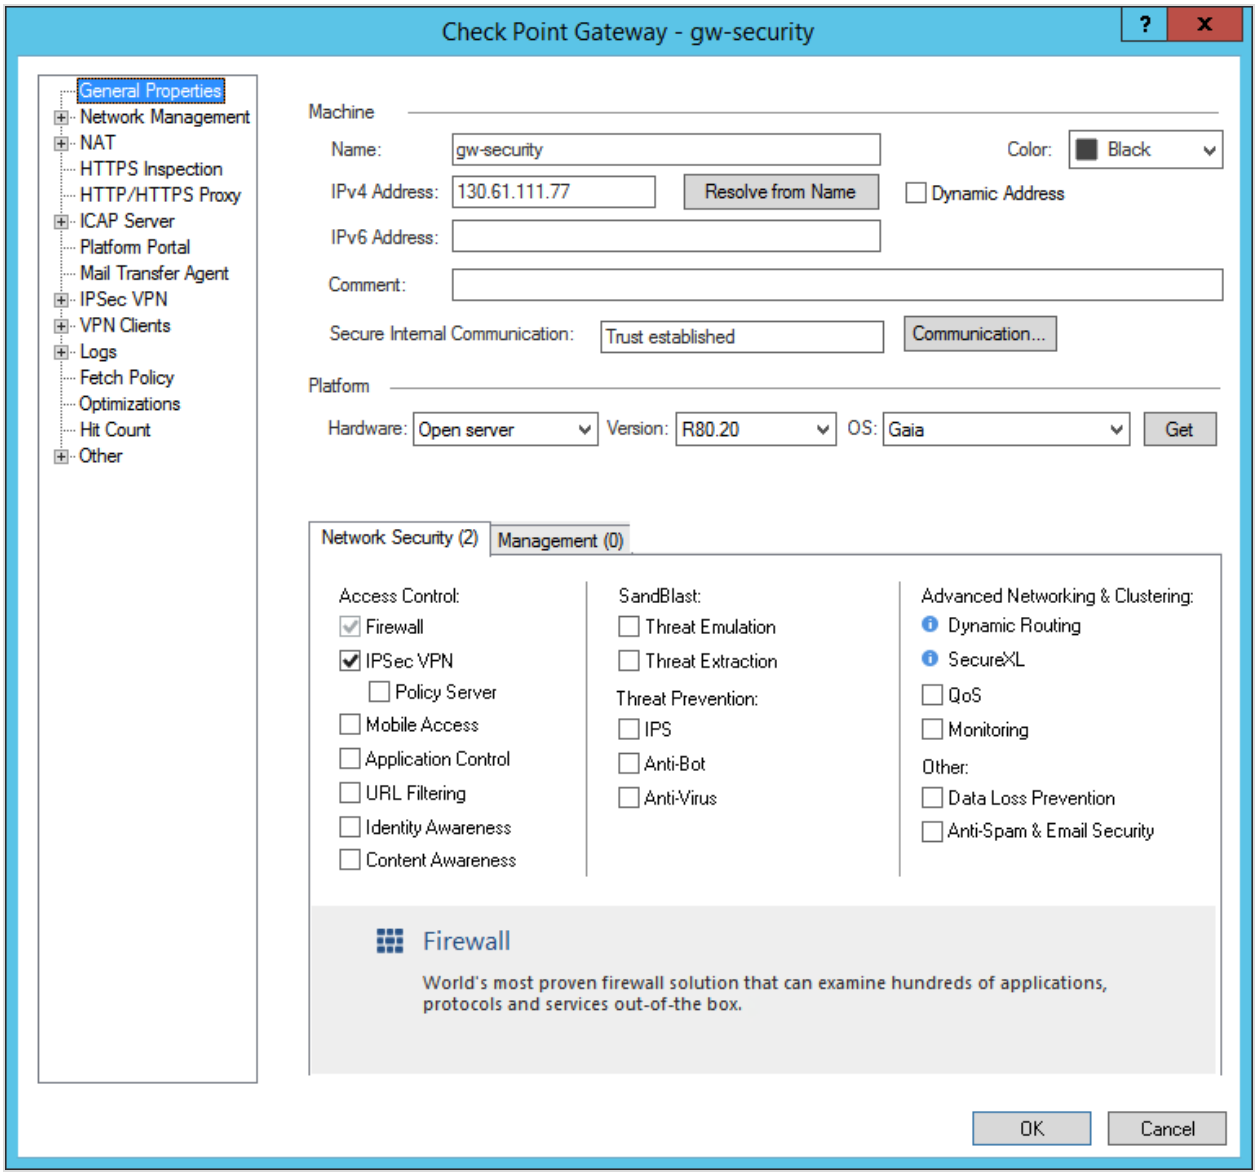
If you want to use IKEv2, there's a variation on one of the tasks presented in the next section. Specifically, in task 4, when configuring encryption, select **IKEv2 only** for the encryption method.

CONFIGURATION PROCESS

Task 1: Install IPSec VPN on Check Point CloudGuard Security Gateway

Prerequisite: Before starting, add Check Point CloudGuard Security Gateway to Check Point CloudGuard Security Manager. Also establish the Secure Internal Communication (SIC) so you can configure the IPSec tunnel by using the Check Point Smart Console. For instructions to add the Security Gateway to CloudGuard or to establish the SIC, see the Check Point documentation.

1. Install the IPSec VPN module. Oracle recommends that you also install the Monitoring module for traffic analysis.

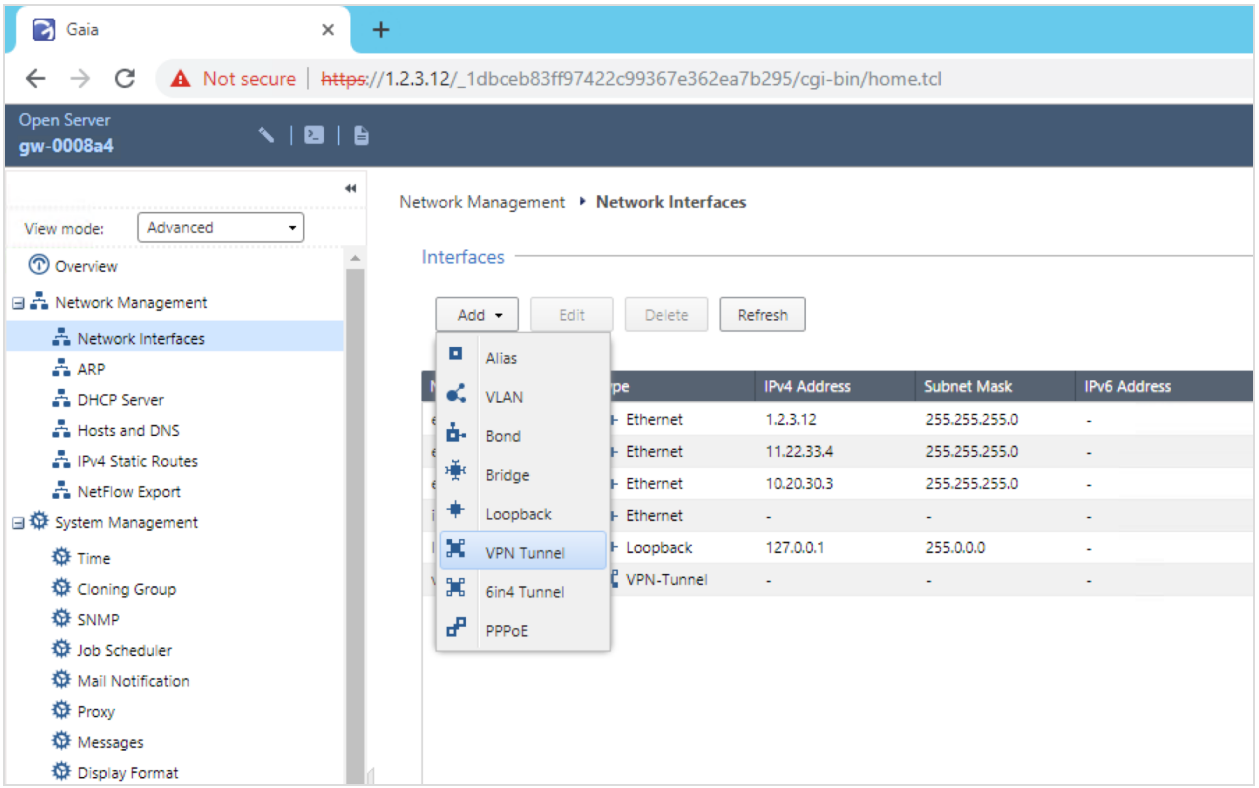


2. Click **OK** to save your changes.

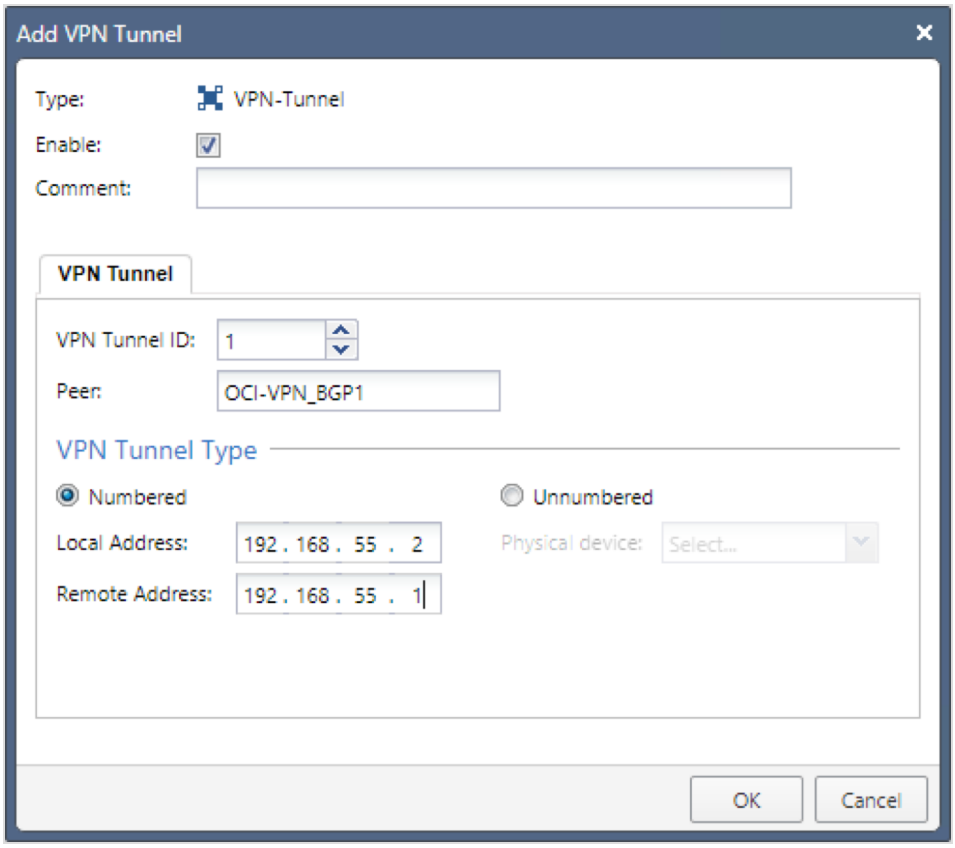
Task 2: Create the VTI interface from GAIA

In this task, you configure a VTI interface that passes traffic by using routing rules from the VTI interface to the newly created IPSec tunnel.

1. Log in to the GAIA portal using the Check Point CloudGuard Security Gateway public or private IP address.
2. On the GAIA portal, select the **Advanced** view.
3. Under **Network Management**, go to **Network Interfaces**.
4. Click **Add**, and then click **VPN Tunnel**.

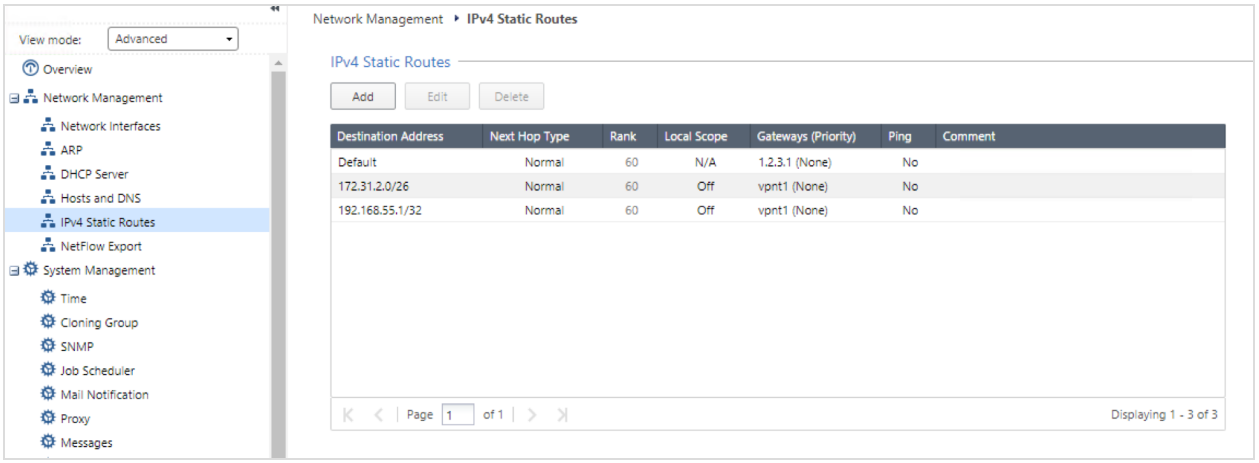


5. Specify the following items:
    - **VPN Tunnel ID:** A number that will be added to the VTI interface called vpnt*, where the asterisk is the VPN tunnel ID number specified . For VPN tunnel ID = 1, the interface is labeled vpnt1.
    - **Peer:** The name of the interoperable device that you created earlier for the IPSec tunnel. In this case, the name is OCI-VPN_BGP1. **Important:** If the name you specify here does not match the name of the interoperable device, traffic does not flow through the IPSec tunnel.
    - **Numbered:** Select **Numbered** to create a numbered interface.
    - **Local Address:** The local IP address that was specified in the Oracle Console as the **Inside Tunnel Interface - CPE**.
    - **Remote Address:** The remote IP address that was specified in the Oracle Console as the **Inside Tunnel Interface - Oracle**.



6. Click **OK**.
7. Under **Network Management**, go to **IPv4 Static Routes**.
8. Specify the following items:
    - **Static route for the Oracle IP address:** Add an IP address with /32 mask for the remote IP address that was specified in the Oracle Console as the **Inside Tunnel Interface - Oracle**.
    - **Static routes to the VCN subnets:** If you're using static routing for this IPSec connection to Oracle, add at least one subnet for the Oracle VCN to be reached

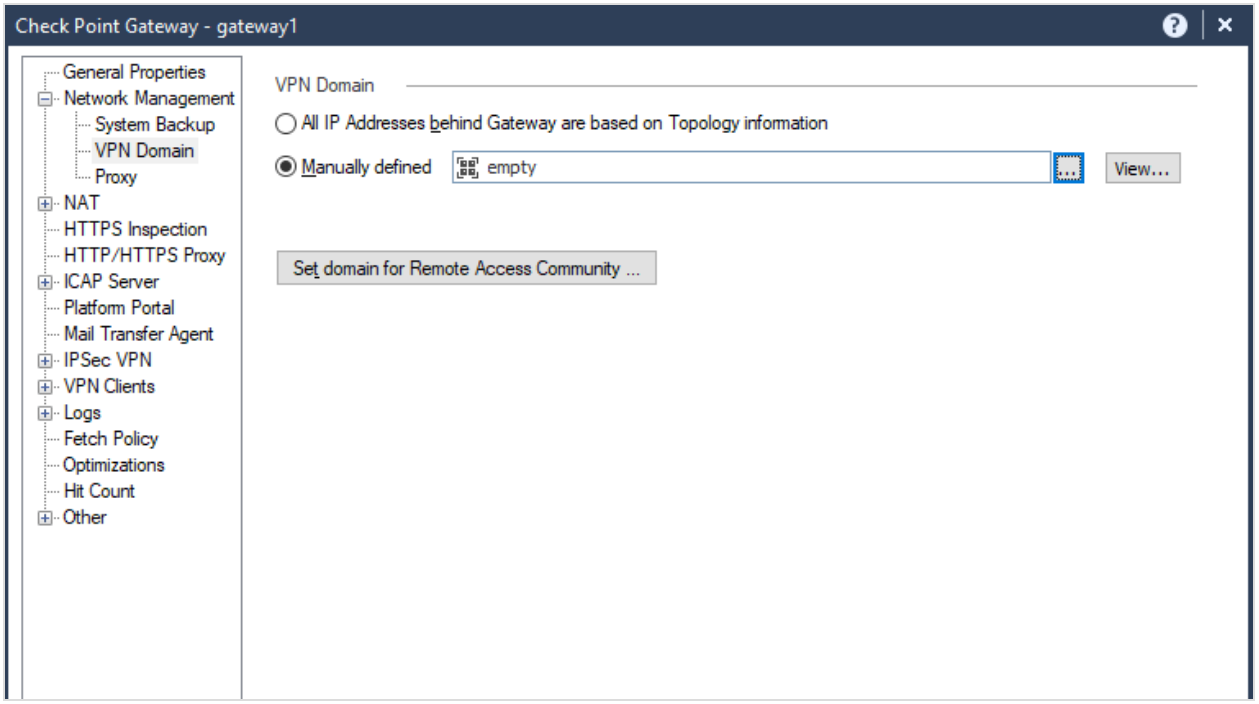
through the IPSec tunnel. The following screenshot shows a static route to 172.31.2.0/26. If you're using BGP for this IPSec connection to Oracle, skip this item because thoe routes are learned through BGP (see the next section).



Now all traffic with a specific destination learned from a static route will pass through the newly created IPSec tunnel.

9. Get the interfaces and verify that the VPN tunnel is in the list:
   a. In the Smart Console, go to **Gateways & Servers**.
   b. Select the **Check Point Security Gateways**, and double-click.
   c. Under **General Properties**, on the **Network Management** page, select **Get Interfaces**.
      The VPN tunnel interface should appear in the list.
10. To force a route-based VPN to take priority, create an empty group and assign it to the VPN domain:
    a. On the **VPN Domain** page, select **Manually defined**, and then select **Create empty group**.
    b. Click **New**, select **Group**, and then select **Simple Group**.

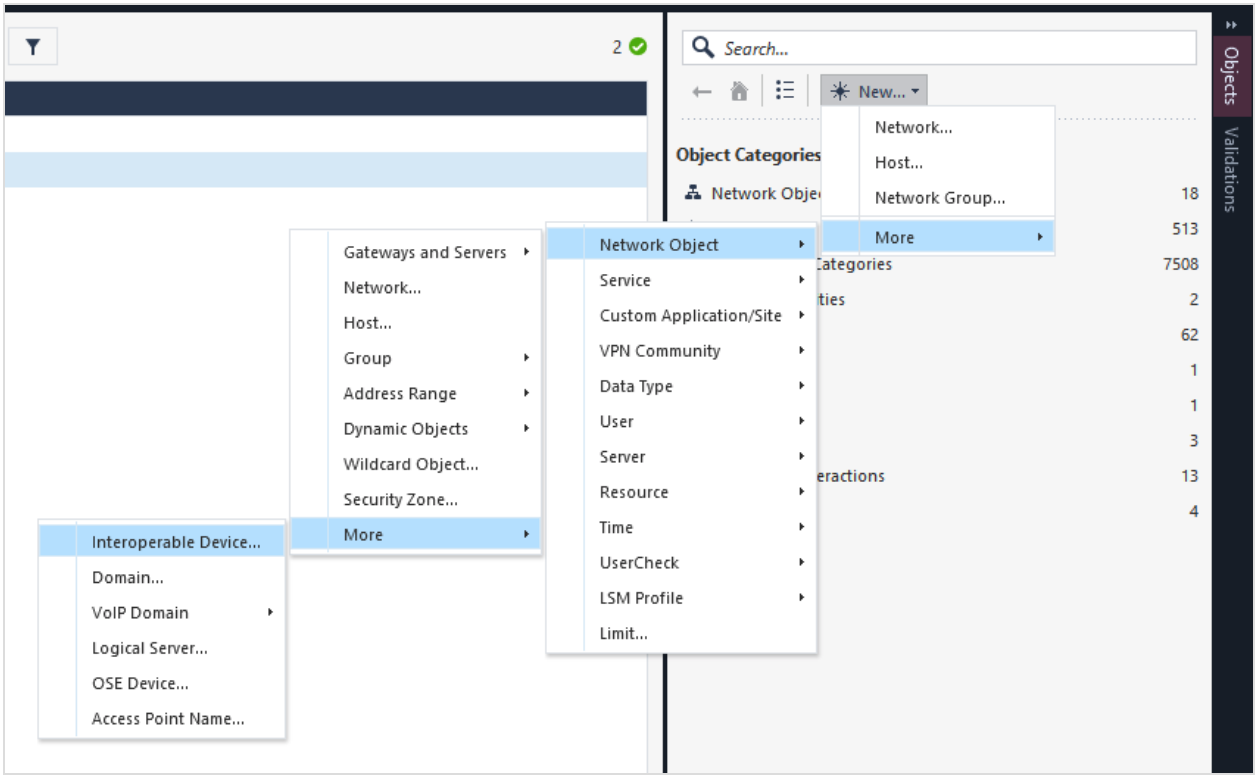
c. Enter an **Object Name**, and then click **OK**. Do not assign any objects to this empty group.



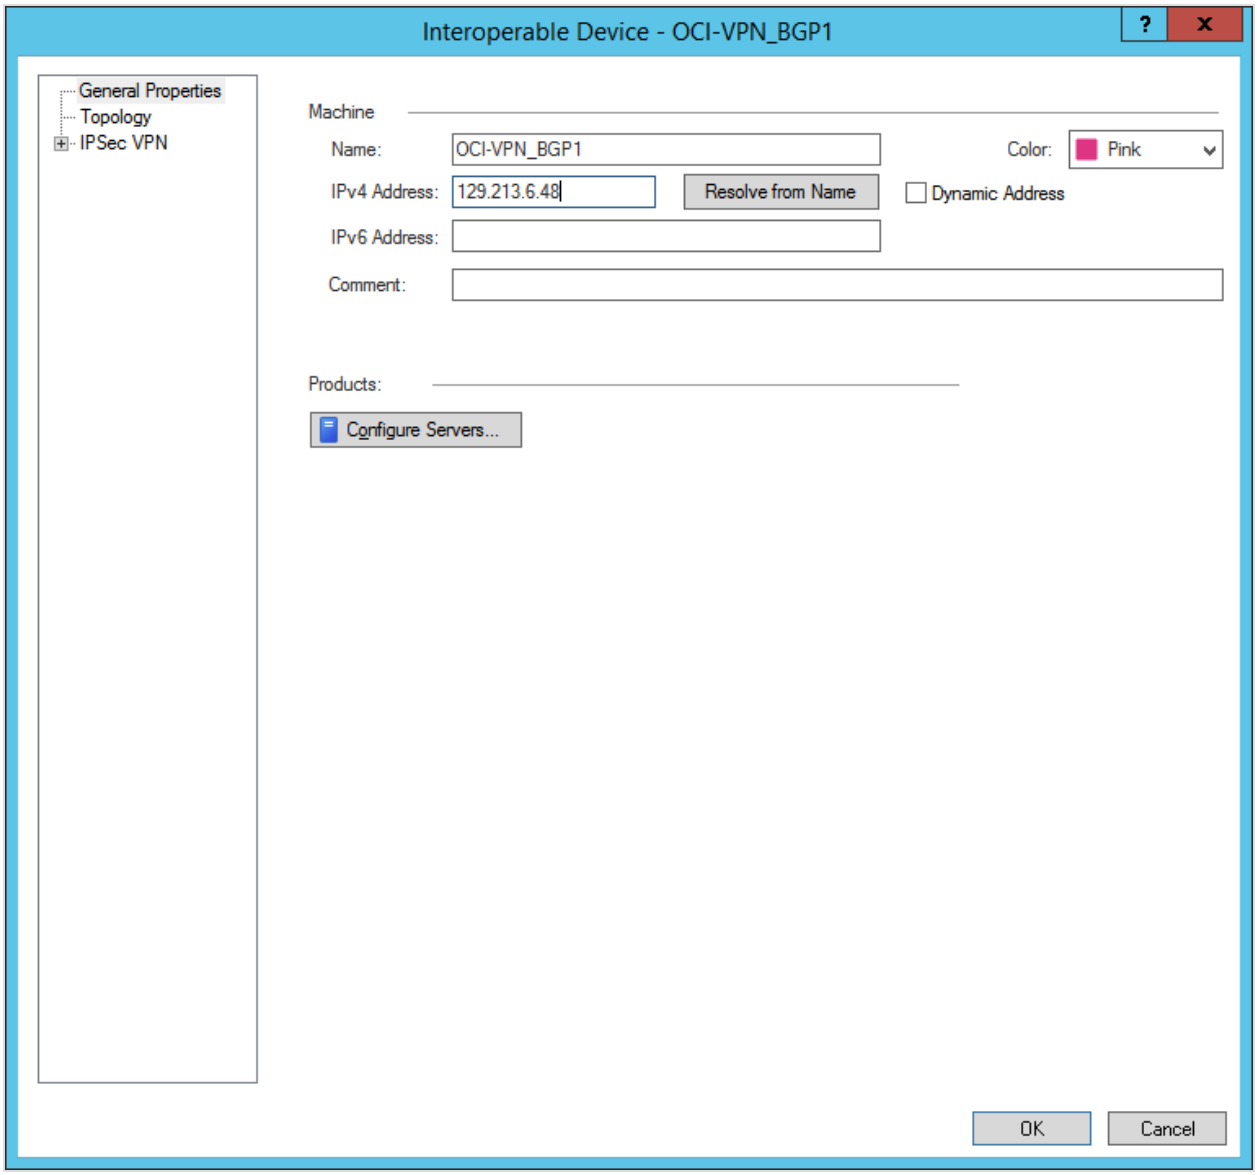
Task 3: Create an interoperable device

Later, you will create a VPN Community. Before you can, you must create an **Interoperable Device** that will be used in Check Point CloudGuard Security Gateway to define the Oracle DRG.

1. Create the new interoperable device.



2. On the **General Properties** page of the new interoperable device, add a name to identify the IPSec tunnel. Enter the IP address that Oracle assigned for the Oracle end of the tunnel when creating the IPSec connection.

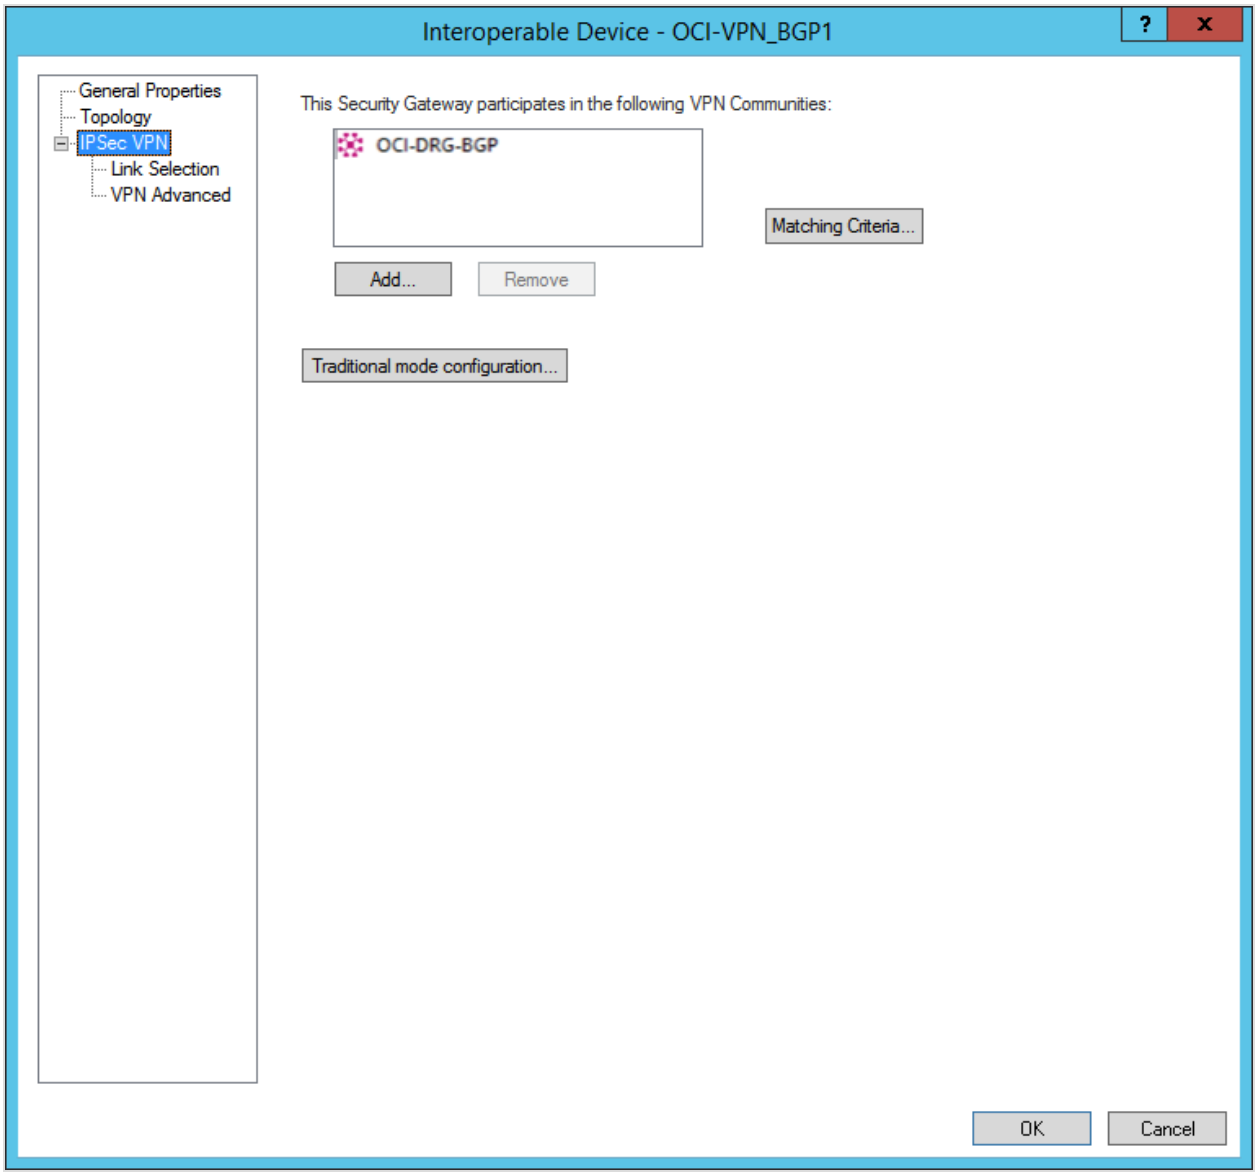


3. To force the route-based VPN to take priority, you must create an empty group and assign it to the VPN domain. To do that, on the **Topology** page, in the **VPN Domain**

section, select **Manually defined**, and select the empty group.

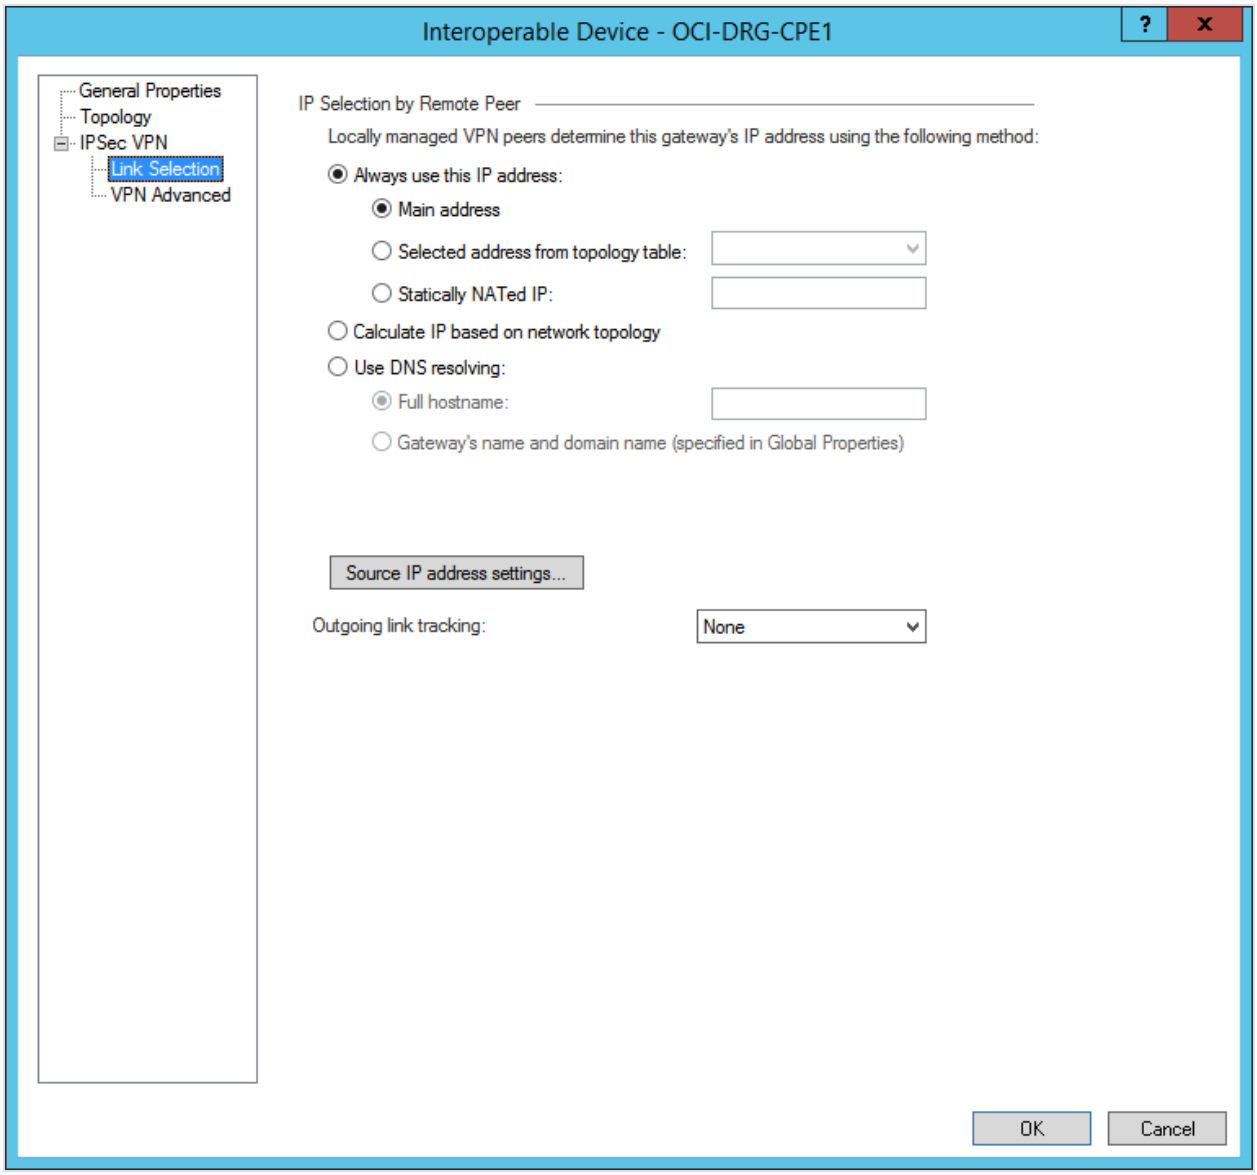
4. On the **IPSec VPN** page, you can optionally add the new interoperable device to an existing VPN Community. You can skip this step if you don't yet have any VPN Communities created.

   Notice that you skip the **Traditional mode configuration**, because you will define all the Phase 1 and Phase 2 parameters in the VPN Community in a later step. The VPN Community applies those parameters to all interoperable devices that belong to the VPN Community.



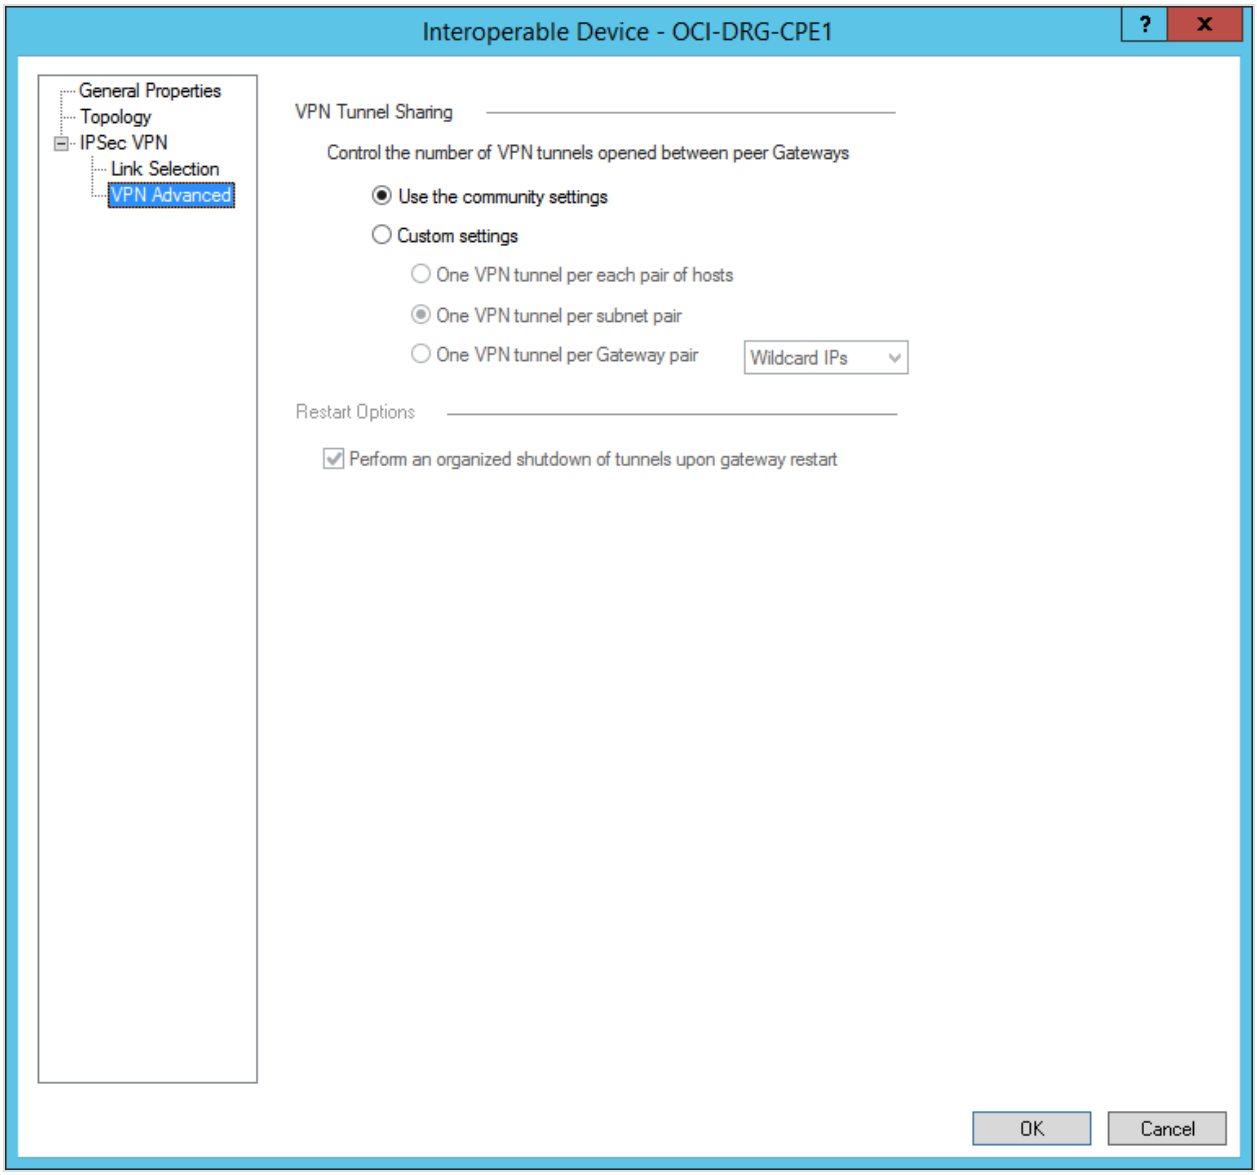
5. On the **Link Selection** page, under **Always use this IP address**, select **Main address**, which was the address you specified when creating the interoperable device.

If necessary, you can use a specific IP address that will be used as the IKE ID.



6. On the **VPN Advanced** page, select **Use the community settings**, which applies all the options and values in the VPN Community, including the Phase 1 and Phase 2

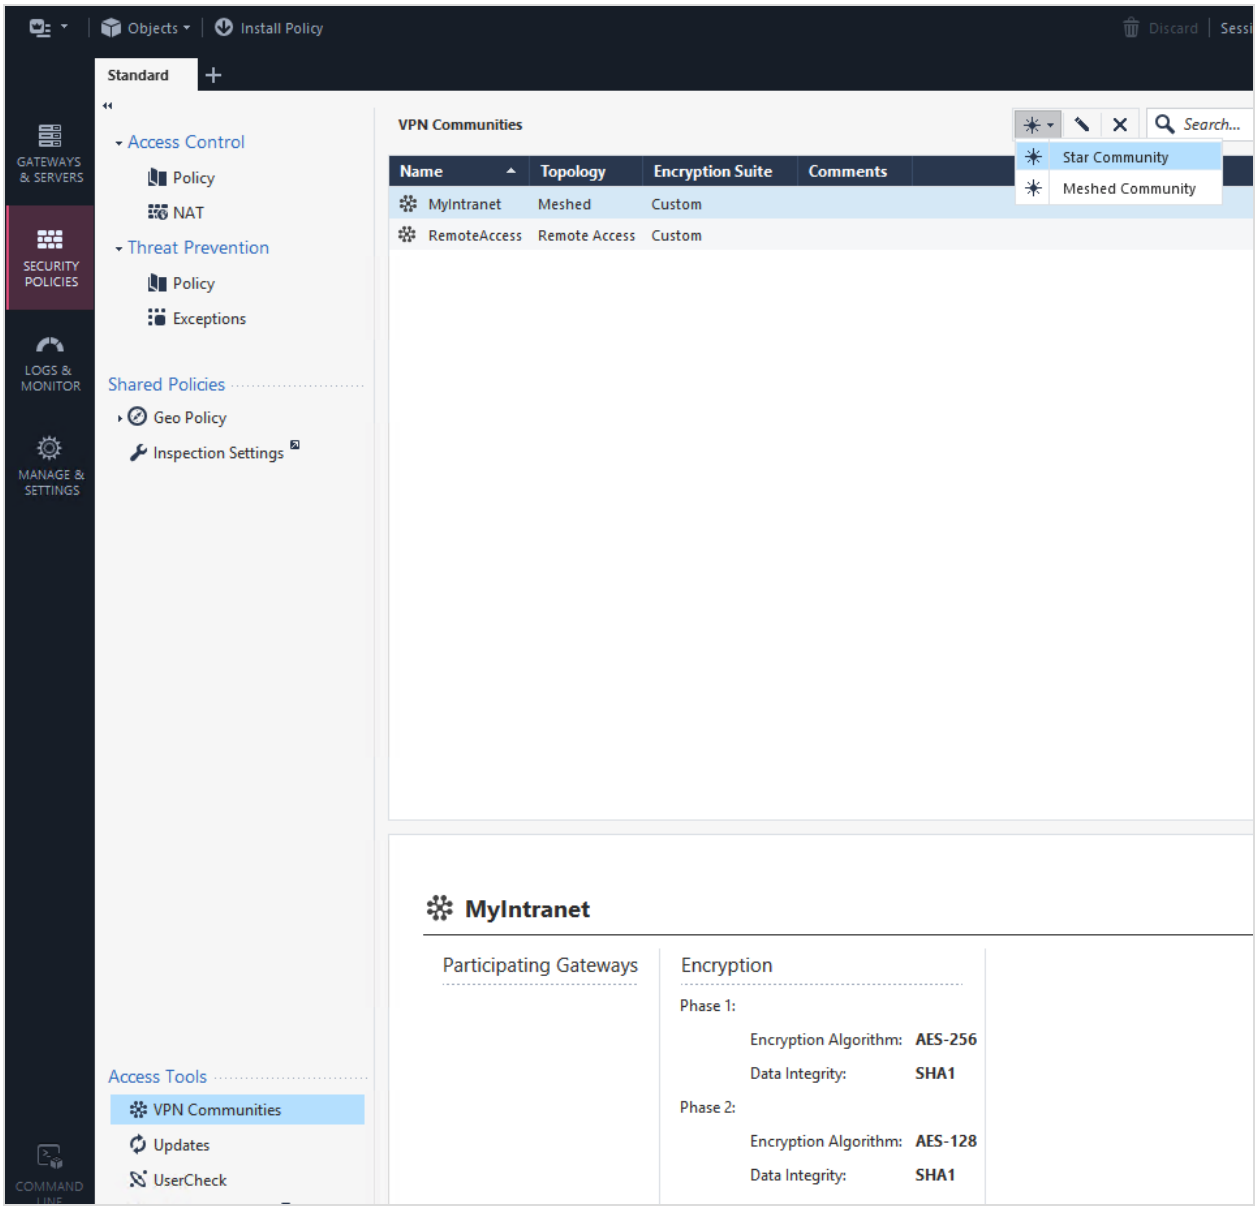
parameters.



7. Click **OK** to save your changes.

Task 4: Create a VPN community

1. Go to **Security Policies**, and then from **Access Tools**, select **VPN Communities**.
2. Create a **Star Community**.



3. For the star community, add a name.

4. On the **Gateways** page, select the values for **Center Gateways** and **Satellite Gateways**. This star community acts as a settings template for the interoperable devices you specify in **Center Gateways** and **Satellite Gateways**.
    - **Center Gateways**: For the Check Point CloudGuard Security Gateway.
    - **Satellite Gateways**: For the CPE that connects to the Oracle DRG for each IPSec tunnel.

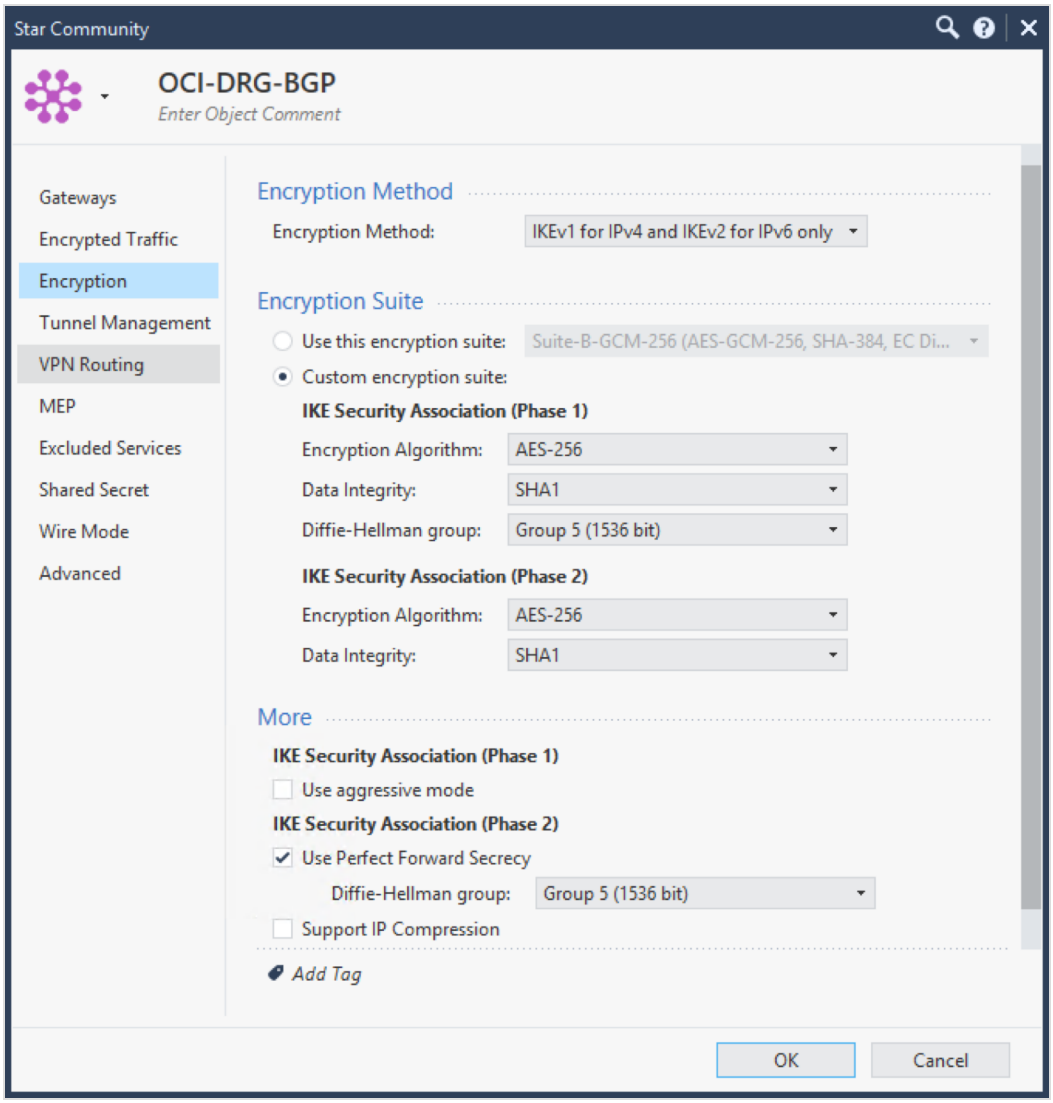
Note: VPN Directional Match is supported only on Gaia, SecurePlatform, Linux and IPSO.
OK
Cancel

6. Select the check box for **Enable VPN Directional Match in VPN Column**. Later you will create a security policy that uses a directional match condition to allow traffic to pass based on routing rules.
7. Click **OK**.
8. On the **Encryption** page, configure the Phase 1 and Phase 2 parameters that Oracle supports. For a list of those values, see Supported IPSec Parameters.
   If you're configuring VPN Connect for the Government Cloud, see Required VPN Connect Parameters for Government Cloud.
   Notice that if you want to use IKEv2, for the **Encryption Method**, instead select **IKEv2 only**.



9. On the **Tunnel Management** page, select **Set Permanent Tunnels**. Oracle recommends that you:

- Select **On all tunnels in the community** to keep all the Oracle IPSec tunnels up all the time.
- In the **VPN Tunnel Sharing** section, select **One VPN tunnel per Gateway pair**.

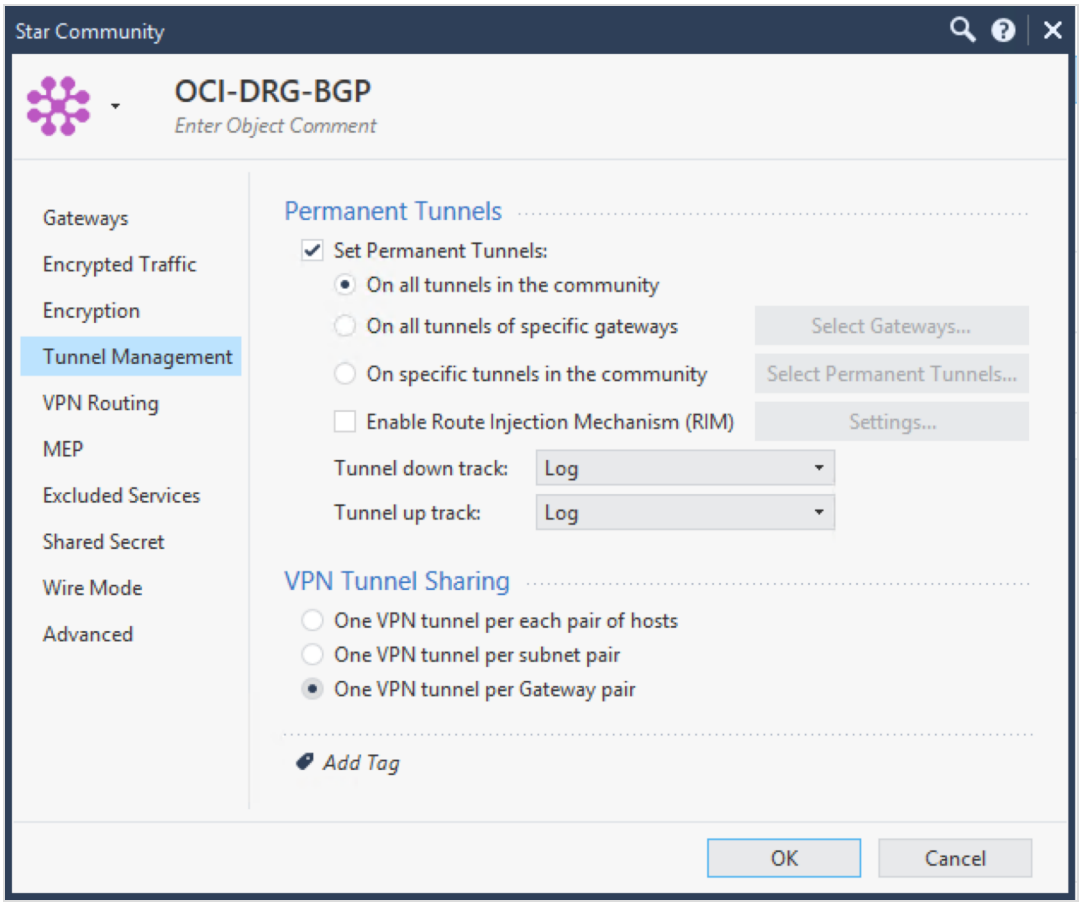
The latter option generates only one pair of IPSec security associations (SAs), and each SA with only one security parameter index (SPI) (unidirectional).

When you use policy-based tunnels, every policy entry generates a pair of IPSec SAs, (also referred to as an *encryption domain*).

Important

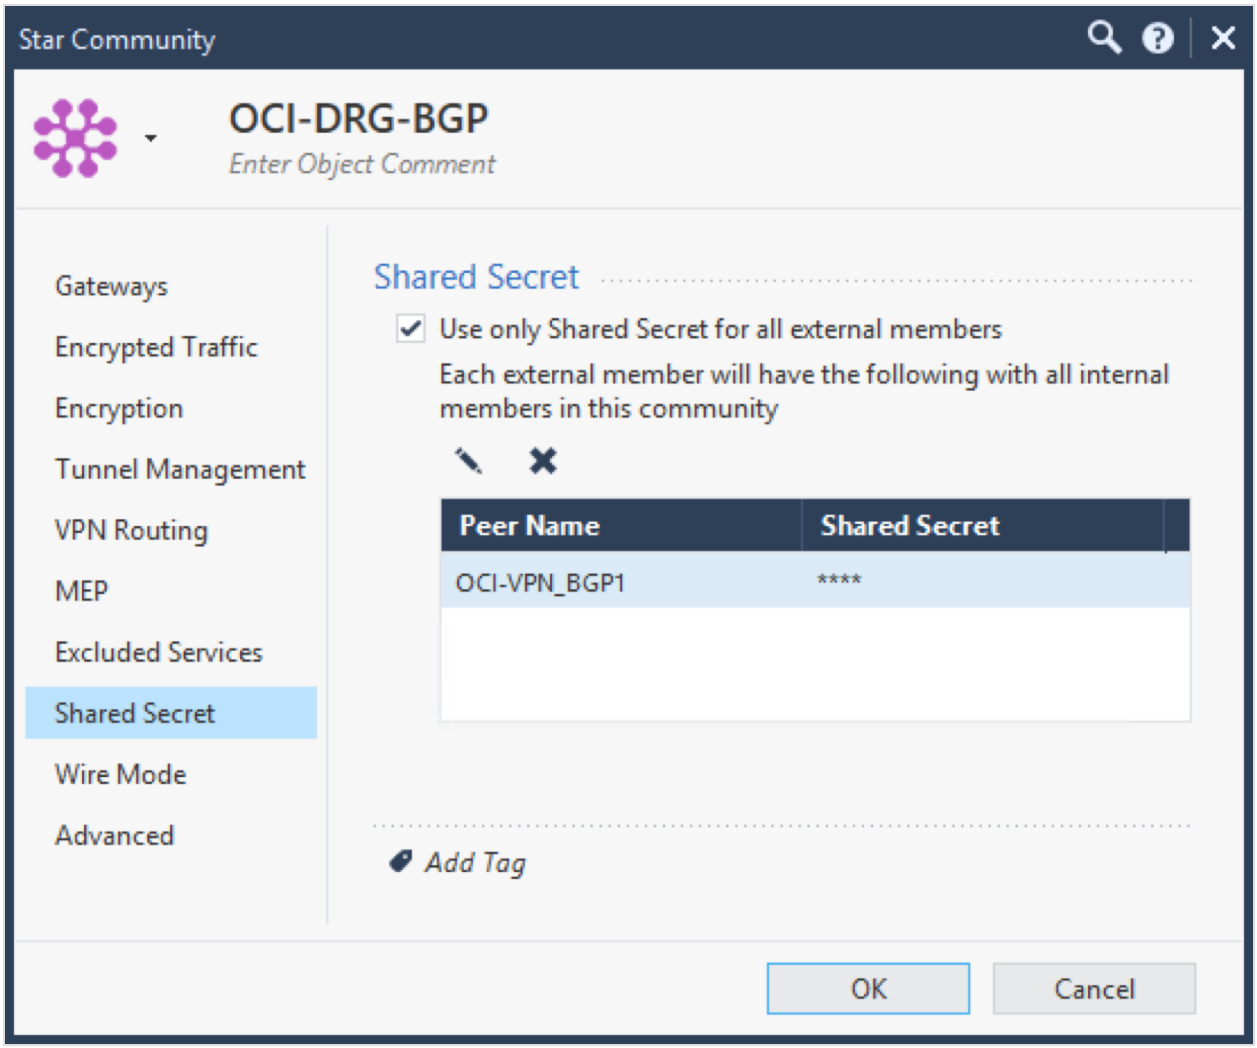
The Oracle VPN headend supports only a single encryption domain. If your policy includes multiple entries, the tunnel will flap or there will be connectivity problems in which only a single policy works at any one time.

Oracle creates a route-based IPSec connection, which means that everything is routed through an encryption domain that has 0.0.0.0/0 (any) for local traffic and 0.0.0.0/0 (any) for remote traffic. For more information, see Supported Encryption Domain or Proxy ID.



10. On the **Shared Secret** page, select **Use only Shared Secret for all external members**, and add the shared secret that Oracle generated for the tunnel when creating the IPSec connection.

    Currently Oracle supports only shared secret keys. Note that you can change the shared secret in the Oracle Console.

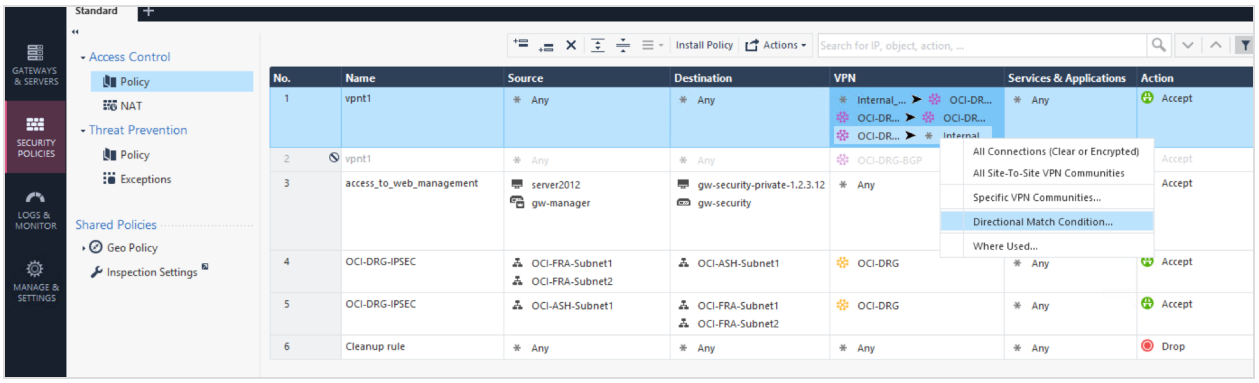


11. Click **OK** to save your changes.

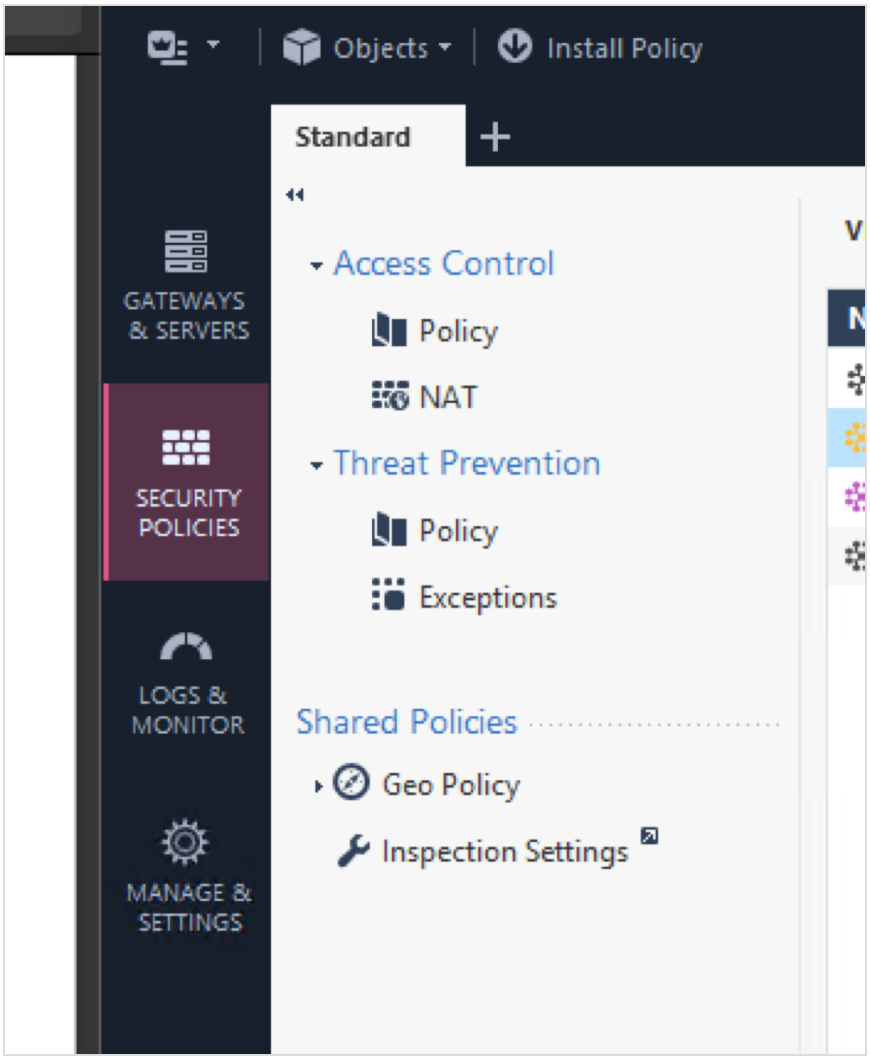
Task 5: Create a security policy

1. Go to **Access Control**, and then the **Policy** tab. Create specific security policies by using **Directional Match Condition**, which allows traffic to pass based on routing tables. Set up the condition with these settings:
   - **Internal_Clear** > *VPN Community* created
   - *VPN Community* created > *VPN Community* created
   - *VPN Community* created > **Internal_Clear**

   In this case, the *VPN Community* is **OCI-DRG-BGP** and the **Internal_Clear** is predefined by Check Point.



2. Click **OK** to save your changes.
3. Click **Install Policy** to apply the configuration.



Redundancy with BGP Over IPSec

For redundancy, Oracle recommends using BGP over IPSec. By default, if you have two connections of the same type (for example, two IPSec VPNs that both use BGP), and you advertise the same routes across both connections, Oracle prefers the oldest established route when responding to requests or initiating connections. If you want to force routing to be

symmetric, Oracle recommends using BGP and AS path prepending with your routes to influence which path Oracle uses when responding to and initiating connections. For more information, see Routing Details for Connections to Your On-Premises Network.

The Oracle DRG uses /30 or /31 as subnets for configuring IP addresses on the interface tunnels. Remember that the IP address must be part of the IPSec VPN's encryption domain and must be allowed in the firewall policy to reach the peer VPN through the interface tunnel. You might need to implement a static route through the tunnel interface for the peer IP address.

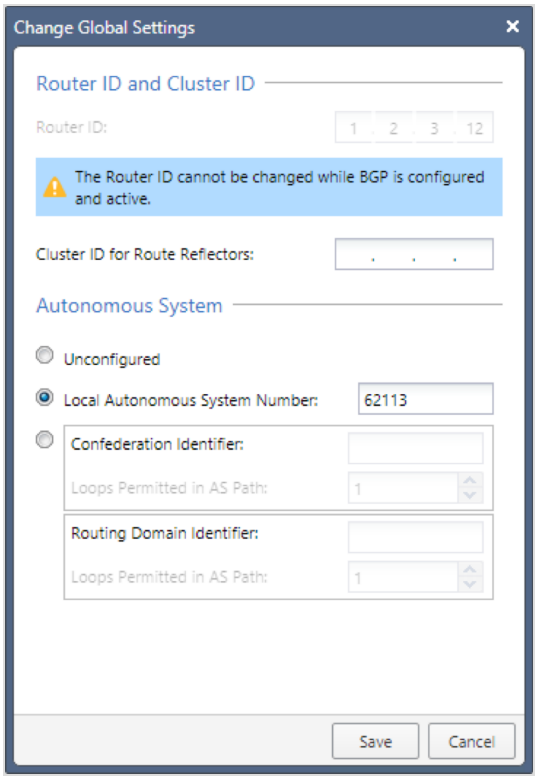
Oracle's BGP ASN in commercial regions is 31898. If you're configuring VPN Connect for the Government Cloud, see Required VPN Connect Parameters for Government Cloud and also Oracle's BGP ASN.

For your side, you can use a private ASN. Private ASNs are in the range 64512–65534.

Task 1: Enable BGP

Perform the following steps for each tunnel.

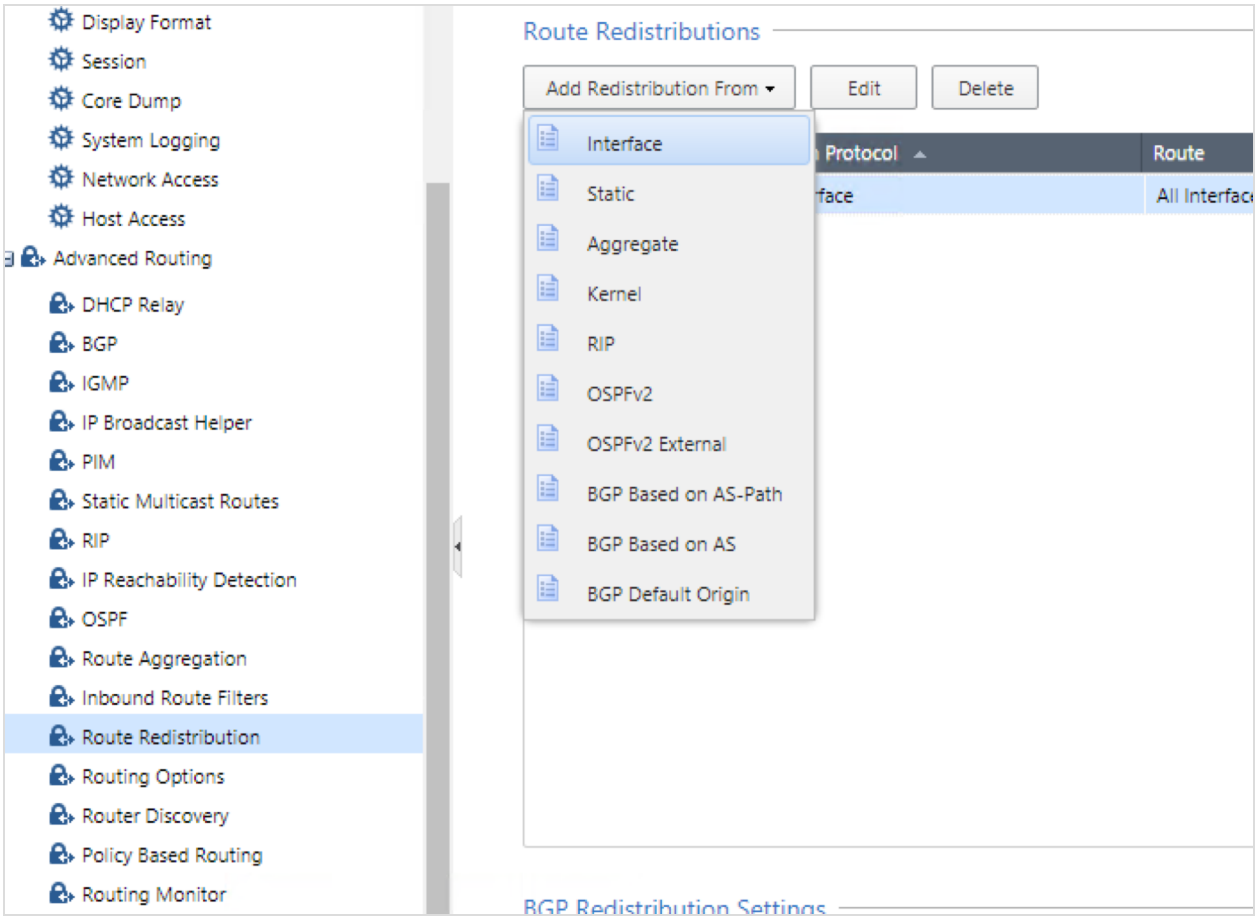
1. Go to **Advanced Routing,** and then **BGP**.
2. Under **BGP Global Settings**, click **Change Global Settings**, and then add a router ID and local ASN.



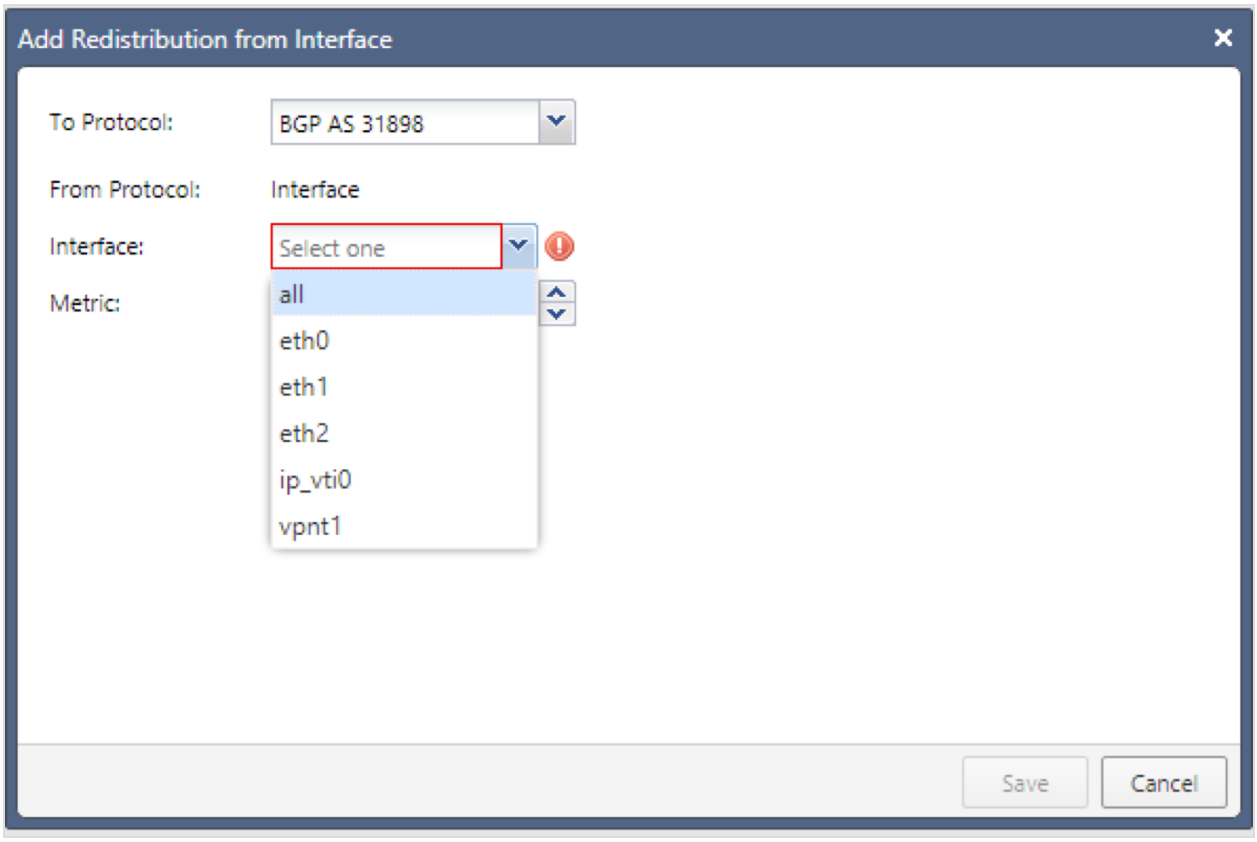
3. Click **Save**.

Task 2: Redistribute routes into BGP

1. Go to **Advanced Routing,** and then **Route Distribution**.
2. Click **Add Redistribution From**, and then select **Interface**, which is for adding all connected subnets.



3. In the **Add Redistribution from Interface** dialog, configure the following items:
   - **To Protocol:** Select **BGP AS 31898**, which is the Oracle ASN for commercial regions. If you're configuring VPN Connect for the Government Cloud, see Oracle's BGP ASN.
   - **Interface:** Select **all** to advertise all connected subnets.



4. Click **Save**.

Now the BGP session should be up and advertising and receiving subnets.

Verification

The following CLI command verifies BGP peers and routing.

```
show bgp peers
```

The following command verifies that you're receiving BGP routes.

```
show route bgp
```

The following command verifies the routes that are being advertised. In this example, replace *<remote_IP_address>* with the remote IP address that was specified in the Oracle Console as the **Inside Tunnel Interface - Oracle**

```
show bgp peer <remote_IP_address> advertise
```

The following command verifies the routes that are being received.

```
show bgp peer <remote_IP_address> received
```

Use options 2 and 4 in the following command to verify security associations (SAs).

```
vpn tunnelutil

A Monitoring service is also available from Oracle Cloud Infrastructure to actively and passively monitor your cloud resources. For information about monitoring your VPN Connect, see VPN Connect Metrics.

If you have issues, see VPN Connect Troubleshooting.

Check Point: Policy-Based

This topic provides a policy-based configuration for Check Point CloudGuard. The instructions were validated with Check Point CloudGuard version R80.20.

This topic is for policy-based configuration. If you instead want route-based (VTI-based) configuration, see Check Point: Route-Based.

Check Point experience is required. This topic does not include how to add Check Point CloudGuard Security Gateway to Check Point CloudGuard Security Manager. For more information about using Check Point products, see the Check Point documentation.

Important

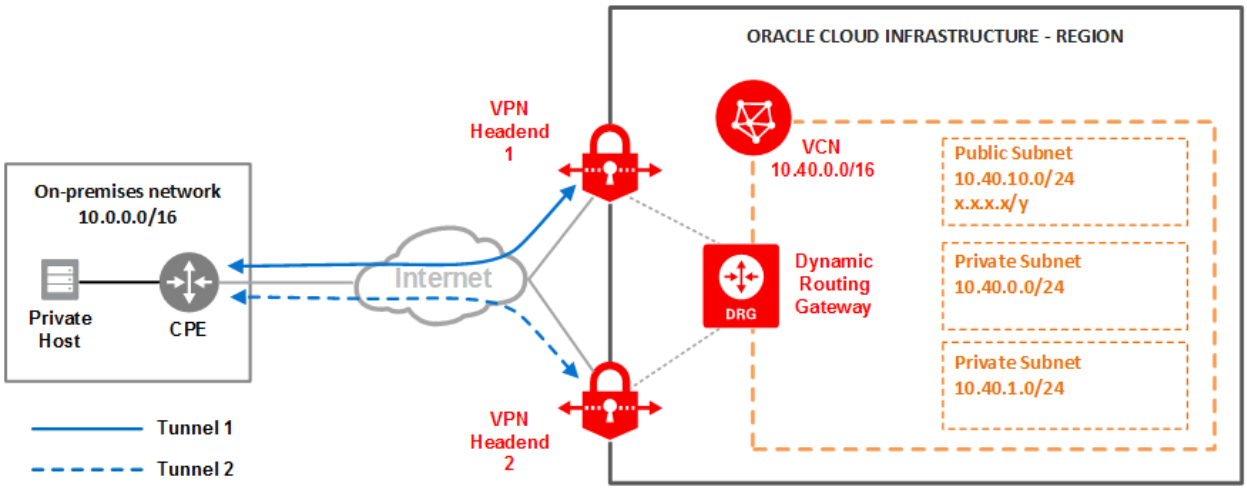
Oracle provides configuration instructions for a set of vendors and devices. Make sure to use the configuration for the correct vendor.

If the device or software version that Oracle used to verify the configuration does not exactly match your device or software, the configuration might still work for you. Consult your vendor's documentation and make any necessary adjustments.

If your device is for a vendor not in the list of verified vendors and devices, or if you're already familiar with configuring your device for IPSec, see the list of supported IPSec parameters and consult your vendor's documentation for assistance.

VPN Connect is the IPSec VPN that Oracle Cloud Infrastructure offers for connecting your on-premises network to a virtual cloud network (VCN).

The following diagram shows a basic IPSec connection to Oracle Cloud Infrastructure with redundant tunnels. IP addresses used in this diagram are for example purposes only.



Best Practices

This section covers general best practices and considerations for using VPN Connect.

Configure All Tunnels for Every IPSec Connection

Oracle deploys two IPSec headends for each of your connections to provide high availability for your mission-critical workloads. On the Oracle side, these two headends are on different routers for redundancy purposes. Oracle recommends configuring all available tunnels for maximum redundancy. This is a key part of the "Design for Failure" philosophy.

Have Redundant CPEs in Your On-Premises Network Locations

Each of your sites that connects with IPSec to Oracle Cloud Infrastructure should have redundant edge devices (also known as customer-premises equipment (CPE)). You add each CPE to the Oracle Console and create a separate IPSec connection between your dynamic routing gateway (DRG) and each CPE. For each IPSec connection, Oracle provisions two tunnels on geographically redundant IPSec headends. For more information, see the Connectivity Redundancy Guide (PDF).

Routing Protocol Considerations

When you create an IPSec VPN, it has two redundant IPSec tunnels. Oracle encourages you to configure your CPE to use both tunnels (if your CPE supports it). Note that in the past, Oracle created IPSec VPNs that had up to four IPSec tunnels.

The following two routing types are available, and you choose the routing type separately for each tunnel in the IPSec VPN:

- **BGP dynamic routing:** The available routes are learned dynamically through BGP. The DRG dynamically learns the routes from your on-premises network. On the Oracle side, the DRG advertises the VCN's subnets.
- **Static routing:** When you set up the IPSec connection to the DRG, you specify the particular routes to your on-premises network that you want the VCN to know about. You also must configure your CPE device with static routes to the VCN's subnets. These routes are not learned dynamically.

For more information about routing with VPN Connect, including Oracle recommendations on how to manipulate the BGP best path selection algorithm, see Routing for the Oracle IPSec VPN.

Other Important CPE Configurations

Ensure access lists on your CPE are configured correctly to not block necessary traffic from or to Oracle Cloud Infrastructure.

If you have multiple tunnels up simultaneously, ensure that your CPE is configured to handle traffic coming from your VCN on any of the tunnels. For example, you need to disable ICMP inspection, configure TCP state bypass, and so on. For more details about the appropriate configuration, contact your CPE vendor's support.

Caveats and Limitations

This section covers general important characteristics and limitations of VPN Connect to be aware of.

Asymmetric Routing

Oracle uses asymmetric routing across the multiple tunnels that make up the IPSec connection. Configure your firewalls accordingly. Otherwise, ping tests or application traffic across the connection will not reliably work.

When you use multiple tunnels to Oracle Cloud Infrastructure, Oracle recommends that you configure your routing to deterministically route traffic through the preferred tunnel. If you want to use one IPSec tunnel as primary and another as backup, configure more-specific routes for the primary tunnel (BGP) and less-specific routes (summary or default route) for the backup tunnel (BGP/static). Otherwise, if you advertise the same route (for example, a default route) through all tunnels, return traffic from your VCN to your on-premises network will route to any of the available tunnels (because Oracle uses asymmetric routing).

For specific Oracle routing recommendations about how to force symmetric routing, see Preferring a Specific Tunnel in the IPSec VPN.

Route-Based or Policy-Based IPSec VPN

The IPSec protocol uses Security Associations (SAs) to determine how to encrypt packets. Within each SA, you define encryption domains to map a packet's source and destination IP address and protocol type to an entry in the SA database to define how to encrypt or decrypt a packet.

Note

Other vendors or industry documentation might use the term *proxy ID, security parameter index (SPI)*, or *traffic selector* when referring to SAs or encryption domains.

There are two general methods for implementing IPSec tunnels:

- **Route-based tunnels:** Also called *next-hop-based tunnels*. A route table lookup is performed on a packet's destination IP address. If that route's egress interface is an

IPSec tunnel, the packet is encrypted and sent to the other end of the tunnel.

- **Policy-based tunnels:** The packet's source and destination IP address and protocol are matched against a list of policy statements. If a match is found, the packet is encrypted based on the rules in that policy statement.

The Oracle VPN headends use route-based tunnels but can work with policy-based tunnels with some caveats listed in the following sections.

Important

The Oracle VPN headend supports only a single encryption domain. If your policy includes multiple entries, the tunnel will flap or there will be connectivity problems in which only a single policy works at any one time.

Encryption domain for route-based tunnels

If your CPE supports route-based tunnels, use that method to configure the tunnel. It's the simplest configuration with the most interoperability with the Oracle VPN headend.

Route-based IPSec uses an encryption domain with the following values:

- **Source IP address:** Any (0.0.0.0/0)
- **Destination IP address:** Any (0.0.0.0/0)
- **Protocol:** IPv4

If you need to be more specific, you can use a single summary route for your encryption domain values instead of a default route.

Encryption domain for policy-based tunnels

If your CPE supports only policy-based tunnels, there are restrictions on the policy that you

can use on the CPE.

When you use policy-based tunnels, every policy entry that you define generates a pair of IPSec SAs. This pair is referred to as an *encryption domain*.

> **Important**
>
> The Oracle VPN headend supports only a single encryption domain. If your policy includes multiple entries, the tunnel will flap or there will be connectivity problems in which only a single policy works at any one time.

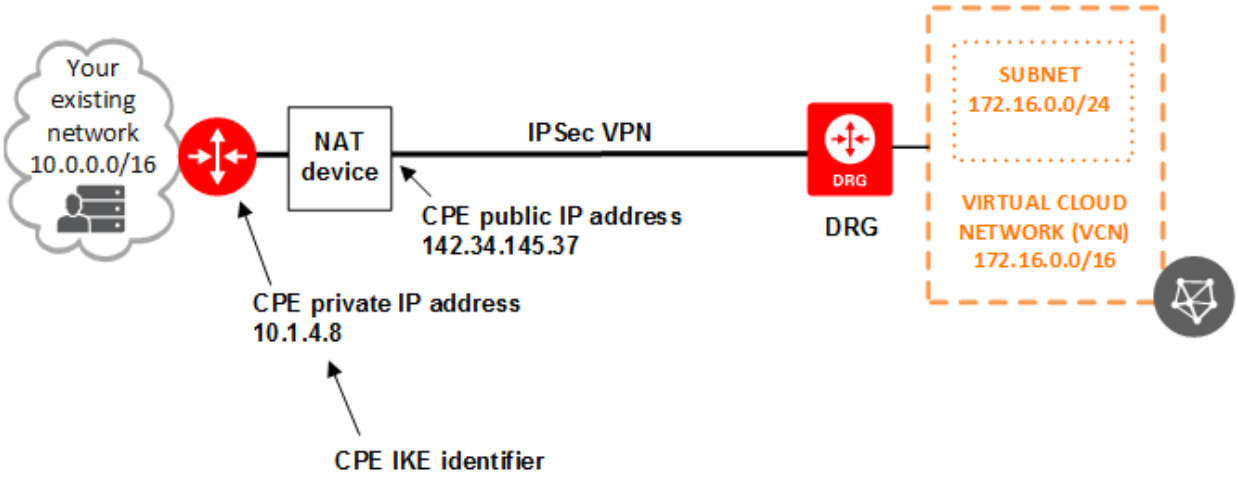
If you use policy-based IPSec, Oracle recommends using a *single encryption domain* with the following values:

- **Source IP address:** Any (0.0.0.0/0)
- **Destination IP address:** VCN CIDR (example: 10.120.0.0/20)
- **Protocol:** IPv4

Make sure the single encryption domain matches any traffic that needs to go from your on-premises network across the IPSec tunnel to the VCN. The VCN CIDR must not overlap with your on-premises network.

If Your CPE Is Behind a NAT Device

In general, the CPE IKE identifier configured on your end of the connection must match the CPE IKE identifier that Oracle is using. By default, Oracle uses the CPE's *public* IP address, which you provide when you create the CPE object in the Oracle Console. However, if your CPE is behind a NAT device, the CPE IKE identifier configured on your end might be the CPE's *private* IP address, as show in the following diagram.



Note

Some CPE platforms do not allow you to change the local IKE identifier. If you cannot, you must change the remote IKE ID in the Oracle Console to match your CPE's local IKE ID. You can provide the value either when you set up the IPSec connection, or later, by editing the IPSec connection. Oracle expects the value to be either an IP address or a fully qualified domain name (FQDN) such as *cpe.example.com*. For instructions, see Changing the CPE IKE Identifier That Oracle Uses.

Supported IPSec Parameters

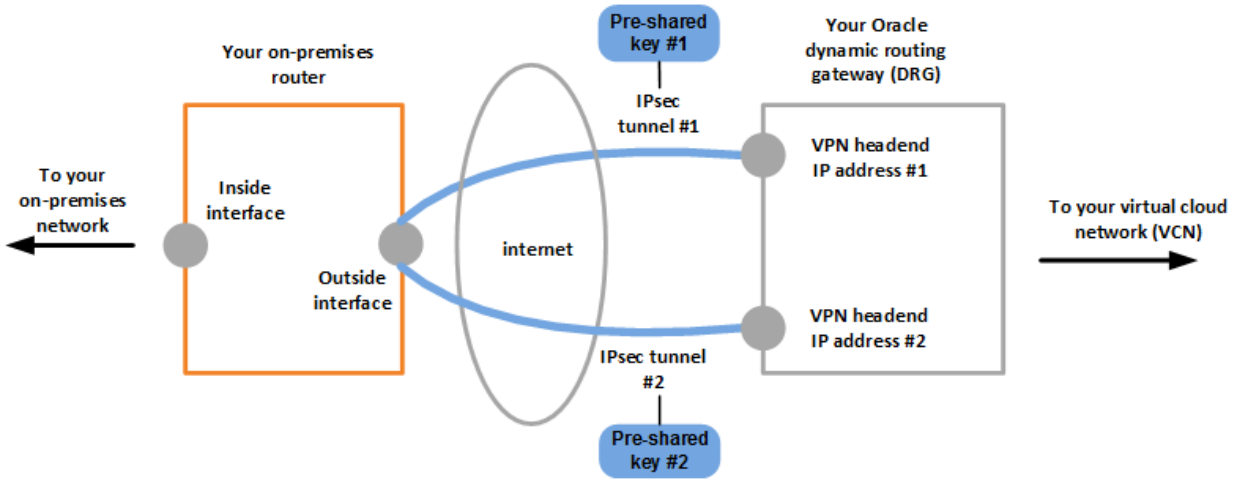
For a vendor-neutral list of supported IPSec parameters for all regions, see Supported IPSec Parameters.

The Oracle BGP ASN for the commercial cloud is 31898. If you're configuring VPN Connect for the Government Cloud, see Required VPN Connect Parameters for Government Cloud and also Oracle's BGP ASN.

CPE Configuration (Policy-Based)

> **Important**
>
> The configuration instructions in this section are provided by Oracle Cloud Infrastructure for your CPE. If you need support or further assistance, contact your CPE vendor's support directly.

The following figure shows the basic layout of the IPSec connection.



About Using IKEv2

Oracle supports Internet Key Exchange version 1 (IKEv1) and version 2 (IKEv2). If you configure the IPSec connection in the Console to use IKEv2, you must configure your CPE to

use only IKEv2 and related IKEv2 encryption parameters that your CPE supports. For a list of parameters that Oracle supports for IKEv1 or IKEv2, see Supported IPSec Parameters.

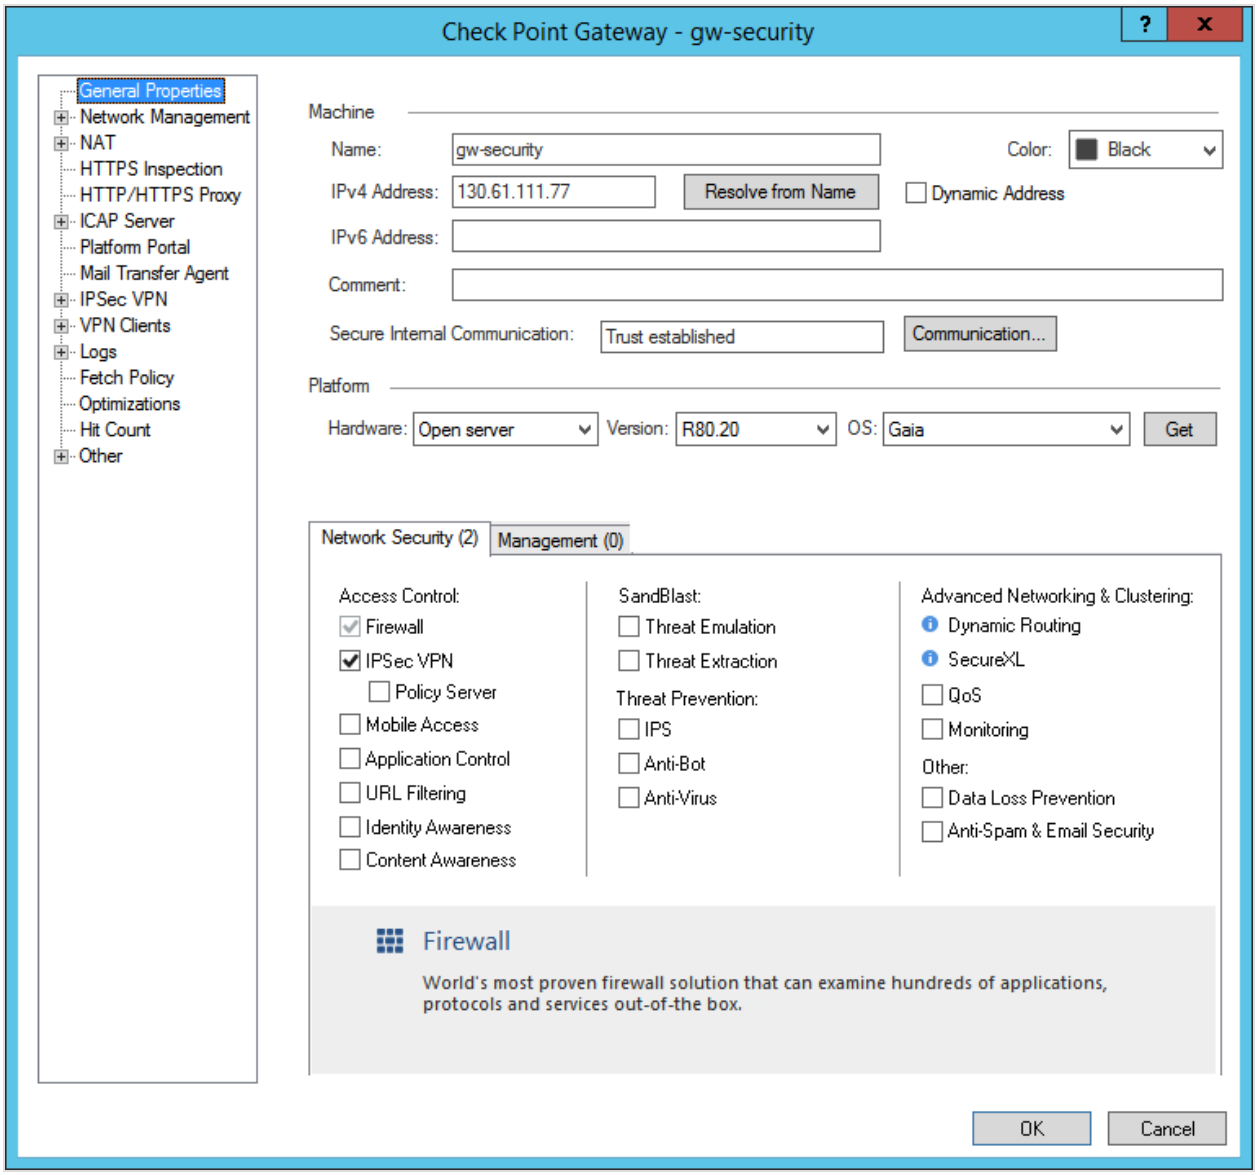
If you want to use IKEv2, there's a variation on one of the tasks presented in the next section. Specifically, in task 4, when configuring encryption, select **IKEv2 only** for the encryption method.

CONFIGURATION PROCESS

Task 1: Install IPSec VPN on Check Point CloudGuard Security Gateway

Prerequisite: Before starting, add Check Point CloudGuard Security Gateway to Check Point CloudGuard Security Manager. Also establish the Secure Internal Communication (SIC) so you can configure the IPSec tunnel by using the Check Point Smart Console. For instructions to add the Security Gateway to CloudGuard or to establish the SIC, see the Check Point documentation.

1. Install the IPSec VPN module. Oracle recommends that you also install the Monitoring module for traffic analysis.



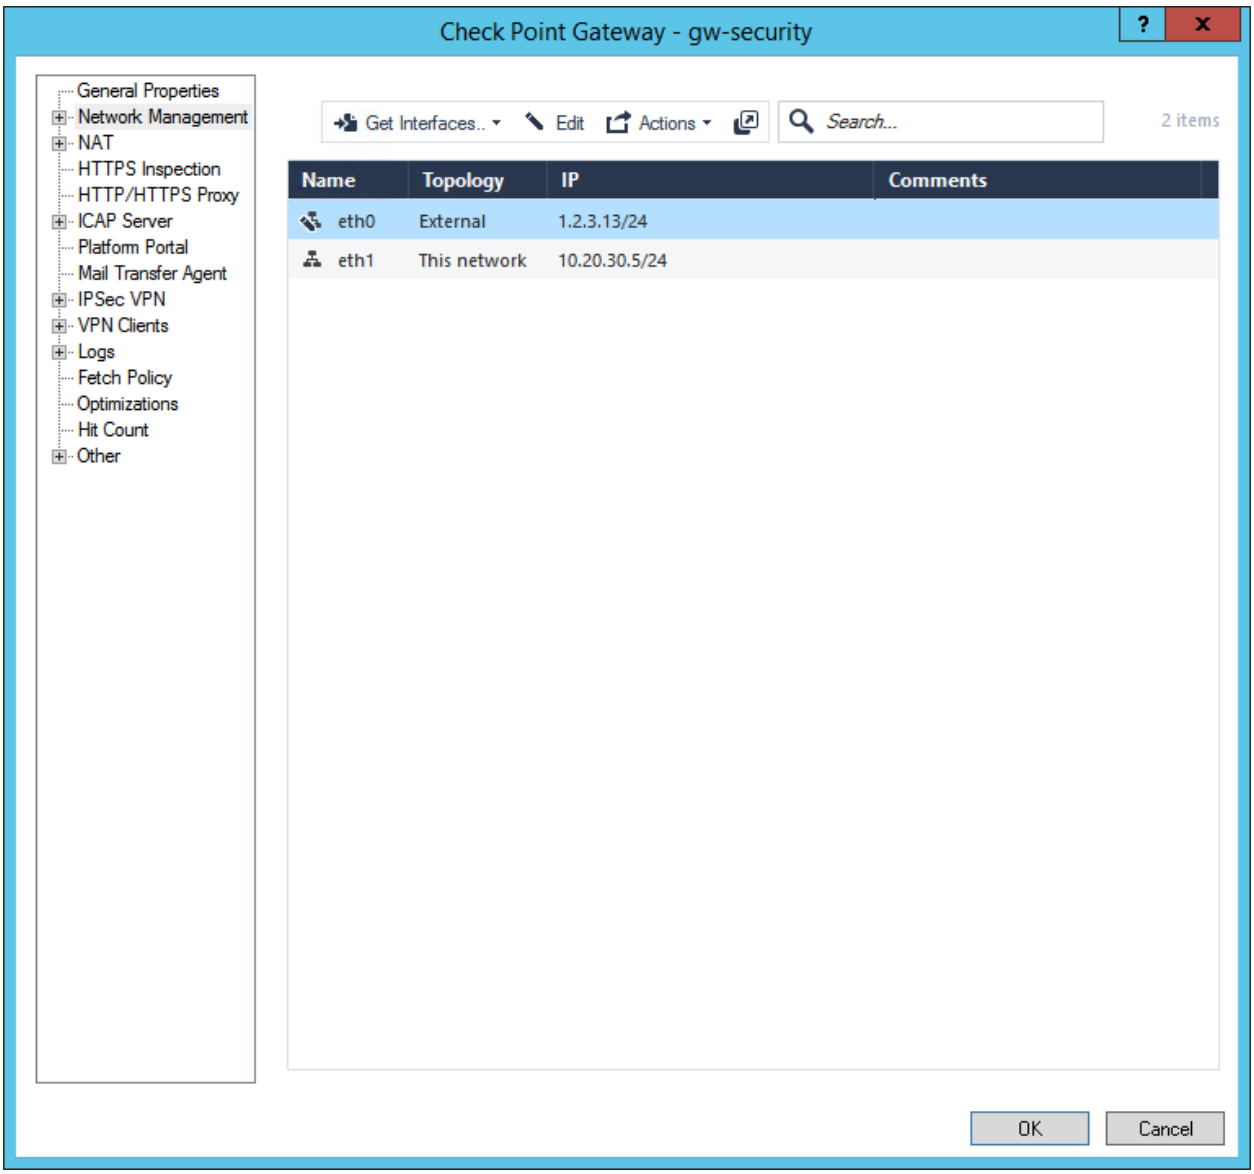
2. Click **OK** to save your changes.

Task 2: Configure IPSec settings for Check Point CloudGuard Security Gateway

This task covers the most important options used for an IPSec tunnel with Oracle Cloud Infrastructure.

1. On the **Network Management** page, import all the interfaces. You can do this by clicking **Get Interfaces**, which contains options for **Get Interfaces With Toplogy** and **Get Interfaces Without Toplogy**. This example uses **Get Interfaces Without Topology** so that you can define the purpose of each interface as an external or internal network.

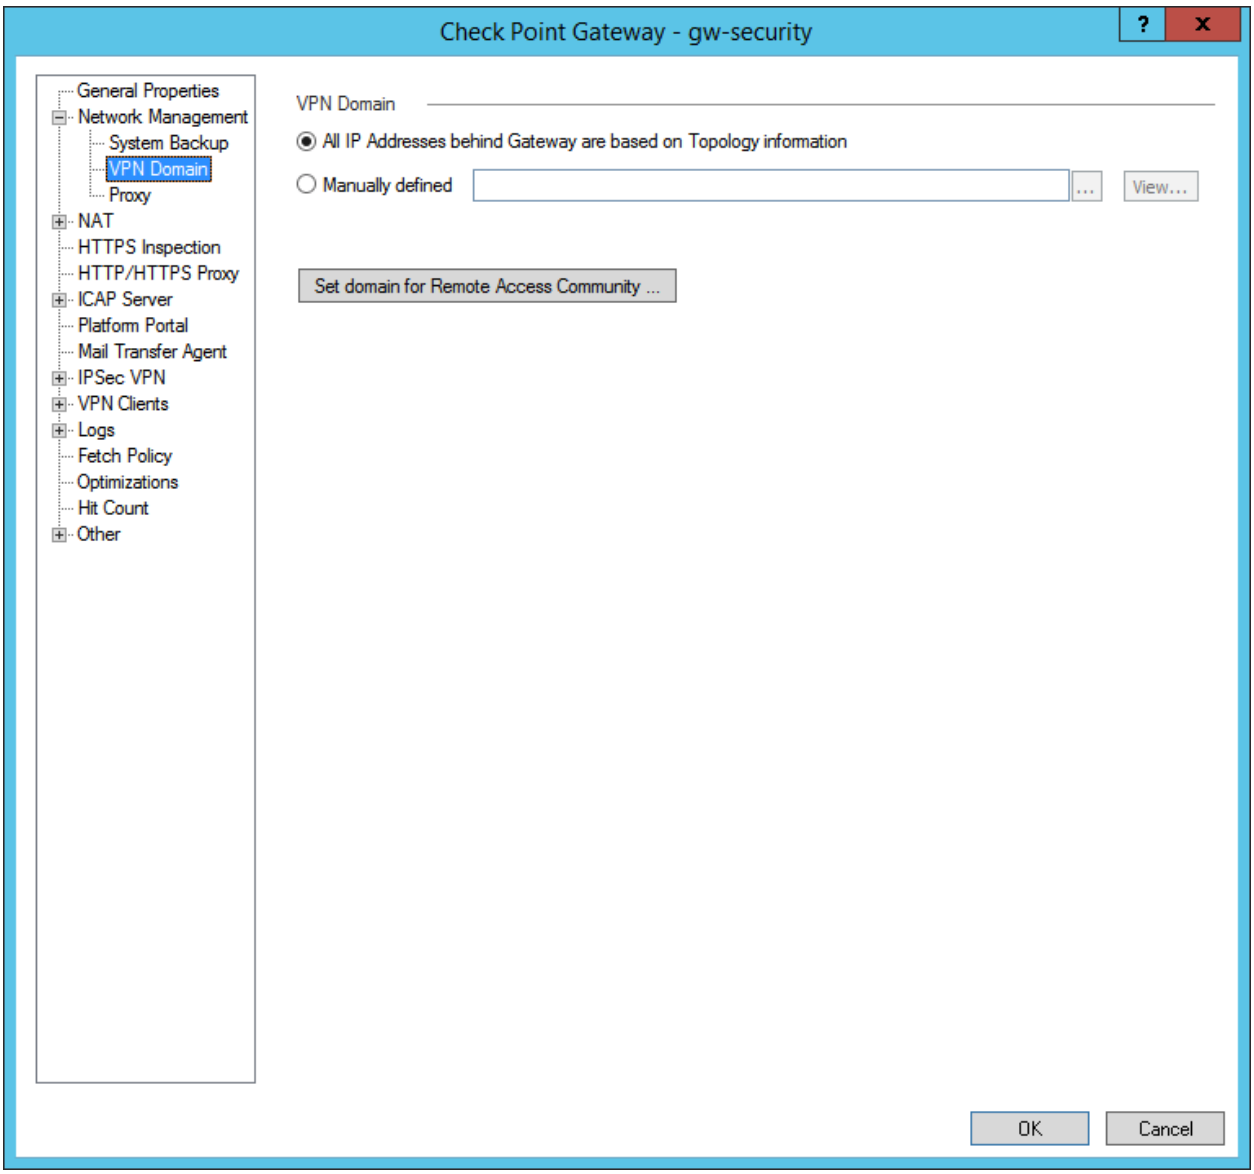
   All of these interfaces will be used in the **VPN Domain** as subnets advertised by Check Point CloudGuard Security Gateway in the IPSec encryption domain.



2. On the **VPN Domain** page, Oracle recommends that you select the option **for All IP Addresses behind Gateway are based on Topology information**. This option

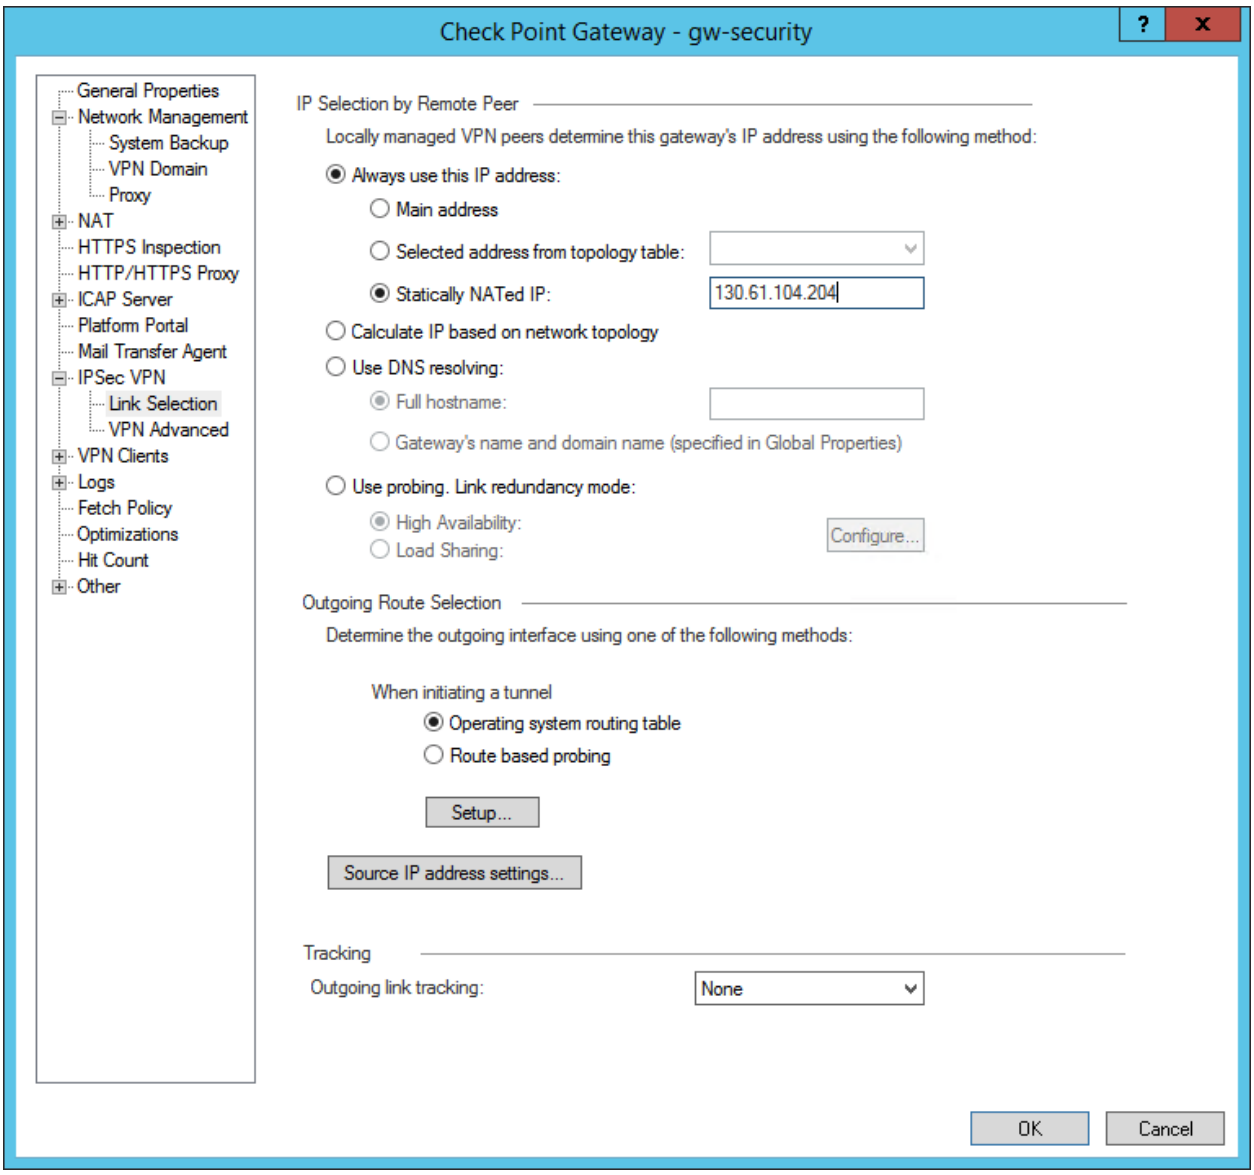
adds all the subnets discovered in **Network Management** to the IPSec Encryption Domain.

You can instead select the option for **Manually defined**. However, that requires a **Network Object** with all subnets to include in the IPSec encryption domain.



3. If your Check Point CloudGuard Security Gateway uses 1:1 NAT to map private IP addresses to public IP addresses: On the **Link Selection** page, under **Always use this**

IP address, select **Statically NATed IP** and specify the IP address that you want to use as your IKE ID.



If you don't want to use a public IP address as the local IKE ID, you can use another value (such as a private IP address), but the value will not match the one expected on

the Oracle DRG. To resolve this, you can change the value that Oracle uses in the Oracle Console (see the instructions that follow).

To change the CPE IKE identifier that Oracle uses (Oracle Console)

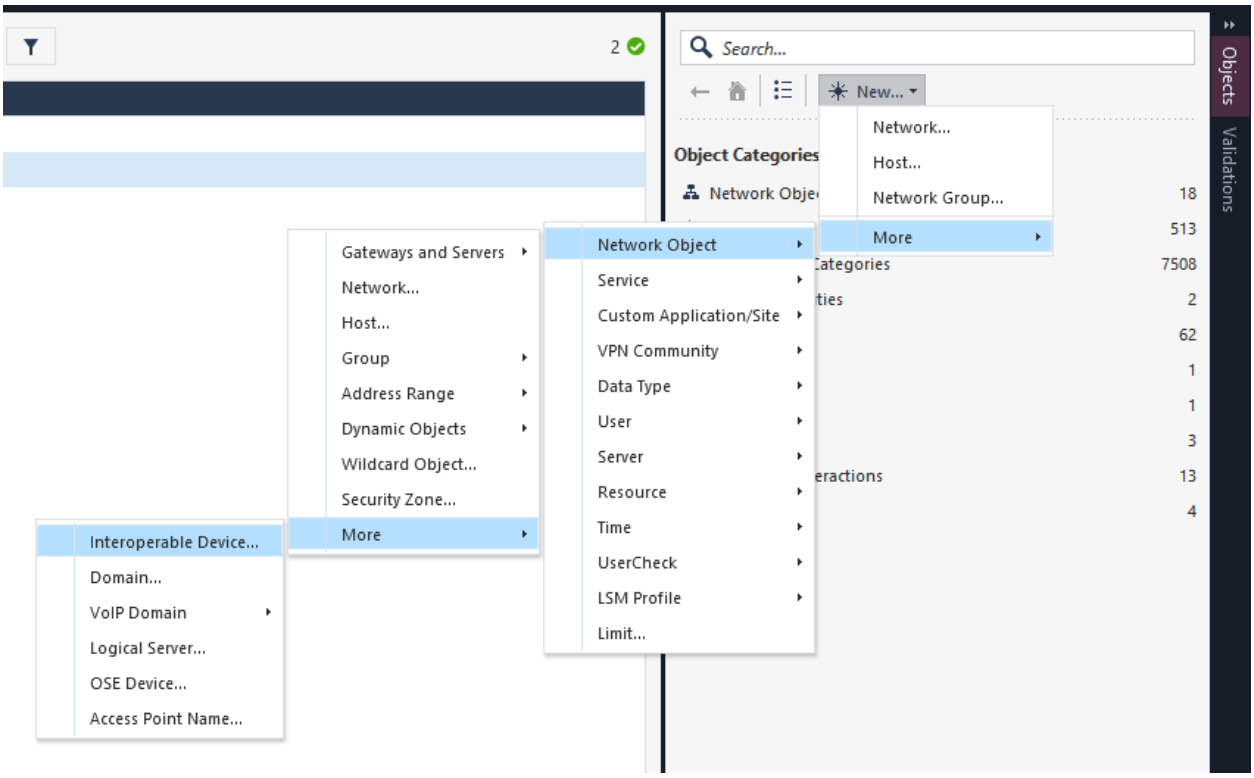
a. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **IPSec Connections**.
   A list of the IPSec connections in the compartment that you're viewing is displayed. If you don't see the one you're looking for, verify that you're viewing the correct compartment (select from the list on the left side of the page).
b. For the IPSec connection you're interested in, click the Actions icon (three dots), and then click **Edit**.
   The current CPE IKE identifier that Oracle is using is displayed at the bottom of the dialog.
c. Enter your new values for **CPE IKE Identifier Type** and **CPE IKE Identifier**, and then click **Save Changes**.

4. Click **OK** to save your changes.

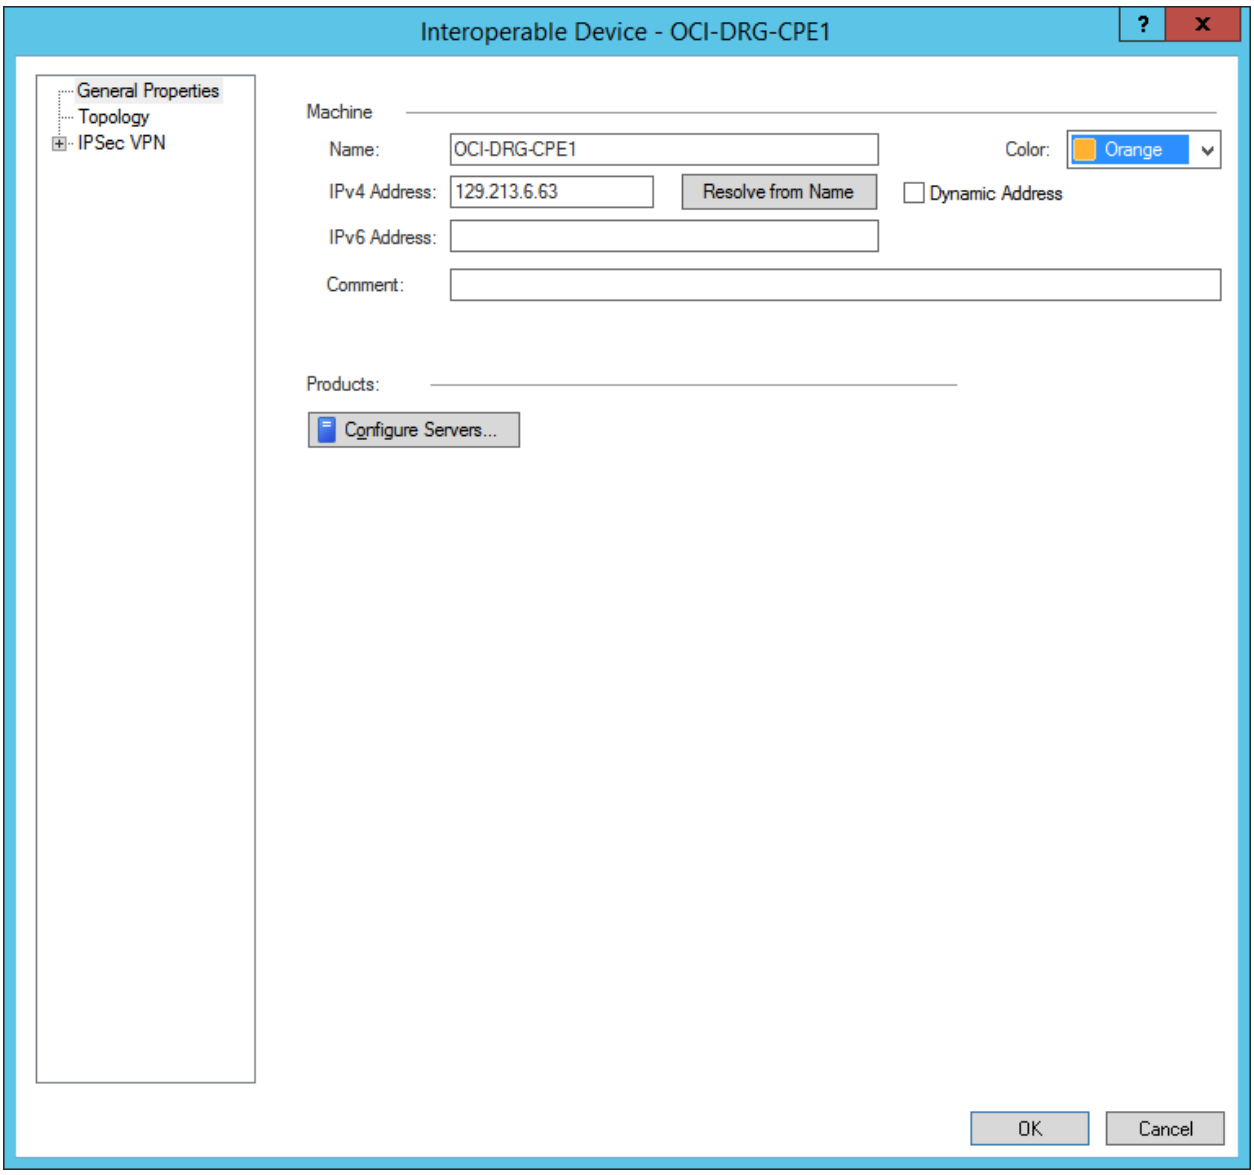
Task 3: Create an interoperable device

Later, you will create a VPN Community. Before you can, you must create an **Interoperable Device** that will be used in Check Point CloudGuard Security Gateway to define the Oracle DRG.

1. Create the new interoperable device.

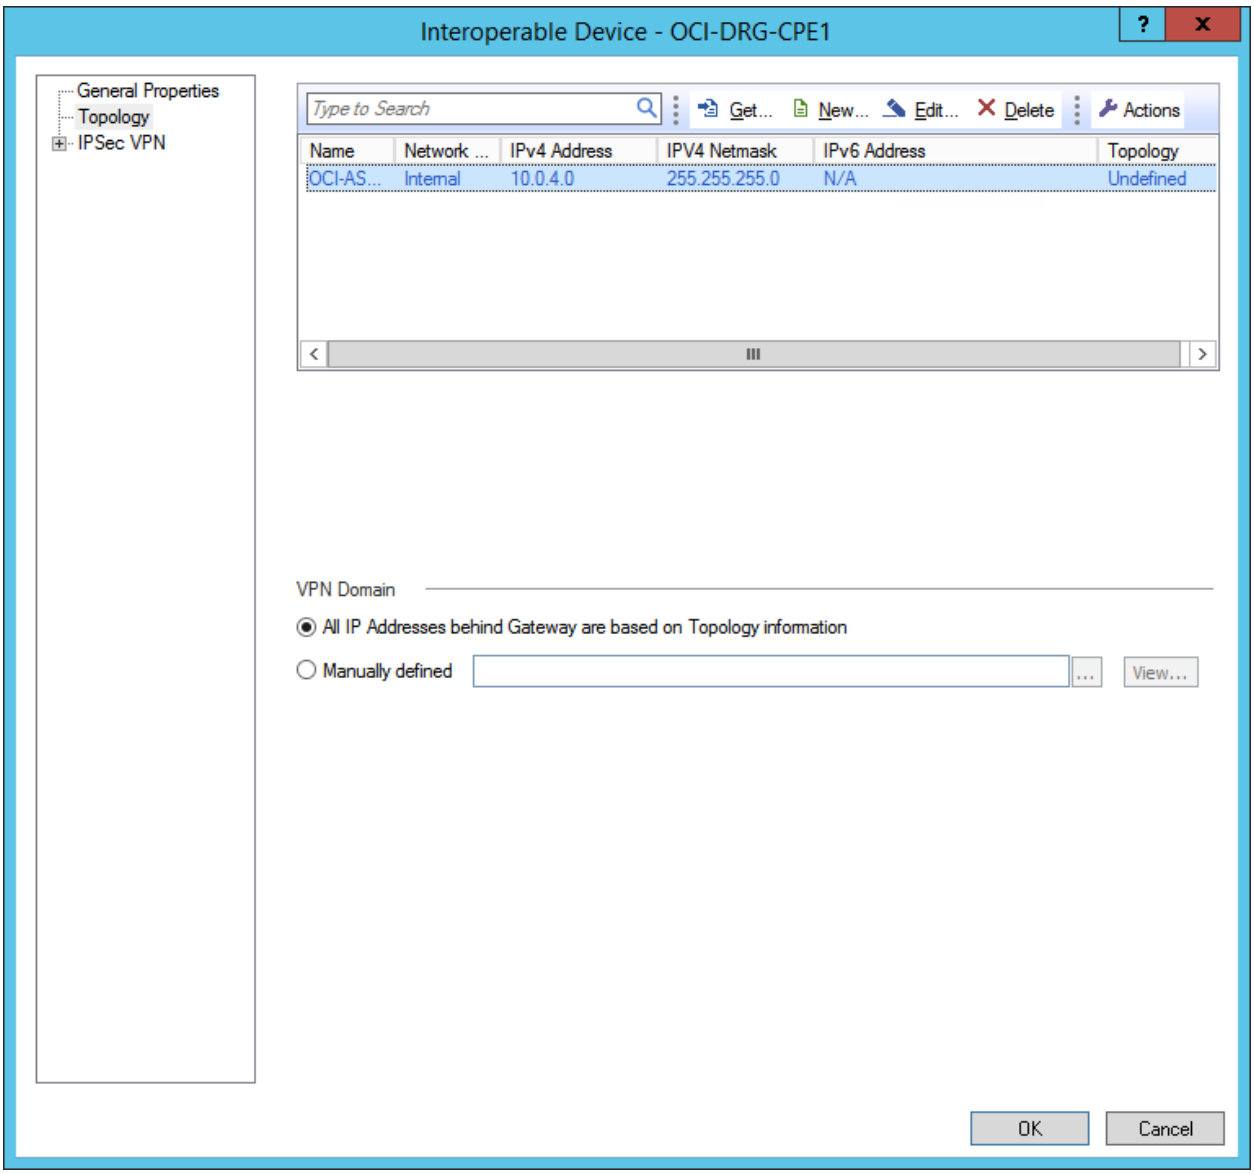


2. On the **General Properties** page of the new interoperable device, add a name to identify the IPSec tunnel. Enter the IP address that Oracle assigned for the Oracle end of the tunnel when creating the IPSec connection.



3. On the **Topology** page, Oracle recommends that you create a new toplogy by clicking **New** and then adding the Oracle VCN subnets to be used for the tunnel.

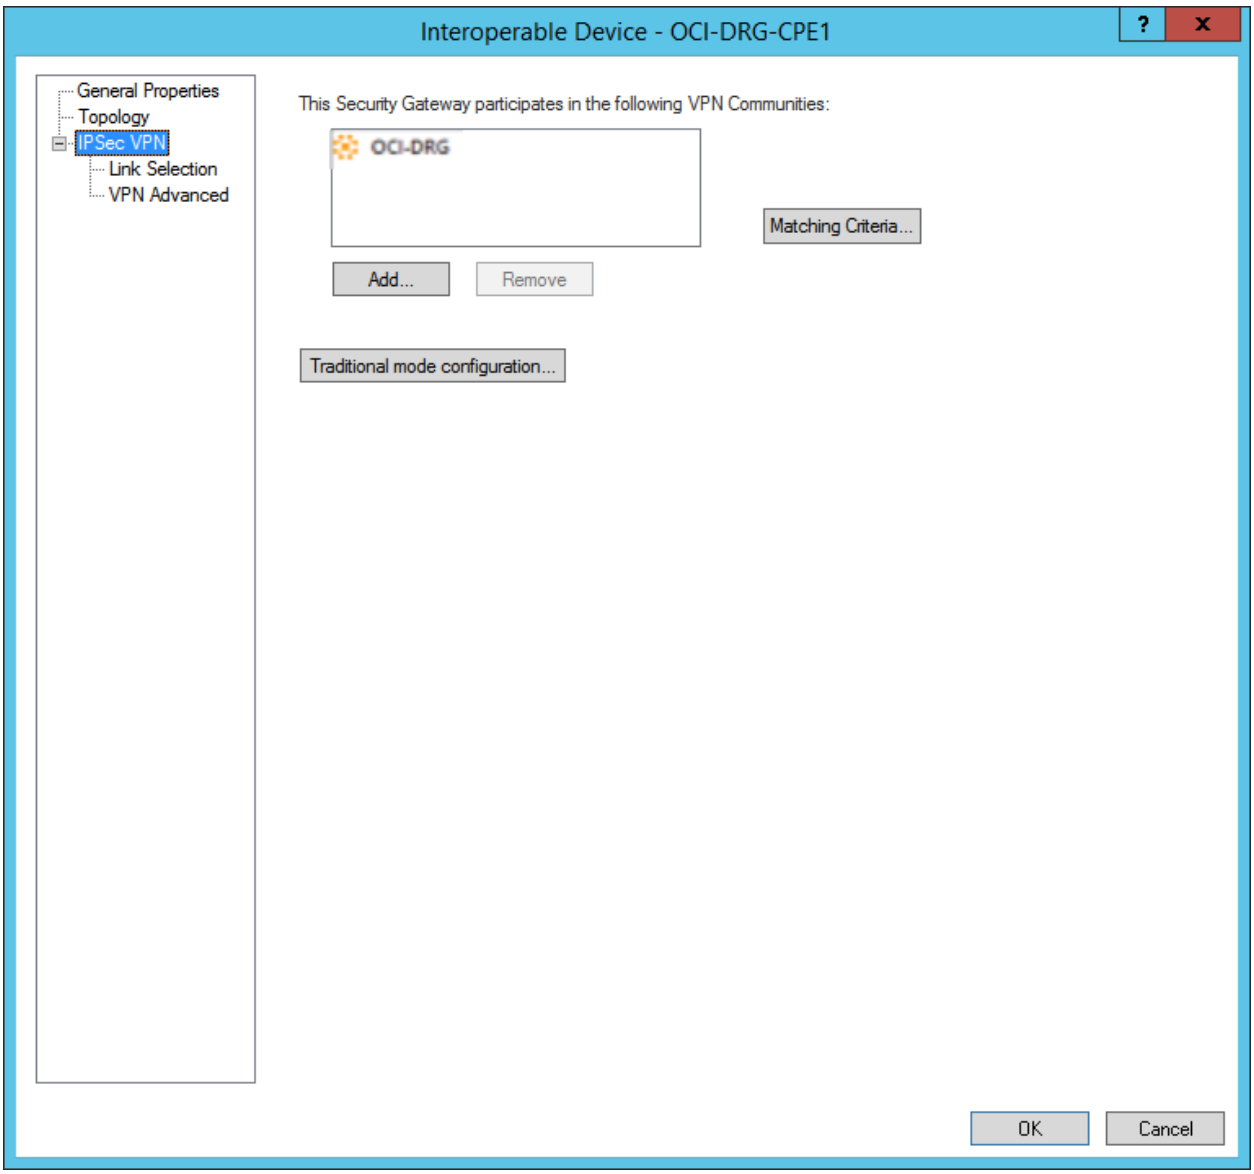
You can instead select the option for **Manually defined**. However, that requires a **Network Object** with all subnets to include in the IPSec Encryption Domain.



4. On the **IPSec VPN** page, you can optionally add the new interoperable device to an existing VPN Community. You can skip this step if you don't yet have any VPN

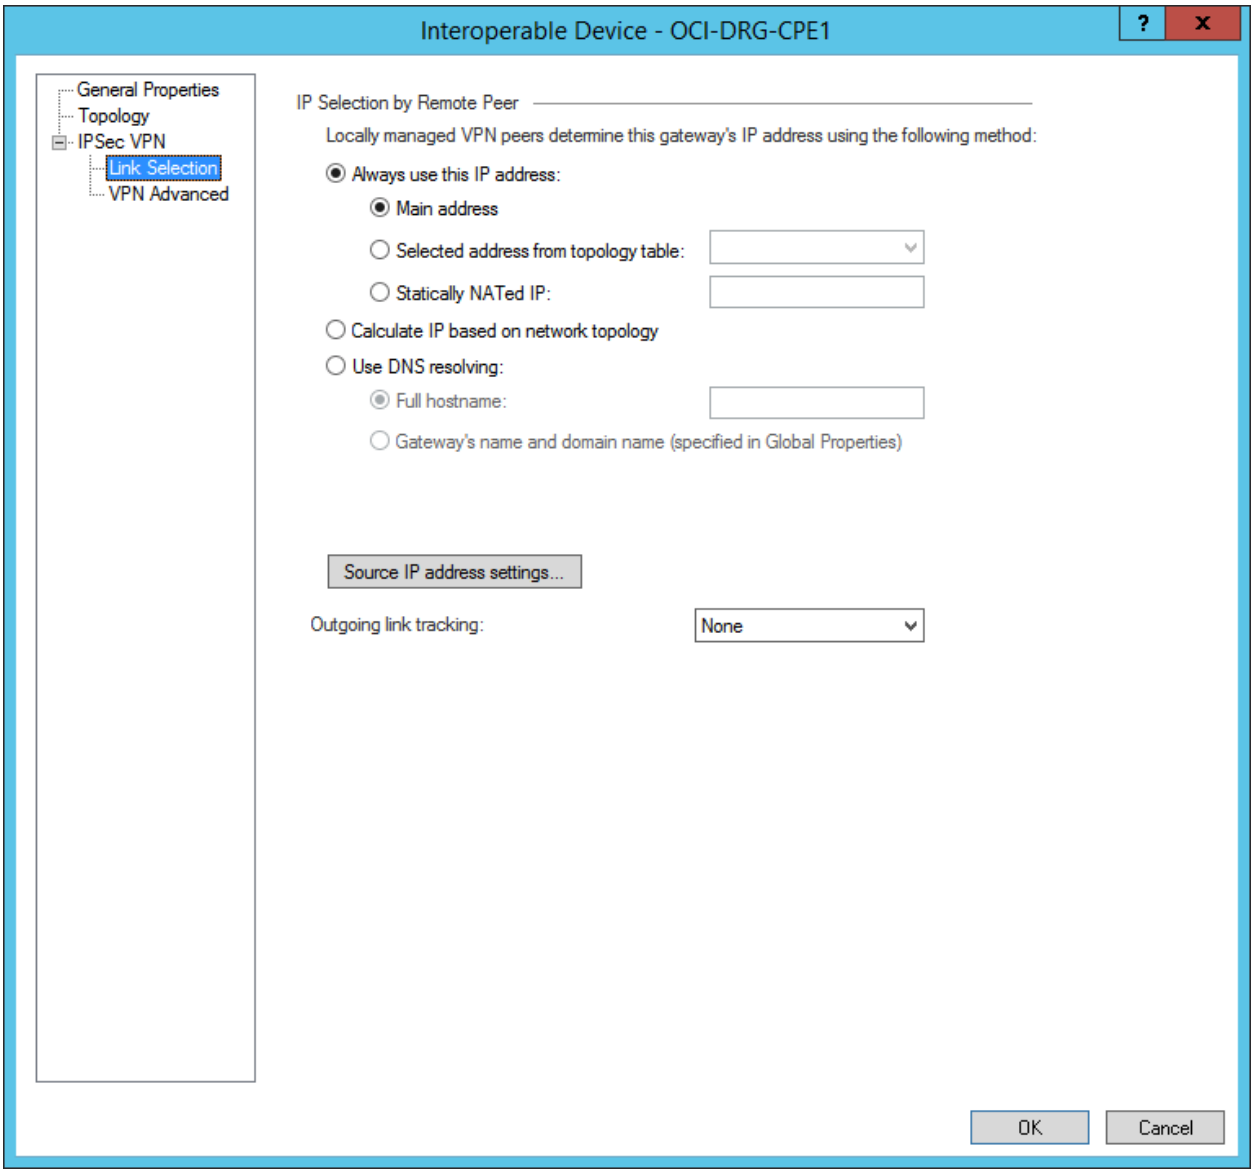
Communities created.

Notice that you skip the **Traditional mode configuration**, because you will define all the Phase 1 and Phase 2 parameters in the VPN Community in a later step. The VPN Community applies those parameters to all interoperable devices that belong to the VPN Community.

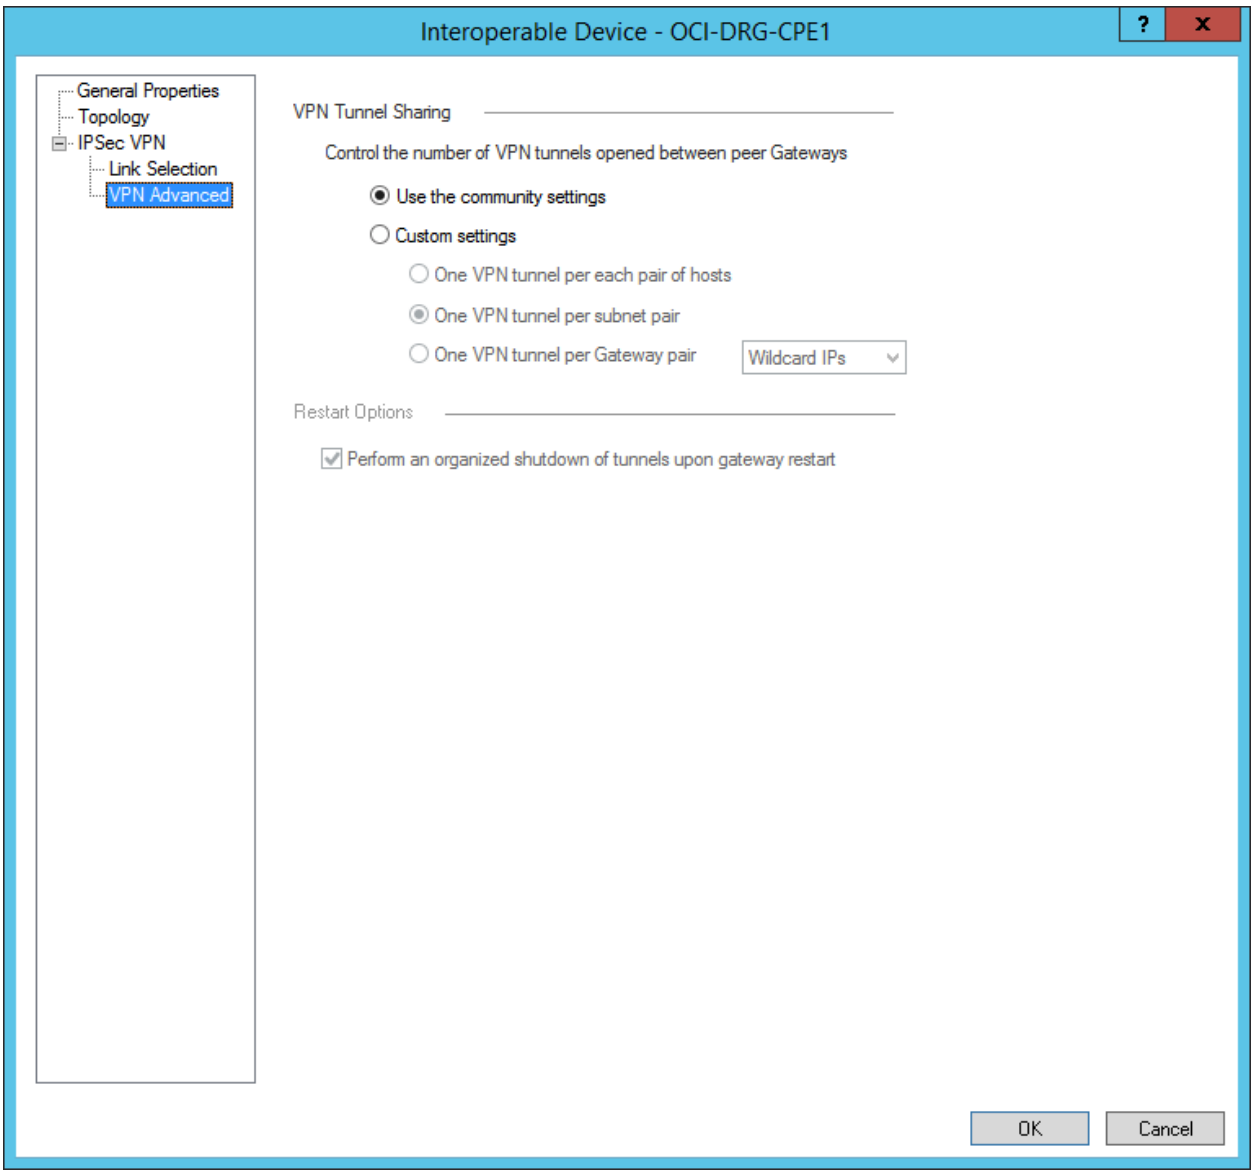


5. On the **Link Selection** page, under **Always use this IP address**, select **Main address**, which is the address that you specified when creating the interoperable

device. If necessary, you can use a specific IP address that will be used as the IKE ID.



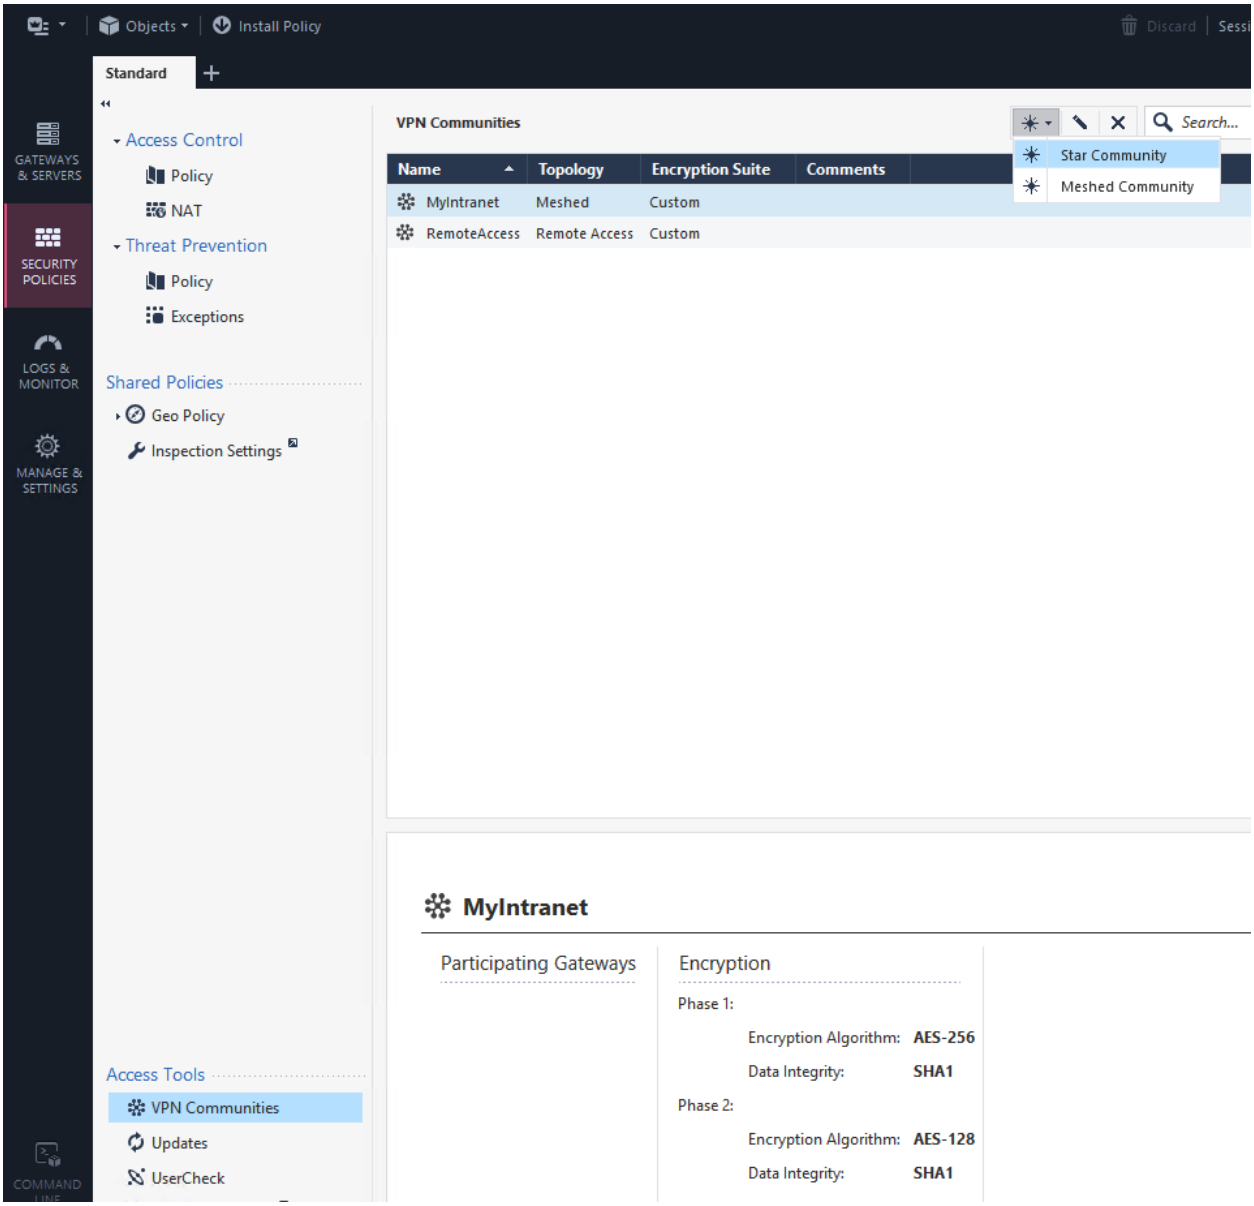
6. On the **VPN Advanced** page, select **Use the community settings**, which applies all the options and values in the VPN Community, including the Phase 1 and Phase 2 parameters.



7. Click **OK** to save your changes.

Task 4: Create a VPN community

1. Go to **Security Policies**, and then from **Access Tools**, select **VPN Communities**.
2. Create a **Star Community**.



3. For the star community, add a name.

4. On the **Gateways** page, select the values for **Center Gateways** and **Satellite Gateways**. This star community acts as a settings template for the interoperable devices you specify in **Center Gateways** and **Satellite Gateways**.
    - **Center Gateways**: For the Check Point CloudGuard Security Gateway.
    - **Satellite Gateways**: For the CPE that connects to the Oracle DRG for each IPSec tunnel.

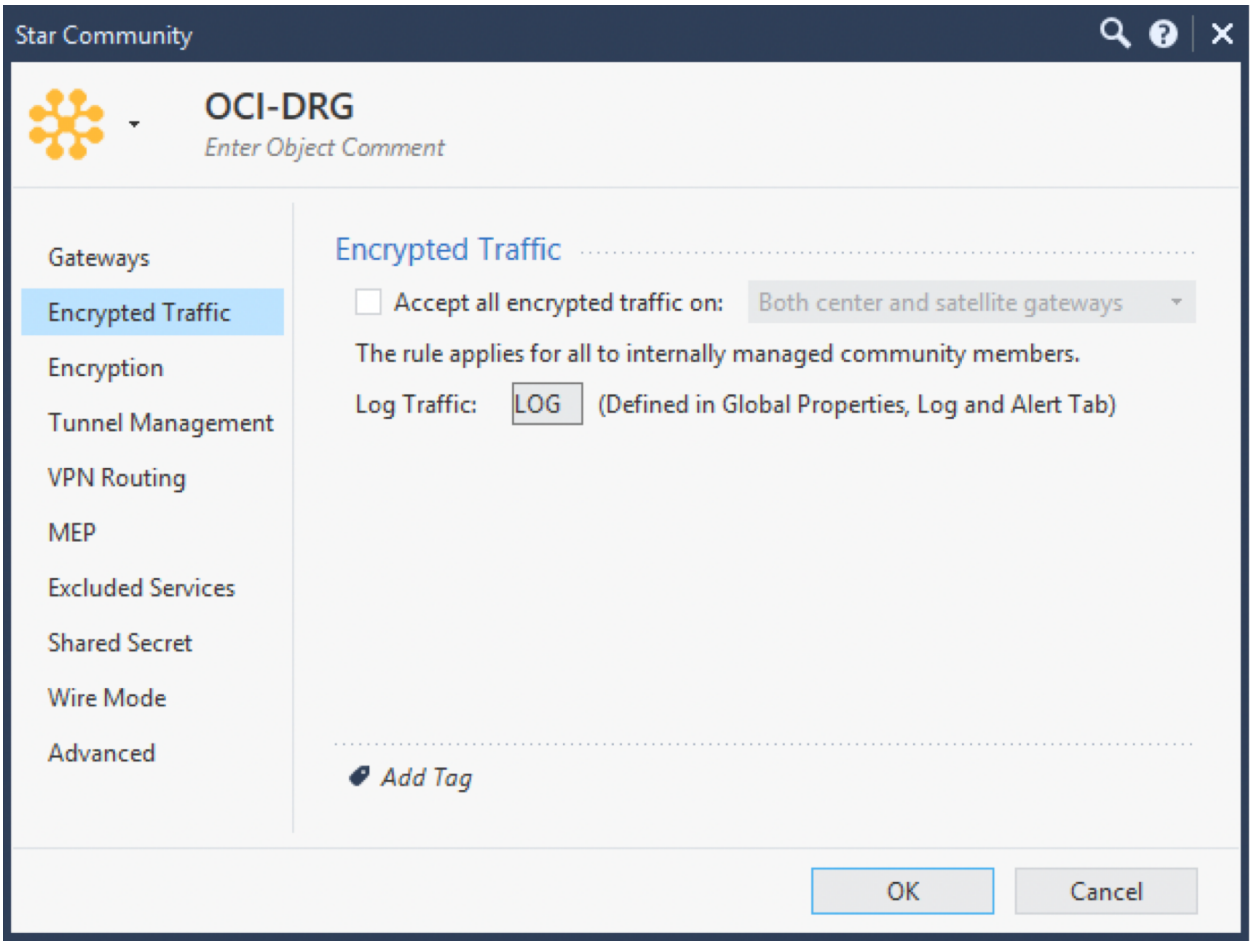
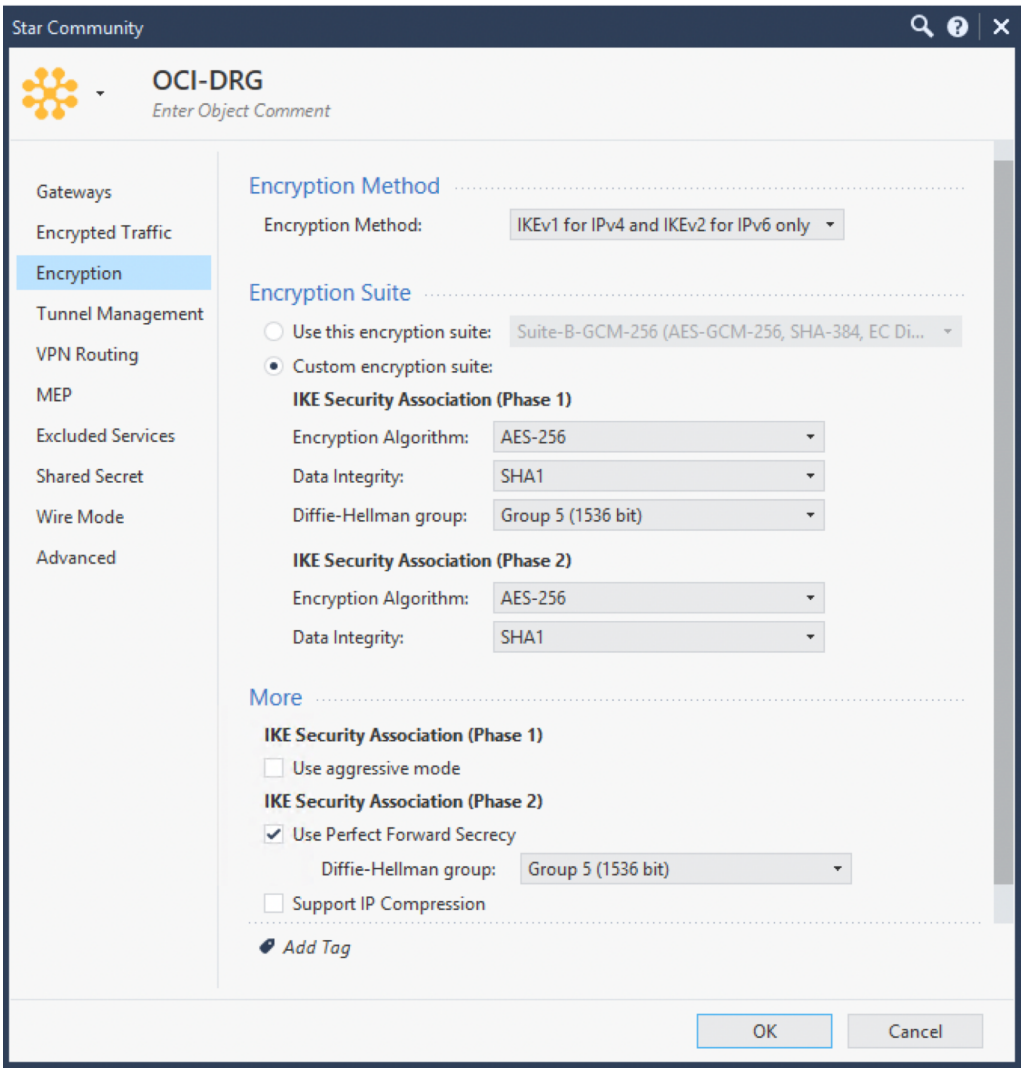
5. If this is a proof of concept (POC) scenario: On the **Encrypted Traffic** page, select the check box for **Accept all encrypted traffic on**. The default value for this setting allows the traffic between both center and satellite gateways. This setting is appropriate for a POC scenario. However, for a production scenario, Oracle recommends that you instead create specific security policies under **Access Control** and on the **Policy** tab. That is covered in the final task in this process.



6. On the **Encryption** page, configure the Phase 1 and Phase 2 parameters that Oracle supports. For a list of those values, see Supported IPSec Parameters.
   If you're configuring VPN Connect for the Government Cloud, see Required VPN Connect Parameters for Government Cloud.
   Notice that if you want to use IKEv2, for the **Encryption Method**, instead select **IKEv2 only**.



7. On the **Tunnel Management** page, select **Set Permanent Tunnels**. Oracle recommends that you:
    - Select **On all tunnels in the community** to keep all the Oracle IPSec tunnels up all the time.

- In the **VPN Tunnel Sharing** section, select **One VPN tunnel per Gateway pair**.

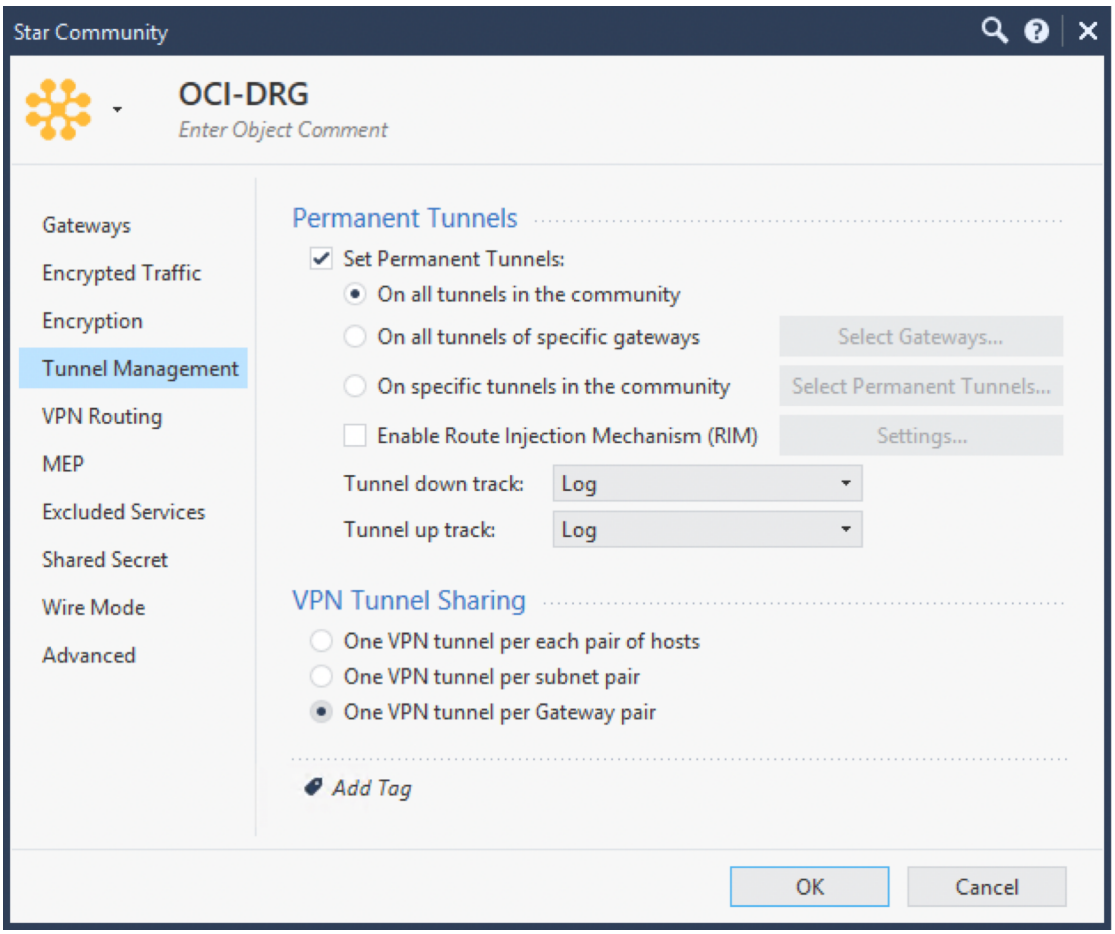
The latter option generates only one pair of IPSec security associations (SAs), and each SA with only one security parameter index (SPI) (unidirectional).

When you use policy-based tunnels, every policy entry generates a pair of IPSec SAs, (also referred to as an *encryption domain*).

Important

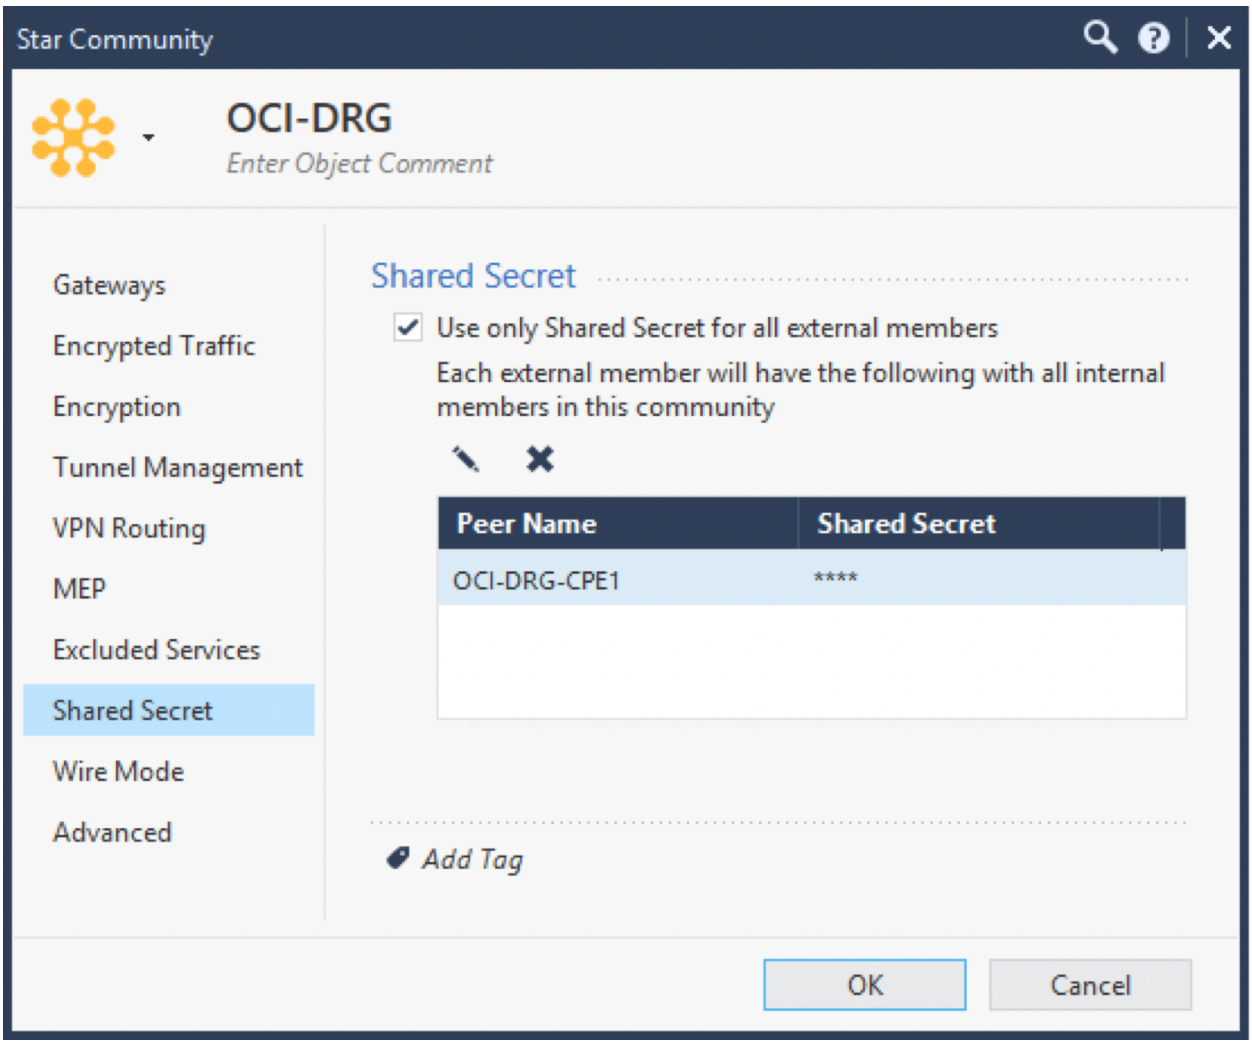
The Oracle VPN headend supports only a single encryption domain. If your policy includes multiple entries, the tunnel will flap or there will be connectivity problems in which only a single policy works at any one time.

Oracle creates a route-based IPSec connection, which means that everything is routed through an encryption domain that has 0.0.0.0/0 (any) for local traffic and 0.0.0.0/0 (any) for remote traffic. For more information, see Supported Encryption Domain or Proxy ID.



8. On the **Shared Secret** page, select **Use only Shared Secret for all external members**, and add the shared secret that Oracle generated for the tunnel when creating the IPSec connection.

   Currently Oracle supports only shared secret keys. Note that you can change the shared secret in the Oracle Console.



9. Click **OK** to save your changes.

Task 5: Create a security policy (recommended for a production scenario)

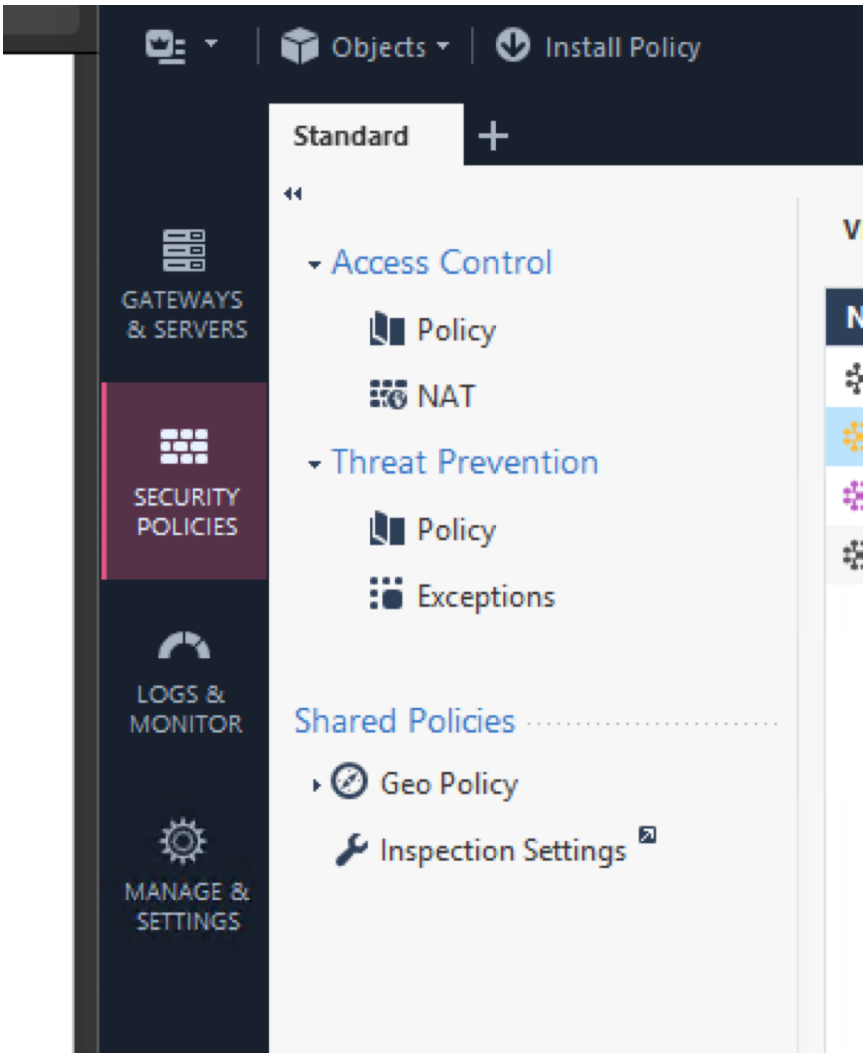
If this is a proof of concept (POC) scenario, earlier you selected **Accept all encrypted**

traffic on the **Encrypted Traffic** page. If this is instead a production scenario, Oracle recommends creating security policies.

1. Under Security Policies, click Access Control, and then select the Policy tab.
2. Configure the required values.

3. Click **OK** to save your changes.

4. Click **Install Policy** to apply the configuration.



The IPSec tunnel should now be up.

Verification

Use options 2 and 4 in the following command to verify security associations (SAs).

```
vpn tunnelutil

**********     Select Option     **********

(1)                List all IKE SAs
(2)              * List all IPsec SAs
(3)                List all IKE SAs for a given peer (GW) or user (Client)
(4)              * List all IPsec SAs for a given peer (GW) or user (Client)
(5)                Delete all IPsec SAs for a given peer (GW)
(6)                Delete all IPsec SAs for a given User (Client)
(7)                Delete all IPsec+IKE SAs for a given peer (GW)
(8)                Delete all IPsec+IKE SAs for a given User (Client)
(9)                Delete all IPsec SAs for ALL peers and users
(0)                Delete all IPsec+IKE SAs for ALL peers and users

* To list data for a specific CoreXL instance, append "-i <instance number>" to your selection.

(Q)              Quit

*****************************************
```

A Monitoring service is also available from Oracle Cloud Infrastructure to actively and passively monitor your cloud resources. For information about monitoring your VPN Connect, see VPN Connect Metrics.

If you have issues, see VPN Connect Troubleshooting.

Cisco ASA Configuration Options

Choose the configuration based on the ASA software version:

- **9.7.1 or newer:** Route-based configuration
- **8.5 to 9.7.0:** Policy-based configuration
- **Older than 8.5:** Not supported by the Oracle configuration instructions. Consider upgrading to a newer version.

Important

Oracle recommends using a route-based configuration to avoid interoperability issues and to achieve tunnel redundancy with a single Cisco ASA device.

The Cisco ASA does not support route-based configuration for software versions older than 9.7.1. For the best results, if your device allows it, Oracle recommends that you upgrade to a software version that supports route-based configuration.

With policy-based configuration, you can configure only a single tunnel between your Cisco ASA and your dynamic routing gateway (DRG).

Cisco ASA: Route-Based

This topic provides a route-based configuration for a Cisco ASA that is running software version 9.7.1 (or newer).

As a reminder, Oracle provides different configurations based on the ASA software:

- **9.7.1 or newer:** Route-based configuration (this topic)
- **8.5 to 9.7.0:** Policy-based configuration
- **Older than 8.5:** Not supported by the Oracle configuration instructions. Consider upgrading to a newer version.

Important

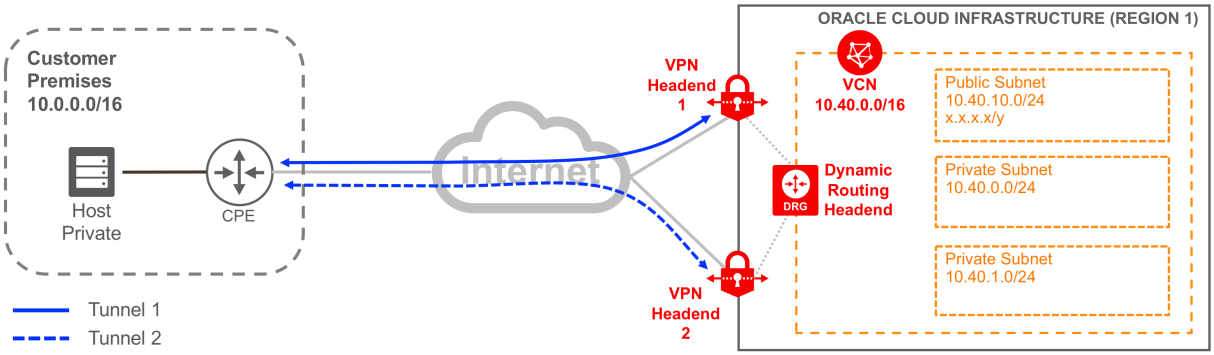
Oracle provides configuration instructions for a set of vendors and devices. Make sure to use the configuration for the correct vendor.

If the device or software version that Oracle used to verify the configuration does not exactly match your device or software, the configuration might still work for you. Consult your vendor's documentation and make any necessary adjustments.

If your device is for a vendor not in the list of verified vendors and devices, or if you're already familiar with configuring your device for IPSec, see the list of supported IPSec parameters and consult your vendor's documentation for assistance.

VPN Connect is the IPSec VPN that Oracle Cloud Infrastructure offers for connecting your on-premises network to a virtual cloud network (VCN).

The following diagram shows a basic IPSec connection to Oracle Cloud Infrastructure with redundant tunnels. The IP addresses in this diagram are examples only and not for literal use.



Best Practices

This section covers general best practices and considerations for using VPN Connect.

Configure All Tunnels for Every IPSec Connection

Oracle deploys two IPSec headends for each of your connections to provide high availability for your mission-critical workloads. On the Oracle side, these two headends are on different routers for redundancy purposes. Oracle recommends configuring all available tunnels for maximum redundancy. This is a key part of the "Design for Failure" philosophy.

Have Redundant CPEs in Your On-Premises Network Locations

Each of your sites that connects with IPSec to Oracle Cloud Infrastructure should have redundant edge devices (also known as customer-premises equipment (CPE)). You add each CPE to the Oracle Console and create a separate IPSec connection between your dynamic routing gateway (DRG) and each CPE. For each IPSec connection, Oracle provisions two tunnels on geographically redundant IPSec headends. For more information, see the Connectivity Redundancy Guide (PDF).

Routing Protocol Considerations

When you create an IPSec VPN, it has two redundant IPSec tunnels. Oracle encourages you to configure your CPE to use both tunnels (if your CPE supports it). Note that in the past, Oracle

created IPSec VPNs that had up to four IPSec tunnels.

The following two routing types are available, and you choose the routing type separately for each tunnel in the IPSec VPN:

- **BGP dynamic routing:** The available routes are learned dynamically through BGP. The DRG dynamically learns the routes from your on-premises network. On the Oracle side, the DRG advertises the VCN's subnets.
- **Static routing:** When you set up the IPSec connection to the DRG, you specify the particular routes to your on-premises network that you want the VCN to know about. You also must configure your CPE device with static routes to the VCN's subnets. These routes are not learned dynamically.

For more information about routing with VPN Connect, including Oracle recommendations on how to manipulate the BGP best path selection algorithm, see Routing for the Oracle IPSec VPN.

Other Important CPE Configurations

Ensure access lists on your CPE are configured correctly to not block necessary traffic from or to Oracle Cloud Infrastructure.

If you have multiple tunnels up simultaneously, ensure that your CPE is configured to handle traffic coming from your VCN on any of the tunnels. For example, you need to disable ICMP inspection, configure TCP state bypass, and so on. For more details about the appropriate configuration, contact your CPE vendor's support.

Specific to Cisco ASA: Caveats and Limitations

This section covers important characteristics and limitations that are specific to Cisco ASA.

Tunnel MTU and Path MTU Discovery

You have two options for addressing tunnel MTU and path MTU discovery with Cisco ASA:

- Option 1: TCP MSS adjustment
- Option 2: Clear/set the Don't Fragment bit

OPTION 1: TCP MSS ADJUSTMENT

The maximum transmission unit (packet size) through the IPSec tunnel is less than 1500 bytes. You can fragment packets that are too large to fit through the tunnel. Or, you can signal back to the hosts that are communicating through the tunnel that they need to send smaller packets.

You can configure the Cisco ASA to change the maximum segment size (MSS) for any new TCP flows through the tunnel. The ASA looks at any TCP packets where the SYN flag is set and changes the MSS value to the configured value. This configuration might help new TCP flows avoid using path maximum transmission unit discovery (PMTUD).

Use the following command to change the MSS. This command is not part of the sample configuration in the CPE Configuration section of this topic. Apply the TCP MSS adjustment command manually, if needed.

```
sysopt connection tcpmss 1387
```

OPTION 2: CLEAR/SET THE DON'T FRAGMENT BIT

Path MTU discovery requires that all TCP packets have the **Don't Fragment** (DF) bit set. If the DF bit is set and a packet is too large to go through the tunnel, the ASA drops the packet when it arrives. The ASA sends an ICMP packet back to the sender indicating that the received packet was too large for the tunnel. The ASA offers three options for handling the DF bit. Choose one of the options and apply it to the configuration:

- **Set the DF bit (recommended):** Packets have the DF bit set in their IP header. The ASA may still fragment the packet if the original received packet cleared the DF bit.

  ```
  crypto ipsec df-bit set-df ${outsideInterface}
  ```

- **Clear the DF bit:** The DF bit is cleared in the packet's IP header. Allows the packet to be fragmented and sent to the end host in Oracle Cloud Infrastructure for reassembly.

  ```
  crypto ipsec df-bit clear-df ${outsideInterface}
  ```

- **Ignore (copy) the DF bit**: The ASA looks at the original packet's IP header information and copies the DF bit setting.

  ```
  crypto ipsec df-bit copy-df ${outsideInterface}
  ```

VPN Traffic Might Enter One Tunnel and Exit Another

If VPN traffic enters an interface with the same security level as an interface toward the packet's next hop, you must allow that traffic. By default, the packets between interfaces that have identical security levels on your ASA are dropped.

Add the following command manually if you need to permit traffic between interfaces with the same security levels. This command is not part of the sample configuration in the CPE Configuration section.

```
same-security-traffic permit inter-interface
```

General Caveats and Limitations

This section covers general characteristics and limitations of VPN Connect.

Asymmetric Routing

Oracle uses asymmetric routing across the multiple tunnels that make up the IPSec connection. Configure your firewalls accordingly. Otherwise, ping tests or application traffic across the connection will not reliably work.

When you use multiple tunnels to Oracle Cloud Infrastructure, Oracle recommends that you configure your routing to deterministically route traffic through the preferred tunnel. If you want to use one IPSec tunnel as primary and another as backup, configure more-specific routes for the primary tunnel (BGP) and less-specific routes (summary or default route) for the backup tunnel (BGP/static). Otherwise, if you advertise the same route (for example, a default route) through all tunnels, return traffic from your VCN to your on-premises network will route to any of the available tunnels (because Oracle uses asymmetric routing).

For specific Oracle routing recommendations about how to force symmetric routing, see Preferring a Specific Tunnel in the IPSec VPN.

Route-Based or Policy-Based IPSec VPN

The IPSec protocol uses Security Associations (SAs) to determine how to encrypt packets. Within each SA, you define encryption domains to map a packet's source and destination IP address and protocol type to an entry in the SA database to define how to encrypt or decrypt a packet.

Note

Other vendors or industry documentation might use the term *proxy ID, security parameter index (SPI)*, or *traffic selector* when referring to SAs or encryption domains.

There are two general methods for implementing IPSec tunnels:

- **Route-based tunnels:** Also called *next-hop-based tunnels*. A route table lookup is performed on a packet's destination IP address. If that route's egress interface is an IPSec tunnel, the packet is encrypted and sent to the other end of the tunnel.
- **Policy-based tunnels:** The packet's source and destination IP address and protocol are matched against a list of policy statements. If a match is found, the packet is encrypted based on the rules in that policy statement.

The Oracle VPN headends use route-based tunnels but can work with policy-based tunnels with some caveats listed in the following sections.

Important

The Oracle VPN headend supports only a single encryption domain. If your policy includes multiple entries, the tunnel will flap or there will be connectivity problems in which only a single policy works at any one time.

Encryption domain for route-based tunnels

If your CPE supports route-based tunnels, use that method to configure the tunnel. It's the simplest configuration with the most interoperability with the Oracle VPN headend.

Route-based IPSec uses an encryption domain with the following values:

- **Source IP address:** Any (0.0.0.0/0)
- **Destination IP address:** Any (0.0.0.0/0)
- **Protocol:** IPv4

If you need to be more specific, you can use a single summary route for your encryption domain values instead of a default route.

Encryption domain for policy-based tunnels

If your CPE supports only policy-based tunnels, there are restrictions on the policy that you can use on the CPE.

When you use policy-based tunnels, every policy entry that you define generates a pair of IPSec SAs. This pair is referred to as an *encryption domain*.

Important

The Oracle VPN headend supports only a single encryption domain. If your policy includes multiple entries, the tunnel will flap or there will be connectivity problems in which only a single policy works at any one time.

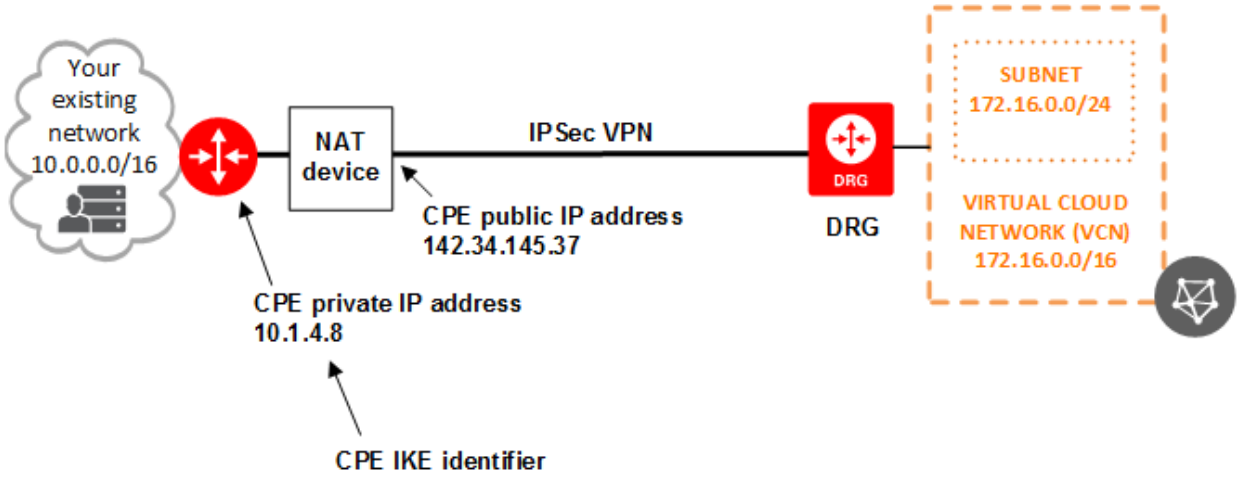
If you use policy-based IPSec, Oracle recommends using a *single encryption domain* with the following values:

- **Source IP address:** Any (0.0.0.0/0)
- **Destination IP address:** VCN CIDR (example: 10.120.0.0/20)
- **Protocol:** IPv4

Make sure the single encryption domain matches any traffic that needs to go from your on-premises network across the IPSec tunnel to the VCN. The VCN CIDR must not overlap with your on-premises network.

If Your CPE Is Behind a NAT Device

In general, the CPE IKE identifier configured on your end of the connection must match the CPE IKE identifier that Oracle is using. By default, Oracle uses the CPE's *public* IP address, which you provide when you create the CPE object in the Oracle Console. However, if your CPE is behind a NAT device, the CPE IKE identifier configured on your end might be the CPE's *private* IP address, as show in the following diagram.



Note

Some CPE platforms do not allow you to change the local IKE identifier. If you cannot, you must change the remote IKE ID in the Oracle Console to match your CPE's local IKE ID. You can provide the value either when you set up the IPSec connection, or later, by editing the IPSec connection. Oracle expects the value to be either an IP address or a fully qualified domain name (FQDN) such as *cpe.example.com*. For instructions, see Changing the CPE IKE Identifier That Oracle Uses.

Supported IPSec Parameters

For a vendor-neutral list of supported IPSec parameters for all regions, see Supported IPSec Parameters.

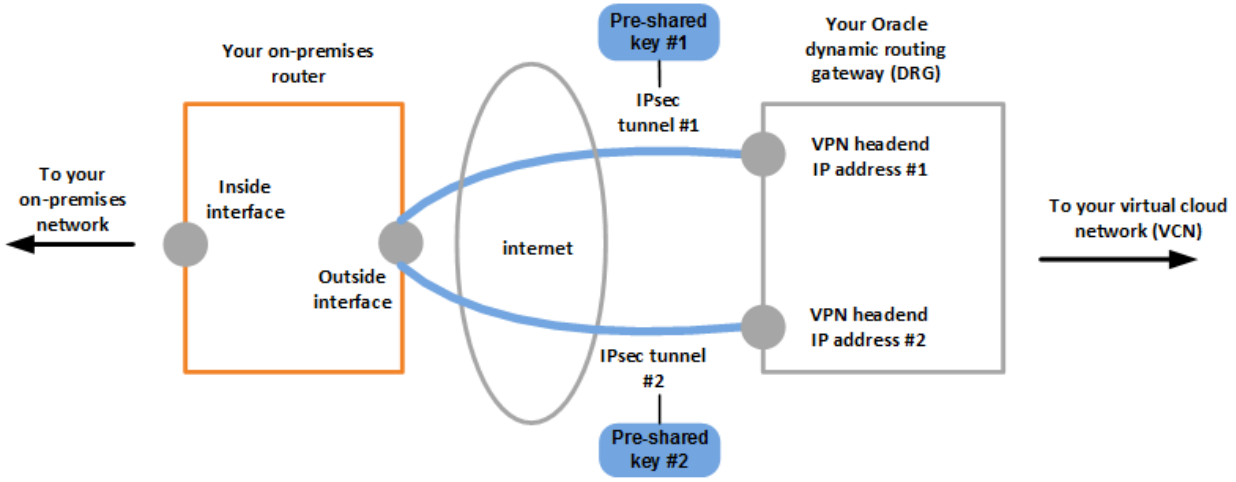
The Oracle BGP ASN for the commercial cloud is 31898. If you're configuring VPN Connect for the Government Cloud, see Required VPN Connect Parameters for Government Cloud and also Oracle's BGP ASN.

CPE Configuration

Important

The configuration instructions in this section are provided by Oracle Cloud Infrastructure for your CPE. If you need support or further assistance, contact your CPE vendor's support directly.

The following figure shows the basic layout of the IPSec connection.



The configuration template provided is for a Cisco router running Cisco ASA 9.7.1 software (or later). The template provides information for each tunnel that you must configure. Oracle recommends setting up all configured tunnels for maximum redundancy.

The configuration template refers to these items that you must provide:

- **CPE public IP address:** The internet-routable IP address that is assigned to the external interface on the CPE. You or your Oracle administrator provides this value to Oracle when creating the CPE object in the Oracle Console.
- **Inside tunnel interface (required if using BGP):** The IP addresses for the CPE and Oracle ends of the inside tunnel interface. You provide these values when creating the IPSec connection in the Oracle Console.
- **BGP ASN (required if using BGP):** Your BGP ASN.

In addition, you must:

- Configure internal routing that routes traffic between the CPE and your local network.
- Ensure that you permit traffic between your ASA and your Oracle VCN.

- Identify the IPSec profile used (the following configuration template references this group policy as `oracle-vcn-vpn-policy`).
- Identify the transform set used for your crypto map (the following configuration template references this transform set as `oracle-vcn-transform`).
- Identify the virtual tunnel interface names used (the following configuration template references these as variables `${tunnelInterfaceName1}` and `${tunnelInterfaceName2}`).

Important

This following configuration template from Oracle Cloud Infrastructure **is a starting point for what you need to apply to your CPE.** Some of the parameters referenced in the template must be unique on the CPE, and the uniqueness can only be determined by accessing the CPE. Ensure that the parameters are valid on your CPE and do not overwrite any previously configured values. In particular, ensure these values are unique:

- Policy names or numbers
- Interface names or numbers
- Access list numbers (if applicable)

Oracle supports Internet Key Exchange version 1 (IKEv1) and version 2 (IKEv2). If you configure the IPSec connection in the Console to use IKEv2, you must configure your CPE to use only IKEv2 and related IKEv2 encryption parameters that your CPE supports. For a list of parameters that Oracle supports for IKEv1 or IKEv2, see Supported IPSec Parameters.

There's a separate configuration template for IKEv1 versus IKEv2.

IKEv1 Configuration Template

```
!-----------------------------------------------------------------------------------------------------------
-------------------------------------------------------
! IKEv1 Configuration Template
! The configuration consists of two IPSec tunnels. Oracle highly recommends that you configure both
tunnels for maximum redundancy.
!-----------------------------------------------------------------------------------------------------------
-------------------------------------------------------
! The configuration template involves setting up the following:
! ISAKMP Policy
! IPSec Configuration
! IPSec Tunnel Group Configuration
! VTI Interface Configuration
! IP Routing (BGP or Static)
!-----------------------------------------------------------------------------------------------------------
-------------------------------------------------------
! The configuration template has various parameters that you must define before applying the
configuration.
!-----------------------------------------------------------------------------------------------------------
-------------------------------------------------------
! PARAMETERS REFERENCED:
! ${OracleInsideTunnelIpAddress1} = Inside tunnel IP address of Oracle-side for the first tunnel. You
provide these values when creating the IPSec connection in the Oracle Console.
! ${OracleInsideTunnelIpAddress2} = Inside tunnel IP address of Oracle-side for the second tunnel. You
provide these values when creating the IPSec connection in the Oracle Console.
! ${bgpASN} = Your BGP ASN
! ${cpePublicIpAddress} = The public IP address for the CPE. This is the IP address of your outside
interface
! ${oracleHeadend1} = Oracle public IP endpoint obtained from the Oracle Console.
! ${oracleHeadend2} = Oracle public IP endpoint obtained from the Oracle Console.
! ${sharedSecret1} = You provide when you set up the IPSec connection in the Oracle Console, or you can
use the default Oracle-provided value.
! ${sharedSecret2} = You provide when you set up the IPSec connection in the Oracle Console, or you can
use the default Oracle-provided value.
! ${outsideInterface} = The public interface or outside of tunnel interface which is configured with the
CPE public IP address.
! ${tunnelInterfaceName1} = The name of the first VTI used on your ASA.
! ${tunnelInterfaceName2} = The name of the second VTI used on your ASA.
! ${cpeInsideTunnelIpAddress1} = The CPE's inside tunnel IP for the first tunnel.
```

```
! ${cpeInsideTunnelIpAddress2} = The CPE's inside tunnel IP for the second tunnel.
! ${cpeInsideTunnelNetmask1} = The CPE's inside tunnel netmask for the first tunnel.
! ${cpeInsideTunnelNetmask2} = The CPE's inside tunnel netmask for the second tunnel.
! ${vcnCidrNetwork} = VCN IP range
! ${vcnCidrNetmask} = Subnet mask for VCN
! ${onPremCidrNetwork} = On-premises IP range
! ${onPremCidrNetmask} = ON-premises subnet mask
!-----------------------------------------------------------------------------------------------------
-----------------------------------------------------

! ISAKMP Policy

! ISAKMP Phase 1 configuration.
! IKEv1 is enabled on the outside interface.
! IKEv1 policy is created for Phase 1 which specifies to use a Pre-Shared Key, AES256, SHA1, Diffie-
Hellman Group 5, and a Phase 1 lifetime of 28800 seconds (8 hours).
! If different parameters are required, modify this template before applying the configuration.
! WARNING: The IKEv1 group policy is created with a priority of 10. Make sure this doesn't conflict with
any pre-existing configuration on your ASA.

crypto ikev1 enable ${outsideInterface}

crypto ikev1 policy 10
  authentication pre-share
  encryption aes-256
  hash sha
  group 5
  lifetime 28800

! IPSec Configuration

! Create an IKEv1 transform set named 'oracle-vcn-transform' which defines a combination of IPSec (Phase
2) policy options. Specifically, AES256 for encryption and SHA1 for authentication.
! If different parameters are required, modify this template before applying the configuration.

crypto ipsec ikev1 transform-set oracle-vcn-transform esp-aes-256 esp-sha-hmac

! A IPSec profile named 'oracle-vcn-vpn-policy' is created.
! The previously created transform set is added to this policy along with settings for enabling PFS
Group 5 and the security association lifetime to 3600 seconds (1 hour).
! If different parameters are required, modify this template before applying the configuration.
```

```
crypto ipsec profile oracle-vcn-vpn-policy
 set ikev1 transform-set oracle-vcn-transform
 set pfs group5
 set security-association lifetime seconds 3600

! IPSec Tunnel Group Configuration

! A tunnel group is created for each Oracle VPN Headend. Each tunnel group defines the pre-shared key
used for each respective tunnel.

tunnel-group ${oracleHeadend1} type ipsec-l2l
tunnel-group ${oracleHeadend1} ipsec-attributes
  ikev1 pre-shared-key ${sharedSecret1}

tunnel-group ${oracleHeadend2} type ipsec-l2l
tunnel-group ${oracleHeadend2} ipsec-attributes
 ikev1 pre-shared-key ${sharedSecret2}

! VTI Interface Configuration

! A virtual tunnel interface (VTI) is a logical interface representing the local end of a VPN tunnel to
a remote VPN peer. Two VTIs are created representing two tunnels, one to each Oracle VPN Headend. The IP
address of each VPN headend is provided when you create your IPSec connection in Oracle Console.
! All traffic routed to a VTI will be encrypted and sent across the tunnel towards Oracle Cloud
Infrastructure.
! Each VTI configuration also references the previously created IPSec profile 'oracle-vcn-vpn-policy'
for its IPSec parameters.

interface ${tunnelInterfaceName1}
  nameif ORACLE-VPN1
  ip address ${cpeInsideTunnelIpAddress1} ${cpeInsideTunnelNetmask1}
  tunnel source interface ${outsideInterface}
  tunnel destination ${oracleHeadend1}
  tunnel mode ipsec ipv4
  tunnel protection ipsec profile oracle-vcn-vpn-policy

interface ${tunnelInterfaceName2}
  nameif ORACLE-VPN2
  ip address ${cpeInsideTunnelIpAddress2} ${cpeInsideTunnelNetmask2}
  tunnel source interface ${outsideInterface}
```

```
  tunnel destination ${oracleHeadend2}
  tunnel mode ipsec ipv4
  tunnel protection ipsec profile oracle-vcn-vpn-policy

! IP Routing
! Pick either dynamic (BGP) or static routing. Uncomment the corresponding commands prior to applying
configuration.

! Border Gateway Protocol (BGP) Configuration
! Uncomment below lines if you want to use BGP.

! router bgp ${bgpASN}
!  address-family ipv4 unicast
!   neighbor ${OracleInsideTunnelIpAddress1} remote-as 31898
!   neighbor ${OracleInsideTunnelIpAddress1} activate
!   neighbor ${OracleInsideTunnelIpAddress2} remote-as 31898
!   neighbor ${OracleInsideTunnelIpAddress2} activate
!   network ${onPremCidrNetwork} mask ${onPremCidrNetmask}
!   no auto-summary
!   no synchronization
!  exit-address-family

! Static Route Configuration
! Each static route references the other VTI by its nameif value.
! Uncomment below line if you want to use static routing.

! route ORACLE-VPN1 ${VcnCidrNetwork} ${VcnCidrNetmask} ${OracleInsideTunnelIpAddress1} 1 track
! route ORACLE-VPN2 ${VcnCidrNetwork} ${VcnCidrNetmask} ${OracleInsideTunnelIpAddress2} 100

! Configuration for Tunnel Failover

! Uncomment the below IP SLA lines if using static routing.
! Use this IP SLA configuration for static route failover This IP SLA configuration is used for static
route failover between the two tunnels.
! Make sure that the SLA monitor and tracking numbers used do not conflict with any existing
configuration on your ASA.

! sla monitor 10
!  type echo protocol ipIcmpEcho ${oracleHeadend1} interface outside
!  frequency 5
!  sla monitor schedule 10 life forever start-time now
```

```
! track 1 rtr 10 reachability
```

IKEv2 Configuration Template

```
!-------------------------------------------------------------------------------------------------------------
-------------------------------------------------------
! IKEv2 Configuration Template
! The configuration consists of two IPSec tunnels. Oracle highly recommends that you configure both
tunnels for maximum redundancy.
!-------------------------------------------------------------------------------------------------------------
-------------------------------------------------------
! The configuration template involves setting up the following:
! IKEv2 Policy
! IPSec Configuration
! IPSec Tunnel Group Configuration
! VTI Interface Configuration
! IP Routing (BGP or Static)
!-------------------------------------------------------------------------------------------------------------
-------------------------------------------------------
! The configuration template has various parameters that you must define before applying the
configuration.
!-------------------------------------------------------------------------------------------------------------
-------------------------------------------------------
! PARAMETERS REFERENCED:
! ${OracleInsideTunnelIpAddress1} = Inside tunnel IP address of Oracle-side for the first tunnel. You
provide these values when creating the IPSec connection in the Oracle Console.
! ${OracleInsideTunnelIpAddress2} = Inside tunnel IP address of Oracle-side for the second tunnel. You
provide these values when creating the IPSec connection in the Oracle Console.
! ${bgpASN} = Your BGP ASN
! ${cpePublicIpAddress} = The public IP address for the CPE. This is the IP address of your outside
interface
! ${oracleHeadend1} = Oracle public IP endpoint obtained from the Oracle Console.
! ${oracleHeadend2} = Oracle public IP endpoint obtained from the Oracle Console.
! ${sharedSecret1} = You provide when you set up the IPSec connection in the Oracle Console, or you can
use the default Oracle-provided value.
! ${sharedSecret2} = You provide when you set up the IPSec connection in the Oracle Console, or you can
use the default Oracle-provided value.
! ${outsideInterface} = The public interface or outside of tunnel interface which is configured with the
CPE public IP address.
```

```
! ${tunnelInterfaceName1} = The name of the first VTI used on your ASA.
! ${tunnelInterfaceName2} = The name of the second VTI used on your ASA.
! ${cpeInsideTunnelIpAddress1} = The CPE's inside tunnel IP for the first tunnel.
! ${cpeInsideTunnelIpAddress2} = The CPE's inside tunnel IP for the second tunnel.
! ${cpeInsideTunnelNetmask1} = The CPE's inside tunnel netmask for the first tunnel.
! ${cpeInsideTunnelNetmask2} = The CPE's inside tunnel netmask for the second tunnel.
! ${vcnCidrNetwork} = VCN IP range
! ${vcnCidrNetmask} = Subnet mask for VCN
! ${onPremCidrNetwork} = On-premises IP range
! ${onPremCidrNetmask} = ON-premises subnet mask
!-----------------------------------------------------------------------------------------------------
-------------------------------------------------------

! IKEv2 Policy

! IKEv2 is enabled on the outside interface.
! IKEv2 policy is created and specifies use of a Pre-Shared Key, AES256, SHA1, Diffie-Hellman Group 5,
and a lifetime of 28800 seconds (8 hours).
! If different parameters are required, modify this template before applying the configuration.
! WARNING: The IKEv2 group policy is created with a priority of 10. Make sure this doesn't conflict with
any pre-existing configuration on your ASA.

crypto ikev2 enable ${outsideInterface}

crypto ikev2 policy 10
 encryption aes-256
 integrity sha
 group 5
 prf sha
 lifetime seconds 28800

! IPSec Configuration

! Create an IKEv2 IPSec proposal named 'oracle_v2_ipsec_proposal' which defines AES256 for encryption
and SHA1 for authentication.
! If different parameters are required, modify this template before applying the configuration.

crypto ipsec ikev2 ipsec-proposal oracle_v2_ipsec_proposal
 protocol esp encryption aes-256
 protocol esp integrity sha-1
```

```
! An IPSec profile named 'oracle-vcn-vpn-policy' is created.
! The previously created IPSec proposal is added to this policy along with settings for enabling PFS
Group 5 and the security association lifetime to 3600 seconds (1 hour).
! If different parameters are required, modify this template before applying the configuration.

crypto ipsec profile oracle-vcn-vpn-policy
 set ikev2 ipsec-proposal oracle_v2_ipsec_proposal
 set pfs group5
 set security-association lifetime seconds 3600

! IPSec Tunnel Group Configuration

group-policy oracle_v2_group_policy internal
group-policy oracle_v2_group_policy attributes
 vpn-tunnel-protocol ikev2

! A tunnel group is created for each Oracle VPN Headend. Each tunnel group defines the pre-shared key
used for each respective tunnel.

tunnel-group ${oracleHeadend1} type ipsec-l2l

!   neighbor ${OracleInsideTunnelIpAddress2} activate
!   network ${onPremCidrNetwork} mask ${onPremCidrNetmask}
!   no auto-summary
!   no synchronization
!  exit-address-family

! Static Route Configuration
! Each static route references the other VTI by its nameif value.
! Uncomment below line if you want to use static routing.

! route ORACLE-VPN1 ${VcnCidrNetwork} ${VcnCidrNetmask} ${OracleInsideTunnelIpAddress1} 1 track
```

```
! route ORACLE-VPN2 ${VcnCidrNetwork} ${VcnCidrNetmask} ${OracleInsideTunnelIpAddress2} 100

! Configuration for Tunnel Failover

! Uncomment the below IP SLA lines if using static routing.
! Use this IP SLA configuration for static route failover This IP SLA configuration is used for static
route failover between the two tunnels.
! Make sure that the SLA monitor and tracking numbers used do not conflict with any existing
configuration on your ASA.

! sla monitor 10
!  type echo protocol ipIcmpEcho ${oracleHeadend1} interface outside
!  frequency 5
!  sla monitor schedule 10 life forever start-time now

! track 1 rtr 10 reachability
```

Verification

The following ASA commands are included for basic troubleshooting. For more exhaustive information, refer to Cisco's IPSec Troubleshooting document.

Use the following command to verify that ISAKMP security associations are being built between the two peers.

```
show crypto isakmp sa
```

Use the following command to verify the status of all your BGP connections.

```
show bgp summary
```

Use the following command to verify the ASA's route table.

```
show route
```

A Monitoring service is also available from Oracle Cloud Infrastructure to actively and passively monitor your cloud resources. For information about monitoring your VPN Connect, see VPN Connect Metrics.

If you have issues, see VPN Connect Troubleshooting.

Cisco ASA: Policy-Based

This topic provides a policy-based configuration for a Cisco ASA that is running software version 8.5 to 9.7.0.

As a reminder, Oracle provides different configurations based on the ASA software:

- **9.7.1 or newer:** Route-based configuration
- **8.5 to 9.7.0:** Policy-based configuration (this topic)
- **Older than 8.5:** Not supported by the Oracle configuration instructions. Consider upgrading to a newer version.

Important

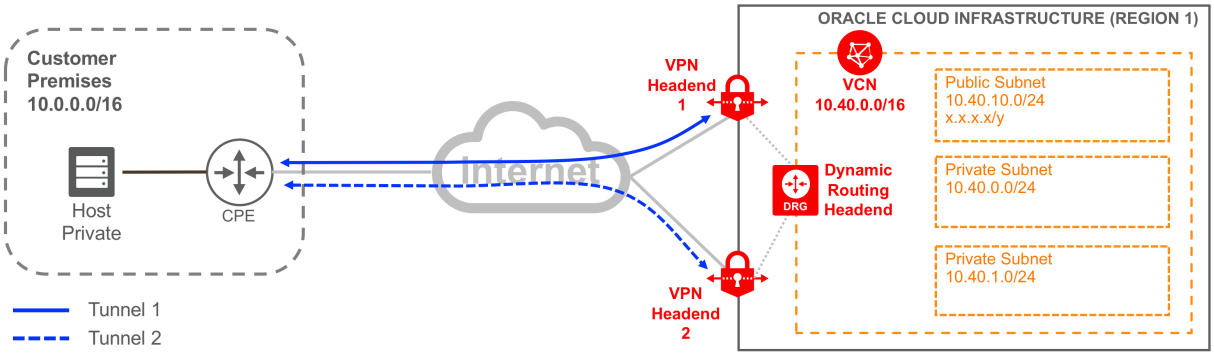
Oracle recommends using a route-based configuration to avoid interoperability issues and to achieve tunnel redundancy with a single Cisco ASA device.

The Cisco ASA does not support route-based configuration for software versions older than 9.7.1. For the best results, if your device allows it, Oracle recommends that you upgrade to a software version that supports route-based configuration.

With policy-based configuration, you can configure only a single tunnel between your Cisco ASA and your dynamic routing gateway (DRG).

VPN Connect is the IPSec VPN that Oracle Cloud Infrastructure offers for connecting your on-premises network to a virtual cloud network (VCN).

The following diagram shows a basic IPSec connection to Oracle Cloud Infrastructure with redundant tunnels. The IP addresses in this diagram are examples only and not for literal use.



Important

Oracle provides configuration instructions for a set of vendors and devices. Make sure to use the configuration for the correct vendor.

If the device or software version that Oracle used to verify the configuration does not exactly match your device or software, the configuration might still work for you. Consult your vendor's documentation and make any necessary adjustments.

If your device is for a vendor not in the list of verified vendors and devices, or if you're already familiar with configuring your device for IPSec, see the list of supported IPSec parameters and consult your vendor's documentation for assistance.

Best Practices

This section covers best practices and considerations for using VPN Connect.

Specific to Cisco ASA: VPN filters

VPN filters let you further filter traffic either before it enters or after it exits a tunnel. Use VPN filters if you need additional granularity for filtering different traffic types or source/destination flows. For more information, see Cisco's VPN Filter documentation.

VPN filter configuration is not included in the configuration template that appears in the CPE Configuration section. To use VPN filters, add the following configuration items manually.

- **Access control list (ACL):** Create an ACL that the VPN filter can use to restrict the traffic permitted through the tunnels. If you have an ACL already used for a VPN filter, do not also use it for an interface access group.

```
access-list ${vpnFilterAclName} extended permit ip ${VcnCidrNetwork} ${VcnCidrNetmask}
${onPremCidrNetwork} ${onPremCidrNetmask}
```

- **Group policy:** Apply the VPN filter to your group policy.

```
group-policy oracle-vcn-vpn-policy attributes
 vpn-filter value ${vpnFilterAclName}
```

- **Tunnel group:** Apply the group policy to your tunnel group.

```
tunnel-group ${oracleHeadend1} general-attributes
 default-group-policy oracle-vcn-vpn-policy
```

Configure All Tunnels for Every IPSec Connection

Oracle deploys two IPSec headends for each of your connections to provide high availability for your mission-critical workloads. On the Oracle side, these two headends are on different routers for redundancy purposes. Oracle recommends configuring all available tunnels for maximum redundancy. This is a key part of the "Design for Failure" philosophy.

Have Redundant CPEs in Your On-Premises Network Locations

Each of your sites that connects with IPSec to Oracle Cloud Infrastructure should have redundant edge devices (also known as customer-premises equipment (CPE)). You add each CPE to the Oracle Console and create a separate IPSec connection between your dynamic routing gateway (DRG) and each CPE. For each IPSec connection, Oracle provisions two

tunnels on geographically redundant IPSec headends. For more information, see the Connectivity Redundancy Guide (PDF).

Routing Protocol Considerations

When you create an IPSec VPN, it has two redundant IPSec tunnels. Oracle encourages you to configure your CPE to use both tunnels (if your CPE supports it). Note that in the past, Oracle created IPSec VPNs that had up to four IPSec tunnels.

The following two routing types are available, and you choose the routing type separately for each tunnel in the IPSec VPN:

- **BGP dynamic routing:** The available routes are learned dynamically through BGP. The DRG dynamically learns the routes from your on-premises network. On the Oracle side, the DRG advertises the VCN's subnets.
- **Static routing:** When you set up the IPSec connection to the DRG, you specify the particular routes to your on-premises network that you want the VCN to know about. You also must configure your CPE device with static routes to the VCN's subnets. These routes are not learned dynamically.

For more information about routing with VPN Connect, including Oracle recommendations on how to manipulate the BGP best path selection algorithm, see Routing for the Oracle IPSec VPN.

Other Important CPE Configurations

Ensure access lists on your CPE are configured correctly to not block necessary traffic from or to Oracle Cloud Infrastructure.

If you have multiple tunnels up simultaneously, ensure that your CPE is configured to handle traffic coming from your VCN on any of the tunnels. For example, you need to disable ICMP inspection, configure TCP state bypass, and so on. For more details about the appropriate configuration, contact your CPE vendor's support.

Specific to Cisco ASA: Caveats and Limitations

This section covers important characteristics and limitations that are specific to Cisco ASA.

TUNNEL MTU AND PATH MTU DISCOVERY

You have two options for addressing tunnel MTU and path MTU discovery with Cisco ASA:

- Option 1: TCP MSS adjustment
- Option 2: Clear/set the Don't Fragment bit

OPTION 1: TCP MSS ADJUSTMENT

The maximum transmission unit (packet size) through the IPSec tunnel is less than 1500 bytes. You can fragment packets that are too large to fit through the tunnel. Or, you can signal back to the hosts that are communicating through the tunnel that they need to send smaller packets.

You can configure the Cisco ASA to change the maximum segment size (MSS) for any new TCP flows through the tunnel. The ASA looks at any TCP packets where the SYN flag is set and changes the MSS value to the configured value. This configuration might help new TCP flows avoid using path maximum transmission unit discovery (PMTUD).

Use the following command to change the MSS. This command is not part of the sample configuration in the CPE Configuration section of this topic. Apply the TCP MSS adjustment command manually, if needed.

```
sysopt connection tcpmss 1387
```

OPTION 2: CLEAR/SET THE DON'T FRAGMENT BIT

Path MTU discovery requires that all TCP packets have the **Don't Fragment** (DF) bit set. If the DF bit is set and a packet is too large to go through the tunnel, the ASA drops the packet when it arrives. The ASA sends an ICMP packet back to the sender indicating that the received packet was too large for the tunnel. The ASA offers three options for handling the DF bit. Choose one of the options and apply it to the configuration:

- **Set the DF bit (recommended):** Packets have the DF bit set in their IP header. The ASA may still fragment the packet if the original received packet cleared the DF bit.

  ```
  crypto ipsec df-bit set-df ${outsideInterface}
  ```

- **Clear the DF bit:** The DF bit is cleared in the packet's IP header. Allows the packet to

be fragmented and sent to the end host in Oracle Cloud Infrastructure for reassembly.

```
crypto ipsec df-bit clear-df ${outsideInterface}
```

- **Ignore (copy) the DF bit**: The ASA looks at the original packet's IP header information and copies the DF bit setting.

```
crypto ipsec df-bit copy-df ${outsideInterface}
```

VPN Traffic Might Enter One Tunnel and Exit Another

If VPN traffic enters an interface with the same security level as an interface toward the packet's next hop, you must allow that traffic. By default, the packets between interfaces that have identical security levels on your ASA are dropped.

Add the following command manually if you need to permit traffic between interfaces with the same security levels. This command is not part of the sample configuration in the CPE Configuration section.

```
same-security-traffic permit inter-interface
```

General Caveats and Limitations

This section covers general characteristics and limitations of VPN Connect.

Asymmetric Routing

Oracle uses asymmetric routing across the multiple tunnels that make up the IPSec connection. Configure your firewalls accordingly. Otherwise, ping tests or application traffic across the connection will not reliably work.

When you use multiple tunnels to Oracle Cloud Infrastructure, Oracle recommends that you configure your routing to deterministically route traffic through the preferred tunnel. If you want to use one IPSec tunnel as primary and another as backup, configure more-specific routes for the primary tunnel (BGP) and less-specific routes (summary or default route) for the backup tunnel (BGP/static). Otherwise, if you advertise the same route (for example, a default route) through all tunnels, return traffic from your VCN to your on-premises network will route to any of the available tunnels (because Oracle uses asymmetric routing).

For specific Oracle routing recommendations about how to force symmetric routing, see Preferring a Specific Tunnel in the IPSec VPN.

ROUTE-BASED OR POLICY-BASED IPSEC VPN

The IPSec protocol uses Security Associations (SAs) to determine how to encrypt packets. Within each SA, you define encryption domains to map a packet's source and destination IP address and protocol type to an entry in the SA database to define how to encrypt or decrypt a packet.

Note

Other vendors or industry documentation might use the term *proxy ID, security parameter index (SPI)*, or *traffic selector* when referring to SAs or encryption domains.

There are two general methods for implementing IPSec tunnels:

- **Route-based tunnels:** Also called *next-hop-based tunnels*. A route table lookup is performed on a packet's destination IP address. If that route's egress interface is an IPSec tunnel, the packet is encrypted and sent to the other end of the tunnel.
- **Policy-based tunnels:** The packet's source and destination IP address and protocol are matched against a list of policy statements. If a match is found, the packet is encrypted based on the rules in that policy statement.

The Oracle VPN headends use route-based tunnels but can work with policy-based tunnels with some caveats listed in the following sections.

Important

The Oracle VPN headend supports only a single encryption domain. If your policy includes multiple entries, the tunnel will flap or there will be connectivity problems in which only a single policy works at any one time.

Encryption domain for route-based tunnels

If your CPE supports route-based tunnels, use that method to configure the tunnel. It's the simplest configuration with the most interoperability with the Oracle VPN headend.

Route-based IPSec uses an encryption domain with the following values:

- **Source IP address:** Any (0.0.0.0/0)
- **Destination IP address:** Any (0.0.0.0/0)
- **Protocol:** IPv4

If you need to be more specific, you can use a single summary route for your encryption domain values instead of a default route.

Encryption domain for policy-based tunnels

If your CPE supports only policy-based tunnels, there are restrictions on the policy that you can use on the CPE.

When you use policy-based tunnels, every policy entry that you define generates a pair of IPSec SAs. This pair is referred to as an *encryption domain*.

Important

The Oracle VPN headend supports only a single encryption domain. If your policy includes multiple entries, the tunnel will flap or there will be connectivity problems in which only a single policy works at any one time.

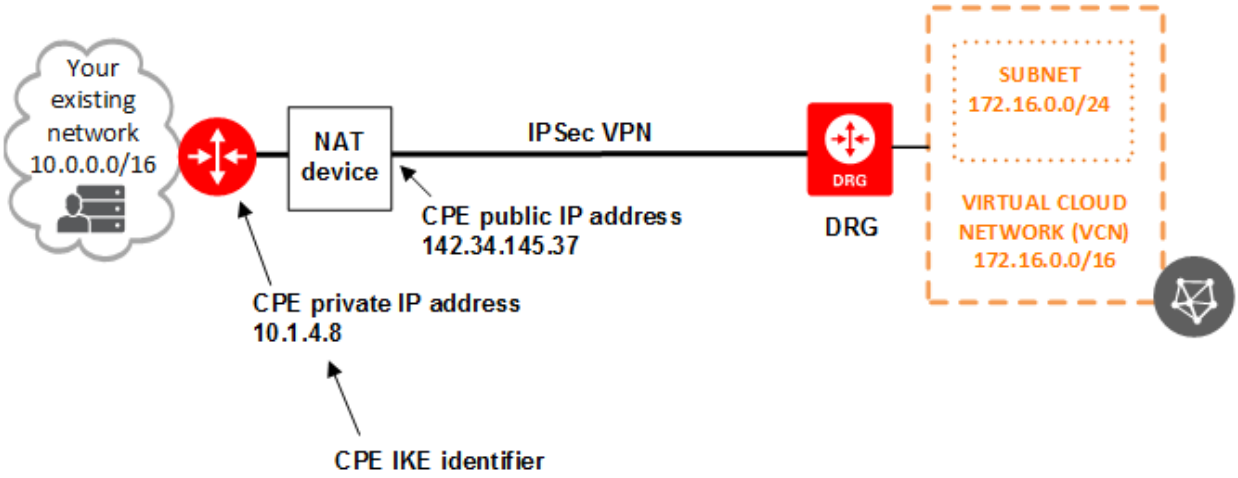
If you use policy-based IPSec, Oracle recommends using a *single encryption domain* with the following values:

- **Source IP address:** Any (0.0.0.0/0)
- **Destination IP address:** VCN CIDR (example: 10.120.0.0/20)
- **Protocol:** IPv4

Make sure the single encryption domain matches any traffic that needs to go from your on-premises network across the IPSec tunnel to the VCN. The VCN CIDR must not overlap with your on-premises network.

If Your CPE Is Behind a NAT Device

In general, the CPE IKE identifier configured on your end of the connection must match the CPE IKE identifier that Oracle is using. By default, Oracle uses the CPE's *public* IP address, which you provide when you create the CPE object in the Oracle Console. However, if your CPE is behind a NAT device, the CPE IKE identifier configured on your end might be the CPE's *private* IP address, as show in the following diagram.



Note

Some CPE platforms do not allow you to change the local IKE identifier. If you cannot, you must change the remote IKE ID in the Oracle Console to match your CPE's local IKE ID. You can provide the value either when you set up the IPSec connection, or later, by editing the IPSec connection. Oracle expects the value to be either an IP address or a fully qualified domain name (FQDN) such as *cpe.example.com*. For instructions, see Changing the CPE IKE Identifier That Oracle Uses.

Supported IPSec Parameters

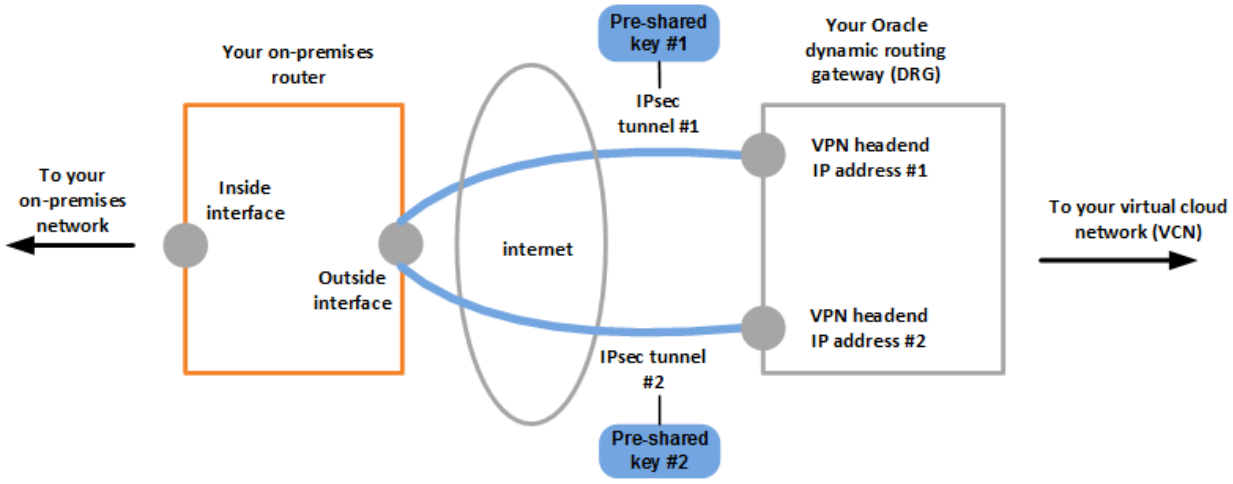
For a vendor-neutral list of supported IPSec parameters for all regions, see Supported IPSec Parameters.

The Oracle BGP ASN for the commercial cloud is 31898. If you're configuring VPN Connect for the Government Cloud, see Required VPN Connect Parameters for Government Cloud and also Oracle's BGP ASN.

CPE Configuration

> **Important**
>
> The configuration instructions in this section are provided by Oracle Cloud Infrastructure for your CPE. If you need support or further assistance, contact your CPE vendor's support directly.

The following figure shows the basic layout of the IPSec connection.



The configuration template provided is for a Cisco ASA running version 8.5 software (or later).

Note

Cisco ASA versions 9.7.1 and newer support route-based configuration, which is the recommended method to avoid interoperability issues.

If you want tunnel redundancy with a single Cisco ASA device, you must use the route-based configuration. With policy-based configuration, you can configure only a single tunnel between your Cisco ASA and your dynamic routing gateway (DRG).

The configuration template refers to these items that you must provide:

- **CPE public IP address:** The internet-routable IP address that is assigned to the external interface on the CPE. You or your Oracle administrator provides this value to Oracle when creating the CPE object in the Oracle Console.
- **Inside tunnel interface (required if using BGP):** The IP addresses for the CPE and Oracle ends of the inside tunnel interface. You provide these values when creating the IPSec connection in the Oracle Console.
- **BGP ASN (required if using BGP):** Your BGP ASN.

In addition, you must:

- Configure internal routing that routes traffic between the CPE and your local network.
- Ensure that you permit traffic between your ASA and your Oracle VCN (the following configuration template references this access list with the variable `${outboundAclName}`).
- Identify the internal VPN group policy (the following configuration template references this group policy as `oracle-vcn-vpn-policy`).
- Identify the transform set used for your crypto map (the following configuration template references this transform set as `oracle-vcn-transform`).

- Identify the crypto map name and sequence number (the following configuration template references the map name as `oracle-vpn-map-v1` and sequence number 1).
- Identify the operation number for IP SLA continuous ping (the following configuration template uses operation number 1).

Important

This following configuration template from Oracle Cloud Infrastructure **is a starting point for what you need to apply to your CPE.** The syntax for each CPE device configuration may be different and depends on the model and software versions. Be sure to compare your CPE model and version to the appropriate configuration template.

Some of the parameters referenced in the template must be unique on the CPE, and the uniqueness can only be determined by accessing the CPE. Ensure that the parameters are valid on your CPE and do not overwrite any previously configured values. In particular, ensure that the following values are unique:

- Policy names or numbers
- Crypto map names and sequence numbers
- Interface names
- Access list names or numbers (if applicable)

Oracle supports Internet Key Exchange version 1 (IKEv1) and version 2 (IKEv2). If you configure the IPSec connection in the Console to use IKEv2, you must configure your CPE to use only IKEv2 and related IKEv2 encryption parameters that your CPE supports. For a list of parameters that Oracle supports for IKEv1 or IKEv2, see Supported IPSec Parameters.

There's a separate configuration template for IKEv1 versus IKEv2.

IKEv1 Configuration Template

```
!-------------------------------------------------------------------------------------------------------------------
-------------------------------------------------------
! IKEv1 Configuration Template
! The configuration consists of a single IPSec tunnel.
!-------------------------------------------------------------------------------------------------------------------
-------------------------------------------------------
! The configuration template involves setting up the following:
! Access Lists
! ISAKMP Policy
! Base VPN Policy
! IPSec Configuration
! IPSec Tunnel Group Configuration
! IP Routing (BGP or Static)
! Optional: Disable NAT for VPN Traffic
!-------------------------------------------------------------------------------------------------------------------
-------------------------------------------------------
! The configuration template has various parameters that you must define before applying the
configuration.
!-------------------------------------------------------------------------------------------------------------------
-------------------------------------------------------
! PARAMETERS REFERENCED:
! ${OracleInsideTunnelIpAddress1} = Inside tunnel IP address of Oracle-side for the first tunnel. You
provide these values when creating the IPSec connection in the Oracle Console.
! ${bgpASN} = Your BGP ASN
! ${cpePublicIpAddress} = The public IP address for the CPE. This is the IP address of your outside
interface
! ${outboundAclName} = ACL used to control traffic out of your inside and outside interfaces
! ${oracleHeadend1} = Oracle public IP endpoint obtained from the Oracle Console.
! ${sharedSecret1} = You provide when you set up the IPSec connection in the Oracle Console, or you can
use the default Oracle-provided value.
! ${outsideInterface} = The public interface or outside of tunnel interface which is configured with the
CPE public IP address.
! ${vcnCidrNetwork} = VCN IP range
! ${vcnCidrNetmask} = Subnet mask for VCN
! ${onPremCidrNetwork} = On-premises IP range
! ${onPremCidrNetmask} = ON-premises subnet mask
! ${cryptoMapAclName} = Name of ACL which will be associated with the IPSec security association.
! ${vcnHostIp} = IP address of a VCN host. Used for IP SLA continuous ping to maintain tunnel UP state.
```

```
!-------------------------------------------------------------------------------------------------------------
-----------------------------------------------------

! Access Lists

! Permit Traffic Between Your ASA and Your Oracle VCN
! Assuming there is an access-list controlling traffic in and out of your Internet facing interface, you
will need to permit traffic between your CPE and the Oracle VPN Headend
! WARNING: The new ACL entry you add to permit the traffic between your ASA and VPN headend needs to be
above any deny statements you might have in your existing access-list

access-list ${outboundAclName} extended permit ip host ${oracleHeadend1} host ${cpePublicIpAddress}

! Crypto ACL
! Create an ACL named ${cryptoMapAclName} which will later be associated with the IPSec security
association using the 'crypto-map' command. This will define which source/destination traffic needs to
be encrypted and sent across the VPN tunnel.
! Keep this ACL to a single entry. In a policy based configuration each ACL line will establish a
separate encryption domain.
! The single encryption domain used in this configuration sample will have a source/destination of
any/VCN CIDR. Refer to the 'Encryption domain for policy-based tunnels' subsection for supported
alternatives.

access-list ${cryptoMapAclName} extended permit ip any ${vcnCidrNetwork} ${vcnCidrNetmask}

! ISAKMP Policy

! ISAKMP Phase 1 configuration.
! IKEv1 is enabled on the outside interface.
! IKEv1 policy is created for Phase 1 which specifies to use a Pre-Shared Key, AES256, SHA1, Diffie-
Hellman Group 5, and a Phase 1 lifetime of 28800 seconds (8 hours).
! If different parameters are required, modify this template before applying the configuration.
! WARNING: The IKEv1 group policy is created with a priority of 10. Make sure this doesn't conflict with
any pre-existing configuration on your ASA.

crypto ikev1 enable outside
crypto ikev1 policy 10
 authentication pre-share
 encryption aes-256
 hash sha
 group 5
```

```
 lifetime 28800

! Base VPN Policy

! An internal VPN group policy named 'oracle-vcn-vpn-policy' is created to define some basic VPN tunnel
settings
! Idle and session timeouts are disabled to maintain the tunnel UP state and tunnel protocol is set to
IKEv1

group-policy oracle-vcn-vpn-policy internal
group-policy oracle-vcn-vpn-policy attributes
 vpn-idle-timeout none
 vpn-session-timeout none
 vpn-tunnel-protocol ikev1

! IPSec Configuration

! Create an IKEv1 transform set named 'oracle-vcn-transform' which defines a combination of IPSec (Phase
2) policy options. Specifically, AES256 for encryption and SHA1 for authentication.
! If different parameters are required, modify this template before applying the configuration.

crypto ipsec ikev1 transform-set oracle-vcn-transform esp-aes-256 esp-sha-hmac

! A crypto map is used to tie together the important traffic that needs encryption (via crypto map ACL)
with defined security policies (from the transform set along with other crypto map statements), and the
destination of the traffic to a specific crypto peer.
! In this configuration example, a single crypto map is created named 'oracle-vpn-map-v1' This crypto
map references the previously created crypto map ACL, the 'oracle-vcn-transform' transform set and
further defines PFS Group 5 and the security association lifetime to 3600 seconds (1 hour).
! WARNING: Make sure your crypto map name and sequence numbers do not overlap with existing crypto maps.
! WARNING: DO NOT use the 'originate-only' option with an Oracle IPSec VPN tunnel. It causes the
tunnel's traffic to be inconsistently blackholed. The command is only for tunnels between two Cisco
devices. Here's an example of the command that you should NOT use for the Oracle IPSec VPN tunnels:
crypto map <map name> <sequence number> set connection-type originate-only

crypto map oracle-vpn-map-v1 1 match address ${cryptoMapAclName}
crypto map oracle-vpn-map-v1 1 set pfs group5
crypto map oracle-vpn-map-v1 1 set peer ${oracleHeadend1}
crypto map oracle-vpn-map-v1 1 set ikev1 transform-set oracle-vcn-transform
crypto map oracle-vpn-map-v1 1 set security-association lifetime seconds 3600
```

```
! WARNING: The below command will apply the 'oracle-vpn-map-v1' crypto map to the outside interface. The
Cisco ASA supports a single crypto map per interface. Make sure no other crypto map is applied to the
outside interface before using this command.

crypto map oracle-vpn-map-v1 interface outside

! IPSec Tunnel Group Configuration

! This configuration matches the group policy 'oracle-vcn-vpn-policy' with an Oracle VPN headend
endpoint.
! The pre-shared key for each Oracle VPN headend is defined in the corresponding tunnel group.

tunnel-group ${oracleHeadend1} type ipsec-l2l
tunnel-group ${oracleHeadend1} general-attributes
 default-group-policy oracle-vcn-vpn-policy
tunnel-group ${oracleHeadend1} ipsec-attributes
 ikev1 pre-shared-key ${sharedSecret1}

! IP SLA Configuration

! The Cisco ASA doesn't establish a tunnel if there's no interesting traffic trying to pass through the
tunnel.
! You must configure IP SLA on your device for a continuous ping so that the tunnel remains up at all
times.
! You must allow ICMP on the outside interface.
! Make sure that the SLA monitor number used is unique.

sla monitor 1
 type echo protocol ipIcmpEcho ${vcnHostIp} interface outside
 frequency 5
sla monitor schedule 1 life forever start-time now

icmp permit any ${outsideInterface}

! IP Routing
! Pick either dynamic (BGP) or static routing. Uncomment the corresponding commands prior to applying
configuration.

! Border Gateway Protocol (BGP) Configuration
! Uncomment below lines if you want to use BGP.
```

```
! router bgp ${bgpASN}
!  address-family ipv4 unicast
!   neighbor ${OracleInsideTunnelIpAddress1} remote-as 31898
!   neighbor ${OracleInsideTunnelIpAddress1} activate
!   network ${onPremCidrNetwork} mask ${onPremCidrNetmask}
!   no auto-summary
!   no synchronization
!  exit-address-family

! Static Route Configuration
! Uncomment below line if you want to use static routing.

! route outside ${VcnCidrNetwork} ${VcnCidrNetmask} ${OracleInsideTunnelIpAddress1}

! Disable NAT for VPN Traffic

! If you are using NAT for traffic between your inside and outside interfaces, you might need to disable
NAT for traffic between your on-premises network and the Oracle VCN.
! Two objects are created for this NAT exemption. 'obj-OnPrem' represents the on-premises network as a
default route, and 'obj-oracle-vcn-1' represents the VCN CIDR block used in Oracle Cloud Infrastructure.
! If different address ranges are required, modify this template before applying the configuration.

! object network obj-onprem
!  subnet 0.0.0.0 0.0.0.0
! object network obj-oracle-vcn-1
!  subnet ${vcnCidrNetwork} ${vcnCidrNetmask}
! nat (inside,outside) source static obj-onprem obj-onprem destination static obj-oracle-vcn-1 obj-
oracle-vcn-1
```

IKEv2 Configuration Template

```
!------------------------------------------------------------------------------------------------------
-------------------------------------------------------

! IKEv2 Configuration Template
! The configuration consists of a single IPSec tunnel.
!------------------------------------------------------------------------------------------------------
-------------------------------------------------------
! The configuration template involves setting up the following:
! Access Lists
```

```
! IKEv2 Policy
! Base VPN Policy
! IPSec Configuration
! IPSec Tunnel Group Configuration
! IP Routing (BGP or Static)
! Optional: Disable NAT for VPN Traffic
!-----------------------------------------------------------------------------------------------------
-----------------------------------------------------
! The configuration template has various parameters that you must define before applying the
configuration.
!-----------------------------------------------------------------------------------------------------
-----------------------------------------------------
! PARAMETERS REFERENCED:
! ${OracleInsideTunnelIpAddress1} = Inside tunnel IP address of Oracle-side for the first tunnel. You
provide these values when creating the IPSec connection in the Oracle Console.
! ${bgpASN} = Your BGP ASN
! ${cpePublicIpAddress} = The public IP address for the CPE. This is the IP address of your outside
interface
! ${outboundAclName} = ACL used to control traffic out of your inside and outside interfaces
! ${oracleHeadend1} = Oracle public IP endpoint obtained from the Oracle Console.
! ${sharedSecret1} = You provide when you set up the IPSec connection in the Oracle Console, or you can
use the default Oracle-provided value.
! ${outsideInterface} = The public interface or outside of tunnel interface which is configured with the
CPE public IP address.
! ${vcnCidrNetwork} = VCN IP range
! ${vcnCidrNetmask} = Subnet mask for VCN
! ${onPremCidrNetwork} = On-premises IP range
! ${onPremCidrNetmask} = ON-premises subnet mask
! ${cryptoMapAclName} = Name of ACL which will be associated with the IPSec security association.
! ${vcnHostIp} = IP address of a VCN host. Used for IP SLA continuous ping to maintain tunnel UP state.
!-----------------------------------------------------------------------------------------------------
-----------------------------------------------------

! Access Lists

! Permit Traffic Between Your ASA and Your Oracle VCN
! Assuming there is an access-list controlling traffic in and out of your Internet facing interface, you
will need to permit traffic between your CPE and the Oracle VPN Headend
! WARNING: The new ACL entry you add to permit the traffic between your ASA and VPN headend needs to be
above any deny statements you might have in your existing access-list
```

```
access-list ${outboundAclName} extended permit ip host ${oracleHeadend1} host ${cpePublicIpAddress}

! Crypto ACL
! Create an ACL named ${cryptoMapAclName} which will later be associated with the IPSec security
association using the 'crypto-map' command. This will define which source/destination traffic needs to
be encrypted and sent across the VPN tunnel.
! Keep this ACL to a single entry. In a policy based configuration each ACL line will establish a
separate encryption domain.
! The single encryption domain used in this configuration sample will have a source/destination of
any/VCN CIDR. Refer to the 'Encryption domain for policy-based tunnels' subsection for supported
alternatives.

access-list ${cryptoMapAclName} extended permit ip any ${vcnCidrNetwork} ${vcnCidrNetmask}

! IKEv2 Policy

! IKEv2 is enabled on the outside interface.
! IKEv2 policy is created and specifies use of a Pre-Shared Key, AES256, SHA1, Diffie-Hellman Group 5,
and a lifetime of 28800 seconds (8 hours).
! If different parameters are required, modify this template before applying the configuration.
! WARNING: The IKEv2 group policy is created with a priority of 10. Make sure this doesn't conflict with
any pre-existing configuration on your ASA.

crypto ikev2 enable outside
crypto ikev2 policy 10
 encryption aes-256
 integrity sha384
 group 5
 prf sha
 lifetime seconds 28800

! Base VPN Policy

! An internal VPN group policy named 'oracle-vcn-vpn-policy' is created to define some basic VPN tunnel
settings
! Idle and session timeouts are disabled to maintain the tunnel UP state and tunnel protocol is set to
IKEv2

group-policy oracle-vcn-vpn-policy internal

 vpn-idle-timeout none
```

```
 vpn-session-timeout none
 vpn-tunnel-protocol ikev2

! IPSec Configuration

! Create an IKEv2 IPSec proposal named 'oracle_v2_ipsec_proposal' which defines AES256 for encryption
and SHA1 for authentication.
! If different parameters are required, modify this template before applying the configuration.

crypto ipsec ikev2 ipsec-proposal oracle_v2_ipsec_proposal
 protocol esp encryption aes-256
 protocol esp integrity sha-1

! A crypto map is used to tie together the important traffic that needs encryption (via crypto map ACL)
with defined security policies (from the IPSec proposal along with other crypto map statements), and the
destination of the traffic to a specific crypto peer.
! In this configuration example, a single crypto map is created named 'oracle-vpn-map-v2' This crypto
map references the previously created crypto map ACL, the 'oracle_v2_ipsec_proposal' IPSec proposal and
further defines PFS Group 5 and the security association lifetime to 3600 seconds (1 hour).
! WARNING: Make sure your crypto map name and sequence numbers do not overlap with existing crypto maps.
! WARNING: DO NOT use the 'originate-only' option with an Oracle IPSec VPN tunnel. It causes the
tunnel's traffic to be inconsistently blackholed. The command is only for tunnels between two Cisco
devices. Here's an example of the command that you should NOT use for the Oracle IPSec VPN tunnels:
crypto map <map name> <sequence number> set connection-type originate-only

crypto map oracle-vpn-map-v2 1 match address ${cryptoMapAclName}
crypto map oracle-vpn-map-v2 1 set pfs group5
crypto map oracle-vpn-map-v2 1 set peer ${oracleHeadend1}
crypto map oracle-vpn-map-v2 1 set ikev2 ipsec-proposal oracle_v2_ipsec_proposal
crypto map oracle-vpn-map-v2 1 set security-association lifetime seconds 3600

! WARNING: The below command will apply the 'oracle-vpn-map-v2' crypto map to the outside interface. The
Cisco ASA supports a single crypto map per interface. Make sure no other crypto map is applied to the
outside interface before using this command.

crypto map oracle-vpn-map-v2 interface outside

! IPSec Tunnel Group Configuration

! This configuration matches the group policy 'oracle-vcn-vpn-policy' with an Oracle VPN headend
endpoint.
```

```
! The pre-shared key for each Oracle VPN headend is defined in the corresponding tunnel group.

tunnel-group ${oracleHeadend1} type ipsec-l2l
tunnel-group ${oracleHeadend1} general-attributes
 default-group-policy oracle-vcn-vpn-policy
tunnel-group ${oracleHeadend1} ipsec-attributes
 ikev2 local-authentication pre-shared-key ${sharedSecret1}
 ikev2 remote-authentication pre-shared-key ${sharedSecret1}

! IP SLA Configuration

! The Cisco ASA doesn't establish a tunnel if there's no interesting traffic trying to pass through the
tunnel.
! You must configure IP SLA on your device for a continuous ping so that the tunnel remains up at all
times.
! You must allow ICMP on the outside interface.
! Make sure that the SLA monitor number used is unique.

sla monitor 1
type echo protocol ipIcmpEcho ${vcnHostIp} interface outside
frequency 5
sla monitor schedule 1 life forever start-time now

icmp permit any ${outsideInterface}

! IP Routing
! Pick either dynamic (BGP) or static routing. Uncomment the corresponding commands prior to applying
configuration.

! Border Gateway Protocol (BGP) Configuration
! Uncomment below lines if you want to use BGP.

! router bgp ${bgpASN}
!  address-family ipv4 unicast
!   neighbor ${OracleInsideTunnelIpAddress1} remote-as 31898
!   neighbor ${OracleInsideTunnelIpAddress1} activate
!   network ${onPremCidrNetwork} mask ${onPremCidrNetmask}
!   no auto-summary
!   no synchronization
!  exit-address-family
```

```
! Static Route Configuration
! Uncomment below line if you want to use static routing.

! route outside ${VcnCidrNetwork} ${VcnCidrNetmask} ${OracleInsideTunnelIpAddress1}

! Disable NAT for VPN Traffic

! If you are using NAT for traffic between your inside and outside interfaces, you might need to disable
NAT for traffic between your on-premises network and the Oracle VCN.
! Two objects are created for this NAT exemption. 'obj-OnPrem' represents the on-premises network as a
default route, and 'obj-oracle-vcn-1' represents the VCN CIDR block used in Oracle Cloud Infrastructure.
! If different address ranges are required, modify this template before applying the configuration.

! object network obj-onprem
!  subnet 0.0.0.0 0.0.0.0
! object network obj-oracle-vcn-1
!  subnet ${vcnCidrNetwork} ${vcnCidrNetmask}
! nat (inside,outside) source static obj-onprem obj-onprem destination static obj-oracle-vcn-1 obj-
oracle-vcn-1
```

Verification

The following ASA commands are included for basic troubleshooting. For more exhaustive information, refer to Cisco's IPSec Troubleshooting document.

Use the following command to verify that ISAKMP security associations are being built between the two peers.

```
show crypto isakmp sa
```

Use the following command to verify the status of all your BGP connections.

```
show bgp summary
```

Use the following command to verify the ASA's route table.

```
show route
```

A Monitoring service is also available from Oracle Cloud Infrastructure to actively and passively monitor your cloud resources. For information about monitoring your VPN Connect, see VPN Connect Metrics.

If you have issues, see VPN Connect Troubleshooting.

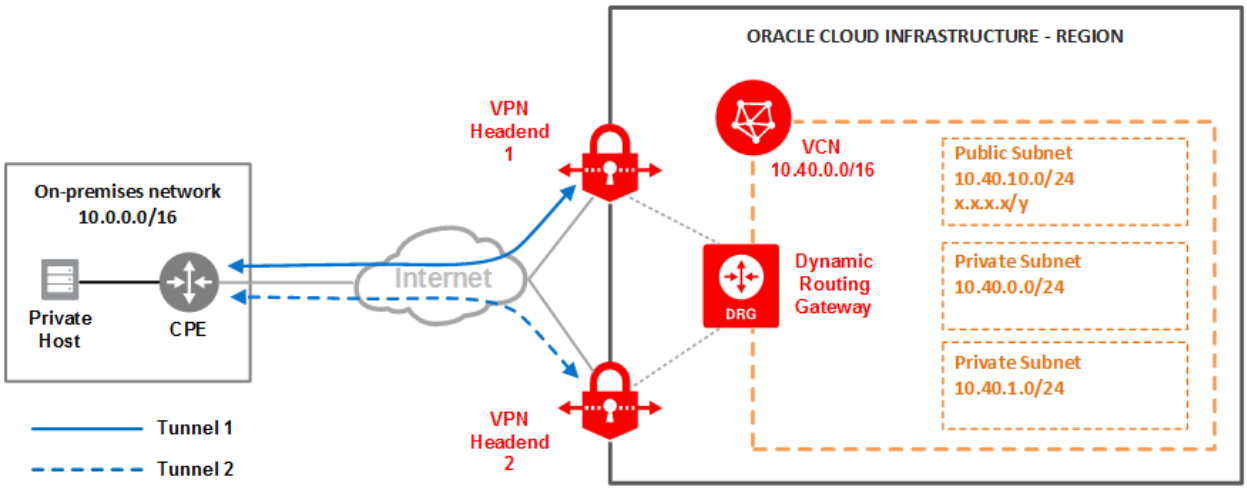
Cisco IOS

This topic provides a route-based configuration for a Cisco IOS device. The configuration was validated using a Cisco 2921 running IOS version 15.4(3)M3.

> **Important**
>
> Oracle provides configuration instructions for a set of vendors and devices. Make sure to use the configuration for the correct vendor.
>
> If the device or software version that Oracle used to verify the configuration does not exactly match your device or software, the configuration might still work for you. Consult your vendor's documentation and make any necessary adjustments.
>
> If your device is for a vendor not in the list of verified vendors and devices, or if you're already familiar with configuring your device for IPSec, see the list of supported IPSec parameters and consult your vendor's documentation for assistance.

VPN Connect is the IPSec VPN that Oracle Cloud Infrastructure offers for connecting your on-premises network to a virtual cloud network (VCN).

The following diagram shows a basic IPSec connection to Oracle Cloud Infrastructure with redundant tunnels. IP addresses used in this diagram are for example purposes only.



Best Practices

This section covers general best practices and considerations for using VPN Connect.

Configure All Tunnels for Every IPSec Connection

Oracle deploys two IPSec headends for each of your connections to provide high availability for your mission-critical workloads. On the Oracle side, these two headends are on different routers for redundancy purposes. Oracle recommends configuring all available tunnels for maximum redundancy. This is a key part of the "Design for Failure" philosophy.

Have Redundant CPEs in Your On-Premises Network Locations

Each of your sites that connects with IPSec to Oracle Cloud Infrastructure should have redundant edge devices (also known as customer-premises equipment (CPE)). You add each CPE to the Oracle Console and create a separate IPSec connection between your dynamic routing gateway (DRG) and each CPE. For each IPSec connection, Oracle provisions two tunnels on geographically redundant IPSec headends. For more information, see the Connectivity Redundancy Guide (PDF).

Routing Protocol Considerations

When you create an IPSec VPN, it has two redundant IPSec tunnels. Oracle encourages you to configure your CPE to use both tunnels (if your CPE supports it). Note that in the past, Oracle created IPSec VPNs that had up to four IPSec tunnels.

The following two routing types are available, and you choose the routing type separately for each tunnel in the IPSec VPN:

- **BGP dynamic routing:** The available routes are learned dynamically through BGP. The DRG dynamically learns the routes from your on-premises network. On the Oracle side, the DRG advertises the VCN's subnets.
- **Static routing:** When you set up the IPSec connection to the DRG, you specify the particular routes to your on-premises network that you want the VCN to know about. You also must configure your CPE device with static routes to the VCN's subnets. These routes are not learned dynamically.

For more information about routing with VPN Connect, including Oracle recommendations on how to manipulate the BGP best path selection algorithm, see Routing for the Oracle IPSec VPN.

Other Important CPE Configurations

Ensure access lists on your CPE are configured correctly to not block necessary traffic from or to Oracle Cloud Infrastructure.

If you have multiple tunnels up simultaneously, ensure that your CPE is configured to handle traffic coming from your VCN on any of the tunnels. For example, you need to disable ICMP inspection, configure TCP state bypass, and so on. For more details about the appropriate configuration, contact your CPE vendor's support.

Caveats and Limitations

This section covers general important characteristics and limitations of VPN Connect to be aware of.

Asymmetric Routing

Oracle uses asymmetric routing across the multiple tunnels that make up the IPSec connection. Configure your firewalls accordingly. Otherwise, ping tests or application traffic across the connection will not reliably work.

When you use multiple tunnels to Oracle Cloud Infrastructure, Oracle recommends that you configure your routing to deterministically route traffic through the preferred tunnel. If you want to use one IPSec tunnel as primary and another as backup, configure more-specific routes for the primary tunnel (BGP) and less-specific routes (summary or default route) for the backup tunnel (BGP/static). Otherwise, if you advertise the same route (for example, a default route) through all tunnels, return traffic from your VCN to your on-premises network will route to any of the available tunnels (because Oracle uses asymmetric routing).

For specific Oracle routing recommendations about how to force symmetric routing, see Preferring a Specific Tunnel in the IPSec VPN.

Route-Based or Policy-Based IPSec VPN

The IPSec protocol uses Security Associations (SAs) to determine how to encrypt packets. Within each SA, you define encryption domains to map a packet's source and destination IP address and protocol type to an entry in the SA database to define how to encrypt or decrypt a packet.

Note

Other vendors or industry documentation might use the term *proxy ID, security parameter index (SPI)*, or *traffic selector* when referring to SAs or encryption domains.

There are two general methods for implementing IPSec tunnels:

- **Route-based tunnels:** Also called *next-hop-based tunnels*. A route table lookup is performed on a packet's destination IP address. If that route's egress interface is an

IPSec tunnel, the packet is encrypted and sent to the other end of the tunnel.

- **Policy-based tunnels:** The packet's source and destination IP address and protocol are matched against a list of policy statements. If a match is found, the packet is encrypted based on the rules in that policy statement.

The Oracle VPN headends use route-based tunnels but can work with policy-based tunnels with some caveats listed in the following sections.

Important

The Oracle VPN headend supports only a single encryption domain. If your policy includes multiple entries, the tunnel will flap or there will be connectivity problems in which only a single policy works at any one time.

Encryption domain for route-based tunnels

If your CPE supports route-based tunnels, use that method to configure the tunnel. It's the simplest configuration with the most interoperability with the Oracle VPN headend.

Route-based IPSec uses an encryption domain with the following values:

- **Source IP address:** Any (0.0.0.0/0)
- **Destination IP address:** Any (0.0.0.0/0)
- **Protocol:** IPv4

If you need to be more specific, you can use a single summary route for your encryption domain values instead of a default route.

Encryption domain for policy-based tunnels

If your CPE supports only policy-based tunnels, there are restrictions on the policy that you

can use on the CPE.

When you use policy-based tunnels, every policy entry that you define generates a pair of IPSec SAs. This pair is referred to as an *encryption domain*.

Important

The Oracle VPN headend supports only a single encryption domain. If your policy includes multiple entries, the tunnel will flap or there will be connectivity problems in which only a single policy works at any one time.

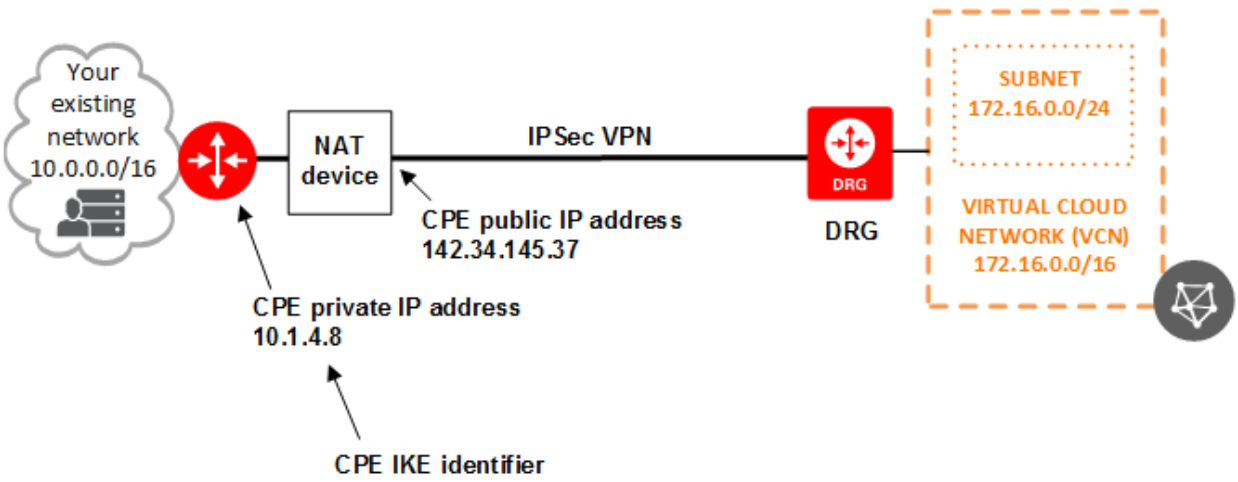
If you use policy-based IPSec, Oracle recommends using a *single encryption domain* with the following values:

- **Source IP address:** Any (0.0.0.0/0)
- **Destination IP address:** VCN CIDR (example: 10.120.0.0/20)
- **Protocol:** IPv4

Make sure the single encryption domain matches any traffic that needs to go from your on-premises network across the IPSec tunnel to the VCN. The VCN CIDR must not overlap with your on-premises network.

If Your CPE Is Behind a NAT Device

In general, the CPE IKE identifier configured on your end of the connection must match the CPE IKE identifier that Oracle is using. By default, Oracle uses the CPE's *public* IP address, which you provide when you create the CPE object in the Oracle Console. However, if your CPE is behind a NAT device, the CPE IKE identifier configured on your end might be the CPE's *private* IP address, as show in the following diagram.



Note

Some CPE platforms do not allow you to change the local IKE identifier. If you cannot, you must change the remote IKE ID in the Oracle Console to match your CPE's local IKE ID. You can provide the value either when you set up the IPSec connection, or later, by editing the IPSec connection. Oracle expects the value to be either an IP address or a fully qualified domain name (FQDN) such as *cpe.example.com*. For instructions, see Changing the CPE IKE Identifier That Oracle Uses.

Supported IPSec Parameters

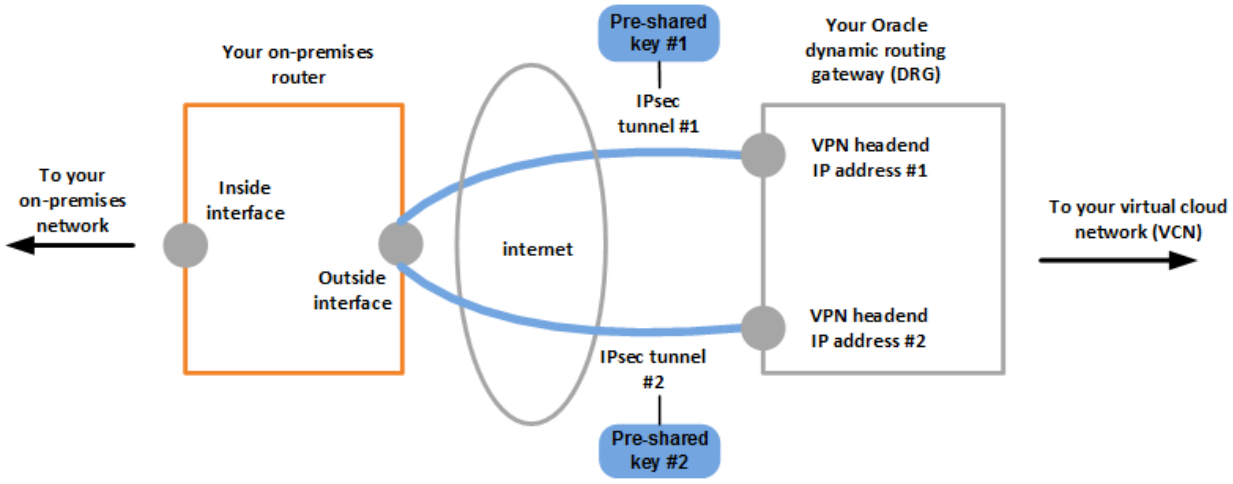
For a vendor-neutral list of supported IPSec parameters for all regions, see Supported IPSec Parameters.

The Oracle BGP ASN for the commercial cloud is 31898. If you're configuring VPN Connect for the Government Cloud, see Required VPN Connect Parameters for Government Cloud and also Oracle's BGP ASN.

CPE Configuration

> **Important**
>
> The configuration instructions in this section are provided by Oracle Cloud Infrastructure for your CPE. If you need support or further assistance, contact your CPE vendor's support directly.

The following figure shows the basic layout of the IPSec connection.



The configuration template was validated using a Cisco 2921 running IOS version 15.4(3)M3. The template provides information for each tunnel that you must configure. Oracle recommends setting up all configured tunnels for maximum redundancy.

The configuration template refers to these items that you must provide:

- **CPE public IP address:** The internet-routable IP address that is assigned to the external interface on the CPE. You or your Oracle administrator provides this value to Oracle when creating the CPE object in the Oracle Console.
- **Inside tunnel interface (required if using BGP):** The IP addresses for the CPE and Oracle ends of the inside tunnel interface. You provide these values when creating the IPSec connection in the Oracle Console.
- **BGP ASN (required if using BGP):** Your BGP ASN.

In addition, you must:

- Configure internal routing that routes traffic between the CPE and your local network.
- Ensure that you permit traffic between your CPE and your Oracle VCN.
- Identify the IPSec profile used (the following configuration template references this group policy as `oracle-vpn`).
- Identify the transform set used for your crypto map (the following configuration template references this transform set as `oracle-vpn-transform`).

Important

This following configuration template from Oracle Cloud Infrastructure **is a starting point for what you need to apply to your CPE.** Some of the parameters referenced in the template must be unique on the CPE, and the uniqueness can only be determined by accessing the CPE. Ensure the parameters are valid on your CPE and do not overwrite any previously configured values. In particular, ensure these values are unique:

- Policy names or numbers
- Interface names
- Keyrings
- Access list numbers (if applicable)

Oracle supports Internet Key Exchange version 1 (IKEv1) and version 2 (IKEv2). If you configure the IPSec connection in the Console to use IKEv2, you must configure your CPE to use only IKEv2 and related IKEv2 encryption parameters that your CPE supports. For a list of parameters that Oracle supports for IKEv1 or IKEv2, see Supported IPSec Parameters.

There's a separate configuration template for IKEv1 versus IKEv2.

IKEv1 Configuration Template

```
!-------------------------------------------------------------------------------------------------------
-----------------------------------------------------
! IKEv1 Configuration Template
! The configuration consists of two IPSec tunnels. Oracle highly recommends that you configure both
tunnels for maximum redundancy.
!-------------------------------------------------------------------------------------------------------
-----------------------------------------------------
! The configuration template involves setting up the following:
```

```
! Keyring (Pre-Shared Key)
! Basic ISAKMP Options
! ISAKMP and IPSec Policy Configuration
! IPSec Peers
! Virtual Tunnel Interfaces
! IP Routing (BGP or Static)
! Update Any Internet Facing Access List to Allow IPSec and ISAKMP Packets
!-------------------------------------------------------------------------------------------------------
-----------------------------------------------------
! The configuration template has various parameters that you must define before applying the
configuration.
!-------------------------------------------------------------------------------------------------------
-----------------------------------------------------
! PARAMETERS REFERENCED:
! ${OracleInsideTunnelIpAddress1} = Inside tunnel IP address of Oracle-side for the first tunnel. You
provide these values when creating the IPSec connection in the Oracle Console.
! ${OracleInsideTunnelIpAddress2} = Inside tunnel IP address of Oracle-side for the second tunnel. You
provide these values when creating the IPSec connection in the Oracle Console.
! ${bgpASN} = Your BGP ASN
! ${cpePublicIpAddress} = The public IP address for the CPE. This is the IP address of your outside
interface
! ${oracleHeadend1} = Oracle public IP endpoint obtained from the Oracle Console.
! ${oracleHeadend2} = Oracle public IP endpoint obtained from the Oracle Console.
! ${sharedSecret1} = You provide when you set up the IPSec connection in the Oracle Console, or you can
use the default Oracle-provided value.
! ${sharedSecret2} = You provide when you set up the IPSec connection in the Oracle Console, or you can
use the default Oracle-provided value.
! ${outsideInterface} = The public interface or outside of tunnel interface which is configured with the
CPE public IP address.
! ${vcnCidrNetwork} = VCN IP range
! ${vcnCidrNetmask} = Subnet mask for VCN
! ${onPremCidrNetwork} = On-premises IP range
! ${onPremCidrNetmask} = ON-premises subnet mask
!-------------------------------------------------------------------------------------------------------
-----------------------------------------------------

! Keyring (Pre-Shared Key)

! For authentication during IKE a separate keyring is defined for each Oracle VPN Headend peer.
! Add the pre-shared key for each Oracle VPN headend under the corresponding keyring.
```

```
crypto keyring oracle-vpn-${oracleHeadend1}
  local-address ${cpePublicIpAddress}
  pre-shared-key address ${oracleHeadend1} key ${sharedSecret1}
crypto keyring oracle-vpn-${oracleHeadend2}
  local-address ${cpePublicIpAddress}
  pre-shared-key address ${oracleHeadend2} key ${sharedSecret2}

! Basic ISAKMP Options

! Optional IPSec settings are included here.
! All optional settings included are recommended by Oracle. Remove or comment out any unneeded commands
prior to applying this configuration.
! WARNING: These settings are global and may impact other IPSec connections

! Enables fragmentation of IKE packets prior to encryption.
crypto isakmp fragmentation

! Enables Dead Peer Detection (DPD)
crypto isakmp keepalive 10 10

! The Router will clear the DF-bit in the IP header. Allows the packet to be fragmented and sen to the
end host in Oracle Cloud Infrastructure for reassembly.
crypto ipsec df-bit clear

! Increases security association anti-replay window. An increased window size is helpful for scenarios
where packets are regularly being dropped due to delays.
crypto ipsec security-association replay window-size 128

! ISAKMP and IPSec Policy Configuration

! An ISAKMP policy is created for Phase 1 which specifies to use a Pre-Shared Key, AES256, SHA384,
Diffie-Hellman Group 5, and a Phase 1 lifetime of 28800 seconds (8 hours).
! If different parameters are required, modify this template before applying the configuration.
! WARNING: The ISAKMP group policy is created with a priority of 10. Make sure this doesn't conflict
with any pre-existing configuration before applying.

crypto isakmp policy 10
 encr aes 256
 hash sha384
 authentication pre-share
 group 5
```

```
 lifetime 28800

! Create an IPSec transform set named 'oracle-vpn-transform' which defines a combination of IPSec (Phase
2) policy options. Specifically, AES256 for encryption and SHA1 for authentication. This is also where
tunnel mode is set for IPSec.
! If different parameters are required, modify this template before applying the configuration.

crypto ipsec transform-set oracle-vpn-transform esp-aes 256 esp-sha-hmac
 mode tunnel

! A IPSec profile named 'oracle-vpn' is created.
! The previously created transform set is added to this policy along with settings for enabling PFS
Group 5 and the security association lifetime to 3600 seconds (1 hour).
! If different parameters are required, modify this template before applying the configuration.

crypto ipsec profile oracle-vpn
 set pfs group5
 set security-association lifetime seconds 3600
 set transform-set oracle-vpn-transform

! IPSec Peers

! Two ISAKMP profiles are created for each Oracle VPN Headend.
! An ISAKMP profile is used as a repository for various Phase 1 commands tied to a specific IPSec peer.
In this case, we match the previously created keyrings to an Oracle VPN headend.

crypto isakmp profile oracle-vpn-${oracleHeadend1}
   keyring oracle-vpn-${oracleHeadend1}
   self-identity address
   match identity address ${oracleHeadend1} 255.255.255.255

! Keyring (Pre-Shared Key)

! For authentication during IKE a separate keyring is defined for each Oracle VPN Headend peer.
! Add the pre-shared key for each Oracle VPN headend under the corresponding keyring.

crypto ikev2 keyring oracle-vpn-${oracleHeadend1}
peer oracle_vpn
 address ${oracleHeadend1}
 pre-shared-key local ${sharedSecret1}
 pre-shared-key remote ${sharedSecret1}

crypto ikev2 keyring oracle-vpn-${oracleHeadend2}
peer oracle_vpn
 address ${oracleHeadend2}
 pre-shared-key local ${sharedSecret2}
 pre-shared-key remote ${sharedSecret2}

! Optional IPSec settings are included here.
! All optional settings included are recommended by Oracle. Remove or comment out any unneeded commands
```

```
prior to applying this configuration.
! WARNING: These settings are global and may impact other IPSec connections

! The Router will clear the DF-bit in the IP header. Allows the packet to be fragmented and sen to the
end host in Oracle Cloud Infrastructure for reassembly.
crypto ipsec df-bit clear

! Increases security association anti-replay window. An increased window size is helpful for scenarios
where packets are regularly being dropped due to delays.
crypto ipsec security-association replay window-size 128

! IKEv2 and IPSec Policy Configuration

! An IKEv2 proposal is created and specifies use of a Pre-Shared Key, AES256, SHA384, and Diffie-Hellman
Group 5.
! If different parameters are required, modify this template before applying the configuration.

crypto ikev2 proposal oracle_v2_proposal
 encryption aes-cbc-256
 integrity sha384
 group 5

crypto ikev2 policy oracle_v2_policy
 proposal oracle_v2_proposal

! Create an IPSec transform set named 'oracle-vpn-transform' which defines a combination of IPSec (Phase
2) policy options. Specifically, AES256 for encryption and SHA1 for authentication. This is also where
tunnel mode is set for IPSec.
! If different parameters are required, modify this template before applying the configuration.

crypto ipsec transform-set oracle-vpn-transform esp-aes 256 esp-sha-hmac
 mode tunnel

! An IPSec profile named 'oracle_v2_ipsec_profile_tunnel#' is created for each tunnel.
! The previously created transform set is added to this policy along with settings for enabling PFS
Group 5 and the security association lifetime to 3600 seconds (1 hour).
! If different parameters are required, modify this template before applying the configuration.

crypto ipsec profile oracle_v2_ipsec_profile_tunnel1
 set ikev2-profile oracle_v2_profile_tunnel1
```

```
 set pfs group5
 set security-association lifetime seconds 3600
 set transform-set oracle-vpn-transform

crypto ipsec profile oracle_v2_ipsec_profile_tunnel2
 set ikev2-profile oracle_v2_profile_tunnel2
 set pfs group5
 set security-association lifetime seconds 3600
 set transform-set oracle-vpn-transform

! IPSec Peers

! Two IKEv2 profiles are created for each Oracle VPN Headend.

crypto ikev2 profile oracle-vpn-${oracleHeadend1}
 keyring oracle-vpn-${oracleHeadend1}
 identity local address ${cpePublicIpAddress}
 match identity remote address ${oracleHeadend1} 255.255.255.255
 authentication remote pre-share
 authentication local pre-share

crypto ikev2 profile oracle-vpn-${oracleHeadend2}
 keyring oracle-vpn-${oracleHeadend2}
 identity local address ${cpePublicIpAddress}
 match identity remote address ${oracleHeadend2} 255.255.255.255
 authentication remote pre-share
 authentication local pre-share

! Virtual Tunnel Interfaces

! Each tunnel interface is a logical interface representing the local end of a VPN tunnel to a remote
VPN peer. Each tunnel interface represents a single tunnel to a different Oracle VPN Headend. The IP
address of each VPN headend is provided when you create your IPSec connection in Oracle Console.
! All traffic routed to a tunnel interface will be encrypted and sent across the tunnel towards Oracle
Cloud Infrastructure.
! Each tunnel interface configuration also references the previously created IPSec profile 'oracle-vpn'
for its IPSec parameters.
! WARNING: When doing static routing you do NOT have to set IPs on the tunnel interfaces unless you have
pre-configured inside tunnel interfaces in Oracle Console when creating your IPSec connection. Inside
tunnel interfaces are required if using BGP.
```

```
interface Tunnel${tunnelNumber1}
 ip address ${cpeInsideTunnelIpAddress1} ${cpeInsideTunnelNetmask1}
 tunnel source ${cpePublicIpAddress}
 tunnel mode ipsec ipv4
 tunnel destination ${oracleHeadend1}
 tunnel protection ipsec profile oracle_v2_ipsec_profile_tunnel1

!  permit esp host ${oracleHeadend1} host ${cpePublicIpAddress}
!  permit udp host ${oracleHeadend2} host ${cpePublicIpAddress} eq isakmp
```

```
!  permit esp host ${oracleHeadend2} host ${cpePublicIpAddress}
!  permit icmp any any echo
!  permit icmp any any echo-reply
!  permit icmp any any unreachable

! interface ${outsideInterface}
!  ip address ${cpePublicIpAddress} $(netmask}
!  ip access-group INTERNET-INGRESS in
```

Verification

The following IOS commands are included for basic troubleshooting.

Use the following command to verify that ISAKMP security associations are being built between the two peers.

```
show crypto isakmp sa
```

Use the following command to verify the status of all your BGP connections or neighbors.

```
show ip bgp summary
show ip bgp neighbors
```

Use the following command to verify the route table.

```
show ip route
```

A Monitoring service is also available from Oracle Cloud Infrastructure to actively and passively monitor your cloud resources. For information about monitoring your VPN Connect, see VPN Connect Metrics.

If you have issues, see VPN Connect Troubleshooting.

FortiGate

This topic provides configuration for a FortiGate that is running software version 6.0.4.

FortiGate experience is recommended. For more details on how to use FortiGate products, visit their official site. For FortiGate documentation for high availability (HA) or manual deployment, see the Fortinet Document Library.

Important

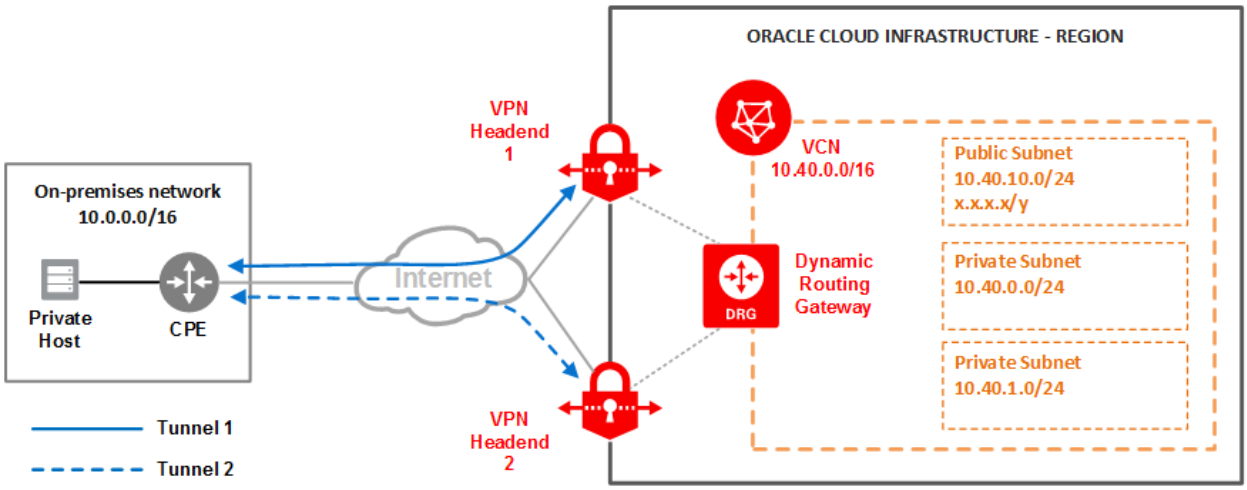
Oracle provides configuration instructions for a set of vendors and devices. Make sure to use the configuration for the correct vendor.

If the device or software version that Oracle used to verify the configuration does not exactly match your device or software, the configuration might still work for you. Consult your vendor's documentation and make any necessary adjustments.

If your device is for a vendor not in the list of verified vendors and devices, or if you're already familiar with configuring your device for IPSec, see the list of supported IPSec parameters and consult your vendor's documentation for assistance.

VPN Connect is the IPSec VPN that Oracle Cloud Infrastructure offers for connecting your on-premises network to a virtual cloud network (VCN).

The following diagram shows a basic IPSec connection to Oracle Cloud Infrastructure with redundant tunnels. IP addresses used in this diagram are for example purposes only.



Best Practices

This section covers general best practices and considerations for using VPN Connect.

Configure All Tunnels for Every IPSec Connection

Oracle deploys two IPSec headends for each of your connections to provide high availability for your mission-critical workloads. On the Oracle side, these two headends are on different routers for redundancy purposes. Oracle recommends configuring all available tunnels for maximum redundancy. This is a key part of the "Design for Failure" philosophy.

Have Redundant CPEs in Your On-Premises Network Locations

Each of your sites that connects with IPSec to Oracle Cloud Infrastructure should have redundant edge devices (also known as customer-premises equipment (CPE)). You add each CPE to the Oracle Console and create a separate IPSec connection between your dynamic routing gateway (DRG) and each CPE. For each IPSec connection, Oracle provisions two tunnels on geographically redundant IPSec headends. For more information, see the Connectivity Redundancy Guide (PDF).

Routing Protocol Considerations

When you create an IPSec VPN, it has two redundant IPSec tunnels. Oracle encourages you to configure your CPE to use both tunnels (if your CPE supports it). Note that in the past, Oracle created IPSec VPNs that had up to four IPSec tunnels.

The following two routing types are available, and you choose the routing type separately for each tunnel in the IPSec VPN:

- **BGP dynamic routing:** The available routes are learned dynamically through BGP. The DRG dynamically learns the routes from your on-premises network. On the Oracle side, the DRG advertises the VCN's subnets.
- **Static routing:** When you set up the IPSec connection to the DRG, you specify the particular routes to your on-premises network that you want the VCN to know about. You also must configure your CPE device with static routes to the VCN's subnets. These routes are not learned dynamically.

For more information about routing with VPN Connect, including Oracle recommendations on how to manipulate the BGP best path selection algorithm, see Routing for the Oracle IPSec VPN.

Other Important CPE Configurations

Ensure access lists on your CPE are configured correctly to not block necessary traffic from or to Oracle Cloud Infrastructure.

If you have multiple tunnels up simultaneously, ensure that your CPE is configured to handle traffic coming from your VCN on any of the tunnels. For example, you need to disable ICMP inspection, configure TCP state bypass, and so on. For more details about the appropriate configuration, contact your CPE vendor's support.

Caveats and Limitations

This section covers general important characteristics and limitations of VPN Connect to be aware of.

Asymmetric Routing

Oracle uses asymmetric routing across the multiple tunnels that make up the IPSec connection. Configure your firewalls accordingly. Otherwise, ping tests or application traffic across the connection will not reliably work.

When you use multiple tunnels to Oracle Cloud Infrastructure, Oracle recommends that you configure your routing to deterministically route traffic through the preferred tunnel. If you want to use one IPSec tunnel as primary and another as backup, configure more-specific routes for the primary tunnel (BGP) and less-specific routes (summary or default route) for the backup tunnel (BGP/static). Otherwise, if you advertise the same route (for example, a default route) through all tunnels, return traffic from your VCN to your on-premises network will route to any of the available tunnels (because Oracle uses asymmetric routing).

For specific Oracle routing recommendations about how to force symmetric routing, see Preferring a Specific Tunnel in the IPSec VPN.

Route-Based or Policy-Based IPSec VPN

The IPSec protocol uses Security Associations (SAs) to determine how to encrypt packets. Within each SA, you define encryption domains to map a packet's source and destination IP address and protocol type to an entry in the SA database to define how to encrypt or decrypt a packet.

Note

Other vendors or industry documentation might use the term *proxy ID, security parameter index (SPI)*, or *traffic selector* when referring to SAs or encryption domains.

There are two general methods for implementing IPSec tunnels:

- **Route-based tunnels:** Also called *next-hop-based tunnels*. A route table lookup is performed on a packet's destination IP address. If that route's egress interface is an

IPSec tunnel, the packet is encrypted and sent to the other end of the tunnel.

- **Policy-based tunnels:** The packet's source and destination IP address and protocol are matched against a list of policy statements. If a match is found, the packet is encrypted based on the rules in that policy statement.

The Oracle VPN headends use route-based tunnels but can work with policy-based tunnels with some caveats listed in the following sections.

Important

The Oracle VPN headend supports only a single encryption domain. If your policy includes multiple entries, the tunnel will flap or there will be connectivity problems in which only a single policy works at any one time.

Encryption domain for route-based tunnels

If your CPE supports route-based tunnels, use that method to configure the tunnel. It's the simplest configuration with the most interoperability with the Oracle VPN headend.

Route-based IPSec uses an encryption domain with the following values:

- **Source IP address:** Any (0.0.0.0/0)
- **Destination IP address:** Any (0.0.0.0/0)
- **Protocol:** IPv4

If you need to be more specific, you can use a single summary route for your encryption domain values instead of a default route.

Encryption domain for policy-based tunnels

If your CPE supports only policy-based tunnels, there are restrictions on the policy that you

can use on the CPE.

When you use policy-based tunnels, every policy entry that you define generates a pair of IPSec SAs. This pair is referred to as an *encryption domain*.

> **Important**
>
> The Oracle VPN headend supports only a single encryption domain. If your policy includes multiple entries, the tunnel will flap or there will be connectivity problems in which only a single policy works at any one time.

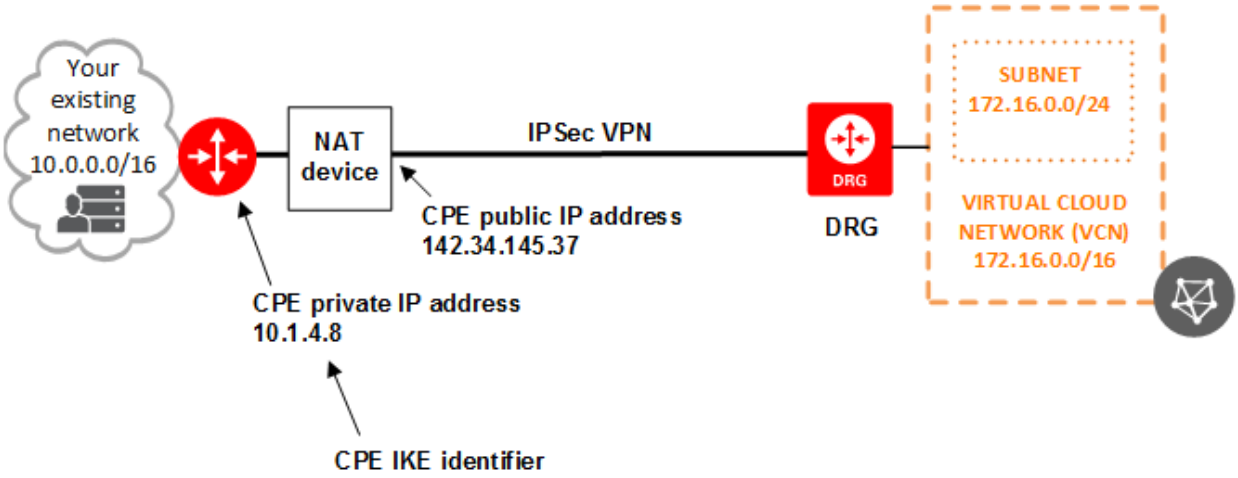
If you use policy-based IPSec, Oracle recommends using a *single encryption domain* with the following values:

- **Source IP address:** Any (0.0.0.0/0)
- **Destination IP address:** VCN CIDR (example: 10.120.0.0/20)
- **Protocol:** IPv4

Make sure the single encryption domain matches any traffic that needs to go from your on-premises network across the IPSec tunnel to the VCN. The VCN CIDR must not overlap with your on-premises network.

If Your CPE Is Behind a NAT Device

In general, the CPE IKE identifier configured on your end of the connection must match the CPE IKE identifier that Oracle is using. By default, Oracle uses the CPE's *public* IP address, which you provide when you create the CPE object in the Oracle Console. However, if your CPE is behind a NAT device, the CPE IKE identifier configured on your end might be the CPE's *private* IP address, as show in the following diagram.



Note

Some CPE platforms do not allow you to change the local IKE identifier. If you cannot, you must change the remote IKE ID in the Oracle Console to match your CPE's local IKE ID. You can provide the value either when you set up the IPSec connection, or later, by editing the IPSec connection. Oracle expects the value to be either an IP address or a fully qualified domain name (FQDN) such as *cpe.example.com*. For instructions, see Changing the CPE IKE Identifier That Oracle Uses.

Supported IPSec Parameters

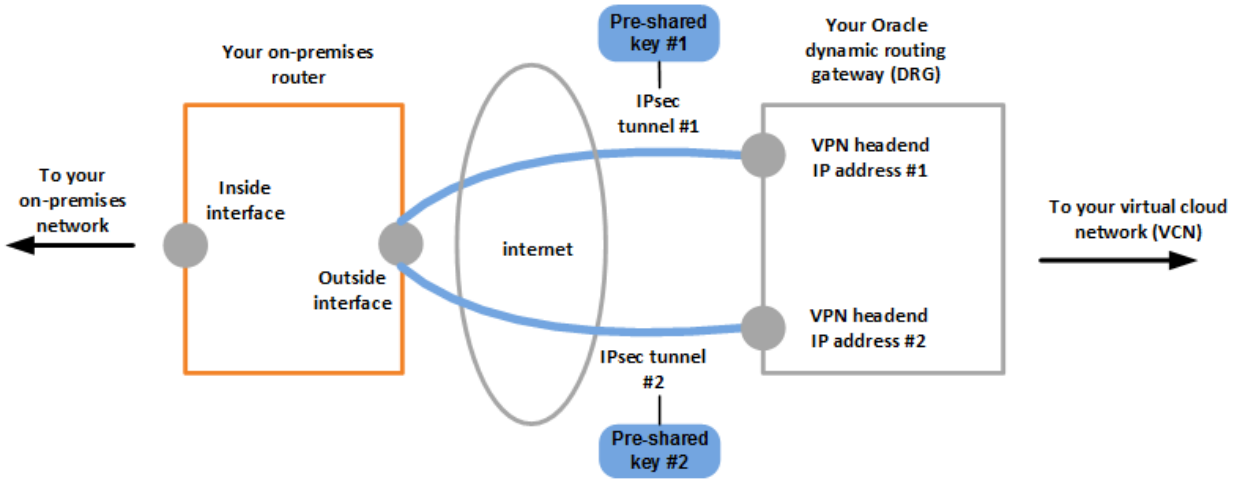
For a vendor-neutral list of supported IPSec parameters for all regions, see Supported IPSec Parameters.

The Oracle BGP ASN for the commercial cloud is 31898. If you're configuring VPN Connect for the Government Cloud, see Required VPN Connect Parameters for Government Cloud and also Oracle's BGP ASN.

CPE Configuration

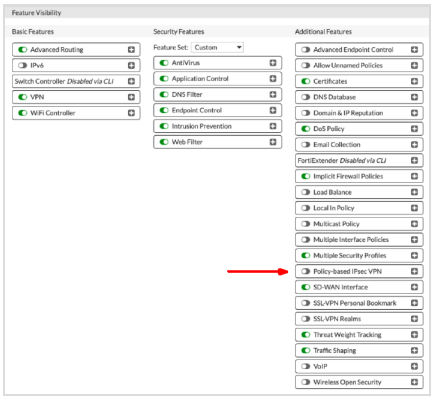
> **Important**
>
> The configuration instructions in this section are provided by Oracle Cloud Infrastructure for your CPE. If you need support or further assistance, contact your CPE vendor's support directly.

The following figure shows the basic layout of the IPSec connection.



By default, FortiGate provisions the IPSec tunnel in route-based mode. This topic focuses on FortiGate with a route-based VPN configuration.

If necessary, you can have FortiGate provision the IPSec tunnel in policy-based mode. To enable the feature, go to **System**, and then to **Feature Visiblity**. Under **Additional Features**, enable the **Policy-based IPsec VPN** feature.



About Using IKEv2

Oracle supports Internet Key Exchange version 1 (IKEv1) and version 2 (IKEv2). If you configure the IPSec connection in the Console to use IKEv2, you must configure your CPE to use only IKEv2 and related IKEv2 encryption parameters that your CPE supports. For a list of parameters that Oracle supports for IKEv1 or IKEv2, see Supported IPSec Parameters.

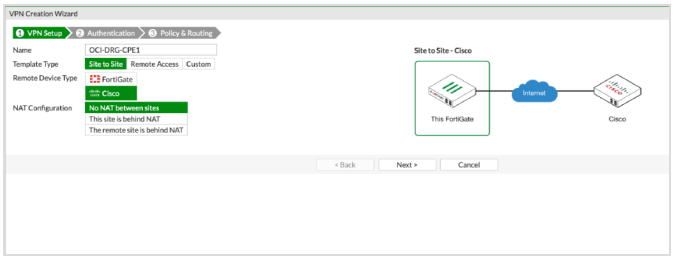
If you want to use IKEv2, there's a variation on one of the tasks presented in the next section. Specifically, in task 2, when configuring authentication, select IKE version 2.

Configuration Process

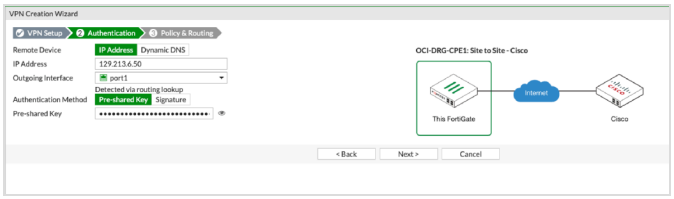
> **Important**
>
> Before starting, ensure you have a valid license or trial license to configure FortiGate.

Task 1: Use the wizard to create the VPN

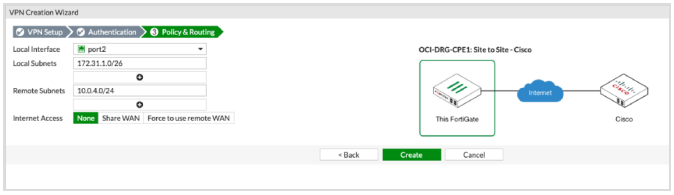
1. Go to **VPN**, and then to **IPsec Wizard** to create a new VPN tunnel.
2. On the **VPN Creation Wizard** page, specify the following items:
    - **Name:** Description used to identify the IPSec tunnel.
    - **Template Type:** Site to Site
    - **Remote Device Type:** Cisco
    - **NAT Configuration:** No NAT between sites



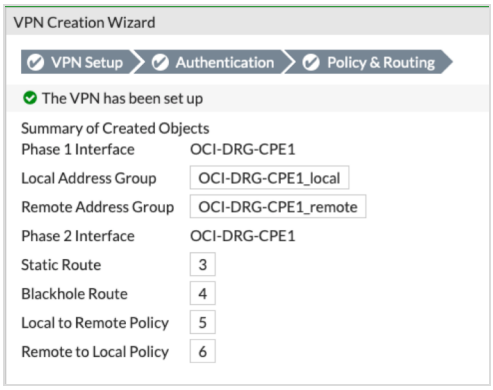
3. Click **Next**.
4. On the **Authentication** page, specify the following items:
    - **Remote Device:** IP Address
    - **IP Address:** IP address for the Oracle VPN headend. Oracle generated this value when creating the IPSec tunnel.
    - **Outgoing Interface:** The WAN interface configured for external traffic.
    - **Authentication Method:** Pre-shared Key. Oracle supports only shared secret keys.
    - **Pre-shared Key:** The shared secret. Oracle generated this value when creating the IPSec tunnel.



5. Click **Next**.
6. On the **Policy & Routing** page, specify the following items:
   - **Local Interface:** The LAN interface configured for internal traffic.
   - **Local Subnets:** The subnet used for internal traffic.
   - **Remote Subnets:** The Oracle VCN subnets that will be used for the IPSec tunnel.
   - **Internet Access:** None



7. Click **Create**.
   A summary message is shown with details about the configuration. Notice that the wizard automatically creates security policies with the subnets that you specified and adds the required static routes.



Task 2: Add Phase 1 and Phase 2 parameters to each IPSec tunnel

You must convert each newly created IPSec tunnel into a custom tunnel to add the recommended parameters for Phase 1 and Phase 2.

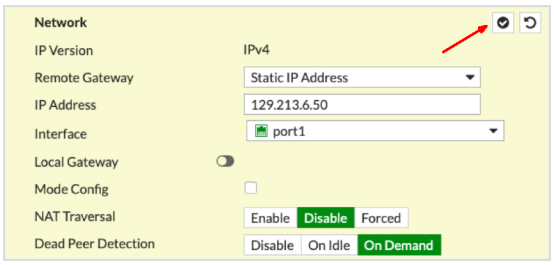
Perform the following steps for each tunnel.

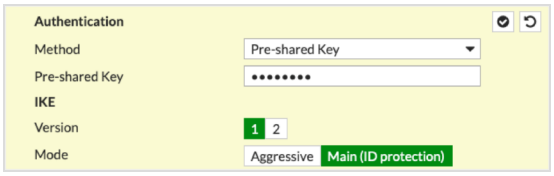
1. Go to **VPN**, and then click **IPsec Tunnels**.
2. Select the tunnel and click **Edit** to view the **Edit VPN Tunnel** page.
3. Click **Convert to Custom Tunnel**.

4. Edit the relevant sections to match the required settings shown in the following screenshots. Remember to click the check mark icon in the top-right corner of each section after making your changes.

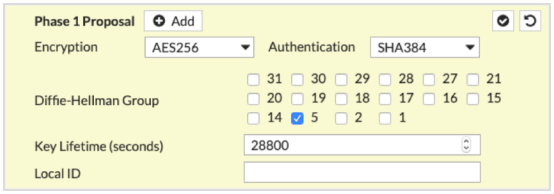
   The IP address shown in the first screenshot is an example address.

   Notice that if you want to use IKEv2, on the **Authentication** screen, instead select **IKE Version 2**.

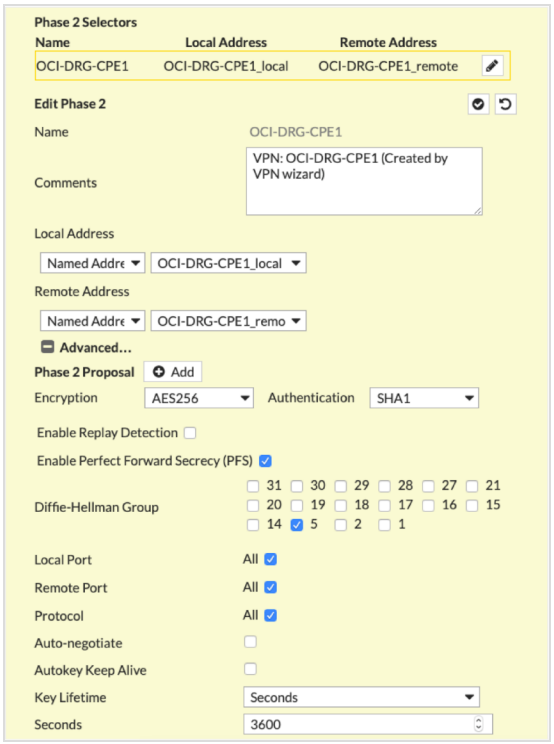




Authentication
Method
Pre-shared Key
Pre-shared Key
IKE
Version
1
2
Mode
Aggressive
Main (ID protection)



Phase 1 Proposal
Add
Encryption
AES256
Authentication
SHA384
Diffie-Hellman Group
31 30 29 28 27 21
20 19 18 17 16 15
14 5 2 1
Key Lifetime (seconds)
28800
Local ID



5. After configuring all sections, click **OK** to save and close the dialogs.

Task 3: Verify the IPSec connection

At this point, the IPSec tunnel will not be established by default because FortiGate uses the IP address assigned on the WAN interface. In this case, this IP address is a private IP address because Oracle does 1:1 NAT. This private IP address will be used as the local IKE ID and will not match the one expected on the Oracle DRG. To resolve this, you can manually change the local IKE ID on your FortiGate by using the CPE's CLI, or you can change the value that Oracle uses in the Oracle Console (see the instructions that follow). Either way, this fixes the incompatibility and brings up the IPSec tunnel.

To change the CPE IKE identifier that Oracle uses (Oracle Console)

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **IPSec Connections**.
   A list of the IPSec connections in the compartment that you're viewing is displayed. If you don't see the one you're looking for, verify that you're viewing the correct compartment (select from the list on the left side of the page).
2. For the IPSec connection you're interested in, click the Actions icon (three dots), and then click **Edit**.
   The current CPE IKE identifier that Oracle is using is displayed at the bottom of the dialog.
3. Enter your new values for **CPE IKE Identifier Type** and **CPE IKE Identifier**, and then click **Save Changes**.

REDUNDANCY WITH BGP OVER IPSEC

For redundancy, Oracle recommends using BGP over IPSec. By default, if you have two connections of the same type (for example, two IPSec VPNs that both use BGP), and you advertise the same routes across both connections, Oracle prefers the oldest established route when responding to requests or initiating connections. If you want to force routing to be symmetric, Oracle recommends using BGP and AS path prepending with your routes to influence which path Oracle uses when responding to and initiating connections. For more information, see Routing Details for Connections to Your On-Premises Network.

The Oracle DRG uses /30 or /31 as subnets for configuring IP addresses on the interface tunnels. Remember that the IP address must be part of the IPSec VPN's encryption domain and must be allowed in the firewall policy to reach the peer VPN through the interface tunnel. You might need to implement a static route through the tunnel interface for the peer IP address.

Oracle's BGP ASN in commercial regions is 31898. If you're configuring VPN Connect for the Government Cloud, see Required VPN Connect Parameters for Government Cloud and also Oracle's BGP ASN.

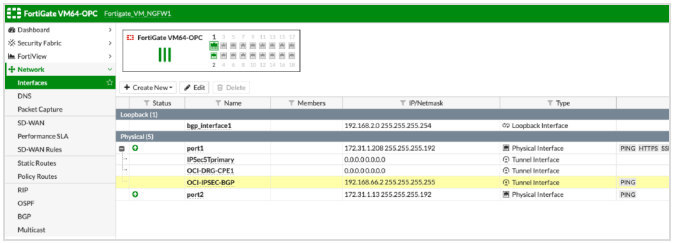
For your side, you can use a private ASN. Private ASNs are in the range 64512–65534.

Task 1: Edit the tunnel interface

In the first task, you add the BGP IP address to the newly created FortiGate tunnel interface.

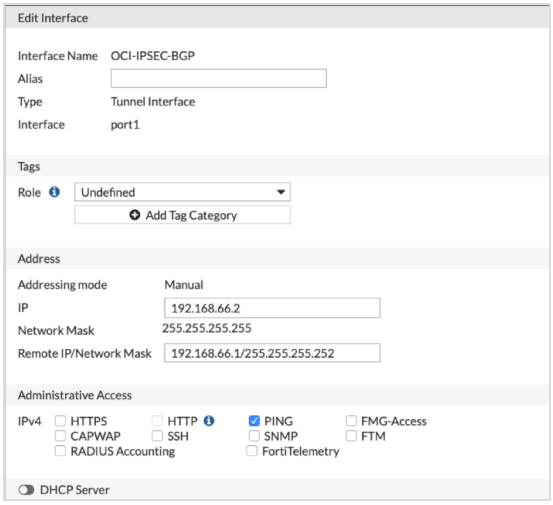
Perform the following steps for each tunnel.

1. Go to **Network**, and then **Interface**.
2. Select the interface you're interested in and click **Edit**.



3. Configure the following items:
   - **IP:** Enter the BGP IP address that you assigned to the FortiGate end of the tunnel interface. The following screenshot shows an example value of 192.168.66.2.
   - **Remote IP/Network Mask:** Add the BGP IP address that you assigned to the Oracle end of the tunnel interface. Include either a /30 or /31 mask, depending on how you specified the addresses in the Oracle Console. In the following screenshot, 192.168.66.0/30 was used, where 192.168.66.2 is assigned to the FortiGate end, and 192.168.66.1 is assigned to the Oracle end.
   - **Ping access** (recommended): In the **Administrative Access** section, enable

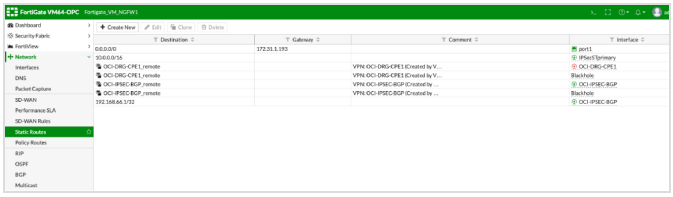
ping access.



4. Click **OK**.

Task 2: Add a static route for the Oracle IP address

For each tunnel, add a /32 static route towards the Oracle IP address through the tunnel, as shown in the following screenshot.

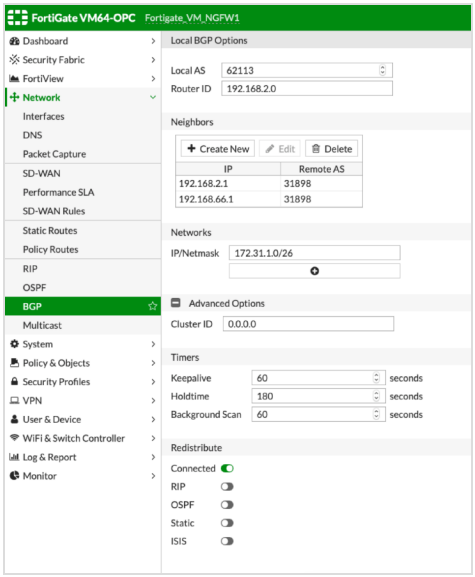


Task 3: Configure BGP

Perform the following steps for each tunnel.

1. Go to **Network**, and then **BGP**.
2. Enter the following items:
    - **Local AS:** Your BGP ASN. You can use a private ASN. Private ASNs are in the range 64512–65534.
    - **Router ID:** A value to provide a unique identity for this BGP router among its peers.
    - **Neighbors:** Click **Create New** and enter the BGP IP address for the Oracle end of the tunnel, and the Oracle BGP ASN (31898 for commercial regions). If you're configuring VPN Connect for connecting to the Government Cloud, see Oracle's BGP ASN.
    - **Networks:** Optionally use this field to advertise a specific subnet over BGP. You can also advertise subnets by using the **Redistribute** section in the **Advanced**

Options section.



3. Click **OK**.

Verification

The following CLI command is useful for gathering statistical data such as the number of packets encrypted versus decrypted, the number of bytes sent versus received, the encryption domain (SPI) identifier, and so on. This kind of information can be critical for determining an issue with the VPN.

```
diagnose vpn tunnel list
```

The following command indicates a lack of firewall policy, a lack of forwarding route, and policy ordering issues. If there are no communication issues, this command returns blank output.

```
diagnose debug flow
```

The following command verifies BGP neighbor status information. Remember that an "Active" state doesn't mean that the BGP session is up. "Active" refers to a BGP state message. For more information, see BGP Background and Concepts in the FortiGate documentation.

```
get router info bgp summary
```

The following command provides more detailed information about a BGP neighbor.

```
get router info bgp neighbors
```

A Monitoring service is also available from Oracle Cloud Infrastructure to actively and passively monitor your cloud resources. For information about monitoring your VPN Connect, see VPN Connect Metrics.

If you have issues, see VPN Connect Troubleshooting.

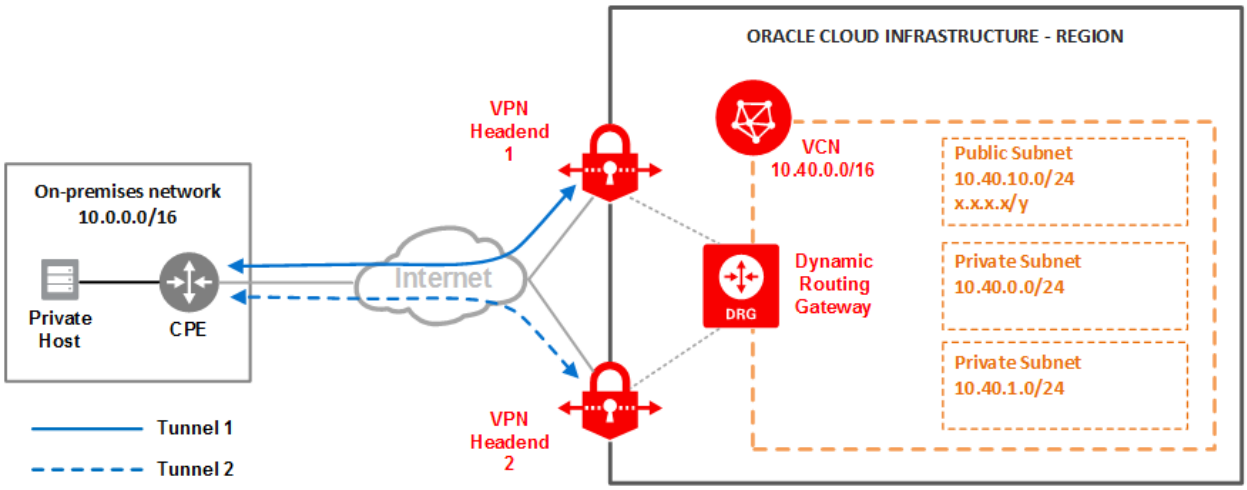
Juniper MX

This topic provides configuration for a Juniper MX that is running software version JunOS 15.0 (or newer).

> **Important**
>
> Oracle provides configuration instructions for a set of vendors and devices. Make sure to use the configuration for the correct vendor.
>
> If the device or software version that Oracle used to verify the configuration does not exactly match your device or software, the configuration might still work for you. Consult your vendor's documentation and make any necessary adjustments.
>
> If your device is for a vendor not in the list of verified vendors and devices, or if you're already familiar with configuring your device for IPSec, see the list of supported IPSec parameters and consult your vendor's documentation for assistance.

VPN Connect is the IPSec VPN that Oracle Cloud Infrastructure offers for connecting your on-premises network to a virtual cloud network (VCN).

The following diagram shows a basic IPSec connection to Oracle Cloud Infrastructure with redundant tunnels. IP addresses used in this diagram are for example purposes only.



Best Practices

This section covers general best practices and considerations for using VPN Connect.

Configure All Tunnels for Every IPSec Connection

Oracle deploys two IPSec headends for each of your connections to provide high availability for your mission-critical workloads. On the Oracle side, these two headends are on different routers for redundancy purposes. Oracle recommends configuring all available tunnels for maximum redundancy. This is a key part of the "Design for Failure" philosophy.

Have Redundant CPEs in Your On-Premises Network Locations

Each of your sites that connects with IPSec to Oracle Cloud Infrastructure should have redundant edge devices (also known as customer-premises equipment (CPE)). You add each CPE to the Oracle Console and create a separate IPSec connection between your dynamic routing gateway (DRG) and each CPE. For each IPSec connection, Oracle provisions two tunnels on geographically redundant IPSec headends. For more information, see the Connectivity Redundancy Guide (PDF).

Routing Protocol Considerations

When you create an IPSec VPN, it has two redundant IPSec tunnels. Oracle encourages you to configure your CPE to use both tunnels (if your CPE supports it). Note that in the past, Oracle created IPSec VPNs that had up to four IPSec tunnels.

The following two routing types are available, and you choose the routing type separately for each tunnel in the IPSec VPN:

- **BGP dynamic routing:** The available routes are learned dynamically through BGP. The DRG dynamically learns the routes from your on-premises network. On the Oracle side, the DRG advertises the VCN's subnets.
- **Static routing:** When you set up the IPSec connection to the DRG, you specify the particular routes to your on-premises network that you want the VCN to know about. You also must configure your CPE device with static routes to the VCN's subnets. These routes are not learned dynamically.

For more information about routing with VPN Connect, including Oracle recommendations on how to manipulate the BGP best path selection algorithm, see Routing for the Oracle IPSec VPN.

Other Important CPE Configurations

Ensure access lists on your CPE are configured correctly to not block necessary traffic from or to Oracle Cloud Infrastructure.

If you have multiple tunnels up simultaneously, ensure that your CPE is configured to handle traffic coming from your VCN on any of the tunnels. For example, you need to disable ICMP inspection, configure TCP state bypass, and so on. For more details about the appropriate configuration, contact your CPE vendor's support.

Caveats and Limitations

This section covers general important characteristics and limitations of VPN Connect to be aware of.

Asymmetric Routing

Oracle uses asymmetric routing across the multiple tunnels that make up the IPSec connection. Configure your firewalls accordingly. Otherwise, ping tests or application traffic across the connection will not reliably work.

When you use multiple tunnels to Oracle Cloud Infrastructure, Oracle recommends that you configure your routing to deterministically route traffic through the preferred tunnel. If you want to use one IPSec tunnel as primary and another as backup, configure more-specific routes for the primary tunnel (BGP) and less-specific routes (summary or default route) for the backup tunnel (BGP/static). Otherwise, if you advertise the same route (for example, a default route) through all tunnels, return traffic from your VCN to your on-premises network will route to any of the available tunnels (because Oracle uses asymmetric routing).

For specific Oracle routing recommendations about how to force symmetric routing, see Preferring a Specific Tunnel in the IPSec VPN.

Route-Based or Policy-Based IPSec VPN

The IPSec protocol uses Security Associations (SAs) to determine how to encrypt packets. Within each SA, you define encryption domains to map a packet's source and destination IP address and protocol type to an entry in the SA database to define how to encrypt or decrypt a packet.

Note

Other vendors or industry documentation might use the term *proxy ID, security parameter index (SPI)*, or *traffic selector* when referring to SAs or encryption domains.

There are two general methods for implementing IPSec tunnels:

- **Route-based tunnels:** Also called *next-hop-based tunnels*. A route table lookup is performed on a packet's destination IP address. If that route's egress interface is an

IPSec tunnel, the packet is encrypted and sent to the other end of the tunnel.

- **Policy-based tunnels:** The packet's source and destination IP address and protocol are matched against a list of policy statements. If a match is found, the packet is encrypted based on the rules in that policy statement.

The Oracle VPN headends use route-based tunnels but can work with policy-based tunnels with some caveats listed in the following sections.

Important

The Oracle VPN headend supports only a single encryption domain. If your policy includes multiple entries, the tunnel will flap or there will be connectivity problems in which only a single policy works at any one time.

Encryption domain for route-based tunnels

If your CPE supports route-based tunnels, use that method to configure the tunnel. It's the simplest configuration with the most interoperability with the Oracle VPN headend.

Route-based IPSec uses an encryption domain with the following values:

- **Source IP address:** Any (0.0.0.0/0)
- **Destination IP address:** Any (0.0.0.0/0)
- **Protocol:** IPv4

If you need to be more specific, you can use a single summary route for your encryption domain values instead of a default route.

Encryption domain for policy-based tunnels

If your CPE supports only policy-based tunnels, there are restrictions on the policy that you

can use on the CPE.

When you use policy-based tunnels, every policy entry that you define generates a pair of IPSec SAs. This pair is referred to as an *encryption domain*.

Important

The Oracle VPN headend supports only a single encryption domain. If your policy includes multiple entries, the tunnel will flap or there will be connectivity problems in which only a single policy works at any one time.

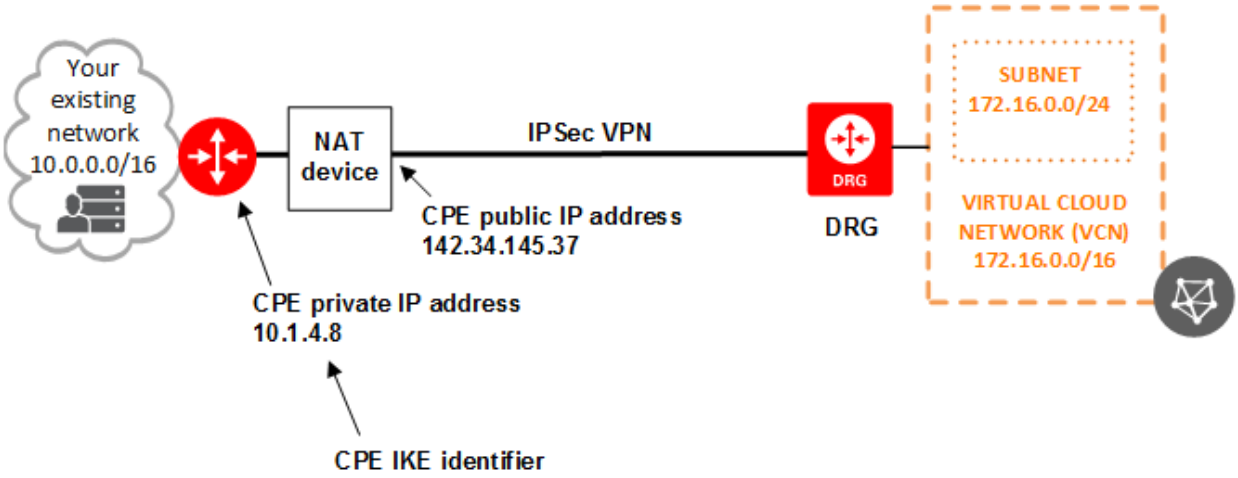
If you use policy-based IPSec, Oracle recommends using a *single encryption domain* with the following values:

- **Source IP address:** Any (0.0.0.0/0)
- **Destination IP address:** VCN CIDR (example: 10.120.0.0/20)
- **Protocol:** IPv4

Make sure the single encryption domain matches any traffic that needs to go from your on-premises network across the IPSec tunnel to the VCN. The VCN CIDR must not overlap with your on-premises network.

If Your CPE Is Behind a NAT Device

In general, the CPE IKE identifier configured on your end of the connection must match the CPE IKE identifier that Oracle is using. By default, Oracle uses the CPE's *public* IP address, which you provide when you create the CPE object in the Oracle Console. However, if your CPE is behind a NAT device, the CPE IKE identifier configured on your end might be the CPE's *private* IP address, as show in the following diagram.



Note

Some CPE platforms do not allow you to change the local IKE identifier. If you cannot, you must change the remote IKE ID in the Oracle Console to match your CPE's local IKE ID. You can provide the value either when you set up the IPSec connection, or later, by editing the IPSec connection. Oracle expects the value to be either an IP address or a fully qualified domain name (FQDN) such as *cpe.example.com*. For instructions, see Changing the CPE IKE Identifier That Oracle Uses.

Supported IPSec Parameters

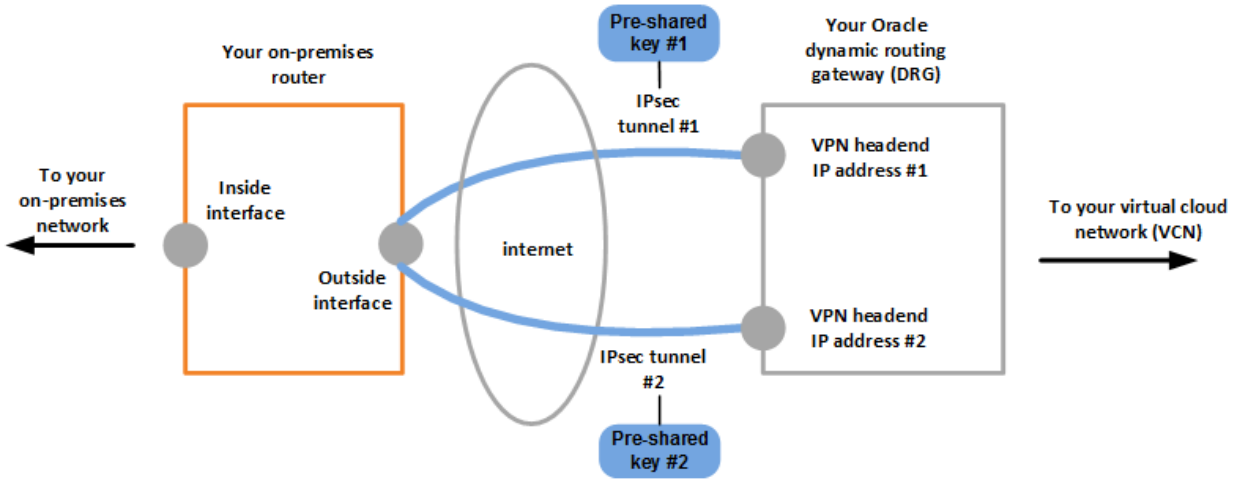
For a vendor-neutral list of supported IPSec parameters for all regions, see Supported IPSec Parameters.

The Oracle BGP ASN for the commercial cloud is 31898. If you're configuring VPN Connect for the Government Cloud, see Required VPN Connect Parameters for Government Cloud and also Oracle's BGP ASN.

CPE Configuration

> **Important**
>
> The configuration instructions in this section are provided by Oracle Cloud Infrastructure for your CPE. If you need support or further assistance, contact your CPE vendor's support directly.

The following figure shows the basic layout of the IPSec connection.



The configuration template provided is for a Juniper MX router running JunOS 15.0 (or newer). The template provides information for each tunnel that you must configure. Oracle recommends setting up all configured tunnels for maximum redundancy.

The configuration template refers to these items that you must provide:

- **CPE public IP address:** The internet-routable IP address that is assigned to the external interface on the CPE. You or your Oracle administrator provides this value to Oracle when creating the CPE object in the Oracle Console.
- **Inside tunnel interface (required if using BGP):** The IP addresses for the CPE and Oracle ends of the inside tunnel interface. You provide these values when creating the IPSec connection in the Oracle Console.
- **BGP ASN (required if using BGP):** Your BGP ASN.

In addition, you must:

- Configure the Juniper MX public interface (the CPE public IP address is bound to this interface).
- Configure internal routing that routes traffic between the CPE and your local network.
- Configure the tunnel interfaces. See the next section for more information.

About the Tunnel Interfaces

In the following configuration template, the tunnel interfaces are referred to with the following variables:

- `msInterface#` - one per tunnel
    - These interfaces correspond to one of the four encryption ASICs on the MS-MPC card.
    - You can distribute load across the ASICs by spreading your tunnels across them.
    - Example values: ms-2/3/0, ms-2/3/1
- `insideMsUnit#` and `outsideMsUnit#` - one pair per tunnel
    - For every tunnel, you need an ms-mpc interface pair of units.
    - One represents the outside of the IPSec tunnel. The other represents the inside of the tunnel.
    - The router forwards packets from your on-premises network to your VCN into the inside unit.

- The encryption ASIC then encrypts the packets based on the rules and policies.
- Then the encrypted packet egresses out the outside unit as an ESP packet, ready to be forwarded to the Oracle VPN headend routers.

◦ There are over 16,000 possible values for unit numbers.

- One way to allocate the units is to offset them by 8,000.
- You can pick values between 0 - 7999 for `insideMsUnit#` and 8000-15999 for `outsideMsUnit#`.

Important

This following configuration template from Oracle Cloud Infrastructure **is a starting point for what you need to apply to your CPE.** Some of the parameters referenced in the template must be unique on the CPE, and the uniqueness can only be determined by accessing the CPE. Ensure the parameters are valid on your CPE and do not overwrite any previously configured values. In particular, ensure these values are unique:

- Policy names or numbers
- Interface names
- Access list numbers (if applicable)

To find parameters that you must define before applying the configuration, search for the keyword `USER_DEFINED` in the template.

About Using IKEv2

Oracle supports Internet Key Exchange version 1 (IKEv1) and version 2 (IKEv2). If you configure the IPSec connection in the Console to use IKEv2, you must configure your CPE to use only IKEv2 and related IKEv2 encryption parameters that your CPE supports. For a list of parameters that Oracle supports for IKEv1 or IKEv2, see Supported IPSec Parameters.

You specify the IKE version when defining the IKE policy. In the following configuration, there's a comment showing how to configure the IKE policy for IKEv1 versus IKEv2.

Configuration Template

```
-----------------------------------------------------------------------------------------------------------
-----------------------------------------------------
# Configuration Template
# The configuration consists of two IPSec tunnels. Oracle highly recommends that you configure both
tunnels for maximum redundancy.
-----------------------------------------------------------------------------------------------------------
-----------------------------------------------------
# The configuration template involves setting up the following:
# PHASE 1
# PHASE 2
# SETTING THE TUNNEL INTERFACES FOR ORACLE
# SETTING THE SERVICES FOR ORACLE.
# SETTING BGP/STATIC ROUTING
# SETTING ROUTING-INSTANCES FOR ORACLE (OPTIONAL).
-----------------------------------------------------------------------------------------------------------
-----------------------------------------------------
# The configuration template has various parameters that you must define before applying the
configuration.
# Search in the template for the keyword "USER_DEFINED" to find those parameters.
-----------------------------------------------------------------------------------------------------------
-----------------------------------------------------
# PARAMETERS REFERENCED:
# oracle_headend_1 = Oracle public IP endpoint obtained from the Oracle Console.
# oracle_headend_2 = Oracle public IP endpoint obtained from the Oracle Console.
# connection_presharedkey_1 = You provide when you set up the IPSec connection in the Oracle Console, or
you can use the default Oracle-provided value.
# connection_presharedkey_2 = You provide when you set up the IPSec connection in the Oracle Console, or
you can use the default Oracle-provided value.
# cpe_public_ip_address = The internet-routable IP address that is assigned to the public interface on
the CPE. You provide this when creating the CPE object in the Oracle Console.
```

```
# cpe_public_interface = The name of the Juniper interface where the CPE IP address is configured. Eg:
ge-0/0/1.0
# msInterface1 = The interface correspond to one of the four encryption ASICs on the MS-MPC card. Eg:
ms-2/3/0, ms-2/3/1
# msInterface2 = Second tunnel interface that needs to be configured. Eg: ms-2/3/0, ms-2/3/1
# insideMsUnit1 = The inside interface of the MS-MPC interface pair for tunnel_1
# insideMsUnit2 = The inside interface of the MS-MPC interface pair for tunnel_2
# outsideMsUnit1 = The outside interface of the MS-MPC interface pair for tunnel_1
# outsideMsUnit2 = The outside interface of the MS-MPC interface pair for tunnel_2
# inside_tunnel_interface_ip_address = The IP addresses for the CPE and Oracle ends of the inside tunnel
interface. You provide these when creating the IPSec connection in the Oracle Console.
# inside_tunnel_interface_ip_address_neighbor = The neighbor IP address between the MX and Oracle end
points of the inside tunnel interface.
# bgp_asn = Your ASN
# vcn_range = VCN IP Range

# OPTIONAL PARAMETERS:
# customer_on-prem_to_oracle = Name of the routing instance to be defined on the CPE for the tunnel
interfaces connecting to the Oracle headends.
# internet_routing_instance = Name of the routing instance to be defined on the CPE for the tunnel
interfaces that are connected to the Internet.
-------------------------------------------------------------------------------------------------------
-----------------------------------------------------

fragmentation.

set services service-set oracle-vpn_1 tcp-mss 1387

# #5a: Border Gateway Protocol (BGP) Configuration

# USER_DEFINED: Replace the parameters in the section below as needed
```

```
# BGP is used within the tunnel to exchange prefixes between the dynamic routing gateway and your CPE.
The DRG dynamically learns the routes from your on-premises network. On the Oracle side, the DRG
advertises the VCN's subnets.
# THe configuration templates uses a basic route policy to advertise a default route to the DRG.
# To advertise additional prefixes to the Oracle VCN, add additional prefixes to the term ORACLE-DEFAULT
policy. Make sure the prefix is present in the routing table of the device with a valid next-hop.

# You configure the local BGP Autonomous System Number (BGP ASN) when you set up the IPSec connection in
the Oracle Console. If you later need to change the ASN, you must recreate the CPE object and IPSec
connection in the Oracle Console.

set policy-options policy-statement ORACLE-DEFAULT term default from route-filter 0.0.0.0/0 exact

set policy-options policy-statement ORACLE-DEFAULT term default then accept
set policy-options policy-statement ORACLE-DEFAULT term reject then reject

set protocols bgp group ebgp type external
set protocols bgp group ebgp neighbor <inside_tunnel_interface_ip_address_neighbor> export ORACLE-
DEFAULT
set protocols bgp group ebgp neighbor <inside_tunnel_interface_ip_address_neighbor> peer-as 31898
set protocols bgp group ebgp neighbor <inside_tunnel_interface_ip_address_neighbor> local-as <bgp_asn>

# #5b: Static Route Configuration

# USER_DEFINED: Replace the parameters in the section below as needed
# In case you plan to use static routing to get traffic through the IPSec tunnels, you can point the
routes down to the tunnel interfaces. You should redistribute these routes into your on-premises
network. Configuration for CPE to VCN static routes:

set routing-options static route <vcn_range> next-hop <msInterface2>.<insideMsUnit2>

##6: Routing Instances Configuration (Optional)
# USER_DEFINED: Replace the parameters in the section below as needed.
# If you are using routing-instances on your CPE, you need to make sure you account for them in your
configuration. Merge the following configuration into the template provided above.

set routing-instances <customer_on-prem_to_oracle> interface <msInterface2>.<insideMsUnit2>
set routing-instances <internet_routing_instance> interface <msInterface2>.<outsideMsUnit2>
set services service-set oracle-vpn-tunnel-tunnel_2 ipsec-vpn-options local-gateway <cpe_public_ip_
address> routing-instance <internet_routing_instance>
```

Verification

Use the following command to verify security associations (SAs).

```
show services ipsec-vpn ipsec security-associations detail
```

Use the following command to check the BGP status.

```
show bgp summary
```

Use the following commands to check the routes advertised to and received from Oracle Cloud Infrastructure. If you've configured the CPE to use routing instances, use the commands with `table` *<table-name>* at the end.

```
show route advertising-protocol bgp <neighbor-address>

show route receive-protocol bgp <neighbor-address>

show route advertising-protocol bgp <neighbor-address> table <table-name>

show route receive-protocol bgp <neighbor-address> table <table-name>
```

A Monitoring service is also available from Oracle Cloud Infrastructure to actively and passively monitor your cloud resources. For information about monitoring your VPN Connect, see VPN Connect Metrics.

If you have issues, see VPN Connect Troubleshooting.

Juniper SRX

This topic provides configuration for a Juniper SRX that is running software version JunOS 11.0 (or newer).

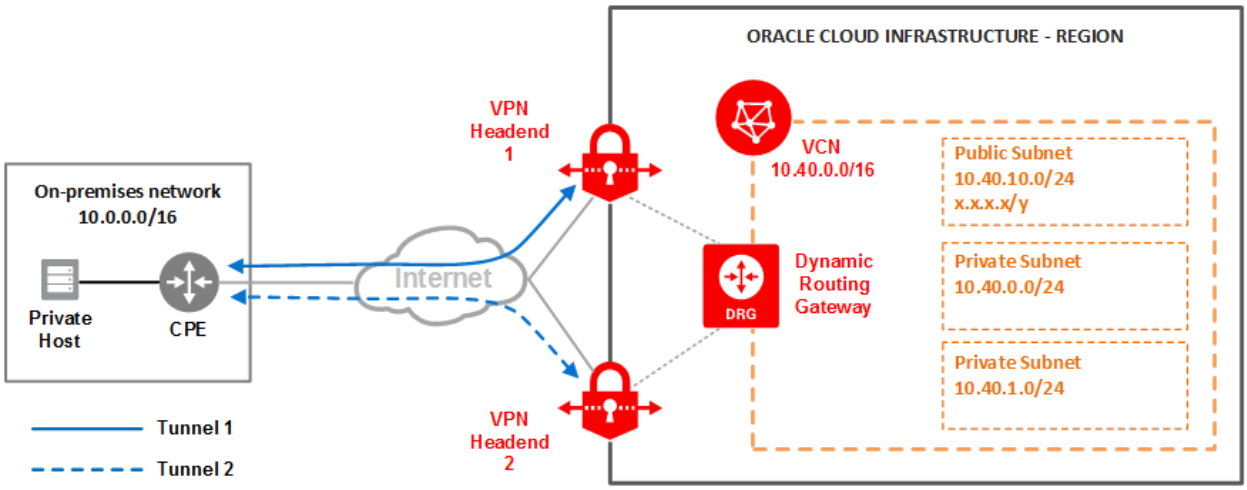
Important

Oracle provides configuration instructions for a set of vendors and devices. Make sure to use the configuration for the correct vendor.

If the device or software version that Oracle used to verify the configuration does not exactly match your device or software, the configuration might still work for you. Consult your vendor's documentation and make any necessary adjustments.

If your device is for a vendor not in the list of verified vendors and devices, or if you're already familiar with configuring your device for IPSec, see the list of supported IPSec parameters and consult your vendor's documentation for assistance.

The following diagram shows a basic IPSec connection to Oracle Cloud Infrastructure with redundant tunnels. IP addresses used in this diagram are for example purposes only.



Best Practices

This section covers general best practices and considerations for using VPN Connect.

Configure All Tunnels for Every IPSec Connection

Oracle deploys two IPSec headends for each of your connections to provide high availability for your mission-critical workloads. On the Oracle side, these two headends are on different routers for redundancy purposes. Oracle recommends configuring all available tunnels for maximum redundancy. This is a key part of the "Design for Failure" philosophy.

Have Redundant CPEs in Your On-Premises Network Locations

Each of your sites that connects with IPSec to Oracle Cloud Infrastructure should have redundant edge devices (also known as customer-premises equipment (CPE)). You add each CPE to the Oracle Console and create a separate IPSec connection between your dynamic routing gateway (DRG) and each CPE. For each IPSec connection, Oracle provisions two tunnels on geographically redundant IPSec headends. For more information, see the Connectivity Redundancy Guide (PDF).

Routing Protocol Considerations

When you create an IPSec VPN, it has two redundant IPSec tunnels. Oracle encourages you to configure your CPE to use both tunnels (if your CPE supports it). Note that in the past, Oracle created IPSec VPNs that had up to four IPSec tunnels.

The following two routing types are available, and you choose the routing type separately for each tunnel in the IPSec VPN:

- **BGP dynamic routing:** The available routes are learned dynamically through BGP. The DRG dynamically learns the routes from your on-premises network. On the Oracle side, the DRG advertises the VCN's subnets.
- **Static routing:** When you set up the IPSec connection to the DRG, you specify the particular routes to your on-premises network that you want the VCN to know about. You also must configure your CPE device with static routes to the VCN's subnets. These routes are not learned dynamically.

For more information about routing with VPN Connect, including Oracle recommendations on how to manipulate the BGP best path selection algorithm, see Routing for the Oracle IPSec VPN.

Other Important CPE Configurations

Ensure access lists on your CPE are configured correctly to not block necessary traffic from or to Oracle Cloud Infrastructure.

If you have multiple tunnels up simultaneously, ensure that your CPE is configured to handle traffic coming from your VCN on any of the tunnels. For example, you need to disable ICMP inspection, configure TCP state bypass, and so on. For more details about the appropriate configuration, contact your CPE vendor's support.

Caveats and Limitations

This section covers general important characteristics and limitations of VPN Connect to be aware of.

Asymmetric Routing

Oracle uses asymmetric routing across the multiple tunnels that make up the IPSec connection. Configure your firewalls accordingly. Otherwise, ping tests or application traffic across the connection will not reliably work.

When you use multiple tunnels to Oracle Cloud Infrastructure, Oracle recommends that you configure your routing to deterministically route traffic through the preferred tunnel. If you want to use one IPSec tunnel as primary and another as backup, configure more-specific routes for the primary tunnel (BGP) and less-specific routes (summary or default route) for the backup tunnel (BGP/static). Otherwise, if you advertise the same route (for example, a default route) through all tunnels, return traffic from your VCN to your on-premises network will route to any of the available tunnels (because Oracle uses asymmetric routing).

For specific Oracle routing recommendations about how to force symmetric routing, see Preferring a Specific Tunnel in the IPSec VPN.

Route-Based or Policy-Based IPSec VPN

The IPSec protocol uses Security Associations (SAs) to determine how to encrypt packets. Within each SA, you define encryption domains to map a packet's source and destination IP address and protocol type to an entry in the SA database to define how to encrypt or decrypt a packet.

Note

Other vendors or industry documentation might use the term *proxy ID, security parameter index (SPI)*, or *traffic selector* when referring to SAs or encryption domains.

There are two general methods for implementing IPSec tunnels:

- **Route-based tunnels:** Also called *next-hop-based tunnels*. A route table lookup is performed on a packet's destination IP address. If that route's egress interface is an

IPSec tunnel, the packet is encrypted and sent to the other end of the tunnel.

- **Policy-based tunnels:** The packet's source and destination IP address and protocol are matched against a list of policy statements. If a match is found, the packet is encrypted based on the rules in that policy statement.

The Oracle VPN headends use route-based tunnels but can work with policy-based tunnels with some caveats listed in the following sections.

Important

The Oracle VPN headend supports only a single encryption domain. If your policy includes multiple entries, the tunnel will flap or there will be connectivity problems in which only a single policy works at any one time.

Encryption domain for route-based tunnels

If your CPE supports route-based tunnels, use that method to configure the tunnel. It's the simplest configuration with the most interoperability with the Oracle VPN headend.

Route-based IPSec uses an encryption domain with the following values:

- **Source IP address:** Any (0.0.0.0/0)
- **Destination IP address:** Any (0.0.0.0/0)
- **Protocol:** IPv4

If you need to be more specific, you can use a single summary route for your encryption domain values instead of a default route.

Encryption domain for policy-based tunnels

If your CPE supports only policy-based tunnels, there are restrictions on the policy that you

can use on the CPE.

When you use policy-based tunnels, every policy entry that you define generates a pair of IPSec SAs. This pair is referred to as an *encryption domain*.

> **Important**
>
> The Oracle VPN headend supports only a single encryption domain. If your policy includes multiple entries, the tunnel will flap or there will be connectivity problems in which only a single policy works at any one time.

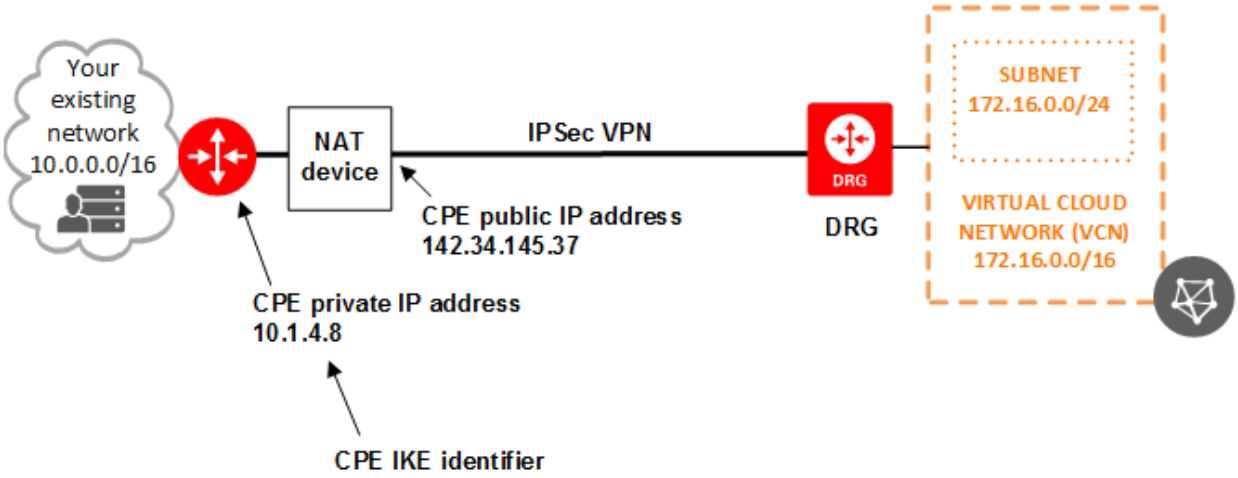
If you use policy-based IPSec, Oracle recommends using a *single encryption domain* with the following values:

- **Source IP address:** Any (0.0.0.0/0)
- **Destination IP address:** VCN CIDR (example: 10.120.0.0/20)
- **Protocol:** IPv4

Make sure the single encryption domain matches any traffic that needs to go from your on-premises network across the IPSec tunnel to the VCN. The VCN CIDR must not overlap with your on-premises network.

If Your CPE Is Behind a NAT Device

In general, the CPE IKE identifier configured on your end of the connection must match the CPE IKE identifier that Oracle is using. By default, Oracle uses the CPE's *public* IP address, which you provide when you create the CPE object in the Oracle Console. However, if your CPE is behind a NAT device, the CPE IKE identifier configured on your end might be the CPE's *private* IP address, as show in the following diagram.



Note

Some CPE platforms do not allow you to change the local IKE identifier. If you cannot, you must change the remote IKE ID in the Oracle Console to match your CPE's local IKE ID. You can provide the value either when you set up the IPSec connection, or later, by editing the IPSec connection. Oracle expects the value to be either an IP address or a fully qualified domain name (FQDN) such as *cpe.example.com*. For instructions, see Changing the CPE IKE Identifier That Oracle Uses.

Supported IPSec Parameters

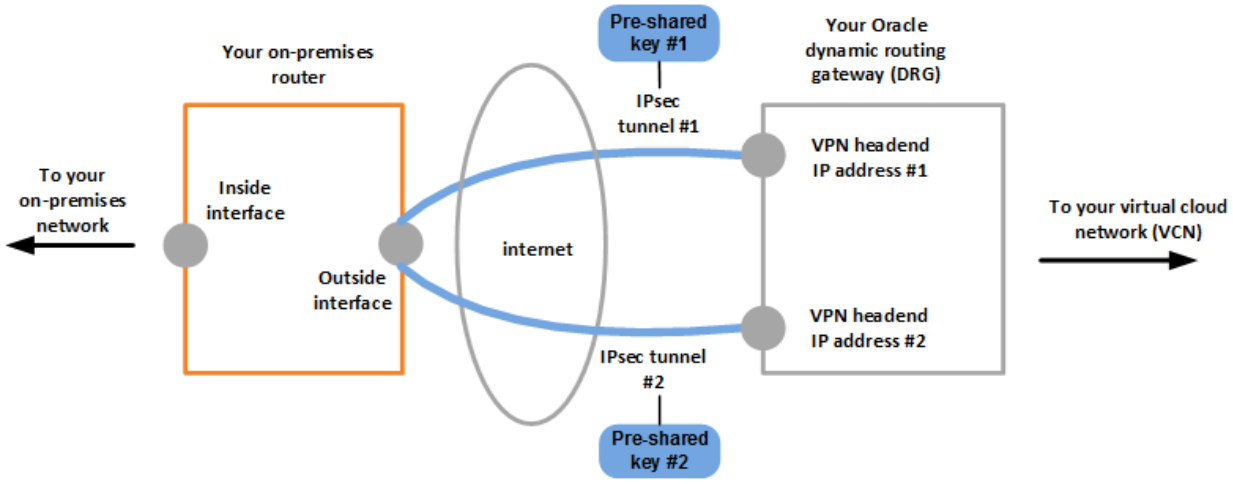
For a vendor-neutral list of supported IPSec parameters for all regions, see Supported IPSec Parameters.

The Oracle BGP ASN for the commercial cloud is 31898. If you're configuring VPN Connect for the Government Cloud, see Required VPN Connect Parameters for Government Cloud and also Oracle's BGP ASN.

CPE Configuration

> **Important**
>
> The configuration instructions in this section are provided by Oracle Cloud Infrastructure for your CPE. If you need support or further assistance, contact your CPE vendor's support directly.

The following figure shows the basic layout of the IPSec connection.



The configuration template provided is for a Juniper SRX router running JunOS 11.0 software (or later). The template provides information for each tunnel that you must configure. Oracle recommends setting up all configured tunnels for maximum redundancy.

The configuration template refers to these items that you must provide:

- **CPE public IP address:** The internet-routable IP address that is assigned to the external interface on the CPE. You or your Oracle administrator provides this value to Oracle when creating the CPE object in the Oracle Console.
- **Inside tunnel interface (required if using BGP):** The IP addresses for the CPE and Oracle ends of the inside tunnel interface. You provide these values when creating the IPSec connection in the Oracle Console.
- **BGP ASN (required if using BGP):** Your BGP ASN.

In addition, you must:

- Configure the outside tunnel interface (the CPE public IP address is bound to this interface).
- Configure the tunnel interface IDs (referred to as st0.1 and st0.2 in the following configuration template). You need multiple tunnel unit numbers per IPSec connection.
- Configure internal routing that routes traffic between the CPE and your local network.
- Identify the security zone for the outside interface (the following configuration template references this zone as `internet_untrust`).
- Identify the security zone for the inside interface (the following configuration template references this zone as `oracle_trust`).
- Identify the security zone for the tunnel interface (the following configuration template references this zone as `oracle_vpn`).

Important

This following configuration template from Oracle Cloud Infrastructure **is a starting point for what you need to apply to your CPE.** Some of the parameters referenced in the template must be unique on the CPE, and the uniqueness can only be determined by accessing the CPE. Ensure the parameters are valid on your CPE and do not overwrite any previously configured values. In particular, ensure these values are unique:

- Policy names or numbers
- Interface names
- Access list numbers (if applicable)

To find parameters that you must define before applying the configuration, search for the keyword `USER_DEFINED` in the template.

About Using IKEv2

Oracle supports Internet Key Exchange version 1 (IKEv1) and version 2 (IKEv2). If you configure the IPSec connection in the Console to use IKEv2, you must configure your CPE to use only IKEv2 and related IKEv2 encryption parameters that your CPE supports. For a list of parameters that Oracle supports for IKEv1 or IKEv2, see Supported IPSec Parameters.

You specify the IKE version when defining the IKE gateway. In the following configuration, there's a comment showing how to configure the IKE gateway for IKEv1 versus IKEv2.

Configuration Template

```
-----------------------------------------------------------------------------------------------------------
-------------------------------------------------------
# Configuration Template
```

```
# The configuration consists of two IPSec tunnels. Oracle highly recommends that you configure both
tunnels for maximum redundancy.
-----------------------------------------------------------------------------------------------------
-------------------------------------------------------
# The configuration template involves setting up the following:
# PHASE 1
# PHASE 2
# SETTING THE SECURITY ZONES FOR ORACLE
# SETTING THE SECURITY POLICIES FOR ORACLE
# SETTING THE SECURITY SETTING FOR ORACLE
# SETTING BGP/STATIC ROUTING
-----------------------------------------------------------------------------------------------------
-------------------------------------------------------
# The configuration template has various parameters that you must define before applying the
configuration.
# Search in the template for the keyword "USER_DEFINED" to find those parameters.
-----------------------------------------------------------------------------------------------------
-------------------------------------------------------
# PARAMETERS REFERENCED:
# oracle_headend_1 = Oracle public IP endpoint obtained from the Oracle Console.
# oracle_headend_2 = Oracle public IP endpoint obtained from the Oracle Console.
# connection_presharedkey_1 = You provide when you set up the IPSec connection in the Oracle Console, or
you can use the default Oracle-provided value.
# connection_presharedkey_2 = You provide when you set up the IPSec connection in the Oracle Console, or
you can use the default Oracle-provided value.
# outside_public_interface = The public interface or outside of tunnel interface which is configured
with the CPE public IP address. Example: ge-0/0/1.0
# cpe_public_ip_address = The internet-routable IP address that is assigned to the public interface on
the CPE. You provide this when creating the CPE object in the Oracle Console.
# inside_tunnel_interface = The internal-facing interface for the on-premises network behind the SRX
that needs to reach the Oracle VCN. Example: ge-0/0/0.0
# inside_tunnel_interface_ip_address = The IP addresses for the CPE and Oracle ends of the inside tunnel
interface. You provide these when creating the IPSec connection in the Oracle Console.
# inside_tunnel_interface_ip_address_neighbor = The neighbor IP address between tbe SRX and Oracle end
points of the inside tunnel interface.
# internal_network_ip_range = Internal on-premise network behind the SRX that needs to reach resources
in the Oracle VCN.
# bgp_asn = Your ASN
# vcn_range = VCN IP Range
-----------------------------------------------------------------------------------------------------
-------------------------------------------------------

# #5b: Static Route Configuration

# USER_DEFINED: Replace the parameters in the section below as needed
# In case you plan to use static routing to get traffic through the IPSec tunnels, you can point the
routes down to the tunnel interfaces. You should redistribute these routes into your on-premises
network. Configuration for CPE to VCN static routes:

set routing-options static route <vcn_range> next-hop st0.2
```

Verification

Use the following command to verify security associations (SAs).

```
show security ipsec security-associations
```

Use the following command to check the BGP status.

```
show bgp summary
```

Use the following commands to check the routes advertised to and received from Oracle Cloud Infrastructure.

```
show route advertising-protocol bgp <neighbor-address>

show route receive-protocol bgp <neighbor-address>
```

A Monitoring service is also available from Oracle Cloud Infrastructure to actively and passively monitor your cloud resources. For information about monitoring your VPN Connect, see VPN Connect Metrics.

If you have issues, see VPN Connect Troubleshooting.

Libreswan

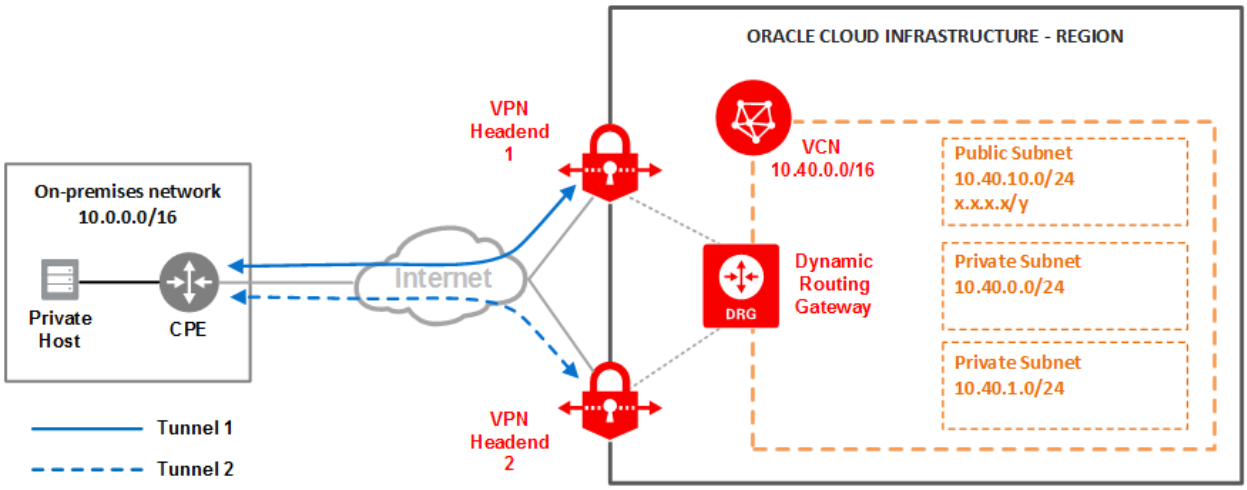
Libreswan is an open source IPSec implementation that is based on FreeS/WAN and Openswan. Most Linux distributions include Libreswan or make it easy to install. You can install it on hosts in either your on-premises network or a cloud provider network. For an example of setting up a Libreswan host in another cloud provider to connect to your Oracle Cloud Infrastructure VCN, see Access to Other Clouds with Libreswan.

This topic provides configuration for CPE that is running Libreswan. Virtual tunnel interface (VTI) support for this route-based configuration requires minimum Libreswan version 3.18 and a recent Linux 3.x or 4.x kernel. This configuration was validated using Libreswan version 3.29.

> **Important**
>
> Oracle provides configuration instructions for a set of vendors and devices. Make sure to use the configuration for the correct vendor.
>
> If the device or software version that Oracle used to verify the configuration does not exactly match your device or software, the configuration might still work for you. Consult your vendor's documentation and make any necessary adjustments.
>
> If your device is for a vendor not in the list of verified vendors and devices, or if you're already familiar with configuring your device for IPSec, see the list of supported IPSec parameters and consult your vendor's documentation for assistance.

VPN Connect is the IPSec VPN that Oracle Cloud Infrastructure offers for connecting your on-premises network to a virtual cloud network (VCN).

The following diagram shows a basic IPSec connection to Oracle Cloud Infrastructure with redundant tunnels. IP addresses used in this diagram are for example purposes only.



Best Practices

This section covers general best practices and considerations for using VPN Connect.

Configure All Tunnels for Every IPSec Connection

Oracle deploys two IPSec headends for each of your connections to provide high availability for your mission-critical workloads. On the Oracle side, these two headends are on different routers for redundancy purposes. Oracle recommends configuring all available tunnels for maximum redundancy. This is a key part of the "Design for Failure" philosophy.

Have Redundant CPEs in Your On-Premises Network Locations

Each of your sites that connects with IPSec to Oracle Cloud Infrastructure should have redundant edge devices (also known as customer-premises equipment (CPE)). You add each CPE to the Oracle Console and create a separate IPSec connection between your dynamic routing gateway (DRG) and each CPE. For each IPSec connection, Oracle provisions two tunnels on geographically redundant IPSec headends. For more information, see the Connectivity Redundancy Guide (PDF).

Routing Protocol Considerations

When you create an IPSec VPN, it has two redundant IPSec tunnels. Oracle encourages you to configure your CPE to use both tunnels (if your CPE supports it). Note that in the past, Oracle created IPSec VPNs that had up to four IPSec tunnels.

The following two routing types are available, and you choose the routing type separately for each tunnel in the IPSec VPN:

- **BGP dynamic routing:** The available routes are learned dynamically through BGP. The DRG dynamically learns the routes from your on-premises network. On the Oracle side, the DRG advertises the VCN's subnets.
- **Static routing:** When you set up the IPSec connection to the DRG, you specify the particular routes to your on-premises network that you want the VCN to know about. You also must configure your CPE device with static routes to the VCN's subnets. These routes are not learned dynamically.

For more information about routing with VPN Connect, including Oracle recommendations on how to manipulate the BGP best path selection algorithm, see Routing for the Oracle IPSec VPN.

Other Important CPE Configurations

Ensure access lists on your CPE are configured correctly to not block necessary traffic from or to Oracle Cloud Infrastructure.

If you have multiple tunnels up simultaneously, ensure that your CPE is configured to handle traffic coming from your VCN on any of the tunnels. For example, you need to disable ICMP inspection, configure TCP state bypass, and so on. For more details about the appropriate configuration, contact your CPE vendor's support.

Caveats and Limitations

This section covers general important characteristics and limitations of VPN Connect to be aware of.

Asymmetric Routing

Oracle uses asymmetric routing across the multiple tunnels that make up the IPSec connection. Configure your firewalls accordingly. Otherwise, ping tests or application traffic across the connection will not reliably work.

When you use multiple tunnels to Oracle Cloud Infrastructure, Oracle recommends that you configure your routing to deterministically route traffic through the preferred tunnel. If you want to use one IPSec tunnel as primary and another as backup, configure more-specific routes for the primary tunnel (BGP) and less-specific routes (summary or default route) for the backup tunnel (BGP/static). Otherwise, if you advertise the same route (for example, a default route) through all tunnels, return traffic from your VCN to your on-premises network will route to any of the available tunnels (because Oracle uses asymmetric routing).

For specific Oracle routing recommendations about how to force symmetric routing, see Preferring a Specific Tunnel in the IPSec VPN.

Route-Based or Policy-Based IPSec VPN

The IPSec protocol uses Security Associations (SAs) to determine how to encrypt packets. Within each SA, you define encryption domains to map a packet's source and destination IP address and protocol type to an entry in the SA database to define how to encrypt or decrypt a packet.

Note

Other vendors or industry documentation might use the term *proxy ID, security parameter index (SPI)*, or *traffic selector* when referring to SAs or encryption domains.

There are two general methods for implementing IPSec tunnels:

- **Route-based tunnels:** Also called *next-hop-based tunnels*. A route table lookup is performed on a packet's destination IP address. If that route's egress interface is an

IPSec tunnel, the packet is encrypted and sent to the other end of the tunnel.

- **Policy-based tunnels:** The packet's source and destination IP address and protocol are matched against a list of policy statements. If a match is found, the packet is encrypted based on the rules in that policy statement.

The Oracle VPN headends use route-based tunnels but can work with policy-based tunnels with some caveats listed in the following sections.

Important

The Oracle VPN headend supports only a single encryption domain. If your policy includes multiple entries, the tunnel will flap or there will be connectivity problems in which only a single policy works at any one time.

Encryption domain for route-based tunnels

If your CPE supports route-based tunnels, use that method to configure the tunnel. It's the simplest configuration with the most interoperability with the Oracle VPN headend.

Route-based IPSec uses an encryption domain with the following values:

- **Source IP address:** Any (0.0.0.0/0)
- **Destination IP address:** Any (0.0.0.0/0)
- **Protocol:** IPv4

If you need to be more specific, you can use a single summary route for your encryption domain values instead of a default route.

Encryption domain for policy-based tunnels

If your CPE supports only policy-based tunnels, there are restrictions on the policy that you

can use on the CPE.

When you use policy-based tunnels, every policy entry that you define generates a pair of IPSec SAs. This pair is referred to as an *encryption domain*.

Important

The Oracle VPN headend supports only a single encryption domain. If your policy includes multiple entries, the tunnel will flap or there will be connectivity problems in which only a single policy works at any one time.

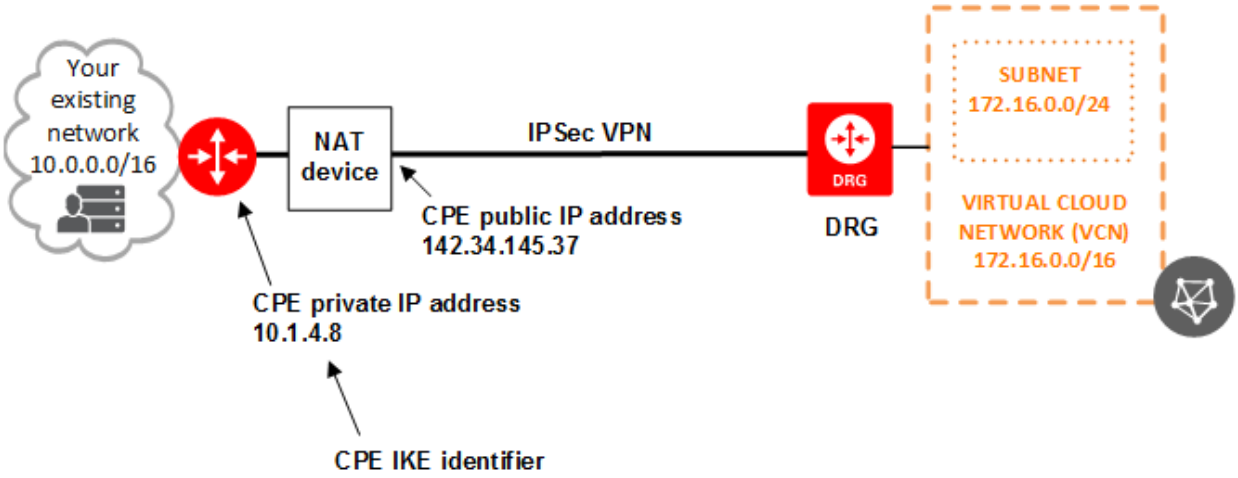
If you use policy-based IPSec, Oracle recommends using a *single encryption domain* with the following values:

- **Source IP address:** Any (0.0.0.0/0)
- **Destination IP address:** VCN CIDR (example: 10.120.0.0/20)
- **Protocol:** IPv4

Make sure the single encryption domain matches any traffic that needs to go from your on-premises network across the IPSec tunnel to the VCN. The VCN CIDR must not overlap with your on-premises network.

If Your CPE Is Behind a NAT Device

In general, the CPE IKE identifier configured on your end of the connection must match the CPE IKE identifier that Oracle is using. By default, Oracle uses the CPE's *public* IP address, which you provide when you create the CPE object in the Oracle Console. However, if your CPE is behind a NAT device, the CPE IKE identifier configured on your end might be the CPE's *private* IP address, as show in the following diagram.



Note

Some CPE platforms do not allow you to change the local IKE identifier. If you cannot, you must change the remote IKE ID in the Oracle Console to match your CPE's local IKE ID. You can provide the value either when you set up the IPSec connection, or later, by editing the IPSec connection. Oracle expects the value to be either an IP address or a fully qualified domain name (FQDN) such as *cpe.example.com*. For instructions, see Changing the CPE IKE Identifier That Oracle Uses.

Supported IPSec Parameters

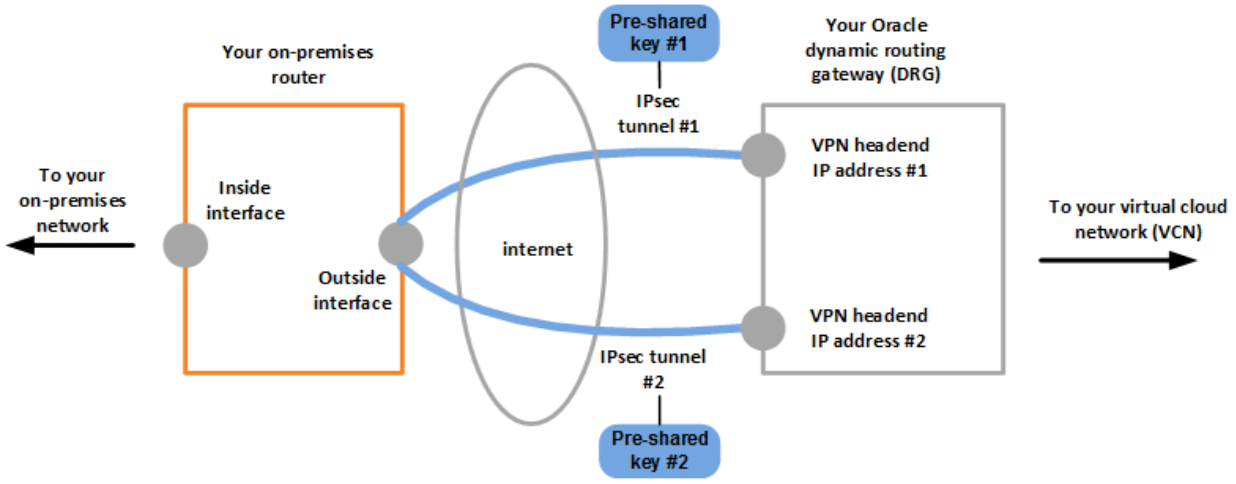
For a vendor-neutral list of supported IPSec parameters for all regions, see Supported IPSec Parameters.

The Oracle BGP ASN for the commercial cloud is 31898. If you're configuring VPN Connect for the Government Cloud, see Required VPN Connect Parameters for Government Cloud and also Oracle's BGP ASN.

CPE Configuration

> **Important**
>
> The configuration instructions in this section are provided by Oracle Cloud Infrastructure for your CPE. If you need support or further assistance, contact your CPE vendor's support directly.

The following figure shows the basic layout of the IPSec connection.



Default Libreswan Configuration Files

The default Libreswan installation creates the following files:

- `etc/ipsec.conf`: The root of the Libreswan configuration.
- `/etc/ipsec.secrets`: The root of the location where Libreswan looks for secrets (the tunnel pre-shared keys).
- `/etc/ipsec.d/`: A directory for storing the `.conf` and `.secrets` files for your Oracle Cloud Infrastructure tunnels (for example: `oci-ipsec.conf` and `oci-ipsec.secrets`). Libreswan encourages you to create these files in this folder.

The default `etc/ipsec.conf` file includes this line:

```
include /etc/ipsec.d/*.conf
```

The default `etc/ipsec.secrets` file includes this line:

```
include /etc/ipsec.d/*.secrets
```

The preceding lines automatically merge all the `.conf` and `.secrets` files in the `/etc/ipsec.d` directory into the main configuration and secrets files that Libreswan uses.

About Using IKEv2

Oracle supports Internet Key Exchange version 1 (IKEv1) and version 2 (IKEv2). If you configure the IPSec connection in the Console to use IKEv2, you must configure your CPE to use only IKEv2 and related IKEv2 encryption parameters that your CPE supports. For a list of parameters that Oracle supports for IKEv1 or IKEv2, see Supported IPSec Parameters.

You specify the IKE version when setting up the IPSec configuration file in task 3 in the next section. In that example file, there's a comment showing how to configure IKEv1 versus IKEv2.

Configuration Process

Libreswan supports both route-based and policy-based tunnels. The tunnel types can coexist without interfering with each other. The Oracle VPN headends use route-based tunnels. Oracle recommends that you configure Libreswan with the Virtual Tunnel Interface (VTI) configuration syntax.

For details about the specific parameters used in this document, see Supported IPSec Parameters.

Task 1: Prepare the Libreswan instance

Depending on the Linux distribution you're using, you might need to enable IP forwarding on your interface to allow clients to send and receive traffic through Libreswan. In the `/etc/sysctl.conf` file, set the following values and apply the updates with `sudo sysctl -p`.

If you're using an interface other than eth0, change `eth0` in the following example to your interface (lines 5 and 7).

```
net.ipv4.ip_forward=1
net.ipv4.conf.all.accept_redirects = 0
net.ipv4.conf.all.send_redirects = 0
net.ipv4.conf.default.send_redirects = 0
net.ipv4.conf.eth0.send_redirects = 0
net.ipv4.conf.default.accept_redirects = 0
net.ipv4.conf.eth0.accept_redirects = 0
```

Task 2: Determine the required configuration values

The Libreswan configuration uses the following variables. Determine the values before proceeding with the configuration.

- `${cpeLocalIP}`: The IP address of your Libreswan device.
- `${cpePublicIpAddress}`: The public IP address for Libreswan. This is the IP address of your outside interface. Depending on your network topology, the value might be different from `${cpeLocalIP}`.
- `${oracleHeadend1}`: For the first tunnel, the Oracle public IP endpoint obtained from the Oracle Console.
- `${oracleHeadend2}`: For the second tunnel, the Oracle public IP endpoint obtained from the Oracle Console.
- `${vti1}`: The name of the first VTI used. For example, vti1.
- `${vti2}` :The name of the second VTI used. For example, vti2.

- `${sharedSecret1}`: The pre-shared key for the first tunnel. You can use the default Oracle-provided pre-shared key, or provide your own when you set up the IPSec connection in the Oracle Console.
- `${sharedSecret2}`: The pre-shared key for the second tunnel. You can use the default Oracle-provided pre-shared key, or provide your own when you set up the IPSec connection in the Oracle Console.
- `${vcnCidrNetwork}`: The VCN IP range.

Task 3: Set up the configuration file: /etc/ipsec.d/oci-ipsec.conf

Libreswan configuration uses the concept of *left* and *right* to define the configuration parameters for your local CPE device and the remote gateway. Either side of the connection (the *conn* in the Libreswan configuration) can be left or right, but the configuration for that connection must be consistent. In this example:

- **left:** Your local Libreswan CPE
- **right:** The Oracle VPN headend

Use the following template for your `/etc/ipsec.d/oci-ipsec.conf` file. The file defines the two tunnels that Oracle creates when you set up the IPSec connection.

Important

If your CPE is behind a 1-1 NAT device, uncomment the `leftid` parameter and set it equal to the `${cpePublicIpAddress}`.

```
conn oracle-tunnel-1
     left=${cpeLocalIP}
     # leftid=${cpePublicIpAddress} # See preceding note about 1-1 NAT device
     right=${oracleHeadend1}
     authby=secret
     leftsubnet=0.0.0.0/0
```

```
     rightsubnet=0.0.0.0/0
     auto=start
     mark=5/0xffffffff # Needs to be unique across all tunnels
     vti-interface=${vti1}
     vti-routing=no
     ikev2=no # To use IKEv2, change to ikev2=insist
     ike=aes_cbc256-sha2_384;modp1536
     phase2alg=aes_gcm256;modp1536
     encapsulation=no
     ikelifetime=28800s
     salifetime=3600s
conn oracle-tunnel-2
     left=${cpeLocalIP}
     # leftid=${cpePublicIpAddress} # See preceding note about 1-1 NAT device
     right=${oracleHeadend2}
     authby=secret
     leftsubnet=0.0.0.0/0
     rightsubnet=0.0.0.0/0
     auto=start
     mark=6/0xffffffff # Needs to be unique across all tunnels
     vti-interface=${vti2}
     vti-routing=no
     ikev2=no # To use IKEv2, change to ikev2=insist
     ike=aes_cbc256-sha2_384;modp1536
     phase2alg=aes_gcm256;modp1536
     encapsulation=no
     ikelifetime=28800s
     salifetime=3600s
```

Task 4: Set up the secrets file: /etc/ipsec.d/oci-ipsec.secrets

Use the following template for your `/etc/ipsec.d/oci-ipsec.secrets` file. It contains two lines per IPSec connection (one line per tunnel).

```
${cpePublicIpAddress} ${oracleHeadend1}: PSK "${sharedSecret1}"
${cpePublicIpAddress} ${oracleHeadend2}: PSK "${sharedSecret2}"
```

Task 5: Restart the Libreswan configuration

After setting up your configuration and secrets files, you must restart the Libreswan service.

Important

Restarting the Libreswan service may impact existing tunnels.

The following command rereads the config file and restarts the Libreswan service.

```
service ipsec restart
```

Task 6: Configure IP routing

Use the following `ip` command to create static routes that send traffic to your VCN through the IPSec tunnels. If you're logged in with an unprivileged user account, you might need to use `sudo` before the command.

Important

Static routes created with the `ip route` command do not persist through a reboot. To determine how to make your routes persist, refer to the documentation of your Linux distribution of choice.

```
ip route add ${VcnCidrBlock} nexthop dev ${vti1} nexthop dev ${vti2}
ip route show
```

Verification

A Monitoring service is also available from Oracle Cloud Infrastructure to actively and passively monitor your cloud resources. For information about monitoring your VPN Connect, see VPN Connect Metrics.

If you have issues, see VPN Connect Troubleshooting.

Checking the Libreswan Status

Check the current state of your Libreswan tunnels by using the following command.

```
ipsec status
```

The tunnel is established if you see a line that includes the following:

```
STATE_MAIN_I4: ISAKMP SA established
```

If you're using IKEv2, you see the following:

```
STATE_V2_IPSEC_I (IPsec SA established)
```

In the future, if you need to open a support ticket with Oracle about your Libreswan tunnel, include the output of the preceding `ipsec status` command.

CHECKING THE TUNNEL INTERFACE STATUS

Check if the virtual tunnel interfaces are up or down by using the `ifconfig` command or the `ip link show` command. You can also use applications such as tcpdump with the interfaces.

Here's an example of the `ifconfig` output with a working Libreswan implementation that shows the available VTIs.

```
ifconfig
<output trimmed>

vti01: flags=209<UP,POINTOPOINT,RUNNING,NOARP> mtu 8980
     inet6 fe80::5efe:a00:2 prefixlen 64 scopeid 0x20<link>
     tunnel txqueuelen 1000 (IPIP Tunnel)
     RX packets 0 bytes 0 (0.0 B)
     RX errors 0 dropped 0 overruns 0 frame 0
     TX packets 0 bytes 0 (0.0 B)
     TX errors 10 dropped 0 overruns 0 carrier 10 collisions 0

vti02: flags=209<UP,POINTOPOINT,RUNNING,NOARP> mtu 8980
     inet6 fe80::5efe:a00:2 prefixlen 64 scopeid 0x20<link>
     tunnel txqueuelen 1000 (IPIP Tunnel)
     RX packets 0 bytes 0 (0.0 B)
     RX errors 0 dropped 0 overruns 0 frame 0
     TX packets 0 bytes 0 (0.0 B)
     TX errors 40 dropped 0 overruns 0 carrier 40 collisions 0
```

Here's an example of the `ip link show` output:

```
ip link show
<output trimmed>

9: vti01@NONE: <POINTOPOINT,NOARP,UP,LOWER_UP> mtu 8980 qdisc noqueue
state UNKNOWN mode DEFAULT group default qlen 1000
   link/ipip 10.0.0.2 peer 129.213.240.52

10: vti02@NONE: <POINTOPOINT,NOARP,UP,LOWER_UP> mtu 8980 qdisc noqueue
```

```
state UNKNOWN mode DEFAULT group default qlen 1000
   link/ipip 10.0.0.2 peer 129.213.240.51
```

Also, in the Oracle Console, each IPSec tunnel should now be in the UP state.

NEC IX Series

This configuration was validated using an IX3315 running Firmware Ver.10.1.16 and IX2106 running Firmware Ver.10.1.16.

Important

Oracle uses asymmetric routing across the multiple tunnels that make up the IPSec VPN connection. Even if you configure one tunnel as primary and another as backup, traffic from your VCN to your on-premises network can use any tunnel that is "up" on your device. Configure your firewalls accordingly. Otherwise, ping tests or application traffic across the connection will not reliably work.

Before Starting

Before configuring your CPE, make sure to:

- Configure your internet provider settings.
- Configure firewall rules to open UDP port 500, UDP port 4500, and ESP.

Supported Encryption Domain or Proxy ID

The values for the encryption domain (also known as a proxy ID, security parameter index (SPI), or traffic selector) depend on whether your CPE supports route-based tunnels or policy-based tunnels. For more information about the correct encryption domain values to use, see Supported Encryption Domain or Proxy ID.

Parameters from API or Console

Get the following parameters from the Oracle Cloud Infrastructure Console or API.

${ipAddress#} - one per tunnel

- Oracle VPN headend IPSec tunnel endpoints.
- Example values: 129.146.12.52, 129.146.13.52

${sharedSecret#} - one per tunnel

- The IPSec IKE pre-shared-key.
- Example value: EXAMPLEDPfAMkD7nTH3SWr6OFabdT6exXn6enSlsKbE

${cpePublicIpAddress}

- The public IP address for the CPE (previously made available to Oracle via the Console).

${vcnCidrBlock}

- When creating the VCN, your company selected this CIDR to represent the IP aggregate network for all VCN hosts.
- Example Value: 10.0.0.0/20

Parameters Based on Current CPE Configuration and State

The following parameters are based on your current CPE configuration.

${tunnelNumber#} - one per tunnel

- You will need one unused unit number per tunnel.
- Example values: 1, 2

${ikePolicy#} - one per tunnel

- You will need one unused IKE policy name per tunnel.
- Example values: ike-policy1, ike-policy2

${ipsecPolicy#} - one per tunnel

- You will need one unused autokey policy map name per tunnel.
- Example values: ipsec-policy1, ipsec-policy2

${lanIpAddress}

- The local IP address of your CPE.
- Example value: 192.168.100.254

${lanInterfaceNumber}

- The LAN interface of your CPE
- Example value: 1.0

Config Template Parameter Summary

Each region has multiple Oracle IPSec headends. The template below allows you to set up multiple tunnels on your CPE, each to a corresponding headend. In the table below, "User" is you/your company.

Parameter	Source	Example Value
`${ipAddress1}`	Console/API	129.146.12.52
`${ipAddress2}`	Console/API	129.146.13.52
`${sharedSecret1}`	Console/API	(long string)
`${sharedSecret2}`	Console/API	(long string)
`${cpePublicIpAddress}`	User	203.0.113.1
`${vcnCidrBlock}`	User	10.0.0.0/20
`${tunnelNumber1}`	User	1
`${tunnelNumber2}`	User	2

Parameter	Source	Example Value
`${ikePolicy1}`	User	ike-policy1
`${ikePolicy2}`	User	ike-policy2
`${ipsecPolicy1}`	User	ipsec-policy1
`${ipsecPolicy2}`	User	ipsec-policy2
`${lanInterfaceNumber}`	User	1.0
`${lanIpAddress}`	User	192.168.100.254

Important

The following ISAKMP and IPSec policy parameter values are applicable to VPN Connect in the commercial cloud. For the Government Cloud, you must use the values listed in Required VPN Connect Parameters for Government Cloud.

Commercial Cloud: ISAKMP Policy Options

Parameter	Recommended Value
ISAKMP protocol version	Version 1
Exchange type	Main mode
Authentication method	Pre-shared keys
Encryption	AES-256-cbc

Parameter	Recommended Value
Authentication algorithm	SHA-256
Diffie-Hellman Group	Group 5
IKE session key lifetime	28800 seconds (8 hours)

Commercial Cloud: IPSec Policy Options

Parameter	Recommended Value
IPSec protocol	ESP, tunnel-mode
Encryption	AES-256-cbc
Authentication algorithm	HMAC-SHA1-96
Diffie-Hellman Group	Group 5
Perfect Forward Secrecy	Enabled
IPSec session key lifetime	3600 seconds (1 hour)

CPE Configuration

Configure ISAKMP and IPSec Policies

```
ip access-list sec-list permit ip src any dest any
ike nat-traversal
!
ike proposal ike-prop encryption aes-256 hash sha2-256 group 1536-bit
ike policy ${ikePolicy1} peer ${ipAddress1} key ${sharedSecret1} ike-prop
ike policy ${ikePolicy2} peer ${ipAddress2} key ${sharedSecret2} ike-prop
!
ipsec autokey-proposal ipsec-prop esp-aes-256 esp-sha lifetime time 3600
ipsec autokey-map ${ipsecPolicy1} sec-list peer ${ipAddress1} ipsec-prop pfs 1536-bit
ipsec autokey-map ${ipsecPolicy2} sec-list peer ${ipAddress2} ipsec-prop pfs 1536-bit
```

CONFIGURE KEEPALIVE SETTING OF ICMP

```
watch-group watch_tunnel1 10
  event 20 ip unreach-host ${lanIpAddress} Tunnel${tunnelNumber1} source

Openswan

If you want to use Openswan to create an IPSec VPN to Oracle Cloud Infrastructure, see Libreswan.

How Openswan and Libreswan Are Related

Openswan is a well-known IPSec implementation for Linux. It began as a fork of the now-defunct FreeS/WAN project in 2003. Unlike the FreeS/WAN project, it didn't exclusively target the GNU/Linux operation system, but expanded its use to other operating systems. In 2012, FreeS/WAN renamed itself to The Libreswan Project because of a lawsuit over a trademark of the name *openswan*.

As a result, when you try to install or query the Openswan package on Oracle Linux, by default the Libreswan package is installed or shown instead. The following yum search query command illustrates this behavior:

```
$ sudo yum search openswan
Loaded plugins: langpacks, ulninfo
Matched: openswan ============================================
NetworkManager-libreswan.x86_64 : NetworkManager VPN plugin for libreswan
NetworkManager-libreswan-gnome.x86_64 : NetworkManager VPN plugin for libreswan-GNOME files
libreswan.x86_64 : IPsec implementation with IKEv1 and IKEv2 keying protocols
```

Libreswan is maintained by The Libreswan Project and has been under active development for over 15 years, going back to the FreeS/WAN Project. For more information, see the project's history.

Palo Alto

This topic provides configuration for a Palo Alto device. The configuration was validated using PAN-OS version 8.0.0.

Palo Alto experience is required.

Important

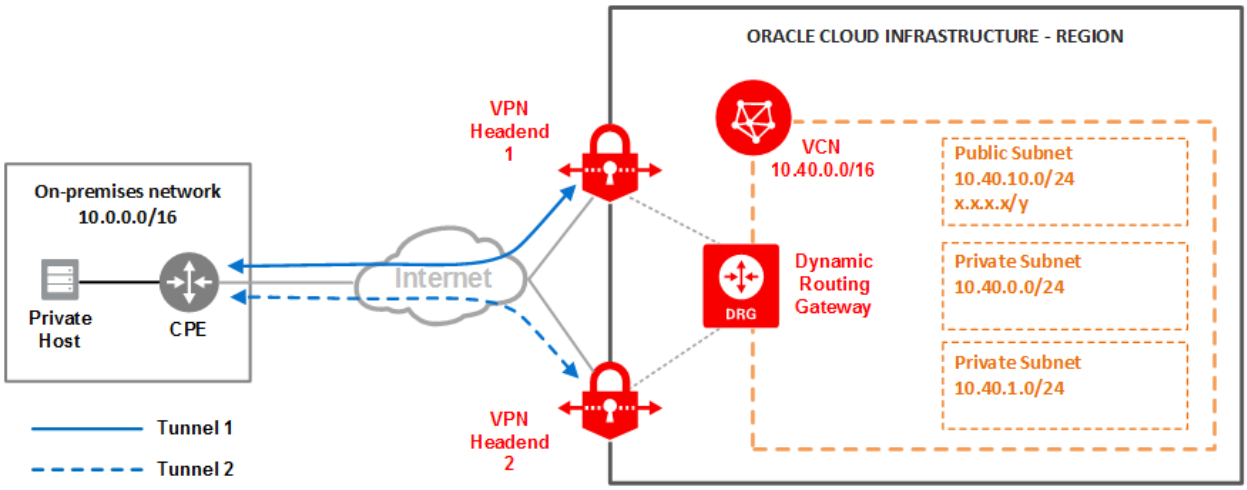
Oracle provides configuration instructions for a set of vendors and devices. Make sure to use the configuration for the correct vendor.

If the device or software version that Oracle used to verify the configuration does not exactly match your device or software, the configuration might still work for you. Consult your vendor's documentation and make any necessary adjustments.

If your device is for a vendor not in the list of verified vendors and devices, or if you're already familiar with configuring your device for IPSec, see the list of supported IPSec parameters and consult your vendor's documentation for assistance.

VPN Connect is the IPSec VPN that Oracle Cloud Infrastructure offers for connecting your on-premises network to a virtual cloud network (VCN).

The following diagram shows a basic IPSec connection to Oracle Cloud Infrastructure with redundant tunnels. IP addresses used in this diagram are for example purposes only.



Best Practices

This section covers general best practices and considerations for using VPN Connect.

Configure All Tunnels for Every IPSec Connection

Oracle deploys two IPSec headends for each of your connections to provide high availability for your mission-critical workloads. On the Oracle side, these two headends are on different routers for redundancy purposes. Oracle recommends configuring all available tunnels for maximum redundancy. This is a key part of the "Design for Failure" philosophy.

Have Redundant CPEs in Your On-Premises Network Locations

Each of your sites that connects with IPSec to Oracle Cloud Infrastructure should have redundant edge devices (also known as customer-premises equipment (CPE)). You add each CPE to the Oracle Console and create a separate IPSec connection between your dynamic routing gateway (DRG) and each CPE. For each IPSec connection, Oracle provisions two tunnels on geographically redundant IPSec headends. For more information, see the Connectivity Redundancy Guide (PDF).

Routing Protocol Considerations

When you create an IPSec VPN, it has two redundant IPSec tunnels. Oracle encourages you to configure your CPE to use both tunnels (if your CPE supports it). Note that in the past, Oracle created IPSec VPNs that had up to four IPSec tunnels.

The following two routing types are available, and you choose the routing type separately for each tunnel in the IPSec VPN:

- **BGP dynamic routing:** The available routes are learned dynamically through BGP. The DRG dynamically learns the routes from your on-premises network. On the Oracle side, the DRG advertises the VCN's subnets.
- **Static routing:** When you set up the IPSec connection to the DRG, you specify the particular routes to your on-premises network that you want the VCN to know about. You also must configure your CPE device with static routes to the VCN's subnets. These routes are not learned dynamically.

For more information about routing with VPN Connect, including Oracle recommendations on how to manipulate the BGP best path selection algorithm, see Routing for the Oracle IPSec VPN.

Other Important CPE Configurations

Ensure access lists on your CPE are configured correctly to not block necessary traffic from or to Oracle Cloud Infrastructure.

If you have multiple tunnels up simultaneously, ensure that your CPE is configured to handle traffic coming from your VCN on any of the tunnels. For example, you need to disable ICMP inspection, configure TCP state bypass, and so on. For more details about the appropriate configuration, contact your CPE vendor's support.

Caveats and Limitations

This section covers general important characteristics and limitations of VPN Connect to be aware of.

Asymmetric Routing

Oracle uses asymmetric routing across the multiple tunnels that make up the IPSec connection. Configure your firewalls accordingly. Otherwise, ping tests or application traffic across the connection will not reliably work.

When you use multiple tunnels to Oracle Cloud Infrastructure, Oracle recommends that you configure your routing to deterministically route traffic through the preferred tunnel. If you want to use one IPSec tunnel as primary and another as backup, configure more-specific routes for the primary tunnel (BGP) and less-specific routes (summary or default route) for the backup tunnel (BGP/static). Otherwise, if you advertise the same route (for example, a default route) through all tunnels, return traffic from your VCN to your on-premises network will route to any of the available tunnels (because Oracle uses asymmetric routing).

For specific Oracle routing recommendations about how to force symmetric routing, see Preferring a Specific Tunnel in the IPSec VPN.

Route-Based or Policy-Based IPSec VPN

The IPSec protocol uses Security Associations (SAs) to determine how to encrypt packets. Within each SA, you define encryption domains to map a packet's source and destination IP address and protocol type to an entry in the SA database to define how to encrypt or decrypt a packet.

Note

Other vendors or industry documentation might use the term *proxy ID, security parameter index (SPI)*, or *traffic selector* when referring to SAs or encryption domains.

There are two general methods for implementing IPSec tunnels:

- **Route-based tunnels:** Also called *next-hop-based tunnels*. A route table lookup is performed on a packet's destination IP address. If that route's egress interface is an

IPSec tunnel, the packet is encrypted and sent to the other end of the tunnel.

- **Policy-based tunnels:** The packet's source and destination IP address and protocol are matched against a list of policy statements. If a match is found, the packet is encrypted based on the rules in that policy statement.

The Oracle VPN headends use route-based tunnels but can work with policy-based tunnels with some caveats listed in the following sections.

Important

The Oracle VPN headend supports only a single encryption domain. If your policy includes multiple entries, the tunnel will flap or there will be connectivity problems in which only a single policy works at any one time.

Encryption domain for route-based tunnels

If your CPE supports route-based tunnels, use that method to configure the tunnel. It's the simplest configuration with the most interoperability with the Oracle VPN headend.

Route-based IPSec uses an encryption domain with the following values:

- **Source IP address:** Any (0.0.0.0/0)
- **Destination IP address:** Any (0.0.0.0/0)
- **Protocol:** IPv4

If you need to be more specific, you can use a single summary route for your encryption domain values instead of a default route.

Encryption domain for policy-based tunnels

If your CPE supports only policy-based tunnels, there are restrictions on the policy that you

can use on the CPE.

When you use policy-based tunnels, every policy entry that you define generates a pair of IPSec SAs. This pair is referred to as an *encryption domain*.

> **Important**
>
> The Oracle VPN headend supports only a single encryption domain. If your policy includes multiple entries, the tunnel will flap or there will be connectivity problems in which only a single policy works at any one time.

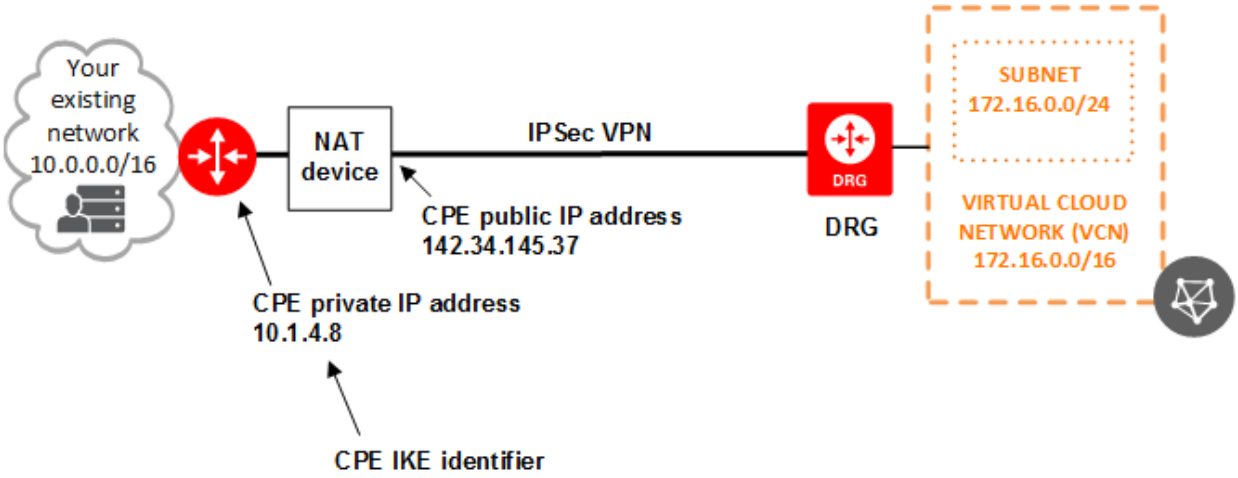
If you use policy-based IPSec, Oracle recommends using a *single encryption domain* with the following values:

- **Source IP address:** Any (0.0.0.0/0)
- **Destination IP address:** VCN CIDR (example: 10.120.0.0/20)
- **Protocol:** IPv4

Make sure the single encryption domain matches any traffic that needs to go from your on-premises network across the IPSec tunnel to the VCN. The VCN CIDR must not overlap with your on-premises network.

If Your CPE Is Behind a NAT Device

In general, the CPE IKE identifier configured on your end of the connection must match the CPE IKE identifier that Oracle is using. By default, Oracle uses the CPE's *public* IP address, which you provide when you create the CPE object in the Oracle Console. However, if your CPE is behind a NAT device, the CPE IKE identifier configured on your end might be the CPE's *private* IP address, as show in the following diagram.



Note

Some CPE platforms do not allow you to change the local IKE identifier. If you cannot, you must change the remote IKE ID in the Oracle Console to match your CPE's local IKE ID. You can provide the value either when you set up the IPSec connection, or later, by editing the IPSec connection. Oracle expects the value to be either an IP address or a fully qualified domain name (FQDN) such as *cpe.example.com*. For instructions, see Changing the CPE IKE Identifier That Oracle Uses.

Supported IPSec Parameters

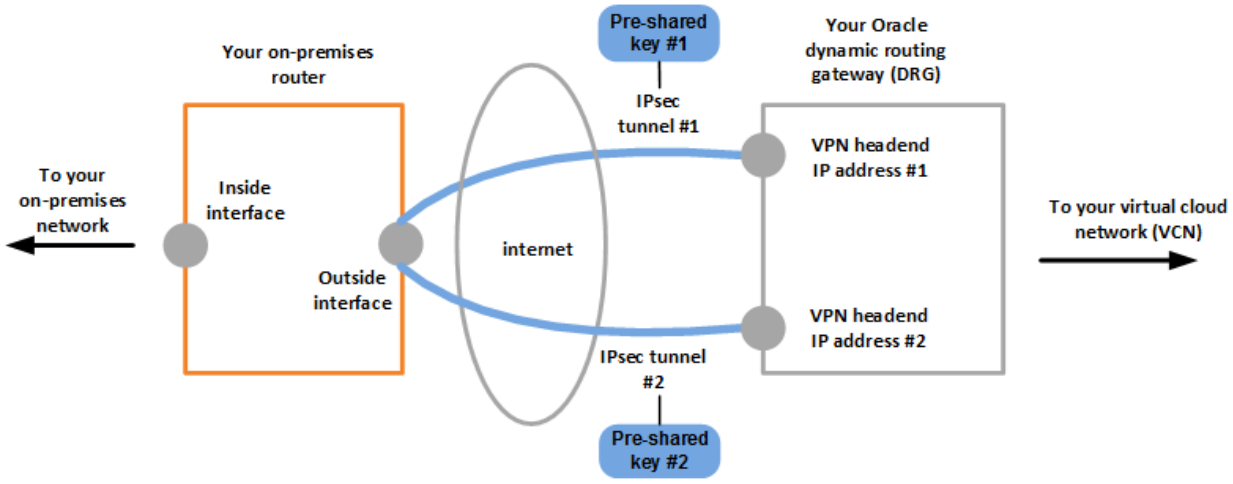
For a vendor-neutral list of supported IPSec parameters for all regions, see Supported IPSec Parameters.

The Oracle BGP ASN for the commercial cloud is 31898. If you're configuring VPN Connect for the Government Cloud, see Required VPN Connect Parameters for Government Cloud and also Oracle's BGP ASN.

CPE Configuration

> **Important**
>
> The configuration instructions in this section are provided by Oracle Cloud Infrastructure for your CPE. If you need support or further assistance, contact your CPE vendor's support directly.

The following figure shows the basic layout of the IPSec connection.



Important Details About the Configuration Instructions

- **Commits:** For PAN to activate the configuration, you must perform the commit action after any configuration change.
- **Example IP addresses:** The example configuration uses IP addresses from class A 10.0.0.0/8 (RFC1918) and 198.51.100.0/24 (RFC5735). When you perform the configuration on the CPE, use the correct IP addressing plan for your networking topology.

The example configuration uses the following variables and values:

- **Inside tunnel1 interface - CPE:** 198.51.100.1/30
- **Inside tunnel2 interface - CPE:** 198.51.100.5/30
- **Inside tunnel1 interface - Oracle:** 198.51.100.2/30
- **Inside tunnel2 interface - Oracle:** 198.51.100.6/30
- **CPE ASN:** 64511
- **On-premises network :** 10.200.1.0/24
- **VCN CIDR block:** 10.200.0.0/24
- **CPE public IP address:** 10.100.0.100/24
- **Oracle VPN headend (DRG) IP address 1:** 10.150.128.1/32
- **Oracle VPN headend (DRG) IP address 2:** 10.150.127.1/32
- **Tunnel number 1:** tunnel.1
- **Tunnel number 2:** tunnel.2
- **Exit interface:** ethernet1/1

About Using IKEv2

Oracle supports Internet Key Exchange version 1 (IKEv1) and version 2 (IKEv2). If you configure the IPSec connection in the Console to use IKEv2, you must configure your CPE to use only IKEv2 and related IKEv2 encryption parameters that your CPE supports. For a list of parameters that Oracle supports for IKEv1 or IKEv2, see Supported IPSec Parameters.

If you want to use IKEv2, there are special variations of some steps presented in the next section. Here is a summary of the special steps:

- For task 2 (defining the ISAKMP peers), when you add the IKE gateway:
  - On the **General** tab, for the **Version**, select **IKEv2 only mode**.
  - On the **Advanced Options** tab, select the IKE crypto profile associated with the IKEv2 tunnel.
- For task 5 (configuring the IPSec sessions), configure the proxy ID.

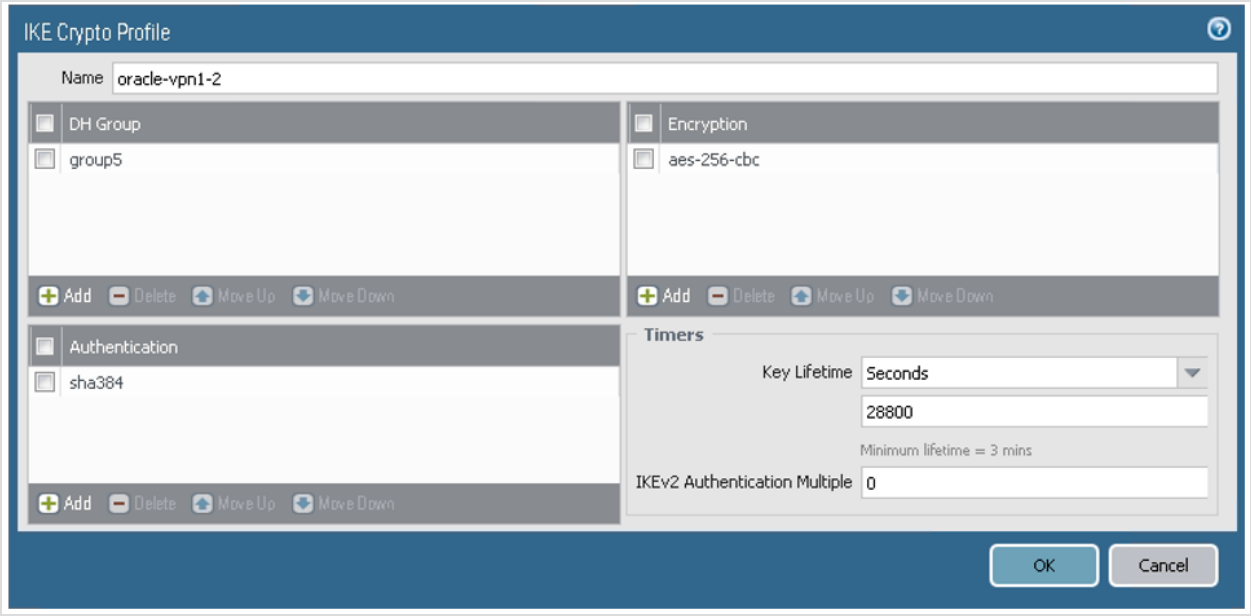
CONFIGURATION PROCESS

The following process includes BGP configuration for the IPSec connection. If you instead want to use static routing, perform tasks 1-5, and then skip to Configuring Static Routing.

Task 1: Configure the ISAKMP Phase 1 policy

In this example, the same ISAKMP policy is used for both tunnels.

1. Go to **Network**, to **IKE Crypto**, and then click **Add**.
2. Configure the parameters as shown in the next screenshot. For a list of the values, see Supported IPSec Parameters. If you're configuring VPN Connect for the Government Cloud, see Required VPN Connect Parameters for Government Cloud.

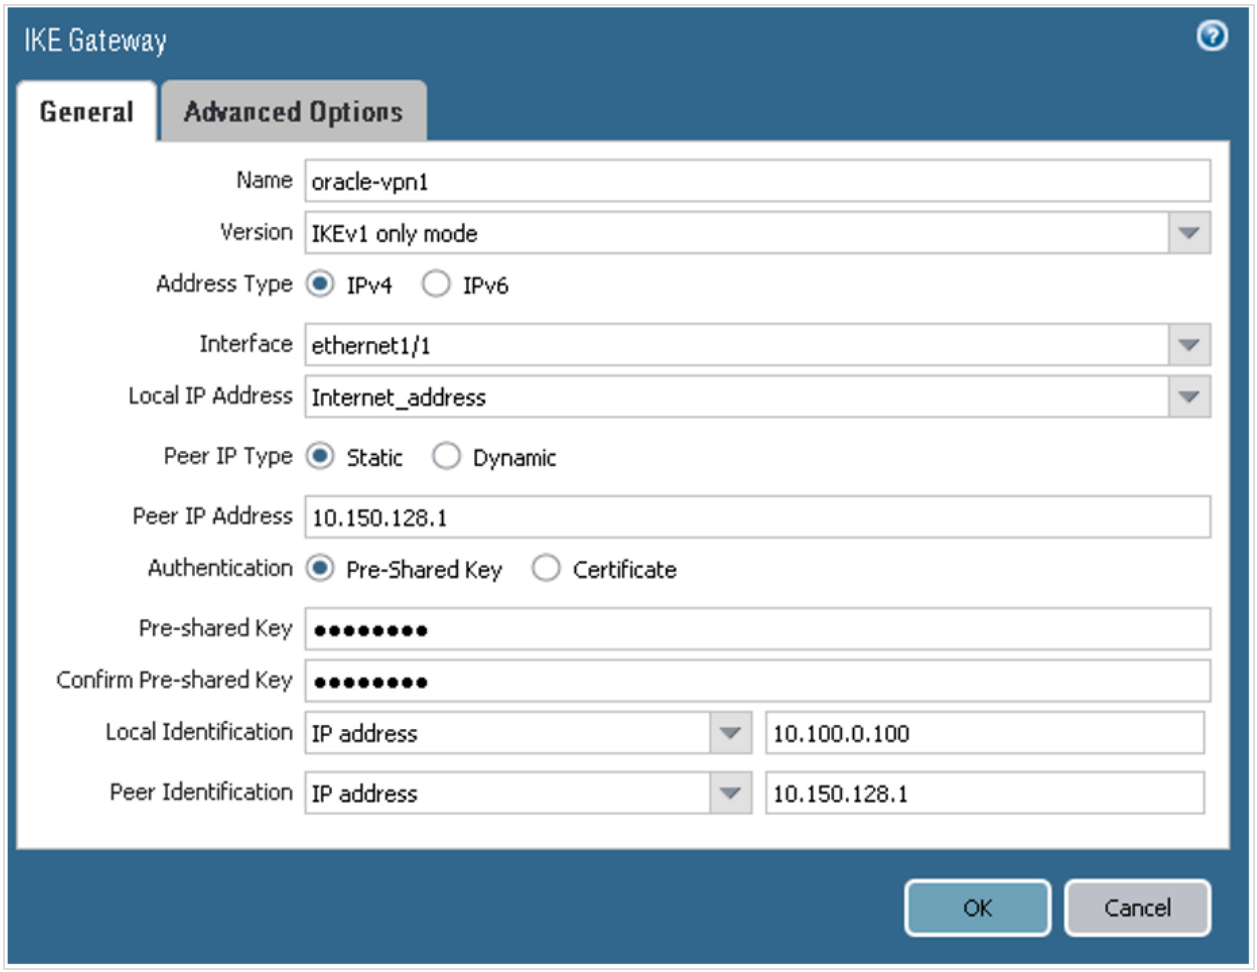


The next screenshot shows the final result for this task:

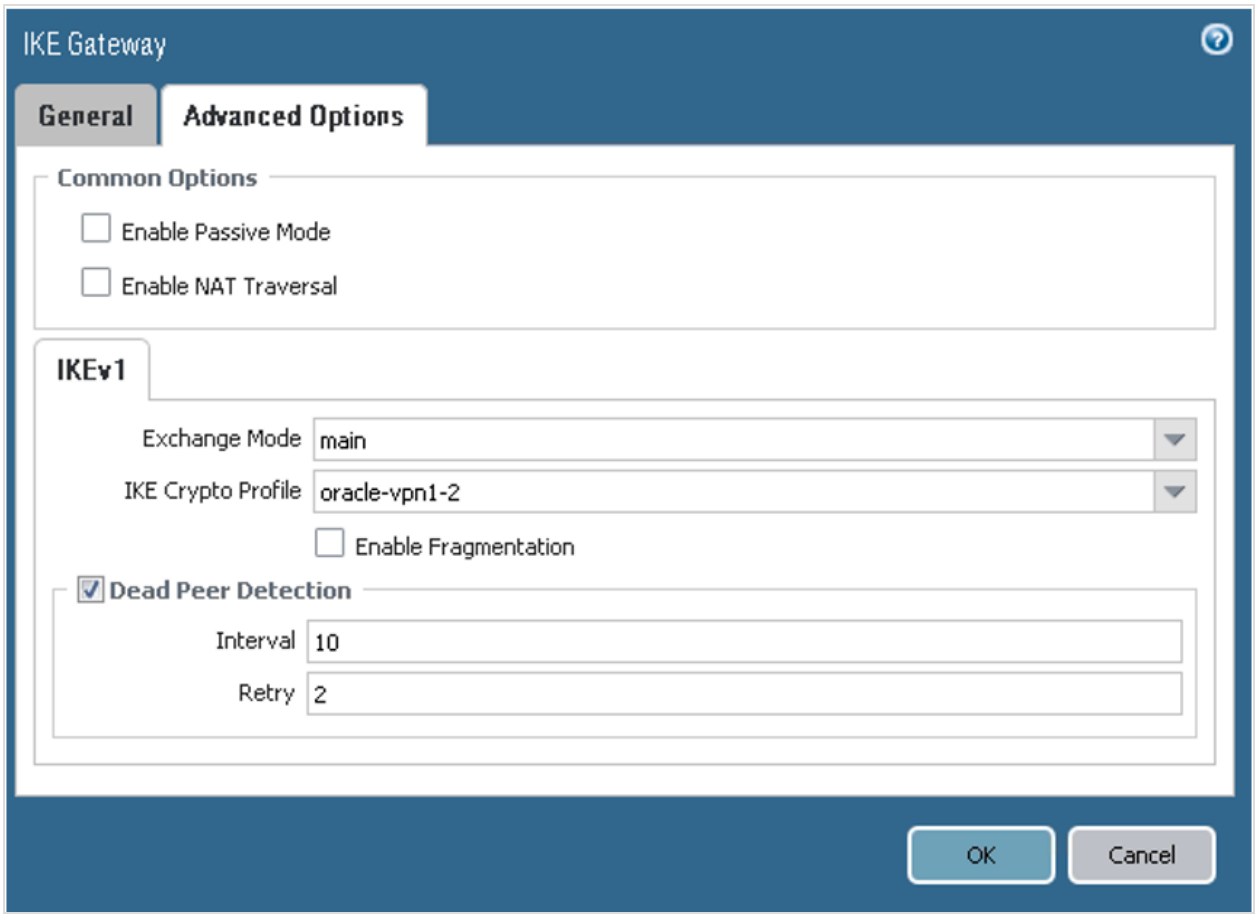
Task 2: Define the ISAKMP peers

1. Go to **Network**, to **IKE Gateways**, and then click **Add**.
2. For peer 1, configure the parameters as shown in the next screenshots.
    a. On the **General** tab:
        - **Version:** For IKEv1, select **IKEv1 only mode**. If you want to use IKEv2, select **IKEv2** only mode. Notice that if you're using IKEv2, later in task 5 you also add proxy IDs.

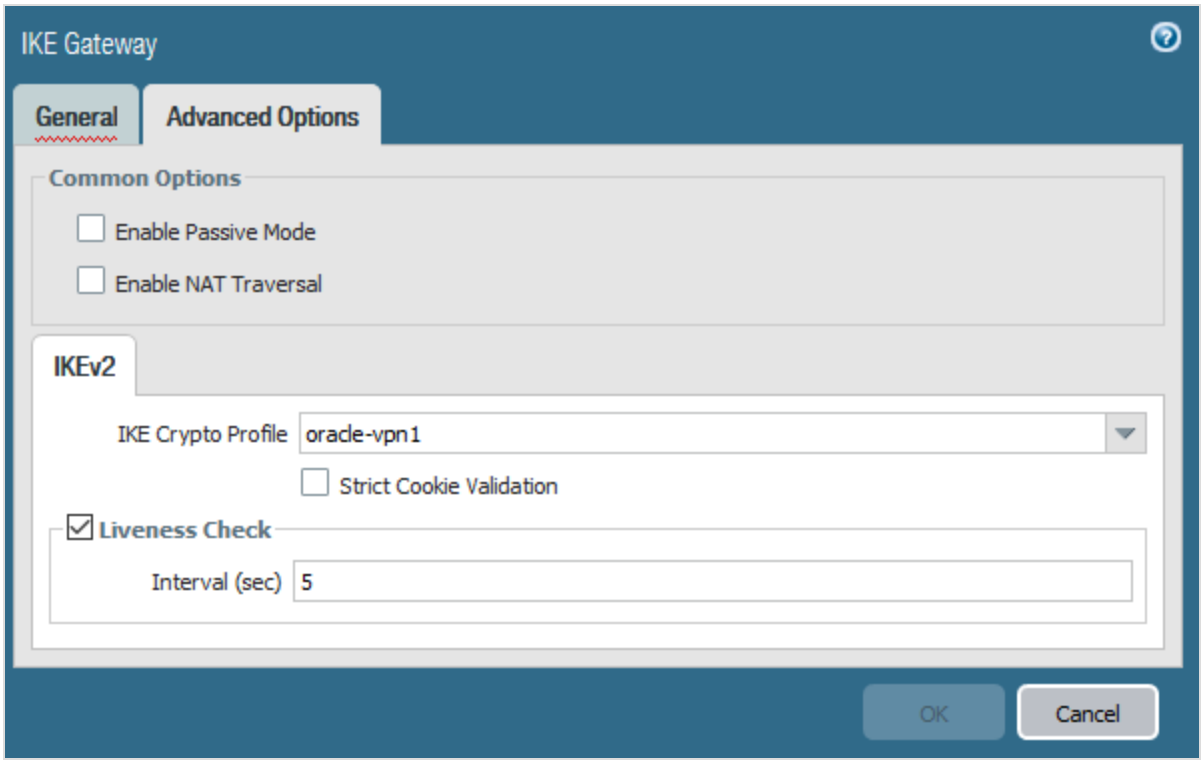
- **Interface:** The interface that owns the public IP address on the CPE. Change **ethernet1/1** to the particular value for your networking toplogy.
- **Peer IP addresses:** The public IP address that Oracle assigned to the Oracle headend of the tunnel. Change the value to the correct IP address for your first tunnel.
- **Pre-shared Key:** The shared secret that Oracle automatically assigned during IPSec tunnel creation. If you want, you can specify a different value. Make sure to enter the same value here and in the Oracle Console.
- **Local Identification** and **Peer Identification**: The IKE IDs. The **Local Identification** is the CPE's public IP address. The **Remote Identification** is the Oracle VPN headend IP address for the first tunnel.



b. On the **Advanced Options** tab, ensure the values are set for the first peer according to the following screenshot.

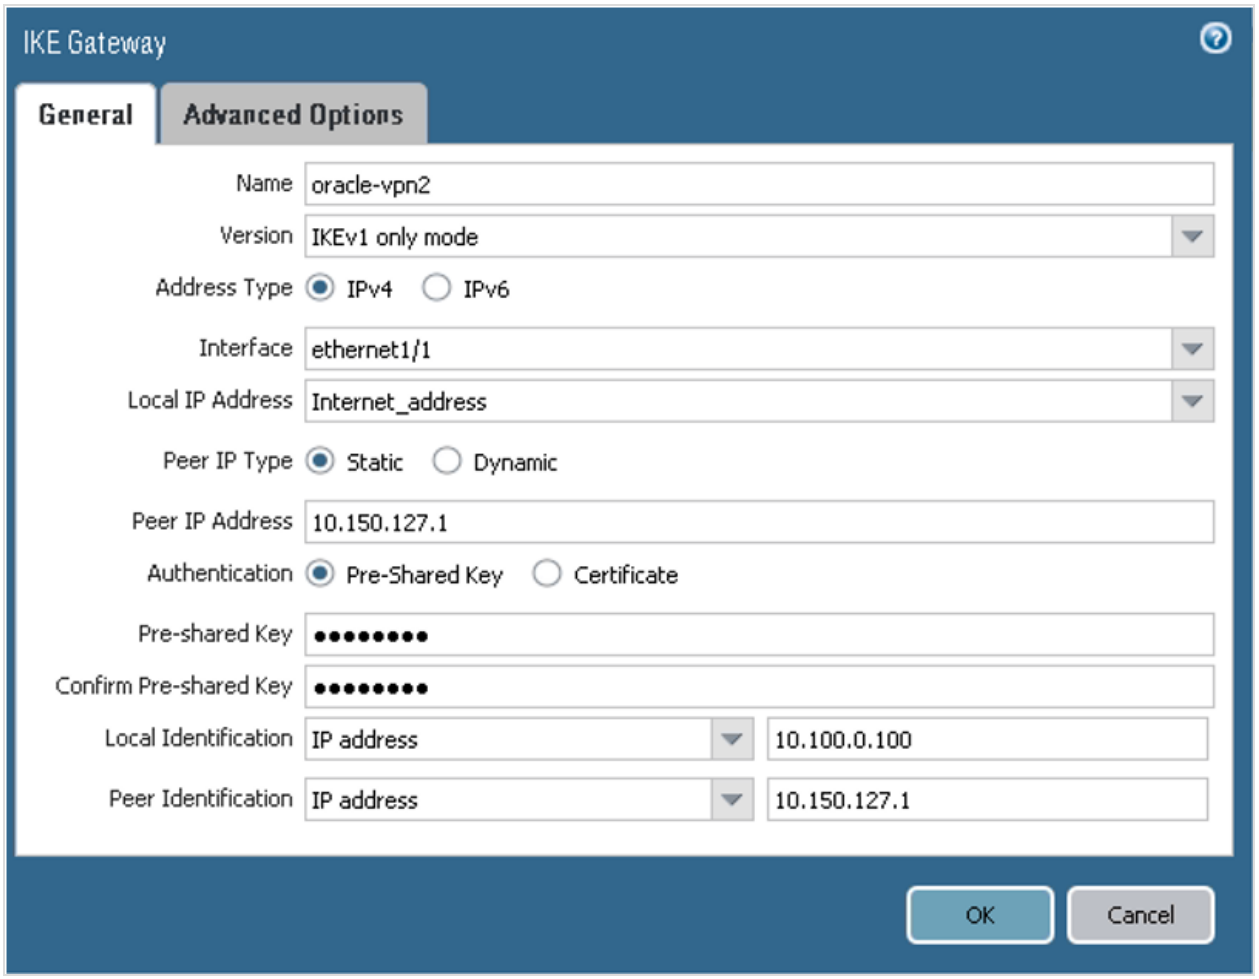


If you are using IKEv2 instead, select the IKE crypto profile associated with the IKEv2 tunnel.

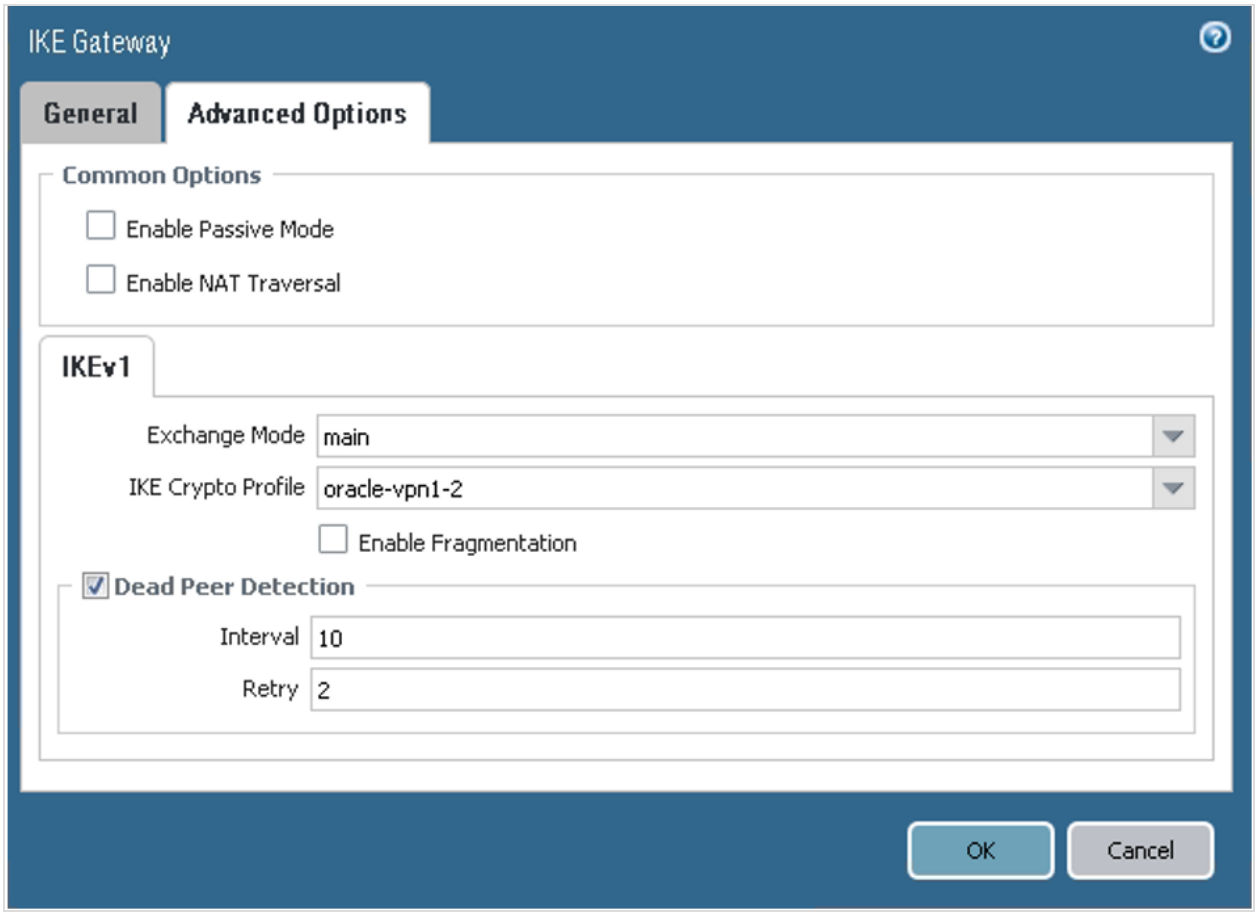


3. For peer 2, configure the parameters as shown in the next screenshots.
    a. On the **General** tab:
        - **Version:** For IKEv1, select **IKEv1 only mode**. If you want to use IKEv2, select **IKEv2 only mode**. For IKEv2, notice that you also need to provide a proxy ID later in task 5.
        - **Interface:** The interface that owns the public IP address on the CPE. Change **ethernet1/1** to the particular value for your networking toplogy.
        - **Peer IP addresses:** The public IP address that Oracle assigned to the Oracle headend of the tunnel. Change the value to the correct IP address for your second tunnel.

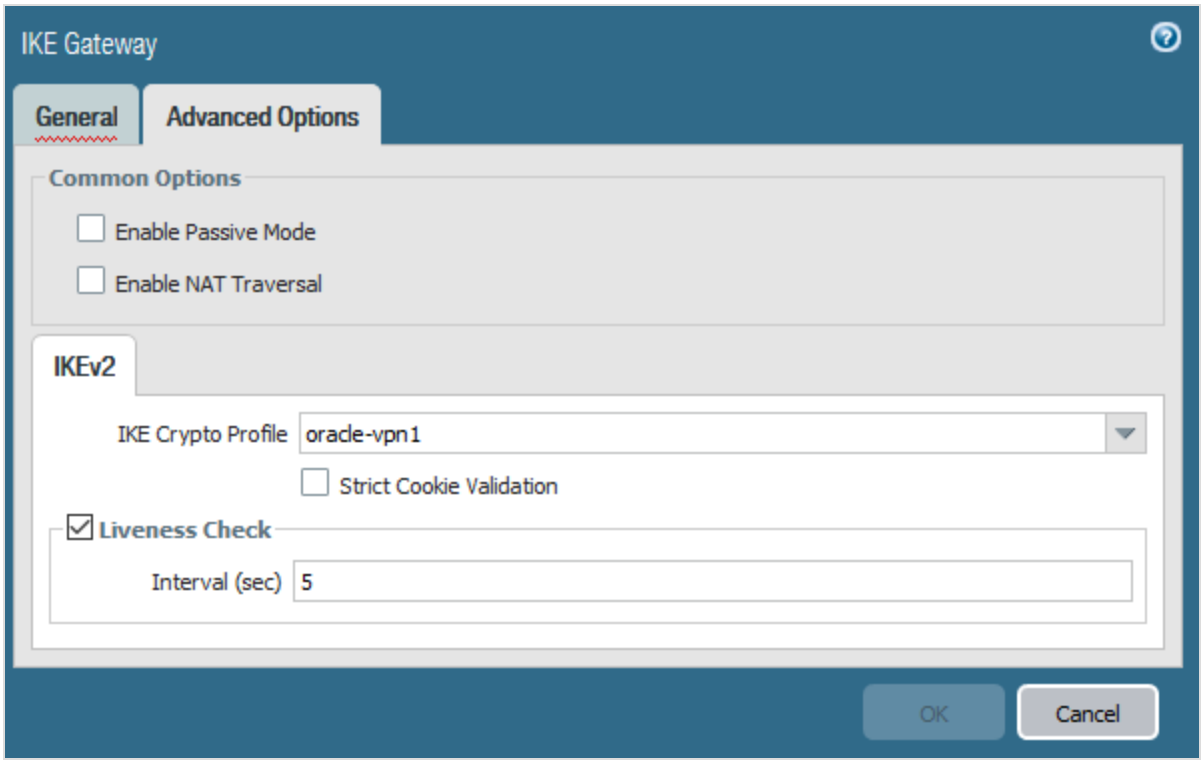
- **Pre-shared Key:** The shared secret that Oracle automatically assigned during IPSec tunnel creation. If you want, you can specify a different value. Make sure to enter the same value here and in the Oracle Console.
- **Local Identification** and **Peer Identification**: The IKE IDs. The **Local Identification** is the CPE's public IP address. The **Remote Identification** is the Oracle VPN headend IP address for the second tunnel.



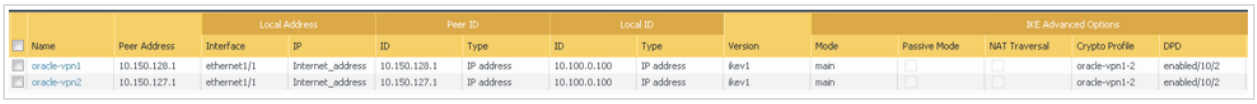
b. On the **Advanced Options** tab, ensure the values are set for the second peer according to this screenshot:



If you are using IKEv2 instead, select the IKE crypto profile associated with the IKEv2 tunnel.



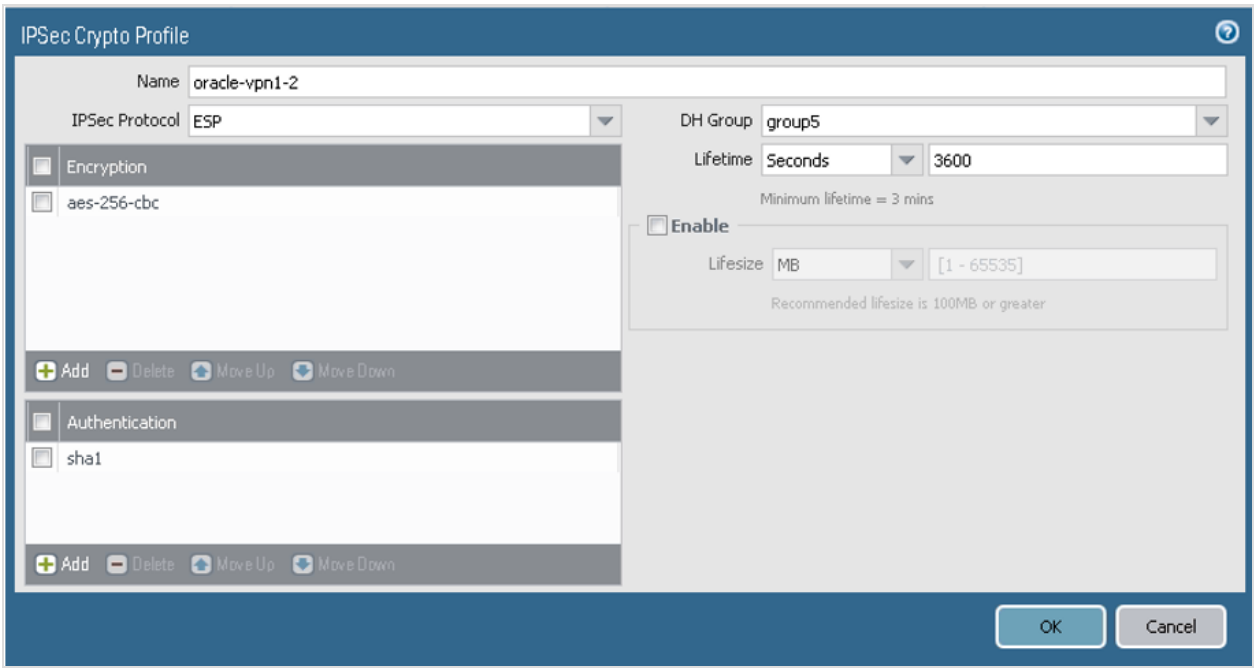
The next screenshot shows the final result for this task:



Task 3: Define the IPSec Phase 2 policy

In this example, the same IPSec crypto profile is used for both tunnels.

1. Go to **Network**, to **IPSec Crypto**, and then click **Add**.
2. Configure the parameters as shown in the next screenshot.

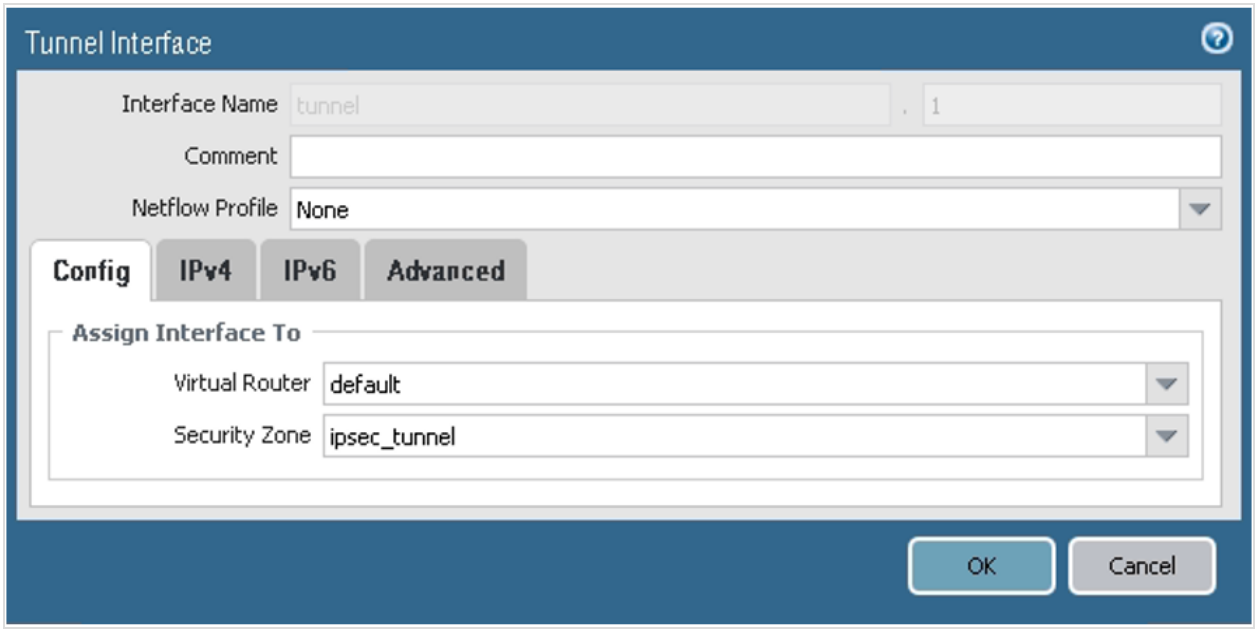


The next screenshot shows the final result for this task:

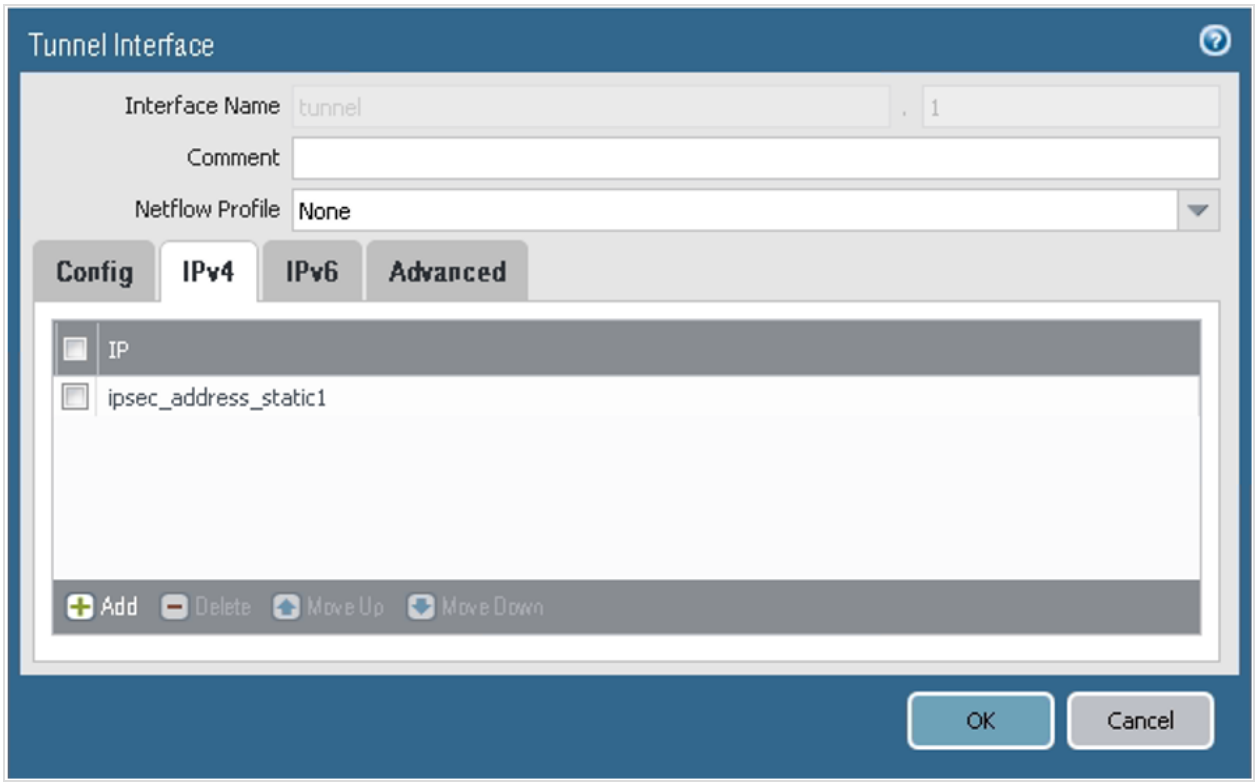
Task 4: Configure the virtual tunnel interfaces

1. Go to **Network**, to **Interfaces**, to **Tunnel**, and then click **Add**.
2. For peer 1, configure the parameters as shown in the next screenshots.

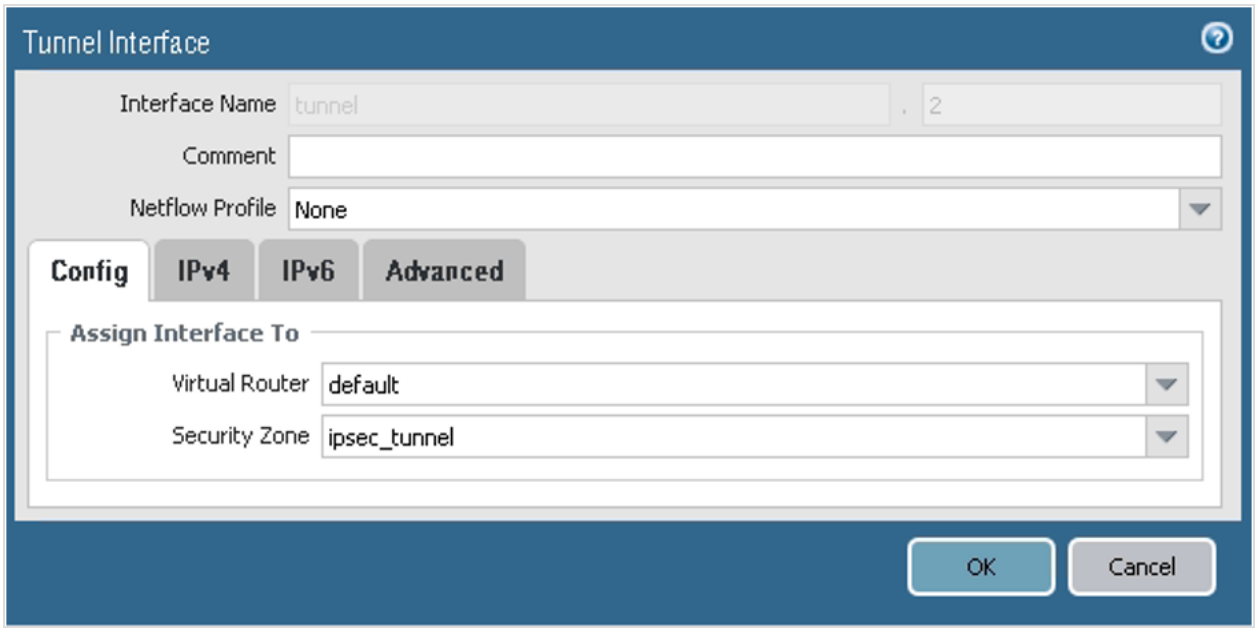
a. On the **Config** tab, assign the interface according to your virtual router and security zone configuration. In this example, the default virtual router and ipsec_ tunnel security zone are used.



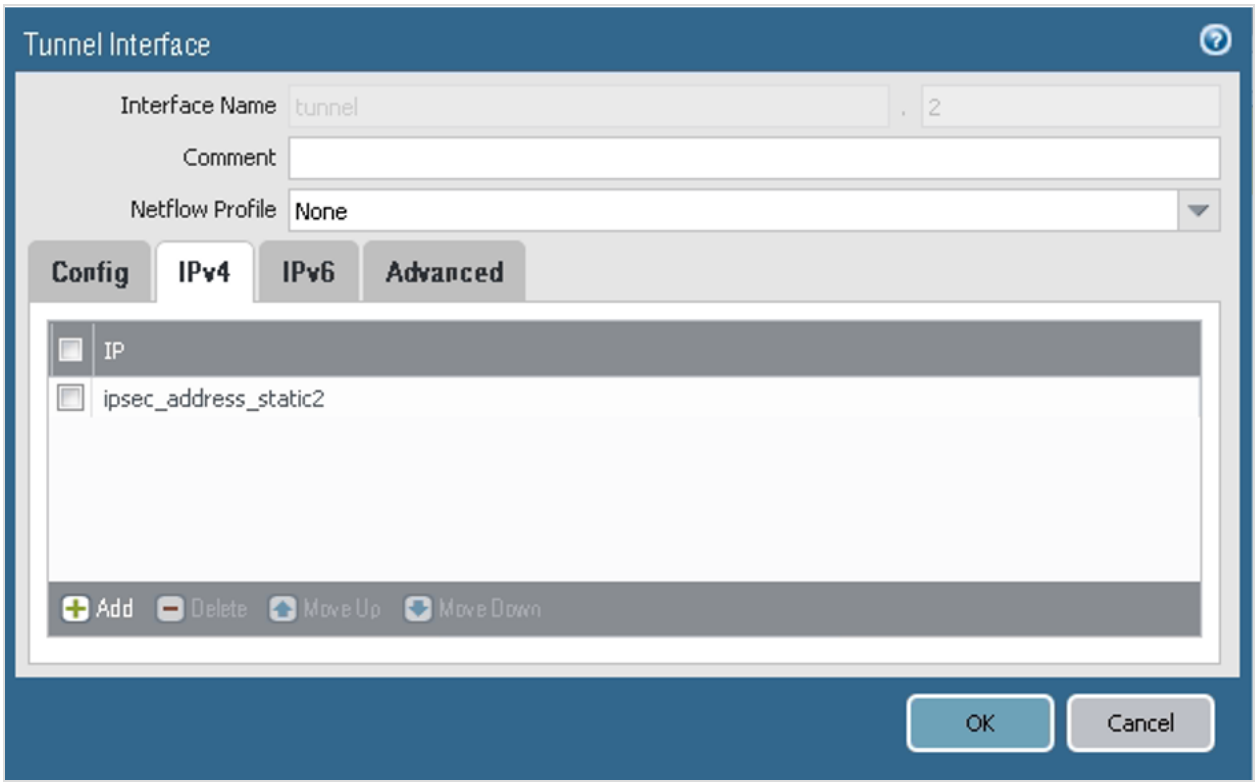
b. On the **IPv4** tab, ensure the values are set for the first peer according to the following screenshot. In this example, the IP address for the tunnel interface is ipsec_address_static1 = 198.51.100.1/30. Configure your tunnel IP address according to your networking IP addressing plan.



3. For peer 2, configure the parameters as shown in the next screenshots.
    a. On the **Config** tab, assign the interface according to your virtual router and security zone configuration. In this example, the default virtual router and ipsec_tunnel security zone are used.



b. On the **IPv4** tab, ensure the values are set for the second peer according to the following screenshot. In this example, the IP address for the tunnel interface is ipsec_address_static2 = 198.51.100.5/30. Configure your tunnel IP address according to your networking IP addressing plan.



The next screenshot shows the final result for this task:

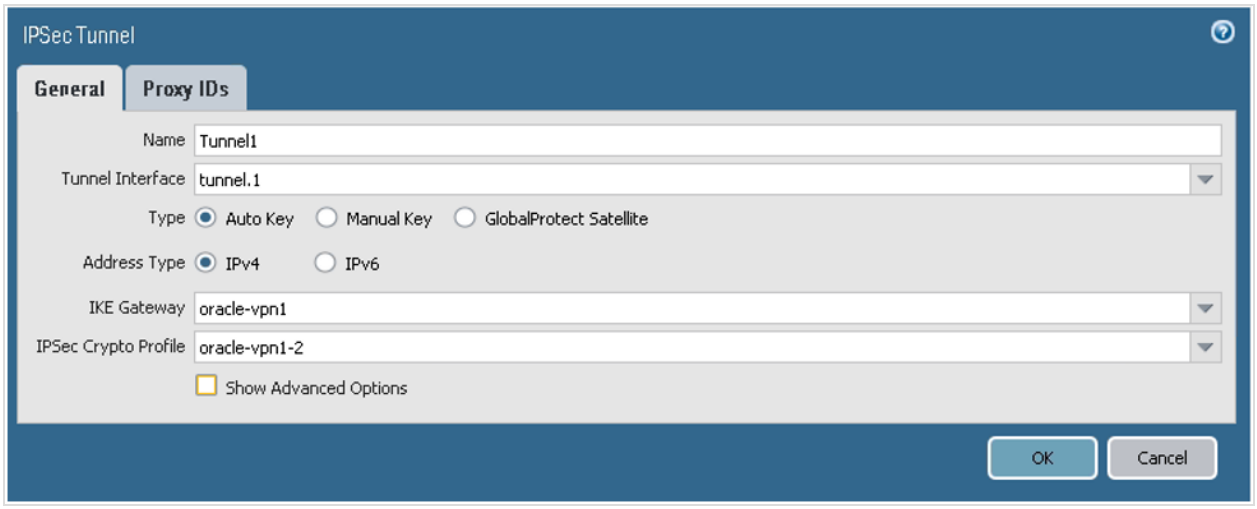
Interface	Management Profile	IP Address	Virtual Router	Security Zone	Features	Comment
tunnel		none	none	none		
tunnel.1		ipsec_address_static1	default	ipsec_tunnel		
tunnel.2		ipsec_address_static2	default	ipsec_tunnel		

Task 5: Configure the IPSec sessions

1. Go to **Network**, to **IPSec Tunnels**, and then click **Add**.
2. For peer 1, configure the parameters on the **General** tab as shown in the next screenshot.

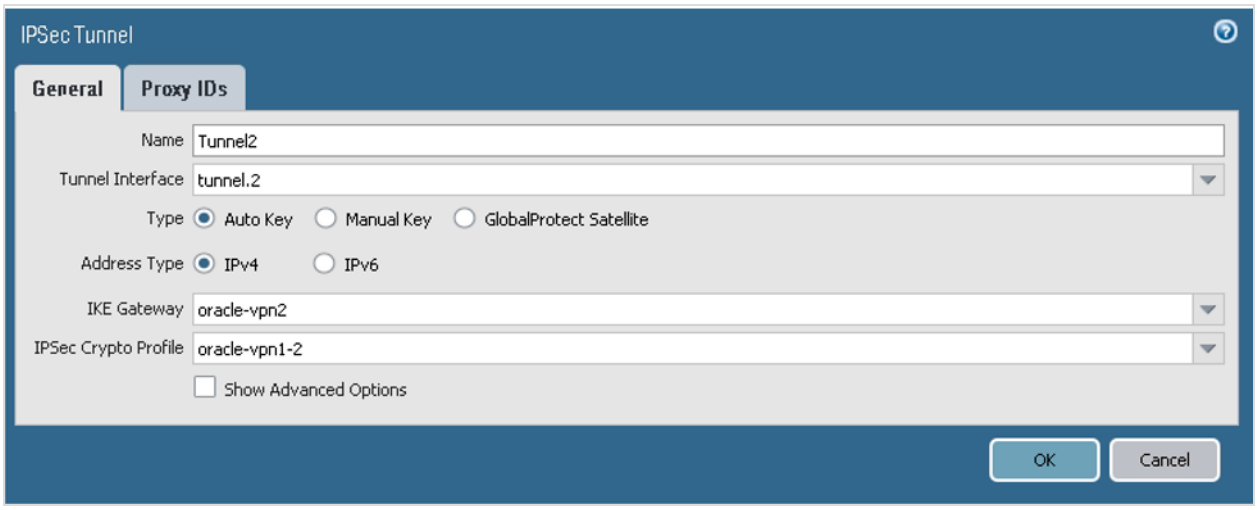
   Notice that if you're using IKEv1, you do not need to add specific proxy IDs to the **Proxy IDs** tab. They are not needed for an IKEv1 route-based VPN configuration.

   However, for IKEv2, do add proxy IDs to the **Proxy IDs** tab for better interoperability. Ensure that you also configured the IKE gateway to use IKEv2 earlier in task 2.



3. For peer 2, configure the parameters on the **General** tab as shown in the next screenshot.

   If you are using IKEv2, also add proxy IDs on the **Proxy IDs** tab.



Task 6: Configure BGP over IPSec

> **Note**
>
> If you want to use static routing instead of BGP, skip task 6 and go to Configuring Static Routing.

BGP over IPSec requires IP addresses on the tunnel interfaces on both ends.

The screenshots in this example use these subnets for the tunnel interfaces:

- 198.51.100.0/30
  - CPE: 198.51.100.1/30
  - DRG: 198.51.100.2/30

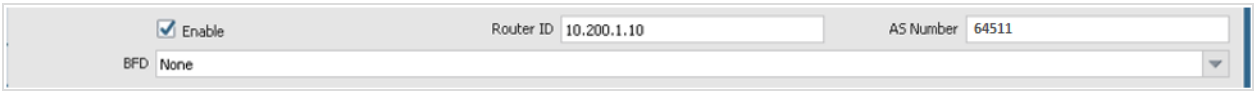
- 198.51.100.4/30
    - CPE: 198.51.100.5/30
    - DRG: 198.51.100.6/30

Make sure to replace the example values with the BGP IP addresses you specified in the Oracle Console for the inside tunnel interfaces.

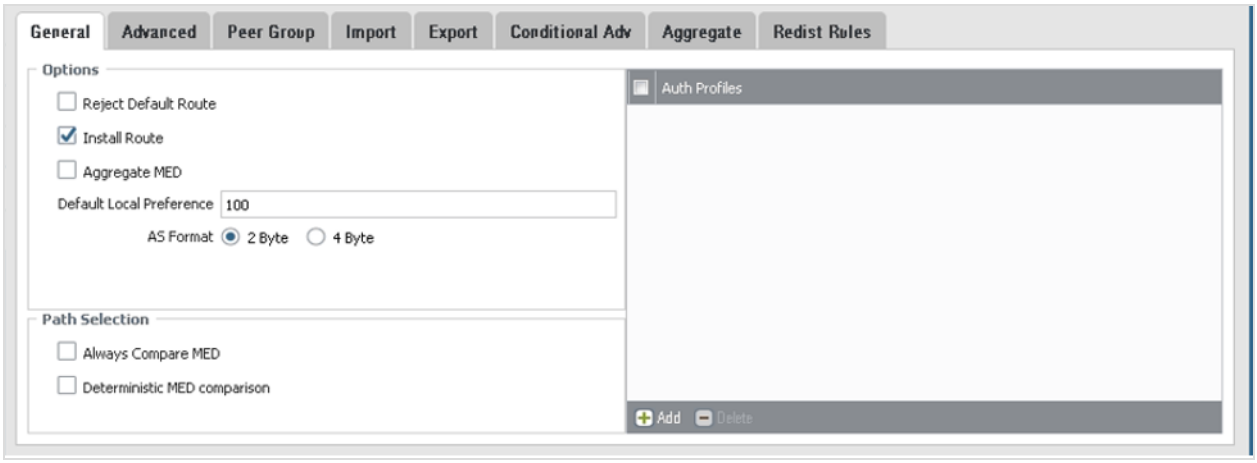
This task consists of three sub-tasks, each with multiple steps.

Subtask 6-a: Configure the BGP parameters

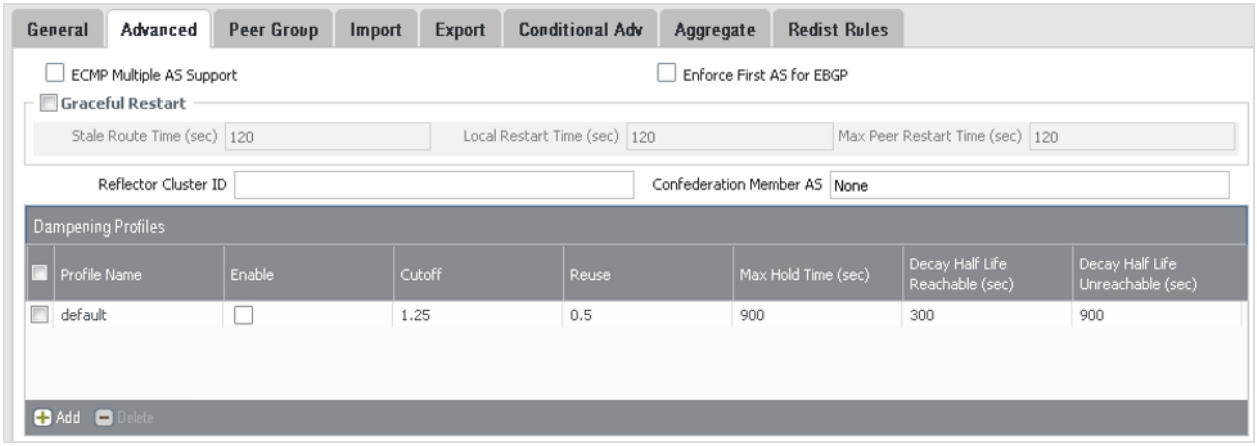
1. Go to **Network**, to **Virtual Routers**, to **default**, and then to **BGP**. This example uses the default virtual router. Also, the example uses 10.200.1.10 for the router ID and 64511 for the ASN. Make sure to use the correct virtual router based on your networking configuration, and use the correct router ID and ASN for your environment.



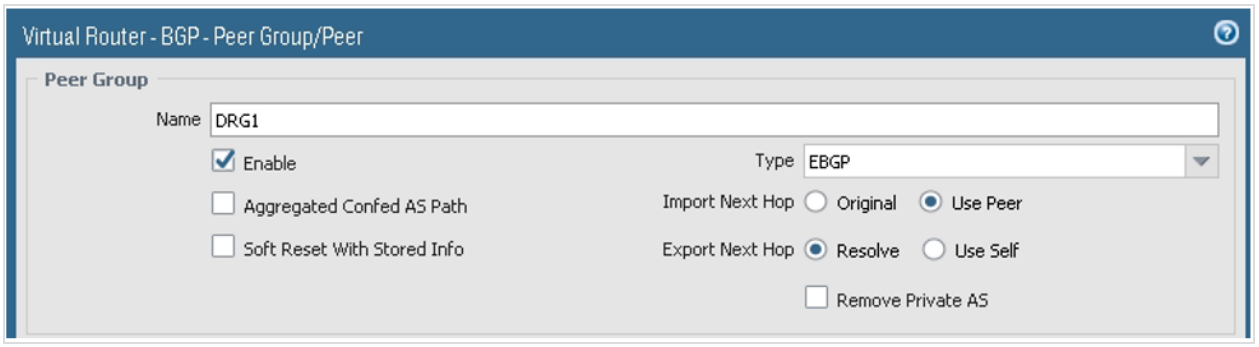
2. On the **General** tab, configure the parameters as shown in the next screenshot.



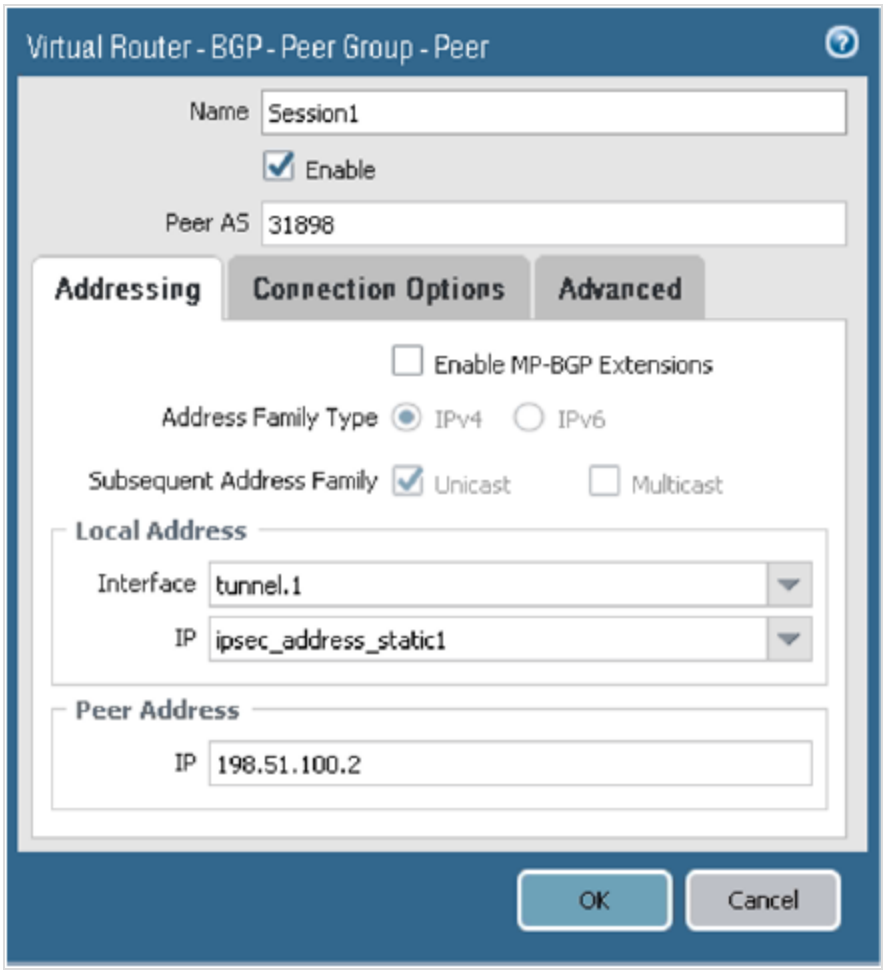
3. On the **Advanced** tab, configure the parameters as shown in the next screenshot.



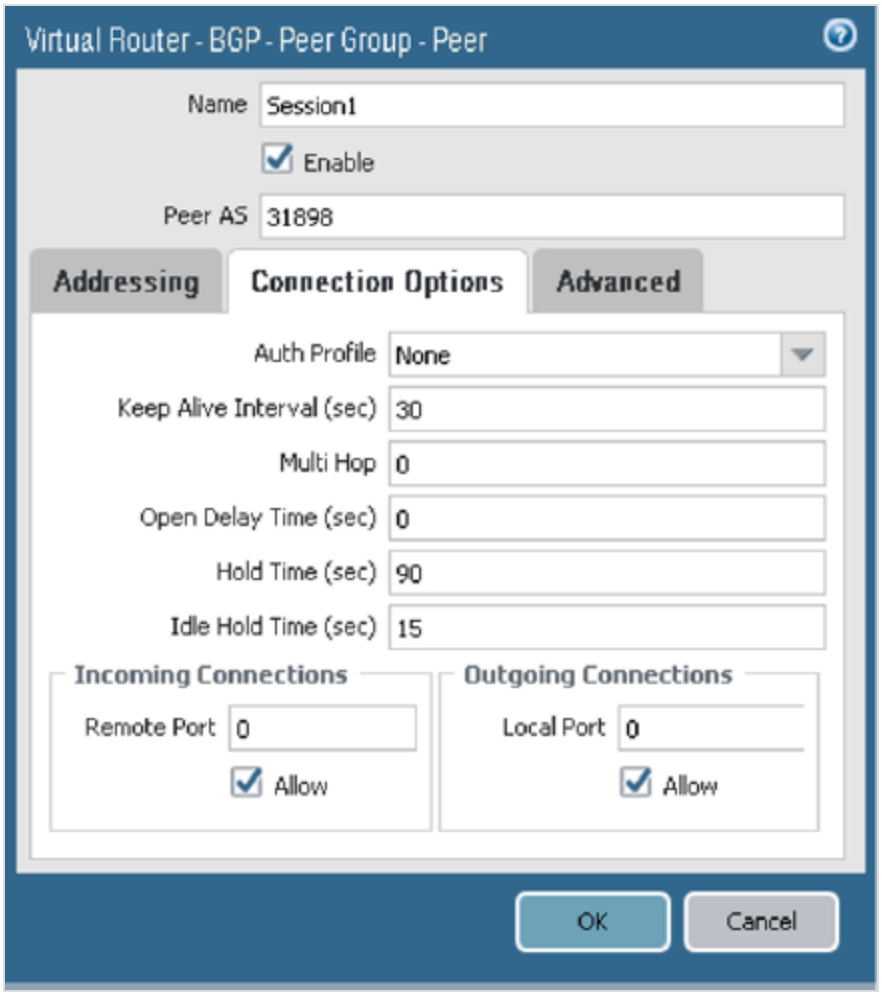
4. On the **Peer Group** tab:
    a. Add the first Peer Group, and under the **Peer Group Name**, add the first session. Add the BGP session with the DRG.



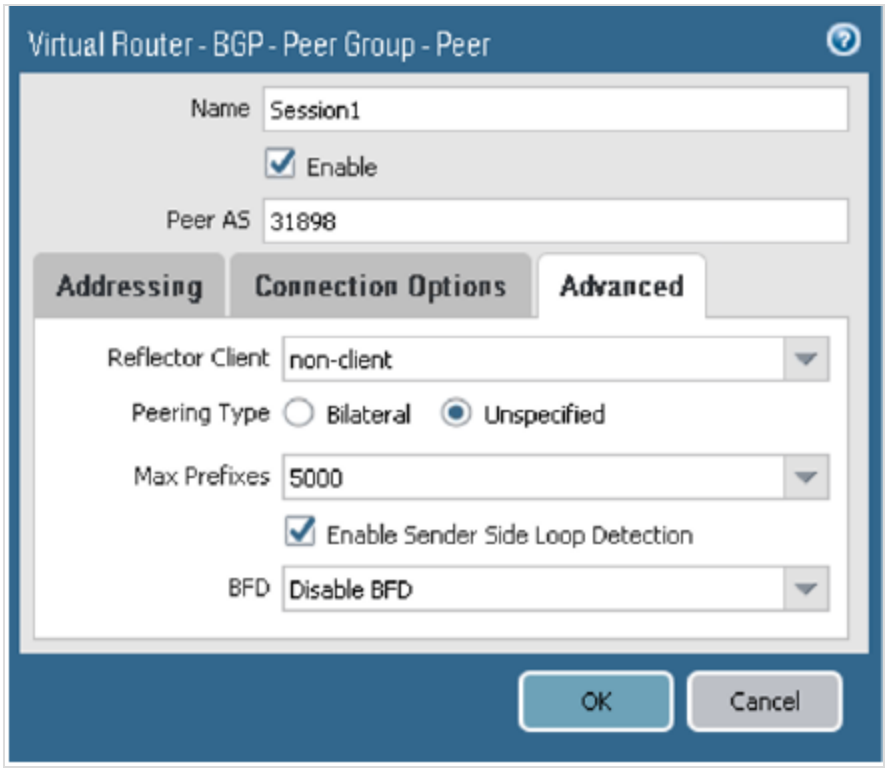
b. For the first tunnel, on the **Addressing** tab, configure the parameters as shown in the next screenshot. Oracle's BGP ASN in commercial regions is 31898. If you're configuring VPN Connect for the Government Cloud, see Oracle's BGP ASN.



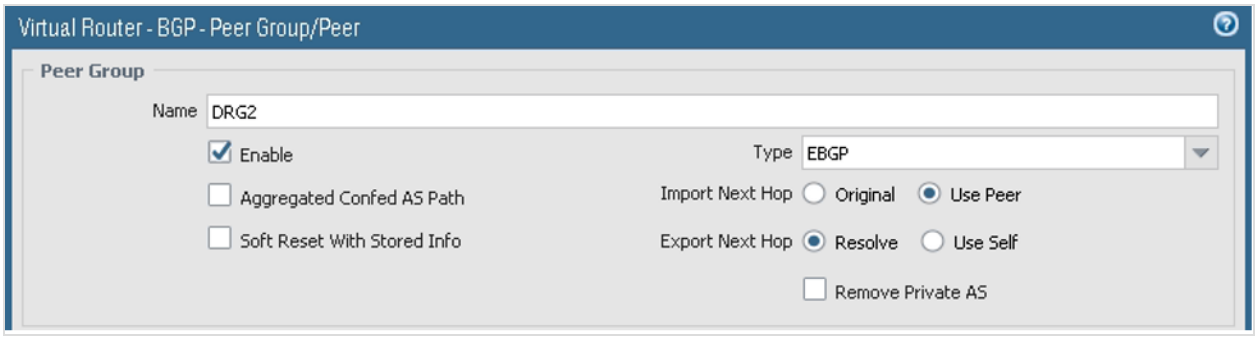
c. On the **Connection Options** tab, configure the parameters as shown in the next screenshot.



d. On the **Advanced** tab, configure the parameters as shown in the next screenshot.

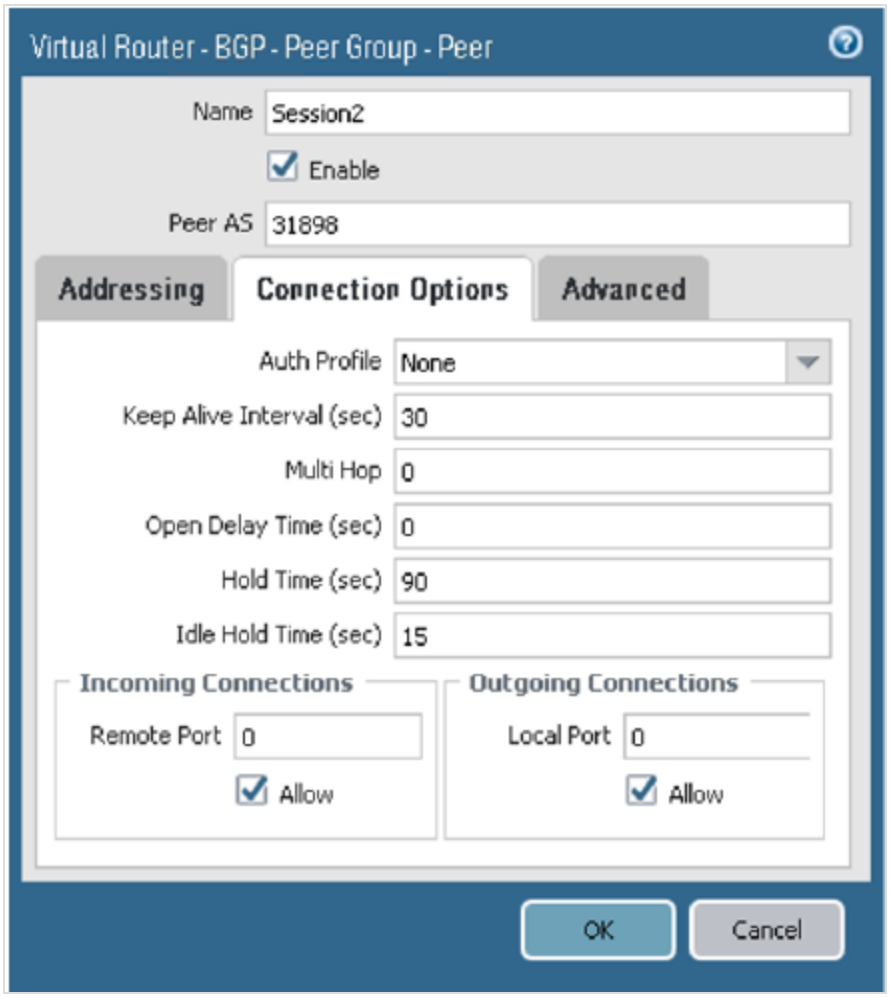


e. On the **Peer Group** tab, add the second Peer Group, and under the **Peer Group Name**, add the second session. Add the BGP session with the DRG.

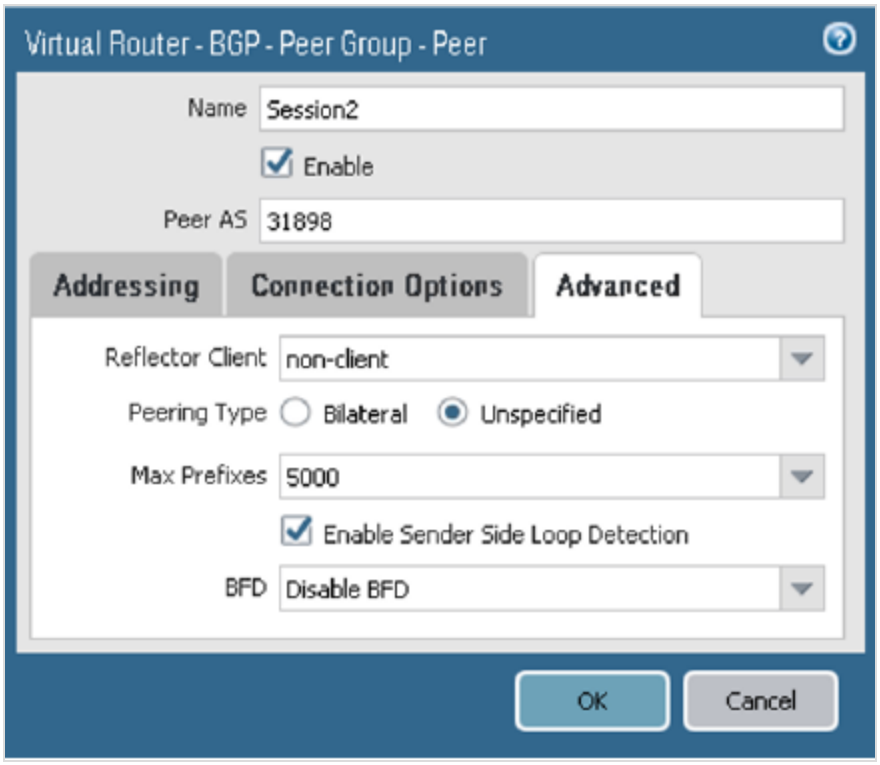


f. For the second tunnel, on the **Addressing** tab, configure the parameters as shown in the next screenshot.

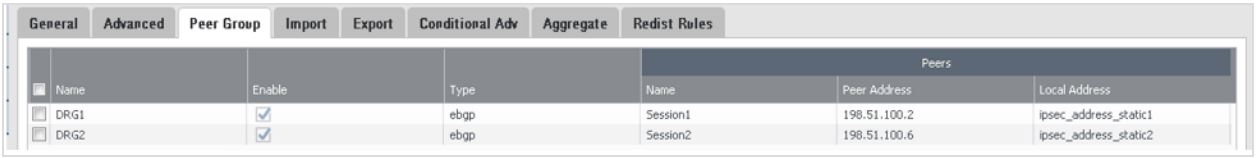
g. On the **Connection Options** tab, configure the parameters as shown in the next screenshot.



h. On the **Advanced** tab, configure the parameters as shown in the next screenshot.



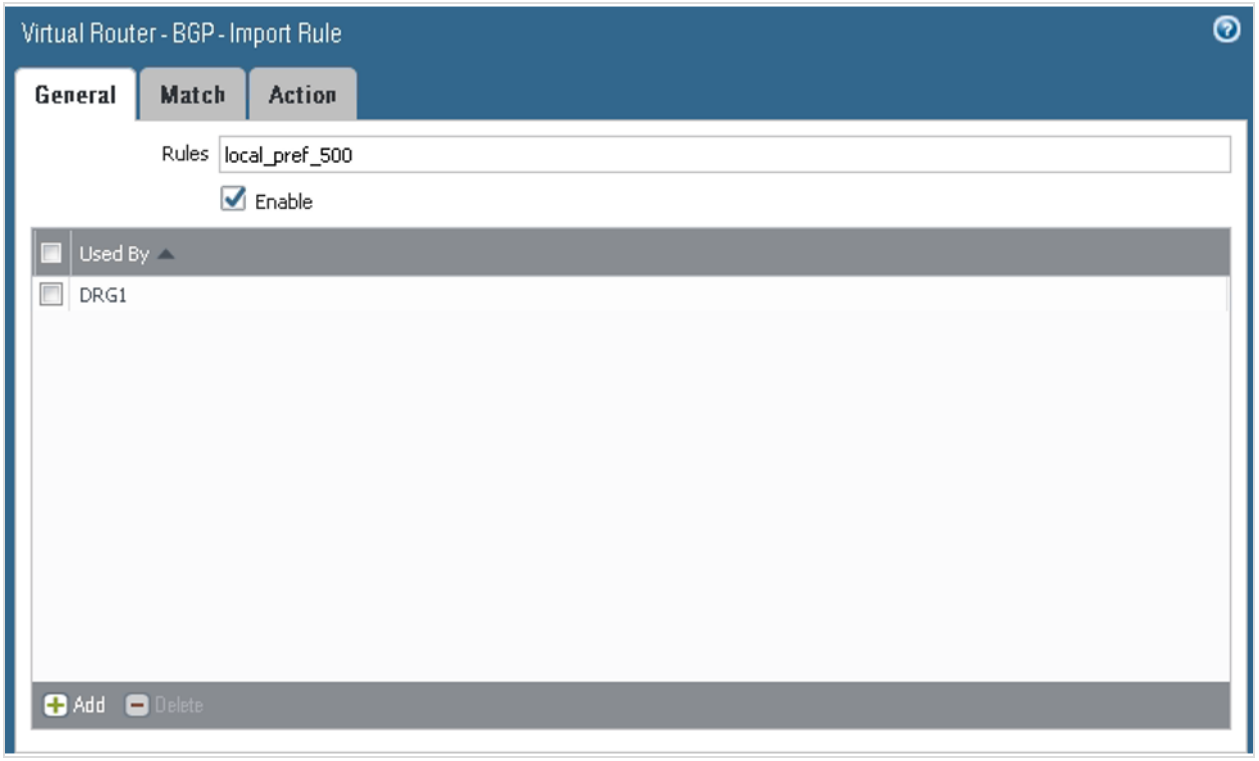
The next screenshot shows the final Peer Group configuration:



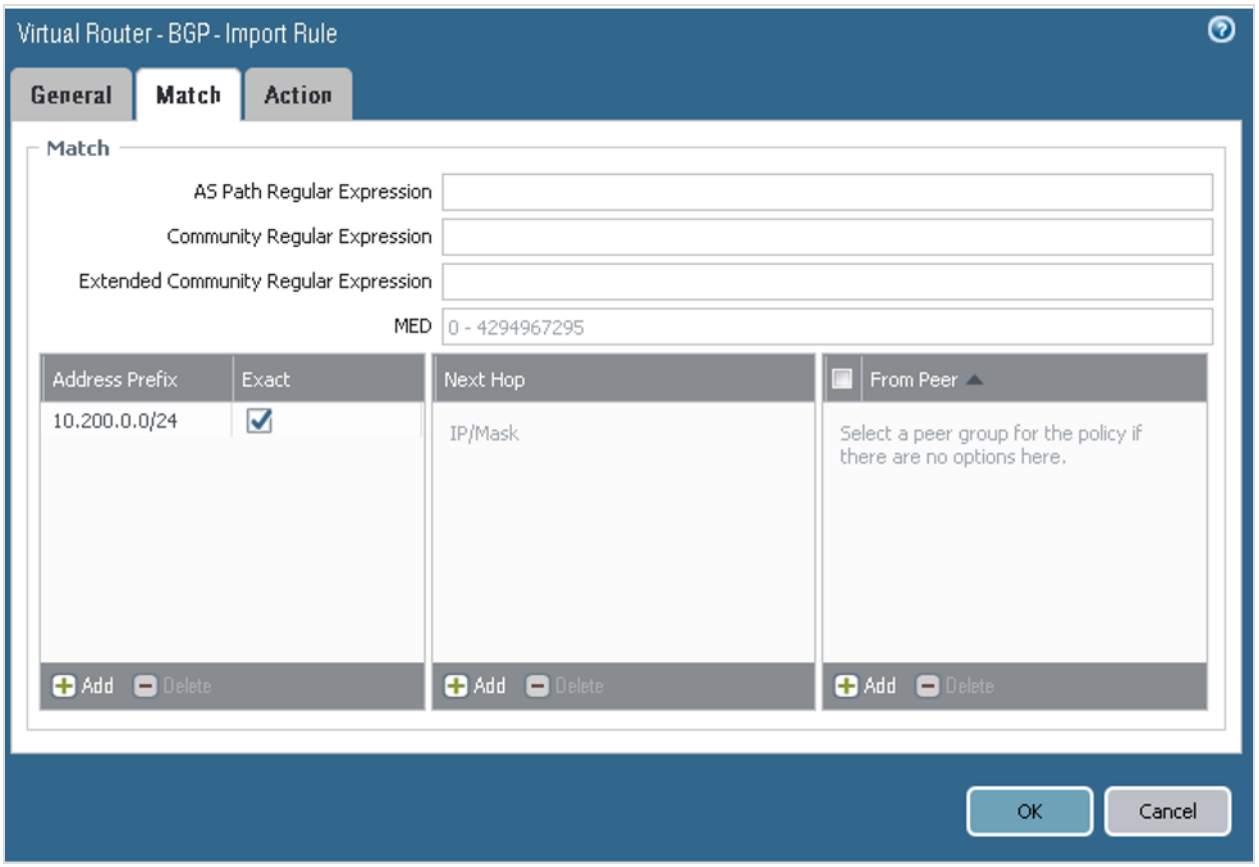
5. On the **Import** tab, configure the parameters as shown in the next screenshots. Here you configure tunnel.1 as the primary and tunnel.2 as the backup for the VCN route received from the DRG by way of BGP (10.200.0.0/24). From the BGP perspective, both

tunnels will be in the Established state.

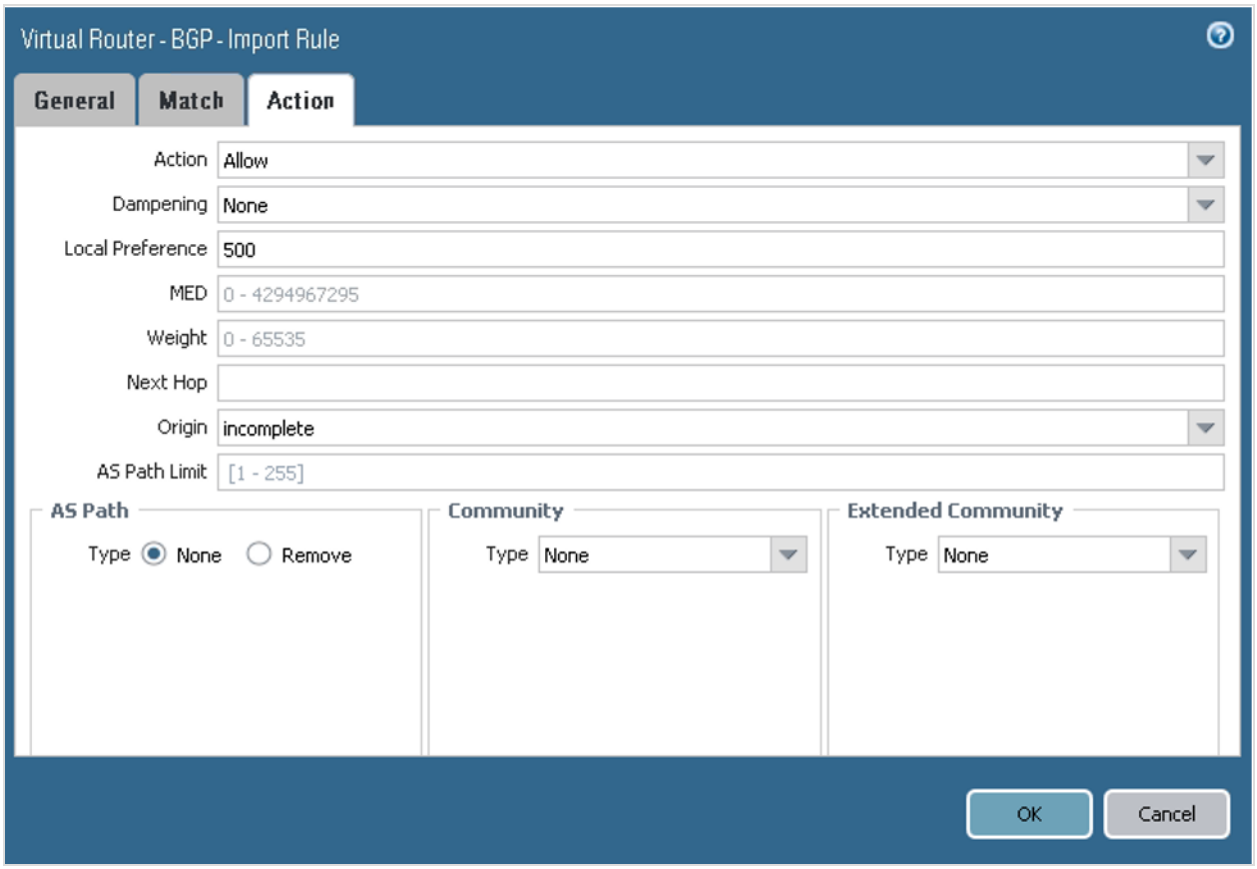
a. For the first rule, on the **General** tab, configure the parameters as shown in the next screenshot.



b. On the **Match** tab, configure the parameters as shown in the next screenshot.

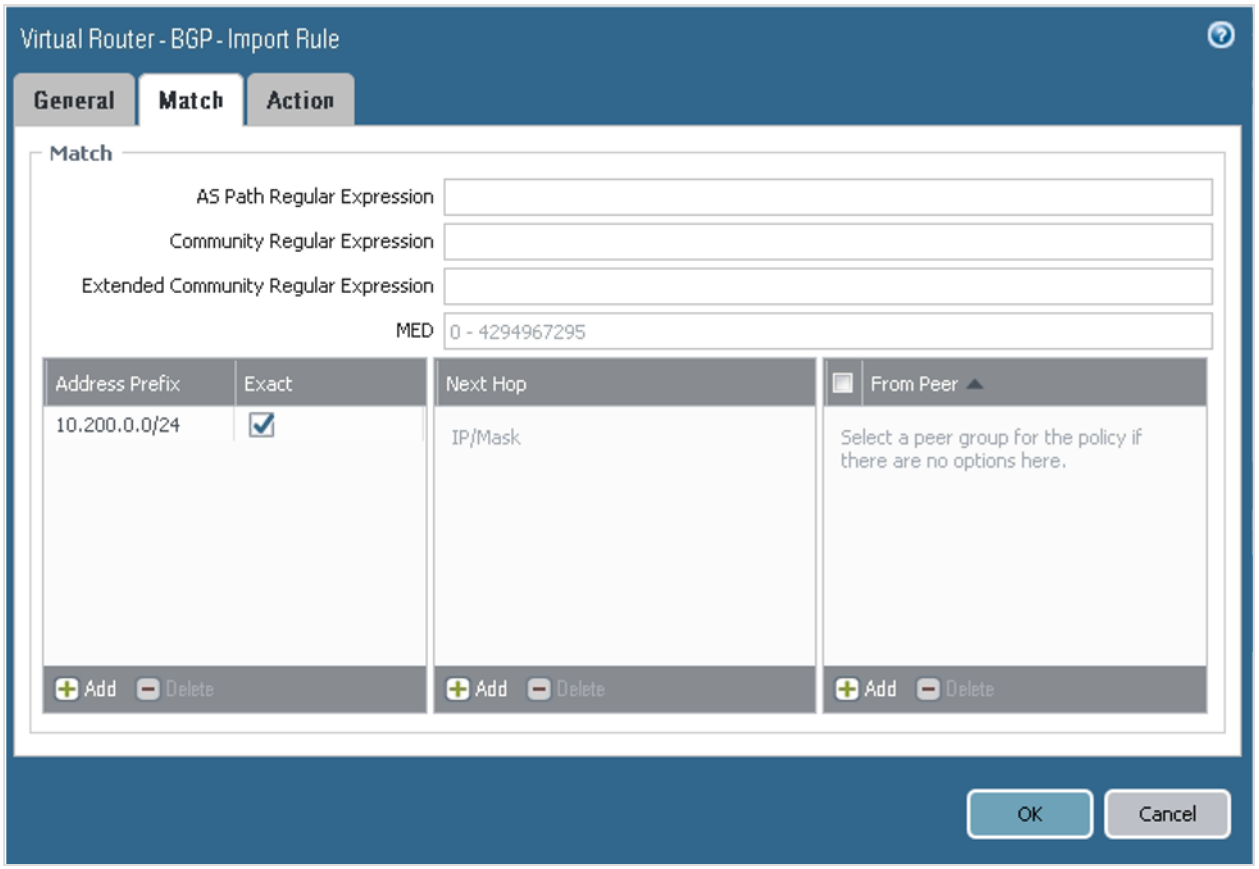


c. On the **Action** tab, configure the parameters as shown in the next screenshot.

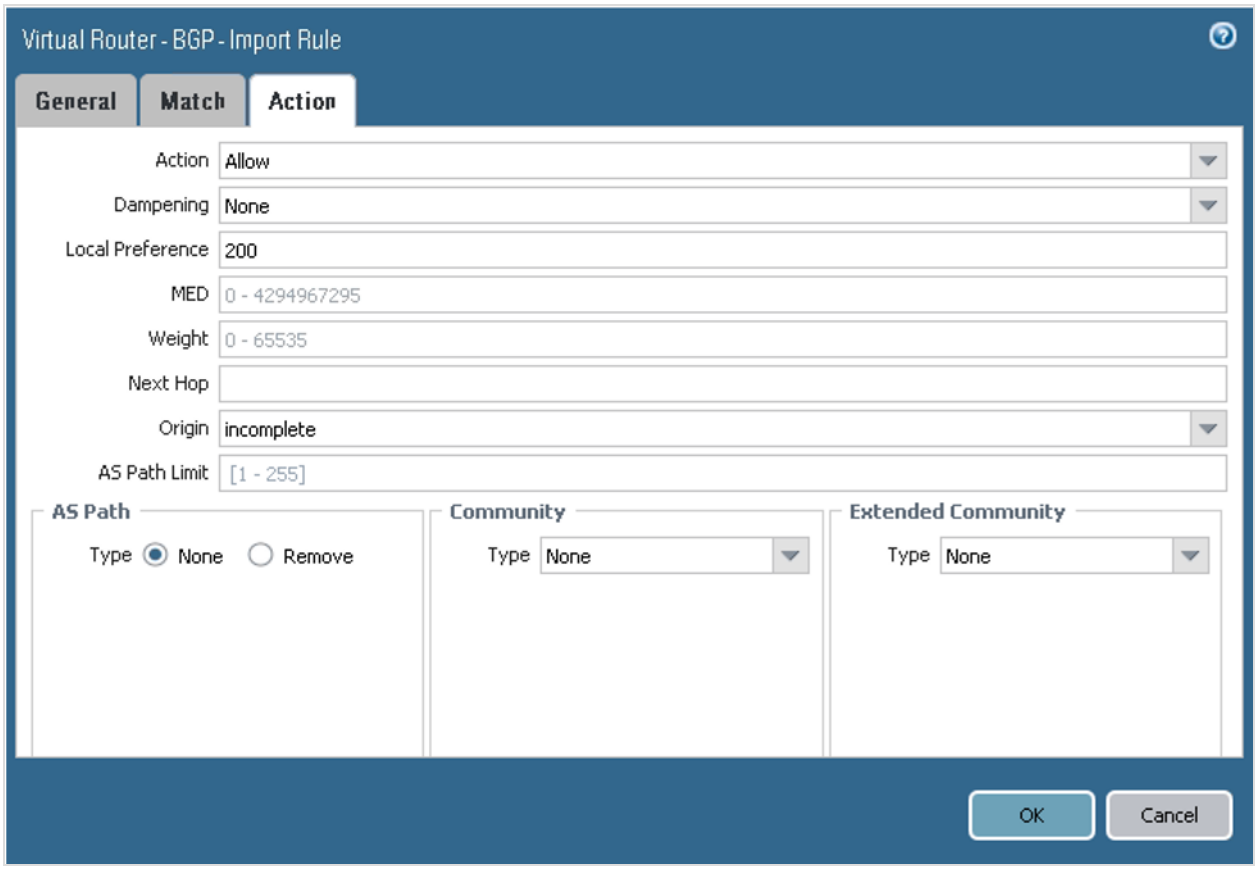


d. For the second rule, on the **General** tab, configure the parameters as shown in the next screenshot.

e. On the **Match** tab, configure the parameters as shown in the next screenshot.

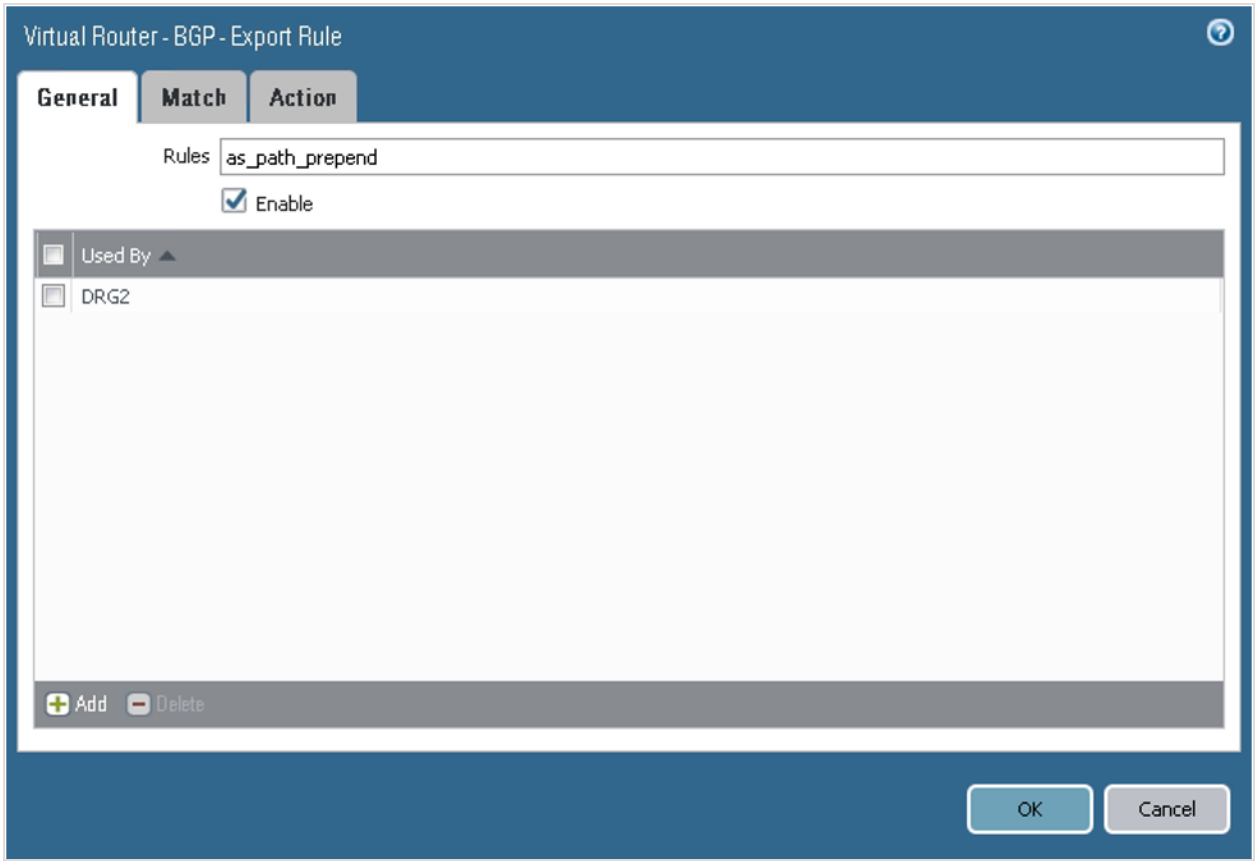


f. On the **Action** tab, configure the parameters as shown in the next screenshot.

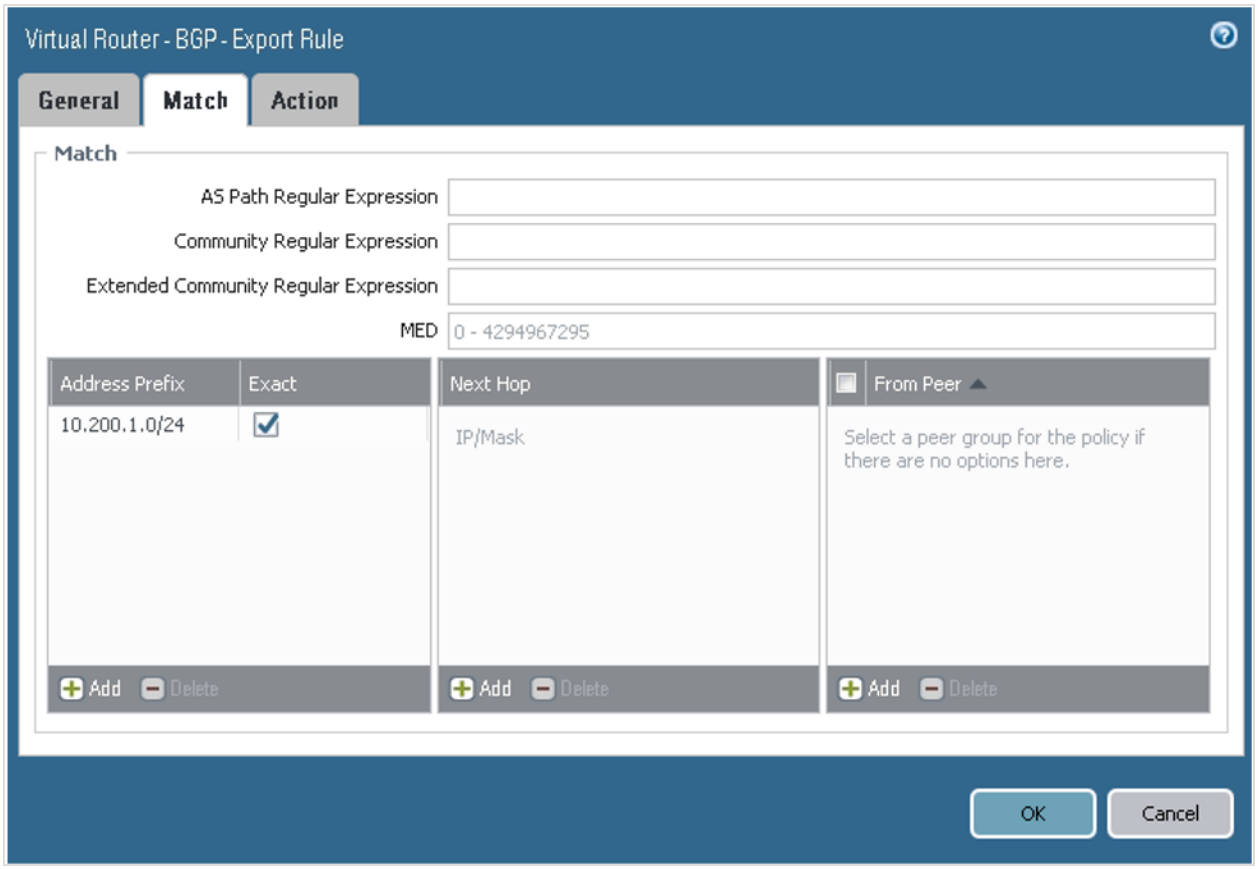


6. On the **Export** tab, configure the parameters as shown in the next screenshots. Here you configure a policy to force the DRG to prefer tunnel.1 for the returning path to the on-premises network CIDR (10.200.1.0/24).

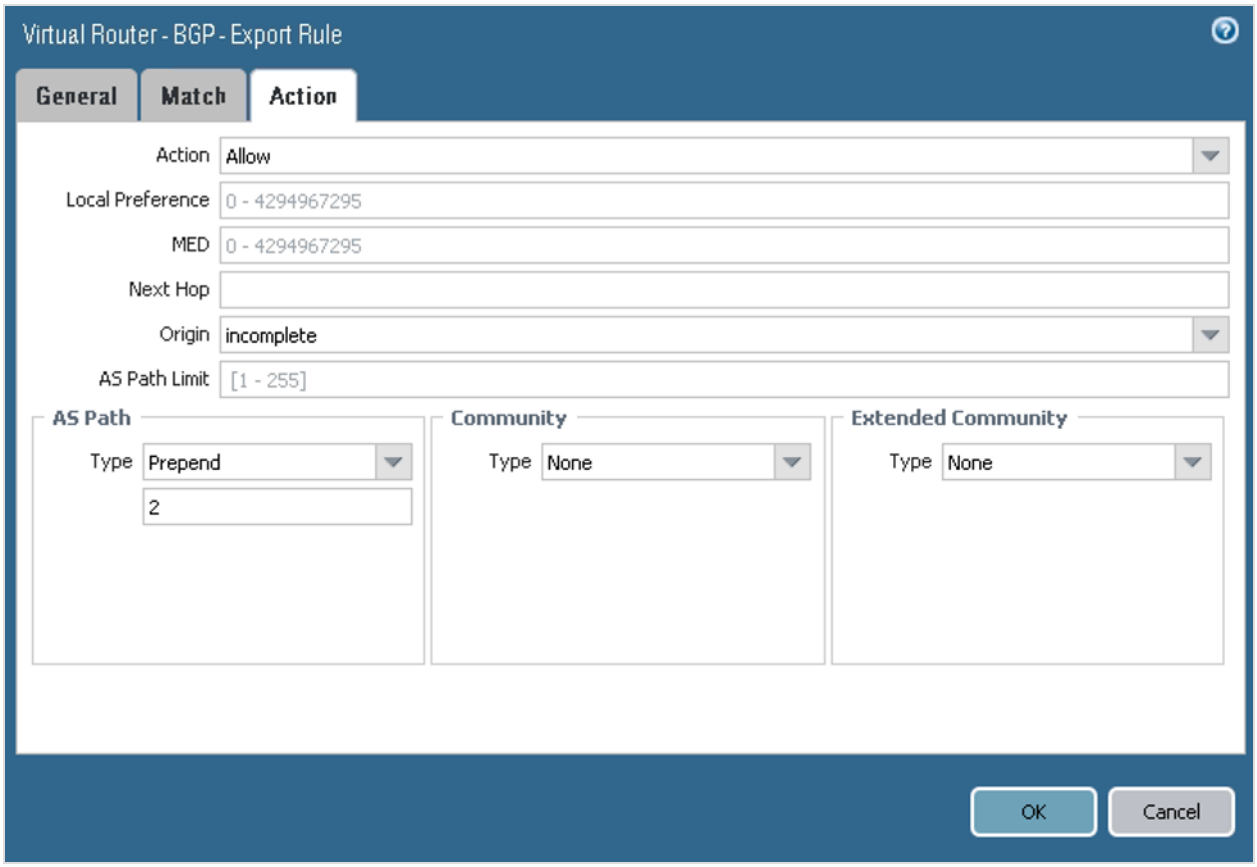
a. On the **General** tab, configure the parameters as shown in the next screenshot.



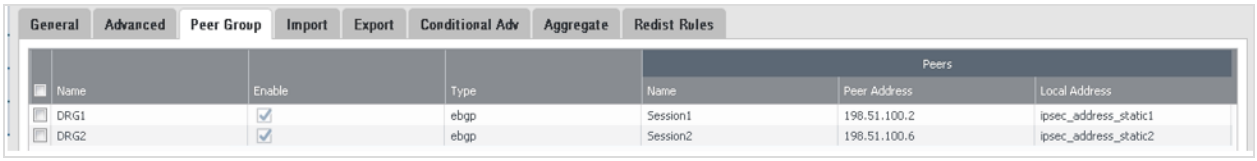
b. On the **Match** tab, configure the parameters as shown in the next screenshot.



c. On the **Action** tab, configure the parameters as shown in the next screenshot.



The next screenshot shows the final Export configuration:

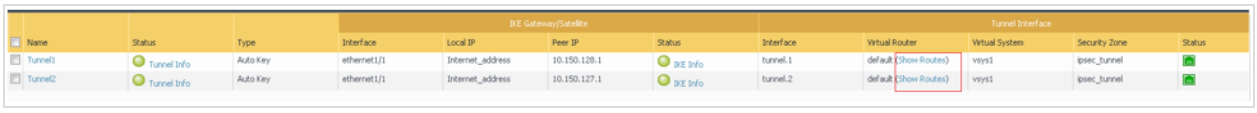


Notice that no configuration is required for the **Conditional Adv** or **Aggregate** tabs.

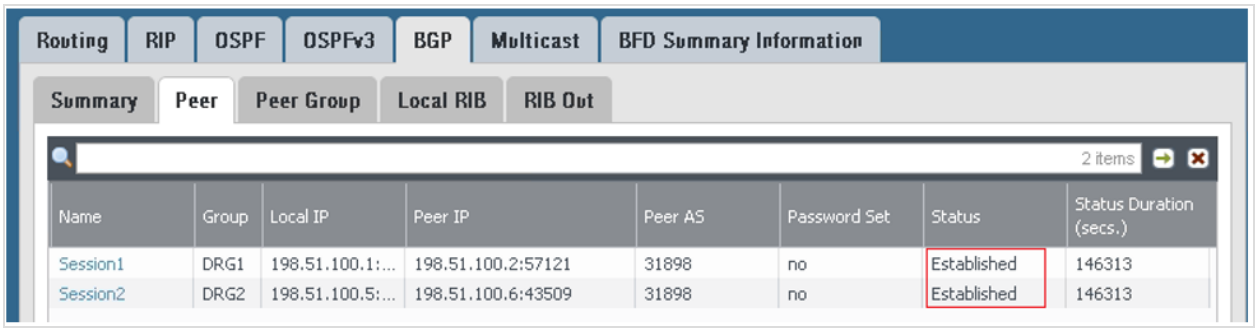
7. On the **Redist Rules** tab, configure the parameters as shown in the next screenshot. Here you announce the on-premises network CIDR in BGP.

Subtask 6-b: Wait for the BGP sessions to establish and then check the BGP status

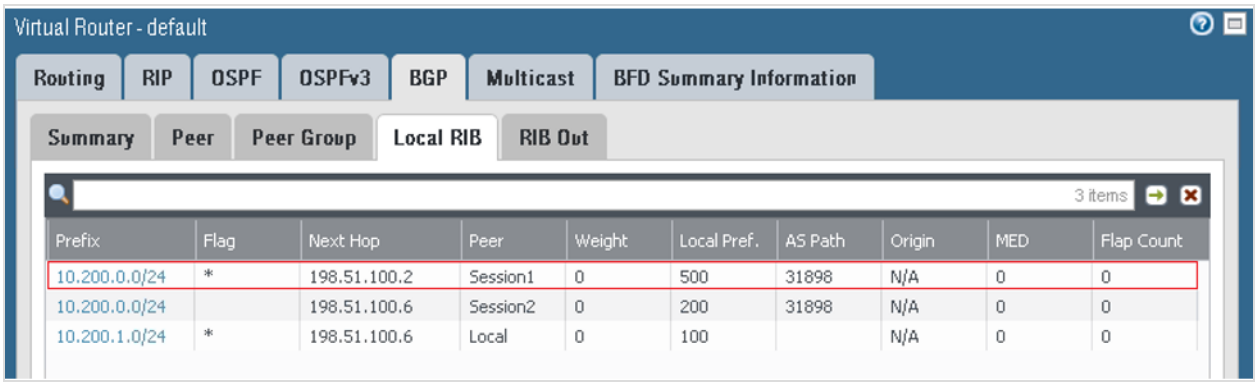
1. Go to **Network**, to **IPSec Tunnels**, to the **Virtual Router** column, and then click **Show Routes**.



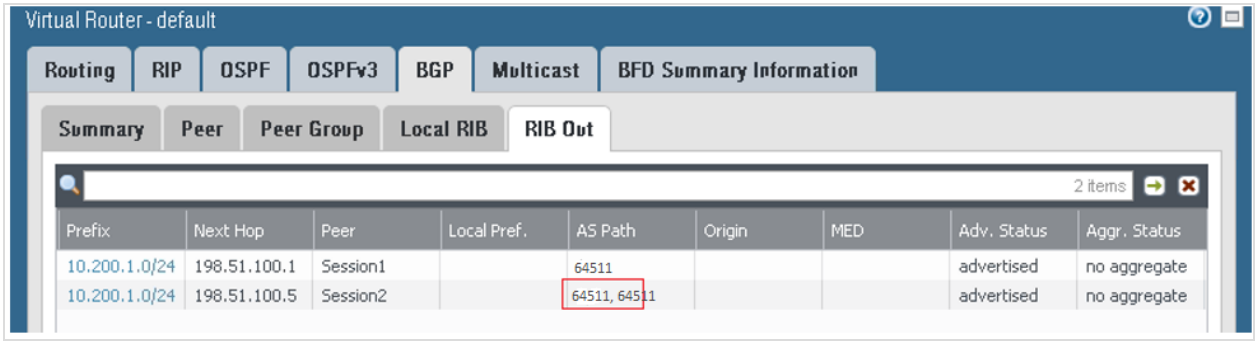
2. Go to **BGP**, and then to the **Peer** tab to verify that the BGP session is established. Any other value means that the BGP session has not been established successfully and route exchange will not occur.



3. On the **Local RIB** tab: The prefixes are received from the DRG, with tunnel.1 being preferred.

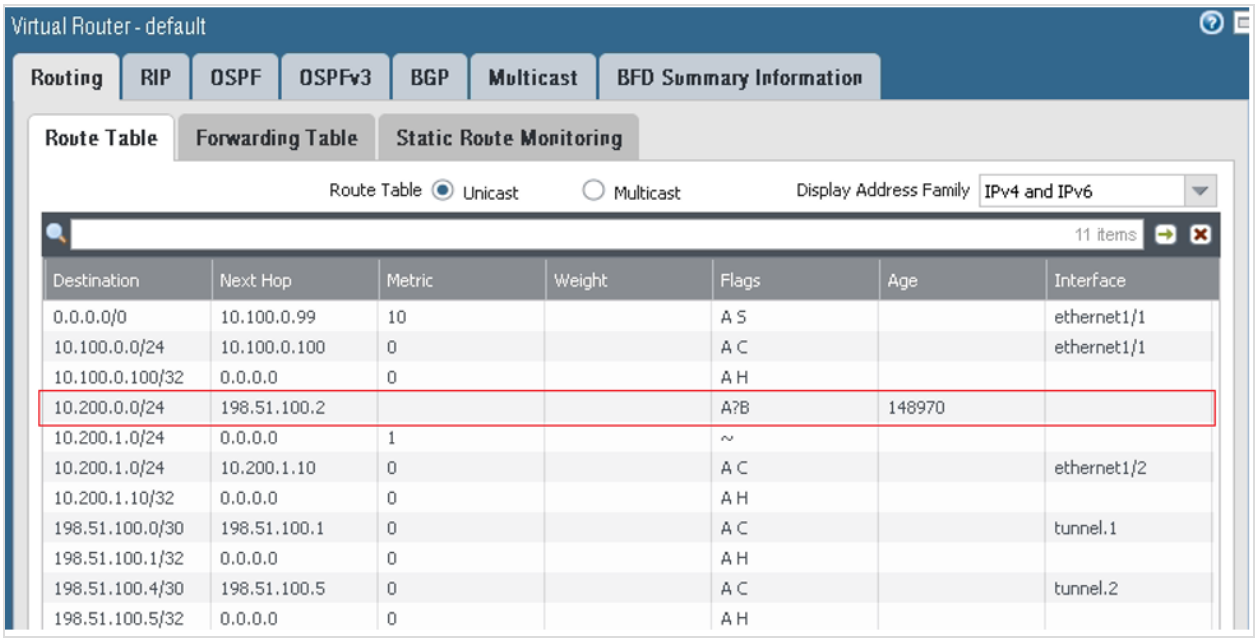


4. On the **RIB Out** tab: The on-premises network CIDR is sent by way of BGP to DRG1 with as_path of 64511, and for DRG2, with an as_path of 64511, 64511. In this way, based on the BGP Best Path Algorithm, the route preferred by the DRG to reach the on-premises network CIDR uses the connection over tunnel.1.



Subtask 6-c: Confirm the BGP routes have been inserted in the routing table

Go to **Routing**, and then to the **Route Table** tab to view the routes.

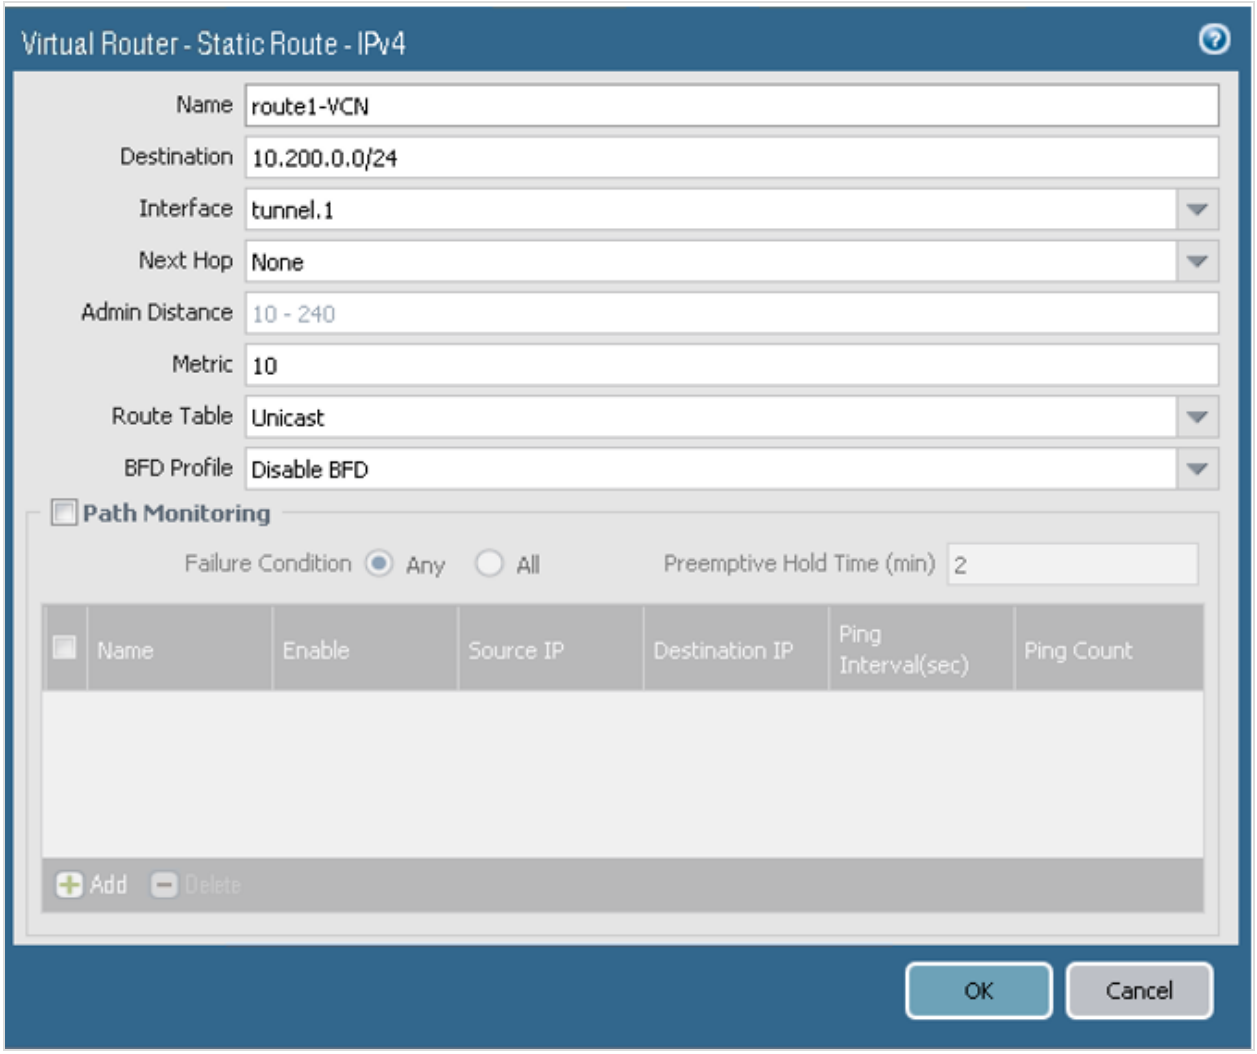


CONFIGURING STATIC ROUTING

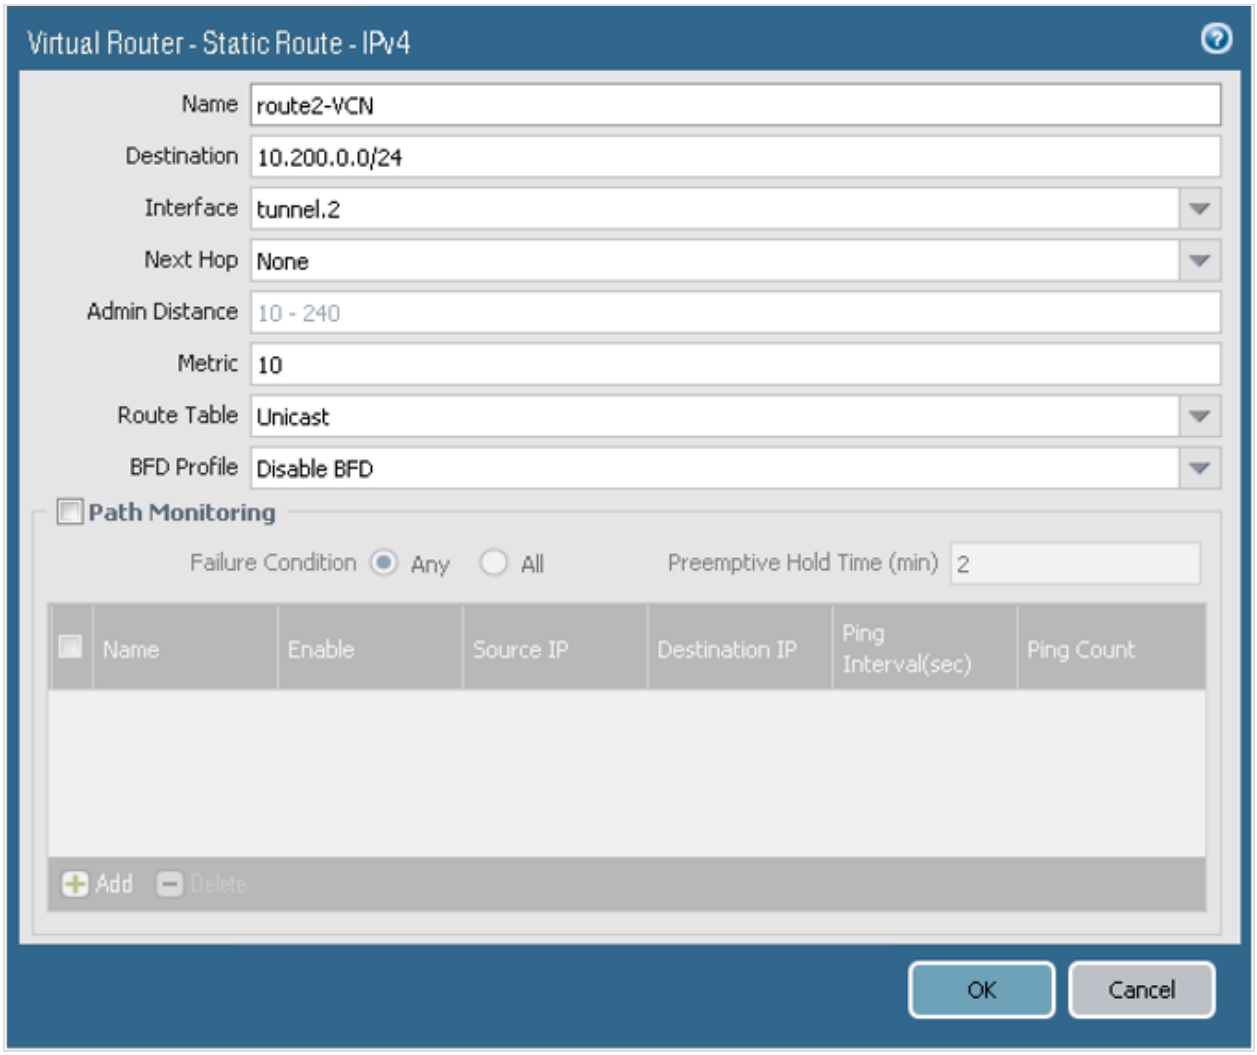
Use the instructions here if your CPE does not support BGP over IPSec, or you do not want to use BGP over IPSec.

In this task, you configure static routes to direct traffic through the tunnel interfaces to reach the DRG and finally the VCN hosts.

1. Follow tasks 1-5 in the preceding section.
2. Configure static routes:
    a. Go to **Network**, to **Virtual Routers**, to **default**, to **Static Routes**, and then click **Add**.
    b. For Route 1, configure the parameters as shown in the next image.



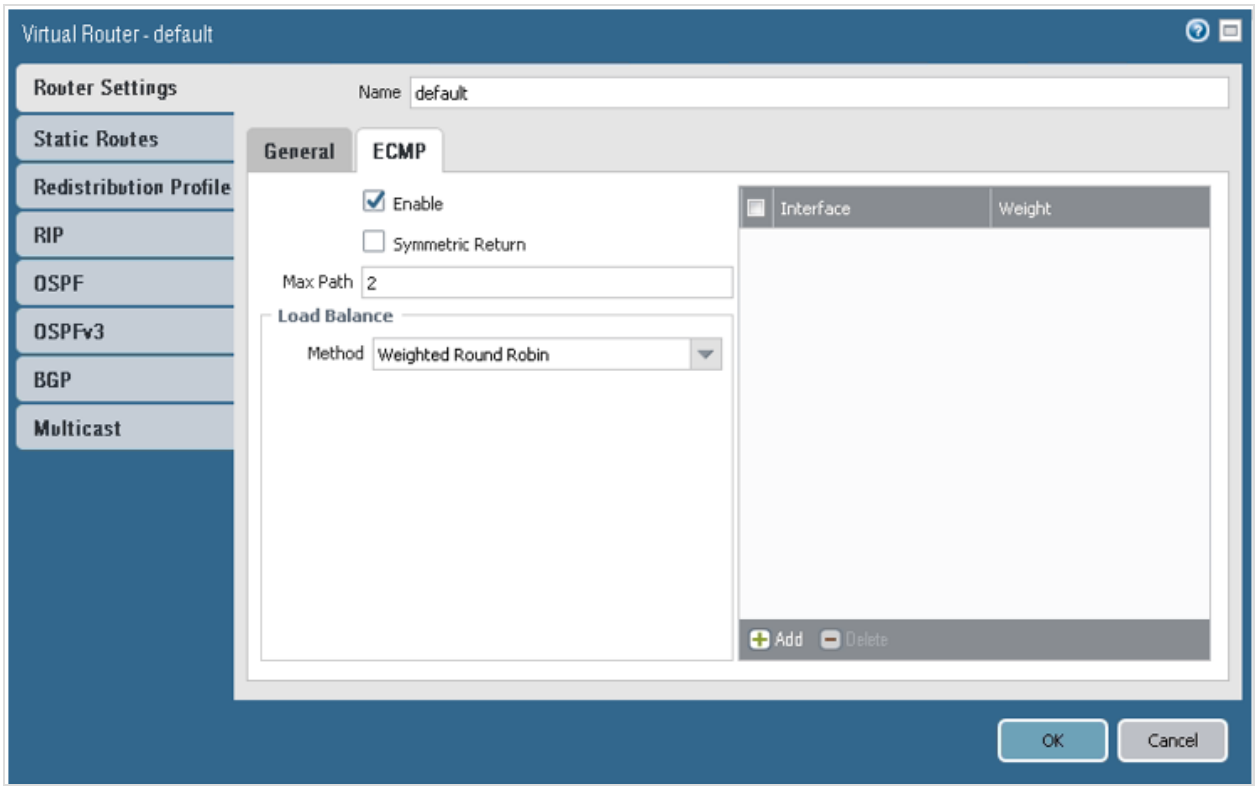
c. For Route 2, configure the parameters as shown in the next image.



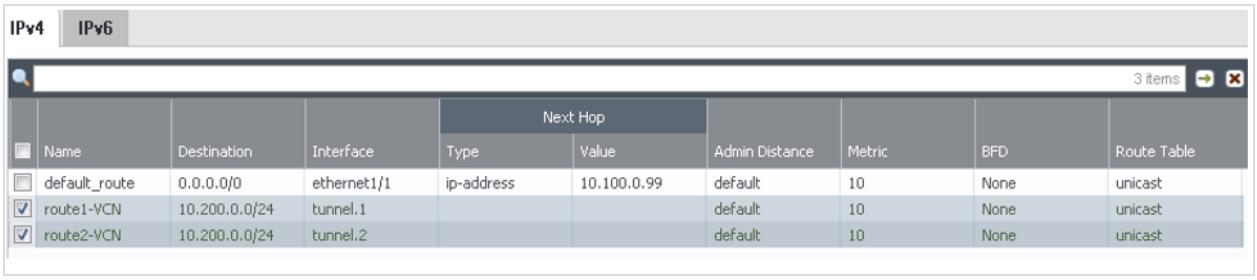
3. (Recommended) Enable ECMP for traffic sent through the two tunnels. The metric for both routes is set to 10. Here are some important notes about enabling ECMP:
    - First check to see if your networking design allows for ECMP.
    - Enabling or disabling ECMP on an existing virtual router causes the system to restart the virtual router. This might cause existing sessions to be terminated.

- This example uses the default virtual router. Use the correct virtual router for your network environment.

To enable ECMP, go to **Network**, to **Virtual Routers**, to **default**, to **Router Settings**, to **ECMP**, and then select the check box for **Enable**.

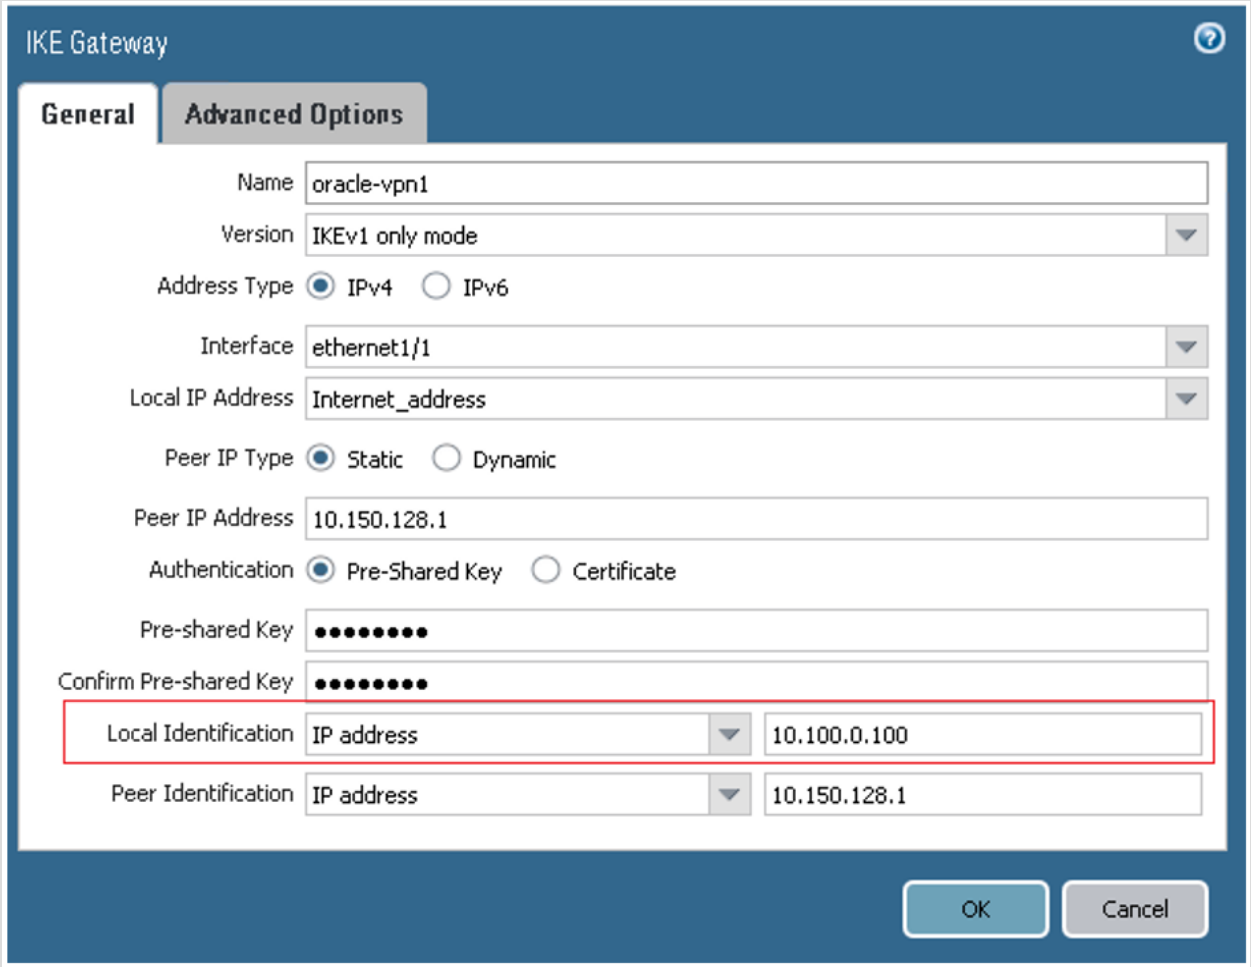


Here are screenshots that show the final configuration after this task is complete:



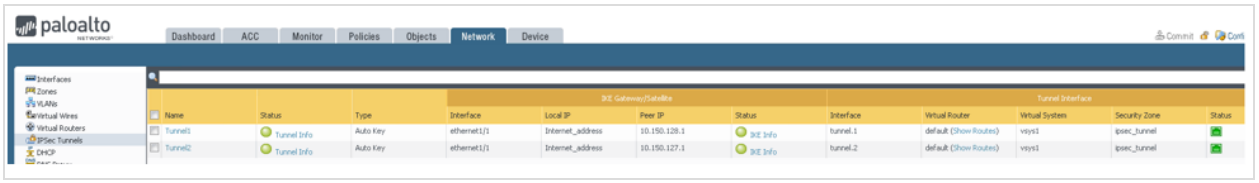
CHANGING THE IKE IDENTIFIER

If the CPE is behind a NAT device with a private IP address on the exit interface that the tunnel interfaces use as the source, you must specify the public IP address of the NAT device as the local IKE ID. You can do this by setting the **Local Identification** value in the **IKE Gateway** configuration:



Verification

To verify the IPSec tunnel status:



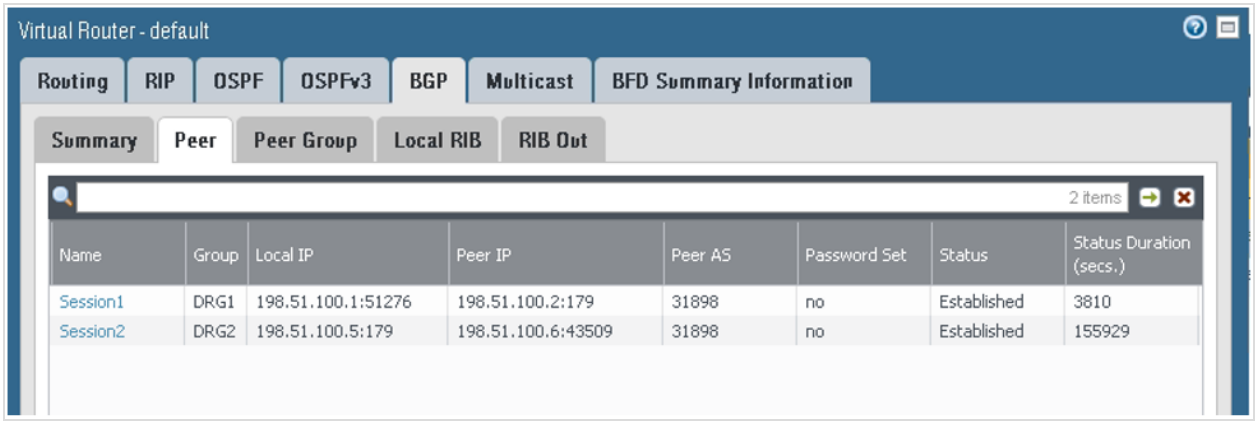
Use this command to verify the IKE SA:

```
show vpn ike-sa
```

Use this command to verify the IPSec tunnel configuration:

```
show vpn tunnel name <tunnel_name>
```

To verify the BGP status, look for **Established**:



To verify the BGP status from the command line:

```
show routing protocol bgp peer peer-name <name>
```

To verify that the routes are installed in the routing table:

```
show routing route
```

A Monitoring service is also available from Oracle Cloud Infrastructure to actively and passively monitor your cloud resources. For information about monitoring your VPN Connect, see VPN Connect Metrics.

If you have issues, see VPN Connect Troubleshooting.

WatchGuard

You can configure a WatchGuard Firebox as your CPE device for an IPSec VPN.

Go to the WatchGuard knowledge base article to download the configuration instructions.

Yamaha RTX Series

This configuration was validated using a RTX1210 running Firmware Rev.14.01.28 and RTX830 running Firmware Rev.15.02.03.

Important

Oracle uses asymmetric routing across the multiple tunnels that make up the IPSec VPN connection. Even if you configure one tunnel as primary and another as backup, traffic from your VCN to your on-premises network can use any tunnel that is "up" on your device. Configure your firewalls accordingly. Otherwise, ping tests or application traffic across the connection will not reliably work.

Before Starting

Before configuring your CPE, make sure to:

- Configure your internet provider settings
- Configure firewall rules to open UDP port 500, UDP port 4500, and ESP.

Supported Encryption Domain or Proxy ID

The values for the encryption domain (also known as a proxy ID, security parameter index (SPI), or traffic selector) depend on whether your CPE supports route-based tunnels or policy-based tunnels. For more information about the correct encryption domain values to use, see Supported Encryption Domain or Proxy ID.

Parameters from API or Console

Get the following parameters from the Oracle Cloud Infrastructure Console or API.

${ipAddress#}

- Oracle VPN headend IPSec tunnel endpoints. There is one value for each tunnel.
- Example value: 129.146.12.52

${sharedSecret#}

- The IPSec IKE pre-shared-key. There is one value for each tunnel.
- Example value: EXAMPLEDPfAMkD7nTH3SWr6OFabdT6exXn6enSlsKbE

${cpePublicIpAddress}

- The public IP address for the CPE (previously made available to Oracle via the Console).

${VcnCidrBlock}

- When creating the VCN, your company selected this CIDR to represent the IP aggregate network for all VCN hosts.
- Example Value: 10.0.0.0/20

Parameters Based on Current CPE Configuration and State

The following parameters are based on your current CPE configuration.

${tunnelInterface#}

- An interface number to identify the specific tunnel.
- Example value: 1

${ipsecPolicy#}

- The SA policy to be used for the selected inline interface.
- Example value: 1

${localAddress}

- The public IP address of your CPE.
- Example value: 146.56.2.52

Config Template Parameter Summary

Each region has multiple Oracle IPSec headends. The template below allows you to set up multiple tunnels on your CPE, each to a corresponding headend. In the table below, "User" is you/your company.

Parameter	Source	Example Value
`${ipAddress1}`	Console/API	129.146.12.52
`${sharedSecret1}`	Console/API	(long string)
`${ipAddress2}`	Console/API	129.146.13.52
`${sharedSecret2}`	Console/API	(long string)
`${cpePublicIpAddress}`	User	1.2.3.4
`${VcnCidrBlock}`	User	10.0.0.0/20

Important

The following ISAKMP and IPSec policy parameter values are applicable to VPN Connect in the commercial cloud. For the Government Cloud, you must use the values listed in Required VPN Connect Parameters for Government Cloud.

ISAKMP Policy Options

Parameter	Recommended Value
ISAKMP protocol version	Version 1
Exchange type	Main mode
Authentication method	Pre-shared keys
Encryption	AES-256-cbc
Authentication algorithm	SHA-256
Diffie-Hellman Group	Group 5
IKE session key lifetime	28800 seconds (8 hours)

IPSec Policy Options

Parameter	Recommended Value
IPSec protocol	ESP, tunnel-mode
Encryption	AES-256-cbc

Parameter	Recommended Value
Authentication algorithm	HMAC-SHA1-96
Diffie-Hellman Group	Group 5
Perfect Forward Secrecy	Enabled
IPSec session key lifetime	3600 seconds (1 hour)

CPE Configuration

ISAKMP AND IPSEC CONFIGURATION

```
tunnel select 1
description tunnel OCI-VPN1
ipsec tunnel 1
  ipsec sa policy 1 1 esp aes256-cbc sha-hmac
  ipsec ike duration ipsec-sa 1 3600
  ipsec ike duration isakmp-sa 1 28800
  ipsec ike encryption 1 aes256-cbc
  ipsec ike group 1 modp1536
  ipsec ike hash 1 sha256
  ipsec ike keepalive log 1 off
  ipsec ike keepalive use 1 on dpd 5 4
  ipsec ike local address 1 ${cpePublicIpAddress}
  ipsec ike local id 1 0.0.0.0/0

Working with VPN Connect

This topic contains some details about working with VPN Connect and the related components. Also see these topics:

- VPN Connect Overview
- VPN Connect Quickstart
- Setting Up VPN Connect
- CPE Configuration
- VPN Connect FAQ
- VPN Connect Metrics
- VPN Connect Troubleshooting

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Viewing Tunnel Status and Configuration

When you successfully create the IPSec connection, Oracle produces important configuration information for each of the resulting IPSec tunnels. For example, see task 2h in the overall setup process. You can view that information and the status of the tunnels at any time. This includes the BGP status if the tunnel is configured to use BGP dynamic routing.

To view the status and configuration information for the IPSec tunnels

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **IPSec Connections**.
   A list of the IPSec connections in the compartment that you're viewing is displayed. If you don’t see the one you're looking for, verify that you’re viewing the correct compartment (select from the list on the left side of the page).
2. Click the IPSec connection you're interested in.
   Each tunnel's details are displayed, including the IPSec status, the BGP status (if the tunnel uses BGP dynamic routing), and the Oracle VPN IP address (the VPN headend).
3. To view a tunnel's shared secret:
   a. Click the tunnel you're interested in.
   b. Next to the **Shared Secret** field, click **Show**.

Changing the Static Routes

You can change the static routes for an existing IPSec connection. You can provide up to 10 static routes.

Remember that an IPSec connection can use either static routing or BGP dynamic routing. You associate the static routes with the overall IPSec connection and not the individual tunnels. If an IPSec connection has static routes associated with it, Oracle uses them for routing a tunnel's traffic *only* if the tunnel itself is configured to use static routing. If it's configured to use BGP dynamic routing, the IPSec connection's static routes are ignored.

Important

The IPSec connection goes down while it is reprovisioned with your static route changes.

To edit the static routes

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **IPSec Connections**.
   A list of the IPSec connections in the compartment that you're viewing is displayed. If you don’t see the one you're looking for, verify that you’re viewing the correct compartment (select from the list on the left side of the page).
2. For the IPSec connection you're interested in, click the Actions icon (three dots), and then click **Edit**.
   The current static routes are displayed.
3. Make your changes and click **Save Changes**.

Changing the CPE IKE Identifier That Oracle Uses

If your CPE is behind a NAT device, you might need to give Oracle your CPE IKE identifier. You can either specify it when you create the IPSec connection, or later edit the IPSec connection

and change the value. Oracle expects the value to be an IP address or fully qualified domain name (FQDN). When you specify the value, you also specify which type it is.

Important

The IPSec connection goes down while it is reprovisioned to use your CPE IKE identifier.

To change the CPE IKE identifier that Oracle uses

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **IPSec Connections**.
   A list of the IPSec connections in the compartment that you're viewing is displayed. If you don't see the one you're looking for, verify that you're viewing the correct compartment (select from the list on the left side of the page).
2. For the IPSec connection you're interested in, click the Actions icon (three dots), and then click **Edit**.
   The current CPE IKE identifier that Oracle is using is displayed at the bottom of the dialog.
3. Enter your new values for **CPE IKE Identifier Type** and **CPE IKE Identifier**, and then click **Save Changes**.

Using IKEv2

Oracle supports Internet Key Exchange (IKE) version 1 and version 2 (IKEv2).

If you want to use IKEv2 and your CPE supports it, you must:

- Configure each IPSec tunnel to use IKEv2 in the Oracle Console. See the following procedures.

- Configure your CPE to use IKEv2 encryption parameters that the CPE supports. For a list of parameters that Oracle supports, see Supported IPSec Parameters.

New IPSec connection: using IKEv2

Note

If you create a new IPSec connection manually, you can specify IKEv2 when you create the IPSec connection in the Oracle Console. See the procedure that immediately follows.

If you instead use the VPN quickstart workflow, the IPSec connection is configured to use IKEv1 only. However, after the workflow is complete, you can edit the resulting IPSec tunnels in the Oracle Console and change them to use IKEv2.

To manually set up a new IPSec connection that uses IKEv2:

1. While creating the IPSec connection in the Oracle Console, in the **Advanced Options** section, click the **Tunnel 1** tab.
2. From the **IKE Version** menu, select **IKEv2**.
3. Repeat the preceding step for the **Tunnel 2** tab.
4. Later when configuring your CPE, configure it to use only IKEv2 and related IKEv2 encryption parameters that the CPE supports.

Existing IPSec connection: upgrading to IKEv2

Important

Oracle recommends performing the following process for one tunnel at a time to avoid disruption in your overall connection. If your connection is not redundant (for example, does not have multiple tunnels), expect downtime while you upgrade to IKEv2.

1. Change the tunnel's IKE version in the Oracle Console:
    a. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **IPSec Connections**.
    b. Click the IPSec connection you're interested in.
    c. Click the tunnel to view its details.
    d. Click **Edit**.
    e. From the **IKE Version** menu, select **IKEv2**.
    f. Click **Save Changes**.
2. Update your CPE configuration for the tunnel to use IKEv2 and the related encryption parameters that the CPE supports. For a list of parameters that Oracle supports, see Supported IPSec Parameters.
3. If the security associations did not rekey immediately, force a rekey for that tunnel on your CPE. In other words, clear the phase 1 and phase 2 security associations and do not wait for them to expire. Some CPE devices wait for the SAs to expire before rekeying. Forcing the rekey lets you confirm immediately that the IKE version configuration is correct.
4. To verify, ensure that the security associations for the tunnel rekey correctly. If they don't, confirm that the correct IKE version is set in the Oracle Console and on your CPE, and that the CPE is using the desired parameters.

After you've confirmed the first tunnel is up and running again, repeat the preceding steps for the second tunnel.

Changing the Shared Secret That an IPSec Tunnel Uses

When you set up an IPSec VPN, by default Oracle provides each tunnel's shared secret (also called the pre-shared key). You might have a particular shared secret that you want to use instead. You can specify each tunnel's shared secret when you create the IPSec connection, or you can edit the tunnels and provide each new shared secret then. For the shared secret, only numbers, letters, and spaces are allowed. Oracle recommends using a different shared secret for each tunnel.

Important

When you change a tunnel's shared secret, both the overall IPSec connection and the tunnel go into the Provisioning state while the tunnel is reprovisioned with the new shared secret. The other tunnel in the IPSec connection remains in the Available state. However, while the first tunnel is being reprovisioned, you cannot change the second tunnel's configuration.

To change the shared secret that an IPSec tunnel uses

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **IPSec Connections**.
   A list of the IPSec connections in the compartment that you're viewing is displayed. If you don’t see the one you're looking for, verify that you’re viewing the correct compartment (select from the list on the left side of the page).
2. Click the IPSec connection you're interested in.
3. Click the tunnel you're interested in.

4. Next to the **Shared Secret** field, click **Edit**.
5. Enter your new value. Only numbers, letters, and spaces are allowed.
6. Click **Save Changes**.

Changing from Static Routing to BGP Dynamic Routing

If you want to change an existing IPSec VPN from using static routing to using BGP dynamic routing, follow the process in this section.

Warning

When you change a tunnel's routing type, the tunnel's IPSec status does not change during reprovisioning. However, routing through the tunnel is affected. Traffic is temporarily disrupted until your network engineer configures your CPE device in accordance with the routing type change. **If your existing IPSec VPN is currently configured to use only a single tunnel, this process will disrupt your connection to Oracle.** If your IPSec VPN instead uses multiple tunnels, Oracle recommends reconfiguring one tunnel at a time to avoid disrupting your connection to Oracle.

To change from static routing to BGP dynamic routing

Prerequisites:

- You've read this section: Routing for the Oracle IPSec VPN
- You've gathered the necessary BGP routing information:

- Your network's ASN. Oracle's BGP ASN for the commercial cloud is 31898. For the Government Cloud, see Oracle's BGP ASN.
- For each tunnel: The BGP IP address for each end of the tunnel (the two addresses for a given tunnel must be a pair from a /30 or /31 subnet, and they must be part of the IPSec VPN's encryption domain)

Repeat the following process for each tunnel in the IPSec connection:

1. Reconfigure the tunnel's routing type from static routing to BGP dynamic routing:
   a. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **IPSec Connections**.
   b. Click the IPSec connection you're interested in.
      The tunnels are listed, and the status for each tunnel is shown. The **BGP Status** for the tunnel you're interested in should show only a hyphen (no value), which means that the tunnel is currently configured to use static routing.
   c. Click the tunnel to view all of its details.
   d. Click **Edit**.
   e. Do the following:
      - **Routing Type:** Select the radio button for **BGP Dynamic Routing**.
      - **BGP ASN:** Enter your network's BGP ASN.
      - **Inside Tunnel Interface - CPE:** Enter the BGP IP address with subnet mask (either /30 or /31) for the CPE end of the tunnel. For example: 10.0.0.16/31.
      - **Inside Tunnel Interface - Oracle:** Enter the BGP IP address with subnet mask (either /30 or /31) for the Oracle end of the tunnel. For example: 10.0.0.17/31.
   f. Click **Save Changes**.

   The tunnel's **BGP Status** changes to Down.
2. Have your network engineer update your CPE device's tunnel configuration to use BGP.

3. On your side of the connection, confirm that the tunnel's BGP session is in an established state. If it is not, make sure you've configured the correct IP addresses for the tunnel in the Oracle Console and also for your CPE device.
4. In the Oracle Console, confirm that the tunnel's **BGP Status** is now Up.
5. Confirm that your CPE device is learning routes from Oracle, and your CPE device is advertising routes to Oracle. If you want to re-advertise the Oracle routes from BGP back to your on-premises network, make sure your CPE device is configured accordingly. Your existing policy to advertise the static routes to your on-premises network may not work for the BGP learned routes.
6. Ping the Oracle BGP IP address from your side of the connection to confirm that traffic is flowing.

After you've confirmed the first tunnel is up and running with BGP, repeat the process for the second tunnel.

Important

As noted in Routing for the Oracle IPSec VPN, the static routes that are still configured for the overall IPSec connection do NOT override the BGP routing. Those static routes are ignored when Oracle routes traffic through a tunnel that is configured to use BGP.

Also, you can change a tunnel's routing type back to static routing if necessary. You might do this if the scheduled downtime window for the CPE device is ending soon and you're having trouble establishing the BGP session. When you switch back to static routing, make sure the overall IPSec connection still has your desired static routes configured.

Monitoring Your IPSec VPN

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications. For more information, see Monitoring Overview and Notifications Overview.

For information about monitoring your connection, see VPN Connect Metrics.

Disabling or Terminating the IPSec VPN

If you want to disable the IPSec VPN between your on-premises network and VCN, you can simply detach the DRG from the VCN instead of deleting the IPSec connection. If you're also using the DRG with FastConnect, detaching the DRG would also interrupt the flow of traffic over FastConnect.

You can delete the IPSec connection. However, if you later want to re-establish it, your network engineer would have to configure your CPE device again with a new set of tunnel configuration information from Oracle.

If you want to permanently delete the entire IPSec VPN, you must first terminate the IPSec connection. Then you can delete the CPE object. If you're not using the DRG for another connection to your on-premises network, you can detach it from the VCN and then delete it.

To delete an IPSec connection

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **IPSec Connections**.
   A list of the IPSec connections in the compartment you're viewing is displayed. If you don’t see the one you're looking for, verify that you’re viewing the correct compartment (select from the list on the left side of the page).
2. Click the IPSec connection you're interested in.
3. Click **Terminate**.
4. Confirm the deletion when prompted.

The IPSec connection will be in the Terminating state for a short period while it's being deleted.

To delete a CPE object

Prerequisite: There must not be an IPSec connection between the CPE object and a DRG.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Customer-Premises Equipment**.
   A list of the CPE objects in the compartment you're viewing is displayed. If you don't see the one you're looking for, verify that you're viewing the correct compartment (select from the list on the left side of the page).
2. For the CPE object that you want to delete, click the Actions icon (three dots), and then click **Delete**.
3. Confirm the deletion when prompted.

The object will be in the Terminating state for a short period while it's being deleted.

Managing Tags for an IPSec Connection or CPE Object

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the desired tags. For general information about applying tags, see Resource Tags.

To manage tags for an IPSec connection

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **IPSec Connections**.
   A list of the IPSec connections in the compartment you're viewing is displayed. If you don't see the one you're looking for, verify that you're viewing the correct compartment (select from the list on the left side of the page).
2. Click the IPSec connection you're interested in.

3. Click the **Tags** tab to view or edit the existing tags. Or click **Add tags** to add new ones.

To manage tags for a CPE object

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Customer-Premises Equipment**.
   A list of the CPE objects in the compartment you're viewing is displayed. If you don't see the one you're looking for, verify that you're viewing the correct compartment (select from the list on the left side of the page).
2. Click the CPE object you're interested in.
3. Click the **Tags** tab to view or edit the existing tags. Or click **Apply tag(s)** to add new ones.

Moving a CPE Object to a Different Compartment

You can move your resources from one compartment to another. After you move the resource to the new compartment, inherent policies apply immediately and affect access to the resource through the Console. Moving the CPE object to a different compartment does not affect the connection between your data center and Oracle Cloud Infrastructure. For more information, see Moving Resources to a Different Compartment.

To move a CPE object to a different compartment

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Customer-Premises Equipment**.
2. Find the CPE object in the list, click the the Actions icon (three dots), and then click **Move Resource**.
3. Choose the destination compartment from the list.
4. Click **Move Resource**.

Managing Your DRG

For tasks related to DRGs, see Dynamic Routing Gateways (DRGs).

VPN Connect FAQ

Can I customize configuration parameters such as IKE ID or IPSec VPN tunnel lifetime on the DRG?

No. Oracle has predetermined the configuration parameters that work with the IPSec VPN service. Your IPsec VPN can't be established if there is a mismatch.

If your CPE is behind a NAT device, you can provide Oracle with your CPE's IKE identifier so that Oracle can use the same value on the Oracle side. For more information, see Changing the CPE IKE Identifier That Oracle Uses.

Can Oracle initiate the IPsec VPN connection?

No. You must initiate it from your end.

Is an IPSec VPN supported over FastConnect?

No, FastConnect and the IPSec VPN are two different services.

Can packets from the VCN be sourced with the public IP of the DRG? In other words, can the DRG source the NAT VCN traffic?

No. Packets from the VCN have the private IP address of the instance as a source IP address. Oracle cannot change the source IP address to the private or public IP address of the DRG.

Oracle has provided two VPN endpoints to build tunnels to. Does Oracle route the same network over both tunnels?

Yes. Traffic for all the subnets in the VCN attached to your DRG is routed over both tunnels.

How many VPN tunnels can I have from a single CPE device?

You can have a maximum of eight tunnels from a unique CPE IP address per region. If you want more than eight tunnels, either use a different IP address for the additional ones, or use a different CPE device (recommended).

I'm having trouble with my IPSec connection. What can I do?

See VPN Connect Troubleshooting.

Using the API for VPN Connect

This topic lists the Networking service API operations for managing VPN Connect components.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

To manage your VCN and subnets, use these operations:

- ListVcns
- CreateVcn
- GetVcn
- UpdateVcn
- DeleteVcn
- ChangeVcnCompartment
- ListSubnets
- CreateSubnet
- GetSubnet
- UpdateSubnet
- DeleteSubnet
- ChangeSubnetCompartment

To manage your DRG, use these operations:

- ListDrgs
- CreateDrg
- GetDrg
- UpdateDrg
- DeleteDrg
- ListDrgAttachments
- CreateDrgAttachment: This operation attaches a DRG to a VCN and results in a `DrgAttachment` object with its own OCID.
- GetDrgAttachment
- UpdateDrgAttachment
- DeleteDrgAttachment: This operation detaches a DRG from a VCN by deleting the `DrgAttachment` object.

To manage routing for your VCN, use these operations:

- ListRouteTables
- GetRouteTable
- UpdateRouteTable
- CreateRouteTable
- DeleteRouteTable

To manage security lists for your VCN, use these operations:

- ListSecurityLists
- GetSecurityList
- UpdateSecurityList
- CreateSecurityList
- DeleteSecurityList

To manage your CPEs, use these operations:

- ListCpes
- CreateCpe
- GetCpe
- UpdateCpe
- DeleteCpe
- ChangeCpeCompartment

To manage your IPSec connections, use these operations:

- ListIPSecConnections
- CreateIPSecConnection: Use this operation to get the configuration information for each tunnel, including the IP address of the DRG (the VPN headend) and the shared secret. See CPE Configuration.
- GetIPSecConnection

- UpdateIPSecConnection
- DeleteIPSecConnection
- ChangeIPSecConnectionCompartment
- GetIPSecConnectionDeviceStatus: Use this operation to determine the status of the IPSec tunnels (up or down).
- GetIPSecConnectionDeviceConfig: Use this operation to get the configuration information for each tunnel.

VPN Connect Metrics

You can monitor the health, capacity, and performance of your VPN Connect by using metrics, alarms, and notifications. For more information, see Monitoring Overview and Notifications Overview.

This topic describes the metrics emitted by the metric namespace `oci_vpn`.

Resources: IPSec connections.

Overview of Metrics: oci_vpn

The available metrics help you determine quickly if your VPN Connect is up, how much data is flowing over the connection, and if packets are being dropped for unexpected errors.

A VPN Connect includes these resources:

- An IPSec connection, which you can think of as the *parent resource* (identified by `parentResourceId` in the following discussion).
- One or more individual tunnels associated with that IPSec connection (each identified by the tunnel's `publicIp` in the following discussion).

Required IAM Policy

To monitor resources, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources

being monitored. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.

Available Metrics: oci_vpn

The metrics listed in the following table are automatically available for any VPN Connect that you create. You do not need to enable monitoring on the resource to get these metrics.

You also can use the Monitoring service to create custom queries.

Each metric includes the following dimensions:

PARENTRESOURCEID

The OCID of the IPSec connection (the parent resource). The connection has multiple individual tunnels.

PUBLICIP

Although each tunnel has its own OCID, it can be easier to use the `publicIp` dimension to identify a specific IPSec tunnel in the connection. The value is the public IP address of the Oracle end of the tunnel (also known as the *Oracle VPN headend*).

Metric	Metric Display Name	Unit	Description	Dimensions
`TunnelState`	**IPSec Tunnel State**	Binary (1 or 0)	Whether the tunnel is up (1) or down (0).	`parentResourceId` `publicIp`
`PacketsReceived`	**Packets Received**	Packets	Number of packets received at the Oracle end of the connection.	
`BytesReceived`	**Bytes Received**	Bytes	Number of bytes received at the Oracle end of the connection.	
`PacketsSent`	**Packets Sent**	Packets	Number of packets sent from the Oracle end of the connection.	
`BytesSent`	**Bytes Sent**	Bytes	Number of bytes sent from the Oracle end of the connection.	
`PacketsError`	**Packets with Errors**	Packets	Number of packets dropped at the Oracle end of the connection. Dropped packets indicate a misconfiguration in some part of the overall system. Check if there's been a change to the configuration of your VCN, the IPSec VPN, or your CPE.	

Using the Console

To view default metrics charts for an individual tunnel in an IPSec connection

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **IPSec Connections**.
2. Click the IPSec connection to view its details.
3. Click the tunnel you're interested in to view its details and default metrics charts.

For more information about monitoring metrics and using alarms, see Monitoring Overview. For information about notifications for alarms, see Notifications Overview.

To view default metric charts for all IPSec connections in a compartment

1. Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Service Metrics**.
2. For **Compartment**, select the compartment that contains the IPSec connection you're interested in.
3. For **Metric Namespace**, select **oci_vpn**.
   The **Service Metrics** page dynamically updates the page to show charts for each metric that is emitted by the selected metric namespace.

Each IPSec tunnel is a single line in a given chart. The tunnel is identified in the chart by the public IP address of the Oracle end of the tunnel.

For more information about monitoring metrics and using alarms, see Monitoring Overview. For information about notifications for alarms, see Notifications Overview.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the following APIs for monitoring:

- Monitoring API for metrics and alarms
- Notifications API for notifications (used with alarms)

VPN Connect Troubleshooting

This topic covers troubleshooting techniques for an IPSec VPN that has issues.

Some of the troubleshooting techniques assume that you are a network engineer with access to your CPE device's configuration.

General Issues

IPSec tunnel is DOWN

Check these items:

- **Basic configuration:** The IPSec tunnel consists of both phase-1 (ISAKMP) and phase-2 (IPSec) configuration. Confirm that both are configured correctly on your CPE device. See the configuration appropriate for your CPE device:

  #### List of configurations

  - Verified CPE Devices
  - Checkpoint:
    - Check Point: Route-Based
    - Check Point: Policy-Based
  - Cisco ASA:
    - Cisco ASA: Route-Based
    - Cisco ASA: Policy-Based

- Cisco IOS
- FortiGate
- Juniper MX
- Juniper SRX
- Libreswan
- NEC IX Series
- Openswan
- Palo Alto
- WatchGuard
- Yamaha RTX Series

- **Local and remote proxy IDs:** If you're using a policy-based configuration, check if your CPE is configured with more than one pair of local and remote proxy IDs (subnets). The Oracle VPN router supports only one pair. If your CPE has more than one pair, update the configuration to include only one pair, and choose one of the following two options:

Option	Local Proxy ID	Remote Proxy ID
1	ANY (or 0.0.0.0/0)	ANY (or 0.0.0.0/0)
2	On-premises CIDR (an aggregate that covers all the subnets of interest)	VCN's CIDR

- **NAT device:** If the CPE is behind a NAT device, the CPE IKE identifier configured on your CPE might not match the CPE IKE identifier Oracle is using (the public IP address of your CPE). If your CPE does not support setting the CPE IKE identifier on your end, you can provide Oracle with your CPE IKE identifier in the Oracle Console. For more information, see If Your CPE Is Behind a NAT Device.

- **NAT-T:** Although NAT-T is supported in most regions, it is not yet fully supported in the US East (Ashburn) region (see this known issue). If your IPSec tunnels connect to that region, and your CPE is currently configured for NAT-T, disable NAT-T and then re-initiate the IPSec connection on your CPE.

IPSec tunnel is UP, but no traffic is passing through

Check these items:

- **Phase 2 (IPSec) configuration:** Confirm that the phase 2 (IPSec) parameters are configured correctly on your CPE device. See the configuration appropriate for your CPE device:

List of configurations

  - Verified CPE Devices
  - Checkpoint:
    - Check Point: Route-Based
    - Check Point: Policy-Based
  - Cisco ASA:
    - Cisco ASA: Route-Based
    - Cisco ASA: Policy-Based
  - Cisco IOS
  - FortiGate
  - Juniper MX
  - Juniper SRX
  - Libreswan
  - NEC IX Series
  - Openswan

    - Palo Alto
    - WatchGuard
    - Yamaha RTX Series

- **NAT-T:** Although NAT-T is supported in most regions, it is not yet fully supported in the US East (Ashburn) region (see this known issue). If your IPSec tunnels connect to that region, and your CPE is currently configured for NAT-T, disable NAT-T and then re-initiate the IPSec connection on your CPE.
- **VCN security lists:** Ensure you've set up the VCN security lists to allow the desired traffic (both ingress and egress rules). Note that the VCN's default security list does not allow ping traffic (ICMP type 8 and ICMP type 0). You must add the appropriate ingress and egress rules to allow ping traffic.
- **Firewall rules:** Ensure that your firewall rules allow both ingress and egress traffic with the Oracle VPN headend IPs and the VCN CIDR block.
- **Asymmetric routing:** Oracle uses asymmetric routing across the multiple tunnels that make up the IPSec VPN connection. Even if you configure one tunnel as primary and another as backup, traffic from your VCN to your on-premises network can use any tunnel that is "up" on your device. Configure your firewalls accordingly. Otherwise, ping tests or application traffic across the connection will not reliably work.
- **Cisco ASA:** Do not use the `originate-only` option with an Oracle IPSec VPN tunnel. It causes the tunnel's traffic to be inconsistently blackholed. The command is only for tunnels between two Cisco devices. Here's an example of the command that you should NOT use for the Oracle IPSec VPN tunnels: `crypto map <map name> <sequence number> set connection-type originate-only`

IPSec tunnel is UP, but traffic is passing in only one direction

Check these items:

- **Asymmetric routing:** Oracle uses asymmetric routing across the multiple tunnels that make up the IPSec VPN connection. Even if you configure one tunnel as primary and

another as backup, traffic from your VCN to your on-premises network can use any tunnel that is "up" on your device. Configure your firewalls accordingly. Otherwise, ping tests or application traffic across the connection will not reliably work.

- **Single tunnel preferred:** If you want to use only one of the tunnels, make sure that you have the proper policy or routing in place on the CPE to prefer that tunnel.
- **Multiple IPSec connections:** If you have multiple IPSec connections with Oracle, make sure to specify more specific static routes for the preferred IPSec connection.
- **VCN security lists:** Ensure that your VCN security lists allow traffic in both directions (ingress and egress).
- **Firewall rules:** Ensure that your firewall rules allow traffic in *both* directions with the Oracle VPN headend IPs and the VCN CIDR block.

For an IPSec VPN with a Policy-Based Configuration

IPSec tunnel is DOWN

Check these items:

- **Basic configuration:** The IPSec tunnel consists of both phase-1 (ISAKMP) and phase-2 (IPSec) configuration. Confirm that both are configured correctly on your CPE device. See the configuration appropriate for your CPE device:

List of configurations

  - Verified CPE Devices
  - Checkpoint:
    - Check Point: Route-Based
    - Check Point: Policy-Based

    - Cisco ASA:
        - Cisco ASA: Route-Based
        - Cisco ASA: Policy-Based
    - Cisco IOS
    - FortiGate
    - Juniper MX
    - Juniper SRX
    - Libreswan
    - NEC IX Series
    - Openswan
    - Palo Alto
    - WatchGuard
    - Yamaha RTX Series

- **Local and remote proxy IDs:** If you're using a policy-based configuration, check if your CPE is configured with more than one pair of local and remote proxy IDs (subnets). The Oracle VPN router supports only one pair. If your CPE has more than one pair, update the configuration to include only one pair, and choose one of the following two options:

Option	Local Proxy ID	Remote Proxy ID
1	ANY (or 0.0.0.0/0)	ANY (or 0.0.0.0/0)
2	On-premises CIDR (an aggregate that covers all the subnets of interest)	VCN's CIDR

- **NAT device:** If the CPE is behind a NAT device, the CPE IKE identifier configured on your CPE might not match the CPE IKE identifier Oracle is using (the public IP address of your CPE). If your CPE does not support setting the CPE IKE identifier on your end, you can provide Oracle with your CPE IKE identifier in the Oracle Console. For more information, see If Your CPE Is Behind a NAT Device.
- **Cisco ASA:** Do not use the `originate-only` option with an Oracle IPSec VPN tunnel. It causes the tunnel's traffic to be inconsistently blackholed. The command is only for tunnels between two Cisco devices. Here's an example of the command that you should NOT use for the Oracle IPSec VPN tunnels: `crypto map <map name> <sequence number> set connection-type originate-only`

IPSec tunnel is UP but keeps flapping

Check these items:

- **Initiation of connection:** Ensure that your CPE device is initiating the connection.
- **Local and remote proxy IDs:** If you're using a policy-based configuration, check if your CPE is configured with more than one pair of local and remote proxy IDs (subnets). The Oracle VPN router supports only one pair. If your CPE has more than one pair, update the configuration to include only one pair, and choose one of the following two options:

Option	Local Proxy ID	Remote Proxy ID
1	ANY (or 0.0.0.0/0)	ANY (or 0.0.0.0/0)
2	On-premises CIDR (an aggregate that covers all the subnets of interest)	VCN's CIDR

- **Interesting traffic at all times:** In general, Oracle recommends having interesting traffic running through the IPSec tunnels at all times if your CPE supports it.

Certain Cisco ASA versions require the SLA monitor to be configured, which keeps interesting traffic running through the IPSec tunnels. For more information, see the section for "IP SLA Configuration" in the Cisco ASA policy-based configuration template.

IPSec tunnel is UP but traffic is unsteady

Check these items:

- **Local and remote proxy IDs:** If you're using a policy-based configuration, check if your CPE is configured with more than one pair of local and remote proxy IDs (subnets). The Oracle VPN router supports only one pair. If your CPE has more than one pair, update the configuration to include only one pair, and choose one of the following two options:

Option	Local Proxy ID	Remote Proxy ID
1	ANY (or 0.0.0.0/0)	ANY (or 0.0.0.0/0)
2	On-premises CIDR (an aggregate that covers all the subnets of interest)	VCN's CIDR

- **Interesting traffic at all times:** In general, Oracle recommends having interesting traffic running through the IPSec tunnels at all times if your CPE supports it.
  Certain Cisco ASA versions require the SLA monitor to be configured, which keeps interesting traffic running through the IPSec tunnels. For more information, see the section for "IP SLA Configuration" in the Cisco ASA policy-based configuration template.

BGP Session Troubleshooting

BGP status is DOWN

Check these items:

- **IPSec status:** For the BGP session to be up, the IPSec tunnel itself must be up.
- **BGP address:** Verify that both ends of the tunnel are configured with the correct BGP peering IP address.
- **ASN:** Verify that both ends of the tunnel are configured with the correct BGP local ASN and Oracle BGP ASN. Oracle's BGP ASN for the commercial cloud is 31898. For the Government Cloud, see Oracle's BGP ASN.
- **MD5:** Verify that MD5 authentication is disabled or not configured on your CPE device. The Oracle IPSec VPN does not support MD5 authentication.
- **Firewalls:** Verify that your on-premises firewall or access control lists are not blocking the following ports:
  - TCP port 179 (BGP)
  - UDP port 500 (IKE)
  - IP protocol port 50 (ESP)

  If your CPE device's firewall is blocking TCP port 179 (BGP), the BGP neighborship will be down. Traffic cannot flow through the tunnel because the CPE device and Oracle router do not have any routes.

BGP status is flapping

Check these items:

- **IPSec status:** For the BGP session to be up and not flapping, the IPSec tunnel itself must be up and not flapping.
- **Maximum prefixes:** Verify that you are advertising no more than 2000 prefixes. If you're advertising more, BGP won't be established.

BGP status is UP, but no traffic is passing through

Check these items:

- **VCN security lists:**Ensure you've set up the VCN security lists to allow the desired traffic (both ingress and egress rules). Note that the VCN's default security list does not allow ping traffic (ICMP type 8 and ICMP type 0). You must add the appropriate ingress and egress rules to allow ping traffic.
- **Correct routes on both ends:** Verify that you have received the correct VCN routes from Oracle and the CPE device is using those routes. Likewise, verify that you are advertising the correct on-premises network routes over the IPSec VPN, and the VCN route tables use those routes.

BGP status is UP, but traffic is passing in only one direction

Check these items:

- **VCN security lists:** Ensure that your VCN security lists allow traffic in both directions (ingress and egress).
- **Firewalls:** Verify that your on-premises firewall or access control lists are not blocking traffic to or from the Oracle end.
- **Asymmetric routing:** Oracle uses asymmetric routing. If you have multiple IPSec connections, make sure that your CPE device is configured for asymmetric route processing.
- **Redundant connections:** If you have redundant IPSec connections, make sure they're both advertising the same routes.

Redundant Connections

Remember these important notes:

- FastConnect uses BGP dynamic routing. IPSec connections can use either static routing or BGP, or a combination.
- For important details about routing and preferred routes when using redundant connections, see Route Advertisements and Path Preferences When You Have Multiple Connections.

- You can use two IPSec connections for redundancy. If both IPSec connections have only a default route (0.0.0.0/0) configured, traffic will route to either of those connections because Oracle uses asymmetric routing. If you want one IPSec connection as primary and another one as backup, configure more-specific routes for the primary connection and less-specific routes (or the default route of 0.0.0.0/0) on the backup connection.

IPSec and FastConnect are both set up, but traffic is only passing through IPSec

Make sure to use more specific routes for the connection you want as primary. If you're using the same routes for both IPSec and FastConnect, see the discussion of routing preferences in Route Advertisements and Path Preferences When You Have Multiple Connections.

Two on-premises data centers each have an IPSec connection to Oracle, but only one is passing traffic

Verify that both IPSec connections are up and ensure that you have asymmetric route processing enabled on the CPE.

If both IPSec connections have only a default route (0.0.0.0/0) configured, traffic will route to either of those connections because Oracle uses asymmetric routing. If you want one IPSec connection as primary and another one as backup, configure more-specific routes for the primary connection and less-specific routes (or the default route of 0.0.0.0/0) on the backup connection.

For more information about this type of setup, see Example Layout with Multiple Geographic Areas.

FastConnect

The following topics have information about setting up Oracle Cloud Infrastructure FastConnect between your on-premises network and virtual cloud network (VCN):

- FastConnect Overview
- FastConnect Requirements
- FastConnect Redundancy Best Practices
- Routing Details for Connections to Your On-Premises Network
- FastConnect: With an Oracle Provider
- FastConnect: With a Third-Party Provider
- FastConnect: Colocation with Oracle
- FastConnect Metrics
- FastConnect Troubleshooting

FastConnect Overview

Oracle Cloud Infrastructure FastConnect provides an easy way to create a dedicated, private connection between your data center and Oracle Cloud Infrastructure. FastConnect provides higher-bandwidth options, and a more reliable and consistent networking experience compared to internet-based connections.

Uses for FastConnect

With FastConnect, you can choose to use *private peering*, *public peering*, or both.

- **Private peering:** To extend your existing infrastructure into a virtual cloud network (VCN) in Oracle Cloud Infrastructure (for example, to implement a hybrid cloud, or a lift and shift scenario). Communication across the connection is with IPv4 private addresses (typically RFC 1918).
- **Public peering:** To access public services in Oracle Cloud Infrastructure without using the internet. For example, Object Storage, the Oracle Cloud Infrastructure Console and APIs, or public load balancers in your VCN. Communication across the connection is with IPv4 public IP addresses. Without FastConnect, the traffic destined for public IP addresses would be routed over the internet. With FastConnect, that traffic goes over your private physical connection. For a list of the services available with public peering,

see FastConnect Supported Cloud Services. For a list of the public IP address ranges (routes) that Oracle advertises, see FastConnect Public Peering Advertised Routes.

In general it's assumed you'll use private peering, and you *might* also use public peering. Most of this documentation is relevant to both, with specific details called out for private versus public.

If you choose to have multiple paths from your on-premises network to Oracle, see Routing Details for Connections to Your On-Premises Network.

IPv6 addressing is currently supported only in the US Government Cloud. For more information, see IPv6 Addresses.

How and Where to Connect

With FastConnect, there are different connectivity models to choose from.

Oracle Provider

- List of Oracle Cloud Infrastructure FastConnect providers
- Port speeds in 1-Gbps and 10-Gbps increments
- Instructions for integrating: FastConnect: With an Oracle Provider

Third-Party Provider

- Port speed of 1 Gbps or 10 Gbps per cross-connect
- Instructions for integrating: FastConnect: With a Third-Party Provider

Colocation with Oracle in an Oracle Cloud Infrastructure FastConnect Location

- List of Oracle Cloud InfrastructureFastConnect locations (see the FAQ for specific addresses)
- Port speed of 1 Gbps or 10 Gbps per cross-connect
- Instructions for integrating: FastConnect: Colocation with Oracle

The following table summarizes several important requirements for each connectivity model.

Requirement	With Oracle Provider	With Third-Party Provider	Colocation with Oracle
Routing requirements	Yes	Yes	Yes
BGP support	Yes	Yes	Yes
Layer 3 support	Recommended	Recommended	Recommended
Obtain a Letter of Authority (LOA) from Oracle	N/A	Yes	Yes
Network connectivity	Yes	Yes	N/A
Cross-connect	Yes (from the provider)	Yes	Yes
Redundant network connectivity	Recommended	Recommended	Recommended
Cloud connectivity solution architecture support	Recommended	Recommended	Recommended
FastConnect SKU	Yes	Yes	Yes
Oracle Cloud Infrastructure Console user login (IAM policy unique setup)	Yes	Yes	Yes
Tenancy established (see "Setting Up Your Tenancy" in the *Oracle Cloud Infrastructure Getting Started Guide*)	Yes	Yes	Yes

Concepts

Here are some important concepts to understand (also see the following diagrams):

FastConnect

The general concept of a connection between your existing network and Oracle Cloud Infrastructure over a private physical network instead of the internet.

FastConnect location

A specific Oracle data center where you can connect to Oracle Cloud Infrastructure.

metro area

A geographical area (for example, Ashburn) with multiple FastConnect locations. All locations in a metro area connect to the same set of availability domains for resiliency in case of failure in a single location.

Oracle provider

A network service provider that has integrated with Oracle in a FastConnect location. See the list of the Oracle providers in How and Where to Connect. If your provider is in the list, see FastConnect: With an Oracle Provider.

third-party provider

A network service provider that is NOT on the list of Oracle providers in How and Where to Connect. If you have a third-party provider and want to use FastConnect, see FastConnect: With a Third-Party Provider.

colocation

The situation where your equipment is deployed into a FastConnect location. If your network service provider is not on the list of Oracle providers in How and Where to Connect, you must colocate.

cross-connect

In a colocation or third-party provider scenario, this is the physical cable connecting your existing network to Oracle in the FastConnect location.

CROSS-CONNECT GROUP

In a colocation or third-party provider scenario, this is a link aggregation group (LAG) that contains at least one cross-connect. You can add additional cross-connects to a cross-connect group as your bandwidth needs increase. This is applicable only for colocation.

VIRTUAL CLOUD NETWORK (VCN)

Your virtual network in Oracle Cloud Infrastructure. You can use a VCN to extend your infrastructure into the cloud. For more information, see VCNs and Subnets.

DYNAMIC ROUTING GATEWAY (DRG)

A virtual edge router attached to your VCN. Necessary for private peering. The DRG is a single point of entry for private traffic coming in to your VCN, whether it's over FastConnect or an IPSec VPN. After creating the DRG, you must attach it to your VCN and add a route for the DRG in the VCN's route table to enable traffic flow. Instructions for everything are included in the sections that follow.

VIRTUAL CIRCUIT

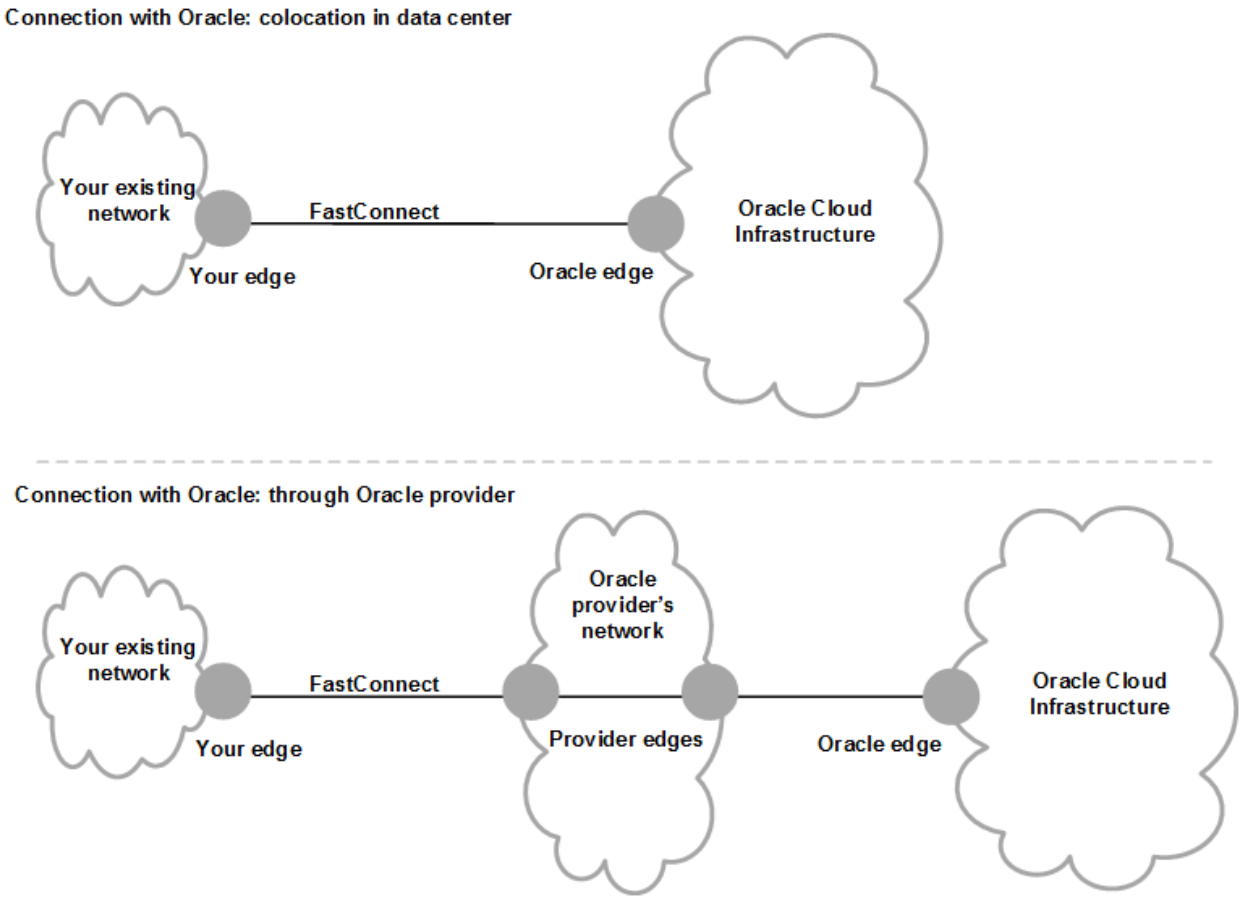
An isolated network path that runs over one or more physical network connections to provide a single, logical connection between the edge of your existing network and Oracle Cloud Infrastructure. *Private virtual circuits* support private peering, and *public virtual circuits* support public peering (see Uses for FastConnect). Each virtual circuit is made up of information shared between you and Oracle, as well as a provider (if you're connecting through an Oracle provider). You could have multiple private virtual circuits, for example, to isolate traffic from different parts of your organization (one virtual circuit for 10.0.1.0/24; another for 172.16.0.0/16), or to provide redundancy.

Basic Network Diagrams

The diagrams in this section introduce the basic logical and physical connections involved in FastConnect. Details specific to private versus public peering are called out.

General Concept of FastConnect

The following diagram illustrates the two ways to connect to Oracle with FastConnect: either through colocation with Oracle in the FastConnect location, or through an Oracle provider. In both cases, the connection goes between the edge of your existing network and Oracle.

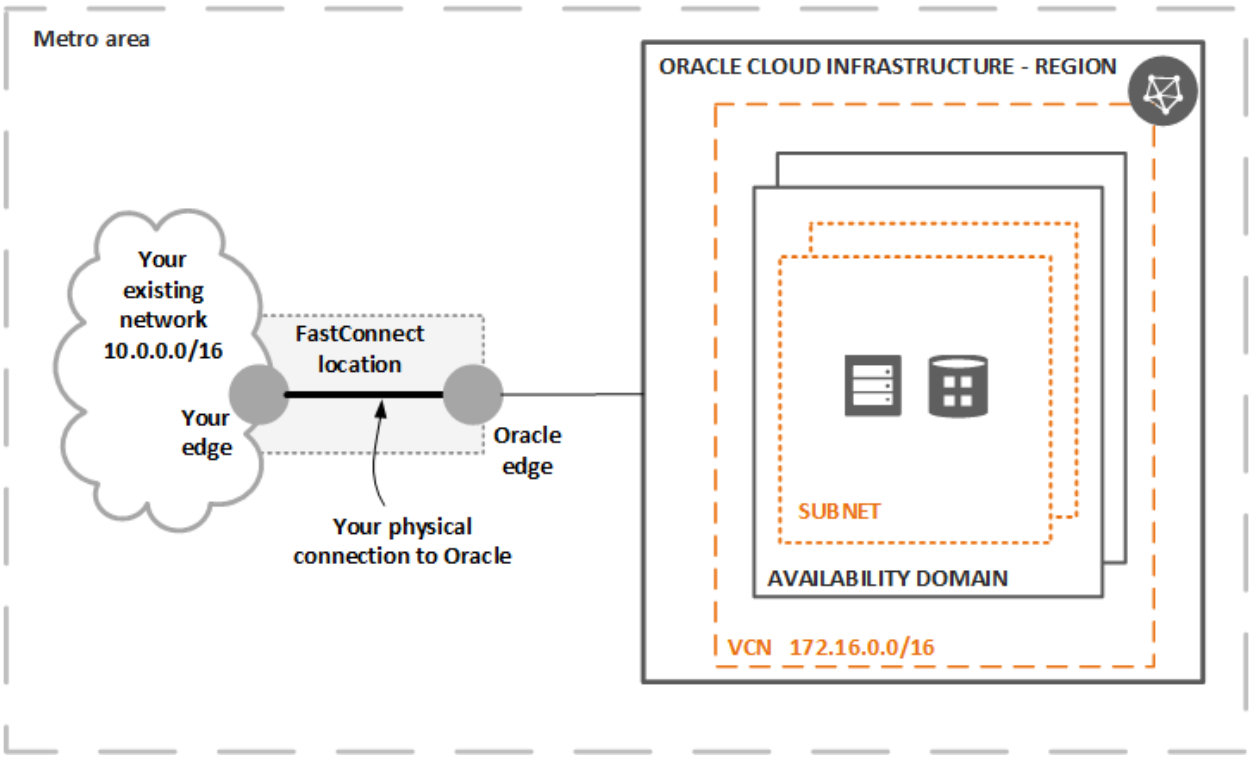


Physical Connection

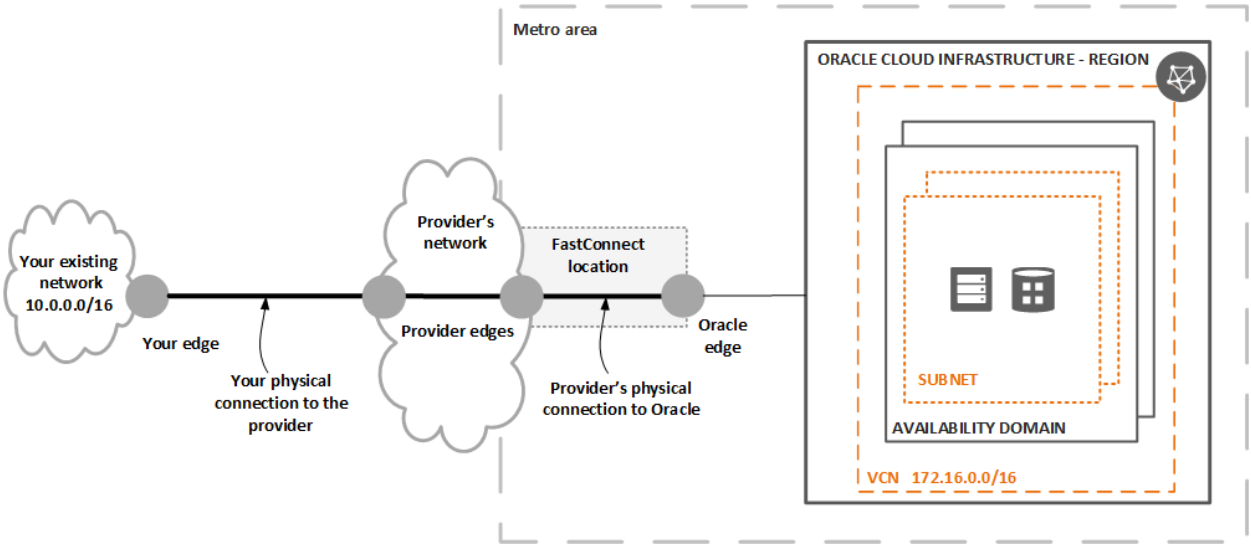
The next two diagrams give more detail about the physical connections. They also show the metro area that contains the FastConnect location, and a VCN within an Oracle Cloud

Infrastructure region.

The first diagram shows the colocation scenario, with your physical connection to Oracle within the FastConnect location.



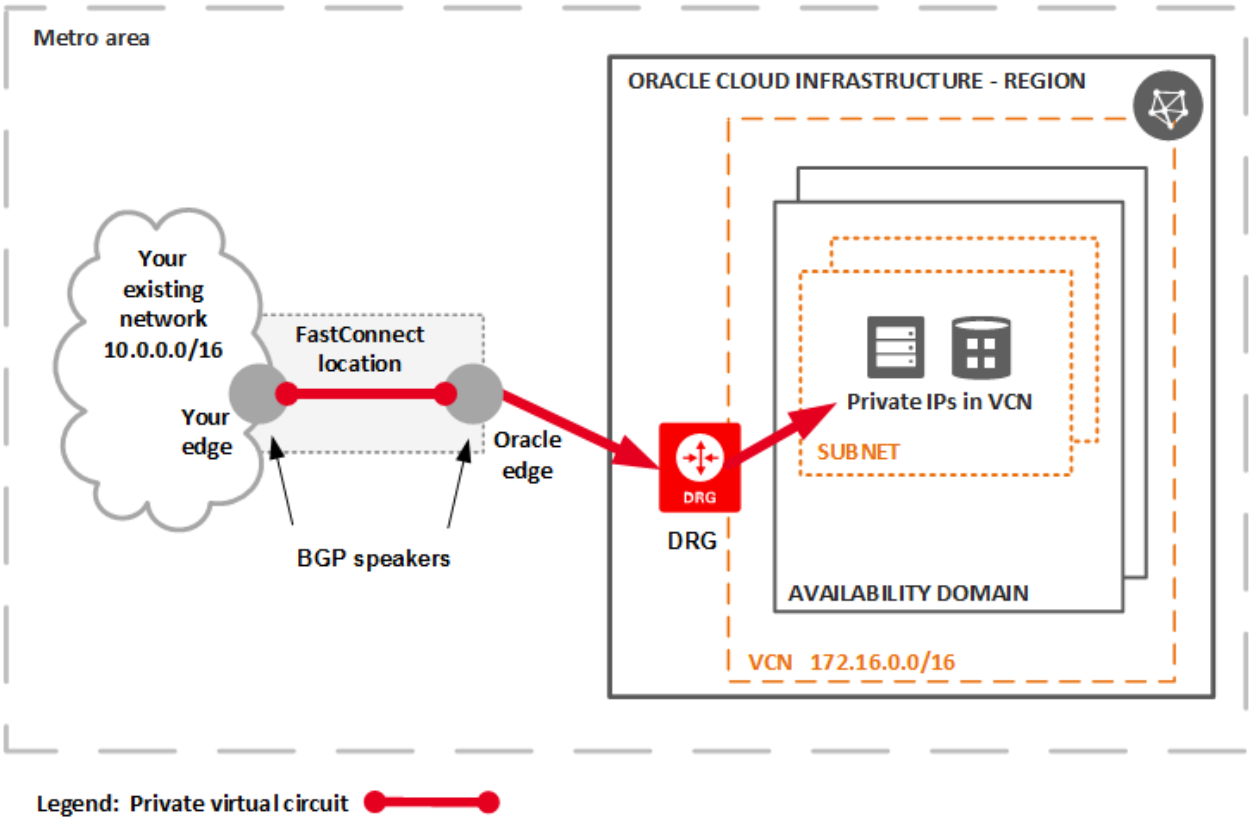
The next diagram shows a scenario with either an Oracle provider or third-party provider. It shows your physical connection to the provider, and the provider's physical connection to Oracle within the FastConnect location.



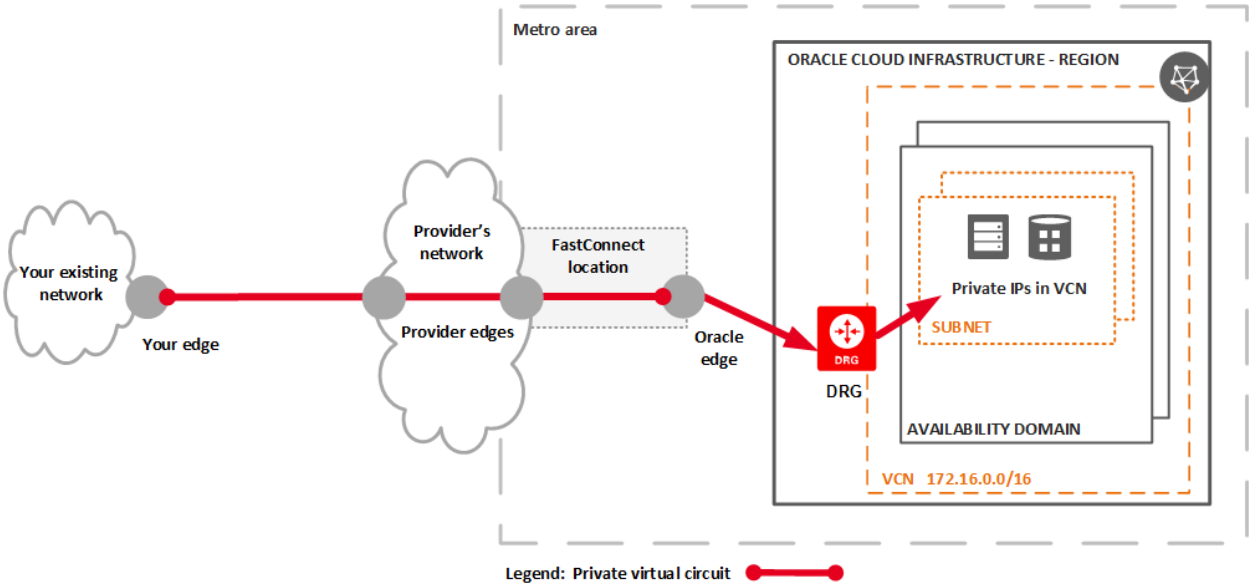
Logical Connection: Private Virtual Circuit

The next two diagrams show a private virtual circuit, which is a single, logical connection between your edge and Oracle Cloud Infrastructure by way of your DRG. Traffic is destined for private IP addresses in your VCN.

The first diagram shows the colocation scenario.



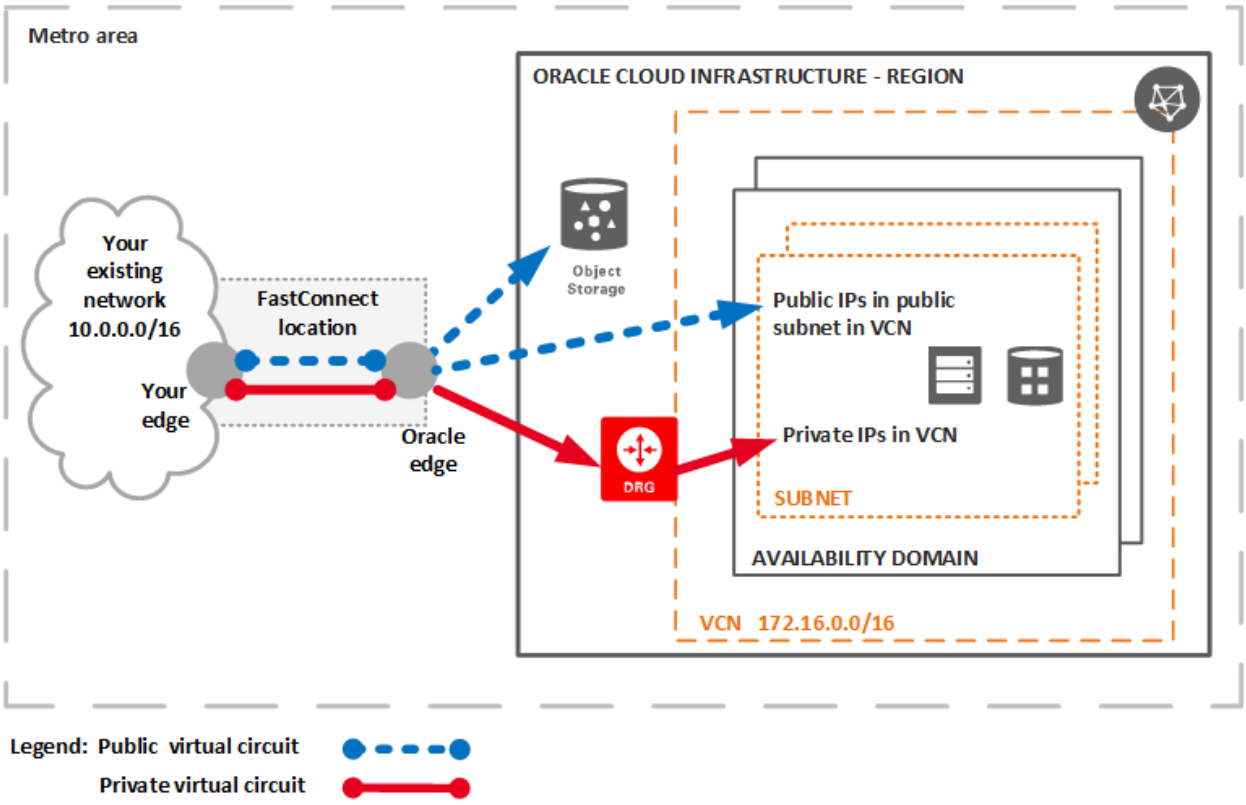
The next diagram shows the scenario with either an Oracle provider or third-party provider.



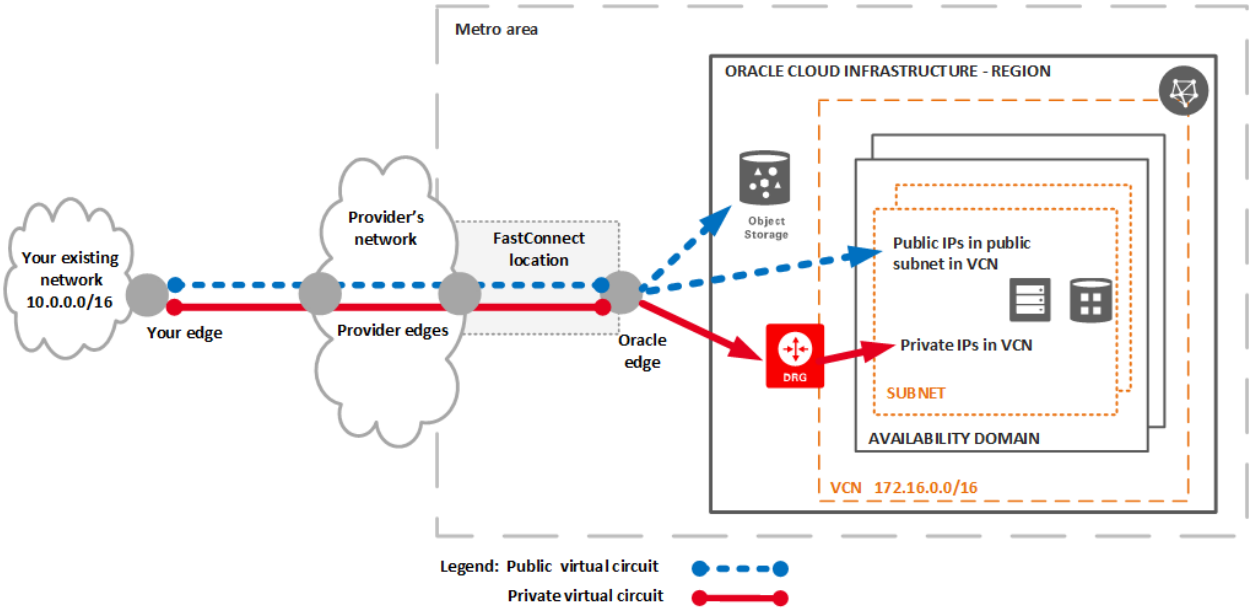
Logical Connection: Public Virtual Circuit

A public virtual circuit gives your existing network access to Oracle services in Oracle Cloud Infrastructure. For example, Object Storage, the Oracle Cloud Infrastructure Console and APIs, and public load balancers in your VCN. All communication across a public virtual circuit uses public IP addresses. For a list of services available with FastConnect public peering, see FastConnect Supported Cloud Services. For a list of the public IP address ranges (routes) that Oracle advertises, see FastConnect Public Peering Advertised Routes.

The first diagram shows the colocation scenario with both a private virtual circuit and a public virtual circuit. Notice that the DRG is not involved with the public virtual circuit, only the private virtual circuit.



The next diagram shows the scenario with either an Oracle provider or third-party provider.



Here are a few basics to know about public virtual circuits:

- You choose which of your organization's public IP prefixes you want to use with the virtual circuit. Each prefix must be /31 or less specific. Oracle verifies your organization's ownership of each prefix before sending any traffic for it across the connection. Oracle's verification for a given prefix can take up to three business days. You can get the status of the verification of each prefix in the Oracle Console or API. **Oracle begins advertising the Oracle Cloud Infrastructure public IP addresses across the connection only after successfully verifying at least one of your public prefixes.**
- You must configure your firewall rules to allow the desired traffic coming from the Oracle public IP addresses.
- Your existing network can receive advertisements for Oracle's public IP addresses through multiple paths (for example: FastConnect and your internet service provider).

Make sure to give higher preference to FastConnect over your ISP. You must configure your edge appropriately so that traffic uses your desired path and you receive the benefits of FastConnect. This is particularly important if you decide to *also* set up your existing network with private access to Oracle services. For important information about path preferences, see Routing Details for Connections to Your On-Premises Network.

- You can add or remove public IP prefixes at any time by editing the virtual circuit. If you add a new prefix, Oracle first verifies your company's ownership before advertising it across the connection. If you remove a prefix, Oracle stops advertising the prefix within a few minutes of your editing the virtual circuit.

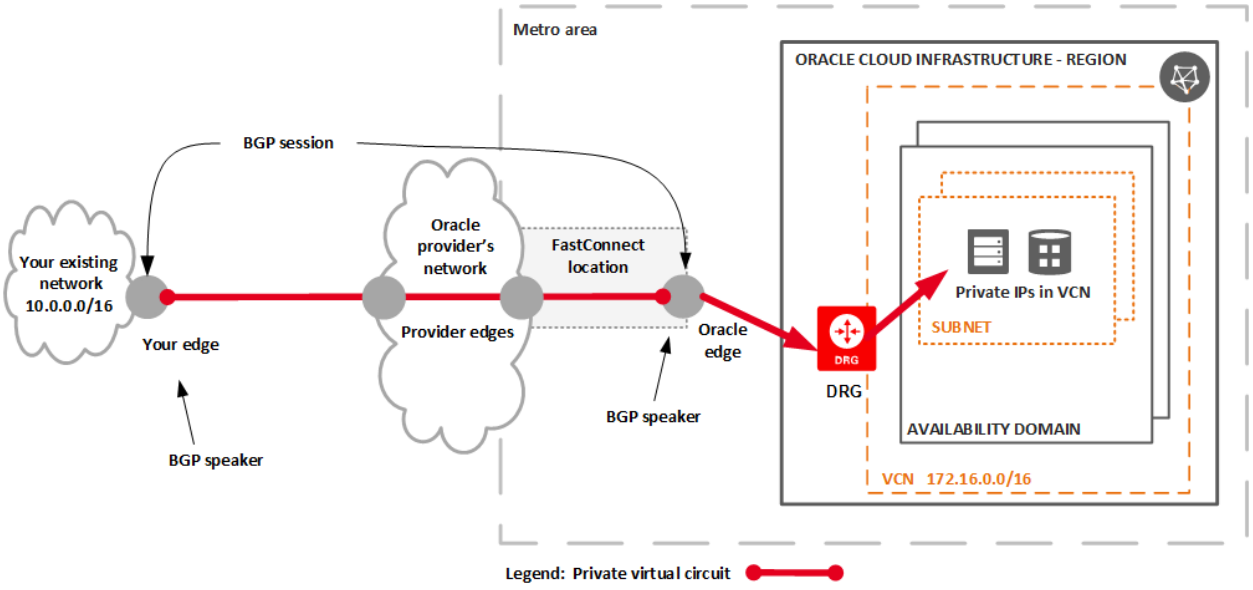
Oracle Provider Scenario: BGP Session to Either Oracle or the Oracle Provider

This section is applicable if you're using FastConnect through an Oracle provider. A Border Gateway Protocol (BGP) session is established from your edge, but where it goes to depends on which Oracle provider you use.

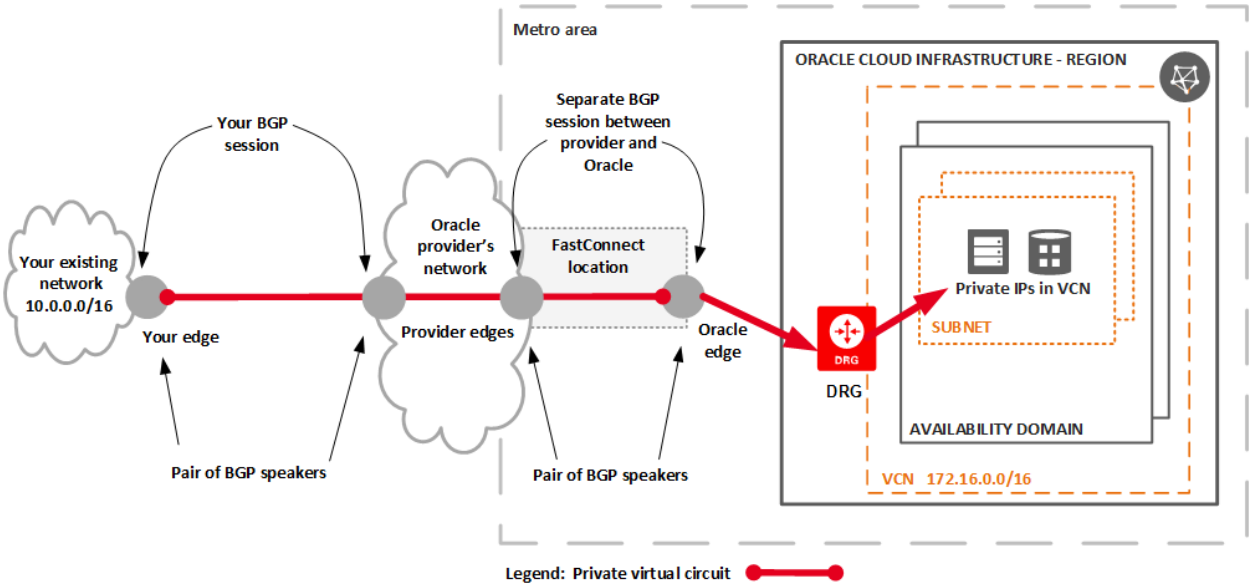
Tip

For simplicity, the following diagrams show only a private virtual circuit. However, the location of the BGP session is the same for a public virtual circuit.

To Oracle: With some of the Oracle providers, the BGP session goes from your edge to Oracle, as shown in the following diagram. When setting up the virtual circuit with Oracle, you are asked to provide basic BGP peering information (see General Requirements).



To the Oracle provider: With other Oracle providers, your BGP session goes from your edge to the provider's, as shown in the following diagram. When setting up the virtual circuit with Oracle, you are NOT asked for any BGP session information. Instead, you share BGP information with your Oracle provider. Notice that there's a separate BGP session that the provider establishes with Oracle.



FastConnect with Access to Multiple VCNs

You can use a single FastConnect to access multiple VCNs. There are different network scenarios available depending on your needs and which FastConnect connectivity model you use. For more information, see these topics:

- Transit Routing: Access to Multiple VCNs in the Same Region: This scenario can be used with either FastConnect or VPN Connect. It involves a single DRG, and multiple VCNs in a hub-and-spoke layout.

- FastConnect with Multiple DRGs and VCNs: This scenario can be used only with FastConnect, and only if you're using a third-party provider or colocated with Oracle. It involves multiple DRGs and private virtual circuits.

What's Next?

See these topics to get started:

- FastConnect Requirements
- FastConnect Redundancy Best Practices
- Routing Details for Connections to Your On-Premises Network
- FastConnect: With an Oracle Provider
- FastConnect: With a Third-Party Provider
- FastConnect: Colocation with Oracle

FastConnect Requirements

This topic covers the requirements for implementing FastConnect.

For general information about FastConnect, see FastConnect.

Before Getting Started: Learn and Plan

Here are basic things you need to do before getting started with FastConnect:

- **FastConnect concepts:** Make sure you're familiar with the basic concepts covered in FastConnect.
- **Limits increase:** If you are colocated with Oracle, you must ask Oracle to increase your account limits for cross-connects. By default, these limits are initially set to 0, and a request to create a cross-connect will fail. For instructions, see Requesting a Service Limit Increase. In your request, make sure to indicate the region where you need the resources. It can take a couple of business days for the limit increase to take effect.
- **Hardware or routing requirements:** Review the requirements.

- **Tenancy setup and compartment design:** If you haven't yet, set up your tenancy. Think about who needs access to Oracle Cloud Infrastructure and how. For more information, see "Setting Up Your Tenancy" in the *Oracle Cloud Infrastructure Getting Started Guide*. Specifically for FastConnect, see Required IAM Policy to understand the policy required to work with FastConnect components.
- **Cloud network design:** Design your virtual cloud network (VCN), including how you want to allocate your VCN's subnets, define security list rules, define route rules, set up load balancers, and so on. For more information, see Overview of Networking.
- **Redundancy:** Think through your overall redundancy model to ensure your network can handle planned maintenance by Oracle or your organization, and unexpected failures of the various components. For best practices, see FastConnect Redundancy Best Practices.
- **Public IP prefixes:** If you plan to set up a public virtual circuit, get the list of the public IP prefixes that you want to use with the connection. Oracle must validate your organization's ownership of each of the prefixes before advertising each one over the connection.
- **Cloud network setup:** Set up your VCN, subnets, DRG, security lists, IAM policies, and so on, according to your design.

General Requirements

Before getting started with FastConnect, make sure you meet the following requirements:

- Oracle Cloud Infrastructure account, with at least one user with appropriate Oracle Cloud Infrastructure Identity and Access Management (IAM) permissions (for example, a user in the Administrators group).
- Network equipment that supports Layer 3 routing using BGP.
- For colocation with Oracle: Ability to connect using single mode fiber in your selected FastConnect location. Also see Hardware and Routing Requirements.
- For connection to an Oracle provider: At least one physical network connection with the provider. Also see Hardware and Routing Requirements.

- For connection to a third-party provider: At least one physical connection with the provider. Also see Hardware and Routing Requirements.
- For private peering only: At least one existing DRG set up for your VCN.
- For public peering only: The list of public IP address prefixes that you want to use with the connection. Oracle will validate your ownership of each prefix.

Important

If you're colocating with Oracle, you must ask Oracle to increase your account limits for cross-connects. By default, these limits are initially set to 0, and a request to create one of these resources will fail. For instructions, see Requesting a Service Limit Increase. In your request, make sure to **indicate the region where you need the resources**. It can take a couple of business days for the limit increase to take effect.

Hardware and Routing Requirements

If you're using an Oracle provider

Here are general routing requirements for FastConnect. These are particularly relevant if your BGP session is between your edge and Oracle.

- **IP addressing supported:** IPv4. IPv6 addressing is currently supported only in the US Government Cloud. For more information, see IPv6 Addresses.
- **P2P IP addresses:**
  - For public virtual circuits, Oracle specifies the IP addresses.
  - For private virtual circuits where your BGP session is between your edge and Oracle, you specify these addresses (/30 or /31, and one pair per virtual circuit).

If you set up multiple private virtual circuits that go to the same DRG, you must use a different address on your edge router for each virtual circuit.

- **Maximum IP MTU:** 9000
- **Routing protocol:** BGPv4
- **BGP prefix limit:** For public virtual circuits: 200 prefixes. For private virtual circuits: 2000 prefixes.
- **BGP ASN:** 2-byte or 4-byte ASNs are supported, except for those listed in Special-Purpose Autonomous System (AS) Numbers. Public virtual circuits require a public ASN. Oracle's BGP ASN for the commercial cloud is 31898. For the Government Cloud, see Oracle's BGP ASN.
- **BGP MD5 authentication:** Optional to use with your virtual circuit. Oracle supports up to 128-bit MD5 authentication
- **BGP keep-alive interval:** 60s
- **BGP hold-time interval:** 180s

Tip

By default, Oracle uses the default BGP timers of 60 seconds for keep-alive and 180 seconds for hold-time. If you need fast BGP convergence, you can use any value in these supported ranges: 6-60 seconds for keep-alive, and 18-180 seconds for hold-time.

If you're colocating in an FastConnect location or using a third-party provider

For the cross-connect group and cross-connects:

- **Bandwidth (two choices)**:
  - 1 Gbps:
    - 1000Base-LX, 10 km range, 1310 nm optics
    - **You must configure your edge device so that auto-negotiation is OFF**
  - 10 Gbps:
    - 10 GbE, LR (10 km range), 1310 nm optics
- **General:**
  - Single Mode Fiber
  - Duplex LC connectors
  - Minimum Rx level > 12 dBm
- **Redundancy:**
  - Device redundancy highly recommended
  - In some regions, location redundancy is available and recommended
- **Capacity:**
  - Minimum: 1 x 1 GbE or 1 x 10 GbE
  - Maximum: 8 x 1 GbE or 8 x 10 GbE
- **LAG protocol:** LACP with short timers (3 @ 1s). If your router doesn't support LAG, you can set up a single non-LAG cross-connect.
- **VLAN tagging:** 802.1q (single tag)
- **VLAN range:** 100-4094 (you assign the VLANs)
- **Maximum interface MTU:** 9196 (include 4-byte FCS trailer)

For routing:

- **IP addressing supported:** IPv4. IPv6 addressing is currently supported only in the US Government Cloud. For more information, see IPv6 Addresses.
- **P2P IP addresses:**
  - For public virtual circuits, Oracle specifies the IP addresses.
  - For private virtual circuits, you specify the addresses (a /30 or /31). You need one pair of IP addresses per private virtual circuit. If you set up multiple private virtual circuits that go to the same DRG, you must use a different address on your edge router for each virtual circuit.
- **Maximum IP MTU:** 9000
- **Routing protocol:** BGPv4
- **BGP prefix limit:** For public virtual circuits: 200 prefixes. For private virtual circuits: 2000 prefixes.
- **BGP ASN:** 2-byte or 4-byte ASNs are supported, except for those listed in Special-Purpose Autonomous System (AS) Numbers. Public virtual circuits require a public ASN. Oracle's BGP ASN is 31898. For the Government Cloud, see Oracle's BGP ASN.
- **BGP MD5 authentication:** Optional to use with your virtual circuit. Oracle supports up to 128-bit MD5 authentication
- **BGP keep-alive interval:** 60s
- **BGP hold-time interval:** 180s

Tip

By default, Oracle uses the default BGP timers of 60 seconds for keep-alive and 180 seconds for hold-time. If you need fast BGP convergence, you can use any value in these supported ranges: 6-60 seconds for keep-alive, and 18-180 seconds for hold-time.

Required IAM Policy

If you're using an Oracle provider

To work with Networking resources such as dynamic routing gateways (DRGs), VCNs, and virtual circuits, you need to have a user login to the Console, and your user needs sufficient authority (by way of an IAM policy) to perform all the instructions below. If your user is in the Administrators group, you have the required authority.

If your user is not, then a policy like this would generally cover all the Networking resources:

```
Allow group NetworkAdmins to manage virtual-network-family in tenancy
```

To *only* create and manage a virtual circuit, you would need a policy like this:

```
Allow group VirtualCircuitAdmins to manage drgs in tenancy

Allow group VirtualCircuitAdmins to manage virtual-circuits in tenancy
```

The first statement (to manage DRGs) is necessary only for private virtual circuits.

For more information, see Getting Started with Policies and Common Policies.

If you're colocating in a FastConnect location or using a third-party provider

To work with Networking resources such as dynamic routing gateways (DRGs), VCNs, virtual circuits, and cross-connects, you need to have a user login to the Console, and your user needs sufficient authority (by way of an IAM policy) to perform all the instructions that follow. If your user is in the Administrators group, you have the required authority.

If your user is not, then a policy like this would generally cover all the Networking resources:

```
Allow group NetworkAdmins to manage virtual-network-family in tenancy
```

To *only* create and manage cross-connects, cross-connect groups, and virtual circuits, you would need a policy like this:

```
Allow group FastConnectAdmins to manage drgs in tenancy

Allow group FastConnectAdmins to manage cross-connects in tenancy

Allow group FastConnectAdmins to manage cross-connect-groups in tenancy

Allow group FastConnectAdmins to manage virtual-circuits in tenancy
```

The first statement (to manage DRGs) is necessary only for private virtual circuits.

For more information, see Getting Started with Policies and Common Policies.

Identifiers for Your FastConnect Resources

There are several identifiers for your resources:

- **Name for the overall connection:** When you create a new FastConnect connection, you can give it a descriptive name of your choice. If you don't specify one, Oracle automatically assigns a name to the connection.
- **Reference name for each cross-connect:** Each cross-connect has an optional reference name. If you set up a cross-connect, Oracle recommends that you fill in the reference name with the identifier for the cross-connect's physical fiber cable. That makes it easier for Oracle to help if future troubleshooting is required for the connection. After cabling is done and you have the identifier from the data center, you can add it to the cross-connect's information in the Oracle Console.
- **OCID for each resource:** Each cross-connect group, cross-connect, and virtual circuit has its own unique Oracle-assigned identifier called an OCID.

What's Next?

Choose the topic that suits your situation:

- FastConnect: With an Oracle Provider
- FastConnect: With a Third-Party Provider
- FastConnect: Colocation with Oracle

FastConnect Redundancy Best Practices

This topic covers best practices for redundancy when implementing FastConnect.

For general information about FastConnect, see FastConnect.

Overview

In general, you should design your network to achieve high availability (HA). In addition, you should be prepared for these types of disruptions:

- Regularly scheduled maintenance by your organization, your provider (if you're using one), or Oracle.
- Unexpected failures on the part of your networking components, your provider, or Oracle. Failures are rare, but you should plan for them.

For redundancy, Oracle provides:

- Multiple providers for each region
- Two FastConnect locations for each of the following regions (all other regions have a single FastConnect location)
    - Germany Central (Frankfurt)
    - UK South (London)
    - US East (Ashburn)
    - US West (Phoenix)

- Two routers in each FastConnect location
- Multiple physical connections between each Oracle provider and Oracle (for a given region)

The redundancy best practices depend on which connectivity model you use. Also see How and Where to Connect.

If You Use an Oracle Provider

Connectivity model:

- FastConnect: With an Oracle Provider

Oracle handles redundancy of the physical connections between the provider and Oracle, and the redundancy of routers in the FastConnect locations. You should then handle redundancy of the physical connection between your existing network and the Oracle provider.

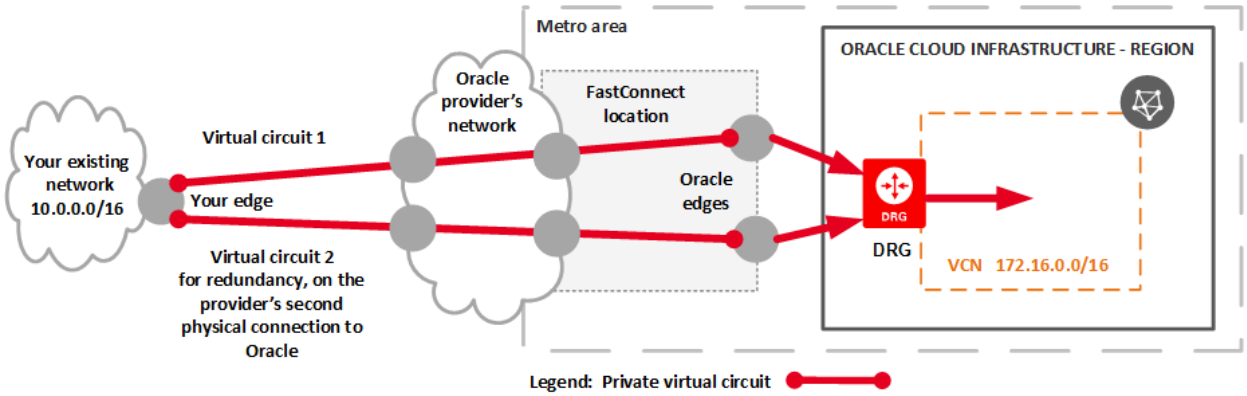
The remaining best practices depend on the provider you're using, and details of the BGP session from your edge:

- For some providers, the BGP session from your edge goes to Oracle. For redundancy best practices, see the next section.
- For other providers, the BGP session from your edge goes to the Oracle provider. For redundancy best practices, see Oracle Provider Scenario: Your BGP Session Is to the Oracle Provider.

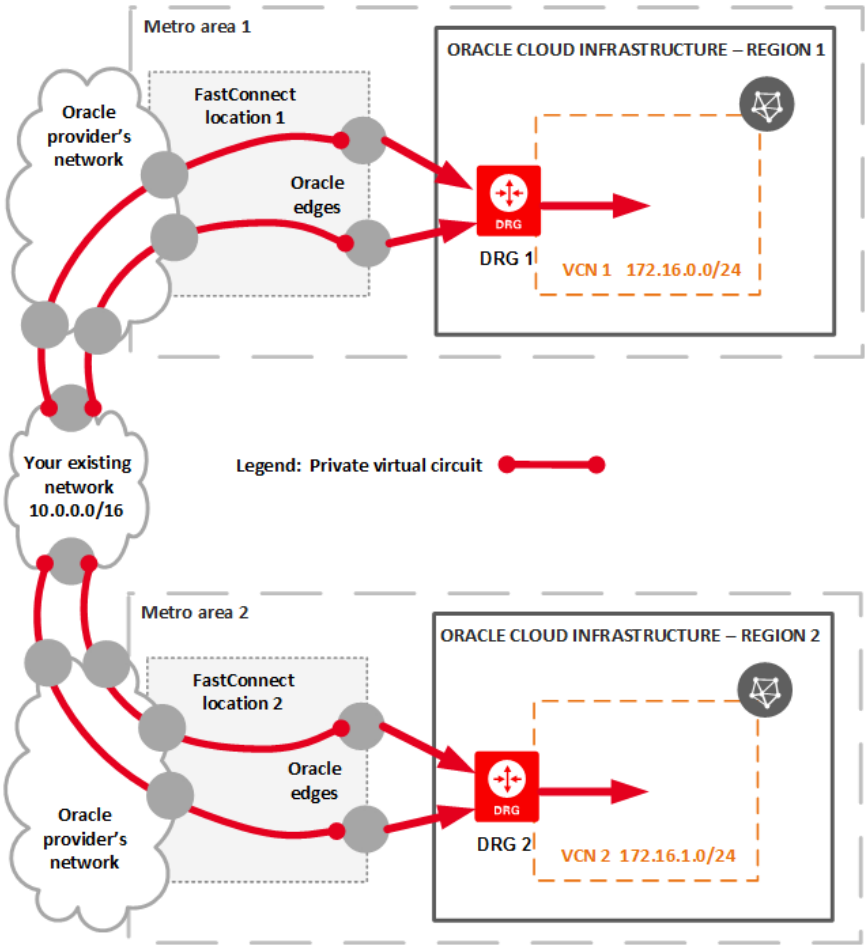
For information about the two scenarios, see Oracle Provider Scenario: BGP Session to Either Oracle or the Oracle Provider.

Oracle Provider Scenario: Your BGP Session Is to Oracle

At a minimum, each Oracle provider has two separate physical connections to Oracle. Set up one virtual circuit on one physical connection (as primary), and the other virtual circuit on another physical connection (as secondary). The following diagram illustrates two virtual circuits, each going to a different router in a single FastConnect location. If the region has a second location, your provider's second physical connection might instead go to that location.



If you're working in a region that has only a single FastConnect location, you might also want location diversity. To achieve that, repeat the preceding setup of two virtual circuits with the same Oracle provider, but in a second FastConnect location in a nearby region. Notice that you must have a duplicate setup of your Oracle cloud resources in that second region, as shown in the following diagram.

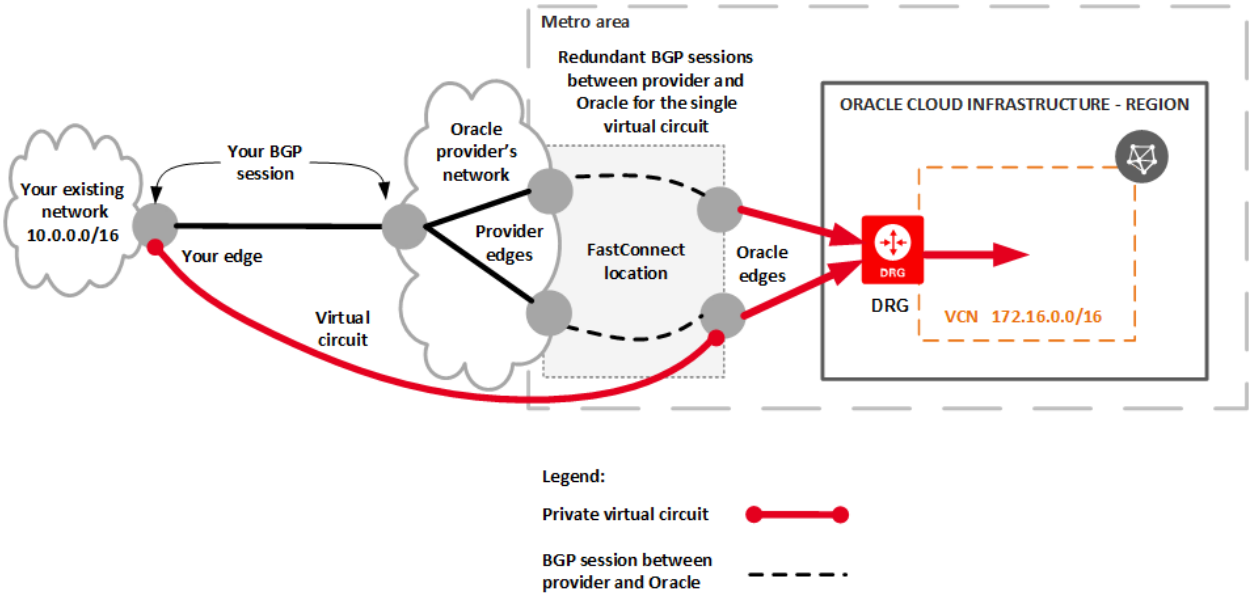


If you also want provider diversity, repeat your entire setup with another provider in each region that you're using.

Oracle Provider Scenario: Your BGP Session Is to the Oracle Provider

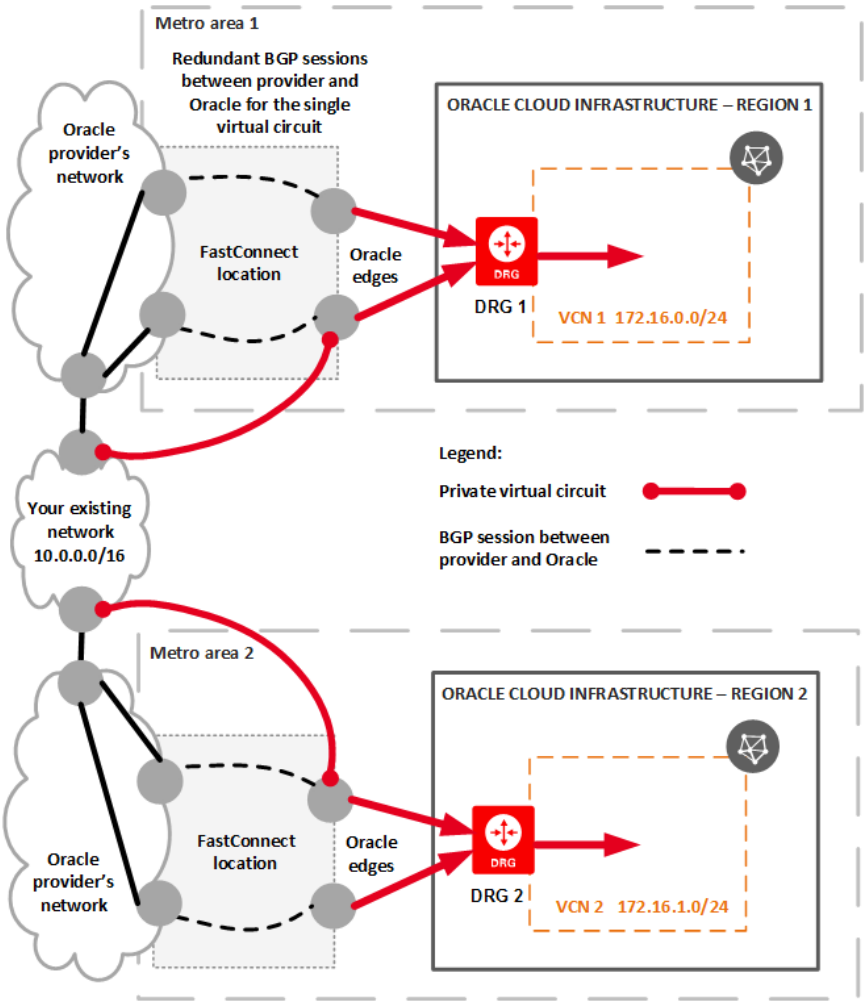
In this scenario, the BGP session *from your edge* goes to the Oracle provider (as shown in the following diagram). Separate from your BGP session, the Oracle provider has *its own* BGP sessions with Oracle (between the provider's edge and Oracle's edge). The virtual circuit is a logical connection that goes from your edge to the Oracle edge.

The provider has two separate physical connections to Oracle. You create one virtual circuit with the provider. In this scenario, the virtual circuit is automatically designed to be redundant and diverse. The virtual circuit has two separate BGP sessions between the provider and Oracle, each on a different physical connection. The following diagram shows the two separate BGP sessions for the single virtual circuit as dotted lines.



Separately, you must ensure that the connection between your edge and the provider is redundant and diverse.

If you're working in a region that has only a single FastConnect location, you might also want location diversity. To achieve that, repeat the preceding setup of a virtual circuit with the same Oracle provider, but in a second FastConnect location in a nearby region. Notice that you must also have a duplicate setup of your Oracle cloud resources in that second region, as shown in the following diagram.



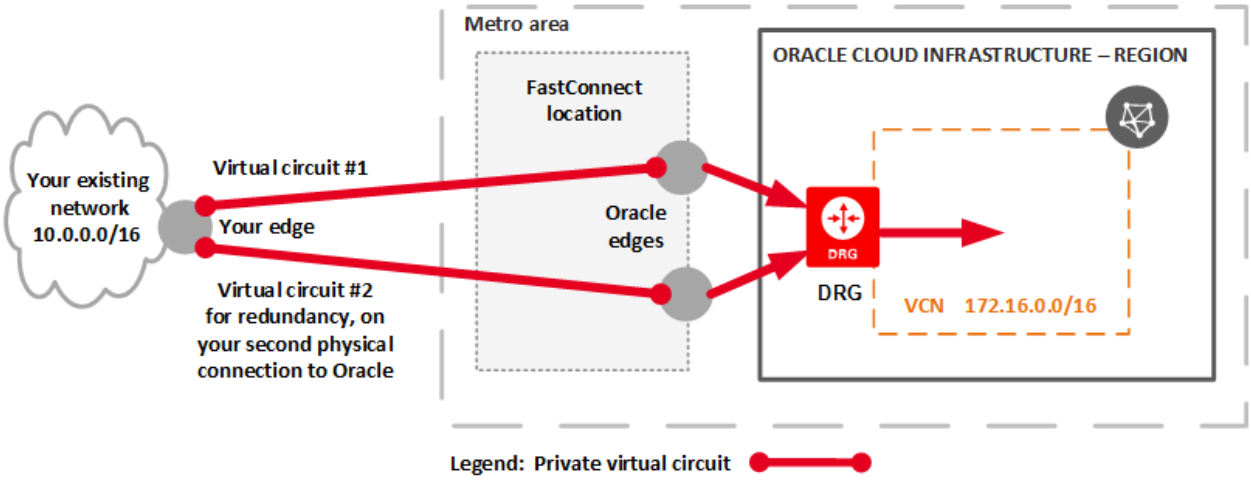
If You Use a Third-Party Provider or Colocate with Oracle

Connectivity models:

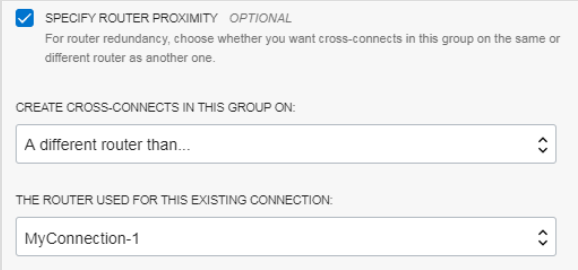
- FastConnect: With a Third-Party Provider
- FastConnect: Colocation with Oracle

Oracle handles redundancy of the Oracle routers in the FastConnect locations. You should then handle redundancy of the physical connection between your existing network and Oracle.

To do this, create two physical connections to Oracle, one for each FastConnect location that serves the region. This means that in the Oracle Console, you set up two separate FastConnect connections. You then create two virtual circuits. Set up the first one on the first physical connection (the first FastConnect connection), and the second one on the second physical connection. The following diagram shows the general setup.

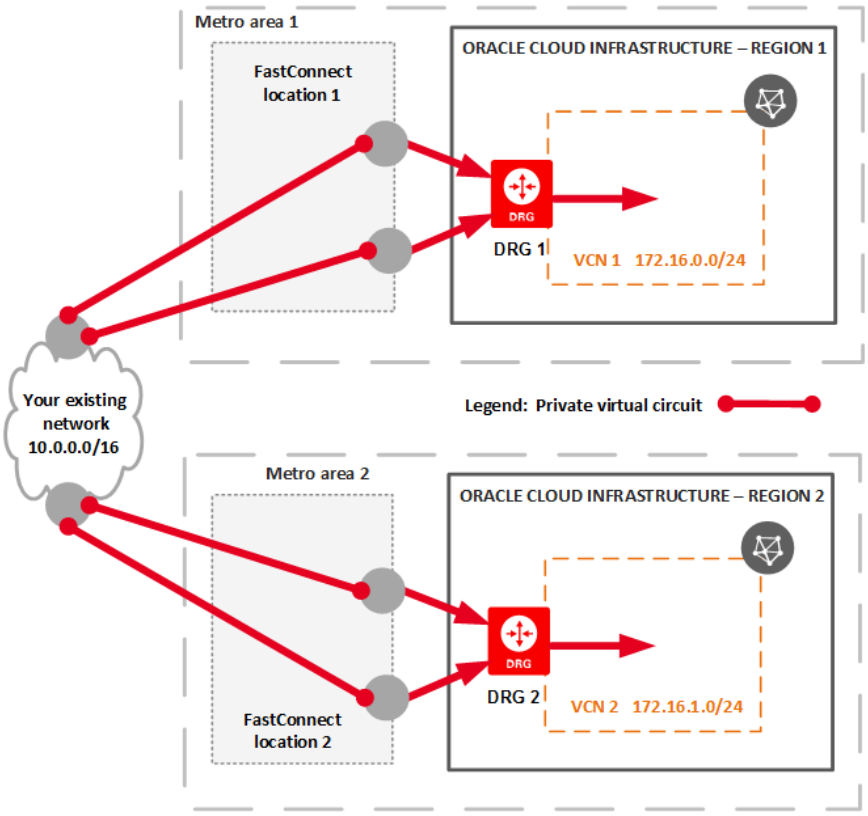


You might prefer to connect to only a single FastConnect location because of cost concerns, or if the region has only a single FastConnect location. In that case, create two physical connections and ensure each goes to a different Oracle router in that FastConnect location. You can do this in the Oracle Console when you set up the second physical connection. You can specify the proximity of that connection to other FastConnect connections in that location. For example, the following image shows how to request that your second physical connection (which is a cross-connect group) is created on a different router than your first connection in that FastConnect location (called MyConnection-1).



You must scale the bandwidth of both physical connections evenly, and by using a cross-connect group (LAG) for each connection. Imagine that you have two individual 10-Gbps cross-connects in a single FastConnect location (each to a different Oracle router for redundancy and diversity). If you need to have 20-Gpbs bandwidth *at a given time*, you must ensure that each of your physical connections consists of a cross-connect group (LAG) to contain the cross-connect. Then you need to add another 10-Gbps cross-connect to each LAG, so that *each* redundant physical connection has two 10-Gbps cross-connects. FastConnect currently does not support equal-cost multi-path routing (ECMP).

If you're working in a region that has only a single FastConnect location, you might also want location diversity. To achieve that, repeat your setup in a second FastConnect location in a nearby region. Notice that you must also have a duplicate setup of your Oracle cloud resources in that second region, as shown in the following diagram.



VPN Connect as Backup for FastConnect

Oracle recommends using VPN Connect as a backup for your FastConnect connection. If you do, ensure that the VPN Connect tunnels are configured to use BGP routing. Within your existing network, manipulate the routing to prefer routes learned through FastConnect over routes learned through VPN Connect. For example, use AS_Path Prepend to influence egress traffic from Oracle, and use local preference to influence egress traffic from your network.

The following diagram shows a setup with redundant FastConnect virtual circuits and redundant VPN Connect tunnels.

What's Next?

Choose the topic that suits your situation:

- FastConnect: With an Oracle Provider
- FastConnect: With a Third-Party Provider
- FastConnect: Colocation with Oracle

FastConnect: With an Oracle Provider

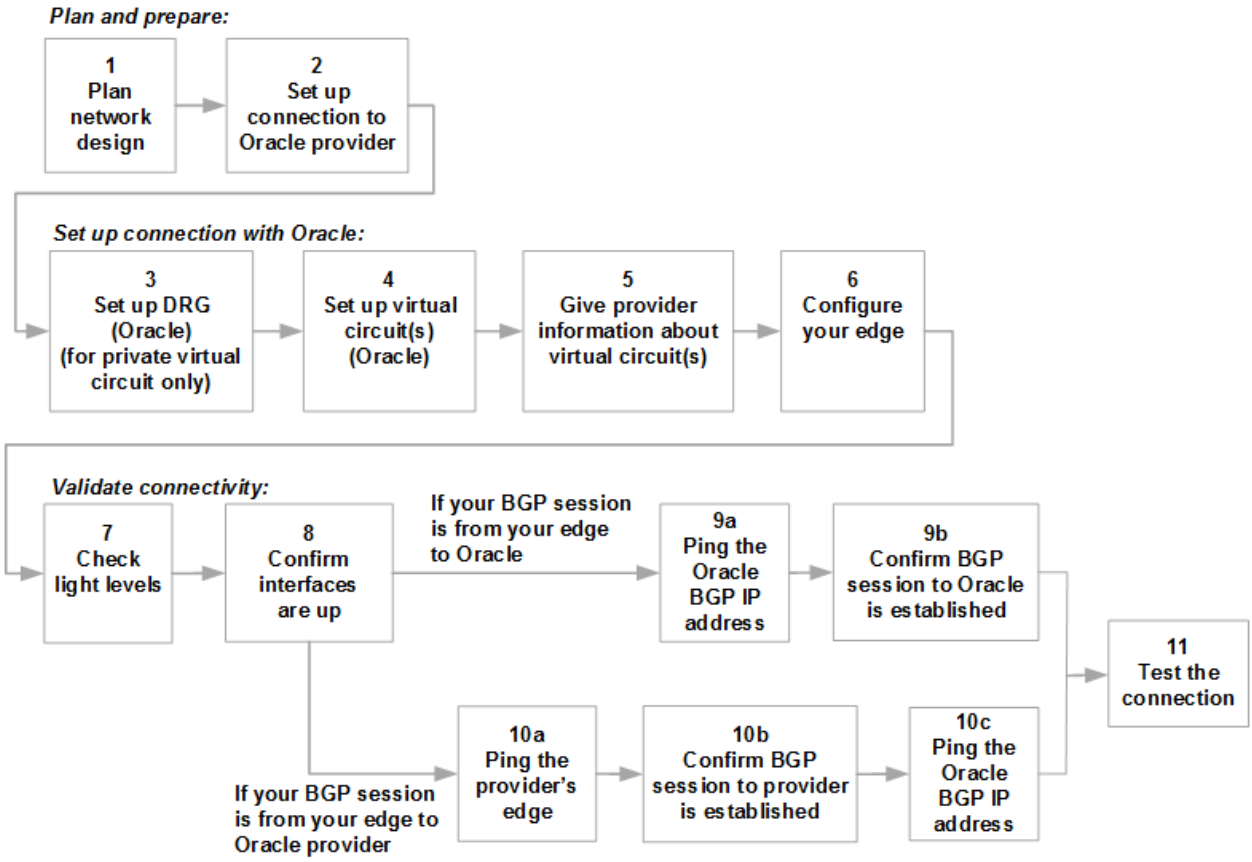
This topic is for customers who want to use Oracle Cloud Infrastructure FastConnect by connecting to an Oracle provider. For a summary of the different ways to connect, see the connectivity models.

If you instead want to use a network provider that is not on the list of Oracle providers, see FastConnect: With a Third-Party Provider. Or if you want to use FastConnect by colocating with Oracle, see FastConnect: Colocation with Oracle.

For general information about FastConnect, see FastConnect.

Getting Started with FastConnect

The following flow chart shows the overall process of setting up FastConnect.



Also see the sequence diagram in To get the status of your virtual circuit.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Task 1: Learn and plan

If you haven't yet, walk through the planning in Before Getting Started: Learn and Plan. Also see FastConnect Redundancy Best Practices.

Task 2: Set up connection to the Oracle provider

If you haven't already, start the process of ordering the connection from the Oracle provider, setting it up, and then testing it with the provider. It can take some time, depending on the provider.

Task 3: Set up a DRG (private peering only)

Summary: If you plan to use a private virtual circuit (private peering), you need a DRG. If you haven't already, use the Oracle Cloud Infrastructure Console to set up a DRG, attach it to your VCN, and update routing in your VCN to include a route rule to send traffic to the DRG. It's easy to forget to update the route table. Without the route rule, no traffic will flow.

Instructions:

- To create a DRG
- To attach a DRG to a VCN
- To update rules in an existing route table

Task 4: Set up your virtual circuit

Summary: Create one or more virtual circuits for your connection in the Oracle Console. If your network design includes more than one virtual circuit, complete the following steps for each one.

Instructions:

Repeat the following steps for each virtual circuit you want to create.

1. In the Console, confirm you're viewing the compartment that you want to work in. If you're not sure which one, use the compartment that contains the DRG that you'll connect to (for a private virtual circuit). This choice of compartment, in conjunction with a corresponding IAM policy, controls who has access to the virtual circuit you're about to create.
2. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **FastConnect**.
   The resulting **FastConnect** page is where you'll create a new connection and later return to when you need to manage the connection.
3. Click **Create FastConnect**.
4. Select **Connect Through a Provider** and choose the provider from the list.
5. Click **Next**.
6. Enter the following for your virtual circuit:
   - **Name:** A friendly name that helps you keep track of your virtual circuits. The value does not need to be unique across your virtual circuits, and you can change it later. Avoid entering confidential information.
   - **Create in Compartment:** Leave as is (the compartment you're currently working in).
7. Choose the virtual circuit type (private or public). A private virtual circuit is for private peering (where your existing network receives routes for your VCN's private IP addresses). A public virtual circuit is for public peering (where your existing network

receives routes for the Oracle Cloud Infrastructure public IP addresses). Also see Uses for FastConnect.

- For a private virtual circuit, enter the following:
  - **Dynamic Routing Gateway:** Select the DRG to route the FastConnect traffic to.
  - **Provisioned Bandwidth:** Choose your desired value. If your bandwidth needs increase later, you can update the virtual circuit to use a different value (see To edit a virtual circuit).

  If your BGP session goes to Oracle (see Oracle Provider Scenario: BGP Session to Either Oracle or the Oracle Provider), the dialog box includes additional fields for the BGP session:
  - **Customer BGP IP Address:** The BGP peering IP address for your edge (your CPE), with either a /30 or /31 subnet mask.
  - **Oracle BGP IP Address:** The BGP peering IP address you want to use for the Oracle edge (the DRG), with either a /30 or /31 subnet mask.
  - **Enable IPv6 Address Assignment:** Available only in the Government Cloud. For more information, see FastConnect and IPv6.
  - **Customer BGP ASN:** The public or private ASN for your network.
  - **Use a BGP MD5 Authentication Key (optional):** Select this check box and provide a key if your system requires MD5 authentication. Oracle supports up to 128-bit MD5 authentication.
- For a public virtual circuit, enter the following:
  - **Provisioned Bandwidth:** Choose your desired value. If your bandwidth needs increase later, you can update the virtual circuit to use a different value (see To edit a virtual circuit).
  - **Public IP Prefixes:** The public IP prefixes that you want Oracle to receive over the connection (each one must be /31 or less specific). You can enter a comma-separated list of prefixes, or one per line.

- **Customer BGP ASN:** The public ASN for your network. Present only if your BGP session goes to Oracle (see Oracle Provider Scenario: BGP Session to Either Oracle or the Oracle Provider). Note that Oracle specifies the BGP IP addresses for a public virtual circuit.
- **Use a BGP MD5 Authentication Key (optional):** Select this check box and provide a key if your system requires MD5 authentication. Oracle supports up to 128-bit MD5 authentication.

8. Click **Create**.
   The virtual circuit is created. Its OCID and a link to the provider's portal are displayed in the resulting confirmation box at the top of the page. The OCID is also available with the other virtual circuit details.
9. Copy and paste the OCID to another location. You give it to your provider in the next task.

The virtual circuit is listed on the FastConnect page.

Until you complete the next task and the provider does their provisioning work, the virtual circuit's Lifecycle State is PENDING PROVIDER and the BGP state is DOWN. After the provider does their work, the Lifecycle State switches to PROVISIONED. When the BGP session is established and working, the BGP state changes to UP.

Tip

For a virtual circuit where your BGP session goes to the Oracle provider, the BGP state for the virtual circuit reflects the status of the *separate BGP session between the Oracle provider and Oracle*. For reference, see Oracle Provider Scenario: BGP Session to Either Oracle or the Oracle Provider.

Also see the diagram in To get the status of your virtual circuit.

Task 5: Give the provider information about the virtual circuit

Contact the provider and give the OCID of each virtual circuit that you created, along with any other information the provider requests. Depending on the provider, you might do this in the provider's portal, or over the phone. The provider then configures each virtual circuit on their end to complete the connectivity.

If your provider is AT&T: After AT&T gives you the service key for your virtual circuit, create a ticket at My Oracle Support to request provisioning, and give Oracle the service key.

Task 6: Configure your edge

If your BGP session goes to Oracle: (see Oracle Provider Scenario: BGP Session to Either Oracle or the Oracle Provider), configure your edge (your CPE) to use the BGP peering information (see General Requirements). Oracle's BGP ASN for the commercial cloud is 31898. For the Government Cloud, see Oracle's BGP ASN. By default, Oracle uses the default BGP timers of 60 seconds for keep-alive and 180 seconds for hold-time. If you need fast BGP convergence, you can use any value in these supported ranges: 6-60 seconds for keep-alive, and 18-180 seconds for hold-time. Also configure the router for redundancy according to the network design you decided on earlier (see FastConnect Redundancy Best Practices). After you successfully configure the BGP session, the virtual circuit's BGP session state changes to UP.

If your BGP session instead goes to the Oracle provider: You still need to configure your router if you haven't already. You may need to contact your provider to get the required BGP peering information. This BGP session must be up and running for FastConnect to work. Also configure your edge router for redundancy according to the network design you decided on earlier (see FastConnect Redundancy Best Practices).

Important

For a public virtual circuit: Your existing network can receive advertisements for Oracle's public IP addresses through multiple paths (for example: FastConnect and your internet service provider). Make sure to give higher preference to FastConnect over your ISP. You must configure your edge appropriately so that traffic uses your desired path and you receive the benefits of FastConnect. This is particularly important if you decide to *also* set up your existing network with private access to Oracle services. For important information about path preferences, see Routing Details for Connections to Your On-Premises Network.

Task 7: Check light levels

Confirm the light levels are good for each of your physical network connections to the provider. Don't proceed until they are.

Task 8: Confirm your interfaces are up

Confirm your side of the interfaces for the connections to the provider are up. Don't proceed until they are.

BGP Session Goes to Oracle

Task 9a: Ping the Oracle BGP IP address

For each virtual circuit, ping the Oracle BGP IP address assigned to the virtual circuit. Check

the error counters and look for any dropped packets. Don't proceed until you can successfully ping this IP address without errors.

Task 9b: Confirm the BGP session is established

For each virtual circuit, confirm the BGP session is in an established state. When it is, the connection is ready to test (see Task 11: Test the connection).

BGP Session Goes to the Provider

Task 10a: Ping the provider's edge

For each virtual circuit, ping the provider's edge. Check the error counters and look for any dropped packets. Don't proceed until you can successfully ping the provider's edge without errors.

Task 10b: Confirm the BGP session is established

Confirm the BGP session you have with the provider is in an established state. Don't proceed until it is.

Task 10c: Ping the Oracle BGP IP address

For each virtual circuit, ping the Oracle BGP IP address (which you can get from the provider). Check the error counters and look for any dropped packets. When you can successfully ping this IP address without errors, the connection is ready to test.

Task 11: Test the connection

For a private virtual circuit: You should be able to launch an instance in your VCN and access it (for example, with SSH) from a host in your existing private network. See Creating an Instance. If you can, your FastConnect private virtual circuit is ready to use.

For a public virtual circuit:

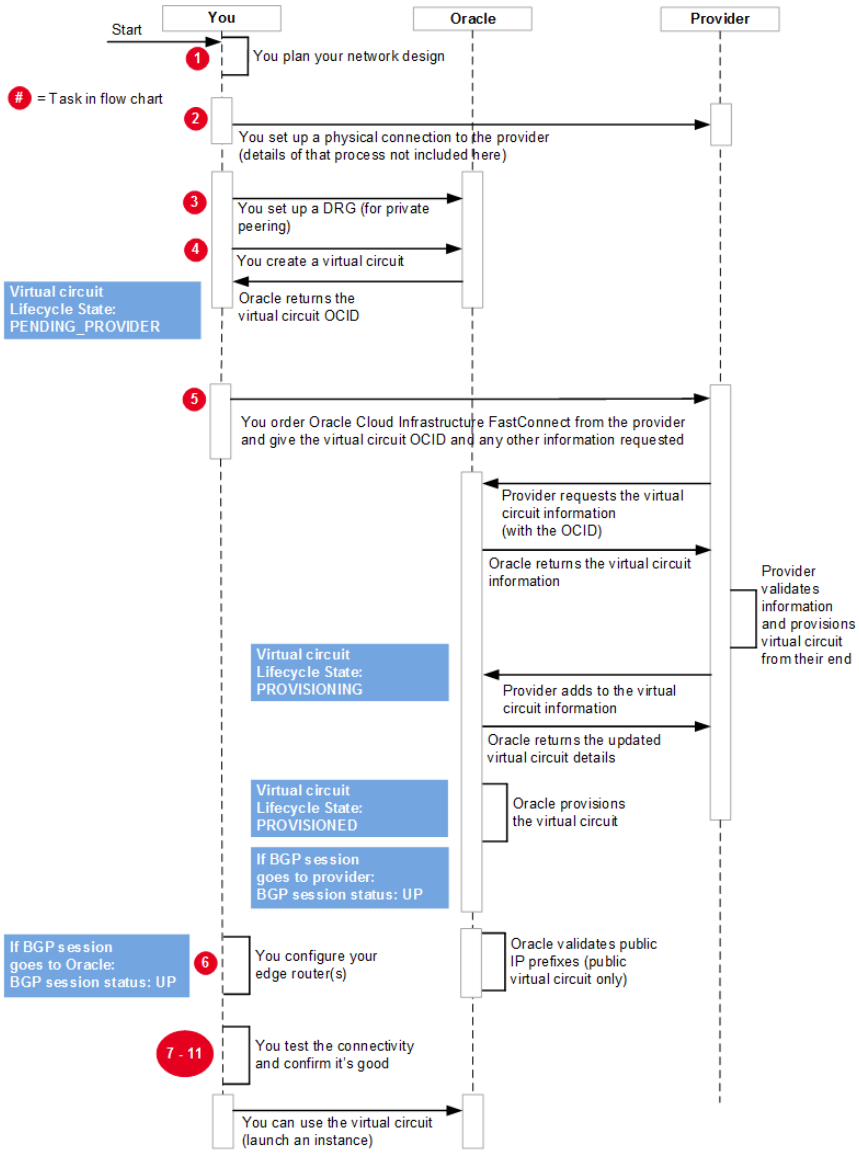
1. Make sure that Oracle has successfully verified *at least one* of the public prefixes you've submitted. You can see the status of each prefix by viewing the virtual circuit's details in the Console. When one of the prefixes has been validated, Oracle starts advertising the regional Oracle Cloud Infrastructure public addresses over the connection.
2. Launch an instance with a public IP address.
3. Ping the public IP address from a host in your existing private network. You should see the packet on the FastConnect interface on the virtual circuit. If you do, your FastConnect public virtual circuit is ready to use. However, remember that *only the public prefixes that Oracle has successfully verified so far* are advertised on the connection.

Managing Your Virtual Circuit

To get the status of your virtual circuit

1. In the Console, go to **Networking**, and then click **FastConnect** to view your list of connections.
2. Click the virtual circuit you're interested in to view its details.

The following diagram shows the different states of the virtual circuit when you're setting it up.



You
Oracle
Provider
Start
1
You plan your network design
= Task in flow chart
2
You set up a physical connection to the provider (details of that process not included here)
3
You set up a DRG (for private peering)
4
You create a virtual circuit
Oracle returns the virtual circuit OCID
Virtual circuit Lifecycle State: PENDING_PROVIDER
5
You order Oracle Cloud Infrastructure FastConnect from the provider and give the virtual circuit OCID and any other information requested
Provider requests the virtual circuit information (with the OCID)
Oracle returns the virtual circuit information
Provider validates information and provisions virtual circuit from their end
Virtual circuit Lifecycle State: PROVISIONING
Provider adds to the virtual circuit information
Oracle returns the updated virtual circuit details
Virtual circuit Lifecycle State: PROVISIONED
Oracle provisions the virtual circuit
If BGP session goes to provider: BGP session status: UP
If BGP session goes to Oracle: BGP session status: UP
6
You configure your edge router(s)
Oracle validates public IP prefixes (public virtual circuit only)
7 - 11
You test the connectivity and confirm it's good
You can use the virtual circuit (launch an instance)

To edit a virtual circuit

You can change these items for a virtual circuit:

- The name
- The bandwidth
- Which DRG it uses (for a private virtual circuit)
- The public IP prefixes (for a public virtual circuit)
- Depending on the situation, you might also have access to the BGP session information for the virtual circuit and thus can change it.

Important

If your virtual circuit is working and in the PROVISIONED state before you edit it, be aware that changing any of the properties besides the name, bandwidth, and public prefixes (for a public virtual circuit) causes the virtual circuit's state to switch to PROVISIONING and **may cause the related BGP session to go down.** After Oracle re-provisions the virtual circuit, its state returns to PROVISIONED. Make sure you confirm that the associated BGP session is back up.

If you change the public IP prefixes for a public virtual circuit, the BGP status is unaffected. Oracle begins advertising a new IP prefix over the connection only after verifying your ownership of it. The virtual circuit's state changes to PROVISIONING while Oracle implements any prefix changes.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **FastConnect**.
2. Select the compartment where the connection resides, and then click the connection to view its details.
3. Click **Edit** and make your changes.
4. Click **Save Changes**.

To terminate a virtual circuit

Important

Also terminate the connection with the provider, or else the provider may continue to bill you.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **FastConnect**.
2. Select the compartment where the connection resides, and then click the connection to view its details.
3. Click **Delete**.
4. Confirm when prompted.

The virtual circuit's Lifecycle State changes to TERMINATING and then to TERMINATED.

To manage public IP prefixes for a public virtual circuit

For general information about the prefixes, see Logical Connection: Public Virtual Circuit.

You can specify your public IP prefixes when you create the virtual circuit. See Task 4: Set up your virtual circuit.

You can add or remove public IP prefixes later after creating the virtual circuit. See To edit a virtual circuit. If you add a new prefix, Oracle first verifies your company's ownership before advertising it across the connection. If you remove a prefix, Oracle stops advertising the prefix within a few minutes of your editing the virtual circuit.

You can view the state of Oracle's verification of a given public prefix by viewing the virtual circuit's details in the Console. Here are the possible values:

- **In progress:** Oracle is in the process of verifying your organization's ownership of the prefix.
- **Failed:** Oracle could not verify your organization's ownership. Oracle will not advertise the prefix over the virtual circuit.
- **Completed:** Oracle successfully verified your organization's ownership. Oracle is advertising the prefix over the virtual circuit.

To move a connection to a different compartment

You can move a connection from one compartment to another. After you move the connection to the new compartment, inherent policies apply immediately and affect access to the connection through the Console. Moving the connection to a different compartment does not affect the connection between your data center and Oracle Cloud Infrastructure. For more information, see Moving Resources to a Different Compartment.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **FastConnect**.
2. Find the connection in the list, click the the Actions icon (three dots), and then click **Move Resource**.
3. Choose the destination compartment from the list.
4. Click **Move Resource**.
5. If there are alarms monitoring the connection, update the alarms to reference the new compartment. See To update an alarm after moving a resource for more information.

Monitoring Your Connection

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications. For more information, see Monitoring Overview and Notifications Overview.

For information about monitoring your connection, see FastConnect Metrics.

Troubleshooting

See FastConnect Troubleshooting.

FastConnect: With a Third-Party Provider

This topic is for customers who want to use Oracle Cloud Infrastructure FastConnect by connecting to a *third-party network provider* of their choice, and not an Oracle provider. For a summary of the different ways to connect, see the connectivity models.

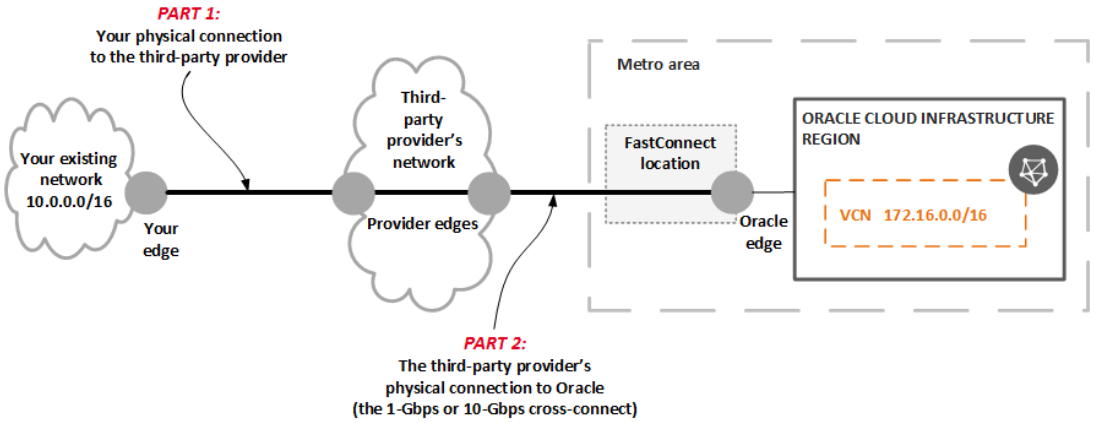
If you are using an Oracle provider, see FastConnect: With an Oracle Provider. Or, if you want to use FastConnect by colocating with Oracle, see FastConnect: Colocation with Oracle.

For general information about FastConnect, see FastConnect.

Important Points and Responsibilities

- You can use FastConnect by working with a third-party network service provider or carrier of your choice. The network provider must be capable of connecting to the Oracle routers in one of the FastConnect data center locations over single-mode fiber. For more detailed technical requirements, see Hardware and Routing Requirements.
- Your overall connection with the third-party provider includes two parts, as illustrated in the following diagram:
    - **Part 1:** Your physical connection to the third-party provider. The rest of this topic assumes you've already set up this part of the overall connection.

- **Part 2:** The physical fiber connection (cross-connect) that the third-party provider sets up in the FastConnect location data center on your behalf.



- To obtain the Letter of Authorization (LOA) for the cross-connect, you must use the Oracle Console to set up a cross-connect or cross-connect group. The resulting LOA from Oracle covers part 2 of the connection in the preceding diagram.
- You must forward the LOA to your third-party provider, who is responsible for working with the data center to set up the physical cross-connect on your behalf.
- The third-party provider issues a cross-connect order with the data center facility to run fiber optics to complete the connection from the third-party provider's cage to Oracle's patch panel as described in the LOA. Typically the data center colocation staff are the ones who run the fiber optics to complete the connection.
- Each LOA is valid for only a limited time. If the physical cross-connect is not set up before the LOA's expiration, the LOA is revoked.
- **The third-party provider is responsible for charging you for the *entire* connection (both parts 1 and 2)**. Oracle does not set up this cross-connect in the data center, does not pay for it, and does not include it in your FastConnect charges.

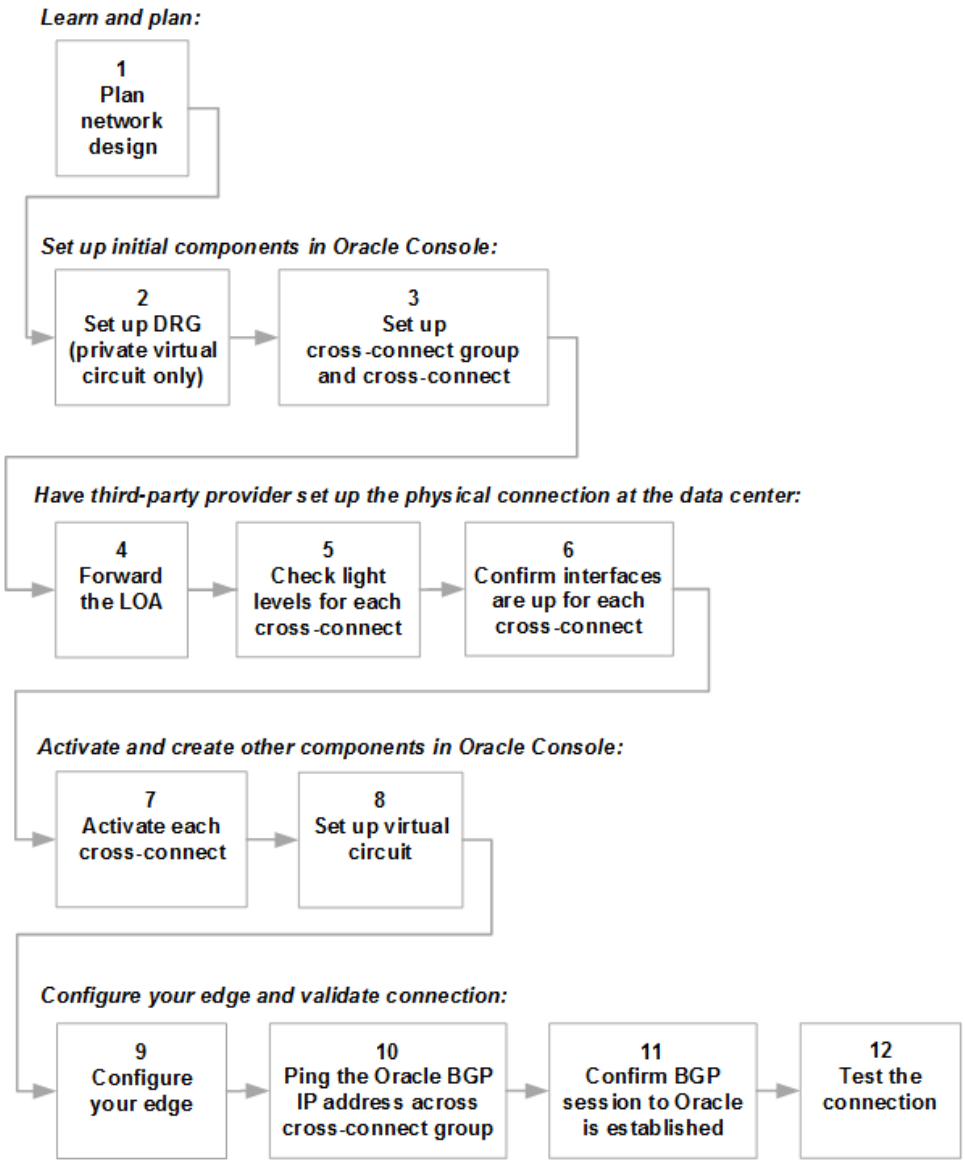
- The LOA specifies an Oracle demarcation point. If your network provider is located at a different demarcation point in the data center cage, they must set up the cross-connect from their demarcation point to the Oracle demarcation point.

Getting Started with FastConnect

The following flow chart shows the overall process of setting up FastConnect.

Note

In general, this topic assumes that your router supports link aggregation (LAG) and you will set up a cross-connect group (a LAG) with at least one cross-connect in it. The following procedures and screenshots reflect that. However, if your router doesn't support link aggregation, you can instead set up a single non-LAG cross-connect (with no cross-connect group). The procedures in this topic are still generally applicable. Instead you work only with a single cross-connect and not one or more in a cross-connect group.



Learn and plan:
1
Plan network design
Set up initial components in Oracle Console:
2
Set up DRG (private virtual circuit only)
3
Set up cross-connect group and cross-connect
Have third-party provider set up the physical connection at the data center:
4
Forward the LOA
5
Check light levels for each cross-connect
6
Confirm interfaces are up for each cross-connect
Activate and create other components in Oracle Console:
7
Activate each cross-connect
8
Set up virtual circuit
Configure your edge and validate connection:
9
Configure your edge
10
Ping the Oracle BGP IP address across cross-connect group
11
Confirm BGP session to Oracle is established
12
Test the connection

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Task 1: Learn and plan

If you haven't yet, walk through the planning in Before Getting Started: Learn and Plan. Also see FastConnect Redundancy Best Practices.

Task 2: Set up a DRG (private peering only)

Summary: If you plan to use a private virtual circuit (private peering), you need a DRG. If you haven't already, use the Oracle Cloud Infrastructure Console to set up a DRG, attach it to your VCN, and update routing in your VCN to include a route rule to send traffic to the DRG. It's easy to forget to update the route table. Without the route rule, no traffic will flow.

Instructions:

- To create a DRG
- To attach a DRG to a VCN
- To update rules in an existing route table

Task 3: Set up your cross-connect group and cross-connect

Summary: Create a connection in the Console, which consists of a cross-connect group (for link aggregation, or LAG) that contains at least one cross-connect. If you need more cross-connects in the group, you can add them later. You can have a maximum of eight cross-connects in a group.

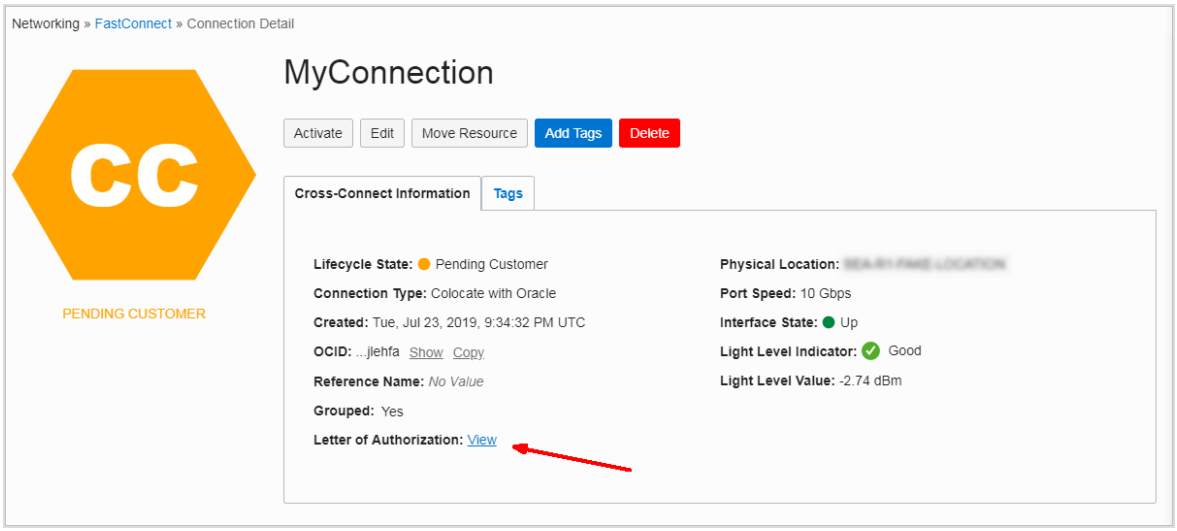
You have the option to set up a single non-LAG cross-connect (with no cross-connect group) if your router does not support link aggregation (LAG).

Instructions:

1. In the Console, confirm you're viewing the compartment that you want to work in. If you're not sure which one, use the compartment that contains the DRG that you'll connect to (for a private virtual circuit). This choice of compartment, in conjunction with a corresponding IAM policy, controls who has access to the cross-connect group and each cross-connect you're about to create.
2. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **FastConnect**.
   The resulting **FastConnect** page is where you'll create a new connection and later return to when you need to manage the connection and its components.
3. Click **Create FastConnect**.
4. Select **Colocate with Oracle** and click **Next**. Select this option even though a third-party provider will set up the physical connection to Oracle in the FastConnect location.
5. Enter the following items:
   - **Name:** A descriptive name that helps you keep track of this connection. You can't change the name later. Avoid entering confidential information. If you're creating a cross-connect group (LAG), the cross-connect group will use this name. Each cross-connect in this group will also use it, but with a hyphen and number appended (for example, MyName-1, MyName-2, and so on).
   - **Compartment:** Leave as is (the compartment you're currently working in).
   - **Cross-Connect Type:**
     - If your router supports LAG, select **Cross-Connect Group**. You will create a cross-connect group (a LAG) with at least one cross-connect.
     - If your router does not support link aggregation (LAG), select **Single Cross-Connect**. You will create a single non-LAG cross-connect with no cross-connect group.

- **Reference Name:** The ID for the physical LAG for the cross-connect group. This makes future connection troubleshooting easier. You might need to get this value from your third-party provider. If you don't have it, you can add it later. If you're creating a single non-LAG cross-connect, enter the ID for the physical fiber cable for the cross-connect.
- **Number of cross-connects:** Available only if you're creating a cross-connect group. This is the number of individual cross-connects to create in the cross-connect group. In the Console, you can create three. If you need more, you can add more cross-connects later (total eight in a cross-connect group).
- **Port speed:** All cross-connects must use a 10-Gbps port speed.
- **Physical location:** The FastConnect location for this connection.
- **Specify Router Proximity**: Optionally specify whether you want the new connection to be on the same or different router than one of your other connections.

6. Click **Create**.
   The new connection is created and listed on the FastConnect page.
7. Click the new connection to see its details.
8. **Print the LOA for each cross-connect:** Each cross-connect you just created has a Letter of Authorization (LOA). View each cross-connect's details, and then view and print the cross-connect's LOA. In the next task, you forward it to your third-party provider so they can request cabling at the FastConnect location. The cross-connect's status is PENDING CUSTOMER until you complete the next few tasks.



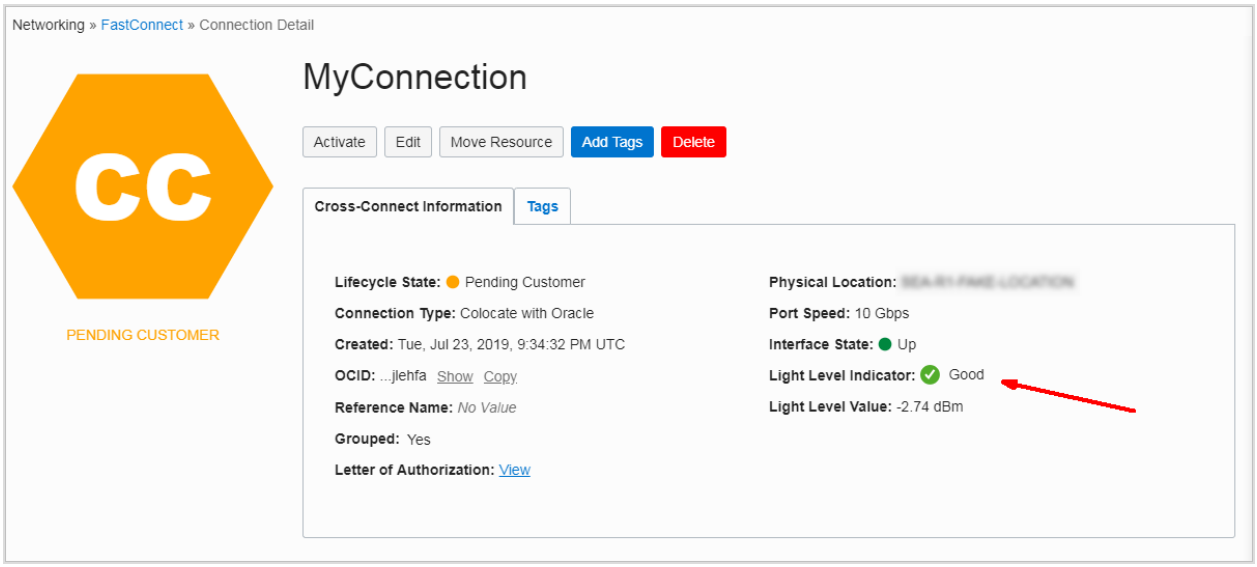
Task 4: Forward the LOA to your third-party provider

Forward the LOA or LOAs from the preceding task to your third-party network provider so they can request cabling at the FastConnect location. Each LOA is valid for a limited time. The details are printed on the LOA.

Task 5: Check light levels

After the third-party provider completes setup of the physical cross-connect in the FastConnect location, confirm from your side that the light levels for each physical connection (cross-connect) are good (> -15 dBm). Don't proceed until they are.

In the Console, you can see the light levels that Oracle detects by viewing the details of the cross-connect, as shown in the following screenshot:



If they are not good, contact your third-party network provider.

Task 6: Confirm your interfaces are up

For each cross-connect's physical fiber cable, confirm your side of the interfaces are up. Don't proceed until they are.

In the Console, you can see the status of Oracle's side of the interfaces (up or down) by viewing the details of the cross-connect (see the preceding screenshot).

If the interfaces are not up, contact your third-party network provider.

Task 7: Activate each cross-connect

Summary: When your physical fiber cables in the FastConnect location are set up and ready to use, return to the Oracle Console and activate each cross-connect that you set up earlier. The process of activating a cross-connect informs Oracle that the corresponding physical fiber cable is ready. Oracle will then complete the router configuration for each cross-connect.

Instructions:

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **FastConnect**.
2. Select the compartment where the connection resides, and then click the connection to view its details.
3. Click through to view the cross-connect's details, and then click **Activate**.
4. Confirm when prompted.
5. While still viewing the cross-connect's details, click **Edit** and enter the ID for the physical fiber cable for this cross-connect. Adding this value can help with any connection troubleshooting in the future. If you don't have the value available now, you can add it later.

If you have other cross-connects that are ready to use, wait for the first to be provisioned, and then activate the next one. Only one cross-connect in a group can be activated and then provisioned at a time.

After you complete this task, each cross-connect's status changes to PROVISIONING and then to PROVISIONED (typically within one minute).

Task 8: Set up your virtual circuit

Summary: Create one or more virtual circuits for your connection in the Oracle Console. The cross-connect group (or your single non-LAG cross-connect) must first be in the PROVISIONED state.

> **Important**
>
> If you want to use a *single* FastConnect to connect your existing network to *multiple* DRGs and VCNs, you must set up a different private virtual circuit for each VCN. Each virtual circuit must have a different VLAN and a different set of BGP IP addresses. For more information, see FastConnect with Multiple DRGs and VCNs.

Instructions:

1. In the Console, return to the connection you created earlier. Under **Resources**, click **Virtual Circuits**.
2. Click **Add Virtual Circuit**.
3. Enter the following for your virtual circuit:
   - **Name:** A descriptive name that helps you keep track of your virtual circuits. The value does not need to be unique across your virtual circuits, and you can change it later. Avoid entering confidential information.
   - **Compartment:** Select the compartment where you want to create the virtual circuit. If you're not sure, use the current compartment. This choice of compartment, in conjunction with a corresponding IAM policy, controls who has access to the virtual circuit.
4. Choose the virtual circuit type (private or public). A private virtual circuit is for private peering (where your existing network receives routes for your VCN's private IP addresses). A public virtual circuit is for public peering (where your existing network receives routes for the Oracle Cloud Infrastructure public IP addresses). Also see Uses for FastConnect.

- For a private virtual circuit, enter the following:
  - **Dynamic Routing Gateway:** Select the DRG to route the FastConnect traffic to.
  - **Provisioned Bandwidth:** Choose your desired value. If your bandwidth needs increase later, you can update the virtual circuit to use a different value (see To edit a virtual circuit).
  - **VLAN:** The number of the VLAN to use for this virtual circuit. It must be a VLAN that is not already assigned to another virtual circuit.
  - **Customer BGP IP Address:** The BGP peering IP address for your edge (your CPE), with either a /30 or /31 subnet mask.
  - **Oracle BGP IP Address:** The BGP peering IP address you want to use for the Oracle edge (the DRG), with either a /30 or /31 subnet mask.
  - **Enable IPv6 Address Assignment:** Available only in the US Government Cloud. For more information, see FastConnect and IPv6.
  - **Customer BGP ASN:** The public or private ASN for your network.
  - **Use a BGP MD5 Authentication Key (optional):** Select this check box and provide a key if your system requires MD5 authentication. Oracle supports up to 128-bit MD5 authentication.
- For a public virtual circuit, enter the following:
  - **Provisioned Bandwidth:** Choose your desired value. If your bandwidth needs increase later, you can update the virtual circuit to use a different value (see To edit a virtual circuit).
  - **Public IP Prefixes:** The public IP prefixes that you want Oracle to receive over the connection (each one must be /31 or less specific). You can enter a comma-separated list of prefixes, or one per line.
  - **VLAN:** The number of the VLAN to use for this virtual circuit. It must be a VLAN that is not already assigned to another virtual circuit.

- **Customer BGP ASN:** The public ASN for your network. Note that Oracle specifies the BGP IP addresses for a public virtual circuit.
- **Use a BGP MD5 Authentication Key (optional):** Select this check box and provide a key if your system requires MD5 authentication. Oracle supports up to 128-bit MD5 authentication.

5. Click **Create**.
   The virtual circuit is created.
   The virtual circuit's status is PROVISIONING briefly while Oracle's system provisions the virtual circuit. The status then switches to DOWN if the BGP session between your edge and Oracle's edge is not yet correctly configured, if the VLAN isn't configured correctly, or if there any other problems. Otherwise the status switches to UP.

Task 9: Configure your edge

Configure each of your edge routers to use the BGP information and VLAN for the virtual circuit. Oracle's BGP ASN for the commercial cloud is 31898. For the Government Cloud, see Oracle's BGP ASN. By default, Oracle uses the default BGP timers of 60 seconds for keep-alive and 180 seconds for hold-time. If you need fast BGP convergence, you can use any value in these supported ranges: 6-60 seconds for keep-alive, and 18-180 seconds for hold-time.

Important

For a public virtual circuit: Your existing network can receive advertisements for Oracle's public IP addresses through multiple paths (for example: FastConnect and your internet service provider). Make sure to give higher preference to FastConnect over your ISP. You must configure your edge appropriately so that traffic uses your desired path and you receive the benefits of FastConnect. This is particularly important if you decide to *also* set up your existing network with private access to Oracle services. For important information about path preferences, see Routing Details for Connections to Your On-Premises Network.

If you have a cross-connect group (a LAG) with one or more cross-connects in it, here are details to know about LACP:

- LACP is required on the network interface that is directly plugged in to Oracle's router.
- LACP is required even if you have only a single cross-connect in the cross-connect group.
- If the third-party provider is performing any media conversion, LACP must be configured on the provider's device instead of your device.

Also configure the router for redundancy according to the network design you decided on earlier. After you successfully configure BGP and the VLAN, the virtual circuit's status will switch to UP.

Task 10: Ping the Oracle BGP IP address

Ping the Oracle BGP IP address assigned to the virtual circuit. Check the error counters and look for any dropped packets. Don't proceed until you can successfully ping this IP address

without errors.

If you've set up a cross-connect group: if the ping is not successful, and you're NOT learning MAC addresses, verify that you configured LACP as mentioned in Task 9.

Task 11: Confirm the BGP session is established

For each virtual circuit you set up, confirm the BGP session is in an established state on your side of the connection.

Task 12: Test the connection

For a private virtual circuit: You should be able to launch an instance in your VCN and access it (for example, with SSH) from a host in your existing private network. See Creating an Instance. If you can, your FastConnect private virtual circuit is ready to use.

For a public virtual circuit:

1. Make sure that Oracle has successfully verified *at least one* of the public prefixes you've submitted. You can see the status of each prefix by viewing the virtual circuit's details in the Console. When one of the prefixes has been validated, Oracle starts advertising the regional Oracle Cloud Infrastructure public addresses over the connection.
2. Launch an instance with a public IP address.
3. Ping the public IP address from a host in your existing private network. You should see the packet on the FastConnect interface on the virtual circuit. If you do, your FastConnect public virtual circuit is ready to use. However, remember that *only the public prefixes that Oracle has successfully verified so far* are advertised on the connection.

Managing Your Connection

To get the status of your connection

Look at the icon for the particular part of the connection that you're interested in (cross-connect group, cross-connect, or virtual circuit).

Here are reasons for particular status values:

Cross-Connect: PENDING CUSTOMER

- You need to forward the LOA to your third-party provider so they can request cabling at the FastConnect location. See Task 4: Forward the LOA to your third-party provider.
- Or, you need to activate a cross-connect after confirming it's ready to use. See Task 7: Activate each cross-connect, but make sure you've performed tasks 5 and 6 first.

Virtual circuit: DOWN

In general this means you've created a virtual circuit, but configuration is incomplete or incorrect:

- You need to configure your edge. See Task 9: Configure your edge.
- Or, you've configured BGP or the VLAN incorrectly on your edge (make sure to configure the router to use the BGP and VLAN values assigned to the virtual circuit).

The following table summarizes the different states of each component involved in the connection at different points during setup:

Task in Setup Process	CCG Icon	CC Icon	VC Icon
Task 3: Set up your cross-connect group and cross-connect	PENDING PROVISIONING	PENDING CUSTOMER	N/A
Task 7: Activate each cross-connect	PROVISIONED	PROVISIONED	N/A
Task 8: Set up your virtual circuit	PROVISIONED	PROVISIONED	PROVISIONING > DOWN
Task 9: Configure your edge	PROVISIONED	PROVISIONED	DOWN > UP

To add a new cross-connect to an existing cross-connect group

When you first create a cross-connect group in the Console, you're allowed to create three cross-connects in the group. You can later add more to increase the bandwidth and resiliency of the group. The total allowed number is eight.

1. Create the new cross-connect in the existing cross-connect group:
    a. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **FastConnect**.
    b. Select the compartment where the connection resides, and then click the connection to view its details.
    c. Click **Add Cross-Connect**.
    d. Enter the following items:
        - **Name:** A descriptive name that helps you keep track of this cross-connect. The value does not need to be unique across your cross-connects. You can't change the name later. Avoid entering confidential information.

- **Reference Name:** Your ID for the physical fiber cable for the cross-connect. This makes future connection troubleshooting easier. If you don't have it, you can add it later.

e. Click **Add**.
The cross-connect is created. The status of the cross-connect is PENDING CUSTOMER to indicate that you have more work to do.

f. Print the new cross-connect's LOA. You forward it to your third-party provider in the next step.

2. Perform tasks 4-7 in Getting Started with FastConnect. In summary, you need to have the cabling set up for the new cross-connect, validate the light levels and interfaces are good, and then activate the cross-connect.

To edit a virtual circuit

You can change these items for a virtual circuit:

- The name
- The bandwidth
- Which DRG it uses (for a private virtual circuit)
- Which VLAN it uses
- The BGP session information
- The public IP prefixes (for a public virtual circuit)

Important

Notes About Editing a Virtual Circuit

If your virtual circuit is working and in the PROVISIONED state before you edit it, be aware that changing any of the properties besides the name, bandwidth, and public prefixes (for a public virtual circuit) causes the virtual circuit's state to switch to PROVISIONING and **may cause the related BGP session to go down.** After Oracle re-provisions the virtual circuit, its state returns to PROVISIONED. Make sure you confirm that the associated BGP session is back up.

If you change the public IP prefixes for a public virtual circuit, the BGP status is unaffected. Oracle begins advertising a new IP prefix over the connection only after verifying your ownership of it. The virtual circuit's state changes to PROVISIONING while Oracle implements any prefix changes.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **FastConnect**.
2. Select the compartment where the connection resides, and then click the connection to view its details.
3. Click **Virtual Circuits**, and then click the virtual circuit to view its details.
4. Click **Edit** and make your changes.
5. Click **Save Changes**.

To terminate a connection, or part of it

To stop being billed for a connection, you must terminate the virtual circuit, each cross-connect, and the cross-connect group associated with the connection (in that order).

Important

Also terminate the connection with the data center or third-party provider, or else they may continue to bill you.

To terminate a virtual circuit

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **FastConnect**.
2. Select the compartment where the connection resides, and then click the connection to view its details.
3. Click **Virtual Circuits**, and then click the virtual circuit to view its details.
4. Click **Delete**.
5. Confirm when prompted.

The virtual circuit's status changes to TERMINATING and then to TERMINATED.

To terminate a cross-connect

If you have multiple cross-connects to delete in a cross-connect group, wait until the state of the first one changes to TERMINATED before deleting the next one. Also, you can't delete a cross-connect if it's the *last* provisioned cross-connect in a cross-connect group that's being used by a provisioned virtual circuit.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **FastConnect**.
2. Select the compartment where the connection resides, and then click the connection to view its details.
3. Click **Cross-Connects**, and then click the cross-connect to view its details.
4. Click **Delete**.
5. Confirm when prompted.

The cross-connect's status changes to TERMINATING and then to TERMINATED.

To terminate a cross-connect group

Prerequisite: The cross-connect group must have no virtual circuits running on it and contain no cross-connects.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **FastConnect**.
2. Select the compartment where the connection resides, and then click the connection to view its details.
3. Click **Delete**.
4. Confirm when prompted.

The cross-connect group's status changes to TERMINATING and then to TERMINATED.

To manage public IP prefixes for a public virtual circuit

For general information about the prefixes, see Logical Connection: Public Virtual Circuit.

You can specify your public IP prefixes when you create the virtual circuit. See Task 8: Set up your virtual circuit.

You can add or remove public IP prefixes later after creating the virtual circuit. See To edit a virtual circuit. If you add a new prefix, Oracle first verifies your company's ownership before advertising it across the connection. If you remove a prefix, Oracle stops advertising the prefix within a few minutes of your editing the virtual circuit.

You can view the state of Oracle's verification of a given public prefix by viewing the virtual circuit's details in the Console. Here are the possible values:

- **In progress:** Oracle is in the process of verifying your organization's ownership of the prefix.
- **Failed:** Oracle could not verify your organization's ownership. Oracle will not advertise the prefix over the virtual circuit.
- **Completed:** Oracle successfully verified your organization's ownership. Oracle is advertising the prefix over the virtual circuit.

To move a connection to a different compartment

You can move a connection from one compartment to another. After you move the connection to the new compartment, inherent policies apply immediately and affect access to the connection through the Console. Moving the connection to a different compartment does not affect the connection between your data center and Oracle Cloud Infrastructure. For more information, see Moving Resources to a Different Compartment.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **FastConnect**.
2. Find the connection in the list, click the the Actions icon (three dots), and then click **Move Resource**.
3. Choose the destination compartment from the list.
4. Click **Move Resource**.
5. If there are alarms monitoring the connection, update the alarms to reference the new compartment. See To update an alarm after moving a resource for more information.

Monitoring Your Connection

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications. For more information, see Monitoring Overview and Notifications Overview.

For information about monitoring your connection, see FastConnect Metrics.

Troubleshooting

See FastConnect Troubleshooting.

FastConnect: Colocation with Oracle

This topic is for customers who are colocated with Oracle in a FastConnect location. For a summary of the different ways to connect, see the connectivity models.

If you instead have a relationship with an Oracle provider, see FastConnect: With an Oracle Provider. Or if you have a relationship with a third-party provider, see FastConnect: With a Third-Party Provider.

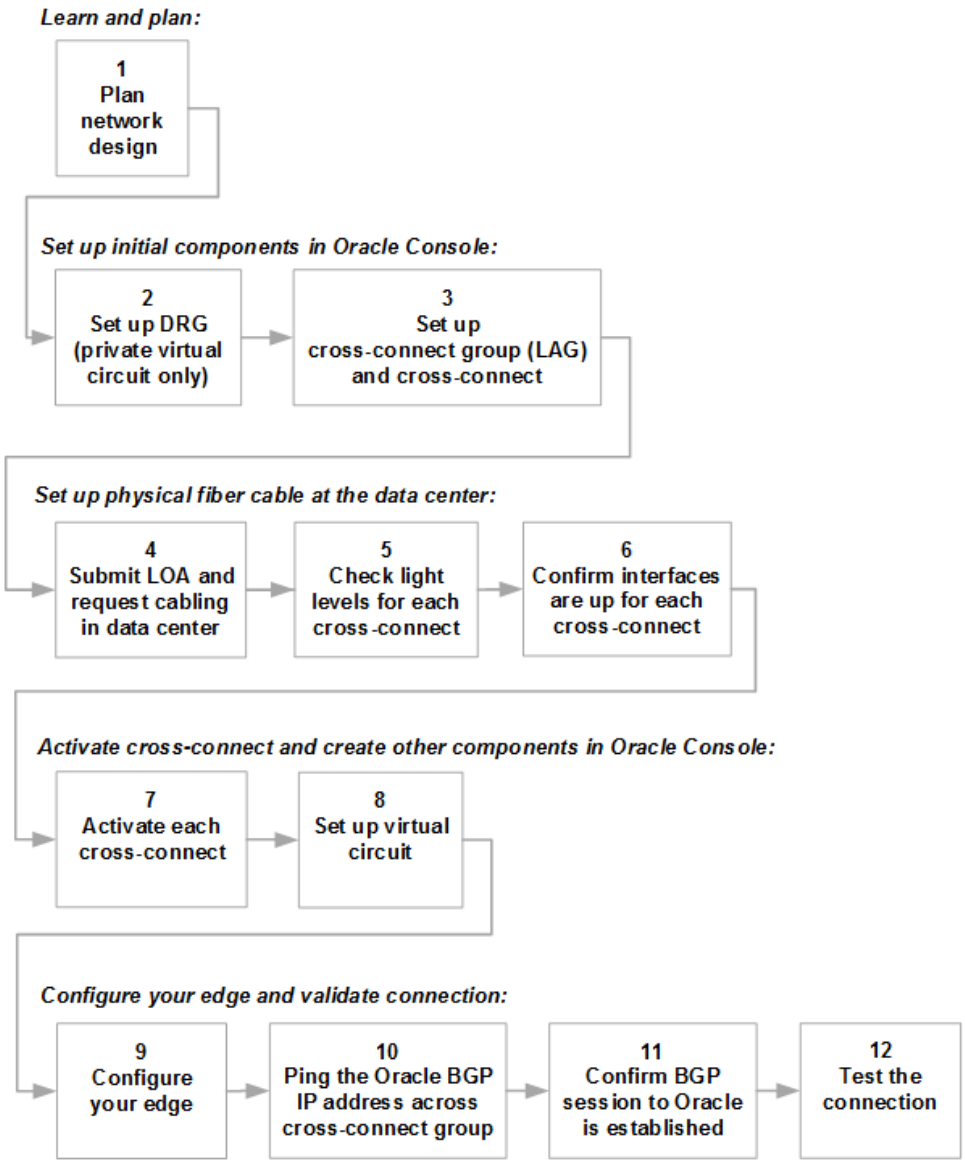
For general information about FastConnect, see FastConnect.

Getting Started with FastConnect

The following flow chart shows the overall process of setting up FastConnect.

Note

In general, this topic assumes that your router supports link aggregation (LAG) and you will set up a cross-connect group (a LAG) with at least one cross-connect in it. The following procedures and screenshots reflect that. However, if your router doesn't support link aggregation, you can instead set up a single non-LAG cross-connect (with no cross-connect group). The procedures in this topic are still generally applicable. Instead you work only with a single cross-connect and not one or more in a cross-connect group.



Learn and plan:
1
Plan network design
Set up initial components in Oracle Console:
2
Set up DRG (private virtual circuit only)
3
Set up cross-connect group (LAG) and cross-connect
Set up physical fiber cable at the data center:
4
Submit LOA and request cabling in data center
5
Check light levels for each cross-connect
6
Confirm interfaces are up for each cross-connect
Activate cross-connect and create other components in Oracle Console:
7
Activate each cross-connect
8
Set up virtual circuit
Configure your edge and validate connection:
9
Configure your edge
10
Ping the Oracle BGP IP address across cross-connect group
11
Confirm BGP session to Oracle is established
12
Test the connection

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Task 1: Learn and plan

If you haven't yet, walk through the planning in Before Getting Started: Learn and Plan. Also see FastConnect Redundancy Best Practices.

Task 2: Set up a DRG (private peering only)

Summary: If you plan to use a private virtual circuit (private peering), you need a DRG. If you haven't already, use the Oracle Cloud Infrastructure Console to set up a DRG, attach it to your VCN, and update routing in your VCN to include a route rule to send traffic to the DRG. It's easy to forget to update the route table. Without the route rule, no traffic will flow.

Instructions:

- To create a DRG
- To attach a DRG to a VCN
- To update rules in an existing route table

Task 3: Set up your cross-connect group and cross-connect

Summary: Create a connection in the Console, which consists of a cross-connect group (for link aggregation, or LAG) that contains at least one cross-connect. If you need more cross-connects in the group, you can add them later. You can have a maximum of eight cross-connects in a group.

You have the option to set up a single non-LAG cross-connect (with no cross-connect group) if your router does not support link aggregation (LAG).

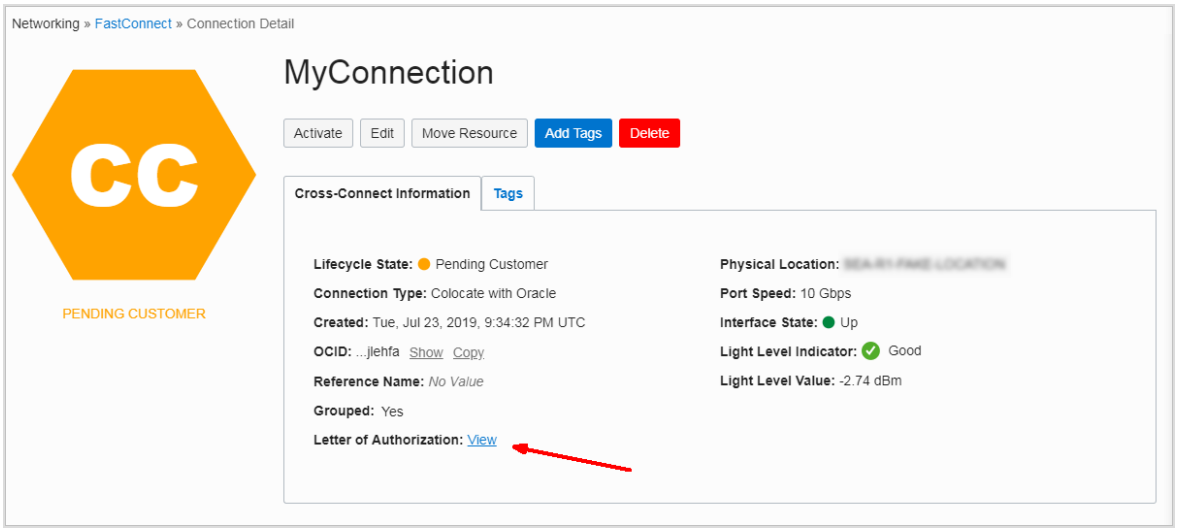
Instructions:

1. In the Console, confirm you're viewing the compartment that you want to work in. If you're not sure which one, use the compartment that contains the DRG that you'll connect to (for a private virtual circuit). This choice of compartment, in conjunction with a corresponding IAM policy, controls who has access to the cross-connect group and each cross-connect you're about to create.
2. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **FastConnect**.
   The resulting **FastConnect** page is where you'll create a new connection and later return to when you need to manage the connection and its components.
3. Click **Create FastConnect**.
4. Select **Colocate with Oracle** and click **Next**.
5. Enter the following items:
   - **Name:** A descriptive name that helps you keep track of this connection. You can't change the name later. Avoid entering confidential information. If you're creating a cross-connect group (LAG), the cross-connect group will use this name. Each cross-connect in this group will also use it, but with a hyphen and number appended (for example, MyName-1, MyName-2, and so on).
   - **Compartment:** Leave as is (the compartment you're currently working in).
   - **Cross-Connect Type:**
     - If your router supports LAG, select **Cross-Connect Group**. You will create a cross-connect group (a LAG) with at least one cross-connect.
     - If your router does not support link aggregation (LAG), select **Single Cross-Connect**. You will create a single non-LAG cross-connect with no cross-connect group.
   - **Reference Name:** The ID for the physical LAG for the cross-connect group. This makes future connection troubleshooting easier. If you don't have it, you can add

it later. If you're creating a single non-LAG cross-connect, enter the ID for the physical fiber cable for the cross-connect.

- **Number of cross-connects:** Available only if you're creating a cross-connect group. This is the number of individual cross-connects to create in the cross-connect group. In the Console, you can create three. If you need more, you can add more cross-connects later (total eight in a cross-connect group).
- **Port speed:** All cross-connects must use a 10-Gbps port speed.
- **Physical location:** The FastConnect location for this connection.
- **Specify Router Proximity**: Optionally specify whether you want the new connection to be on the same or different router than one of your other connections.

6. Click **Create**.
   The new connection is created and listed on the FastConnect page.
7. Click the new connection to see its details.
8. **Print the LOA for each cross-connect:** Each cross-connect you just created has a Letter of Authorization (LOA). View each cross-connect's details, and then view and print the cross-connect's LOA. In the next task, you submit it with your cabling request at the FastConnect location. The cross-connect's status is PENDING CUSTOMER until you complete the next few tasks.



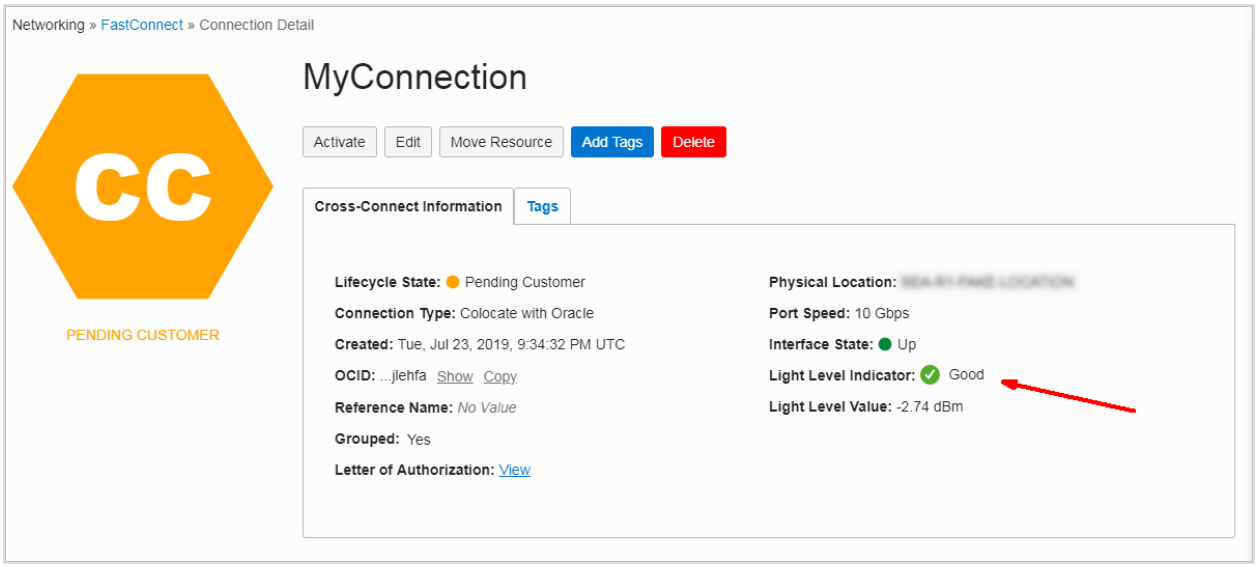
Task 4: Submit LOA and request cabling in the FastConnect location

At the FastConnect location, submit each LOA from the preceding task and request cabling for each cross-connect. Each LOA is valid for a limited time. The details are printed on the LOA.

Task 5: Check light levels

For each cross-connect's physical fiber cable, confirm from your side that the light levels are good (> -15 dBm). Don't proceed until they are.

In the Console, you can see the light levels that Oracle detects by viewing the details of the cross-connect, as shown in the following screenshot:



Task 6: Confirm your interfaces are up

For each cross-connect's physical fiber cable, confirm your side of the interfaces are up. Don't proceed until they are.

In the Console, you can see the status of Oracle's side of the interfaces (up or down) by viewing the details of the cross-connect (see the preceding screenshot).

Task 7: Activate each cross-connect

Summary: When your physical fiber cables in the FastConnect location are set up and ready to use, return to the Oracle Console and activate each cross-connect that you set up earlier. The process of activating a cross-connect informs Oracle that the corresponding physical fiber cable is ready. Oracle will then complete the router configuration for each cross-connect.

Instructions:

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **FastConnect**.
2. Select the compartment where the connection resides, and then click the connection to view its details.
3. Click through to view the cross-connect's details, and then click **Activate**.
4. Confirm when prompted.
5. While still viewing the cross-connect's details, click **Edit** and enter the ID for the physical fiber cable for this cross-connect. Adding this value can help with any connection troubleshooting in the future. If you don't have the value available now, you can add it later.

If you have other cross-connects that are ready to use, wait for the first to be provisioned, and then activate the next one. Only one cross-connect in a group can be activated and then provisioned at a time.

After you complete this task, each cross-connect's status changes to PROVISIONING and then to PROVISIONED (typically within one minute).

Task 8: Set up your virtual circuit

Summary: Create one or more virtual circuits for your connection in the Oracle Console. The cross-connect group (or your single non-LAG cross-connect) must first be in the PROVISIONED state.

> **Important**
>
> If you want to use a *single* FastConnect to connect your existing network to *multiple* DRGs and VCNs, you must set up a different private virtual circuit for each VCN. Each virtual circuit must have a different VLAN and a different set of BGP IP addresses. For more information, see FastConnect with Multiple DRGs and VCNs.

Instructions:

1. In the Console, return to the connection you created earlier. Under **Resources**, click **Virtual Circuits**.
2. Click **Add Virtual Circuit**.
3. Enter the following for your virtual circuit:
   - **Name:** A descriptive name that helps you keep track of your virtual circuits. The value does not need to be unique across your virtual circuits, and you can change it later. Avoid entering confidential information.
   - **Compartment:** Select the compartment where you want to create the virtual circuit. If you're not sure, use the current compartment. This choice of compartment, in conjunction with a corresponding IAM policy, controls who has access to the virtual circuit.
4. Choose the virtual circuit type (private or public). A private virtual circuit is for private peering (where your existing network receives routes for your VCN's private IP addresses). A public virtual circuit is for public peering (where your existing network receives routes for the Oracle Cloud Infrastructure public IP addresses). Also see Uses for FastConnect.

- For a private virtual circuit, enter the following:
  - **Dynamic Routing Gateway:** Select the DRG to route the FastConnect traffic to.
  - **Provisioned Bandwidth:** Choose your desired value. If your bandwidth needs increase later, you can update the virtual circuit to use a different value (see To edit a virtual circuit).
  - **VLAN:** The number of the VLAN to use for this virtual circuit. It must be a VLAN that is not already assigned to another virtual circuit.
  - **Customer BGP IP Address:** The BGP peering IP address for your edge (your CPE), with either a /30 or /31 subnet mask.
  - **Oracle BGP IP Address:** The BGP peering IP address you want to use for the Oracle edge (the DRG), with either a /30 or /31 subnet mask.
  - **Enable IPv6 Address Assignment:** Available only in the US Government Cloud. For more information, see FastConnect and IPv6.
  - **Customer BGP ASN:** The public or private ASN for your network.
  - **Use a BGP MD5 Authentication Key (optional):** Select this check box and provide a key if your system requires MD5 authentication. Oracle supports up to 128-bit MD5 authentication.
- For a public virtual circuit, enter the following:
  - **Provisioned Bandwidth:** Choose your desired value. If your bandwidth needs increase later, you can update the virtual circuit to use a different value (see To edit a virtual circuit).
  - **Public IP Prefixes:** The public IP prefixes that you want Oracle to receive over the connection (each one must be /31 or less specific). You can enter a comma-separated list of prefixes, or one per line.
  - **VLAN:** The number of the VLAN to use for this virtual circuit. It must be a VLAN that is not already assigned to another virtual circuit.

- **Customer BGP ASN:** The public ASN for your network. Note that Oracle specifies the BGP IP addresses for a public virtual circuit.
- **Use a BGP MD5 Authentication Key (optional):** Select this check box and provide a key if your system requires MD5 authentication. Oracle supports up to 128-bit MD5 authentication.

5. Click **Create**.
   The virtual circuit is created.
   The virtual circuit's status is PROVISIONING briefly while Oracle's system provisions the virtual circuit. The status then switches to DOWN if the BGP session between your edge and Oracle's edge is not yet correctly configured, if the VLAN isn't configured correctly, or if there any other problems. Otherwise the status switches to UP.

Task 9: Configure your edge

Configure each of your edge routers to use the BGP information and VLAN for the virtual circuit. Oracle's BGP ASN for the commercial cloud is 31898. For the Government Cloud, see Oracle's BGP ASN. By default, Oracle uses the default BGP timers of 60 seconds for keep-alive and 180 seconds for hold-time. If you need fast BGP convergence, you can use any value in these supported ranges: 6-60 seconds for keep-alive, and 18-180 seconds for hold-time.

Important

For a public virtual circuit: Your existing network can receive advertisements for Oracle's public IP addresses through multiple paths (for example: FastConnect and your internet service provider). Make sure to give higher preference to FastConnect over your ISP. You must configure your edge appropriately so that traffic uses your desired path and you receive the benefits of FastConnect. This is particularly important if you decide to *also* set up your existing network with private access to Oracle services. For important information about path preferences, see Routing Details for Connections to Your On-Premises Network.

If you have a cross-connect group (a LAG) with one or more cross-connects in it, here are details to know about LACP:

- LACP is required on the network interface that is directly plugged in to Oracle's router.
- LACP is required even if you have only a single cross-connect in the cross-connect group.

Also configure the router for redundancy according to the network design you decided on earlier. After you successfully configure BGP and the VLAN, the virtual circuit's status will switch to UP.

Task 10: Ping the Oracle BGP IP address

Ping the Oracle BGP IP address assigned to the virtual circuit. Check the error counters and look for any dropped packets. Don't proceed until you can successfully ping this IP address without errors.

If you've set up a cross-connect group: if the ping is not successful, and you're NOT learning MAC addresses, verify that you configured LACP as mentioned in Task 9.

Task 11: Confirm the BGP session is established

For each virtual circuit you set up, confirm the BGP session is in an established state on your side of the connection.

Task 12: Test the connection

For a private virtual circuit: You should be able to launch an instance in your VCN and access it (for example, with SSH) from a host in your existing private network. See Creating an Instance. If you can, your FastConnect private virtual circuit is ready to use.

For a public virtual circuit:

1. Make sure that Oracle has successfully verified *at least one* of the public prefixes you've submitted. You can see the status of each prefix by viewing the virtual circuit's details in the Console. When one of the prefixes has been validated, Oracle starts advertising the regional Oracle Cloud Infrastructure public addresses over the connection.
2. Launch an instance with a public IP address.
3. Ping the public IP address from a host in your existing private network. You should see the packet on the FastConnect interface on the virtual circuit. If you do, your FastConnect public virtual circuit is ready to use. However, remember that *only the public prefixes that Oracle has successfully verified so far* are advertised on the connection.

Managing Your Connection

To get the status of your connection

Look at the icon for the particular part of the connection that you're interested in (cross-

connect group, cross-connect, or virtual circuit).

Here are reasons for particular status values:

Cross-Connect: PENDING CUSTOMER

- You need to submit the LOA and request cabling at the FastConnect location. See Task 4: Submit LOA and request cabling in the FastConnect location.
- Or, you need to activate a cross-connect after confirming it's ready to use. See Task 7: Activate each cross-connect, but make sure you've performed tasks 5 and 6 first.

Virtual circuit: DOWN

In general this means you've created a virtual circuit, but configuration is incomplete or incorrect:

- You need to configure your edge. See Task 9: Configure your edge.
- Or, you've configured BGP or the VLAN incorrectly on your edge (make sure to configure the router to use the BGP and VLAN values assigned to the virtual circuit).

The following table summarizes the different states of each component involved in the connection at different points during setup:

Task in Setup Process	CCG Icon	CC Icon	VC Icon
Task 3: Set up your cross-connect group and cross-connect	PENDING PROVISIONING	PENDING CUSTOMER	N/A
Task 7: Activate each cross-connect	PROVISIONED	PROVISIONED	N/A
Task 8: Set up your virtual circuit	PROVISIONED	PROVISIONED	PROVISIONING > DOWN
Task 9: Configure your edge	PROVISIONED	PROVISIONED	DOWN > UP

To add a new cross-connect to an existing cross-connect group

When you first create a cross-connect group in the Console, you're allowed to create three cross-connects in the group. You can later add more to increase the bandwidth and resiliency of the group. The total allowed number is eight.

1. Create the new cross-connect in the existing cross-connect group:
    a. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **FastConnect**.
    b. Select the compartment where the connection resides, and then click the connection to view its details.
    c. Click **Add Cross-Connect**.
    d. Enter the following items:
        - **Name:** A descriptive name that helps you keep track of this cross-connect. The value does not need to be unique across your cross-connects. You can't change the name later. Avoid entering confidential information.
        - **Reference Name:** Your ID for the physical fiber cable for the cross-connect. This makes future connection troubleshooting easier. If you don't have it, you can add it later.
    e. Click **Add**.
    The cross-connect is created. The status of the cross-connect is PENDING CUSTOMER to indicate that you have more work to do.
    f. Print the new cross-connect's LOA. You submit it with your cabling order in the next step.
2. Perform tasks 4-7 in Getting Started with FastConnect. In summary, you need to have the cabling set up for the new cross-connect, validate the light levels and interfaces are good, and then activate the cross-connect.

To edit a virtual circuit

You can change these items for a virtual circuit:

- The name
- The bandwidth
- Which DRG it uses (for a private virtual circuit)
- Which VLAN it uses
- The BGP session information
- The public IP prefixes (for a public virtual circuit)

Important

Notes About Editing a Virtual Circuit

If your virtual circuit is working and in the PROVISIONED state before you edit it, be aware that changing any of the properties besides the name, bandwidth, and public prefixes (for a public virtual circuit) causes the virtual circuit's state to switch to PROVISIONING and **may cause the related BGP session to go down.** After Oracle re-provisions the virtual circuit, its state returns to PROVISIONED. Make sure you confirm that the associated BGP session is back up.

If you change the public IP prefixes for a public virtual circuit, the BGP status is unaffected. Oracle begins advertising a new IP prefix over the connection only after verifying your ownership of it. The virtual circuit's state changes to PROVISIONING while Oracle implements any prefix changes.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **FastConnect**.
2. Select the compartment where the connection resides, and then click the connection to view its details.
3. Click **Virtual Circuits**, and then click the virtual circuit to view its details.
4. Click **Edit** and make your changes.
5. Click **Save Changes**.

To terminate a connection, or part of it

To stop being billed for a connection, you must terminate the virtual circuit, each cross-connect, and the cross-connect group associated with the connection (in that order).

To terminate a virtual circuit

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **FastConnect**.
2. Select the compartment where the connection resides, and then click the connection to view its details.
3. Click **Virtual Circuits**, and then click the virtual circuit to view its details.
4. Click **Delete**.
5. Confirm when prompted.

The virtual circuit's status changes to TERMINATING and then to TERMINATED.

To terminate a cross-connect

If you have multiple cross-connects to delete in a cross-connect group, wait until the state of the first one changes to TERMINATED before deleting the next one. Also, you can't delete a cross-connect if it's the *last* provisioned cross-connect in a cross-connect group that's being used by a provisioned virtual circuit.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **FastConnect**.
2. Select the compartment where the connection resides, and then click the connection to view its details.
3. Click **Cross-Connects**, and then click the cross-connect to view its details.

4. Click **Delete**.
5. Confirm when prompted.

The cross-connect's status changes to TERMINATING and then to TERMINATED.

To terminate a cross-connect group

Prerequisite: The cross-connect group must have no virtual circuits running on it and contain no cross-connects.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **FastConnect**.
2. Select the compartment where the connection resides, and then click the connection to view its details.
3. Click **Delete**.
4. Confirm when prompted.

The cross-connect group's status changes to TERMINATING and then to TERMINATED.

To manage public IP prefixes for a public virtual circuit

For general information about the prefixes, see Logical Connection: Public Virtual Circuit.

You can specify your public IP prefixes when you create the virtual circuit. See Task 8: Set up your virtual circuit.

You can add or remove public IP prefixes later after creating the virtual circuit. See To edit a virtual circuit. If you add a new prefix, Oracle first verifies your company's ownership before advertising it across the connection. If you remove a prefix, Oracle stops advertising the prefix within a few minutes of your editing the virtual circuit.

You can view the state of Oracle's verification of a given public prefix by viewing the virtual circuit's details in the Console. Here are the possible values:

- **In progress:** Oracle is in the process of verifying your organization's ownership of the prefix.
- **Failed:** Oracle could not verify your organization's ownership. Oracle will not advertise the prefix over the virtual circuit.
- **Completed:** Oracle successfully verified your organization's ownership. Oracle is advertising the prefix over the virtual circuit.

To move a connection to a different compartment

You can move a connection from one compartment to another. After you move the connection to the new compartment, inherent policies apply immediately and affect access to the connection through the Console. Moving the connection to a different compartment does not affect the connection between your data center and Oracle Cloud Infrastructure. For more information, see Moving Resources to a Different Compartment.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **FastConnect**.
2. Find the connection in the list, click the the Actions icon (three dots), and then click **Move Resource**.
3. Choose the destination compartment from the list.
4. Click **Move Resource**.
5. If there are alarms monitoring the connection, update the alarms to reference the new compartment. See To update an alarm after moving a resource for more information.

Monitoring Your Connection

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications. For more information, see Monitoring Overview and Notifications Overview.

For information about monitoring your connection, see FastConnect Metrics.

Troubleshooting

See FastConnect Troubleshooting.

FastConnect Public Peering Advertised Routes

This topic lists the public IP address ranges (routes) that are advertised to your on-premises network by way of FastConnect public peering (a public virtual circuit).

When you connect with FastConnect to Oracle Cloud Infrastructure in a particular region, the routes advertised over the public virtual circuit may include routes for *other* Oracle Cloud Infrastructure regions, and for specific Oracle Cloud Infrastructure Classic regions. The following sections list the regional routes that are advertised over the public virtual circuit.

Americas

If you use FastConnect public peering to connect to this Oracle Cloud Infrastructure region...	**These Oracle Cloud Infrastructure regional routes are advertised over the public virtual circuit**	**These Oracle Cloud Infrastructure Classic regional routes are advertised over the public virtual circuit**
Brazil East (Sao Paulo)	Brazil East (Sao Paulo)	Sao Paulo-Classic
Canada Southeast (Toronto)	Canada Southeast (Toronto) US East (Ashburn) US West (Phoenix)	Ashburn-Classic Chicago-Classic

If you use FastConnect public peering to connect to this Oracle Cloud Infrastructure region...	These Oracle Cloud Infrastructure regional routes are advertised over the public virtual circuit	These Oracle Cloud Infrastructure Classic regional routes are advertised over the public virtual circuit
US East (Ashburn)	Canada Southeast (Toronto) US East (Ashburn) US West (Phoenix)	Ashburn-Classic Chicago-Classic
US West (Phoenix)	Canada Southeast (Toronto) US East (Ashburn) US West (Phoenix)	Ashburn-Classic Chicago-Classic

Asia-Pacific (APAC)

If you use FastConnect public peering to connect to this Oracle Cloud Infrastructure region...	These Oracle Cloud Infrastructure regional routes are advertised over the public virtual circuit	These Oracle Cloud Infrastructure Classic regional routes are advertised over the public virtual circuit
Australia East (Sydney)	Australia East (Sydney) India West (Mumbai) Japan East (Tokyo) South Korea Central (Seoul)	Sydney-Classic

FastConnect Metrics

You can monitor the health, capacity, and performance of your FastConnect connection by using metrics, alarms, and notifications. For more information, see Monitoring Overview and Notifications Overview.

This topic describes the metrics emitted by the metric namespace `oci_fastconnect`.

Resources: cross-connect groups, virtual circuits

Overview of Metrics: oci_fastconnect

Metrics are available for multiple resources in the FastConnect connection. The metrics help you determine quickly whether your FastConnect connection is up, how much data is flowing over the connection, and whether packets are being dropped for unexpected errors.

FastConnect offers different connectivity models:

- Connect with an Oracle provider: Metrics are available for virtual circuits in the connection.
- Connect with a third-party provider: Metrics are available for the cross-connect group (LAG) and virtual circuits in the connection. Metrics for cross-connects will be available in a future release.
- Colocate with Oracle: Metrics are available for the cross-connect group (LAG) and virtual circuits in the connection. Metrics for cross-connects will be available in a future release.

A cross-connect group (LAG) contains one or more cross-connects. If there are multiple and one goes down, the cross-connect group stays up, but the group might experience a lower overall bandwidth.

Required IAM Policy

To monitor resources, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources

being monitored. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.

Available Metrics: oci_fastconnect

The metrics listed in the following table are automatically available for each virtual circuit or cross-connect group that you create. You do not need to enable monitoring to get these metrics.

You also can use the Monitoring service to create custom queries.

Each metric includes the following dimensions:

COMPONENT

Possible values are `crossconnectgroup` and `virtualcircuit`. If you connect through an Oracle provider, only the `virtualcircuit` component is available.

RESOURCEID

The OCID of the resource (either a cross-connect group or virtual circuit).

Metric	Metric Display Name	Unit	Description	Dimensions
`ConnectionState`	**Connection State**	Binary (1 or 0)	The values are up (1) or down (0). For a virtual circuit, this is the operational state of the virtual circuit's interface. For a cross-connect group, this reflects the overall operational state of the cross-connects that make up the cross-connect group (LAG). If at least one of the cross-connects is up, this value is up (1). If *all* the cross-connects in the group are down, this value is down (0).	`component` `resourceId`
`PacketsReceived`	**Packets Received**	Packets	Number of packets received on the FastConnect interface at the Oracle end of the connection. For a cross-connect group (LAG), the value is the sum across all cross-connects in the group.	

Metric	Metric Display Name	Unit	Description	Dimensions
`BytesReceived`	**Bytes Received**	Bytes	Number of bytes received on the FastConnect interface at the Oracle end of the connection. For a cross-connect group (LAG), the value is the sum across all cross-connects in the group.	
`PacketsSent`	**Packets Sent**	Packets	Number of packets sent from the FastConnect interface at the Oracle end of the connection. For a cross-connect group (LAG), the value is the sum across all cross-connects in the group.	

Metric	Metric Display Name	Unit	Description	Dimensions
`BytesSent`	**Bytes Sent**	Bytes	Number of bytes sent from the FastConnect interface at the Oracle end of the connection. For a cross-connect group (LAG), the value is the sum across all cross-connects in the group.	
`PacketsError`	**Packets with Errors**	Packets	Number of packets dropped at the Oracle end of the connection. Dropped packets indicate a misconfiguration in some part of the overall system. Check if there's been a change to the configuration of your VCN, the virtual circuit, or your CPE. For a cross-connect group (LAG), the value is the sum across all cross-connects in the group.	

Using the Console

The instructions depend on which FastConnect connectivity model you use.

If You Use an Oracle Provider

To view default metric charts for a single FastConnect connection

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **FastConnect**.
2. Click the connection you're interested in.
3. The default metrics charts for the connection's virtual circuit are displayed on the resulting page.

For more information about monitoring metrics and using alarms, see Monitoring Overview. For information about notifications for alarms, see Notifications Overview.

To view default metric charts for all FastConnect connections in a compartment

1. Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Service Metrics**.
2. For **Compartment**, select the compartment that you're interested in.
3. For **Metric Namespace**, select **oci_fastconnect**.
   The **Service Metrics** page dynamically updates the page to show charts for each metric that is emitted by the selected metric namespace.

If there are multiple FastConnect connections in the compartment, by default the charts show a separate line for each one (each virtual circuit).

For more information about monitoring metrics and using alarms, see Monitoring Overview. For information about notifications for alarms, see Notifications Overview.

If You Use a Third-Party Provider or Colocate with Oracle

In this situation, you manage both the physical connection (cross-connects) and logical connection (virtual circuit).

For the physical connection, metrics are available for the cross-connect group (LAG), but not the individual cross-connects. If you are using only a single cross-connect with no cross-connect group, then no metrics are available for the physical connection.

For the logical connection, metrics are available for each virtual circuit.

To view default metric charts for a single FastConnect connection

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **FastConnect**.
2. Click the connection you're interested in.
3. View the metrics for the resource you're interested in:
    - For a cross-connect group: Under **Resources**, click **Metrics**. The default metrics charts are displayed on the resulting page.
    - For a virtual circuit:
        a. Under **Resources**, click **Virtual Circuits**.
        b. Click the virtual circuit you're interested in. If it's a private virtual circuit, the default metrics charts are displayed on the resulting page. If it's a public virtual circuit, click **Metrics** to view the charts.

For more information about monitoring metrics and using alarms, see Monitoring Overview. For information about notifications for alarms, see Notifications Overview.

To view default metric charts for all FastConnect connections in a compartment

1. Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Service Metrics**.
2. For **Compartment**, select the compartment that you're interested in.
3. For **Metric Namespace**, select **oci_fastconnect**.
   The **Service Metrics** page dynamically updates the page to show charts for each metric that is emitted by the selected metric namespace.

By default the charts show a separate line for each resource in the compartment (each cross-connect group and virtual circuit).

For more information about monitoring metrics and using alarms, see Monitoring Overview. For information about notifications for alarms, see Notifications Overview.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the following APIs for monitoring:

- Monitoring API for metrics and alarms
- Notifications API for notifications (used with alarms)

FastConnect Troubleshooting

This topic covers troubleshooting techniques for a FastConnect connection that has issues.

Some of the troubleshooting techniques assume that you are a network engineer with access to your CPE's configuration.

Microsoft Azure Connection Issues

Problems terminating the Azure connection

The connection components must be terminated in a specific order. If you don't follow this order, the FastConnect virtual circuit switches to a "Failed" state and cannot be deleted.

To fix a virtual circuit in the "Failed" state, go to the Azure portal and confirm the following items:

- The ExpressRoute circuit is not in the "Failed" state. If it is, click the ExpressRoute circuit's **Refresh** button. The circuit should return to its normal state.
- The ExpressRoute circuit has no connections. You must first delete all its connections.

After you've confirmed the preceding items, you can continue with the termination process in the following steps:

1. In the Oracle Console, delete your FastConnect virtual circuit. Make sure it is deleted before proceeding.
2. In the Azure portal, confirm that the private peering for the ExpressRoute circuit has been deleted. Also confirm that the ExpressRoute circuit's status has changed to "Not Provisioned".
3. In the Azure portal, delete the ExpressRoute circuit.

General Issues

FastConnect is DOWN

Important

If you're working with an Oracle provider or a third-party provider, contact both the provider and Oracle for help troubleshooting the issue. If you're colocated with Oracle, contact Oracle.

Cross-connect and physical connection (layer 1)

Check these items:

- **Port allocation:** Verify that your connection is using the correct port, and the port is UP and activated.
- **Optical signal:** Verify that your connection is using the correct optics and transceiver, and the port is sending and receiving an optimal signal. For more information, see FastConnect Requirements.
- **Fiber strands:** Try rolling or flipping the Tx/Rx fiber strands.
- **End-to-end physical connectivity:** Verify the end-to-end physical connectivity. Also verify the Tx/Rx optic signal between your CPE, the provider's network device (if you're working with a provider), and the Oracle FastConnect router.

Data-link (layer 2)

Check the following items on your CPE. If you're working with a provider, also have them check the items on their network device:

- **BGP address:** Verify that the router is configured with the correct BGP peering IP address under the correct VLAN on the interface.
- **MAC address:** Verify that the router is receiving the MAC address from the Oracle FastConnect router, and that the MAC address has an entry in the router's address resolution protocol (ARP) table.
- **LAG and LACP:** Verify that the router has LAG configured and LACP is enabled on the interface (the Oracle FastConnect router requires both). For more information, see FastConnect Requirements.

Network and transport (layers 3 and 4)

Check the following items on your CPE. If you're working with a provider, also have them check the items on their network device:

- **BGP address:** Verify that the router is configured with the correct BGP peering IP address.

- **ASN:** Verify that the router is configured with the correct BGP local ASN and Oracle BGP ASN. Oracle's BGP ASN for the commercial cloud is 31898. For the Government Cloud, see Oracle's BGP ASN.
- **MD5:** If you're using MD5 authentication, verify that the authentication string (the password) is correct.
- **Maximum prefixes:** Verify that you are advertising no more than the maximum allowed number of prefixes for virtual circuits. If you're advertising more, BGP won't be established. Here are the limits:
  - Public virtual circuits: maximum 200 prefixes
  - Private virtual circuits: maximum 2000 prefixes
- **Firewalls:** Verify that your on-premises firewall or access control lists are not blocking TCP port 179 (BGP) or any high-numbered TCP ports.

FastConnect virtual circuit is UP, but BGP session is DOWN

The Oracle Console displays an alert if the virtual circuit is in the PROVISIONED state, but the BGP session is DOWN.

Typically, the alert indicates one of the following issues:

- You have not yet configured your CPE with the required information for the FastConnect connection. After you configure the CPE, the alert should no longer appear.
- You have configured your CPE with incorrect information. Verify that your CPE is configured with the correct information.

The CPE configuration information includes these items:

- BGP address for each side of the connection
- ASN for your network and for Oracle's network
- MD5 authentication string (if you're using MD5 authentication)
- Maximum number of allowed prefixes

For more details, see the preceding information shown for network and transport (layers 3 and 4) in FastConnect is DOWN.

Exception: The preceding information is not relevant if you're using an Oracle provider, and the BGP session from your CPE goes to that provider and not Oracle. In that case, contact your provider to confirm that the BGP session they have with Oracle is configured correctly.

FastConnect virtual circuit is UP, but no traffic is passing through

Check these items:

- **VCN security lists:** Ensure you've set up the VCN security lists to allow the desired traffic (both ingress and egress rules). Note that the VCN's default security list does not allow ping traffic (ICMP type 8 and ICMP type 0). You must add the appropriate ingress and egress rules to allow ping traffic.
- **Correct routes on both ends:** Verify that you have received the correct VCN routes from FastConnect and the CPE is using those routes. Likewise, verify that you are advertising the correct on-premises network routes to FastConnect and the VCN route tables use those routes.

FastConnect virtual circuit is UP, but traffic is passing in only one direction

Check these items:

- **VCN security lists:** Ensure that your VCN security lists allow traffic in both directions (ingress and egress).
- **Firewalls:** Verify that your on-premises firewall or access control lists are not blocking traffic to or from the Oracle end.
- **Asymmetric routing:** Oracle uses asymmetric routing. If you have multiple virtual circuits, make sure that your CPE is configured for asymmetric route processing.
- **Redundant connections:** If you have redundant FastConnect virtual circuits, make sure they're both advertising the same routes.

Redundant Connections

Remember that FastConnect uses BGP dynamic routing, and IPSec connections can use either static routing or BGP, or a combination.

IPSec and FastConnect are both set up, but traffic is only passing through IPSec

Make sure to use more specific routes for the connection you want as primary. If you're using the same routes for both IPSec and FastConnect, see the discussion of routing preferences in Route Advertisements and Path Preferences When You Have Multiple Connections.

Internet Gateway

This topic describes how to set up and manage an internet gateway to give your VCN internet access.

Tip

Oracle also offers a NAT gateway, which is recommended for subnets in your VCN that do not require ingress connections from the internet.

Highlights

- An internet gateway is an optional virtual router you can add to your VCN to enable direct connectivity to the internet.
- The gateway supports connections initiated from within the VCN (egress) and connections initiated from the internet (ingress).

- Resources that need to use the gateway for internet access must be in a public subnet and have public IP addresses. Resources that have private IP addresses can instead use a NAT gateway to initiate connections to the internet.
- Each public subnet that needs to use the internet gateway must have a route table rule that specifies the gateway as the target.
- You use security rules to control the types of traffic allowed in and out of resources in that subnet. Make sure to allow only the desired types of internet traffic.
- The internet gateway can be used only by resources in the gateway's VCN. Hosts in the connected on-premises network or in a peered VCN cannot use that internet gateway.

Overview of Internet Gateways

Before continuing, make sure you've read Access to the Internet and also understand how to set up security rules for the resources in a subnet.

An internet gateway as an optional virtual router that connects the edge of the VCN with the internet. To use the gateway, the hosts on both ends of the connection must have public IP addresses for routing. Connections that originate in your VCN and are destined for a public IP address (either inside or outside the VCN) go through the internet gateway. Connections that originate outside the VCN and are destined for a public IP address inside the VCN go through the internet gateway.

A given VCN can have only one internet gateway. You control which public subnets in the VCN can use the gateway by configuring the subnet's associated route table. You use security rules to control the types of traffic allowed in and out of resources in those public subnets.

The following diagram illustrates a simple VCN setup with two public subnets. The VCN has an internet gateway, and the two public subnets are both configured to use the VCN's default route table. The table has a route rule that sends all egress traffic from the subnets to the internet gateway. The gateway allows any ingress connections from the internet with a destination IP address equal to the public IP address of a resource in the VCN. However, the public subnet's security list rules ultimately determine the specific *types* of traffic that are allowed in and out of the resources in the subnet. Those specific security rules are not shown in the diagram.

Tip

When an internet gateway receives traffic from your VCN destined for a public IP address that is part of Oracle Cloud Infrastructure (such as Object Storage), the internet gateway routes the traffic to the destination without sending the traffic over the internet.

Working with Internet Gateways

You create an internet gateway in the context of a specific VCN. In other words, the internet gateway is automatically attached to a VCN. However, you can disable and re-enable the internet gateway at any time. Compare this with a dynamic routing gateway (DRG), which you create as a standalone object that you then *attach* to a particular VCN. DRGs use a different model because they're intended to be modular building blocks for privately connecting VCNs to your on-premises network.

For traffic to flow between a subnet and an internet gateway, you must create a route rule accordingly in the subnet's route table (for example, destination CIDR = 0.0.0.0/0 and target = internet gateway). If the internet gateway is disabled, that means no traffic will flow to or from the internet even if there's a route rule that enables that traffic. For more information, see Route Tables.

For the purposes of access control, you must specify the compartment where you want the internet gateway to reside. If you're not sure which compartment to use, put the internet gateway in the same compartment as the cloud network. For more information, see Access Control.

You may optionally assign a friendly name to the internet gateway. It doesn't have to be unique, and you can change it later. Oracle automatically assigns the internet gateway a unique identifier called an Oracle Cloud ID (OCID). For more information, see Resource Identifiers.

To delete an internet gateway, it does not have to be disabled, but there must not be a route table that lists it as a target.

Using the Console

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

To set up an internet gateway

Prerequisites:

- You've determined which subnets in the VCN need access to the internet, and you've created those public subnets.
- You've determined the types of ingress and egress internet traffic that you want to enable for the resources in each public subnet (examples: ingress HTTPS connections, ingress ICMP ping connections).
- The required IAM policy is in place to allow you to work with Networking service resources. For administrators: see IAM Policies for Networking.

Important

If you've configured the public subnet to use the default security list, remember that the list includes several helpful default rules that enable basic required access (examples: ingress SSH, egress access to all destinations). Oracle recommends that you become familiar with the basic access that these default rules provide. If you choose not to use the default security list, make sure to provide this basic access by implementing these security rules either in network security groups (NSGs) or custom security lists.

The following procedure uses security lists, but you could instead implement the security rules in a network security group and then create all of the subnet's resources in that NSG.

1. For each public subnet that needs to use the internet gateway, set up the subnet's security list rules to allow the desired internet traffic.
    a. In the Console, while viewing the VCN you're interested in, click **Security Lists**.
    b. Click the security list you're interested in (a security list associated with the public subnet).
    c. Under **Resources**, click either **Ingress Rules** or **Egress Rules** depending on the type of rule you want to work with.
    d. If you want to add a new rule, click **Add Ingress Rule** (or **Add Egress Rule**).

    ### Example

    Imagine you have web servers in the public subnet. This example shows how to

add an ingress rule for HTTPS connections (TCP port 443) coming from the internet to the web server. Without this rule, inbound HTTPS connections are not allowed.

i. Leave the **Stateless** check box unselected.
ii. **Source Type:** CIDR
iii. **Source CIDR:** 0.0.0.0/0
iv. **IP Protocol:** Leave as TCP.
v. **Source Port Range:** Leave as All.
vi. **Destination Port Range**: Enter 443.

e. If you want to delete an existing rule, click the Actions icon (three dots), and then click **Remove**.
f. If you wanted to edit an existing rule, click the Actions icon (three dots), and then click **Edit**.

2. Create the VCN's internet gateway:
   a. In the Console, while viewing the VCN you're interested in, click **Internet Gateways**
   b. Click **Create Internet Gateway**.
   c. Enter the following:
      - **Name:** A friendly name for the internet gateway. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
      - **Create in Compartment:** The compartment where you want to create the internet gateway, if different from the compartment you're currently working in.
      - **Tags:** Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag

namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.

d. Click **Create Internet Gateway**.
   Your internet gateway is created and displayed on the **Internet Gateways** page of the compartment you chose. It's already enabled, but you still need to add a route rule that allows traffic to flow to the gateway.

3. For each public subnet that needs to use the internet gateway, update the subnet's route table:
   a. While viewing the VCN's details, click **Route Tables**.
   b. Click the public subnet's route table to view its details.
   c. Click **Add Route Rule**.
   d. Enter the following:
      - **Target Type:** Internet Gateway
      - **Destination CIDR block:** 0.0.0.0/0 (which means that all non-intra-VCN traffic that is not already covered by other rules in the route table will go to the target specified in this rule)
      - **Compartment:** The compartment where the internet gateway is located.
      - **Target:** The internet gateway you just created.
   e. Click **Save**.

An internet gateway is now enabled and working for your cloud network.

To disable/enable an internet gateway

This is available only through the API. If you don't have access to the API and need to disable or enable an internet gateway, contact Oracle Support. You can also easily delete and recreate the internet gateway if needed. Just make sure to update any route tables that refer to the internet gateway.

To delete an internet gateway

Prerequisite: The internet gateway does not have to be disabled, but there must not be a route table that lists it as a target.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Under **Resources**, click **Internet Gateways**.
4. Click the Actions icon (three dots) for the internet gateway, and then click **Terminate**.
5. Confirm when prompted.

To manage tags for an internet gateway

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Under **Resources**, click **Internet Gateways**.
4. Click the Actions icon (three dots) for the internet gateway, and then click **View Tags**. From there you can view the existing tags, edit them, and apply new ones.

For more information, see Resource Tags.

To move an internet gateway to a different compartment

You can move an internet gateway from one compartment to another. When you move an internet gateway to a new compartment, inherent policies apply immediately.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.

3. Under **Resources**, click **Internet Gateways**.
4. Click the the Actions icon (three dots) for the internet gateway, and then click **Move Resource**.
5. Choose the destination compartment from the list.
6. Click **Move Resource**.

For more information about using compartments and policies to control access to your cloud network, see Access Control. For general information about compartments, see Managing Compartments.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

To manage your internet gateways, use these operations:

- ListInternetGateways
- CreateInternetGateway
- GetInternetGatway
- UpdateInternetGateway
- DeleteInternetGateway
- ChangeInternetGatewayCompartment

NAT Gateway

This topic describes how to set up and manage a Network Address Translation (NAT) gateway. A NAT gateway gives cloud resources without public IP addresses access to the internet without exposing those resources to incoming internet connections.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Highlights

- You can add a NAT gateway to your VCN to give instances in a private subnet access to the internet.
- Instances in a private subnet don't have public IP addresses. With the NAT gateway, they can initiate connections to the internet and receive responses, but not receive inbound connections initiated from the internet.
- NAT gateways are highly available and support TCP, UDP, and ICMP ping traffic.

Overview of NAT

NAT is a networking technique commonly used to give an entire private network access to the internet without assigning each host a public IPv4 address. The hosts can initiate connections to the internet and receive responses, but not receive inbound connections initiated from the internet.

When a host in the private network initiates an internet-bound connection, the NAT device's public IP address becomes the source IP address for the outbound traffic. The response traffic from the internet therefore uses that public IP address as the destination IP address. The NAT device then routes the response to the host in the private network that initiated the connection.

Overview of NAT Gateways

The Networking service offers a reliable and highly available NAT solution for your VCN in the form of a NAT gateway.

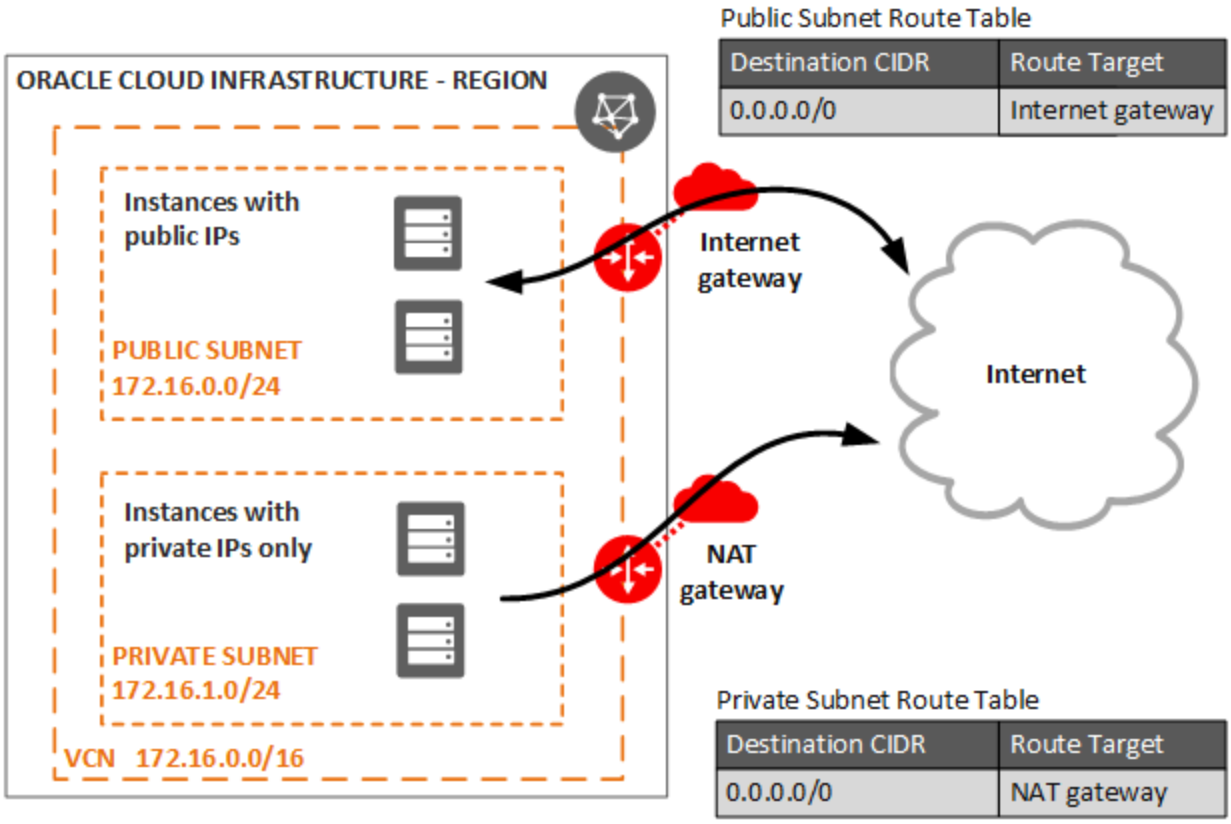
Example scenario: Imagine you have resources that need to receive inbound traffic from the internet (for example, web servers). You also have private resources that need to be protected from inbound traffic from the internet. All of these resources need to initiate connections to the internet to request software updates from sites on the internet.

You set up a VCN and add a public subnet to hold the web servers. When launching the instances, you assign public IP addresses to them so they can receive inbound internet traffic. You also add a private subnet to hold the private instances. They cannot have public IP addresses because they are in a private subnet.

You add an internet gateway to the VCN. You also add a route rule in the public subnet's route table that directs internet-bound traffic to the internet gateway. The public subnet's instances can now initiate connections to the internet and also receive inbound connections initiated from the internet. Remember that you can use security rules to control the types of traffic that are allowed in and out of the instances at the packet level.

You add a NAT gateway to the VCN. You also add a route rule in the private subnet's route table that directs internet-bound traffic to the NAT gateway. The private subnet's instances can now initiate connections to the internet. The NAT gateway allows responses, but it does not allow connections that are *initiated from the internet*. Without that NAT gateway, the private instances would instead need to be in the public subnet and have public IP addresses to get their software updates.

The following diagram illustrates the basic network layout for the example. The arrows indicate whether connections can be initiated in only one direction or both.



Note

A NAT gateway can be used only by resources in the gateway's own VCN. If the VCN is peered with another, resources in the other VCN cannot access the NAT gateway.

Also, resources in an on-premises network connected to the NAT gateway's VCN with FastConnect or an IPSec VPN cannot use the NAT gateway.

Here are a few basics about NAT gateways:

- The NAT gateway supports TCP, UDP, and ICMP ping traffic.
- The gateway supports a maximum of approximately 20,000 concurrent connections to a single destination address and port.
- The Networking service automatically assigns a public IP address to the NAT gateway. You can't choose the public IP address or use one of your reserved public IP addresses.
- There's a limit on the number of NAT gateways per VCN. You can request an increase to that limit. See Service Limits.

Routing for a NAT Gateway

You control routing in your VCN at the subnet level, so you can specify which subnets in your VCN use a NAT gateway. You can have more than one NAT gateway on a VCN (although you must request an increase in your limits). For example, if you want an external application to distinguish traffic from the VCN's different subnets, you could set up a different NAT gateway (and thus a different public IP address) for each subnet. A given subnet can route traffic to only a single NAT gateway.

Blocking Traffic Through a NAT Gateway

You create a NAT gateway in the context of a specific VCN. In other words, the NAT gateway is automatically always attached to only one VCN of your choice. However, you can block or allow traffic through the NAT gateway at any time. By default, the gateway allows traffic upon creation. Blocking the NAT gateway prevents all traffic from flowing, regardless of any existing route rules or security rules in your VCN. For instructions on how to block traffic, see To block/allow traffic for a NAT gateway.

Transitioning to a NAT Gateway

If you're switching from using a NAT instance in your VCN to a NAT gateway, consider that the public IP address for your NAT device will change.

If you're switching from using an internet gateway to a NAT gateway, the instances with access to the NAT gateway no longer need public IP addresses to reach the internet. Also, the

instances no longer need to be in a public subnet. You can't switch a subnet from public to private. However, you can delete the ephemeral public IPs from your instances if you like.

Deleting a NAT Gateway

To delete a NAT gateway, its traffic does not have to be blocked, but there must not be a route table that lists it as a target. For instructions, see To delete a NAT gateway.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: see IAM Policies for Networking.

Setting Up a NAT Gateway

Task 1: Create the NAT gateway

1. In the Console, confirm you're viewing the compartment that contains the VCN that you want to add the NAT gateway to. For information about compartments and access control, see Access Control.
2. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
3. Click the VCN you're interested in.
4. Under **Resources**, click **NAT Gateways**.
5. Click **Create NAT Gateway**.
6. Enter the following values:

- **Name:** A friendly name for the NAT gateway. It doesn't have to be unique. Avoid entering confidential information.
- **Create in compartment**: The compartment where you want to create the NAT gateway, if different from the compartment you're currently working in.
- **Tags:** Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.

7. Click **Create NAT Gateway**.
   The NAT gateway is then created and displayed on the **NAT Gateways** page in the compartment you chose. The gateway allows traffic by default. At any time, you can block or allow traffic through it.

Task 2: Update routing for the subnet

When you create a NAT gateway, you must also create a route rule that directs the desired traffic from the subnet to the NAT gateway. You do this for each subnet that needs to access the gateway.

1. Determine which subnets in your VCN need access to the NAT gateway.
2. For each of those subnets, update the subnet's route table to include a new rule:
   a. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
   b. Click the VCN you're interested in.
   c. Under **Resources**, click **Route Tables**.
   d. Click the route table you're interested in.
   e. Click **Add Route Rule** and enter the following values:

- **Target Type:** NAT Gateway.
- **Destination CIDR Block:** 0.0.0.0/0
- **Compartment:** The compartment where the NAT gateway is located.
- **Target NAT Gateway:** The NAT gateway.

f. Click **Add Route Rule**.

Any subnet traffic with a destination that matches the rule is routed to the NAT gateway. For more information about setting up route rules, see Route Tables.

Later, if you no longer need the NAT gateway and want to delete it, you must first delete all the route rules in your VCN that specify the NAT gateway as the target.

Tip

Without the required routing, traffic doesn't flow over the NAT gateway. If a situation occurs where you need to temporarily stop the traffic flow over the gateway, you can simply remove the route rule that enables traffic. Or you can block traffic through the gateway entirely. You do not need to delete it.

Using the Console

To create a NAT gateway

See the instructions in Task 1: Create the NAT gateway.

To block/allow traffic for a NAT gateway

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click

Virtual Cloud Networks.

2. Click the VCN you're interested in.
3. Under **Resources**, click **NAT Gateways**.
4. For the NAT gateway you're interested in, click the Actions icon (three dots) and then click **Block Traffic** (or **Allow Traffic** if you're enabling traffic for the NAT gateway).
5. Confirm when prompted.
   When the traffic is blocked, the NAT gateway's icon turns gray, and the label changes to BLOCKED. When the traffic is allowed, the NAT gateway's icon turns green, and the label changes to AVAILABLE.

To update a NAT gateway

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Under **Resources**, click **NAT Gateways**.
4. For the NAT gateway you're interested in, click the Actions icon (three dots), and then click **Edit**.
5. Make your changes and click **Save Changes**.

To delete a NAT gateway

Prerequisite: There must not be a route table that lists the NAT gateway as a target.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Under **Resources**, click **NAT Gateways**.

4. For the NAT gateway you want to delete, click the Actions icon (three dots), and then click **Terminate**.
5. Confirm when prompted.

To manage tags for a NAT gateway

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Under **Resources**, click **NAT Gateways**.
4. Click the Actions icon (three dots) for the NAT gateway, and then click **View Tags**. From there you can view the existing tags, edit them, and apply new ones.

For more information, see Resource Tags.

To move a NAT gateway to a different compartment

You can move a NAT gateway from one compartment to another. When you move a NAT gateway to a new compartment, inherent policies apply immediately.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. In **Resources**, click **NAT Gateways**.
4. Find the NAT gateway in the list, click the the Actions icon (three dots), and then click **Move Resource**.
5. Choose the destination compartment from the list.
6. Click **Move Resource**.

The NAT gateway moves to the new compartment immediately. Depending on your permissions, you can select the compartment in the left side menu to view the NAT gateway.

For more information about using compartments and policies to control access to your cloud network, see Access Control. For general information about compartments, see Managing Compartments.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

To manage your NAT gateways, use these operations:

- ListNatGateways
- CreateNatGateway
- GetNatGateway
- UpdateNatGateway
- DeleteNatGateway
- ChangeNatGatewayCompartment

To manage route tables, see Route Tables.

Access to Oracle Services: Service Gateway

This topic describes how to set up and manage a service gateway. A service gateway enables cloud resources without public IP addresses to privately access Oracle services.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Access to Oracle Services

The *Oracle Services Network* is a conceptual network in Oracle Cloud Infrastructure that is reserved for Oracle services. These services have public IP addresses that you typically reach over the internet. However, you can access the Oracle Services Network *without the traffic going over the internet*. There are different ways, depending on which of your hosts need the access:

- **Hosts in your on-premises network:**
  - Private access through a VCN with FastConnect private peering or VPN Connect: The on-premises hosts use private IP addresses and reach the Oracle Services Network by way of the VCN and the VCN's service gateway.
  - Public access with FastConnect public peering: The on-premises hosts use public IP addresses.
- **Hosts in your VCN:**
  - Private access through a service gateway: This is the scenario covered in this topic. The VCN's hosts use private IP addresses.

Highlights

- A service gateway lets your virtual cloud network (VCN) privately access specific Oracle services without exposing the data to the public internet. No internet gateway or NAT is required to reach those specific services. The resources in the VCN can be in a private subnet and use only private IP addresses. The traffic from the VCN to the Oracle service travels over the Oracle network fabric and never traverses the internet.
- The service gateway is regional and enables access only to supported Oracle services *in the same region* as the VCN.
- The service gateway allows access to supported Oracle services within the region to protect your data from the internet. Your workloads may require access to public endpoints or services not supported by the service gateway (for example, to download updates or patches). Ensure you have a NAT gateway or other access to the internet if necessary.

- The supported Oracle services are Oracle Cloud Infrastructure Object Storage and others in the Oracle Services Network. For a list, see Service Gateway: Supported Cloud Services in Oracle Services Network.
- The service gateway uses the concept of a *service CIDR label*, which is a string that represents all the regional public IP address ranges for the service or group of services of interest (for example, *OCI PHX Object Storage* is the string for Object Storage in US West (Phoenix)). You use that service CIDR label when you configure the service gateway and related route rules to control traffic to the service. You can optionally use it when configuring security rules. If the service's public IP addresses change in the future, you don't have to adjust those rules.
- You can set up a VCN so that your on-premises network has *private access* to Oracle services by way of the VCN and the VCN's service gateway. The hosts in your on-premises network communicate with their private IP addresses and the traffic does not go over the internet. For more information, see Transit Routing: Private Access to Oracle Services

Overview of Service Gateways

A service gateway lets resources in your VCN privately access specific Oracle services, without exposing the data to an internet gateway or NAT. The resources in the VCN can be in a private subnet and use only private IP addresses. The traffic from the VCN to the service of interest travels over the Oracle network fabric and never traverses the internet.

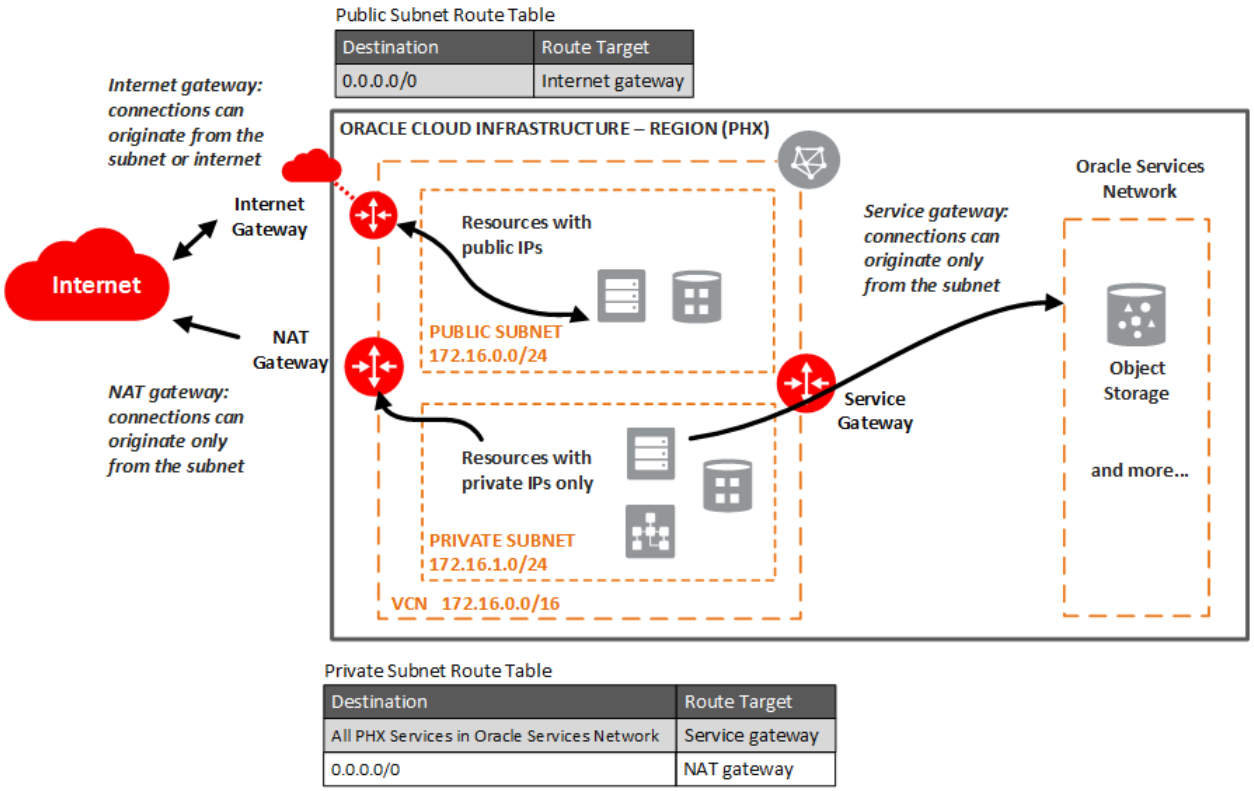
The following simple diagram illustrates a VCN that has both a public subnet and a private subnet. Resources in the private subnet have only private IP addresses.

The VCN has three gateways:

- **Internet gateway:** To provide the public subnet direct access to public endpoints on the internet. Connections can be initiated from the subnet or from the internet. The resources in the public subnet must have public IP addresses. For more information, see Internet Gateway.
- **Service gateway:** To provide the private subnet with private access to supported Oracle services within the region. Connections can be initiated only from the subnet.

- **NAT gateway:** To provide the private subnet with private access to public endpoints on the internet. Connections can be initiated only from the subnet. For more information, see NAT Gateway.

You control routing in your VCN at the subnet level, so you can specify which subnets in your VCN use each gateway. In the diagram, the route table for the public subnet sends non-local traffic through the internet gateway. The route table for the private subnet sends traffic destined for the Oracle services through the service gateway. It sends all remaining traffic to the NAT gateway.



Important

See this known issue for information about configuring route rules with *service gateway* as the target on route tables associated with public subnets.

A service gateway can be used by resources in the gateway's own VCN. However, if the VCN is peered with another, resources in the other VCN cannot access the service gateway.

Resources in your on-premises network that is connected to the service gateway's VCN with FastConnect or VPN Connect can also use the service gateway. For more information, see Transit Routing: Private Access to Oracle Services.

Notice that your on-premises network can *also* use FastConnect public peering for private access to public Oracle services. That means that your on-premises network could have multiple paths to access Oracle services public IP address ranges. If that is the case, your edge device receives route advertisement of the Oracle services public IP address ranges over multiple paths. For important information about configuring your edge device correctly, see Routing Details for Connections to Your On-Premises Network.

A VCN can have only one service gateway. For more information about limits, see Service Limits.

For instructions on setting up a service gateway, see Setting Up a Service Gateway in the Console.

About Service CIDR Labels

Each Oracle service has a regional public endpoint that uses public IP addresses for access. When you set up a service gateway with access to an Oracle service, you also set up Networking service route rules and optionally security rules that control traffic with the service. That means you need to know the service's public IP addresses to set up those rules. To make it easier for you, the Networking service uses *service CIDR labels* to represent all the public CIDRs for a given Oracle service or a group of Oracle services. If a service's CIDRs change in the future, you don't have to adjust your route rules or security rules.

Examples:

- **OCI PHX Object Storage** is a service CIDR label that represents all the Object Storage CIDRs in the US West (Phoenix) region.
- **All PHX Services in Oracle Services Network** is a service CIDR label that represents all the CIDRs for the supported services in the Oracle Services Network in the US West (Phoenix) region. For a list of the services, see Service Gateway: Supported Cloud Services in Oracle Services Network.

As you can see, a service CIDR label can be associated with either a single Oracle service (example: Object Storage), or multiple Oracle services.

The term *service* is often used in this topic in place of the more accurate term *service CIDR label*. The important thing to remember is that when you set up a service gateway (and related route rules), you specify the *service CIDR label* you're interested in. In the Console, you're presented with the available service CIDR labels. If you use the REST API, the ListServices operation returns the available `Service` objects. The `Service` object's `cidrBlock` attribute contains the service CIDR label (example: `all-phx-services-in-oracle-services-network`).

Available Service CIDR Labels

Here are the available service CIDR labels:

- **OCI *<region>* Object Storage:** For information about the service, see Overview of Object Storage
- **All *<region>* Services in Oracle Services Network:** For a list of supported services, see Service Gateway: Supported Cloud Services in Oracle Services Network.

Important

See this known issue for information about accessing Oracle YUM services through the service gateway.

Enabling a Service CIDR Label for a Service Gateway

To give your VCN access to a given service CIDR label, you must *enable* that service CIDR label for the VCN's service gateway. You can do that when you create the service gateway, or later after it's created. You can also disable a service CIDR label for the service gateway at any time.

Important

Because Object Storage is covered by both **OCI *<region>* Object Storage** and **All *<region>* Services in Oracle Services Network**, a service gateway can use **only one of those service CIDR labels**. Likewise, a route table can have a single rule for one of the service CIDR labels. It cannot have two separate rules, one for each label.

If the service gateway is configured to use **All *<region>* Services in Oracle Services Network**, the route rule can use either CIDR label. However, if the service gateway is configured to use **OCI *<region>* Object Storage** and the route rule uses **All *<region>* Services in Oracle Services Network**, traffic to services in the Oracle Services Network except Object Storage will be blackholed. The Console prohibits you from configuring the service gateway and corresponding route table in that manner.

If you want to switch the service gateway to use a different service CIDR label, see To switch to a different service CIDR label.

Blocking Traffic Through a Service Gateway

You create a service gateway in the context of a specific VCN. In other words, the service gateway is always attached to that one VCN. However, you can block or allow traffic through the service gateway at any time. By default, the gateway allows traffic flow upon creation. Blocking the service gateway traffic prevents all traffic from flowing, regardless of what service CIDR labels are enabled, or any existing route rules or security rules in your VCN. For instructions on how to block traffic, see To block or allow traffic for a service gateway.

Route Rules and Security Rules for a Service Gateway

For traffic to be routed from a subnet in your VCN to a service gateway, you must add a rule accordingly to the subnet's route table. The rule must use the service gateway as the target. For the destination, you must use the service CIDR label that is enabled for the service gateway. This means that you don't have to know the specific public CIDRs, which could change over time.

Any traffic leaving the subnet and destined for the service's public CIDRs is then routed to the service gateway. If the service gateway traffic is blocked, no traffic flows through it even if there's a route rule that matches the traffic. For instructions on setting up route rules for a service gateway, see Task 2: Update routing for the subnet.

The VCN's security rules must also allow the desired traffic. If you like, you can use a service CIDR label instead of a CIDR for the source or destination of the desired traffic. Again, this means that you don't have to know the specific public CIDRs for the service. For convenience, you can use a service CIDR label in security rules even if your VCN doesn't have a service gateway, and the traffic to the services uses an internet gateway.

You can use stateful or stateless security rules that use a service CIDR label:

- **For stateful rules:** Create an egress rule with the destination service = the service CIDR label of interest. As with any security rule, you can specify other items such as the IP protocol and source and destination ports.
- **For stateless rules:** You must have both egress and ingress rules. Create an egress rule with the destination service = the service CIDR label of interest. Also create an ingress rule with the source service = the service CIDR label of interest. As with any

security rule, you can specify other items such as the IP protocol and source and destination ports.

For instructions on setting up security rules that use a service CIDR label, see Task 3: (Optional) Update security rules.

Object Storage: Allowing Bucket Access from Only a Particular VCN or CIDR Range

If you use a service gateway to access Object Storage, you can write an IAM policy that allows access to a particular Object Storage bucket only if these requirements are met:

- The request goes through a service gateway.
- The request originates from the particular VCN or CIDR (for example, a subnet within a VCN) that is specified in the policy.

For examples of this particular type of IAM policy, and important caveats about its use, see Task 4: (Optional) Update IAM Policies to Restrict Object Storage Bucket Access.

Deleting a Service Gateway

To delete a service gateway, its traffic does not have to be blocked, but there must not be a route table that lists it as a target. See To delete a service gateway.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: see IAM Policies for Networking.

Setting Up a Service Gateway in the Console

Following is the process for setting up a service gateway. It assumes that you already have a VCN with a subnet (either private or public).

Important

The service gateway allows access to supported Oracle services within the region to protect your data from the internet. Your applications may require access to public endpoints or services not supported by the service gateway (for example, to download updates or patches). Ensure you have a NAT gateway or other access to the internet if necessary.

Task 1: Create the service gateway

1. In the Console, confirm you're viewing the compartment that contains the VCN that you want to add the service gateway to. For information about compartments and access control, see Access Control.
2. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
3. Click the VCN you're interested in.
4. On the left side of the page, click **Service Gateways**.
5. Click **Create Service Gateway**.
6. Enter the following values:
   - **Name:** A descriptive name for the service gateway. It doesn't have to be unique. Avoid entering confidential information.
   - **Create in compartment**: The compartment where you want to create the service gateway, if different from the compartment you're currently working in.

- **Services:** Optionally select the service CIDR label you're interested in. If you don't select one now, you can later update the service gateway and add a service CIDR label then. Without at least one service CIDR label enabled for the gateway, no traffic flows through it.
- **Tags:** Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.

7. Click **Create Service Gateway**.
   The service gateway is then created and displayed on the **Service Gateways** page in the compartment you chose. The gateway allows traffic through it by default. At any time, you can block or allow the traffic through it.

Task 2: Update routing for the subnet

When you configure a service gateway for a particular service CIDR label, you must also create a route rule that specifies that label as the destination and the target as the service gateway. You do this for each subnet that needs to access the gateway.

1. Determine which subnets in your VCN need access to the service gateway.
2. For each of those subnets, update the subnet's route table to include a new rule:
   a. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
   b. Click the VCN you're interested in.
   c. Under **Resources**, click **Route Tables**.
   d. Click the route table you're interested in.
   e. Click **Edit Route Rules.**
   f. Click **Add Route Rule** and enter the following values:

- **Target Type:** Service Gateway.
- **Destination Service:** The service CIDR label that is enabled for the gateway.
- **Compartment:** The compartment where the service gateway is located.
- **Target:** The service gateway.

g. Click **Save**.

Any subnet traffic with a destination that matches the rule is routed to the service gateway. For more information about setting up route rules, see Route Tables.

Later, if you no longer need the service gateway and want to delete it, you must first delete all the route rules in your VCN that specify the service gateway as the target.

Tip

Without the required routing, traffic doesn't flow over the service gateway. If a situation occurs where you want to temporarily stop the traffic flow over the gateway to a particular service, you can simply remove the route rule that enables traffic. You can also disable that particular service CIDR label for the gateway. Or you can block all traffic through the service gateway entirely. You do not have to delete the gateway.

Task 3: (Optional) Update security rules

When you configure a service gateway to access a service CIDR label, you must also ensure that the security rules are configured to allow the desired traffic. Your security rules might already allow this traffic, which is why this task is optional. The following procedure assumes you are using security lists to implement your security rules. The procedure describes how to set up a rule that uses the service CIDR label. You do this for each subnet that needs to access

the gateway.

Tip

Security lists are one way to control traffic in and out of the VCN's resources. You can also use network security groups, which let you apply a set of security rules to a set of resources that all have the same security posture.

1. Determine which subnets in your VCN need to connect to the services you're interested in.
2. Update the security list for each of those subnets to include rules to allow the desired egress or ingress traffic with the particular service:
    a. In the Console, while viewing the VCN you're interested in, click **Security Lists**.
    b. Click the security list you're interested in.
    c. Click **Edit All Rules** and create one or more rules, each for the specific type of traffic you want to allow. See the following example for more details.

Example

Let's say you want to add a stateful rule that enables egress HTTPS (TCP port 443) traffic from the subnet to both Object Storage and Oracle YUM repos. Here are the basic steps you take when adding a rule:

i. In the **Allow Rules for Egress** section, click **+Add Rule**.
ii. Leave the **Stateless** check box unselected.
iii. **Destination Type:** Service.
iv. **Destination Service:** The service CIDR label that you're interested in. To access both Object Storage and Oracle YUM repos, it's **All *<region>* Services in Oracle Services Network**.

v. **IP Protocol:** Leave as TCP.

vi. **Source Port Range:** Leave as All.

vii. **Destination Port Range**: Enter 443.

d. Click **Save Security List Rules** at the bottom of the dialog box.

For more information about setting up security rules, see Security Rules.

Task 4: (Optional) Update IAM Policies to Restrict Object Storage Bucket Access

This task is applicable only if you're using a service gateway to access Object Storage. You can optionally write an IAM policy to allow only the resources in a specific VCN to write objects to a particular bucket.

Important

If you use one of the following IAM policies to restrict access to a bucket, the bucket is *not accessible from the Console*. It's accessible only from within the specific VCN or CIDR block.

Also, the IAM policies allow requests to Object Storage only if they go from the specified VCN or CIDR block *through the service gateway*. If they go through the internet gateway, the requests are denied.

The following example lets resources in the example ObjectBackup group write objects to an existing bucket called db-backup that resides in a compartment called ABC.

```
Allow group ObjectBackup to read buckets in compartment ABC

Allow group ObjectBackup to manage objects in compartment ABC where
   all {target.bucket.name='db-backup',
```

```
        request.vcn.id='<VCN_OCID>',
        any {request.permission='OBJECT_CREATE', request.permission='OBJECT_INSPECT'}}
```

In addition to specifying a VCN's OCID, you can specify an IP address or ranges of addresses within the VCN. For example, the next version of the policy includes a `request.ipv4.ipaddress` variable with a value of 10.0.1.0/24. If the resource making the request has an IP address that is not in this CIDR block, the request is denied.

```
Allow group ObjectBackup to read buckets in compartment ABC

Allow group ObjectBackup to manage objects in compartment ABC where
   all {target.bucket.name='db-backup',
        request.vcn.id='<VCN_OCID>',
        request.ipv4.ipaddress in ['10.0.1.0/24'],
        any {request.permission='OBJECT_CREATE', request.permission='OBJECT_INSPECT'}}
```

You can specify multiple VCNs in the policy. The next example has OCIDs for two VCNs. You might do this if you've set up your on-premises network with private access to Oracle services through a VCN, and you've also set up one or more *other* VCNs with their own service gateways. For more information, see Multiple VCNs with Private Access to Oracle Services.

```
Allow group ObjectBackup to read buckets in compartment ABC

Allow group ObjectBackup to manage objects in compartment ABC where
   all {target.bucket.name='db-backup',
        any {request.vcn.id='<VCN_OCID_1>', request.vcn.id='<VCN_OCID_2>'},
        any {request.permission='OBJECT_CREATE', request.permission='OBJECT_INSPECT'}}
```

Managing a Service Gateway in the Console

To create a service gateway

See the instructions in Task 1: Create the service gateway.

To switch to a different service CIDR label

To avoid disrupting your Object Storage connections while switching between the **OCI**

<region> **Object Storage** service CIDR label and **All *<region>* Services in Oracle Services Network**, use the following process:

1. Update the service gateway: Remove the existing service CIDR label, and then add the one you want to switch to. You can't enable both labels for the service gateway.
2. Update relevant route rules: For each rule that uses the service gateway as the target, switch the rule's destination service from the existing service CIDR label to the one you want to switch to.
3. Update relevant security rules: Change any security rules that specify the existing service CIDR label to instead use the one you want to switch to. The rules can be in network security groups or security lists.

If you instead delete your existing service gateway and create a new one, your Object Storage connections will be disrupted. Remember that before you can delete a service gateway, you must delete any route rules that specify that gateway as a target.

To update a service gateway

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Click **Service Gateways**.
4. For the service gateway you're interested in, click the Actions icon (three dots), and then click **Edit**.
5. Make your changes and click **Save**.

To block or allow traffic for a service gateway

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.

3. Click **Service Gateways**.
4. For the service gateway you're interested in, click the Actions icon (three dots), and then click **Block Traffic** (or **Allow Traffic** if you're enabling traffic for the service gateway).
   When the traffic is blocked, the service gateway's icon turns gray, and the label changes to BLOCKED. When the traffic is allowed, the service gateway's icon turns green, and the label changes to AVAILABLE.

To associate a route table with an existing service gateway

You perform this task only if you're implementing an advanced transit routing scenario.

A service gateway can exist without a route table associated with it. However, after you associate a route table with a service gateway, there must always be a route table associated with it. But, you can associate a *different* route table. You can also edit the table's rules, or delete some or all of the rules.

Prerequisite: The route table must exist and belong to the VCN that the service gateway belongs to.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Under **Resources**, click **Service Gateways**.
4. For the service gateway you're interested in, click the Actions icon (•••), and then click either:
   - **Associate With Route Table:** If the service gateway has no route table associated with it yet.
   - **Associate Different Route Table:** If you're changing which route table is associated with the service gateway.
5. Select the compartment where the route table resides, and select the route table itself.
6. Click **Associate**.

To delete a service gateway

Prerequisite: The service gateway does not have to block traffic, but there must not be a route table that lists it as a target.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Click **Service Gateways**.
4. For the service gateway you're interested in, click the Actions icon (three dots), and then click **Delete**.
5. Confirm when prompted.

To manage tags for a service gateway

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. For the service gateway you're interested in, click the Actions icon (three dots), and then click **View Tags**. From there you can view the existing tags, edit them, and apply new ones.

For more information, see Resource Tags.

To move a service gateway to a different compartment

You can move a service gateway from one compartment to another. When you move a service gateway to a new compartment, inherent policies apply immediately.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.

3. In **Resources**, click **Service Gateways**.
4. Find the service gateway in the list, click the the Actions icon (three dots), and then click **Move Resource**.
5. Choose the destination compartment from the list.
6. Click **Move Resource**.

The service gateway moves to the new compartment immediately. Depending on your permissions, you can select the compartment in the left side menu to view the service gateway.

For more information about using compartments and policies to control access to your cloud network, see Access Control. For general information about compartments, see Managing Compartments.

Managing a Service Gateway with the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Warning

If anyone in your organization implements a service gateway, be aware that you **may need to update any client code that works with Networking service route rules and security lists**. There are possible breaking API changes. For more information, see the service gateway release notes.

To manage your service gateways, use these operations:

- ListServiceGateways
- CreateServiceGateway

- GetServiceGateway
- UpdateServiceGateway
- DeleteServiceGateway
- ChangeServiceGatewayCompartment
- ListServices: Use this to determine the available service CIDR labels.
- GetService: Gets the details for a particular service CIDR label.
- AttachServiceId: Enables a service CIDR label for a service gateway.
- DetachServiceId: Disables a service CIDR label for a service gateway.

To manage route tables, see Route Tables. To manage security lists, see Security Lists. To manage network security groups, see Network Security Groups. To manage IAM policies, see Managing Policies.

Access to Other VCNs: Peering

VCN peering is the process of connecting multiple virtual cloud networks (VCNs). There are two types of VCN peering:

- Local VCN peering (within region)
- Remote VCN peering (across regions)

You can use VCN peering to divide your network into multiple VCNs (for example, based on departments or lines of business), with each VCN having direct, private access to the others. There's no need for traffic to flow over the internet or through your on-premises network by way of an IPSec VPN or FastConnect. You can also place shared resources into a single VCN that all the other VCNs can access privately.

Because remote VCN peering crosses regions, you can use it (for example) to mirror or back up your databases in one region to another.

Important Implications of Peering

This section summarizes some access control, security, and performance implications for peered VCNs. In general, you can control access and traffic between two peered VCNs by using IAM policies, route tables in each VCN, and security lists in each VCN.

Controlling the Establishment of Peerings

With IAM policies, you can control:

- Who can subscribe your tenancy to another region (required for remote VCN peering).
- Who in your organization has the authority to establish VCN peerings (for example, see the IAM policies in Setting Up a Local Peering and Setting Up a Remote Peering). Be aware that deletion of these IAM policies does not affect any existing peerings, only the ability for future peerings to be created.
- Who can manage route tables and security lists.

Controlling Traffic Flow Over the Connection

Even if a peering connection has been established between your VCN and another, you can control the packet flow over the connection with route tables in your VCN. For example, you can restrict traffic to only specific subnets in the other VCN.

Without terminating the peering, you can stop traffic flow to the other VCN by simply removing route rules that direct traffic from your VCN to the other VCN. You can also effectively stop the traffic by removing any security list rules that enable ingress or egress traffic with the other VCN. This doesn't stop traffic flowing over the peering connection, but stops it at the VNIC level.

For more information about the routing and security lists, see the discussions in these sections:

Local VCN peering:

- Important Local Peering Concepts
- Task E: Configure the route tables

- Task F: Configure the security rules

Remote VCN peering:

- Important Remote Peering Concepts
- Task E: Configure the route tables
- Task F: Configure the security rules

Controlling the Specific Types of Traffic Allowed

It's important that each VCN administrator ensure that all outbound and inbound traffic with the other VCN is intended/expected and well defined. In practice, this means implementing security list rules that explicitly state the types of traffic your VCN can send to the other and accept from the other.

Important

Your instances running Oracle-provided Linux images or Windows images also have OS firewall rules that control access to the instance. When troubleshooting access to an instance, make sure that all of the following items are set correctly:

- The rules in the network security groups that the instance is in
- The rules in the security lists associated with the instance's subnet
- The instance's OS firewall rules

For more information, see Oracle-Provided Images.

If your instance is running Oracle Linux 7, you need to use firewalld to interact with the iptables rules. For your reference, here are commands for opening a port (1521 in this example):

```
sudo firewall-cmd --zone=public --permanent --add-
port=1521/tcp

sudo firewall-cmd --reload
```

For instances with an iSCSI boot volume, the preceding `--reload` command can cause problems. For details and a workaround, see Instances experience system hang after running firewall-cmd --reload.

In addition to security lists and firewalls, you should evaluate other OS-based configuration on the instances in your VCN. There could be default configurations that don't apply to your own VCN's CIDR, but inadvertently apply to the other VCN's CIDR.

Using Default Security List Rules

If your VCN's subnets use the default security list with the default rules it comes with, be aware that there are two rules that allow ingress traffic from anywhere (that is, 0.0.0.0/0, and thus the other VCN):

- Stateful ingress rule that allows TCP port 22 (SSH) traffic from 0.0.0.0/0 and any source port
- Stateful ingress rule that allows ICMP type 3, code 4 traffic from 0.0.0.0/0 and any source port

Make sure to evaluate these rules and whether you want to keep or update them. As stated earlier, you should ensure that all inbound or outbound traffic that you permit is intended/expected and well defined.

Preparing for Performance Impact and Security Risks

In general, you should prepare your VCN for the ways it could be affected by the other VCN. For example, the load on your VCN or its instances could increase. Or your VCN could experience a malicious attack directly from or by way of the other VCN.

Regarding performance: If your VCN is providing a service to another, be prepared to scale up your service to accommodate the demands of the other VCN. This might mean being prepared to launch additional instances as necessary. Or if you're concerned about high levels of network traffic coming to your VCN, consider using stateless security list rules to limit the level of connection tracking your VCN must perform. Stateless security list rules can also help slow the impact of a denial-of-service (DoS) attack.

Regarding security risks: You can't necessarily control whether the other VCN is connected to the internet. If it is, be aware that your VCN can be exposed to bounce attacks in which a malicious host on the internet can send traffic to your VCN but make it look like it's coming from the VCN you're peered with. To guard against this, as mentioned earlier, use your security lists to carefully limit the inbound traffic from the other VCN to expected and well-defined traffic.

Local VCN Peering (Within Region)

This topic is about *local VCN peering.* In this case, *local* means that the VCNs reside *in the same region.* If the VCNs are in different regions, see Remote VCN Peering (Across Regions).

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Overview of Local VCN Peering

Local VCN peering is the process of connecting two VCNs in the same region so that their resources can communicate using private IP addresses without routing the traffic over the internet or through your on-premises network. The VCNs can be in the same Oracle Cloud Infrastructure tenancy or different ones. Without peering, a given VCN would need an internet gateway and public IP addresses for the instances that need to communicate with another VCN.

For more information, see Access to Other VCNs: Peering.

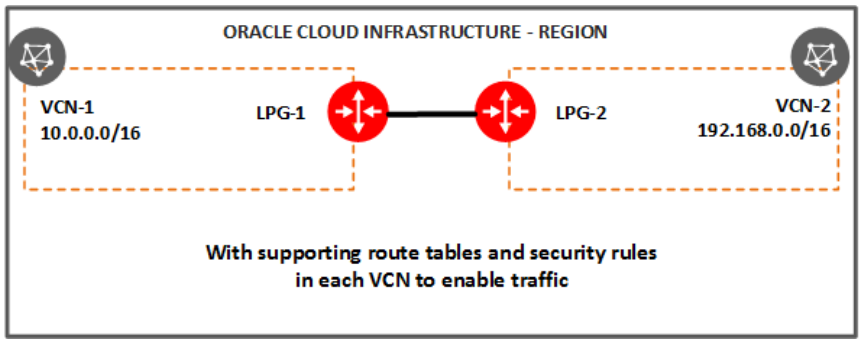
Summary of Networking Components for Peering

At a high level, the Networking service components required for a local peering include:

- Two VCNs with non-overlapping CIDRs, in the same region
- A *local peering gateway (LPG)* on each VCN in the peering relationship.
- A *connection* between those two LPGs.
- Supporting route rules to enable traffic to flow over the connection, and only to and from select subnets in the respective VCNs (if desired).

- Supporting security rules to control the types of traffic allowed to and from the instances in the subnets that need to communicate with the other VCN.

The following diagram illustrates the components.



Note

A given VCN can use the peered LPGs to reach these resources:

- VNICs in the other VCN
- An on-premises network attached to the other VCN, if an advanced routing scenario called transit routing has been set up for the VCNs

A VCN can't use its peered VCN to reach other destinations outside of the VCNs (such as the internet). For example, if VCN-1 in the preceding diagram were to have an internet gateway, the instances in VCN-2 could not use it to send traffic to endpoints on the internet. However, be aware that VCN-2 could *receive* traffic from the internet by way of VCN-1. For more information, see Important Implications of VCN Peering.

Explicit Agreement Required from Both Sides

Peering involves two VCNs that might be owned by the same party or two different ones. The two parties might both be in your company but in different departments. Or the two parties might be in entirely different companies (for example, in a service-provider model).

Peering between two VCNs requires explicit agreement from both parties in the form of Oracle Cloud Infrastructure Identity and Access Management policies that each party implements for their own VCN's compartment or tenancy. If the VCNs are in different tenancies, each administrator must provide their tenancy OCID and put in place special policy statements to enable the peering.

Advanced Scenario: Transit Routing

There's an advanced routing scenario called transit routing that enables communication between an on-premises network and multiple VCNs over a *single* Oracle Cloud Infrastructure FastConnect or IPSec VPN. The VCNs must be in the same region and locally peered in a hub-and-spoke layout. As part of the scenario, the VCN that is acting as the hub has a route table *associated with each LPG* (typically route tables are associated with a VCN's subnets).

When you create an LPG, you can optionally associate a route table with it. Or if you already have an existing LPG without a route table, you can associate a route table with it. The route table must belong to the LPG's VCN. A route table associated with an LPG can contain only rules that use the VCN's attached DRG as the target.

An LPG can exist without a route table associated with it. However, after you associate a route table with an LPG, there must always be a route table associated with it. But, you can associate a *different* route table. You can also edit the table's rules, or delete some or all of the rules.

Important Local Peering Concepts

The following concepts help you understand the basics of VCN peering and how to establish a local peering.

PEERING

A *peering* is a single peering relationship between two VCNs. Example: If VCN-1 peers with three other VCNs, then there are three peerings. The *local* part of *local peering* indicates that the VCNs are in the same region. A given VCN can have a maximum of ten local peerings at a time.

Warning

The two VCNs in the peering relationship must not have overlapping CIDRs. However, if VCN-1 is peered with three other VCNs, those three VCNs can have overlapping CIDRs with each other. You would set up the subnets in VCN-1 to have route rules that direct traffic to the targeted peered VCN.

VCN ADMINISTRATORS

In general, VCN peering can occur only if both of the VCN administrators agree to it. In practice, this means that the two administrators must:

- Share some basic information with each other.
- Coordinate to set up the required Oracle Cloud Infrastructure Identity and Access Management policies to enable the peering.
- Configure their VCNs for the peering.

Depending on the situation, a single administrator might be responsible for both VCNs and the related policies.

For more information about the required policies and VCN configuration, see Setting Up a Local Peering.

ACCEPTOR AND REQUESTOR

To implement the IAM policies required for peering, the two VCN administrators must designate one administrator as the *requestor* and the other as the *acceptor*. The requestor must be the one to initiate the request to connect the two LPGs. In turn, the acceptor must create a particular IAM policy that gives the requestor permission to connect to LPGs in the acceptor's compartment. Without that policy, the requestor's request to connect fails.

LOCAL PEERING GATEWAY (LPG)

A *local peering gateway (LPG)* is a component on a VCN for routing traffic to a locally peered VCN. As part of configuring the VCNs, each administrator must create an LPG for their VCN. A given VCN must have a separate LPG for each local peering it establishes (maximum ten LPGs per VCN). To continue with the previous example: VCN-1 would have three LPGs to peer with three other VCNs. In the API, a LocalPeeringGateway is an object that contains information about the peering. You can't reuse an LPG to later establish another peering.

PEERING CONNECTION

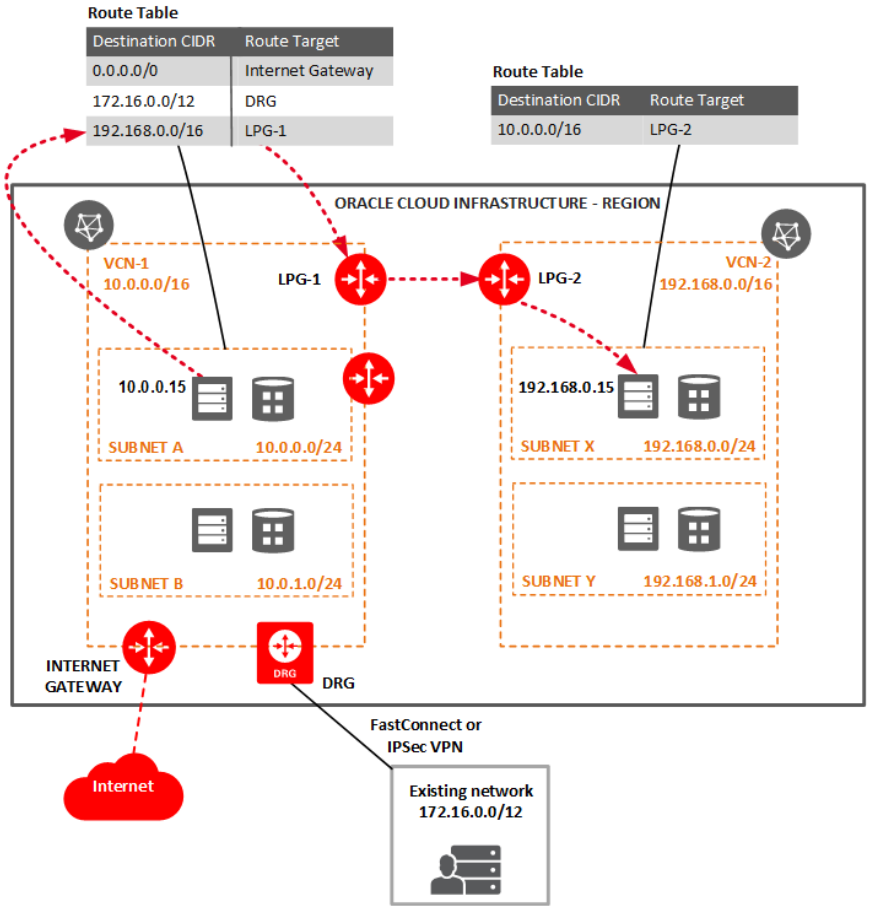
When the requestor initiates the request to peer (in the Console or API), they're effectively asking to *connect the two LPGs*. The requestor must have information to identify each LPG (such as the LPG's compartment and name, or the LPG's OCID). Each administrator must put the required IAM policies in place for their compartment or tenancy.

Either VCN administrator can terminate a peering by deleting their LPG. In that case, the other LPG's status switches to REVOKED. The administrator could instead render the connection non-functional by removing the route rules or security rules that enable traffic to flow across the connection (see the next sections).

ROUTING TO THE LPG

As part of configuring the VCNs, each administrator must update the VCN's routing to enable traffic to flow between the VCNs. In practice, this looks just like routing you set up for any gateway (such as an internet gateway or dynamic routing gateway). For each subnet that needs to communicate with the other VCN, you update the subnet's route table. The route rule specifies the destination traffic's CIDR and your LPG as the target. Your LPG routes traffic that matches that rule to the other LPG, which in turn routes the traffic to the next hop in the other VCN.

In the following diagram, VCN-1 and VCN-2 are peered. Traffic from an instance in Subnet A (10.0.0.15) that is destined for an instance in VCN-2 (192.168.0.15) is routed to LPG-1 based on the rule in Subnet A's route table. From there the traffic is routed to LPG-2, and then from there, on to its destination in Subnet X.



Note

As mentioned earlier, a given VCN can use the peered LPGs to reach VNICs in the other VCN, or the on-premises network if transit routing is set up for

the VCNs. But a VCN can't use the peered VCN to reach other destinations outside of the VCNs (such as the internet). For example, in the preceding diagram, VCN-2 cannot use the internet gateway attached to VCN-1.

SECURITY RULES

Each subnet in a VCN has one or more security lists that control traffic in and out of the subnet's VNICs at the packet level. You can use security lists to control the type of traffic allowed with the other VCN. As part of configuring the VCNs, each administrator must determine which subnets in their own VCN need to communicate with VNICs in the other VCN and update their subnet's security lists accordingly.

If you use network security groups (NSGs) to implement security rules, notice that you have the option to write security rules for an NSG that specify *another* NSG as the source or destination of traffic. However, the two NSGs *must belong to the same VCN*.

Important Implications of VCN Peering

If you haven't yet, read Important Implications of Peering to understand important access control, security, and performance implications for peered VCNs.

Setting Up a Local Peering

Here's the general process for setting up a peering between two VCNs in the same region:

A. **Create the LPGs:** Each VCN administrator creates an LPG for their own VCN.

B. **Share information:** The administrators share the basic required information.

C. **Set up the required IAM policies for the connection:** The administrators set up IAM policies to enable the connection to be established.

D. **Establish the connection:** The requestor connects the two LPGs.

E. **Update route tables:** Each administrator updates their VCN's route tables to enable traffic between the peered VCNs as desired.

F. **Update security rules:** Each administrator updates their VCN's security rules to enable traffic between the peered VCNs as desired.

If desired, the administrators can perform tasks E and F *before* establishing the connection. In that case, each administrator must know the CIDR block or specific subnets from the other's VCN and share that in task B. After the connection is established, you can also get the CIDR block of the other VCN by viewing your own LPG's details in the Console. Look for **Peer Advertised CIDR**. Or if you're using the API, see the `peerAdvertisedCidr` parameter.

Task A: Create the LPGs

Each administrator creates an LPG for their own VCN. "You" in the following procedure means an administrator (either the acceptor or requestor).

Note

Required IAM Policy to Create LPGs

If the administrators already have broad network administrator permissions (see Let network admins manage a cloud network), then they have permission to create, update, and delete LPGs. Otherwise, here's an example policy giving the necessary permissions to a group called LPGAdmins. The second statement is required because creating an LPG affects the VCN it belongs to, so the administrator must have permission to manage VCNs.

```
Allow group LPGAdmins to manage local-peering-gateways in
tenancy
Allow group LPGAdmins to manage vcns in tenancy
```

1. In the Console, confirm you're viewing the compartment that contains the VCN that you want to add the LPG to. For information about compartments and access control, see Access Control.
2. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
3. Click the VCN you're interested in.
4. Under **Resources**, click **Local Peering Gateways**.
5. Click **Create Local Peering Gateway**.
6. Enter the following:
   - **Name:** A friendly name for the LPG. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
   - **Create in compartment**: The compartment where you want to create the LPG, if different from the compartment you're currently working in.
   - **Associate with Route Table (optional)**: Only if you're setting up the advanced routing scenario called transit routing. Select the compartment that contains the route table you want to associate with the LPG, and the route table itself. You can skip this part and associate the LPG with a route table later if you like.
   - **Tags:** Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.
7. Click **Create Local Peering Gateway**.
   The LPG is then created and displayed on the **Local Peering Gateways** page in the compartment you chose.

Task B: Share information

If you're the **requestor**, give this information to the acceptor (for example, by email or other out-of-band method):

- If the VCNs are in the **same tenancy:** Name of the IAM group that should be granted permission to create a connection in the acceptor's compartment. In the example in the next task, the group is RequestorGrp.
- If the VCNs are in **different tenancies:** OCID for your tenancy, and OCID for the IAM group that should be granted permission to create a connection in the acceptor's compartment. In the example in the next task, it's the OCID for the RequestorGrp.
- Optional: Your VCN's CIDR, or specific subnets for peering with the other VCN.

If you're the **acceptor**, give this information to the requestor:

- If the VCNs are in the **same tenancy:** OCID for your LPG. Optionally, also the names of your VCN, LPG, and the compartment each is in.
- If the VCNs are in **different tenancies:** OCID for your LPG, and OCID for your tenancy.
- Optional: Your VCN's CIDR, or specific subnets for peering with the other VCN.

Task C: Set up the IAM policies (VCNs in same tenancy)

In this version of task C, both VCNs are in the same tenancy. If they're in different tenancies, instead see Task C: Set up the IAM policies (VCNs in different tenancies) .

Both the requestor and acceptor must ensure that the right policies are in place:

- **Policy R (implemented by the requestor):**

  ```
  Allow group RequestorGrp to manage local-peering-from in compartment RequestorComp
  ```

  The requestor is in an IAM group called RequestorGrp. This policy lets anyone in the group initiate a connection from any LPG in the requestor's compartment (RequestorComp). Policy R can be attached to either the tenancy (root compartment) or

to RequestorComp. For information about why you would attach it to one versus the other, see Policy Attachment.

- **Policy A (implemented by the acceptor):**

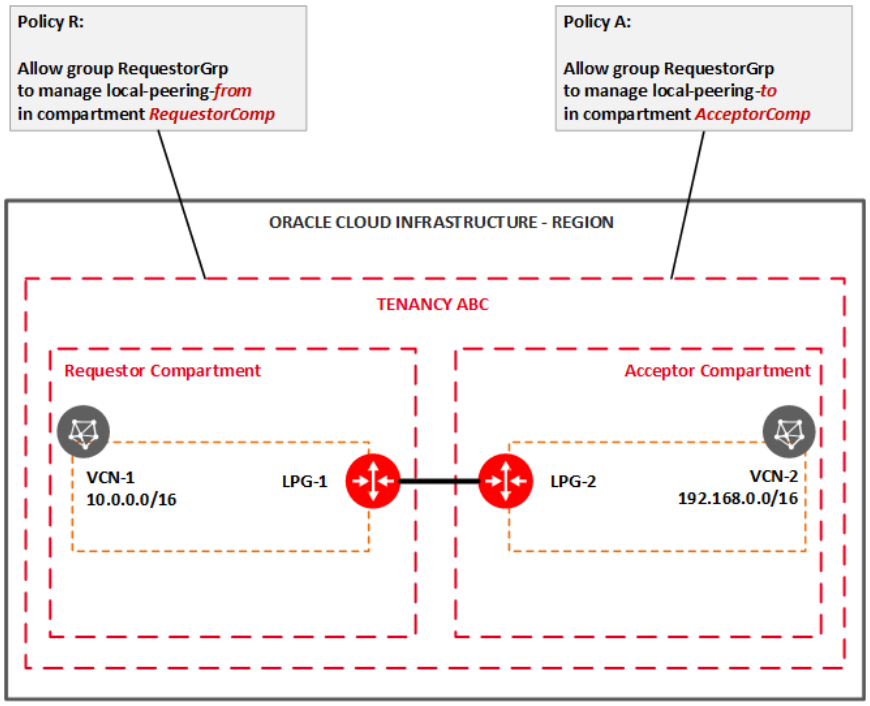
```
Allow group RequestorGrp to manage local-peering-to in compartment AcceptorComp

Allow group RequestorGrp to inspect vcns in compartment AcceptorComp
Allow group RequestorGrp to inspect local-peering-gateways in compartment AcceptorComp
```

The first statement in the policy lets the requestor connect to any LPG in the acceptor's compartment (AcceptorComp). This statement reflects the required agreement from the acceptor for the peering to be established. Policy A can be attached to either the tenancy (root compartment) or to AcceptorComp.

Tip

The second and third statements in Policy A let the requestor list the VCNs and LPGs in AcceptorComp. The statements are required for the requestor to use the Console UI to select from a list of VCNs and LPGs in AcceptorComp and establish the connection. The following diagram focuses only on the first statement, which is the critical one that permits the connection.



Both Policy R and Policy A give RequestorGrp access. However, Policy R has a resource-type called local-peering-*from*, and Policy A has a resource-type called local-peering-*to*. Together, these policies let someone in RequestorGrp establish the connection *from* an LPG in the requestor's compartment *to* an LPG in the acceptor's compartment. The API call to create the connection specifies which two LPGs.

Tip

The permission granted by Policy R might already be in place if the requestor has permission in another policy to manage all of the Networking components in RequesterComp. For example, there might be a general Network Admin policy like this:

```
Allow group NetworkAdmin to manage virtual-network-family in
compartment RequestorComp
```

If the requestor is in the NetworkAdmin group, then they already have the required permissions covered in Policy R (the virtual-network-family includes LPGs). And further, if the policy is instead written to cover the *entire tenancy* instead of only compartment RequestorComp, then the requestor already has all the required permissions in both compartments to establish the connection. In that case, policy A is not required.

Task C: Set up the IAM policies (VCNs in different tenancies)

In this version of task C, the VCNs are in different tenancies (in other words, it's a *cross-tenancy* peering). If the VCNs are in the same tenancy, instead see Task C: Set up the IAM policies (VCNs in same tenancy).

Both the requestor and acceptor must ensure that the right policies are in place:

- **Policy R (implemented by the requestor):**

```
Define tenancy Acceptor as <acceptor_tenancy_OCID>

Allow group RequestorGrp to manage local-peering-from in compartment RequestorComp
```

```
Endorse group RequestorGrp to manage local-peering-to in tenancy Acceptor

Endorse group RequestorGrp to associate local-peering-gateways in compartment RequestorComp
   with local-peering-gateways in tenancy Acceptor
```

The requestor is in an IAM group called RequestorGrp. This policy lets anyone in that group initiate a connection from any LPG in the requestor's compartment (RequestorComp).

The first statement is a "define" statement that assigns a friendly label to the acceptor's tenancy OCID. The statement happens to use "Acceptor" as the label, but it could be a value of the requestor's choice. **All "define" statements in a policy must be the first ones (at the top).**

The second statement lets the RequestorGrp establish a connection from an LPG in the requestor's compartment.

The third and fourth statements are special ones required because the LPGs are in different tenancies. They let the RequestorGrp connect an LPG in the requestor's tenancy to an LPG in the acceptor's tenancy.

If the desire is to give the RequestorGrp permission to connect to an LPG *in any tenancy*, the policy would instead look like this:

```
Allow group RequestorGrp to manage local-peering-from in compartment RequestorComp

Endorse group RequestorGrp to manage local-peering-to in any-tenancy

Endorse group RequestorGrp to associate local-peering-gateways in compartment RequestorComp
    with local-peering-gateways in any-tenancy
```

Regardless, Policy R must be attached to the requestor's tenancy (root compartment), and not the requestor's compartment. Policies that enable cross-tenancy access must be attached to the tenancy. For more information about attachment of policies, see Policy Attachment.

- **Policy A (implemented by the acceptor):**

```
Define tenancy Requestor as <requestor_tenancy_OCID>

Define group RequestorGrp as <RequestorGrp_OCID>
```

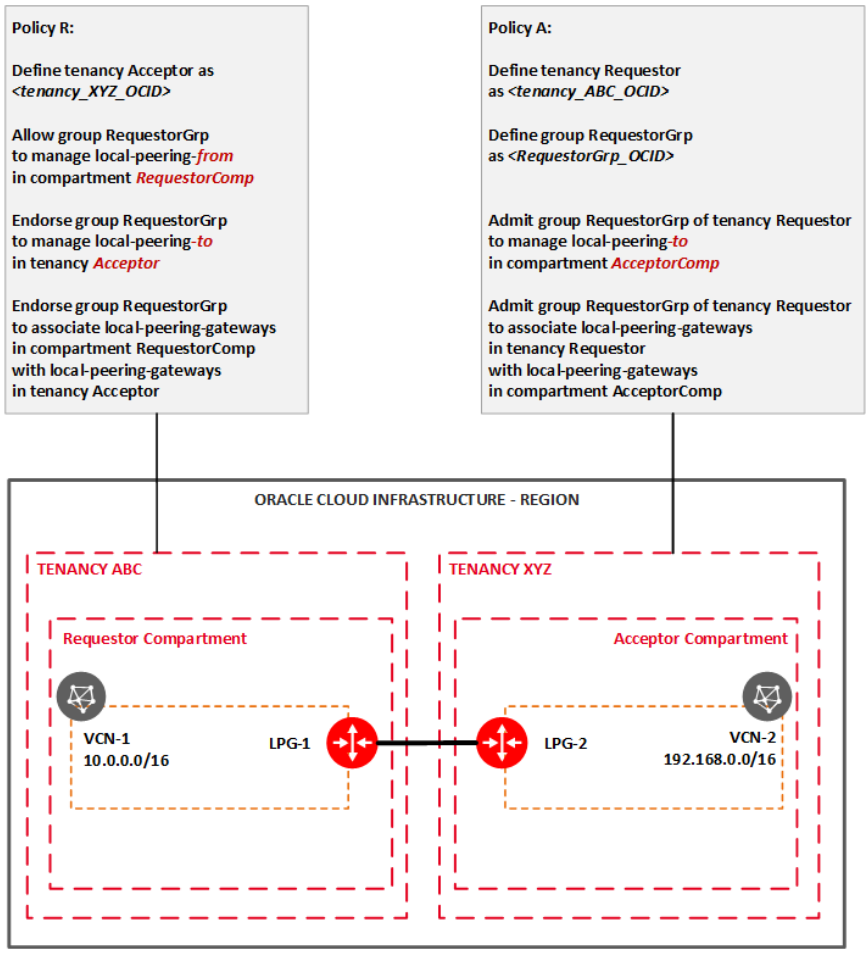
```
Admit group RequestorGrp of tenancy Requestor to manage local-peering-to in compartment
AcceptorComp

Admit group RequestorGrp of tenancy Requestor to associate local-peering-gateways in tenancy
Requestor
    with local-peering-gateways in compartment AcceptorComp
```

Similar to the requestor's policy, this policy first uses "define" statements to assign friendly labels to the requestor's tenancy OCID and the RequestorGrp OCID. As mentioned earlier, the acceptor could use other values for those labels if desired.

The third and fourth statements let the RequestorGrp connect to an LPG in the acceptor's compartment (AcceptorComp). **These statements reflect the critical agreement required for the peering to be established.** The word `Admit` indicates that the access applies to a group *outside the tenancy* where the policy resides.

Policy A must be attached to the acceptor's tenancy (root compartment), and not the acceptor's compartment.



Task D: Establish the connection

The requestor must perform this task.

Prerequisite: The requestor must have the OCID of the acceptor's LPG.

Tip

If you're using the Console and the peering is between two VCNs in the same tenancy: Instead of specifying the acceptor's LPG OCID, you can instead pick the acceptor's VCN and LPG from lists of resources in the tenancy. However, you need to know both the name and compartment for the acceptor's VCN and LPG instead of the LPG's OCID. For reference, see Task B: Share information.

1. In the Console, view the details for the requestor LPG that you want to connect to the acceptor LPG.
2. For the requestor LPG, click the Actions icon (three dots), and then click **Establish Peering Connection**.
3. Specify which LPG you want to peer with:
   - If the VCNs are in different tenancies: Select **Enter Local Peering Gateway OCID**, and enter the acceptor LPG's OCID.
   - If the VCNs are in the same tenancy: Do one of the following:
     - Select **Enter Local Peering Gateway OCID**, and enter the acceptor LPG's OCID.
     - Select **Browse Below**, and then select the acceptor's VCN and LPG from the lists provided. Remember that the VCN and LPG each might be in a different compartment than the one you're currently working in.
4. Click **Establish Peering Connection**.

The connection is established and the LPG's state changes to PEERED.

At this point, the details of each LPG update to show the **Peer VCN CIDR Block** for the other VCN. This is the CIDR of the other VCN across the peering from the LPG. Each administrator can use this information to update the route tables and security rules for their own VCN.

Task E: Configure the route tables

As mentioned earlier, each administrator can do this task before or after the connection is established.

Prerequisite: Each administrator must have the CIDR block or specific subnets for the other VCN. If the connection is already established, look at the **Peer VCN CIDR Block** for your LPG in the Console. Otherwise, get the information from the other administrator by email or other method.

For your own VCN:

1. Determine which subnets in your VCN need to communicate with the other VCN.
2. Update the route table for each of those subnets to include a new rule that directs traffic destined for the other VCN's CIDR to your LPG:
    a. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
    b. Click the VCN you're interested in.
    c. Under **Resources**, click **Route Tables**.
    d. Click the route table you're interested in.
    e. Click **Add Route Rule** and enter the following:
        - **Target Type:** Local Peering Gateway.
        - **Destination CIDR Block:** The other VCN's CIDR block. If you want, you can specify a subnet or particular subset of the peered VCN's CIDR.
        - **Target Compartment:** The compartment where the LPG is located, if not the current compartment.
        - **Target:** The LPG.
    f. Click **Add Route Rule**.

Any subnet traffic with a destination that matches the rule is routed to your LPG. For more information about setting up route rules, see Route Tables.

Later, if you no longer need the peering and want to delete your LPG, you must first delete all the route rules in your VCN that specify the LPG as the target.

Tip

Without the required routing, traffic doesn't flow between the peered LPGs. If a situation occurs where you need to temporarily stop the peering, you can simply remove the route rules that enable traffic. You don't need to delete the LPGs.

Task F: Configure the security rules

As mentioned earlier, each administrator can do this task before or after the connection is established.

Prerequisite: Each administrator must have the CIDR block or specific subnets for the other VCN. In general, you should use the same CIDR block you used in the route table rule in Task E: Configure the route tables.

What rules should you add?

- Ingress rules for the types of traffic you want to allow from the other VCN, specifically from the VCN's CIDR or specific subnets.
- Egress rule to allow outgoing traffic from your VCN to the other VCN. If the subnet already has a broad egress rule for all types of protocols to all destinations (0.0.0.0/0), then you don't need to add a special one for the other VCN.

Note

The following procedure uses security lists, but you could instead implement the security rules in a network security group and then create all of the subnet's resources in that NSG.

For your own VCN:

1. Determine which subnets in your VCN need to communicate with the other VCN.
2. Update the security list for each of those subnets to include rules to allow the desired egress or ingress traffic specifically with the CIDR block or subnet of the other VCN:
    a. In the Console, while viewing the VCN you're interested in, click **Security Lists**.
    b. Click the security list you're interested in.
    c. Under **Resources**, click either **Ingress Rules** or **Egress Rules** depending on the type of rule you want to work with.
    d. If you want to add a new rule, click **Add Ingress Rule** (or **Add Egress Rule**).

    ## Example

    Let's say you want to add a stateful rule that enables ingress HTTPS (port 443) traffic from the other VCN's CIDR. Here are the basic steps you take when adding a rule:

    i. Leave the **Stateless** check box unselected.
    ii. **Source Type:** Leave as CIDR.
    iii. **Source CIDR:** Enter the same CIDR block that the route rules use (see Task E: Configure the route tables).
    iv. **IP Protocol:** Leave as TCP.

v. **Source Port Range:** Leave as All.

vi. **Destination Port Range**: Enter 443.

e. If you want to delete an existing rule, click the Actions icon (three dots), and then click **Remove**.

f. If you wanted to edit an existing rule, click the Actions icon (three dots), and then click **Edit**.

For more information about security rules, see Security Rules.

Using the Console

To create a local peering gateway

See the instructions in Task A: Create the LPGs.

To associate a route table with an existing local peering gateway

This task is related to an advanced routing scenario called transit routing.

An LPG can exist without a route table associated with it. However, after you associate a route table with an LPG, there must always be a route table associated with it. But, you can associate a *different* route table. You can also edit the table's rules, or delete some or all of the rules.

Prerequisite: The route table must exist and belong to the VCN that the LPG belongs to.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Under **Resources**, click **Local Peering Gateways**.
4. For the LPG you're interested in, click the Actions icon (•••), and then click either:

- **Associate With Route Table:** If the LPG has no route table associated with it yet.
- **Replace Route Table Association:** If you're changing which route table is associated with the LPG.

5. Select the compartment where the route table resides, and select the route table itself.
6. Click **Associate**.

To delete a local peering gateway

Prerequisite: First delete all the route rules in your VCN that specify the LPG as the target. Deleting those rules stops the routing in your VCN to the LPG. However, the LPG's state may still be PEERED if the other LPG still exists. Whenever an LPG is deleted, the LPG at the other side of the peering changes to the REVOKED state.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Click **Local Peering Gateways**.
4. For the LPG you want to delete, click the Actions icon (three dots), and then click **Terminate**.
5. Confirm when prompted.

Note

After deleting an LPG (and thus terminating a peering), it's recommended you review your security rules to remove any rules that enabled traffic with the other VCN.

To manage tags for a local peering gateway

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Under **Resources**, click **Local Peering Gateways**.
4. Click the Actions icon (three dots) for the local peering gateway, and then click **View Tags**. From there you can view the existing tags, edit them, and apply new ones.

For more information, see Resource Tags.

To move a local peering gateway to a different compartment

You can move a local peering gateway from one compartment to another. When you move a local peering gateway to a new compartment, inherent policies apply immediately.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the VCN you're interested in.
3. Under **Resources**, click **Local Peering Gateways**.
4. Click the Actions icon (three dots) for the local peering gateway, and then click **Move Resource**.
5. Choose the destination compartment from the list.
6. Click **Move Resource**.

For more information about using compartments and policies to control access to your cloud network, see Access Control. For general information about compartments, see Managing Compartments.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

To manage your LPGs and create connections, use these operations:

- ListLocalPeeringGateways
- CreateLocalPeeringGateway
- GetLocalPeeringGateway
- UpdateLocalPeeringGateway
- DeleteLocalPeeringGateway
- ConnectLocalPeeringGateways
- ChangeLocalPeeringGatewayCompartment

Remote VCN Peering (Across Regions)

This topic is about *remote VCN peering.* In this case, *remote* means that the VCNs reside *in different regions.* If the VCNs you want to connect are in the same region, see Local VCN Peering (Within Region).

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Overview of Remote VCN Peering

Remote VCN peering is the process of connecting two VCNs in different regions (but the same tenancy). The peering allows the VCNs' resources to communicate using private IP addresses without routing the traffic over the internet or through your on-premises network. Without peering, a given VCN would need an internet gateway and public IP addresses for the instances that need to communicate with another VCN in a different region.

Summary of Networking Components for Remote Peering

At a high level, the Networking service components required for a remote peering include:

- Two VCNs with non-overlapping CIDRs, in different regions that support remote peering. The VCNs must be in the same tenancy.

  Note

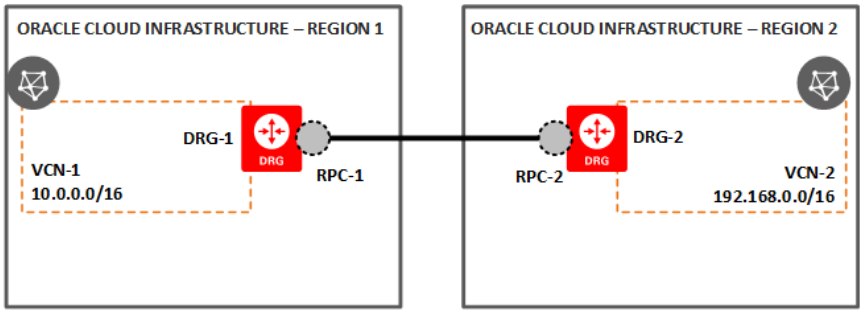
  All VCN CIDRs Must Not Overlap

  The two VCNs in the peering relationship must not have overlapping CIDRs. Also, if a particular VCN has multiple peering relationships, those other VCNs must not have overlapping CIDRs with each other. For example, if VCN-1 is peered with VCN-2 and also VCN-3, then VCN-2 and VCN-3 must not have overlapping CIDRs.

- A dynamic routing gateway (DRG) attached to each VCN in the peering relationship. Your VCN already has a DRG if you're using an IPSec VPN or an Oracle Cloud Infrastructure FastConnect private virtual circuit.
- A *remote peering connection (RPC)* on each DRG in the peering relationship.
- A *connection* between those two RPCs.

- Supporting route rules to enable traffic to flow over the connection, and only to and from select subnets in the respective VCNs (if desired).
- Supporting security rules to control the types of traffic allowed to and from the instances in the subnets that need to communicate with the other VCN.

The following diagram illustrates the components.



With supporting route tables and security rules in each VCN to enable traffic

Note

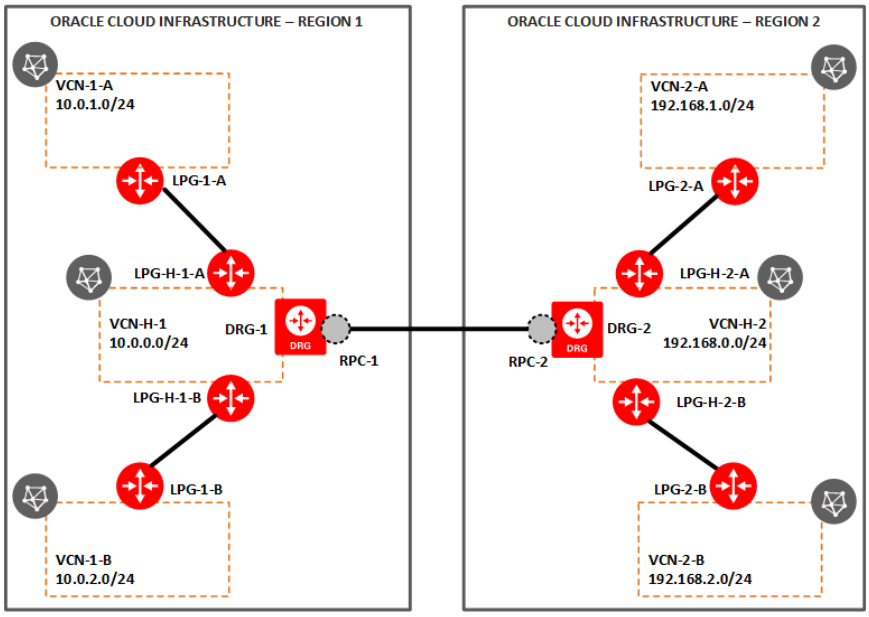
A given VCN can use the connected RPCs to reach only VNICs in the other VCN, and not destinations outside of the VCNs (such as the internet or your on-premises network). For example, if VCN-1 in the preceding diagram were to have an internet gateway, the instances in VCN-2 could NOT use it to send traffic to endpoints on the internet. However, be aware that VCN-2 could *receive* traffic from the internet via VCN-1. For more information, see Important Implications of Peering.

Spoke-to-Spoke: Remote Peering with Transit Routing

Imagine that in each region you have multiple VCNs in a hub-and-spoke layout, as shown in the following diagram. This type of layout within a region is discussed in detail in Transit Routing: Access to Multiple VCNs in the Same Region. The spoke VCNs in a given region are locally peered with the hub VCN in the same region, using local peering gateways.

You can set up remote peering between the two hub VCNs. You can then also set up transit routing for the hub VCN's DRG and LPGs, as discussed in Transit Routing: Access to Multiple VCNs in the Same Region. This setup allows a spoke VCN in one region to communicate with one or more spoke VCNs in the other region without needing a remote peering connection directly between those VCNs.

For example, you could configure routing so that resources in VCN-1-A could communicate with resources in VCN-2-A and VCN-2-B by way of the hub VCNs. That way, VCN 1-A is not required to have a *separate* remote peering with each of the spoke VCNs in the other region. You could also set up routing so that VCN-1-B could communicate with the spoke VCNs in region 2, without needing its own remote peerings to them.



Explicit Agreement Required from Both Sides

Peering involves two VCNs in the same tenancy that might be administered by the same party or two different ones. The two parties might both be in your company but in different departments.

Peering between two VCNs requires explicit agreement from both parties in the form of Oracle Cloud Infrastructure Identity and Access Management policies that each party implements for their own VCN's compartment.

Important Remote Peering Concepts

The following concepts help you understand the basics of VCN peering and how to establish a remote peering.

PEERING

A *peering* is a single peering relationship between two VCNs. Example: If VCN-1 peers with two other VCNs, then there are two peerings. The *remote* part of *remote peering* indicates that the VCNs are in different regions. For remote peering, the VCNs must be in the same tenancy.

VCN ADMINISTRATORS

In general, VCN peering can occur only if both of the VCN administrators agree to it. In practice, this means that the two administrators must:

- Share some basic information with each other.
- Coordinate to set up the required Oracle Cloud Infrastructure Identity and Access Management policies to enable the peering.
- Configure their VCNs for the peering.

Depending on the situation, a single administrator might be responsible for both VCNs and the related policies. The VCNs must be in the same tenancy.

For more information about the required policies and VCN configuration, see Setting Up a Remote Peering.

ACCEPTOR AND REQUESTOR

To implement the IAM policies required for peering, the two VCN administrators must designate one administrator as the *requestor* and the other as the *acceptor*. The requestor must be the one to initiate the request to connect the two RPCs. In turn, the acceptor must create a particular IAM policy that gives the requestor permission to connect to RPCs in the acceptor's compartment. Without that policy, the requestor's request to connect fails.

REGION SUBSCRIPTION

To peer with a VCN in another region, your tenancy must first be subscribed to that region. For information about subscribing, see Managing Regions.

REMOTE PEERING CONNECTION (RPC)

A *remote peering connection (RPC)* is a component you create on the DRG attached to your VCN. The RPC's job is to act as a connection point for a remotely peered VCN. As part of configuring the VCNs, each administrator must create an RPC for the DRG on their VCN. A given DRG must have a separate RPC for each remote peering it establishes for the VCN (maximum 10 RPCs per tenancy). To continue with the previous example: the DRG on VCN-1 would have two RPCs to peer with two other VCNs. In the API, a RemotePeeringConnection is an object that contains information about the peering. You can't reuse an RPC to later establish another peering with it.

CONNECTION BETWEEN TWO RPCS

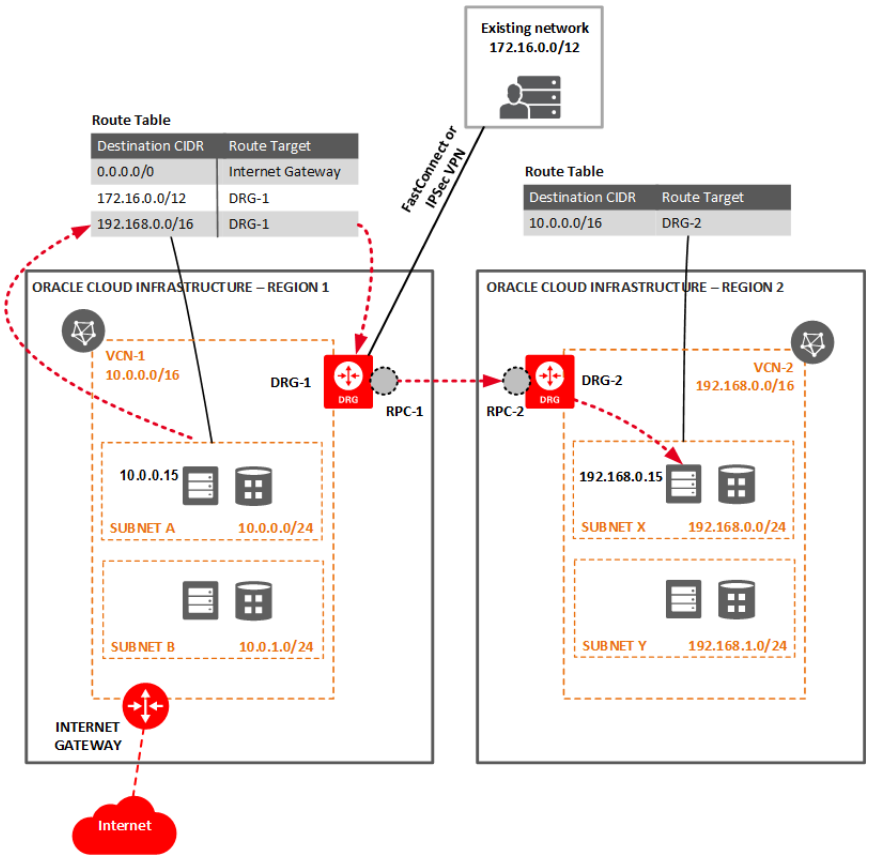
When the requestor initiates the request to peer (in the Console or API), they're effectively asking to *connect the two RPCs*. This means the requestor must have information to identify each RPC (such as the RPC's region and OCID).

Either VCN administrator can terminate a peering by deleting their RPC. In that case, the other RPC's status switches to REVOKED. The administrator could instead render the connection non-functional by removing the route rules that enable traffic to flow across the connection (see the next section).

ROUTING TO THE DRG

As part of configuring the VCNs, each administrator must update the VCN's routing to enable traffic to flow between the VCNs. For each subnet that needs to communicate with the other VCN, you update the subnet's route table. The route rule specifies the destination traffic's CIDR and your DRG as the target. Your DRG routes traffic that matches that rule to the other DRG, which in turn routes the traffic to the next hop in the other VCN.

In the following diagram, VCN-1 and VCN-2 are peered. Traffic from an instance in Subnet A (10.0.0.15) that is destined for an instance in VCN-2 (192.168.0.15) is routed to DRG-1 based on the rule in Subnet A's route table. From there the traffic is routed through the RPCs to DRG-2, and then from there, on to the destination in Subnet X.



Note

As mentioned earlier, a given VCN can use the connected RPCs to reach only VNICs in the other VCN, and not destinations outside of the VCNs (such as the internet or your on-premises network). For example, in the preceding diagram, VCN-2 cannot

use the internet gateway attached to VCN-1.

SECURITY RULES

Each subnet in a VCN has one or more security lists that control traffic in and out of the subnet's VNICs at the packet level. You can use security lists to control the type of traffic allowed with the other VCN. As part of configuring the VCNs, each administrator must determine which subnets in their own VCN need to communicate with VNICs in the other VCN and update their subnet's security lists accordingly.

If you use network security groups (NSGs) to implement security rules, notice that you have the option to write security rules for an NSG that specify *another* NSG as the source or destination of traffic. However, the two NSGs *must belong to the same VCN*.

Important Implications of Peering

If you haven't yet, read Important Implications of Peering to understand important access control, security, and performance implications for peered VCNs.

Setting Up a Remote Peering

This section covers the general process for setting up a peering between two VCNs in different regions.

Important

The following procedure assumes that:

- Your tenancy is subscribed to the other VCN's region. If it's not, see Managing Regions.
- You already have a DRG attached to your VCN. If you don't, see Dynamic Routing Gateways (DRGs).

A. **Create the RPCs:** Each VCN administrator creates an RPC for their own VCN's DRG.
B. **Share information:** The administrators share the basic required information.
C. **Set up the required IAM policies for the connection:** The administrators set up IAM policies to enable the connection to be established.
D. **Establish the connection:** The requestor connects the two RPCs.
E. **Update route tables:** Each administrator updates their VCN's route tables to enable traffic between the peered VCNs as desired.
F. **Update security rules:** Each administrator updates their VCN's security rules to enable traffic between the peered VCNs as desired.

If desired, the administrators can perform tasks E and F *before* establishing the connection. Each administrator needs to know the CIDR block or specific subnets from the other's VCN and share that in task B.

Task A: Create the RPCs

Each administrator creates an RPC for their own VCN's DRG. "You" in the following procedure means an administrator (either the acceptor or requestor).

Note

Required IAM Policy to Create RPCs

If the administrators already have broad network administrator permissions (see Let network admins manage a cloud network), then they have permission to create, update, and delete RPCs. Otherwise, here's an example policy giving the necessary permissions to a group called RPCAdmins. The second statement is required because creating an RPC affects the DRG it belongs to, so the administrator must have permission to manage DRGs.

```
Allow group RPCAdmins to manage remote-peering-connections in
tenancy
Allow group RPCAdmins to manage drgs in tenancy
```

1. In the Console, confirm you're viewing the compartment that contains the DRG that you want to add the RPC to. For information about compartments and access control, see Access Control.
2. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Dynamic Routing Gateways**.
3. Click the DRG you're interested in.
4. Under **Resources**, click **Remote Peering Connections**.
5. Click **Create Remote Peering Connection**.
6. Enter the following:
   - **Name:** A friendly name for the RPC. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.

- **Create in compartment**: The compartment where you want to create the RPC, if different from the compartment you're currently working in.

7. Click **Create Remote Peering Connection**.
   The RPC is then created and displayed on the **Remote Peering Connections** page in the compartment you chose.
8. If you're the acceptor, record the RPC's region and OCID to later give to the requestor.

Task B: Share information

- If you're the acceptor, give this information to the requestor (for example, by email or other out-of-band method):
  - The region your VCN is in (the requestor's tenancy must be subscribed to this region).
  - Your RPC's OCID.
  - The CIDR blocks for subnets in your VCN that should be available to the other VCN. The requestor needs this information when setting up routing for the requestor VCN.
- If you're the requestor, give this information to the acceptor:
  - The region your VCN is in (the acceptor's tenancy must be subscribed to this region).
  - The name of the IAM group that should be granted permission to create a connection in the acceptor's compartment (in the example in the next task, the group is RequestorGrp).
  - The CIDR blocks for subnets in your VCN that should be available to the other VCN. The acceptor needs this information when setting up routing for the acceptor VCN.

Task C: Set up the IAM policies

Both the requestor and acceptor must ensure the right policies are in place. These consist of:

- **Policy R (implemented by the requestor):**

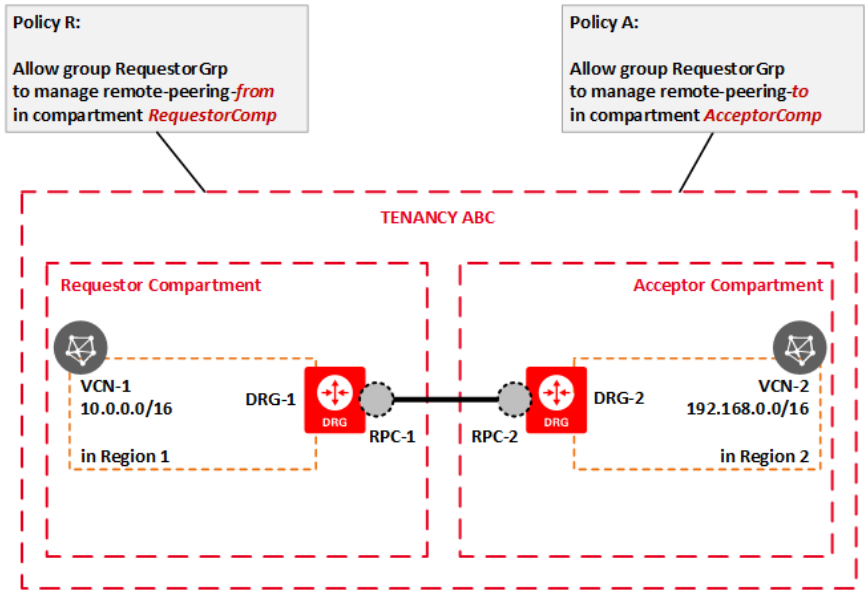
```
Allow group RequestorGrp to manage remote-peering-from in compartment RequestorComp
```

  The requestor is in an IAM group called RequestorGrp. This policy lets anyone in the group initiate a connection from any RPC in the requestor's compartment (RequestorComp). Policy R can be attached to either the tenancy (root compartment) or to RequestorComp. For information about why you would attach it to one versus the other, see Policy Attachment.

- **Policy A (implemented by the acceptor):**

```
Allow group RequestorGrp to manage remote-peering-to in compartment AcceptorComp
```

  This policy lets the requestor connect to any RPC in the acceptor's compartment (AcceptorComp). This statement reflects the required agreement from the acceptor for the peering to be established. Policy A can be attached to either the tenancy (root compartment) or to AcceptorComp.



Both Policy R and Policy A give RequestorGrp access. However, Policy R has a resource-type called remote-peering-*from*, and Policy A has a resource-type called remote-peering-*to*. Together, these policies let someone in RequestorGrp establish the connection *from* an RPC in the requestor's compartment *to* an RPC in the acceptor's compartment. The API call to actually create the connection specifies which two RPCs.

Tip

The permission granted by Policy R might already be in place if the requestor has permission in another policy to manage all of the Networking components in RequesterComp. For example, there might be a general Network Admin policy like this: `Allow group NetworkAdmin to manage virtual-network-family in compartment RequestorComp`. If the requestor is in the NetworkAdmin group, then they already have the required permissions covered in Policy R (the virtual-network-family includes RPCs). And further, if the policy is instead written to cover the *entire tenancy* (`Allow group NetworkAdmin to manage virtual-network-family in tenancy`), then the requestor already has all the required permissions in both compartments to establish the connection. In that case, policy A is not required.

Task D: Establish the connection

The requestor must perform this task.

Prerequisite: The requestor must have:

- The region the acceptor's VCN is in (the requestor's tenancy must be subscribed to the region).
- The OCID of the acceptor's RPC.

1. In the Console, view the details for the requestor RPC that you want to connect to the acceptor RPC.
2. Click **Establish Connection**.
3. Enter the following:
    - **Region:** The region that contains the acceptor's VCN. The drop-down list includes only those regions that both support remote VCN peering and your tenancy is subscribed to.
    - **Remote Peering Connection OCID:** The OCID of the acceptor's RPC.
4. Click **Establish Connection**.

The connection is established and the RPC's state changes to PEERED.

Task E: Configure the route tables

As mentioned earlier, each administrator can do this task before or after the connection is established.

Prerequisite: Each administrator must have the CIDR block or specific subnets for the other VCN.

For your own VCN:

1. Determine which subnets in your VCN need to communicate with the other VCN.
2. Update the route table for each of those subnets to include a new rule that directs traffic destined for the other VCN to your DRG:
    a. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
    b. Click the VCN you're interested in.

c. Under **Resources**, click **Route Tables**.

d. Click the route table you're interested in.

e. Click **Add Route Rule** and enter the following:

- **Target Type:** Dynamic Routing Gateway. The VCN's attached DRG is automatically selected as the target, and you don't have to specify the target yourself.
- **Destination CIDR Block:** The other VCN's CIDR block. If you want, you can specify a subnet or particular subset of the peered VCN's CIDR.

f. Click **Add Route Rule**.

Any subnet traffic with a destination that matches the rule is routed to your DRG. For more information about setting up route rules, see Route Tables.

Tip

Without the required routing, traffic doesn't flow between the peered DRGs. If a situation occurs where you need to temporarily stop the peering, you can simply remove the route rules that enable traffic. You don't need to delete the RPCs.

Task F: Configure the security rules

As mentioned earlier, each administrator can do this task before or after the connection is established.

Prerequisite: Each administrator must have the CIDR block or specific subnets for the other VCN. In general, you should use the same CIDR block you used in the route table rule in Task E: Configure the route tables.

What rules should you add?

- Ingress rules for the types of traffic you want to allow from the other VCN, specifically from the VCN's CIDR or specific subnets.
- Egress rule to allow outgoing traffic from your VCN to the other VCN. If the subnet already has a broad egress rule for all types of protocols to all destinations (0.0.0.0/0), then you don't need to add a special one for the other VCN.

Note

The following procedure uses security lists, but you could instead implement the security rules in a network security group and then create all of the subnet's resources in that NSG.

For your own VCN:

1. Determine which subnets in your VCN need to communicate with the other VCN.
2. Update the security list for each of those subnets to include rules to allow the desired egress or ingress traffic specifically with the CIDR block or subnet of the other VCN:
    a. In the Console, while viewing the VCN you're interested in, click **Security Lists**.
    b. Click the security list you're interested in.
    c. Under **Resources**, click either **Ingress Rules** or **Egress Rules** depending on the type of rule you want to work with.
    d. If you want to add a new rule, click **Add Ingress Rule** (or **Add Egress Rule**).

Example

Let's say you want to add a stateful rule that enables ingress HTTPS (port 443) traffic from the other VCN's CIDR. Here are the basic steps you take when adding a rule:

i. In the **Allow Rules for Ingress** section, click **+Add Rule**.
ii. Leave the **Stateless** checkbox unchecked.
iii. **Source Type:** Leave as CIDR.
iv. **Source CIDR:** Enter the same CIDR block that the route rules use (see Task E: Configure the route tables).
v. **IP Protocol:** Leave as TCP.
vi. **Source Port Range:** Leave as All.
vii. **Destination Port Range**: Enter 443.

e. If you want to delete an existing rule, click the Actions icon (three dots), and then click **Remove**.
f. If you wanted to edit an existing rule, click the Actions icon (three dots), and then click **Edit**.

For more information about security rules, see Security Rules.

Using the Console

To create a remote peering connection

See the instructions in Task A: Create the RPCs.

To delete a remote peering connection

Deleting an RPC terminates the peering. The RPC at the other side of the peering changes to the REVOKED state.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Dynamic Routing Gateways**.
2. Click the DRG you're interested in.

3. Under **Resources**, click **Remote Peering Connections**.
4. Click the RPC you're interested in.
5. Click **Terminate**.
6. Confirm when prompted.

Note

After deleting an RPC (and thus terminating a peering), it's recommended you review your route tables and security rules to remove any rules that enabled traffic with the other VCN.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

To manage your RPCs and create connections, use these operations:

- ListAllowedPeerRegionsForRemotePeering
- ListRemotePeeringConnections
- CreateRemotePeeringConnection
- GetRemotePeeringConnection
- UpdateRemotePeeringConnection
- DeleteRemotePeeringConnection
- ConnectRemotePeeringConnections

Access to Oracle Cloud Infrastructure Classic

There are two ways to set up a connection between an Oracle Cloud Infrastructure Classic IP network and an Oracle Cloud Infrastructure virtual cloud network (VCN):

- Option 1: Connection over the Oracle network
    - You file a ticket with My Oracle Support and Oracle provisions a connection between the IP network's private gateway and the VCN's attached dynamic routing gateway (DRG). The connection runs over Oracle's network and not the internet.
    - The two environments must be in the same geographical area, and the connection is available only between the specific regions listed in Overview.
    - The two environments must belong to the same company. Oracle validates this when setting up the connection.
- Option 2: Connection over an IPSec VPN
    - You set up an IPSec VPN between the IP network's VPN as a Service (VPNaaS) gateway and the VCN's attached DRG. The connection runs over the internet.
    - The two environments do not have to be in the same geographical area or regions.
    - The two environments do not have to belong to the same company.

Connection Over Oracle Network

This topic describes one way to set up a connection between an Oracle Cloud Infrastructure Classic IP network and an Oracle Cloud Infrastructure virtual cloud network (VCN). The connection runs over Oracle's network.

Another option is to connect the two clouds with an IPSec VPN. For more information, see Connection Over IPSec VPN.

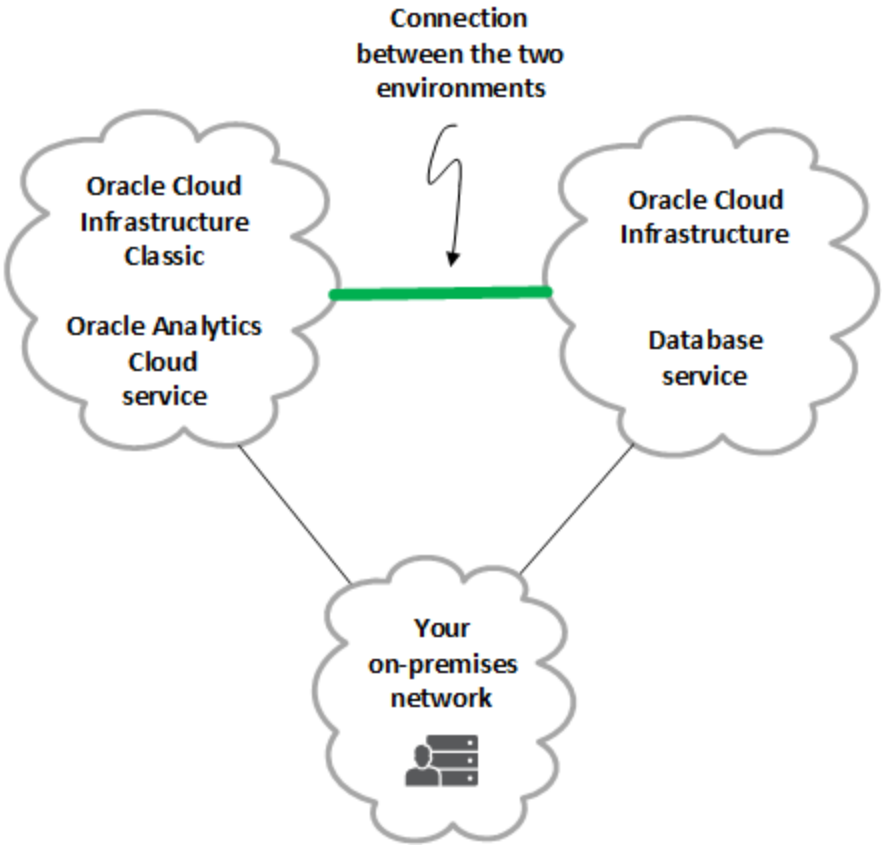
Highlights

- You can run a hybrid workload between your Oracle Cloud Infrastructure Classic and Oracle Cloud Infrastructure environments.
- Oracle connects the IP network's private gateway to the VCN's attached dynamic routing gateway (DRG). The connection runs over the Oracle network. You configure routing and security rules in the environments to enable traffic.
- The two environments must belong to the same company and not have overlapping CIDRs. The cloud resources can communicate over the connection only with private IP addresses.
- The two environments must both be in the Ashburn area, the London area, or the Sydney area, and in specific regions listed in the next section. Connectivity to other regions is not supported.
- The connection is free of charge.

Overview

You can request Oracle to provision a connection between your Oracle Cloud Infrastructure environment and your Oracle Cloud Infrastructure Classic environment. The connection facilitates a hybrid deployment with application components that are set up across the two environments. You can also use the connection to migrate workloads from Oracle Cloud Infrastructure Classic to Oracle Cloud Infrastructure. Compared to an IPSec VPN: the resources in the two environments have a more reliable and consistent network connection, with better throughput, because the traffic uses Oracle's internal links. Compared to FastConnect: you don't incur the additional cost and operational overhead of working with a FastConnect partner.

The following diagram shows an example of a hybrid deployment. Oracle Analytics Cloud is running in an Oracle Cloud Infrastructure Classic IP network and accessing the Database service in Oracle Cloud Infrastructure over the connection.



Here are other important details to know:

- The connection is supported only between these regions:
  - Oracle Cloud Infrastructure Australia East (Sydney) region and the Sydney Classic region
  - Oracle Cloud Infrastructure US East (Ashburn) region and the Ashburn Classic region
  - Oracle Cloud Infrastructure UK South (London) region and the Slough Classic region
- The connection enables communication that uses private IP addresses only.

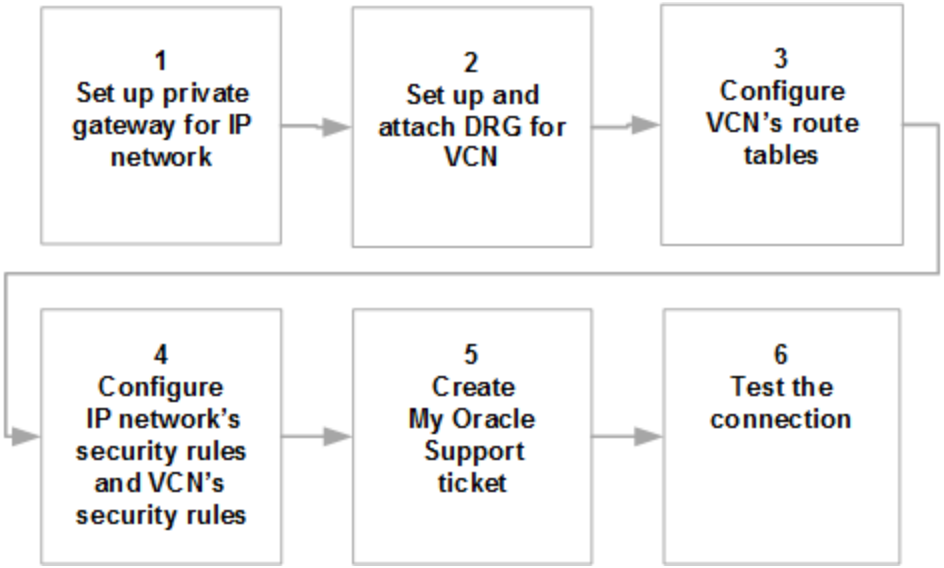
- The CIDR blocks of the IP network and VCN subnets that need to communicate must not overlap.
- The IP network and VCN must belong to the same company. Oracle validates this when setting up the connection.
- This connection enables communication only between resources in the Oracle Cloud Infrastructure Classic IP network and Oracle Cloud Infrastructure VCN. It does not enable traffic between your on-premises network through the IP network to the VCN, or from your on-premises network through the VCN to the IP network.
- The connection also does not enable traffic to flow from the IP network through the connected VCN to a peered VCN in the same Oracle Cloud Infrastructure region, or a different region.

The following table lists the comparable networking components required on each side of the connection.

Component	Oracle Cloud Infrastructure Classic	Oracle Cloud Infrastructure
Cloud network	IP network	VCN
Gateway	private gateway	dynamic routing gateway (DRG)
Routing	routes	route tables with route rules
Security rules	security rules	network security groups, security lists

Connecting Your IP Network and VCN

The following flow chart shows the overall process of connecting your IP network and VCN.



Prerequisites:

You must already have:

- An Oracle Cloud Infrastructure Classic IP network.
- An Oracle Cloud Infrastructure VCN with subnets.

Task 1: Set up a private gateway for your IP network

If you do not already have a private gateway for your IP network, create one.

Task 2: Set up a dynamic routing gateway (DRG) for your VCN

If you do not already have a DRG attached to your VCN, create a DRG and attach it:

- To create a DRG
- To attach a DRG to a VCN

Task 3: Configure route tables

For the IP network

When you create the private gateway and attach an IP network to it, traffic from cloud resources in the IP network uses the private gateway as the next hop. You do not need to update any routes for the IP network.

For the VCN

You must add a route rule that directs traffic from the VCN's subnets to the DRG:

1. Determine which subnets in your VCN need to communicate with the IP network.
2. Update the route table for each of those subnets to include a new rule that directs traffic destined for the IP network's CIDR to your DRG:
    a. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
    b. Click the VCN you're interested in.
    c. Under **Resources**, click **Route Tables**.
    d. Click the route table you're interested in.
    e. Click **Add Route Rule** and enter the following:
        - **Destination CIDR Block:** The IP network's CIDR block.
        - **Target Type:** Dynamic Routing Gateway. The VCN's attached DRG is automatically selected as the target, and you don't have to specify the

target yourself.

f. Click **Add Route Rule**.

Any subnet traffic with a destination that matches the rule is routed to your DRG. For more information about setting up route rules, see Route Tables.

Later, if you no longer need the connection and want to delete your DRG, you must first delete all the route rules in your VCN that specify the DRG as the target.

Task 4: Configure the security rules

To ensure traffic flows between the IP network and VCN, make sure the IP network security rules and the VCN's security rules allow the desired traffic.

Here are the types of rules to add:

- Ingress rules for the types of traffic you want to allow into one cloud from the other, specifically from the other cloud's CIDR block.
- Egress rule to allow outgoing traffic from one cloud to the other. If the VCN's subnet already has a broad egress rule for all types of protocols to all destinations (0.0.0.0/0), then you don't need to add a special one for the IP network.

For the IP network

Configure the network security rules for the IP network to allow the desired traffic.

For the VCN

Note

The following procedure uses security lists, but you

> could instead implement the security rules in one or more network security groups and then place the VCN's resources in NSGs.

1. Determine which subnets in your VCN need to communicate with the IP network.
2. Update the security list for each of those subnets to include rules to allow the desired egress or ingress traffic specifically with the CIDR block of the IP network:
    a. In the Console, while viewing the VCN you're interested in, click **Security Lists**.
    b. Click the security list you're interested in.
    Under **Resources**, you can click **Ingress Rules** or **Egress Rules** to switch between the different types of rules.
    c. Add one or more rules, each for the specific type of traffic you want to allow.

    Example:

    Let's say you want to add a stateful rule that enables ingress HTTPS (port 443) traffic from the IP network's CIDR. Here are the basic steps you take when adding a rule:

    i. On the **Ingress Rules** page, click **Add Ingress Rule**.
    ii. Leave the **Stateless** check box unselected.
    iii. **Source CIDR:** Enter the same CIDR block that the route rules use (see Task 3: Configure route tables).
    iv. **IP Protocol:** Leave as TCP.
    v. **Source Port Range:** Leave as All.
    vi. **Destination Port Range**: Enter 443.
    vii. Click **Add Ingress Rule**.

For more information about setting up security rules, see Security Rules.

Important

The VCN's default security list does not allow ICMP echo reply and echo request (ping). You must add rules to enable that traffic. See Rules to Enable Ping

Task 5: Create a My Oracle Support ticket

To have Oracle set up the connection, create a ticket at My Oracle Support and provide the following information:

- Ticket name: Create IP Network - VCN Connection - *<your_company_name>* - Ashburn
- OCI-C identity domain
- OCI-C private gateway name
- Region
- OCI tenancy OCID
- OCI DRG OCID

For example:

- Ticket name: Create IP Network - VCN Connection - ACME - Ashburn
- OCI-C identity domain: 123456789, uscom-east-1
- OCI-C private gateway name: Compute-acme/jack.jones@example.com/privategateway1
- Region: uscom-east-1 (OCI-C) / us-ashburn-1 (OCI)
- OCI tenancy OCID: ocid1.tenancy.oc1..examplefbpnk5cmdl7gkr6kcakfqmvhvbpcv
- OCI DRG OCID: ocid1.drg.oc1.iad.exampleutg6cmd3fqwqbea7ctadcatm

It can take 3 to 4 business days before your My Oracle Support ticket is complete and the connection is ready to test.

Task 6: Test the connection

After you receive confirmation from your support person that the connection is ready, test the connection. Depending on how you've set up your IP network's security rules and VCN security rules, you should be able to launch an instance in your VCN and access it from an instance in the IP network. Or you should be able to connect from the VCN instance to an instance in the IP network. If you can, your connection is ready to use.

Terminating the Connection

If you want to terminate the connection, file a ticket at My Oracle Support.

Connection Over IPSec VPN

This topic describes one way to set up a connection between an Oracle Cloud Infrastructure Classic IP network and an Oracle Cloud Infrastructure virtual cloud network (VCN). The connection runs over an IPSec VPN.

Another option is to have Oracle set up a connection over the Oracle network. For more information, see Connection Over Oracle Network.

Highlights

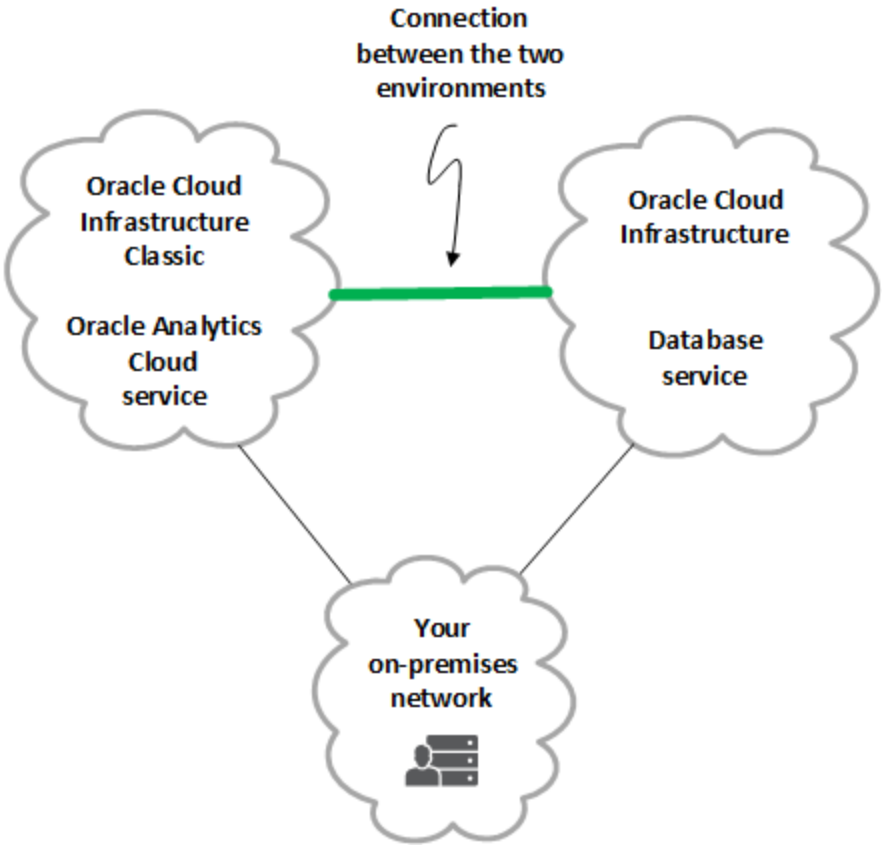
- You can run a hybrid workload between your Oracle Cloud Infrastructure Classic and Oracle Cloud Infrastructure environments.
- You set up an IPSec VPN between the IP network's VPN as a Service (VPNaaS) gateway and the VCN's attached dynamic routing gateway (DRG). The connection runs over the internet. You configure routing and security rules in the environments to enable traffic.

- The two environments must not have overlapping CIDRs. The cloud resources can communicate over the connection only with private IP addresses.
- The two environments do not have to be in the same geographical area or region.
- The connection is free of charge.

Overview

You can connect your Oracle Cloud Infrastructure environment and your Oracle Cloud Infrastructure Classic environment with an IPSec VPN. The connection facilitates a hybrid deployment with application components that are set up across the two environments. You can also use the connection to migrate workloads from Oracle Cloud Infrastructure Classic to Oracle Cloud Infrastructure. Compared to using the Oracle network for the connection: you can set up the IPSec VPN yourself in a matter of minutes. Compared to FastConnect: you don't incur the additional cost and operational overhead of working with a FastConnect partner.

The following diagram shows an example of a hybrid deployment. Oracle Analytics Cloud is running in an Oracle Cloud Infrastructure Classic IP network and accessing the Database service in Oracle Cloud Infrastructure over the connection.



Here are other important details to know:

- The connection is supported in any of the Oracle Cloud Infrastructure and Oracle Cloud Infrastructure Classic regions. The two environments do not need to be in the same geographical area.
- The connection enables communication that uses private IP addresses only.
- The CIDR blocks of the IP network and VCN subnets that need to communicate must not overlap.
- This connection enables communication only between resources in the Oracle Cloud Infrastructure Classic IP network and Oracle Cloud Infrastructure VCN. It does not

enable traffic between your on-premises network through the IP network to the VCN, or from your on-premises network through the VCN to the IP network.

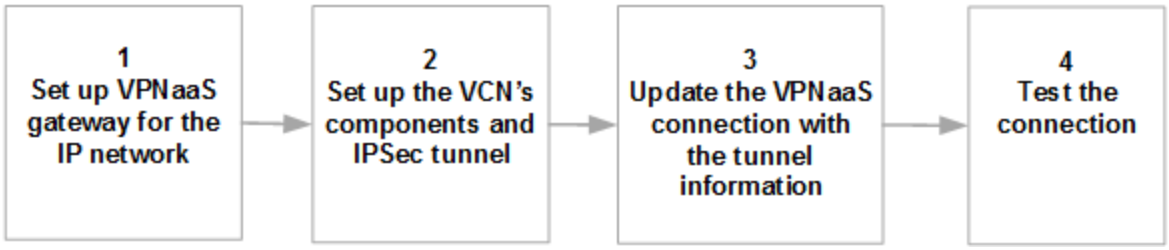
- The connection also does not enable traffic to flow from the IP network through the connected VCN to a peered VCN in the same Oracle Cloud Infrastructure region, or a different region.

The following table lists the comparable networking components required on each side of the connection.

Component	Oracle Cloud Infrastructure Classic	Oracle Cloud Infrastructure
Cloud network	IP network	VCN
Gateway	VPNaaS gateway	dynamic routing gateway (DRG)
Security rules	security rules	network security groups, security lists

Setting Up the IPSec VPN Between Your IP Network and VCN

The following flow chart shows the overall process of connecting your IP network and VCN with an IPSec VPN.



Prerequisites:

You must already have:

- An Oracle Cloud Infrastructure Classic IP network.
- An Oracle Cloud Infrastructure VCN with subnets.

Task 1: Set up a VPNaaS gateway for your IP network

1. Use these values when setting up the VPNaaS gateway:
    - **IP Network:** The Oracle Cloud Infrastructure Classic IP network you want to connect to your VCN. Note that you can specify only a single IP network.
    - **Customer Gateway:** A placeholder value such as 129.213.240.51. Using this placeholder value lets you move forward in the process. You will change the value later with the Oracle Cloud Infrastructure VPN router's IP address.
    - **Customer Reachable Routes:** The CIDR block for the VCN. Note that you can specify only a single VCN.
    - **Specify Phase 2 ESP Proposal:** Check box selected.
    - **ESP Encryption:** AES 256
    - **ESP Hash:** SHA1
    - **IPSec Lifetime:** 1800
    - **Require Perfect Forward Secrecy:** Check box selected.
2. Record the resulting public IP address of the VPNaaS gateway.

Task 2: Set up the VCN's components and IPSec tunnel

Task 2a: Set up a dynamic routing gateway (DRG) for your VCN

If you do not already have a DRG attached to your VCN, create a DRG and attach it:

- To create a DRG
- To attach a DRG to a VCN

Task 2b: Configure routing to the DRG

You must add a route rule that directs traffic from the VCN's subnets to the DRG. Use the IP network's CIDR block as the destination for the rule.

1. Determine which subnets in your VCN need to communicate with the IP network.
2. Update the route table for each of those subnets to include a new rule that directs traffic destined for the IP network's CIDR to your DRG:
    a. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
    b. Click the VCN you're interested in.
    c. Under **Resources**, click **Route Tables**.
    d. Click the route table you're interested in.
    e. Click **Add Route Rule** and enter the following:
        - **Destination CIDR Block:** The IP network's CIDR block.
        - **Target Type:** Dynamic Routing Gateway. The VCN's attached DRG is automatically selected as the target, and you don't have to specify the target yourself.
    f. Click **Add Route Rule**.

Any subnet traffic with a destination that matches the rule is routed to your DRG. For more information about setting up route rules, see Route Tables.

Later, if you no longer need the connection and want to delete your DRG, you must first delete all the route rules in your VCN that specify the DRG as the target.

Task 2c: Configure the security rules

To ensure traffic flows between the IP network and VCN, make sure the IP network security rules and the VCN's security rules allow the desired traffic.

Here are the types of rules to add:

- Ingress rules for the types of traffic you want to allow into one cloud from the other, specifically from the other cloud's CIDR block.
- Egress rule to allow outgoing traffic from one cloud to the other. If the VCN's subnet already has a broad egress rule for all types of protocols to all destinations (0.0.0.0/0), then you don't need to add a special one for the IP network.

For the IP network

Configure the network security rules for the IP network to allow the desired traffic.

For the VCN

Note

The following procedure uses security lists, but you could instead implement the security rules in one or more network security groups and then place the VCN's resources in NSGs.

1. Determine which subnets in your VCN need to communicate with the IP network.
2. Update the security list for each of those subnets to include rules to allow the desired egress or ingress traffic specifically with the CIDR block of the IP network:
    a. In the Console, while viewing the VCN you're interested in, click **Security Lists**.
    b. Click the security list you're interested in.
    Under **Resources**, you can click **Ingress Rules** or **Egress Rules** to switch between the different types of rules.
    c. Add one or more rules, each for the specific type of traffic you want to allow.

Example

Let's say you want to add a stateful rule that enables ingress HTTPS (port 443) traffic from the IP network's CIDR. Here are the basic steps you take when adding a rule:

i. On the **Ingress Rules** page, click **Add Ingress Rule**.
ii. Leave the **Stateless** check box unselected.
iii. **Source CIDR:** Enter the same CIDR block that the route rules use (see Task 2b: Configure routing to the DRG).
iv. **IP Protocol:** Leave as TCP.
v. **Source Port Range:** Leave as All.
vi. **Destination Port Range**: Enter 443.
vii. Click **Add Ingress Rule**.

For more information about setting up security list rules, see Security Lists.

Important

The VCN's default security list does not allow ICMP echo reply and echo request (ping). You must add rules to enable that traffic. See Rules to Enable Ping

Task 2d: Create a CPE object

Create a CPE object. You must provide an IP address. Use the VPNaaS gateway's public IP address.

Task 2e: Create the IPSec connection

From your DRG, create an IPSec connection to the CPE object. You must provide one or more static routes. The values must match the IP network's subnets or aggregate.

The resulting IPSec connection consists of two tunnels. Record the IP address and shared secret for one of those tunnels. In the next task, you will provide those values.

Task 3: Update the VPNaaS connection with the tunnel information

Update the VPNaaS connection. Use these values:

- **Customer Gateway:** The tunnel's IP address from the preceding task.
- **VPNaaS VPN Connection's Pre-shared Key:** The tunnel's shared secret from the preceding task.

After the VPNaaS connection is updated and provisioned, the state of your VCN's IPSec tunnel should change to Available. This might take a few minutes.

Task 4: Test the connection

After the tunnel state changes to Available, test the connection. Depending on how you've set up your IP network's security rules and VCN security rules, you should be able to launch an instance in your VCN and access it from an instance in the IP network. Or you should be able to connect from the VCN instance to an instance in the IP network. If you can, your connection is ready to use.

Terminating the Connection

If you want to terminate the connection, delete the IPSec connection:

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **IPSec Connections**.

A list of the IPSec connections in the compartment you're viewing is displayed. If you don’t see the one you're looking for, verify that you’re viewing the correct compartment (select from the list on the left side of the page).

2. Click the IPSec connection you're interested in.
3. Click **Terminate**.
4. Confirm the deletion when prompted.

The IPSec connection will be in the Terminating state for a short period while it's being deleted.

Access to Microsoft Azure

Oracle and Microsoft have created a cross-cloud connection between Oracle Cloud Infrastructure and Microsoft Azure in certain regions. This connection lets you set up cross-cloud workloads without the traffic between the clouds going over the internet. This topic describes how to set up virtual networking infrastructure resources to enable this kind of cross-cloud deployment.

Highlights

- You can connect a Microsoft Azure virtual network (VNet) with an Oracle Cloud Infrastructure virtual cloud network (VCN) and run a cross-cloud workload. In the typical use case, you deploy your Oracle Database on Oracle Cloud Infrastructure, and deploy an Oracle, .NET, or custom application in Microsoft Azure.
- The two virtual networks must belong to the same company and not have overlapping CIDRs. The connection requires you to create an Azure ExpressRoute circuit and an Oracle Cloud Infrastructure FastConnect virtual circuit.
- The connection is currently available only in these areas:
    - Between the Oracle Cloud Infrastructure location in the US East (Ashburn) region and the Azure Washington DC and Washington DC2 locations.

- Between the Oracle Cloud Infrastructure location in the UK South (London) region and the Azure London location.

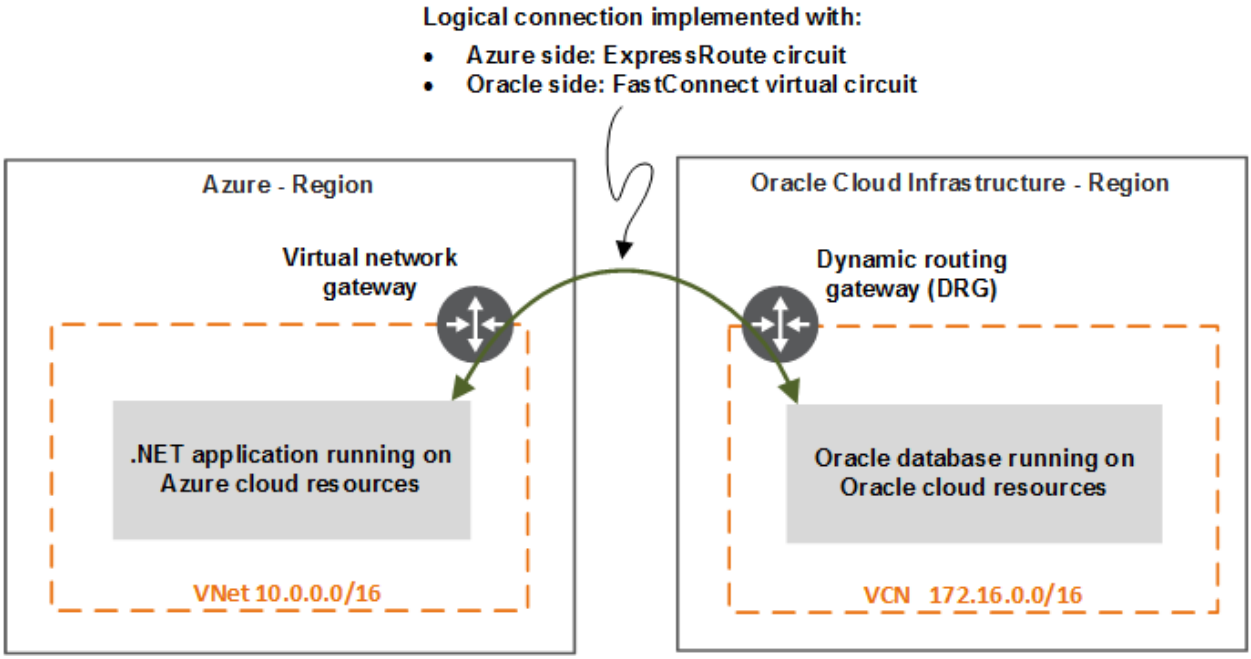
Overview of Supported Traffic

Here are more details about the supported types of traffic.

VNet-to-VCN Connection: Extension from One Cloud to Another

You can connect your VNet and VCN so that traffic that uses private IP addresses goes over the cross-cloud connection.

For example, the following diagram shows a VNet that is connected to a VCN. Resources in the VNet are running a .NET application that access an Oracle database that runs on Database service resources in the VCN. The traffic between the application and database uses a logical circuit that runs on the cross-cloud connection between Azure and Oracle Cloud Infrastructure.



To enable the connection between the VNet and VCN, you set up an Azure ExpressRoute circuit and an Oracle Cloud Infrastructure FastConnect virtual circuit. The connection has built-in redundancy, which means you need to set up only a single ExpressRoute circuit and single FastConnect virtual circuit. The bandwidth for the connection is the bandwidth value you choose for the ExpressRoute circuit.

For instructions, see Setting Up a VNet-to-VCN Connection.

Peered VCNs

The connection enables traffic to flow from the VNet through the connected VCN to a peered VCN in the same Oracle Cloud Infrastructure region, or a different region.

Types of Traffic Not Supported by the Connection

This cross-cloud connection does not enable traffic between your on-premises network through the VCN to the VNet, or from your on-premises network through the VNet to the VCN.

Important Implications of Connecting Clouds

This section summarizes some access control, security, and performance implications of connecting your VCN to a VNet. In general, you can control access and traffic by using IAM policies, route tables in the VCN, and security rules in the VCN.

The sections that follow discuss implications from the perspective of your VCN. There are similar implications for your VNet. As with your VCN, you can use Azure resources such as route tables and network security groups to secure your VNet.

Controlling the Establishment of a Connection

With Oracle Cloud Infrastructure IAM policies, you can control:

- Who in your organization has the authority to create a FastConnect virtual circuit (see Prerequisites: Required IAM Policy). Be aware that deletion of the relevant IAM policy does not affect any existing connections to a VNet, only the ability for a future

connection to be created.

- Who can manage route tables, network security groups, and security lists.

Controlling Traffic Flow Over the Connection

Even if a connection has been established between your VCN and VNet, you can control the packet flow over the connection with route tables in your VCN. For example, you can restrict traffic to only specific subnets in the VNet.

Without terminating the connection, you can stop traffic flow to the VNet by simply removing route rules that direct traffic from your VCN to the VNet. You can also effectively stop the traffic by removing any security rules that enable ingress or egress traffic with the VNet. This doesn't stop traffic flowing over the connection, but stops it at the VNIC level.

Controlling the Specific Types of Traffic Allowed

It's important that you ensure that all outbound and inbound traffic with the VNet is intended/expected and well defined. In practice, this means implementing Azure network security group and Oracle security rules that explicitly state the types of traffic one cloud can send to the other and accept from the other.

Important

Your Oracle Cloud Infrastructure instances running Oracle-provided Linux images or Windows images also have firewall rules that control access to the instance. When troubleshooting access to an instance, make sure all of the following items are set correctly: the network security groups that the instance is in, the security lists associated with the instance's subnet, and the instance's firewall rules. For more information, see Oracle-Provided Images.

If your instance is running Oracle Linux 7, you need to use firewalld to interact with the iptables rules. For your reference, here are commands for opening a port (1521 in this example):

```
sudo firewall-cmd --zone=public --permanent --add-
port=1521/tcp

sudo firewall-cmd --reload
```

For instances with an iSCSI boot volume, the preceding `--reload` command can cause problems. For details and a workaround, see Instances experience system hang after running firewall-cmd --reload.

In addition to security rules and firewalls, you should evaluate other OS-based configuration on the instances in your VCN. There could be default configurations that don't apply to your own VCN's CIDR, but inadvertently apply to the VNet's CIDR.

Using Default Security List Rules with Your VCN

If your VCN's subnets use the default security list with the default rules, be aware that there are two rules that allow ingress traffic from anywhere (that is, 0.0.0.0/0, and thus the VNet):

- Stateful ingress rule that allows TCP port 22 (SSH) traffic from 0.0.0.0/0 and any source port
- Stateful ingress rule that allows ICMP type 3, code 4 traffic from 0.0.0.0/0 and any source port

Make sure to evaluate these rules and whether you want to keep or update them. As stated earlier, you should ensure that all inbound or outbound traffic that you permit is intended/expected and well defined.

Preparing for Performance Impact and Security Risks

In general, you should prepare your VCN for the ways it could be affected by the VNet. For example, the load on your VCN or its instances could increase. Or your VCN could experience a malicious attack directly from or by way of the VNet.

Regarding performance: If your VCN is providing a service to the VNet, be prepared to scale up your service to accommodate the demands of the VNet. This might mean being prepared to launch additional instances as necessary. Or if you're concerned about high levels of network traffic coming to your VCN, consider using stateless security rules to limit the level of connection tracking your VCN must perform. Stateless security rules can also help slow the impact of a denial-of-service (DoS) attack.

Regarding security risks: If the VNet is connected to the internet, be aware that your VCN can be exposed to bounce attacks in which a malicious host on the internet can send traffic to your VCN but make it look like it's coming from the VNet. To guard against this, as mentioned earlier, use your security rules to carefully limit the inbound traffic from the VNet to expected and well-defined traffic.

Setting Up a VNet-to-VCN Connection

This section describes how to set up the logical connection between a VNet and VCN (for background, see Overview of Supported Traffic).

Prerequisites: Resources You Need

You must already have:

- An Azure VNet with subnets and virtual network gateway
- An Oracle Cloud Infrastructure VCN with subnets and an attached dynamic routing gateway (DRG). It's easy to forget to attach the DRG to your VCN after you create it. If you already have an IPSec VPN or FastConnect between your on-premises network and VCN, then your VCN already has an attached DRG. You use that same DRG here when setting up the connection to Azure.

As a reminder, here is a table that lists the comparable networking components involved in each side of the connection.

Component	Azure	Oracle Cloud Infrastructure
Virtual network	VNet	VCN
Virtual circuit	ExpressRoute circuit	FastConnect private virtual circuit
Gateway	virtual network gateway	dynamic routing gateway (DRG)
Routing	route tables	route tables
Security rules	network security groups (NSGs)	network security groups (NSGs), security lists

Prerequisites: BGP Information You Need

The connection between the VNet and VCN uses BGP dynamic routing. When you set up the Oracle virtual circuit, you provide the BGP IP addresses that will be used for the two

redundant BGP sessions between Oracle and Azure:

- A primary pair of BGP addresses (one IP address for the Oracle side, one IP address for the Azure side)
- A separate, secondary pair of BGP addresses (one IP address for the Oracle side, one IP address for the Azure side)

For each pair, you must provide a separate /30 block of addresses (each /30 has four IP addresses).

The second and third addresses in each /30 are used for the BGP IP address pair. Specifically:

- The second address in the block is for the Oracle side of the BGP session
- The third address in the block is for the Azure side of the BGP session

The first and last addresses in the block are used for other internal purposes.

For example, if the /30 is 10.0.0.20/30, then the addresses in the block are:

- 10.0.0.20/30
- 10.0.0.21/30: Use this for the Oracle side
- 10.0.0.22/30: Use this for the Azure side (also referred to as the "Customer" side in the Oracle Console)
- 10.0.0.23/30

Remember that you must also provide a /30 block for the secondary BGP addresses. For example: 10.0.0.24/30. In this case, 10.0.0.25/30 is for the Oracle side, and 10.0.0.26/30 is for the Azure side.

Prerequisites: Required IAM Policy

It's assumed that you have the necessary Azure Active Directory access and Oracle Cloud Infrastructure IAM access to create and work with the relevant Azure and Oracle networking resources. Specifically for IAM: If your user is in the Administrators group, you have the required authority.

If your user is not, then a policy like this one generally covers all the Networking resources:

```
Allow group NetworkAdmins to manage virtual-network-family in tenancy
```

To *only* create and manage a virtual circuit, you must have a policy like this:

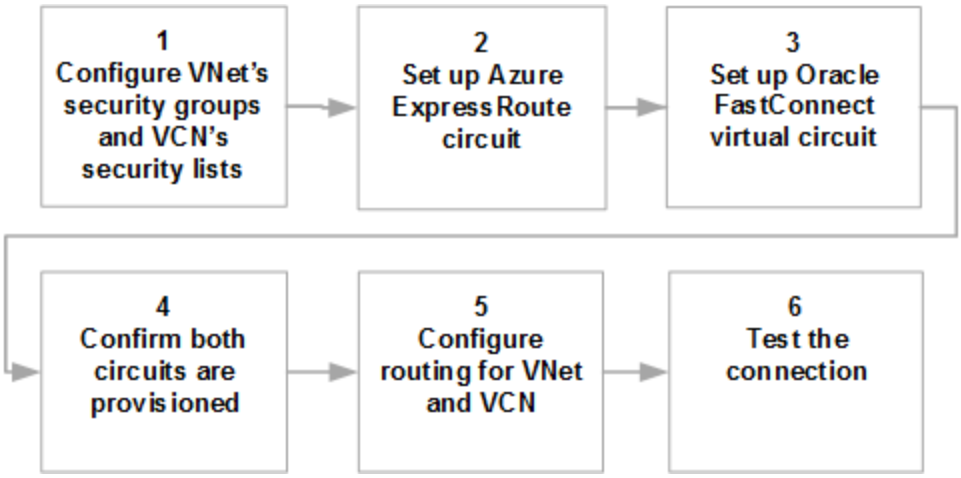
```
Allow group VirtualCircuitAdmins to manage drgs in tenancy

Allow group VirtualCircuitAdmins to manage virtual-circuits in tenancy
```

For more information, see IAM Policies for Networking.

Overall Process

The following flow chart shows the overall process of connecting your VNet and VCN.



Task 1: Configure the network security groups and security rules

The first task is to determine what traffic needs to flow between the relevant subnets within the VNet and VCN, and then configure the VNet security groups and VCN security rules accordingly. Here are the general types of rules to add:

- Ingress rules for the types of traffic you want to allow into one cloud from the other, specifically from the other cloud's relevant subnets.
- Egress rule to allow outgoing traffic from one cloud to the other. If the VCN's subnet already has a broad egress rule for all types of protocols to all destinations (0.0.0.0/0), then you don't need to add a special one for the traffic to the VNet. The VCN's default security list includes a broad default egress rule like this.

More specifically, here are recommended types of traffic to allow between the VNet and VCN:

- Ping traffic in both directions for testing the connection from each side
- SSH (TCP port 22)
- Client connections to an Oracle database (SQL*NET on TCP port 1521)

Make sure to only allow traffic to and from the specific address ranges of interest (for example, the other cloud's relevant subnets).

For the VNet: Determine which subnets in your VNet need to communicate with the VCN. Then configure the network security groups for those subnets to allow the desired traffic.

For the VCN:

Note

The following procedure uses security lists, but you could instead implement the security rules in one or more network security groups and then place the VCN's relevant resources in NSGs.

1. Determine which subnets in your VCN need to communicate with the VNet.
2. Update the security list for each of those subnets to include rules to allow the desired egress or ingress traffic specifically with the VNet's CIDR block or a subnet of the VNet:

a. In the Console, while viewing the VCN you're interested in, click **Security Lists**.
b. Click the security list you're interested in.
c. Click **Edit All Rules** and create one or more rules, each for the specific type of traffic you want to allow.

Example: Outgoing ping from VCN to VNet

The following egress security rule lets an instance initiate a ping request to a host outside the VCN (echo request ICMP type 8). This is a stateful rule that automatically allows the response. No separate ingress rule for echo reply ICMP type 0 is required.

i. In the **Allow Rules for Egress** section, click **+Add Rule**.
ii. Leave the **Stateless** check box unselected.
iii. **Destination CIDR:** The relevant subnet in the VNet (10.0.0.0/16 in the preceding diagram)
iv. **IP Protocol:** ICMP
v. **Type and Code:** 8

Example: Incoming ping to VCN from VNet

The following ingress security rule lets an instance receive a ping request from a host in the VNet (echo request ICMP type 8). This is a stateful rule that automatically allows the response. No separate egress rule for echo reply ICMP type 0 is required.

i. In the **Allow Rules for Ingress** section, click **+Add Rule**.
ii. Leave the **Stateless** check box unselected.
iii. **Source CIDR:** The relevant subnet in the VNet (10.0.0.0/16 in the preceding diagram)

iv. **IP Protocol:** ICMP

v. **Type and Code:** 8

Example: Incoming SSH to VCN

The following ingress security rule lets an instance receive an SSH connection (TCP port 22) from a host in the VNet.

i. In the **Allow Rules for Ingress** section, click **+Add Rule**.

ii. Leave the **Stateless** check box unselected.

iii. **Source CIDR:** The relevant subnet in the VNet (10.0.0.0/16 in the preceding diagram)

iv. **IP Protocol:** TCP

v. **Source Port Range:** All

vi. **Destination Port Range**: 22

Example: SQL*Net connections to database

The following ingress security rule allows SQL*Net connections (TCP port 1521) from hosts in the VNet.

i. In the **Allow Rules for Ingress** section, click **+Add Rule**.

ii. Leave the **Stateless** check box unselected.

iii. **Source CIDR:** The relevant subnet in the VNet (10.0.0.0/16 in the preceding diagram)

iv. **IP Protocol:** TCP

v. **Source Port Range:** All

vi. **Destination Port Range**: 1521

d. Click **Save Security List Rules** at the bottom of the dialog box.

For more information about setting up security rules, see Security Rules.

Task 2: Set up Azure ExpressRoute circuit

Set up an ExpressRoute circuit to *Oracle Cloud FastConnect*. During the circuit setup, you receive a service key from Microsoft. Record that service key, because you must provide it to Oracle in the next task.

Note that in the next task, you set up a FastConnect private virtual circuit to *Microsoft Azure: ExpressRoute*. When that virtual circuit finishes being provisioned, your ExpressRoute circuit will update to show that private peering is enabled.

Task 3: Set up an Oracle Cloud Infrastructure FastConnect virtual circuit

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

1. In the Console, confirm you're viewing the compartment that you want to work in. If you're not sure which one, use the compartment that contains the DRG that you'll connect to. This choice of compartment, along with a corresponding IAM policy, control who has access to the virtual circuit you're about to create.
2. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **FastConnect**.
   The resulting **FastConnect** page is where you create a new virtual circuit and later return to when you need to manage the virtual circuit.
3. Click **Create Connection**.

4. Select **Connect through a provider** and choose **Microsoft Azure: ExpressRoute** from the list.
5. Enter the following for your virtual circuit:
    - **Name:** A friendly name of your choice. The value does not need to be unique across your virtual circuits, and you can change it later. Avoid entering confidential information.
    - **Create in Compartment:** Leave as is (the compartment you're currently working in).
    - **Virtual Circuit Type:** Select **Private Virtual Circuit**.
    - **Dynamic Routing Gateway Compartment:** Select the compartment where the DRG resides (it should already be selected).
    - **Dynamic Routing Gateway:** Select the DRG.
    - **Provisioned Bandwidth:** Choose the same bandwidth level you chose for the ExpressRoute circuit (or the closest value available).
    - **Provider Service Key:** Enter the key you received from Microsoft when you set up the ExpressRoute circuit.
    - **Customer Primary BGP IP Address:** This is the Azure primary BGP IP address. Enter the third address in the primary /30 block that you provide. For example: 10.0.0.22/30. For more information about this field and the next ones, see Prerequisites: BGP Information You Need.
    - **Oracle Primary BGP IP address (optional):** You can leave this blank and Oracle will infer the address based on the /30 block you provided for the Azure BGP IP address. In this example, the correct value would be 10.0.0.21/30.
    - **Customer Secondary BGP IP Address:** This is the Azure secondary BGP IP address. Enter the third address in the secondary /30 block that you provide. For example: 10.0.0.26/30.

- **Oracle Primary BGP IP Address (optional):** You can leave this blank and Oracle will infer the address based on the /30 block you provided for the Azure BGP IP address. In this example, the correct value would be 10.0.0.25/30.

6. Click **Continue**.
   The virtual circuit is created.
7. Click **Close**.

After you create the Oracle virtual circuit, you do not need to contact Azure to request provisioning of the circuit. It happens automatically.

Task 4: Confirm that both circuits are provisioned

Within a few minutes, both circuits should be provisioned. To verify:

- For the ExpressRoute circuit, confirm that private peering is provisioned.
- For the FastConnect virtual circuit, confirm that its status is UP. See To get the status of your FastConnect virtual circuit.

Task 5: Configure the route tables

For the VNet: Determine which subnets in your VNet need to communicate with the VCN. Then configure the route tables for those subnets to route the desired traffic to the VNet gateway.

For the VCN:

1. Determine which subnets in your VCN need to communicate with the VNet.
2. Update the route table for each of those subnets to include a new rule that directs traffic destined for the VNet's CIDR to your DRG:
   a. In the Console, while viewing the VCN you're interested in, click **Route Tables**.
   b. Click the route table you're interested in.

c. Click **Edit Route Rules**.

d. Click **+ Another Route Rule** and enter the following:

- **Target Type:** Dynamic Routing Gateway.
- **Destination CIDR Block:** The relevant subnet in the VNet (10.0.0.0/16 in the preceding diagram).
- **Compartment:** The compartment where the DRG is located, if not the current compartment.
- **Target Dynamic Routing Gateway:** The DRG.

e. Click **Save**.

Any subnet traffic with a destination that matches the rule is routed to your DRG. The DRG then knows to route the traffic to the VNet based on the virtual circuit's BGP session information.

Later, if you no longer need the connection and want to delete your DRG, you must first delete all the route rules in your VCN that specify the DRG as the target.

For more information about setting up route rules, see Route Tables.

Task 6: Test the connection

Depending on how you've set up your VNet security groups and VCN security rules, you should be able to create an instance in your VCN and access it from a host in the VNet. Or you should be able to connect from the instance to a host in the VNet. If you can, your connection is ready to use.

Important

If you decide to terminate the connection, you must follow a particular process. See To terminate the connection to Azure.

Managing a VNet-to-VCN Connection

To get the status of your FastConnect virtual circuit

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **FastConnect**.
2. Select the compartment where the connection resides, and then click the connection you're interested in. If the icon for the virtual circuit is green and says UP, the virtual circuit is provisioned and BGP has been correctly configured. The virtual circuit is ready to use.

To edit a FastConnect virtual circuit

You can change these items for your virtual circuit:

- The name
- Which DRG it uses

Warning

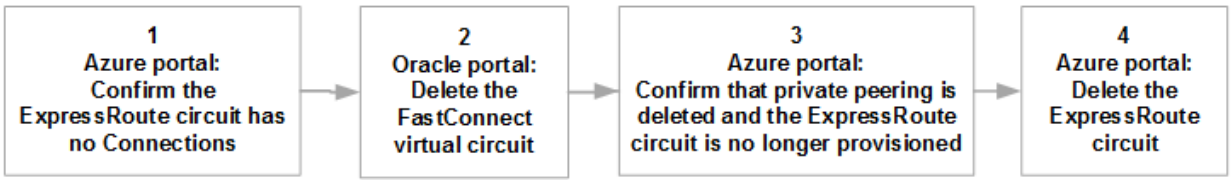
If your virtual circuit is in the PROVISIONED state, be aware that changing which DRG it uses switches the state to PROVISIONING and **may cause the connection to go down.** After Oracle reprovisions the virtual circuit, its state returns to PROVISIONED. Make sure to confirm that the connection is back up and working.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **FastConnect**.
2. Select the compartment where the connection resides, and then click the connection.

3. Click the virtual circuit.
4. Click **Edit** and make your changes.
5. Click **Save**.

To terminate the connection to Azure

The following flow chart shows the overall process of terminating a VNet-to-VCN connection.



1. In the Azure portal, view the ExpressRoute circuit, and then view its **Connections**. Confirm that there are no **Connections** still in existence for the ExpressRoute circuit. All **Connections** must first be deleted before proceeding.
2. In the Oracle portal, delete your FastConnect virtual circuit:
    a. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **FastConnect**.
    b. Select the compartment where the connection resides, and then click the connection.
    c. Click the virtual circuit.
    d. Click **Delete**.
    e. Confirm when prompted.
    The virtual circuit's Lifecycle State switches to TERMINATING.
3. In the Azure portal, confirm that the private peering for the ExpressRoute circuit has been deleted. Also confirm that the ExpressRoute circuit's status has changed to "Not

Provisioned".

4. In the Azure portal, delete the ExpressRoute circuit.

The connection between Azure and Oracle Cloud Infrastructure is terminated.

Access to Other Clouds with Libreswan

Libreswan is an open source IPSec implementation that is based on FreeS/WAN and Openswan. Most Linux distributions include Libreswan or make it easy to install. You can install it on hosts in either your on-premises network or a cloud provider network. This topic shows how to connect your Oracle Cloud Infrastructure virtual cloud network (VCN) with another cloud provider by using an IPSec VPN with a Libreswan VM as the customer-premises equipment (CPE).

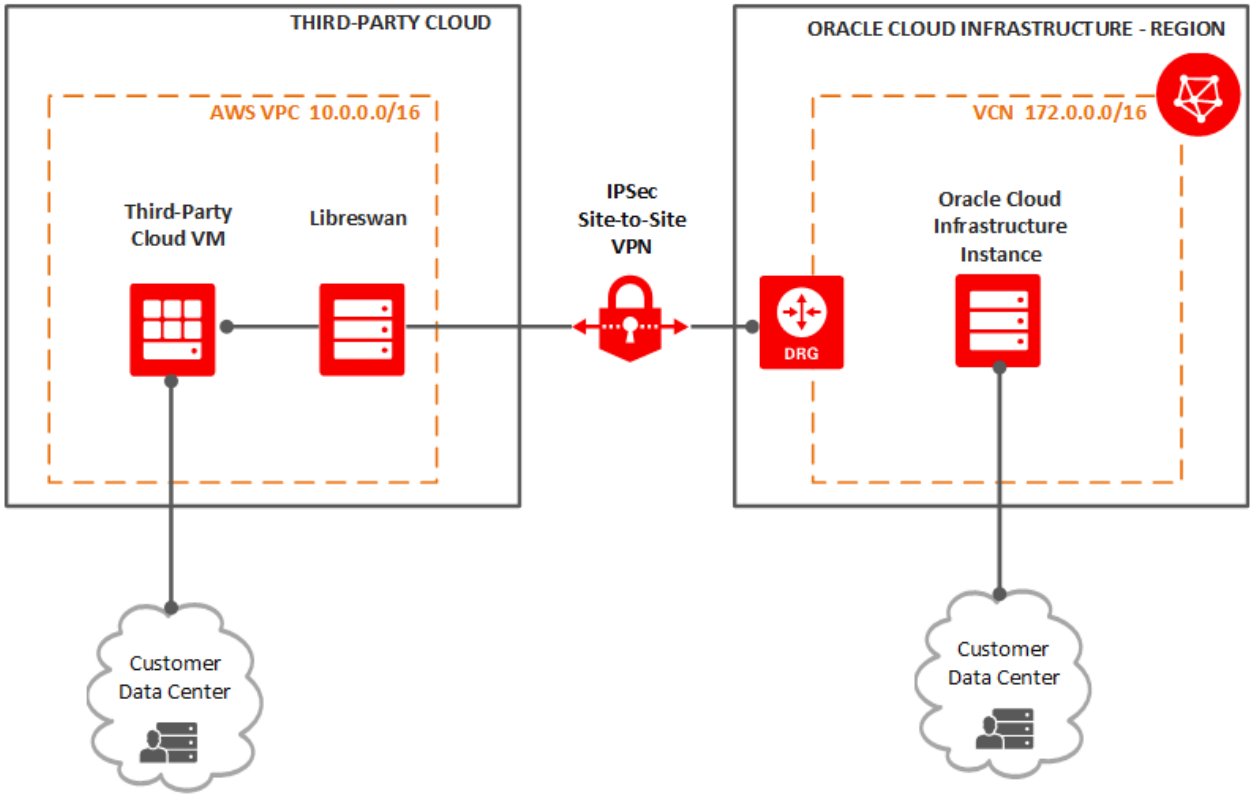
In the example shown here, the other cloud provider is Amazon Web Services (AWS). The connection is a secure and encrypted site-to-site IPSec VPN between the Oracle and Amazon environments. It enables resources in the two clouds to communicate with each other using their private IP addresses as if they are in the same network segment.

A Libreswan CPE guide is also available for all other use cases.

Virtual tunnel interface (VTI) support for this route-based configuration requires minimum Libreswan version 3.18 and a recent Linux 3.x or 4.x kernel. This configuration was validated using Libreswan version 3.29.

Architecture

The following diagram shows the general layout of the connection.



Supported IPSec Parameters

For a vendor-neutral list of supported IPSec parameters for all regions, see Supported IPSec Parameters.

The Oracle BGP ASN for the commercial cloud is 31898. If you're configuring VPN Connect for the Government Cloud, see Required VPN Connect Parameters for Government Cloud and also Oracle's BGP ASN.

Configuration

Important

The configuration instructions in this section are provided by Oracle Cloud Infrastructure for Libreswan. If you need support or further assistance, consult the Libreswan documentation.

Libreswan supports both route-based and policy-based tunnels. The tunnel types can coexist without interfering with each other. The Oracle VPN headends use route-based tunnels. Oracle recommends that you configure Libreswan with the Virtual Tunnel Interface (VTI) configuration syntax.

Refer to Supported IPSec Parameters for more details about the specific parameters used in this document.

Default Libreswan Configuration Files

The default Libreswan installation creates the following files:

- `etc/ipsec.conf`: The root of the Libreswan configuration.
- `/etc/ipsec.secrets`: The root of the location where Libreswan looks for secrets (the tunnel pre-shared keys).
- `/etc/ipsec.d/`: A directory for storing the `.conf` and `.secrets` files for your Oracle Cloud Infrastructure tunnels (for example: `oci-ipsec.conf` and `oci-ipsec.secrets`). Libreswan encourages you to create these files in this folder.

The default `etc/ipsec.conf` file includes this line:

```
include /etc/ipsec.d/*.conf
```

The default `etc/ipsec.secrets` file includes this line:

```
include /etc/ipsec.d/*.secrets
```

The preceding lines automatically merge all the `.conf` and `.secrets` files in the `/etc/ipsec.d` directory into the main configuration and secrets files that Libreswan uses.

About Using IKEv2

Oracle supports Internet Key Exchange version 1 (IKEv1) and version 2 (IKEv2). If you configure the IPSec connection in the Console to use IKEv2, you must configure your CPE to use only IKEv2 and related IKEv2 encryption parameters that your CPE supports. For a list of parameters that Oracle supports for IKEv1 or IKEv2, see Supported IPSec Parameters.

You specify the IKE version when setting up the IPSec configuration file in task 4 in the next section. In that example file, there's a comment showing how to configure IKEv1 versus IKEv2.

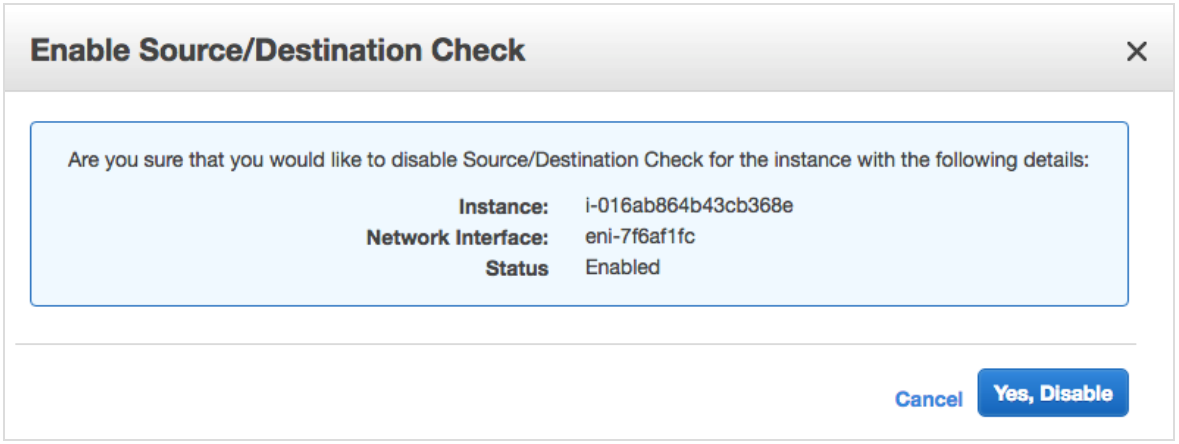
Configuration Process

Task 1: Prepare the AWS Libreswan instance

1. Using the AWS Console or APIs, create a Libreswan VM by using its provisioning process. Use Oracle Linux, CentOS, or Red Hat as the main operating system.
2. After the new instance starts, connect to it with SSH and install the Libreswan package:

```
sudo yum -y install libreswan
```

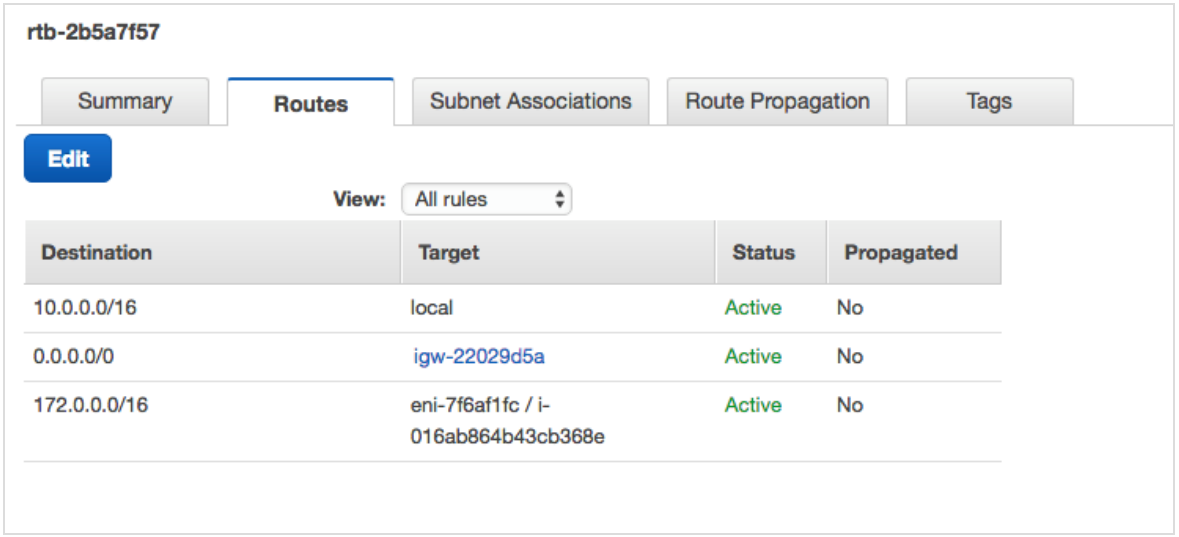
3. In the AWS Console, disable the source and destination checks on the Libreswan VM instance by right-clicking the instance, clicking **Networking**, and then clicking **Change Source/Dest. Check**. When prompted, click **Yes, Disable.**



4. On the Libreswan VM, configure IP_forward to allow AWS clients to send and receive traffic through the Libreswan VM. In the `/etc/sysctl.conf` file, set the following values and apply the updates with `sudo sysctl -p`.

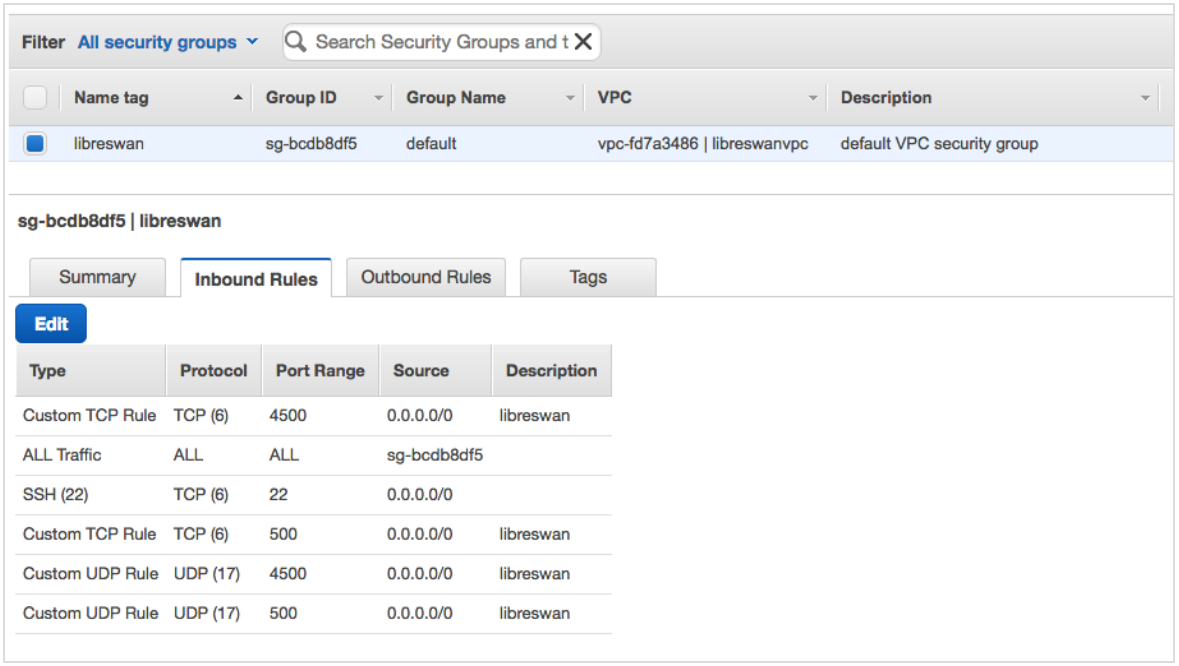
```
net.ipv4.ip_forward=1
net.ipv4.conf.all.accept_redirects = 0
net.ipv4.conf.all.send_redirects = 0
net.ipv4.conf.default.send_redirects = 0
net.ipv4.conf.eth0.send_redirects = 0
net.ipv4.conf.default.accept_redirects = 0
net.ipv4.conf.eth0.accept_redirects = 0
```

5. In the AWS Console, edit your AWS route table. Add a rule with the VCN CIDR (172.0.0.0/16) as the destination and the AWS Libreswan instance ID (i-016ab864b43cb368e in this example) as the target.

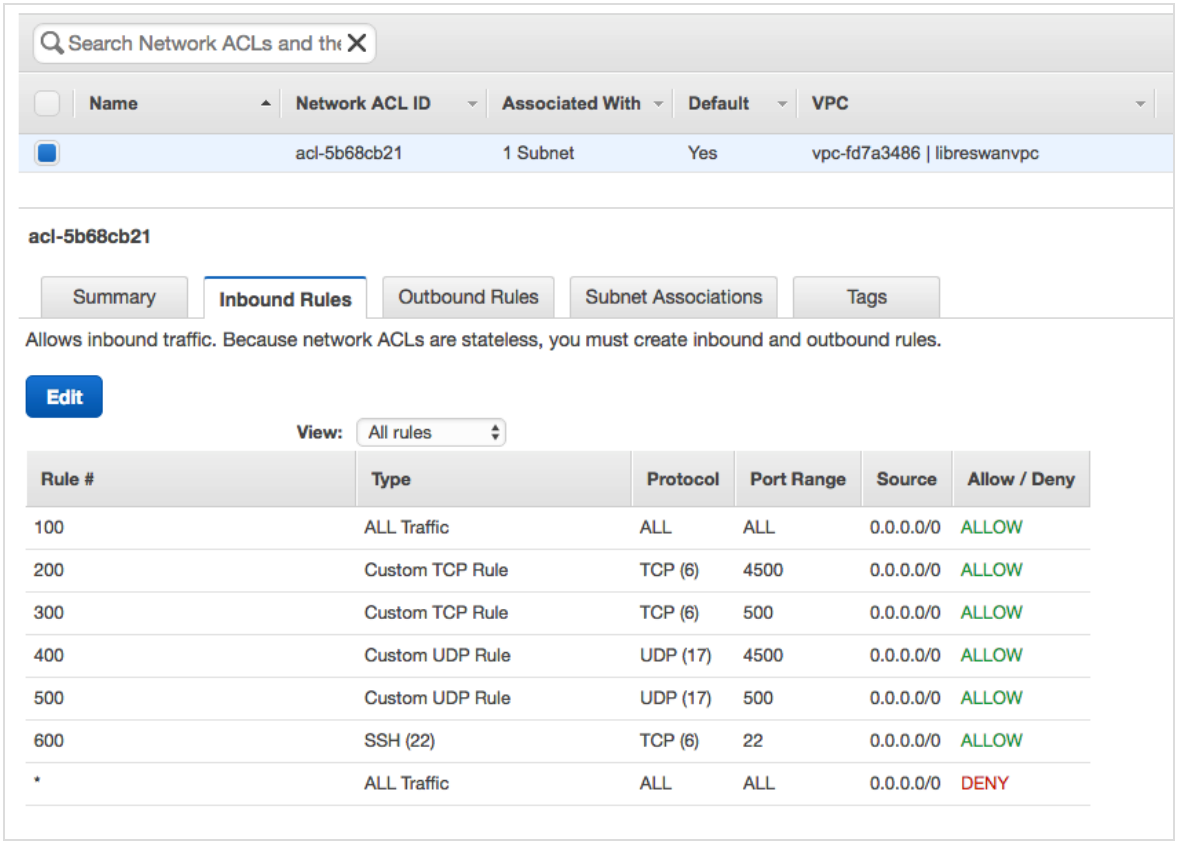


6. In the AWS Console, enable inbound TCP and UDP traffic on ports 4500 and 500 to allow Oracle Cloud Infrastructure IPSec VPN communication with the AWS Libreswan VM. This task includes editing both the AWS security groups and network ACLs. You can set the source value can be the Oracle public IP (the Oracle VPN headend IPSec tunnel endpoint) instead of 0.0.0.0/0.

For security groups:

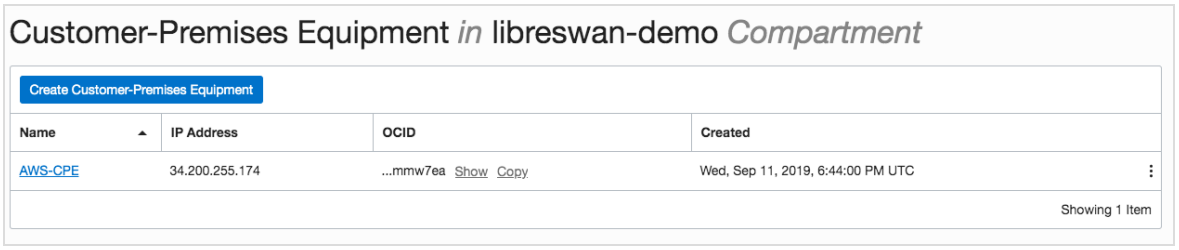


For network ACLs:

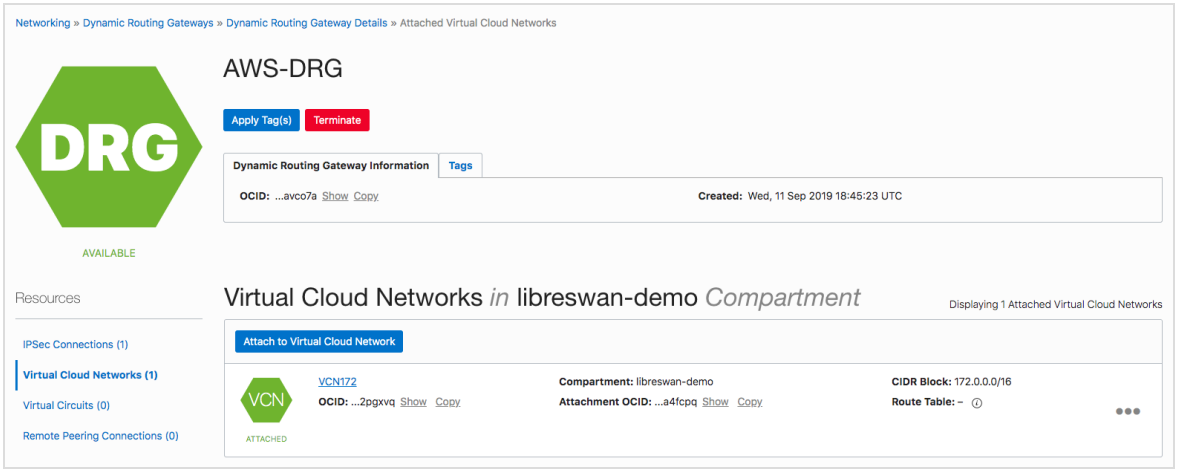


Task 2: Configure the Oracle Cloud Infrastructure DRG and CPE object

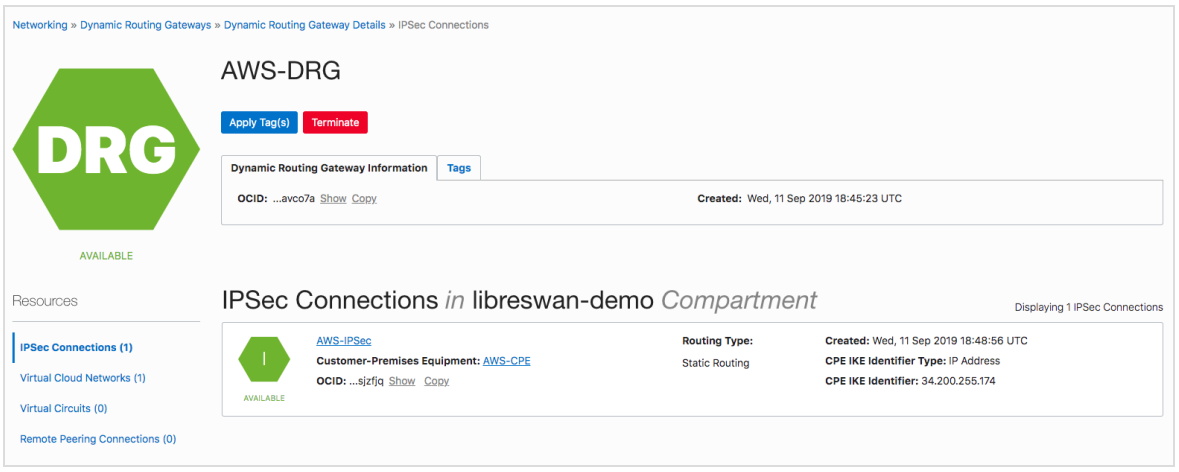
1. In the Oracle Console, create a customer-premises equipment (CPE) object that points to the Libreswan AWS instance public IP address (34.200.255.174).



2. If you don't already have a DRG attached to your VCN: in the Oracle Console, create a DRG and then attach it to the VCN (172.0.0.0/16).



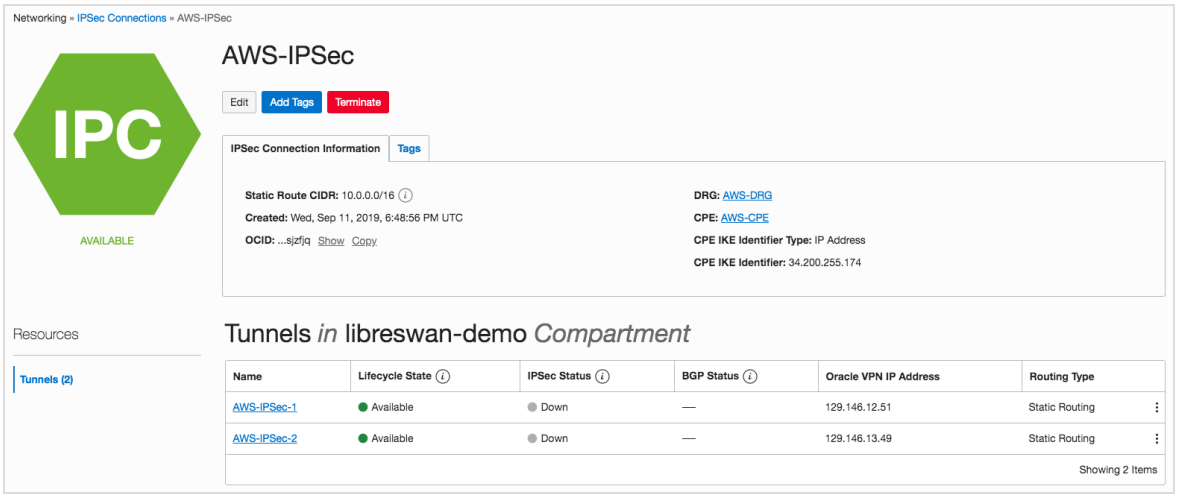
3. In the Oracle Console, create an IPSec connection and point it to the AWS VPC CIDR (10.0.0.0/16). In other words, when you create the IPSec connection, set its static route to the AWS VPC CIDR.



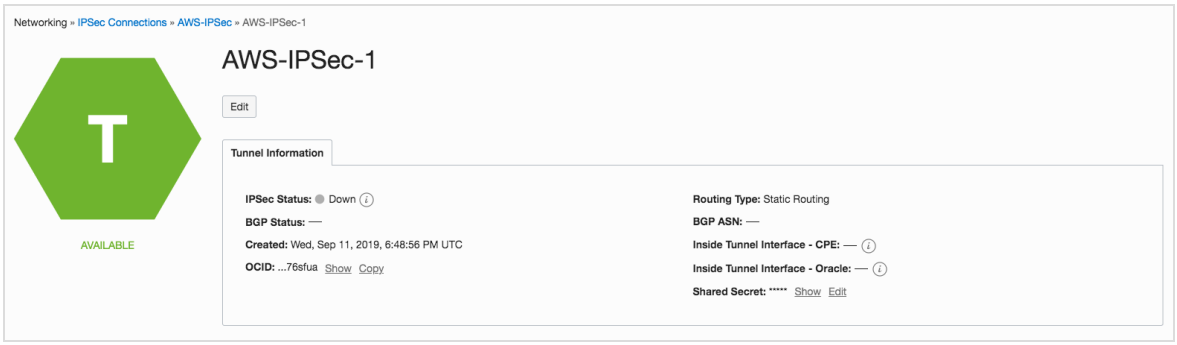
For each configured IPSec connection, Oracle creates two tunnels and assigns these items to each one:

- Oracle VPN headend IPSec tunnel endpoint
- Oracle VPN tunnel shared secret

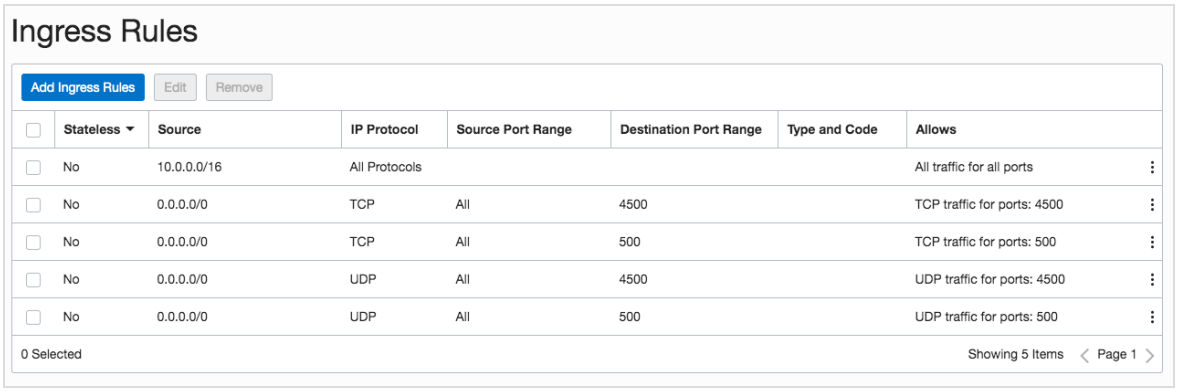
You can view the IPSec tunnel status and Oracle VPN headend IP by clicking the Actions icon (three dots) for the IPSec connection, and then clicking **View Details**. Initially each tunnel is in the DOWN state (offline) because you still have some additional configuration to do later on the AWS Libreswan VM.



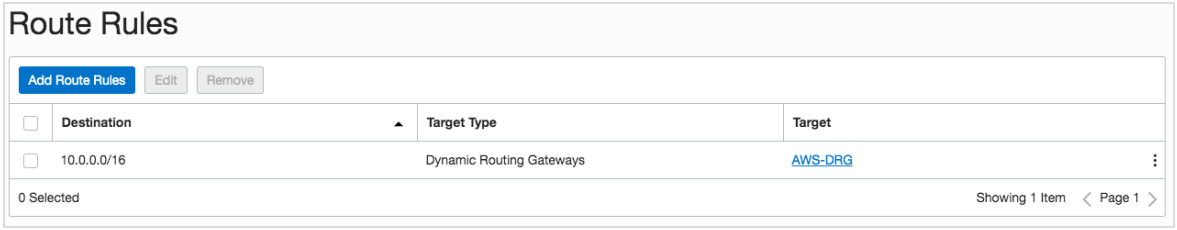
To view the shared secret, click the Actions icon (three dots) for an individual tunnel, and then click **View Details**. Next to **Shared Secret**, click **Show**.



4. In the Oracle Console, edit the VCN's security rules to enable ingress TCP and UDP traffic on ports 4500 and 500 like you did for the AWS security groups and network ACLs. You can use the AWS Libreswan VM public IP address instead of 0.0.0.0/0 if it's a persistent public IP. Also open all protocols and ports for ingress traffic from the AWS VPC CIDR (10.0.0.0/16). Remember: Security lists are associated with a subnet, so edit the security list associated with each subnet that needs to communicate with the AWS VPC. Or, if you're using VCN network security groups, edit the rules in the relevant NSGs.



5. In the Oracle Console, edit the VCN's route tables to add a rule that has the AWS VPC CIDR (10.0.0.0/16) as the destination CIDR block and the DRG you created earlier as the target. Remember: Route tables are associated with a subnet, so edit the route table associated with each subnet that needs to communicate with the AWS VPC. The following screenshot shows the route table for the VCN with an added route for the AWS VPC CIDR.



Task 3: Determine the required configuration values

The Libreswan configuration uses the following variables. Determine the values before proceeding with the configuration.

- `${cpeLocalIP}`: The IP address of your Libreswan device.
- `${cpePublicIpAddress}`: The public IP address for Libreswan. This is the IP address of your outside interface. Depending on your network topology, the value might be different from `${cpeLocalIP}`.
- `${oracleHeadend1}`: For the first tunnel, the Oracle public IP endpoint obtained from the Oracle Console.
- `${oracleHeadend2}`: For the second tunnel, the Oracle public IP endpoint obtained from the Oracle Console.
- `${vti1}`: The name of the first VTI used. For example, vti1.
- `${vti2}` :The name of the second VTI used. For example, vti2.

- `${sharedSecret1}`: The pre-shared key for the first tunnel. You can use the default Oracle-provided pre-shared key, or provide your own when you set up the IPSec connection in the Oracle Console.
- `${sharedSecret2}`: The pre-shared key for the second tunnel. You can use the default Oracle-provided pre-shared key, or provide your own when you set up the IPSec connection in the Oracle Console.
- `${vcnCidrNetwork}`: The VCN IP range.

Task 4: Set up the configuration file: /etc/ipsec.d/oci-ipsec.conf

Libreswan configuration uses the concept of *left* and *right* to define the configuration parameters for your local CPE device and the remote gateway. Either side of the connection (the *conn* in the Libreswan configuration) can be left or right, but the configuration for that connection must be consistent. In this example:

- **Left:** Your local Libreswan CPE
- **Right:** The Oracle VPN headend

Use the following template for your `/etc/ipsec.d/oci-ipsec.conf` file. The file defines the two tunnels that Oracle creates when you set up the IPSec connection.

Important

If your CPE is behind a 1-1 NAT device, uncomment the `leftid` parameter and set it equal to the `${cpePublicIpAddress}`.

```
conn oracle-tunnel-1
     left=${cpeLocalIP}
     # leftid=${cpePublicIpAddress} # See preceding note about 1-1 NAT device
     right=${oracleHeadend1}
     authby=secret
     leftsubnet=0.0.0.0/0
     rightsubnet=0.0.0.0/0
     auto=start
     mark=5/0xffffffff # Needs to be unique across all tunnels
```

```
     vti-interface=${vti1}
     vti-routing=no
     ikev2=no # To use IKEv2, change to ikev2=insist
     ike=aes_cbc256-sha2_384;modp1536
     phase2alg=aes_gcm256;modp1536
     encapsulation=no
     ikelifetime=28800s
     salifetime=3600s
conn oracle-tunnel-2
     left=${cpeLocalIP}
     # leftid=${cpePublicIpAddress} # See preceding note about 1-1 NAT device
     right=${oracleHeadend2}
     authby=secret
     leftsubnet=0.0.0.0/0
     rightsubnet=0.0.0.0/0
     auto=start
     mark=6/0xffffffff # Needs to be unique across all tunnels
     vti-interface=${vti2}
     vti-routing=no
     ikev2=no # To use IKEv2, change to ikev2=insist
     ike=aes_cbc256-sha2_384;modp1536
     phase2alg=aes_gcm256;modp1536
     encapsulation=no
     ikelifetime=28800s
     salifetime=3600s
```

Task 5: Set up the secrets file: /etc/ipsec.d/oci-ipsec.secrets

Use the following template for your `/etc/ipsec.d/oci-ipsec.secrets` file. It contains two lines per IPSec connection (one line per tunnel).

```
${cpePublicIpAddress} ${ipAddress1}: PSK "${sharedSecret1}"
${cpePublicIpAddress} ${ipAddress2}: PSK "${sharedSecret2}"
```

Task 6: Restart the Libreswan configuration

After setting up your configuration and secrets files, you must restart the Libreswan service with the following command.

Important

Restarting the Libreswan service may impact existing tunnels.

```
service ipsec restart
```

Task 7: Configure IP routing

Use the following `ip` command to create static routes that send traffic to your VCN through the IPSec tunnels. If you're logged in with an unprivileged user account, you might need to use `sudo` before the command.

Important

Static routes created with the `ip route` command do not persist through a reboot. To determine how to make your routes persist, refer to the documentation of your Linux distribution of choice.

```
ip route add ${VcnCidrBlock} nexthop dev ${vti1} nexthop dev ${vti2}
ip route show
```

Verification

A Monitoring service is also available from Oracle Cloud Infrastructure to actively and passively monitor your cloud resources. For information about monitoring your VPN Connect, see VPN Connect Metrics.

If you have issues, see VPN Connect Troubleshooting.

Checking the Libreswan Status

Check the current state of your Libreswan tunnels by using the following command:

```
ipsec status
```

The tunnel is established if you see a line that includes the following:

```
STATE_MAIN_I4: ISAKMP SA established
```

If you're using IKEv2, you see the following:

```
STATE_V2_IPSEC_I (IPsec SA established)
```

In the future, if you need to open a support ticket with Oracle about your Libreswan tunnel, include the output of the preceding `ipsec status` command.

Checking the Tunnel Interface Status

Check if the virtual tunnel interfaces are up or down by using the `ifconfig` command or the `ip link show` command. You can also use applications such as tcpdump with the interfaces.

Here's an example of the `ifconfig` output with a working Libreswan implementation that shows the available VTIs.

```
ifconfig
<output trimmed>

vti01: flags=209<UP,POINTOPOINT,RUNNING,NOARP> mtu 8980
     inet6 fe80::5efe:a00:2 prefixlen 64 scopeid 0x20<link>
     tunnel txqueuelen 1000 (IPIP Tunnel)
     RX packets 0 bytes 0 (0.0 B)
     RX errors 0 dropped 0 overruns 0 frame 0
     TX packets 0 bytes 0 (0.0 B)
     TX errors 10 dropped 0 overruns 0 carrier 10 collisions 0

vti02: flags=209<UP,POINTOPOINT,RUNNING,NOARP> mtu 8980
     inet6 fe80::5efe:a00:2 prefixlen 64 scopeid 0x20<link>
     tunnel txqueuelen 1000 (IPIP Tunnel)
     RX packets 0 bytes 0 (0.0 B)
     RX errors 0 dropped 0 overruns 0 frame 0
     TX packets 0 bytes 0 (0.0 B)
     TX errors 40 dropped 0 overruns 0 carrier 40 collisions 0
```

Here's an example of the `ip link show` output:

```
ip link show
<output trimmed>

9: vti01@NONE: <POINTOPOINT,NOARP,UP,LOWER_UP> mtu 8980 qdisc noqueue
state UNKNOWN mode DEFAULT group default qlen 1000
   link/ipip 10.1.2.3 peer 129.146.12.51

10: vti02@NONE: <POINTOPOINT,NOARP,UP,LOWER_UP> mtu 8980 qdisc noqueue
state UNKNOWN mode DEFAULT group default qlen 1000
   link/ipip 10.1.2.3 peer 129.146.13.49
```

Also, in the Oracle Console, each IPSec tunnel should now be in the UP state.

Network Performance

The content in the sections below apply to **Category 7** and **Section 3.c** of the Oracle PaaS and IaaS Public Cloud Services Pillar documentation, which you can download in PDF format from the Oracle Cloud Infrastructure Service Level Agreement page.

Oracle Cloud Infrastructure provides a service-level agreement (SLA) for network throughput between instances in the same availability domain in a virtual cloud network (VCN). You might think of this as a measurement of LAN performance.

Important

This SLA applies only to bare metal instances.

To meet the SLA, the network throughput for instances within the same availability domain and VCN must be at least 90% of the stated maximum for at least 99.9% of the billing month. Network throughput is measured in megabits per second (Mbps) or gigabits per second (Gbps).

For the stated maximum bandwidth by instance shape, see the "Network Bandwidth" column in the "Shape" tables.

Testing Methodology

Summary: Launch two bare metal instances in the same availability domain and VCN. Install and run the `iperf3` utility, with one instance as server and the other as client. Look at the `iperf3` bandwidth results to determine your VCN's network throughput.

Instructions:

1. Launch two bare metal instances in the same availability domain in a single VCN. Designate one as the server and the other as the client. For launch instructions, see

Creating an Instance.

2. Install `iperf3` on both instances. Example Linux command:

```
sudo yum install -y iperf3
```

3. Enable communication to the server instance on TCP port 5201 (for `iperf3`):
   a. For the subnet that the server instance is in, add a rule to the subnet's security list to allow stateless ingress traffic on TCP port 5201 from any source IP address (0.0.0.0/0) and any source port. For instructions, see To update rules in an existing security list. If you are instead using network security groups (NSGs) with the instance, add the rule to the instance's NSG.
   b. On the instance itself, open the firewall to allow `iperf3` traffic. Example Linux commands:

Warning

For instances with an iSCSI boot volume, the following `--reload` command can cause problems. For details and a workaround, see Instances experience system hang after running firewall-cmd --reload.

```
sudo firewall-cmd --zone=public --permanent --add-port 5201/tcp

sudo firewall-cmd --reload
```

4. Start the `iperf3` test:
   a. On the server instance, run `iperf3` in server mode. Example Linux command:

```
iperf3 -s
```

   b. On the client instance, run `iperf3` in client mode and specify the private IP address of the server instance. Example Linux command:

```
iperf3 -c <server_instance_private_ip_address>
```

5. Look at the `iperf3` results on the client instance. The network throughput between the two instances is shown under "Bandwidth" in the last five lines of the client's `iperf3` test output. For example:

```
- - - - - - - - - - - - - - - - - - - - - - - - -
[ ID] Interval           Transfer     Bandwidth       Retr
[  4] 0.00-10.00  sec  XX.YY GBytes  NN.NN Gbits/sec  752             sender
[  4] 0.00-10.00  sec  XX.YY GBytes  NN.NN Gbits/sec                  receiver

iperf Done.
```

Frequently Asked Questions

Q: My VCN isn't meeting the bandwidth SLA. What should I do?

A: Make sure that the CPU on the instance isn't loaded heavily with other services or applications. Confirm this with a utility such as `top` to look at the average CPU utilization. It should be less than one.

Troubleshooting

These topics cover some common issues you might run into and how to address them:

- Hanging Connection
- Subnet or VCN Deletion
- VPN Connect Troubleshooting
- FastConnect Troubleshooting

Hanging Connection

This topic covers one of the most common issues seen with communications between your cloud network and on-premises network: a hanging connection, even though you can ping hosts across the connection.

Summary of Problem and Solutions

Symptom: Your virtual cloud network (VCN) is connected to your existing on-premises network via an IPSec VPN, or Oracle Cloud Infrastructure FastConnect. Hosts on one side of the connection can ping hosts on the other side, but the connection hangs. For example:

- You can SSH to a host across the connection, but after you log in to the host, the connection hangs.
- You can start a Virtual Networking Computing (VNC) connection, but the session hangs.
- You can start an SFTP download, but the download hangs.

General problem: *Path Maximum Transmission Unit Discovery (PMTUD)* is probably not working on one or both sides of the connection. It must be working on both sides of the connection so that both sides can know if they're trying to send packets that are too large for the connection and adjust accordingly. For a brief overview of Maximum Transmission Unit (MTU) and PMTUD, see Overview of MTU and Overview of PMTUD.

Solutions for fixing PMTUD:

1. **Make sure your hosts are configured to use PMTUD:** If the hosts in your on-premises network don't use PMTUD (that is, if they don't set the Don't Fragment flag in the packets), they have no way to discover if they're sending packets that are too large for the connection. Your instances on the Oracle side of the connection use PMTUD by default. Do not change that configuration on the instances.
2. **Make sure both the VCN security lists and the instance firewalls allow ICMP type 3 code 4 messages:** When PMTUD is in use, the sending hosts receive a special ICMP message if they send packets that are too large for the connection. Upon receipt of the message, the host can dynamically update the size of the packets to fit the connection. However, your instances can't receive these important ICMP messages if the security lists for the subnet in the VCN and/or the instance firewalls aren't configured to accept them.

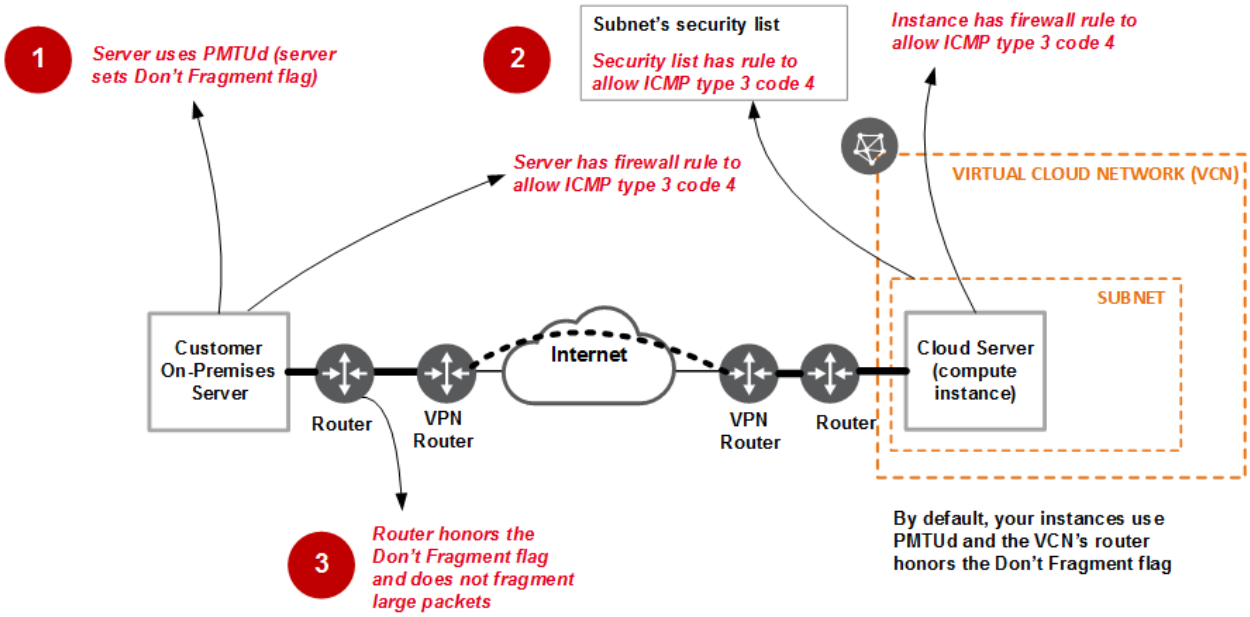
Tip

If you're using stateful security list rules (for TCP, UDP, or ICMP traffic), you don't need to ensure that your security list has a rule to allow ICMP type 3 code 4 messages. With stateful rules, the Networking service tracks the connections and automatically allows corresponding ICMP type 3 code 4 messages without needing an explicit rule to allow them. Only if you're using stateless rules must you have an explicit ingress security list rule for ICMP type 3 code 4 messages. You must also confirm the instance firewalls are set up correctly.

To check to see if a host is receiving the messages, see Finding Where PMTUD Is Broken.

3. **Make sure your router honors the *Don't Fragment* flag:** If the router doesn't honor the flag and thus ignores the use of PMTUD, it sends fragmented packets to the instances in the VCN, which is bad (see Why Avoid Fragmentation?). The VCN's security lists are most likely configured in such a way that they recognize only the initial fragment, and the remaining ones are dropped, causing the connection to hang. Instead, your router should use PMTUD and honor the Don't Fragment flag to determine the correct size of unfragmented packets to send through the connection.

The parts of the solution are numbered and called out in red italics in the following diagram. It shows an example scenario with your on-premises network connected to your VCN over an IPSec VPN.



Keep reading for a brief overview of MTU and PMTUD, and how to check if PMTUD is working on both sides of the network connection.

Why Avoid Fragmentation?

You may be wondering why you want to avoid fragmentation. First, it adversely affects the performance of your application. Fragmentation requires reassembly of the fragments and retransmission if fragments are lost. Reassembly and retransmission require time and CPU resources.

Second, only the first fragment contains the source and destination port information. This means the other packets will probably be dropped by firewalls or your VCN's security lists, which are typically configured to evaluate the port information. For fragmentation to work

with your firewalls and security lists, you would have to configure them to be more permissive than usual, which is not desirable.

Overview of MTU

The communications between any two hosts across an Internet Protocol (IP) network use packets. Each packet has a source and destination IP address and a payload of data. Every network segment between the two hosts has a *Maximum Transmission Unit (MTU)* that represents the number of bytes that a single packet can carry.

Across the internet, the MTU is 1500 bytes. This is also true for most home networks and many corporate networks (and their Wi-Fi networks). Some data centers, including those for Oracle Cloud Infrastructure, have a larger MTU. The Compute instances use an MTU of 9000 by default. On a Linux host, you can use the `ifconfig` command to display the MTU of the host's network connection. For example, here's the `ifconfig` output from an Ubuntu instance (the MTU is highlighted in red italics):

```
ifconfig
ens3 Link encap:Ethernet HWaddr 00:00:17:01:17:83
inet addr:10.0.6.9 Bcast:10.0.6.31 Mask:255.255.255.224
inet6 addr: fe80::200:17ff:fe01:1783/64 Scope:Link
UP BROADCAST RUNNING MULTICAST MTU:9000 Metric:1
```

For comparison, here's the output from a machine connected to a corporate network:

```
ifconfig
en0: flags=8863<UP,BROADCAST,SMART,RUNNING,SIMPLEX,MULTICAST>
mtu 1500
```

Notice that its MTU is the more typical 1500 bytes.

If the host is connected through a corporate VPN, the MTU is even smaller, because the VPN tunnel must encapsulate the traffic inside an IPSec packet and send it across the local network. For example:

```
ifconfig
utun0: flags=81d1<UP,POINTOPOINT,RUNNING,NOARP,PROMISC,MULTICAST>
mtu 1300
```

How do the two hosts figure out how large of a packet they can send to each other? For many types of network traffic, such as HTTP, SSH, and FTP, the hosts use the Transmission Control

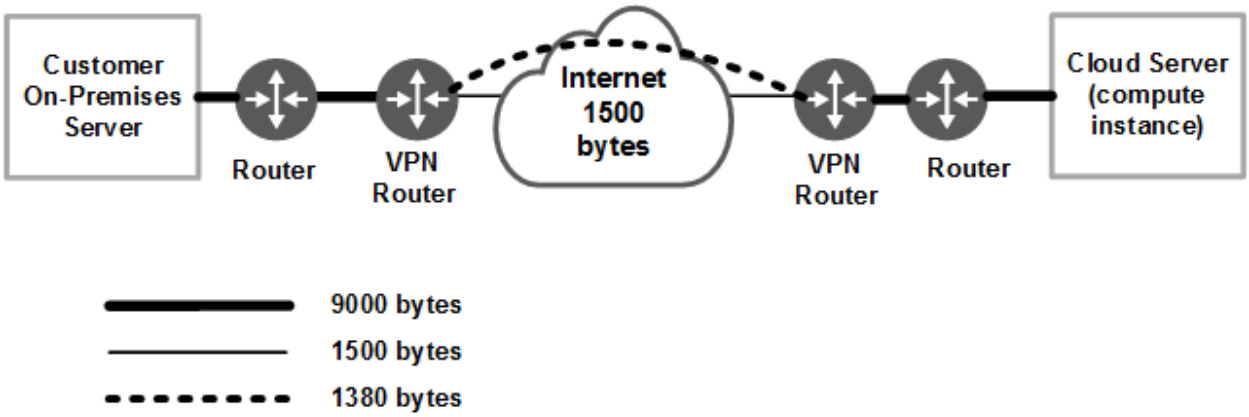
Protocol (TCP) to establish new connections. During the initial three-way handshake between two hosts, they each send the *Maximum Segment Size (MSS)* for how large their payload can be. This is smaller than the MTU. (TCP runs inside the Internet Protocol (IP), which is why it's referred to as TCP/IP. Segments are to TCP what packets are to IP.)

Using the tcpdump application, you can see the MSS value shared during the handshake. Here's an example from tcpdump (with the MSS highlighted in red italics):

```
12:11:58.846890 IP 129.146.27.25.22 > 10.197.176.19.58824: Flags [S.], seq
2799552952, ack 2580095593, win 26844, options [mss 1260,sackOK,TS val
44858491 ecr 1321638674,nop,wscale 7], length 0
```

The preceding packet is from an SSH connection to an instance from a laptop connected to a corporate VPN. The local network the laptop uses for its internet connection has an MTU of 1500 bytes. The VPN tunnel enforces an MTU of 1300 bytes. Then when the SSH connection is attempted, TCP (running inside the IP connection) tells the Oracle Cloud Infrastructure instance that it supports TCP segments that are less than or equal to 1260 bytes. With a corporate VPN connection, the laptop connected to the VPN typically has the smallest MTU and MSS compared to anything it's communicating with across the internet.

A more complex case is when the two hosts have a larger MTU than some network link between them *that is not directly connected to either of them*. The following diagram illustrates an example.



In this example, there are two servers, each directly connected to its own routed network that supports a 9000-byte MTU. The servers are in different data centers. Each data center is connected to the internet, which supports a 1500-byte MTU. There is an IPSec VPN tunnel between the two data centers. That tunnel crosses the internet, so the inside of the tunnel has a smaller MTU than the internet. In this diagram, the MTU is 1380 bytes.

If the two servers try to communicate (with SSH, for example), during the three-way handshake, they agree on an MSS around 8960. The initial SSH connection might succeed, because the maximum packet sizes during the initial SSH connection setup are usually less than 1380 bytes. When one side tries to send a packet larger than the smallest link between the two endpoints, Path MTU Discovery (PMTUD) becomes critical.

Overview of PMTUD

Path MTU Discovery is defined in RFC 1191. It works by requiring the two communicating hosts to set a *Don't Fragment* flag in the packets they each send. If a packet from one of these hosts reaches a router where the egress (or outbound) interface has an MTU smaller than the packet length, the router drops that packet. The router also returns an ICMP type 3 code 4 message to the host. This message specifically says "Destination Unreachable, Fragmentation Needed and Don't Fragment Was Set" (defined in RFC 792). Effectively the router tells the host: "You told me not to fragment packets that are too large, and this one's too large. I'm not sending it." The router also tells the host the maximum size packets allowed through that egress interface. The sending host then adjusts the size of its outbound packets so they're smaller than the value the router provided in the message.

Here's an example that shows the results when an instance tries to ping a host (8.8.8.8) over the internet with an 8000-byte packet and the Don't Fragment flag set (that is, with PMTUD in use). The returned ICMP message is highlighted in red italics:

```
ping 8.8.8.8 -M do -s 8000
PING 8.8.8.8 (8.8.8.8) 8000(8028) bytes of data.
From 4.16.139.250 icmp_seq=1 Frag needed and DF set (mtu = 1500)
```

The response is exactly what's expected. The destination host is across the internet, which has an MTU of 1500 bytes. Even though the sending host's local network connection has an MTU of 9000 bytes, the host can't reach the destination host with the 8000-byte packet and gets an ICMP message accordingly. PMTUD is working correctly.

For comparison, here's the same ping, but the destination host is across an IPSec VPN tunnel:

```
ping 192.168.6.130 -M do -s 8000
PING 192.168.6.130 (192.168.6.130) 8000(8028) bytes of data.
From 129.146.13.49 icmp_seq=1 Frag needed and DF set
```

Here the VPN router sees that to send this packet to its destination, the outbound interface is a VPN tunnel. That tunnel goes across the internet, so the tunnel must fit inside the internet's 1500-byte MTU link. The result is that the inside of the tunnel only allows packets up to 1360 bytes (which the router then lowered to 1358, which can make things more confusing).

Finding Where PMTUD Is Broken

If PMTUD isn't working somewhere along the connection, you need to figure out why and where. Typically it's because the ICMP type 3 code 4 packet (from the router with the constrained link that can't fit the packet) never gets back to the sending host. This can happen if there's something blocking that kind of traffic between the host and the router. And it can happen on either side of the VPN tunnel (or other constrained MTU link).

Try Pinging From Each Side of the Connection

To troubleshoot the broken PMTUD, you must determine if PMTUD is working on each side of the connection. In this scenario, let's assume the connection is an IPSec VPN.

How to ping: Like in Overview of PMTUD, ping a host on the other side of the connection with a packet that you know is too large to fit through the VPN tunnel (for example, 1500 bytes or larger). Depending on which operating system the sending host uses, you might need to format the ping command slightly different to ensure the Don't Fragment flag is set. For both Ubuntu and Oracle Linux, you use the `-M` flag with the ping command.

Here's information about the `-M` flag:

```
-M pmtudisc_opt
Select Path MTU Discovery strategy. pmtudisc_option may be either do
(prohibit fragmentation, even local one), want (do PMTU discovery, fragment
locally when packet size is large), or dont (do not set DF flag).
```

Here's an example ping (with the -M flag and the resulting ICMP message highlighted in red italics)

```
ping -M do -s 1500 192.168.6.130
PING 192.168.6.130 (192.168.6.130) 1500(1528) bytes of data.
From 129.146.13.49 icmp_seq=1 Frag needed and DF set (mtu = 1358)
```

Good: PMTUD is working

If the result includes the line "From x.x.x.x icmp_seq=1 Frag needed and DF set (mtu = xxxx)", then PMTUD is working on that side of the tunnel. Note that the source address of the ICMP message is the public IP address of the tunnel the traffic is trying to go out (for example 129.146.13.49 in the preceding Ubuntu example).

Make sure to also ping from the other side of the connection to confirm PMTUD is working from that side. Both sides of the connection must recognize that there is a tunnel between them that can't fit the large packets.

Bad: If you're testing your side of the connection and the ping succeeds

If you're sending the ping from a host in your on-premises network, and the ping succeeds, that probably means your edge router is not honoring the Don't Fragment flag. Instead the router is fragmenting the large packet. The first fragment reaches the destination host, so the ping succeeds, which is misleading. If you try to do more than just ping, the fragments after the first get dropped, and the connection will hang.

Make sure to configure your router to honor the Don't Fragment flag. The router's default configuration is to honor it, but someone might have changed the default.

Bad: If you're testing the VCN side of the connection and you don't see the ICMP message

When testing from the VCN side of the connection, if you don't see the ICMP message in the response, there is probably something dropping the ICMP packet before it reaches your instance.

There could be two issues:

- **Security list:** The Networking security list could be missing an ingress rule that allows ICMP type 3 code 4 messages to reach the instance. This is an issue only if you're using stateless security list rules. If you're using stateful rules, your connections are tracked and the ICMP message is automatically allowed without needing a specific security list rule to allow it. **If you're using stateless rules, make sure that the subnet the instance is in has a security list with an ingress rule that allows ICMP traffic type 3 code 4 from source 0.0.0.0/0 and any source port.** For more information, see Security Lists, and specifically To update rules in an existing security list.
- **Instance firewall:** The instance's firewall rules (set in the OS) could be missing a rule that allows ICMP type 3 code 4 messages to reach the instance. Specifically for a Linux instance, make sure that iptables or firewalld is configured to allow the ICMP type 3 code 4 messages.

Avoiding the Need for PMTUD

Oracle recommends using PMTUD. However, in some situations it's possible to configure servers so they don't need to rely on it. Consider the case of the instances in your VCN communicating across an IPSec VPN to hosts in your on-premises network. You know the range of IP addresses for your on-premises network. You can add a special route to your instances that specifies the maximum MTU to use when communicating with hosts in that address range. The instance-to-instance communication within the VCN still uses an MTU of 9000 bytes.

The following information shows how to set that route on a Linux instance.

The default route table on the instance typically has two routes: the default route (for the default gateway), and a local route (for the local subnet). For example:

```
ip route show
default via 10.0.6.1 dev ens3
10.0.6.0/27 dev ens3  proto kernel  scope link  src 10.0.6.9
```

You can add another route that points to the same default gateway, but with the address range of the on-premises network and a smaller MTU. For example, in the following command, the

on-premises network is 1.0.0.0/8, the default gateway is 10.0.6.1, and the maximum MTU size is 1300 for packets being sent to the on-premises network.

```
ip route add 1.0.0.0/8 via 10.0.6.1 mtu 1300
```

The updated route table looks like this:

```
ip route show
default via 10.0.6.1 dev ens3
1.0.0.0/8 via 10.0.6.1 dev ens3  mtu 1300
10.0.6.0/27 dev ens3  proto kernel  scope link  src 10.0.6.9
```

Within the VCN, the instance-to-instance communication continues to use 9000 MTU. However, communication to the on-premises network uses a maximum of 1300. This example assumes there's no part of the connection between the on-premises network and VCN that uses an MTU smaller than 1300.

Important

The preceding commands do not persist if you reboot the instance. You can make the route permanent by adding it to a configuration file in the OS. For example, for Oracle Linux, it's an interface-specific file called `/etc/sysconfig/network-scripts/route-<interface>`. For more information, see the documentation for your variant of Linux.

Subnet or VCN Deletion

This topic covers reasons why deletion of a subnet or VCN might fail.

Remember:

- To delete a VCN, it must first be empty and have no related resources or attached gateways (for example: no internet gateway, dynamic routing gateway, and so on).
- To delete a VCN's subnets, they must first be empty.

The Subnet Isn't Empty

The most common reason a subnet (and thus a VCN) can't be deleted is because the subnet contains one or more of these resources:

- Load balancer
- Mount target
- DB system

Note

When you create one of the preceding resources, you specify a VCN and subnet for it. The relevant service creates at least one VNIC in the subnet and attaches the VNIC to the resource. The service manages the VNICs on your behalf, so they are not readily apparent to you in the Console. The VNIC enables the resource to communicate with other resources over the network. Although this documentation commonly talks about the resource itself being in the subnet, it's actually the resource's attached VNIC. This documentation uses the term *parent resource* to refer to this type of resource.

If the subnet *is* empty when you try to delete it, its state changes to TERMINATING briefly and then to TERMINATED.

If the subnet is not empty, you instead get an error indicating that there are still resources that you must delete first. The error includes the OCID of a VNIC that is in the subnet (there could be more, but the error returns only a single VNIC's OCID).

You can use the Oracle Cloud Infrastructure command line interface (CLI) or another SDK or client to call the `GetVnic` operation with the VNIC OCID. The response includes the VNIC's *display name*. Depending on the type of parent resource, the display name can indicate which parent resource the VNIC belongs to. You can then delete that parent resource, or you can contact your administrator to determine who owns the resource. When the VNIC's parent

resource is deleted, the attached VNIC is also deleted from the subnet. If there are remaining VNICs in the subnet, repeat the process of determining and deleting each parent resource until the subnet is empty. Then you can delete the subnet.

For example, if you're using the CLI, use this command to get information about the VNIC.

```
oci network vnic get --vnic_id <VNIC_OCID>
```

Load balancer example

Here is an example CLI response for a VNIC that belongs to a load balancer. The display name shows the load balancer's OCID:

```
{
  "data": {
    "availability-domain": "fooD:PHX-AD-1",
    "compartment-id": "ocid1.compartment.oc1..<unique_id_1>",
    "defined-tags": {},
    "display-name": "VNIC for LB ocid1.loadbalancer.oc1.phx.<unique_id_2>",
    "freeform-tags": {},
    "hostname-label": null,
    "id": "ocid1.vnic.oc1.phx.<unique_id_3>",
    "is-primary": false,
    "lifecycle-state": "AVAILABLE",
    "mac-address": "00:00:17:00:BB:CA",
    "private-ip": "10.0.0.6",
    "public-ip": null,
    "skip-source-dest-check": false,
    "subnet-id": "ocid1.subnet.oc1.phx.<unique_id_4>",
    "time-created": "2019-05-11T04:28:31.950000+00:00"
  },
  "etag": "5d8213fa"
}
```

File Storage example

Here's an example for a VNIC that belongs to a File Storage mount target:

```
"display-name": "fss-<integer>",
```

Although the display name does not include an OCID, the `fss` characters indicate that the resource is for the File Storage service.

Database example

Here's an example of the display name for a VNIC that belongs to a DB system:

```
"display-name": "ocid1.dbnode.oc1.phx.<unique_id>",
```

A Network Security Group Isn't Empty

Another reason a VCN can't be deleted is because it contains a one or more network security groups (NSGs) that are not yet empty. To delete an NSG, it must not contain any VNICs (or parent resources with VNICs). You can determine what parent resources are in an NSG by using either the Console or REST API. For more information, see Deleting NSGs.

There Are Resources in Compartments You Don't Have Access To

You might not be able to see all the resources in a subnet or VCN. This is because subnets and VCNs can contain resources in multiple compartments, and you might not have access to all the compartments. For example, the subnet might contain instances that your team manages but also DB systems that another team manages. Another example: The VCN might have security lists or a gateway in a compartment that another team manages. You might need to contact your tenancy administrator to help you determine who owns the resources in the subnet or VCN.

CHAPTER 24 Notifications

This chapter explains how to use the Notifications service.

Notifications Overview

The Oracle Cloud Infrastructure Notifications service broadcasts messages to distributed components through a publish-subscribe pattern, delivering secure, highly reliable, low latency and durable messages for applications hosted on Oracle Cloud Infrastructure and externally. Use Notifications to get notified when event rules are triggered or alarms are breached, or to directly publish a message.

Note

Notifications is not available in Oracle Cloud Infrastructure Government Cloudrealms.

How Notifications Works

The Notifications service enables you to set up communication channels for publishing messages using topics and subscriptions. When a message is published to a topic, the Notifications service sends the message to all of the topic's subscriptions.

When a subscriber’s endpoint does not acknowledge receipt of the message, the Notifications service retries delivery. This situation can occur when the endpoint is offline. For example, the email server for an email address may be down.

Delivery retry details

Notifications retries delivery following these steps until either (a) acknowledgement is received or (b) the subscription's retry duration is over. By default, the retry duration is two

hours.

1. Immediate retry.
2. Exponential backoff retry for the period of the subscription's retry duration, using the following timing:
    a. 1 minute
    b. 2 minutes
    c. 4 minutes
    d. 8 minutes
    e. 16 minutes
    f. 32 minutes
3. Discarding of the message at the end of the retry duration.

You can change the retry duration for a subscription. For instructions using the Console, see To update the retry duration for a subscription. For the API, use the following operation: UpdateSubscription.

Notifications Concepts

The following concepts are essential to working with Notifications.

MESSAGE

The content that is published to a *topic*. Each message is delivered at least once per *subscription*. Every message sent out as email contains a link to *unsubscribe* from the related topic.

SUBSCRIPTION

An endpoint for a *topic*. Published *messages* are sent to each subscription for a *topic*. For supported subscription protocols, see To create a subscription.

TOPIC

A communication channel for sending *messages* to the *subscriptions* in the topic. Each topic name is unique across the tenancy.

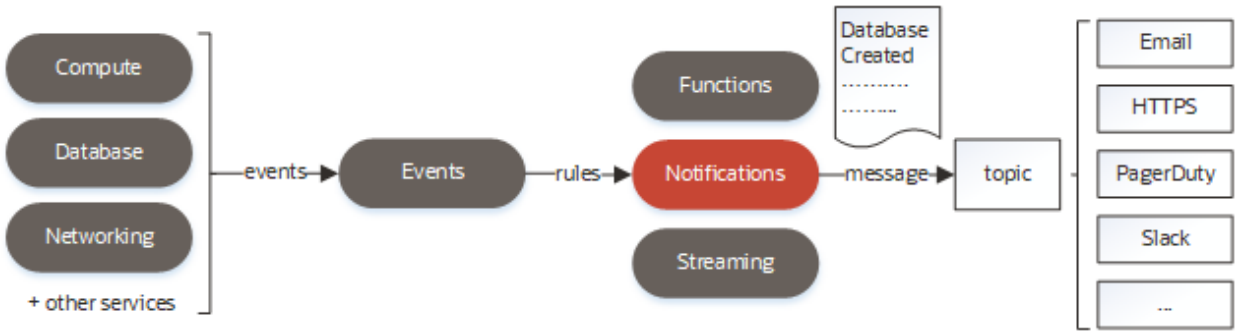
Note

Messages sent out as email by the Oracle Cloud Infrastructure Notifications service are processed and delivered through Oracle resources in U.S.-based regions.

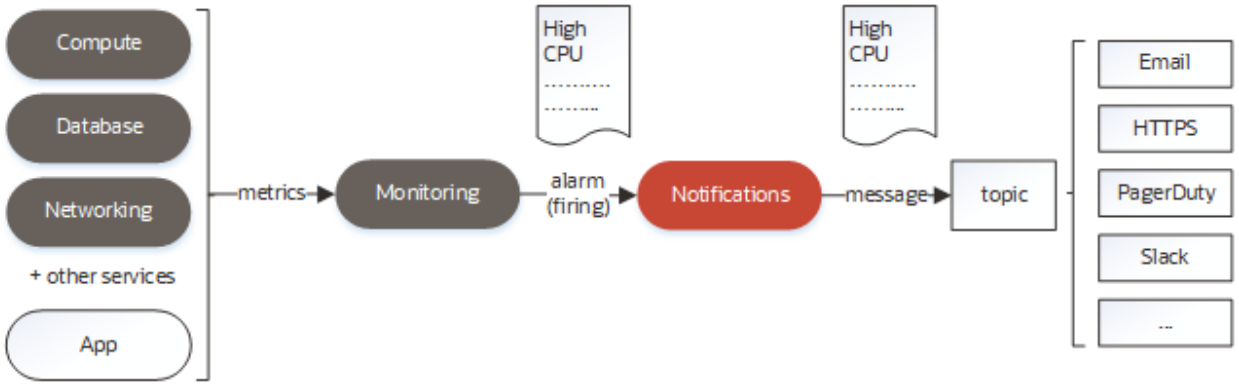
Flow of Message Publication

Notifications publishes messages when event rules are triggered, alarms are breached, or someone directly publishes a message.

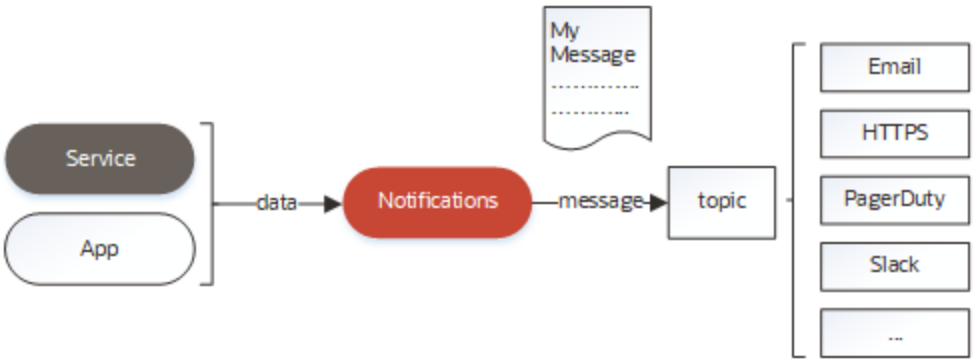
Event rules: Notifications sends messages when rules are triggered. The message is sent to the topic specified in the rule. For example, a message might be configured for new databases. See Managing Rules for Events.



Alarms: Notifications sends alarm messages when alarms are breached. The alarm message is sent to the topic specified in the alarm. For example, an alarm message might be configured for high CPU usage. See Managing Alarms.



Direct publication: Notifications sends messages when you (or a service or app) publish the messages directly. The message is sent to the topic you specify. See Publishing Messages.



Availability

Notifications is currently available in the following regions:

Region Name	Region Location	Region Key
India West (Mumbai)	Asia-Pacific: Mumbai, India	BOM
South Korea Central (Seoul)	Asia-Pacific: Seoul, South Korea	ICN
Australia East (Sydney)	Asia-Pacific: Sidney, Australia	SYD
Japan East (Tokyo)	Asia-Pacific: Tokyo, Japan	NRT
Canada Southeast (Toronto)	Canada: Toronto	YYZ
Germany Central (Frankfurt)	Europe: Frankfurt, Germany	FRA
Switzerland North (Zurich)	Europe: Zurich, Switzerland	ZRH
Brazil East (Sao Paulo)	South America: Sao Paulo	GRU
UK South (London)	United Kingdom: London	LHR
US East (Ashburn)	United States: Ashburn, VA	IAD
US West (Phoenix)	United States: Phoenix, AZ	PHX

Service Comparison for Sending Email Messages

Consider the following service features when deciding whether to use the Notifications service or the Email Delivery service to send your email messages. For more information about Email Delivery, see Overview of the Email Delivery Service.

Service Feature	Notifications service	Email Delivery service
Requires confirmation before sending email.	Yes	No
Allows email decorations, such as signatures.	Yes	No
Allows raw email messages.	No	Yes
Supports MIME attachments.	No	Yes
Supports special handling for failed email delivery.	No	Yes
Priced for small messages (less than 32 KB, with a 64-KB limit).	Yes	No
Priced for large messages (greater than 32 KB, with a 2-MB limit).	No	Yes

Resource Identifiers

Most types of Oracle Cloud Infrastructure resources have a unique, Oracle-assigned identifier called an Oracle Cloud ID (OCID). For information about the OCID format and other ways to identify your resources, see Resource Identifiers.

Moving Topics and Subscriptions to a Different Compartment

You can move topics and subscriptions from one compartment to another. When you move a topic to a new compartment, its associated subscriptions remain in their existing compartment. The same consideration applies when moving a subscription: its associated topic remains in its existing compartment.

After you move the topic or subscription to the new compartment, inherent policies apply immediately and affect access to the moved topic or subscription through the Console. For more information, see Moving Resources to a Different Compartment.

Important

To move resources between compartments, resource users must have sufficient access permissions on the compartment that the resource is being moved to, as well as the current compartment. For more information about permissions for Notifications resources, see Details for the Notifications Service.

Ways to Access Notifications

You can access the Notifications service using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. For a list of available SDKs, see Software Development Kits and Command Line Interface.

Console: To access Notifications using the Console, you must use a supported browser. Oracle Cloud Infrastructure supports the latest desktop versions of Google Chrome, Microsoft Edge, Internet Explorer 11, Safari, Firefox, and Firefox ESR. Note that private browsing mode is not supported for Firefox, Internet Explorer, or Edge. Mobile browsers are not supported. Open the navigation menu. Under **Solutions and Platform**, go to **Application Integration** and click **Notifications**.

API: To access Notifications through API, use Notifications API.

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies. For specific details about writing policies for each of the different services, see Policy Reference.

If you're a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

Administrators: For common policies that give groups access to Notifications, see Allow a group to manage topics, Allow a group to manage topic subscriptions, and Allow a group to publish messages to topics.

Limits on Notifications

See Service Limits for a list of applicable limits and instructions for requesting a limit increase. To set compartment-specific limits on a resource or resource family, administrators can use compartment quotas.

Managing Topics and Subscriptions

This section describes how to manage topics and their subscriptions.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

A topic is a communication channel for sending messages to its subscriptions. A topic can have zero, one, or multiple subscriptions that are notified whenever a message is published to a topic.

Prerequisites

IAM policies: To use Notifications, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a response that you don’t have permission or are unauthorized, check with your administrator. You may not have the required type of access in the current compartment. For more information on user authorizations, see Notifications Overview.

Creating Automation with Events

You can create automation based on state changes for your Oracle Cloud Infrastructure resources by using event types, rules, and actions. For more information, see Overview of Events.

Using the Console

To create a topic

1. Open the navigation menu. Under **Solutions and Platform**, go to **Application Integration** and click **Notifications**.

2. Click **Create Topic** at the top of the topic list.
3. In the **Create Topic** dialog box, configure your topic.
    - **Name**: Required. Specify a friendly name for the topic. It must be unique across the tenancy; validation is case-sensitive. Avoid entering confidential information.
    - **Description**: Optional. Enter a description for the topic. Avoid entering confidential information.
4. Click **Create**.

To delete a topic

1. Open the navigation menu. Under **Solutions and Platform**, go to **Application Integration** and click **Notifications**.
2. For the topic you want to delete, click the Actions icon (three dots), and then click **Delete**.
3. Confirm when prompted.

To update the description for a topic

1. Open the navigation menu. Under **Solutions and Platform**, go to **Application Integration** and click **Notifications**.
2. Click the name of the topic you want to update.
3. On the topic detail page, next to **Description**, click the edit icon.
4. Edit the description.
5. Click the save icon.

To move a topic to a different compartment

Associated subscriptions remain in their current compartments. For more information, see Moving Topics and Subscriptions to a Different Compartment.

Note

To move resources between compartments, resource users must have sufficient access permissions on the compartment that the resource is being moved to, as well as the current compartment. For more information about permissions for Notifications resources, see Details for the Notifications Service.

1. Open the navigation menu. Under **Solutions and Platform**, go to **Application Integration** and click **Notifications**.
2. In the **Scope** section, select a compartment.
3. Find the topic in the list, click the Actions icon (three dots), and then click **Move Resource**.
4. Choose the destination compartment from the list.
5. Click **Move Resource**.

To create a subscription

Note

While new subscriptions must be created in the same compartment as the topic, you can move them to different compartments after creating them.

1. Open the navigation menu. Under **Solutions and Platform**, go to **Application Integration** and click **Notifications**.
2. Click the name of the topic that you want to add the subscription to.

3. On the topic detail page, click **Create Subscription**.
4. In the **Create Subscription** dialog box, configure your subscription for the protocol you want:

Email subscription

Sends an email message when you publish a message to the subscription's parent topic.

- **Protocol**: Select **Email**.
- **Email**: Type an email address.

HTTPS (Custom URL) subscription

Sends specified information when you publish a message to the subscription's parent topic.

Endpoint format (URL using HTTPS protocol):

```
https://<anyvalidURL>
```

Basic access authentication is supported, allowing you to specify a username and password in the URL, as in `https://user:password@domain.com` or `https://user@domain.com`. The username and password are encrypted over the SSL connection established when using HTTPS. For more information about Basic Access Authentication, see RFC-2617.

Query parameters are not allowed in URLs.

- **Protocol**: Select **HTTPS (Custom URL)**.
- **URL**: Type (or copy and paste) the URL you want to use as the endpoint.

PagerDuty subscription

Creates a PagerDuty incident by default when you publish a message to the subscription's parent topic.

Endpoint format (URL):

```
https://events.pagerduty.com/integration/<integrationkey>/enqueue
```

Query parameters are not allowed in URLs.

To create an endpoint for a PagerDuty subscription (set up and retrieve an integration key), see the PagerDuty documentation.

- **Protocol**: Select **PagerDuty**.
- **URL**: Type (or copy and paste) the *integration key* portion of the URL for your PagerDuty subscription. (The other portions of the URL are hard-coded.)

Slack subscription

Note

See the following known issue for up-to-date information about creating Slack subscriptions.

Sends a message to the specified Slack channel by default when you publish a message to the subscription's parent topic.

Endpoint format (URL):

```
https://hooks.slack.com/services/<webhook-token>
```

The *<webhook-token>* portion of the URL contains two slashes (/).

Query parameters are not allowed in URLs.

To create an endpoint for a Slack subscription (using a webhook for your Slack channel), see the Slack documentation.

- **Protocol**: Select **Slack**.
- **URL**: Type (or copy and paste) the Slack endpoint, including your webhook token.

5. Click **Create**.
   The subscription has been created and a subscription confirmation URL will be sent. The subscription remains in "Pending" status until it has been confirmed.

To confirm a subscription

Navigate to the confirmation URL that is sent to the subscription's endpoint.

Some protocols provide confirmation URLs in unique ways:

- **HTTPS (Custom URL)**: You can find the confirmation URL in the request header or body of the subscription confirmation message (request of content-type: "application/json") that is sent to the endpoint.
  - In the request header, see the value of the `X-OCI-NS-ConfirmationURL` field.

    ### Example request header:

    ```
    "X-OCI-NS-SignatureVersion":"1.0"
    "X-OCI-NS-Signature":"<example-signature>"
    "X-OCI-NS-SigningCertURL":"<example-url>"
    "X-OCI-NS-TopicOcid":"ocid.compartment.oc1..<unique_ID>"
    "X-OCI-NS-Timestamp":"2019-04-19T21:26:00.310+0000"
    "X-OCI-NS-MessageId":"<unique_ID>"
    "X-OCI-NS-TopicName":"mytopic"
    "X-OCI-NS-MessageType":"SubscriptionConfirmation"
    "X-OCI-NS-ConfirmationURL":"<exampleConfirmationURL>"
    "X-OCI-NS-SubscriptionId":"ocid1.onssubscription.oc1.phx.<unique_ID>"
    "X-OCI-NS-State":"Pending"
    ```

  - In the request body, see the value of the `ConfirmationURL` key.
    Example ConfirmationURL key and value (request body):

    ```
    "ConfirmationURL":"<exampleConfirmationURL>"
    ```

- **PagerDuty**: Incident titled "Oracle Notification Service Subscription Confirmation". For more information, see the PagerDuty documentation for Oracle Cloud Infrastructure.
- **Slack**: Message sent to Slack channel containing the text "To confirm the subscription".

To resend a subscription confirmation

The ability to resend subscription confirmations is only applicable for pending subscriptions.

1. Open the navigation menu. Under **Solutions and Platform**, go to **Application Integration** and click **Notifications**.
2. For the subscription you want to resend the confirmation for, click the Actions icon (three dots), and then click **Resend Confirmation**.

To update the retry duration for a subscription

The retry duration is part of the delivery policy for the subscription. By default, Notifications retries delivery of a message for up to two hours.

1. Open the navigation menu. Under **Solutions and Platform**, go to **Application Integration** and click **Notifications**.
2. For the subscription you want to update, click the Actions icon (three dots), and then click **Update Delivery Policy**.
3. In the **Update Delivery Policy** dialog box, click the edit icon for **Max Retry Duration in Minutes**, type the new value, and then click the save icon.

To move a subscription to a different compartment

The associated topic remains in its current compartment. For more information, see Moving Topics and Subscriptions to a Different Compartment.

Note

To move resources between compartments, resource users must have sufficient access permissions on the compartment that the resource is being moved to, as well as the current compartment. For more information about permissions for Notifications resources, see Details for the Notifications Service.

1. Open the navigation menu. Under **Solutions and Platform**, go to **Application Integration** and click **Notifications**.
2. In the **Scope** section, select a compartment.
3. Find the subscription in the list, click the Actions icon (three dots), and then click **Move Resource**.
4. Choose the destination compartment from the list.
5. Click **Move Resource**.

To delete a subscription (unsubscribe)

Note

Every message sent out as email contains a link to *unsubscribe* from the related topic.

1. Open the navigation menu. Under **Solutions and Platform**, go to **Application Integration** and click **Notifications**.
2. For the subscription you want to delete, click the Actions icon (three dots), and then

click **Delete**.

3. Confirm when prompted.

Managing Tags for a Topic or Subscription

You can apply tags to your resources, such as topics and subscriptions, to help you organize them according to your business needs. You can apply tags at the time you create a topic or subscription, or you can update the topic or subscription later with the tags you want. For general information about applying tags, see Resource Tags.

To manage tags for a topic

1. Open the navigation menu. Under **Solutions and Platform**, go to **Application Integration** and click **Notifications**.
2. Choose the **Compartment** that contains the topic you want to tag, and then click the topic's name.
3. Click the **Tags** tab to view or edit existing tags, or click **Add Tags** to add new ones.

For more information, see Resource Tags.

To manage tags for a subscription

1. Open the navigation menu. Under **Solutions and Platform**, go to **Application Integration** and click **Notifications**.
2. Choose the **Compartment** that contains the subscription you want to tag, and then click the name of the topic that has the subscription.
3. For the subscription you want to tag, click the Actions icon (three dots), and then click **Add Tags**.
   To view or edit existing tags, click the Actions icon (three dots), and then click **View Tags**.

For more information, see Resource Tags.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use these API operations to manage topics:

- CreateTopic
- GetTopic
- ListTopics
- UpdateTopic
- ChangeTopicCompartment
- DeleteTopic

Use these API operations to manage subscriptions:

- CreateSubscription
- GetSubscription
- ListSubscriptions
- UpdateSubscription
- ChangeSubscriptionCompartment
- GetConfirmSubscription
- ResendSubscriptionConfirmation
- GetUnsubscription
- DeleteSubscription

Publishing Messages

This topic describes how to publish messages directly using the Notifications service. You can manually enter the message content or allow a service or app to programmatically define the message content.

Each message is broadcast to all subscriptions in the specified topic. Every message sent out as email contains a link to *unsubscribe* from the related topic.

Message delivery rate limits per endpoint: 60 messages per minute for HTTP-based protocols. (HTTP-based protocols use URL endpoints that begin with "http:" or "https:".) 10 messages per minute for Email protocol.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Prerequisites

- IAM policies: To use Notifications, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a response that you don’t have permission or are unauthorized, check with your administrator. You may not have the required type of access in the current compartment. For more information on user authorizations, see Notifications Overview.
- Before you can publish a message, you need a topic with at least one subscription. See Managing Topics and Subscriptions.

Creating Automation with Events

You can create automation based on state changes for your Oracle Cloud Infrastructure resources by using event types, rules, and actions. For more information, see Overview of Events.

Using the Console

To publish a message

1. Open the navigation menu. Under **Solutions and Platform**, go to **Application Integration** and click **Notifications**.
2. On the **Topics** page, for the topic you want, click the Actions icon (three dots), and then click **Publish Message**.
3. In the **Publish Message** dialog box, fill in the fields:
    - **Title**: Enter the title you want to send.

      #### Rendering of the title by protocol

Protocol	Rendering of the title
Email	Subject line of the email message.
HTTPS (Custom URL)	Not rendered.
PagerDuty	Title field of the published message.
Slack	Not rendered.

    - **Message**: Enter the content you want to send.

Note

Message size limit per request: 64KB.

4. Click **Publish**.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use these API operations to publish messages:

PublishMessage

Notifications Metrics

You can monitor the health, capacity, and performance of your messages by using metrics, alarms, and notifications.

This topic describes the metrics emitted by the metric namespace `oci_notification` (the Notifications service).

Resources: Not applicable. Measures data for messages, which are not resources.

Overview of the Notifications Service Metrics

The Notifications service metrics help you measure the number and size of messages that are in initial requests, are delivered, and are not delivered.

Prerequisites

- IAM policies: To monitor resources, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.

Available Metrics

The metrics listed in the following table are automatically available for messages you publish to topics. You do not need to enable monitoring on any resources to get these metrics.

Each metric includes a subset of the following dimensions:

AVAILABILITYDOMAIN

The availability domain in which the associated topic resides.

ENDPOINTTYPE

The subscription protocol of the endpoint used for the delivery attempt.

REGION

The region in which the associated topic resides.

RESOURCEID

The OCID of the resource to which the metric applies.

TOPICDISPLAYNAME

The friendly name of the associated topic.

Metric	Metric Display Name	Unit	Description	Dimensions
PublishedMessagesSize	**Published Messages Size (Bytes)**	bytes	Size of messages in request.	availabilityDomain region resourceId topicDisplayName
PublishedMessagesCount	**Published Messages Count**	count	Count of messages in request.	
DeliveredMessagesSize	**Delivered Messages Size (Bytes)**	bytes	Size of messages successfully delivered to endpoints.	availabilityDomain endpointType region resourceId topicDisplayName
FailedMessagesSize	**Failed Messages Sizes (Bytes)**	bytes	Size of messages that did not get delivered to endpoints.	
DeliveredMessagesCount	**Delivered Messages Count**	count	Count of messages successfully delivered to endpoints.	
FailedMessagesCount	**Failed Messages Count**	count	Count of messages that did not get delivered to endpoints.	

Using the Console

To view default metric charts for a single topic

1. Open the navigation menu. Under **Solutions and Platform**, go to **Application Integration** and click **Notifications**.
2. Choose the **Compartment** that contains the topic you want to view, and then click the topic's name.
3. In the **Resources** menu, click **Metrics** (if necessary).
   The **Metrics** page displays a default set of charts for the current topic.

For more information about monitoring metrics and using alarms, see Monitoring Overview. For information about notifications for alarms, see Notifications Overview.

To view default metric charts for multiple topics

1. Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Service Metrics**.

2. For **Metric Namespace**, select **oci_notification**.
   The **Service Metrics** page displays a default set of charts for the selected metric namespace. For more information about the emitted metrics, see the foregoing table. You can also use the Monitoring service to create custom queries.

Tip

- Filter metrics by dimension, such as a selected topic, by clicking **Add** above the charts (to the right of **Dimensions**).
- Aggregate data across all topics (show a single line in the chart) by selecting the check box for **Aggregate Metric Streams** on the right.

For more information about monitoring metrics and using alarms, see Monitoring Overview. For information about notifications for alarms, see Notifications Overview.

Using the API

Use the following APIs for monitoring:

- Monitoring API for metrics and alarms
- Notifications API for notifications (used with alarms)

CHAPTER 25 Object Storage

This chapter explains how to upload, manage, and access data using Object Storage.

Overview of Object Storage

Oracle Cloud Infrastructure offers two distinct storage class tiers to address the need for both performant, frequently accessed "hot" storage, and less frequently accessed "cold" storage. Storage tiers help you maximize performance where appropriate and minimize costs where possible.

- Use **Object Storage** for data to which you need fast, immediate, and frequent access. Data accessibility and performance justifies a higher price point to store data in the Object Storage tier.
- Use **Archive Storage** for data to which you seldom or rarely access, but that must be retained and preserved for long periods of time. The cost efficiency of the Archive Storage tier offsets the long lead time required to access the data. For more information, see Overview of Archive Storage.

About Object Storage

The Oracle Cloud Infrastructure Object Storage service is an internet-scale, high-performance storage platform that offers reliable and cost-efficient data durability. The Object Storage service can store an unlimited amount of unstructured data of any content type, including analytic data and rich content, like images and videos.

With Object Storage, you can safely and securely store or retrieve data directly from the internet or from within the cloud platform. Object Storage offers multiple management interfaces that let you easily manage storage at scale. The elasticity of the platform lets you start small and scale seamlessly, without experiencing any degradation in performance or service reliability.

Object Storage is a regional service and is not tied to any specific compute instance. You can access data from anywhere inside or outside the context of the Oracle Cloud Infrastructure, as

long you have internet connectivity and can access one of the Object Storage endpoints. Authorization and resource limits are discussed later in this topic.

Object Storage also supports private access from Oracle Cloud Infrastructure resources in a VCN through a *service gateway*. A service gateway allows connectivity to the Object Storage public endpoints from private IP addresses in private subnets. For example, you can back up DB systems to an Object Storage bucket over the Oracle Cloud Infrastructure backbone instead of over the internet. You can optionally use IAM policies to control which VCNs or ranges of IP addresses can access Object Storage. See Access to Oracle Services: Service Gateway for details.

Object Storage is Always Free eligible. For more information about Always Free resources, including additional capabilities and limitations, see Oracle Cloud Infrastructure's Free Tier.

The following list summarizes some of the ways that you can use Object Storage.

HADOOP/BIG DATA SUPPORT

You can use Object Storage as the primary data repository for big data. Object Storage offers a scalable storage platform that lets you store large datasets and operate seamlessly on those datasets. The HDFS connector provides connectivity to various big data analytic engines like Apache Spark and MapReduce. This connectivity enables the analytics engines to work directly with data stored in Object Storage. For more information, see Hadoop Support.

BACKUP/ARCHIVE

You can use Object Storage to preserve backup and archive data that must be stored for an extended duration to adhere to various compliance mandates.

CONTENT REPOSITORY

You can use Object Storage as your primary content repository for data, images, logs, and video. You can reliably store and preserve this data for a long time, and serve this content directly from Object Storage. The storage scales as your data storage needs scale.

LOG DATA

You can use Object Storage to preserve application log data so that you can retroactively analyze this data to determine usage pattern and debug issues.

LARGE DATASETS

You can use Object Storage to store generated application data that needs to be preserved for future use. Pharmaceutical trials data, genome data, and Internet of Things (IoT) data are examples of generated application data that you can preserve using Object Storage.

Object Storage Resources

The following summarizes the Object Storage resources. Authorization and resource limits are discussed later in this topic.

OBJECT

Any type of data, regardless of content type, is stored as an object. The object is composed of the object itself and metadata about the object. Each object is stored in a bucket.

BUCKET

A logical container for storing objects. Users or systems create buckets as needed within a region. A bucket is associated with a single compartment that has policies that determine what actions a user can perform on a bucket and on all the objects in the bucket.

NAMESPACE

A logical entity that serves as a top-level container for all buckets and objects, allowing you to control bucket naming within your tenancy. Each Oracle Cloud Infrastructure tenant is assigned one unique and uneditable Object Storage namespace that spans all compartments within a region. Bucket names must be unique within each region. Within an Object Storage namespace, buckets and objects exist in flat hierarchy, but you can simulate a directory structure to help navigate a large set of objects (for example, `guitars/fender/stratocaster.jpg`, `guitars/gibson/lespaul.jpg`).

Tip

If your namespace was created based on your tenancy name, your namespace uses all lower-case letters (regardless of the presence of capital letters in your tenancy name). When using the API, CLI, or SDKs, do not use capital letters in your namespace string.

COMPARTMENT

Primary building block used to organize your cloud resources. When your tenancy is provisioned, a root compartment is created for you. You can then create compartments under your root compartment to organize your resources. You control access by creating policies that specify what actions groups of users can take on the resources in those compartments. An Object Storage bucket can only exist in one compartment.

Object Storage Features

Object Storage provides the following features:

STRONG CONSISTENCY

When a read request is made, Object Storage always serves the most recent copy of the data that was written to the system.

DURABILITY

Object Storage is a regional service. Data is stored redundantly across multiple storage servers. Object Storage actively monitors data integrity using checksums and automatically detects and repairs corrupt data. Object Storage actively monitors and ensures data redundancy. If a redundancy loss is detected, Object Storage automatically creates more data copies. For more details about Object Storage durability, see the Oracle Cloud Infrastructure Object Storage FAQ.

CUSTOM METADATA

You can define your own extensive metadata as key-value pairs for any purpose. For example, you can create descriptive tags for objects, retrieve those tags, and sort through the data. You can assign custom metadata to objects and buckets using the Oracle Cloud Infrastructure CLI or SDK. See Software Development Kits and Command Line Interface for details.

ENCRYPTION

Object Storage employs 256-bit Advanced Encryption Standard (AES-256) to encrypt object data on the server. Each object is encrypted with its own data encryption key. Data encryption keys are always encrypted with a master encryption key that is assigned to the bucket. Encryption is enabled by default and cannot be turned off. By default, Oracle manages the master encryption key. However, you can optionally configure a bucket so that it's assigned an Oracle Cloud Infrastructure Key Management master encryption key that you control and rotate on your own schedule.

Ways to Access Object Storage

You can access Object Storage using any of the following options, based on your preference and its suitability for the task you want to complete:

- The Console is an easy-to-use, browser-based interface. To access the Console, you must use a supported browser. Oracle Cloud Infrastructure supports the latest desktop versions of Google Chrome, Microsoft Edge, Internet Explorer 11, Safari, Firefox, and Firefox ESR. Note that private browsing mode is not supported for Firefox, Internet Explorer, or Edge. Mobile browsers are not supported. You are prompted to enter your cloud tenant, your user name, and your password.
- The command line interface (CLI) provides both quick access and full functionality without the need for programming. For more information, see Using the CLI.
- The REST API provides the most functionality, but requires programming expertise. API Reference and Endpoints provides endpoint details and links to the available API reference documents. For general information about using the API, see REST APIs. Object Storage is accessible with the following APIs:

    - Object Storage Service API
    - Amazon S3 Compatibility API
    - Swift API (for use with Oracle RMAN)
- Oracle Cloud Infrastructure provides SDKs that interact with Object Storage without you having to create a framework. For general information about using the SDKs, see Software Development Kits and Command Line Interface.

Using Object Storage

If you are ready to use Object Storage, you can find more information in the following topics:

- For instructions on how to create a bucket and store an object in the bucket, see "Putting Data into Object Storage" in the *Oracle Cloud Infrastructure Getting Started Guide*.
- For task documentation related to buckets, see Managing Buckets.
- For task documentation related to objects, see Managing Objects and Copying Objects.
- For task documentation related to lifecycle management, see Using Object Lifecycle Management.
- For API reference documentation, see Object Storage Service API.
- For SDK and CLI information, see Software Development Kits and Command Line Interface.
- For more information about using Archive Storage, see Overview of Archive Storage.

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API). IAM also manages user credentials for things like API signing keys, auth tokens, and customer secret keys for Amazon S3 Compatibility API. See User Credentials for details.

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For

example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies. For specific details about writing policies for each of the different services, see the Policy Reference. For specific details about writing policies for Object Storage, see Details for Object Storage, Archive Storage, and Data Transfer.

If you're a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

Object Storage IP Addresses

The Oracle Cloud Infrastructure Object Storage service uses the CIDR block IP range 134.70.0.0/17 for all regions.

Limits on Object Storage Resources

See Service Limits for a list of applicable limits and instructions for requesting a limit increase.

Other limits include:

- Number of Object Storage namespaces per root compartment: 1
- Maximum object size: 10 TiB
- Maximum object part size in a multipart upload: 50 GiB
- Maximum number of parts in a multipart upload: 10,000
- Maximum size of object metadata: 2 K

Understanding Object Storage Namespaces

Each Oracle Cloud Infrastructure tenant is assigned an Object Storage namespace that spans all compartments within a region. The namespace is a unique and uneditable system-

generated string assigned during account creation and applies to all regions. For some older tenancies, the namespace string might be the tenancy name in all lower-case letters.

The Object Storage namespace serves as a container for all of your buckets and objects. You control bucket names within your namespace, however, bucket names must be unique within each region. You can have a bucket named **MyBucket** in US West (Phoenix) and a bucket named **MyBucket** in Germany Central (Frankfurt).

The namespace metadata stores the default compartment assignments for the Amazon S3 Compatibility API and the Swift API. For more information, see Viewing and Specifying Designated Compartments.

Using the Console

To view your Object Storage namespace string:

Open the **Profile** menu () and click **Tenancy:** *<your_tenancy_name>*. Your namespace string is listed under **Object Storage Settings**.

Note

While the Object Storage namespace string is displayed under **Object Storage Settings**, you cannot edit the namespace string. The namespace string appears here for information only.

Using the Command Line Interface (CLI)

Open a command prompt and run the following command to get your Object Storage namespace:

```
oci os ns get
```

Your Object Storage namespace is returned:

```
{
    "data": "MyNamespace"
}
```

Tip

You can use `-ns`, `--namespace`, or `--namespace-name` for options that require you to specify the Object Storage namespace string.

For information about using the CLI, see Command Line Interface (CLI). For a complete list of flags and options available for CLI commands, see CLI Help.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the GetNamespace operation to get your Object Storage namespace. If you have the `OBJECTSTORAGE_NAMESPACE_READ` permission and supply the compartment or tenancy OCID in the optional `compartmentId` parameter, you can also get the namespace of a different tenancy's Object Storage namespace.

Managing Buckets

In the Oracle Cloud Infrastructure Object Storage service, a bucket is a container for storing objects in a compartment within an Object Storage namespace. A bucket is associated with a single compartment. The compartment has policies that indicate what actions you can perform on a bucket and all the objects in the bucket.

You cannot nest buckets—a bucket cannot contain other buckets.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

If you are new to policies, see Getting Started with Policies and Common Policies.

For administrators:

- The policy Let Object Storage admins manage buckets and objects lets the specified group do everything with buckets and the associated objects.
- If you must write more restrictive policies for buckets, see Details for Object Storage, Archive Storage, and Data Transfer.

Pre-Authenticated Requests

Pre-authenticated requests provide a way to let you access a bucket or an object without having your own credentials. For example, you can create a request that lets you upload backups to a bucket without owning API keys. See Using Pre-Authenticated Requests for details.

Object Lifecycle Policies

Using object lifecycle policies applied at the bucket level, you can automatically manage the archiving and deletion of objects according to a pre-defined schedule. See Using Object Lifecycle Management for information on this feature.

Tagging Resources

You can add tags to your resources to help you organize them according to your business needs. You can add tags at the time you create a resource, or you can update the resource

later with the desired tags. For general information about applying tags, see Resource Tags.

Object Storage currently supports adding tags to buckets.

Monitoring Resources

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications. For more information, see Monitoring Overview and Notifications Overview.

For more information about monitoring buckets, see Object Storage Metrics.

Usage Reports

A usage report is a comma-separated value (CSV) file that can be used to get a detailed breakdown of resources in Oracle Cloud Infrastructure for audit or invoice reconciliation. A usage report is generated daily and stored in an Object Storage bucket. For more information, see Usage Reports Overview and Accessing Usage Reports.

Creating Automation for Buckets and Objects Using the Events Service

You can create automation based on state changes for your Oracle Cloud Infrastructure resources by using event types, rules, and actions. For more information, see Overview of Events.

Buckets emit events for bucket state changes by default. Events for objects are handled differently than other resources. Objects do not emit events by default. Use the Console, CLI, or API to enable a bucket to emit events for object state changes. You can enable events for object state changes during or after bucket creation.

Bucket Names

Bucket names are system generated by default, but you can overwrite the default with a name you specify.

System-Generated Bucket Names

When a bucket is created, the system generates a default name for that bucket, for example **bucket-20190306-1359**. This bucket name identifies the current year, month, and day that the bucket was created. You can use that system-generated name for your new bucket or you can specify a different name for it.

User-Specified Bucket Names

If you change this default bucket name or the name of any bucket, observe the following:

- Use from 1 to 256 characters.
- Valid characters are letters (upper or lower case), numbers, hyphens, underscores, and periods.

Important

Bucket names and object names are case-sensitive. Object Storage handles accounts-payable and Accounts-Payable as separate buckets.

- Do not include confidential information.
- Make the name unique within your tenancy's Object Storage namespace.

Storage Tiers

When you create a bucket, you also decide which tier is appropriate for storing objects:

- Use the standard Object Storage tier for data to which you need fast, immediate, and frequent access. For more information, see Overview of Object Storage.
- Use the Archive Storage tier for data to which you seldom or rarely access, but that must be retained and preserved for long periods of time. For more information, see Overview of Archive Storage.

Important

You cannot change the storage tier in which a bucket resides.

Public Buckets

When you create a bucket, the bucket is considered a private bucket and the access to the bucket and its contents requires authentication and authorization. However, Object Storage supports anonymous, unauthenticated access to a bucket. You make a bucket *public* by enabling read access to the bucket.

Important

Carefully assess the business requirement for public access to a bucket. When you enable anonymous access to a bucket, any user can obtain object metadata, download bucket objects, and optionally list bucket contents.

Required Permissions

The following permissions are required to configure a public bucket:

- To enable public access when creating a bucket, use permission `BUCKET_CREATE`.
- To enable public access for an existing bucket, use permission `BUCKET_UPDATE`.

Options

When creating a public bucket, you have the following options:

- You can configure the access to allow listing and downloading objects. List and download access is the default.
- You can configure the access to allow downloading objects only. A user would not be able to list bucket contents.

Scope and Constraints

Understand the following scope and constraints regarding public access:

- Changing the type of access is bi-directional. You can change a bucket's access from public to private or from private to public.
- Changing the type of access doesn't affect existing pre-authenticated requests. Existing pre-authenticated requests still work.

You can enable anonymous public access for new or existing buckets using the Console, CLI, or an SDK to access the API.

Using the Console

To get a list of buckets

Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.

A list of the buckets in the compartment you're viewing is displayed. If you don’t see the one you're looking for, verify that you’re viewing the correct compartment (select from the list on the left side of the page).

To create a bucket

1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.
   A list of the buckets in the compartment you're viewing is displayed. If you don’t see the one you're looking for, verify that you’re viewing the correct compartment (select from the list on the left side of the page).

2. Select a compartment from the **Compartment** list on the left side of the page.
   A list of existing buckets is displayed.
3. Click **Create Bucket**.
4. In the **Create Bucket** dialog box, specify the attributes of the bucket:
   - **Bucket Name:** The system generates a default bucket name that reflects the current year, month, day, and time, for example **bucket-20190306-1359**. If you change this default to any other bucket name, use letters, numbers, dashes, underscores, and periods. Do not include any confidential information.
   - **Storage Tier:** Select the tier in which you want to store your data. Available tiers include:
     - **Standard** is the primary, default Object Storage tier for storing frequently accessed data that requires fast and immediate access.
     - **Archive** is a special tier for storing infrequently accessed data that requires long retention periods. Access to data in the **Archive** tier is not immediate. You must restore archived data before it's accessible. For more information, see "Overview of Archive Storage" in the *Oracle Cloud Infrastructure User Guide.*
   - **Object Events:** Select **Emit Object Events** if you want to enable the bucket to emit events for object state changes. For more information about events, see Overview of Events.
   - **Encryption:** Buckets are encrypted with keys managed by Oracle by default, but you can optionally encrypt the data in this bucket using your own Key Management encryption key. To use Key Management for your encryption needs, select **Encrypt Using Customer-Managed Keys**. Then, select the **Vault Compartment** and **Vault** that contain the master encryption key you want to use. Also select the **Master Encryption Key Compartment** and **Master Encryption Key**. For more information about encryption, see Overview of Key Management. For details on how to create a vault, see Managing Vaults.

- **Tags:**Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.

5. Click **Create Bucket**.

The bucket is created immediately and you can add objects to it. Objects added to archive buckets are immediately archived and must be restored before they are available for download.

To view bucket details

1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.
2. Choose the compartment that contains your buckets.
   A list of buckets is displayed.
3. Click the Actions icon (three dots) to the right of the bucket name, and then click **View Bucket Details**.
   Object Storage displays bucket details including the following:
   - Visibility
   - Encryption Key
   - Namespace
   - Created
   - Storage tier
   - Compartment
   - Approximate Count
   - Approximate Size

- ETag (entity tag)
- Emit Object Events

To change the visibility of a bucket

A bucket is either private (the default) or public. See Public Buckets for more information.

1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.
   A list of the buckets in the compartment you're viewing is displayed. If you don't see the one you're looking for, verify that you're viewing the correct compartment (select from the list on the left side of the page).
2. Click the bucket name to see the bucket details.
   Visibility: shows the current bucket setting, which is **Private** by default.
3. Click **Edit Visibility**.
4. In the **Edit Visibility** dialog box, edit the visibility settings:
   - **Visibility**
     - **Public**
     - **Private**
   - If you select **Public** to enable public access, decide whether or not you want to let users list the bucket contents. Click **Allow users to list objects from this bucket** to set the visibility of bucket object lists.
5. Click **Save Changes**.

To move a bucket to a different compartment

Important

When moving buckets resources between compartments, ensure that the resource users have sufficient access permissions for the compartment to which the resource is being moved.

1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.
2. In the **Scope** section, select a compartment.
3. Find the bucket in the list, click the the Actions icon (three dots), and then click **Move Resource**.
   Alternatively, you can choose a bucket, and then click **Move Resource** on the bucket details page.
4. Choose the destination compartment from the list.
5. Click **Move Resource**.

To manage tags for a bucket

1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.
   A list of the buckets in the compartment you're viewing is displayed. If you don't see the one you're looking for, verify that you're viewing the correct compartment (select from the list on the left side of the page).
2. Click the bucket name.
3. You can manage tags in the following ways:
   - To view the tags associated with the bucket, click the **Tags** tab, located to the right of the **Bucket Information** tab.
   - To add one or more tags, click **Add Tags**.

- To rename a tag, click the pencil icon to the left of a tag name, edit the name, and save.
- To delete a tag, click the pencil icon to the left of a tag name and click **Remove Tag**.

For more information, see Resource Tags.

To delete a bucket

You can permanently delete an *empty* bucket. The bucket cannot contain any objects. For information on deleting objects from a bucket, see To delete objects from a bucket. In addition, you cannot delete a bucket that has a multipart upload in progress or a pre-authenticated request associated with that bucket.

Warning

You cannot recover a deleted bucket.

1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.
   A list of the buckets in the compartment you're viewing is displayed. If you don't see the one you're looking for, verify that you're viewing the correct compartment (select from the list on the left side of the page).
2. Find the bucket that you want to delete.
3. Click the Actions icon (three dots), and then click **Delete**.
4. Confirm deletion when prompted.

To assign a Key Management master encryption key to a bucket

Buckets are encrypted with keys managed by Oracle by default, but you can optionally encrypt the data encryption keys that encrypt the objects in a bucket using your own Key Management master encryption key.

1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.
   A list of the buckets in the compartment you're viewing is displayed. If you don't see the one you're looking for, verify that you're viewing the correct compartment (select from the list on the left side of the page).
2. Click the name of the bucket that you want to encrypt.
3. Next to **Encryption Key**, do one of the following:
   - If the bucket is encrypted with a key managed by Oracle, click the **Assign** link.
   - If the bucket already has a Key Management master encryption key assigned, to assign a different key, click the **Edit** link.
4. In the dialog box, provide or edit the following information:
   - **Vault Compartment** and **Vault** that contain the master encryption key you want to use. The current compartment is displayed by default.
   - **Master Encryption Key Compartment** and **Master Encryption Key**. The current compartment is displayed by default.
5. When you are finished, click **Assign** or **Edit**.

See Overview of Key Management for more details.

To remove a Key Management master encryption key from a bucket

1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.
   A list of the buckets in the compartment you're viewing is displayed. If you don't see the one you're looking for, verify that you're viewing the correct compartment (select from the list on the left side of the page).
2. Click the name of the bucket for which you want to remove a Key Management key assignment.
3. Next to **Encryption Key**, click the **Unassign** link.
4. In the **Confirm** dialog box, click **OK** to remove the key assignment from the bucket.

To re-encrypt a bucket's data encryption keys

If you've rotated a master encryption key since the time you assigned it to a bucket, you might want to re-encrypt the bucket. Until you explicitly re-encrypt a bucket, the key version associated with the bucket when an object was inserted into the bucket continues to decrypt all data encryption keys. To encrypt and decrypt all data encryption keys with the same, most recent version of the assigned master encryption key, re-encrypt the bucket.

1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.
   A list of the buckets in the compartment you're viewing is displayed. If you don't see the one you're looking for, verify that you're viewing the correct compartment (select from the list on the left side of the page).
2. Click the name of the bucket for which you want to re-encrypt all data encryption keys.
3. Click **Re-encrypt**. (If the button is not enabled, that's because the bucket is using a master encryption key managed by Oracle rather than a Key Management master encryption. Or, the bucket does not contain any objects.)
4. In the confirmation dialog box, click **Re-encrypt** to generate a work request to re-encrypt all data encryption keys associated with the bucket.

The **Work Requests Details** dialog box that displays tells you about the work request, including the percentage completed and the work request ID. You can copy the work request ID to monitor its status later.

To view the approximate bucket size and number of objects in the bucket

1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.
2. Choose the compartment that contains your buckets.
   A list of buckets is displayed.
3. Click the Actions icon (three dots) to the right of the bucket name, and then click **View Bucket Details**.

- **Approximate Count** is the approximate number of objects in the bucket. Count statistics are reported periodically. A lag can occur between what is displayed and the actual object count.
- **Approximate Size** is the approximate total size of all objects in the bucket. Size statistics are reported periodically. A lag can occur between what is displayed and the actual size of the bucket.

To enable or disable emitting events for object state changes

You can create automation based on state changes for your Oracle Cloud Infrastructure resources by using event types, rules, and actions. For more information, see Overview of Events.

1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.
2. Choose the compartment that contains your buckets.
   A list of buckets is displayed.
3. Click the Actions icon (three dots) to the right of the bucket name, and then click **View Bucket Details**.
4. Next to **Emit Object Events**, click **Edit**.
5. In the dialog box, select (to enable) or deselect (to disable) **Emit Object Events**.
6. Click **Save Changes**.

Using the Command Line Interface (CLI)

For information about using the CLI, see Command Line Interface (CLI). For a complete list of flags and options available for CLI commands, see CLI Help.

Note

The examples in this section use the full syntax for all parameters, for example `--namespace` and `--compartment-id`. In some cases, there are shortened parameter terms that you can use instead of the full ones, for example `-ns` and `-c`. See the CLI online help for instances of a shortened parameter associated with a command.

To get a list of buckets

```
oci os bucket list --namespace <object_storage_namespace> --compartment-id <target_compartment_id>
```

For example:

```
oci os bucket list --namespace MyNamespace --compartment-id ocid.compartment.oc1..exampleuniqueID

{
  "data": [
    {
      "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
      "created-by": "ocid1.user.oc1..exampleuniqueID",
      "defined-tags": null,
      "etag": "c8889cd1-8414-41fb-84b7-3738c39e62c5",
      "freeform-tags": null,
      "name": "MyBucket1",
      "namespace": "MyNamespace",
      "time-created": "2019-10-22T19:22:25.032000+00:00"
    },
    {
      "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
      "created-by": "ocid1.user.oc1..exampleuniqueID",
      "defined-tags": null,
      "etag": "7b7c3dc1-713f-4996-b176-a938345cae8e",
      "freeform-tags": null,
      "name": "MyBucket2",
```

```
      "namespace": "MyNamespace ",
      "time-created": "2019-10-22T19:04:05.879000+00:00"
    }
  ]
}
```

By default, getting a list of buckets returns up to the first 1,000 buckets in the compartment.

To list all buckets in a compartment, use the `--all` option:

```
oci os bucket list --namespace <object_storage_namespace> --compartment-id <target_compartment_id> --
all
```

To include resource tag data, use the `--fields tags` option:

```
oci os bucket list --namespace <object_storage_namespace> --compartment-id <target_compartment_id> --
fields tags
```

For example:

```
oci os bucket list --namespace MyNamespace --compartment-id ocid.compartment.oc1..exampleuniqueID --
fields tags

{
  "data": [
       {
         "compartment-id": "ocid1.compartment.oc1..exampleuniqueID",
         "created-by": "ocid1.user.oc1..exampleuniqueID",
         "defined-tags": {
               "example_tag_namespace_Financials": {
                 "production": "Unit 5"
               },
               "example_tag_namespace_Operations": {
                 "costcenter": "85"
               }
         },
         "etag": "48af18cf-1edd-4b05-9f36-a629d5032260",
         "freeform-tags": {
           "Project": "prototype 3"
         },
         "name": "MyBucket",
         "namespace": "MyNamespace",
         "time-created": "2019-02-27T18:52:16.951000+00:00"
       }
```

```
  ]
}
```

Note

If you do not specify the `--fields tags` option when listing buckets, `null` is returned as the value for both freeform and defined tags.

To create a standard Object Storage tier bucket

```
oci os bucket create --namespace <object_storage_namespace> --name <bucket_name> --compartment-id
<target_compartment_id>
```

For example:

```
oci os bucket create --namespace MyNamespace --name MyBucket --compartment-id
ocid.compartment.oc1..exampleuniqueID
{
  "data": {
    "approximate-count": null,
    "approximate-size": null,
    "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
    "created-by": "ocid1.user.oc1..exampleuniqueID",
    "defined-tags": {},
    "etag": "7b7c3dc1-713f-4996-b176-a938345cae8e",
    "freeform-tags": {},
    "kms-key-id": null,
    "metadata": {},
    "name": "MyBucket",
    "namespace": "MyNamespace",
    "object-events-enabled": false,
    "object-lifecycle-policy-etag": null,
    "public-access-type": "NoPublicAccess",
    "storage-tier": "Standard",
    "time-created": "2019-10-22T19:04:05.879000+00:00"
  },
```

```
  "etag": "7b7c3dc1-713f-4996-b176-a938345cae8e"
}
```

By default, a bucket is created in the standard Object Storage tier. You do not need to explicitly set `--storage-tier`.

A Standard tier bucket is created immediately and you can add objects to it.

To create an Archive tier bucket

To create an Archive tier bucket, you must explicitly set `--storage-tier Archive`.

```
oci os bucket create --namespace <object_storage_namespace> --name <archivebucket_name> --compartment-id <target_compartment_id> --storage-tier Archive
```

For example:

```
oci os bucket create -ns MyNamespace --name MyArchiveBucket --compartment-id
ocid.compartment.oc1..exampleuniqueID --storage-tier Archive
{
  "data": {
    "approximate-count": null,
    "approximate-size": null,
    "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
    "created-by": "ocid1.user.oc1..exampleuniqueID",
    "defined-tags": {},
    "etag": "c8889cd1-8414-41fb-84b7-3738c39e62c5",
    "freeform-tags": {},
    "kms-key-id": null,
    "metadata": {},
    "name": "MyArchiveBucket",
    "namespace": "MyNamespace",
    "object-events-enabled": false,
    "object-lifecycle-policy-etag": null,
    "public-access-type": "NoPublicAccess",
    "storage-tier": "Archive",
    "time-created": "2019-10-22T19:22:25.032000+00:00"
  },
  "etag": "c8889cd1-8414-41fb-84b7-3738c39e62c5"
}
```

An Archive Storage bucket is created and you can add objects to it. Objects added to Archive Storage buckets are immediately archived and must be restored before they are available for download.

To create a public bucket that allows listing and downloading bucket objects

To create a public bucket that allows listing and downloading bucket objects, you must explicitly set `--public-access-type ObjectRead`.

```
oci os bucket create --namespace <object_storage_namespace> --name <bucket_name> --compartment-id
<target_compartment_id> --public-access-type ObjectRead
```

For example:

```
oci os bucket create --namespace MyNamespace --name MyPublicObjectReadBucket --compartment-id
ocid.compartment.oc1..exampleuniqueID --public-access-type ObjectRead
{
  "data": {
    "approximate-count": null,
    "approximate-size": null,
    "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
    "created-by": "ocid1.user.oc1..exampleuniqueID",
    "defined-tags": {},
    "etag": "01096e0b-659a-4d9d-a806-d57568cf1b22",
    "freeform-tags": {},
    "kms-key-id": null,
    "metadata": {},
    "name": "MyPublicObjectReadBucket",
    "namespace": "MyNamespace",
    "object-events-enabled": false,
    "object-lifecycle-policy-etag": null,
    "public-access-type": "ObjectRead",
    "storage-tier": "Standard",
    "time-created": "2019-10-22T19:47:11.649000+00:00"
  },
  "etag": "01096e0b-659a-4d9d-a806-d57568cf1b22"
}
```

To create a public bucket that allows downloading bucket objects only

To create a public bucket that allows downloading bucket objects only, you must explicitly set `--public-access-type ObjectReadWithoutList`.

```
oci os bucket create --namespace <object_storage_namespace> --name <bucket_name> --compartment-id
<target_compartment_id> --public-access-type ObjectReadWithoutList
```

For example:

```
oci os bucket create -ns MyNamespace --name MyPublicObjectReadBucket --compartment-id
ocid.compartment.oc1..exampleuniqueID --public-access-type ObjectReadWithoutList{
{
  "data": {
    "approximate-count": null,
    "approximate-size": null,
    "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
    "created-by": "ocid1.user.oc1..exampleuniqueID",
    "defined-tags": {},
    "etag": "ec20c59a-f5ba-4a6d-8a7e-b69bb9bb76ad",
    "freeform-tags": {},
    "kms-key-id": null,
    "metadata": {},
    "name": "MyPublicObjectReadWithoutListBucket",
    "namespace": "MyNamespace",
    "object-events-enabled": false,
    "object-lifecycle-policy-etag": null,
    "public-access-type": "ObjectReadWithoutList",
    "storage-tier": "Standard",
    "time-created": "2019-10-22T20:18:29.203000+00:00"
  },
  "etag": "ec20c59a-f5ba-4a6d-8a7e-b69bb9bb76ad"
}
```

To create a bucket with resource tags

You can create standard Object Storage tier or Archive tier buckets with resource tags.

To add resource tags when creating a bucket,set one or both of the `--defined-tags` and `--freeform-tags` options.

Tip

The `--defined-tags` and `--freeform-tags` options require that the input to be a complex type formatted in valid JSON. See Passing Complex Input and Using a JSON File for Complex Input for information JSON formatting.

The following example syntax creates a standard Object Storage tier bucket with a defined tag:

```
oci os bucket create --namespace <object_storage_namespace> --name <bucket_name> --compartment-id
<target_compartment_id> --defined-tags '<JSON_formatted_defined_tag>'
```

Examples of defined tag formatting:

```
'{"Operations": {"CostCenter": "42"}'
```

```
'{"Logistics": {"Procurement": "Madrid Center"}},"Financials":{"Production": "Unit 5"}}'
```

Note

If you are running the CLI on a Windows computer, you might need to use the backslash (\) character to escape the strings containing the tag values. For example, a single defined tag is formatted as follows: `'{\"Logistics\": {\"Procurement\": \"Madrid Center\"}}'`

For example:

```
oci os bucket create --namespace MyNamespace --name MyBucketDefined --compartment-id
ocid.compartment.oc1..exampleuniqueID --defined-tags {"Operations": {"CostCenter": "42"}}
{
  "data": {
    "approximate-count": null,
```

```
    "approximate-size": null,
    "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
    "created-by": "ocid1.user.oc1..exampleuniqueID",
    "defined-tags": {
      "operations": {
        "costcenter": "42"                              }
    },
    "etag": "ea88f444-842c-462d-965e-d3540b3b54f6",
    "freeform-tags": {},
    "kms-key-id": null,
    "metadata": {},
    "name": "MyBucketDefined",
    "namespace": "MyNamespace",
    "object-events-enabled": false,
    "object-lifecycle-policy-etag": null,
    "public-access-type": "NoPublicAccess",
    "storage-tier": "Standard",
    "time-created": "2019-10-23T19:47:51.362000+00:00"
  },
  "etag": "ea88f444-842c-462d-965e-d3540b3b54f6"
}
```

The following example syntax creates a Standard tier bucket with a free-form tag:

```
oci os bucket create --namespace <object_storage_namespace> --name <bucket_name> --compartment-id
<target_compartment_id> --freeform-tags <JSON_formatted_free-form_tag>
```

Examples of free-form tag formatting:

```
'{"Chicago_Team": "marketing_videos"}'
```

```
'{"Project": "prototype 3","Manager": "Meadows"}'
```

Note

If you are running the CLI on a Windows computer, you might need to use the backslash (\) character to escape the strings containing the tag values. For example, a single free-form tag is formatted as:
`'{\"Chicago_Team\": {\"marketing_videos\"}}'`

For example:

```
oci os bucket create --namespace MyNamespace --name MyBucketFreeform --compartment-id
ocid.compartment.oc1..exampleuniqueID --freeform-tags {"Chicago_Team": "marketing_videos"}
{
  "data": {
    "approximate-count": null,
    "approximate-size": null,
    "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
    "created-by": "ocid1.user.oc1..exampleuniqueID",
    "defined-tags": {},
    "etag": "6f4bda10-fc8b-462e-8563-875639fd7294",
    "freeform-tags": {
      "Chicago_Team": "marketing_videos"
    },
    "kms-key-id": null,
    "metadata": {},
    "name": "MyBucketFreeform",
    "namespace": "MyNamespace",
    "object-events-enabled": false,
    "object-lifecycle-policy-etag": null,
    "public-access-type": "NoPublicAccess",
    "storage-tier": "Standard",
    "time-created": "2019-10-23T20:51:16.260000+00:00"
  },
  "etag": "6f4bda10-fc8b-462e-8563-875639fd7294"
}
```

To view bucket details

```
oci os bucket get --name <bucket_name>
```

Object Storage displays bucket details including the following:

- Visibility
- Encryption Key
- Namespace
- Created

- Storage tier
- Compartment
- Approximate Count
- Approximate Size
- ETag (entity tag)
- Emit Object Events

For example:

```
oci os bucket get --name MyBucket
{
  "data": {
    "approximate-count": null,
    "approximate-size": null,
    "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
    "created-by": "ocid1.user.oc1..exampleuniqueID",
    "defined-tags": {},
    "etag": "7b7c3dc1-713f-4996-b176-a938345cae8e",
    "freeform-tags": {},
    "kms-key-id": null,
    "metadata": {},
    "name": "MyBucket",
    "namespace": "MyNamespace",
    "object-events-enabled": false,
    "object-lifecycle-policy-etag": null,
    "public-access-type": "NoPublicAccess",
    "storage-tier": "Standard",
    "time-created": "2019-10-22T19:04:05.879000+00:00"
  },
  "etag": "7b7c3dc1-713f-4996-b176-a938345cae8e"
}
```

To view bucket metadata

```
oci os bucket get --namespace <object_storage_namespace> --name <bucket_name>
```

For example:

```
oci os bucket get --namespace MyNamespace --name MyBucket

{
  "data": {
    "approximate-count": null,
    "approximate-size": null,
    "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
    "created-by": "ocid1.user.oc1..exampleuniqueID",
    "defined-tags": {},
    "etag": "7b7c3dc1-713f-4996-b176-a938345cae8e",
    "freeform-tags": {},
    "kms-key-id": null,
    "metadata": {},
    "name": "MyBucket",
    "namespace": "MyNamespace",
    "object-events-enabled": false,
    "object-lifecycle-policy-etag": null,
    "public-access-type": "NoPublicAccess",
    "storage-tier": "Standard",
    "time-created": "2019-10-22T19:04:05.879000+00:00"
  },
  "etag": "7b7c3dc1-713f-4996-b176-a938345cae8e"
}
```

To add custom metadata key-value pairs to a bucket

```
oci os bucket update --namespace <object_storage_namespace> --name <bucket_name> --metadata <JSON-formatted_key-value_pair>
```

<JSON-formatted_key-value_pair> is a key-value pair input as valid formatted JSON. See Passing Complex Input and Using a JSON File for Complex Input for more information about JSON formatting.

For example:

```
oci os bucket update --namespace MyNamespace --name MyBucket --metadata '{"Department": "Finance"}'

{
  "data": {
    "approximate-count": null,
    "approximate-size": null,
```

```
    "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
    "created-by": "ocid1.user.oc1..exampleuniqueID",
    "defined-tags": {},
    "etag": "4b09d7b9-a8bf-42f6-8d67-bb357694f92d",
    "freeform-tags": {},
    "kms-key-id": null,
    "metadata": {
      "department": "Finance"
    },
    "name": "MyBucket",
    "namespace": "MyNamespace",
    "object-events-enabled": false,
    "object-lifecycle-policy-etag": null,
    "public-access-type": "NoPublicAccess",
    "storage-tier": "Standard",
    "time-created": "2019-10-22T19:04:05.879000+00:00"
  },
  "etag": "4b09d7b9-a8bf-42f6-8d67-bb357694f92d"
}
```

To make a bucket private or public

```
oci os bucket update --namespace <object_storage_namespace> --name <bucket_name> --public-access-type
[NoPublicAccess|ObjectReadWithoutList|ObjectRead]
```

- `NoPublicAccess`: Allows only an authenticated caller to access the bucket and its contents. This is the default value.
- `ObjectReadWithoutList`: Allows public access for the GetObject, HeadObject, and ListObjects operations.
- `ObjectRead`: Allows public access for the GetObject and HeadObject operations.

For example:

```
oci os bucket update --namespace MyNamespace --name MyBucket --public-access-type ObjectRead
{
  "data": {
    "approximate-count": null,
    "approximate-size": null,
    "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
```

```
    "created-by": "ocid1.user.oc1..exampleuniqueID",
    "defined-tags": {},
    "etag": "09ab3193-a441-43cc-a8e2-e468e94c7c60",
    "freeform-tags": {},
    "kms-key-id": null,
    "metadata": {
      "department": "Finance"
    },
    "name": "MyBucket",
    "namespace": "MyNamespace",
    "object-events-enabled": false,
    "object-lifecycle-policy-etag": null,
    "public-access-type": "ObjectRead",
    "storage-tier": "Standard",
    "time-created": "2019-10-22T19:04:05.879000+00:00"
  },
  "etag": "09ab3193-a441-43cc-a8e2-e468e94c7c60"
}
```

To move a bucket to a different compartment

```
oci os bucket update --namespace <object_storage_namespace> --name <bucket_name> --compartment-id
<new_target_compartment_id>
```

<new_target_compartment_id> is the compartment ID associated with the compartment to which you are moving the bucket.

For example:

```
oci os bucket update --namespace MyNamespace --name MyBucket --compartment-id
ocid.compartment.oc1..exampleuniqueID
{
  "data": {
    "approximate-count": null,
    "approximate-size": null,
    "compartment-id": "new_ocid.compartment.oc1..exampleuniqueID",
    "created-by": "ocid1.user.oc1..exampleuniqueID",
    "defined-tags": {},
    "etag": "fe4fb648-8ddd-42eb-9732-d431aafac354",
    "freeform-tags": {},
    "kms-key-id": null,
```

```
    "metadata": {
      "department": "Finance"
    },
    "name": "MyBucket",
    "namespace": "MyNamespace",
    "object-events-enabled": false,
    "object-lifecycle-policy-etag": null,
    "public-access-type": "ObjectRead",
    "storage-tier": "Standard",
    "time-created": "2019-10-22T19:04:05.879000+00:00"
  },
  "etag": "fe4fb648-8ddd-42eb-9732-d431aafac354"
}
```

To add resource tags to a bucket

To add defined resource tags to a bucket, open a command prompt and run `oci os bucket update` with the `--defined-tags` option:

```
oci os bucket update --namespace <object_storage_namespace> --name <bucket_name> --defined-tags <JSON_formatted_defined_tag>
```

For example:

```
oci os bucket update --namespace MyNamespace --name MyBucket --defined-tags '{"Operations":
{"CostCenter": "42"}}'
{
  "data": {
    "approximate-count": null,
    "approximate-size": null,
    "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
    "created-by": "ocid1.user.oc1..exampleuniqueID",
     "defined-tags": {
      "operations": {
        "costcenter": "42"
      }
    },
    "etag": "0a26b47d-c43f-4ef8-9c26-02bb8d69fa34",
    "freeform-tags": {},
    "kms-key-id": null,
    "metadata": {
      "department": "Finance"
    },
    "name": "MyBucket",
    "namespace": "MyNamespace",
    "object-events-enabled": false,
    "object-lifecycle-policy-etag": null,
    "public-access-type": "ObjectRead",
    "storage-tier": "Standard",
    "time-created": "2019-10-22T19:04:05.879000+00:00"
```

```
  },
  "etag": "0a26b47d-c43f-4ef8-9c26-02bb8d69fa34"
}
```

To add free-form resource tags to a bucket, open a command prompt and run `oci os bucket update` with the `--freeform-tags` option:

```
oci os bucket update --namespace <object_storage_namespace> --name <bucket_name> --freeform-tags
<JSON_formatted_free-form_tag>
```

For example:

```
oci os bucket update --namespace MyNamespace --name MyBucket --freeform-tags '{"Chicago_Team":
"marketing_videos"}'
{
  "data": {
    "approximate-count": null,
    "approximate-size": null,
    "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
    "created-by": "ocid1.user.oc1..exampleuniqueID",
    "defined-tags": {
      "operations": {
        "costcenter": "42"
      }
    },
    "etag": "856a3c73-0194-4c02-8c6b-1b20be3c9a48",
    "freeform-tags": {
      "Chicago_Team": "marketing_videos"
    },
    "kms-key-id": null,
    "metadata": {
    "department": "Finance"
    },
    "name": "MyBucket",
    "namespace": "MyNamespace",
    "object-events-enabled": false,
    "object-lifecycle-policy-etag": null,
    "public-access-type": "ObjectRead",
    "storage-tier": "Standard",
    "time-created": "2019-10-22T19:04:05.879000+00:00"
  },
  "etag": "856a3c73-0194-4c02-8c6b-1b20be3c9a48"
}
```

Tip

The `--defined-tags` and `--freeform-tags` options require that you provide key-value pair input as valid formatted JSON. For examples of JSON-formatted resource tags, see To create a Standard or Archive tier bucket with resource tags. See Passing Complex Input and Using a JSON File for Complex Input for more information about JSON formatting.

To delete a bucket

You can permanently delete an empty bucket. The bucket cannot contain any objects. For information on deleting objects, see To delete objects from a bucket. You also cannot delete a bucket that has a multipart upload in progress or a pre-authenticated request associated with that bucket.

```
oci os bucket delete --namespace <object_storage_namespace> --name <bucket_name>
```

For example:

```
oci os bucket delete --namespace MyNamespace --name MyDeletedBucket
Are you sure you want to delete this resource? [y/N]:
```

Select `y` and press `Enter`. The bucket is deleted with no further prompting.

Warning

You cannot recover a deleted bucket.

To assign a Key Management key to a bucket

```
oci os bucket create --namespace <object_storage_namespace> --name <bucket_name> --compartment-id
```

```
<target_compartment_id> --kms-key-id <target_key_id>
```

<target_key_id> is the ID of the key versions that contain the cryptographic material used to encrypt and decrypt data, protecting the data where it is stored.

For example:

```
oci os bucket create --namespace MyNamespace --name MyKeyBucket --compartment-id
ocid.compartment.oc1..exampleuniqueID --kms-key-id ocid1.key.region1.sea..exampleuniqueID
{
  "data": {
    "approximate-count": null,
    "approximate-size": null,
    "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
    "created-by": "ocid1.user.oc1..exampleuniqueID",
    "defined-tags": {},
    "etag": "e7f29fdd-b5f5-42e5-a98b-80883f9f2f32",
    "freeform-tags": {},
    "kms-key-id": "ocid1.key.region1.sea..exampleuniqueID",
    "metadata": {},
    "name": "MyKeyBucket",
    "namespace": "MyNamespace",
    "object-events-enabled": false,
    "object-lifecycle-policy-etag": null,
    "public-access-type": "NoPublicAccess",
    "storage-tier": "Standard",
    "time-created": "2019-10-29T23:00:35.490000+00:00"
  },
  "etag": "e7f29fdd-b5f5-42e5-a98b-80883f9f2f32"
}
```

See Overview of Key Management for more details.

To update the Key Management key assigned to a bucket

```
oci os bucket update --namespace <object_storage_namespace> --name <bucket_name> --kms-key-id <target_
key_id>
```

<target_key_id> is the ID of the key versions that contain the cryptographic material used to encrypt and decrypt data, protecting the data where it is stored.

For example:

```
oci os bucket update --namespace MyNamespace --name MyKeyBucket --kms-key-id
ocid1.key.region1.sea.exampleuniqueID_updated
{
  "data": {
    "approximate-count": null,
    "approximate-size": null,
    "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
    "created-by": "ocid1.user.oc1..exampleuniqueID",
    "defined-tags": {},
    "etag": "e7f29fdd-b5f5-42e5-a98b-80883f9f2f32",
    "freeform-tags": {},
    "kms-key-id": "ocid1.key.region1.sea..exampleuniqueID_updated",
    "metadata": {},
    "name": "MyKeyBucket",
    "namespace": "MyNamespace",
    "object-events-enabled": false,
    "object-lifecycle-policy-etag": null,
    "public-access-type": "NoPublicAccess",
    "storage-tier": "Standard",
    "time-created": "2019-10-29T23:00:35.490000+00:00"
  },
  "etag": "e7f29fdd-b5f5-42e5-a98b-80883f9f2f32"
}
```

To remove the Key Management key assigned to a bucket

```
oci os bucket update --namespace <object_storage_namespace> --name <bucket_name> --kms-key-id ""
```

For example:

```
oci os bucket update --namespace MyNamespace --name MyKeyBucket --kms-key-id ""
{
  "data": {
    "approximate-count": null,
    "approximate-size": null,
    "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
    "created-by": "ocid1.user.oc1..exampleuniqueID",
    "defined-tags": {},
    "etag": "10a50818-e495-45a9-b1ce-cc815f7b39ad",
```

```
    "freeform-tags": {},
    "kms-key-id": null,
    "metadata": {},
    "name": "MyKeyBucket",
    "namespace": "MyNamespace",
    "object-events-enabled": false,
    "object-lifecycle-policy-etag": null,
    "public-access-type": "NoPublicAccess",
    "storage-tier": "Standard",
    "time-created": "2019-10-29T23:00:35.490000+00:00"
  },
  "etag": "10a50818-e495-45a9-b1ce-cc815f7b39ad"
}
```

To re-encrypt a bucket's data encryption keys

If you rotated a master encryption key since the time you assigned it to a bucket, you might want to re-encrypt the bucket. Until you explicitly re-encrypt a bucket, the key version associated with the bucket when an object was inserted into the bucket continues to decrypt all data encryption keys. To encrypt and decrypt all data encryption keys with the same current version of the assigned master encryption key, re-encrypt the bucket.

```
oci os bucket reencrypt --name <bucket_name>
```

For example:

```
oci os bucket reencrypt --name MyBucket
```

To view the approximate bucket size and number of objects in the bucket

```
oci os bucket get --name <bucket_name> --fields approximateCount --fields approximateSize
```

- `approximateCount` is the approximate number of objects in the bucket. Count statistics are reported periodically. You will see a lag between what is displayed and the actual object count.

- `approximateSize` is the approximate total size of all objects in the bucket. Size statistics are reported periodically. You will see a lag between what is displayed and the actual size of the bucket.

For example:

```
oci os bucket get --name MyBucket --fields approximateCount --fields approximateSize
{
  "data": {
    "approximate-count": 7,
    "approximate-size": 8075918,
    "compartment-id": "ocid1.compartment.oc1..exampleuniqueID",
    "created-by": "ocid1:user:oc1:phx:1458751937789:exampleuniqueID",
    "defined-tags": {},
    "etag": "218f201f-28a4-434d-9591-f05b6223c67a",
    "freeform-tags": {},
    "kms-key-id": null,
    "metadata": {},
    "name": "MyBucket",
    "namespace": "MyNamespace",
    "object-events-enabled": false,
    "object-level-audit-mode": "Disabled",
    "object-lifecycle-policy-etag": null,
    "public-access-type": "NoPublicAccess",
    "storage-tier": "Standard",
    "time-created": "2017-10-19T04:11:32.040000+00:00"
  },
  "etag": "218f201f-28a4-434d-9591-f05b6223c67a"
}
```

To enable or disable emitting events for object state changes

You can create automation based on state changes for your Oracle Cloud Infrastructure resources by using event types, rules, and actions. For more information, see Overview of Events.

Open a command prompt and run `oci os bucket update` to enable or disable:

```
oci os bucket update --namespace <object_storage_namespace> --name <bucket_name> --object-events-
enabled [true|false]
```

For example, to enable emitting events for all objects in the bucket named `MyBucket`:

```
oci os bucket update --namespace example_namespace --name MyBucket --object-events-enabled true
{
  "data": {
    "approximate-count": null,
    "approximate-size": null,
    "compartment-id": "ocid1.compartment.oc1..exampleuniqueID",
    "created-by": "ocid1:user:oc1:phx:1458751937789:exampleuniqueID",
    "defined-tags": {
      "operations": {
        "costcenter": "42"
      }
    },
    "etag": "39d1db02-27d0-4263-b3ff-5e6450495457",
    "freeform-tags": {
      "Chicago_Team": "marketing_videos"
    },
    "kms-key-id": null,
    "metadata": {
      "department": "Finance"
    },
    "name": "MyBucket",
    "namespace": "MyNamespace",
    "object-events-enabled": true,
    "object-lifecycle-policy-etag": null,
    "public-access-type": "ObjectRead",
    "storage-tier": "Standard",
    "time-created": "2019-10-22T19:04:05.879000+00:00"
  },
  "etag": "39d1db02-27d0-4263-b3ff-5e6450495457"
}
```

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

When accessing the Object Storage API, the bucket name is used with the Object Storage namespace name to form the request URL:

```
n/<object_storage_namespace>/b/<bucket>
```

Use the following operations to manage buckets:

- CreateBucket
- DeleteBucket
- GetBucket
- HeadBucket
- ListBuckets
- ReencryptBucket
- UpdateBucket

Note

There are two key properties worthy of mention in the CreateBucket and UpdateBucket APIs:

- `publicAccessType` property controls whether the bucket is private or public and limits the capability to list public bucket contents.
- `objectEventsEnabled` property controls if events are emitted for the objects in this bucket.

Managing Objects

In the Oracle Cloud Infrastructure Object Storage service, an object is a file or unstructured data you upload to a bucket within a compartment within an Object Storage namespace. The object can be any type of data, for example, multimedia files, data backups, static web content, or logs. You can store objects that are up to 10 TiB. Objects are processed as a single entity. You can't edit or append data to an object, but you can replace the entire object.

This topic describes how to manage objects within a single bucket. For information on copying an object to another bucket, see Copying Objects.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don't have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

If you're new to policies, see Getting Started with Policies and Common Policies.

For administrators:

- The policy Let Object Storage admins manage buckets and objects lets the specified group do everything with buckets and objects. Objects always reside in the same compartment as the bucket.
- If you need to write a more restrictive policy for objects, the `inspect objects` lets you list all the objects in a bucket and do a HEAD operation for a particular object. In comparison, `read objects` lets you download the object itself. See Details for Object Storage, Archive Storage, and Data Transfer.

Pre-Authenticated Requests

Pre-authenticated requests provide a way to let users access a bucket or object without having their own credentials. For example, you can create a request that lets a user upload backups to a bucket without owning API keys. See Using Pre-Authenticated Requests for details.

Object Names

Unlike other resources, objects do not have Oracle Cloud Identifiers (OCIDs). Instead, users define an object name when they upload an object.

Use the following guidelines when naming an object:

- Use from 1 to 1024 characters.
- Valid characters are letters (upper or lower case), numbers, and characters other than linefeed, newline, and NULL.

Important

Bucket names and object names are case-sensitive. Object Storage handles q3-field-assets.xslx and Q3-Field-Assets.XSLX as separate objects.

- Use only Unicode characters for which the UTF-8 encoding does not exceed 1024 bytes. Clients are responsible for URL-encoding characters.
- Do not include confidential information.
- Make the name unique within the bucket. Do not use the name of an existing object within the bucket when naming an object unless you intend to overwrite the existing object with the contents of the new or renamed object.

Tip

Object names can include one or more forward slash (/) characters in the name . See Object Naming Using Prefixes and Hierarchies for more information on using the forward slash in object names to create hierarchies.

Object Naming Using Prefixes and Hierarchies

Within an Object Storage namespace, buckets and objects exist in a flat hierarchy, but you can simulate a directory structure using a prefix string that includes the forward slash (/) to add hierarchy to an object name. Doing so lets you list one directory at a time, which is helpful when navigating a large set of objects.

For example:

```
marathon/finish_line.jpg
marathon/participants/p_21.jpg
```

If you added hierarchy to object names, you can use the CLI or API to perform bulk downloads and bulk deletes of all objects at a specified level of the hierarchy. Bulk downloads and bulk deletes a specified level of the hierarchy do not affect objects in any level above.

When naming objects, you can also use prefix strings without a delimiter. No delimiters would allow certain bulk operations in the CL or API to match on the prefix portion of the object name. For example, in the object names below, the string `gloves_27_` can serve as a prefix for matching purposes when performing bulk downloads or deletions:

```
gloves_27_dark_green.jpg
gloves_27_light_blue.jpg
```

When you perform bulk uploads with the CLI or API, you can also prepend a prefix string to the names of the files you are uploading.

Object Lifecycle Management

Using Object Lifecycle Management feature, you can automatically manage the archiving and deletion of objects according to a pre-defined schedule. See Using Object Lifecycle Management for information on this feature.

Multipart Uploading and Downloading

The Oracle Cloud Infrastructure Object Storage service supports multipart uploading and downloading for objects. See Using Multipart Uploads for more information. This page includes links to API documentation for this functionality. For CLI information on multipart downloading, see the procedure for downloading an object using multipart download. For API documentation related to multipart downloading, see the GetObject API call and its **range** parameter.

Monitoring Resources

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications. For more information, see Monitoring Overview and Notifications Overview.

For more information about monitoring objects, see Object Storage Metrics.

Creating Automation for Objects Using the Events Service

You can create automation based on state changes for your Oracle Cloud Infrastructure resources by using event types, rules, and actions. For more information, see Overview of Events.

Events for objects are handled differently than other resources. Objects do not emit events by default. Use the Console, CLI, or API to enable a bucket to emit events for object state changes. You can enable events for object state changes during or after bucket creation.

Using Storage Gateway to Upload and Download Objects

Storage Gateway is another way you can upload objects to and download objects from Oracle Cloud Infrastructure Object Storage.

Storage Gateway is installed in an Oracle Cloud Infrastructure compute instance or as a Linux Docker instance on one or more hosts in your on-premises data center. Applications store and retrieve objects from Oracle Cloud Infrastructure Object Storage through *file systems* that you create in Storage Gateway. Storage Gateway exposes an NFS mount point that can be mounted to any host that supports an NFSv4 client. The Storage Gateway mount point maps to an Object Storage bucket to upload and download objects.

See Overview of Storage Gateway for details.

Using the Console

To upload objects to a bucket

1. From the Object Storage Details screen, click the bucket name to view its details.
2. Click **Objects** under **Resources**.
3. In the **Objects** table, click **Upload Objects**.
4. Optionally, specify an **Object Name Prefix**. If provided, this prefix is prepended to each one of the files you upload. The prefix lets you simulate hierarchy and perform bulk operations. See Object Naming Using Prefixes and Hierarchies for details.
5. In the **Upload Objects** dialog box, select the objects that you want to upload in one of two ways:
   - Drag and drop one or more files from your computer.
   - Click the **select files** link and use the **File Upload** dialog box.

   The files you select to upload are displayed in a list. If you decide that you do not want to upload a particular file, click the **X** to the right of the file name.
   If the files you select to upload are already stored in the bucket with the same name, the Console displays messages warning you of an overwrite.
6. Click **Upload Objects**.
   The selected objects are uploaded and displayed in the list of objects in the bucket.

To download an object from a bucket

1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.
2. Choose the compartment that contains the bucket that contains your object.
   A list of buckets is displayed.
3. Click the bucket name that contains your object.
4. Click **Objects** under **Resources**.
   A list of objects in the bucket is displayed.

5. For the object you want to download, click the Actions icon (three dots), and then click **Download**.

To view object details

1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.
2. Choose the compartment that contains the bucket that contains your object.
   A list of buckets is displayed.
3. Click the bucket name that contains your object.
4. Click **Objects** under **Resources**.
   A list of objects in the bucket is displayed.
5. Choose the object for which you want details.
6. Click the Actions icon (three dots), and then click **View Object Details**. The following object details are displayed:
   - Name
   - URL Path (URI)
   - Storage Tier
   - Size
   - Content Type
   - ETag (entity tag)
   - Last Modified
7. Optionally, click **Download** to download the selected object.

To rename an object

1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.
2. Choose the compartment that contains the bucket that contains your object.
   A list of buckets is displayed.

3. Click the bucket name that contains your object.
4. Click **Objects** under **Resources**.
   A list of objects in the bucket is displayed.
5. For the object you want to rename, click the Actions icon (three dots), and then click **Rename**.
6. In the **Rename Object** dialog box, provide the new name for the object and an optional delimited directory structure prefix. For example, `p_94.jpg` or `/marathon/participants/p_94.jpg`.
   Avoid entering confidential information in the object name.

   Warning

   Buckets cannot store two objects that use identical names (case-sensitive). If you choose to rename an object using the name of another object in the same bucket, the object that originally used the name is overwritten.

7. Click **Save Changes**.

To restore objects from Archive Storage

Depending on the size of the object, it can take four or more hours to restore an object from Archive Storage. You cannot download an item until the item is fully restored.

Tip

You need OBJECT_RESTORE permissions to restore Archive Storage objects.

1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.
2. Choose the compartment your bucket is in.
   A list of buckets is displayed.
3. Click the bucket name that contains your object.
4. Click **Objects** under **Resources**.
   A list of objects in the bucket is displayed.
5. To restore a single object, click the Actions icon (three dots) to the right of the object you want to restore, and then click **Restore**. To restore multiple objects, select the check boxes to the left of each object you want to restore, then click **Restore**.
6. Optionally, specify the **Time Available for Download in Hours**.
   By default, you have 24 hours to download an object after restoration. However you can alternatively specify a download time of from 1 to 240 hours. You can find out how much download time is remaining by looking at **Available for Download** in object **Details** or by looking at the Actions icon (three dots) menu to the right of **Download**. Refresh the browser to obtain up-to-date remaining download time information.
   After the allotted download time expires, the object returns to Archive Storage.
7. Click **Restore Objects**.
   Error messages are generated if there is a problem with restoring the selected objects. You can optionally click **Retry failed restore option.**

To check the status of an Archive Storage object restoration

1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.
2. Choose the compartment your bucket is in.
   A list of buckets is displayed.
3. Click the bucket name that contains your object.
4. Click **Objects** under **Resources**.
   A list of objects in the bucket is displayed.
5. Click the Actions icon (three dots) to the right of the object you want to check the

restoration or download status of, then click **Details**.

6. Check the **Status**.
   Status displays one of the following:
   - Archived
   - Restoring
   - Restored

To delete objects from a bucket

You can permanently delete an object from a bucket. You cannot, however, recover a deleted object.

1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.
2. Choose the compartment that contains the bucket that contains the object or objects you want to delete.
   A list of buckets is displayed.
3. Click the bucket name that contains your object.
4. Click **Objects** under **Resources**.
   A list of objects in the bucket is displayed.
5. To delete a single object, click the Actions icon (three dots) to the right of the object you want to delete, and then click **Delete**. To delete multiple objects, select the check boxes to the left of each object you want to delete, and then click **Delete**.
6. Confirm when prompted.

Using the Command Line Interface (CLI)

For information about using the CLI, see Command Line Interface (CLI). For a complete list of flags and options available for CLI commands, see CLI Help.

To list objects in a bucket

Open a command prompt and run `oci os object list` to get a list of the objects in a bucket:

```
oci os object list -ns <object_storage_namespace> -bn <bucket_name>
```

By default, the following details are displayed for each object:

- Name
- Object size
- "Last Modified" timestamp
- MD5 hash

To get object details

Open a command prompt and run `oci os object head` to get object details:

```
oci os object head -ns <object_storage_namespace> -bn <bucket_name> --name <object_name>
```

The system output includes the following object details:

- ETag (entity tag)
- Content length (object body size)
- Custom metadata key-value pairs
- Storage tier
- MD5 hash
- Archival state

To upload an object to a bucket

Open a command prompt and run `oci os object put` to upload an object:

```
oci os object put -ns <object_storage_namespace> -bn <bucket_name> --file <file_location> --name
<object_name>  --no-multipart
```

Where *<file_location>* refers to a directory path like `C:\workspace\myfile.txt`. If you want to use the filename as the uploaded object's name, you can omit the `--name` option. The resulting object name does not include the path information (for example, `C:\workspace\`).

To add custom metadata key-value pairs, use the `--metadata` option:

```
oci os object put -ns <object_storage_namespace> -bn <bucket_name> --file <file_location> --name
<object_name>  --metadata <json_formatted_key-value_pairs> --no-multipart
```

Tip

The `--metadata` option requires that you provide complex type key-value pair input in valid JSON. See Passing Complex Input and Using a JSON File for Complex Input for more information about JSON formatting.

An object can be uploaded as a single part or as multiple parts. Here we describe a single part upload. For information on multipart uploads, see Using Multipart Uploads.

To bulk upload objects to a bucket

Open a command prompt and run `oci os object bulk-upload` to upload all files in a given directory (including files in subdirectories):

```
oci os object bulk-upload -ns <object_storage_namespace> -bn <bucket_name> --src-dir <source_
directory_location> --no-multipart
```

Where *<source_directory_location>* refers to a directory path like `C:\workspace\files_to_upload\`. If your source directory has subdirectories, the subdirectory names are prepended to the names of the files stored in those subdirectories, delimited with a forward slash (/) character. For example, if a file named `maple.jpg` is stored in the subdirectory `trees`, when the file is uploaded, Object Storage assigns the name `trees/maple.jpg` to the resulting object.

To append a prefix string to the object names created by your uploads, use the `--object-prefix` option:

```
oci os object bulk-upload -ns <object_storage_namespace> -bn <bucket_name> --src-dir <source_
directory_location> --object-prefix <object_name_prefix_string> --no-multipart
```

For example:

```
oci os object bulk-upload -ns ansh8tvru7zp -bn apparel --src-dir C:\workspace\new_
items\bicycling\gloves\ --object-prefix /bicycling/gloves/ --no-multipart
```

To add custom metadata key-value pairs, use the `--metadata` option:

```
oci os object bulk-upload -ns <object_storage_namespace> -bn <bucket_name> --src-dir <source_
directory_location> --metadata <json_formatted_key-value_pairs> --no-multipart
```

Tip

The `--metadata` option requires that you provide complex type key-value pair input in valid JSON format. See Passing Complex Input and Using a JSON File for Complex Input for more information about JSON formatting.

To download an object from a bucket

Open a command prompt and run `oci os object get` to download an object:

```
oci os object get -ns <object_storage_namespace> -bn <bucket_name> --name <object_name> --file <file_
location>
```

Where *<file_location>* refers to a directory path like `C:\workspace\myfile.txt`.

To download an object using multipart download

Multipart object downloading is available using the byte-range request standard defined in RFC 7233, section 2.1.

To initiate a multipart download, open a command prompt and run `oci os object get` with the `--range` option and the `bytes=<byte_range>` byte-range specifier:

```
oci os object get -ns <object_storage_namespace> -bn <bucket_name> --name <object_name> --file <file_location> --range bytes=<byte_range>
```

For example:

```
oci os object get -ns ansh8lvru1zp -bn my_bucket --name my_object.mp4 --file /Users/me/my_object.mp4 --range bytes=0-499
```

To bulk download all objects within a bucket

Open a command prompt and run `oci os object bulk-download` to download all the objects in a bucket:

```
oci os object bulk-download -ns <object_storage_namespace> -bn <bucket_name> --download-dir <download_directory_location>
```

Where *<download_directory_location>* refers to a directory path like `C:\workspace\objects\` where downloaded objects are saved. If the directory does not exist, Object Storage creates the directory.

For a complete list of object bulk download options, see CLI Help.

To bulk download objects by object name prefix string

If you have named your objects with prefix strings, you can bulk download those objects in a bucket that match a specified prefix string. Open a command prompt and run `oci os object bulk-download` command with the `--prefix` option:

```
oci os object bulk-download -ns <object_storage_namespace> -bn <bucket_name> --download-dir <download_directory_location> --prefix <prefix_string>
```

Where *<download_directory_location>* refers to a directory path like `C:\workspace\objects\` where downloaded objects are saved. If the directory does not exist, Object Storage creates the directory.

For example:

```
oci os object bulk-download -ns ansh8tvru7zp -bn apparel --download-dir C:\objects\ --prefix gloves_27
```

In the example above, an object named `gloves_27_A.jpg` is downloaded, while an object named `gloves_31_A.jpg` is not downloaded.

If you named your objects so that they exist in Object Storage in a hierarchy, you can download objects at a specified level and below. Specify the prefix that matches the level of your choosing:

```
oci os object bulk-download -ns <object_storage_namespace> -bn <bucket_name> --download-dir <download_
directory_location> --prefix <level_1/level_2/>
```

The preceding command downloads the following objects:

- *<level_1/level_2/object_name>*
- *<level_1/level_2/level_3/object_name>*
- *<level_1/level_2/level_3/level_4/object_name>*

To download only those objects at a given hierarchy level (and not objects in levels above or below), see To bulk download objects at a specified hierarchy level.

To bulk download objects at a specified hierarchy level

If you named your objects so that they exist in Object Storage in a hierarchy, you can bulk download all objects at a specified hierarchy level.

Open a command prompt and run `oci os object bulk-download` command with the `--prefix` and `--delimiter` flags:

```
oci os object bulk-download -ns <object_storage_namespace> -bn <bucket_name> --download-dir <download_
directory_location> --prefix <level_1/level_2/> --delimiter /
```

Where *<download_directory_location>* refers to a directory path like `C:\workspace\objects\` where files downloaded objects are saved. If the directory you specify does not exist, Object Storage creates this directory.

Note

Currently, only the forward slash (/) is the supported delimiter for the `--delimiter` option.

The preceding command downloads objects only at *<level_2>* of the hierarchy. For example, the following object is downloaded:

<level_1/level_2/object_name>

The preceding command does not download objects in levels *above* or *below* *<level_2>*. For example, the preceding command does not download the following objects:

- *<level_1/object_name>*
- *<level_1/level_2/level_3/object_name>*
- *<level_1/level_2/level_3/level_4/object_name>*

To download objects at a given hierarchy level along with all objects in the hierarchy sublevels, see To bulk download objects by object name prefix string.

To rename an object

Open a command prompt and run `oci os object rename` to rename an object:

```
oci os object rename -ns <object_storage_namespace> -bn <bucket_name> --name <object_original_name> --
new-name <object_new_name>
```

Warning

Avoid entering confidential information in object name.

For example:

```
oci os object rename -ns ansh8tvru7zp -bn photo_collection --name /marathon/participants/p_93.jpg --new-
name /marathon/participants/p_94.jpg
```

To make the rename operation dependent on the object having a specific entity tag, use the `--src-obj-if-match-e-tag` option:

```
oci os object rename -ns <object_storage_namespace> -bn <bucket_name>--name <object_original_name> --
new-name <object_new_name> --src-obj-if-match-e-tag <etag_required_for_object_rename>
```

For example:

```
oci os object rename -ns ansh8lvru1zp -bn my_bucket --name my_object.jpg --new-name my_renamed_
object.jpg --src-obj-if-match-e-tag 6672BECB67CCFFBCE0530292F20ZBACE
```

For rename operations where you intend to overwrite one object in a bucket with another, you can make the renaming dependent on having a specific entity tag. To do so, use the `--new-obj-if-match-e-tag` option:

```
oci os object rename -ns <object_storage_namespace> -bn <bucket_name> --name <source_object_name> --
new-name <name_of_object_to_be_overwritten> --new-obj-if-match-e-tag <etag_of_object_to_be_
overwritten>
```

For example:

```
oci os object rename -ns ansh8lvru1zp -bn my_bucket --name my_object.jpg --new-name my_renamed_
object.jpg --new-obj-if-match-e-tag 6672BECB67CCFFBCE0530292F20ZBACE
```

When renaming an object, you can prevent the system from overwriting another object in the same bucket by using the `--new-obj-if-none-match-e-tag *` option. This option prevents the renaming operation from completing if an object exists with the `--new-name` value specified and the same entity tag of the source object.

```
oci os object rename -ns <object_storage_namespace> -bn <bucket_name> --name <source_object_name> --
new-name <new_name_for_object> --new-obj-if-none-match-e-tag *
```

For example:

```
 oci os object rename -ns ansh8lvru1zp -bn my_bucket --name my_object.jpg --new-name my_renamed_
object.jpg --new-obj-if-none-match-e-tag *
```

To restore an Archive Storage tier object

Tip

You need OBJECT_RESTORE permissions to restore Archive Storage objects.

Open a command prompt and run `oci os object restore` to restore an object from Archive Storage:

```
oci os object restore -ns <object_storage_namespace> -bn <archive_bucket_name> --name <archived_object_name> [--hours <#_of_hours>]
```

By default, you have 24 hours to download an object after restoration. However, you can optionally specify `--hours` with an integer value of download time of from 1 to 240 hours.

To check the status of an Archive Storage object restoration

Open a command prompt and run `oci os object restore-status` to check the status of restoring an object from Archive Storage:

```
oci os object restore-status -ns <object_storage_namespace> -bn <archive_bucket_name> --name <archived_object_name>
```

To delete an object

You can permanently delete an object. Open a command prompt and run `oci os object delete` to delete an object:

```
oci os object delete -ns <object_storage_namespace> -bn <bucket_name> --name <object_name>
```

To bulk delete all objects within a bucket

Open a command prompt and run `oci os object bulk-delete` to delete all the objects in a bucket:

```
oci os object bulk-delete -ns <object_storage_namespace> -bn <bucket_name>
```

Tip

To see a list of the files that will be deleted by a bulk delete command without actually deleting the files, use the `--dry-run` option.

To bulk delete objects by object name prefix string

If you named your objects with prefix strings, you can bulk delete objects in a given bucket by providing a prefix to match. Open a command prompt and run `oci os object bulk-delete` command with the `--prefix` option:

```
oci os object bulk-delete -ns <object_storage_namespace> -bn <bucket_name> --prefix <prefix_string>
```

For example:

```
oci os object bulk-delete -ns ansh8tvru7zp -bn apparel --prefix gloves_27
```

The preceding command deletes an object named `gloves_27_A.jpg`, but does not delete an object named `gloves_31_A.jpg`.

If you named your objects so that they exist in a hierarchy, you can bulk delete objects at a given level and below by specifying a prefix to match:

```
oci os object bulk-delete -ns <object_storage_namespace>-bn <bucket_name> --prefix <level_1/level_2/>
```

The preceding command deletes the following files:

- *<level_1/level_2/object_name>*
- *<level_1/level_2/level_3/object_name>*
- *<level_1/level_2/level_3/level_4/object_name>*

To delete only those objects at a given hierarchy level (and not objects in levels above or below), see To bulk delete objects at a specified hierarchy level.

Tip

To see a list of the files that will be deleted by a bulk delete command without actually deleting the files, use the `--dry-run` option.

To bulk delete objects at a specified hierarchy level

If you named your objects so that they exist in a hierarchy, you can bulk delete only those objects at a given hierarchy level (and not objects in levels above or below). Open a command prompt and run the `oci os object bulk-delete` command with the `--prefix` and `--delimiter` flags:

```
oci os object bulk-delete -ns <object_storage_namespace> -bn <bucket_name> --prefix <level_1/level_2/>
--delimiter /
```

Note

Currently, only the forward slash (/) is the supported delimiter for the `--delimiter` option.

The preceding bulk delete command deletes the following object:

<level_1/level_2/>object_name

The preceding command does not bulk delete objects in levels above or below *<level_2>*. For example, the command would not delete the following objects:

- *<level_2/object_name>*
- *<level_1/level_2/level_3/object_name>*
- *<level_1/level_2/level_3/level_4/object_name>*

To delete objects at a given hierarchy level along with all objects in the hierarchy sublevels, see To bulk delete objects by object name prefix string.

Tip

To see a list of the files that will be deleted by a bulk delete command without actually deleting the files, use the `--dry-run` option.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Object Storage prepends the Object Storage namespace string and bucket name to the object name when constructing a URL for use with the API. Everything :

```
/n/<object_storage_namespace>/b/<bucket>/o/<object_name>
```

The object name is everything after the `/o/`, which could include hierarchy levels and prefix strings.

Use the following operations to manage objects:

- DeleteObject
- GetObject
- HeadObject
- ListObjects
- PutObject (see Special Instructions for Object Storage PUT for signing request requirements)
- RenameObject
- RestoreObjects

Copying Objects

This topic describes how to copy objects in Object Storage. You can copy objects to other buckets in the same region and to buckets in other regions.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

If you're new to policies, see Getting Started with Policies and Common Policies.

Warning

Object copy does not work if you do not authorize the Object Storage service to copy objects on your behalf. See Service Permissions for more information.

User Permissions

You must have the required access to both the source and destination buckets when performing an object copy. You must also have permissions to manage objects in the source and destination buckets.

For administrators:

- You can create a policy that lets the specified IAM group manage Object Storage namespaces, buckets, and their associated objects in all compartments in the tenancy:

  ```
  Allow group <IAM_group_name> to manage object-family in tenancy
  ```

- Alternatively, you can create policies that reduce the scope of access. For example, to

let the specified group manage only buckets and objects in a particular compartment in the tenancy:

```
Allow group <IAM_group_name> to manage buckets in compartment <compartment_name>
```

For more information about other alternatives for writing policies, see Details for Object Storage, Archive Storage, and Data Transfer.

Service Permissions

Because Object Storage is a regional service, you must authorize the Object Storage service for each region carrying out copy operations on your behalf. For example, you might authorize the Object Storage service in region US East (Ashburn) to manage objects on your behalf. Once you authorize the Object Storage service and ensure that you have the required user permissions, you can copy an object stored in a US East (Ashburn) bucket to a bucket in another region.

To determine the region name value of an Oracle Cloud Infrastructure region, see Regions and Availability Domains .

For administrators:

To enable object copy, you must authorize the service to manage objects on your behalf:

- You can create a policy that authorizes the service in the specified region to manage Object Storage namespaces, buckets, and their associated objects in all compartments in the tenancy:

  ```
  Allow service objectstorage-<region_name> to manage object-family in tenancy
  ```

- Rather than use the policy verb `manage`, you can create a policy that reduces the scope of access by instead using one of the following statements:

  ```
  Allow service objectstorage-<region_name> to {OBJECT_READ, OBJECT_INSPECT, OBJECT_CREATE,
  OBJECT_OVERWRITE, OBJECT_DELETE} in tenancy
  ```

  ```
  Allow service objectstorage-<region_name> to {OBJECT_READ, OBJECT_INSPECT, OBJECT_CREATE,
  OBJECT_OVERWRITE, OBJECT_DELETE} in compartment <compartment_name>
  ```

Copy Object Work Requests

The Object Storage service handles copy requests asynchronously. The service creates a queue for copy requests, and then processes the requests when system resources become available. To provide visibility for in-progress copy operations, Object Storage creates a work request. You can track the progress of the copy operation by monitoring the status of the work request.

The work request statuses are:

ACCEPTED

The copy request is in the work request queue to be processed.

IN PROGRESS

The object copy is in progress.

SUCCEEDED

The copy operation has successfully completed.

CANCELING

The copy request is in the process of being canceled.

CANCELED

The copy request has been canceled.

FAILED

The copy operation has failed. Work requests that do not complete because of overwrite rules or insufficient user authorizations are assigned the failed status.

Copy Object Overwrite Rules

You can use overwrite rules to control the copying of objects based on their entity tag (ETag) values.

- **Overwrite destination object**: Use this option when you do not want to limit a copy operation by an ETag value. This option is the default. This option can be used for any copy operation, regardless of whether it involves overwriting an existing object.
- **Do not overwrite any destination object**: Use this option to prevent the overwriting an existing copy of an object in the destination location, regardless of the destination object's ETag value.
- **Overwrite destination object only if it matches the specified ETag**: Use this option to prevent the accidental overwriting of an object in the destination location that does not have the specified ETag. When you use this option, the copy operation only succeeds if the ETag you supply when initiating the copy request matches the ETag of the destination object.
- **Copy object only if the source matches the specified ETag**: Use this option if you want the copy operation successful only if the ETag you supply when initiating the copy request matches the ETag of the source object. For objects that are intentionally updated and overwritten as part of data management activity, this option ensures that only the specified *version* of the object (as indicated by the ETag) is allowed to be copied. If the object's ETag value changes after the copy work request is created, but before the copy operation is executed, the copy operation will not complete.

Warning

If you overwrite an object, the operation cannot be undone.

Scope and Constraints

- Objects cannot be copied directly from Archive Storage. To copy objects that are currently in Archive Storage, you must first restore the object to the standard Object Storage tier. Objects can be copied directly to Archive Storage tier buckets from the standard Object Storage tier. When you copy objects into an Archive Storage bucket,

the copy of the object is immediately archived.

- Specify an existing target bucket for the copy request. The copy operation does not automatically create buckets.
- When an object is copied, the destination object receives a new ETag value.
- If you rename, overwrite, or delete a source object during a copy operation, the copy operation fails and the destination object is not created or overwritten.
- Bulk copying is not supported. Identify a single object in the copy request.

Using the Console

The Console consumes the REST API and is subject to the same considerations as any Oracle Cloud Infrastructure client.

To make a copy of an object

1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.
2. Choose the compartment that contains the bucket that contains your object.
3. Select the bucket containing the object that you want to copy.
4. Click **Objects** under **Resources** to display a list of objects in the bucket.
5. For the object you want to copy (the source object), click the Actions icon (three dots), and then click **Copy**.
6. In the **Copy** dialog, enter the following:
    - **Destination Namespace**: The Object Storage Namespace of the destination bucket for your copied object. The namespace string of your tenancy is supplied as the default value.
    - **Destination Region**: The Oracle Cloud Infrastructure region containing the destination bucket for your copied object. Your tenancy must be subscribed to a region in order for you to copy an object to a bucket in that region.

- **Destination Bucket**: The name of the destination bucket for your copied object. Specify an existing target bucket. The copy operation does not automatically create buckets.
- **Destination Object Name**: Optionally, you can specify a different destination object name. By default, the **Destination Object Name** is the same name as the object you are copying.
- **Overwrite Rule**: Select the overwrite rule appropriate for your copy request. See Copy Object Overwrite Rules for information on the overwrite rule options.

7. Click **Copy Object**.
   A dialog confirms that your copy request was submitted successfully.

To monitor the status of an object copy work request

1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.
2. Choose the compartment containing your bucket.
3. Click the bucket name of the bucket containing the object being copied.
4. Click **Work Requests** under **Resources**.
   A list of work requests is displayed. The status of the request and details including object name, request ID, and the destination bucket's name, region, and namespace is also displayed.

Using the Command Line Interface (CLI)

For information about using the CLI, see Command Line Interface (CLI). For a complete list of flags and options available for CLI commands, see CLI Help.

To make a copy of an object

Open a command prompt and run `oci os object copy` to copy an object:

```
oci os object copy --namespace-name <object_storage_namespace> --bucket-name <source_bucket_name> --
source-object-name <source_object> --destination-namespace <destination_namespace_string> --
destination-region <destination_region> --destination-bucket <destination_bucket_name> --destination-
object-name <destination_object_name>
```

For example:

```
oci os object copy --namespace-name ansh8lvru1zp  --bucket-name photos --source-object-name
hummingbird.jpg --destination-namespace ansh8lvru1zp --destination-region uk-london-1 --destination-
bucket UK_photos --destination-object-name hummingbird.jpg
```

For a complete list of object copy options, see CLI Help.

To get the status of an object copy work request

Use the `work-request get` command to get the status of an object copy work request using the work request ID. If you do not have the work request ID, you can get a list of work requests, including the request IDs, for a specified compartment using the `work-request list` command.

Open a command prompt and run `oci os work-request get` to get the status of a work request:

```
oci os work-request get --work-request-id <request_id>
```

For a complete list of work request options, see CLI Help.

To get a list of work requests for a compartment

Open a command prompt and run `oci os work-request list` to get a list of a work requests for a specified compartment:

```
oci os work-request list --compartment-id <compartment_id>
```

For a complete list of work request options, see CLI Help.

To cancel a copy object work request

Open a command prompt and run `oci os work-request cancel` to cancel a work request:

```
oci os work-request cancel --work-request-id <request_id>
```

For a complete list of work request options, see CLI Help.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use these operations to view and manage work requests for copy object operations:

- CopyObject
- ListWorkRequests
- GetWorkRequest
- CancelWorkRequest

Using Pre-Authenticated Requests

Pre-authenticated requests provide a way to let users access a bucket or an object without having their own credentials, as long as the request creator has permissions to access those objects. For example, you can create a request that lets an operations support user upload backups to a bucket without owning API keys. Or, you can create a request that lets a business partner update shared data in a bucket without owning API keys.

When you create a pre-authenticated request, a unique URL is generated. Anyone you provide this URL to can access the Object Storage resources identified in the pre-authenticated request, using standard HTTP tools like curl and wget.

Important

Assess the business requirement for and the security ramifications of pre-authenticated access to a bucket or objects.

A pre-authenticated request URL gives anyone who has the URL access to the targets identified in the request. Carefully manage the distribution of the URL.

Required Permissions

To Create a Pre-Authenticated Request

To create or manage pre-authenticated requests, you need `PAR_MANAGE` permission to the target bucket or object.

While you only need `PAR_MANAGE` permission to create a pre-authenticated request, you must also have the appropriate permissions for the access type that you are granting. For example:

- If you are creating a pre-authenticated request for uploading objects to a bucket, you need `OBJECT_CREATE` and `OBJECT_OVERWRITE` permissions in addition to `PAR_MANAGE`.
- If you are creating a pre-authenticated request for read/write access to objects in a bucket, you need `OBJECT_READ`, `OBJECT_CREATE`, and `OBJECT_OVERWRITE` permissions in addition to `PAR_MANAGE` to grant user read/write access to objects.

Important

If the creator of a pre-authenticated request is deleted or loses the required permissions after they created the request, the request will no longer work.

To Use a Pre-Authenticated Request

Permissions of the pre-authenticated request creator are checked each time you use a pre-authenticated request. The pre-authenticated request no longer works if any of the following occurs:

- Permissions of the pre-authenticated request creator change
- User who created the pre-authenticated request is deleted
- Federated user who created the pre-authenticated request has lost the user capabilities that they had when they created the request
- Pre-authenticated request has expired

Options

When creating a pre-authenticated request, you have the following options:

- You can specify the name of a bucket that a pre-authenticated request user has write access to and can upload one or more objects to.
- You can specify the name of an object that a pre-authenticated request user can read from, write to, or read from and write to.

Scope and Constraints

Understand the following scope and constraints regarding pre-authenticated requests:

- Users can't list bucket contents.
- You can create an unlimited number of pre-authenticated requests.
- There is no time limit to the expiration date that you can set.
- You can't edit a pre-authenticated request. If you want to change user access options in response to changing requirements, you must create a new pre-authenticated request.
- The target and actions for a pre-authenticated request are based on the creator's permissions. The request is not, however, bound to the creator's account login

credentials. If the creator's login credentials change, a pre-authenticated request is not affected.

- You cannot delete a bucket that has a pre-authenticated request associated with that bucket or with an object in that bucket.

Working with Pre-Authenticated Requests

You can create, delete, or list pre-authenticated requests using the Console, using the CLI, or by using an SDK to access the API.

Important

The unique URL provided by the system when you create a pre-authenticated request is the only way a user can access the bucket or object specified as the request target. Copy the URL to durable storage. The URL is displayed only at the time of creation and cannot be retrieved later.

After creating a pre-authenticated request, you can use a tool like curl to read and write data using the pre-authenticated request.

To put an object

```
$ curl -X PUT <unique-PAR-URL>
```

For example:

```
$ curl -X PUT https://objectstorage.us-phoenix-1.oraclecloud.com/p/j3DoSvgQHbUaw6ADzHkDlnaqMuXWef_
lhTxCiS9ngCw/n/docs/b/par-bucket/o/using-dita-guide.pdf
```

To get an object

```
$ curl -X GET <unique-PAR-URL>
```

For example:

```
$ curl -X GET https://objectstorage.us-phoenix-1.oraclecloud.com/p/j3DoSvgQHbUaw6ADzHkDlnaqMuXWef_
lhTxCiS9ngCw/n/namespace/b/par-bucket/o/using-dita-guide.pdf
```

Using the Console

To create a pre-authenticated request for a bucket

See Service Limits for a list of applicable limits and instructions for requesting a limit increase.

1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.
2. Choose the compartment where the bucket is.
3. Click the bucket name.
4. Click **Pre-Authenticated Requests** under **Resources** to display the list of pre-authenticated requests.
5. Click **Create Pre-Authenticated Request**.
6. Provide the following information:
   - **Name:** The system automatically generates a default, pre-authenticated request name that reflects the current year, month, day, and time, for example **par-bucket-20191101-1327**.
     If you change this default or any other pre-authenticated request name, use letters, numbers, dashes, underscores, and periods. Avoid entering confidential information.
   - **Pre-Authenticated Request Target**: Select **Bucket**.
   - **Expiration**: Accept the one week, system-generated expiration date or use the date and time editor to use a different expiration date and time.
7. Click **Create Pre-Authenticated Request**.
   After a request is created, the **Pre-Authenticated Request Details** dialog box displays the URL used to access the bucket.

8. Click **Copy** to copy the URL for future reference.

Note

The unique URL provided by the system when you create a pre-authenticated request is the only way a user can access the bucket or object specified as the request target. Copy the URL to durable storage. The URL is displayed only at the time of creation and cannot be retrieved later.

9. Click **Close**.

To create a pre-authenticated request for an object

1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.
2. Choose the compartment where the bucket is.
3. Click the bucket name.
4. Click **Objects** under **Resources** to display the list of objects.
5. For the object you want to create a pre-authenticated request, click the Actions icon (three dots), and then click **Create Pre-Authenticated Request**.
6. Provide the following information:
   - **Name:** The system generates a default, pre-authenticated request name that reflects the current year, month, day, and time, for example **par-object-object-name-20191101-1429**.

     If you change this default or any other pre-authenticated request name, use letters, numbers, dashes, underscores, and periods. Avoid entering confidential information.
   - **Pre-Authenticated Request Target:** Select **Object**.

- **Object Name:** The name of the object that you want authenticated by this rule.
- **Access Type:** Select one of the following.
  - Permit read on the object
  - Permit writes to the object
  - Permit reads on and writes to the object
- **Expiration:** Accept the one week, system-generated expiration date or use the date and time editor to a different expiration date and time.

7. Click **Create Pre-Authenticated Request**.
   After a request is created, the **Pre-Authenticated Request Details** dialog displays the URL used to access the object.
8. Click **Copy** to copy the URL for future reference.

Note

The unique URL provided by the system when you create a pre-authenticated request is the only way a user can access the bucket or object specified as the request target. Copy the URL to durable storage. The URL is displayed only at the time of creation and cannot be retrieved later.

9. Click **Close**.

To copy a pre-authenticated request ID

To copy the ID for a pre-authenticated request to the clipboard, do the following:

1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.
2. Choose the compartment where the bucket is.
3. Click the bucket name.

4. Click **Pre-Authenticated Requests** under **Resources** to display the list of pre-authenticated requests.
5. For the pre-authenticated request ID that you want to copy, click the Actions icon (three dots), and then click **Copy Pre-Authenticated Request ID**.
   The ID for the selected pre-authentication request is copied to the clipboard.

Using the Command Line Interface (CLI)

For information about using the CLI, see Command Line Interface (CLI). For a complete list of flags and options available for CLI commands, see CLI Help.

To create a pre-authenticated request for a bucket

```
oci os preauth-request create -ns <object_storage_namespace> -bn <bucket_name> --name
<preauthenticated_request_name> --access-type AnyObjectWrite --time-expires <timestamp>
```

Note the following:

- To create a pre-authenticated request for a bucket, use the `AnyObjectWrite` enum value with the `--access-type` flag. Pre-authenticated requests for buckets permit writes to the bucket by default.
- The *<timestamp>* is required and must be an RFC 3339 timestamp. For example: `2017-09-01T00:09:51.000+02:00`.

Note

The unique URL provided by the system when you create a pre-authenticated request is the only way a user can access the bucket or object specified as the request target. Copy the URL to durable storage. The URL is displayed only at the time of creation and cannot be retrieved later.

To create a pre-authenticated request for an object

```
oci os preauth-request create -ns <object_storage_namespace> -bn <bucket_name> --name
<preauthenticated_request_name> --access-type <enum_value> --time-expires <timestamp> -on <object_
name_or_null>
```

The *<enum_value>* for `--access-type` is one of the following:

- `ObjectRead` (permits read on the object)
- `ObjectWrite` (permits writes to the object)
- `ObjectReadWrite` (permits reads on and writes to the object)

The *<timestamp>* is required and must be an RFC 3339 timestamp. For example: `2017-09-01T00:09:51.000+02:00`.

Avoid entering confidential information in the pre-authenticated request name.

Note

The unique URL provided by the system when you create a pre-authenticated request is the only way a user can access the bucket or object specified as the request target. Copy the URL to durable storage. The URL is displayed only at the time of creation and cannot be retrieved later.

To list a pre-authenticated request

```
oci os preauth-request list -ns <object_storage_namespace> -bn <bucket_name>
```

To get a pre-authenticated request

```
oci os preauth-request get -ns <object_storage_namespace> -bn <bucket_name> --par-id
<preauthenticated_request_id>
```

To delete a pre-authenticated request

```
oci os preauth-request delete -ns <object_storage_namespace> -bn <bucket_name> --par-id
<preauthenticated_request_id>
```

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the following operations to work with pre-authenticated requests:

- CreatePreauthenticatedRequest
- DeletePreauthenticatedRequest
- GetPreauthenticatedRequest
- ListPreauthenticatedRequests

Using Multipart Uploads

The Oracle Cloud Infrastructure Object Storage service supports multipart uploads for more efficient and resilient uploads, especially for large objects. You can perform multipart uploads using the API, the Software Development Kits and Command Line Interface, or the Command Line Interface (CLI). With multipart uploads, individual parts of an object can be uploaded in parallel to reduce the amount of time you spend uploading. Multipart uploads performed through the API can also minimize the impact of network failures by letting you retry a failed part upload instead of requiring you to retry an entire object upload.

Multipart uploads can accommodate objects that are too large for a single upload operation. Oracle recommends that you perform a multipart upload to upload objects larger than 100 MiB. The maximum size for an uploaded object is 10 TiB. Object parts must be no larger than 50 GiB. For large uploads performed through the API, you have the flexibility of pausing between the uploads of individual parts, and resuming the upload when your schedule and resources allow.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

If you are new to policies, see Getting Started with Policies and Common Policies.

For administrators:

- The policy in Let Object Storage admins manage buckets and objects lets the specified group do everything with buckets and objects.
- If you need to write more restrictive policies for buckets, see Details for Object Storage, Archive Storage, and Data Transfer.

Monitoring Resources

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications. For more information, see Monitoring Overview and Notifications Overview.

For more information about monitoring multipart uploads, see Object Storage Metrics.

Using the Multipart Upload API

A multipart upload performed using the API consists of the following steps:

1. Initiating an upload
2. Uploading object parts
3. Committing the upload

Before you use the multipart upload API, you are responsible for creating the parts to upload. Object Storage provides API operations for the remaining steps. The service also provides API

operations for listing in-progress multipart uploads, listing the object parts in an in-progress multipart upload, and aborting in-progress multipart uploads initiated through the API.

Here we provide a high-level overview of the API steps, but you can refer to the API Reference for specifics about supported API calls.

Creating Object Parts

With multipart upload, you split the object you want to upload into individual parts. Individual parts can be as large as 50 GiB or as small as 10 MiB. (Object Storage waives the minimum part size restriction for the last uploaded part.) Decide what part number you want to use for each part. Part numbers can range from 1 to 10,000. You do not need to assign contiguous numbers, but Object Storage constructs the object by ordering part numbers in ascending order.

Initiating an Upload

After you finish creating object parts, initiate a multipart upload by making a CreateMultipartUpload REST API call. Provide the object name and any object metadata. Object Storage Responds with a unique upload ID that you must include in any requests related to this multipart upload. Object Storage also marks the upload as active. The upload remains active until you explicitly commit it or abort it.

Uploading Object Parts

Make an UploadPart request for each object part upload. In the request parameters, provide the Object Storage namespace, bucket name, upload ID, and part number. In the request body, include the object part. Object parts can be uploaded in parallel and in any order. When you commit the upload, Object Storage uses the part numbers to sequence object parts. Part numbers do not have to be contiguous. If multiple object parts are uploaded using the same upload ID and part number, the last upload overwrites the part and is committed when you call the CommitMultipartUpload API.

Object Storage returns an ETag (entity tag) value for each part uploaded. You need both the part number and corresponding ETag value for each part when you commit the upload.

If you have network issues, you can restart a failed upload for an individual part. You do not need to restart the entire upload. If for some reason, you cannot perform an upload all at once, multipart upload lets you continue uploading parts at your own pace. While a multipart upload is still active, you can keep adding parts as long as the total number is less than 10,000.

You can check on an active multipart upload by listing all parts that have been uploaded. (You cannot list information for an individual object part in an active multipart upload.) The ListMultipartUploadParts operation requires the Object Storage namespace, bucket name, and upload ID. Object Storage responds with information about the parts associated with the specified upload ID. Parts information includes the part number, ETag value, MD5 hash, and part size (in bytes).

Similarly, if you have multiple multipart uploads occurring simultaneously, you can see what uploads are in-progress. Make an ListMultipartUploads API call to list active multipart uploads in the specified Object Storage namespace and bucket.

Charges for parts storage begin accruing when you upload data.

Committing the Upload

When you have uploaded all object parts, commit the upload. Use the CommitMultipartUpload request parameters to specify the Object Storage namespace, bucket name, and upload ID. Include the part number and corresponding ETag value for each part in the body of the request. When you commit the upload, Object Storage constructs the object from its constituent parts. The object is stored in the specified bucket and Object Storage namespace. You can treat it like you would any other object. Garbage collection releases storage space occupied by any part numbers you uploaded, but did not include in the CommitMultipartUpload request.

You cannot list or retrieve parts from a completed upload. You cannot append or remove parts from the completed upload either. If you want, you can replace the object by initiating a new upload.

If you decide to abort a multipart upload instead of committing it, wait for in-progress part uploads to complete and then use the AbortMultipartUpload operation. If you abort an upload

while part uploads are still in progress anyway, Object Storage cleans up both completed and in-progress parts. Upload IDs from aborted multipart uploads cannot be reused.

API Documentation

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the following operations to manage multipart uploads:

- AbortMultipartUpload
- CommitMultipartUpload
- CreateMultipartUpload
- ListMultipartUploadParts
- ListMultipartUploads
- UploadPart (see Special Instructions for Object Storage PUT for signing request requirements)

Using the CLI

When you perform a multipart upload using the CLI, you do not need to split the object into parts as you are required to do by the API. Instead, you specify the part size of your choice, and Object Storage splits the object into parts and performs the upload of all parts automatically. You can choose to set the maximum number of parts that can be uploaded in parallel. By default, the CLI limits the number of parts that can be uploaded in parallel to three. When using the CLI, you do not have to perform a commit when the upload is complete.

You can also use the CLI to list in-progress multipart uploads, and to abort multipart uploads initiated through the API.

For information about using the CLI, see Command Line Interface (CLI). For a complete list of flags and options available for CLI commands, see CLI Help.

To perform a multipart upload using the CLI

To upload an object, open a command prompt and run `oci os object put` with the `--part-size` flag. The `--part-size` value represents the size of each part in mebibytes (MiBs). Object Storage waives the minimum part size restriction for the last uploaded part. The `--part-size` value must be an integer.

Optionally, you can use the `--parallel-upload-count` flag to set the maximum number of parallel uploads allowed.

```
oci os object put --namespace <object_storage_namespace> -bn <bucket_name> --file <file_location> --
name <object_name> --part-size <upload_part_size_in_MB> --parallel-upload-count <maximum_number_
parallel_uploads>
```

For example:

```
oci os object put --namespace MyNamespace -bn MyBucket --file ~/path/to/file --name MyObject --parallel-
upload-count 10 --part-size 500
Upload ID: 277ffff5-e1b5-e81d-5f81-c374a8f33998
Split file into 12 parts for upload.
Uploading object ################################## 100%
{ "etag": "861c8341-74d8-4142-8da4-28e1ce7783ba", "last-modified": "Wed, 25 Sep 2019 19:59:15 GMT",
"opc-multipart-md5": "9Qn1eyou2yMiyOO9Bc7o1A==-12" }
```

For more information on the `oci os object put` command, see To upload an object to a bucket.

To list the parts of an unfinished or failed multipart upload

```
oci os multipart list -ns <object_storage_namespace> -bn <bucket_name>
```

For example:

```
oci os multipart list --bucket-name MyBucket{
  "data": [
    {
      "bucket": "MyBucket",
      "namespace": "MyNamespace",
      "object": "MyObject",
      "time-created": "2019-07-25T21:55:21.973000+00:00",
      "upload-id": "0b7abd48-9ff2-9d5f-2034-63a02fdd7afa"
    },
    {
      "bucket": "MyBucket",
      "namespace": "MyNamespace",
```

```
      "object": "MyObject",
      "time-created": "2019-07-25T21:53:09.246000+00:00",
      "upload-id": "1293ac9d-83f8-e055-a5a7-d1e13277b5c0"
    },
    {
      "bucket": "MyBucket",
      "namespace": "MyNamespace",
      "object": "MyObject",
      "time-created": "2019-07-25T21:46:34.981000+00:00",
      "upload-id": "33e7a875-9e94-c3bc-6577-2ee5d8226b53"
    }
...
```

Tip

See CLI Help for command options to control the pagination of the list output.

To remove a part of an unfinished or failed multipart upload

```
oci os multipart abort -ns <object_storage_namespace> -bn <bucket_name> --object-name <object_name> --upload-id <upload_ID>
```

For example:

```
oci os multipart abort --bucket-name MyBucket --object-name MyObject --upload-id 0b7abd48-9ff2-9d5f-2034-63a02fdd7afa
WARNING: Are you sure you want to permanently remove this incomplete upload? [y/N]: y
```

Tip

The CLI interface asks you to confirm the deletion request. To abort without the confirmation prompt, use the `--force` flag.

To remove all parts of an unfinished or failed multipart upload

Use the following script with the `--force` flag to remove all parts:

```
#!/bin/bash

BUCKET=$1

oci os multipart list --bucket-name $BUCKET | \
    jq -c '.data | map({'o': .object, 'i': ."upload-id"}) | .[]' | \
    while read JSON; do
        OBJECTNAME=$(echo $JSON | jq '.o' | sed -e 's/\"//g;')
        UPLOADID=$(echo $JSON | jq '.i' | sed -e 's/\"//g;')
        echo Removing Object name $OBJECTNAME, ID $UPLOADID
        oci os multipart abort --bucket-name $BUCKET \
                --object-name $OBJECTNAME \
                --upload-id $UPLOADID \
                --force
    done
```

Using Object Lifecycle Management

Object Lifecycle Management lets you automatically manage the archiving and deletion of objects. By using Object Lifecycle Management to manage your Object Storage and Archive Storage data, you can reduce your storage costs and the amount of time you spend managing data.

Object Lifecycle Management works by defining rules that instruct Object Storage to archive or delete objects on your behalf within a given bucket. A bucket's lifecycle rules are collectively known as an object lifecycle policy. For example, you could have Object Storage automatically move objects to Archive Storage 30 days after creation, and then automatically delete the archived objects 120 days after creation.

Each Object Storage or Archive Storage bucket can have a single lifecycle policy consisting of up to 1,000 rules. Rules can have object name prefix and pattern matching conditions. You can create, edit, delete, enable, and disable individual rules in the Console as needed. To update a lifecycle policy using the CLI or API, overwrite the entire policy with a new policy that is inclusive of all the policy rules that you want to apply to the bucket.

Required IAM Policy

Important

You cannot use Object Lifecycle Management until you authorize the Object Storage service to archive and delete objects on your behalf. See Service Permissions for more information.

User Permissions

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

The policy Let Object Storage admins manage buckets and objects lets the specified group do everything with buckets and objects, including adding and managing lifecycle policies. See Details for Object Storage, Archive Storage, and Data Transfer for more information on Object Storage user permissions.

Service Permissions

To execute object lifecycle policies, you must authorize the service to archive and delete objects on your behalf. To do so, create the following policy in the root compartment of your tenancy:

```
Allow service objectstorage-<region_name> to manage object-family in compartment <compartment_name>
```

Because Object Storage is a regional service, you must authorize the Object Storage service in each region you use lifecycle policies. Object Storage ensures that your data is not read from any unauthorized region.

If you don't have permissions to write policies for the root compartment of your tenancy, contact your Oracle Cloud Infrastructure administrator. To determine the region name value of an Oracle Cloud Infrastructure region, see Regions and Availability Domains.

If you want to grant individual permissions to the service rather than use the policy verb `manage`, you can use the following syntax:

```
Allow service objectstorage-<region_name> to {BUCKET_INSPECT, BUCKET_READ, OBJECT_INSPECT, OBJECT_
CREATE,  OBJECT_DELETE} in compartment <compartment_name>
```

If you're new to policies, see Getting Started with Policies and Common Policies.

Options

When creating object lifecycle policy rules, you have the following options:

- When a lifecycle rule is created, the system generates a default name for that rule, for example **lifecycle-rule-20190321-1559**. This rule name identifies the current year, month, day, and time that the rule was created. You can use that system-generated name for your new rule or you can specify a different name for it.
- You can use a rule to either archive or delete objects and specify the number of days until the specified action is taken.
- You can apply a rule to all objects in a bucket. Alternatively, you can use object name filters to specify which objects the lifecycle rule applies to. You can select objects using both object name prefixes and pattern matching. See Using Object Name Filters for details.
- You can decide whether a new rule is enabled or disabled upon creation.

Using Object Name Filters

Use object name filters to specify which objects the lifecycle rule applies to.

Important

If you want the rule to apply to all objects in the bucket, do not specify any object name filters.

You can add object filters in any order. Object Lifecycle Management evaluates the precedence of the rules as follows:

1. Pattern exclusions
2. Pattern inclusions
3. Prefix inclusions

Using Prefix Matching to Filter Objects

When naming objects, you can use prefix strings without a delimiter so that certain bulk operations can be performed by matching on the prefix portion of the object name. For example, in the object names below, the string `gloves_27_` serves as a prefix for matching purposes when performing lifecycle management archive or deletions:

```
gloves_27_dark_green.jpg
gloves_27_light_blue.jpg
gloves_27_deep_purple.jpg
gloves_27_bright_orange.jpg
```

See Object Naming Using Prefixes and Hierarchies for complete object naming details.

Using Pattern Matching to Filter Objects

Object Storage supports the following pattern matching characters to either include or exclude objects:

Character	Description	Pattern Examples	Matches	Doesn't Match
*	Matches 0 or more characters	*.tmp	foo.tmp foo/bar/baz.tmp	tmp Atmp
		*.xls	.xls /home/user/file.xlsx	xls .xl
		/archive/*	/archive/sub/dir/ /archive/1/2/3/4/foo.txt	/src/archive/a archive/b
?	Matches any one character	X?Z	XyZ X_Z	XZ XYYZ
\	Escapes the next character	\\dir\\sub*	\dir\sub\ABC \dir\sub\	dir\sub\abc dirsub

Character	Description	Pattern Examples	Matches	Doesn't Match
[...]	Matches a group of characters, which can be: • A set of characters, for example: [Zafg9@]. Matches any character in the brackets. • A range of characters, for example: [a-f]. Matches any character in the range: ◦ [a-f] is equivalent to [abcdef]. ◦ For character ranges only the CHARACTER-CHARACTER pattern is	[-ab3]	- a b 3	-a -ab 3b

Character	Description	Pattern Examples	Matches	Doesn't Match
	supported: ▪ [ab-yz] is not valid ▪ [a-mn-z] is not valid ◦ Character ranges cannot start with ^ or : ◦ To include a hyphen (-) in the range, make it the first or last character.			
		backup.tar.gz.[0-9]	backup.tar.gz.0 backup.tar.gz.5 backup.tar.gz.9	backup.tar.gz10 backup.tar.gz
		page-[0-9]*	page-0 page-2 page-22 page-2X	page- page-A1
		\[a-z\]	[a-z]	a z [a-z

Patterns are limited to 1024 characters. The following are examples of invalid patterns:

- \
- [^a-z]

- [z-a]
- [:isalpha:]

Scope and Constraints

Understand the following scope and constraints regarding object lifecycle policies:

- When you create a lifecycle policy for a bucket, Object Storage applies that policy to all objects that exist in the bucket unless you add object name filters.
- A rule that deletes an object always takes priority over a rule that would archive that same object.
- When creating a lifecycle policy rule that deletes objects from Archive Storage, Archive Storage has a minimum retention requirement of 90 days. Objects deleted from Archive Storage that have not met the 90-day retention minimum are billed for 90 days of storage.
- You can create up to 1,000 lifecycle rules per bucket.

Working with Object Lifecycle Management Policies

You can create, delete, edit, or disable lifecycle policy rules using the Console, the Command Line Interface (CLI), an SDK, or the API.

Warning

Objects deleted on your behalf by lifecycle policies cannot be recovered. Be sure when creating and editing your lifecycle policies that you are not unintentionally deleting data you want to retain. Oracle recommends that you test your lifecycle policy on development data before using the policy in production.

Using the Console

To create a lifecycle policy rule

1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.
2. Choose the compartment containing bucket for which you want to create a lifecycle rule.
3. Click the bucket name.
4. Click **Lifecycle Policy Rules** under **Resources** to access the lifecycle policy rule list.
5. Click **Create Rule**.
6. Provide the following information:
   - **Name:** Required. The system generates a default rule name that reflects the current year, month, day, and time, for example **lifecycle-rule-20190321-1559**. If you change this default to any other rule name, use letters, numbers, dashes, underscores, and periods. Do not include any confidential information.
   - **Lifecycle Action:** Select rule type **Archive** or **Delete**.
   - **Number of Days:** The number of days until the specified action is taken.
7. Optionally, you can add one or more **Object Name Filters** to specify which objects the lifecycle rule applies to. You can choose objects using prefixes and pattern matching. If no object name filters are specified, the rule applies to all objects in the bucket.
   To create an object name filter:
   a. Click **Add Filter**.
   b. Select the **Filter Type**.
   c. Enter the **Filter Value**.
   d. Click **Add Another Filter** to add as many filters as you need for this rule.
8. Select whether the rule is enabled or disabled upon creation using the **State** selector.
9. Click **Create**.

To edit a lifecycle policy rule

1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.
2. Choose the compartment where the bucket is.
3. Click the bucket name.
4. Click **Lifecycle Policy Rules** under **Resources** to access the rule list.
5. For the rule you want to edit, click the Actions icon (three dots), and then click **Edit**.
6. In the **Edit Lifecycle Rule** dialog box, edit the following as needed for each rule you want to change:
    - **Name:** A user-friendly name for the rule. Avoid entering confidential information.
    - **Lifecycle Action:** Rule type **Archive** or **Delete**.
    - **Number of Days:** The number of days until the specified action is taken.
    - **Object Name Filters:** Edit, delete, or add a prefix or pattern filter.
7. Click **Save Changes**.

To enable, disable, or delete a lifecycle policy rule

You can disable and enable a rule on demand using the Console. The system stops the execution of disabled or deleted rules immediately.

1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.
2. Choose the compartment where the bucket is.
3. Click the bucket name.
4. Click **Lifecycle Policy Rules** under **Resources** to access the rule list.
5. For the rule you want to manage, click the Actions icon (three dots), and then click one of the following:
    - **Enable** (only displays if the rule is disabled)
    - **Disable** (only displays if the rule is enabled)

- **Delete**

Using the Command Line Interface (CLI)

For information about using the CLI, see Command Line Interface (CLI). For a complete list of flags and options available for CLI commands, see CLI Help.

To create or replace a lifecycle policy for a bucket

Open a command prompt and run `oci os object-lifecycle-policy put` to create or replace the object lifecycle policy for a bucket. To edit individual rules, replace the bucket's existing policy with a new version of the policy that includes the changes to your rules.

```
oci os object-lifecycle-policy put -ns <object_storage_namespace> -bn <bucket_name> --items <json_formatted_lifecycle_policy>
```

Tip

The `--items` option requires that you provide key-value pair input as valid formatted JSON. See Passing Complex Input and Using a JSON File for Complex Input for information on JSON formatting.

For example, the following lifecycle policy archives objects after 30 days and deletes them after 180 days:

```
oci os object-lifecycle-policy put -ns MyNamespace -bn MyBucket --items '[
    {
        "action": "ARCHIVE",
        "is-enabled": true,
        "name": "ArchiveAfter30Days",
        "object-name-filter": {
          "exclusion-patterns": [
            "*.jpg"
          ],
          "inclusion-patterns": [
            "*.doc"
          ],
          "inclusion-prefixes": [
            "documents/"
```

```
          ]
        },
        "time-amount": 30,
        "time-unit": "DAYS"
      },
      {
        "action": "DELETE",
        "is-enabled": true,
        "name": "DeleteAfter180Days",
        "object-name-filter": {
          "exclusion-patterns": null,
          "inclusion-patterns": null,
          "inclusion-prefixes": null
        },
        "time-amount": 180,
        "time-unit": "DAYS"
      }
]'
```

On Windows, to pass complex input to the CLI as a JSON string, you must enclose the entire block in double quotes. Inside the block, each double quote for the key and value strings must be escaped with a backslash (\) character.

For example:

```
oci os object-lifecycle-policy put -ns MyNamespace -bn MyBucket --items "
[{\"action\":\"ARCHIVE\",\"is-enabled\":true,\"name\":\"Archive After 30 Days\",\"object-name-
filter\":{\"exclusion-patterns\":[\"*.jpg\"],\"inclusion-patterns\":[\"*.doc\"],\"inclusion-
prefixes\":[\"documents/\"]},\"time-amount\":30,\"time-unit\":\"DAYS\"},{\"action\":\"DELETE\",\"is-
enabled\":true,\"name\":\"DeleteAfter180Days\",\"object-name-filter\":{\"exclusion-
patterns\":null,\"inclusion-patterns\":null,\"inclusion-prefixes\":null},\"time-amount\":180,\"time-
unit\":\"DAYS\"}]"
```

To delete a bucket's lifecycle policy

Open a command prompt and run `oci os object-lifecycle-policy delete` to delete a bucket's object lifecycle policy.

```
oci os object-lifecycle-policy delete -ns <object_storage_namespace> -bn <bucket_name>
```

To get a bucket's lifecycle policy

Open a command prompt and run `oci os object-lifecycle-policy get` to get a bucket's object lifecycle policy.

```
oci os object-lifecycle-policy get -ns <object_storage_namespace> -bn <bucket_name>
```

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the following operations to manage object lifecycle policies:

- PutObjectLifecyclePolicy
- GetObjectLifecyclePolicy
- DeleteObjectLifecyclePolicy

Object Storage Metrics

You can monitor the health, capacity, and performance of your buckets and objects by using metrics, alarms, and notifications.

This topic describes the metrics emitted by the metric namespace `oci_objectstorage` (the Object Storage service).

Resources include buckets and objects.

Overview of the Object Storage Service Metrics

Object Storage can store an unlimited amount of unstructured data of any content type, including analytic data and rich content, like images and videos. The Object Storage service metrics help you measure the amount of storage you're using. You can also use these metrics to monitor the performance of requests in terms of latency, and utilization as measured by counts of various types of requests made per bucket.

Required IAM Policy

To monitor resources, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources

being monitored. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.

Available Metrics: oci_ objectstorage

The metrics listed in the following tables are automatically available for any buckets you create. You do not need to enable monitoring on the resource to get these metrics. However, you must have an object stored in a bucket to get *any* metrics. Buckets with no objects emit *no* metric data.

Each metric includes the following dimensions:

RESOURCEID

The OCID of the bucket to which the metric applies.

RESOURCEDISPLAYNAME

The name of the bucket.

TIER

The current storage tier of the object: standard or archive.

Default Metrics

Default metrics are available on buckets in default charts.

Metric	Metric Display Name	Unit	Description	Dimensions
`StoredBytes`	**Bucket Size**	bytes	The size of the bucket, excluding any multipart upload parts that have not been discarded (aborted) or committed.	`resourceID` `resourceDisplayName` `tier`
`ObjectCount`	**Number of Objects**	count	The count of objects in the bucket, excluding any multipart upload parts that have not been discarded (aborted) or committed.	

Custom Query Metrics

The following metrics are only available from a custom query. See To view Object Storage metrics with a custom query.

Metric	Metric Display Name	Unit	Description	Dimensions
`UncommittedParts`	**Incomplete MultiPart Upload Size**	bytes	The size of any multipart upload parts that have not been discarded (aborted) or committed.	`resourceID` `resourceDisplayName` `tier`

Metric	Metric Display Name	Unit	Description	Dimensions
`GetRequests`	**GetObject Request Count**	count	The total number of GetObject requests made in a bucket.	`resourceID` `resourceDisplayName`
`HeadRequests`	**HeadObject Request Count**	count	The total number of HeadObject requests made in a bucket.	
`DeleteRequests`	**DeleteObject Request Count**	count	The total number of DeleteObject requests made in a bucket.	
`PutRequests`	**PutObject Request Count**	count	The total number of PutObject requests made in a bucket.	
`ListRequests`	**ListObjects Request Count**	count	The total number of ListObjects requests made in a bucket.	

Metric	Metric Display Name	Unit	Description	Dimensions
RenameRequests	**RenameObject Request Count**	count	The total number of RenameObject requests made in a bucket.	
PostRequests	**Post Object Request Count**	count	The total number of HTTP Post requests made in a bucket.	
ClientErrors	**Client Side Error Count**	count	The total number of 4xx errors for requests made in a bucket.	
TotalRequestLatency	**Overall Latency Time**	time (ms)	The per-request time from the first byte received by Object Storage to the last byte sent from Object Storage.	

Metric	Metric Display Name	Unit	Description	Dimensions
`FirstByteLatency`	**First Byte Latency Time**	time (ms)	The per-request time measured from the time Object Storage receives the complete request to when Object Storage returns the first byte of the response.	
`AllRequests`	**All Request Count**	count	The total number of all HTTP requests made in a bucket.	

Metric	Metric Display Name	Unit	Description	Dimensions
CopyRequests	**Copy Object Request Count**	count	The total number of CopyObject requests made in a bucket.	
ArchiveRequests	**Archive Object Request Count**	count	The total number of ArchiveObject requests made in a bucket. To archive objects, you must configure an Object Lifecycle policy. See Using Object Lifecycle Management.	

Using the Console

To view default metric charts for a bucket

1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.
2. Choose the **Compartment** that contains the bucket you want to view, and then click the bucket's name.

3. In the **Resources** menu, click **Metrics**.
   The **Metrics** page displays a default set of charts for the current bucket.

For more information about monitoring metrics and using alarms, see Monitoring Overview. For information about notifications for alarms, see Notifications Overview.

To view default metric charts by dimension

1. Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Service Metrics**.
2. For **Metric Namespace**, select **oci_objectstorage**.
3. For **Dimensions**, click **Add**.
4. For **Dimension Name**, select a dimension and then select a **Dimension Value**.
   Add more dimensions as needed.
5. Click **Done**.
   The **Service Metrics** page displays a default set of charts for the selected metric namespace and dimension. For more information about the emitted metrics, see the foregoing table. You can also use the Monitoring service to create custom queries.

For more information about monitoring metrics and using alarms, see Monitoring Overview. For information about notifications for alarms, see Notifications Overview.

To view Object Storage metrics with a custom query

1. Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Metrics Explorer**.
   The **Metrics Explorer** page displays an empty chart with fields to build a query.
2. Select a compartment.
3. From **Metric Namespace**, select **oci_objectstorage**.
4. From **Metric Name**, select a metric.

5. (Optional) Refine your query.
   For instructions, see To create a query.
6. Click **Update Chart**.
   The chart shows the results of your new query. You can optionally add more queries by clicking **Add Query** below the chart.

For more information about monitoring metrics and using alarms, see Monitoring Overview. For information about notifications for alarms, see Notifications Overview.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the following APIs for monitoring:

- Monitoring API for metrics and alarms
- Notifications API for notifications (used with alarms)

Hadoop Support

Using the HDFS connector, you can run Hadoop or Spark jobs against data in the Oracle Cloud Infrastructure Object Storage service. The connector has the following features:

- Supports read and write data stored in Object Storage
- Is compatible with existing buckets of data
- Is compatible with Hadoop 2.7.2

For information about downloading, configuring, and using the HDFS connector, see HDFS Connector for Object Storage.

Designating Compartments for the Amazon S3 Compatibility and Swift APIs

In the Oracle Cloud Infrastructure Object Storage service, a bucket is a container for storing objects in a compartment within an Object Storage namespace. A bucket is associated with a single compartment and data is stored as objects in buckets.

In addition to the native Object Storage APIs, Object Storage provides API support for both Amazon S3 Compatibility API and Swift API. However these APIs do not understand the Oracle Cloud Infrastructure concept of a compartment. By default, buckets created using the Amazon S3 Compatibility API or the Swift API are created in the root compartment of the Oracle Cloud Infrastructure tenancy. Instead, you can designate a different compartment for the Amazon S3 Compatibility API or Swift API to create buckets in.

When you designate a different compartment to use for the Amazon S3 Compatibility API or Swift API, any new buckets you create using the Amazon S3 Compatibility API or the Swift API are created in this newly designated compartment. Buckets previously created in a different compartment are not automatically moved to the newly designated compartment. See Managing Buckets if you want to move previously created buckets to this newly designated compartment.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

Compartments have policies that indicate what actions a user can perform on a bucket and all the objects in the bucket.

For administrators:

- To change the default compartments for Amazon S3 Compatibility API and Swift API, a user must belong to a group with `NAMESPACE_UPDATE` permissions.

- To see the current default compartments for Amazon S3 Compatibility API and Swift API, a user must belong to a group with `NAMESPACE_READ` permissions.
- To move a bucket to a different compartment, a user must belong to a group with `BUCKET_UPDATE` and `BUCKET_CREATE` permissions in the source compartment, and `BUCKET_CREATE` permissions in the target compartment.

If you're new to policies, see Getting Started with Policies and Common Policies. If you want to dig deeper into writing policies for buckets and objects, see Details for Object Storage, Archive Storage, and Data Transfer.

Viewing and Specifying Designated Compartments

You can view the current default compartment designations for Amazon S3 Compatibility API and Swift API data. If your permissions allow, you can also change the Amazon S3 Compatibility API and Swift API compartment designations.

Designated compartment names:

- Must be unique across all the compartments in your tenancy.
- Can be from 1 to 100 characters in length.
- Must not contain confidential information.
- Valid are letters (upper or lower case), numbers, hyphens, and underscore.

Using the Console

To view your Amazon S3 Compatibility API and Swift API compartment designations

Open the **Profile** menu () and click **Tenancy:** *<your_tenancy_name>*.

Your default compartment designations for the APIs are listed under **Object Storage Settings**.

To edit your tenancy's Amazon S3 Compatibility API and Swift API compartment designations

1. Open the **Profile** menu () and click **Tenancy:** *<your_tenancy_name>*.
2. Click **Edit Object Storage Settings**.
3. In the **Edit Object Storage Settings** dialog:
   - Select the compartment that you want for the **Amazon S3 Compatibility API Designated Compartment** from the drop-down menu.
   - Select the compartment that you want for the **Swift API Designated Compartment** from the drop-down menu.
4. Click **Save**.
   The new **Object Storage Settings** are displayed.

Using the Command Line Interface (CLI)

For information about using the CLI, see Command Line Interface (CLI). For a complete list of flags and options available for CLI commands, see CLI Help.

To get your tenancy's Amazon S3 Compatibility API and Swift API compartment designations

Use this CLI command to display metadata associated with the Amazon S3 and Swift compartments for the specified namespace in your tenancy.

```
oci os ns get-metadata --namespace <object_storage_namespace>
```

For example:

```
oci os ns get-metadata --namespace MyNamespace
{
    "data": {
    "default-s3-compartment-id": "ocid.compartment.oc1..exampleuniqueID",
    "default-swift-compartment-id": "ocid.compartment.oc1..exampleuniqueID",
    "namespace": "MyNamespace"
```

```
    }
}
```

To update your tenancy's Amazon S3 Compatibility API compartment designation

Use this CLI command to specify the default Amazon S3 compartment for the specified namespace in your tenancy.

```
oci os ns update-metadata --namespace <object_storage_namespace> --default-s3-compartment-id <your_oci_compartment_id>
```

<your_oci_compartment_id> specifies a compartment that is not the root compartment of your tenancy.

For example:

```
oci os ns update-metadata --namespace MyNamespace --default-s3-compartment-id
ocid.compartment.oc1..exampleuniqueID
{
    "data": {
    "default-s3-compartment-id": "ocid.compartment.oc1..exampleuniqueID",
    "default-swift-compartment-id": null,
    "namespace": null
    }
}
```

To update your tenancy's Swift API compartment designations

Use this CLI command to specify the default Swift compartment for the specified namespace in your tenancy.

```
oci os ns update-metadata --namespace <object_storage_namespace> --default-swift-compartment-id <your_oci_compartment_id>
```

<your_oci_compartment_id> specifies a compartment that is not the root compartment of your tenancy.

For example:

```
oci os ns update-metadata --namespace MyNamespace --default-swift-compartment-id
ocid.compartment.oc1..exampleuniqueID
{
    "data": {
    "default-s3-compartment-id": null,
    "default-swift-compartment-id": "ocid.compartment.oc1..exampleuniqueID",
    "namespace": null
    }
}
```

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the following operation to get your default Amazon S3 Compatibility API and Swift API compartment designations, and change those compartment designations:

- GetNamespaceMetadata
- UpdateNamespaceMetadata

Amazon S3 Compatibility API

Using the Amazon S3 Compatibility API, customers can continue to use their existing Amazon S3 tools (for example, SDK clients) and partners can make minimal changes to their applications to work with Object Storage. The Amazon S3 Compatibility API and Object Storage datasets are congruent. If data is written to the Object Storage using the Amazon S3 Compatibility API, the data can be read back using the native Object Storage API and conversely.

Differences between the Object Storage API and the Amazon S3 Compatibility API

The Object Storage Service provided by Oracle Cloud Infrastructure and Amazon S3 use similar concepts and terminology. In both cases, data is stored as objects in buckets. The differences are in the implementation of features and tools for working with objects.

The following highlights the differences between the two storage technologies:

- **Compartments**
  Amazon S3 doesn't use compartments. By default, buckets created using the Amazon S3 Compatibility API or the Swift API are created in the root compartment of the Oracle Cloud Infrastructure tenancy. Instead, you can designate a different compartment for the Amazon S3 Compatibility API or Swift API to create buckets in.
- **Global bucket namespace**
  Object Storage doesn't use a global bucket namespace. Each tenant is associated with one default namespace that spans all compartments within a region. The namespace serves as a container for all of your buckets and objects. You control bucket names within your namespace, however, bucket names must be unique within each region. You can have a bucket named **MyBucket** in US West (Phoenix) and a bucket named **MyBucket** in Germany Central (Frankfurt).
- **Encryption**
  The Oracle Cloud Infrastructure Object Storage service encrypts all data at rest by default. Encryption can't be turned on or off using the API.
- **Object Level Access Control Lists (ACLs)**
  Oracle Cloud Infrastructure does not use ACLs for objects. Instead, IAM policies are used to manage access to compartments, buckets, and objects.

For more information, see Overview of the Object Storage service.

Amazon S3 Compatibility API Prerequisites

To enable application access from Amazon S3 to Object Storage, you need to set up access to

Oracle Cloud Infrastructure and modify your application.

Setting up access to Oracle Cloud Infrastructure:

- Sign Up for Oracle Cloud Infrastructure and obtain a unique namespace.
- Create an Amazon S3 Compatibility API key. An Amazon S3 Compatibility API key consists of an Access Key/Secret key pair.

Modifying your application:

- Configure a new endpoint for the application that includes . For example: `mynamespace.compat.objectstorage.us-phoenix-1.oraclecloud.com`.
- Set the target region as one of the Oracle Cloud Infrastructure regions.

Important

If your application does not support setting the region name to the correct Oracle Cloud Infrastructure region name, you must either set the region to `us-east-1` or leave it blank. Using this configuration, you can only use the Amazon S3 Compatibility API in your Oracle Cloud Infrastructure home region.
If you can manually set the region, you can use the application against any Oracle Cloud Infrastructure region.

- Configure the application to use the Amazon S3 Compatibility API key.
- The application must use path -based access. Virtual host-style access (accessing a bucket as `bucketname.namespace.compat.objectstorage.region.oraclecloud.com`) is not supported.

You can now use the Amazon S3 Compatibility API to access Object Storage in Oracle Cloud Infrastructure.

Amazon S3 Compatibility API Support

Amazon S3 Compatibility API support is provided at the bucket level and object level.

Bucket APIs

The following bucket APIs are supported:

- DeleteBucket
- GetLocation
- HeadBucket
- GetService (list all my buckets)
- ListObjects
- PutBucket

Object APIs

The following object APIs are supported:

- BulkDelete
- DeleteObject
- GetObject
- HeadObject
- PutObject
- RestoreObjects

Multipart Upload APIs

The following multipart upload APIs are supported:

- AbortMultipartUpload
- CompleteMultipartUpload
- InitiateMultipartUpload
- ListParts
- ListUploads
- UploadPart

Tagging APIs

The following tagging APIs are supported:

- DeleteBucketTagging
- GetBucketTagging
- PutBucketTagging

Supported Amazon S3 Clients

Here are some examples of configuring various client applications to talk to Object Storage's Amazon S3-compatible endpoints.

AWS SDK for Java

The following is an example of configuring AWS SDK for Java.

```
// Get S3 credentials from the console and put them here
AWSCredentialsProvider credentials = new AWSStaticCredentialsProvider(new BasicAWSCredentials(
 "ocid1.credential.oc1..anEXAMPLE",
 "anEXAMPLE="));

// The name of your tenancy
String tenancy = "tenancy";

// The region to connect to
String region = "us-ashburn-1";

// Create an S3 client pointing at the region
String endpoint = String.format("%s.compat.objectstorage.%s.oraclecloud.com",tenancy,region);
```

```
AwsClientBuilder.EndpointConfiguration endpointConfiguration = new
AwsClientBuilder.EndpointConfiguration(endpoint, region);
AmazonS3 client = AmazonS3Client.builder()
 .standard()
 .withCredentials(credentials)
 .withEndpointConfiguration(endpointConfiguration)
 .disableChunkedEncoding()
 .enablePathStyleAccess()
 .build();
```

AWS SDK for Javascript

The following is an example of configuring AWS SDK for Javascript.

```
s3 = new AWS.S3({
  region: 'us-ashburn-1',
  endpoint: 'https://' + namespace + '.compat.objectstorage.us-ashburn-1.oraclecloud.com',
  accessKeyId: 'ocid1.credential.oc1..something',
  secretAccessKey: 'something=',
  s3ForcePathStyle: true,
  signatureVersion: 'v4',
});
```

AWS SDK for Python (Boto 3)

The following is an example of configuring AWS SDK for Python (Boto 3).

```
import boto3

s3 = boto3.resource(
    's3',
    aws_access_key_id="ocid1.credential.oc1..something",    # Put your ocid for the secret key here
    aws_secret_access_key="something=",                     # Put your secret key here
    region_name="us-phoenix-1",                             # Set the region to match the endpoint
    endpoint_url="https://namespace.compat.objectstorage.us-phoenix-1.oraclecloud.com" # Endpoint url
has namespace ahead of compat
)

# Print out bucket names
for bucket in s3.buckets.all():
    print bucket.name
```

AWS Command Line Interface (CLI)

The following is an example of configuring AWS Command Line Interface (CLI).

```
pip3 install awscli --upgrade --user

# Configure AWS Cli
aws configure --profile mynamespace
AWS Access Key ID [None]: ocid1.credential.oc1..something
AWS Secret Access Key [None]: secretkey=
Default region name [None]: us-phoenix-1
Default output format [None]:
# Install this plugin to override the url or you need to pass it on command line
pip3 install awscli-plugin-endpoint --upgrade --user

# Enable the plugin or it won't work
aws configure set plugins.endpoint_url awscli_plugin_endpoint

# Let the plugin set the endpoint URL
aws configure --profile mynamespace set s3.endpoint_url https://mynamespace.compat.objectstorage.us-
phoenix-1.oraclecloud.com

# Test out the command!
aws s3 ls --profile mynamespace
```

CHAPTER 26 Registry

This chapter explains how to store, share, and manage development artifacts like Docker images in an Oracle-managed registry.

Overview of Registry

Oracle Cloud Infrastructure Registry is an Oracle-managed registry that enables you to simplify your development to production workflow. Oracle Cloud Infrastructure Registry makes it easy for you as a developer to store, share, and manage development artifacts like Docker images. And the highly available and scalable architecture of Oracle Cloud Infrastructure ensures you can reliably deploy your applications. So you don't have to worry about operational issues, or scaling the underlying infrastructure.

You can use Oracle Cloud Infrastructure Registry as a private Docker registry for internal use, pushing and pulling Docker images to and from the Registry using the Docker V2 API and the standard Docker command line interface (CLI). You can also use Oracle Cloud Infrastructure Registry as a public Docker registry, enabling any user with internet access and knowledge of the appropriate URL to pull images from public repositories in Oracle Cloud Infrastructure Registry.

Oracle Cloud Infrastructure Registry supports private access from other Oracle Cloud Infrastructure resources in a virtual cloud network (VCN) in the same region through a service gateway. Setting up and using a service gateway on a VCN lets resources (such as worker nodes in clusters managed by Container Engine for Kubernetes) access Oracle Cloud Infrastructure services such as Oracle Cloud Infrastructure Registry without exposing them to the public internet. No internet gateway is required and resources can be in a private subnet and use only private IP addresses. For more information, see Access to Oracle Services: Service Gateway.

Oracle Cloud Infrastructure Registry is integrated with IAM, which provides easy authentication with native Oracle Cloud Infrastructure identity.

For an introductory tutorial, see Pushing an Image to Oracle Cloud Infrastructure Registry.

Note

Registry is not available in Oracle Cloud Infrastructure Government Cloudrealms.

Ways to Access Oracle Cloud Infrastructure

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. For a list of available SDKs, see Software Development Kits and Command Line Interface.

To access the Console, you must use a supported browser. Oracle Cloud Infrastructure supports the latest desktop versions of Google Chrome, Microsoft Edge, Internet Explorer 11, Safari, Firefox, and Firefox ESR. Note that private browsing mode is not supported for Firefox, Internet Explorer, or Edge. Mobile browsers are not supported.

For general information about using the API, see REST APIs.

Note that Oracle Cloud Infrastructure Registry fully implements a Docker protocol that enables you to use the Docker Registry HTTP API (rather than the Oracle Cloud Infrastructure API) to manage images. See the Docker documentation for information about using the Docker Registry HTTP API.

Resource Identifiers

Most types of Oracle Cloud Infrastructure resources have a unique, Oracle-assigned identifier called an Oracle Cloud ID (OCID). For information about the OCID format and other ways to identify your resources, see Resource Identifiers.

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies. For specific details about writing policies for each of the different services, see Policy Reference.

If you're a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

Registry Capabilities and Limits

In each region that is enabled for your tenancy, you can create up to 500 repositories in Oracle Cloud Infrastructure Registry. Each repository can hold up to 500 images. See Service Limits.

Required IAM Service Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don't have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

If you're new to policies, see Getting Started with Policies and Common Policies.

For more details about policies for Oracle Cloud Infrastructure Registry, see:

- Policies to Control Repository Access
- Details for Registry

Preparing for Registry

Before you can push and pull Docker images to and from Oracle Cloud Infrastructure Registry:

- You must have access to an Oracle Cloud Infrastructure tenancy. The tenancy must be subscribed to one or more of the regions in which Registry is available (see Availability by Region Name and Region Code).
- You must have access to the Docker CLI (for example, to push and pull images on a local machine, you'll need to have installed Docker on the local machine).
- You must either belong to a group to which a policy grants the appropriate permissions, or belong to the tenancy's Administrators group. See Policies to Control Repository Access.
- You must have an Oracle Cloud Infrastructure auth token. If you don't have an auth token already, see Getting an Auth Token.

Availability by Region Name and Region Code

Registry is available in the following regions. Note that you have to use the region code in some commands. In some cases, you might have to use shortened versions of availability domain names.

Region Name	Region Code	Shortened Availability Domain Names
US East (Ashburn)	iad	• US-ASHBURN-AD-1 • US-ASHBURN-AD-2 • US-ASHBURN-AD-3
Germany Central (Frankfurt)	fra	• EU-FRANKFURT-1-AD-1 • EU-FRANKFURT-1-AD-2 • EU-FRANKFURT-1-AD-3
UK South (London)	lhr	• UK-LONDON-1-AD-1 • UK-LONDON-1-AD-2 • UK-LONDON-1-AD-3
India West (Mumbai)	bom	• AP-MUMBAI-1-AD-1
US West (Phoenix)	phx	• PHX-AD-1 • PHX-AD-2 • PHX-AD-3
Brazil East (Sao Paulo)	gru	• SA-SAOPAULO-1-AD-1
South Korea Central (Seoul)	icn	• AP-SEOUL-1-AD-1
Australia East (Sydney)	syd	• AP-SYDNEY-1-AD-1
Japan East (Tokyo)	nrt	• AP-TOKYO-1-AD-1
Canada Southeast (Toronto)	yyz	• CA-TORONTO-1-AD-1
Switzerland North (Zurich)	zrh	• EU-ZURICH-1-AD-1

About Images

You can store, share, and manage Docker images in Oracle Cloud Infrastructure Registry. A Docker image is a read-only template with instructions for creating a Docker container. A Docker image holds the application that you want Docker to run as a container, along with any dependencies. To create a Docker image, you first create a Dockerfile to describe that application. You then build the Docker image from the Dockerfile. Having created a Docker image, you store it in a Docker registry such as Oracle Cloud Infrastructure Registry.

About Repositories

Related images in Oracle Cloud Infrastructure Registry can be grouped into meaningfully named repositories for convenience.

Repositories can be private or public. Any user with internet access and knowledge of the appropriate URL can pull images from a public repository in Oracle Cloud Infrastructure Registry.

A repository exists within a particular region and tenancy. When referring to the tenancy that owns a repository, you specify the tenancy's namespace. The tenancy namespace is an auto-generated random string of alphanumeric characters. For example, the namespace of the acme-dev tenancy might be `ansh81vru1zp`. Note that for some older tenancies, the namespace string might be the same as the tenancy name in all lower-case letters (for example, `acme-dev`). To find out the tenancy namespace of the current tenancy, open the **Profile** menu () and click **Tenancy:**.

You must belong to the tenancy's Administrators group or have been granted the REPOSITORY_MANAGE permission to:

- create a new public repository
- change an existing repository into a public repository
- change an existing public repository into a private repository

If you make a repository private, you (along with users belonging to the tenancy's Administrators group) will be able to perform any operation on the repository. You can use

identity policies to allow other users to perform other operations on repositories (both public and private) that you create.

Typically, the images in a repository are all different versions of the same source image (for example 'acme-web-app'), with each version identified by a tag (for example, 'acme-web-app:4.6.3').

For example, for convenience you might want to group together multiple versions of the acme-web-app image in the acme-dev tenancy in the Ashburn region into a repository called project01. You do this by including the name of the repository in the image name when you push the image, in the format `<region-code>.ocir.io/<tenancy-namespace>/<repo-name>/<image-name>:<tag>`. For example, `iad.ocir.io/ansh81vru1zp/project01/acme-web-app:4.6.3`. Subsequently, when you use the `docker push` command, the presence of the repository in the image's name ensures the image is pushed to the intended repository.

If you push an image and include the name of a repository that doesn't already exist, a new private repository is created automatically. For example, if you enter a command like `docker push iad.ocir.io/ansh81vru1zp/project02/acme-web-app:7.5.2` and the `project02` repository doesn't exist, a private repository called `project02` is created automatically.

If you push an image and don't include a repository name, the image's name is used as the name of the repository. For example, if you enter a command like `docker push iad.ocir.io/ansh81vru1zp/acme-web-app:7.5.2` that doesn't contain a repository name, the image's name (`acme-web-app`) is used as the name of a private repository.

Alternatively, you can use the Console to create an empty repository and give it a name. If you belong to the tenancy's Administrators group or have been granted the REPOSITORY_ MANAGE permission, you can also specify whether the repository is to be private or public. Any images you subsequently push to Oracle Cloud Infrastructure Registry that include the repository in the image name are pushed to that repository.

Creating a Repository

Using the Console, you can create an empty repository in Oracle Cloud Infrastructure Registry and give it a name. Any images you subsequently push to the registry that include the repository in the image name are grouped into that repository.

Having created the new repository, you can push an image to the repository using the Docker CLI (see Pushing Images Using the Docker CLI).

Note that although creating an empty repository in advance can be a convenient placeholder, it is not strictly necessary. When you push an image, you use a command in the format `docker push <region-code>.ocir.io/<tenancy-namespace>/<repo-name>/<image-name>:<tag>`. However:

- If you push an image and the command includes the name of a repository that doesn't already exist, a new private repository is created automatically. For example, if you enter a command like `docker push iad.ocir.io/ansh81vru1zp/project02/acme-web-app:7.5.2` and the `project02` repository doesn't exist, a private repository called `project02` is created automatically.
- If you push an image and the command doesn't include a repository name, the image's name is used as the name of the repository. For example, if you enter a command like `docker push iad.ocir.io/ansh81vru1zp/acme-web-app:7.5.2` that doesn't contain a repository name, the image's name (`acme-web-app`) is used as the name of a private repository.

Using the Console

To create a repository in Oracle Cloud Infrastructure Registry:

1. In the Console, open the navigation menu. Under **Solutions and Platform**, go to **Developer Services** and click **Registry**.
2. Choose the region in which to create the repository.
3. Click **Create Repository**.
4. In the **Add Repository** dialog box, specify details for the new repository:
    - **Repository Name:** A name of your choice for the new repository. Avoid entering confidential information.
    - **Public:** Whether the new repository will be a public repository or a private repository. You can only make the new repository public if you belong to the tenancy's Administrators group or have been granted the REPOSITORY_MANAGE

permission. If you make the new repository public, any user with internet access and knowledge of the appropriate URL will be able to pull images from the repository. If you make the repository private, you (along with users belonging to the tenancy's Administrators group) will be able to perform any operation on the repository.

5. Click **Submit**.

Pushing Images Using the Docker CLI

You use the Docker CLI to push images to Oracle Cloud Infrastructure Registry.

To push an image, you first use the `docker tag` command to create a copy of the local source image as a new image (the new image is actually just a reference to the existing source image). As a name for the new image, you specify the fully qualified path to the target location in Oracle Cloud Registry where you want to push the image, optionally including the name of a repository.

For example, assume you have a local image named acme-web-app:latest. Let's say you want to push this image to Oracle Cloud Infrastructure Registry with a name of acme-web-app:version2.0.test into a repository called project01 in the Ashburn region of the acme-dev tenancy. When you use the `docker tag` command, you'd name the new image with the fully qualified path to its destination, in the format `<region-code>.ocir.io/<tenancy-namespace>/<repo-name>/<image-name>:<tag>`. So in this case, you'd name the new image `iad.ocir.io/ansh81vru1zp/project01/acme-web-app:version2.0.test`. Subsequently, when you use the `docker push` command, the image's name ensures it is pushed to the correct destination.

Your permissions control the images you can push to Oracle Cloud Infrastructure Registry. You can push images to repositories you've created, and to repositories that the groups to which you belong have been granted access by appropriate identity policies. If you belong to the Administrators group, you can push images to any repository in the tenancy.

To push images to Oracle Cloud Infrastructure Registry using the Docker CLI:

1. If you already have an auth token, go to the next step. Otherwise:
    a. In the top-right corner of the Console, open the **Profile** menu () and then click **User Settings** to view the details.
    b. On the **Auth Tokens** page, click **Generate Token**.
    c. Enter a friendly description for the auth token. Avoid entering confidential information.
    d. Click **Generate Token**. The new auth token is displayed.
    e. Copy the auth token immediately to a secure location from where you can retrieve it later, because you won't see the auth token again in the Console.
    f. Close the Generate Token dialog.
2. In a terminal window on the client machine running Docker, log in to Oracle Cloud Infrastructure Registry by entering `docker login <region-code>.ocir.io`, where `<region-code>` corresponds to the code for the Oracle Cloud Infrastructure Registry region you're using. For example, `docker login iad.ocir.io`. See Availability by Region Name and Region Code for the list of region codes.
3. When prompted, enter your username in the format `<tenancy-namespace>/<username>`, where `<tenancy-namespace>` is the auto-generated Object Storage namespace string of your tenancy (as shown on the **Tenancy Information** page). For example, `ansh81vru1zp/jdoe@acme.com`. If your tenancy is federated with Oracle Identity Cloud Service, use the format `<tenancy-namespace>/oracleidentitycloudservice/<username>`.
4. When prompted, enter the auth token you copied earlier.
5. Locate the image on the client machine that you want to push:
    a. In a terminal window on your client machine, enter `docker images` to list the available images.
    For example:

```
$ docker images
```

```
REPOSITORY          TAG                 IMAGE ID       CREATED         SIZE
acme-web-app        latest              8e0506e14874   2 hours ago     162.6 MB
acme-web-app        version1.0          7d9495d03763   2 hours ago     162.6 MB
<none>              <none>              6ebd328f833d   5 hours ago     162.6 MB
hello-world         latest              80b84820d442   5 weeks ago     890 B
```

b. Find the image on the client machine that you want to push to Oracle Cloud Infrastructure Registry.

   In the output of the `docker images` command, look for the specific image that you want to push. You'll need to uniquely identify this image later, in one of the following ways:

   - using its id
   - using its name and tag, separated by a colon

   For example, you might have an image named `acme-web-app` on the client machine. In the output of the `docker images` command, look for the specific acme-web-app image that you want to push. You can uniquely identify that particular image in one of the following ways:

   - using its id (for example, `8e0506e14874`)
   - using its name and tag, separated by a colon (for example `acme-web-app:latest`)

c. Give a tag to the image that you're going to push to Oracle Cloud Infrastructure Registry by entering:

   ```
   docker tag <image-identifier> <target-tag>
   ```

   where:

   - `<image-identifier>` uniquely identifies the image, either using the image's id (for example, `8e0506e14874`), or the image's name and tag separated by a colon (for example, `acme-web-app:latest`).

- `<target-tag>` is in the format `<region-code>.ocir.io/<tenancy-namespace>/<repo-name>/<image-name>:<tag>` where:
  - `<region-code>` is the code for the Oracle Cloud Infrastructure Registry region you're using. For example, `iad`. See Availability by Region Name and Region Code for the list of region codes.
  - `ocir.io` is the Oracle Cloud Infrastructure Registry name.
  - `<tenancy-namespace>` is the auto-generated Object Storage namespace string of the tenancy that owns the repository to which you want to push the image (as shown on the **Tenancy Information** page). For example, the namespace of the acme-dev tenancy might be `ansh81vru1zp`. Note that for some older tenancies, the namespace string might be the same as the tenancy name in all lower-case letters (for example, `acme-dev`). Note also that your user must have access to the tenancy.
  - `<repo-name>` (if specified) is the name of a repository to which you want to push the image (for example, `project01`). Note that specifying a repository is optional (see About Repositories).
  - `<image-name>` is the name you want to give the image in Oracle Cloud Infrastructure Registry (for example, `acme-web-app`).
  - `<tag>` is an image tag you want to give the image in Oracle Cloud Infrastructure Registry (for example, `version2.0.test`).

  For example, combining the previous examples, you might enter:

```
docker tag 8e0506e14874 iad.ocir.io/ansh81vru1zp/project01/acme-web-app:version2.0.test
```

6. Confirm that the Docker image has been correctly tagged on the client machine by entering `docker images` and verifying that the list of images includes an image with the tag you specified.

   For example:

```
$ docker images
REPOSITORY                                  TAG                 IMAGE ID      CREATED
SIZE
```

```
iad.ocir.io/ansh81vru1zp/project01/acme-web-app version2.0.test       8e0506e14874  1 minute ago
162.6 MB
acme-web-app                                    latest                8e0506e14874  2 hours ago
162.6 MB
acme-web-app                                    version1.0            7d9495d03763  2 hours ago
162.6 MB
<none>                                          <none>                6ebd328f833d  5 hours ago
162.6 MB
hello-world                                     latest                80b84820d442  5 weeks ago
890 B
```

7. Push the Docker image from the client machine to Oracle Cloud Infrastructure Registry by entering:

```
docker push <target-tag>
```

where `<target-tag>` is in the format `<region-code>.ocir.io/<tenancy-namespace>/<repo-name>/<image-name>:<tag>` where:

- `<region-code>` is the code for the Oracle Cloud Infrastructure Registry region you're using. For example, `iad`. See Availability by Region Name and Region Code for the list of region codes.
- `ocir.io` is the Oracle Cloud Infrastructure Registry name.
- `<tenancy-namespace>` is the auto-generated Object Storage namespace string of the tenancy that owns the repository to which you want to push the image (as shown on the **Tenancy Information** page). For example, the namespace of the acme-dev tenancy might be `ansh81vru1zp`. Note that for some older tenancies, the namespace string might be the same as the tenancy name in all lower-case letters (for example, `acme-dev`). Note also that your user must have access to the tenancy.
- `<repo-name>` (if specified) is the name of a repository to which you want to push the image (for example, `project01`). Note that specifying a repository is optional (see About Repositories).
- `<image-name>` is the name you want to give the image in Oracle Cloud Infrastructure Registry (for example, `acme-web-app`).

- `<tag>` is an image tag you want to give the image in Oracle Cloud Infrastructure Registry (for example, `version2.0.test`).

For example:

```
docker push iad.ocir.io/ansh81vru1zp/project01/acme-web-app:version2.0.test
```

Pulling Images Using the Docker CLI

You use the Docker CLI to pull images from Oracle Cloud Infrastructure Registry.

Your permissions control the images you can pull from Oracle Cloud Infrastructure Registry. You can pull images from repositories you've created, from public repositories, and from repositories that the groups to which you belong have been granted access by identity policies. If you belong to the Administrators group, you can pull images from any repository in the tenancy.

To pull images from Oracle Cloud Infrastructure Registry using the Docker CLI:

1. If you already have an auth token, go to the next step. Otherwise:
   a. In the top-right corner of the Console, open the **Profile** menu () and then click **User Settings** to view the details.
   b. On the **Auth Tokens** page, click **Generate Token**.
   c. Enter a friendly description for the auth token. Avoid entering confidential information.
   d. Click **Generate Token**. The new auth token is displayed.
   e. Copy the auth token immediately to a secure location from where you can retrieve it later, because you won't see the auth token again in the Console.
   f. Close the Generate Token dialog.
2. In a terminal window on the client machine running Docker, log in to Oracle Cloud Infrastructure Registry by entering `docker login <region-code>.ocir.io`, where `<region-code>` corresponds to the code for the Oracle Cloud Infrastructure Registry region you're using. For example, `docker login iad.ocir.io`. See Availability by Region Name and Region Code for the list of region codes.

3. When prompted, enter your username in the format `<tenancy-namespace>/<username>`, where `<tenancy-namespace>` is the auto-generated Object Storage namespace string of your tenancy (as shown on the **Tenancy Information** page). For example, `ansh81vru1zp/jdoe@acme.com`. If your tenancy is federated with Oracle Identity Cloud Service, use the format `<tenancy-namespace>/oracleidentitycloudservice/<username>`.
4. When prompted, enter the auth token you copied earlier.
5. Pull the Docker image from Oracle Cloud Infrastructure Registry to the client machine by entering:

   ```
   docker pull <region-code>.ocir.io/<tenancy-namespace>/<repo-name>/<image-name>:<tag>
   ```

   where:

   - `<region-code>` is the code for the Oracle Cloud Infrastructure Registry region you're using. For example, `iad`. See Availability by Region Name and Region Code for the list of region codes.
   - `ocir.io` is the Oracle Cloud Infrastructure Registry name.
   - `<tenancy-namespace>` is the auto-generated Object Storage namespace string of the tenancy that owns the repository from which you want to pull the image (as shown on the **Tenancy Information** page). For example, the namespace of the acme-dev tenancy might be `ansh81vru1zp`. Note that for some older tenancies, the namespace string might be the same as the tenancy name in all lower-case letters (for example, `acme-dev`). Note also that your user must have access to the tenancy.
   - `<repo-name>` (optional) is the name of a repository from which you want to pull the image (for example, `project01`). Note that your user must have access to the repository. Omit this argument if the image does not exist within a repository (see About Repositories).
   - `<image-name>` is the name of the image that you want to pull from Oracle Cloud Infrastructure Registry (for example, `acme-web-app`)

- `<tag>` is the tag of the image that you want to pull from Oracle Cloud Infrastructure Registry (for example, `version2.0.test`)

For example:

```
docker pull iad.ocir.io/ansh81vru1zp/project01/acme-web-app:version2.0.test
```

Note that if you don't specify a `<tag>` in the `docker pull` command, Docker pulls the image that has the `latest` tag.

6. Confirm that the image has been pulled from Oracle Cloud Infrastructure Registry by entering `docker images` and verifying that the list of images on the client machine now includes the image you just pulled.

   For example:

```
$ docker images
REPOSITORY                                          TAG                 IMAGE ID            CREATED
  SIZE
iad.ocir.io/ansh81vru1zp/project01/acme-web-app version2.0.test     8e0506e14874      1 minute
ago  162.6 MB
acme-web-app                                        latest              8e0506e14874      2 hours ago
  162.6 MB

```

Pulling Images from Registry during Kubernetes Deployment

During the deployment of an application to a Kubernetes cluster, you'll typically want one or more images to be pulled from a Docker registry. In the application's manifest file you specify the images to pull, the registry to pull them from, and the credentials to use when pulling the images. The manifest file is commonly also referred to as a pod spec, or as a deployment.yaml file (although other filenames are allowed).

If you want the application to pull images that reside in Oracle Cloud Infrastructure Registry, you have to perform two steps:

- You have to use kubectl to create a Docker registry secret. The secret contains the Oracle Cloud Infrastructure credentials to use when pulling the image. When creating secrets, Oracle strongly recommends you use the latest version of kubectl (see the kubectl documentation).
- You have to specify the image to pull from Oracle Cloud Infrastructure Registry, including the repository location and the Docker registry secret to use, in the application's manifest file.

To create a Docker registry secret:

1. If you haven't already done so, follow the steps to download the cluster's kubeconfig configuration file and set the KUBECONFIG environment variable to point to the file. Note that you must download your own kubeconfig file. You cannot access a cluster using a kubeconfig file that a different user downloaded. See Downloading a kubeconfig File to Enable Cluster Access.
2. In a terminal window, enter:

   ```
   $ kubectl create secret docker-registry <secret-name> --docker-server=<region-code>.ocir.io --docker-username='<tenancy-namespace>/<oci-username>' --docker-password='<oci-auth-token>' --docker-email='<email-address>'
   ```

   where:

   - `<secret-name>` is a name of your choice, that you will use in the manifest file to refer to the secret . For example, `ocirsecret`
   - `<region-code>` is the code for the Oracle Cloud Infrastructure Registry region you're using. For example, `iad`. See Availability by Region Name and Region Code for the list of region codes.
   - `ocir.io` is the Oracle Cloud Infrastructure Registry name.
   - `<tenancy-namespace>` is the auto-generated Object Storage namespace string of the tenancy containing the repository from which the application is to pull the image (as shown on the **Tenancy Information** page). For example, the namespace of the acme-dev tenancy might be `ansh81vru1zp`. Note that for some

older tenancies, the namespace string might be the same as the tenancy name in all lower-case letters (for example, `acme-dev`).

- `<oci-username>` is the username to use when pulling the image. The username must have access to the tenancy specified by `<tenancy-namespace>`. For example, `jdoe@acme.com` . If your tenancy is federated with Oracle Identity Cloud Service, use the format `oracleidentitycloudservice/<oci-username>`
- `<oci-auth-token>` is the auth token of the user specified by `<oci-username>`. For example, `k]j64r{1sJSSF-;)K8`
- `<email-address>` is an email address. An email address is required, but it doesn't matter what you specify. For example, `jdoe@acme.com`

Note the use of single quotes around strings containing special characters.

For example, combining the previous examples, you might enter:

```
$ kubectl create secret docker-registry ocirsecret --docker-server=phx.ocir.io --docker-username='ansh81vru1zp/jdoe@acme.com' --docker-password='k]j64r{1sJSSF-;)K8' --docker-email='jdoe@acme.com'
```

Having created the Docker secret, you can now refer to it in the application manifest file.

To specify the image to pull from Oracle Cloud Infrastructure Registry, along with the Docker secret to use, during deployment of an application to a cluster:

1. Open the application's manifest file in a text editor.
2. Add the following sections to the manifest file:
   a. Add a `containers` section that specifies the name and location of the container you want to pull from Oracle Cloud Infrastructure Registry, along with other deployment details.
   b. Add an `imagePullSecrets` section to the manifest file that specifies the name of the Docker secret you created to access the Oracle Cloud Infrastructure Registry.

Here's an example of what the manifest might look like when you've added the `containers` and `imagePullSecrets` sections:

```
apiVersion: v1
kind: Pod
metadata:
  name: ngnix-image
spec:
  containers:
    - name: ngnix
      image: phx.ocir.io/ansh81vru1zp/project01/ngnix-lb:latest
      imagePullPolicy: Always
      ports:
      - name: nginx
        containerPort: 8080
        protocol: TCP
  imagePullSecrets:
    - name: ocirsecret
```

3. Save and close the manifest file.

Viewing Images and Image Details

To make sure you pull the correct image or to identify images that you no longer need, you can find out detailed information about the images in Oracle Cloud Infrastructure Registry.

Your permissions control the images in Oracle Cloud Infrastructure Registry that you can view information about. You can view information about images in repositories you've created, and in repositories that the groups to which you belong have been granted access by identity policies. If you belong to the Administrators group, you can view information about images in any repository in the tenancy.

Using the Console

To view images and image details:

1. In the Console, open the navigation menu. Under **Solutions and Platform**, go to **Developer Services** and click **Registry**.

2. Choose the registry's region. You see all the repositories in the registry to which you have access.
3. Click the name of the repository that contains the image you want to see detailed information about. You see all the different images in the repository, along with the tag of each image and when it was pushed to the registry. You can sort the different images by the date they were pushed or by their tag.
4. Click the image for which you want to see detailed information. The **Summary** page shows you the size of the image, when it was pushed and by which user, and the number of times the image has been pulled. Use the options on the **Summary** page as follows:
    - Display the **Layers** tab to see the SHA message digest of each layer in the selected image.
    - Display the **Associated Tags** tab to see the full path for the image with the tag you select. Note that if you select a different tag, the summary details change accordingly.
5. (Optional) If you want to pull an image, click the **Download** button beside the image name and copy the command shown. The command includes the image name in the format `<region-code>.ocir.io/<tenancy-namespace>/<repo-name>/<image-name>:<tag>`. For example, `docker pull iad.ocir.io/ansh81vru1zp/project01/acme-web-app:version2.0.test`. See Pulling Images Using the Docker CLI.

Deleting an Image

When you no longer need an old image or you simply want to clean up the list of image tags in a repository, you can delete images from Oracle Cloud Infrastructure Registry.

Your permissions control the images in Oracle Cloud Infrastructure Registry that you can delete. You can delete images from repositories you've created, and from repositories that the groups to which you belong have been granted access by identity policies. If you belong to the Administrators group, you can delete images from any repository in the tenancy.

Note that as well deleting individual images as described below, you can set up image retention policies to delete images automatically based on selection criteria you specify (see Retaining and Deleting Images Using Retention Policies).

Using the Console

To delete an image from Oracle Cloud Infrastructure Registry:

1. In the Console, open the navigation menu. Under **Solutions and Platform**, go to **Developer Services** and click **Registry**.
2. Choose the registry's region. You see all the repositories to which you have access.
3. Click the name of the repository from which to delete the image.
4. Click the name of the image that you want to delete.
5. Click **Delete** on the **Summary** page and confirm that you want to delete the image.

The image is permanently removed from Oracle Cloud Infrastructure Registry.

Retaining and Deleting Images Using Retention Policies

You can set up image retention policies to automatically delete images that meet particular selection criteria, namely:

- images that have not been pulled for a certain number of days
- images that have not been tagged for a certain number of days
- images that have not been given particular Docker tags specified as exempt from automatic deletion

An hourly process checks images against the selection criteria, and any that meet the selection criteria are automatically deleted.

You'll often find image retention policies are a more convenient way to manage the images in a repository than manually deleting individual images (see Deleting an Image).

In each region in a tenancy, there's a global image retention policy. The global image retention policy's default selection criteria retain all images, so that no images are

automatically deleted. However, you can change the global image retention policy so that images are deleted if they meet the criteria you specify. A region's global image retention policy applies to all repositories in the region, unless it is explicitly overridden by one or more custom image retention policies.

You can set up custom image retention policies to override the global image retention policy with different criteria for specific repositories in a region. Having created a custom image retention policy, you apply the custom retention policy to a repository by adding the repository to the policy. The global image retention policy no longer applies to repositories that you add to a custom retention policy.

If you have `manage` permission on the tenancy, you can:

- modify each region's own global image retention policy
- create new custom image retention policies
- modify the criteria of existing custom image retention policies
- delete custom image retention policies

If you have `manage` permission on a repository, you can:

- add the repository to a custom image retention policy
- remove the repository from a custom image retention policy

Note the following:

- Only one custom image retention policy at a time can apply to a repository. If a repository has already been added to a custom retention policy and you want to add the repository to a different custom retention policy, you have to remove the policy from the first retention policy before adding it to the second.
- When you create or update an image retention policy, the hourly process that checks images for deletion will ignore the new or updated policy for several hours. This cooling-off period enables you to refine the policy criteria to select only the images you want to delete, and thus reduces the chance of images being deleted unexpectedly. After this period, the policy is included in the hourly process and images are checked and deleted accordingly.

- The global image retention policy (and any custom image retention policies you create) are specific to a particular region. To delete images consistently in different regions in your tenancy, set up image retention policies in each region with identical selection criteria .

Using the Console to Edit the Global Image Retention Policy

Provided you have `manage` permission on the tenancy, you can edit the region's global image retention policy that applies to all repositories in a region (except for repositories that have been explicitly added to a custom image retention policy).

To edit the global image retention policy:

1. In the Console, open the navigation menu. Under **Solutions and Platform**, go to **Developer Services** and click **Registry**.
2. Choose the registry's region. You see all the repositories to which you have access.
3. Click **Settings**, and then select **Image retention policies**.
   You see the current selection criteria of the region's global image retention policy, along with any custom image retention policies that override the global image retention policy for specific repositories.
4. Click **Edit Global Policy**.
5. In the **Global Image Retention Policy** dialog, specify new criteria for the global retention policy:
   - **Delete any images that haven't been pulled in *n* days:** Select this option if you want to delete images that have not been pulled for the number of days you specify.
   - **Delete any images that haven't been tagged in *n* days:** Select this option if you want to delete images that have not been tagged for the number of days you specify.
   - **Exempt Tags:** If you want to prevent images from being deleted on the basis of Docker tags they've been given, specify those tags as exempt in a comma-separated list. An image that has been given one of the exempt tags will not be

deleted, even if the image meets the other criteria. You can include the asterisk (*) as a wildcard to represent none, one, or more characters. For example, you might specify `latest,prod-*,*-tail,*.100.*`.

6. Click **Save Settings**.

Going forward, the criteria you entered for the region's global image retention policy will apply to all repositories in the region, except for repositories that have been explicitly added to a custom image retention policy. Images in repositories that have not been added to a custom image retention policy will be deleted from Oracle Cloud Infrastructure Registry if they meet the criteria you specified in the global image retention policy.

When you create or update an image retention policy, the hourly process that checks images for deletion will ignore the new or updated policy for several hours. This cooling-off period enables you to refine the policy criteria to select only the images you want to delete, and thus reduces the chance of images being deleted unexpectedly. After this period, the policy is included in the hourly process and images are checked and deleted accordingly.

Using the Console to Create a New Custom Image Retention Policy to Override the Global Policy

Provided you have `manage` permission on the tenancy, you can create a new custom image retention policy to override the region's global image retention policy for the repositories you specify. A custom image retention policy is specific to the region in which you create it.

To create a new custom image retention policy:

1. In the Console, open the navigation menu. Under **Solutions and Platform**, go to **Developer Services** and click **Registry**.
2. Choose the registry's region. You see all the repositories to which you have access.
3. Click **Settings**, and then select **Image retention policies**.
   You see the current selection criteria of the region's global image retention policy, along with any existing custom image retention policies that override the global image retention policy for specific repositories.
4. Click **Create Policy**.

5. In the **Create Repository Image Retention Policy** dialog, specify criteria for the new retention policy:
    - **Policy Name:** A name of your choice for the policy. Avoid entering confidential information.
    - **Delete any images that haven't been pulled in *n* days:** Select this option if you want to delete images that have not been pulled for the number of days you specify.
    - **Delete any images that haven't been tagged in *n* days:** Select this option if you want to delete images that have not been tagged for the number of days you specify.
    - **Exempt Tags:** If you want to prevent images from being deleted on the basis of Docker tags they've been given, specify those tags as exempt in a comma-separated list. An image that has been given one of the exempt tags will not be deleted, even if the image meets the other criteria. You can include the asterisk (*) as a wildcard to represent none, one, or more characters. For example, you might specify `latest,prod-*,*-tail,*.100.*`.
6. Click **Save Settings**.

You can now add repositories to the new custom retention policy.

Using the Console to Remove a Repository from a Custom Image Retention Policy

Provided you have `manage` permission on a repository, you can remove a repository from a custom image retention policy to which it was previously added.

You might want to remove the repository from a custom image retention policy:

- if you want the region's global image retention policy to apply to the repository
- if you want a different custom image retention policy to apply to the repository (only one custom image retention policy at a time can apply to a repository)

To remove a repository from a custom image retention policy:

1. In the Console, open the navigation menu. Under **Solutions and Platform**, go to **Developer Services** and click **Registry**.
2. Choose the registry's region. You see all the repositories to which you have access.
3. Click **Settings**, and then select **Image retention policies**.
   You see the current selection criteria of the region's global image retention policy, along with any existing custom image retention policies that override the global image retention policy for specific repositories.
4. Locate the custom image retention policy to which the repository has been added.
5. Click the delete icon beside the repository name to remove it from the custom image retention policy.

Going forward, the region's global image retention policy will apply to the repository (unless you add the repository to a different custom image retention policy). The images in the repository will be deleted from Oracle Cloud Infrastructure Registry if they meet the criteria specified in the global image retention policy.

When you create or update an image retention policy, the hourly process that checks images for deletion will ignore the new or updated policy for several hours. This cooling-off period enables you to refine the policy criteria to select only the images you want to delete, and thus reduces the chance of images being deleted unexpectedly. After this period, the policy is included in the hourly process and images are checked and deleted accordingly.

Using the Console to Add a Repository to a Custom Image Retention Policy

Provided you have `manage` permission on a repository, you can add a repository to an existing custom image retention policy.

Note that if a custom image retention policy already applies to the repository, you'll have to remove the repository from the current policy before adding it to a different policy. Note also that a custom image retention policy is specific to the region in which it was created.

To add a repository to an existing custom image retention policy:

1. In the Console, open the navigation menu. Under **Solutions and Platform**, go to **Developer Services** and click **Registry**.
2. Choose the registry's region. You see all the repositories to which you have access.
3. Click **Settings**, and then select **Image retention policies**.
   You see the current selection criteria of the region's global image retention policy, along with the custom image retention policies that have been defined to override the global image retention policy for specific repositories.
4. Locate the custom image retention policy to which you want to add the repository.
5. Click **Add Repository** and select from the list the repository you want to add to the custom image retention policy.
   Note that the repository list includes all repositories in the region, regardless of whether you have permission to add them to a retention policy. You can only add a repository to a retention policy if you have `manage` permission on that repository,
   If a repository in the list has a policy name beside it, the repository has already been added to a policy. Before you can add the repository to a different policy, you'll have to remove it from the first policy.

Going forward, the custom retention policy to which you added the repository will override the region's global image retention policy. The images in the repository will be deleted from Oracle Cloud Infrastructure Registry if they meet the criteria specified in the custom retention policy.

When you create or update an image retention policy, the hourly process that checks images for deletion will ignore the new or updated policy for several hours. This cooling-off period enables you to refine the policy criteria to select only the images you want to delete, and thus reduces the chance of images being deleted unexpectedly. After this period, the policy is included in the hourly process and images are checked and deleted accordingly.

Deleting a Repository

There is a limit to the number of repositories you can have in any given region in a tenancy. So when you no longer need a repository, it makes sense to delete it from Oracle Cloud Infrastructure Registry.

Your permissions control the repositories in Oracle Cloud Infrastructure Registry that you can delete. You can delete repositories you've created, and from repositories that the groups to which you belong have been granted access by identity policies. If you belong to the Administrators group, you can delete any repository in the tenancy.

Using the Console

To delete a repository from Oracle Cloud Infrastructure Registry:

1. In the Console, open the navigation menu. Under **Solutions and Platform**, go to **Developer Services** and click **Registry**.
2. Choose the registry's region. You see all the repositories in the registry to which you have access.
3. Click the name of the repository that you want to delete.
4. Click **Delete** on the **Summary** page and confirm that you want to delete the repository.

The repository is permanently removed from Oracle Cloud Infrastructure Registry.

Getting an Auth Token

Before you can push and pull Docker images to and from Oracle Cloud Infrastructure Registry, you must already have an Oracle Cloud Infrastructure username and an auth token. If you

haven't got an auth token, or you've forgotten it, or you're not sure, you can create a new auth token. You only see the auth token string when you create it, so be sure to copy the auth token to a secure location immediately.

Tip: Each user can have up to two auth tokens at a time. So if you do lose or forget the auth token, you can always create a second auth token.

To create a new auth token:

1. In the top-right corner of the Console, open the **Profile** menu ( ) and then click **User Settings** to view the details.
2. On the **Auth Tokens** page, click **Generate Token**.
3. Enter a friendly description for the auth token. Avoid entering confidential information.
4. Click **Generate Token**. The new auth token is displayed.
5. Copy the auth token immediately to a secure location from where you can retrieve it later, because you won't see the auth token again in the Console.
6. Close the Generate Token dialog.

Policies to Control Repository Access

You have fine-grained control over the operations that users are allowed to perform on repositories in Oracle Cloud Infrastructure Registry.

A user's permissions to access repositories comes from the groups to which they belong. The permissions for a group are defined by identity policies. Policies define which actions the members of a group can perform. Users access repositories and perform operations based on the policies set for the groups they are members of. Identity policies to control repository access must be set at the tenancy level. See Details for Registry .

Before you can control access to repositories, you must have already created users and already placed them in appropriate groups (see Managing Users and Managing Groups). You can then create policies and policy statements to control repository access (see Managing Policies).

Note that users in the tenancy's Administrators group can perform any operation on any repository in Oracle Cloud Infrastructure Registry that belongs to the tenancy.

Common Policies

Note

The policies in this section use example group names, as follows:

- acme-viewers: A group that you want to limit to seeing a list of repositories in the tenancy.
- acme-pullers: A group that you want to limit to pulling images.
- acme-pushers: A group that you want to allow to push and pull images.
- acme-managers: A group that you want to allow to push and pull images, delete repositories, and edit repository metadata (for example, to make a private repository public).

Make sure to replace the example group names with your own group names.

Enable users to view a list of all the repositories belonging to the tenancy

Type of access: Ability to see a list of all repositories in Oracle Cloud Infrastructure Registry belonging to the tenancy. Users will not be able to:

- view the images or layers in a repository
- push or pull images from or to a repository

Note that there is currently no way to restrict the repositories shown on the Registry page in the Console.

Where to create the policy: In the tenancy.

```
Allow group acme-viewers to inspect repos in tenancy
```

Enable users to pull images from any repository belonging to the tenancy

Type of access: Ability to pull images (layers and manifests) from any repository in Oracle Cloud Infrastructure Registry that belongs to the tenancy.

Where to create the policy: In the tenancy.

```
Allow group acme-pullers to read repos in tenancy
```

Enable users to pull images from specific repositories

Type of access: Ability to pull images (layers and manifests) from any repository in Oracle Cloud Infrastructure Registry that belongs to the tenancy and that has a name starting with "acme-web-app".

Where to create the policy: In the tenancy.

```
Allow group acme-pullers to read repos in tenancy where all { target.repo.name=/acme-web-app*/ }
```

Enable users to push images to any repositories (and create new repositories if necessary)

Type of access: Ability to push images (layers and manifests) to any repository in Oracle Cloud Infrastructure Registry that belongs to the tenancy. If a repository with the same name as the image doesn't exist yet, the `REPOSITORY_CREATE` permission ensures users are able to

create the repository when they push the image.

Where to create the policy: In the tenancy.

```
Allow group acme-pushers to use repos in tenancy
```

```
Allow group acme-pushers to manage repos in tenancy where ANY {request.permission = 'REPOSITORY_
CREATE', request.permission = 'REPOSITORY_UPDATE'}
```

Enable managers to perform any operation on any repository belonging to the tenancy

Type of access: Ability to perform any operation on any repository in Oracle Cloud Infrastructure Registry that belongs to the tenancy, including:

- pull an image from any repository
- push an image to any repository
- create a new repository (either an empty repository, or when pushing an image for which no repository exists yet)
- delete a repository
- change a public repository to a private repository, or a private repository to a public repository

Where to create the policy: In the tenancy.

```
Allow group acme-managers to manage repos in tenancy
```

CHAPTER 27 Overview of Resource Manager

Resource Manager is an Oracle Cloud Infrastructure service that allows you to automate the process of provisioning your Oracle Cloud Infrastructure resources. Using Terraform, Resource Manager helps you install, configure, and manage resources through the "infrastructure-as-code" model.

Note

Resource Manager is not available in Oracle Cloud Infrastructure Government Cloudrealms.

A Terraform configuration codifies your infrastructure in declarative configuration files. Resource Manager allows you to share and manage infrastructure configurations and state files across multiple teams and platforms. This infrastructure management can't be done with local Terraform installations and Oracle Terraform modules alone. For more information about the Oracle Cloud Infrastructure Terraform provider, see Terraform Provider. For a general introduction to Terraform and the "infrastructure-as-code" model, see https://www.terraform.io.

Key Concepts

Following are brief descriptions of key concepts and the main components of Resource Manager.

CONFIGURATION

A set of one or more Terraform configuration files that codify your infrastructure. Use your configuration to specify the Oracle Cloud Infrastructure resources in a given stack. For example, specify resource metadata, data source definitions, and variable declarations. Each Terraform configuration file is either HashiCorp Configuration Language (HCL) format or JSON format, as indicated by the file's extension (either `.tf` or `.tf.json`, respectively).

For example configuration files, see Terraform provider examples. For more information, see Terraform Configurations for Resource Manager and Writing Terraform Configurations; see also Hashicorp: Configuration.

JOB

Instructions to perform the actions defined in your configuration. Only one job at a time can run on a given stack; further, you can have only one set of Oracle Cloud Infrastructure resources on a given stack. To provision a different set of resources, you must create a separate stack and use a different configuration.

Resource Manager provides the following job types:

- **Plan**: Parses your Terraform configuration and creates an execution plan for the associated stack. The execution plan lists the sequence of specific actions planned to provision your Oracle Cloud Infrastructure resources. The execution plan is handed off to the apply job, which then executes the instructions.
- **Apply**. Applies the execution plan to the associated stack to create (or modify) your Oracle Cloud Infrastructure resources. Depending on the number and type of resources specified, a given apply job can take some time. You can check status while the job runs.
- **Destroy**. Releases resources associated with a stack. Released resources are not deleted. For example, terminates a Compute instance controlled by a stack. The stack's job history and state remain after running a destroy job. You can monitor the status and review the results of a destroy job by inspecting the stack's log files.
- **Import State**. Sets the provided Terraform state file as the current state of the stack. Use this job to migrate local Terraform environments to Resource Manager.

Jobs store history about their associated stack. For example, plan jobs store generated execution plans and apply jobs store configurations (snapshots) and state files. Jobs reside in the compartment that is occupied by the stack they are associated with. An OCID is assigned to each job.

MODULE

A group of related resources. Use modules to create lightweight and reusable abstractions, so that you can describe your infrastructure in terms of its architecture. For more information, see Creating Modules.

STACK

The collection of Oracle Cloud Infrastructure resources corresponding to a given Terraform configuration. Each stack resides in the compartment you specify, in a single region; however, resources on a given stack can be deployed across multiple regions. An OCID is assigned to each stack.

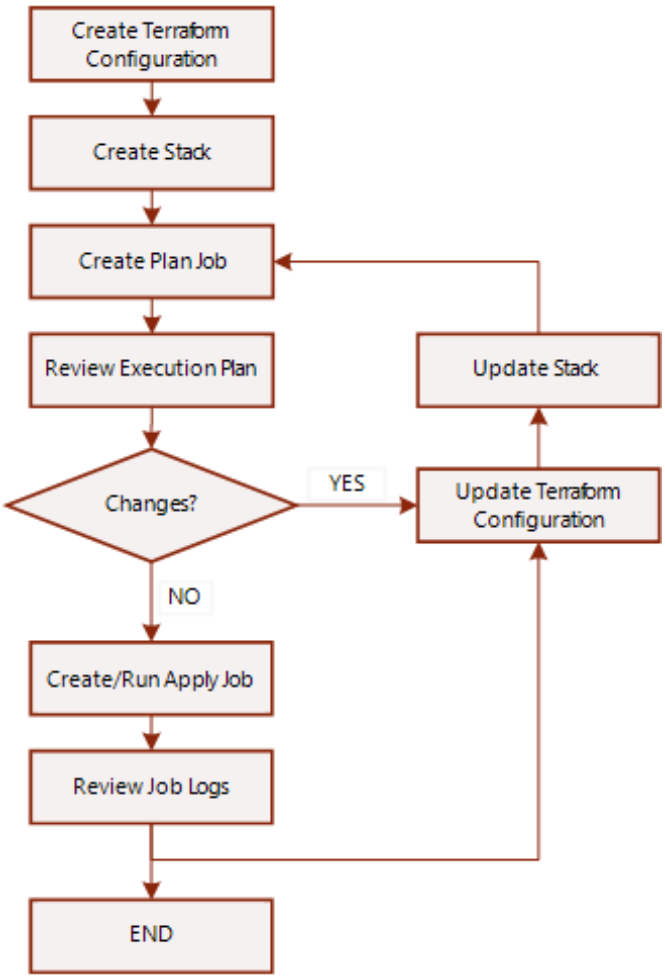
STATE

The state of your resource configuration, stored in JSON format in a state file (.tfstate). The state file maps your stack's resources to your configuration and also maintains essential configuration metadata, such as resource dependencies. Resource Manager generates and updates state files automatically. You cannot edit the file manually.

Resource Manager supports state locking by allowing only one job at a time to run on a given stack. For more information about state files, see Hashicorp: State.

Generalized Workflow

The following image represents a generalized view of the Resource Manager workflow.



Links in the following steps reference Console instructions; however, you can do the same tasks using the API (through the CLI or other tool).

1. Create a Terraform configuration.
2. Create a stack.
3. Run a plan job, which produces an execution plan.
4. Review the execution plan.

5. If changes are needed in the execution plan, update the configuration and run a plan job again.
6. Run an apply job to provision resources.
7. Review state file and log files, as needed.
8. You can optionally reapply your configuration, with or without making changes, by running an apply job again.
9. Optionally, to release the resources running on a stack, run a destroy job.

For a detailed walkthrough of the Resource Manager workflow, see Sample: Creating a Compute Instance Using Resource Manager.

Ways to Access Resource Manager

You can access the Resource Manager service using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. For a list of available SDKs, see Software Development Kits and Command Line Interface.

Console: To access Resource Manager using the Console, you must use a supported browser. Oracle Cloud Infrastructure supports the latest desktop versions of Google Chrome, Microsoft Edge, Internet Explorer 11, Safari, Firefox, and Firefox ESR. Note that private browsing mode is not supported for Firefox, Internet Explorer, or Edge. Mobile browsers are not supported. Open the navigation menu. Under **Solutions and Platform**, go to **Resource Manager** and click **Stacks**.

API: To access Resource Manager through APIs, use Resource Manager API. To access this API using the Command Line Interface (CLI), use the `oci resource-manager` designation.

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies. For specific details about writing policies for each of the different services, see Policy Reference.

If you're a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

Administrators: For common policies that give groups access to stacks and jobs, see Policies for Managing Stacks and Jobs. For a complete list of Resource Manager permissions, see Details for Resource Manager. Policies for managing accessed resource types are also required.

Important

Policies for managing Oracle Cloud Infrastructure resources are also required for Resource Manager operations that access resources. For example, running an apply job on a stack that includes Compute instances and subnets requires policies that grant you permissions for those resource types, in the compartments where you want to provision the resources. To see examples of policies for managing Oracle Cloud Infrastructure resources, see Common Policies.

Limits on Resource Manager Resources

See Service Limits for a list of applicable limits and instructions for requesting a limit increase. To set compartment-specific limits on a resource or resource family, administrators can use compartment quotas.

Managing Stacks and Jobs

This topic describes how to create, edit, and delete stacks as well as work with jobs, including generating and applying execution plans.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Prerequisites

- IAM policies: To manage stacks and jobs, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

  Administrators: For common policies that give groups access to stacks and jobs, see Policies for Managing Stacks and Jobs. For a complete list of Resource Manager permissions, see Details for Resource Manager. Policies for managing accessed resource types are also required.

Important

Policies for managing Oracle Cloud Infrastructure resources are also required for Resource Manager operations that access resources. For example, running an apply job on a stack that includes Compute instances and subnets requires policies that grant you permissions for those resource types, in the compartments where you want to provision the resources. To see examples of policies for managing Oracle Cloud Infrastructure resources, see Common Policies.

- Terraform configuration file: To create or update a stack, you must have a valid Terraform configuration file. See Terraform Configurations for Resource Manager and Writing Terraform Configurations.

Tagging Resources

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the desired tags. For general information about applying tags, see Resource Tags.

Moving Resources to a Different Compartment

You can move stacks from one compartment to another. When you move a stack to a new compartment, its associated jobs move with it. After you move the stack to the new compartment, inherent policies apply immediately and affect access to the stack and associated jobs through the Console. For more information, see Managing Compartments.

Using the Console

To create a stack

Creating a stack involves uploading your Terraform configuration file, providing identifying information for the new stack, and optionally updating variables. You can always edit your stack later.

Important

Make sure your Terraform configuration file is valid. See Writing Terraform Configurations and Terraform Configurations for Resource Manager.

1. Open the navigation menu. Under **Solutions and Platform**, go to **Resource Manager** and click **Stacks**.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
3. Click **Create Stack**.
4. In the **Create Stack** dialog, add your Terraform configuration (.zip) file.
   You can either drag and drop it onto the dialog's control or click **Browse** and navigate to the file location.
   The dialog box is populated with information contained in the configuration file.
5. Enter a **Name** for the new stack (or accept the default name provided).
6. Optionally enter a **Description**.
7. From the **Create in Compartment** drop-down, select the compartment where you want to create the stack.
   A compartment from the list scope is set by default.
8. Select a **Terraform Version**.

Note

Terraform version 0.12.x is not backward-compatible.

9. Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.
10. Click **Next**.
    The **Configure Variables** panel displays variables auto-populated from the Terraform file you uploaded in step 1.
11. Review the variables and make changes as necessary.

Important

Do not add your private key or other confidential information to configuration variables.

12. Click **Next**.
13. In the **Review** panel, verify your stack configuration.
14. Click **Create** to create your stack.

To view stacks

You can view stack names, descriptions, states, and time created.

1. Open the navigation menu. Under **Solutions and Platform**, go to **Resource Manager** and click **Stacks**.

2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.

To edit a stack

You can edit stacks. When editing a stack, you can upload a different .zip file and change its name, description, Terraform version, and variables.

1. Open the navigation menu. Under **Solutions and Platform**, go to **Resource Manager** and click **Stacks**.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
3. Click the Actions icon (three dots), and then select **Edit**.
   You can also edit a stack from its detail page. Click the name of the stack to display its detail page and then click **Edit Stack**.
4. In the **Edit Stack** dialog, change the properties you want.

Note

Changing the Terraform version requires the stack's Resource Manager configuration (.zip) file to be compatible with the new version. Downgrading the Terraform version from 0.12.x to 0.11.x is only available before an apply job is run on the stack.

- To edit the values assigned to variables in a stack, click **Configure Variables**.
  You can also edit a stack from its detail page. Click the name of the stack to display the **Stack Details** page, click **Variables** (under **Resources**) and then click **Edit Variables**.

Important

Do not add your private key or other confidential information to configuration variables.

If you want to add, reconfigure, or delete variables in a stack, update the Terraform configuration (.zip) file.

5. Click **Save Changes**.

To manage tags for a stack

Tags are key/value pairs that you can attach to resources to help you organize and track your resources across compartments. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.

1. Open the navigation menu. Under **Solutions and Platform**, go to **Resource Manager** and click **Stacks**.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
3. Click the name of the stack you want.
   The **Stack Details** page lists the details about the selected job.
4. Click **Tags** to view or edit existing tags, or click **Add Tags** to add new ones.

To move a stack to a different compartment

1. Open the navigation menu. Under **Solutions and Platform**, go to **Resource Manager** and click **Stacks**.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
3. Click the Actions icon (three dots), and then select **Move Stack**.
   You can also move a stack from its detail page. Click the name of the stack to display the **Stack Details** and then click **Move Stack**.
4. In the **Move Resource To A Different Compartment** dialog box, select the compartment that you want to move the stack to.
5. Click **Move Resource**.

To delete a stack

Note

Associated resources persist after stack deletion. When you delete a stack, its associated state file is also deleted; therefore, you lose track of the state of its associated resources. Cleaning up resources associated with a deleted stack can be difficult without the state file, especially when those resources are spread across multiple compartments. To avoid difficult cleanup later, we recommend that you release associated resources first by running a destroy job.

1. Open the navigation menu. Under **Solutions and Platform**, go to **Resource Manager** and click **Stacks**.

2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
3. Click the Actions icon (three dots), select **Delete**, and confirm the operation when prompted.

Note

You cannot undo the delete stack operation.

You can also delete a stack from its detail page. Click the name of the stack to display the **Stack Details** and then click **Delete Stack**.

To view jobs and job details

You can view name, type, status, and other key information about jobs for a given compartment or stack. You can view name, type, status, and other key information about a given job. You can also access the job's execution plan (represented by the job log), Terraform configuration, and Terraform state, as well as view the variables used in the job.

1. Open the navigation menu. Under **Solutions and Platform**, go to **Resource Manager** and click **Jobs**.
   You can also access jobs from a stack detail page. Click **Stacks** and then click the name of the stack you want.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
3. To view job details, click the name of the job you want.
   The **Job Details** page lists the details about the selected job.
4. To view variables used in the job, click **Variables** under **Resources**.

To manage tags for a job

Tags are key/value pairs that you can attach to resources to help you organize and track your resources across compartments. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.

1. Open the navigation menu. Under **Solutions and Platform**, go to **Resource Manager** and click **Jobs**.
   You can also access jobs from a stack detail page. Click **Stacks** and then click the name of the stack you want.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
3. Click the name of the job you want.
   The **Job Details** page lists the details about the selected job.
4. Click **Tags** to view or edit existing tags, or click **Add Tags** to add new ones.

To generate an execution plan (run a plan job)

Running a plan job parses your Terraform configuration (.zip) file and converts it into an execution plan listing resources and actions that will result when an apply job is run. We recommend generating an execution plan before running an apply job.

1. Open the navigation menu. Under **Solutions and Platform**, go to **Resource Manager** and click **Stacks**.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
3. Click the name of the stack that you want to use.

The **Stack Details** page is displayed.

4. Go to **Terraform Actions** and select **Plan**.
5. In the **Plan** dialog, review the plan job **Name** and update it if needed.
6. Click **Plan**.
   The new plan job is listed under **Jobs**, with an initial state of "Accepted." Soon the status changes to "In Progress." When the job is complete, you can review the execution plan or download the job information.

To view the job log

1. Open the navigation menu. Under **Solutions and Platform**, go to **Resource Manager** and click **Jobs**.
   You can also access jobs from a stack detail page. Click **Stacks** and then click the name of the stack you want.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
3. Click the name of the plan job that you ran.
4. On the **Job Details** page, under **Resources**, click **Logs**.
   For plan jobs, the log file is the execution plan. View the log file for the plan job and note the "message" fields in the sequence of log entries of the log file. These values represent the sequence of operations specified in your configuration.
   You can also download the job information.

To update the configuration for a stack

Updating a stack involves uploading a new Terraform configuration (.zip) file, which overwrites the existing configuration. You might want to update a stack after reviewing the generated execution plan.

Important

Make sure your Terraform configuration file is valid. See Writing Terraform Configurations and Terraform Configurations for Resource Manager.

1. Open the navigation menu. Under **Solutions and Platform**, go to **Resource Manager** and click **Stacks**.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
3. Click the name of the stack that you want to update.
   The **Stack Details** page is displayed.
4. In the **Stack Information** tab, next to **Terraform Configuration File (.zip)**, click **Upload New**.
5. In the **Edit Stack** dialog, add your revised Terraform configuration (.zip) file.
   You can either drag and drop it onto the dialog's control or click **Browse** and navigate to the file location.
   The dialog box is populated with information contained in the configuration file.
6. Click **Next** as needed and then click **Save Changes**.
   Now you can generate a new execution plan using your revised configuration.

To download job information

You can download files associated with jobs: Terraform configurations, Terraform states, and logs.

1. Open the navigation menu. Under **Solutions and Platform**, go to **Resource Manager** and click **Jobs**.

You can also access jobs from a stack detail page. Click **Stacks** and then click the name of the stack you want.

2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
3. Click the name of the job you want.
   The **Job Details** page is displayed.
   You can view the log by clicking **Logs** under **Resources**.
   You can view the state of your resources (for relevant jobs) by clicking **View State** under **Resources**.
4. Download the job information you want:

To download this job-associated file	Click
Terraform configuration (.zip file)	**Download Terraform Configuration**
Terraform state (.json file)	**Download Terraform State**
Logs (.txt file)	**Download Logs** (**Logs** section under **Resources**) **Note:** In cases of a long-running job, click the **Refresh** button to update the log.

To run an apply job

When you run an apply job for a stack, Terraform creates the resources and executes the actions defined in your Terraform configuration (.zip) file. The time required to complete an apply job depends on the number and type of cloud resources to be created.

1. Open the navigation menu. Under **Solutions and Platform**, go to **Resource Manager** and click **Stacks**.

2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
3. Click the name of the stack that you want to use.
   The **Stack Details** page is displayed.
4. Go to **Terraform Actions** and select **Apply**.
5. In the **Apply** dialog, review the apply job **Name** and other settings and update it if needed.
6. Click **Apply**.
   The new apply job is listed under **Jobs**. Monitor its status: "Succeeded" indicates that the job has completed. While the job runs, or after it completes, you can download its log file.
7. To view the Terraform state file (shows the state of your resources after running the job), click the name of the apply job and then click **View State** under **Resources**.

To view the state of a job

1. Open the navigation menu. Under **Solutions and Platform**, go to **Resource Manager** and click **Jobs**.
   You can also access jobs from a stack detail page. Click **Stacks** and then click the name of the stack you want.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
3. Click the name of the job you want.
4. On the **Job Details** page, click **View State** under **Resources**.

To import an existing Terraform state file (run an import job)

You can import state files for existing resources already managed by Terraform.

1. Open the navigation menu. Under **Solutions and Platform**, go to **Resource Manager** and click **Stacks**.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
3. Click the name of the stack that you want to use.
   The **Stack Details** page is displayed.
4. Go to **Terraform Actions** and select **Import State**.
5. In the **Import State File** dialog, review the job **Name** and update it if needed.
6. Add your Terraform state file, either by dragging and dropping it onto the dialog's control, or by clicking **Browse** and navigating to the file location.
7. Click **Import**.

To release a stack's resources (run a destroy job)

Run a destroy job to tear down the resources and clean up the tenancy.

Note

We recommend running a destroy job before deleting a stack to release associated resources first. When you delete a stack, its associated state file is also deleted; therefore, you lose track of the state of its associated resources. Cleaning up resources associated with a deleted stack can be difficult without the state file, especially when those resources are spread across multiple compartments. To avoid difficult cleanup later, we recommend that you release associated resources first by running a destroy job.

1. Open the navigation menu. Under **Solutions and Platform**, go to **Resource Manager** and click **Stacks**.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
3. Click the name of the stack that you want to use.
   The **Stack Details** page is displayed.
4. Go to **Terraform Actions** and select **Destroy**.
5. Click **Destroy** again to confirm your action.
   You can monitor the status and review the results of a destroy job by viewing the state or the logs.
6. To view the Terraform state file (shows the state of your resources after running the job), click the name of the job to display the **Job Details** page, then click **View State** under **Resources**.
7. To view the logs for the job, click the name of the job to display the **Job Details** page, then click **Logs** under **Resources**.

Using the CLI

This section provides basic sample CLI commands for managing stacks and jobs. For information about using the CLI, see Command Line Interface (CLI). For a complete list of flags and options available for CLI commands, see CLI Help.

To create a stack

On Windows, be sure the .zip file and variables.json files are in the same directory from which you're running the CLI. The CLI currently has a limitation on Windows that prevents correct handling of the files if either one is in a subdirectory.

Open a command prompt and run `oci resource-manager stack create` to create a stack:

```
oci resource-manager stack create --compartment-id <compartment_OCID> --config-source <config_file_
name> --variables <var_file_path> --display-name "<friendly_name>" --description "<description>" --
working-directory ""
```

Note

You can return later to update stack settings or add variables after you have created the stack.

Options

For a complete list of flags and options available for CLI commands, see CLI Help.

- `--compartment-id` is the OCID of the compartment where you want to create the stack.
- `--config-source` is the name of a .zip file that contains one or more Terraform configuration files.
- `--variables` is the path to the file specifying input variables for your resources. Optional.
  The Oracle Cloud Infrastructure Terraform provider requires additional parameters when running Terraform locally (unless you are using instance principals). For more information on using variables in Terraform, see Input Variables. See also Input Variable Configuration.
- `--display-name` is the friendly name for the new stack. Optional.
- `--description` is the description for the new stack. Optional.
- `--working-directory` is the root configuration file in the directory. Optional. If not specified, or if null as in this example, then the service assumes that the top-level file in the directory is the root configuration file.

For example:

```
oci resource-manager stack create --compartment-id ocid1.tenancy.oc1..uniqueid --config-source vcn.zip -
-variables file://variables.json --display-name "My Example Stack" --description "My Tutorial to Create
a VCN" --working-directory ""
```

Example response

```
{
  "data": {
    "config-source": {
      "working-directory": null,
      "config-source-type": "ZIP_UPLOAD"
    },
    "defined-tags": {},
    "description": "My Tutorial to Create a VCN",
    "display-name": "My Example Stack",
    "freeform-tags": {},
    "id": "ocid1.ormstack.oc1..uniqueid",
    "lifecycle-state": "ACTIVE",
    "time-created": "2019-04-03T18:26:56.299000+00:00",
    "variables": {
      "compartment_ocid": "ocid1.compartment.oc1..uniqueid",
      "region": "us-phoenix-1"
    }
  }
}
```

To list stacks in a compartment

Open a command prompt and run `oci resource-manager stack list` to list the stacks in a compartment:

```
oci resource-manager stack list --compartment-id <compartment_OCID>
```

To list full details of a stack

Open a command prompt and run `oci resource-manager stack get` to list the details for the specified stack:

```
oci resource-manager stack get --stack-id <stack_OCID>
```

To delete a stack

Note

Associated resources persist after stack deletion. When you delete a stack, its associated state file is also deleted; therefore, you lose track of the state of its associated resources. Cleaning up resources associated with a deleted stack can be difficult without the state file, especially when those resources are spread across multiple compartments. To avoid difficult cleanup later, we recommend that you release associated resources first by running a destroy job.

Open a command prompt and run `oci resource-manager stack delete` to delete the specified stack:

```
oci resource-manager stack delete --stack-id <stack_OCID>
```

To generate an execution plan (run a plan job)

Open a command prompt and run `oci resource-manager job create-plan-job` to run a plan job on the specified stack (`--display-name` is optional):

```
oci resource-manager job create-plan-job --stack-id <stack_OCID> --display-name "<friendly_name>"
```

Depending on the complexity of the configuration, the plan job can take several minutes to complete. When the job is complete, make sure you review the generated execution plan before running an apply job.

To check the current state of the plan job

Open a command prompt and run `oci resource-manager job get` to retrieve information

about the job:

```
oci resource-manager job get --job-id <plan_job_OCID>
```

Lifecycle states

Possible values for `lifecycle-state`:

- `ACCEPTED`: The job is queued for execution.
- `IN_PROGRESS`: The job is running.
- `FAILED`: The job has failed and stopped running.
- `SUCCEEDED`: The job has completed successfully.
- `CANCELING`: The job has been notified to cancel, but has not yet stopped running.
- `CANCELED`: The job was canceled and has stopped running.

Example response

This example shows `ACCEPTED` for `lifecycle-state`.

```
{
  "data": {
    "compartment-id": " ocid1.compartment.oc1..uniqueid",
    "defined-tags": null,
    "display-name": "Example Plan Job",
    "freeform-tags": {},
    "id": "ocid1.ormjob.oc1..uniqueid",
    "lifecycle-state": "ACCEPTED",
    "operation": "PLAN",
    "jobOperationDetails": {
      "operation": "PLAN"
    },
    "stack-id": " ocid1.ormstack.oc1..uniqueid",
    "time-created": "2019-03-09T20:52:13.922000+00:00",
    "time-finished": null,
```

```
    "variables": {
      "compartment_ocid": "ocid1.compartment.oc1..uniqueid",
      "region": "us-phoenix-1"
    }
  }
}
```

To review an execution plan (view the log for a plan job)

Review the execution plan to ensure that it accurately reflects your intentions. View the log file and note the "message" fields in the sequence of log entries of the log file. These values represent the sequence of operations specified in your configuration.

Open a command prompt and run `oci resource-manager job get-job-logs` to view the log file for the specified job:

```
oci resource-manager job get-job-logs --job-id <plan_job_OCID>
```

If you see problems or errors and wish to make changes, then update the appropriate configuration file (.tf file), update the stack to use the revised configuration, generate a new execution plan, and then review the new execution plan.

Example response

The command returns JSON objects that describe log entries. Each object has a message member with a property that displays one line of the execution plan. In the example shown below, the plan creates a single virtual cloud network (VCN); the remaining members show details about the VCN.

```
...
 {
   "level": "INFO",
   "message": "Terraform will perform the following actions:",
   "timestamp": "2018-05-24T00:57:14.170000+00:00",
   "type": "TERRAFORM_CONSOLE"
 },
```

```
{

},
...
```

To update an execution plan (update the configuration for a stack)

Important

To update the execution plan after running the plan job, you must first update the configuration and recreate the configuration .zip file. Then, upload the new .zip file and rerun the plan job.

Open a command prompt and run `oci resource-manager stack update` with the option `--config-source` to update the Terraform configuration for the specified stack:

```
oci resource-manager stack update --stack-id <stack_OCID> --config-source <config_file_name>
```

After updating the stack, regenerate and review an execution plan (run a new plan job and then view the log file).

To run an apply job

To check the current state of the apply job

Open a command prompt and run `oci resource-manager job create-apply-job` with the relevant value for `--execution-plan-strategy` (examples use `--display-name`, which is optional):

- To specify a plan job ("apply" an execution plan), use `FROM_PLAN_JOB_ID`:

  ```
  oci resource-manager job create-apply-job --stack-id <stack_OCID> --execution-plan-strategy
  FROM_PLAN_JOB_ID --execution-plan-job-id <plan_job_OCID> --display-name "Example Apply Job"
  ```

  Use this option to "apply" your confirmed execution plan to the stack, execute the instructions, and provision the stack with the specified resources.

- To automatically approve the apply job (no plan job specified), use `AUTO_APPROVED`:

  ```
  oci resource-manager job create-apply-job --stack-id <stack_OCID> --execution-plan-strategy
  AUTO_APPROVED --display-name "Example Apply Job"
  ```

Depending on the complexity of your execution plan, the operation can take some time. Periodically check the lifecycle state of your apply job to see when it switches from `IN_PROGRESS` to `SUCCEEDED`.

To check the current state of the apply job

Open a command prompt and run `oci resource-manager job get` to retrieve information about the job:

```
oci resource-manager job get --job-id <apply_job_OCID>
```

Lifecycle states

Possible values for `lifecycle-state`:

- `ACCEPTED`: The job is queued for execution.
- `IN_PROGRESS`: The job is running.
- `FAILED`: The job has failed and stopped running.
- `SUCCEEDED`: The job has completed successfully.

- `CANCELING`: The job has been notified to cancel, but has not yet stopped running.
- `CANCELED`: The job was canceled and has stopped running.

To confirm existence of newly provisioned resources, inspect resources in the compartment.

To download or view job information

You can download Terraform configurations and Terraform states associated with jobs. You can also view logs associated with jobs.

To download the configuration for a job

Open a command prompt and run `oci resource-manager job get-job-tf-config` to download the Terraform configuration of the specified job to the specified file:

```
oci resource-manager job get-job-tf-config -job-id <job_OCID> --file <output_file_name>
```

To download the state file for a job

Open a command prompt and run `oci resource-manager job get-job-tf-state` to download the Terraform state of the specified job to the specified file:

```
oci resource-manager job get-job-tf-state --job-id <job_OCID> --file <output_file_name>
```

Example response for an apply job

```
{
  "data": {

    "version": 3
  }
}
```

To view the log for a job

View the log file and note the "message" fields in the sequence of log entries of the log file. You can view the log file for the specified job as either a paged list of entries or in its raw form.

To view the log as a paged list of entries, open a command prompt and run `oci resource-manager job get-job-logs`:

```
oci resource-manager job get-job-logs --job-id <job_OCID>
```

To view the log in raw form, open a command prompt and run `oci resource-manager job get-job-logs-content`:

```
oci resource-manager job get-job-logs-content --job-id <job_OCID>
```

To import an existing Terraform state file (run an import job)

Open a command prompt and run `oci resource-manager x` to import an existing state file for resources already managed by Terraform:

```
oci resource-manager job create-import-tf-state-job --stack-id stack_id --tf-state-file state_file
```

To inspect resources in a compartment

Inspecting resources in a compartment allows you to confirm existence of a resource that you provisioned (by running an apply job) or absence of a resource that you released (by running a destroy job).

Open a command prompt and run the CLI command corresponding to the resources you want to inspect.

For example, run `oci network vcn list` to inspect VCN resources in the specified compartment:

```
oci network vcn list --compartment-id <compartment_OCID>
```

To release a stack's resources (run a destroy job)

Note

We recommend running a destroy job before deleting a stack to release associated resources first. When you delete a stack, its associated state file is also deleted; therefore, you lose track of the state of its associated resources. Cleaning up resources associated with a deleted stack can be difficult without the state file, especially when those resources are spread across multiple compartments. To avoid difficult cleanup later, we recommend that you release associated resources first by running a destroy job.

Open a command prompt and run `oci resource-manager job create-destroy-job` to tear down and clean up the resources provisioned by the specified stack:

```
oci resource-manager job create-destroy-job --stack-id <stack_OCID> --execution-plan-strategy=AUTO_
APPROVED
```

To confirm deletion of the resources, inspect resources in the compartment.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line

Interface.

Use these API operations to manage stacks:

- CreateStack
- GetStack
- GetStackTfConfig
- ListStacks
- ListTerraformVersions
- UpdateStack
- ChangeStackCompartment
- DeleteStack

Use these API operations to manage jobs:

- CreateJob
- GetJob
- GetJobLogs
- GetJobLogsContent
- GetJobTfConfig
- GetJobTfState
- ListJobs
- UpdateJob
- CancelJob

Use these API operations to manage work requests:

- GetWorkRequest
- ListWorkRequestErrors
- ListWorkRequestLogs
- ListWorkRequests

Sample: Creating a Compute Instance Using Resource Manager

This sample provides an end-to-end walkthrough of the tasks required to create and deploy an Oracle Cloud Infrastructure Compute instance using Resource Manager. For a brief introduction to Resource Manager, see Overview of Resource Manager.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Highlights

This walkthrough provides samples that demonstrate how to use Resource Manager to create a Compute instance. Resource Manager uses Terraform to provision the resources that you've defined in a Terraform configuration. The resources are organized into stacks, which you create and provision using jobs.

The walkthrough covers the following tasks:

- Create a Terraform configuration using the HashiCorp configuration language (HCL). For more information, see Configuration Syntax.
- Provision the infrastructure:
  - Create a stack in which to provision your infrastructure.
  - Run a plan job against your stack, which parses your configuration and creates an execution plan.
  - Review the generated execution plan.
  - Run an apply job against your stack, which provisions your resources. The apply

job follows the execution plan, which is based on your Terraform configuration.
    - Review the resulting infrastructure.

Before We Begin

Ensure that you have installed, obtained, or created the prerequisites:

- An Oracle Cloud Infrastructure tenancy
- The OCID for the compartment where you wish to create your stack.
- A user account that includes the following:
    - An API signing key. For guidance, see Required Keys and OCIDs.
    - Required IAM permissions. For more information, see How Policies Work and Details for Resource Manager.
- If you want to use the Oracle Cloud Infrastructure CLI, install and configure the CLI first. See Quickstart and Configuration

Task 1: Create the Terraform Configuration

A Terraform configuration is a .zip file containing one or more files that codify your infrastructure. The configuration defines your Terraform provider, the resources you intend to provision, variables, and specific instructions for provisioning the resources. You need a Terraform configuration to get started with Resource Manager. For more information, see Terraform Configuration.

Warning

Do not provide user credentials or other confidential information in your Terraform configuration.

In this example, our configuration uses several configuration files (.tf files) to direct Resource Manager to execute the following sequence of operations.

Create an Oracle Cloud Infrastructure Provider

The following code sample creates a basic Oracle Cloud Infrastructure Terraform provider. You can provide values as variables that are defined either in a variables file or in the provider definition (.tf) file. For more information, see Provider Configuration.

```
provider "oci" {
  region = "${var.region}"
}
```

Define Variables

Define the variables you want to use when provisioning your resources. A best practice is to create a "variables" file in the configuration package that you upload. Following is an example from a configuration file that we've named `variables.tf`. For more information about using variables, see Input Variables. See also Configuring Input Variables.

```
variable "compartment_ocid" {
       default = "ocid1.compartment.oc1..uniqueid"
}

variable "region" {
       default = "us-phoenix-1"
}

variable "InstanceImageOCID" {
    type = "map"
    default = {
        // See https://docs.cloud.oracle.com/images/
        // Oracle-provided image "Oracle-Linux-7.5-2018.10.16-0"
        eu-frankfurt-1 = "ocid1.image.oc1.eu-frankfurt-
1.aaaaaaaaitzn6tdyjer7jl34h2ujz74jwy5nkbukbh55ekp6oyzwrtfa4zma"
        uk-london-1 = "ocid1.image.oc1.uk-london-
1.aaaaaaaa32voyikkkzfxyo4xbdmadc2dmvorfxxgdhpnk6dw64fa3l4jh7wa"
        us-ashburn-1 =
"ocid1.image.oc1.iad.aaaaaaaageeenzyuxgia726xur4ztaoxbxyjlxogdhreu3ngfj2gji3bayda"
        us-phoenix-1 =
"ocid1.image.oc1.phx.aaaaaaaaoqj42sokaoh42l76wsyhn3k2beuntrh5maj3gmgmzeyr55zzrwwa"
    }
}
```

```
variable "ssh_public_key" {
       default = "ssh-rsa <public_key_value>"
}

# Defines the number of instances to deploy
variable "NumInstances" {
    default = "1"
}

variable "InstanceShape" {
    default = "VM.Standard2.1"
}

# Specifies the Availability Domain
variable "localAD" {
    default = "<AD_name>"
}
```

For more information about variables declared in the preceding examples, see the following:

- `InstanceImageOCID`: Oracle-Provided Images
- `InstanceShape`: Compute Shapes
- `region` and `localAD`: Regions and Availability Domains

Create a Virtual Cloud Network (VCN)

The following code sample creates an Oracle Cloud Infrastructure virtual cloud network (VCN) named "ExampleVCN."

```
resource "oci_core_virtual_network" "ExampleVCN" {
  cidr_block = "10.1.0.0/16"
  compartment_id = "${var.compartment_ocid}"
  display_name = "TFExampleVCN"
  dns_label = "tfexamplevcn"
}
```

Create a Subnet in Your VCN

The following code sample creates a subnet named "ExampleSubnet" in the VCN defined in the

previous code sample.

```
resource "oci_core_subnet" "ExampleSubnet" {
  availability_domain = "${var.localAD}"
  cidr_block = "10.1.20.0/24"
  display_name = "TFExampleSubnet"
  dns_label = "tfexamplesubnet"
  security_list_ids = ["${oci_core_virtual_network.ExampleVCN.default_security_list_id}"]
  compartment_id = "${var.compartment_ocid}"
  vcn_id = "${oci_core_virtual_network.ExampleVCN.id}"
  route_table_id = "${oci_core_route_table.ExampleRT.id}"
  dhcp_options_id = "${oci_core_virtual_network.ExampleVCN.default_dhcp_options_id}"
}
```

Create an Internet Gateway

The following code sample creates an internet gateway named "ExampleIG" in the VCN that we created.

```
resource "oci_core_internet_gateway" "ExampleIG" {
  compartment_id = "${var.compartment_ocid}"
  display_name = "TFExampleIG"
  vcn_id = "${oci_core_virtual_network.ExampleVCN.id}"
}
```

Create a Core Route Table

The following code sample creates a Oracle Cloud Infrastructure core route table in the VCN and then applies two route rules.

```
resource "oci_core_route_table" "ExampleRT" {
  compartment_id = "${var.compartment_ocid}"
  vcn_id = "${oci_core_virtual_network.ExampleVCN.id}"
  display_name = "TFExampleRouteTable"
  route_rules {
    cidr_block = "0.0.0.0/0"
    network_entity_id = "${oci_core_internet_gateway.ExampleIG.id}"
  }
}
```

Create a Compute Instance

The following extended code example creates an Oracle Cloud Infrastructure Compute instance. The code also references the image on which the Compute instance is created, sets boot volume size, adds essential metadata, and applies both free-form and defined tags.

```
resource "oci_core_instance" "TFInstance" {
  count = "${var.NumInstances}"
  availability_domain = "${var.localAD}"
  compartment_id = "${var.compartment_ocid}"
  display_name = "TFInstance${count.index}"
  shape = "${var.InstanceShape}"

  create_vnic_details {
    subnet_id = "${oci_core_subnet.ExampleSubnet.id}"
    display_name = "primaryvnic"
    assign_public_ip = true
    hostname_label = "tfexampleinstance${count.index}"
  },

  source_details {
    source_type = "image"
    source_id = "${var.InstanceImageOCID[var.region]}"

    # Apply this to set the size of the boot volume that's created for this instance.
    # Otherwise, the default boot volume size of the image is used.
    # This should only be specified when source_type is set to "image".
    #boot_volume_size_in_gbs = "60"
  }

  # Apply the following flag only if you wish to preserve the attached boot volume upon destroying this
instance
  # Setting this and destroying the instance will result in a boot volume that should be managed outside
of this config.
  # When changing this value, make sure to run 'terraform apply' so that it takes effect before the
resource is destroyed.
  #preserve_boot_volume = true

  metadata {
    ssh_authorized_keys = "${var.ssh_public_key}"

  }
  timeouts {
    create = "60m"
  }
}
```

Finalize the Configuration

Ensure that all of the configuration files are in a single directory. When using the CLI, you create the configuration .zip file, then specify it using the `--config-source` parameter. When using the Console, you create the configuration .zip file , then upload it.

Important

Make sure your Terraform configuration file is valid. See Writing Terraform Configurations and Terraform Configurations for Resource Manager.

Task 2: Provision the Infrastructure

Use your Terraform configuration to build and deploy your infrastructure by taking the following actions:

1. Create a stack in a tenancy compartment of your choosing.
   A stack is a collection of resources that you can act on as a group. All of the resources that you specify in your configuration are provisioned in the stack that you create.

   #### To create a stack (Console)

   a. Open the navigation menu. Under **Solutions and Platform**, go to **Resource Manager** and click **Stacks**.
   b. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
   c. Click **Create Stack**.
   d. In the **Create Stack** dialog, add your Terraform configuration (.zip) file.

You can either drag and drop it onto the dialog's control or click **Browse** and navigate to the file location.

The dialog box is populated with information contained in the configuration file.

e. Enter a **Name** for the new stack (or accept the default name provided).

f. Optionally enter a **Description**.

g. From the **Create in Compartment** drop-down, select the compartment where you want to create the stack.

A compartment from the list scope is set by default.

h. Select a **Terraform Version**.

Note

Terraform version 0.12.x is not backward-compatible.

i. Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.

j. Click **Next**.

The **Configure Variables** panel displays variables auto-populated from the Terraform file you uploaded in step 1.

k. Review the variables and make changes as necessary.

Important

Do not add your private key or other confidential information to configuration variables.

l. Click **Next**.

m. In the **Review** panel, verify your stack configuration.

n. Click **Create** to create your stack.

To create a stack (CLI)

a. Open the navigation menu. Under **Solutions and Platform**, go to **Resource Manager** and click **Stacks**.

b. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.

c. Click **Create Stack**.

d. In the **Create Stack** dialog, add your Terraform configuration (.zip) file.
You can either drag and drop it onto the dialog's control or click **Browse** and navigate to the file location.
The dialog box is populated with information contained in the configuration file.

e. Enter a **Name** for the new stack (or accept the default name provided).

f. Optionally enter a **Description**.

g. From the **Create in Compartment** drop-down, select the compartment where you want to create the stack.
A compartment from the list scope is set by default.

h. Select a **Terraform Version**.

Note

Terraform version 0.12.x is not backward-compatible.

i. Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.

j. Click **Next**.
The **Configure Variables** panel displays variables auto-populated from the Terraform file you uploaded in step 1.

k. Review the variables and make changes as necessary.

Important

Do not add your private key or other confidential information to configuration variables.

l. Click **Next**.

m. In the **Review** panel, verify your stack configuration.

n. Click **Create** to create your stack.

2. Generate an execution plan.
The plan job parses your configuration to create an "execution plan," which is a step-by-step representation of the planned deployment in job log entries. Once the plan job has completed, you can evaluate the execution plan by viewing the job's log entries to confirm that it performs the expected operations, and in the intended sequence.

To run a plan job (Console)

a. Open the navigation menu. Under **Solutions and Platform**, go to **Resource Manager** and click **Stacks**.

b. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.

c. Click the name of the stack that you want to use.
   The **Stack Details** page is displayed.

d. Go to **Terraform Actions** and select **Plan**.

e. In the **Plan** dialog, review the plan job **Name** and update it if needed.

f. Click **Plan**.
   The new plan job is listed under **Jobs**, with an initial state of "Accepted." Soon the status changes to "In Progress." When the job is complete, you can review the execution plan or download the job information.

To run a plan job (CLI)

Open a command prompt and run `oci resource-manager job create-plan-job` to run a plan job on the specified stack (`--display-name` is optional):

```
oci resource-manager job create-plan-job --stack-id <stack_OCID> --display-name "<friendly_name>"
```

Depending on the complexity of the configuration, the plan job can take several minutes to complete. When the job is complete, make sure you review the generated execution plan before running an apply job.

To check the current state of the plan job

Open a command prompt and run `oci resource-manager job get` to retrieve information about the job:

```
oci resource-manager job get --job-id <plan_job_OCID>
```

Lifecycle states

Possible values for `lifecycle-state`:

- `ACCEPTED`: The job is queued for execution.
- `IN_PROGRESS`: The job is running.
- `FAILED`: The job has failed and stopped running.
- `SUCCEEDED`: The job has completed successfully.
- `CANCELING`: The job has been notified to cancel, but has not yet stopped running.
- `CANCELED`: The job was canceled and has stopped running.

Example response

This example shows `ACCEPTED` for `lifecycle-state`.

```
{
  "data": {
    "compartment-id": " ocid1.compartment.oc1..uniqueid",
    "defined-tags": null,
    "display-name": "Example Plan Job",
    "freeform-tags": {},
    "id": "ocid1.ormjob.oc1..uniqueid",
    "lifecycle-state": "ACCEPTED",
    "operation": "PLAN",
    "jobOperationDetails": {
      "operation": "PLAN"
    },
    "stack-id": " ocid1.ormstack.oc1..uniqueid",
    "time-created": "2019-03-09T20:52:13.922000+00:00",
    "time-finished": null,
    "variables": {
```

```
      "compartment_ocid": "ocid1.compartment.oc1..uniqueid",
      "region": "us-phoenix-1"
    }
  }
}
```

3. Review the execution plan to confirm that it represents your intentions.
   The execution plan is represented in the log for the plan job you ran previously.

To review an execution plan (the log for the plan job) (Console)

a. Open the navigation menu. Under **Solutions and Platform**, go to **Resource Manager** and click **Jobs**.
   You can also access jobs from a stack detail page. Click **Stacks** and then click the name of the stack you want.

b. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.

c. Click the name of the plan job that you ran.

d. On the **Job Details** page, under **Resources**, click **Logs**.
   For plan jobs, the log file is the execution plan. View the log file for the plan job and note the "message" fields in the sequence of log entries of the log file. These values represent the sequence of operations specified in your configuration.
   You can also download the job information.

If changes are needed, revise the configuration, update your stack, then rerun the plan job to obtain an updated execution plan.

To update a stack

a. Open the navigation menu. Under **Solutions and Platform**, go to **Resource**

Manager and click **Stacks**.

b. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.

c. Click the name of the stack that you want to update.
The **Stack Details** page is displayed.

d. In the **Stack Information** tab, next to **Terraform Configuration File (.zip)**, click **Upload New**.

e. In the **Edit Stack** dialog, add your revised Terraform configuration (.zip) file.
You can either drag and drop it onto the dialog's control or click **Browse** and navigate to the file location.
The dialog box is populated with information contained in the configuration file.

f. Click **Next** as needed and then click **Save Changes**.
Now you can generate a new execution plan using your revised configuration.

To review an execution plan (the log for the plan job) (CLI)

Review the execution plan to ensure that it accurately reflects your intentions. View the log file and note the "message" fields in the sequence of log entries of the log file. These values represent the sequence of operations specified in your configuration.

Open a command prompt and run `oci resource-manager job get-job-logs` to view the log file for the specified job:

```
oci resource-manager job get-job-logs --job-id <plan_job_OCID>
```

If you see problems or errors and wish to make changes, then update the appropriate configuration file (.tf file), update the stack to use the revised configuration, generate a new execution plan, and then review the new execution plan.

If changes are needed, revise the configuration, update your stack, then rerun the plan job to obtain an updated execution plan.

To update a stack

Important

To update the execution plan after running the plan job, you must first update the configuration and recreate the configuration .zip file. Then, upload the new .zip file and rerun the plan job.

Open a command prompt and run `oci resource-manager stack update` with the option `--config-source` to update the Terraform configuration for the specified stack:

```
oci resource-manager stack update --stack-id <stack_OCID> --config-source <config_file_name>
```

After updating the stack, regenerate and review an execution plan (run a new plan job and then view the log file).

4. Provision your resources by running an apply job against the execution plan.
   When satisfied with the execution plan, we're ready to do the work of provisioning the stack with the resources that we've defined. The apply job takes the execution plan and "applies" it to the stack. The result is a fully provisioned stack.

To run an apply job (Console)

a. Open the navigation menu. Under **Solutions and Platform**, go to **Resource Manager** and click **Stacks**.

b. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.

c. Click the name of the stack that you want to use.
   The **Stack Details** page is displayed.

d. Go to **Terraform Actions** and select **Apply**.

e. In the **Apply** dialog, review the apply job **Name** and other settings and update it if needed.

f. Click **Apply**.

The new apply job is listed under **Jobs**. Monitor its status: "Succeeded" indicates that the job has completed. While the job runs, or after it completes, you can download its log file.

g. To view the Terraform state file (shows the state of your resources after running the job), click the name of the apply job and then click **View State** under **Resources**.

To run an apply job (CLI)

To check the current state of the apply job

Open a command prompt and run `oci resource-manager job create-apply-job` with the relevant value for `--execution-plan-strategy` (examples use `--display-name`, which is optional):

- To specify a plan job ("apply" an execution plan), use `FROM_PLAN_JOB_ID`:

```
oci resource-manager job create-apply-job --stack-id <stack_OCID> --execution-plan-
strategy FROM_PLAN_JOB_ID --execution-plan-job-id <plan_job_OCID> --display-name "Example
Apply Job"
```

  Use this option to "apply" your confirmed execution plan to the stack, execute the instructions, and provision the stack with the specified resources.

- To automatically approve the apply job (no plan job specified), use `AUTO_APPROVED`:

```
oci resource-manager job create-apply-job --stack-id <stack_OCID> --execution-plan-
strategy AUTO_APPROVED --display-name "Example Apply Job"
```

Depending on the complexity of your execution plan, the operation can take some time. Periodically check the lifecycle state of your apply job to see when it switches from `IN_PROGRESS` to `SUCCEEDED`.

To check the current state of the apply job

Open a command prompt and run `oci resource-manager job get` to retrieve information about the job:

```
oci resource-manager job get --job-id <apply_job_OCID>
```

Lifecycle states

Possible values for `lifecycle-state`:

- `ACCEPTED`: The job is queued for execution.
- `IN_PROGRESS`: The job is running.
- `FAILED`: The job has failed and stopped running.
- `SUCCEEDED`: The job has completed successfully.
- `CANCELING`: The job has been notified to cancel, but has not yet stopped running.
- `CANCELED`: The job was canceled and has stopped running.

To confirm existence of newly provisioned resources, inspect resources in the compartment.

5. Review the log entries and state file for the apply job you just ran.
   - See the entries in the job log for more details about the job.

To view the job log (Console)

a. Open the navigation menu. Under **Solutions and Platform**, go to **Resource Manager** and click **Jobs**.
   You can also access jobs from a stack detail page. Click **Stacks** and then click the name of the stack you want.

b. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that

compartment. If you're not sure which compartment to use, contact an administrator.

c. Click the name of the plan job that you ran.

d. On the **Job Details** page, under **Resources**, click **Logs**.
For plan jobs, the log file is the execution plan. View the log file for the plan job and note the "message" fields in the sequence of log entries of the log file. These values represent the sequence of operations specified in your configuration.
You can also download the job information.

To view the job log (CLI)

View the log file and note the "message" fields in the sequence of log entries of the log file. You can view the log file for the specified job as either a paged list of entries or in its raw form.
To view the log as a paged list of entries, open a command prompt and run `oci resource-manager job get-job-logs`:

```
oci resource-manager job get-job-logs --job-id <job_OCID>
```

To view the log in raw form, open a command prompt and run `oci resource-manager job get-job-logs-content`:

```
oci resource-manager job get-job-logs-content --job-id <job_OCID>
```

- The job state file represents the job's output in JSON format.
The state file maps your stack's resources to your configuration and also maintains essential configuration metadata, such as resource dependencies. Resource Manager generates and updates state files automatically when you run jobs.
The Resource Manager supports state locking by allowing only one job at a time to run on a given stack. For more information about state files, see Hashicorp: State.

To view the state of the job (Console)

a. Open the navigation menu. Under **Solutions and Platform**, go to **Resource Manager** and click **Jobs**.
   You can also access jobs from a stack detail page. Click **Stacks** and then click the name of the stack you want.
b. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
c. Click the name of the job you want.
d. On the **Job Details** page, click **View State** under **Resources**.

To view the state of the job (CLI)

Open a command prompt and run `oci resource-manager job get-job-tf-state` to download the Terraform state of the specified job to the specified file:

```
oci resource-manager job get-job-tf-state --job-id <job_OCID> --file <output_file_name>
```

Example response for an apply job

```

  "terraform_version": "0.11.7",
  "version": 3
}
```

```
}
```

Note

You can also import state files for resources already managed by Terraform.

6. When you need to release the resources that you provisioned, run a destroy job on the stack.

   A destroy job tears down the stack that you created and then cleans up associated resources without deleting them. For example, the destroy job terminates Compute instances associated with the stack.

To run a destroy job (Console)

Note

We recommend running a destroy job before deleting a stack to release associated resources first. When you delete a stack, its associated state file is also deleted; therefore, you lose track of the state of its associated resources. Cleaning up resources associated with a deleted stack can be difficult without the state file, especially when those resources are spread across multiple compartments. To avoid difficult cleanup later, we recommend that you release associated resources first by running a destroy job.

a. Open the navigation menu. Under **Solutions and Platform**, go to **Resource Manager** and click **Stacks**.
b. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
c. Click the name of the stack that you want to use.
   The **Stack Details** page is displayed.
d. Go to **Terraform Actions** and select **Destroy**.
e. Click **Destroy** again to confirm your action.
   You can monitor the status and review the results of a destroy job by viewing the state or the logs.
f. To view the Terraform state file (shows the state of your resources after running the job), click the name of the job to display the **Job Details** page, then click **View State** under **Resources**.
g. To view the logs for the job, click the name of the job to display the **Job Details** page, then click **Logs** under **Resources**.

To run a destroy job (CLI)

Note

We recommend running a destroy job before deleting a stack to release associated resources first. When you delete a stack, its associated state file is also deleted; therefore, you lose track of the state of its associated resources. Cleaning up resources associated with a deleted stack can be difficult without the state file, especially when those

resources are spread across multiple compartments. To avoid difficult cleanup later, we recommend that you release associated resources first by running a destroy job.

Open a command prompt and run `oci resource-manager job create-destroy-job` to tear down and clean up the resources provisioned by the specified stack:

```
oci resource-manager job create-destroy-job --stack-id <stack_OCID> --execution-plan-strategy=AUTO_APPROVED
```

To confirm deletion of the resources, inspect resources in the compartment.

Using Remote Exec

With Resource Manager, you can use Terraform's remote exec functionality to execute scripts or commands on a remote computer. You can also use this technique for other provisioners that require access to the remote resource.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Prerequisites

- The location where the script is remotely executed must be an Oracle Cloud Infrastructure resource that has a public IP and supports remote login.
- On Windows, WinRM must be enabled. On Linux or Unix, SSH must be enabled.

- A key pair used for signing API requests, with the public key uploaded to Oracle. For more information on generating and uploading keys, see Required Keys and OCIDs.

Authenticating

We recommend using one of the following approaches, depending on whether you have access to the Key Management service. For more information, see Overview of Key Management.

With Key Management

First, use Key Management to encrypt your private key. For more information, see Managing Keys and Using Keys.

Next, provide the encrypted private key to Resource Manager. You can use the decrypt data source to decrypt it.

The following code sample demonstrates this process.

```
data "oci_kms_decrypted_data" "private_key_decrypted" {
    #Required
    ciphertext = "${file(var.encrypted_private_key_path)}"
    crypto_endpoint = "${var.decrypted_data_crypto_endpoint}"
    key_id = "${var.kms_encryption_key_id}"
}

resource "oci_core_instance" "TFInstance1" {
  availability_domain = "${lookup(data.oci_identity_availability_domains.ADs.availability_domains
[var.availability_domain - 1],"name")}"
  compartment_id      = "${var.compartment_ocid}"
  display_name        = "TFInstance"
  hostname_label      = "instance3"
  shape               = "${var.instance_shape}"
  subnet_id           = "${oci_core_subnet.ExampleSubnet.id}"

  source_details {
    source_type = "image"
    source_id   = "${var.instance_image_ocid[var.region]}"
  }
```

```
  extended_metadata {
    ssh_authorized_keys = "${var.ssh_public_key}"
  }
}

resource "null_resource" "remote-exec" {
      connection {
      agent       = false
      timeout     = "30m"
      host        = "${oci_core_instance.TFInstance1.public_ip}"
      user        = "${var.opc_user_name}"
      private_key = "${data.oci_kms_decrypted_data.test_decrypted_data.plaintext}"
    }

    inline = [
      "touch ~/IMadeAFile.Right.Here"
    ]

  }
```

Without Key Management

If you do not have access to the Key Management service, you can dynamically generate a key pair and store them in the state file.

1. Generate a key pair using a TLS resource.
2. When you launch the Compute instance, use the public key from the TLS resource.
3. When you establish the SSH connection, provide the private key.

Warning

You should not save your private key in your Terraform configuration file because that is not a secure location.

The following sample demonstrates how to use the TLS private key resource to provision a Compute instance, then perform a remote execution on that instance.

```
resource "tls_private_key" "public_private_key_pair" {
  algorithm   = "RSA"
}

resource "oci_core_instance" "TFInstance1" {
  availability_domain = "${lookup(data.oci_identity_availability_domains.ADs.availability_domains
[var.availability_domain - 1],"name")}"
  compartment_id      = "${var.compartment_ocid}"
  display_name        = "TFInstance"
  hostname_label      = "instance3"
  shape               = "${var.instance_shape}"
  subnet_id           = "${oci_core_subnet.ExampleSubnet.id}"

  source_details {
    source_type = "image"
    source_id   = "${var.instance_image_ocid[var.region]}"
  }

  extended_metadata {
    ssh_authorized_keys = "${tls_private_key.public_private_key_pair.public_key_openssh}"
  }
}

resource "null_resource" "remote-exec" {
  depends_on = ["oci_core_instance.TFInstance1"]

  provisioner "remote-exec" {
    connection {
      agent       = false
      timeout     = "30m"
      host        = "${oci_core_instance.TFInstance1.public_ip}"
      user        = "${var.opc_user_name}"
      private_key = "${tls_private_key.public_private_key_pair.private_key_pem}"
    }

    inline = [
      "touch ~/IMadeAFile.Right.Here"
    ]
  }
}
```

Connection Construct

This example demonstrates how to use a `connection` construct for remote exec. Terraform uses a number of defaults when connecting to a resource, but these can be overridden using a `connection` block in either a `resource` or `provisioner`. For more information, see Provisioner Connections.

Terraform Configurations for Resource Manager

This topic describes requirements and recommendations for Terraform configurations used with Resource Manager. For basic information about Terraform configurations, see Writing Terraform Configurations. For instructions on using configurations with stacks and jobs, see Managing Stacks and Jobs.

Warning

Do not provide user credentials or other confidential information in your Terraform configurations.

Terraform Provider

When using Resource Manager, the `region` field in the `provider "oci"` block is the only required field. All other fields, such as `userid` or `fingerprint`, are optional.

File Structure

Resource Manager requires the following Terraform configuration file (`.zip`) structure for the configuration:

- The working directory must contain at least one `.tf` file. The working directory cannot contain a `.terraform` directory.

The working directory is the path from which to run Terraform. By default, the working directory is the root of the `.zip` file. When using the API, you can specify a different location for the working directory by setting the `workingDirectory` parameter.

- The configuration must follow guidelines specified in Writing Terraform Configurations.
- No Terraform state files (`.tfstate`) can exist in the configuration.

Modules: We recommend that all modules used by a Resource Manager stack are included locally in the configuration and referenced using a local path. To use a module for Oracle Cloud Infrastructure from the Terraform Module Registry, do the following.

- Download the source from GitHub and include the relevant portion in a subdirectory in your .zip file.
- Reference the module using a local path. For more information, see Local Paths.

Variables

Resource Manager supports the native Terraform behavior for handling variables. You can include a `terraform.tfvars` file and files with the `.auto.tfvars` extension in the configuration .zip file. For more information about defining variables, see Define Variables and Input Variables.

Adding a Schema Document to Facilitate Variable Entry

You can make it easier for your users to enter variables when they create or update a stack in the Console using your Terraform configuration. A Resource Manager schema document clarifies the meaning and use of variables in the Console. The schema document allows you to:

- Validate and constrain variables to communicate permitted values more clearly.
- Name, group, and order variables.
- Require variables.
- Control visibility of variables.
- Dynamically prepopulate variable values.

Schema Document Requirements

The Resource Manager schema document has the following requirements:

- YAML format.
- Placement under the root folder of the Resource Manager Terraform configuration (.zip) file. (By default, the schema document assumes that the root folder is the working folder.)

For example schema documents and more information, see the example schema and meta schema.

Validating and Constraining Variable Entries

Terraform's configuration language supports a default value, a description, and three types for input variables: strings, lists, and maps. Because these three types are all strings, users can have difficulty understanding what values are permitted for each variable.

Use a schema document to define validations and constraints for your variables. These validations and constraints help users determine permitted values when creating and editing stacks using the Console.

Example 1: Enum type for validating and constraining entry in a variable field. The Console renders the `num_nodes` field as a selectable list, with available selections of 1 and 2. The default value is 2.

```
num_nodes:
  type: enum
  enum:
  - "1"
  - "2"
  default: "2"
```

Example 2: Pattern for validating entry in a variable field. The Console renders the `url` field as a free text entry field, validating the entered value against the provided URL pattern (and the type).

```
url:
  type: string
  pattern: ^https?:\/\/(www\.)?[-a-zA-Z0-9@:%._\+~#=]{2,256}\.[a-z]{2,4}\b([-a-zA-Z0-9@:%_\+.~#?&//=]*)$
```

NAMING AND REQUIRING VARIABLES

In your schema document, add a `groupings` node. In this node, add a `title` and list the variables you want in the group in the order you want. You can specify friendly names and descriptions for the variables and explicitly requiring variables. When a variable is required, the user must specify a value.

The following example defines a group titled "Create A VCN" that lists the `region` and `compartment_ocid`. Defining a variable by type (such as `oci:identity:region:name` for `region`) makes the fields selectable instead of free text input. Each field also includes a friendly name and description. Both variables are required.

```
schemaVersion: 1.0.0
version: "20190612"
locale: "en"
groupings:
  - title: "Create A VCN"
    variables:
    - region
    - compartment_ocid

variables:
  region:
    type: oci:identity:region:name
    title: Region
    description: The region in which to create all resources
    required: true

  compartment_ocid:
    type: oci:identity:compartment:id
    title: Target Compartment
    description: The target compartment for all of the provisioned resources
    required: true
```

The Console renders the "Create A VCN" variable group as follows.

CONTROLLING VISIBILITY OF VARIABLES

In more complex stack launches, you sometimes specify input variables for certain configurations of the stack only. Use the schema to control visibility of groups and variables based on the values of other variables. Supported operations include "eq", "and", "or", and "not".

In the following example, the "Equality Conditional Section" is visible if the value of the variable "objectStorageTier" is equal to "standard":

```
- title: "Equality Conditional Section"
  variables:
  - ${myVcn}
  visible:
    eq:
      - ${objectStorageTier}
      - standard
```

In the next example, the "mySubnet" variable is visible if the value of the variable "useExistingVcn" is true:

```
mySubnet:
```

```
  type: oci:core:subnet:id
  dependsOn:
    compartmentId: ${subnetCompartment}
    vcnId: ${myVcn}
  visible: ${useExistingVcn}
```

Groups have higher priority than the groups' constituent variables. For example, if a variable is visible within a group that is not visible, then the entire group is not visible.

DYNAMICALLY PREPOPULATING VARIABLE VALUES

Use the schema to define variables that can be dynamically prepopulated in the Console. Dynamic prepopulation has two requirements to find the elements to prepopulate with: type and dependencies. Type describes the entity you're listing. Dependencies describe what is needed to be able to find the list.

The following example shows variables that can be prepopulated based on the VCN and compartment IDs:

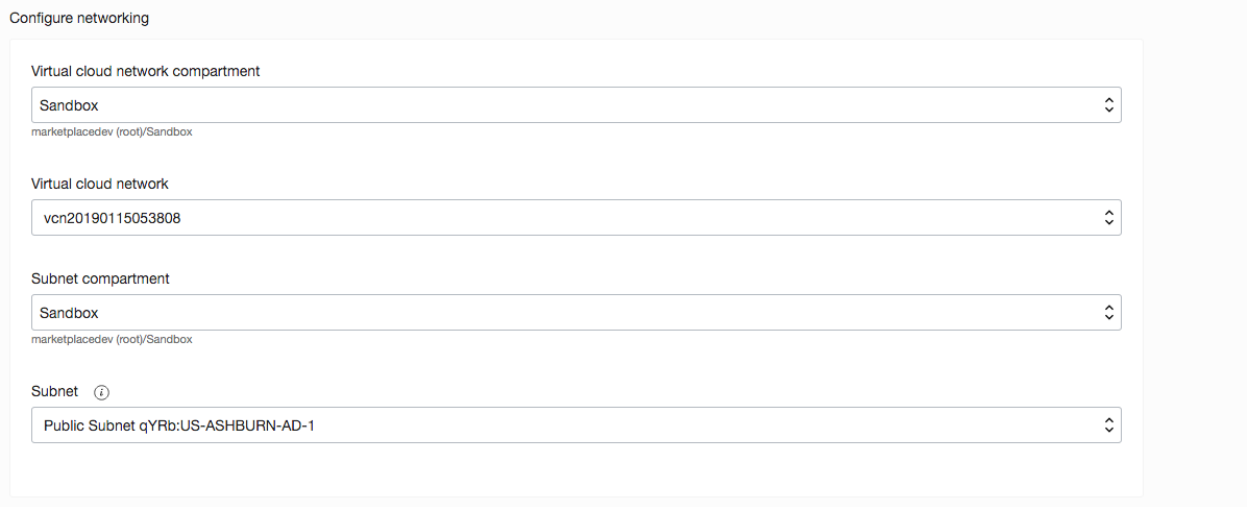
```
vcnCompartment:
   type: oci:identity:compartment:id

myVcn:
   type: oci:core:vcn:id
   dependsOn:
     compartmentId: ${vcnCompartment}

subnetCompartment:
   type: oci:identity:compartment:id

mySubnet:
   type: oci:core:subnet:id
   dependsOn:
     compartmentId: ${subnetCompartment}
     vcnId: ${myVcn}
```

The Console renders the dynamically prepopulated variables from this schema as follows.



Example Configuration

The following example shows a Terraform configuration that is contained in a single file. This basic sample defines just one Terraform provider, one Oracle Cloud Infrastructure resource, and a set of variables.

```
variable "compartment_ocid" {}
variable "region" {}

provider "oci" {
  region = "${var.region}"
}

resource "oci_core_virtual_network" "vcn1" {
  cidr_block = "10.0.0.0/16"
  dns_label = "vcn1"
  compartment_id = "${var.compartment_ocid}"
  display_name = "vcn1"
}
```

More often, Terraform configurations consist of two or more files bundled together and uploaded in a .zip file. To see more complex, multi-file Terraform configurations, explore the examples at the Oracle Cloud Infrastructure GitHub: terraform-provider-oci/docs/examples.

CHAPTER 28 Search

This chapter explains how to search for resources across compartments.

Overview of Search

Oracle Cloud Infrastructure Search lets you find resources in your tenancy without requiring you to navigate through different services and compartments. You do not need to know the compartment or availability domain where a resource exists in order to locate and view its details. Rather, with a query, you can use as little as a single piece of information, such as the creation date or other supported attribute, to find a resource. Querying also helps you avoid the latency associated with loading a long list of results onto a single page or the inconvenience of viewing a long list that spans multiple pages.

You might find it helpful to use Search to find related resources when creating or deleting another resource. For example, you might want to find what compartments already exist before creating a new one because compartments cannot be deleted. Or, if you want to delete a volume, you can use a query to verify that a backup exists.

Another benefit of Search is that you can find resources that require action. For example, you might want to delete terminated block volumes because you no longer need them and don't want them to count against your service limits. Or, you can search for all resources that match a specific naming scheme, in case you want to act on a category of associated resources. Sometimes, resources in a specific lifecycle state, such as databases in a failed state, require troubleshooting. With Search, you can quickly identify those resources and resolve problems.

Note

Search is not available in Oracle Cloud Infrastructure Government Cloudrealms.

Supported Resources

Search supports queries for the following Oracle Cloud Infrastructure services and resources. This table will be updated as query support is added for more resources.

Service	Resource Type	Attributes
Block Volume	`bootvolume`	See BootVolume Reference.
Block Volume	`bootvolumebackup`	See BootVolumeBackup Reference.
Block Volume	`volume`	See Volume Reference.
Block Volume	`volumebackup`	See VolumeBackup Reference.
Compute	`autoscalingconfiguration`	See AutoScalingConfiguration Reference.  **Note** Queries for the `policies` attribute are not supported.
Compute	`consolehistory`	See ConsoleHistory Reference.
Compute	`image`	See Image Reference.
Compute	`instance`	See Instance Reference.
Database	`autonomousdatabase`	See AutonomousDatabase Reference.
Database	`database`	See Database Reference.

Service	Resource Type	Attributes
Database	`dbsystem`	See DbSystem Reference.
Events	`eventrule`	See Rule Reference.
Functions	`functionsapplication`	See Application Reference.
Functions	`functionsfunction`	See Function Reference.
IAM	`compartment`	See Compartment Reference.
IAM	`group`	See Group Reference.
IAM	`identityprovider`	See IdentityProvider Reference.
IAM	`user`	See User Reference.
Key Management	`key`	See Key Reference.
Key Management	`vault`	See Vault Reference.
Monitoring	`alarm`	See Search-Supported Attributes for Alarms.
Networking	`routetable`	See RouteTable Reference.
Networking	`securitylist`	See SecurityList Reference.
Networking	`subnet`	See Subnet Reference.
Networking	`vcn`	See Vcn Reference.

Service	Resource Type	Attributes
Notifications	`onssubscription`	See Subscription Reference.  **Note** Queries for the `endpoint` attribute are not supported.
Notifications	`onstopic`	See NotificationTopic Reference.
Object Storage	`bucket`	See Bucket Reference.
Resource Manager	`ormjob`	See Job Reference.
Resource Manager	`ormstack`	See Stack Reference.
WAF	`waascertificate`	See WaasCertificate Reference.
WAF	`waaspolicy`	See WaasPolicy Reference.

Although you can use the query language to search fields and values for any supported attribute, query results only provide information about the following resource attributes:

- Resource type
- Oracle Cloud Identifier (OCID)

- Compartment
- Availability domain
- Display name
- Creation date and time
- Lifecycle state
- Tags (visible in the API only)

The preceding attributes are common to most Oracle Cloud Infrastructure resources. Their meaning is consistent across resource types. Query results do not contain information specific to any resource type. For example, you can query for volumes of a certain size, but search results will not display the **Size** attribute. You must view the details of a resource to see resource-specific information.

Tip

If you use the Console, neither query results nor resource details will include either defined tags or free-form tags, due to display constraints. Any given resource might contain hundreds of tags. If you want to see tags, use the API to view resource details.

Required IAM Permissions

The resources that you see in query results depend on the permissions you have in place for the resource type. You do not necessarily see results for everything in the compartment or tenancy. For example, if your user account is not associated with a policy that grants you the ability to, at a minimum, `inspect` the `dbsystem` resource type, then you can't query for DB systems. (The verb `inspect` lets you list and get resources.) Instead, Search will show no results for queries of DB system resources. For more information about policies, see How Policies Work. For information about the specific permissions required for the list

API operation for your desired resource type, see the Policy Reference for the appropriate service.

Search Language Syntax

This topic describes the basics of the query language for Search, including an explanation of syntax and rules so you can create your own queries. Queries apply search conditions to specific resource types and let you sort results. If you want to search across all supported resource types and resource attributes and do not need ordered search results, you do not need to construct a query. Instead, you can search for a partial or exact match of free-form text without applying query language syntax to your search.

When you are ready to run a query, see Querying Resources for instructions.

Query Basics

The following examples show the basic syntax of a query:

```
query <resourceType> resources where <conditions> sorted by <fieldName> <order>
```

Or:

```
query <resourceType> resources matching <keywords>
```

Search ignores white space, indentation, and line breaks. Sample queries include indentation to improve readability. For the purposes of demonstrating syntax only, angle brackets (<>) and italicized text indicate variables, which can consist of one or more keywords.

In a query, clauses include the following:

- `query` - (Required) Selects which resources to return based on subsequent clauses. Query statements always begin with the word `query`.
- `where` - Matches resources to the specified `conditions`.
- `matching` - Matches resources to the specified text regardless of whether the text matches exactly, matches the resource type, or appears in an indexed resource attribute.

- `sorted by` - Orders resources according to `fieldName` in the order specified by `order`. If you do not include this clause, Search lists results by creation date in descending order, with the newest resources listed first.

Clauses are optional unless indicated otherwise. For matching purposes, you can use the `where` clause and the `matching` clause either separately or together.

In the `query` clause, you specify the following information:

- `resourceType` - (Required) Specifies the resource type to which the subsequent clauses apply when you run the query. You can specify either the resource type name (for example, `database` or `group`) or `all`. If you specify `all`, Search searches for the `conditions` against all resource types. You can query for individual resource types, but not family types. For a list of supported resource types, see the Supported Resources section of Overview of Search.
- `resources` - (Required) Specifies that this is a resource query.

Conditions

The `where` clause applies `conditions` that act as a filter to restrict the results returned by Search. You can specify one or more condition statements. For more information about multiple conditions, see Grouping Conditions.

In a query, `conditions` consist of the following:

```
<fieldName> <operation> <value>
```

The `fieldName` keyword is the resource attribute against which the `operation` and desired `value` of that attribute are evaluated. Each field is associated with a field type. The type of `operation` you can use in your `conditions` filter depends on the field type. The API documentation includes a reference for each supported resource type that specifies attributes, their field types, and any restrictions. For more information, see the Supported Resources section of Overview of Search.

In query `conditions`, an `operation` is a comparison operator that applies to the `value` in the statement. The `value` keyword refers to the value of the `fieldName` you specified. Search evaluates whether the specified attribute of the desired resource type matches or does not

match the desired `value`, according to the operation. You must enclose a value in opening and closing straight single quotes (').

The following table describes supported operations for resource queries:

Operation	Description	Supported Field Types	Case-sensitive?	Example
=	Equals, or exact matching for strings	String, integer, rational, Boolean, date-time	No	If the `value` was '**backUp**', it would match "backup", "BACKUP", "BackUp", "backUp", or any other variation in casing.
!=	Does not equal	String, integer, rational, Boolean, date-time	No	If the `value` was '**backUp**', it would match anything that does not equal "backUp", "backup", or any other variation in casing. It also would match anything that does not contain the characters 'backup' in that order.
==	Strictly equals	String	Yes	If the `value` was '**backUp**', it would only match "backUp" and no other variation in casing.
!==	Strictly does not equal	String	Yes	If the `value` was '**backUp**', it would match "backup", "BACKup", or anything except "backUp", with that exact casing.

Operation	Description	Supported Field Types	Case-sensitive?	Example
=~	Contains	String	No	If the `value` was '**backUp**', it would match anything that equals "backup", "BACKUP", "BackUp", "backUp", or any other variation in casing, or contains those characters in that order, alongside other characters.
>=	Greater than or equal to	Integer, rational, date-time	Not applicable	For a query where you have `size >= 5` as the condition, all results have a value of **5** or greater in the field named **size**.
>	Greater than	Integer, rational, date-time	Not applicable	For a query where you have `size > 5` as the condition, all results have a value of greater than **5** in the field named **size**.
<=	Less than or equal to	Integer, rational, date-time	Not applicable	For a query where you have `size <= 5` as the condition, all results have a value of **5** or less in the field named **size**.
<	Less than	Integer, rational, date-time	Not applicable	For a query where you have `size < 5` as the condition, all results have a value of **5** or less in the field named **size**.

Date and Time Values

You can specify date and time values by using any of the following pattern string formats:

Format	Examples	Comments
<yyyy>-*<MM>*-*<dd>* *<HH>*:*<mm>*:*<ss>* *<TimeZone>*	'2018-06-19 16:15:41 PDT', '2018-06-19 16:15:41 -08:00'	`TimeZone` is optional. If `TimeZone` is omitted, UTC is used.
<EEE>, *<d>* *<MMM>* *<yyyy>* *<HH>*:*<mm>*:*<ss>* *<TimeZone>*	'Tue, 19 Jun 2018 16:15:41 +0300', '19 June 2018 16:15:41'	`TimeZone` is optional. If `TimeZone` is omitted, UTC is used.
<yyyy>-*<MM>*-*<dd>*T*<HH>*:*<mm>*:*<ss>*Z	2018-06-19T16:15:41Z	Time in UTC. '`T`' and '`Z`' are case-sensitive.

You must observe spacing. Interpret dashes, colons, commas, and the characters 'T' and 'Z' literally. To interpret placeholder values in the preceding table, you can refer to the following pattern syntax:

Letter	Date or Time Component	Presentation
`y`	Year	Year
`M`	Month in year	Month
`d`	Day in month	Day
`H`	Hour in day (from 00-23)	Number
`m`	Minute in hour	Number
`s`	Seconds in minute	Number
`E`	Day in week	Text

Repeating pattern letters indicate their exact presentation. For example, 'HH' means you must use '00' and not '0' to represent midnight. Similarly, 'EEE' means 'Tue' and not 'Tuesday'. Likewise, 'MM' requires '09' instead of '9' to represent the month of September.

`TimeZone` is optional, but in your chosen format, you can specify `TimeZone` in any of the following ways:

- **Name**. You can specify a time zone by its name, such as **GMT** or **PDT**. Values are case-insensitive.
- **GMT offset value**. You can specify a time zone according to its GMT offset. For example, **GMT-08:00**. Values are case-insensitive.
- **ISO 8601 time zone**. You can specify a time zone according to ISO 8601 standards. For example, **-08**, **-0800**, or **-08:00**.

Instead of using one of the preceding formats, you can also specify a date-time value as the constant `now`. The constant `now` represents the current time to the level of granularity of seconds in a minute.

Lastly, you can add or subtract time intervals from any date-time values. For example, you can query for resources that were created within five minutes of a specific time. Search supports the following time intervals:

Letter	Date or Time Component
`s`	Seconds
`m`	Minutes
`h`	Hours
`d`	Days
`w`	Weeks

To specify a time interval in relation to a date-time value, use one of the following formats:

- **now - 3h**
- **2018-06-19 16:15:41 PDT + 1h**

Matching

For matching purposes, instead of or in addition to using a `where` clause with `conditions`, you might want to use the `matching` clause. The `matching` clause obviates the need to specify `conditions` (that contain a field name, operation, and value). A `matching` clause effectively queries all indexed fields by applying the `=` (equals) operator along with the text you specify. However, it does so without strictly requiring an exact match. For example, the following query uses a `matching` clause to behave the same way as a free text search: `query all resources matching 'instance'`. The query produces results that match all resources and resource attributes that contain the word "instance".

Sorting

The last clause of a resource query is the `sorted by` clause and is optional. The `sorted by` clause orders the results returned by Search based on the field name and lists them according to the `order` you specify. By default, if you do not specify sort order, results are always sorted by date-time created in descending order.

In the `sorted by` clause, you can specify the following:

- `fieldName` - The field that Search uses to sort results. You can specify any field of any resource. Resources that do not contain the field you specify are listed after the resources that do.
- `order` - You can specify either **asc** or **desc**. Specifying **asc** lists results in ascending order. Specifying **desc** lists results in descending order.

Grouping Conditions

You can group multiple conditions by using either the logical operators `&&` (ampersands, to indicate a logical AND) or `||` (vertical bars, to indicate a logical OR). For example:

```
licenseModel = 'LICENSE_INCLUDED' && dataStoragePercentage > 40 && lifecycleState != 'FAILED'
```

You cannot combine two different logical operators in the same query unless you wrap parentheses around one group of predicates. (Multiple conditions can only use the same logical operator otherwise.) For example:

```
(licenseModel = 'LICENSE_INCLUDED' && dataStoragePercentage > 40) || lifecycleState != 'FAILED'
```

In the preceding example, all results returned will have either “LICENSE_INCLUDED” as the value in the field named “licenseModel” and a value greater than 40 for the field named “dataStoragePercentage” or the value of their “lifecycleState” field name is anything other than “FAILED”.

The following group is also acceptable:

```
licenseModel = 'LICENSE_INCLUDED' && (dataStoragePercentage > 40 || lifecycleState != 'FAILED')
```

In the preceding example, all results returned will have “LICENSE_INCLUDED” as the value in the field named “licenseModel” and either a value greater than 40 as the value for the field named “dataStoragePercentage” or anything that is not “FAILED” for the value of the field named “lifecycleState”.

Search does not perform left-to-right evaluation to reduce ambiguity or clarify intent.

Querying Multiple Resource Types

You can query multiple resource types at once by joining queries. Each query can have its own conditional clause. If the queries that you want to join have different "where" conditions, then the syntax is different from when you have queries for multiple resource types that share the same "where" condition.

The basic syntax for a query for multiple resource types is as follows:

```
query <resourceType>, <resourceType> resources
```

For example:

```
query group, user resources
```

The preceding example query returns all groups and all users in the tenancy.

The following shows the syntax for a query for multiple resource types with conditions, but where the conditions are the same for all resource types:

```
query <resourceType>, <resourceType> resources where <conditions>
```

For example:

```
query group, user resources where displayName = 'administrator'
```

The preceding example query returns all groups with the display name "administrator" and all users with the display name "administrator," with any variation in casing.

If you need to apply differing conditions to any resource type, you must use a `union` keyword instead of comma separation between the joined queries. The following shows the syntax for a query for multiple resource types where some of the resource types share conditions while others do not:

```
query <resourceType>, <resourceType> resources where <conditions> union <resourceType> resources
```

For example:

```
query group, user resources where displayName = 'administrator' union compartment resources
```

The preceding example returns all groups with the display name "administrator" and all users with the display name "administrator," with any variation in casing, and all compartment resources.

Or, for example:

```
query group resources union user resources where displayName = 'administrator' union compartment
resources
```

The preceding example returns all groups and all compartments. It also returns all users with the display name "administrator," with any variation in casing.

Optionally, you can add the `sorted by` clause to the end of the query to order all results in ascending or descending order.

Sample Queries

This topic provides an explanation of sample queries, including what results to expect from a given sample query. For more information about the syntax for constructing a query, see Search Language Syntax.

Example Values

Sample queries show example values for resource attributes. Replace those examples with values from your own tenancy.

Search provides the following sample queries in the Console:

- Query for everything
- Query for everything, sorted by time created
- Query for volumes and users
- Query for volumes and users, sorted by time created
- Query for volumes and users that have any indexed field matching “production," sorted by time created
- Query for all resources that have a specific freeform tag
- Query for all resources that have one of two specific defined tags
- Query for instances in a "Running" state
- Query for instances in either a "Terminated" or "Terminating" state
- Query for all resources in a specific compartment
- Query for all instances due for a maintenance reboot

Query All Resources

Query name: Query for everything

Expected results: Returns all supported resources in the tenancy across all compartments. Lists results, by default, in order of time created, from newest to oldest.

Sample query language:

```
query
 all resources
```

Query All Resources, Sort by Time Created

Query name: Query for everything, sorted by timeCreated

Expected results: Returns all supported resources in the tenancy across all compartments, listed in order of time created, from newest to oldest.

Sample query language:

```
query
 all resources
sorted by timeCreated desc
```

Query Volumes and Users

Query name: Query for volumes and users

Expected results: Returns all block volumes and users in the tenancy. Lists results, by default, in order of time created, from newest to oldest.

Sample query language:

```
query
 volume, user resources
```

Query All Volumes and Users, Sort by Time Created

Query name: Query for volumes and users, sorted by timeCreated

Expected results: Returns all block volumes and users in the tenancy, listed in order of time created, from newest to oldest

Sample query language:

```
query
 volume, user resources
sorted by timeCreated desc
```

Query Volumes and Users Matching "Production," Sorted by Time Created

Query name: Query for volumes and users, with anything matching production, sorted by timeCreated

Expected results: Returns all block volumes and users in the tenancy that have any indexed fields that exactly or partially match the search string "production", irrespective of casing. Lists results, by default, in order of time created, from newest to oldest.

Sample query language:

```
query
 volume, user resources
matching 'production'
sorted by timeCreated desc
```

Query All Resources With Specific Freeform Tags

Query name: Query for all resources that have specific freeform tags

Expected results: Returns all resources in the tenancy that have a freeform tag of "costcenter" with a value of "1234."

Sample query language:

```
query
 all resources
  where
   (freeformTags.key = 'costcenter' && freeformTags.value = '1234')
```

Query All Resources According to Defined Tags

Query name: Query for all resources that have one of two specific defined tags

Expected results: Returns all resources in the tenancy that have either a tag with the key “region” and value “phx” in the tag namespace “categorization," or all resources in the tenancy that have a tag with the key “region” and value “iad” in the namespace “categorization.” Ignores casing for all keys and values.

Sample query language:

```
query
 all resources
 where
 (definedTags.namespace = 'categorization' && definedTags.key = 'region' && definedTags.value = 'phx')
||
 (definedTags.namespace = 'categorization' && definedTags.key = 'region' && definedTags.value = 'iad')
```

Query Instances According to Specific Lifecycle State

Query name: Query for running instances

Expected results: Returns all instances in the tenancy in a "Running" state. Lists results, by default, in order of time created, from newest to oldest.

Sample query language:

```
query
 instance resources
  where lifeCycleState = 'RUNNING'
```

Query Instances According to One of Two Lifecycle States

Query name: Query for instances terminated or terminating

Expected results: Returns all instances in the tenancy in either a "Terminated" or "Terminating" state. Lists results, by default, in order of time created, from newest to oldest.

Sample query language:

```
query
 instance resources
  where lifeCycleState = 'TERMINATED' || lifeCycleState = 'TERMINATING'
```

Query All Resources According to Compartment ID

Query name: Query for all resources in a compartment

Expected results: Returns all resources in the tenancy with a specific compartment ID. Lists results, by default, in order of time created, from newest to oldest.

Sample query language:

```
query
 all resources
  where compartmentId = 'compartmentOcid'
```

Query All Instances Due for Maintenance Reboot

Query name: Query for all instances which have an upcoming scheduled maintenance reboot

Expected results: Returns all instances in the tenancy with a scheduled maintenance reboot time value of "now." Lists results, by default, in order of time created, from newest to oldest.

Sample query language:

```
query
 instance resources
  where timeMaintenanceRebootDue = 'now'
```

Query All Always Free Resources

Query name: Query for all resources that are Always Free

Expected results: Returns all resources in the tenancy that are free of charge for the life of the account. Lists results, by default, in order of time created, from newest to oldest.

Sample query language:

```
query
 all resources
  where
   systemTags.namespace = 'orcl-cloud' &&
   systemTags.key = 'free-tier-retained' &&
   systemTags.value = 'true'
```

Querying Resources

This topic describes how to find Oracle Cloud Infrastructure resources in your tenancy by performing a free text search or running a query. Queries let you find resources according to specific fields and conditions while free text searches locate resources with the desired text anywhere in the resource metadata.

Note

Supported Resources and Query Language Syntax

Search bases search results on supported resources. To see what Oracle Cloud Infrastructure services and resources Search supports, see the Supported Resources section of Overview of Search.

Furthermore, if free text search results do not produce the results you want, you might need to run a query using query language syntax. For more information about syntax for queries, see Search Language Syntax.

Using the Console

You can find resources by doing one of the following:

- typing free-form text for a free text search
- typing a query (based on resource query language syntax)
- modifying a sample query

By default, text entered into the **Search** box is interpreted as a free text search.

To perform a free text search

1. Open the Console, and then, in the top navigation bar, click **Search**.
2. Type the free-form text you want to search for, and then press ENTER.
3. In the left-hand navigation bar, under **Resource Type**, click the type of supported resource to filter query results.
4. (Optional) If you do not see the results that you expect, you can refine your search with

a query by clicking **Advanced Search**. Then, follow the instructions in To run a custom, free-form query or To run a sample query.

Except for volume backups, compartments, and subnets, you can click the display name of the resource to view details. Search results are eventually consistent, but might not immediately include resources that you created very recently.

To run a custom, free-form query

1. In the Console, if you are not already there, append "/a/query" to the end of your base Console URL. For example, https://console.us-ashburn-1.oraclecloud.com/a/query.
2. In the query text box, type a query using query language syntax, and then click **Search**.
3. In the left-hand navigation bar, under **Resource Type**, click the type of supported resource to filter query results.

Except for volume backups, compartments, and subnets, you can click the display name of the resource to view details. Query results are eventually consistent, but might not immediately include resources that you created very recently.

To run a sample query

1. In the Console, if you are not already there, append "/a/query" to the end of your base Console URL. For example, https://console.us-ashburn-1.oraclecloud.com/a/query.
2. Click **Select Sample Query**, and then click one of the listed sample queries. For an explanation of sample queries, see Sample Queries.
3. Verify that the query language in the query text box satisfies your needs. Change all example values. Add, delete, or modify clauses, as appropriate, and then click **Search**.
4. In the left-hand navigation bar, under **Resource Type**, click the type of supported resource to filter query results.

Except for volume backups, compartments, and subnets, you can click the display name of the resource to view details. Query results are eventually consistent, but might not immediately include resources that you created very recently.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the following operations to search for resources or find out what resources you can search for:

- SearchResources
- ListResourceTypes

Example: Finding Instance Resources With a Specific Defined Tag

This section describes how to use the API to query for a specific type of resource based on the resource's defined tags.

The following query will find instances with a defined tag within the namespace "rqs", where the tag's key is "costcenter" and the key's value is "1234".

```
query
 instance resources
 where
 (definedTags.namespace = 'rqs' && definedTags.key = 'costcenter' && definedTags.value = '1234')
```

When you use the SearchResources operation to issue the query, the request will look similar to the following. (This example purposefully omits the authorization header and other headers.)

```
POST /20180409/resources
Host: query.us-phoenix-1.oraclecloud.com
<authorization and other headers>
{
  "type": "Structured",
  "query": "query instance resources where (definedTags.namespace = 'rqs' && definedTags.key =
```

```
'costcenter' && definedTags.value = '1234')",
  "matchingContextType": "HIGHLIGHTS"
}
```

If your query produces results, the response will list the resources that match the resource type and tag that you specified. The response will look similar to the following:

```
{
  "items" : [ {
    "resourceType" : "Instance",
    "identifier" :
"ocid1.instance.oc1.phx.exampleawcbfhncvbh3siw2svbpgr3bopovy6hgnywfauxqo37ckdmr6hjya",

    "availabilityDomain" : "ABCd:PHX-AD-2",
    "lifecycleState" : "TERMINATED",
    "freeformTags" : { },
    "definedTags" : {
      "rqs" : {
        "costcenter" : "1234"
      }
    },
    "searchContext" : null
  }, {
    "resourceType" : "Instance",
    "identifier" :
"ocid1.compartment.oc1..examplealrskzczjqmrb3cvbj4yxdvqxahhffauxtu24tk5dhikoff4uliha",
    "compartmentId" : "ocid1.tenancy.oc1..examplea46vssm7l5wsk5qa7gg5l63cvbjep4bh6lv4fauxf4iz6ec7jzg4q",
    "timeCreated" : "2018-11-29T23:40:29.005Z",
    "displayName" : "test_unused",
    "availabilityDomain" : null,
    "lifecycleState" : "AVAILABLE",
    "freeformTags" : { },
    "definedTags" : {
      "rqs" : {
```

```
        "costcenter" : "1234"
      }
    },
    "searchContext" : null
  } ]
}
```

With these results, you can take additional action, if needed. For more information about a resource type, such as its attributes, see its reference page in the API Reference Guide. For the reference pages of resource types that have been indexed for Search, see Supported Resources.

Troubleshooting Search

This topic covers common issues related to Search and how you can address them:

- Query or Search Results are Not as Expected

Query or Search Results are Not as Expected

There are several reasons why you might not see results that you expect from a search or query.

Not all resource types have been indexed for Search. For a list of currently supported resource types, see Supported Resources.

You might not have the required permissions for the resource type that you want to view in search or query results. If there's no policy that grants you the permissions you need, then an administrator must create one for you or add you to a group that's already named in a policy. For more information, see Details for Search.

The query syntax you used might need adjustment. Verify that the conditions in your query language haven't restricted the results to a narrower set than you intended.

If you recently created a resource, it might not show up in search results immediately. Similarly, if you recently updated a resource, your changes might not immediately appear. At times, you might see a resource in a list view before you can see it in search results. The Search service is eventually consistent. Wait, and then try again.

CHAPTER 29 Security Guide and Announcements

This section of the Oracle Cloud Infrastructure documentation provides a guide to help you securely configure services and resources, and timely announcements relevant to emerging security issues.

- Oracle Cloud Infrastructure Security Guide
- Oracle Cloud Security Response to Intel L1TF Vulnerabilities
- Oracle Cloud Security Response to Intel Microarchitectural Data Sampling (MDS) Vulnerabilities

Oracle Cloud Infrastructure Security Guide

Oracle Cloud Infrastructure enables enterprises to maximize the number of mission-critical workloads that they can migrate to the cloud while continuing to maintain their desired security posture and reduce the overhead of building and operating data-center infrastructure. With Oracle Cloud Infrastructure, enterprise customers get unparalleled control of and transparency into their applications running in the cloud, including:

- Customer isolation that allows you to deploy your application and data assets in an environment that commits full isolation from other tenants and Oracle's staff, as well as between the same tenant's workloads.
- Always-on encryption that protects customer data at-rest and HTTPS-only public APIs.
- Easy-to-use security policy that allows you to constrain access to your services and segregate operational responsibilities to reduce risk associated with malicious and accidental user actions.
- Comprehensive log data that allows you to audit and monitor actions on your resources, helping you to meet your audit requirements while reducing security and operational risk.
- Identity federation that allows you to use your existing users and groups in the cloud.

- Support for bringing in third-party software solutions for protecting customer data and resources in the cloud.
- Fault-independent data centers that enable high availability scale-out architectures and are resilient against network attacks, ensuring constant uptime in the face of disaster and security attack.
- Rigorous internal processes and use of effective security controls in all phases of cloud service development and operation.
- Adherence to Oracle's strict security standards through third-party audits, certifications, and attestations. Oracle helps customers demonstrate compliance readiness to internal security and compliance teams, their customers, auditors, and regulators.

All of the Oracle Cloud Infrastructure security capabilities have been designed with one goal in mind: allowing you to run your mission-critical workloads in the cloud with complete control and confidence. Oracle continues to invest in the above areas and more to offer unmatched security and assurance to enterprise customers.

For an overview of Oracle Cloud Infrastructure's security, see Security Overview.

For service-specific best practices and policy examples, see Security Best Practices .

Security Overview

Oracle's mission is to build cloud infrastructure and platform services for your business to have effective and manageable security to run your mission-critical workloads and store your data with confidence.

Oracle Cloud Infrastructure's security approach is based on seven core pillars. Each pillar has multiple solutions designed to maximize the security and compliance of the platform.

CUSTOMER ISOLATION

Allow customers to deploy their application and data assets in an environment that commits full isolation from other tenants and Oracle's staff.

DATA ENCRYPTION

Protect customer data at-rest and in-transit in a way that allows customers to meet their security and compliance requirements for cryptographic algorithms and key management.

SECURITY CONTROLS

Offer customers effective and easy-to-use security management solutions that allow them to constrain access to their services and segregate operational responsibilities to reduce risk associated with malicious and accidental user actions.

VISIBILITY

Offer customers comprehensive log data and security analytics that they can use to audit and monitor actions on their resources, allowing them to meet their audit requirements and reduce security and operational risk.

SECURE HYBRID CLOUD

Enable customers to use their existing security assets, such as user accounts and policies, as well as third-party security solutions when accessing their cloud resources and securing their data and application assets in the cloud.

HIGH AVAILABILITY

Offer fault-independent data centers that enable high availability scale-out architectures and are resilient against network attacks, ensuring constant uptime in the face of disaster and security attack.

VERIFIABLY SECURE INFRASTRUCTURE

Follow rigorous processes and use effective security controls in all phases of cloud service development and operation. Demonstrate adherence to Oracle's strict security standards through third-party audits, certifications, and attestations. Help customers demonstrate compliance readiness to internal security and compliance teams, their customers, auditors, and regulators.

Also, Oracle employs some of the world's foremost security experts in information, database, application, infrastructure, and network security. By using Oracle Cloud Infrastructure, our customers directly benefit from Oracle's deep expertise and continuous investments in security.

Basic Security Considerations

The following principles are fundamental to using any application securely:

- Keep software up-to-date. This includes the latest product release and any patches that apply to it.
- Limit privileges as much as possible. Users should be given only the access necessary to perform their work. User privileges should be reviewed periodically to determine relevance to current work requirements.
- Monitor system activity. Establish who should access which system components, and how often, and monitor those components.
- Learn about and use the Oracle Cloud Infrastructure security features. For more information, see Security Services and Features.
- Use secure best practices. For more information, see Security Best Practices .
- Keep up-to-date on security information. Oracle regularly issues security-related patch updates and security alerts. Install all security patches as soon as possible. See the Critical Patch Updates and Security Alerts website.

Understanding the Oracle Cloud Infrastructure Environment

When planning your Oracle Cloud Infrastructure deployment, consider the following:

WHICH RESOURCES MUST BE PROTECTED?

- Protect customer data, such as credit card numbers.
- Protect internal data, such as proprietary source code.
- Protect system components from being disabled by external attacks or intentional system overloads.

WHO ARE YOU PROTECTING DATA FROM?

For example, you must protect your subscribers' data from other subscribers, but someone in your organization needs to access that data to manage it. Analyze your workflows to determine who needs access to the data. Consider carefully how much access to give a

system administrator; it is possible that a system administrator can manage your system components without needing to access the system data.

WHAT WILL HAPPEN IF PROTECTIONS ON A STRATEGIC RESOURCE FAIL?

Sometimes, a fault in your security scheme is nothing more than an inconvenience. In other cases, a fault might cause great damage to you or your customers. Understanding the security ramifications of each resource will help you protect it properly.

Shared Security Model

Oracle Cloud Infrastructure offers best-in-class security technology and operational processes to secure its enterprise cloud services. However, for you to securely run your workloads in Oracle Cloud Infrastructure, you must be aware of your security and compliance responsibilities. By design, Oracle provides security of cloud infrastructure and operations (cloud operator access controls, infrastructure security patching, and so on), and you are responsible for securely configuring your cloud resources. Security in the cloud is a shared responsibility between you and Oracle.

In a shared, multi-tenant compute environment, Oracle is responsible for the security of the underlying cloud infrastructure (such as data-center facilities, and hardware and software systems) and you are responsible for securing your workloads and configuring your services (such as compute, network, storage, and database) securely.

In a fully isolated, single-tenant, bare metal server with no Oracle software on it, your responsibility increases as you bring the entire software stack (operating systems and above) on which you deploy your applications. In this environment, you are responsible for securing your workloads, and configuring your services (compute, network, storage, database) securely, and ensuring that the software components that you run on the bare metal servers are configured, deployed, and managed securely.

More specifically, your and Oracle's responsibilities can be divided into the following areas:

- **Identity and Access Management (IAM):** As with all Oracle cloud services, you should protect your cloud access credentials and set up individual user accounts. You are responsible for managing and reviewing access for your own employee accounts

and for all activities that occur under your tenancy. Oracle is responsible for providing effective IAM services such as identity management, authentication, authorization, and auditing.

- **Workload Security:** You are responsible for protecting and securing the operating system and application layers of your compute instances from attacks and compromises. This protection includes patching applications and operating systems, operating system configuration, and protection against malware and network attacks. Oracle is responsible for providing secure images that are hardened and have the latest patches. Also, Oracle makes it simple for you to bring the same third-party security solutions that you use today.
- **Data Classification and Compliance:** You are responsible for correctly classifying and labeling your data and meeting any compliance obligations. Also, you are responsible for auditing your solutions to ensure that they meet your compliance obligations.
- **Host Infrastructure Security:** You are responsible for securely configuring and managing your compute (virtual hosts, containers), storage (object, local storage, block volumes), and platform (database configuration) services. Oracle has a shared responsibility with you to ensure that the service is optimally configured and secured. This responsibility includes hypervisor security and the configuration of the permissions and network access controls required to ensure that hosts can communicate correctly and that devices are able to attach or mount the correct storage devices.
- **Network Security:** You are responsible for securely configuring network elements such as virtual networking, load balancing, DNS, and gateways. Oracle is responsible for providing a secure network infrastructure.
- **Client and Endpoint Protection:** Your enterprise uses various hardware and software systems, such as mobile devices and browsers, to access your cloud resources. You are responsible for securing all clients and endpoints that you allow to access Oracle Cloud Infrastructure services.
- **Physical Security:** Oracle is responsible for protecting the global infrastructure that runs all of the services offered in Oracle Cloud Infrastructure. This infrastructure

consists of the hardware, software, networking, and facilities that run Oracle Cloud Infrastructure services.

For information about using security credentials to access Oracle Cloud Infrastructure, see Security Credentials.

Infrastructure Security

Our security model is built around people, process, tooling, and a common security "platform" of methodologies and approaches from which we build our products. We apply this model to our core security components of Security Culture, Security Design and Controls, Secure Software Development, Personnel Security, Physical Security, and Security Operations that we use to protect and secure our customers and business.

Security Culture

We believe that a dynamic security-first culture is vital to building a successful security-minded organization. We have cultivated a holistic approach to security culture in which all our team members internalize the role that security plays in our business and are actively engaged in managing and improving our products' security posture. We have also implemented mechanisms that assist us in creating and maintaining a security-aware culture.

- **Security-minded leadership:** Our senior leadership is actively involved in our security planning, monitoring and management. We define and measure ourselves against security metrics and include security as a component of our team evaluation processes.
- **Embedded expertise:** To help with driving security practices within our team, we have an embedded security-engineering model with security team members sitting and working with our product development teams. This approach enables our security organization to build deep understanding of the product-development processes and system architectures. We are also able to better assist teams in solving security challenges in real time and drive security initiatives more effectively.
- **Common security standards:** We actively work to integrate security into our products and operations. One way we have done this is to establish a security standards baseline. Our objective in creating this baseline is to provide a single security point of

reference for business that establishes clear and actionable guidelines. The security baseline is updated frequently to incorporate learned lessons and reflect emerging business factors. We have also created a series of support materials to assist our teams in implementing security controls including reference architectures, implementation guides, and access to security experts.

- **Values of openness, constructive debate, and encouraged escalation:** Security issues can be addressed only when the people who can fix them are aware of them. We believe that openness and transparency, constructive debate, and encouraged escalation make us stronger. We encourage escalation, and we work to create an environment where raising issues early and often is rewarded.
- **Security training awareness:** We maintain robust security and awareness training programs that raise awareness and reinforce our security culture. We require in-depth security training sessions for all new employees as well as annual refresher trainings, and we provide security training that is tailored to our employees' specific job roles. All our software developers undergo a secure development training that establishes baseline security requirements for product development and provides best practices. We also work to provide engaging and innovative forms of security awareness training such as guest speakers and interactive forums (and we're not above providing food, drinks, or swag to drive attendance).

Security Designs and Controls

Security is integrated into our products and operations through our Oracle Cloud Infrastructure Methodology. This centralized methodology defines our approach for the core security areas that form the security foundation from which we build our products. This approach lends itself to agility and helps us apply best practices and lessons learned from one product across the business, thus raising the security of all our products.

- **User authentication and access control:** Least-privilege access is used to grant access to production systems, and the approved lists of service team members are periodically reviewed to revoke access when there is no justifiable need. Access to production environments requires multi-factor authentication (MFA). The MFA tokens are granted by the security team, and tokens of inactive members are disabled. All access to production systems is logged, and the logs are stored for security analysis.

- **Change management:**Oracle Cloud Infrastructure follows a defined and rigorous change management and deployment process that uses purpose-built proprietary testing and deployment tools. All changes deployed into our production environment follow a testing and approval process prior to release. This process is designed to ensure that changes operate as intended, and can otherwise be rolled back to a previous known good state to recover gracefully from unforeseen bugs or operational issues. We also track the integrity of critical system configurations to ensure that they align with expected state.
- **Vulnerability management:** We use both internal penetration testing teams and external industry experts to help us identify potential vulnerabilities in our products. These exercises help us improve the security of our products, and we work to incorporate the lessons that we learn into our future development work. Oracle Cloud Infrastructure hosts undergo periodic vulnerability scanning using industry-standard scanners. Scan results are triaged to validate applicability of findings to the Oracle Cloud Infrastructure environment, and that applicable findings are patched by our product teams.
- **Incident response:** We have developed strong processes and mechanisms to enable us to respond to and address incidents as they arise. We maintain 24/7 incident response teams ready to detect and respond to events. Our critical staff members carry paging devices that enable us to call on the expertise needed to bring issues to resolution. We have also built a process to help us learn from our incidents. We perform root cause analysis through our Corrective Action/Preventative Action (CAPA) process. CAPAs are intended to discover process gaps and changes that should be made by the business after an incident. CAPAs act as a common language that we can use to reflect on an issue and capture concrete steps to improve future operational readiness. CAPAs capture the root cause of an issue, what is required to contain or fix the issue, and what steps we must take to ensure that the issue does not recur. Our leadership team reviews all CAPAs, looks for cross-organizational applications for learned lessons, and ensures that actions are implemented in a timely manner.
- **Security logging and monitoring:** We have created automated mechanisms to log various security-relevant events (for example, API calls and network events) in the

infrastructure, and monitor the logs for anomalous behavior. Alerts generated by monitoring mechanisms are tracked and triaged by the security team.

- Network security: By default, customer communications with Oracle Cloud Infrastructure services are done using the latest TLS ciphers and configuration to secure customer data in transit, and hinder any man-in-the-middle attacks. As a further defense in depth, customer commands to the services are digitally signed using public keys, to prevent any tampering. The services also deploy proven, industry-leading tools and mechanisms to mitigate distributed denial of service (DDoS) attacks and maintain high availability.
- **Control plane security:**Oracle Cloud Infrastructure back-end (control plane) hosts are securely isolated from customer instances by using network ACLs. Provisioning and management of customer instances are done by software agents that must interact with the backend hosts. Only authenticated and authorized software agents can successfully interact with Oracle Cloud Infrastructure back-end hosts. For back-end hosts, pre-production environments (for example, dev, test, and integ) are separated from production environments so that any development and test activities do not have any impact on production systems.
- **Server security and media management:** Oracle has a long history of enterprise-class secure hardware development. Our Hardware Security team is responsible for designing and testing the security of the hardware used to deliver Oracle Cloud Infrastructure services. This team works with our supply chain and tests hardware components to validate them against rigorous Oracle Cloud Infrastructure hardware security standards. This team also works closely with our product development functions to ensure that hardware can be returned to a pristine, safe state after being released by customers.
- **Secure host wipe and media destruction:**Oracle Cloud Infrastructure instances are securely wiped after hardware is released by customers. This secure wipe restores hardware to a pristine state. We have re-engineered the platform with proprietary hardware components that allow us to wipe and reinitialize the hardware in a secure manner. When the underlying hardware has reached end-of-life, it is securely destroyed. Before leaving our data centers, drives are rendered unusable by using industry-leading media destruction devices.

Secure Software Development

Secure product development requires consistently applied methodologies that conform to clear security objectives and principles. We build security practices into every element of our product development life cycle. Oracle employs formal secure product development standards that are a roadmap and guide for developers. These standards discuss general security knowledge areas such as design principles and common vulnerabilities, and provide specific guidance on topics such as data validation, data privacy, and user management.

Oracle secure product development standards have evolved and expanded over time to address the common issues affecting code, new threats as they are discovered, and new use cases by Oracle customers. The standards incorporate insights and learned lessons; they do not live in a vacuum, nor are they an "after the fact" addendum to software development. They are integral to language-specific standards such as C/C++, Java, PL/SQL, and others, and are a cornerstone to Oracle's secure development programs and processes.

Security assurance analysis and testing verify security qualities of Oracle products against various types of attacks. There are two broad categories of tests employed for testing Oracle products: static and dynamic analysis. These tests fit differently in the product development lifecycle and tend to find different categories of issues, so they are used together by Oracle product teams.

Personnel Security

Our people make our business. We strive to hire the best, and we invest in and continue to develop our employees. We value training, and we require not only baseline security training for all our employees but also specialized training to keep our teams abreast of the latest security technologies, exploits, and methodologies. In addition to standard annual corporate training programs that cover our information security and privacy programs (among many others), we engage with a broad spectrum of industry groups and send our employees to specialist conferences to collaborate with other industry experts on emerging challenges. The objectives of our security training programs are to help our employees better protect our customers and products, to enable employees to grow in their knowledge areas around security, and to further our mission to attract and retain the best talent.

We work to recruit the best talent for our team as we grow, and we hire people with strong ethics and good judgment. All our employees undergo pre-employment screening as

permitted by law, including criminal background checks and prior-employment validation. We also maintain performance evaluation processes to recognize good performance and help our teams and employees identify opportunities for growth. We maintain both team and employee evaluation processes, and we use security as a component of our team evaluation processes. This approach provides our teams and leadership visibility into how our teams are performing against our security standards and enables us to identify best practices and improvement areas for critical security processes.

PHYSICAL SECURITY

Oracle Cloud Infrastructure data centers are designed for security and availability of customer data. This approach begins with our site selection process. Candidate build sites and provider locations undergo an extensive risk evaluation process that considers environmental threats, power availability and stability, vendor reputation and history, neighboring facility functions (for example, high-risk manufacturing or high-threat targets), and geopolitical considerations, among other criteria.

Oracle Cloud Infrastructure data centers align with Uptime Institute and Telecommunications Industry Association (TIA) ANSI/TIA-942-A Tier 3 or Tier 4 standards and follow a N2 redundancy methodology for critical equipment operation. Data centers housing Oracle Cloud Infrastructure services use redundant power sources and maintain generator backups in case of widespread electrical outage. Server rooms are closely monitored for air temperature and humidity, and fire suppression systems are in place. Data center staff are trained in incident response and escalation procedures to address security or availability events that may arise.

We take a layered approach to physical security that starts with the site build. Oracle Cloud Infrastructure data center facilities are durably built with steel, concrete, or comparable materials and are designed to withstand impact from a light vehicle strike. Our sites are staffed with security guards who are ready to respond to incidents 24 hours a day, 7 days a week, 365 days a year. The exterior of the sites is secured with perimeter barriers and vehicle checks are actively monitored by a guard force and cameras that cover the building perimeter.

All persons entering our data centers must first go through a layer of security at the site entrances, which are staffed with security guards. Persons without site-specific security badges entering the site must present government-issued identification and have an approved

access request granting them access to the data center building. All employees and visitors must wear visible, official identification badges at all times. There are additional security layers between the entrance and server rooms that vary depending on the site build and risk profile. Data center server rooms are built with additional security layers including cameras that cover server rooms, two-factor access control, and intrusion-detection mechanisms. Physical barriers are in place to create isolated security zones around server and networking racks that span from the floor (including below the raised floor where applicable) to the ceiling (including above ceiling tiles where applicable).

Access to Oracle Cloud Infrastructure data centers is carefully controlled and follows a least-privilege access approach. All access to server rooms must be approved by authorized personnel and is granted only for the necessary period. Access usage is audited, and access provisioned within the system is periodically reviewed by data-center leadership. Server rooms are isolated into secure zones that are managed on a zone-by-zone basis, and access is provisioned only for those zones required by personnel.

Security Operations

The Oracle Cloud Infrastructure Security Operations team is responsible for monitoring and securing the unique Oracle Cloud Infrastructure hosting and virtual networking technologies. The team works and trains directly with the Oracle engineers who develop these technologies to leverage the unique security and introspection capabilities they provide.

We monitor emerging internet security threats daily and implement appropriate response and defense plans to address risks to the business. When we determine that urgent changes are recommended that are within the scope of the customers' responsibilities, we issue security alert bulletins to those customers to ensure their protection.

In the case of a detected or reported security issue that affects Oracle Cloud Infrastructure servers or networks, Security Operations staff is available 24/7 to respond, escalate, or take required corrective action. When necessary, we will escalate and coordinate with external parties (including network and hosting service providers, hardware vendors, or law enforcement) to protect Oracle Cloud Infrastructure, our customers, and our network's security and reputation.

All actions performed in response to a security issue by the Security Operations team are done according to our documented process, and are logged in accordance with compliance

requirements. Care is always taken to protect the goals of service and data integrity, privacy, and business continuity.

Customer Data Protection

Data Rights and Ownership

Oracle Cloud Infrastructure customers retain all ownership and intellectual property rights in and to their content. Customer data protection is critically important, and we strive to be transparent with our data protection processes as well as law enforcement requests that we might receive.

Data Privacy

Oracle complies with the EU-U.S. Privacy Shield Framework as set forth by the U.S. Department of Commerce regarding the collection, use, and retention of personal information transferred from the European Union to the United States. Oracle is also responsible for ensuring that third parties who act as an agent on our behalf do the same.

Oracle has certified to the Department of Commerce that it adheres to the Privacy Shield Principles. If there is any conflict between the terms in our privacy policy and the Privacy Shield Principles, the Privacy Shield Principles shall govern. To learn more about the Privacy Shield program, and to view our certification, visit https://www.privacyshield.gov/list.

For personal information received or transferred pursuant to the Privacy Shield Framework, Oracle is subject to the regulatory enforcement powers of the U.S. Federal Trade Commission.

Oracle continues to adhere to the underlying European privacy principles of the U.S.-Swiss Safe Harbor for the processing of Personal Information received from Switzerland. To learn more about the Safe Harbor program, and to view our certification, visit https://safeharbor.export.gov/swisslist.aspx.

Law Enforcement Requests

Except as otherwise required by law, Oracle will promptly notify customers of any subpoena, judicial, administrative or arbitral order of an executive or administrative agency or other governmental authority that it receives and which relates to the personal data Oracle is

processing on the customer's behalf. Upon customer request, Oracle will provide customers with reasonable information in its possession relevant to the law enforcement request and any assistance reasonably required for them to respond to the request in a timely manner.

COMPLIANCE

Oracle Cloud Infrastructure is built for enterprises. We operate under practices aligned with the ISO/IEC 27002 Code of Practice for information security controls, from which we have identified a comprehensive set of security controls that apply to our business. Oracle Cloud Infrastructure is still a new product line, and we must operate for a period of time in order for these security controls and our operations to undergo external audit. As an enterprise cloud, we plan to pursue a broad suite of industry and government certifications, audits, and regulatory programs.

Security Services and Features

A key objective of Oracle Cloud Infrastructure is to allow you to create a logical extension of your on-premises infrastructure and data centers in Oracle Cloud Infrastructure. You can gain the benefits of a modern public cloud without having to compromise or reinvent your existing security posture. This idea was central to the design of all our infrastructure and services.

Regions and Availability Domains

To provide data availability and durability, Oracle Cloud Infrastructure enables you to select from infrastructure with distinct geographic and threat profiles. A region is the top-level component of the infrastructure. Each region is a separate geographic area with multiple, fault-isolated locations called availability domains. An availability domain is the subcomponent of a region and is independent and highly reliable. Each availability domain is built with fully independent infrastructure: buildings, power generators, cooling equipment, and network connectivity. With physical separation comes protection against natural and other disasters. Availability domains within the same region are connected by a secure, high-speed, low-latency network, which allows customers to build and run highly reliable applications and workloads with minimum impact to application latency and performance. All links between availability domains are encrypted. Each region has one or more availability domains, each allowing customers to deploy highly available applications.

Identity and Access Management (IAM) Service

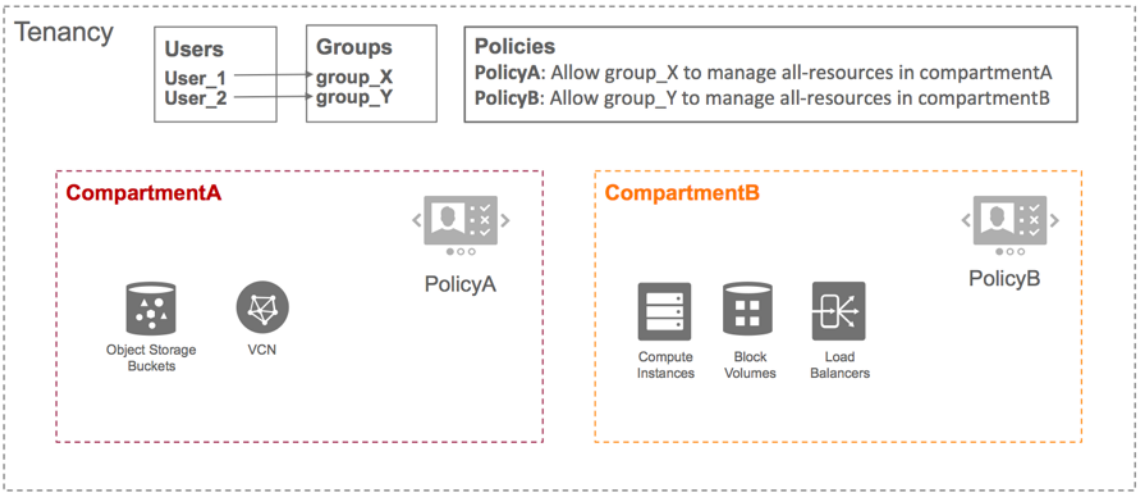
The Oracle Cloud Infrastructure Identity and Access Management (IAM) service is built to meet the requirements of enterprises, and it provides authentication and authorization for all their Oracle Cloud Infrastructure resources and services. An enterprise can use a single tenancy shared by various business units, teams, and individuals while maintaining security, isolation, and governance.

When a customer joins Oracle Cloud Infrastructure, a tenancy is created. A tenancy is a virtual construct that contains all of the Oracle Cloud Infrastructure resources that belong to the customer. The administrator of the tenancy can create users and groups and assign them least-privileged access to resources that are partitioned into compartments. A compartment is a group of resources that can be managed as a single logical unit, providing a streamlined way to manage large infrastructure. For example, a customer can create a compartment (`HR-Compartment`) to host a specific set of cloud network, compute instances, and storage volumes necessary to host its HR applications. Compartments are a fundamental component of Oracle Cloud Infrastructure for organizing and isolating cloud resources. Customers use them to clearly separate resources for the purposes of isolation (separating the resources for one project or business unit from another). A common approach is to create a compartment for each major part of an organization. Unlike most Oracle Cloud Infrastructure services that are regionally scoped, the IAM service resources are global. Customers can have a single tenancy across multiple regions.

The following are key IAM primitives:

- **Resource:** A cloud object that a company's employees create and use when interacting with Oracle Cloud Infrastructure services, for example, compute instances, block storage volumes, virtual cloud networks (VCNs), subnets, and route tables.
- **Policy:** A set of authorization rules that define access to resources within a tenancy.
- **Compartment:** A heterogeneous collection of resources for the purposes of security isolation and access control.
- **Tenancy:** The root compartment that contains all of an organization's resources. Within a tenancy, administrators can create one or more compartments, create more users and groups, and assign policies that grant groups the ability to use resources within a compartment.

- **User:** A human being or system that needs access to manage their resources. Users must be added to groups in order to access resources. Users have one or more credentials that must be used to authenticate to Oracle Cloud Infrastructure services. Federated users are also supported.
- **Group:** A collection of users who share a similar set of access privileges. Administrators can grant access policies that authorize a group to consume or manage resources within a tenancy. All users in a group inherit the same set of privileges.
- **Identity Provider:** A trusted relationship with a federated identity provider. Federated users who attempt to authenticate to the Oracle Cloud Infrastructure console are redirected to the configured identity provider. After successfully authenticating, federated users can manage Oracle Cloud Infrastructure resources in the console just like a native IAM user. Currently, Oracle Cloud Infrastructure supports the Oracle Identity Cloud Service and Microsoft Active Directory Federation Service (ADFS) as identity providers. Federated groups are mapped to native IAM groups to define the policies apply to a federated user.



All customer calls to access Oracle Cloud Infrastructure resources are first authenticated by the IAM service (or federated provider) and then authorized based on IAM policies. A customer can create a policy that gives a set of users permission to access the infrastructure resources (network, compute, storage, and so on) within a compartment in the tenancy.

These policies are flexible and are written in a human-readable form that is easy to understand and audit. A policy contains one or more policy statements that follow this easy-to-understand syntax:

```
Allow group <group_name> to <verb> <resource-type> in compartment <compartment_name>
```

A verb defines the type of access covered. Oracle defines the following verbs that you can use in your policy statements:

- **inspect:** Provides the ability to list resources, without access to any confidential information or user-specified metadata that might be part of that resource.
- **read:** Includes inspect plus the ability to get user-specified metadata and the actual resource itself.
- **use:** Includes read plus the ability to work with existing resources (the actions vary by resource type). Includes the ability to update the resource, except for resource types where the update operation has the same effective impact as the create operation (for example, `UpdatePolicy` and `UpdateSecurityList`). In such cases, the update ability is available only with the manage verb. In general, this verb does not include the ability to create or delete that type of resource.
- **manage:** Includes all permissions for the resource.

The following example policy enables the `GroupAdmins` group to create, update, or delete any groups:

```
Allow group GroupAdmins to manage groups in tenancy
```

Each user has one or more of the following credentials to authenticate themselves to Oracle Cloud Infrastructure. Users can generate and rotate their own credentials. In addition, a tenancy security administrator can reset credentials for any user within their tenancy.

- **Console password:** Used to authenticate a user to the Oracle Cloud Infrastructure Console.
- **API key:** All API calls are signed using a user-specific 2048-bit RSA private key. The user creates a public key pair, and uploads the public key in the Console.
- **Auth token:** Auth tokens are Oracle-generated token strings that you can use to authenticate with third-party APIs that do no support Oracle Cloud Infrastructure's

signature-based authentication. For example, use an auth token to authenticate with a Swift client. To ensure sufficient complexity, the token is created by the IAM service and cannot be provided by a customer.

- **Customer secret key:** Used by Amazon S3 clients to access the Object Storage service's S3-compatible API. To ensure sufficient complexity, the password is created by the IAM service and cannot be provided by a customer.

Audit Service

The Oracle Cloud Infrastructure Audit service records all API calls to resources in a customer's tenancy as well as login activity from the graphical management Console. Using the Audit service, customers can achieve their own security and compliance goals by monitoring all user activity within their tenancy. Because all Console, SDK, and command line (CLI) calls go through our APIs, all activity from those sources is included. Audit records are available through an authenticated, filterable query API or can be retrieved as batched files from Oracle Cloud Infrastructure Object Storage. Audit log contents include what activity occurred, the user that initiated it, the date and time of the request, as well as source IP, user agent, and HTTP headers of the request.

Compute Service

Compute is a core component of Oracle Cloud Infrastructure and provides on-demand and elastic compute capabilities with enterprise-grade security and performance. Customers can provision thousands of compute instances and scale them up or down through an easy-to-use web-based management console. Programmatic support to do the same is available through feature-rich SDKs and command-line interfaces (CLIs). All compute instances are hosted in Oracle enterprise-grade data centers.

Compute instances are based on high-performance server hardware that uses latest-generation, multi-core server CPUs, large amounts of memory, and high-throughput NVMe local storage. Oracle Cloud Infrastructure provides bare metal (BM) and virtual machine (VM) instances. Customers can choose instances that fit their performance, cost, and software flexibility requirements.

- **Bare metal instances:** In bare metal instances, physical servers are dedicated to a single customer who has complete control over the server. There is no Oracle-managed hypervisor and Oracle personnel have no access to memory or local (NVMe) storage while the instance is running. All network virtualization is performed off-box and only the Oracle Integrated Lights Out Manager (ILOM) is accessible to the infrastructure (required in order to remotely reboot or reprovision instances). These bare metal instances offer consistent high performance and are immune to any noisy-neighbor issues. Customers have OS-level administrative privileges to the bare metal instance. After a customer terminates their bare metal instance, the server undergoes an automated disk and firmware-level wipe process to ensure isolation between customers.
- **Virtual machine (VM) instances:** Customers with flexibility requirements or those who don't need a dedicated bare metal instance can opt for VMs. Multi-tenant customer VMs in Oracle Cloud Infrastructure are managed by a security hardened hypervisor that provides strong isolation between customers.

Oracle Cloud Infrastructure instances use key-based SSH by default. Customers provide the SSH public keys to Oracle Cloud Infrastructure and securely use the SSH private keys for accessing the instances. Oracle recommends using key-based SSH to access Oracle Cloud Infrastructure instances. Password-based SSH could be susceptible to brute-forcing attacks, and are not recommended.

Oracle Linux images hardened with the latest security updates are available for you to run on Oracle Cloud Infrastructure instances. Oracle Linux images run the Unbreakable Enterprise Kernel (UEK) and support advanced security features such as Ksplice to apply security patches without booting, which allows enterprises to live-update their instances without any disruption. In addition to Oracle Linux, Oracle Cloud Infrastructure makes a growing list of other OS images available, including CentOS, Ubuntu, and Windows Server. You can also bring your own custom images. All Oracle-provided images come with secure defaults including OS-level firewalls turned on by default.

Networking Service

High-throughput and reliable networking is fundamental to public-cloud infrastructure that delivers compute and storage services at scale. As a result, we invested significant innovation

in Oracle Cloud Infrastructure networking to support requirements of enterprise customers and their workloads. Oracle Cloud Infrastructure regions have been built with a state-of-the-art, non-blocking Clos network that is not over-subscribed and provides customers with a predictable, high-bandwidth, low latency network. The data centers in a region are networked to be highly available and have low-latency connectivity between them.

The Oracle Cloud Infrastructure Networking service offers a customizable private network (a VCN, or virtual cloud network) to customers, which enforces logical isolation of customer Oracle Cloud Infrastructure resources. As with their on-premises network in their data centers, customers can set up a VCN with hosts with private IP addresses, subnets, route tables and gateways using VCN. The VCN can be configured for internet connectivity, or connected to the customer's private data center through an IPSec VPN gateway or FastConnect. FastConnect offers a private connection between an existing network's edge router and Dynamic Routing Gateways (DRG). Traffic does not traverse the internet.

The Networking service also supports bi-directional, stateful and stateless firewalls that allow customers to initialize network security access controls. Firewalls and ACLs specified for a customer VCN are propagated throughout the network topology and control plane, ensuring a multi-tiered and defense-in-depth implementation. Each tenant (customer) can create multiple VCNs to implement logical grouping of their resources.

The following are key networking concepts associated with a VCN:

- **Subnets:** The primary subdivision of a VCN. Subnets have historically been specific to an availability domain, but can now be regional (covering all availability domains in the region). Subnets can be marked as private upon creation, which prevents instances launched in that subnet from having public IP addresses.
- **Internet gateway:** A virtual router that provides public internet connectivity from a VCN. By default, a newly created VCN has no internet connectivity.
- **Dynamic routing gateway:** A virtual router that provides a path for private traffic between a VCN and a data center’s network. It is used with an IPSec VPN or Oracle Cloud Infrastructure FastConnect connection to establish private connectivity between a VCN and an on-premises or other cloud network.

- **NAT gateway:** A virtual router that gives cloud resources without public IP addresses access to the internet without exposing those resources to incoming internet connections.
- **Service gateway:** A virtual router that gives cloud resources private access to Oracle services such as Object Storage without using an internet gateway or NAT gateway.
- **Routing tables:** Virtual routing tables that give the subnets access to the VCN's gateways (Internet Gateway and Dynamic Routing Gateway). Routes can also use private IPs as a target to implement network functionality such as NAT, firewalls, IDS, and so on.
- **Primary VNICs:** Subnets contain virtual network interface cards (VNICs) that attach to instances. The VNIC determines how the instance connects with endpoints inside and outside the VCN. Each instance has a primary VNIC that is created during instance launch and cannot be removed. During instance launch, the Networking service also assigns a public IP address. Customers can override that behavior during instance launch and request to have no public IP address assigned.
- **Secondary VNICs:** VNICs with public and private IP addresses that can be attached to an instance. In a bring-your-own-hypervisor (BYOH) scenario, where customers can run their hypervisor on a BM instance, a secondary VNIC can be assigned to a VM, to allow VCN networking for the VM. This is very useful for running virtual security appliances in a VCN.
- **IPSec VPN connection:** A secure VPN connection between a VCN and a data center.
- **Security lists:** Virtual firewall rules that define allowed ingress and egress to an instance at the packet level. Individual rules can be defined to be stateful or stateless.

Virtual firewalls are implemented by using VCN security lists. Customers can specify a set of firewall rules and associate them with one or more subnets. Associating a security list with a subnet applies those firewall rules to all instances running inside the subnet, at the packet level. There are two types of firewall rules:

- **Ingress rules:** Ingress rules specify the source (IP CIDR and port range), destination port range, and protocol to match on, and are applied to ingress network connections.

- **Egress rules:** Egress rules specify the destination (IP CIDR and port range), source port range, and protocol to match on, and are applied to egress network connections.

Every VCN has a default security list customers may optionally use that allows only SSH and certain types of important ICMP ingress traffic, and all egress traffic. Customers can associate multiple security lists with a subnet. The subnet uses the default security list if the customer doesn't specify another list for the subnet to use.

For further information about security in the Networking service, see:

- Ways to Secure Your Network
- Access Control
- Security Lists

Storage Services

Oracle Cloud Infrastructure offers multiple storage solutions to meet the performance and durability requirements of customers:

- Local Storage: NVMe-backed storage on compute instances, offering extremely high IOPS.
- Block Volumes: Network-attached storage volumes, attachable to compute instances.
- Object Storage: Regional service for storing large amounts of data as objects, providing strong consistency and durability.

The Oracle Cloud Infrastructure Block Volumes service provides persistent storage that can be attached to compute instances using the iSCSI protocol. The volumes are stored in high-performance network storage and support automated backup and snapshot capabilities. Volumes and their backups are accessible only from within a customer's VCN and are encrypted at rest using unique keys. For additional security, iSCSI CHAP authentication can be required on a per-volume basis.

The Oracle Cloud Infrastructure Object Storage service provides highly scalable, strongly consistent, and durable storage for objects. API calls over HTTPS provide high-throughput access to data. All objects are encrypted at rest using unique keys. Objects are organized by

bucket, and, by default, access to buckets and objects within them requires authentication. Users can use IAM security policies to grant users and groups access privileges to buckets.

To allow bucket access by users who do not have IAM credentials, the bucket owner (or a user with necessary privileges) can create pre-authenticated requests that allow authorized actions on buckets or objects for a specified duration. Alternately, buckets can be made public, which allows unauthenticated and anonymous access. Given the security risk of inadvertent information disclosure, Oracle highly recommends carefully considering the business case for making buckets public. Object Storage enables you to verify that an object was not unintentionally corrupted by allowing an MD5 hash to be sent with the object (or with each part, in the case of multipart uploads) and returned upon successful upload. This hash can be used to validate the integrity of the object.

In addition to its native API, the Object Storage service supports Amazon S3 compatible APIs. Using the Amazon S3 Compatibility API, customers can continue to use the existing Amazon S3 tools (for example, SDK clients), and partners can modify their applications to work with Object Storage, with minimal changes to their applications. Their native API can co-exist with the Amazon S3 Compatibility API, which supports CRUD operations. Before customers can use the Amazon S3 Compatibility API, they must create an S3 Compatibility API key. After they've generated the necessary key, they can use the Amazon S3 Compatibility API to access Object Storage in Oracle Cloud Infrastructure.

Database Service

Oracle Cloud Infrastructure makes it easy to run, scale, and secure your Oracle databases (DBs) in the cloud. The Oracle Cloud Infrastructure Database service offers three types of DB systems:

- Bare metal: Comprising 1-node DB and 2-node Real Application Cluster (RAC) systems, providing exceptional performance at cost-effective pricing.
- Exadata: Proven industry-leading Exadata DB systems in quarter, half, and full rack configurations.
- Virtual machine: Allows customers to create full-featured Oracle databases on VM shapes with various cores.

DB systems are accessible only from a customer's VCN, and customers can configure VCN security lists to control network access to their databases. The Database service is integrated with Oracle Cloud Infrastructure IAM for controlling which users can launch and manage DB systems. By default, data is encrypted at rest using Oracle TDE with master keys stored in an Oracle Wallet on each DB system. RMAN backups of DB systems are encrypted and stored in customer-owned buckets in the Object Storage service. Customers need to create a bucket for DB backups and configure the Oracle Database Cloud Backup module with an auth token (to use with the Swift API) and IAM permissions to access the bucket. Alternately, DB backups can be made to local NVMe storage on the DB system.

Each user automatically has the ability to create, update, and delete their own auth tokens in the Console or the API. An administrator does not need to create a policy to give a user those abilities. Administrators (or anyone with permission to the tenancy) also have the ability to manage auth tokens for other users. Any user of a Swift client that integrates with Object Storage needs permission to work with the service.

Load Balancing Service

Oracle Cloud Infrastructure Load Balancing provides automated traffic distribution to compute instances in a customer's VCN. Load balancers (LBs) can be created as public (accepting traffic from the internet and directing it to private instances) or private (directing traffic between private instances). LBs can be configured for SSL termination using customer-provided certificates; end-to-end SSL, whereby the LB terminates the SSL connection and creates a new SSL connection to the backend; or SSL tunneling, in which the SSL connection is passed through to the backend (TCP load balances only). The Load Balancing service supports TLS 1.2 by default, and prioritizes the following forward-secrecy ciphers in the TLS cipher-suite:

- ECDHE-RSA-AES256-GCM-SHA384
- ECDHE-RSA-AES256-SHA384
- ECDHE-RSA-AES128-GCM-SHA256
- ECDHE-RSA-AES128-SHA256
- DHE-RSA-AES256-GCM-SHA384
- DHE-RSA-AES256-SHA256

- DHE-RSA-AES128-GCM-SHA256
- DHE-RSA-AES128-SHA256

Managed Domain Name Servers (DNS) Service

The Oracle Cloud Infrastructure DNS service provides dynamic, static, and recursive DNS solutions for enterprise customers. The service connects visitors to customer websites and applications with fast and secure services. The DNS service operates on a global anycast network with 18 points of presence (PoPs) on five continents and offers fully redundant DNS constellations and multiple Tier 1 transit providers per PoP. The solution provides a DNS-based Distributed Denial of Services (DDoS) protection and in-house security expertise that leverages a vast sensor network that collects and analyzes over 240 billion data points per day. The DNS service also fully supports the secondary DNS features to complement the customer's existing DNS service, providing resiliency at the DNS layer.

Oracle Cloud Security Testing Policy

This section describes the Oracle Cloud Security Testing policy and how you can submit a request to schedule the tests of your Oracle Cloud services. The Oracle Cloud Security Testing Policy describes when and how you may conduct certain types of security testing of Oracle Cloud Services, including vulnerability and penetration tests, as well as tests involving data scraping tools. Notwithstanding anything to the contrary, any such testing of Oracle Cloud Services may be conducted only by customers who have an Oracle Account with the necessary privileges to file service maintenance requests, and who are signed-in to the environment that will be the subject of such testing.

Penetration and Vulnerability Testing

Oracle regularly performs penetration and vulnerability testing and security assessments against the Oracle cloud infrastructure, platforms, and applications. These tests are intended to validate and improve the overall security of Oracle Cloud Services.

However, Oracle does not assess or test any components (including, non-Oracle applications, non-Oracle databases or other non-Oracle software, code or data, as may be applicable) that you manage through or introduce into – including introduction through your development in or

creation in - the Oracle Cloud Services (the "**Customer Components**"). This policy does not address or provide any right to conduct testing of any third party materials included in the Customer Components.

Except as otherwise permitted or restricted in your Oracle Cloud Services agreements, your service administrator who has system level access to your Oracle Cloud Services may run penetration and vulnerability tests for the Customer Components included in certain of your Oracle Cloud Services in accordance with the following rules and restrictions.

Permitted Cloud Penetration and Vulnerability Testing

The following explains where penetration and vulnerability testing of Customer Components is permitted:

- **IaaS:** Using your own monitoring and testing tools, you may conduct penetration and vulnerability tests of your acquired single-tenant Oracle Infrastructure as a Service (IaaS) offerings. You must notify Oracle prior to conducting any such penetration and vulnerability tests in accordance with the process set forth below. Pursuant to such penetration and vulnerability tests, you may assess the security of the Customer Components; however, you may not assess any other aspects or components of these Oracle Cloud Services including the facilities, hardware, software, and networks owned or managed by Oracle or its agents and licensors.
- **PaaS:** Using your own monitoring and testing tools, you may conduct penetration and vulnerability tests of your acquired single-tenant PaaS offerings. You must notify Oracle prior to conducting any such penetration and vulnerability tests in accordance with the process set forth below. Pursuant to such penetration and vulnerability tests, you may assess the security of the Customer Components; however, you may not assess any other aspects or components of these Oracle Cloud Services including the facilities, hardware, networks, applications, and software owned or managed by Oracle or its agents and licensors. To be clear, you may not assess any Oracle applications that are installed on top of the PaaS service.
- **SaaS:** Penetration and vulnerability testing is not permitted for Oracle Software as a Service (SaaS) offerings.

Rules of Engagement

The following rules of engagement apply to cloud penetration and vulnerability testing:

- Your testing must not target any other subscription or any other Oracle Cloud customer resources, or any shared infrastructure components.
- You must not conduct any tests that will exceed the bandwidth quota or any other subscribed resource for your subscription.
- You are strictly prohibited from utilizing any tools or services in a manner that perform Denial-of-Service (DoS) attacks or simulations of such, or any "load testing" against any Oracle Cloud asset including yours.
- Any port scanning must be performed in a non-aggressive mode.
- You are responsible for independently validating that the tools or services employed during penetration and vulnerability testing do not perform DoS attacks, or simulations of such, prior to assessment of your instances. This responsibility includes ensuring any contracted third parties perform assessments in a manner that does not violate this policy.
- Social Engineering of Oracle employees and physical penetration and vulnerability testing of Oracle facilities is prohibited.
- You must not attempt to access another customer's environment or data, or to break out of any container (for example, virtual machine).
- Your testing will continue to be subject to terms and conditions of the agreement(s) under which you purchased Oracle Cloud Services, and nothing in this policy shall be deemed to grant you additional rights or privileges with respect to such Cloud Services.
- If you believe you have discovered a potential security issue related to Oracle Cloud, you must report it to Oracle within 24 hours by conveying the relevant information to My Oracle Support. You must create a service request within 24 hours and must not disclose this information publicly or to any third party. Note that some of the vulnerabilities and issues you may discover may be resolved by you by applying the most recent patches in your instances.
- In the event you inadvertently access another customer's data, you must immediately terminate all testing and report it to Oracle within one hour by conveying the relevant information to My Oracle Support.
- You are responsible for any damages to Oracle Cloud or other Oracle Cloud customers

that are caused by your testing activities by failing to abide by these rules of engagement.

Notification Process

The process for notifying Oracle of Your election to conduct a penetration or vulnerability test as required by this policy can be found in Submitting a Cloud Security Testing Notification.

DATA SCRAPING TOOLS

Any use of data scraping tools or technologies with Oracle Cloud Services to collect data available through any Oracle user interface or via web service calls requires the express written permission of Oracle. Oracle reserves the right to require that your proposed data scraping tools are validated and tested by Oracle prior to use in production, and are subsequently re-validated and tested annually.

Security Best Practices

This guide provides actionable guidance and recommendations to Oracle Cloud Infrastructure customers for securely configuring Oracle Cloud Infrastructure services and resources. Understanding Oracle Cloud Infrastructure services and their security features is an essential prerequisite before reading. As a prerequisite, Oracle recommends that you become familiar with security of services. For more information, see Oracle Cloud Infrastructure Security Guide.

Security of an Oracle Cloud Infrastructure tenancy is based on a combination of factors, all of which must be thought through and securely configured. From a practical perspective, take a hierarchical view of Oracle Cloud Infrastructure tenancy security configuration, where we start with addressing the foundational security issues. The following steps provide a roadmap of high-level guidelines to follow when configuring security of a tenancy, where we provide a link to a section enumerating detailed security guidance related to each step.

- **User authentication and authorization:** The initial step in securely configuring a tenancy is to create mechanisms for authenticating users and authorizing users to access tenancy resources in a least-privilege manner. This step comprises creating Oracle Cloud Infrastructure Identity and Access Management (IAM) users, creating IAM

groups, formulating authentication mechanisms (for example, Console access using password, API access using API keys, and auth token for object store) for the IAM users created, grouping customer tenancy resources into logical groups using compartments, and formulating IAM security policies authorizing access of IAM groups to tenancy or compartment resources. For enterprises, federating their on-premises users and groups to their tenancy is an important consideration. IAM allows you to create users, groups, security polices, and federation mechanisms. Security recommendations for configuring IAM are provided in the IAM section.

- **Network security architecture:** After formulating IAM user authentication and authorization, a next step is creating a network security architecture for securely running the customer applications and storing their data in a tenancy. All the customer's compute and storage resources are enclosed in a virtual cloud network (VCN) created for the customer. VCN is a software-defined network, resembling the on-premises physical network used by customers to run their workloads. Formulating a VCN security architecture includes tasks such as:
  - Creating VCN subnets for network segmentation
  - Formulating VCN and load balancer firewalls using VCN security lists
  - Using load balancing for high-availability and TLS
  - Determining type of VCN external connectivity whether internet, on-premises network, peered VCN, or combination of these
  - Using virtual network security appliances (for example, next-generation firewalls, IDs)
  - Creating DNS zones and mappings. An important security consideration in load balancers is using customer Transport Layer Security (TLS) certificates to configure TLS connections to customer's VCN. Security recommendations for VCN are provided in the Networking section.
- **Compute instances security configuration:** Within a customer VCN, the customer applications run on compute instances including Bare Metal (BM) instances, Virtual Machine (VM) instances and GPUs. Compute instances are the basic compute building blocks. Bare metal instances have no Oracle-managed software running on them, with

the result that the instances and data stored (in memory and local drives) are completely controlled by the customer. VM instances are architected with least privilege mechanisms, and with corporate industry-leading hypervisor security best-practices. Depending on their security and performance requirements, customers have a choice of using BM and VM instances, to run their application workloads in their tenancy. It is imperative to securely configure compute instances, to maintain security of customer applications running on them. Recommendations related to instance security configuration with respect to instance firewalls, instance credential management, entropy, security patching, and security logging and monitoring are provided in the Compute section.

- **Data storage security configuration:** Depending on the type of data and access required, customers can store data in local drives (attached to compute instances), remote block volumes, object store buckets, databases, or file storage in their tenancy. To handle these data storage requirements, Oracle Cloud Infrastructure offers multiple data storage services such as Block Volume, Object Storage, Database, and File Storage. In order to meet their data security requirements, customers need to formulate a tenancy data storage architecture for storing their data in their tenancy, and securely configure the storage services used. Compliance and regulatory requirements are an important factor in determining an appropriate data storage security architecture. Recommendations related to storage services security configuration are available in Block Volume, Object Storage, Database, and File Storage sections. In addition to these services, customers need to consider security of data stored ephemerally in compute instance memory (DRAM) and local NVMe storage.

API Audit logs record calls to APIs (for example, through the Console, SDKs, CLIs, and custom clients using the APIs) as log events. The API Audit logs are always on by default and can't be turned off. These logs are available to customers for 90 days, with retention period configurable up to 365 days. Information in the API Audit logs show what time API activity occurred, the source of the activity, the target of the activity, what the action was, and what the response was. Oracle recommends that customers periodically review the OCI API Audit logs to ensure they are in accordance with actions they took on their tenancy resources.

For service-specific best practices, see the following topics:

- Securing Block Volume
- Securing Compute
- Securing Data Transfer
- Securing Database
- Securing Email Delivery
- Securing File Storage
- Securing IAM
- Securing Networking: VCN, Load Balancers, and DNS
- Securing Object Storage
- Securing Resource Manager

Securing Block Volume

SECURITY RECOMMENDATIONS

- There are two types of volumes: block volumes and boot volumes. Block volumes allow instance storage capacity to be expanded dynamically. A boot volume contains the image used to boot the compute instance. The IAM service groups the family of related volume resource types into a combined resource type called `volume-family`.
- Assign least privilege access for IAM users and groups to resource types in `volume-family`. The resource types in `volume-family` are`volumes` ,`volume-attachments`, and `volume-backups`. The`volume-family` resources are detachable block volume devices that allow dynamic expansion of instance storage capacity or contain the image for booting the instance. The `volume-attachments` resources are attachments between volumes and instances. The `volume-backups` resources are point-in-time copies of volumes that can be used to create block volumes or recover block volumes.

DATA DURABILITY

To minimize loss of data due to inadvertent deletes by an authorized user or malicious deletes, Oracle recommends to giving `VOLUME_DELETE`, `VOLUME_ATTACHMENT_DELETE` and

`VOLUME_BACKUP_DELETE` permissions to a minimum possible set of IAM users and groups. `DELETE` permissions should be given only to tenancy and compartment administrators.

To minimize loss of data due to deletes or corruption, Oracle recommends that you make periodic backups of volumes. Oracle Cloud Infrastructure allows automated scheduled backups. For more information about scheduled backups, see Policy-Based Backups.

Data-at-rest Encryption

By default, volumes and their backups are encrypted at rest using AES-256. You can also encrypt your data volumes using tools like dm-crypt, veracrypt, and Bit-Locker. Instructions on dm-crypt encryption are presented in the next section.

Security Policy Examples

Prevent Delete of Volumes

The following example policy allows group `VolumeUsers` to perform all actions on volumes and backups, except deleting them.

```
Allow group VolumeUsers to manage volumes in tenancy
 where request.permission!='VOLUME_DELETE'
Allow group VolumeUsers to manage volume-backups in tenancy
 where request.permission!='VOLUME_BACKUP_DELETE'
```

If `VolumeUsers` can't detach volumes from instances, you can add the following policy to the previous example.

```
Allow group VolumeUsers to manage volume-attachments in tenancy
 where request.permission!='VOLUME_ATTACHMENT_DELETE'
```

Security-related Tasks

Encrypting Non-root Volumes with dm-crypt

dm-crypt is a kernel-level encryption mechanism (part of Linux device mapper framework) to provide encrypted volumes. It encrypts data passed from the filesystem (for example, ext4 and NTFS), and stores it on a storage device in Linux Unified Key Setup (LUKS) format. The encrypted volumes can be stored on a complete disk, disk partition, logical volume, or a file-backed storage created using loopback devices. Cryptsetup is the user-level utility used to

manage dm-crypt, and used to encrypt partitions and files. dm-crypt uses the Linux crypto APIs for encryption routines.

1. Attach block storage volume to an instance (for example, `/dev/sdb`)
2. Format `/dev/sdb` for LUKS encryption. Enter LUKS passphrase when prompted. The passphrase is used to encrypt the LUKS master key used for encrypting the volume.

   ```
   cryptsetup -y luksFormat /dev/sdb
   ```

3. Verify that the LUKS formatting is successful.

   ```
   cryptsetup isLuks /dev/sdb && echo Success
   ```

4. Get encryption information about the device.

   ```
   cryptsetup luksDump /dev/sdb
   ```

5. Get LUKS UUID of the device. The UUID value is used to configure the `/etc/crypttab`.

   ```
   cryptsetup luksUUID /dev/sdb
   ```

6. Create a LUKS container with device name, `dev_name`. This also creates a device node, `/dev/mapper/<dev_name>`.

   ```
   cryptsetup luksOpen /dev/sdb <dev_name>
   ```

7. Get information about the mapped device.

   ```
   dmsetup info <dev_name>
   ```

8. Format the device node as ext4 filesystem.

   ```
   sudo mkfs -t ext4 /dev/sdb
   ```

9. Mount the device node.

   ```
   mount /dev/mapper/<dev_name> /home/encrypt_fs
   ```

10. Add an entry to `/etc/crypttab`.

    ```
    <dev_name> UUID=<LUKS UUID of /dev/sdb> none
    ```

    All the files copied to `/home/encrypt_fs` are encrypted by LUKS.

11. Add a keyfile to an available keyslot of the encrypted volume. This keyfile can be used to access the encrypted volume.

```
dd if=/dev/urandom of=$HOME/keyfile bs=32 count=1
chmod 600 $HOME/keyfile
cryptsetup luksAddKey /dev/sdb ~/keyfile
```

12. Verify the encryption status of files.

```
cryptsetup status /home/encrypt_fs
```

13. Unmount after you're finished.

```
umount /home/encrypt_fs
cryptsetup luksClose <dev_name>
```

To access the encrypted volume:

```
cryptsetup luksOpen /dev/sdb <dev_name> --key-file=/home/opc/keyfile
mount /dev/mapper/<dev_name> /home/encrypt_fs
```

If you lose the keyfile, or if the keyfile or passphrase gets corrupted, you can't decrypt the encrypted volume . This results in permanent loss of data. Oracle recommends that you store durable copies of the keyfile on an on-premises host.

REMOTE MOUNTING OF DM-CRYPT ENCRYPTED DATA VOLUMES

The following steps assume that the keyfile is on an on-premises host (`SRC_IP`) and that `<OCI_SSH_KEY>` is the SSH private key of the instance.

1. Copy keyfile from the on-premises host to an instance.

```
scp -i <OCI_SSH_KEY> keyfile opc@SRC_IP:/home/opc
```

2. Open the encrypted volume.

```
ssh i <OCI_SSH_KEY> opc@SRC_IP "cryptsetup luksOpen /dev/sdb <dev_name> --key-
file=/home/opc/keyfile"
```

3. Mount the volume.

```
ssh -i <OCI_SSH_KEY> opc@SRC_IP "mount /dev/mapper/<dev_name> /home/encrypt_fs"
```

4. Perform operations on data in the mounted volume.
5. Unmount the encrypted volume.

```
ssh -i <OCI_SSH_KEY> opc@SRC_IP "umount /home/encrypt_fs"
ssh -i <OCI_SSH_KEY> opc@SRC_IP "cryptsetup luksClose <dev_name>"
```

6. Delete the keyfile from the instance.

```
ssh -i <OCI_SSH_KEY> opc@SRC_IP "\rm -f /home/opc/keyfile"
```

Securing Compute

Security Recommendations

Oracle Cloud Infrastructure Compute provides both bare metal and virtual machine (VM) instances, architected and managed in accordance with industry-leading security best practices.

Managing Instances and Credentials

- To prevent inadvertent or malicious termination of critical instances (for example, production instances), Oracle recommends that you give `INSTANCE_DELETE` permission to a minimal set of groups. Give `DELETE` permissions only to tenancy and compartment admins.
- Instances can be authorized to access Oracle Cloud Infrastructure services (Compute, Block volume, Networking, Load balancing, Object storage), on behalf of an IAM user, by using Oracle Cloud Infrastructure instance principals feature. To use this feature, you create dynamic groups and grant them access to service APIs. Members of dynamic groups are instances that you define based on rules to match instances to the group. A short-lived private key to sign API calls, is delivered through instance metadata service (http://169.254.169.254/opc/v1/identity/cert.pem), and the key is rotated multiple times a day. For more information about accessing services from instances, see Calling Services from an Instance.

Instance Metadata Access Control

- Instance metadata (http://169.254.169.254) provides predefined instance information (for example, OCID and display name), along with custom fields. Short-lived credentials, such as dynamic group credentials, could be provided through the instance metadata. Oracle recommends that you limit instance metadata access to only

privileged users on the instance. For example, iptables can be used to restrict instance metadata access only to privileged users such as root, using the following rule.

```
iptables -A OUTPUT -m owner ! --uid-owner root -d 169.254.169.254 -j DROP
```

- Instances use link local addresses to access instance metadata service (169.254.169.254:80), DNS (169.254.169.254:53), NTP (169.254.169.254:123), kernel updates (169.254.0.3), and iSCSI connections to boot volumes (169.254.0.2:3260, 169.254.2.0/24:3260). Host-based firewalls such as iptables can be used to authorize only root user to access these IPs. Ensure that these OS firewall rules are not altered.

INSTANCE NETWORK ACCESS CONTROLS

- Harden secure shell (SSH) on all instances. Some SSH security recommendations are shown in the following table. SSH configuration options can be set in the sshd_config file (located at /etc/ssh/sshd_config in Linux).

Security Recommendation	Configuration sshd_ config	Comments
Use public-key logins only	PubkeyAuthentication yes	Periodically review SSH public keys in ~/.ssh/authorized_keys file
Disable password logins	PasswordAuthentication no	Mitigates password brute-force attacks
Disable root logins	PermitRootLogin no	Prevents root privileges for remote logins
Change SSH port to non-standard port	Port <port number>	This is optional. Ensure that this change does not break applications using port 22 for SSH

- Secure SSH private keys used to access instances and prevent any inadvertent disclosure. For more information about creating an SSH key pair and configuring an instance with the keys, see Creating a Key Pair.

- Use VCN network security groups or security lists as a mechanism to allow instance access from authorized IP addresses. Fail2ban is an application that blacklists IP addresses involved in brute-force login attempts (that is, too many failed attempts to an instance). Fail2ban inspects SSH accesses by default, and can be configured for other protocols. For more information about Fail2ban, see Fail2ban Main Page.
- In addition to VCN network security groups and security lists, host-based firewalls (such as iptables and firewalld) can be used to restrict network access to instances, in terms of ports, protocols, and packet types. These firewalls can be used to prevent potential network security attack reconnaissance (for example, port scanning) and intrusion attempts. Custom firewall rules can be configured, saved, and initialized on every instance boot. The following example shows commands for iptables.

```
# save iptables rules after configuration
sudo iptables-save > /etc/iptables/iptables.rules
# restore iptables rules on next reboot
sudo /sbin/iptables-restore < /etc/iptables.rules
# restart iptables after restore
sudo service iptables restart
```

INSTANCE ENTROPY

Both bare metal and VM instances provide high-quality and high-throughput entropy source. Instances have hardware random number generator support, whose output is fed into the entropy pools used by the OS to generate random numbers. In Linux instances, `/dev/random` is non-blocking, and recommended to be used for security applications requiring random numbers. You can use the following commands to check the throughput and quality of random numbers generated by `/dev/random`, before using its output in applications.

```
# check sources of entropy
sudo rngd -v
# enable rngd, if not already
sudo systemctl start rngd
# verify rngd status
sudo systemctl status rngd
# verify /dev/random throughput and quality using rngtest
cat /dev/random | rngtest -c 1000
```

HOST SECURITY HARDENING AND PATCHING

- Establish baseline for security hardening of OS images (Linux, Windows) running on instances. For more information about security hardening of Oracle Linux images, see Tips for Hardening an Oracle Linux Server. The Center for Internet Security Benchmarks provides a comprehensive set of OS security hardening benchmarks for various distributions of Linux and Windows Server.
- Keep the instance software up-to-date with security patches. Oracle recommends that you periodically apply the latest available software updates to your instances. For Oracle Linux, you can run `sudo yum update` command. On Oracle Linux, you can get information about available and installed security patches using the `yum-security` plugin. Commands for yum-security are available below. For Oracle Linux instances launched after February 15, 2017, Ksplice support is available for applying patches without rebooting the instance. For more information about using Ksplice on Oracle Cloud Infrastructureinstances, see Installing and Running Oracle Ksplice.

```
# Install yum-security plugin
yum install yum-plugin-security
# Get list of security patches without installing them
yum updateinfo list security all
# Get list of installed security patches
yum updateinfo list security all
```

INSTANCE SECURITY LOGGING AND MONITORING

- Various security-related events are captured in log files. Oracle recommends that you periodically review these log files for detecting any security issues. In Oracle Linux, the log files are located in `/var/log`. Some security-relevant log files are listed in the table below.

Log File or Directory	Description
`/var/log/secure`	Auth log showing failed and successful logins
`/var/log/audit`	Auditd logs capturing system calls issued, sudo attempts, user logins, etc. ausearch and aureport are two tools used to query auditd logs
`/var/log/yum.log`	Lists various packages installed or updated on the instance with yum
`/var/log/cloud-init.log`	cloud-init can run user-provided scripts as privileged user, during instance boot. For example, SSH keys can be introduced using cloud-init. Oracle recommends that you review the cloud-init logs for any unrecognized commands.

- Host-based intrusion detection system (IDS) monitors instances for unauthorized accesses. OSSEC and Wazuh (OSSEC fork) are popular open-source IDS that can monitor for unauthorized access, malware, file modifications, and security misconfigurations. In the case of Wazuh, Wazuh server and ELK stack are deployed on an instance, and agents are deployed on other instances in the VCN to send logs to the Wazuh server. The resulting alerts are displayed on a Kibana dashboard. Wazuh IDS was prototyped on instances, and below are instructions for deploying a working Wazuh server on an instance (with ELK version 5.6.3). For more information about installing Wazuh agents and accessing the Kibana dashboard, see the Wazuh documentation.

```

sudo apt-get install kibana=5.6.3;
sudo -u kibana /usr/share/kibana/bin/kibana-plugin install
https://packages.wazuh.com/wazuhapp/wazuhapp-2.1.1_5.6.3.zip;

sudo systemctl daemon-reload;
sudo systemctl enable kibana.service;
sudo systemctl start kibana.service;
```

SECURITY POLICY EXAMPLES

In all the following examples, the policies are scoped to a tenancy. However, by specifying a compartment name, they can be scoped down to specific compartment in a tenancy.

RESTRICT USERS ABILITY TO DELETE INSTANCES

The following example allows the `InstanceUsers` group to launch instances but not delete them

```
Allow group InstanceUsers to manage instance-family in tenancy
 where request.permission!='INSTANCE_DELETE'
Allow group InstanceUsers to use volume-family in tenancy
Allow group InstanceUsers to use virtual-network-family in tenancy
```

RESTRICT ABILITY TO USE INSTANCE CONSOLE

For security compliance reasons, some customers do not want to expose instance console to users in their tenancy. The following policy example restricts ability to create or read from consoles.

```
Allow group InstanceUsers to manage instance-console-connection in tenancy
 where all {request.permission!= INSTANCE_CONSOLE_CONNECTION_READ,
            request.permission!= INSTANCE_CONSOLE_CONNECTION_CREATE}
```

Securing Data Transfer

Oracle offers offline data transfer solutions that let you migrate large amounts of data to buckets in a tenancy in Oracle Cloud Infrastructure. Data transfer solutions include:

- Disk-Based Data Transfer
  For more information about securely transferring data using this service, see Secure Disk Data Transfer to Oracle Cloud Infrastructure
- Appliance-Based Data Transfer
  For more information about securely transferring data using this service, see Secure Disk Data Transfer to Oracle Cloud Infrastructure.

Securing Database

Security Recommendations

This section lists security recommendations for managing Oracle Cloud Infrastructure Database instances. Recommendations for securely configuring Oracle databases are available in the Oracle Database Security Guide.

Database Access Control

- Users authenticate to the database using their password. Oracle recommends that these passwords be strong. For guidelines on choosing Oracle database passwords, see Guidelines for Securing Passwords. In addition, Oracle database provides a PL/SQL script to verify database password complexity. This script is located at `$ORACLE_HOME/rdbms/admin/UTLPWDMG.SQL`. For instructions on running UTLPWDMG.SQL script to verify password complexity, see Enforcing Password Complexity Verification.
- In addition to the database password, you can use VCN network security groups or security lists to enforce network access control to database instances. Oracle recommends that you configure VCN network security groups or security lists to allow least privilege access to customer databases in Oracle Cloud Infrastructure Database.
- DB systems created within a public subnet can send outbound traffic directly to the Internet. DB systems created within a private subnet do not have internet connectivity, and internet traffic (both egress and ingress) cannot reach the instance directly. If you try to define a route to a DB system within a private subnet using an internet gateway, the route is ignored.

  To perform OS patching and backup for a DB system on private subnet, you can use a service gateway or a NAT gateway to connect to your patching or backup endpoints.

  In an virtual cloud network (VCN), you can use security rules along with a private subnet to restrict access to a DB system. In multi-tier deployments, a private subnet and VCN security rules can be used to restrict access to the DB system from the application tiers.

DATA DURABILITY

- Oracle recommends that you give database delete permissions (`DATABASE_DELETE`, `DB_SYSTEM_DELETE`) to a minimum possible set of IAM users and groups. This minimizes loss of data due to inadvertent deletes by an authorized user or due to malicious deletes. Only give `DELETE` permissions to tenancy and compartment administrators.
- You can use RMAN to do periodic backups of Database databases, where encrypted backup copies are stored in local storage (block volumes, for example) or Oracle Cloud Infrastructure Object Storage. RMAN encrypts each backup of a database with a unique encryption key. In transparent mode, the encryption key is stored in the Oracle Wallet. RMAN backups to Object Storage require internet gateway (IGW), and VCN network security groups or security lists need to be configured to allow secure access to Object Storage. For information about setting up the VCN for backing up bare metal databases, see Backing Up a Database to Oracle Cloud Infrastructure Object Storage. For information about backing up and Exadata databases, see Managing Exadata Database Backups by Using bkup_api.

DATABASE ENCRYPTION AND KEY MANAGEMENT

- All databases created in Oracle Cloud Infrastructure are encrypted using transparent data encryption (TDE). Note that if you migrate an unencrypted database from on-premise to Oracle Cloud Infrastructure using RMAN, the migrated database will not be encrypted. Oracle strongly recommends encrypting such databases after migrating them to the cloud.

  To learn how to encrypt your database with minimum downtime during migration, see the Oracle Maximum Availability Architecture white paper Converting to Transparent Data Encryption with Oracle Data Guard using Fast Offline Conversion.

  Note that virtual machine DB systems use Oracle Cloud Infrastructure block storage instead of local storage. Block storage is encrypted by default.
- User-created tablespaces are encrypted by default in Oracle Cloud Infrastructure Database. In these databases, `ENCRYPT_NEW_TABLESPACES` parameter is set to `CLOUD_ONLY` where tablespaces created in a Database Cloud Service (DBCS) database are

transparently encrypted with the AES128 algorithm unless a different algorithm is specified.

- The Database administrator creates a local Oracle Wallet on a newly created database instance, and initializes the Transparent Data Encryption (TDE) master key. Then the Oracle Wallet is configured to be "auto-open". However, a customer can choose to set a password for the Oracle Wallet, and Oracle recommends that you set a strong password (eight characters or more, with at least one capital letter, one small letter, one number, and one special symbol).
- Oracle recommends that you periodically rotate the TDE master key. The recommended rotation period is 90 days or less. You can rotate the TDE master key by using native database commands ("administer key management" in 12c, for example) or dbaascli. All previous versions of TDE master key are maintained in the Oracle Wallet.
- Oracle Key Vault (OKV) is a key management appliance used for managing Oracle TDE master keys. OKV can store, rotate, and audit accesses to TDE master keys. For instructions about installing and configuring OKV in Oracle Cloud Infrastructure, see Managing Oracle Database Encryption Keys in Oracle Cloud Infrastructure with Oracle Key Vault.

DATABASE PATCHING

Applying Oracle database security patches (Oracle Critical Patch Updates) is imperative to mitigate known security issues, and Oracle recommends that you keep patches up-to-date. Patchsets and Patch Set Updates (PSUs) are released on a quarterly basis . These patch releases contain security fixes and additional high-impact/low-risk critical bug fixes.

For information about the latest known security issues and available fixes, see Critical Patch Updates, Security Alerts and Bulletins. If your application does not support the latest patches and needs to use a DB system with older patches, you can provision a DB system with an older version of the Oracle Database edition you are using. In addition to reviewing the critical patch updates and security alerts for your Oracle Database, Oracle recommends that you analyze and patch the operating system provisioned with the DB system.

For information about applying patches to Oracle Cloud Infrastructure Database instances, see Patching a DB System and Patching an Exadata DB System.

Database Security Configuration Checking

- The Oracle Database Security Assessment Tool (DBSAT) provides automated security configuration checks of Oracle databases in Oracle Cloud Infrastructure. DBSAT performs security checks for user privilege analysis, database authorization controls, auditing polices, database listener configuration, OS file permissions, and sensitive data stored. Oracle database images in Oracle Cloud Infrastructure Database are scanned with DBSAT before provisioning. After provisioning, Oracle recommends that you periodically scan databases with DBSAT, and remediate any issues found. DBSAT is available free of charge to Oracle customers.

Database Security Auditing

Oracle Audit Vault and Database Firewall (AVDF) monitors database audit logs and creates alerts. For instructions about installing and configuring AVDF in Oracle Cloud Infrastructure, see Deploying Oracle Audit Vault and Database Firewall in Oracle Cloud Infrastructure.

Database Backups

Oracle recommends using Managed backups (backups created using the Oracle Cloud Infrastructure Console or the API) whenever possible. When you use managed backups, Oracle manages the object store user and credentials, and rotates these credentials every 3 days. Oracle Cloud Infrastructure encrypts all managed backups in the object store. Oracle uses the Database Transparent Encryption feature by default for encrypting the backups.

If you are not using managed backups, Oracle recommends that you change the object store passwords at regular intervals.

Security Policy Examples

Prevent Delete of Database Instances

The following example policy allows the group `DBUsers` to perform all management actions except delete databases and any artifacts.

```
Allow group DBUsers to manage db-systems in tenancy
 where request.permission!='DB_SYSTEM_DELETE'
Allow group DBUsers to manage databases in tenancy
 where request.permission!='DATABASE_DELETE'
```

```
Allow group DBUsers to manage db-homes in tenancy
 where request.permission!='DB_HOME_DELETE'
```

Securing Email Delivery

The Email Delivery service offers an SMTP endpoint, secured by a password generated in the Console. The SMTP password is required for sending emails using Email Delivery. Oracle recommends that you create a separate IAM user for SMTP. This user must have manage permissions for `approved-senders` and `suppressions` resource types. Oracle recommends that you securely store the SMTP credential, and periodically rotate it. For more information about generating an SMTP credential for Email Delivery, see Generate SMTP Credentials for a User.

For Email Delivery best practices, including managing your sender reputation and help for avoiding being blacklisted, see Deliverability Best Practices.

Securing File Storage

The File Storage Service exposes an NFSv3 endpoint as a mount target in each customer's VCN subnet. The mount target is identified by a DNS name and is mapped to an IP address. Oracle recommends that you use VCN security lists (of the mount target subnet) to configure network access to the mount target from only authorized IP addresses.

You can mount a file system using the Console or from a Linux command line using NFS utilities. You can authorize users to mount file systems using IAM security policies, but this applies to the console only.

For data durability, Oracle recommends that you take periodic snapshots of the file system. To minimize accidental deletion of data, constrain the set of users having privileges to delete mount targets, file-systems, and snapshots.

All file-system data is encrypted at rest.

Access to mounted NFS file systems from a remote host is determined by POSIX user and group permissions. Oracle recommends that you use well-known NFS security best practices such as the `all_squash` option to map all users to `nfsnobody`, and NFS ACLs to enforce access control to the mounted file system.

SECURITY POLICY EXAMPLES

PREVENT MOUNT TARGET AND FILE SYSTEM DELETION

The following example prevents group FileUsers from deleting mount targets and file-systems.

```
Allow group FileUsers to manage file-systems in tenancy
 where request.permission!='FILE_SYSTEM_DELETE'
Allow group FileUsers to manage mount-targets in tenancy
 where request.permission!='MOUNT_TARGET_DELETE'
Allow group FileUsers to manage export-sets in tenancy
 where request.permission!='EXPORT_SET_DELETE'
```

Securing IAM

SECURITY RECOMMENDATIONS

Oracle Cloud Infrastructure Identity and Access Management (IAM) provides authentication of users, and authorization to access resources. Security-relevant IAM concepts include:

IAM concepts and descriptions

Concept	Description
Compartment	A compartment is a fundamental mechanism to aggregate resources into logical groups. They also provide isolation.
Tenancy	Oracle Cloud Infrastructure automatically creates a tenancy for an account created by an organization. It is the root compartment that contains all the organization's resources.
Users and groups	A group is an aggregation of users who need similar access to a group of resources.
Resource	A resource is an object created in Oracle Cloud Infrastructure services.

Concept	Description
Security policy	A security policy specifies the type of access IAM groups have to resources in a specified aggregation level. An aggregation level can be the tenancy, a compartment, or a service.
Dynamic groups	A dynamic group allows aggregating Compute instances as principal actors (similar to user groups), in order to authorize instances to make calls to Oracle Cloud Infrastructure APIs.
Tags	Tags allow you to organize resources across multiple compartments for reporting purposes or for taking bulk actions.
Federation	Mechanism to federate IAM with other identity providers (IdP) used by an organization to authenticate their users.

Oracle recommends that you periodically monitor Audit logs to review changes to IAM users, groups, and security policies.

IAM Tenancy and Compartments

- Compartments are unique to IAM, and offer a mechanism that allows an enterprise customer to meet its central needs by having a single account or tenancy. This single account or tenancy provides full central control and visibility while also allowing the account or tenancy to be subdivided to meet the needs of constituent teams, projects, and initiatives.
- For security and governance reasons, users should only have access to resources they need. For example, enterprise users working on a project or belonging to a business unit should have access only to resources belonging to the project or business unit. Compartments provide an effective mechanism to group tenancy resources based on their access privileges and authorize groups of users to access the compartments on as needed basis. In the example above, a compartment can be created to include all resources belonging to a business unit, and authorize only members of the business unit to access the compartment. Similarly, a groups' access to a compartment can be revoked when they do not need it anymore.

- Keep the following in mind when you create a compartment and assign resources:
    - Every resource should belong to a compartment.
    - A resource can be reassigned to a different compartment after creation. See Managing Compartments.
    - A compartment can be deleted after creation. See Managing Compartments.
- Resource tags provide a way to logically aggregate resources distributed across multiple compartments. For example, tenancy resources can be tagged as `test` or `production` depending on their use. For more information about resource tags (free-form and defined tags), see Resource Tags.
- Every tenancy comes with a default administrators group. This group can perform any action on all resources in a tenancy (that is, they have root access to the tenancy). Oracle recommends that you keep the group of tenancy administrators as small as possible. Some security recommendations on managing tenancy administrators:
    - Have security policies granting membership of tenancy administrator group strictly on a as-needed basis.
    - Tenancy administrators should use high-complexity passwords, along with MFA, and periodically rotate their passwords.
    - After account set up and configuration, Oracle recommends that you don't use the tenancy administrator account for day-to-day operations. Instead, create less privileged users and groups.
    - Though administrator accounts are not used for daily operations, they are still needed to address emergency scenarios impacting customer tenancy and operations. Specify secure and auditable "break-glass" procedures for using administrator accounts in such emergencies.
    - Disable tenancy administration access immediately when an employee leaves the organization.
    - Because the tenancy administrator group membership is restricted, Oracle recommends that you create security policies which prevent administrator account lock-out (for example, if the tenancy administrator leaves the company and no current employees have administrator privileges).

IAM Users and Groups

- Create an IAM user for everyone in the customer organization who needs access to resources. Do not share IAM user accounts across multiple users, especially those with administrative accounts. Using distinct IAM users enables enforcing least privilege access for each user, and captures their actions in audit logs.
- The recommended unit of administration is IAM groups, which makes it easier to manage and keep track of security permissions (as opposed to individual users). Create IAM groups with permissions to do commonly needed tasks (for example, network administration, volume administration), and assign users to these groups on an as-needed basis. IAM permissions can be used to give a group access to resources across multiple compartments in a tenancy.
- Periodically review membership of IAM users in IAM groups, and remove IAM users from groups they do not need access to anymore. Using group membership to manage user access scales well with increasing number of users.
- Deactivate IAM users who do not need access to tenancy resources. Deleting an IAM user removes the user permanently. You can temporarily deactivate an IAM user by doing the following:
    - Rotate the user password and throw it away.
    - Remove all tenancy permissions of the user by removing membership from all groups.

IAM Credentials

IAM user credentials (Console password, API signing key, auth tokens, and customer secret keys) grant access to resources. It is important to secure these credentials to prevent unauthorized access to Oracle Cloud Infrastructure resources. General guidelines for handling credentials include:

- Create a strong console password for each IAM user, with sufficient complexity. Oracle recommends the following for a complex password:
    - Password has a minimum length of 12 characters
    - Password contains at least one uppercase letter

    - Password contains at least one lowercase letter
    - Password contains at least one symbol
    - Password contains at least one number
- Rotate IAM passwords and API keys regularly, every 90 days or less. In addition to a security engineering best practice, this is also a compliance requirement. For example, PCI-DSS Section 3.6.4 states, "Verify that key-management procedures include a defined cryptoperiod for each key type in use and define a process for key changes at the end of the defined crypto period(s)."
- Do not hard code sensitive IAM credentials directly in software or documents accessible to a wide audience. Examples include code uploaded to GitHub, presentations, or documents available on the internet. There have been known, highly publicized cases of hackers breaching customer cloud accounts, using credentials inadvertently disclosed on public sites. When software applications need to access Oracle Cloud Infrastructure resources, Oracle recommends that you use instance principals. If it is not feasible to use instance principals, other recommendations include using user environment variables to store credentials, and using locally stored credential files with API keys to be used by the Oracle Cloud Infrastructure SDK or CLI.
- Do not share IAM credentials between multiple users.
- By federating the Console login through Oracle Identity Cloud Service, customers can use multifactor authentication (MFA) for IAM users, especially administrators.

When rotating API keys, verify that the rotated keys work as expected before disabling older keys. For information about generating and uploading IAM API keys, see Required Keys and OCIDs. The high-level steps in rotating an API key are:

1. Generate and upload a new API key.
2. Update the SDK and CLI configuration files with the new API key.
3. Verify that the SDK and CLI calls are working correctly with the new key.
4. Disable the old API key. Use ListApiKeys to list all active API keys.

IAM Security Policies

IAM policies are used to govern access of IAM groups to resources in compartments and in the tenancy. Oracle recommends that you assign least privilege access to IAM groups for accessing resources. The common format for IAM policies is shown in the following example.

```
Allow group <group_name> to <verb> <resource-type> in compartment <compartment_name>
Allow group <group_name> to <verb> <resource-type> in tenancy
```

IAM policies allow four predefined verbs: inspect, read, use and manage. Inspect allows least privilege and manage allows the maximum. The four verbs are shown in increasing order of privilege in the following table.

IAM policy verbs

Verb	Access Type	Example User
`inspect`	Should only show metadata. This usually results in ability to list resources only	third-party auditor
`read`	inspect plus ability to read resource and user metadata. This is the permission most users need to get work done.	internal auditors
`use`	read plus ability to work with resources (the actions vary by resource type). Excludes ability to create or delete resource	regular users (software developers, system engineers, dev managers, etc) setting up and configuring tenancy resources, and applications running on them
`manage`	All the permissions for all the resources	administrators, executives (for break-glass scenarios)

The resource types of Oracle Cloud Infrastructure resources are shown in the following table.

IAM resource families, descriptions, and resource types

Resource Type Family	Description	Resource Types
`all-resources`	All resource types	
No name by design	Resource types in IAM service	`compartments`, `users`, `groups`, `dynamic-groups`, `policies`, `identity-providers`, `tenancy tag-namespaces`, `tag-definitions`
`instance-family`	Resource types in compute service	`console-histories`, `instance-console-connection`, `instance-images`, `instances`, `volume-attachments`
`volume-family`	Resource types in block storage service	`volumes`, `volume-attachments`, `volume-backups`
`virtual-network-family`	Resource types in virtual networking service	`vcns`, `subnets`, `route-tables`, `security-lists`, `dhcp-options`, `private-ips`, `public-ips`, `internet-gateways`, `local-peering-gatewaysdrgs`, `deg-attachments`, `cpes`, `ipsec-connections`, `cross-connects`, `cross-connect-groups`, `virtual-circuits`, `vnics`, `vnic-attachments`
`object-family`	Resource types in object storage service	`buckets`, `objects`

Resource Type Family	Description	Resource Types
`database-family`	Resource types in DbaaS service	`db-systems`, `db-nodes`, `db-homes`, `databases`, `backups`
`load-balancers`	Resources in Load Balancer service	`load-balancers`
`file-family`	Resources in file storage service	`file-systems`, `mount-targets`, `export-sets`
`dns`	Resources in DNS service	`dns-zones`, `dns-records`, `dns-traffic`
`email-family`	Resources in email delivery service	`approved-senders`, `suppressions`

For more information about IAM verbs and resource type permission mappings, see Details for the Core Services.

IAM security policies can be made fine-grained through conditions. Access specified in the policy is allowed only if the condition statements evaluate to true. Conditions are specified using predefined variables. The variables use the key words `request` or `target`, depending on whether the variable is relevant to the request or the resource being acted on, respectively. For information about supported predefined variables, see Policy Reference.

IAM dynamic groups are used to authorize Compute instances to access Oracle Cloud Infrastructure APIs. The instance principals feature can be used by applications, running on the instances, to programmatically access Oracle Cloud Infrastructure services. Customers create dynamic groups, which include instances as members, and authorize access to their tenancy resources using IAM security policies. All access by instances is captured in the audit logs available to customers.

IAM Federation

- Oracle recommends that you use federation to manage logins into the Console. Identity federation supports SAML 2.0 compliant identity providers, and can be used to federate on-premises users and groups to IAM users and groups. The enterprise administrator needs to set up a federation trust between the on-premises identity provider (IdP) and IAM, in addition to creating mapping between on-premises groups and IAM groups. Then, on-premises users can single sign-on (SSO) into the Console, and access resources based on authorization of IAM groups they belong to. For more information about federating to the Console, see Federating with Identity Providers. Federation is especially important for enterprises using custom policies for user authentication (for example, multifactor authentication) . For more information about managing users and groups under federation, see Federating with Identity Providers.
- When using federation, Oracle recommends that you create a federation administrators group that maps to the federated IdP administrator group. The federation administrators group will have administrative privileges to manage customer tenancy, while being governed by the same security policies as the federated IdP administrator group. In this scenario, it is a good idea to have access to the local tenancy administrator user (that is, member of the default tenancy administrator IAM group), to handle any break-glass type scenarios (for example, inability to access resources through federation). However, you must prevent any unauthorized use of this highly privileged local tenancy administrator user. Oracle recommends the following approach to securely managing the tenancy administrator user:
    1. Create a local user belonging to the default tenancy administrator group.
    2. Create a highly complex Console password or passphrase (18 characters or more, with at least one lowercase letter, one uppercase letter, one number, and one special character) for the local tenancy administrator user.

3. Securely escrow the local tenancy administrator user password in an on-premises location (for example, place the password in a sealed envelope in an on-premises physical safe).
4. Create security policies for accessing the escrowed password only under specific "break-glass" scenarios.
5. Have IAM security policy to prevent the federated administrators IAM group from adding or modifying membership of the default tenancy administrator group to prevent security by-passes.
6. Monitor audit logs for accesses by default tenancy administrator and changes to the administrator group, to alert on any unauthorized actions. For additional security, the local tenancy administrator user password can be rotated after every login, or periodically, based on a password policy.

For an example that shows the way various IAM components fit together, see Example Scenario. Periodically monitor Audit logs to review changes to IAM users, groups, policies, compartments, and tags.

Security Policy Examples

Common IAM security policy examples are available at Common Policies. In all the examples that follow, the policies are scoped to a tenancy. However, by specifying a compartment name, you can scope down the policies to specific compartments in a tenancy.

Create Service-level Admins for Least Privilege

To implement security principle of least privilege, you can create service-level admins in the tenancy to further scope down administrative access. This means that service-level administrators can only manage resources of a specific service. For instance, network administrators need administrative (`manage`) access only to VCN resources, and not to other resources. The following example shows how to create administrator groups for block storage (`VolumeAdmins`), VCN (`NetworkAdmins`), databases (`DBAdmins`), and object storage (`StorageAdmins`).

```
Allow group TenancyAdmins to manage all-resources in tenancy
Allow group VolumeAdmins to manage volume-family in tenancy
Allow group NetworkAdmins to manage virtual-network-family in tenancy
```

```
Allow group StorageAdmins to manage object-family in tenancy
Allow group DBAdmins to manage database-family in tenancy
```

You can further constrain the security policies to a specific compartment. For example, the HR department in an enterprise can create group `HRAdmins` to manage resources within its compartment, `HR-compartment`. The `HRNetworkAdmins` group has administrative access to VCN resources only within the `HR-compartment` compartment.

```
Allow group HRAdmins to manage all-resources in compartment HR-compartment
Allow group HRNetworkAdmins to manage virtual-network-family in compartment HR-compartment
```

Compliance auditors are tasked with examining cloud resources and verifying for policy violations. The following policy allows group `InternalAuditors` to inspect (`list`) all resources in a tenancy.

```
Allow group InternalAuditors to inspect all-resources in tenancy
```

If you want to limit auditors to only inspect users and groups in a tenancy, you can create a group `UserAuditors` with the following policy:

```
Allow group UserAuditors to inspect users in tenancy
Allow group UserAuditors to inspect groups in tenancy
```

If you want to create an auditor group that can only inspect VCN firewalls in the tenancy, use the following policy:

```
Allow group FirewallAuditors to inspect security-lists in tenancy
```

In all the policy examples, you can constrain the policies to a compartment by specifying `Compartment` *`<name>`* (where ***<name>*** is the compartment name) in the policy.

Restrict Ability to Change Tenancy Administrators Group Membership

Members in the group `Administrators` can manage all resources in a tenancy. Membership of the `Administrators` group is controlled by users in the group. Usually, it's convenient to have a group to create and add users in the tenancy, but restrict them from making changes to the `Administrators` group membership. The following example creates a group `UserAdmins` to do this.

```
Allow group UserAdmins to inspect users in tenancy
Allow group UserAdmins to inspect groups in tenancy
Allow group UserAdmins to use users in tenancy
 where target.group.name!='Administrators'
```

```
Allow group UserAdmins to use groups in tenancy
 where target.group.name!='Administrators'
```

Use verb with conditions (third and fourth policy statements) allows `UserAdmins` to add users and groups using APIs (`UpdateUser`, `UpdateGroup`) to all groups in the tenancy except the `Administrators` group. However, because `target.group.name!='Administrators'` is not related to the `list` and `get` APIs (`ListUsers`, `GetUser`, `ListGroups`, and `GetGroup`), these APIs will fail. So you must explicitly add the `inspect` verb (first and second policy statements) to allow `UserAdmins` to get user and group membership information.

Prevent Delete or Update of Security Policies

The following example creates a group `PolicyAdmins` to be able to create and list security policies created by tenancy administrators, but not delete or update them.

```
Allow group PolicyAdmins to use policies in tenancy
Allow group PolicyAdmins to manage policies in tenancy
 where request.permission='POLICY_CREATE'
```

This security policy statement explicitly only allows `POLICY_CREATE` permission, and not to `POLICY_DELETE` and `POLICY_UPDATE`.

Prevent Admins from Accessing or Altering User Credentials

Some compliance requirements need separation of duties, especially where user credential management functionality is separated from tenancy management. In this case, you can create two administration groups, `TenancyAdmins` and `CredentialAdmins` where `TenancyAdmins` can perform all tenancy management functions except user credential management, and `CredentialAdmins` can manage user credentials. `TenancyAdmins` can access all APIs except those that list, update, or delete user credentials. `CredentialAdmins` can only manage the user credentials.

```
Allow group TenancyAdmins to manage all resources in tenancy
 where all {request.operation!='ListApiKeys',
            request.operation!='ListAuthTokens',
            request.operation!='ListCustomerSecretKeys',
            request.operation!='UploadApiKey',
            request.operation!='DeleteApiKey',
            request.operation!='UpdateAuthToken',
            request.operation!='CreateAuthToken',
            request.operation!='DeleteAuthToken',
```

```
            request.operation!='CreateSecretKey',
            request.operation!='UpdateCustomerSecretKey',
            request.operation!='DeleteCustomerSecretKey'}
Allow group CredentialAdmins to manage users in tenancy
 where any {request.operation='ListApiKeys',
            request.operation='ListAuthTokens',
            request.operation='ListCustomerSecretKeys',
            request.operation='UploadApiKey',
            request.operation='DeleteApiKey',
            request.operation='UpdateAuthToken',
            request.operation='CreateAuthToken',
            request.operation='DeleteAuthToken',
            request.operation='CreateSecretKey',
            request.operation='UpdateCustomerSecretKey',
            request.operation='DeleteCustomerSecretKey'}
```

USEFUL CLI COMMANDS

In all the following examples, environment variables `$T` and `$C`are set to tenancy OCID and compartment OCID, respectively.

LIST COMPARTMENTS IN A TENANCY

```
# list all compartments (OCID, display name, description) in tenancy $T
oci iam compartment list -c $T
# grep above command for important fields
oci iam compartment list -c $T | grep -E "name|description|\"id\""
```

LIST IAM USERS

```
# lists all users (OCID, display name, description) in tenancy $T
oci iam user list -c $T
# grep above command for important fields
oci iam user list -c $T | grep -E "name|description|\"id\""
```

LIST IAM GROUPS

```
# lists all groups (OCID, display name, description) in tenancy $T.
oci iam group list -c $T
# grep above command for important fields
oci iam group list -c $T | grep -E "name|description|\"id\""
```

LIST USERS IN A GROUP

The following command is helpful for listing users in groups, especially users with administrative privileges. This command requires the OCID of the group whose users are listed.

```
# list users in group with OCID <GROUP_OCID>
oci iam group list-users -c $T --group-id <GROUP_OCID>
```

LIST SECURITY POLICIES

```
# lists all policies (OCID, name, statements) in tenancy $T. Remove pipe to grep to get entire
information
oci iam policy list -c $T
# grep above command for important fields
oci iam policy list -c $T | grep -E "name|Allow|\"id\""
```

Securing Networking: VCN, Load Balancers, and DNS

SECURITY RECOMMENDATIONS

The Networking service has a collection of features for enforcing network access control and securing VCN traffic. These features are listed in the following table.

VCN Feature	Security Description
Public and private subnets	Your VCN can be partitioned into subnets. Subnets have historically been specific to an availability domain, but can now be regional (covering all availability domains in the region). Instances inside private subnets cannot have public IP addresses. Instances inside public subnets can optionally have public IP addresses at your discretion.
Security rules	Security rules provide stateful and stateless firewall capability to control network access to your instances. To implement security rules in your VCN, you can use network security groups (NSGs) or security lists. For more information, see Comparison of Security Lists and Network Security Groups.

VCN Feature	Security Description
Gateways	Gateways let resources in a VCN communicate with destinations outside the VCN. The gateways include: • Internet gateway: for internet connectivity (for resources with public IP addresses in public subnets) • NAT gateway: for internet connectivity without exposing the resources to incoming internet connections (for resources in private subnets) • Dynamic routing gateway (DRG): for connectivity to networks outside the VCN's region (for example, your on-premises network by way of an IPSec VPN or FastConnect, or a peered VCN in another region) • Service gateway: for private connectivity to Oracle services such as Object Storage • Local peering gateway (LPG): for connectivity to a peered VCN in the same region
Route table rules	Route tables control how traffic is routed from your VCN's subnets to destinations outside the VCN. Routing targets can be VCN gateways or a private IP address in the VCN.
IAM polices for virtual-network-family	IAM policies specify access and actions permitted by IAM groups to resources in a VCN. For example, IAM polices can give administrative privileges to network administrators who manage the VCNs, and scoped-down permissions to normal users.

Oracle recommends that you periodically monitor Oracle Cloud Infrastructure Audit logs to review changes to VCN network security groups, security lists, route table rules, and VCN gateways.

NETWORK SEGMENTATION: VCN SUBNETS

- Formulate a tiered subnet strategy for the VCN, to control network access. A common design pattern is to have the following subnet tiers:
  1. **DMZ subnet** for load balancers
  2. **Public subnet** for externally accessible hosts such as NAT instances, intrusion detection (IDS) instances, and web application servers
  3. **Private subnet** for internal hosts such as databases

  No special routing is required for the instances in the different subnets to communicate. However, you can control the types of traffic between the different tiers by using the VCN's network security groups or security lists.
- Instances in the private subnet only have private IP addresses and can be reached only by other instances in the VCN. Oracle recommends that you place security-sensitive hosts (DB systems, for example) in a private subnet, and use security rules to control the type of connectivity to hosts in a public subnet. In addition to VCN security rules, configure host-based firewalls such as iptables, firewalld for network access control, as a defense-in-depth mechanism.
- You can add a service gateway to your VCN to enable DB systems in the private subnet to directly back up to Object Storage without the traffic traversing the internet. You must set up the routing and security rules to enable that traffic. For more information for bare metal or virtual machine DB systems, see Network Setup for DB Systems. For more information for Exadata DB systems, see Network Setup for Exadata DB Systems.

NETWORK ACCESS CONTROL: VCN SECURITY RULES

- Use your VCN's security rules to restrict network access to instances. A security rule is stateful by default, but can also be configured to be stateless. A common practice is to use stateless rules for high-performance applications. In a case where network traffic matches both stateful and stateless security lists, the stateless rule takes precedence. For more information about configuring VCN security rules, see Security Rules.
- To prevent unauthorized access or attacks on Compute instances, Oracle recommends that you use a VCN security rule to allow SSH or RDP access only from authorized CIDR blocks rather than leave them open to the internet (0.0.0.0/0). For additional security,

you can temporarily enable SSH (port 22) or RDP (port 3389) access on an as-needed basis using the VCN API `UpdateNetworkSecurityGroupSecurityRules` (if you're using network security groups) or `UpdateSecurityList` (if you're using security lists). For more information about enabling RDP access, see To enable RDP access in Creating an Instance. For performing instance health checks, Oracle recommends that you configure VCN security rules to allow ICMP pings. For more information, see Rules to Enable Ping.

- Oracle recommends bastion hosts as a way to control external access (for example, SSH) to VCN hosts. Usually bastion hosts in a VCN public subnet control access to VCN private subnet hosts. For more information about setting up an SSH bastion host in a VCN, see the white paper Bastion Hosts: Protected Access for Virtual Cloud Networks.
- VCN network security groups (NSGs) and security lists enable security-critical network access control to Compute instances, and it is important to prevent any unintended or unauthorized changes to NSGs and security lists. To prevent unauthorized changes, Oracle recommends that you use IAM policies to allow only network administrators to make NSG and security list changes.

Secure Connectivity: VCN Gateways and FastConnect Peering

- VCN gateways provide external connectivity (internet, on-premises, or peered VCN) to VCN hosts. See the table earlier in this topic for a list of the type of gateways. Oracle recommends that you use an IAM policy to allow only network administrators to create or modify VCN gateways.
- Carefully consider allowing internet access to any instances. For example, you don't want to accidentally allow internet access to sensitive database instances. In order for an instance in a VCN to be *publicly accessible from the internet*, you must configure the following VCN options:
    - The instance must be in a VCN public subnet.
    - The VCN containing the instance must have an internet gateway enabled and configured to be the routing target for outbound traffic.
    - The instance must have a public IP address assigned to it.

    - The VCN security list for the instance's subnet must be configured to allow inbound traffic from `0.0.0.0/0`. Or if you're using network security groups (NSG), the instance must be in an NSG that allows that traffic.
- VPN IPSec provides connectivity between a customer's on-premises network and VCN. You can create two IPSec tunnels for high availability. For more information about creating VPN tunnels to connect VCN DRG to customer CPEs, see VPN Connect.
- FastConnect peering allows you to connect your on-premises network to your VCN with a private circuit so that the traffic does not traverse the public internet. You can set up private peering (to connect to private IP addresses), or public peering (to connect to Oracle Cloud Infrastructure public endpoints, such as for Object Storage). For more information about FastConnect peering options, see FastConnect.

VIRTUAL SECURITY APPLIANCES IN A VCN

- The Networking service lets you implement network security functions such as intrusion detection, application-level firewalls, and NAT (although you can instead use a NAT gateway with your VCN). You can do this by routing all the subnet traffic to a network security host, using route table rules that use a local VCN private IP address as a target. For more information, see Using a Private IP as a Route Target. For high availability, you can assign the gateway security host a secondary private IP address, which you can move to a VNIC on a standby host in case of primary host failure. For more information about setting up a NAT instance in a VCN, see the white paper NAT Instance Configuration: Enabling Internet Access for Private Subnets. Full network packet capture or network flow logs can be captured on the NAT instances using tcpdump, and the logs can be uploaded periodically to an Object Storage bucket.
- Virtual security appliances can be run as virtual machines (VMs) on a bring-your-own-hypervisor (BYOH) model on a bare metal instance. Virtual security appliance VMs running on the BYOH bare metal instance each have their own secondary VNIC, giving direct connectivity to other instances and services in the VNIC's VCN. For information about enabling BYOH on a bare metal instance using an open-source KVM hypervisor, see Installing and Configuring KVM on Bare Metal Instances with Multi-VNIC.
- Virtual security appliances can also be installed on Compute virtual machines (VMs) where VMDK or QCOW2 images of security appliances can be imported using the bring

your own image (BYOI) feature. However, due to infrastructure dependencies, the BYOI feature might not work for some appliances, in which case the BYOH model would be another option to use. For more information about importing appliance images into Oracle Cloud Infrastructure, see Bring Your Own Image (BYOI).

LOAD BALANCERS

- Oracle Cloud Infrastructure load balancers enable end-to-end TLS connections between a client's applications and a customer's VCN. The TLS connection can be terminated at an HTTP load balancer, or on a back-end server by using a TCP load balancer. The load balancers use TLS1.2 by default. For information about configuring an HTTPS listener, see Managing Load Balancer Listeners. You can also upload your own TLS certificates. For more information see Managing SSL Certificates.
- You can configure network access to load balancers by using VCN network security groups or security lists. This method provides similar functionality to traditional load balancer firewalls. For public load balancers, Oracle recommends that you use a regional public subnet (for example, DMZ subnet) for instantiating the load balancers in a highly available configuration across two different availability domains. You can configure the load balancer firewall rules by setting up the load balancer's network security groups or the subnet's security lists. For more information about creating load balancer security lists, see Update Load Balancer Security Lists and Allow Internet Traffic to the Listener. Similarly, you must configure the VCN network security groups or security lists for the backend servers to limit traffic only from the public load balancers. For more information about configuring backend server security lists, see Update Rules to Limit Traffic to Backend Servers.

DNS ZONES AND RECORDS

DNS zones and records are critical for accessibility of web properties. Incorrect updates or unauthorized deletions could result in outage of services, accessed through the DNS names. Oracle recommends that you limit IAM users who can modify DNS zones and records.

SECURITY POLICY EXAMPLES

ALLOW USERS TO ONLY VIEW SECURITY LISTS

Your network administrators are the personnel who should have the ability to create and manage network security groups and security lists.

However, you may have network users who need to know what security rules are in a particular network security group (NSG) or security list.

The first line in the following example policy allows the NetworkUsers group to view security lists and their contents. This policy does not let the group create, attach, delete, or modify security lists.

The second line lets the NetworkUsers group view the security rules in NSGs, and also view what VNICs and parent resources are in NSGs. The second line does not let the NetworkUsers group change the security rules in NSGs.

```
Allow group NetworkUsers to inspect security-lists in tenancy
Allow group NetworkUsers to use network-security-groups in tenancy
```

PREVENT USERS FROM CREATING EXTERNAL CONNECTION TO THE INTERNET

In some cases, you might need to prevent users from creating external internet connectivity to their VCN. In the following example policy, the NetworkUsers group is prevented from creating an internet gateway.

```
Allow group NetworkUsers to manage internet-gateways in tenancy
 where request.permission!='INTERNET_GATEWAY_CREATE'
```

PREVENT USERS FROM UPDATING DNS RECORDS AND ZONES

In the following example policy, the NetworkUsers group is prevented from deleting and updating DNS zones and records

```
Allow group NetworkUsers to manage dns-records in tenancy
 where all {request.permission!='DNS_RECORD_DELETE',
            request.permission!='DNS_RECORD_UPDATE'}
Allow group NetworkUsers to manage dns-zones in tenancy
 where all {request.permission!='DNS_ZONE_DELETE',
            request.permission!='DNS_ZONE_UPDATE'}
```

USEFUL CLI COMMANDS

In all the following examples, the environment variables $T , $C and $VCN are set to tenancy OCID, compartment OCID, and VCN OCID, respectively.

LIST OPEN SECURITY LISTS IN A VCN

```
# list open (0.0.0.0/0) security lists in VCN $VCN in compartment $C
oci network security-list list -c $C --vcn-id $VCN | grep "source" | grep "\"0.0.0.0/0\""
```

LIST GATEWAYS IN A VCN

```
# list all internet gateways in VCN $VCN in compartment $C
oci network internet-gateway list -c $C --vcn-id $VCN
# list all DRGs in compartment $C
oci network drg list -c $C
# list all local peering gateways in vcn $VCN in compartment $C
oci network local-peering-gateway list -c $C --vcn-id $VCN
```

LIST ROUTE TABLE RULES IN A VCN

```
# list route table rules in VCN $VCN in compartment $C
oci network route-table list -c $C --vcn-id $VCN
```

Securing Object Storage

SECURITY RECOMMENDATIONS

Assign least privileged access for IAM users and groups to resource types in object-family (buckets and objects). For example, the inspect verb gives the least privilege. Inspect lets you check to see if a bucket exists (`HeadBucket`) and list the buckets in a compartment (`ListBucket`). The manage verb gives all permissions on the resource. You can create IAM security policies to give appropriate bucket and object access to various IAM groups. For more information about IAM verbs and permissions for Object Storage buckets and objects, see Details for Object Storage, Archive Storage, and Data Transfer. For users without IAM credentials, we recommend that you use pre-authenticated requests (PARs) to give time-bound access to objects or buckets.

PUBLIC BUCKETS SECURITY CONTROLS

- A public bucket allows unauthenticated and anonymous reads to all objects in the bucket. Carefully evaluate the intended use case for public buckets before you enable public buckets. We recommend that you use pre-authenticated requests (PARs) to give bucket or object access(read or write) to users without IAM credentials. By defaults, buckets are created with no public access (access type is set to `NoPublicAccess`).
- You can make existing buckets public by updating the bucket access type to `ObjectRead` or `ObjectReadWithoutList`. To minimize the possibility of existing buckets being made public inadvertently or maliciously, `BUCKET_UPDATE` permission should be restricted to a minimal set of IAM groups.

PRE-AUTHENTICATED REQUEST (PAR)

- Pre-authenticated requests (PARs) provide a mechanism to provide access to objects stored in buckets, to users who do not have IAM user credentials. In a PAR, an IAM user who has appropriate privileges for accessing objects, can create URLs which grant time-bound read or write access to these objects. For more information about creating PARs, see Using Pre-Authenticated Requests.
- The creator of a PAR must have `PAR_MANAGE` IAM permission. You can create the following PARs:
  - Bucket PAR to allow writes to a bucket
  - Object PAR for reading an object
  - Object PAR for writing an object
  - Object PAR to read or write an object
- A PAR cannot be used to list objects in a bucket.
- All PAR accesses to a bucket or object are logged in Audit logs.
- We recommend that you note down the PAR URL created. By design, it is not possible to retrieve a forgotten PAR URL. If you forget a PAR URL, you must create a new PAR.

DATA DURABILITY

- Minimize data loss because of inadvertent deletes by an authorized user or malicious deletes. We recommended giving `BUCKET_DELETE` and `OBJECT_DELETE` permissions to a minimum set of IAM users and groups. Grant `DELETE` permission only to tenancy and compartment admins.
- Write once read many (WORM) compliance requires that objects cannot be deleted or modified. WORM is achieved by granting `OBJECT_CREATE`, `OBJECT_READ`, and `OBJECT_INSPECT` permissions to an IAM group. Grant `OBJECT_OVERWRITE` permission to prevent modification to existing an object.

DATA ENCRYPTION

- All data in Object Storage is encrypted at rest by using AES-256. Encryption is on by default and cannot be turned off. Each object is encrypted with its encryption key, and the object encryption keys are encrypted with a master encryption key. In addition, customers can use client-side encryption to encrypt objects with their encryption keys before storing them in Object Storage buckets. An available option for customers is to use the Amazon S3 Compatibility API, along with client-side object encryption support available in AWS SDK for Java. See Amazon S3 Compatibility API for more details about on this SDK.
- Data in transit between customer clients (for example, SDKs and CLIs) and Object Storage public endpoints is encrypted with TLS 1.2 by default. FastConnect public peering allows on-premises access to Object Storage to go over a private network, rather than the public internet.

DATA INTEGRITY

- To verify object data integrity, a cryptographic hash using MD5 is provided for all objects uploaded to Object Storage. We recommend that you verify that the offline MD5 hash of an object matches the hash value returned by the Console or API after upload. Oracle Cloud Infrastructure provides the object hash value in base64 encoding. To covert the base64 encoded hash value to hexadecimal, use the following command:

```
python -c 'print "BASE64-ENCODED-MD5-VALUE".decode("base64").encode("hex")'
```

Linux provides an md5sum command line utility to compute MD5 hash value of an object in hexadecimal format.

- Object Storage service supports multipart uploads for more efficient and resilient uploads, especially for large objects. In a multipart upload, a large object is broken up into smaller parts by specifying a part size in MiB. Each part is uploaded separately. Object Storage then combines all the parts to create the original object. If any of the parts fail to upload, only those parts need to be retried for upload, and not the entire object. In a multipart upload, the MD5 hash values are computed for each part, and an MD5 hash computed over all the individual hash values to get the output MD5 value. To verify the MD5 value returned for a multipart upload, follow the same process for offline MD5 hash calculation. A sample script for offline calculation of MD5 hash value for a multipart upload to Object Storage is available here (link: https://gist.github.com/itemir/f5bc9fded6483cd79c89ebf4ca1cfd30).

SECURITY POLICY EXAMPLES

In the following examples, the policies are scoped to a tenancy. However, specifying a compartment name reduces the scope to a specific compartment in a tenancy.

RESTRICT GROUP ACCESS TO SPECIFIC BUCKETS

You can restrict access by a group to a specific bucket by using the specific bucket name (target.bucket.name), regular expression matching (/*name/, /name*/, /*name*/), or defined tags (target.tag.definition.name).

The following is an example of restricting access by groups `BucketUsers` to a specific bucket.

```
Allow group BucketUsers to use buckets in tenancy
 where target.bucket.name='BucketFoo'.
```

You can modify this policy to restrict access by group `BucketUsers` to all buckets whose names are prefixed with `ProjectA_`.

```
Allow group BucketUsers to use buckets in tenancy
 where target.bucket.name=/ProjectA_*/
```

You can also match for post-fix (/*_ProjectA/) or substring (/*ProjectA*/).

RESTRICT GROUP ACCESS TO READ OR WRITE TO OBJECTS IN A SPECIFIC BUCKET

The following example allows listing and reading objects by group `BucketUsers` from a specific bucket named `BucketFoo`.

```
Allow group BucketUsers to read buckets in tenancy
Allow group BucketUsers to manage objects in tenancy
 where all {target.bucket.name='BucketFoo',
            any {request.permission='OBJECT_INSPECT',
                 request.permission='OBJECT_READ'}}
```

The following policy modifies the previous policy to allow listing and writing objects to `BucketFoo`.

```
Allow group BucketUsers to read buckets in tenancy
Allow group BucketUsers to manage objects in tenancy
 where all {target.bucket.name='BucketFoo',
            any {request.permission='OBJECT_INSPECT',
                 request.permission='OBJECT_CREATE'}}
```

You can restrict this policy to read or write access to a set of buckets by using regular expressions or tags rather than a specific bucket.

PREVENT DELETE OF BUCKETS OR OBJECTS

In the following example, the group `BucketUsers` can perform all actions on buckets and objects except delete.

```
Allow group BucketUsers to manage objects in tenancy
 where request.permission!='OBJECT_DELETE'
Allow group BucketUsers to manage buckets in tenancy
 where request.permission!='BUCKET_DELETE'
```

The following example further restricts object deletion from the specific bucket (`BucketFoo`).

```
Allow group BucketUsers to manage objects in tenancy
  where any {target.bucket.name!='BucketFoo',
             all {target.bucket.name='BucketFoo',
                  request.permission!='OBJECT_DELETE'}}
```

ENABLE WORM COMPLIANCE FOR OBJECTS

The following policy enables WORM compliance by removing permissions for group `BucketUsers` to delete or update objects.

```
Allow group BucketUsers to manage objects in tenancy
 where any {request.permission='OBJECT_INSPECT',
            request.permission='OBJECT_READ',
            request.permission='OBJECT_CREATE'}
```

The following policy allows for WORM compliance.

```
Allow group BucketUsers to manage buckets in tenancy
 where any {request.permission='BUCKET_INSPECT',
            request.permission='BUCKET_READ',
            request.permission='BUCKET_CREATE',
            request.permission='PAR_MANAGE'}
```

Prevent Public Buckets Configuration

As mentioned in previous section, `BUCKET_CREATE` and `BUCKET_UDPATE` permissions are required to create buckets or make existing private buckets public. Removing these permissions prevents users from creating buckets or making existing buckets public.

```
Allow group BucketUsers to manage buckets in tenancy
 where any {request.permission='BUCKET_INSPECT',
            request.permission='BUCKET_READ',
            request.permission='PAR_MANAGE'}
```

Useful CLI Commands

Here are some useful commands to determine if you have public buckets or PARS in your tenancy.

List of Public Buckets

The following command returns the public-access-type assigned to a bucket.

```
# "public-access-type" of 'NoPublicAccess' indicates a private bucket, and
# anything else ('ObjectRead') indicates a public bucket
oci os bucket get -ns <your_namespace> --bucket-name <bucket_name> | grep "public-access-type"
```

List of Bucket Pre-Authenticated Requests (PARs)

The following command returns a list of object PARs in a bucket.

```
# list all PARs for objects in bucket $BUCKET_NAME
oci os preauth-request list -ns <your_namespace> -bn <bucket_name>
```

Securing Resource Manager

Resource Manager allows you to automate installing and provisioning Oracle Cloud Infrastructure resources by committing the provisioning instructions to configuration files. These configuration files capture the step-by-step provisioning instructions using a declarative language that follows the "infrastructure-as-code" model. The provisioning instructions are executed as "jobs"; the Oracle Cloud Infrastructure resources that are provisioned when you run the jobs are organized into "stacks."

Executing jobs and provisioning stacks is gated using role-based access control (RBAC), which is enabled by Oracle Cloud Infrastructure Identity and Access Management (IAM). This gives administrators granular control over user access to Oracle Cloud Infrastructure resources and the actions that users can take on these resources.

The Resource Manager security scheme rests on three pillars:

- **Security groups**. Administrator-defined groups that have permission to perform specific operations on stacks and jobs. Individual users are assigned to security groups and can then perform operations that are allowed by that group.
- **Permission sets**. Sets of permissions that are specific to jobs and stacks. Permission sets for jobs and stacks are listed in Table 1.
- **Operations**. The operations (or actions) that are allowed and the permissions that are required to perform each one. These are listed in Table 2.

Resource Manager Operations and Permissions

The Resource Manager supports two permission sets: one for stack resources and another for job resources. Table 1 lists permission sets that are associated with each resource type.

TABLE 1. RESOURCE TYPES AND PERMISSION SETS

Resource Type	Permissions
Stacks (`orm-stacks`)	inspect orm-stackread orm-stack use orm-stack create orm-stack update orm-stack delete orm-stack
Jobs (`orm-jobs`)	inspect orm-job read orm-job manage orm-job

Each of the permissions in the preceding table are associated with specific Resource Manager operations. The table that follows lists Resource Manager operations, then shows which permissions are required to execute each of the operations. Notice that the `CreateJob` operation requires two permissions.

TABLE 2. RESOURCE OPERATIONS AND REQUIRED PERMISSIONS

Operation	Permission
Generate a list of stacks (`ListStacks`)	inspect orm-stack
Create a stack (`CreateStack`)	create orm-stack
Get a stack (`GetStack`)	read orm-stack
Update a stack (`UpdateStack`)	update orm-stack
Delete a stack (`DeleteStack`)	delete orm-stack
Get a stack Terraform configuration (`GetStackTfConfig`)	read orm-stack

Operation	Permission
List jobs (`ListJobs`)	inspect orm-job
Create a job (`CreateJob`)	use orm-stack *and* manage orm-job
Get a job (`GetJob`)	read orm-jobs
Update a job (`UpdateJob`)	manage orm-job
Cancel a job (`CancelJob`)	manage orm-job
Get a job Terraform state file (`GetJobTfState`)	read orm-job
Get a job Terraform configuration (`GetJobTfConfig`)	read orm-job
Get a job Terraform execution plan (`GetJobTfExecutionPlan`)	read orm-job
Get job logs (`GetJobLogs`)	read orm-job

Recommended Security Policies

Following are policy recommendations for securing Resource Manager. For more information about security policies, see Getting Started with Policies. See also How Policies Work and Policy Syntax.

Permission to Manage Stacks and Jobs

The following policy grants permission to a specified group to manage both stacks and jobs, and also to manage resources on the tenancy stacks.

```
Allow group <group_name> to manage orm-stacks in compartment
Allow group <group_name> to manage orm-jobs in compartment
```

Prevent Users from Running Destroy Jobs

In addition to granting permission to perform specific operations, you can also create a policy that prevents certain actions. The following policy example explicitly prevents members of a

specified group from running Destroy jobs on a stack.

```
Allow group <group_name> to use orm-stacks in compartment
Allow group <group_name> to read orm-jobs in compartment
Allow group <group_name> to manage orm-jobs in compartment where any {target.job.operation = 'PLAN',
target.job.operation = 'APPLY'}
```

Notice that you must include the new permission to `read orm-jobs in compartment` because the statement includes a `where` condition that references variables that are not relevant to listing or getting jobs.

Potential Security Risks and Mitigations

Terraform State Files

Terraform state (.tfstate) can contain sensitive data, including resource IDs and in some cases sensitive user data like passwords. HashiCorp provides recommendations for handling Terraform state in the article Sensitive Data in State.

To control access to the Terraform state file, you can create a security policy that limits access to reading jobs, such as the following:

```
Allow group <group_name> to read orm-jobs in compartment
```

Note

Because the permission **read orm-jobs** also affects other operations such as getting logs and Terraform configurations, you should segregate state files in a compartment on which a restrictive policy will not limit the ability to perform other operations.

Terraform Configuration .Zip Files

The Resource Manager workflow includes uploading your Terraform configuration to the service as a .zip file. Because the Terraform configuration can be accessed using the ORM API (`GetJobTfConfig`), it is highly recommended that you do not include sensitive information in your configuration files.

Addressing Basic Configuration Issues

This topic lists procedures to address common configuration issues that affect the security of your cloud resources.

Block Volume

Block volume detached from instance

Issue: Ensure that only Oracle Cloud Infrastructure administrators can detach block volumes from instances.

Basics: When you detach a block volume it decouples the volume from its associated instance, affecting the data available to the instance. This could impact data availability from business-critical data to the successful completion of scheduled volume backups. To minimize loss of data due to inadvertent volume detachments by an authorized user or malicious volume detachments you should restrict the `VOLUME_ATTACHMENT_DELETE` permission to administrators.

To prevent detachment of block volumes:

The following policy allows the group `VolumeUsers` to manage volumes and volume attachments except for detaching volumes:

```
Allow group VolumeUsers to manage volumes in tenancy
Allow group VolumeUsers to manage volume-attachments in tenancy
    where request.permission!='VOLUME_ATTACHMENT_DELETE'
```

This change prevents `VolumeUsers` from detaching volumes from instances.

More information:

- Securing Block Volume
- Getting Started with Policies

- How Policies Work
- For volume-family Resource Types

Compute

Instance created based on unapproved custom image

Issue: An instance was created from a custom image that is unsupported in your environment.

Basics: When users create instances they can select from Oracle-provided images, boot volumes from terminated instances, or custom images. Custom images represent a wide variety of images which can include images that aren't approved for your environment. If you use tags in your Oracle Cloud Infrastructure tenancy to identify approved images, verify whether the image the instance is based on is an approved image and terminate the instance if necessary.

To verify the tags for the image the instance was created from:

The following procedure is for the Oracle Cloud Infrastructure Console.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
2. Click the instance you're interested in.
3. Click the **Image** link to view the source image.
4. Click the **Tags** tab to view the tags applied to this image.

If the custom image does not have an approved tag, and the instance needs to be terminated, see Terminating an Instance

More information:

- Securing Compute
- Resource Tags

- Creating an Instance
- Image Import/Export
- Bring Your Own Image (BYOI)

IAM

Member of the Administrators group used API keys

Issue: A user who is a member of the Administrators group accessed resources using an API key.

Basics:

- API keys are credentials used to grant programmatic access to Oracle Cloud Infrastructure.
- For security and governance reasons, users should only have access to resources they need to interact with.
- For individuals who are members of the Administrators group who also need access to resources through the API, create another user in IAM to which you attach the API keys. Grant the user with the API keys permissions to only the resources they need to interact with programmatically.

To create a user, group, and policy with limited permissions:

The following set of procedures shows you how to set up an example user with limited permissions. In this example, the user needs to be able to launch instances in a specific compartment.

The following procedure is for the Oracle Cloud Infrastructure Console.

Create a User

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity**

and click **Users**.

2. Click **Create User**.
3. In the **New User** dialog:
    - **Name**: Enter a unique name or email address for the new user.
      The value will be the user's login to the Console and must be unique across all other users in your tenancy.
    - **Description**: Enter a description (required).
4. Click **Create User**.

Create a Group

Next, create the group ("InstanceLaunchers") that you will create the policy for.

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Groups**.
2. Click **Create Group**.
3. In the **Create Group** dialog:
    - **Name:** Enter a unique name for your group, for example, "InstanceLaunchers". Note that the name cannot contain spaces.
    - **Description:** Enter a description (required).
4. Click **Create Group**.

Create a Policy

In this example, the policy grants members of the group InstanceLaunchers permissions to launch instances in a specific compartment (CompartmentA).

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Policies**.

2. Click **Create Policy**.
3. Enter a unique **Name** for your policy, for example, "InstanceLaunchersPolicy". Note that the name cannot contain spaces.
4. Enter a **Description** (required), for example, "Grants users permission to launch instances in CompartmentA".
5. Enter the following **Statement**:

   ```
   Allow group InstanceLaunchers to manage instance-family in compartment CompartmentA
   ```

   This statement grants members of the InstanceLaunchers group permissions to launch and manage instances in the compartment called CompartmentA.
6. Click **Create Policy**.

Add the User to the Group

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Users**.
2. In the **Users** list, find the user and click the name.
3. On the user detail page, click **Groups** (on the left side of the page). The list of groups that the user belongs to is displayed.
4. Click **Add User to Group.**
5. From the **Groups** list, select InstanceLaunchers.
6. Click **Add**.

Upload an API signing key for the user

The following procedure works for a regular user or an administrator. Administrators can upload an API key for either another user or themselves.

Important

The API key must be an **RSA key in PEM format (minimum 2048 bits)**. The PEM format looks something like this:

```
-----BEGIN PUBLIC KEY-----
MIIBIjANBgkqhkiG9w0BAQEFAAOCAQ8AMIIBCgKCAQEAoTFqF...
...
-----END PUBLIC KEY——
```

For more information about generating a public PEM key, see Required Keys and OCIDs.

1. View the user's details:
   - If you're uploading an API key for *yourself*: Open the **Profile** menu () and click **User Settings**.
   - If you're an administrator uploading an API key for *another user*: In the Console, click **Identity**, and then click **Users**. Locate the user in the list, and then click the user's name to view the details.
2. Click **Add Public Key**.
3. Paste the key's value into the window and click **Add**.
   The key is added and its fingerprint is displayed (example fingerprint: d1:b2:32:53:d3:5f:cf:68:2d:6f:8b:5f:77:8f:07:13).

- Managing Groups
- Managing Users

Policy grants broad permissions

Issue: A policy grants full management permissions for at least one service in a compartment or in the tenancy.

Basics:

- Access to resources is controlled through policies. A *policy* is a document that specifies who can access which Oracle Cloud Infrastructure resources that your company has, and how. A policy simply allows a group to work in certain ways with specific types of resources in a particular compartment.
- For security and governance reasons, users should only have access to resources they need.
- Consider carefully the access level a user needs. Policy language provides a default set of verbs (`manage`, `use`, `read`, `inspect`) that allow you to easily scope users' permissions to a set of common tasks. For example, if a user needs to be able to update resources, but does not need to create or delete them, grant them the `use` permission, rather than the `manage` permission.
- The policy language is designed to let you write simple statements involving only verbs and resource-types, without having to state the permissions in the statement. For more fine-grained access control, you can use conditions combined with permissions or API operations to reduce the scope of access granted by a particular verb.
- Wherever possible, scope access to the specific compartments a user needs access to, rather than scoping it to the full tenancy.

Tips for writing least-privilege policies:

Scope the policy to a compartment instead of the tenancy

Each policy consists of one or more policy *statements* that follow a basic syntax. Where possible, scope policies to compartments, rather than to the tenancy. For example, update a policy like this:

```
Allow group <group_name> to <verb><resource-type> in tenancy
```

to include just the compartments needed:

```
Allow group <group_name> to <verb><resource-type> in compartment <compartment_name>
```

If the user needs access to multiple compartments, create a policy statement for each compartment. It is then easy to remove access to individual compartments, if necessary.

Scope permissions to those required to perform a job function

Oracle defines the possible verbs you can use in your policies. Here's a summary of the verbs, from least amount of access to the most:

Verb	Types of Access Covered	Target User
`inspect`	Ability to list resources, without access to any confidential information or user-specified metadata that may be part of that resource.	Third-party auditors
`read`	Includes `inspect` plus the ability to get user-specified metadata and the actual resource itself.	Internal auditors
`use`	Includes `read` plus the ability to work with existing resources (the actions vary by resource type). In general, this verb does not include the ability to create or delete that type of resource.	Day-to-day end users of resources
`manage`	Includes all permissions for the resource.	Administrators

Users who don't need to create or delete resources generally don't need manage permissions. If you have a policy like

```
Allow group <group_name> to manage <resource-type> in compartment <compartment_name>
```

but the user will never create or delete the resource-type, consider rewriting the policy to

```
Allow group <group_name> to use <resource-type> in compartment <compartment_name>
```

The Policy Reference includes details of the specific resource-types for each service, and which verb + resource-type combination gives access to which API operations.

- Details for Object Storage, Archive Storage, and Data Transfer
- Details for Registry
- Details for the Search Service

For fine-grained access control, scope access using conditions and API operations

In a policy statement, you can use conditions combined with permissions or API operations to

reduce the scope of access granted by a particular verb.

For example, let's say you want group XYZ to be able to list, get, create, or update groups (change their description), but not delete them. To list, get, create, and update groups, you need a policy with `manage groups` as the verb and resource-type. According to the table in Details for Verbs + Resource-Type Combinations, the permissions covered are:

- GROUP_INSPECT
- GROUP_UPDATE
- GROUP_CREATE
- GROUP_DELETE

To restrict access to only the desired permissions, you could add a condition *that explicitly states the permissions you want to allow*:

```
Allow group XYZ to manage groups in tenancy

 where any {request.permission='GROUP_INSPECT',
            request.permission='GROUP_CREATE',
            request.permission='GROUP_UPDATE'}
```

An alternative would be a policy that *allows all permissions except* GROUP_DELETE:

```
Allow group XYZ to manage groups in tenancy where request.permission != 'GROUP_DELETE'
```

Another alternative would be to write a condition *based on the specific API operations*. Notice that according to the table in Permissions Required for Each API Operation, both `ListGroups` and `GetGroup` require only the GROUP_INSPECT permission. Here's the policy:

```
Allow group XYZ to manage groups in tenancy

 where any {request.operation='ListGroups',
            request.operation='GetGroup',
            request.operation='CreateGroup',
            request.operation='UpdateGroup'}
```

It can be beneficial to use permissions instead of API operations in conditions. In the future, if a new API operation is added that requires one of the permissions listed in the permissions-

based policy above, that policy will already control XYZ group's access to that new API operation.

But notice that you can further scope a user's access to a permission by *also* specifying a condition based on API operation. For example, you could give a user access to GROUP_INSPECT, but then only to `ListGroups`.

```
Allow group XYZ to manage groups in tenancy

 where all {request.permission='GROUP_INSPECT',
            request.operation='ListGroups'}
```

API signing keys over 90 days old

Issue: A user's API signing keys are older than 90 days. Oracle recommends that you rotate API keys at least every 90 days.

Basics:

- API keys are credentials used to grant programmatic access to Oracle Cloud Infrastructure.
- It is a security engineering best practice and compliance requirement to rotate API keys regularly, every 90 days or less.
- Ensure that you test the new keys before you deactivate the old keys.

To generate and upload new API keys:

The following procedure is for the Oracle Cloud Infrastructure Console.

Generate new API keys

You can use the following OpenSSL commands to generate the key pair in the required PEM format. If you're using Windows, you'll need to install Git Bash for Windows and run the commands with that tool.

1. If you haven't already, create a `.oci` directory to store the credentials:

   ```
   mkdir ~/.oci
   ```

2. Generate the private key with one of the following commands.

   - Recommended: To generate the key, encrypted with a passphrase you provide when prompted:

     ```
     openssl genrsa -out ~/.oci/oci_api_key.pem -aes128 2048
     ```

     Note: For Windows, you may need to insert `-passout stdin` to be prompted for a passphrase. The prompt will just be the blinking cursor, with no text.

     ```
     openssl genrsa -out ~/.oci/oci_api_key.pem -aes128 -passout stdin 2048
     ```

   - To generate the key with no passphrase:

     ```
     openssl genrsa -out ~/.oci/oci_api_key.pem 2048
     ```

3. Ensure that only you can read the private key file:

   ```
   chmod go-rwx ~/.oci/oci_api_key.pem
   ```

4. Generate the public key:

   ```
   openssl rsa -pubout -in ~/.oci/oci_api_key.pem -out ~/.oci/oci_api_key_public.pem
   ```

   Note: For Windows, if you generated the private key with a passphrase, you may need to insert `-passin stdin` to be prompted for the passphrase. The prompt will just be the blinking cursor, with no text.

   ```
   openssl rsa -pubout -in ~/.oci/oci_api_key.pem -out ~/.oci/oci_api_key_public.pem -passin stdin
   ```

5. Copy the contents of the public key to the clipboard using pbcopy, xclip or a similar tool (you'll need to paste the value into the Console later). For example:

   ```
   cat ~/.oci/oci_api_key_public.pem | pbcopy
   ```

Your API requests will be signed with your private key, and Oracle will use the public key to verify the authenticity of the request. You must upload the public key to IAM (instructions below).

Get the key's fingerprint

You can get the key's fingerprint with the following OpenSSL command. If you're using Windows, you'll need to install Git Bash for Windows and run the command with that tool.

```
openssl rsa -pubout -outform DER -in ~/.oci/oci_api_key.pem | openssl md5 -c
```

When you upload the public key in the Console, the fingerprint is also automatically displayed there. It looks something like this: 12:34:56:78:90:ab:cd:ef:12:34:56:78:90:ab:cd:ef

Upload the API signing key for the user

You can upload the PEM public key in the Console, located at https://console.us-ashburn-1.oraclecloud.com. If you don't have a login and password for the Console, contact an administrator.

1. Open the Console, and sign in.
2. View the details for the user who will be calling the API with the key pair:
    - If you're signed in as this user, click your username in the top-right corner of the Console, and then click **User Settings**.
    - If you're an administrator doing this for another user, instead click **Identity**, click **Users**, and then select the user from the list.
3. Click **Add Public Key**.
4. Paste the contents of the PEM public key in the dialog box and click **Add**.

The key's fingerprint is displayed (for example, 12:34:56:78:90:ab:cd:ef:12:34:56:78:90:ab:cd:ef).

Notice that after you've uploaded your first public key, you can also use the UploadApiKey API operation to upload additional keys. You can have up to three API key pairs per user. In an API request, you specify the key's fingerprint to indicate which key you're using to sign the request.

Test the new key

Test the key in a sample API call against Oracle Cloud Infrastructure.

Delete the old key

The following procedure works for a regular user or an administrator. Administrators can delete an API key for either another user or themselves.

1. View the user's details:
   - If you're deleting an API key for *yourself*: Open the **Profile** menu () and click **User Settings**.
   - If you're an administrator deleting an API key for *another user*: In the Console, click **Identity**, and then click **Users**. Locate the user in the list, and then click the user's name to view the details.
2. For the API key you want to delete, click **Delete**.
3. Confirm when prompted.

The API key is no longer valid for sending API requests.

- Securing IAM
- API Signing Key

Tenancy administrator privilege grant to an IAM group

Issue: A group other than the Administrators group has been granted administrator privileges.

Basics:

- Granting the tenancy administrator privilege (`manage all-resources in tenancy`) to a group enables the members to have full access to all resources in the tenancy.
- This high-privilege entitlement must be controlled and restricted to only the users who need it to perform their job function.
- Verify with the Oracle Cloud Infrastructure administrator that this entitlement grant was sanctioned and that the membership of the group remains valid after the grant of the administrator privilege.
- Rather than create an alternative group with administrator privileges, consider instead adding users needing administrator privileges to the default Administrators group.

To resolve this issue:

Add users who need administrator privileges to the Administrators group:

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Groups**.
2. In the **Groups** list, click **Administrators**.
3. Click **Add User to Group**.
4. In the **Add User to Group** dialog, select the user from the **User** list.
5. Click **Add User**.

Remove the policy or policy statement that grants the (non-Administrators) group administration privileges.

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Policies**.
   A list of the policies in the compartment you're viewing is displayed. If you don’t see

the one you're looking for, verify that you're viewing the correct compartment (select from the list on the left side of the page).

2. Click the policy you want to update.
   The policy's details and statements are displayed.
3. Find the statement that grants administrator privileges to the group. This policy will look like:

   ```
   Allow group <group_name> to manage all-resources in tenancy
   ```

   Click the the Actions icon (three dots) and then click **Delete**.
4. If the policy has no other statements, you can delete the policy by clicking **Delete** next to the policy name.

Networking: VCN, Load Balancers, and DNS

No ingress rules in security lists

Issue: A VCN's security lists have no ingress rules. This means that the instances in the VCN can't receive incoming traffic.

Basics:

- Security lists provide stateful and stateless firewall capability to control network access to your instances.
- A security list is configured at the subnet level and enforced at the instance level.
- You can associate multiple security lists with a subnet. A packet is allowed if it matches any rule in any of the security lists used by the subnet.

- If there are no ingress (inbound) rules in any of the subnet's security lists, no traffic is allowed to the instances in that subnet.
- For defense in depth, ingress security list rules should state a specific known source and not an open source (0.0.0.0/0).
- You can configure an exception in Oracle CASB Cloud Service to reduce alerts from exempted security lists.

To add an ingress rule to an existing security list:

The following procedure is for the Oracle Cloud Infrastructure Console.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Confirm you're viewing the compartment that contains the cloud network you're interested in.
3. Click the cloud network you're interested in.
4. Click **Security Lists**.
5. Click the security list you're interested in.
6. Click **Edit All Rules**.
7. Add at least one ingress rule:
    a. In the **Allow Rules for Ingress** section, click **+ Rule**.
    b. Choose whether it's a stateful or stateless rule (see Stateful Versus Stateless Rules). By default, rules are stateful unless you specify otherwise.
    c. Enter the source CIDR. Typical CIDRs you might specify in a rule are the CIDR block for your on-premises network or a particular subnet. If you're setting up a security list rule to allow traffic with a service gateway, instead see Task 3: (Optional) Update security rules.
    d. Select the protocol (for example, TCP, UDP, ICMP, "All protocols", and so on).

e. Enter further details depending on the protocol:

- If you chose TCP or UDP, enter a source port range and destination port range. You can enter "All" to cover all ports. If you want to allow a specific port, enter the port number (for example, 22 for SSH or 3389 for RDP) or a port range (for example, 20-22).
- If you chose ICMP, you can enter "All" to cover all types and codes. If you want to allow a specific ICMP type, enter the type and an optional code separated by a comma (for example, 3,4). If the type has multiple codes you want to allow, create a separate rule for each code.

8. When you're done, click **Save Security List Rules**.

This change enables ingress access from the source CIDR block listed in the rule. Add additional rules if you want to allow ingress from other known sources.

More information:

- Securing Networking: VCN, Load Balancers, and DNS
- Security Lists
- UpdateSecurityList

Security list allows traffic from any IP address (open source)

Issue: A security list has at least one rule with an open source (0.0.0.0/0). This means that traffic could come from any source and is not controlled.

Basics:

- Security lists provide stateful and stateless firewall capability to control network access to your instances.
- A security list is configured at the subnet level and enforced at the instance level.
- You can associate multiple security lists with a subnet. A packet is allowed if it matches any rule in any of the security lists used by the subnet.

- If there are no ingress (inbound) rules in any of the subnet's security lists, no traffic is allowed to the instances in that subnet.
- For defense in depth, ingress security list rules should state a specific known source and not an open source (0.0.0.0/0).
- You can configure an exception in Oracle CASB Cloud Service to reduce alerts from exempted security lists.

To change the source of a security list rule:

The following procedure is for the Oracle Cloud Infrastructure Console.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Confirm you're viewing the compartment that contains the cloud network you're interested in.
3. Click the cloud network you're interested in.
4. Click **Security Lists**.
5. Click the security list you're interested in.
6. Click **Edit All Rules**.
7. Locate the rule that lists 0.0.0.0/0 as the source CIDR.
8. For that rule, change 0.0.0.0/0 to the CIDR block of a known source.
9. Click **Save Security List Rules**.

This change restricts ingress so packets are allowed only from a specific CIDR block. Add additional rules if you want to allow ingress from other known sources.

More information:

- Securing Networking: VCN, Load Balancers, and DNS
- Security Lists
- UpdateSecurityList

Security list allows traffic to sensitive ports

Issue: A security list has at least one rule that enables access to a sensitive port.

Basics:

- Security lists provide stateful and stateless firewall capability to control network access to your instances.
- A security list is configured at the subnet level and enforced at the instance level.
- You can associate multiple security lists with a subnet. A packet is allowed if it matches any rule in any of the security lists used by the subnet.
- If there are no ingress (inbound) rules in any of the subnet's security lists, no traffic is allowed to the instances in that subnet.
- For defense in depth, ingress security list rules should state a specific known source and not an open source (0.0.0.0/0).
- You can configure an exception in Oracle CASB Cloud Service to reduce alerts from exempted security lists.

Recommendation: Update the subnet's security list to enable access to instances through SSH (TCP port 22) or RDP (TCP port 3389) on a temporary, as-needed basis, and only from authorized CIDR blocks (not 0.0.0.0/0). To perform instance health checks, update the security list to allow ICMP pings.

To change an existing security list:

The following procedure is for the Oracle Cloud Infrastructure Console.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Confirm you're viewing the compartment that contains the cloud network you're interested in.
3. Click the cloud network you're interested in.
4. Click **Security Lists**.

5. Click the security list you're interested in.
6. Click **Edit All Rules**.
7. Make one or more of these changes:
    - Delete an existing rule by clicking the **X** next to the rule.
    - Change an existing rule in the list. For example: change the source from 0.0.0.0/0 to the CIDR block of a known source.
    - Add a new rule by clicking **+ Rule** and entering values for the new rule.
8. Click **Save Security List Rules**.

More information:

- Securing Networking: VCN, Load Balancers, and DNS
- To enable RDP access
- Security Lists
- UpdateSecurityList

Internet gateway attached to VCN

Issue: A VCN has an internet gateway. The gateway must be authorized to be attached to the VCN and must not unintentionally expose resources to the internet.

Basics:

- Gateways provide external connectivity to hosts in a VCN. For example: an internet gateway enables direct internet connectivity for instances that are in a public subnet and have a public IP address. A dynamic routing gateway (DRG) enables connectivity with the on-premises network over an IPSec VPN or FastConnect.
- To enable traffic through the internet gateway from a particular subnet in the VCN, there must be a rule in the subnet's route table that lists the internet gateway as a route target. To delete the internet gateway from the VCN, you must first delete any route rules that specify the internet gateway as the target.

- You can configure an exception in Oracle CASB Cloud Service to reduce alerts from exempted VCNs.

To remove an internet gateway from a VCN:

Prerequisite: Ensure that there are no route rules that specify the internet gateway as a target.

The following procedure is for the Oracle Cloud Infrastructure Console.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Confirm you're viewing the compartment that contains the cloud network you're interested in.
3. Click the cloud network you're interested in.
4. Click **Internet Gateways**.
5. Click the Actions icon (three dots) for the internet gateway, and then click **Terminate**.
6. Confirm when prompted.

This change disables direct internet connectivity for the VCN.

More information:

- Securing Networking: VCN, Load Balancers, and DNS
- Internet Gateway
- DeleteInternetGateway
- Public IP Addresses

Instance has a public IP

Issue: An instance has a public IP address. This means the instance could be publicly addressable if other required components are present and configured correctly in the VCN.

Basics:

- Carefully consider allowing internet access to any instances. For example, don't accidentally allow internet access to sensitive DB systems.
- For an instance to be publicly addressable:
    - The instance must have a public IP address and reside in a public subnet in the VCN (instances in private subnets cannot have public IP addresses).
    - The subnet's security list must be configured to allow traffic for all IPs (0.0.0.0/0) and all ports.
    - The VCN must have an internet gateway and be configured to route outbound traffic from the subnet to the internet gateway.
- An instance can have more than one public IP address. A given public IP is assigned to a private IP on a particular VNIC on the instance. An instance can have more than one VNIC, and each VNIC can have more than one private IP.

To remove a public IP address from an instance:

The following procedure is for the Oracle Cloud Infrastructure Console.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
2. Confirm you're viewing the compartment that contains the instance you're interested in.
3. Click the instance to view its details.
4. Click **Attached VNICs**.
   The primary VNIC and any secondary VNICs attached to the instance are displayed.
5. Click the VNIC you're interested in.
   The VNIC's primary private IP and any secondary private IPs are displayed.
6. For the private IP you're interested in, click the Actions icon (three dots), and then click **Edit**.
7. In the **Public IP Address** section, for **Public IP Type**, select the radio button for **No Public IP**.
8. Click **Update**.

The public IP is unassigned from the instance.

- DeletePublicIp
- Internet Gateway

Load balancer has no inbound rules or listeners

Issue: A load balancer's subnet security lists have no ingress rules, or a load balancer has no listener. In this case, the load balancer can't receive incoming traffic.

Basics:

- Load balancers provide automated traffic distribution from one entry point to multiple servers reachable from your virtual cloud network (VCN). Each load balancer exists in a subnet governed by security list rules. A load balancer receives incoming data traffic from one or more listeners.
- Security lists provide stateful and stateless firewall capability to control network access to your load balancer and backend servers.
    - If there are no ingress (inbound) rules in any of the subnet's security lists, no traffic is allowed to the instances in that subnet.
    - For defense in depth, configure ingress security list rules to state a specific known source and not an open source (0.0.0.0/0).
- A listener is a logical entity that checks for incoming traffic on the load balancer's IP address.
    - To handle TCP, HTTP, and HTTPS traffic, you must configure at least one listener per traffic type.
    - You can apply path route rules to a listener to route traffic to the correct backend set without using multiple listeners or load balancers. A *path route* is a string that

the listener matches against an incoming URI to determine the appropriate destination backend set.

- Ensure that your Oracle Cloud Infrastructure load balancers use inbound rules or listeners to allow access only from known resources.
- Exceptions can be configured in CASB to reduce alerts from exempted load balancers.

To enable a listener to accept traffic:

The following procedure is for the Oracle Cloud Infrastructure Console.

To enable a listener to accept traffic, you must update your VCN's security list rules:

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
   The list of VCNs in the current compartment appears.
2. Click the name of the VCN containing your load balancer, and then click **Security Groups** or **Security Lists**.
   A list of the security groups or lists in the cloud network appears.
3. Click the name of the NSG or security list that applies to your load balancer.
4. Add or edit the existing rules to allow access from the appropriate resources.
   An NSG's security rules appear on the **Network Security Group Details** page. From there you can add, edit, or remove rules.
   The **Security List Details** page provides access to separate tables in which you can add or edit **Ingress Rules** or **Egress Rules**.
   For details on rule configuration, see Security Rules.

To create a listener:

Usually, you create a listener as part of the load balancer creation workflow. To create a listener for an existing load balancer:

1. Open the navigation menu. Under the **Core Infrastructure** group, go to **Networking** and click **Load Balancers**.

2. Choose the **Compartment** that contains the load balancer you want to modify, and then click the load balancer's name.
3. In the **Resources** menu, click **Listeners**, and then click **Create Listener**.
4. In the **Create Listener** dialog box, enter the following:
    - **Name:** Required. Specify a friendly name for the listener. The name must be unique, and cannot be changed. Avoid entering confidential information.
    - **Hostname:** Optional. Select up to 16 virtual hostnames for this listener.

      

      Important

      To apply a virtual hostname to a listener, the name must be part of the load balancer's configuration. If the load balancer has no associated hostnames, you can create one on the **Hostnames** page.
    - **Protocol:** Required. Specify the protocol to use, either HTTP or TCP.
    - **Port:** Required. Specify the port on which to listen for incoming traffic.
    - **Use SSL:** Optional. Check this box to associate an SSL certificate bundle with the listener. The following settings are required to enable SSL handling. See Managing SSL Certificates for more information.
        - **Certificate Name:** Required. The friendly name of the SSL certificate bundle to use.
        - **Verify Peer Certificate:** Optional. Select this option to enable peer certificate verification.
        - **Verify Depth:** Optional. Specify the maximum depth for certificate chain verification.

- **Backend Set:** Required. Specify the default backend set to which the listener routes traffic.
- **Idle Timeout in Seconds:** Optional. Specify the maximum idle time in seconds. This setting applies to the time allowed between two successive receive or two successive send network input/output operations during the HTTP request-response phase.

Tip

The maximum value is 7200 seconds. For more information, see Connection Management.

- **Path Route Set:** Optional. Specify the name of the set of path-based routing rules that applies to this listener's traffic.

Important

- To apply a path route set to a listener, the set must be part of the load balancer's configuration.
- To remove a path route set from an existing listener, choose **None** as the **Path Route Set** option. The path route set remains available for use by other listeners on this load balancer.

5. Click **Create**.

When you create a listener, you must also update your VCN's security list rules to allow traffic to that listener.

Load balancer has no backend sets

Issue: A load balancer has no backend set. In this case, the load balancer has no place to distribute incoming data and no means to monitor backend server health.

Basics:

- A backend set is a logical entity defined by a load balancing policy, a health check policy, and a list of backend servers.
- The backend set determines the load balancer's traffic distribution policy, such as:
    - IP Hash
    - Least Connections
    - Weighted Round Robin
- You specify the test parameters to confirm the health of backend servers when you create a backend set.
- If you have an existing load balancer with no backend set, you can specify the backend servers that receive traffic from the load balancer after you create a backend set.
- You can configure an exception in Oracle CASB Cloud Service to reduce alerts from exempted load balancers.

To create a backend set:

The following procedure is for the Oracle Cloud Infrastructure Console.

Usually, you create a backend set as part of the load balancer creation workflow. To create a backend set for an existing load balancer:

1. Open the navigation menu. Under the **Core Infrastructure** group, go to **Networking** and click **Load Balancers**.
2. Click the name of the **Compartment** that contains the load balancer you want to modify, and then click the load balancer's name.
3. In the **Resources** menu, click **Backend Sets** (if necessary), and then click **Create Backend Set**.
4. In the **Create Backend Set** dialog box, enter the following:
    - **Name:** Required. Specify a friendly name for the backend set. It must be unique within the load balancer, and it cannot be changed.
      Valid backend set names include only alphanumeric characters, dashes, and underscores. Backend set names cannot contain spaces. Avoid entering confidential information.
    - **Traffic Distribution Policy:** Required. Choose the load balancer policy for the backend set. The available options are:
        - **IP Hash**
        - **Least Connections**
        - **Weighted Round Robin**

      For more information on these policies, see How Load Balancing Policies Work.

Tip

You cannot add a backend server marked as **Backup** to a backend set that uses the IP Hash policy.

- **Use SSL:** Optional. Check this box to associate an SSL certificate bundle with the backend set.

  If there are no certificate bundles attached to the load balancer, this option is disabled.

  - **Certificate Name:** Required. Select the certificate bundle to use. You can choose any certificate bundle that is attached to the current load balancer. See Managing SSL Certificates for more information.
  - **Verify Peer Certificate:** Optional. Select this option to enable peer certificate verification.
  - **Verify Depth:** Optional. Specify the maximum depth for certificate chain verification.
- **Session Persistence:** Optional. Specify how the load balancer manages session persistence.

  Important

  See Session Persistence for important information on configuring these settings.

  - **Disable Session Persistence:** Choose this option to disable cookie-based session persistence.
  - **Enable Application Cookie Persistence:** Choose this option to enable persistent sessions from a single logical client when the response from a backend application server includes a `Set-cookie` header with the cookie name you specify.
    - **Cookie Name:** The cookie name used to enable session persistence. Specify ***** to match any cookie name. Avoid entering confidential information.

        - **Disable Fallback:** Check this box to disable fallback when the original server is unavailable.
    - **Enable Load Balancer Cookie Persistence:** Choose this option to enable persistent sessions based on a cookie inserted by the load balancer.
        - **Cookie Name:** Specify the name of the cookie used to enable session persistence. If blank, the default cookie name is `X-Oracle-BMC-LBS-Route`.

          Ensure that any cookie names used at the backend application servers are different from the cookie name used at the load balancer. Avoid entering confidential information.
        - **Disable Fallback:** Check this box to disable fallback when the original server is unavailable.
        - **Domain Name:** Optional. Specify the domain in which the cookie is valid.

          This attribute has no default value. If you do not specify a value, the load balancer does not insert the domain attribute into the `Set-cookie` header.
        - **Path:** Optional. Specify the path in which the cookie is valid. The default value is `/`.
        - **Expiration Period in Seconds:** Optional. Specify the amount of time the cookie remains valid. If blank, the cookie expires at the end of the client session.
        - **Attributes**
            - **Secure:** Specify whether the `Set-cookie` header should contain the `Secure` attribute. If selected, the client sends the cookie only using a secure protocol.

              If you enable this setting, you cannot associate the corresponding backend set with an HTTP listener.

        - **HTTP Only:** Specify whether the `Set-cookie` header should contain the `HttpOnly` attribute. If selected, the cookie is limited to HTTP requests. The client omits the cookie when providing access to cookies through non-HTTP APIs such as JavaScript channels.
- **Health Check:** Required. Specify the test parameters to confirm the health of backend servers.
    - **Protocol:** Required. Specify the protocol to use, either HTTP or TCP.

      Important

      Configure your health check protocol to match your application or service.
    - **Port:** Optional. Specify the backend server port against which to run the health check.

      Tip

      You can enter the value '0' to have the health check use the backend server's traffic port.
    - **URL Path (URI):** (HTTP only) Required. Specify a URL endpoint against which to run the health check.
    - **Interval in ms:** Optional. Specify how frequently to run the health check, in milliseconds. The default is 10000 (10 seconds).

- **Timeout in ms:** Optional. Specify the maximum time in milliseconds to wait for a reply to a health check. A health check is successful only if a reply returns within this timeout period. The default is 3000 (3 seconds).
- **Number of retries:** Optional. Specify the number of retries to attempt before a backend server is considered "unhealthy". This number also applies when recovering a server to the "healthy" state. The default is '3'.
- **Status Code:** (HTTP only) Optional. Specify the status code a healthy backend server must return.
- **Response Body Regex:** (HTTP only) Optional. Provide a regular expression for parsing the response body from the backend server.

5. Click **Create**.

After your backend set is provisioned, you must specify backend servers for the set. See Managing Backend Servers for more information.

More information:

- Securing Networking: VCN, Load Balancers, and DNS
- Managing Backend Sets
- Editing Health Check Policies
- Managing a Load Balancer

Load balancer SSL certificate expires in *X* days

Issue: A load balancer's SSL certificate expires soon. When the certificate expires, data traffic can be interrupted and security compromised.

Basics:

- To ensure continuous security and usability, SSL certificates must be rotated on a timely basis.

- You can configure an exception in Oracle CASB Cloud Service to reduce alerts from exempted load balancers.

To rotate a load balancer's certificate bundle:

The following procedure is for the Oracle Cloud Infrastructure Console.

To ensure consistent service, you must update (rotate) expiring certificates:

1. Update your client or backend server to work with a new certificate bundle.

Note

The steps to update your client or backend server are unique to your system.

2. Upload the new SSL certificate bundle to the load balancer
    a. Open the navigation menu. Under the **Core Infrastructure** group, go to **Networking** and click **Load Balancers**.
    b. Click the name of the **Compartment** that contains the load balancer you want to modify, and then click the load balancer's name.
    c. Click the load balancer you want to configure.
    d. In the **Resources** menu, click **Certificates**, and then click **Add Certificate**.
    e. In the **Add Certificate** dialog box, enter the following:
        - **Certificate Name:** Required. Specify a friendly name for the certificate bundle. It must be unique within the load balancer, and it cannot be changed in the Console. (It can be changed using the API.) Avoid entering confidential information.
        - **Choose SSL Certificate File:** Required. Drag and drop the certificate file, in PEM format, into the **SSL Certificate** field.

Alternatively, you can choose the **Paste SSL Certificate** option to paste a certificate directly into this field.

> **Important**
>
> If you submit a self-signed certificate for backend SSL, you must submit the same certificate in the corresponding CA Certificate field.

- **Specify CA Certificate:** Optional. (Recommended for backend SSL termination configurations.) Select (check) this box if you want to provide a CA certificate.
  - **Choose CA Certificate File:** Drag and drop the CA certificate file, in PEM format, into the **CA Certificate** field.
    Alternatively, you can choose the **Paste CA Certificate** option to paste a certificate directly into this field.
- **Specify Private Key:** Optional. (Required for SSL termination.) Select (check) this box if you want to provide a private key for the certificate.
  - **Choose Private Key File:** Drag and drop the private key, in PEM format, into the **Private Key** field.
    Alternatively, you can choose the **Paste Private Key** option to paste a private key directly into this field.
  - **Enter Private Key Passphrase:** Optional. Specify the private key passphrase.

f. Click **Add Certificate**.

3. Edit listeners or backend sets (as needed) so they use the new certificate

bundle

EDITING A LISTENER:

a. Open the navigation menu. Under the **Core Infrastructure** group, go to **Networking** and click **Load Balancers**.
b. Choose the **Compartment** that contains the load balancer you want to modify, and then click the load balancer's name.
c. In the **Resources** menu, click **Listeners**.
d. For the listener you want to edit, click the Actions icon (three dots), and then click **Edit Listener**.
e. In the **Certificate Name** drop-down list, choose the new certificate bundle.
f. Click **Submit**.

EDITING A BACKEND SET:

Warning

Updating the backend set temporarily interrupts traffic and can drop active connections.

a. Open the navigation menu. Under the **Core Infrastructure** group, go to **Networking** and click **Load Balancers**.
b. Click the name of the **Compartment** that contains the load balancer you want to modify, and then click the load balancer's name.
c. In the **Resources** menu, click **Backend Sets**, and then click the name of the backend set you want to edit.
d. Click **Edit Backend Set**.

e. In the **Edit Backend Set** dialog box, select (check) **Use SSL**.
f. In the **Certificate Name** drop-down list, choose the new certificate bundle.
g. Click **Save Changes**.

4. (Optional) Remove the expiring SSL certificate bundle

> **Important**
>
> You cannot delete an SSL certificate bundle that is associated with a listener or backend set. Remove the bundle from any additional listeners or backend sets before deleting.

a. Open the navigation menu. Under the **Core Infrastructure** group, go to **Networking** and click **Load Balancers**.
b. Click the name of the **Compartment** that contains the load balancer you want to modify, and then click the load balancer's name.
c. Click the load balancer you want to configure.
d. In the **Resources** menu, click **Certificates**.
e. For the certificate you want to delete, click the Actions icon (three dots), and then click **Delete**.
f. Confirm when prompted.

More information:

- Securing Networking: VCN, Load Balancers, and DNS
- Managing SSL Certificates
- Managing Load Balancer Listeners

- Managing Backend Sets
- Managing a Load Balancer

Object Storage

Public buckets detected

Issue: Public buckets were detected in your tenancy. Confirm that the creation of each public bucket is intentional and authorized. If the bucket is not sanctioned for public access, follow the procedure for changing the visibility of a bucket and make the bucket private.

Basics:

- Carefully assess the business requirement for public access to a bucket. When you enable anonymous access to a bucket, users can obtain object metadata, download bucket objects, and optionally list bucket contents.
- Changing the type of access is bi-directional. You can change a bucket's access from public to private or from private to public.
- Changing the type of access doesn't affect existing pre-authenticated requests. Existing pre-authenticated requests still work.

To change the visibility of a bucket (private or public):

The following procedure is for the Oracle Cloud Infrastructure Console.

1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.
   A list of the buckets in the compartment you're viewing is displayed. If you don't see the one you're looking for, verify that you're viewing the correct compartment (select from the list on the left side of the page).
2. Click the bucket name to see the bucket details.
   Visibility: shows the current bucket setting, which is **Private** by default.
3. Click **Edit Visibility**.
4. In the **Edit Visibility** dialog box, edit the visibility settings:

- **Visibility**
  - **Public**
  - **Private**
- If you select **Public** to enable public access, decide whether or not you want to let users list the bucket contents. Click **Allow users to list objects from this bucket** to set the visibility of bucket object lists.

5. Click **Save Changes**.

More information:

- Securing Object Storage
- Managing Buckets
- Using Pre-Authenticated Requests

Oracle Cloud Security Response to Intel L1TF Vulnerabilities

Intel disclosed a new set of speculative execution side-channel processor vulnerabilities affecting their processors. For more information, see Vulnerability Note VU#584653. These L1 Terminal Fault (L1TF) vulnerabilities affect a number of Intel processors, and they have received the following CVE identifiers:

- CVE-2018-3615, which impacts Intel Software Guard Extensions (SGX) and has a CVSS Base Score of 7.9.
- CVE-2018-3620, which impacts operating systems and System Management Mode (SMM) running on Intel processors and has a CVSS Base Score of 7.1.
- CVE-2018-3646, which impacts virtualization software and Virtual Machine Monitors (VMM) running on Intel processors and has a CVSS Base Score of 7.1.

See Intel Processor L1TF vulnerabilities: CVE-2018-3615, CVE-2018-3620, CVE-2018-3646 for more information.

Oracle Cloud Infrastructure

Oracle has deployed technical mitigations across Oracle Cloud Infrastructure systems designed to prevent a malicious attacker's virtual machine (VM) instance from accessing data from other VM instances.

However, vulnerability CVE-2018-3620 could enable a rogue user mode process to read privileged kernel memory within the same virtual machine. As a result, if you manage your own operating systems (OS), you are advised to keep up with OS security patches to address this vulnerability.

The following sections contain the details of mitigations and actions.

Oracle Cloud Infrastructure Compute

For details and required actions related to the Compute service's VM and bare metal instances, see Oracle Cloud Infrastructure Customer Advisory for L1TF Impact on the Compute Service.

Oracle Cloud Infrastructure Database

If you use Autonomous Data Warehouse and Autonomous Transaction Processing, you have no further action to take.

For details and required actions related to Oracle Cloud Infrastructure offerings for VM DB systems, bare metal DB systems, and Exadata DB systems, see Oracle Cloud Infrastructure Customer Advisory for L1TF Impact on the Database Service.

Platform Service and Kubernetes Services on Oracle Cloud Infrastructure

Oracle has deployed technical mitigations designed to prevent malicious attacker's VM instance from accessing data from other VM instances on the same hypervisor.

However, vulnerability CVE-2018-3620 could enable a rogue user-mode process to read privileged kernel memory within the same virtual machine. As a result, Platform Service hosts managed by Oracle are being patched by Oracle. If you manage your own operating systems you're advised to keep up with the OS security patches to address this vulnerability.

Other Oracle Cloud Infrastructure Services

Mitigations designed to protect all other Oracle Cloud Infrastructure services have been deployed. Oracle will notify and coordinate directly with customers for any additional required maintenance activities.

Oracle Cloud Infrastructure Classic and Oracle Platform Service on Oracle Cloud Infrastructure Classic

For more information see Oracle Cloud Infrastructure Classic.

Oracle is deploying technical mitigations designed for Infrastructure and Platform Services on Oracle Cloud Infrastructure Classic. Some customers may experience reboots or downtime associated while deploying these mitigations.

Vulnerability CVE-2018-3620 could enable a rogue user-mode process to read privileged kernel memory within the same virtual machine. As a result, Platform Service hosts managed by Oracle are being patched by Oracle. If you manage your own operating systems you're advised to keep up with the OS security patches to address this vulnerability.

Oracle Cloud Infrastructure Customer Advisory for L1TF Impact on the Compute Service

Intel disclosed a new set of speculative execution side-channel processor vulnerabilities affecting their processors. For more information, see Vulnerability Note VU#584653. These L1 Terminal Fault (L1TF) vulnerabilities affect a number of Intel processors, and they have received the following CVE identifiers:

- CVE-2018-3615, which impacts Intel Software Guard Extensions (SGX) and has a CVSS Base Score of 7.9.
- CVE-2018-3620, which impacts operating systems and System Management Mode (SMM) running on Intel processors and has a CVSS Base Score of 7.1.
- CVE-2018-3646, which impacts virtualization software and Virtual Machine Monitors (VMM) running on Intel processors and has a CVSS Base Score of 7.1.

See the Oracle Cloud Security Response to Intel L1TF Vulnerabilities for more information.

Oracle has deployed technical mitigations across Oracle Cloud Infrastructure systems designed to prevent a malicious attacker's virtual machine (VM) instance from accessing data from other VM instances.

You should be aware that the vulnerability CVE-2018-3620 could enable a rogue user-mode process to read privileged kernel memory within the same operating system (OS). As a result, you are advised to keep up with OS security patches to address this vulnerability. See Protecting your Compute Instance Against the L1TF Vulnerability for instructions to patch the OS on the instances you manage.

Additional Guidance for Oracle Cloud Infrastructure Bare Metal Instances

Bare metal instances in Oracle Cloud Infrastructure offer you full control of a physical server. Oracle Cloud Infrastructure's network virtualization is designed and configured to protect these instances from unauthorized access of other instances on the Oracle Cloud Infrastructure network, including other customer instances, both VM instances and other bare metal instances.

If you're running your own virtualization stack or hypervisors on bare metal instances, the L1TF vulnerability allows a virtual machine to access privileged information from the underlying hypervisor or other VMs on the same bare metal instance. You should review the Intel recommendations about vulnerabilities CVE-2018-3615, CVE-2018-3620, and CVE-2018-3646, and make changes to your configurations as you deem appropriate.

Protecting your Compute Instance Against the L1TF Vulnerability

Intel disclosed a new set of speculative execution side-channel processor vulnerabilities affecting their processors, for more information, see Vulnerability Note VU#584653. These L1 Terminal Fault (L1TF) vulnerabilities affect a number of Intel processors, and they have received the following CVE identifiers:

- CVE-2018-3615 which impacts Intel Software Guard Extensions (SGX) and has a CVSS Base Score of 7.9.
- CVE-2018-3620 which impacts operating systems and System Management Mode (SMM) running on Intel processors and has a CVSS Base Score of 7.1.

- CVE-2018-3646 which impacts virtualization software and Virtual Machine Monitors (VMM) running on Intel processors and has a CVSS Base Score of 7.1.

See the Oracle Cloud Security Response to Intel L1TF Vulnerabilities for more information.

Recommended Action

Oracle recommends that you patch the operating systems for your existing bare metal and virtual machine (VM) instances, and verify that this includes the patch for the CVE-2018-3620 vulnerability. For VM instances, the Oracle Cloud Infrastructure team has implemented the necessary workarounds designed to mitigate the CVE-2018-3646 vulnerability. For bare metal instances using virtualization technology, you should also follow these instructions to ensure that they are mitigated against the CVE-2018-3646 vulnerability.

If you're running your own virtualization stack or hypervisors on bare metal instances, you should apply the patch for the CVE-2018-3646 vulnerability.

The information in the following sections detail the commands needed to update your running instances created from Oracle-Provided Images.

The following Oracle-provided image releases have been updated with the recommended patches, so instances created from these images or new image releases include the recommended patches for the L1TF vulnerability.

Oracle-provided images updated with recommended patches for the L1TF vulnerability

- Oracle-Linux-7.5-2018.08.14-0
- Oracle-Linux-7.5-Gen2-GPU-2018.08.14-0
- Oracle-Linux-6.10-2018.08.14-0
- CentOS-7-2018.08.15-0
- CentOS-6.10-2018.08.15-0
- Canonical-Ubuntu-18.04-2018.08.15-0
- Canonical-Ubuntu-16.04-2018.08.15-0

- Canonical-Ubuntu-16.04-Gen2-GPU-2018.08.15-0
- Canonical-Ubuntu-14.04-2018.08.15-0 (deprecated)
- Windows-Server-2016-Standard-Edition-VM-Gen2-2018.08.16-0
- Windows-Server-2016-Datacenter-Edition-BM-Gen2-2018.08.16-0
- Windows-Server-2016-Datacenter-Edition-BM-Gen2-DenseIO-2018.08.16-0
- Windows-Server-2012-R2-Standard-Edition-VM-2018.08.14-0
- Windows-Server-2012-R2-Standard-Edition-VM-Gen2-2018.08.14-0
- Windows-Server-2012-R2-Datacenter-Edition-BM-2018.08.15-0
- Windows-Server-2012-R2-Datacenter-Edition-BM-Gen2-DenseIO-2018.08.15-0
- Windows-Server-2012-R2-Datacenter-Edition-BM-Gen2-2018.08.15-0
- Windows-Server-2008-R2-Enterprise-Edition-VM-2018.08.15-0
- Windows-Server-2008-R2-Enterprise-Edition-VM-Gen2-2018.08.15-0

For your running instances created from imported custom images, refer to the operating system (OS) vendor's guidance to patch the OS for the L1TF vulnerability.

Patching Oracle Linux Instances

For Oracle Linux, the patches for the CVE-2018-3620 and CVE-2018-3646 vulnerabilities are addressed by the same set of patches.

Bare metal instances must have the latest microcode updates from Intel. This step is not required for VM instances.

To install the latest microcode updates, run the following command:

```
# sudo yum update microcode_ctl
```

The microcode RPM should be greater than or equal to `microcode_ctl-2.1-29.2.0.4.el7_5.x86_64.rpm`. This is the version of the microcode package that shipped for the Spectre v3a and Spectre v4 updates. No additional update is required. In addition to the microcode update, you should also patch your bare metal instances using the following set of instructions.

To patch the OS for bare metal and VM instances with downtime

The yum-plugin-security package allows you to use yum to obtain a list of all of the errata that are available for your system, including security updates. You can also use Oracle Enterprise Manager 12c Cloud Control or management tools such as Katello, Pulp, Red Hat Satellite, Spacewalk, and SUSE Manager to extract and display information about errata.

1. To install the `yum-plugin-security` package, run the following command:

   ```
   # sudo yum install yum-plugin-security
   ```

2. Use the `--cve` option to display the errata that correspond to a specified CVE, and to install those required packages, by running the following commands:

   ```
   # sudo yum updateinfo list --cve CVE-2018-3620
   # sudo yum update --cve CVE-2018-3620
   ```

   A system reboot will be required once the package is applied. By default, the boot manager will automatically enable the most recent kernel version. For more information on using `yum update`, visit Installing and Using the Yum Security Plugin.

3. After the system reboots, ensure that the following file is populated.

   ```
   cat /sys/devices/system/cpu/vulnerabilities/l1tf
   ```

PATCHING WINDOWS INSTANCES

PROTECTING NEW WINDOWS VM AND BARE METAL INSTANCES

When you create a new VM or bare metal instance based on the latest Oracle-provided Windows images, the image includes the Microsoft-recommended patches to protect against the L1TF vulnerability. Windows bare metal instances also include the latest microcode updates from Intel.

There is no further action required from you to protect your new Windows-based VM or bare metal instances from the L1TF vulnerability. You should ensure that you keep the your instances updated with the latest patches as recommended by your OS vendor.

PROTECTING EXISTING WINDOWS VM AND BARE METAL INSTANCES

To update the microcode for existing bare metal instances

Bare metal instances launched before the Oracle-provided Windows images were updated must have the latest microcode updates from Intel. You need to recycle your Windows bare metal instances in order to receive the latest Intel microcode update. This step is not required for VM instances.

1. Create a new custom image of your Windows bare metal instance, see Creating Windows Custom Images for more information.
2. Terminate your existing Windows bare metal instance.
3. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Custom Images**. Find the custom image you want to use.
4. Click the Actions icon (three dots), and then click **Create Instance**.
5. Provide additional launch options as described in Creating an Instance.

Once you have completed these steps, perform the steps in the next procedure to update the instance with the latest OS updates from Microsoft.

To patch the OS for bare metal and VM instances with downtime

Windows images include the Windows Update utility, which you can run to get the latest Windows updates from Microsoft. You have to configure the security list on the subnet on which the instance is running to allow instances to access Windows update servers. See Windows OS Updates for Windows Images and Security Lists for more information.

1. Verify that you have installed the latest Windows OS security update from Microsoft.
    a. If automatic updates are turned on, the updates should be automatically delivered to the instance.
    b. To manually check for the latest update, select **Start**.
    c. In **Settings** select **Updates & security** and then select **Windows Update**.

d. In **Windows Update**, click **Check for updates**.

e. When you turn on automatic updates, this update will be downloaded and installed automatically. For more information about how to turn on automatic updates, see Windows Update: FAQ.

For additional details see Windows Server guidance to protect against L1 terminal fault.

PATCHING UBUNTU OR CENTOS INSTANCES

When you create a new VM or bare metal instance based on the latest Oracle-provided Ubuntu or CentOS images, the image includes the recommended patches to protect against the L1TF vulnerability, see for more information L1 Terminal Fault (L1TF) and L1TF - L1 Terminal Fault Attack - CVE-2018-3620 & CVE-2018-3646.

For existing VM or bare metal instances you should follow the guidance provided by the OS vendor for patching systems.

Oracle Cloud Infrastructure Customer Advisory for L1TF Impact on the Database Service

Intel disclosed a new set of speculative execution side-channel processor vulnerabilities affecting their processors. For more information, see Vulnerability Note VU#584653. These L1 Terminal Fault (L1TF) vulnerabilities affect a number of Intel processors, and they have received the following CVE identifiers:

- CVE-2018-3615, which impacts Intel Software Guard Extensions (SGX) and has a CVSS Base Score of 7.9.
- CVE-2018-3620, which impacts operating systems and System Management Mode (SMM) running on Intel processors and has a CVSS Base Score of 7.1.
- CVE-2018-3646, which impacts virtualization software and Virtual Machine Monitors (VMM) running on Intel processors and has a CVSS Base Score of 7.1.

See the Oracle Cloud Security Response to Intel L1TF Vulnerabilities for more information.

Oracle has deployed technical mitigations across Oracle Cloud Infrastructure systems designed to prevent a malicious attacker's virtual machine (VM) instance from accessing data from other VM instances.

Autonomous Data Warehouse and Autonomous Transaction Processing

Autonomous Data Warehouse provides fully managed databases optimized for running data warehouse workloads. Autonomous Transaction Processing provides fully managed databases optimized for running online transaction processing and mixed database workloads. Autonomous Data Warehouse and Autonomous Transaction Processing are not affected by the L1TF vulnerabilities, CVE-2018-3615, CVE-2018-3620, and CVE-2018-3646. No further action is required by customers.

Guidance for the DatabaseService on Bare Metal Instances

The Database service on Oracle Cloud Infrastructure bare metal instances offer customers full control over their Oracle Database running on a physical server. Oracle Cloud Infrastructure's network virtualization is designed and configured to protect these instances from unauthorized access from other instances on the Oracle Cloud Infrastructure network, including other customer instances, both VM instances and other bare metal instances.

Actions for Customers with VM DB Systems, Bare Metal DB Systems, or Exadata DB Systems

Vulnerability CVE-2018-3620 could enable a rogue user-mode process to read privileged kernel memory within the same operating system. As a result, you need to patch these systems once these patches are available. These patches will be available shortly and Oracle will update this page when the operating system (OS) patches are published. Oracle will update the Database base images with the latest patches for new instance launches.

Once the patches are available, use the following instructions to patch a running instance:

- For DB systems on bare metal instances, apply the OS patches following the instructions in Updating a DB System.
- For DB systems on a VM instance, configured using the Oracle Cloud Infrastructure

Database service, apply the OS patches following the instructions in Updating a DB System.

- For the DB systems on a VM instance configured using the Oracle Platform Service Manager, apply the OS patches following the instructions in Applying Linux OS Security Patches by Using the dbaascli Utility.
- For Exadata DB systems, apply the OS patches following the instructions in Updating an Exadata DB System.

Oracle Cloud Security Response to Intel Microarchitectural Data Sampling (MDS) Vulnerabilities

Intel disclosed four new speculative execution side-channel processor vulnerabilities affecting Intel processors. These vulnerabilities have received the following CVE identifiers:

- CVE-2019-11091: Microarchitectural Data Sampling Uncacheable Memory (MDSUM)
- CVE-2018-12126: Microarchitectural Store Buffer Data Sampling (MSBDS)
- CVE-2018-12127: Microarchitectural Load Port Data Sampling (MLPDS)
- CVE-2018-12130: Microarchitectural Fill Buffer Data Sampling (MFBDS)

For more information, see https://blogs.oracle.com/security/intelmds.

Oracle Cloud Infrastructure

Oracle has deployed technical mitigations across Oracle Cloud Infrastructure systems designed to prevent a malicious attacker's virtual machine (VM) instance from accessing data from other VM instances.

However, if you manage your own operating systems (OS), you are advised to keep up with OS security patches to address this vulnerability.

The following sections contain the details of mitigations and actions.

Oracle Cloud Infrastructure Compute

For details and required actions related to the Compute service's VM and bare metal instances, see Oracle Cloud Infrastructure Customer Advisory for MDS Impact on the Compute Service.

Oracle Cloud Infrastructure Database

If you use Autonomous Data Warehouse and Autonomous Transaction Processing, you have no further action to take.

For details and required actions related to offerings for VM DB systems, bare metal DB systems, and Exadata DB systems, see Oracle Cloud Infrastructure Customer Advisory for MDS Impact on the Database Service.

Oracle Cloud Infrastructure Container Engine for Kubernetes

To help secure your existing worker nodes for the Oracle Cloud Infrastructure Container Engine for Kubernetes Oracle recommends replacing your current node pools with new node pools. Please follow the instructions described in 'Upgrading' the version of Kubernetes running on worker nodes by creating a new node pool. All worker nodes created or upgraded after May 14th, 2019 are not impacted by this security issue.

Other Oracle Cloud Infrastructure Services

Technical mitigations designed to protect all other Oracle Cloud Infrastructure services against the MDS processor vulnerabilities have been deployed. Oracle will notify customers if additional maintenance activities are required.

Oracle Cloud Infrastructure Classic and Oracle Platform Service on Oracle Cloud Infrastructure Classic

For more information see Oracle Cloud Infrastructure Classic.

In response to the MDS processor vulnerabilities, Oracle is performing mandatory maintenance for Infrastructure and Platform Services on Oracle Cloud Infrastructure Classic.

Platform Service hosts managed by Oracle are being patched by Oracle. If you manage your own operating systems, you are advised to keep up with the appropriate OS security patches to address these vulnerabilities.

Oracle Cloud Infrastructure Customer Advisory for MDS Impact on the Compute Service

Intel disclosed four new speculative execution side-channel processor vulnerabilities affecting Intel processors. These vulnerabilities have received the following CVE identifiers:

- CVE-2019-11091: Microarchitectural Data Sampling Uncacheable Memory (MDSUM)
- CVE-2018-12126: Microarchitectural Store Buffer Data Sampling (MSBDS)
- CVE-2018-12127: Microarchitectural Load Port Data Sampling (MLPDS)
- CVE-2018-12130: Microarchitectural Fill Buffer Data Sampling (MFBDS)

For more information, see https://blogs.oracle.com/security/intelmds.

Oracle has deployed technical mitigations across Oracle Cloud Infrastructure systems designed to prevent a malicious attacker’s virtual machine (VM) instance from accessing data from other VM instances.

You are advised to keep up with OS security patches to address this vulnerability. See Oracle Cloud Infrastructure Compute Content Impact for instructions to patch the OS on the instances you manage.

Additional Guidance for Oracle Cloud Infrastructure Bare Metal Instances

Bare metal instances in Oracle Cloud Infrastructure offer customers full control of a physical server. Oracle Cloud Infrastructure's network virtualization is designed and configured to protect these instances from unauthorized access of other instances on the Oracle Cloud Infrastructure network, including other customer instances, both VM instances and other bare metal instances

However, for customers running their own virtualization stack on bare metal instances, the MDS vulnerabilities could allow a virtual machine to access privileged information from the underlying hypervisor or other VMs on the same bare metal instance. These customers should

review Intel's recommendations about these MDS vulnerabilities and make the recommended changes to their configurations, https://www.intel.com/content/www/us/en/security-center/advisory/intel-sa-00233.html.

Oracle Cloud Infrastructure Compute Content Impact

Intel disclosed four new speculative execution side-channel processor vulnerabilities affecting Intel processors. These vulnerabilities have received the following CVE identifiers:

- CVE-2019-11091: Microarchitectural Data Sampling Uncacheable Memory (MDSUM)
- CVE-2018-12126: Microarchitectural Store Buffer Data Sampling (MSBDS)
- CVE-2018-12127: Microarchitectural Load Port Data Sampling (MLPDS)
- CVE-2018-12130: Microarchitectural Fill Buffer Data Sampling (MFBDS)

For more information, see https://blogs.oracle.com/security/intelmds.

Recommended Action

Oracle recommends that customers patch the operating systems for their existing bare metal and virtual machine (VM) instances and verify that these OS updates include the patch for the MDS vulnerabilities. For VM instances, the Oracle Cloud Infrastructure team has implemented the necessary workarounds designed to mitigate for the MDS vulnerabilities. For bare metal instances using virtualization technology, you should also follow the following instructions

If you are running your own virtualization stack or hypervisors on bare metal instances, you should apply the appropriate patch required to address the MDS processor vulnerabilities.

The information in the following sections detail the commands needed to update your running instances created with Oracle-Provided Images.

The following Oracle-provided image releases have been updated with the recommended patches, as a result instances created using these images or subsequent images include the recommended patches for the MDS vulnerabilities.

Oracle-provided images updated with recommended patches for the MDS vulnerability

- Oracle-Linux-6.10-2019.05.14-0
- Oracle-Linux-7.6-2019.05.14-0
- Oracle-Linux-7.6-Gen2-GPU-2019.05.14-0
- Windows-Server-2008-R2-Enterprise-Edition-VM-2019.05.14-0
- Windows-Server-2008-R2-Enterprise-Edition-VM-Gen2-2019.05.14-0
- Windows-Server-2012-R2-Standard-Edition-VM-2019.05.15-0
- Windows-Server-2012-R2-Standard-Edition-VM-Gen2-2019.05.14-0
- Windows-Server-2012-R2-Standard-Edition-VM-Gen2-E2-2019.05.15-0
- Windows-Server-2012-R2-Datacenter-Edition-BM-Gen2-2019.05.14-0
- Windows-Server-2012-R2-Datacenter-Edition-BM-Gen2-DenseIO-2019.05.15-0
- Windows-Server-2012-R2-Datacenter-Edition-BM-Gen2-E2-2019.05.14-0
- Windows-Server-2012-R2-Datacenter-Edition-BM-2019.06.17-0
- Windows-Server-2016-Standard-Edition-VM-Gen2-2019.05.14-0
- Windows-Server-2016-Standard-Edition-VM-Gen2-E2-2019.05.14-0
- Windows-Server-2016-Datacenter-Edition-BM-Gen2-2019.05.14-0
- Windows-Server-2016-Datacenter-Edition-BM-Gen2-DenseIO-2019.05.14-0
- Windows-Server-2016-Datacenter-Edition-BM-Gen2-E2-2019.05.15-0
- CentOS-6.10-2019.05.15-0
- CentOS-7-2019.05.16-0
- Canonical-Ubuntu-14.04-2019.05.15-0 (deprecated)
- Canonical-Ubuntu-16.04-2019.05.15-0
- Canonical-Ubuntu-16.04-Gen2-GPU-2019.05.15-0
- Canonical-Ubuntu-16.04-Minimal-2019.05.15-0

- Canonical-Ubuntu-18.04-2019.05.15-0
- Canonical-Ubuntu-18.04-Minimal-2019.05.15-0

Customers running instances created from imported third-party images should refer to the operating system (OS) vendor's guidance to patch the OS for the MDS vulnerability.

PATCHING ORACLE LINUX INSTANCES

Oracle has released security patches for Oracle Linux 6, Oracle Linux 7, and Oracle VM Server for X86 products. In addition to the OS patches, customers should run the latest version of the microcode from Intel to mitigate these issues. For both bare metal and VM instances, please install the latest Ksplice via uptrack-upgrade.

Note

See Installing Ksplice Uptrack Within the Oracle Cloud Infrastructure for how to install Ksplice.

For Oracle Linux, the patches for the MDS vulnerabilities are addressed by the same set of patches. For further information please see the following:

- https://linux.oracle.com/cve/CVE-2018-12126.html
- https://linux.oracle.com/cve/CVE-2018-12130.html
- https://linux.oracle.com/cve/CVE-2018-12127.html
- https://linux.oracle.com/cve/CVE-2019-11091.html

Bare metal instances must have the latest microcode updates from Intel. This step is not required for VM instances.

To install the latest microcode updates on bare metal instances, run the following command:

```
# sudo yum update microcode_ctl
```

The required versions of microcode_ctl rpms are:

- **Oracle Linux 7**: microcode_ctl 2.1-47.0.4
- **Oracle Linux 6**: microcode_ctl 1.17-1002

No additional update is required. In addition to the microcode update, you should also patch your bare metal instances using the following set of instructions.

To patch the OS for bare metal and VM instances with downtime

The `yum-plugin-security` package allows you to use yum to obtain a list of all errata that are available for your system, including security updates. You can also use Oracle Enterprise Manager 12c Cloud Control or management tools such as Katello, Pulp, Red Hat Satellite, Spacewalk, and SUSE Manager to extract and display information about errata.

1. To install the `yum-plugin-security` package, run the following command:

   ```
   # sudo yum install yum-plugin-security
   ```

2. Use the `--cve` option to display the errata that correspond to a specified CVE, and to install those required packages, by running the following commands:

   ```
   # sudo yum updateinfo list --cve CVE-####-####
   # sudo yum update --cve CVE-####-####
   ```

   Replace `####-####` in the above commands with the relevant CVE numbers.

3. A system reboot will be required once the package is applied. By default, the boot manager will automatically enable the most recent kernel version. For more information on using yum update, visit Installing and Using the Yum Security Plugin.
4. After the system reboots, ensure that the following file is populated:

   ```
   cat /sys/devices/system/cpu/vulnerabilities/mds
   ```

PATCHING WINDOWS INSTANCES

PROTECTING NEW WINDOWS VM AND BARE METAL INSTANCES

When you create a new VM or bare metal instance based on the latest Oracle-provided Windows images, the image includes the Microsoft-recommended patches to protect against the MDS vulnerability. Windows bare metal instances also include the latest microcode

updates from Intel. To apply the MDS patch install the latest Windows Updates and reboot the instance. You should ensure that you keep your instances updated with the latest patches as recommended by your OS vendor.

PROTECTING EXISTING WINDOWS VM AND BARE METAL INSTANCES

To update the microcode for existing bare metal instances

Bare metal instances launched before the Oracle-provided Windows images were updated must have the latest microcode updates from Intel. You need to recycle your Windows bare metal instances in order to receive the latest Intel microcode update. This step is not required for VM instances.

1. Create a new custom image of your Windows bare metal instance, see Creating Windows Custom Images for more information.
2. Terminate your existing Windows bare metal instance.
3. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Custom Images**. Find the custom image you want to use.
4. Click the Actions icon (three dots), and then click **Create Instance**.
5. Provide additional launch options as described in Creating an Instance.

Once you have completed these steps, perform the steps in the next procedure to update the instance with the latest OS updates from Microsoft

To patch the OS for bare metal and VM instances with downtime

Windows images include the Windows Update utility, which you can run to get the latest Windows updates from Microsoft. You have to configure the security list on the subnet on which the instance is running to allow instances to access Windows update servers. See Windows OS Updates for Windows Images and Security Lists for more information.

1. Verify that you have installed the latest Windows OS security update from Microsoft.
    a. If automatic updates are turned on, the updates should be automatically delivered to the instance.
    b. To manually check for the latest update, select **Start**.
    c. In **Settings** select **Updates & security** and then select **Windows Update**.
    d. In **Windows Update**, click **Check for updates**.
    e. When you turn on automatic updates, this update will be downloaded and installed automatically. For more information about how to turn on automatic updates, see Windows Update: FAQ.

For additional details see Windows Server guidance to protect against speculative execution side-channel vulnerabilities.

PATCHING UBUNTU OR CENTOS INSTANCES

The recommended patches to protect against the MDS vulnerabilities are included when you create a new VM or bare metal instance based on the latest Oracle-provided Ubuntu or CentOS images, see Microarchitectural Data Sampling (MDS) and MDS - Microarchitectural Store Buffer Data - CVE-2018-12130, CVE-2018-12126, CVE-2018-12127, and CVE-2019-11091. For existing VM or bare metal instances you should follow the patching guidance provided by the original OS vendor.

Note

Any images published after May 14th, 2019 listed in the image release notes will include the MDS patches. If using earlier images already launched, follow patching instructions.

Oracle Cloud Infrastructure Customer Advisory for MDS Impact on the Database Service

Intel disclosed 4 new speculative execution side-channel processor vulnerabilities affecting Intel processors. These vulnerabilities have received the following CVE identifiers:

- CVE-2019-11091: Microarchitectural Data Sampling Uncacheable Memory (MDSUM)
- CVE-2018-12126: Microarchitectural Store Buffer Data Sampling (MSBDS)
- CVE-2018-12127: Microarchitectural Load Port Data Sampling (MLPDS)
- CVE-2018-12130: Microarchitectural Fill Buffer Data Sampling (MFBDS)

For more information, see https://blogs.oracle.com/security/intelmds.

Oracle has deployed technical mitigations across Oracle Cloud Infrastructure systems designed to prevent a malicious attacker’s virtual machine (VM) instance from accessing data from other VM instances.

Autonomous Data Warehouse and Autonomous Transaction Processing

Autonomous Data Warehouse provides fully managed databases optimized for running data warehouse workloads.

Autonomous Transaction Processing provides fully managed databases optimized for running online transaction processing and mixed database workloads.

Autonomous Data Warehouse and Autonomous Transaction Processing are not affected by MDS vulnerabilities. These services do not run on their own hypervisor and they do not allow for the execution of untrusted code in their services enclave. Customers can execute code within their own instances and each customer instance is isolated from that of another customer. No further customer action is currently required.

Guidance for the DatabaseService on Bare Metal Instances

The Database service on Oracle Cloud Infrastructure bare metal instances offer customers full control over their Oracle Database running on a physical server. Oracle Cloud Infrastructure's network virtualization is designed and configured to protect these instances from

unauthorized access from other instances on theOracle Cloud Infrastructure network, including other customer instances, both VM instances and other bare metal instances. As a result, the Database service on bare metal instances are not affected by the MDS vulnerabilities.

Actions for Customers with VM DB Systems, Bare Metal DB Systems, or Exadata DB Systems

Customers are advised to apply available patches at the earliest possible time. Use the following instructions to patch a running instance:

- For DB systems on bare metal instances, apply the OS patches following the instructions in Updating a DB System.
- For DB systems on a VM instance, configured using the Oracle Cloud Infrastructure Database service, apply the OS patches following the instructions in Updating a DB System.
- For the DB systems on a VM instance configured using the Oracle Platform Service Manager, apply the OS patches following the instructions in Applying Linux OS Security Patches by Using the dbaascli Utility.
- For Exadata DB systems, apply the OS patches following the instructions in Updating an Exadata DB System.

CHAPTER 30 Storage Gateway

This chapter explains how to use Storage Gateway to connect your on-premise applications with Oracle Cloud Infrastructure.

Overview of Storage Gateway

Storage Gateway is a cloud storage gateway that lets you connect your on-premises applications with Oracle Cloud Infrastructure. Applications that can write data to an NFS target can also write data to the Oracle Cloud Infrastructure Object Storage, without requiring application modification to uptake the REST APIs.

Important

Storage Gateway is the evolution of the Storage Software Appliance that was launched with Oracle Cloud Infrastructure Classic. Now that you're migrating to Oracle Cloud Infrastructure Object Storage, you'll use Storage Gateway, with its enhanced file-to-object transparency and improved scale and performance.

Storage Gateway and Oracle Cloud Infrastructure Concepts

The following concepts are essential to working with Oracle Cloud Infrastructure Storage Gateway.

FILE SYSTEM

A Storage Gateway file system on a local host maps its files and directories to objects with the same names in a corresponding Oracle Cloud Infrastructure Object Storage bucket.

FILE SYSTEM CACHE

Storage Gateway's configurable file system cache enables asynchronous and optimized movement of data to the cloud. The file system cache serves as both a write buffer and a read cache for data storage and retrieval. The write buffer contains data that copied to the disk cache and queued for upload to Oracle Cloud Infrastructure. The read cache contains frequently retrieved data that's accessible locally for read operations.

Proper file system cache configuration is critical to Storage Gateway performance. See Configuring the Cache for File Systems for details.

METADATA

The metadata associated with a Storage Gateway file is stored as custom metadata for the corresponding object in Oracle Cloud Infrastructure Object Storage. Examples of file metadata include object id, creation date, modification date, size, and permissions. Storage Gateway caches all metadata for the file system locally.

NFSv4

NFS is an established and widely adopted distributed file system protocol for handling network storage. NFS lets client computers mount file systems on remote servers and access those remote file systems over the network as though they were local file systems. Storage Gateway performs the NFS to REST API translation needed to interact with Oracle Cloud Infrastructure Object Storage.

ORACLE CLOUD INFRASTRUCTURE

Oracle Cloud Infrastructure is a set of complementary cloud services that lets you build and run a wide range of applications and services in a highly available hosted environment. Oracle Cloud Infrastructure offers high-performance compute capabilities (as physical hardware instances) and storage capacity in a flexible overlay virtual network that is securely accessible from your on-premises network.

TENANCY

A tenancy is a secure and isolated partition within Oracle Cloud Infrastructure where you can create, organize, and administer your cloud resources.

Oracle Cloud Infrastructure Object Storage and Archive Storage

Oracle Cloud Infrastructure offers two distinct storage tiers for you to store your unstructured data. Use the Object Storage **Standard** tier for data to which you need fast, immediate, and frequent access. Use the Archive Storage service's **Archive** tier for data that you access infrequently, but which must be preserved for long periods of time. Both storage tiers use the same manageable resources (for example, objects and buckets). The difference is that when you upload a file to Archive Storage, the object is immediately archived. Before you can access an archived object, you must first restore the object to the Standard tier.

Note

In the Storage Gateway documentation, generic references to Object Storage encompass both the Standard and Archive storage tiers.

Both storage tiers are simple to use, perform well, and scale to an unlimited capacity.

BUCKET

An Object Storage bucket is a logical container for storing objects. A file system created in Storage Gateway maps to a corresponding bucket by the same name in Object Storage. A bucket is associated with a single Oracle Cloud Infrastructure compartment. The compartment has policies that determine what actions a user can perform on the bucket the objects it contains.

OBJECT

An individual file or directory written to a Storage Gateway file system on an NFS share creates an identically named object in the target Object Storage bucket. An object is composed of the object itself and metadata about the object.

NAMESPACE

A logical entity that serves as a top-level container for all Oracle Cloud Infrastructure Object Storage buckets and objects. The namespace enables you to control bucket naming within your tenancy. Each tenancy has one unique and uneditable Object Storage namespace that is global, spanning all compartments and regions. Bucket names must be unique within your tenancy.

COMPARTMENT

A collection of Oracle Cloud Infrastructure-related resources. Only users and groups with access permissions explicitly granted by an administrator can access the resources. Compartments help you organize resources and make it easier to control access to those resources. Object Storage automatically creates a root compartment when a compartment is provisioned. An administrator can then create more compartments within the root compartment and add access rules for those compartments. A bucket can exist in only one compartment.

How Storage Gateway Works

Storage Gateway is installed in an Oracle Cloud Infrastructure compute instance or as a Linux Docker instance on one or more hosts in your on-premises data center. Applications store and retrieve objects from Oracle Cloud Infrastructure Object Storage through *file systems* that you create in Storage Gateway.

Storage Gateway exposes an NFS mount point that can be mounted to any host that supports an NFSv4 client. The Storage Gateway mount point maps to an Object Storage bucket.

There is file to object transparency between Storage Gateway and Object Storage:

- A Storage Gateway file system directory on a local host maps to a bucket with an identical name in Oracle Cloud Infrastructure Object Storage.
- Any file written to a Storage Gateway file system is written as an object with the same name in the associated Object Storage bucket. The system stores associated file attributes as object metadata.

- You can access Object Storage objects directly using native APIs, SDKs, third-party tools, the HDFS connector, and the Oracle Cloud Infrastructure CLI and Console. You use the **Refresh** operation in Storage Gateway to ingest any data that was added or modified directly in Object Storage.

Enterprise applications typically work with files in nested directories. Object Storage buckets, and the objects within those buckets, exist in a flat hierarchy. Storage Gateway flattens the directory hierarchy into nested object prefixes in Object Storage. See Interacting With Object Storage for details.

Recommended Uses and Workloads

The following summarizes some of the ways that you can use Storage Gateway.

DATA TRANSFER

Use Storage Gateway to move data from your on-premises host to Oracle Cloud Infrastructure. Storage Gateway is not a replacement for general-purpose network attached storage (NAS), though it behaves similarly to NAS. Use Storage Gateway's integrated Cloud Sync feature to transfer and synchronize data to Oracle Cloud Infrastructure.

CLOUD TIERING

Use Storage Gateway to expand the capacity of on-premises storage solutions without capital expenditures. Configuring and connecting a Storage Gateway file system with a large cache to Oracle Cloud Infrastructure Object Storage provides unlimited scale to create a workflow in which files get automatically moved to the cloud and retrieved only on demand. Even though on-demand retrieval is slower than access to local storage, capital expenditures or changes to existing tools and software are not required.

BACKUPS

Use Storage Gateway to move files to Oracle Cloud Infrastructure Archive Storage as a cost-effective backup solution. You can move individual files and compressed or uncompressed ZIP or TAR archives. Storing secondary copies of data is an ideal use case for Storage Gateway.

ARCHIVAL

Storage Gateway is ideal for archive use cases.

DISASTER RECOVERY

Storage Gateway lets traditional applications move data to highly durable object storage. When you need to recover data, create a fresh instance of Storage Gateway to return the data from Object Storage.

Uses and Workloads Not Supported

Storage Gateway does not support the following uses and workloads.

GENERAL-PURPOSE NETWORK STORAGE

Storage Gateway isn't a general-purpose storage filer and must not be used as a replacement for traditional network storage appliances.

FILE SYNC AND SHARE

Though Storage Gateway is an effective data mover, it’s not a replacement for file sync and share services. Evaluate Oracle services like Oracle Document Cloud service if you need file sync and share functionality.

CONTENT COLLABORATION

Storage Gateway does not support multiple Storage Gateway instances simultaneously reading from and writing to a single Object Storage bucket. Do not use Storage Gateway as a tool for distributed teams to collaborate on creating and managing content.

FREQUENTLY MODIFIED FILES

Do not use Storage Gateway if you expect your data to be modified frequently. Each time a file is modified and closed, Storage Gateway creates an updated version and uploads it to Object Storage as a new object. Frequently modified data results in substantial inefficiency, in terms of both bandwidth consumption and capacity utilization.

RENAMING LARGE DIRECTORY TREES

Renaming directories in the Storage Gateway works well for a small directory tree. However, renaming a parent directory with many children can be slow. The service updates the object ID of every corresponding child object in the object store to reflect the new path. If you do start a rename, ensure that the action finishes by monitoring the **Pending Uploads** field in the Storage Gateway user interface.

Security Considerations

ADMIN PASSWORD

Because Storage Gateway administrators can create, modify, and delete file systems, follow these password guidelines:

- Set a strong password.
- Ensure that the password is secure.
- Share passwords with others only on a need-to-know basis.

DOCKER

Storage Gateway runs inside a Docker container for security and isolation. Follow these Docker-related guidelines and recommendations:

- Avoid or minimize Docker instance operations.
- Avoid logging in to the Docker container. If there is a genuine requirement to log in to the Docker container, use extreme caution to avoid service disruption. Do not change the Docker configuration or the Docker instance unless instructed to do so by Oracle support personal.
- Although the NFS protocol controls access to the file system from clients, Storage Gateway file systems are also locally mounted inside the Docker container. To prevent unauthorized access to file system data, ensure that a Docker container is accessible only by an administrator or an authorized user.

- Configure the Docker host to limit user access to the Storage Gateway Docker container.
- Files and directories in a Docker container are also visible in the Docker host - typically file systems and directories that are provisioned in the Docker host and mapped to the container. Set the appropriate ownership and modes to ensure that only an administrator or an authorized user can access these folders. We recommend the following:
    - A dedicated Storage Gateway host.
    - Limit who can access the Storage Gateway host.
    - Set firewall rules to limit access to the Docker host and Docker container.
    - Implement backup and retention policies for the files associated with Storage Gateway.

ACCESS CONTROL

Default file system export options are too permissive. Set more restrictive export options so that only trusted NFS clients can access the file system data and metadata. Modify the advanced file system settings for **NFS Allowed Hosts** and **NFS Export Options** to restrict access to a file system. In addition to NFS protocol security, you can also set up and configure a firewall on the host to further control access to the file system. UID/GID/modes control access to files and directories. Set the appropriate ownership mode to protect sensitive data.

OBJECT STORAGE

Files in a file system are uploaded to Oracle Cloud Infrastructure and stored as objects in an Object Storage bucket. Associated file attributes are stored as object metadata. Access control for Object Storage is different from access control for a traditional file system. Anyone with permission to read or modify any object in the bucket can read or modify all objects in the bucket. To protect sensitive data, set up Oracle Cloud Infrastructure IAM policies to limit who can access objects in the bucket.

Storage Gateway transfers data to Oracle Cloud Infrastructure using HTTPS, which encrypts data packets in flight between Storage Gateway and the cloud. Data written to Object Storage is always automatically encrypted in the cloud.

Limits on Storage Gateway Resources

See Service Limits for a list of applicable limits and instructions for requesting a limit increase.

Other limits include:

- Ensure that the number of file systems per Storage Gateway doesn't exceed 10. For best performance, host each file system on a dedicated Storage Gateway.
- Ensure that the number of objects stored in a Storage Gateway file system doesn’t exceed 100 million. For datasets that consist of more than 100 million objects, distribute the objects across multiple Storage Gateways.
- Ensure that you configure adequate local storage for file system cache. Storage Gateway warns you if you have configured less than the recommended 500 GB.
- The minimum amount of memory required for any Storage Gateway file system is 16 GB.
    - File systems with up to 50 million files require 32 GB of memory.
    - Large file systems with up to 100 million files require 64 GB of memory.
- The number of files in the cache is limited to 20,000 regardless of the specified cache size in bytes.
- To improve the efficiency of file ingestion, cloud upload operations, and to reduce the number of objects in the namespace, bin-pack or zip small files before writing them to Storage Gateway.

Storage Gateway Release Notes

Release notes provide version-specific release information and important Storage Gateway issues that you need to be aware of:

https://docs.cloud.oracle.com/iaas/releasenotes/services/storage-gateway/

Features of Storage Gateway

This topic highlights key features of Storage Gateway.

POSIX-Compliant NFS Access to Oracle Cloud Infrastructure Object Storage

Using Storage Gateway, your applications can interact with Oracle Cloud Infrastructure Object Storage through standard NFSv4 protocols. You connect Storage Gateway file systems to Object Storage buckets. Storage Gateway stores files as objects in an Oracle Cloud Infrastructure Object Storage bucket and supports multipart uploads for large objects. Object Storage does not, however, support symbolic links, hard links, or special device files.

Data Integrity with Checksum Verification

The built-in data integrity checks ensure that data is validated as it moves through the data path from Storage Gateway to Oracle Cloud Infrastructure Object Storage. Checksum verification helps ensure data integrity. Metadata integrity checks ensure that the metadata is in a consistent state. The checksum for each file can be read using a custom interface.

Large File Support

The Oracle Cloud Infrastructure Object Storage service supports multipart uploads for faster, more efficient, and resilient uploads. Storage Gateway can use multipart upload for files larger than 128 MB. With multipart uploads, individual parts of an object can be uploaded in parallel to reduce the amount of time you spend uploading. Multipart uploads also minimize the impact of network failures by letting you retry a failed part upload instead of requiring you to retry an entire object upload. See Using Multipart Uploads for details.

Beginning with version 1.3, Storage Gateway provides partial update capabilities to:

- Reduce upload latency.
- Improve the use of available network bandwidth.
- Reduce the minimum required cache size.
- Enable ingestion of single files that are larger than the Storage Gateway cache size.

Storage Gateway's partial update capability leverages the Object Storage service multipart upload functionality to break a large file into smaller parts, and then upload the parts in parallel. After uploading, the service reconstructs them as a single object. With partial update, the service can upload only the modified file parts and reconstruct the object using the unchanged parts that already exist in Object Storage. The service does not need to overwrite the existing object by uploading the entire file.

Since the full file does not have to exist within the Storage Gateway cache at one time, partial update enables the service to ingest single files that are larger than the allocated cache size.

The default file part size is 1GB, with a maximum size of 10TB for the full file. Although the part size is configurable per file system, Oracle does not recommend that you use custom sizes. Custom part sizes do not improve upload performance, but can reduce the maximum supported full file size. The maximum file size is 10,000 times the file part size, with a hard cap of 10TB. If you customize the file part size, you do not need to restart the Storage Gateway, but you must reconnect to the affected file system.

All file parts in the cache are managed by the least recently used (LRU) cache management policy.

To use partial update for objects stored in the Archive Storage tier, you must first restore the object.

See Upgrading Storage Gateway for information about upgrading your Storage Gateway system to use partial update.

Support for Data Archival

In addition to uploading to buckets in the Object Storage Standard tier, Storage Gateway supports uploading to and restoring objects from buckets in the Archive Storage tier.

When you create a file system, you specify the storage tier in which to create the corresponding Object Storage bucket.

- The default Standard Object Storage tier is used for storing data to which you need fast, immediate, and frequent access.

- The Archive Storage tier is used for storing data that is accessed infrequently and requires long retention periods.

While Archive Storage is more cost effective than Object Storage for preserving cold data, you must first *restore* the objects before you can access them. The restoration process can take up to four hours depending on the size of the object. See Overview of Archive Storage and Restoring Files and Objects from Archive Storage for details.

Storage Gateway supports Oracle Cloud Infrastructure Object Storage object lifecycle policies to manage the archiving and deletion of objects in a bucket according to a pre-defined schedule. Using object lifecycle policies, you can specify bucket creation in the Standard Object Storage tier, and then create a policy to schedule the subsequent movement of data to the Archive Storage tier. This lifecycle policy archival method is useful if you have on-premises applications that generate intermediary or temporary files and directories that are inappropriate for immediate archival. See Using Object Lifecycle Management for details.

Automated Object Deletion

When you delete a Storage Gateway file from a file system, the corresponding object in Object Storage is automatically deleted.

Quick Access to Select Files with Cache Pinning

Storage Gateway lets you *pin* files to the file system cache for quick access. You can pin files to the cache for file systems connected to either the Object Storage Standard or Archive tier.

When you write a file to your Storage Gateway file system, the file is initially stored in the file system cache, and then asynchronously uploaded to your Oracle Cloud Infrastructure bucket. After a file has been uploaded, the cache manager can remove the file from the file system cache. To meet the cache threshold specified for the file system, cache is reclaimed using the *Least Recently Used* (LRU) cache management policy. If you want specific files to be available in the cache for quick access, you can pin the files to the file system cache. Once pinned, files are not removed from the file system cache until you explicitly unpin them.

Storage Gateway Health Check

The Storage Gateway performs automated "health checks" on the system to monitor the status of the following:

- Storage Gateway services and resources
- Local storage, file system cache, metadata storage, and log storage

Integrated Cloud Transfer and Synchronization (Cloud Sync)

Storage Gateway provides an integrated cloud transfer and synchronization feature called Cloud Sync that lets you back up and transfer files on local storage to and from Oracle Cloud Infrastructure Object Storage buckets. This new feature replaces the independent, downloadable cloud sync utility that was available in the previous Storage Gateway version.

You can use the Storage Gateway management console or CLI to create, monitor, and manage Cloud Sync jobs similar to other enterprise NAS backup/replication offerings. Cloud Sync runs as part of the Storage Gateway software inside the Docker instance on the host.

Getting Started With Storage Gateway

This topic provides recommendations for getting started with Storage Gateway.

Recommended Reading

- If you have not done so already, read Overview of Storage Gateway. That topic describes:
    - Key concepts for understanding both Storage Gateway and Object Storage.
    - Important security considerations.
    - Recommended uses and workloads.
    - Uses and workloads to avoid.

- Configuring the cache for file systems is key to Storage Gateway. Read Configuring the Cache for File Systems to understand the importance of the file system cache and the guidelines for configuring the cache when you add a file system.
- To understand the prerequisite tasks and requirements for interacting with Object Storage, read Interacting With Object Storage .

Next Steps for Setting Up Storage Gateway

Key topics for setting up Storage Gateway include:

- Installing Storage Gateway
- Logging In to the Storage Gateway Management Console
- Creating Your First File System
- Mounting File Systems on Clients

Next Steps for Using Storage Gateway

Key topics for using and managing Storage Gateway include:

- Managing File Systems
- Managing Storage Gateway
- Monitoring Storage Gateway

Configuring the Cache for File Systems

Storage Gateway caches frequently retrieved data on the local host, minimizing the number of REST API calls to Oracle Cloud Infrastructure Object Storage and enabling faster data retrieval. You configure the cache for a file system when you create the file system. See Creating Your First File System and Adding a File System.

About File System Cache

The file system cache serves as both a read cache and a write buffer for data storage and retrieval. The read cache contains frequently retrieved data that's accessible locally for read operations. The write buffer contains data that has been copied to the disk cache and queued for upload to your Oracle Cloud Infrastructure tenancy.

When you retrieve data from Oracle Cloud Infrastructure, the data is stored in the Storage Gateway read cache. The read cache allows subsequent I/O operations to that data at local disk speed.

When the read cache is full or reaches the configured limit, Storage Gateway removes files from the cache based on a least recently used (LRU) algorithm. Files pending upload to your tenancy are not removed from cache. You can also preserve files that you do not want removed from cache.

For more information on how to preserve files in the read cache, see Preserving Files in the File System Cache.

When an application transfers files through an NFS share, the files are written to the write buffer. The write buffer can contain many files that are queued and pending upload. If the host on which Storage Gateway is installed fails or Storage Gateway stops abruptly, the pending upload operations persist on the local disk. When Storage Gateway restarts, the pending upload operations resume and the data is uploaded to Oracle Cloud Infrastructure.

Configuring Local Storage for File Systems and Cache

Storage Gateway uses local storage attached to the server (or virtual server) for hosting the file systems and cache. Files written to a file system in Storage Gateway are uploaded to the associated Object Storage bucket, with a portion of the file set maintained locally in the file system as a warm cache.

For optimal performance, reliability, and fault tolerance, follow these guidelines when configuring the local Storage Gateway storage:

- Allocate dedicated local storage for each Storage Gateway file system, and associated metadata and logs.
- Multiple disks (hard disk drives or solid-state drives) in a RAID10 set provide an optimal balance of performance, reliability, and fault tolerance. Alternatively, you can use RAID6.

Important

Avoid RAID0 or single disk (no RAID) because of the potential for data loss upon disk failure.

- Provision sufficient space to accommodate the read cache **and** the write buffer (for ingesting new files) without ever becoming more than 80% full.
  In general, provision file system cache storage that is at least 1.5 times the size of the file set that you want to hold in the read cache. For example, assume that the entire file set requires 50 TB of space. You expect frequent access to 10% (5 TB) of that file set. Ensure that the file system cache storage has at least 7.5 TB of usable capacity. If the cache size reaches a near-full threshold, any data ingestion results in an out of space error in Storage Gateway.
- When you provision local storage at installation time, Oracle recommends that you configure the read cache to be equal to the file system cache size minus the desired write buffer size. If the file system cache is less than 300 GB, Storage Gateway generates a warning message.

Determining File System Cache Size

The Storage Gateway file system cache serves as both a read cache and a write buffer. You can specify the maximum size of the read cache. The write buffer uses any remaining available space in the file system cache. You do not explicitly specify a size for the write buffer.

Important

Oracle recommends that you configure the read cache to be equal to the file system cache size minus the desired write buffer size.

Read Cache Size

The default maximum read cache size is 300 GB if the file system cache size is greater than 300 GB. Changing the default maximum read cache size is optional. The appropriate size depends on Storage Gateway workload. While the default setting for the read cache is appropriate for most workloads, consider increasing the size if Storage Gateway must retrieve a significant amount of data from the cloud.

Use the following guidelines to determine the appropriate setting for the read cache size:

- Do not set the read cache maximum equal to the size of the file system cache. Doing so allocates 100% of the space for the read cache and leaves no capacity for ingesting new files. If there is no available space for new file ingestion, Storage Gateway stops ingesting data and begins evicting files from the read cache to create space. Always preserve some space in the file system cache for ingestion.
- Set the read cache size to equal the amount of data that you anticipate to be accessed frequently, while leaving enough capacity for the write buffer.

Note

If the total file system cache size is less than 300 GB, Storage Gateway automatically sets the read cache maximum size to 20% of the file system cache. The system does not honor custom read cache configuration settings for a file system cache less than 300 GB.

After you calculate the optimal file system cache size, you can configure the read cache when creating the file system or adjust it after monitoring the workload. See Adding a File System and Changing the Properties of a File System.

Write Buffer Size

Optimizing the space available for the write buffer is an important part of determining the appropriate file system cache size. The write buffer size increases when data is ingested in Storage Gateway and decreases after the data is uploaded to the cloud.

Important

- When the write buffer uses all available file system cache space, further data ingestion is blocked until a portion of the existing files are uploaded and evicted from the cache.
- Oracle recommends that you allow a minimum of 300 GB for the write buffer under any circumstances.

Use the following guidelines to determine the space needed for the write buffer:

- Identify the amount of data to be uploaded in Storage Gateway. If a large amount of data is uploaded, the Storage Gateway write buffer can reach its maximum size. Exceeding the write buffer leads to I/O failure as the file system cache has no space available. If you cannot regulate data ingestion, you can increase the file system cache space to avoid I/O failure. You can regulate I/O by pausing after a certain amount of data is ingested or by periodically allowing uploads to complete before ingesting more data. For example, you can use this approach for backups run as cron jobs when the file system cache space is less than the amount of data to be ingested.
- Calculate the amount of data that is ingested on any typical day or week in Storage Gateway. Also, calculate the amount of data that is uploaded over a time period, based

on the available bandwidth or historical data. Ensure that the difference between these calculations does not exceed the write buffer size.

- Some applications can handle I/O failure, and then resume writing data. In this case, consider setting the cache size to the amount of data that you'd like the application to tolerate before the cache space can be reclaimed.

As stated earlier, you want to avoid completely filling the file system cache. The write buffer grows by the difference between the ingest rate and the upload rate. The file system cache size must be larger than the *read cache plus the total number of bytes buffered* at any point during the job. If you have workloads that upload large amounts of data in parallel, you can use the following equation to determine the amount of space needed by the write buffer.

```
WB >= D * (1 - UR/IR) + E
```

WB = Recommended write buffer size

D = Total uploaded dataset size

UR = Upload rate (The upload rate is the lesser of the actual upload rate or the disk read speed.)

IR = Ingestion rate (disk write speed)

E = Extra margin (Oracle recommends at least 50 GB.)

Note

This equation applies only if the upload rate is less than the ingest rate.

Run the following command to measure your system's ingestion rate:

```
sudo docker exec -it ocisg python /opt/oracle/gateway/python/packages/ocisg_helper/disk_speed_test.py
```

Example output:

```
Write speed:
2.1 GB copied in 9.4 seconds (228 MB/s)
```

```
Read speed:
2.1 GB copied in 6.8 seconds (315 MB/s)
```

If read and writes occur in parallel during the job, the read and write speeds are about 50% of the returned values.

Run the following command to measure your system's upload rate:

```
sudo docker exec ocisg cat /mnt/gateway/cache-phoenix/:::diag:oci-network-speed-test
```

Example output:

```
Average Upload Speed = 125 MB/s
```

EXAMPLE 1

Daily dataset is 500 GB

Upload rate = 2 MB/s

Disk read = 600 MB/s

Ingestion rate (Disk write) = 600 MB/s

Apply the equation:

WB >= 500 GB * (1 - (2/600)) + 50 GB

WB >= 549 GB

In this case, the upload rate is very slow compared to the ingestion rate, so the entire dataset needs to fit in the write buffer.

EXAMPLE 2

Daily dataset is 1 TB

Upload rate = 300 MB/s

Disk read = 400 MB/s

Ingestion rate (Disk write) = 100 MB/s

In this case, we recommend the minimum write buffer size of 300 GB, since the upload rate is higher than the ingestion rate.

EXAMPLE 3

Daily dataset is 5 TB

Upload rate = 250 MB/s

Disk read = 400 MB/s

Ingestion rate (Disk write) = 300 MB/s

Apply the equation:

WB >= 5 TB * (1 - (250/300)) + 50 GB

WB >= 0.88 TB

WB is 880 GB.

Note

Storage Gateway begins throttling I/O when the free cache space falls below 15 GB. Determine if the application is able to handle the throttling or if you want to provision more cache space.

Preserving Files in the File System Cache

When you write a file to your file system, the file is initially stored in the file system cache, and then uploaded to your Oracle Cloud Infrastructure tenancy. After a file has been uploaded, the cache manager can remove the file from the file system cache. To meet the cache threshold specified for the file system, cache is reclaimed using the *Least Recently Used* (LRU) cache management policy. If you want specific files to be available in the cache for quick access, you can *pin* the files to the file system cache. Once pinned, files are not removed from the file system cache until you explicitly unpin them. You can view the **Maximum Read Cache Size in GiB** for a selected file system in the management console under **Settings**.

You can pin files connected to both **Standard** and **Archive** storage tiers to file system cache. Files that you write to a file system are always uploaded to your tenancy, regardless of whether the files are pinned to the cache.

If the file that you want to pin to cache is not present in the cache, the file is automatically downloaded to the cache if the file system is connected to a **Standard** storage tier. If that file belongs to a file system connected to an **Archive** storage tier, you must first restore the file before the file can be downloaded to the cache. See Restoring Files and Objects from Archive Storage for details.

Important

- By default, the cache pinning feature is enabled on all file systems.
- When selecting the files for cache pinning, consider the overall cache threshold and calculate the residual cache space that remains available for normal cache operations. For example, assume that your cache threshold is 1 TB and you estimate that the files you want to pin to cache occupy 300 GB. That leaves 700 GB of usable space in your cache after pinning the files.
- When you restore a file from the `Archive` storage tier, the file moves to the `Standard` storage tier. The file remains in `Standard` storage for 24 hours or the retention duration you specify. The continued availability of the file in the cache depends on the LRU operation. However, if you pin such a file to the cache, the restored file remains in the cache until you unpin the file.

Enabling and Managing Cache Pinning

To perform cache pinning operations for a file system, run the following command from the NFS client on which the file system is mounted:

```
cat /path/to/mountpoint/<file_path>:::cache:cache_command[:argument]
```

The following table lists the cache pinning operations and the corresponding command and argument for each operation:

Operation	Cache Command	Argument
Enable cache pinning for a file system. By default, cache pinning is enabled for all file systems.	`set-preserve-option`	`true`
Get the cache pinning status for a file system.	`get-preserve-option`	No argument
Disable cache pinning for a file system.	`set-preserve-option`	`false`
List the files that are pinned to the cache.	`list-preserve`	No argument
Remove deleted files from the preserve list.	`list-preserve-update`	No argument
Add a file to the preserve list.	`add-preserve`	No argument
Remove a file from the preserve list.	`remove-preserve`	No argument
Clear the preserve list.	`clear-preserve`	No argument

Example Commands

- To enable cache pinning for the `myFS` file system:

```
cat /mnt/gateway/myFS/:::cache:set-preserve-option:true
```

- To get the cache pinning status for `myFS`:

```
cat /mnt/gateway/myFS/:::cache:get-preserve-option
```

  If cache pinning is enabled for the file system, the output of this command is `true`. Otherwise, the output is `false`.

- To disable cache pinning for the `myFS` file system:

```
cat /mnt/gateway/myFS/:::cache:set-preserve-option:false
```

- To add a file `myFile` of the `myFS` file system to the preserve list:

```
cat /mnt/gateway/myFS/myFile:::cache:add-preserve
```

- To find out which files are added to the preserve list of the `myFS` file system:

```
cat /mnt/gateway/myFS/:::cache:list-preserve
```

  Sample output of the preceding command:

```
["/doNotDelete.txt", "/myFileMetadata", "/myFile"]
```

- To remove the file `myFile` from the preserve list

```
cat /mnt/gateway/myFS/myFile:::cache:remove-preserve
```

- To update the preserve list when the output of the `cache:list-preserve` command indicates that a pinned file has been removed from the file system:

```
cat /mnt/gateway/myFS/:::cache:list-preserve-update
```

  Sample of the original preserve list:

```
["/doNotDelete.txt", "/myFileMetadata"]
```

  Output of the `cache:list-preserve` command after the file `myFileMetadata` is removed from the cache:

```
["/doNotDelete.txt", "Status: 1 files appear to no longer exist. Please run list-preserve-update"]
```

Output of the `cache:list-preserve-update` command:

```
["/doNotDelete.txt"]
```

- To clear the preserve list for a file system:

```
cat /mnt/gateway/myFS/:::cache:clear-preserve
```

Understanding Storage Gateway Performance

This topic covers the performance characteristics of Storage Gateway and the ways you can maximize its efficiency.

Performance Characteristics

It is important to understand the basic performance characteristics of Storage Gateway:

- Because there is transactional overhead for each file, Storage Gateway generally exhibits better performance with large files than with small files. Storage Gateway can only upload data as fast as your connection and the storage host allows. Storage Gateway buffers the data in local disk storage while waiting to upload to Oracle Cloud Infrastructure. Once a file is uploaded, the file's local copy can be removed from the cache to free up space. If file system cache space falls below 10 GB, application I/O and file/directory creation can fail.
- Modifying a file involves uploading a whole new copy of that file. This behavior is not efficient for frequently modified large files.
- Storage Gateway does not support frequently modified files such as logs, databases, or virtual disks. Storage Gateway depends on the closing of a file to trigger an upload of that file. If a file never closes or is modified frequently, the upload event cannot successfully occur.
- Upload throughput to Object Storage (WAN) is typically slower than NFS client throughput (LAN). As a result, Storage Gateway can accumulate a large amount of data that is pending upload.
- You can attach Storage Gateway to an existing Object Storage bucket that contains data. The service is optimized for this type of initialization. Storage Gateway can

initialize about 700 thousand files per hour with a hard disk drive-based cache. It can initialize about 7 million files per hour with an NVMe SSD-based cache.

Factors That Affect Performance

To get the maximum performance benefits from Storage Gateway, follow the practices documented at Best Practices for Using Storage Gateway.

In addition to having sufficient memory and file system cache space, Oracle recommends that you use SSDs to help improve NFS ingestion rate.

Storage Gateway is tuned for maximum upload and download performance by default. No additional tuning is needed.

Performance Testing

While measuring performance is complex and open to variability, we have observed the following in performance benchmark tests with 10-Gb/s link speed:

Workload (Upload/Download)	Configuration	Average Upload Throughput	Average Download Throughput
Single large file of 400 GB	CPU: 8 cores Memory: 32GB Disk Read: 340 MB/s Disk Write: 234 MB/s Link Speed: 10 Gb/s (1.25 GB/s)	239 MB/s	195 MB/s
Multiple files of 10-50 GB (Total data = 400GB)	CPU: 8 cores Memory: 32GB Disk Read: 340 MB/s Disk Write: 234 MB/s Link Speed: 10 Gb/s (1.25 GB/s)	260 MB/s	225 MB/s

Note

Using FastConnect with Storage Gateway makes optimal use of full link speed. We have customers using FastConnect with 10-Gb/s link speed and have seen each gateway achieve 400–450 MB/s uploads to Oracle Cloud Infrastructure.

See FastConnect Overview for more information.

Testing Network Bandwidth

Storage Gateway provides a diagnostic command that you can use to test the bandwidth in your environment and ensure that you get the expected upload and download speeds. The amount of data transferred depends on these factors:

Bandwidth * Delay Product (bits) = total_available_bandwidth (bits/sec) x round_trip_time (sec)

Note

Different buckets can have different upload and download speeds.

The round_trip_time can vary by region.

To run the diagnostic command:

You need `root` permissions to run the `diag` command.

1. Using SSH, log in to the host on which you installed Storage Gateway.
2. Run the `diag` command, specifying the Storage Gateway file system name:

```
[root@ocisg-ashburn opc]# sudo docker exec ocisg cat /mnt/gateway/<file_system_name>/:::diag:oci-network-speed-test
```

The `diag` command responds with the average upload speed, for example:

```
Average Upload Speed = 217 MB/s
```

Interacting With Object Storage

This topic helps you understand the Oracle Cloud Infrastructure Object Storage environment and how it interacts with a Storage Gateway.

Creating the Required IAM Users, Groups, and Policies

An Oracle Cloud Infrastructure administrator must perform prerequisite tasks in preparation for data movement between Storage Gateway and Object Storage. If you are new to Oracle Cloud Infrastructure, we recommend that you read Setting Up Your Tenancy.

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

Access to resources is provided to groups using policies and then inherited by the users that are assigned to those groups. For details on creating groups, see Managing Groups.

For Storage Gateway, an administrator creates these groups with the following policies:

```
Allow group <group_name> to manage buckets in compartment <compartment_name>
```

```
Allow group <group_name> to manage objects in compartment <compartment_name>
```

Content Consistency Between Storage Gateway and Object Storage

Changes to the files in Storage Gateway, including create, write, update, and delete, eventually are consistent with Object Storage. Uploads are asynchronous and buffered for performance, so Storage Gateway file changes might not yet be reflected in Object Storage.

You can access, modify, and upload objects directly to a bucket using Object Storage native APIs, SDKs, the CLI, the Console, or the HDFS connector. Objects modified in these ways do

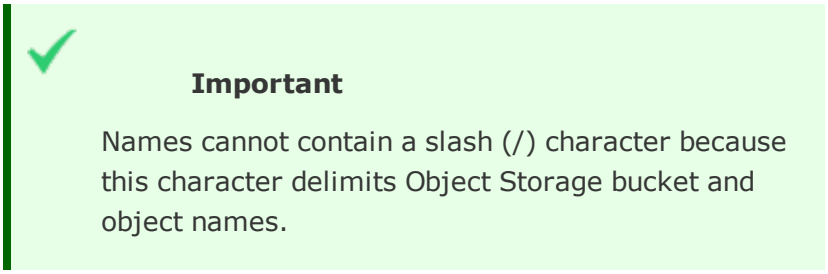
not appear as files in Storage Gateway until you click **Refresh** in the Storage Gateway management console.

Name Restrictions

Storage Gateway file and file system names must adhere to Object Storage bucket and object name restrictions and guidelines.

Use the following guidelines for naming file systems:

- Use from 1 to 256 UTF-8 characters.
- Valid characters are letters (upper or lower case), numbers, hyphens, underscores, and periods.



- Do not include confidential information.
- Make the name unique within a Storage Gateway instance.

Use the following guidelines for naming files:

- Use from 1 to 1024 characters.
- Valid characters are letters (upper or lower case), numbers, and characters other than linefeed, newline, and NULL.
- Use only Unicode characters for which the UTF-8 encoding does not exceed 1024 bytes. Clients are responsible for URL-encoding characters.
- Do not include confidential information.

- Make the name unique within the bucket. Do not use the name of an existing object within the bucket when naming an object unless you intend to overwrite the existing object with the contents of the new or renamed object.

Custom Metadata

POSIX file and directory attributes are stored in custom metadata. These attributes include `uid`, `gid`, `mode`, `atime`, `ctime`, and `mtime`. If existing objects in Object Storage are missing the required custom metadata, Storage Gateway assigns the following default values:

- `uid`=0
- `gid`=0
- `mode`=0644 for file and 0755 for directory

The custom metadata is not updated in Object Storage until a file operation triggers Storage Gateway to update the file in Object Storage.Timestamp metadata (`atime`, `ctime`, and `mtime`) are expressed in milliseconds. Access modes are expressed in octal and include file/directory bit.

The custom metadata names follow these guidelines:

- Only ASCII characters.
- A maximum of 128 bytes.

The custom metadata values follow these guidelines:

- Only UTF-8 characters.
- A maximum of 256 bytes.

Understanding Directory and File Hierarchy Translations in Object Storage

Within an Object Storage namespace, buckets and objects exist in a flat hierarchy. Storage Gateway flattens the file system directory hierarchy into nested object prefixes in Object Storage.

For directories:

- A Storage Gateway file system called `myFS` that contains a directory called `myDir`, appears in Object Storage as:

  ```
  n/<os_namespace>/b/myFS/o/myDir/
  ```

- A Storage Gateway file system called `myFS` that contains a `myDir` subdirectory called `mySubDir`, appears in Object Storage as:

  ```
  n/<os_namespace>/b/myFS/o/myDir/mySubDir/
  ```

You can distinguish a Storage Gateway directory from a Storage Gateway file in the following ways:

- Directories have a trailing slash **/**.
- Directory size or length is **0** (zero).

For files:

- A Storage Gateway file system called `myFS` that contains a directory called `myDir` with a file called `file1`, appears in Object Storage as:

  ```
  n/<os_namespace>/b/myFS/o/myDir/file1
  ```

- A Storage Gateway file system called `myFS` that contains a `myDir` subdirectory called `mySubDir` with a file called `file2`, appears in Object Storage as:

  ```
  n/<os_namespace>/b/myFS/o/myDir/mySubDir/file2
  ```

You can distinguish a Storage Gateway file from a Storage Gateway directory in the following ways:

- Directories have a trailing **/** and files do not.
- File length can be **0** (zero) or non-zero, but directory length is always **0** (zero).

Internal Storage Gateway Objects

Storage Gateway creates some special internal objects in Object Storage. These objects have a `/gateway` directory prefix. For example:

```
/n/<object_storage_namespace>/b/<bucket>/o//gateway
```

Important

Do not modify or remove the objects in the special `/gateway` directory. These objects are critical for Storage Gateway operation.

Installing Storage Gateway

This topic provides instructions for installing the Storage Gateway software.

Prerequisites

These instructions assume that you are familiar with the administration and configuration commands of the operating system on your host machine. To install Storage Gateway, your host system must meet certain hardware and software requirements.

Hardware Recommendations and Requirements

To run Storage Gateway, the host machine must meet the following requirements:

- Two dual-core CPUs or better. Oracle recommends 4-core CPUs.
- Minimum memory requirements:
  - 16 GB for required for any Storage Gateway file system.
  - 32 GB for file systems up to 50 million files.
  - 64 GB for file systems up to 100 million files.
- The recommended local storage disk size is 600 GB, which includes 500 GB for the file system cache, 80 GB for metadata storage, and 20 GB for log storage.

Important

Provision local storage before installing Storage Gateway. For best performance, allocate dedicated local storage file systems for the Storage Gateway cache, the metadata, and the logs. The installation script prompts you for the paths to your Storage Gateway file system cache, metadata storage, and log storage locations. Follow the disk size recommendations provided by the installer.

Oracle recommends that you use the XFS file system for the file system cache, metadata, and logs. XFS is a 64-bit file system designed for parallel I/O. Parallel I/O allows a system to scale based on the number of I/O threads and file system bandwidth.

Software Requirements

- Oracle Linux 7 with UEK Release 4 or later.

Note

If you create an Oracle Cloud Infrastructure Compute instance to host Storage Gateway, the instance creation wizard provides an option to choose the operating system image.

- Docker 1.12.6 or newer. Docker is an open platform for building, shipping and running

distributed applications. For more information, see https://www.docker.com/.

- NFSv4.

Note

The Storage Gateway installation software automatically installs Docker and the NFS protocol.

Hosting Storage Gateway on an Oracle Cloud Infrastructure Compute Instance

To host Storage Gateway on an Oracle Cloud Infrastructure Compute instance, you need:

- An SSH key pair in PEM format.
  - To create a key pair, see Creating a Key Pair.
  - If your public key is not in PEM format, use the following command to convert it:

    ```
    ssh-keygen -f <key_name>.pub -e -m pem
    ```

- An Oracle Cloud Infrastructure user account with an API signing key (the public key from your SSH key pair).
  - If you need to create a user account, see To create a user.
  - To upload an API signing key to an existing user account, see To upload an API signing key.
- A VCN and related resources. For help creating a VCN, see VCNs and Subnets.
  The following configuration points apply to your VCN:
  - Do not select the **Use DNS Hostnames in this VCN** check box unless you plan to use DNS hostnames for your Storage Gateway Compute instance.
  - The security list must include a rule to allow SSL (443) ingress.
  - After you install the Storage Gateway software your host machine, you must add a security list rule to allow communication with the management console port.

More information appears on this page after the Storage Gateway installation instructions.

- A Compute instance. See Creating an Instance.
  The VM.Standard2.4 Compute shape meets the minimum required specifications for Storage Gateway. Large file systems might require an image with more resources.
- A Block Volume. See Creating a Volume.
  - The recommended disk size is 600 GB.
  - Attach the volume to your Compute instance. See Attaching a Volume.
  - If you specify iSCSI as the volume attachment type, you must also connect and mount the volume from the instance for the volume to be usable. For more information, see Volume Attachment Types and Connecting to a Volume.

Installing Storage Gateway

You can install Storage Gateway on an Oracle Cloud Infrastructure Compute instance or an on-premises host that meets the hardware and software requirements.

To install the Storage Gateway software

1. Connect to your Compute instance or on-premises host.
   For help connecting to an Oracle Cloud InfrastructureCompute instance, see Connecting to an Instance.
2. If your host volume is new, you might need to format and mount the disk.

Tip

This task describes the simplest way to create a functional file system to host a Storage Gateway. It uses one device and file system to host the cache, metadata, and log volumes. You specify the paths to those volumes later in this procedure. To optimize performance for your system, you can:

- Create a separate device and file system for each of the cache, metadata, and log volumes.
- Create a single device, but create logical volumes and file systems for the cache, metadata, and log volumes.

To format the disk and create a file system:

a. Run *fdisk*:

```
sudo fdisk /dev/sdb
```

(Optional) Press **m** to view the *fdisk* options.

b. Choose command **g - create a new empty GPT partition table**.

c. Choose command **w - write table to disk and exit**.

d. Run the following command to create an XFS (file system):

```
sudo mkfs -t ext3 /dev/sdb
```

You might see the following warning:

```
/dev/sdb is entire device, not just one partition!
Proceed anyway? (y,n)
```

Choose **y** to proceed.

To mount the formatted volume:

a. Create a mount directory:

```
sudo mkdir /ocisg
```

b. Mount the drive:

```
sudo mount /dev/sdb /ocisg
```

3. Download the Storage Gateway 1.3 tar archive.
4. Use the SFTP tool of your choice to copy the tar archive into the `/tmp` folder of the host machine.
5. On the host machine, change directory to `/tmp` and extract the files from the tar archive:

```
cd /tmp
sudo tar xvzf ocisg-1.3.tar.gz
```

This command extracts the files from the tar archive into a subdirectory named `ocisg-1.3`.

6. Change directory to `ocisg-1.3` and run the installation script as `sudo` or `root` user:

```
cd ocisg-1.3
sudo ./ocisg-install.sh
```

List of installation script options

Optionally, you can specify the following `ocisg-install.sh` script flags:

- **-a** Runs the installation in advanced configuration mode, which lets you specify ports and the Docker network mode.
  In addition to prompting you for the paths to the metadata storage, cache storage, and log storage, advanced configuration mode also prompts you for:
  - The Docker network mode (`host` or `bridge`).
    Bridge mode is the default. It allows multiple instances of Storage Gateway to run on the same host.

Host mode improves network performance. If you plan to run only one instance of Storage Gateway on the host, Oracle recommends host mode. If you encounter issues with host mode, try bridge mode or contact My Oracle Support.

- The host port to use for the management console.
- The host port to use for NFS access.
- The host port to use for the HTTP REST service.

Tip

For each host port specification, you can designate a port or press **Enter** to let Storage Gateway dynamically allocate the port. You can use the `ocisg configure port` command to change the ports later. See Managing Storage Gateway Using the CLI for details.

- **-d** Installs Storage Gateway at the location you specify instead of the default location of `/opt/ocisg`. For example:

```
sudo ./ocisg-install.sh -d /opt/storagegateway
```

- **-h** Displays the installation script help information.
- **-p** Specifies that Storage Gateway is running behind a proxy server. You can specify multiple proxy arguments. For example:

```
./ocisg-install.sh -p http://myproxy.com:80 -p https://mysecureproxy.com:80
```

- **-q** Runs the installation in quiet mode.

If you supply the paths to the Storage Gateway cache, metadata, and log storage locations using **-m***<path_to_metadata_storage>*, **-c***<path_to_cache_storage>*, and **-l***<path_to_log_storage>*, you are not prompted for input . For example:

```
sudo ./ocisg-install.sh -q -m /ocisg/metadata -c /ocisg/cache -l /ocisg/log
```

Note

Ignore the `devicemapper` warning message if it appears during the installation.

The script guides you through the Storage Gateway installation. Depending on your host machine configuration, some steps can require your input:

a. `Docker does not appear to be installed. Do you want to install docker engine with yum? [y/N]`

Press **y**, and then press **Enter**.

The installation script automatically installs Docker and configures the storage driver for use with Storage Gateway.

Important

If Docker is already installed on your system, the installation script does not automatically configure the storage driver and returns a warning message:

```
Checking that docker is installed and using the
correct version
Found docker version Docker version 18.03.1-ol,
build 0d51d18
The storage appliance requires to set devicemapper
as the docker storage driver.
Please follow the setup link below to enable
devicemapper and rerun the install.
```

Manually verify and update the Docker storage driver to be `devicemapper` as required. See Verifying and Updating the Storage Driver in Docker.

b. `NFS server does not appear to be enabled. Do you want to enable NFS? [y/N]`

   Press **y**, and then press **Enter**.

c. When prompted, press **Enter** accept the default installation location.

d. When prompted, specify the paths to your Storage Gateway cache, metadata, and log storage locations.

   The following examples represent paths for a simple system. Your setup might include paths to separate devices and file systems for each location.

   i. Enter a path for the file system cache. For example:

   ```
   /ocisg/sg/cache
   ```

ii. Enter the path for metadata storage. For example:

```
/ocisg/sg/metadata
```

iii. Enter the path for log storage. For example:

```
/ocisg/sg/log
```

If you receive warnings about cache, metadata, and log storage existing on the same volume, enter **y** to proceed with the installation.

After a successful installation, the script provides the following information:

- The URL to log in to the Storage Gateway management console.
- The NFS port number.
- An example command for mounting your Storage Gateway file systems.

If you installed Storage Gateway on a Compute instance, see Security List Requirements for Compute Instance Installations.

Security List Requirements for Compute Instance Installations

If you installed Storage Gateway on an Oracle Cloud Infrastructure Compute instance, that instance must be able to receive HTTPS connections from other hosts and allow communication with the Storage Gateway management console. To open the necessary port, add an ingress rule to the security list governing the instance's host subnet. To learn about VCN security control, see Security Lists.

Important

This installation task assumes that your existing security list already allows traffic to port 443, as described in the Hosting Storage Gateway on an Oracle Cloud Infrastructure Compute Instance section of this page. If port 443 is not open, you must add a security list rule to open it.

To add a security list rule

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. Click the name of the cloud network (VCN) that hosts your Compute instance.
3. Click **Security Lists**.
4. Click the name of the security list that governs the subnet hosting your Compute instance.
5. Click **Edit All Rules**.
6. Add an ingress rule:
    a. Leave **Stateless** unmarked.
    b. Select **CIDR** for the **Source Type**.
    c. Enter **0.0.0.0/0** to indicate all IP addresses.
    d. Select **TCP** as the **IP Protocol**.
    e. Enter **All** in the **Source Port Range** field.
    f. Specify your Storage Gateway management console port in the **Destination Port Range** field. For example:

```
32769
```

If you do not know the management console port for your Storage Gateway installation, run the following command on the host machine:

```
sudo ocisg info
```

The management console port appears at the end of the management console URL:

```
Management Console: https://exampleCompute:32769
```

7. Click **Save Security List Rules**.
   You can now connect to the compute instance using the public IP address (https:*<public_IP_address>*). See Getting the Instance Public IP Address for details.

Verifying and Updating the Storage Driver in Docker

To verify the storage driver in Docker:

1. Start `docker`:

   ```
   sudo systemctl start docker
   ```

2. Verify the information in `docker`:

   ```
   sudo docker info
   ```

3. Look for `Storage Driver` in the output. For example:

   ```
   Containers: 0
    Running: 0
    Paused: 0
    Stopped: 0
   Images: 0
   Server Version: 18.03.1-ol
   Storage Driver: overlay2
    Backing Filesystem: xfs
    Supports d_type: true
    Native Overlay Diff: false
   Logging Driver: json-file
   Cgroup Driver: cgroupfs
   Plugins:
   ```

```
 Volume: local
 Network: bridge host macvlan null overlay
 Log: awslogs fluentd gcplogs gelf journald json-file logentries splunk syslog
Swarm: inactive
Runtimes: runc
Default Runtime: runc
Init Binary: docker-init
containerd version: 773c489c9c1b21a6d78b5c538cd395416ec50f88
runc version: 4fc53a81fb7c994640722ac585fa9ca548971871
init version: 949e6fa
Security Options:
 seccomp
  Profile: default
 selinux
Kernel Version: 4.1.12-124.15.4.el7uek.x86_64
Operating System: Oracle Linux Server 7.5
OSType: linux
Architecture: x86_64
CPUs: 4
Total Memory: 13.45GiB
Name: ocisg-mahesh
ID: OJ2H:QUSK:BWQZ:25L6:VI5V:CXGX:WFXT:NNNP:RK6O:OS4P:4ABE:JWMV
Docker Root Dir: /var/lib/docker
Debug Mode (client): false
Debug Mode (server): false
Registry: https://index.docker.io/v1/
Labels:
Experimental: false
Insecure Registries:
 127.0.0.0/8
Live Restore Enabled: false

Registries: docker.io (secure)
```

Note

You can ignore the `devicemapper` warning message, if it appears.

If `Storage Driver` is *not* `devicemapper`, do the following:

a. Stop `docker`:

```
sudo systemctl stop docker
```

b. Look for `/etc/docker/daemon.json` in the host.
If the file `daemon.json` does not exist, create it.

c. In the `daemon.json` file, set the `storage-driver` variable to `devicemapper`:

```
{
"storage-driver": "devicemapper"
}
```

d. Restart `docker`:

```
sudo systemctl start docker
```

e. Verify the information in `docker`:

```
sudo docker info
```

Look for `Storage Driver` in the output and verify that the storage driver is `devicemapper`.

Next Step

Logging In to the Storage Gateway Management Console

Logging In to the Storage Gateway Management Console

Use the Storage Gateway management console to create, manage, and monitor file systems.

Storage Gateway provides the URL to access the management console after a successful installation. When you access the management console for the first time, a wizard prompts you to create the administrator credentials and your first file system.

Note

Storage Gateway uses a self-signed certificate for the HTTPS connection. Your browser might warn that the SSL certificate couldn't be verified. If you entered the correct public IP address of the Storage Gateway instance, you can safely ignore this warning. The steps to ignore this warning and go to the management console vary depending on the browser you use.

To log in to the management console:

1. Enter one of the following URLs in a supported web browser:
   - If you installed the software on an on-premises host, enter the URL provided at the end of the Storage Gateway installation script:

     ```
     https://<storagegateway_hostname>:<port_number>
     ```

     For example:

     ```
     https://myStorageGatewayHost:3775
     ```

     Note

     If you cannot access Storage Gateway using the hostname, contact your network administrator. Depending on your network configuration, your Storage Gateway hostname might need to be added to DNS or you might need to use an IP address rather than the hostname.

   - If you installed the software in an Oracle Cloud Infrastructure compute instance, enter the URL as follows:

```
https://<instance_public_IP_address>:<port_number>
```

For example:

```
https://192.168.14.5:3775
```

Note

See Getting the Instance Public IP Address for details.

The console log-in page appears. The page prompts you to set and confirm a password for the Storage Gateway `admin` user.

2. Enter a password that meets the following requirements:
   - From 8 to 32 characters.
   - At least one special character, one numerical character, one uppercase character, and one lowercase character.

Next Step

Creating Your First File System

Creating Your First File System

This topic guides you through creating your first Storage Gateway file system.

Think of a file system as a namespace containing a dataset that's accessible through Storage Gateway. A Storage Gateway file system in this context represents a mapping between a directory on your on-premises host and a bucket in Oracle Cloud Infrastructure Object Storage. When you create a Storage Gateway file system, you define the connection credentials that Storage Gateway uses to connect to your Oracle Cloud Infrastructure tenancy.

When you log in to the management console for the first time, a wizard prompts you to create the administrator credentials and your first file system.

To create your first file system

1. Log in to the management console.
2. Click **File Systems** on the upper-right area of the management console.
3. Click **Create File System**.
4. Enter the required information in **Create a File System**:
   - **File System Name:** A unique, friendly name for the file system. Avoid entering confidential information. Use the following guidelines when naming a file system:
     - Use from 1 to 256 characters.
     - Valid characters are letters (upper or lower case), numbers, hyphens, underscores, and periods.

     > **Important**
     >
     > The name **cannot** contain the following:
     >
     > - A slash (/) character because this character delimits bucket and object names in Oracle Cloud Infrastructure Object Storage
     > - The strings "pub" or "priv"

     If an Object Storage bucket by this file system name doesn't exist in your tenancy, the bucket is created.

     If a corresponding Object Storage bucket by this file system name exists in your tenancy and there is data in the bucket, Storage Gateway works asynchronously to sync the bucket and file system contents.
   - **Select the Object Storage tier in which you want to store your data**

Important

Once set, you cannot change the storage tier in which a bucket resides.

You can use the Oracle Cloud Infrastructure Object Storage object lifecycle policies feature to manage the archiving and deletion of objects in a bucket according to a predefined schedule. See Using Object Lifecycle Management for details.

- **Standard:** The Standard tier is the primary default Object Storage tier for storing data that requires frequent and fast access. See Overview of Object Storage for more information.
- **Archive:** The Archive tier is a special tier for storing data that is accessed infrequently and requires long retention periods. See Overview of Archive Storage for more information. Access to data in the Archive tier is not immediate since you must restore archived data before it's accessible (see Restoring Files and Objects from Archive Storage).

- **Object Storage endpoint:** Required. The Object Storage API endpoint for your service instance. To find the object storage API endpoint for your Oracle Cloud Infrastructure Object Storage tenancy, see the API documentation for Oracle Cloud Infrastructure Object Storage.

Important

The following information is required to connect your Storage Gateway file systems to Oracle Cloud Infrastructure. See Required Keys and OCIDs for detailed information on how to generate the required keys and where to obtain these OCIDs.

- **Compartment OCID:** Required. Unique identifier of your Oracle Cloud Infrastructure Object Storage compartment.
- **Tenant OCID:** Required. Unique identifier of your Oracle Cloud Infrastructure Object Storage tenancy.
- **User OCID:** Required. Unique identifier of your Oracle Cloud Infrastructure Object Storage user.
- **Public Key's Finger Print:** Required. Your Oracle Cloud Infrastructure Object Storage public key fingerprint.
- **Private Key:** Required. Your Oracle Cloud Infrastructure Object Storage private key.

- **Private Key Passphrase:** Required if a passphrase was specified during key creation. Your Oracle Cloud Infrastructure Object Storage private key passphrase.

Note

Your private key and passphrase are securely stored in the Storage Gateway docker. The Storage Gateway installation generates a pair of public and private keys. The system uses the public key to encrypt sensitive data.

5. Click **Save**.
   The values you entered must match your Oracle Cloud Infrastructure credentials. If you get an error message, verify your entries, update any incorrect values, and click **Save** again.
6. Click **Show Advanced File System Configuration**.
   Enter the required configuration information or click **Use Default** to accept the default values:
   - **NFS Allowed Hosts:** A comma-separated list of hosts allowed to connect to the NFS export. You can also specify * to allow all hosts to connect.
     For example: `2001:db8:9:e54::/64`, `192.0.2.0/24`
   - **NFS Export Options:** The NFS export options.
     Example: `rw`, `sync`, `insecure`, `no_subtree_check`, `no_root_squash`

Important

Do not specify the `fsid` option.

   - **Concurrent Uploads:** The number of concurrent uploads to Oracle Cloud Infrastructure.

This field indicates the maximum number of files that can be concurrently uploaded in Storage Gateway. If the value is 15, the concurrent file uploads can be between 1-15.

The allowed range is from 1 to 30.

- **Sync Policy:** The metadata operations are flushed to the disk based on the sync policy, but do not affect on-disk consistency. Currently, only **Posix Standard** is supported. Only the synchronous transactions (like fsync, ODSYNC, and OSYNC) are committed to the disk. All other transactions are handled asynchronously.
- **Cloud Read-ahead**: The number of blocks to be downloaded and used to *read ahead* when reading files for improved performance.

  Default value: 50
- **Maximum Read Cache Size in GiB:** The maximum read cache.

  When the read cache is full or reaches the configured limit, Storage Gateway removes files from the cache based on a least recently used (LRU) algorithm. Files pending upload to your tenancy are not removed from cache. You can also preserve files that you do not want removed from cache.

  Note

  The number of files in cache is limited to 20,000, regardless of the specified cache size in bytes.

  See Configuring the Cache for File Systems for details.

  The default value depends on how you provisioned local storage before installing Storage Gateway. The recommended local storage disk size is 600 GB (500 GB for file system cache, 80 GB for metadata, 20 GB for log). If you followed the documented recommendations, the default value for the read cache is approximately 300 GB.

7. Click **Save**.

The file system is created and appears in the **File Systems** listing.

Next Steps

Connect the file system to a directory on the Storage Gateway host. For more information, see Connecting a File System.

You can also do the following in the management console:

- Set up the NFS export. This directory acts as a mount point. For more information, see Mounting File Systems on Clients.
- Add more file systems. For more information, see Adding a File System.
- View the details of a file system. For more information, see Viewing the Details of a File System.

Managing File Systems

A Storage Gateway file system connects a directory on a local host to an Object Storage bucket in Oracle Cloud Infrastructure. This topic describes how to manage Storage Gateway file systems.

Adding a File System

You can add file systems in Storage Gateway and connect each file system to an Object Storage bucket in your tenancy.

To add a file system

1. Log in to the management console.
2. Click **File Systems** on the upper-right area of the management console.
3. Click **Create File System**.
4. Enter the required information in **Create a File System**:

- **File System Name:** A unique, friendly name for the file system. Avoid entering confidential information. Use the following guidelines when naming a file system:
  - Use from 1 to 256 characters.
  - Valid characters are letters (upper or lower case), numbers, hyphens, underscores, and periods.

  Important

  The name **cannot** contain the following:
  - A slash (/) character because this character delimits bucket and object names in Oracle Cloud Infrastructure Object Storage
  - The strings "pub" or "priv"

  If an Object Storage bucket by this file system name doesn't exist in your tenancy, the bucket is created.

  If a corresponding Object Storage bucket by this file system name exists in your tenancy and there is data in the bucket, Storage Gateway works asynchronously to sync the bucket and file system contents.
- **Select the Object Storage tier in which you want to store your data**

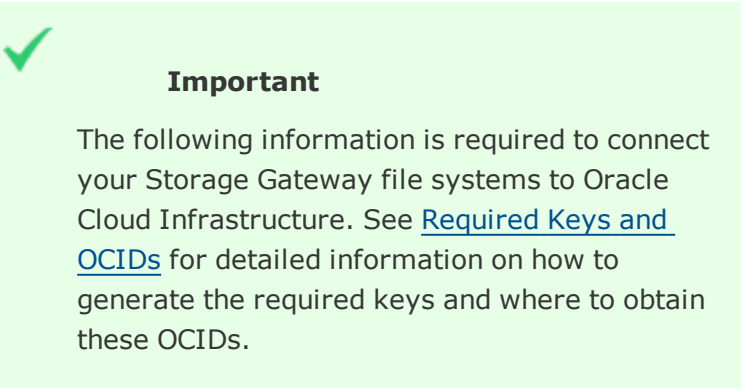
Important

Once set, you cannot change the storage tier in which a bucket resides.

You can use the Oracle Cloud Infrastructure Object Storage object lifecycle policies feature to manage the archiving and deletion of objects in a bucket according to a predefined schedule. See Using Object Lifecycle Management for details.

- **Standard:** The Standard tier is the primary default Object Storage tier for storing data that requires frequent and fast access. See Overview of Object Storage for more information.
- **Archive:** The Archive tier is a special tier for storing data that is accessed infrequently and requires long retention periods. See Overview of Archive Storage for more information. Access to data in the Archive tier is not immediate since you must restore archived data before it's accessible (see Restoring Files and Objects from Archive Storage).

- **Object Storage endpoint:** Required. The Object Storage API endpoint for your service instance. To find the object storage API endpoint for your Oracle Cloud Infrastructure Object Storage tenancy, see the API documentation for Oracle Cloud Infrastructure Object Storage.



- **Compartment OCID:** Required. Unique identifier of your Oracle Cloud Infrastructure Object Storage compartment.
- **Tenant OCID:** Required. Unique identifier of your Oracle Cloud Infrastructure Object Storage tenancy.
- **User OCID:** Required. Unique identifier of your Oracle Cloud Infrastructure Object Storage user.
- **Public Key's Finger Print:** Required. Your Oracle Cloud Infrastructure Object Storage public key fingerprint.
- **Private Key:** Required. Your Oracle Cloud Infrastructure Object Storage private key.

- **Private Key Passphrase:** Required if a passphrase was specified during key creation. Your Oracle Cloud Infrastructure Object Storage private key passphrase.

Note

Your private key and passphrase are securely stored in the Storage Gateway docker. The Storage Gateway installation generates a pair of public and private keys. The system uses the public key to encrypt sensitive data.

5. Click **Save**.
   The values you entered must match your Oracle Cloud Infrastructure credentials. If you get an error message, verify your entries, update any incorrect values, and click **Save** again.
6. Click **Show Advanced File System Configuration**.
   Enter the required configuration information or click **Use Default** to accept the default values:
   - **NFS Allowed Hosts:** A comma-separated list of hosts allowed to connect to the NFS export. You can also specify * to allow all hosts to connect.
     For example: `2001:db8:9:e54::/64`, `192.0.2.0/24`
   - **NFS Export Options:** The NFS export options.
     Example: `rw`, `sync`, `insecure`, `no_subtree_check`, `no_root_squash`

Important

Do not specify the `fsid` option.

   - **Concurrent Uploads:** The number of concurrent uploads to Oracle Cloud Infrastructure.

This field indicates the maximum number of files that can be concurrently uploaded in Storage Gateway. If the value is 15, the concurrent file uploads can be between 1-15.

The allowed range is from 1 to 30.

- **Sync Policy:** The metadata operations are flushed to the disk based on the sync policy, but do not affect on-disk consistency. Currently, only **Posix Standard** is supported. Only the synchronous transactions (like fsync, ODSYNC, and OSYNC) are committed to the disk. All other transactions are handled asynchronously.
- **Cloud Read-ahead**: The number of blocks to be downloaded and used to *read ahead* when reading files for improved performance.

  Default value: 50
- **Maximum Read Cache Size in GiB:** The maximum read cache.

  When the read cache is full or reaches the configured limit, Storage Gateway removes files from the cache based on a least recently used (LRU) algorithm. Files pending upload to your tenancy are not removed from cache. You can also preserve files that you do not want removed from cache.

  Note

  The number of files in cache is limited to 20,000, regardless of the specified cache size in bytes.

  See Configuring the Cache for File Systems for details.

  The default value depends on how you provisioned local storage before installing Storage Gateway. The recommended local storage disk size is 600 GB (500 GB for file system cache, 80 GB for metadata, 20 GB for log). If you followed the documented recommendations, the default value for the read cache is approximately 300 GB.

7. Click **Save**.

The file system is created and appears in the **File Systems** listing.

Connecting a File System

After you create a file system, you must connect the file system to an Oracle Cloud Infrastructure Object Storage bucket before you can store and retrieve data through the file system.

Warning

If network connectivity with Oracle Cloud Infrastructure is lost, your file system is disconnected.

To connect a file system

1. Log in to the Storage Gateway management console.
2. On the **Dashboard** tab, identify the file system that you want to connect to your Object Storage bucket.

   Click **Connect**.
3. If a bucket with the same name as the file system exists in Object Storage, the file system is connected to that bucket. Any existing data cached in the Storage Gateway file system is deleted to ensure consistency with the data stored in the bucket. If a bucket by that name doesn't exist, the bucket is created and the file system is connected to the bucket. If the compartment OCID was specified during file system creation, then the bucket is created in that compartment. Otherwise, the bucket is created in the `root` compartment by default.

Important

You can mount a read/write file system on only one Storage Gateway at a time.

If the file system that you're importing is connected to another Storage Gateway, the **File System: Claim Ownership** window appears. You can claim ownership and confirm that the other Storage Gateway can be disconnected. Enter the following information, and then click **Claim Ownership**:

- Public key finger print
- Private key
- Private key passphrase

Claiming ownership ensures that you don't inadvertently connect a new file system to a bucket that's already connected to another Storage Gateway file system.

Mounting File Systems on Clients

Each Storage Gateway file system maps a directory to an Oracle Cloud Infrastructure Object Storage bucket. To establish the connection between Storage Gateway and an NFS client, you must mount the Storage Gateway file system on the NFS client.

Any Linux/UNIX NFS client certified to work with NFSv4 server running on Oracle Linux 7.x is compatible with Storage Gateway.

Note

Storage Gateway does not currently support NFS clients running on Windows or Mac OS.

To mount a Storage Gateway file system

1. Log in to the Storage Gateway host.
2. Start Storage Gateway:

   ```
   sudo ocisg up
   ```

3. Find the NFS port number:

   ```
   sudo ocisg info
   ```

   Note the NFS port number from the output. For example:

   ```
   Management Console: https://myStorageGatewayHost.example.com:32775

   If you have already configured a OCISG File System via the Management Console, you can access the
   NFS share using the following port.

   NFS Port: 32774

   Example: mount -t nfs -o vers=4,port=32774 myStorageGatewayHost.example.com:/<OCISG File System
   name> /local_mount_point
   ```

   In the sample output:

   - myStorageGatewayHost.example.com is the Storage Gateway host name.
   - 32775 is the management console port number.
   - 32774 is the NFS port number.
4. Log in to the NFS client from which you want to access your service instance through Storage Gateway.
5. Create a directory on the NFS client.

6. Mount the file system on the directory that you created on the NFS client:

   ```
   sudo mount -t nfs -o vers=4,port=<NFS_port_number> <storage_gateway_host_name>:/<ocisg_file system_name> /<local_mount_point>
   ```

   In this command:

   - Replace *<NFS_port_number>* with the NFS port number you noted earlier.
   - Replace *<storage_gateway_host_name>* with the server name or IP address of the server on which Storage Gateway is installed.
   - Replace *<ocisg_file system_name>* with the file system name that you want to mount.
   - Replace *<local_mount_point>* with the path to the directory you created on the NFS client.

   For example:

   ```
   sudo mount -t nfs -o vers=4,port=32774 myStorageGatewayHost.example.com:/myFirstFS /home/xyz/abc
   ```

   In this example,

   - `32774` is the NFS port.
   - `myStorageGatewayHost.example.com` is the Storage Gateway host name.
   - `myFirstFS` is the file system name.
   - /home/xyz/abc is the path to the directory `abc` on the NFS client.

The Storage Gateway file system is now mounted on the NFS client directory. You can now access the Storage Gateway file system from the NFS client.

For more information, see Using Storage Gateway File Management Operations .

Viewing the Details of a File System

You can view the configuration details of a file system and monitor the upload activity through the management console of Storage Gateway.

To view the details of a file system

1. Log in to the management console.
2. Click the name of the file system.
    - The **Details** tab displays the Oracle Cloud Infrastructure service type, storage tier, and the identity domain associated with your tenancy. If the file system is connected, you can see mount point connection information to help you with mounting that file system. For example:
      NFS Client Mount Command: mount -t nfs -o vers=4,port=*<nfs_mount_port>* 129.213.122.84:/perftest01 /*<local_mount_point>*
    - The **Settings** tab displays the following details:
        - Details of the tenancy and scope specified for the file system.
        - File system properties.
        - NFS and cache settings for the file system.

      You can edit these settings. If you make changes, remember to click **Save**.

      If your file system is connected, you can also see:

    - The **Activity** tab, which shows ongoing and pending file upload activity.
      If you contact Oracle Support Services about any issue with the file system, you might need to provide the file system log to help diagnose the issue. To view or download the file system log, click **View Streaming Logs** near the lower-right corner of the **Details** tab.
    - The **Completed Uploads** tab, which shows the last 100 files that were uploaded to Oracle Cloud Infrastructure Object Storage during the current browser session.

Note

The file list doesn't persist across browser sessions. If you refresh the page or open the **Completed Uploads** tab in another browser after the files are uploaded, the list will be empty.

- You can also disconnect the file system. See Disconnecting a File System.

Changing the Properties of a File System

You can change the properties of a file system using the Storage Gateway management console.

To change the properties of a file system

1. Log in to the management console.
2. In the **Dashboard**, click the name of the file system that you want to edit.
3. In the **Settings** tab, edit the file system properties and advanced settings, such as the cache limits.
4. Click **Save**.
5. For the changes to take effect, disconnect and reconnect the file system.

Refreshing a File System

The auto-refresh feature triggers file system refreshes based on a time interval you specify. The system schedules the next refresh after any in-progress refresh completes. That means the elapsed time between the beginning of any two successive refreshes is equal to the specified auto-refresh interval plus the time required to run a file system refresh.

Use the following command to configure the auto-refresh feature:

```
ocisg set <file_system_name> dataset.refreshInterval=<interval_in_minutes>
```

The configuration command works on created and connected file systems. The configuration does not take effect until the file system is disconnected and reconnected or the Storage Gateway application restarts. To apply the changes, run:

```
ocisg down
ocisg up
```

Attribute caching can cause NFS clients to be unaware of files, corresponding to new objects in the bucket, that are created in a Storage Gateway file system during a refresh. You can use the `noac` mount option to turn off attribute caching. Turning off attribute caching can affect system performance.

When you run a refresh, the system reads attributes and fetches information about all objects in the corresponding bucket. Use a larger refresh interval for buckets with many objects.

Note

After you refresh a file system, or create one for a bucket that already contains objects, Oracle recommends that you check for any files that might have been missed due to network connectivity issues.

To check for missing files, run the following command:

```
zgrep -ni "failed to get the object for" <path_to_gateway_logs>/<file_system_name>.*
```

For example, if the path to the gateway logging directory is `/ocisg/log` and the file system name is `my-fs-1`, the command is:

```
zgrep -ni "failed to get the object for" /ocisg/log/my-fs-1.*
```

Files listed in the output of this command were not successfully registered with the gateway. If any file names appear in the list, refresh the file system again.

Disconnecting a File System

When a file system is disconnected, no one can access or modify that file system.

We recommend disconnecting file systems that are not in use. Disconnecting a file system frees up the resources associated with that file system, making those resources available to file systems that are active (connected).

To disconnect a file system

1. Log in to the management console.
2. In the **Dashboard**, click the name of the file system that you want to disconnect.
3. Click **Disconnect**.

When you disconnect a file system, the bucket to which the file system was previously connected and the contents of that bucket remain intact.

4. For the changes to take effect, disconnect and reconnect the file system.

You can resume storing and retrieving data by connecting the file system again. You can delete the disconnected file system when you no longer need it. For more information, see Deleting a File System.

Importing an Existing File System

Before you import an existing file system from another Storage Gateway, ensure that any pending file uploads to Oracle Cloud Infrastructure Object Storage are complete.

To import an existing file system

1. Log in to the management console.
2. Click the **Create File System** navigation link.
3. Click **Create File System** in the navigation pane on the left.
   The **Create a File System** page appears.
4. Enter the required information in **Create a File System**.
   For the file system name, enter the name of the existing file system that you want to import to this Storage Gateway.
5. Click **Save**.
6. Select the options that you'd like to enable in the file system.
7. Click **Show Advanced** and enter the required information.
8. Click **Save**.
   The file system is created and appears on the **Dashboard** tab.
9. Click **Connect** for the file system that you want to import.

a. If the file system that you're importing is connected to another Storage Gateway, the **File System: Claim Ownership** window appears so you can claim ownership and confirm that the other Storage Gateway can be disconnected. Enter the following information and click **Claim Ownership**:
   - Public key finger print
   - Private key
   - Private key passphrase

b. If you connect to a file system that previously belonged to a different gateway, you must restart the new owning gateway:

```
ocisg down
ocisg up
```

10. Mount the file system to a directory on the Storage Gateway host and set up the NFS export. For example:

```
sudo mount -t nfs -o vers=4,port=<NFS_port_number> <storage_gateway_host_name>:/<ocisg_file system_name> /<local_mount_point>
```

In this command:

- Replace *<NFS_port_number>* with the NFS port number you noted earlier.
- Replace *<storage_gateway_host_name>* with the server name or IP address of the server on which Storage Gateway is installed.
- Replace *<ocisg_file system_name>* with the file system name that you want to mount.
- Replace *<local_mount_point>* with the path to the directory you created on the NFS client.

Deleting a File System

You can delete a file system from Storage Gateway when you no longer need it.

To delete a file system:

1. Log in to the management console.
2. On the **Dashboard**, identify the file system that you want to delete.

Important

When you disconnect a file system, the bucket to which the file system was previously connected and the contents of that bucket remain intact.

Deleting a file system does not automatically delete the objects in the bucket. If you want to remove objects from the Object Storage bucket, set the **Delete Old File Versions** property for the file system and delete all the files before disconnecting the file system.

3. Ensure that the file system is disconnected. If it's still connected, click **Disconnect**.
4. After the file system is disconnected, click its name.
   The details of the file system appear.
5. Click **Delete**.
   The file system is deleted from Storage Gateway.

Managing Storage Gateway

This topic describes some basic Storage Gateway management tasks.

Managing Storage Gateway Using the CLI

You can use the `ocisg` command line interface (CLI) to manage Storage Gateway. To use the CLI, open an `ssh` connection and log in to the host on which you installed Storage Gateway.

Note

You can use the `ocisg` command line interface (CLI) to create, manage, and monitor Storage Gateway Cloud Sync jobs. See Using Storage Gateway Cloud Sync for details.

The CLI supports the following Storage Gateway management tasks:

- To start Storage Gateway:

```
sudo ocisg up
```

- To stop Storage Gateway:

```
sudo ocisg down
```

Note

If the server with a Storage Gateway system fails, you can reinstall and start a new one. All the configuration and system data is automatically downloaded and applied. The pending upload and download activities resume when the new Storage Gateway system runs.

If a disk cache is unrecoverable on the Storage Gateway server, data might be lost since the file might not have been transferred to the bucket in your tenancy. To ensure efficient data protection, see Best Practices for Using Storage Gateway.

- To view details about Storage Gateway and how to access the management console:

```
sudo ocisg info
```

- To find the version of Storage Gateway:

```
sudo ocisg version
```

- To configure Storage Gateway to use a proxy server for connections to Oracle Cloud Infrastructure Object Storage:

```
sudo ocisg configure proxy <proxy_server_URL>
```

> **Note**
>
> After configuring the proxy server, you must stop and restart Storage Gateway.

  By default, no proxy server is specified.

- To remove previously configured proxy server details in Storage Gateway:

```
sudo ocisg configure proxy [remove]
```

- To configure Storage Gateway to use SSL when communicating with the management console and REST APIs:

```
sudo ocisg configure ssl true
```

  SSL is enabled by default.

> **Note**
>
> After configuring Storage Gateway to use SSL, you must stop and restart Storage Gateway.

  To disable SSL:

```
sudo ocisg configure ssl false
```

- To specify ports for the Storage Gateway services:

```
sudo ocisg configure port <service> <port_number>
```

- *<service>*: Specify `admin`, `nfs`, or `rest`.
- *<port_number>*: Ensure that the port number you specify is not already in use on the Storage Gateway host.

By default, the port number is assigned dynamically for the Storage Gateway services when you start Storage Gateway.

Note

For the port assignment to take effect, you must stop and start Storage Gateway.

- To remove the static port assignment for a service:

```
sudo ocisg configure port <service> remove
```

- To allocate memory for the Storage Gateway host:

```
sudo ocisg configure memory <memory_in_GB>
```

- To remove the memory allocation:

```
sudo ocisg configure memory remove
```

By default, Storage Gateway uses 4 GB of the available memory on the host server. You can delete the memory information by using the `remove` parameter.

Note

After configuring memory for Storage Gateway, you must stop and restart Storage Gateway.

- To specify the docker network mode:

```
sudo ocisg configure network mode
```

The mode can be either *host* or *bridge*.

The default mode is `bridge`. In this mode, you can run multiple instances of Storage Gateway on your host.

In the `host` mode, you can run only a single instance of Storage Gateway. Network performance is better in `host` mode.

Note

After specifying the docker network mode, you must stop and restart Storage Gateway.

- To change the Storage Gateway `admin` password:

```
sudo ocisg do password:reset
```

Set a new password:

```
sudo ocisg password:set <new_password>
```

Enter a password that meets the following requirements:

  - Uses from 8 to 32 characters.
  - Includes at least one special character, one numerical character, one uppercase character, and one lowercase character.

- To view help for the available commands:

```
sudo ocisg help
```

Using Storage Gateway File Management Operations

This topic describes how to use the Storage Gateway file management operations.

Exercise caution when using the REST API, Java library, or any other client to retrieve, create, update, or delete objects directly in a bucket that's mapped to a file system in Storage Gateway. Until you **Refresh** the Storage Gateway file system, Storage Gateway is not aware of the changes and data is inconsistent between Storage Gateway and Object Storage.

Uploading Files to Buckets

Before you connect the file system to the Oracle Cloud Infrastructure Object Storage bucket, make a note of the Oracle Cloud Infrastructure Object Storage tenancy details such as namespace, tenant OCID, and compartment OCID.

Copy the files to the mounted directory on the Storage Gateway or the NFS client host. Storage Gateway writes the files to the disk cache. The system queues and asynchronously uploads the files to an Object Storage bucket. Corresponding objects are created in the storage tier you specified during file system creation, either **Standard** or **Archive**. See Creating Your First File System or Managing File Systems for details.

Note

Storage Gateway automatically performs multipart upload for files larger than 128 MB. See Using Multipart Uploads for details.

You can view files uploaded to your tenancy during the current browser session. See the **Completed Uploads** tab in Viewing the Details of a File System.

Reading Files

When you write a file to a Storage Gateway file system, the system stores the file in the local disk cache. You can read the file directly from the mounted directory. Storage Gateway asynchronously copies the file to the corresponding Object Storage bucket in your tenancy. To retrieve the data from the bucket using Storage Gateway, read the files from the mounted directory.

If space is available, Storage Gateway automatically places the files in the read cache. If the file is in the read cache, you can retrieve the file immediately. If the file is not available in the read cache and it is stored in the `Archive` tier, you must restore the object. For more information, see Restoring Files and Objects from Archive Storage.

Note

You cannot read or write to a file that is stored in the **Archive** tier and does not exist in the read cache. This action returns an `Input/Ouput error`.

Storage Gateway checks data integrity using checksum verification on uploads. The system might not be able to perform data integrity validation on a partial read, since checksum verification works only on a whole file or object.

To read the upload checksum for a file in a file system, run the following command from the NFS client on which the file system is mounted:

```
sudo docker exec ocisg bash -c "cd /mnt/gateway/${filesystem} && cat ${filepath}:::meta:csm"
```

Restoring Files and Objects from Archive Storage

You can initiate a file restore from the Storage Gateway command line. You can also initiate an object restore from Archive Storage in Oracle Cloud Infrastructure. You can read the corresponding file using Storage Gateway after the object has been restored to Object Storage.

Note

Storage Gateway supports Oracle Cloud Infrastructure Object Storage object lifecycle policies to manage the archiving and deletion of objects in a bucket according to a pre-defined schedule. Using object lifecycle policies, you can specify bucket creation in the Standard Object Storage tier, and then create a policy to schedule the subsequent movement of data to the Archive Storage tier. This lifecycle policy archival method is useful if you have on-premises applications that generate intermediary or temporary files and directories that are inappropriate for immediate archival. See Using Object Lifecycle Management for details.

Restoring Archived Files Using the Storage Gateway Command Line

To restore one or more archived files

Open a command prompt on the Storage Gateway host and run the `ocisg archive restore` command. Specify the full path to a directory or to a file.

```
ocisg archive restore <file_system_name> <full/path/to/directory/or/file> [<#_of_hours>]
```

By default, the file remains restored for 24 hours after restoration. However, you can optionally specify [*<#_of_hours>*] with an integer value of from 1 to 240 hours.

For example, to restore all the files in a directory:

```
ocisg archive restore myFS myDir/mySubDir 240
```

For example, to restore a single file:

```
ocisg archive restore myFS myDir/mySubDir/file2 240
```

To check the archive status of one or more files

You can get the archive status for all files in a file system, for all files in a directory, or for an individual file.

Open a command prompt on the Storage Gateway host and run the `ocisg archive restore-status` command.

```
ocisg archive restore-status <file_system_name> [<full/path/to/directory/or/file]
```

The status can be one of the following:

- Archived
- In progress
- Restored

For example, to check the archive status for all files in a file system:

```
ocisg archive restore-status myFS
```

To check the archive status for all files in directory:

```
ocisg archive restore-status myFS myDir/mySubDir
```

To check the archive status for an individual file:

```
ocisg archive restore-status myFS myDir/mySubDir/file2
```

To check the restoration job status for a file system

You can get the status for all restoration jobs that have been initiated for a file system.

Open a command prompt on the Storage Gateway host and run the `ocisg archive restore-jobs` command.

```
ocisg archive restore-jobs <file_system_name>
```

For example:

```
ocisg archive restore-jobs myFS
```

Restoring Archived Files Using Oracle Cloud Infrastructure

Important

If you use Oracle Cloud Infrastructure to restore archived objects, use the **Refresh** operation in Storage Gateway to display the data that was added or modified directly in Object Storage.

To restore an archived object using the Oracle Cloud Infrastructure Console

Tip

You need OBJECT_RESTORE permissions to restore Archive Storage objects.

1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.
2. Choose the compartment your bucket is in.
   A list of buckets is displayed.
3. Click the bucket name that contains your object.
4. Click **Objects** under **Resources**.
   A list of objects in the bucket is displayed.
5. To restore a single object, click the Actions icon (three dots) to the right of the object you want to restore, and then click **Restore**. To restore multiple objects, select the check boxes to the left of each object you want to restore, then click **Restore**.
6. Optionally, specify the **Time Available for Download in Hours**.
   By default, you have 24 hours to download an object after restoration. However you can alternatively specify a download time of from 1 to 240 hours. You can find out how much download time is remaining by looking at **Available for Download** in object **Details**

or by looking at the Actions icon (three dots) menu to the right of **Download**. Refresh the browser to obtain up-to-date remaining download time information.

After the allotted download time expires, the object returns to Archive Storage.

7. Click **Restore Objects**.
   Error messages are generated if there is a problem with restoring the selected objects. You can optionally click **Retry failed restore option.**

To check the status of an object restoration using the Oracle Cloud Infrastructure Console

1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.
2. Choose the compartment your bucket is in.
   A list of buckets is displayed.
3. Click the bucket name that contains your object.
4. Click **Objects** under **Resources**.
   A list of objects in the bucket is displayed.
5. Click the Actions icon (three dots) to the right of the object you want to check the restoration or download status of, then click **Details**.
6. Check the **Status**.
   Status displays one of the following:
   - Archived
   - Restoring
   - Restored

To restore an archived object using the Oracle Cloud Infrastructure CLI

Tip

You need OBJECT_RESTORE permissions to restore Archive Storage objects.

Open a command prompt and run `oci os object restore` to restore an object from Archive Storage:

```
oci os object restore -ns <object_storage_namespace> -bn <archive_bucket_name> --name <archived_object_name> [--hours <#_of_hours>]
```

By default, you have 24 hours to download an object after restoration. However, you can optionally specify `--hours` with an integer value of download time of from 1 to 240 hours.

To check the status of an object restoration using the Oracle Cloud Infrastructure CLI

Open a command prompt and run `oci os object restore-status` to check the status of restoring an object from Archive Storage:

```
oci os object restore-status -ns <object_storage_namespace> -bn <archive_bucket_name> --name <archived_object_name>
```

Deleting Files

Remove the files that you no longer need from the NFS client by deleting them from the directory on which the file system is mounted.

Monitoring Storage Gateway

This topic describes how to monitor Storage Gateway file system upload activity, system health, and storage usage. The topic also describes how to view system notifications and how to receive notifications in email.

Important

Monitoring file system activity in the Storage Gateway management console consumes system resources. Monitoring file system activity is not recommended when Storage Gateway is under high load.

Monitoring Upload Activity

When you upload a file to a file system, you can view the status of the upload activity. The **Activity** tab shows the ongoing and pending upload activity in a file system.

To monitor upload activity

1. Log in to the management console.
2. Click **File Systems** in the upper-right corner of the management console.
3. On the **File Systems** page, select a file system.
4. Click **Activity**.
   You can see the upload progress of the file in the **Uploading** pane.

Monitoring System Health Status

You can monitor the overall system health status using **System Status** on the right side of the management console.

Storage Gateway performs an automated "health check" on the system to monitor the status of:

- Storage Gateway resources and services.
- Local storage, file system cache, metadata storage, and log storage.

System Status shows the result of Storage Gateway health analysis, either **Healthy** or **Unhealthy**.

System Status also provides information on:

- Any system warnings or errors.
- **Local I/O Mode**, which depends on local disk usage:
    - **Normal**
      The available disk space is greater than 10 GB in Storage Gateway. You can upload files in Storage Gateway and upload them to your Oracle Cloud Infrastructure tenancy.
    - **Rejecting I/O**
      The available disk space is less than 10 GB in Storage Gateway. Storage Gateway runs in protection mode and does not allow any writes to its local disk. All read operations work normally. All Storage Gateway metadata operations fail except for deletions and truncation.
      To return to **Normal** mode, you must wait until all ongoing upload activities complete and the files are removed from the read cache.
- **Throughput**
  The approximate upload throughput to Object Storage. If there is no recent activity, **Throughput** shows **Idle**.
- **Available Read Cache**
  The amount of read cache available. For optimal performance, reliability, and fault tolerance, follow the guidelines for configuring cache storage . See Configuring Local Storage for File Systems and Cache for details.
- **Pending Uploads**
  The number of files or directories, for all file systems, awaiting upload to Object Storage. If **Pending Uploads** is 0 (zero), all files and directories have been uploaded.

Monitoring Storage Usage

You can track the storage usage and availability.

To monitor storage usage

1. Log in to the management console.
2. Click **System** in the upper-right corner of the management console.
3. Click **System Stats**.
   The system data appears in three panes:
   - **Local Storage**
   - **Local I/O**
   - **Local Resources**

Local Storage

This pane provides a graphical representation of the amount of storage being used and the available free storage on the Storage Gateway host. You can see:

- Available local storage.
- Storage used for pending uploads and preserved cache files.
- Storage used for metadata.
- Storage used for logging.
- Storage used for other applications.

Local I/O

This pane displays the local I/O mode of Storage Gateway based on the local disk space usage on the Storage Gateway host.

Local Resources

This pane shows the overall memory usage and availability for Storage Gateway from the following fields:

- **Available Cores:** The number of CPUs being used by Storage Gateway.
- **Maximum Memory Available to Storage Gateway:** The total RAM available for Storage Gateway.
- **Memory Used by Storage Gateway:** The amount of memory being used by the file systems in Storage Gateway.
- **Free Memory:** The amount of free RAM available in Storage Gateway host.

Viewing System Notifications

The **System Notifications** tab shows system notifications and helps you track overall system performance.

To view system notifications

1. Log in to the management console.
2. Click **System** in the upper-right corner of the management console.
3. Click **System Notifications**.
   You can view a list of warnings or critical system notifications.

Configuring Email Notification

You can configure Storage Gateway to notify you by email about system health and Cloud Sync job completion.

To configure email notification

1. Log in to the management console.
2. Click **System** in the upper-right corner of the management console.
3. Click **System Notifications**.

4. If email notifications are not yet configured, click **Click here to configure**.
5. Enter the required information for the following fields:
    - SMTP server.
    - Email addresses to receive notifications.
6. Click **Show Advanced Options** and enter the required information in the advanced configuration fields:
    - SMTP port.
    - SMTP User name.
    - SMTP Password.
    - Sender's Email Address.
      The default value is: `noreply@oracle.com`
7. Click **Save**.
8. Click **Test Email Notification** to verify that the specified email address receives a system notification email.

Using Storage Gateway Cloud Sync

Use Cloud Sync to move on-premises datasets from a local file system to Storage Gateway, where the data is then moved asynchronously to Oracle Cloud Infrastructure Object Storage. You can also use Cloud Sync to synchronize Storage Gateway file system changes back to the local file system.

Cloud Sync generates the following for each sync job:

- Sync status (Created, Running, Completed, Failed, or Canceled).
- Number of files and directories to be copied from the source to the target.
- File and directory upload progress .
- Number of files and directories uploaded to the target.
- Time the job started, the time the job ended, and the run duration.

- The number of files skipped. (Cloud Sync skips non-regular files, such as symlinks, in the source directory.)
- A list of skipped files.

You can use the Storage Gateway management console or the command line interface (CLI) to create, manage, and monitor Cloud Sync jobs.

About Cloud Sync

Cloud Sync is an enhanced wrapper around the Linux `rsync` command and relies on `rsync` to detect new and changed files using size and modification time. Cloud Sync also relies on `rsync` to verify the files once the data transfer is complete using checksums of the files. Cloud Sync calls the Storage Gateway diagnostic commands to provide detailed data movement progress and status between your local server, Storage Gateway, and Oracle Cloud Infrastructure.

Understanding Failure Behavior

Because the file system is mounted locally, the NFS client running on the host handles any issues resulting from file system availability or connectivity.

Cloud Sync does the following:

- Reports and logs any failures to list or copy specific files (for example, resulting from permission issues).
- Monitors and reports on the pending and completed uploads to Object Storage.

Storage Gateway handles any connectivity and access issues to Object Storage and performs retry operations as needed.

Prerequisites for Cloud Sync

- Create the Storage Gateway file system that serves as either the source or target destination for the sync operation. A file system on the Storage Gateway host maps to a bucket with an identical name in Oracle Cloud Infrastructure Object Storage. See Creating Your First File System or Adding a File System for details.
- Obtain the proper credentials to mount the file system share from the local server.
- The local server source must:
    - Have names services set up correctly so that UIDs and GIDs are preserved and are not remapped to `nobody`.
    - Be exported with root permissions to read and traverse the entire source tree.

Using the Management Console

You can use the Storage Gateway management console to create, manage, and monitor Cloud Sync jobs.

To create a Cloud Sync job that syncs all files and directories at the specified source location

1. Log in to the management console.
2. Click **Cloud Sync** in the upper-right corner of the management console.
   By default, a list of all the Cloud Sync jobs that have already been created is displayed.
3. Click **Create Cloud Sync Job**.
4. In **Create Cloud Sync Job** page, specify the attributes of the job:
    - **Job Name**: Required. A unique, user-friendly name for the job. Avoid entering confidential information.
    - **Source Path**: Path to the Cloud Sync source directory containing the files to sync.

- If your are syncing a local file system to Oracle Cloud Infrastructure, specify the source path as:

  ```
  /cloudsync/mounts/<user_mount>[/<path_to_directory>]
  ```

- If your are syncing Oracle Cloud Infrastructure to a local file system, specify the source path as:

  ```
  <storage_gateway_file_system>/<path_to_directory>]
  ```

- **Target Path**: Path to the Cloud Sync target directory for the synced files.
  - If your are syncing a local file system to Oracle Cloud Infrastructure, specify the target path as:

    ```
    <storage_gateway_file_system>/<path_to_directory>]
    ```

  - If your are syncing Oracle Cloud Infrastructure to a local file system, specify the target path as:

    ```
    /cloudsync/mounts/<user_mount>[/<path_to_directory>]
    ```

- **Enable Auto-Deletion:** Enable this option if you want Cloud Sync to automatically delete files from the target when:
  - Files are deleted from the source.
  - Source files have been renamed.

  By default, when a file is deleted on the source, Cloud Sync does not automatically delete the file on the target unless you enable **Enable Auto-Deletion**. Also, when a source file is renamed, the file with the old name is deleted and a file with the new name is created. By default, Cloud Sync does not delete the file with the old name on the target (retaining both a file with the old name and a file with the new name) unless you choose **Enable Auto-Deletion**. The names of all deleted files are stored in a job-specific log directory.

5. Click **Create Cloud Sync Job**.

A Cloud Sync job is created and displayed in the list of jobs.

To list Cloud Sync jobs

1. Log in to the management console.
2. Click **Cloud Sync** in the upper-right corner of the management console.
   By default, a list of all the Cloud Sync jobs is displayed.
3. Optionally, you can filter the job listing by status (Created, Running, Completed, Failed, or Canceled) and type of Cloud Sync job (upload or download) by clicking one of the **Quick Filters**.

To run a Cloud Sync job

1. Log in to the management console.
2. Click **Cloud Sync** in the upper-right corner of the management console.
3. In the list of jobs, find the Cloud Sync job that you want to run.
4. Click **Run** to the right of the job name.
   Cloud Sync runs the job. The management console displays the status of the job just below the job name.

To get the status of a Cloud Sync job

1. Log in to the management console.
2. Click **Cloud Sync** in the upper-right corner of the management console.
3. In the list of jobs, find the Cloud Sync job for which you want status.
   The management console displays the status of the job (Created, Running, Completed, Failed, or Canceled) just below the job name.

To cancel a Cloud Sync job

You can only cancel a job if it is running.

1. Log in to the management console.
2. Click **Cloud Sync** in the upper-right corner of the management console.

3. In the list of jobs, find the Cloud Sync job that you want to cancel.

Tip

Use **Quick Filters** to get a list of **Running** jobs.

4. Click **Cancel** to the right of the job name.

To delete a Cloud Sync job

You cannot delete a running job.

Tip

Cancel a running job before you try to delete it.

1. Log in to the management console.
2. Click **Cloud Sync** in the upper-right corner of the management console.
3. In the list of jobs, find the created, canceled, or failed Cloud Sync job that you want to delete.
4. Click **Delete** to the right of the job name.

Using the CLI

You can use the `ocisg` command line interface (CLI) to create, manage, and monitor Cloud Sync jobs. Using `ssh`, log in to the host on which you installed Storage Gateway to use the CLI.

To create a Cloud Sync job that syncs all files and directories at the specified

source location

Warning

Avoid entering confidential information in the job name.

Open a command prompt and run `ocisg cloudsync create` to create a job:

```
sudo ocisg cloudsync create [--schedule=<schedule>] [--auto-delete] [--parallel=<number>] [--files-from=<file>] [--exclude-from=<file>] --verify-contents <job_name> <source_path> <target_path>
```

--schedule is an option to automate the Cloud Sync job so it runs according to the specified schedule. Set the schedule value using the format used for *cron* jobs. For example, `--schedule="*/5 * * * *"` runs the job every five minutes.

--auto-delete is an option to direct Cloud Sync to automatically delete files from the target when files are deleted from the source, and old names of files that have been renamed. By default, Cloud Sync does not automatically delete the files on the target unless you specify this option. The names of all deleted files are stored in a job-specific log directory.

--parallel=*<number>* is an option to specify the number of processes for data synchronization. By default, the number of processes is set to one. With a single process using a hard disk drive, you can expect a sync rate of 60-70 MB/s. If your system has higher disk throughput, you can use the number of processes that is proportional to the available bandwidth. Oracle recommends from two to five processes for optimal performance. The maximum number of processes allowed is 10.

--files-from=*<file>* is an option to specify a set of files that you want to sync to the target. If you do not set this option, the service syncs all files. The *<file>* should be a file under the `/clousdync/` directory. For example, `--files-from="/cloudsync/files.list"`.

--exclude-from=*<file>* is an option to specify a set of files that you want to exclude from the Cloud Sync job. The *<file>* should be a file under the `/clousdync/` directory. For example, `--exclude-from="/cloudsync/exclude.list"`.

--verify-contents is an option to enable verification of the destination contents against the source. If you do not explicitly enable verification, new files added to Cloud Sync sources after the job has started are not reported as errors when they do not appear in the destination.

The Cloud Sync job is created and displayed in the list of jobs.

To list Cloud Sync jobs

Open a command prompt and run `ocisg cloudsync list` to list jobs:

```
sudo ocisg cloudsync list [-s <status>] [<job_name_or_type>]
```

Optionally, you can filter the list of jobs by specifying job status (Created, Running, Completed, Failed, or Canceled). You can also list a single job by specifying the name of that job.

For example:

```
sudo ocisg cloudsync list sync_to_os1
```

To run a Cloud Sync job

Open a command prompt and run `ocisg cloudsync run` to run a job:

```
sudo ocisg cloudsync run <job_name>
```

For example:

```
sudo ocisg cloudsync run sync_to_os1
```

To get the status of a Cloud Sync job

Open a command prompt and run `ocisg cloudsync status` to get the status of a job:

```
sudo ocisg cloudsync status <job_name>
```

For example:

```
sudo ocisg cloudsync status sync_to_os1
```

To cancel a Cloud Sync job

You can cancel a job only if the job is in progress.

Open a command prompt and run `ocisg cloudsync cancel` to cancel a job:

```
sudo ocisg cloudsync cancel <job_name>
```

For example:

```
sudo ocisg cloudsync cancel sync_to_os1
```

To delete a Cloud Sync job

Open a command prompt and run `ocisg cloudsync delete` to delete a job:

```
sudo ocisg cloudsync delete <job_name>
```

For example:

```
sudo ocisg cloudsync delete sync_to_os1
```

Best Practices for Using Storage Gateway

Apply the recommendations found in the following topics to optimize the manageability, performance, reliability, and security of your Storage Gateway.

- Security Considerations
- Understanding Storage Gateway Performance
- Configuring Local Storage for File Systems and Cache
- Determining File System Cache Size
- Recommended Uses and Workloads
- Uses and Workloads Not Supported

- Renaming Directory Trees
- Limits on Storage Gateway Resources

Troubleshooting Storage Gateway

This topic covers some common Storage Gateway issues and how to address them.

I installed docker and NFS on my host, but I can't install Storage Gateway

1. Add the docker group to the existing groups in your host:

   ```
   sudo groupadd docker
   ```

2. Add your user id to the docker group:

   ```
   usermod -a -G docker <username>
   ```

3. Shut down your host:

   ```
   shutdown -r now
   ```

4. Log in to your host and run the Storage Gateway installation script:

   ```
   sudo ./ocisg-install.sh
   ```

I can't access the management console

1. Run the `ocisg info` command:

   ```
   sudo ocisg info
   ```

   If Storage Gateway is not running, start Storage Gateway:

   ```
   sudo ocisg up
   ```

2. Make a note of the management console port number from the output:

   ```
   Management Console: https://myStorageGatewayHost.example.com:32775

   If you have already configured a OCISG File System via the Management Console, you can access the
   NFS share using the following port.
   ```

```
NFS Port: 32774

Example: mount -t nfs -o vers=4,port=32774 myStorageGatewayHost.example.com:/<OCISG File System
name> /local_mount_point
```

In the example, `myStorageGatewayHost.example.com` is the Storage Gateway host name and `32775` is the management console port number.

3. Ensure that Storage Gateway is running `docker` on the Storage Gateway host.
4. Check that the management console port number in the output from `ocisg info` matches the port you're using to access the management console.
5. Ensure that you are using `https` if you have enabled SSL. SSL is enabled by default.

I am unable to mount a file system

1. Run the `ocisg info` command:

```
sudo ocisg info
```

If Storage Gateway is not running, start Storage Gateway:

```
sudo ocisg up
```

2. Make a note of the management console port number and NFS port number from the output:

```
Management Console: https://myStorageGatewayHost.example.com:32775

If you have already configured a OCISG File System via the Management Console, you can access the
NFS share using the following port.

NFS Port: 32774

Example: mount -t nfs -o vers=4,port=32774 myStorageGatewayHost.example.com:/<OCISG File System
name> /local_mount_point
```

In the sample output:

- myStorageGatewayHost.example.com is the Storage Gateway host name.
- 32775 is the management console port number.
- 32774 is the NFS port number.

4. Log in to the NFS client from which you want to access your service instance through Storage Gateway.
5. Create a directory on the NFS client.
6. Mount the file system on the directory that you created on the NFS client:

```
sudo mount -t nfs -o vers=4,port=<NFS_port_number> <storage_gateway_host_name>:/<ocisg_file system_name>/<local_mount_point>
```

In this command:

- Replace *<NFS_port_number>* with the NFS port number.
- Replace *<storage_gateway_host_name>* with the server name or IP address of the server on which Storage Gateway is installed.
- Replace *<ocisg_file system_name>* with the name of the file system you want to mount.
- Replace *<local_mount_point>* with the path to the directory you created on the NFS client.

For example:

```
sudo mount -t nfs -o vers=4,port=32774 myStorageGatewayHost.example.com:/myFirstFS /home/xyz/abc
```

In this example,

- `32774` is the NFS port number.
- `myStorageGatewayHost.example.com` is the Storage Gateway host name.
- `myFirstFS` is the file system name.
- `/home/xyz/abc` is the path to the directory `abc` on the NFS client.

7. Ensure that Storage Gateway is running `docker` on the Storage Gateway host.
8. Ensure that the NFS protocol is running:

```
sudo systemctl enable nfs-server
```

9. Check that the NFS port number in the output from `ocisg info` matches the port you're using to connect to with your NFS client.

I cannot delete a bucket after canceling a Cloud Sync job

If you cancel an active or stalled Cloud Sync job and disconnect the file system, you might not be able to delete the associated Object Storage bucket. If file uploads were in progress when you canceled the job, the Object Storage service might expect a commit that never completed. In this case, the service does not allow bucket deletion and returns the error "multipart upload pending". You can use the CLI to resolve the issue.

1. List the bucket's pending multipart uploads:

   ```
   oci os multipart list -bn <bucket_name>
   ```

   Be sure to note the relevant object names and upload IDs.

2. Delete all pending uploads:

   ```
   oci os multipart abort -bn <bucket_name> --object-name <object_name> --upload-id <upload_id>
   ```

3. Delete the bucket:

   ```
   oci os bucket delete -ns <object_storage_namespace> --name <bucket_name>
   ```

Additional NFS Troubleshooting

The Storage Gateway installation software installs the NFS, if needed, and automatically configures it. After the installation, the NFS is configured and a file system created. You can then mount the filesystem from a remote client. Sometimes this mount can fail.

To troubleshoot a mount failure:

1. Ensure that the NFS port is included in the Storage Gateway's subnet security list and that it is available there. If the port does not appear in the subnet security list, add it and retry the mount.

2. Run `rpcinfo -p`. The command should return:

   ```
   100003 4 tcp 2049 nfs
   ```

   This result means that NFS is ready, available, and the mount succeeds.

3. If `nfs` does not appear in the response to the `rpcinfo -p` command, enable and restart both `rpcbind` and NFS:

   ```
   sudo systemctl enable rpcbind
   sudo systemctl enable nfs
   sudo systemctl start rpcbind
   sudo systemctl start nfs
   ```

4. Run the `rpcinfo -p` command again to verify that NFS is now available.
   a. If NFS still is not available, reboot the Storage Gateway.
   b. Run the `rpcinfo -p` command again to confirm.
5. If you remain unable to mount the file system, contact My Oracle Support.

Contacting Oracle Support

If you need technical support or help with Storage Gateway, you can go to My Oracle Support and create a service request. See Creating a Service Request for information.

Upgrading Storage Gateway

Storage Gateway notifies you when there is a new version available for you to download and install:

- A pop-up notification appears in the management console after you log in.
- A small banner notification appears at the top of the **Dashboard**.
- If you have configured email notifications, the system sends an email notification. See Configuring Email Notification for details.

Important

If you are upgrading from Storage Gateway 1.0, underlying database and schema changes require you to recreate your Storage Gateway file systems. See Recreating Your File Systems for details.

Before You Begin

- Plan for downtime appropriately since the upgrade takes some time to complete. The downtime varies depending on the system resources, the number of file systems, and the number of files.
- Wait for any pending or ongoing write operations from the NFS client instances to complete, then unmount all file systems.
- Wait for pending uploads to Oracle Cloud Infrastructure Object Storage to complete. On the **Dashboard** under **System Status**, ensure that the **Pending Uploads** field shows 0.
- Disconnect all of the file systems.
- Ensure that there is no ongoing activity in the **Activity** tab for each file system in the management console.

Important

To enable partial update capabilities in Storage Gateway, there must be no pending uploads for any associated file systems before the upgrade. The upgrade process purges the existing local cache across all Storage Gateway file systems.

Upgrading Storage Gateway

To upgrade to Storage Gateway 1.3

1. Log in to your Storage Gateway host.
2. Download the Storage Gateway 1.3 tar archive.
3. Extract the files from the downloaded `ocisg-1.3.tar.gz` file:

   ```
   tar xvzf ocisg-1.3.tar.gz
   ```

   This command extracts the file's contents to a subdirectory named `ocisg-1.3`.
4. Change directory to `ocisg-1.3`:

   ```
   cd ocisg-1.3
   ```
5. Run the installation script as `sudo` or `root` user:

   ```
   sudo ./ocisg-install.sh
   ```

If you encounter any interruption during the upgrade, such as lost connectivity, rerun the installation script to resume the upgrade.

If you are upgrading from Storage Gateway 1.0, you must recreate the file systems that were created in the 1.0 version of the Storage Gateway software. Connect the file systems in the management console and claim ownership if there's a bucket ownership prompt. Storage Gateway version 1.3 rebuilds the local metadata for existing buckets in Object Storage. The more objects there are in the buckets, the more time it takes to rebuild the metadata.

Recreating Your File Systems

When you created file systems in Storage Gateway 1.0, corresponding Oracle Cloud Infrastructure Object Storage buckets were created. Recreate those file systems in Storage Gateway so that you can connect to the same buckets and automatically see the files that have already been uploaded to Object Storage.

When you recreate Storage Gateway file systems, data that you already uploaded to Oracle Cloud Infrastructure Object Storage is automatically included in the newly created file system.

To recreate your file systems

1. Log in to the management console.
2. Click **File Systems** on the upper-right area of the management console.
3. Click **Create File System**.
4. Enter the required information in **Create a File System**:
    - **File System Name:** A unique, friendly name for the file system. Avoid entering confidential information. Use the following guidelines when naming a file system:
        - Use from 1 to 256 characters.
        - Valid characters are letters (upper or lower case), numbers, hyphens, underscores, and periods.

        Important

        The name **cannot** contain the following:

        - A slash (/) character because this character delimits bucket and object names in Oracle Cloud Infrastructure Object Storage
        - The strings "pub" or "priv"

        If an Object Storage bucket by this file system name doesn't exist in your tenancy, the bucket is created.

        If a corresponding Object Storage bucket by this file system name exists in your tenancy and there is data in the bucket, Storage Gateway works asynchronously to sync the bucket and file system contents.

- **Select the Object Storage tier in which you want to store your data**

Important

Once set, you cannot change the storage tier in which a bucket resides.

You can use the Oracle Cloud Infrastructure Object Storage object lifecycle policies feature to manage the archiving and deletion of objects in a bucket according to a predefined schedule. See Using Object Lifecycle Management for details.

  - **Standard:** The Standard tier is the primary default Object Storage tier for storing data that requires frequent and fast access. See Overview of Object Storage for more information.
  - **Archive:** The Archive tier is a special tier for storing data that is accessed infrequently and requires long retention periods. See Overview of Archive Storage for more information. Access to data in the Archive tier is not immediate since you must restore archived data before it's accessible (see Restoring Files and Objects from Archive Storage).

- **Object Storage endpoint:** Required. The Object Storage API endpoint for your service instance. To find the object storage API endpoint for your Oracle Cloud Infrastructure Object Storage tenancy, see the API documentation for Oracle Cloud Infrastructure Object Storage.

Important

The following information is required to connect your Storage Gateway file systems to Oracle Cloud Infrastructure. See Required Keys and OCIDs for detailed information on how to generate the required keys and where to obtain these OCIDs.

- **Compartment OCID:** Required. Unique identifier of your Oracle Cloud Infrastructure Object Storage compartment.
- **Tenant OCID:** Required. Unique identifier of your Oracle Cloud Infrastructure Object Storage tenancy.
- **User OCID:** Required. Unique identifier of your Oracle Cloud Infrastructure Object Storage user.
- **Public Key's Finger Print:** Required. Your Oracle Cloud Infrastructure Object Storage public key fingerprint.
- **Private Key:** Required. Your Oracle Cloud Infrastructure Object Storage private key.

- **Private Key Passphrase:** Required if a passphrase was specified during key creation. Your Oracle Cloud Infrastructure Object Storage private key passphrase.

Note

Your private key and passphrase are securely stored in the Storage Gateway docker. The Storage Gateway installation generates a pair of public and private keys. The system uses the public key to encrypt sensitive data.

5. Click **Save**.
   The values you entered must match your Oracle Cloud Infrastructure credentials. If you get an error message, verify your entries, update any incorrect values, and click **Save** again.
6. Click **Show Advanced File System Configuration**.
   Enter the required configuration information or click **Use Default** to accept the default values:
   - **NFS Allowed Hosts:** A comma-separated list of hosts allowed to connect to the NFS export. You can also specify * to allow all hosts to connect.
     For example: `2001:db8:9:e54::/64`, `192.0.2.0/24`
   - **NFS Export Options:** The NFS export options.
     Example: `rw`, `sync`, `insecure`, `no_subtree_check`, `no_root_squash`

Important

Do not specify the `fsid` option.

   - **Concurrent Uploads:** The number of concurrent uploads to Oracle Cloud Infrastructure.

This field indicates the maximum number of files that can be concurrently uploaded in Storage Gateway. If the value is 15, the concurrent file uploads can be between 1-15.

The allowed range is from 1 to 30.

- **Sync Policy:** The metadata operations are flushed to the disk based on the sync policy, but do not affect on-disk consistency. Currently, only **Posix Standard** is supported. Only the synchronous transactions (like fsync, ODSYNC, and OSYNC) are committed to the disk. All other transactions are handled asynchronously.
- **Cloud Read-ahead**: The number of blocks to be downloaded and used to *read ahead* when reading files for improved performance.

  Default value: 50
- **Maximum Read Cache Size in GiB:** The maximum read cache.

  When the read cache is full or reaches the configured limit, Storage Gateway removes files from the cache based on a least recently used (LRU) algorithm. Files pending upload to your tenancy are not removed from cache. You can also preserve files that you do not want removed from cache.

  Note

  The number of files in cache is limited to 20,000, regardless of the specified cache size in bytes.

  See Configuring the Cache for File Systems for details.

  The default value depends on how you provisioned local storage before installing Storage Gateway. The recommended local storage disk size is 600 GB (500 GB for file system cache, 80 GB for metadata, 20 GB for log). If you followed the documented recommendations, the default value for the read cache is approximately 300 GB.

7. Click **Save**.

The file system is created and appears in the **File Systems** listing.

Uninstalling Storage Gateway

This topic describes how to uninstall Storage Gateway.

Uninstalling

To uninstall Storage Gateway

1. Log in to the on-premises host or compute instance from which you want to uninstall Storage Gateway.
2. Stop Storage Gateway:

```
sudo ocisg down
```

3. If the `ocisg_data` container exists in `docker ps -a output`, remove it:

```
sudo docker rm -v ocisg_data
```

4. Delete the image in `docker`:

```
sudo docker rmi $(sudo docker images| grep ocisg | awk '{print $3}')
```

5. Delete all the files in /usr/bin/ that begin with `ocisg`:

```
sudo rm /usr/bin/ocisg*
```

6. View the contents of the file `gateway_config`:

```
cat /etc/gateway_config
```

Sample output:

```
$ cat /etc/gateway_config

DATASTORAGE=/ocisg/cache
MDSTORAGE=/ocisg/metadata
LOGSTORAGE=/ocisg/log
PROXY=
```

```
USE_SSL=
MEMORY=
NETWORK=bridge
HTTP_FRAMEWORK=
ADMINPORT=443
NFSPORT=32769
RESTPORT=32768
```

5. Delete the `DATASTORAGE` directory, for example:

```
sudo rm -rf /ocisg/cache
```

6. Delete the `MDSTORAGE` directory , for example:

```
sudo rm -rf /ocisg/metadata
```

7. Delete the `LOGSTORAGE` directory , for example:

```
sudo rm -rf /ocisg/log
```

8. Delete the `gateway_config` file:

```
sudo rm /etc/gateway_config
```

9. Delete the Storage Gateway installation directory `ocisg`:

```
sudo rm -rf /opt/ocisg
```

Getting Help with Storage Gateway

This topic provides information about getting help with Oracle Cloud Infrastructure Storage Gateway.

Contacting Oracle Support

If you need technical support or help with Storage Gateway, you can go to My Oracle Support and create a service request. See Creating a Service Request for information.

Downloading the Support Bundle

If you contact Oracle Support about any issue with Storage Gateway, you might need to provide a support bundle to help the Oracle Support technicians diagnose the issue.

1. Log in to the management console.
2. Click **System** in the upper-right corner of the management console.
3. Click **Help**.
4. Click **Download Support Bundle** in **System Logs**.
   You can download and save the support bundle.

Contents of the Support Bundle

The support bundle contains the following information:

- All of the logs needed for diagnostics.
- Local storage usage information.
- Basic system information such as memory size, Docker version, and the Storage Gateway version.
- A list of file systems.
- Cloud Sync job details.

CHAPTER 31 Streaming Service Overview

The Oracle Cloud Infrastructure Streaming service provides a fully managed, scalable, and durable storage solution for ingesting continuous, high-volume streams of data that you can consume and process in real time. Streaming can be used for messaging, ingesting high-volume data such as application logs, operational telemetry, web click-stream data, or other use cases in which data is produced and processed continually and sequentially in a publish-subscribe messaging model.

Note

Streaming is not available in Oracle Cloud Infrastructure Government Cloudrealms.

Streaming Usage Scenarios

Here are some of the many possible uses for Streaming:

- **Metric and log ingestion**: Use the Streaming service as an alternative for traditional file-scraping approaches to help make critical operational data more quickly available for indexing, analysis, and visualization.
- **Messaging**: Use Streaming to decouple components of large systems. Streaming provides a pull/buffer-based communication model with sufficient capacity to flatten load spikes and the ability to feed multiple consumers with the same data independently. Key-scoped ordering and guaranteed durability provide reliable primitives to implement various messaging patterns, while high throughput potential allows for such a system to scale well.
- **Web/Mobile activity data ingestion**: Use Streaming for capturing activity from websites or mobile apps (such as page views, searches, or other actions users may take). This information can be used for real-time monitoring and analytics, as well as in data warehousing systems for offline processing and reporting.

- **Infrastructure and apps event processing**: Use Streaming as a unified entry point for cloud components to report their life cycle events for audit, accounting, and related activities.

Streaming Concepts

The following concepts are essential to working with Streaming.

STREAM

A partitioned, append-only log of messages.

PARTITION

A partition is a section of a stream. Partitions allow you to distribute a stream by splitting messages across multiple nodes. Each partition can be placed on a separate machine to allow for multiple consumers to read from a stream in parallel.

CURSOR

A pointer to a location in a stream. This location could be a pointer to a specific offset or time in a partition, or to a groups' current location.

MESSAGE

A Base64-encoded record that is published to a stream.

PRODUCER

An entity that publishes messages to a stream.

CONSUMER

An entity that reads messages from one or more streams.

CONSUMER GROUP

A consumer group is a set of instances which coordinates messages from all of the partitions in a stream. Instances in a consumer group maintain group membership through interaction; lack of interaction for a period of time results in a timeout, removing the instance from the group.

TOPIC/KEY

An identifier used to group related messages.

OFFSET

The location of a message within a partition. You can use the offset to restart reading from a stream.

PERMISSIONS

You can use IAM to set permissions on the following operations: list, get, update, create, and delete streams.

STREAM ARCHIVE

You can archive a stream to a bucket in Object Storage.

How Streaming Works

The Streaming service provides a robust, scalable mechanism that you can use to produce and consume high volumes of data between application components.

Here's how Streaming works: a *producer* publishes *messages* to a *stream*, which is an append-only log. These messages are distributed among the partitions using the message's key.

Streams are divided into a number of *partitions* for scalability. Partitions allow you to distribute a stream by splitting messages across multiple nodes (or brokers). Each partition can be placed on a separate machine to allow multiple consumers to read a stream in parallel. Multiple consumers can read from any partition regardless of where the partition is hosted.

A *consumer* can read messages from one or more streams. Each message within a stream is marked with an offset value, so a consumer can pick up where it left off if it is interrupted.

You can use the Streaming service by:

- Creating a stream using the Console or API.
- Using a producer to publish data to the stream.
- Building consumers to read and process messages from a stream using the GetMessages API .
- Archiving the stream to an Object Storage bucket.

Stream Archiving

You can archive a stream to an OCI Object Storage bucket. You can set up a stream archiver to start archiving from the latest position in the stream, or from the oldest position in the stream.

For information on setting up a stream archiver, see Managing Streams.

Limits on Streaming Resources

The Streaming service has the following limitations:

- Message retention of up to a maximum 7 days
- Throughput is limited to 1MB per second per partition
- Each partition can handle up to 1MB maximum message size
- Each partition can handle 5 GetMessages API calls per second
- Each partition can support up a maximum total data write rate of 1MB per second
- Each enterprise tenancy has a limit of 5 partitions (non-enterprise partitions have a limit of 0, but you can request more)

See Service Limits for a list of applicable limits and instructions for requesting a limit increase. To set compartment-specific limits on a resource or resource family, administrators can use compartment quotas.

Resource Identifiers

Most types of Oracle Cloud Infrastructure resources have a unique, Oracle-assigned identifier called an Oracle Cloud ID (OCID). For information about the OCID format and other ways to identify your resources, see Resource Identifiers.

Ways to Access Oracle Cloud Infrastructure

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. For a list of available SDKs, see Software Development Kits and Command Line Interface.

To access the Console, you must use a supported browser. Oracle Cloud Infrastructure supports the latest desktop versions of Google Chrome, Microsoft Edge, Internet Explorer 11, Safari, Firefox, and Firefox ESR. Note that private browsing mode is not supported for Firefox, Internet Explorer, or Edge. Mobile browsers are not supported.

For general information about using the API, see REST APIs.

Using Streaming

To get started with Streaming, see the following topics:

- For instructions on how to manage streams, see Managing Streams.
- For information about publishing messages to a stream, see Publishing Messages.
- For information on how to consume messages, see Consuming Messages.
- For SDK information, see Oracle Cloud Infrastructure SDKs.

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies. For specific details about writing policies for each of the different services, see Policy Reference.

If you're a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

For common policies used to authorize Streaming users, see Common Policies.

For in-depth information on granting users permissions for the Streaming service, see Details for the Streaming Service in the IAM policy reference.

Tagging Resources

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the desired tags. For general information about applying tags, see Resource Tags.

Moving Resources to a Different Compartment

You can move streams from one compartment to another. For more information, see Managing Compartments.

Last edited: 11/26/2019 11:10 AM

Managing Streams

This topic describes how to work with streams.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don't have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: The policy in Let streaming users manage streams lets the specified group do everything with streaming and related Streaming service resources.

To set up and use a stream archiver, you must have read access to the stream and write access to the Object Storage. For example:

```
allow service stream-processing to use stream-pull in tenancy
allow service stream-processing to manage objects in tenancy
```

If you're new to policies, see Getting Started with Policies and Common Policies. If you want to dig deeper into writing policies for the Streaming service, see Details for the Streaming Service in the IAM policy reference.

Using the Console

To create a stream

1. Click the **Create Stream** button at the top of the topic list.
2. In the **Create Stream** dialog box, configure your topic:
    a. **Compartment** : Required. Select a compartment from the drop-down list.
    b. **Stream Name**: Required. Specify a friendly name for the topic. It does not have to be unique, but it cannot be changed. Avoid entering confidential information.
3. In the **Stream Settings** panel:
    a. **Retention (in Hours)**: Enter the number of hours (from 24 to 168) to retain messages. The default value is 24.
    b. **Number of Partitions:** Enter the number of partitions for the stream. The maximum number is based on the limits for your tenancy.
        i. You can optionally configure the stream settings based on estimated capacity. To do this, click on the **Configure stream settings based on estimated capacity** link to reveal the **Capacity Estimates** panel.
            i. Fill out the capacity estimates and then click **the Estimate Stream Size** button. This will automatically populate the **Number of**

partitions field.

4. **Tags**: Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.
5. Click **Submit**.

To delete a stream

1. Click the check box next to the topics you want to delete and then click **Delete Topic**.
2. Confirm when prompted.

To produce a test message

1. Click a stream to display the stream details page.
2. Click the **Produce Test Message** button.
3. On the **Test Stream** dialog, enter the text-only message to produce in the **Data** text box.
4. Click the **Produce** button.

To show recent messages on a stream

1. Click a stream to display the stream details page.
2. In the **Recent Messages** panel, click the **Refresh** button.

To archive a stream

1. Click a stream to display the stream details page.

2. In the **Stream Archiver** panel, click the **Configure and create archiver** button to display the **Create Archiver** dialog.
3. Choose whether you want to create a new bucket or use an existing bucket for your stream archiver.
4. Type the name of a new bucket or select the name of an existing bucket.
5. Select where you want to start archiving the stream:
    a. Select **Latest** to start from the most recent position in the stream
    b. Select **Trim Horizon** to start archiving from the oldest position in the stream
6. You can optionally expand the **Object Storage Settings** panel to configure advanced options for your stream archiver:
    a. Set the maximum object size (in MB) in the **Object Rollover Size** field.
    b. Set the maximum timeout before a new object is created in the **Object Rollover Time Threshold** field.
7. Click the **Create** button to display the details page for your new Stream archiver. It will take a few moments for the streaming service to provision the resource for the archiver.
8. Once the resources are provisioned for the Stream archiver, you can press the **Start** button to begin archive the stream.

To move a stream to a different compartment

1. Click a stream to display the stream details page.
2. Find the stream you want to move in the list, click the the Actions icon (three dots), and then click **Move Resource**.
3. Choose the destination compartment from the list.
4. Click **Move Resource**.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use these API operations to manage streams:

- CreateStream
- ListStreams
- GetStream
- UpdateStream
- DeleteStream

Publishing Messages

This topic covers how to emit messages to a stream.

Overview

To publish messages:

- Create a stream using CreateStream.
- Publish a message to a specified stream using PutMessages.

Publishing Messages

Once a stream is created and active, you can publish messages.

A message is composed of a key and a value. Both the key and the value are byte arrays. If you don't explicitly supply a key, one is generated automatically.

The message is published to a partition in the stream. If there is more than one partition, the partition where the message is published is calculated using the message's key. If the key is null, the partition is calculated using a random 16-byte value.

For messages with a null key, do not expect messages with same value to go on the same partition, since the partitioning scheme may change. Passing a null key will put the message

in a random partition. If you want to ensure that messages with the same value go to the same partition, you should use the same key for those messages.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don't have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: The policy in Let streaming users manage streams lets the specified group do everything with streaming and related Streaming service resources.

If you're new to policies, see Getting Started with Policies and Common Policies. If you want to dig deeper into writing policies for databases, see Details for the Streaming Service in the IAM policy reference.

Using the Console

To publish a message

1. Click on the stream that you want to publish on.
2. Click the **Produce Test Message** button.
3. Type the message in the **Data** text box.
4. Click **Produce**.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use these API operations to produce messages:

- PutMessages

Consuming Messages

This topic covers how to consume messages from a stream.

Overview

Consuming messages requires you to:

- Create a cursor
- Use the cursor to read messages

Using Cursors

A cursor is a pointer to a location in a stream. This location could be a pointer to a specific offset or time in a partition, or to a groups' current location.

To consume messages, use the CreateCursor or CreateGroupCursor API to create a cursor on a partition to indicate where to start consuming messages.

There are five supported cursor types:

- `TRIM_HORIZON` - Start consuming from the oldest available message in the stream. Create a cursor at the TRIM_HORIZON to consume all messages in a stream.
- `AT_OFFSET` - Start consuming at a specified offset. The offset must be greater than or equal to the offset of the oldest message and less than or equal to the latest published offset.
- `AFTER_OFFSET` - Start consuming after the given offset. This cursor has the same restrictions as the AT_OFFSET cursor.
- `AT_TIME` - Start consuming from a given time. The timestamp of the returned message will be on or after the supplied time.
- `LATEST` - Start consuming messages that were published after you created the cursor.

Consuming Messages

Once you've created a cursor, you can start to consume messages using GetMessages. Each call to GetMessages returns the cursor to use in the next GetMessages call. The returned cursor will never be null and expires in 5 minutes. As long as you keep consuming, you should never have to re-create a cursor.

Consuming Messages using a Consumer Group

Consumers can be configured to consume messages as part of a group. Stream partitions are distributed among members of a group, such that messages from any single partition are only sent to a single consumer.

Partition assignments are rebalanced as consumers join or leave the group. Group consumption is accomplished using the same cursor mechanism as with single consumers, but using a different kind of cursor.

To create a consumer, create a group cursor, providing a group, instance name, and cursor type. Groups are created on the first request to create a cursor; their retention period is the same as their assigned stream:

```
CreateGroupCursorRequest groupRequest = CreateGroupCursorRequest.builder()
                .streamId(streamId)
                .createGroupCursorDetails(CreateGroupCursorDetails.builder()
                        .groupName(groupName)
                        .instanceName(instanceName)
                        .type(CreateGroupCursorDetails.Type.TrimHorizon)
                        .commitOnGet(true)
                        .build())
                .build());

CreateGroupCursorResponse groupCursorResponse = streamClient.createGroupCursor(groupRequest);
String groupCursor = groupCursorResponse.getCursor().getValue();
// this groupCursor can be used in the same message loop a described above; subsequent getMessages calls
return an updated groupCursor.
```

Once you've created a cursor, you can start to consume messages using GetMessages. Each call to GetMessages returns the cursor to use in the next GetMessages call. The returned cursor will never be null and expires in 5 minutes. As long as you keep consuming, you should never have to re-create a cursor.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: The policy in Let streaming users manage streams lets the specified group do everything with streaming and related Streaming service resources.

If you're new to policies, see Getting Started with Policies and Common Policies. If you want to dig deeper into writing policies for databases, see Details for the Streaming Service in the IAM policy reference.

Using the Console

You cannot use the console to consume messages.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use these API operations to consume messages:

- CreateCursor
- GetMessages

Using the Streaming SDK

This topic covers how to use the Streaming SDK.

Getting Started

For information on installing and configuring the Oracle Cloud Infrastructure SDKs, see Developer Tools.

Architecture Overview

Streaming contains the following key building blocks:

- **Stream:** A partitioned, append-only log of messages.
- **Partition:** A section of a stream. Partitions allow you to distribute a stream by splitting messages across multiple nodes. Each partition can be placed on a separate machine to allow for multiple consumers to read from a topic in parallel.
- **Producer:** An entity that publishes messages to a stream.
- **Consumer:** An entity that reads messages from a stream.
- **Consumer group:** A group of consumers that can read independently read messages from separate partitions of a stream.

Streaming Clients

The Streaming SDK is encapsulated in two clients: the `StreamAdminClient` and the `StreamClient`.

The `StreamAdminClient` incorporates the control plane operations of the streaming service. You can use it to create, delete, update, modify, and list streams.

To instantiate the `StreamAdminClient` object:

```
StreamAdminClient adminClient = new StreamAdminClient([authProvider]);
adminClient.setEndpoint("https://streaming.r2.oracleiaas.com"); // You cannot use the setRegion method
```

The `StreamClient` is used to publish and consume messages.

To instantiate a `StreamClient` object:

```
// First you have to get the stream you want to consume/publish.
// You can either make a CreateStream, GetStream, or ListStream call. They all return a
"messagesEndpoint" as part of a Stream object.
// That endpoint NEEDS to be used when creating the StreamClient object.
GetStreamRequest getStreamRequest = GetStreamRequest.builder().streamId(streamId).build();
Stream stream = adminClient.getStream(getStreamRequest).getStream();

StreamClient streamClient = new StreamClient([authProvider]);
streamClient.setEndpoint(stream.getMessagesEndpoint());
```

Creating a Stream

To create a stream, use the `createStream` method of `StreamAdminClient`. Creating a stream is an asynchronous operation. You can check on the completion of the create operation by checking that the `lifecycleStateDetails` property of your new stream is either `Active` or `Failed`.

The following is an example showing how to create a stream:

```
// No error handling
CreateStreamDetails createStreamDetails =  CreateStreamDetails.builder()
   .partitions(5) // number of partitions you want in your stream

   .name("myStream") // the name of the stream - only used in the console
   .compartmentId(tenancy) // the compartment id you want your stream to live in
   .build();

// You can also add tags to the createStreamDetails object.
CreateStreamRequest createStreamRequest =
   CreateStreamRequest.builder()
     .createStreamDetails(createStreamDetails)
     .build();

Stream stream = adminClient.createStream(createStreamRequest).getStream();

while (stream.getLifecycleState() != Stream.LifecycleState.Active && stream.getLifecycleState() !=
Stream.LifecycleState.Failed) {

   GetStreamRequest getStreamRequest = GetStreamRequest.builder().streamId(stream.getId()).build();
   stream = adminClient.getStream(getStreamRequest).getStream();
}

// Handle stream Failure
```

Deleting a Stream

To delete a stream, use the `deleteStream` method API of the `StreamAdminClient`. Deleting a stream is an asynchronous operation; the stream state changes to `Deleted` once the delete operation is finished. During the deletion process, the stream can't be used for consuming or producing messages.

The following example shows how to use the `deleteStream` method to delete a stream:

```
// No error handling
DeleteStreamRequest deleteStreamRequest =

    DeleteStreamRequest.builder()

      .streamId(stream.getId())
       .build();

adminClient.deleteStream(deleteStreamRequest);
```

Listing Streams

Use the `listStreams` method to return a list of streams for a given compartment.

You can filter the returned list by OCID, life cycle state, and name.

The results can be sorted in ascending or descending order by name or creation time.

The results are passed back in a paginated list. A token is passed back with each page of results; pass this token back to the `getOpcNextPage` method to retrieve the next page of results. A null token returned from `getOpcNextPage` indicates that no more results are available.

For example:

```
// No error handling
ListStreamsRequest listStreamsRequest =
        ListStreamsRequest.builder()
                .compartmentId(tenancy)
                .build();
// You can filter by OCID (exact match only) [builder].id(streamId) -> This will return 0..1 item
// You can filter by name (exact match only) [builder].name(name) -> This will return 0..n items
// You can order the result per TimeCreated or Name [builder].sortBy(SortBy.[TimeCreated|Name])
```

```
// You can change the ordering [builder].sortOrder(SortOrder.[Asc|Desc])
// You can filter by lifecycleState [builder].lifecycleState(lifecycleState)

String page;
do {
    ListStreamsResponse listStreamsResponse = adminClient.listStreams(listStreamsRequest);
    List<StreamSummary> streams = listStreamsResponse.getItems();
    // Do something with the streams
    page = listStreamsResponse.getOpcNextPage();
} while (page != null);
```

Retrieving Stream Details

To get details about a stream, use the `getStream` method and then examine the properties of the stream. For example:

```
// No error handling
GetStreamRequest getStreamRequest =
        GetStreamRequest.builder()
                .streamId(streamId)
                .build();

Stream stream = adminClient.getStream(getStreamRequest).getStream();
```

Publishing Messages

Once a stream is created and active, you can publish messages using the `streamClient.putMessages` method.

A message is composed of a key (which can be null) and a value. Both key and value are byte arrays.

The message is published to a partition in the stream. If there is more than one partition, the partition where the message is published is calculated using the message's key. If the key is null, the partition is calculated using a subset of the value. For messages with a null key, do not expect messages with same value to go on the same partition since the partitioning scheme may change. Sending a null key will put the message in a random partition. If you want to ensure that messages with the same value go to the same partition, you should use the same key for those messages.

The following code shows how to publish a message:

```
// No error handling
List<PutMessagesDetailsEntry> messages = new ArrayList<>();

for (int i = 0; i < 40; i++) {
    byte[] key = "myKey".getBytes(Charsets.UTF_8); // In that case, all messages will go on the same
partition since the key is the same.
    byte[] value = UUID.randomUUID().toString().getBytes(Charsets.UTF_8);
    messages.add(new PutMessagesDetailsEntry(key, value));
}

PutMessagesDetails putMessagesDetails =
        PutMessagesDetails.builder()
                .messages(messages)
                .build();

PutMessagesRequest putMessagesRequest =
        PutMessagesRequest.builder()
                .putMessagesDetails(putMessagesDetails)
                .build();

PutMessagesResult putMessagesResult = streamClient.putMessages(putMessagesRequest).getPutMessagesResult
();
// It's not because the call didn't fail that the messages were successfully published!
int failures = putMessagesResult.getFailures();
// If failures is > 0, it means we have a partial-success call.
List<PutMessagesResultEntry> entries = putMessagesResult.getEntries();
// entries is a list of the same size as the list of messages you sent.
// It is guaranteed that the order of the messages is the same as when you sent them.
// Each entry contains either "offset/partition/timestamp" if the message was successfully published
// or "error/errorMessage" if it failed.
if (failures != 0) {
    entries.forEach(entry -> {
        if (StringUtils.isNotEmpty(entry.getError())) {
            // That particular message failed to get published.
            // It could be a throttle error and in that case error would be "429" and errorMessage would
contain a meaningful message.
            // Or it could be an internal error on our side and error would be "500".

            // Possible solution would be to republish only failed messages.
        }
```

```
    });
}
```

Consuming Messages

Consuming messages requires the use of a cursor, which is a pointer to an offset into a partition.

There are five supported cursor types:

- `TRIM_HORIZON` - Start consuming from the oldest available message in the stream. Create a cursor at the TRIM_HORIZON to consume all messages in a stream.
- `AT_OFFSET` - Start consuming at a specified offset. The offset must be greater than or equal to the offset of the oldest message and less than or equal to the latest published offset.
- `AFTER_OFFSET` - Start consuming after the given offset. This cursor has the same restrictions as the AT_OFFSET cursor.
- `AT_TIME` - Start consuming from a given time. The timestamp of the returned message will be on or after the supplied time.
- `LATEST` - Start consuming messages that were published after you created the cursor.

To create a `TRIM_HORIZON` cursor, which starts consuming starting from the oldest available message:

```
// No error handling
CreateCursorDetails createCursorDetails =
        CreateCursorDetails.builder()
                .type(Type.TrimHorizon)
                .partition("0")
                .build();
// If using AT_OFFSET or AFTER_OFFSET you need to specify the offset [builder].offset(offset)
// If using AT_TIME you need to specify the time [builder].time(new Date(xxx))

CreateCursorRequest createCursorRequest =
        CreateCursorRequest.builder()
                .createCursorDetails(createCursorDetails)
                .build();
```

```
String cursor = streamClient.createCursor(createCursorRequest).getCursor().getValue();
// Cursor will then be used to get messages from the stream.
```

Once you've created a cursor, you can start to consume messages using the GetMessages method. Each call to GetMessages returns the cursor to use in the next GetMessages call. The returned cursor is not null and expires in 5 minutes. As long as you keep consuming, you should never have to re-create a cursor.

Here's an example of using a cursor to retrieve messages:

```
// No error handling (there is a high chance of getting a throttling error using a tight loop)
while (true) { // or your own exit condition
    GetMessagesRequest getMessagesRequest =
            GetMessagesRequest.builder()
                    .cursor(cursor)
                    .build();

    GetMessagesResponse getMessagesResponse = streamClient.getMessages(getMessagesRequest);

    // This could be empty, but we will always return an updated cursor
    getMessagesResponse.getItems().forEach(message -> {
        // Process the message
    });

    cursor = getMessagesResponse.getOpcNextCursor();Consuming Messages
```

Using Consumer Groups

Consumers can be configured to consume messages as part of a group. Stream partitions are distributed among members of a group, such that messages from any single partition are only sent to a single consumer.

Partition assignments are rebalanced as consumers join or leave the group. Group consumption is accomplished using the same cursor mechanism as with single consumers, but using a different kind of cursor.

How Consumer Groups Work

A consumer group is a set of instances which coordinate to consume messages from all of the partitions in a stream. Instances maintain membership to a group through interaction; lack of interaction for a period of time results in a timeout, removing the instance from the group. Partitions are reserved for specific instances in a group; reservations are rebalanced in response to specific group events, such as an instance joining the group, or instance time-out.

While an instance maintains membership to a group, calls to get messages will return messages from only partitions reserved for that instance. Partition reservation attempts to ensure that messages are only processed by a single instance.

The set of instances in a group is expected to change over time; transience can occur for many reasons, commonly because of server failure, scaling patterns, or operational management.

Persisting consumer processing state beyond the lifetime of an instance, allows instances to come and go, picking up where appropriate in context of the group.

An instance commits offsets of processed messages to ensure that they are not processed again by other instances in the same group.

Consuming Messages with a Consumer Group

To create a consumer group, create a group cursor, providing a group, instance name, and cursor type. Groups are created on the first request to create a cursor; their retention period is the same as their assigned stream:

```
CreateGroupCursorRequest groupRequest = CreateGroupCursorRequest.builder()
                .streamId(streamId)
                .createGroupCursorDetails(CreateGroupCursorDetails.builder()
                        .groupName(groupName)
                        .instanceName(instanceName)
                        .type(CreateGroupCursorDetails.Type.TrimHorizon)
                        .commitOnGet(true)
                        .build())
                .build());

CreateGroupCursorResponse groupCursorResponse = streamClient.createGroupCursor(groupRequest);
String groupCursor = groupCursorResponse.getCursor().getValue();
// this groupCursor can be used in the same message loop a described above; subsequent getMessages calls
return an updated groupCursor.
```

Once you've created a cursor, you can start to consume messages using GetMessages. Each call to GetMessages returns the cursor to use in the next GetMessages call. The returned cursor is never null and expires in 5 minutes. As long as you keep consuming, you should never have to re-create a cursor.

Streaming Metrics

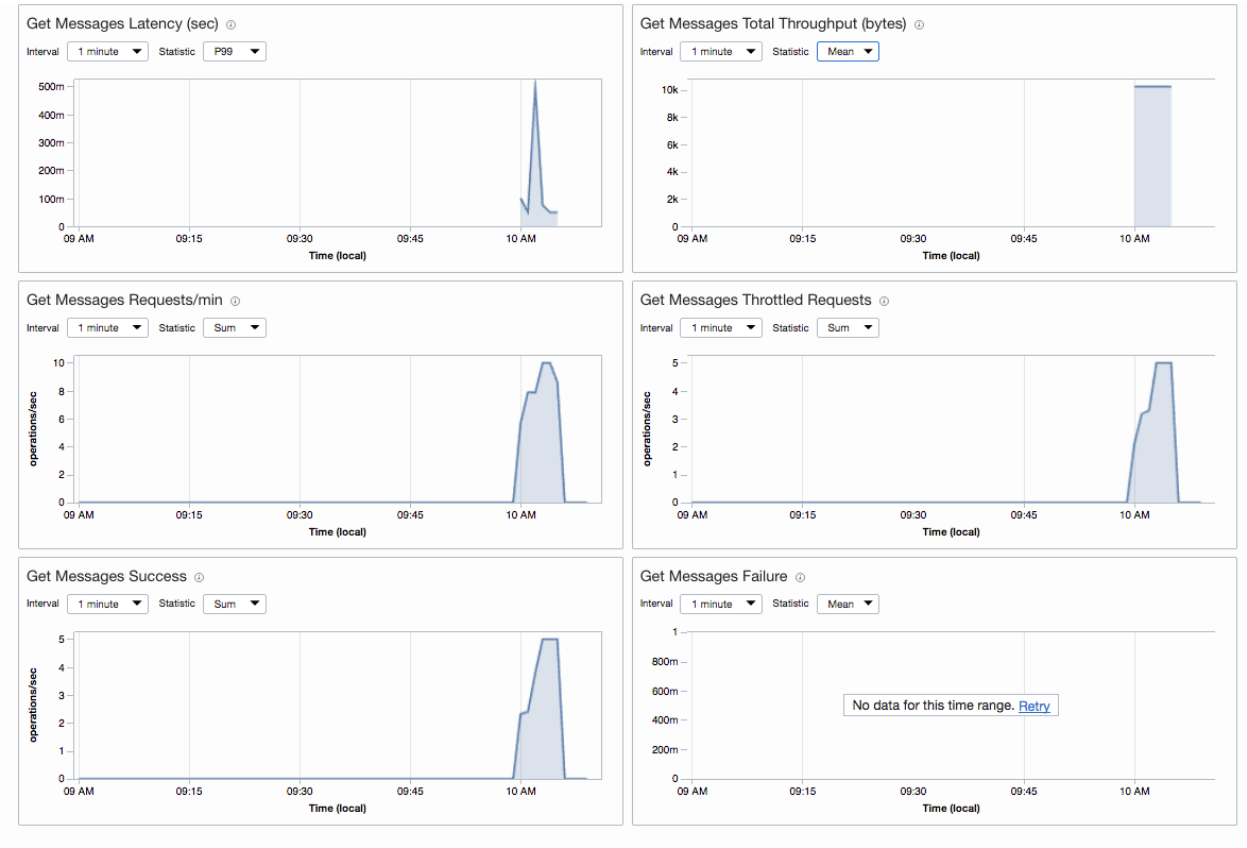
This topic describes the metrics emitted by the Streaming service using the metric namespace `oci_oss`.

Overview of Streaming Metrics

The Streaming service provides metrics showing how the service is performing. These metrics are automatically available.

You can use these metrics to:

- Understand the produce/consume latency for a real-time application.
- Calculate and validate the price of service usage.
- Monitor changes in throughput over time.
- Check the time that the last message was consumed.



To view a default set of metrics charts in the Console, navigate to the Service Metrics page and then select the `oci_oss` metric namespace.

Terminology

The following terms are used when discussing Streaming service metrics:

- *Namespace:* A namespace is a container for Streaming metrics. The namespace identifies the application or service sending the metrics. The namespace for the Streaming is `oci/oss`.
- *Metrics:* Metrics are the fundamental concept in telemetry and monitoring. Metrics define a time-series set of datapoints. Each metric is uniquely defined by namespace,

metric name, compartment identifier, and a set of one or more dimensions, and a unit of measure. Each datapoint has a time stamp, a value, and a count associated with it.

- *Dimensions:* A dimension is a key-value pair that defines the characteristics associated with the metric; for ecample, `resourceId(streamOcid`.
- *Statistics :* Statistics are metric data aggregations over specified periods of time. Aggregations are done using the namespace, metric name, dimensions, and the data point unit of measure within the time period specified.
- *Alarms:* Alarms are used to automate operations monitoring and performance. An alarm keeps track of changes that occur over a specific period of time and performs one or more defined actions, based on the rules defined for the metric.

Available Metrics

The following tables describe the available Streaming metrics.

Producers

Metric	Metric Display Name	Unit	Description	Dimensions
PutMessagesLatency.Time	Put Messages Latency	time (ms)	Time taken for put messages operation measured over time range	streamOcid,regionId
PutMessagesThroughput.Bytes	Put Messages Total Throughput	bytes	Bytes pushed to the stream measured over time	
PutMessagesThroughput.Count	Put Messages Records/sec	count	Count of messages pushed to stream measured over time	
PutMessagesThrottling.Count	Put Messages Throttled Records/sec	count	Number of put messages throttled either due to volume or requests measured over time	

Metric	Metric Display Name	Unit	Description	Dimensions
PutMessagesSuccess.Count	Put Messages Success	count	Successful Requests for put messages per stream measured over time	
PutMessagesFault.Count	Put Messages Failure	count	Total Failed putMessage Requests per stream measured over time	
PutMessagesRecords.Count	Put Messages Requests	count	Number of records published to a stream measured over time	
PutMessages.Bytes	Put Messages Bytes	bytes	Bytes pushed to a stream over time	
PutMessages.Count	Put Messages Count	count	Number of messages pushed over time	

Consumers

Metric	Metric Display Name	Unit	Description	Dimensions
GetMessagesLatency.Time	Get Messages Latency	time (ms)	Time taken for get messages operation measured over time range	streamOcid,regionId
GetMessagesThroughput.Bytes	Get Messages Total Throughput	bytes	Bytes retrieved from stream measured over time	
GetMessagesThroughput.Count	Get Messages Requests/sec	count	Count of messages read from stream measured over time	
GetMessagesThrottling.Count	Get Messages Throttled Requests	count	Number of get messages throttled either due to volume or requests measured over time	

Metric	Metric Display Name	Unit	Description	Dimensions
GetMessagesSuccess.Count	Get Messages Success	count	Successful Requests for get messages per stream measured over time	
GetMessagesFault.Count	Get Messages Failure	count	Total Failed getMessage Requests per stream measured over time	
GetMessages.Bytes	Get Messages Bytes	bytes	Bytes retrieved from a stream over time	
GetMessages.Count	Get Messages Count	count	Number of messages read over time	

Consumer Groups

Metric	Metric Display Name	Unit	Description	Dimensions
totalActiveConsumers.Count	Total Active Consumer Groups	count	Number of active consumers.	streamOcid,regionId
totalActiveConsumersGroups.Count	Total Active Consumers	count	Number of active consumer groups.	

CHAPTER 32 Tagging

This chapter explains how to use tags to add metadata to your resources.

Tagging Overview

Oracle Cloud Infrastructure Tagging enables you to add metadata to resources. This allows you to define keys and values and associate them with resources. You can then use the tags to help you organize and list resources based on your business needs.

How Tagging Works

The Tagging service provides two ways for you to approach adding tags to resources. Each approach offers a different type of tag for you to work with:

- Defined tags - tag administrators manage resource metadata.
- Free-form tags - unmanaged metadata applied to resources by users.

One approach involves a tag administrator creating and managing all the tags that users will apply to resources. You use IAM policy to limit who can *create* tags to a few select tag administrators, while granting all others in the tenancy only the ability to *apply* tags. The benefit to this approach is that you can create and manage the keys and values used to tag resources. This avoids typos that weaken automation based on tags and provides better reporting based on tags.

The other approach is to allow users to add tags to resources. Each tag is edited or applied at the resource by you or a user creating or modifying a resource.

You can use both types of tags throughout your tenancy. Most of the Tagging features require defined-tags. "Tag" is used generically to refer to defined tags. To create metadata that you can trust to manage resources and collect data, use defined tags. With defined tags, the following scenarios become possible:

- You can create default tags that are applied to all resources in compartments. See Managing Tag Defaults.
- Specify that users must apply tags to resources to successfully create resources in compartments.
- If you make a typo using defined tags, you can correct it by editing or even deleting. When you delete a defined tag, Oracle removes the key (and any value) for that tag from all resources. See Deleting Tag Key Definitions and Namespace.
- Associate a list of predefined values for a defined tag. See Using Predefined Values.
- Use system variables to automatically generate values for defined tags or tag defaults. See Using Tag Variables.
- Track costs based on defined tags. See Using Cost-Tracking Tags.

Tagging Concepts

Here's a list of the basic tagging concepts:

Tag Namespace

You can think of a tag *namespace* as a container for your tag keys. It consists of a name, and zero or more tag key definitions. Tag namespaces are not case sensitive, and must be unique across the tenancy. The namespace is also a natural grouping to which administrators can apply policy. One policy on the tag namespace applies to all the tag definitions contained in it.

Tag Key

The name you use to refer to the tag. Tag keys are case insensitive (for example," mytagkey" duplicates "MyTagKey"). Tag keys for defined tags must be created in a namespace. A tag key must be unique within a namespace.

Tag Value Type

The tag value type specifies the data type allowed for the value. Currently two data types are supported: string and a list of strings.

KEY DEFINITION

A key definition defines the schema of a tag and includes a namespace, tag key, and tag value type.

TAG VALUE

The tag value is the value the user applying the tag adds to the tag key. Tag values support two data types: strings and lists of strings. You can define a list of values for the user to select from when you define the tag key, or you can allow the user to enter any value when the tag is applied to the resource. If you select a string tag value when you create the key, the user can leave the value blank when they apply the key.

In the example:

Operations.CostCenter="42"

Operations is the namespace, CostCenter is the tag key, and 42 is the tag value.

TAG (OR DEFINED TAG)

A tag is the instance of a key definition that is applied to a resource. It consists of a namespace, a key, and a value. "Tag" is used generically to refer to defined tags.

FREE-FORM TAG

A basic metadata association that consists of a key and a value only. Free-form tags have limited functionality. See Understanding Free-form Tags.

COST TRACKING

Cost tracking is a feature supported for defined tags. Tags enabled for cost tracking (also called cost-tracking tags) help you to manage costs in your tenancy. You can use cost-tracking tags to track projected costs and set budgets and receive alerts when your costs reach a particular threshold. See Using Cost-Tracking Tags.

TAG DEFAULT

Tag defaults let you specify tags to be applied automatically to all resources, in a specific compartment, at the time of creation, regardless of the permissions of the user who creates the resource. See Managing Tag Defaults.

RETIRE

You can *retire* a tag key definition or a tag namespace. Retired tag namespaces and key definitions can no longer be applied to resources. However, retired tags are not removed from the resources to which they have already been applied. You can still specify retired tags when searching, filtering, reporting, and so on.

REACTIVATE

You can *reactivate* a tag namespace or tag key definition that has been retired to reinstate its usage in your tenancy.

TAG VARIABLE

You can use a variable to set the value of a tag. When you add or update a tag on a resource, the variable resolves to the data it represents. See Using Tag Variables.

PREDEFINED VALUES

You can use a variable to set the value of a tag. When you add or update a tag on a resource, the variable resolves to the data it represents. See Using Predefined Values.

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies. For specific details about writing policies for each of the different services, see Policy Reference.

If you're a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

For administrators: Use the following topics to find example of IAM policy for Tagging:

- Required Permissions for Working with Defined Tags
- Required Permissions for Working with Tag Defaults
- Required Permissions for Working with Free-form Tags

Region Availability

Tagging is currently available in all regions.

Ways to Access Oracle Cloud Infrastructure

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. For a list of available SDKs, see Software Development Kits and Command Line Interface.

To access the Console, you must use a supported browser. Oracle Cloud Infrastructure supports the latest desktop versions of Google Chrome, Microsoft Edge, Internet Explorer 11, Safari, Firefox, and Firefox ESR. Note that private browsing mode is not supported for Firefox, Internet Explorer, or Edge. Mobile browsers are not supported.

Limits on Tags

See Service Limits for a list of applicable limits and instructions for requesting a limit increase.

- Tag namespaces: 100 tag namespaces per tenancy
- Tags per Tag namespace: 100 tags per tag namespace
- Tags per resource: 10 free-form tags and 64 defined tags
- Tags enabled for cost-tracking: 10 per tenancy (includes both active and retired tags)
- Total tag data size: 5 K (JSON). The total tag data size includes all tag data for a single resource (all applied tags and tag values). Sizing is per UTF-8.

Resource	Supported Characters	Max Length
Tag namespace	Printable ASCII, excluding periods (.) and spaces	100 characters
Tag key name (free-form and defined)	Printable ASCII, excluding periods (.) and spaces	100 characters
Tag value (free-form and defined)	Unicode characters	256 characters

Managing Tags and Tag Namespaces

Oracle Cloud Infrastructure supports two kinds of tags: free-form tags and defined tags.

Tip

Watch a video to introduce you to the concepts and features of tagging: Introduction to Tagging.

Required IAM Policy

If you're in the Administrators group, then you have the required access for managing tag namespaces and tags. For more policy samples specific to working with tags and tag namespaces, see Required Permissions for Working with Defined Tags.

If you're new to policies, see Getting Started with Policies and Common Policies. If you want to dig deeper into writing policies for groups or other IAM components, see Details for IAM.

Overview of Tags and Tag Namespaces

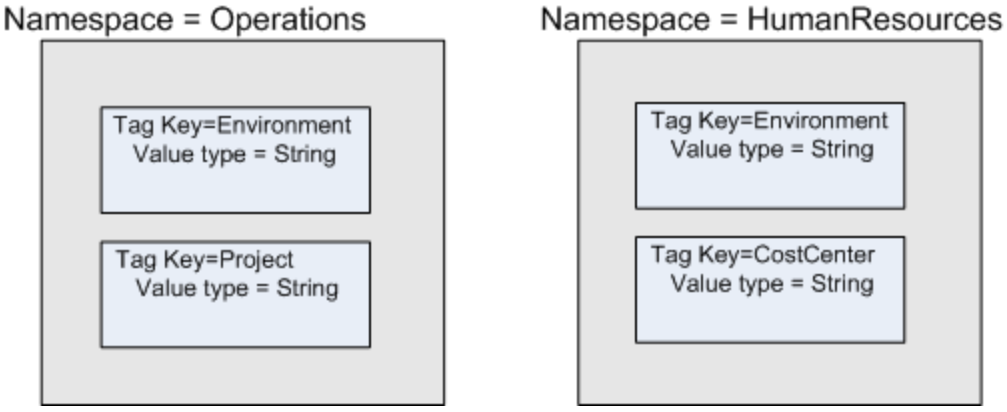
Defined tags provide more features and control than free-form tags. Before you create a defined tag key, you first set up a tag *namespace* for it. You can think of the tag namespace as a container for a set of tag keys. When you create the tag key definition, you must choose the type of value (which also determines how the user applying the tag adds the value):

- You can leave it empty so that a user can fill in the value
- You can create a list of values so that the user must choose from those values

To apply a defined tag to a resource, a user first selects the tag namespace, then the tag key within the namespace, and then they can assign the value. If the tag key contains a blank value, the user can type in a value or leave it blank. If the tag key contains a list, the user must select a value from the list.

Defined tags support policy to allow you to control who can apply your defined tags. The tag namespace is the entity to which you can apply policy. Administrators can control which groups of users are allowed to use each namespace.

The following diagrams illustrate defined tags. Two tag namespaces are set up: Operations and HumanResources. The tag keys are defined in the namespaces. Within each namespace, the tag keys must be unique, but a tag key name can be repeated across namespaces. In the example, both namespaces include a key named "Environment."



The first instance is tagged with two tags from the Operations tag namespace, indicating that it belongs to the Operations production environment and the Operations project "Alpha". The second instance is tagged with tags from both the HumanResources tag namespace and the Operations tag namespace, indicating that it belongs to the HumanResources "Production" environment, the HumanResources cost center "42", and also the Operations project "Beta".

Working with Defined Tags

You must set up the tag namespace and tag keys in your tenancy before users can apply a defined tag to a resource. As part of the set up process, you must also grant permissions to the user groups that will need to use the namespace.

Features of defined tags include:

- Consist of a tag namespace, a key, and a value.
- The tag namespace and tag key definition must be set up in your tenancy before users can apply a defined tag to a resource.
- You can create the tag key with either a tag value type of string (for the user to add a value or leave blank) or a list of values (from which the user must choose).
- When applying a defined tag, users select from the list of tag keys.
- Users can apply a defined tag during resource creation or to an existing resource.

- Defined tag keys are case insensitive.
- Defined tag values are case sensitive. For example, "alpha" and "Alpha" are distinct values.
- You can use tag variables.
- You can create a list of predefined variables to associate with a tag key. Users that apply the tag to a resource must select a value from the list you create.

Required Permissions for Working with Defined Tags

To apply, update, or remove defined tags for a resource, a user must be granted permissions on the resource *and* permissions to use the tag namespace.

Users must be granted `use` access on the *tag namespace* to apply, update, or remove a defined tag for a resource.

Some example policies for tag namespaces:

To allow a group to simply view the tag namespaces in the tenancy (or in a compartment) requires `inspect` access:

```
Allow group GroupA to inspect tag-namespaces in tenancy
```

Important

To apply tags to a resource when using the Console, a user must have permissions to `inspect tag-namespaces in tenancy`. If the user does not have this permission, the list of tag namespaces cannot be presented to the user in the dialog menu.

To allow a group to read the tag definitions contained in tag namespaces requires `read` access:

```
Allow group GroupA to read tag-namespaces in tenancy
```

To allow a group to apply, update, or remove a defined tag for a resource requires the `use` access on the tag namespace:

```
Allow group GroupA to use tag-namespaces in tenancy
```

To allow usage of a specific tag namespace or namespaces , use a `where` clause with the `target.tag-namespace.name` variable. For example:

```
Allow group GroupA to use tag-namespaces in tenancy where target.tag-namespace.name='Operations'
```

or to specify multiple tag namespaces:

```
Allow group GroupA to use tag-namespaces in tenancy where any {target.tag-namespace.name='Operations',
target.tag-namespace.name='HumanResources'}
```

To manage tag namespaces and the tag definitions in them, requires `manage` access:

```
Allow group GroupA to manage tag-namespaces in tenancy
```

In addition to the permissions to work with the tag namespace, to apply or remove defined tags on a resource you must have the update permission for the resource. For many resources, the update permission is granted with the `use` verb. For example, users who can use instances in CompartmentA, can also apply, update, or remove defined tags for instances in CompartmentA.

Some resources don't include the update permission with the `use` verb. To allow a group to apply, update, or remove defined tags for these resources without granting the full permissions of `manage`, you can add a policy statement to grant only the *<RESOURCE>*_ UPDATE permission from the `manage` verb. For example, to allow a group NetworkUsers to work with defined tags with VCNs in CompartmentA, you could write a policy like:

```
Allow group NetworkUsers to use vcns in compartment CompartmentA

Allow group NetworkUsers to manage vcns in compartment CompartmentA where request.permission='VCN_
UDPATE'
```

The `inspect` permission for a resource grants permissions to view defined tags for that resource. For example, users who can `inspect` instances can also view any defined tags applied to the instance.

For information about resource permissions, see Policy Reference.

Example Scenario

Your company has an Operations department. Within the Operations department are several cost centers. You want to be able to tag resources that belong to the Operations department with the appropriate cost center.

1. Create a tag namespace definition called Operations.
2. In the Operations namespace, create a tag key definition called CostCenter.

Alice already belongs to the group InstanceLaunchers. Alice can manage instances in CompartmentA. You want Alice and other members of the InstanceLaunchers group to be able to apply the Operations.CostCenter tag to instances in CompartmentA.

To grant the InstanceLaunchers group access to the Operations tag namespace (and only the Operations tag namespace), add the following statements to the InstanceLaunchers policy:

```
Allow group InstanceLaunchers to use tag-namespaces in compartment CompartmentA where target.tag-namespace.name='Operations'
```

Alice can now apply the Operations.CostCenter tag to resources in CompartmentA.

Retiring Key Definitions and Namespace Definitions

You can retire a tag key definition or a tag namespace definition.

When you retire a tag key definition, you can no longer apply it to resources. However, the tag is not removed from the resources that it was applied to. The tag still exists as metadata on those resources and you can still call the retired tag in operations (such as listing, sorting, or reporting).

Important

Retiring a tag stops cost tracking for the tag, but if you do not disable the cost-tracking option on the tag key definition, the retired tag continues to count against your maximum of 10 cost-tracking tags for your tenancy. Ensure that you disable cost tracking before you retire the tag key definition. To disable cost-tracking after a tag is retired, you must reactivate the tag key definition to update it. You can't update tag key definitions that are in the retired state.

When you retire a tag namespace, all the tag keys in the tag namespace are retired. As described earlier, this means that all tags in the tag namespace can no longer be applied to resources, though existing tags are not removed. No new keys can be created in the retired tag namespace.

Reactivating Tag Key Definitions and Namespace Definitions

You can reactivate retired tag key definitions and tag namespace definitions.

When you reactivate a tag key, it is again available for you to apply to resources.

When you reactivate a tag namespace, you can once again create tag key definitions in the namespace. However, if you want to use any of the tag key definitions that were retired with the namespace, you must explicitly reactivate each tag key definition.

Moving Tag Namespaces to a Different Compartment

You can move a tag namespace to a different compartment. The tag namespace can be active or retired when you move it. When you move the tag namespace, all its tag key definitions are moved along with it.

This functionality is useful if you need to reorganize your compartment hierarchy, or if you need to delete a compartment that contains a retired tag namespace. Remember that you can't delete a compartment that still contains resources. A retired tag namespace, even though it is retired, is still an existing resource. Moving the retired tag namespace to a different compartment can enable you to delete its original containing compartment.

To move a tag namespace, you must be allowed to `manage tag-namespaces` in both compartments.

See the procedure To move a tag namespace to a different compartment.

Deleting Tag Key Definitions and Namespace

You can delete a tag key definition or a tag namespace.

When you delete a tag key definition, you begin a process that removes the tag from all resources in your tenancy. These things happen immediately:

- If the tag was a cost-tracking tag, it no longer counts against your 10 cost-tracking tags limit, whether you first disabled it or not.
- If the tag was used with dynamic groups, none of the rules that contain the tag will be evaluated against the tag.

The delete action is asynchronous and initiates a work request. Once you start the delete operation, the state of the tag changes to deleting and tag removal from resources begins. This process can take up to 48 hours depending on the number of resources that were tagged as well as the regions in which those resources reside. When all tags have been removed, the state changes to deleted. You cannot restore a deleted tag. Once the deleted tag changes its state to Deleted, you can use the same tag name again.

To delete a tag key definition, you must first retire it.

To delete a tag namespace, you must first delete all its tag key definitions.

Tip

To delete a tag namespace that contains tag key definitions, first retire the tag namespace. When you retire a tag namespace, all the tag keys in the tag namespace are retired.

Using the Console

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Managing Tag Namespaces

To create a tag namespace

1. Open the navigation menu. Under **Governance and Administration**, go to **Governance** and click **Tag Namespaces**.
   A list of the tag namespaces in your current compartment is displayed.
2. Click **Create Namespace Definition**.
3. Enter the following:
   - **Create in Compartment:** The compartment in which you want to create the namespace definition.

- **Namespace Definition Name:** A unique name for this set of tags. The name must be unique within your tenancy. Tag namespace is case insensitive. You cannot change this value later.
- **Description:** A friendly description. You can change this value later if you want to.

4. Click **Create Namespace Definition**.

To update a tag namespace's description

1. Open the navigation menu. Under **Governance and Administration**, go to **Governance** and click **Tag Namespaces**.
   A list of the tag namespaces in your tenancy is displayed.
2. Click the tag namespace you want to update.
   The namespace's details are displayed. The description is displayed under the namespace's name.
3. Click the pencil next to the description.
4. Edit the description and save it.

To retire a tag namespace

1. Open the navigation menu. Under **Governance and Administration**, go to **Governance** and click **Tag Namespaces**.
   A list of the tag namespaces in your current compartment is displayed.
2. Click the tag namespace you want to retire.
   The namespace's details are displayed.
3. Click **Retire Namespace**.
4. Confirm when prompted.

To reactivate a tag namespace

1. Open the navigation menu. Under **Governance and Administration**, go to **Governance** and click **Tag Namespaces**.
   A list of the tag namespaces in your current compartment is displayed.
2. Click the tag namespace you want to reactivate.
   The namespace's details are displayed.
3. Click **Reactivate Namespace**.
4. Confirm when prompted.

To move a tag namespace to a different compartment

1. Open the navigation menu. Under **Governance and Administration**, go to **Governance** and click **Tag Namespaces**.
   A list of the tag namespaces in your current compartment is displayed.
2. Click the tag namespace you want to move.
   The namespace's details are displayed.
3. Click **Move Tag Namespace**.
4. Select the **Target Compartment** that you want to move the tag namespace to.
5. Click **Move Tag Namespace**.

To delete a tag namespace

To delete a tag namespace, you must first delete all of its tag key definitions.

1. Open the navigation menu. Under **Governance and Administration**, go to **Governance** and click **Tag Namespaces**.
   A list of the tag namespaces in your current compartment is displayed.
2. Click the empty tag namespace you want to delete.

The namespace's details are displayed.

3. Click **Delete Tag Namespace**.
4. Confirm when prompted.

Managing Key Definitions

To create a key definition

1. Open the navigation menu. Under **Governance and Administration**, go to **Governance** and click **Tag Namespaces**.
   A list of the tag namespaces in your current compartment is displayed.
2. Click the tag namespace you want to add the tag key definition to.
   A list of the tag key definitions that belong to the namespace is displayed.
3. Click **Create Tag Key Definition**.
4. Enter the following:
   - **Tag Key:** Enter the key. The key can be up to 100 characters in length. Tag keys are case insensitive and must be unique within the tag namespace.
   - **Description:** Enter a friendly description.
   - **Cost-tracking:** Select the check box to enable this tag for cost tracking. You have a limit of 10 cost-tracking tags in your tenancy. For more information, see Using Cost-Tracking Tags.
5. Under **Tag Value Type**, choose one of the following:
   - **Static Value:** Specifies that the user applying the tag can specify any value for this key.
   - **A List of Values:** Specifies that the user must apply a value from a list you create. When you select this option, the **Values** box appears. Type the values from which the user can select. Separate multiple values with new lines. You must have at least one value. You can't have blank lines or duplicate values.

6. Click **Create Tag Key Definition**.

To update a tag key definition

1. Open the navigation menu. Under **Governance and Administration**, go to **Governance** and click **Tag Namespaces**.
   A list of the tag namespaces in your current compartment is displayed.
2. Click the tag namespace that includes the tag key definition you want to update.
   A list of the tag key definitions is displayed.
3. Click the tag key definition you want to update.
   The key definition's details are displayed.
4. Click **Edit Tag Key Definition**.
   The edit dialog appears.
   You can change the description, the tag value type, and enable or disable cost tracking.
   If you chose a list of values, the **Values** box appears, and you must add at least one value. You can't have blank lines or duplicate values in the **Values** box.
   You have a limit of 10 cost-tracking tags in your tenancy. For more information, see Using Cost-Tracking Tags.
5. Make your changes and save it.

To retire a tag key definition

1. Open the navigation menu. Under **Governance and Administration**, go to **Governance** and click **Tag Namespaces**.
   A list of the tag namespaces in your current compartment is displayed.
2. Click the tag namespace that includes the tag key definition you want to retire.
   A list of the tag key definitions is displayed.
3. Click the tag key definition you want to retire.

The tag key definition's details are displayed. If this tag is a cost-tracking tag, disable the cost-tracking flag. If you don't disable cost-tracking, this tag will still count against your tenancy maximum of 10 cost-tracking tags, even after it is retired.

4. Click **Retire Tag Key Definition**.
5. Confirm when prompted.

To reactivate a tag key definition

1. Open the navigation menu. Under **Governance and Administration**, go to **Governance** and click **Tag Namespaces**.
   A list of the tag namespaces in your current compartment is displayed.
2. Click the tag namespace that includes the tag key definition you want to reactivate.
   A list of the tag key definitions is displayed.
3. Click the tag key definition you want to reactivate.
   The tag key definition's details are displayed.
4. Click **Reactivate Tag Key Definition**.
5. Confirm when prompted.

To delete a tag key definition

To delete a tag key definition, you must first retire it.

1. Open the navigation menu. Under **Governance and Administration**, go to **Governance** and click **Tag Namespaces**.
   A list of the tag namespaces in your current compartment is displayed.
2. Click the tag namespace that includes the tag key definition you want to delete.
   A list of the tag key definitions is displayed.
3. Click the retired tag key definition you want to delete.
   The tag key definition's details are displayed.

4. Click **Delete Tag Key Definition**.
5. Confirm when prompted.
   After you click OK, the state changes to Deleting. Track the progress of the operation using the work request.

   ### To track the progress of the delete operation

   a. Open the navigation menu. Under **Governance and Administration**, go to **Governance** and click **Tag Namespaces**.
      A list of the tag namespaces in your current compartment is displayed.
   b. Click the tag namespace that includes the tag key definition you deleted.
      A list of the tag key definitions is displayed.
   c. Click **Work Requests**.
      The work requests for deleted tag definitions are displayed.

To monitor a work request for a deleted tag

1. Open the navigation menu. Under **Governance and Administration**, go to **Governance** and click **Tag Namespaces**.
   A list of the tag namespaces in your current compartment is displayed.
2. Click the tag namespace that includes the tag key definition you deleted.
   A list of the tag key definitions is displayed.
3. Click **Work Requests**.
   The work requests for deleted tag definitions are displayed.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use these API operations to manage tag namespaces:

- GetTagNamespace
- ListTagNamespaces
- CreateTagNamespace
- UpdateTagNamespace - use to retire or reactivate a tag namespace
- DeleteTagNamespace
- ChangeTagNamespaceCompartment

Use these API operations to manage tag key definitions:

- GetTag - gets the tag key definition
- ListTags - lists tag key definitions
- ListCostTrackingTags - lists the tags that have been enabled for cost-tracking (can be performed in the root compartment only)
- CreateTag - creates a tag key definition
- UpdateTag - updates the tag key definition (use this operation to retire or reactivate a tag key)
- DeleteTag - deletes the tag key definition

Use these API operations to manage work requests spawned by the DeleteTag operation:

- ListTaggingWorkRequests
- ListTaggingWorkRequestErrors
- ListTaggingWorkRequestLogs
- GetTaggingWorkRequest

Understanding Free-form Tags

Oracle Cloud Infrastructure supports two kinds of tags: free-form tags and defined tags. This topic describes free-form tags.

Because free-from tags are limited in functionality, Oracle recommends that you only use them when you are first getting started with tagging, to try out the tagging feature in your system. For more information about the features and limitations of free-form tags, see Working with Free-form Tags.

Required IAM Policy

If you're in the Administrators group, then you have the required access for free-form tags. For more policy samples specific to working with free-form tags, see Required Permissions for Working with Free-form Tags.

If you're new to policies, see Getting Started with Policies and Common Policies. If you want to dig deeper into writing policies for groups or other IAM components, see Details for IAM.

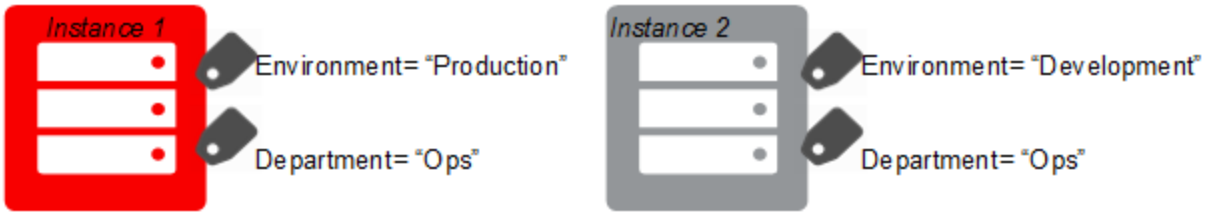
Overview of Free-form Tags

Free-form tags consist simply of a key and a value, for example:

Environment: Production

where "Environment" is the key and "Production" is the value.

You can apply multiple free-form tags to a single resource (up to the limit).



Working with Free-form Tags

Free-form tags consist simply of a key-value pair. Free-form tags have limited features. To experience the full feature set of tagging, use defined tags.

Features of free-form tags include:

- Consist of a key and a value. Free-form tags do not belong to a namespace.
- You can apply free-form tags during resource creation or to an existing resource.
- Free-form tag keys are case sensitive. For example, "Project" and "project" are distinct keys.
- Free-form tag values are case sensitive. For example, "alpha" and "Alpha" are distinct values.

Limitations of free-form tags include:

- When applying a free-form tag, you can't see a list of existing free-form tags, so you don't know what tags and values have already been used.
- You can't see a list of existing free-form tags in your tenancy.
- You can't use free-form tags to control access to resources (that is, you can't include free-form tags in IAM policies).
- You can't use tag variables in free-form tags.
- You can't use predefined values in free-form tags.

Required Permissions for Working with Free-form Tags

To apply, update, or remove free-form tags for a resource, you must have the update permission on the resource. For many resources, the update permission is granted with the `use` verb. For example, users who can use instances in CompartmentA, can also apply, update, or remove free-form tags for instances in CompartmentA.

Some resources don't include the update permission with the `use` verb. To allow a group to apply, update, or remove free-form tags for these resources without granting the full permissions of `manage`, you can add a policy statement to grant only the *<RESOURCE>*_UPDATE permission from the `manage` verb. For example, to allow a group NetworkUsers to work with free-from tags with VCNs in CompartmentA, you could write a policy like:

```
Allow group NetworkUsers to use vcns in compartment CompartmentA

Allow group NetworkUsers to manage vcns in compartment CompartmentA where request.permission='VCN_
UDPATE'
```

The `inspect` verb for a resource grants permissions to view free-form tags for that resource. So users who can `inspect` instances in CompartmentA can also view any free-form tags applied to the instance.

For information about resource permissions, see Policy Reference.

Using Cost-Tracking Tags

You can use cost-tracking tags to help manage costs in your tenancy. Use cost-tracking tags to do any of the following:

- Filter projected costs
- Set budgets

You can only use cost-tracking tag with defined tags. You cannot specify free-form tags as cost-tracking tags.

Required IAM Policy

Cost tracking is a feature of defined tags. To allow users to work with cost tracking, use the same IAM policy for working with managing tag namespaces and tags. For more information, see Required Permissions for Working with Defined Tags.

If you're new to policies, see Getting Started with Policies and Common Policies. If you want to dig deeper into writing policies for groups or other IAM components, see Details for IAM.

Working with Cost-Tracking Tags

Suppose you have a defined tag key definition called Finance.CostCenter. You enable this tag definition for cost tracking. You apply the tag with a value of "W1" (Finance.CostCenter="W1") to some resources, and you apply the tag with a value of "C2" (Finance.CostCenter="C2") to some other resources. These tags enable the following scenarios:

- When you view your Cost Analysis, you can filter the usage information to show you only the costs generated by the resources tagged with "Finance.CostCenter=W1" . You can then filter your usage summary by "Finance.CostCenter=C2".
- Create a budget for resources tagged "Finance.CostCenter=W1" and another budget for resources tagged "Finance.CostCenter=C2". If spending surpasses a certain amount or is forecast to exceed a particular threshold, you can set up alerts that notify you.

Use cost-tracking tags to compare and track resource usage based on tags, or to set up budgets based on resources grouped by tags, rather than by compartments.

Viewing Usage by Cost-Tracking Tags

To view usage by filtering projected costs or creating a budget

- Cost Analysis provides easy-to-use visualization tools to help you track and optimize your spending. For more information, see Checking Your Balance and Usage.
- Budgets can be used to set thresholds for your spending. You can set alerts on your budget to let you know when you might exceed your budget, and you can view all of your budgets and spending from one single place Console. See Budgets Overview for more information.

Limits on Cost-Tracking Tags

- You can have a maximum of 10 tags enabled for cost-tracking in your tenancy at a time. This limitation includes both active and retired tags.

Using the Console

You can enable cost-tracking when you create a tag key definition, or you can update an existing tag key definition to enable cost tracking.

To create a key definition

1. Open the navigation menu. Under **Governance and Administration**, go to **Governance** and click **Tag Namespaces**.
   A list of the tag namespaces in your current compartment is displayed.
2. Click the tag namespace you want to add the tag key definition to.
   A list of the tag key definitions that belong to the namespace is displayed.
3. Click **Create Tag Key Definition**.
4. Enter the following:
   - **Tag Key:** Enter the key. The key can be up to 100 characters in length. Tag keys are case insensitive and must be unique within the tag namespace.
   - **Description:** Enter a friendly description.
   - **Cost-tracking:** Select the check box to enable this tag for cost tracking. You have a limit of 10 cost-tracking tags in your tenancy.
5. Under **Tag Value Type**, choose one of the following:
   - **Static Value:** Specifies that the user applying the tag can specify any value for this key.
   - **A List of Values:** Specifies that the user must apply a value from a list you create. When you select this option, the **Values** box appears. Type the values from which the user can select. Separate multiple values with new lines. You must have at least one value. You can't have blank lines or duplicate values.
6. Click **Create Tag Key Definition**.

To update a tag key definition

1. Open the navigation menu. Under **Governance and Administration**, go to **Governance** and click **Tag Namespaces**.
   A list of the tag namespaces in your current compartment is displayed.
2. Click the tag namespace that includes the tag key definition you want to update.

A list of the tag key definitions is displayed.

3. Click the tag key definition you want to update.
   The key definition's details are displayed.
4. Click **Edit Tag Key Definition**.
   The edit dialog appears.
   You can change the description, the tag value type, and enable or disable cost tracking.
   If you chose a list of values, the **Values** box appears, and you must add at least one value. You can't have blank lines or duplicate values in the **Values** box.
   You have a limit of 10 cost-tracking tags in your tenancy. .
5. Make your changes and save it.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

- ListCostTrackingTags - lists the tags that have been enabled for cost-tracking (can be performed in the root compartment only)

Using Predefined Values

You can create a list of values and associate that list with a tag key definition. When users apply the tag to a resource, they must select a value from the list. Use lists of predefined values to impose limits on the values that users can apply to tags.

You can use predefined values with defined tags and default tags. You cannot create lists of predefined values for free-form tags.

Required IAM Policy

Predefined values are a feature of defined tags. To allow users to work with predefined values, use the same IAM policy for working with managing tag namespaces and tags. For more information, see Required Permissions for Working with Defined Tags.

If you're new to policies, see Getting Started with Policies and Common Policies. If you want to dig deeper into writing policies for groups or other IAM components, see Details for IAM.

Working with Predefined Values

You can update existing tags to use predefined values.

Every predefined list you create must contain at least one value. Your lists can't contain duplicate values or blank entries. With predefined values, users applying tags can't set the value of a tag to `null`. For more information, see Using the Console.

Predefined Values and Default Tags

You can use predefined values and default tags to ensure that users creating resources apply tag values you trust.

Here's how it works:

1. You define a list of predefined values for a tag key.
2. You create a default tag that uses the key with the list of predefined values *and* requires that users who create resources in the compartment add the value to the tag.
3. Oracle prompts all users creating resources in the compartment to enter a tag value. Since the tag key contains a predefined list you created, the value the user applies is a value you trust.

These features help to ensure that new resources contain the values you expect. For more information, see Managing Tag Defaults.

Using the Console

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

To create a key definition

1. Open the navigation menu. Under **Governance and Administration**, go to **Governance** and click **Tag Namespaces**.
   A list of the tag namespaces in your current compartment is displayed.
2. Click the tag namespace you want to add the tag key definition to.
   A list of the tag key definitions that belong to the namespace is displayed.
3. Click **Create Tag Key Definition**.
4. Enter the following:
   - **Tag Key:** Enter the key. The key can be up to 100 characters in length. Tag keys are case insensitive and must be unique within the tag namespace.
   - **Description:** Enter a friendly description.
   - **Cost-tracking:** Select the check box to enable this tag for cost tracking. You have a limit of 10 cost-tracking tags in your tenancy. For more information, see Using Cost-Tracking Tags.
5. Under **Tag Value Type**, choose one of the following:
   - **Static Value:** Specifies that the user applying the tag can specify any value for this key.

- **A List of Values:** Specifies that the user must apply a value from a list you create. When you select this option, the **Values** box appears. Type the values from which the user can select. Separate multiple values with new lines. You must have at least one value. You can't have blank lines or duplicate values.

6. Click **Create Tag Key Definition**.

To update a tag key definition

1. Open the navigation menu. Under **Governance and Administration**, go to **Governance** and click **Tag Namespaces**.
   A list of the tag namespaces in your current compartment is displayed.
2. Click the tag namespace that includes the tag key definition you want to update.
   A list of the tag key definitions is displayed.
3. Click the tag key definition you want to update.
   The key definition's details are displayed.
4. Click **Edit Tag Key Definition**.
   The edit dialog appears.
   You can change the description, the tag value type, and enable or disable cost tracking.
   If you chose a list of values, the **Values** box appears, and you must add at least one value. You can't have blank lines or duplicate values in the **Values** box.
   You have a limit of 10 cost-tracking tags in your tenancy. For more information, see Using Cost-Tracking Tags.
5. Make your changes and save it.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

- CreateTag - creates a tag key definition
- UpdateTag - updates the tag key definition (use this operation to retire or reactivate a tag key)

Using Tag Variables

You can use a variable to set the value of a defined tag. When you add the tag to a resource, the variable resolves to the data it represents. You can use tag variables in defined tags and default tags. You cannot use tag variables in free-form tags.

Required IAM Policy

Tag variables are a feature of defined tags. To allow users to work with tag variables, use the same IAM policy for working with managing tag namespaces and tags. For more information, see Required Permissions for Working with Defined Tags.

If you're new to policies, see Getting Started with Policies and Common Policies. If you want to dig deeper into writing policies for groups or other IAM components, see Details for IAM.

Working with Tag Variables

Consider the following example:

Operations.CostCenter="`${iam.principal.name}` at `${oci.datetime}`"

Operations is the namespace, CostCenter is the tag key, and the tag value contains two tag variables `${iam.principal.name}` and `${oci.datetime}`. When you add this tag to a resource, the variable resolves to your user name (the name of the principal that applied the tag) and a time date stamp for when you added the tag.

```
user_name at 2019-06-18T18:00:57.604Z
```

The variable is replaced with data at the time you apply the tag. If you later edit the tag, the variable is gone and only the data remains. You can edit the tag value in all the ways you would edit any other tag value.

To create a tag variable, you must use a specific format.

```
${<variable>}
```

Type a dollar sign followed by open and close curly brackets. The tag variable goes between the curly brackets. You can use tag variables with other tag variables and with string values.

Supported Tag Variables

The following tag variables are supported.

Variable	Description
`${iam.principal.name}`	The name of the principal that tagged the resource.
`${iam.principal.type}`	The type of principal that tagged the resource.
`${oci.datetime}`	The date and time that the tag was created.

Managing Tag Defaults

This topic describes how to you can specify tags to be automatically applied to resources at creation time.

Required IAM Policy

If you're in the Administrators group, then you have the required access for managing tag defaults and tag namespaces. For specific policy information for this feature, see Required Permissions for Working with Tag Defaults.

If you're new to policies, see Getting Started with Policies and Common Policies. If you want to dig deeper into writing policies for tagging or other IAM components, see Details for IAM.

Overview of Tag Defaults

Tag defaults let you specify tags to be applied automatically to all resources, at the time of creation, in a specific compartment. This feature allows you to ensure that appropriate tags

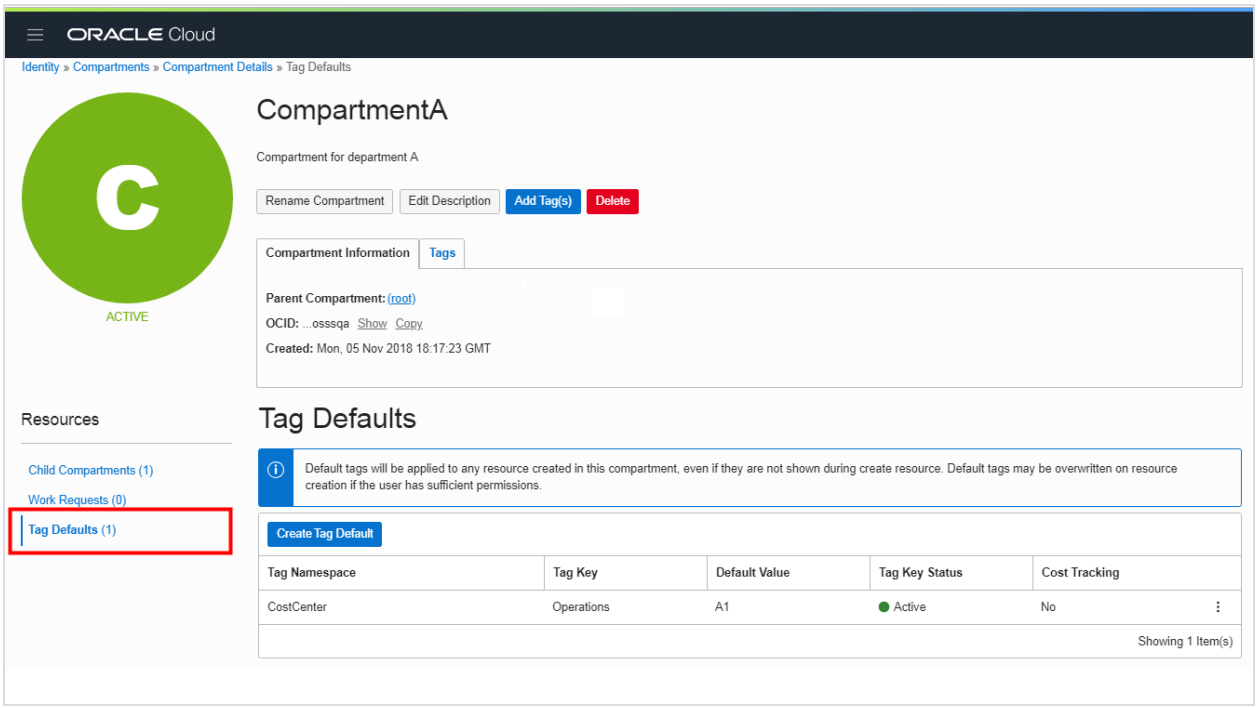
are applied at resource creation without requiring the user who is creating the resource to have access to the tag namespaces. Consider the following example:

Alice is a finance administrator and has access to the restricted tag namespace Finance. Alice can set up a tag default to apply the Finance.CostCenter tag to all resources with a value of W1234. Eli can create resources but does not have access to the Finance tag namespace. When Eli creates a resource, the Finance.CostCenter tag is automatically applied with a value of W1234. Eli cannot change this tag, and Alice is confident that it will always be applied correctly and not changed by the users who create or edit resources.

Tag defaults allow tenancy administrators to create secure permissions boundaries between users concerned with governance and users who need to create and administer resources.

Where to Manage Tag Defaults

Tag defaults are defined for a specific compartment, and in the Console you manage them on the Compartment Details page.



Required Permissions for Working with Tag Defaults

To create or edit a tag default for a compartment, you must be granted, at a minimum, the following combination of permissions:

- `manage tag-defaults` access on the compartment where you are adding the tag default
- `use tag-namespaces` access on the compartment where the tag namespace resides
- `inspect tag-namespaces` access on the tenancy

For the full mapping of permissions to API operations, see Details for IAM.

For example, assume you have created a set of tag namespaces in CompartmentA. To give a group named TagAdmins access to add tag defaults to CompartmentA, write a policy with the following statements:

```
Allow group TagAdmins to manage tag-defaults in compartment CompartmentA

Allow group TagAdmins to use tag-namespaces in compartment CompartmentA

Allow group TagAdmins to inspect tag-namespaces in tenancy
```

Now assume you want to allow TagAdmins to also create tag defaults in CompartmentA using tag namespaces that reside in CompartmentZ. Add a statement to allow TagAdmins to use tag namespaces in CompartmentZ:

```
Allow group TagAdmins to use tag-namespaces in compartment CompartmentZ
```

Now when TagAdmins create tag defaults in CompartmentC, they can use tag namespaces that reside in either CompartmentA or CompartmentZ.

Important

See this known issue for information about the policy statements that are required to use tag defaults with Compute instance pools and cluster networks.

Working with Tag Defaults

Tag defaults can only be set up for defined tags. Free-form tags are not supported for tag defaults.

You can define up to 5 tag defaults per compartment.

After a tag default is created, the default tag is applied to any new resources created in the compartment. Previously existing resources in the compartment are not tagged retro-actively. Similarly, if you change the default value of the tag default, existing occurrences are not updated. And, if you delete the tag default from the compartment, existing occurrences of the tag are not removed from resources.

Required Tag Values

For tag defaults, you must include a tag value, but you have a choice about how the value is applied.

- Default value
- User-applied value

If you use a default value, then you must create it. This value is applied to all resources.

If you specify that a user-applied value is required, then the user creating the resource must enter the value for the tag at resource creation time. Users cannot create resources without entering a value for the tag.

Tip

You can use predefined values and user-applied values to ensure that users only apply a value that you trust. See Using Predefined Values.

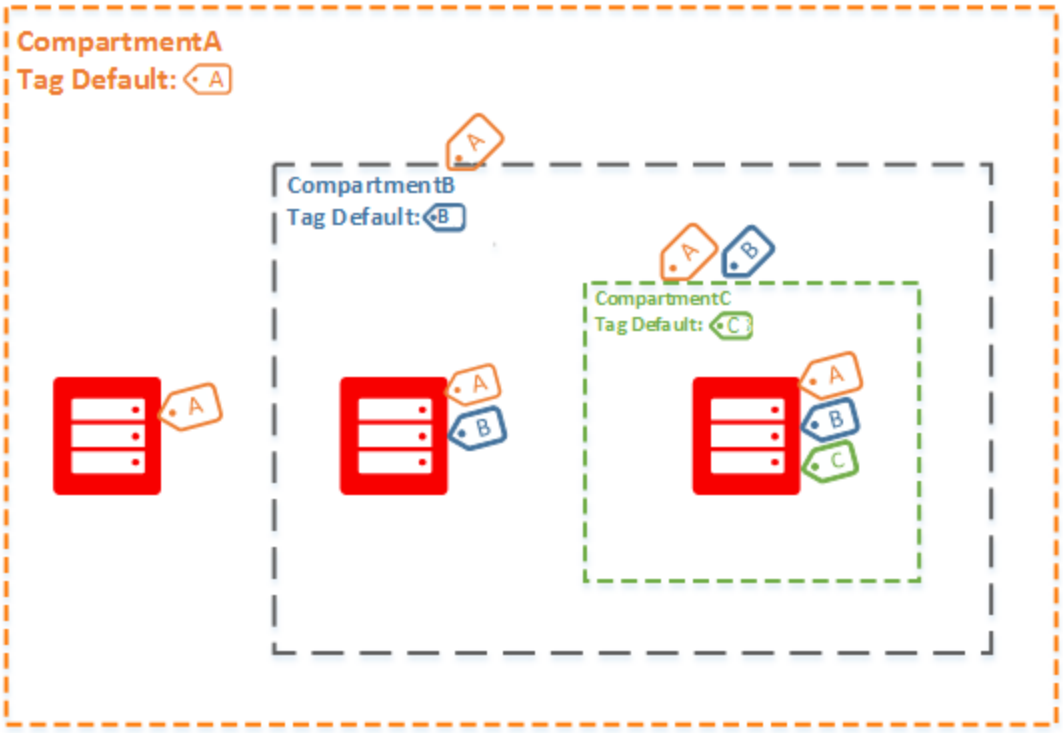
Tag Inheritance

The default tag is applied to all resources that get created in the compartment, including child compartments and the resources created in the child compartments.

Example:

- In CompartmentA, you create a tag default, TagA.
  Resources (and compartments) created in CompartmentA are automatically tagged with TagA.
  - In the subcompartment, CompartmentB, you create tag default, TagB.
    Resources and compartments created in CompartmentB are automatically tagged with TagA and TagB.
    - In the sub-subcompartment, CompartmentC, you create tag default TagC.
      Resources created in CompartmentC are automatically tagged with TagA, TagB, and TagC.

This example is illustrated in the following graphic:



Overriding Tag Defaults

Tag defaults can be overridden at the time of resource creation by users who have the appropriate permissions to both create the resource and use the tag namespace.

Example: CompartmentA has a tag default defined to apply CostCenter.Operations="42". Pradeep belongs to a group that grants him permissions to create instances in CompartmentA and also to use tag namespaces in CompartmentA. He creates an instance in CompartmentA, and in the Create Instance dialog, he applies the tag CostCenter.Operations="50". Because he has the appropriate permissions, when the instance is created, the tag default is overridden, and the instance is tagged with CostCenter.Operations="50".

After a resource is created and tagged, users with the appropriate permissions to both update the resource and use the tag namespace can modify the default tags that were applied at resource creation.

Tag Defaults and Retired Tags

Retired tags can't be applied to new resources. Therefore, if the tag namespace or tag key specified in a tag default is retired, resources can no longer be created in the compartment, because the retired tag cannot be applied. You must delete the tag default that specifies the retired tag to continue to create resources in the compartment.

Tag Defaults and Tag Variables

You can use tag variables in tag defaults. Tag variables dynamically resolve at resource creation time. For example, you enter a tag variable for principal name as the tag default in a particular compartment.

Operations.CostCenter="`${iam.principal.name}`"

Davis and Garcia each create buckets in that compartment. The buckets that Davis creates include default tags that contain his name as the value, while the buckets that Garcia creates have his name.

```
Operations.CostCenter="Davis"

Operations.CostCenter="Garcia"
```

Meanwhile, the tag default still contains the original variables. See Using Tag Variables.

Limits on Tag Defaults

There is a limit of 5 tag defaults that can be defined per compartment.

See Limits on Tags for more limits on tags.

Using the Console

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

To create a tag default

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Compartments**.
   A list of the compartments you have access to is displayed.
2. In the list, find the name of the compartment you want to add a tag default to and click its name.
3. On the compartment details page, click **Tag Defaults**.
   The list of existing tag defaults is displayed.
4. Click **Create Tag Default**.
5. Enter the following (all fields are required):
   - **Tag Namespace:** Select the tag namespace for the tag default.
   - **Tag Key:** Select the tag key.
6. Specify the type of value you want this tag to have:
   - **Default Value:** Enter the value you want this tag to have.
   - **User-applied Value:** Users that create resources must enter the value as resources are created.
7. Click **Create Tag Default**.

To update the default value of a tag default

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Compartments**.
   A list of the compartments you have access to is displayed.
2. In the list, click the name of the compartment that has the tag default you want to update.
3. On the compartment details page, click **Tag Defaults**.
   The list of existing tag defaults is displayed.
4. Find the tag default you want to update. Go to the the Actions icon (three dots) and click **Edit**.
5. Specify the type of value you want this tag to have:
6. - **Default Value:** Enter the value you want this tag to have.
   - **User-applied Value:** Users that create resources must enter the value as resources are created.
7. Click **Save Changes**.

To delete a tag default

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Compartments**.
   A list of the compartments you have access to is displayed.
2. In the list, click the name of the compartment that has the tag default you want to delete.
3. On the compartment details page, click **Tag Defaults**.
   The list of existing tag defaults is displayed.
4. Find the tag default you want to delete. Go to the the Actions icon (three dots) and click **Delete**.
5. Confirm when prompted.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use these API operations to manage tag defaults:

- GetTagDefault
- ListTagDefaults
- CreateTagDefault
- UpdateTagDefault
- DeleteTagDefault

CHAPTER 33 Web Application Firewall

This chapter explains how to make your endpoints more secure by monitoring and filtering out potentially malicious traffic.

Overview of the Web Application Firewall Service

Oracle Cloud Infrastructure Web Application Firewall (WAF) is a cloud-based, Payment Card Industry (PCI) compliant, global security service that protects applications from malicious and unwanted internet traffic. WAF can protect any internet facing endpoint, providing consistent rule enforcement across a customer's applications.

WAF provides you with the ability to create and manage rules for internet threats including Cross-Site Scripting (XSS), SQL Injection and other OWASP-defined vulnerabilities. Unwanted bots can be mitigated while tactically allowed desirable bots to enter. Access rules can limit based on geography or the signature of the request.

The global Security Operations Center (SOC) will continually monitor the internet threat landscape acting as an extension of your IT infrastructure.

Web Application Firewall Service Components

WEB APPLICATION FIREWALL POLICY

WAF policies encompass the overall configuration of your WAF service, including origin management, protection rule settings, and bot detection features.

ORIGIN

Your web application's origin host server. An origin must be defined in your WAF policy in order to set up protection rules or other features.

PROTECTION RULES

Protection rules can be configured to either allow, block, or log network requests when they meet the specified criteria of a protection rule. The WAF will observe traffic to your web

application over time and suggest new rules to apply. To view a list of available WAF rules, see Supported Protection Rules.

BOT MANAGEMENT

The WAF service includes several features that allow you to detect and either block or allow identified bot traffic to your web applications. Bot management features include: JavaScript Challenge, CAPTCHA Challenge, and GoodBot whitelists. For more information, see Bot Management.

Ways to Access the WAF Service

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface), command line interface (CLI), or the REST API. Instructions for the Console and API are included in topics throughout this guide.

To access the Console, you must use a supported browser. You can use the Console link at the top of this page to go to the sign-in page. Enter your tenancy, user name, and your password.

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies. For specific details about writing policies for each of the different services, see Policy Reference.

If you're a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

Note About The API

The WAF service is powered by the Oracle Cloud Infrastructure Web Application Acceleration and Security (WAAS) API. All WAF related calls must be made using the WAAS API. To create a WAF configuration using the API, you must first create a WAAS policy with a defined origin and domain using the API. For the purposes of access control, you must provide the OCID of the compartment where you want the service to reside. For information about access control and compartments, see Overview of the IAM Service.

WAF Service Capabilities and Limits

The WAF service is limited to 50 policies per tenant and 100 access rules per policy. See Service Limits for a list of applicable limits and instructions for requesting a limit increase. To set compartment-specific limits on a resource or resource family, administrators can use compartment quotas.

The WAF service allows a total run time of 20 minutes for upload and download processes through the WAF.

Required IAM Service Policy

To use Oracle Cloud Infrastructure, you must be given access in a policy for waas-policy. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

Policy examples:

- To allow a specific user group to manage policies in the WAF:

```
Allow group <GroupName> to manage waas-policy in compartment <CompartmentName>
```

```
Allow group <GroupName> to read waas-work-request in compartment <CompartmentName>
```

- To allow a specific user group to manage certificates in the WAF:

```
Allow group <GroupName> to manage waas-certificate in compartment <CompartmentName>
```

- To allow a specific user group view policies in the WAF

```
Allow group <GroupName> to read waas-policy in tenancy <TenancyName>
```

If you're new to policies, see Getting Started with Policies and Common Policies. For more details about policies for WAF, see Details for the WAF Service.

Moving WAF Policies to a Different Compartment

You can move WAF policies from one compartment to another. After you move a WAF policy to the new compartment, inherent policies apply immediately and affect access to the WAF policies through the Console, SDK or CLI. For more information, see Managing Compartments.

Monitoring Resources

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications. For more information, see Monitoring Overview and Notifications Overview.

For information about available WAF service metrics and how to view them, see WAF Metrics.

Creating Automation with Events

You can create automation based on state changes for your Oracle Cloud Infrastructure resources by using event types, rules, and actions. For more information, see Overview of Events.

Tagging Resources

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the desired tags. For general information about applying tags, see Resource Tags.

Getting Started with WAF

If you're new to Oracle Cloud Infrastructure WAF, this topic gives guidance on how to proceed.

Before You Begin

To begin using the WAF service, you must have the following available if you plan to run your site on HTTPS/443:

- Public certificate for the fully qualified domain name (FQDN) of the application.
- Corresponding private key for the site.
- IP address of the LBaaS or other public facing endpoint of application.
- Ability to update DNS records for the domain.

Securing Your WAF

To secure your WAF, you must configure your servers to accept traffic from the WAF servers. Configure your origin's ingress rules to only accept connections from the following CIDR ranges:

- 192.157.18.0/23
- 205.147.88.0/21
- 192.69.118.0/23
- 198.181.48.0/21
- 199.195.6.0/23

Create a Policy to Route Traffic Through the WAF

To begin, create a policy to route traffic through the WAF without rules enabled. Creating a policy without rules enabled ensures that there are no regressions by having a reverse proxy in front of the application.

To create a policy

1. Select the region and compartment where the policy should be maintained (there is no constraint around the WAF co-existing with Load Balancing or other application resources in Oracle Cloud Infrastructure.
2. Open the navigation menu. Under **Governance and Administration**, go to **Security** and click **WAF Policies**.
3. Click **Create WAF Policy**.
4. In the **Create WAF Policy** dialog box, enter the following:
    - **Policy Name:** A unique name for the policy. Avoid entering confidential information.
    - **Domains:**
        - **Primary Domain**: The fully qualified domain name (FQDN) of the application where the policy will be applied.
        - **Additional Domains**: (Optional) Subdomains where the policy will be applied.
    - **WAF Origin:** The host or IP address of the public internet facing application that is being protected by the application.
        - **Origin Name**: A unique name for the origin.
        - **URI** - Enter the public facing endpoint (IPv4 or FQDN) of the application.
        - **HTTPS Port**: The port used for secure HTTP connection. The default port is 443.
        - **HTTP Port**: The HTTP port the origin listens on. The default port is 80.
        - **Header(s):** (Optional)
            - **Header Name**: The name displayed in the HTTP request header and the header value that can be added and passed to the origin server with all requests.
            - **Header Value**: Specifies the data requested by the header.

- **Tags**: Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.

5. Click **Create WAF Policy**. The WAF Policy overview appears. Expect the policy to become active within 15 minutes of creation.

Update DNS to Enable WAF

In this step, you update the CNAME for your zone to route requests from internet clients to WAF. Use the following instructions to make this DNS change in the Console. If your DNS setup resides with another provider, refer to their documentation for instructions.

To update the CNAME for your zone

1. In the Policy Information tab of the WAF Policy overview, select the CNAME Target.
2. Copy the CNAME target to your clipboard.
3. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **DNS Zone Management**.
4. Click the Zone Name of the primary domain where you want to update the record. Zone details and a list of records appear.
5. Select the check box for the CNAME record and select **Edit** from the **Actions** drop-down menu.
6. In the **Edit Record** dialog box, update the Target field with the CNAME Target from your clipboard.
7. Click **Submit**.
8. Click **Publish Changes**.
9. In the confirmation dialog box, click **Publish Changes**.

Upload Your Certificate and Key

This step assumes that your site runs on HTTPS/443.

To upload your certificate and key

1. Open the navigation menu. Under **Governance and Administration**, go to **Security** and click **WAF Policies**.
2. Click the name of your WAF Policy. The WAF Policy overview appears.
3. Click **Settings**.
4. Click **Edit**.
5. In the **Edit Settings** dialog box, enter the following:
    - **WAF Origin:** Select the name and IP address of the origin.
    - **Enable HTTPS Support:** Select this option so that communications between the browser and web app are encrypted. Enter the following information:
        - **SSL Certificate:** Drag and drop, select, or paste a valid SSL certificate in PEM format. You must also include intermediate certificates (the website certificate must be first). The following is an example:

          ```
          -----BEGIN CERTIFICATE-----
          <Base64_encoded_certificate>
          -----END CERTIFICATE-----
          -----BEGIN CERTIFICATE-----
          <Intermediate_Base64_encoded_certificate>
          -----END CERTIFICATE-----
          ```

        - **Private Key:** Drag and drop, select, or paste a valid private key in PEM format in this field. The private key cannot be protected by a passphrase. The following is an example:

          ```
          -----BEGIN PRIVATE KEY-----
          <Base64_encoded_private_key>
          -----END PRIVATE KEY-----
          ```

- **Self Signed Certificate:** Enable this field when using a self-signed certificate to show an SSL warning in the browser.
- **HTTP to HTTPS Redirect:** When enabled, all HTTP traffic is automatically redirected to HTTPS.

6. Click **Save**. Updates to your WAF policy appear in the list to be published in Unpublished Changes.
7. In the WAF Policy overview, under **Unpublished Changes**, click **View**.
8. In the Unpublished Changes list, click the drop-down arrow beside an unpublished change to review the change.
9. Click **Publish All**.
10. In the Publish Changes dialog box, click **Publish All**.

Test Your Application

In this step, you ensure that requests are being routed to the WAF and that your application continues to function normally with a reverse proxy in the topology.

To test your application

1. Open a browser.
2. Enter the FQDN of the website protected by WAF.
3. Test the functionality of the application.
4. Inspect HTTP Response Headers to see if traffic is flowing through WAF. Some HTTP Response Headers to look for are:
   - X-Cdn: Served-By-Zenedge
   - Server: ZENEDGE
5. Open the navigation menu. Under **Governance and Administration**, go to **Security** and click **WAF Policies**.
6. Click the name of your WAF Policy. The WAF Policy overview appears.

7. Under **Logs**, click **View**. Logs for the WAF policy appear.

Note

You may experience a one-minute delay on logs aggregated and available through the console.

8. Copy the IP address and User-Agent value of your requests to your clipboard. You can use this information when you enable WAF to passively detect for access rules.

Enable WAF to Passively Detect Rules

In this step, you enable WAF to detect protection rules without blocking requests. Enabling WAF to passively detect rules helps you visualize the traffic that may pose a threat to your site and help you tune the WAF to exclude false positives.

To enable WAF to detect protection rules

1. Open the navigation menu. Under **Governance and Administration**, go to **Security** and click **WAF Policies**.
2. Click the name of the WAF Policy you want to configure rule settings for. The WAF Policy overview appears.
3. Click **Protection Rules**.
4. Use the Protection Rules table to locate the rules you want to detect.
5. Enter the Rule IDs you located from the table into the **Rule ID** filter. For this example, enter **941140** (Cross-Site Scripting) in the **Rule ID** filter.
6. Select **Detect** from the **Actions** drop-down menu for the protection rules you filtered.

To enable WAF to detect access rules

1. Open the navigation menu. Under **Governance and Administration**, go to **Security** and click **WAF Policies**.
2. Click the name of the WAF Policy you want to configure access rules for. The WAF Policy overview appears.
3. Click **Access Control**.
4. Click **Add Access Rule**.
5. In the Add Access Rule dialog box, enter the following:
    a. **Name:** DetectRequestsFromMySpecificBrowser
    b. **Rule Condition:** Select **IP Address is** from the drop-down and enter the IP address you copied to your clipboard while testing your application in the **IP Address** field.
    c. Click **+Additional Condition**.
    d. **Rule Condition:** Select **User Agent is** from the drop-down and enter the agent value you copied to your clipboard while testing your application in the **User Agent Header** field.
    e. **Rule Action:** Select **Detect Only**.

Note

Both the IP Address and the User Agent in the preceding example must match for the rule to be triggered. If a different User Agent is used to test your application, the request will not be detected.

6. Click **Add Access Rule**.
7. Click **Unpublished Changes**.

8. Click **Publish All**.

Test the Rules

When the policy is active, you can test that your rules are detected by WAF.

To initiate requests

1. Use the same browser you used when you tested your application to do the following:
    a. Request the FQDN of your application.
    b. Request the FQDN of your application with the following query parameter appended: `?id=<script>alert("TEST");</script>`.
2. Use a different browser on the same machine and repeat the preceding requests. All requests should go through the application.

To verify that WAF is detecting requests

To verify that WAF is detecting requests identified as a risk:

1. Open the navigation menu. Under **Governance and Administration**, go to **Security** and click **WAF Policies**.
2. Click the name of the WAF Policy you want to view logs for. The WAF Policy overview appears.
3. Click **Logs**. Logs for the WAF policy appear.
4. Select the **Detect** check box from the **Actions** filter.
5. Verify that there are two entries for the protection rule triggered by the Cross-Site Scripting request and one entry for detecting the User Agent and IP Address.

View Recommendations

To view protection rule recommendations

1. Open the navigation menu. Under **Governance and Administration**, go to **Security** and click **WAF Policies**.
2. Click the name of the WAF Policy you want to view protection rule recommendations for. The WAF Policy overview appears.
3. Click **Protection Rules**.
4. Click the **Recommendations** tab. This list is generated based on the traffic the WAF detects flowing through the WAF. If nothing appears in this list, keep testing the FQDN of your application and check back later.
5. Select the protection rules with a **Detect** recommended action and then click **Accept Recommendations**.

Tip

You can use the **Recommended Action** filter to locate a recommendation by **Detect**.

Enable WAF to Actively Block Requests

After you verify that requests are being detected, you can start blocking the undesired traffic.

1. Open the navigation menu. Under **Governance and Administration**, go to **Security** and click **WAF Policies**.
2. Click the name of the WAF Policy you want to configure rule settings for. The WAF Policy overview appears.
3. Click **Protection Rules**.
4. Enter rule ID **941140** in the **Rule ID** filter.
5. (Optional) To search for rules with a Detect action, select the **Detect** check box from the **Rule Action** filter.
6. Select **Block** from the **Actions** drop-down menu for rule ID **941140** and any other protection rules you filtered.

7. Under WAF Policy, click **Unpublished Changes**.
8. Click **Publish All**.
9. In the Publish Changes dialog box, click **Publish All**.
10. Test the rules again by initiating requests. You should get 403 Forbidden errors when testing with the JavaScript on the URL.

Managing WAF Policies

The Oracle Cloud Infrastructure WAF service enables you to create a WAF policy and origin.

Order of Processing

The order in which rules and handlers are processed is:

1. IP Whitelists/Blacklists/Good Bot Whitelists
2. Access Rules
3. JavaScript Challenge
4. Device Fingerprinting Challenge (available in the API)
5. Human Interaction Challenge (available in the API)
6. Captcha Challenge
7. Protection Rules
8. Rate Limiting (available in the API)

Using the Console

Create and Manage WAF Policies

To create a WAF policy

1. Open the navigation menu. Under **Governance and Administration**, go to **Security**

and click **WAF Policies**.

2. Click **Create WAF Policy**.

3. In the **Create WAF Policy** dialog box, enter the following:
    - **Policy Name:** A unique name for the policy. Avoid entering confidential information.
    - **Domains:**
        - **Primary Domain**:The fully qualified domain name (FQDN) of the application where the policy will be applied.
        - **Additional Domains**: (Optional) Subdomains where the policy will be applied.
    - **WAF Origin:** The host or IP address of the public internet facing application that is being protected by the application.
        - **Origin Name**: A unique name for the origin. Avoid entering confidential information.
        - **URI**: The IPv4 address or fully qualified domain name (FQDN) of the origin. The URI can be a full URI, not just a host/IP.
        - **HTTPS Port**: The port used for secure HTTP connection. The default port is 443.
        - **HTTP Port**: The HTTP port the origin listens on. The default port is 80.
        - **Header(s):** (Optional)
            - **Header Name**: The name displayed in the HTTP request header and the header value that can be added and passed to the origin server with all requests.
            - **Header Value**: Specifies the data requested by the header.
    - **Tags**: Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.

Note

You can add multiple origins to your WAF policy and load balance them accordingly using the `orgins` and `originGroups` field of the UpdateWaasPolicy operation in the WAAS API.

4. Click **Create WAF Policy**. The WAF Policy overview appears. You can access Origin Management, Access Control, WAF, Bot Management, Alerts, and any unpublished changes. While the policy is being created, no changes can be made until the process has completed. Expect the policy to become active within 15 minutes of creation.
   A CNAME target is generated for each policy. The CNAME target is a hyphenated version of your FQDN within the Oracle Cloud Infrastructure domain (for example, myapp-mydomain-com.oraclecloud.net).
5. In your DNS zone, update the CNAME record entry with the value of the CNAME target that is generated. This enables traffic to be routed through the WAF before the application. This value is presented soon after you publish your policy the first time on the main page of the policy.

To update a WAF policy

1. Open the navigation menu. Under **Governance and Administration**, go to **Security** and click **WAF Policies**.
2. Click the name of the WAF Policy you want to update. The WAF Policy overview appears.

Tip

You can use the Date Created sort filter to sort policies by the date they were created in ascending or descending order.

3. Click **Edit**.
4. In the Edit WAF Policy dialog box, make the needed changes and then click **Save**.

To delete a WAF policy

1. Open the navigation menu. Under **Governance and Administration**, go to **Security** and click **WAF Policies**.
2. Select the check box for the policy you want to delete.

Tip

You can use the Date Created sort filter to sort policies by the date they were created in ascending or descending order.

3. Click **Delete**.
4. In the confirmation dialog box, click **Delete**.
   The status of the policy changes from **Active** to **Deleting**. Deleted policies are maintained for a short time before they are unavailable in the Console.

To publish changes

Updates to your WAF policy appear in the list to be published in Unpublished Changes. Pending

changes do not persist across browser sessions. Once you publish changes, it cannot be edited until changes propagate to the edge nodes.

1. In the WAF Policy overview, click **Unpublished Changes**.
2. In the Unpublished Changes list, click the drop-down arrow beside an unpublished change to review the change.
3. Click **Publish All**.
4. In the Publish Changes dialog box, click **Publish All**.

To manage tags for a WAF policy

1. Open the navigation menu. Under **Governance and Administration**, go to **Security** and click **WAF Policies**.
2. Click the name of the WAF Policy you want to view. The WAF Policy overview appears.
3. Click the **Tags** tab to view or edit existing tags. Or click **Apply tag(s)** to add new ones.

For more information, see Resource Tags.

To move a WAF policy to a different compartment

1. Open the navigation menu. Under **Governance and Administration**, go to **Security** and click **WAF Policies**.
2. In the **Scope** section, select a compartment.
3. Find the WAF policy in the list, click the the Actions icon (three dots), and then click **Move Resource to a Different Compartment**.
4. Choose the destination compartment from the list.
5. Click **Move Resource**.

Using the CLI

Open a command prompt and run the following command to get the details of a WAAS policy:

```
oci waas waas-policy get --waas-policy-id <policy_ocid>
```

This can be useful in retrieving the necessary information when opening a ticket with Oracle Cloud Infrastructure support. For more information about how to access and use the CLI, see Command Line Interface (CLI).

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

- CreateWaasPolicy
- GetWaasPolicy
- UpdateWaasPolicy
- DeleteWaasPolicy
- ChangeWaasPolicyCompartment

Origin Management

An origin is an endpoint (typically an IP address) of the application protected by the WAF. An origin can be an Oracle Cloud Infrastructure load balancer public IP address. A load balancer IP address can be used for high availability to an origin. Multiple origins can be defined, but only a single origin can be active for a WAF.

You can set HTTP headers for outbound traffic from the WAF to the origin server. These name value pairs are then available to the application.

Securing Your WAF

To secure your WAF, you must configure your servers to accept traffic from the WAF servers. Configure your origin's ingress rules to only accept connections from the following CIDR ranges:

- 192.157.18.0/23
- 205.147.88.0/21
- 192.69.118.0/23
- 198.181.48.0/21
- 199.195.6.0/23

Using the Console

To add an origin to your WAF policy

1. Open the navigation menu. Under **Governance and Administration**, go to **Security** and click **WAF Policies**.
2. Click the name of the WAF Policy you want to add an origin to. The WAF Policy overview appears.
3. Click **Origin Management**.
4. Click **Add Origin**.
5. In the **Add Origin** dialog box, enter the following:
    - **Origin Name**: A unique name for the origin. Avoid entering confidential information.
    - **URI**: The IPv4 address or fully qualified domain name (FQDN) of the origin. The URI can be a full URI, not just a host/IP.
    - **Set as WAF origin?**: Enable this field to designate this origin as the WAF origin.
    - **HTTPS PORT**: The port used for secure HTTP connection. The default is 443.
    - **HTTP PORT**: The HTTP port the origin listens on. The default is 80.
    - **Header(s)**: (Optional) The name displayed in the HTTP request header and the header value that can be added and passed to the origin server with all requests. Additional headers can be added here.
6. Click **Add Origin**. The origin is added to the Origin Management list. You can now

configure WAF rules.

Note

You can add multiple origins to your WAF policy and load balance them accordingly using the `orgins` and `originGroups` field of the UpdateWaasPolicy operation in the WAAS API.

To edit an origin

1. Open the navigation menu. Under **Governance and Administration**, go to **Security** and click **WAF Policies**.
2. Click the name of the WAF Policy you want to edit the origin for. The WAF Policy overview appears.
3. Click **Origin Management**.
4. In the Origin Management view, select the check box for the origin you want to edit.
5. Click **Edit**.
6. In the Edit Origin dialog box, make the needed changes.
7. Click **Save Origin**.

To delete an origin

1. Open the navigation menu. Under **Governance and Administration**, go to **Security** and click **WAF Policies**.
2. Click the name of the WAF Policy you want to delete an origin from. The WAF Policy overview appears.
3. Click **Origin Management**.

4. In the Origin Management view, select the check box for the origin you want to delete.
5. Click **Delete**.
6. In the confirmation dialog box, click **Delete**.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

- CreateWaasPolicy
- GetWaasPolicy
- UpdateWaasPolicy To remove an origin from the policy using the API, use the `UpdateWaasPolicy` method and leave the origin field empty upon update.

Each origin has a unique name (key). The name of the origin to be used by the WAF must be referenced in the `wafConfig` portion of the settings. For example, if you have the following origins in your configuration:

```
{

"compartmentId": "ocid1.compartment.oc1..aaaaatsdfssdfsdsdfsgxz",
"lifecycleState": "ACTIVE",
"displayName": "myWAFprotectedApp",
"origins": {
"primaryorigin": {
"httpPort": 80,
"httpsPort": 443,
"uri": "67.205.161.231",
"customHeaders": []
},

"secondaryorigin": {
"httpPort": 80,
"httpsPort": 443,
"uri": "54.175.154.7",
```

```
                    "customHeaders": [
                    {
                    "name": "OriginHeader",
                    "value": "true"
                    },
                    {
                    "name": "OriginHeader2",
                    "value": "true"
                    }
                    ]
                }
```

Then within the `wafConfig`, the origin in use would be referenced by name:

```
                    "wafConfig": {
                    "deviceFingerprintChallenge": {"isEnabled": false},
                    "origin": "secondaryorigin",
                    "whitelists": [],
```

In this example, the WAF is actively using `secondaryorigin`.

Bot Management

Bot Management enables you to mitigate undesired bot traffic from your site using CAPTCHA and JavaScript detection tools, while enabling known published bot providers to bypass these controls.

Non-human traffic makes up most of the traffic to sites. Bot Manager is designed to detect and block, or otherwise direct, non-human traffic that may interfere with site operations. The Bot Manager features mitigate bots that conduct content and price scraping, vulnerability scanning, comment spam, brute force attacks, and application-layer DDoS attacks. You can also whitelist good bots.

Warning

When you enable Bot Management, you incur a higher rate on requests to the WAF.

JavaScript Challenge

JavaScript Challenge validates that the client can accept JavaScript with a binary decision. JavaScript Challenge is generally the first level of bot mitigation, but not sufficient with more advanced bot tools, which require more advanced challenges. Additional functionality, like detecting Network Address Translation (NAT) traffic, can mitigate the risk of blocking legitimate user traffic from users behind a shared IP address.

The **Action Threshold** parameter defines the number of requests that fail the challenge before the action is taken. The requests that fail under this threshold are not logged. For example, if you set the JavaScript challenge action to **Block** and the **Action Threshold** to 10, and a client that doesn't accept JavaScript makes 11 requests within the **Action Expire Time**, the first 10 requests will be allowed through to origin (assuming there are no other rules) and logs will show one **Block** entry action taken for the JavaScript Challenge.

CAPTCHA Challenge

If a specific URL should be accessed only by a human, you can control it with CAPTCHA protection. You can customize the comments for the CAPTCHA Challenge for each URL. Bots are kept from accessing protected web application functionality using CAPTCHA images designed to be out of reach of computer vision and OCR technologies.

Good Bot Whitelist

Good Bots provides the list of bots managed by known providers, such as Baidu or Google. You can allow the access from a specific good bot, or block the bot if they serve no business purpose. Allowed good bots from this section are whitelisted.

Whitelisted bots are flagged with a Bypass action in the WAF policy Logs. You can select the **Bypass** check box from the **Action** filter in Logs to search for the traffic allowed from these rules. Logged good bot events are categorized as a Threat Intelligence Leads log type, however, they are not a threat when the action taken is to Bypass.

The list of good bots on this menu are managed and continuously updated. Additional good bots can be added as a new access control rule in Access Control.

Using the Console

To configure JavaScript Challenge settings

1. Open the navigation menu. Under **Governance and Administration**, go to **Security** and click **WAF Policies**.
2. Click the name of the WAF Policy you want to configure JavaScript Challenge settings for. The WAF Policy overview appears.
3. Click **Bot Management**.
4. Click **Enable JavaScript Challenge**.
5. In the JavaScript Challenge dialog box, select the **Enable JavaScript Challenge** check box.
6. In the JS Challenge Action section, choose one of the following methods:
    - **Detect Only:** Select this option if you want to be alerted for every matched request.
        - **Set Header for Failed Request:** (Optional) Select this check box to specify an additional HTTP header to requests that fail the challenge.
    - **Block:** Select this option to block requests by returning a response code, error page, or CAPTCHA.
        - **Block Action**: Select the action that will be taken when a matching request is blocked.
        - **Block Response Code:** Select a status code to return in response to blocked requests.
7. Enter the following information:
    - **Action Threshold**: Specify the number of failed requests before taking action.
    - **Action Expire Time**: Enter the number of seconds between challenges to the same IP address.
8. Click **Save**.

The JavaScript Challenge is added to the list of changes to be published.

To edit JavaScript Challenge settings

1. Open the navigation menu. Under **Governance and Administration**, go to **Security** and click **WAF Policies**.
2. Click the name of the WAF Policy you want to edit JavaScript Challenge settings for. The WAF Policy overview appears.
3. Click **Bot Management**.
4. Click **Edit JavaScript Challenge**.
5. In the **Edit JavaScript Challenge** dialog box, make the needed changes.
6. Click **Save**.

To add a CAPTCHA Challenge

1. Open the navigation menu. Under **Governance and Administration**, go to **Security** and click **WAF Policies**.
2. Click the name of the WAF Policy you want to edit CAPTCHA challenge settings for. The WAF Policy overview appears.
3. Click **Bot Management**.
4. Click the **CAPTCHA Challenge** tab.
5. Click **Add CAPTCHA Challenge**.
6. In the Add CAPTCHA Challenge dialog box, enter the following information:
    - **CAPTCHA Title**: Enter the text for the CAPTCHA page title.
    - **CAPTCHA URL Path**: Enter the URL path challenged by CAPTCHA.
    - **Session Duration**: Enter the number of seconds after which the CAPTCHA challenge cannot be resubmitted to the same user.

- **CAPTCHA Header**: Enter the text that will appear before the CAPTCHA image (for example, "I am not a robot").
- **Footer Text:** Enter the text that will be shown after the CAPTCHA input box and before the submit button.
- **Incorrect CAPTCHA Text**: Enter the text that will appear when incorrect text is entered (for example, "The CAPTCHA was incorrect. Please try again.").
- **Submit button**: Enter the text for the Submit button (for example, "Yes, I am human.").

7. Click **Preview CAPTCHA** to preview the CAPTCHA challenge in a new tab.
8. Click **Add**.

To edit a CAPTCHA Challenge

1. Open the navigation menu. Under **Governance and Administration**, go to **Security** and click **WAF Policies**.
2. Click the name of the WAF Policy you want to edit CAPTCHA Challenge settings for. The WAF Policy overview appears.
3. Click **Bot Management**.
4. Click the **CAPTCHA Challenge** tab.
5. Select the check box for the CAPTCHA you want to edit.
6. Select **Edit** from the **Actions** drop-down menu.
7. Update the CAPTCHA Challenge and then click **Save**.

To delete a CAPTCHA Challenge

1. Open the navigation menu. Under **Governance and Administration**, go to **Security** and click **WAF Policies**.
2. Click the name of the WAF Policy you want to delete CAPTCHA Challenge settings for.

The WAF Policy overview appears.

3. Click **Bot Management**.
4. Click the **CAPTCHA Challenge** tab.
5. Select the check box for the CAPTCHA Challenge you want to delete.
6. Select **Delete** from the **Actions** drop-down menu.
7. In the Confirm dialog box, click **Delete**.

The deleted CAPTCHA Challenge is added to the list of changes to be published.

To manage the Good Bots Whitelist

1. Open the navigation menu. Under **Governance and Administration**, go to **Security** and click **WAF Policies**.
2. Click the name of the WAF Policy you want to configure Bot Management for. The WAF Policy overview appears.
3. Click **Bot Management**.
4. Click the **Good Bots Whitelist** tab.
5. Select each bot you want to designate as a good bot.

The designated good bots are added to the list of changes to be published.

To publish changes

Updates to your WAF policy appear in the list to be published in Unpublished Changes. Pending changes do not persist across browser sessions. Once you publish changes, it cannot be edited until changes propagate to the edge nodes.

1. Under WAF Policy, click **Unpublished Changes**.
2. In the Unpublished Changes list, click the drop-down arrow beside an unpublished change to review the change.

3. Click **Publish All**.
4. In the Publish Changes dialog box, click **Publish All**.

To discard changes

Updates to your WAF policy appear in the list to be published in Unpublished Changes.

1. Under WAF Policy, click **Unpublished Changes**.
2. In the Unpublished Changes list, click the drop-down arrow beside an unpublished change to review the change.
3. Select the check box for the change you want to discard.
4. Click **Discard**.
5. In the Discard Change dialog box, click **Discard**.

Using the CLI

You can use the CLI to enable rate limiting, device fingerprinting, and human interaction challenges.

To enable rate limiting

Open a command prompt and run the following command to enable rate limiting:

```
oci waas address-rate-limiting update-waf --is-enabled true  --allowed-rate-per-address 1 --max-delayed-count-per-address 2 --waas-policy-id <policy_ocid>
```

This default rate limit setting will allow one request per second before starting to delay. It will delay for two requests until the traffic falls within the threshold boundaries. It will use the default error response code of 503.

To enable device fingerprinting to detect

Open a command prompt and run the following command to enable device fingerprinting to

detect:

```
oci waas device-fingerprint-challenge update --is-enabled true --action DETECT --failure-threshold 2 --
action-expiration-in-seconds 240 --failure-threshold-expiration-in-seconds 600 --max-address-count 2 --
max-address-count-expiration-in-seconds 255 --waas-policy-id <policy_ocid>
```

To enable the human interaction challenge to detect

Open a command prompt and run the following command to enable the human interaction challenge to detect:

```
oci waas human-interaction-challenge update --is-enabled true  --waas-policy-id <policy_ocid>
```

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

- UpdateJsChallenge
- GetJsChallenge
- UpdateCaptchas
- GetCaptchas
- GetDeviceFingerprintChallenge
- UpdateDeviceFingerprintChallenge
- GetHumanInteractionChallenge
- UpdateHumanInteractionChallenge
- GetWafAddressRateLimiting
- UpdateWafAddressRateLimiting

WAF Protection Rules

Protection rules match web traffic to rule conditions and determine the action to be taken when the conditions are met. Protection Rule Settings allow you to define the parameters for enforcement any time a protection rule is matched. Recommendations aid in the optimization of your WAF security profile. The Security Operations team proactively monitors all events to provide recommendations about the action of a specific ruleset. See Supported Protection Rules for additional information.

Using the Console

To apply an action to a protection rule

1. Open the navigation menu. Under **Governance and Administration**, go to **Security** and click **WAF Policies**.
2. Click the name of the WAF Policy you want to configure rule settings for. The WAF Policy overview appears.
3. Click **Protection Rules**.
4. Click the **Rules** tab.
5. Select the protection rule you want to apply an action to.

Tip

You can use the **Rule ID** or **Rule Action** filters to locate a protection rule.

6. Select one of the following actions from the **Actions** drop-down menu:
   - **Detect**: Matching requests generate an alert and the request is proxied.
   - **Block**: Matching requests are blocked.

- **Off**: The rule is disabled.

The protection rule action is added to the list to be published.

To edit rule settings

1. Open the navigation menu. Under **Governance and Administration**, go to **Security** and click **WAF Policies**.
2. Click the name of the WAF Policy you want to configure rule settings for. The WAF Policy overview appears.
3. Click **Protection Rules**.
4. Click the **Rule Settings** tab.
5. Click **Edit Rule Settings**.
6. In the Edit Rule Settings dialog box, enter the following:
    - **Block Action**: The action taken on malicious requests blocked by WAF.
    - **Block Response Code**: Provides information indicating why the request was blocked.
    - **Max Number of Arguments**: The maximum number of arguments allowed in the request. The recommended setting is 255.
    - **Max Length of Argument**: The maximum argument length allowed in the request. The recommended setting is 400.
    - **Max Total Argument Length**: The maximum argument length for all arguments in the request. The recommended setting is 64000.
    - **Recommendations Period**: The period in days to analyze for recommended actions.
    - **Allowed HTTP Methods**: The list of allowed HTTP protocol methods.
7. Click **Save**.

The accepted protection rules are added to the list to be published.

To accept recommendations

Recommendations will begin appearing once sufficient traffic has gone through the WAF to profile the right security posture.

1. Open the navigation menu. Under **Governance and Administration**, go to **Security** and click **WAF Policies**.
2. Click the name of the WAF Policy you want to configure rule settings for. The WAF Policy overview appears.
3. Click **Protection Rules**.
4. Click the **Recommendations** tab.
5. Select the protection rules you want to accept.

Tip

You can use the **Recommended Action** filter to locate a recommendation by **Detect** or **Block**.

6. Click **Accept Recommendations**.

The accepted protection rules are added to the list to be published.

To publish changes

Updates to your WAF policy appear in the list to be published in Unpublished Changes. Pending changes do not persist across browser sessions. Once you publish changes, it cannot be edited until changes propagate to the edge nodes.

1. Under WAF Policy, click **Unpublished Changes**.
2. In the Unpublished Changes list, click the drop-down arrow beside an unpublished change to review the change.

3. Click **Publish All**.
4. In the Publish Changes dialog box, click **Publish All**.

To discard changes

Updates to your WAF policy appear in the list to be published in Unpublished Changes.

1. Under WAF Policy, click **Unpublished Changes**.
2. In the Unpublished Changes list, click the drop-down arrow beside an unpublished change to review the change.
3. Select the check box for the change you want to discard.
4. Click **Discard**.
5. In the Discard Change dialog box, click **Discard**.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

- GetProtectionRule
- ListProtectionRules
- UpdateProtectionRules
- GetProtectionSettings
- UpdateProtectionSettings
- ListRecommendations
- AcceptRecommendations

Listing and Accepting Protection Rule Recommendations

Use the following operations to get the list of recommended rules:

- ListRecommendations

```
{
   "name": "SQL authentication bypass attempts",
   "action": "OFF",
   "description": "Detects basic SQL authentication bypass attempts.",
   "exclusions": [],
   "key": "981244",
   "tags": "SQL Injections, Recommended"
   },

   {

   "modSecurityRuleIds": [
      "950001",
      "959070",
      "959071",
      "959072",
      "950908",
      "959073"
                              ],

   "name": "Common SQL Injections",
   "action": "OFF",
   "description": "detects common SQL injection attacks",
   "exclusions": [],
   "key": "950001",
   "tags": "SQL Injections, WASCTC, OWASP, A1, PCI, Recommended"

   },
```

Using the key values from the output of the GET call above, you can accept one or more of the recommendations using the following operation passing an array of the keys:

- AcceptRecommendations

Body:

```
[
   “981244”,
   "950001”
]
```

Protection Rule Specific Settings

Several protection rule settings are settings for specific protection rules.

Setting	Rule ID	Rule Name
Allowed HTTP Methods	911100	Restrict HTTP Request Methods
Max Total Argument Length	960341	Total Arguments Limits
Max Number of Arguments	960335	Number of Arguments Limits
Max Length of Argument	960208	Values Limits

The term "Arguments" refers to either query parameters or body parameters in a PUT/POST request. For instance, if the Max Number of Arguments is 2 and RuleID 960335 is set to BLOCK, any of the following requests would be blocked:

```
GET /myapp/path?query=one&query=two&query=three
```

```
POST /myapp/path with Body {"arg1":"one","arg2":"two","arg3":"three"}
```

```
POST /myapp/path?query=one&query=two with Body {"arg1":"one"}
```

Max Length of Argument is the length of either a name or the value of the argument. **Total Argument Length** refers to the sum of the name and value length.

Exclusions

Sometimes a protection rule can trigger a false positive. You can configure an exception if the request(s) generating the false positive have a particular argument or cookie that can be used to identify that request be excluded from the action normally taken on the rule. Exclusions have to be created through the API. The following exclusion parameters can be used:

Name	Value
REQUEST_COOKIES	Cookie Value
REQUEST_COOKIES_NAMES	Cookie Name (value is irrelevant)
ARGS	Argument (Query Parameter or POST/PUT data)
ARGS_NAMES	Query Parameter Name (value is irrelevant)

Example

In this example, a block is applied to WAF Rule 911100 (Restrict HTTP Request Methods) with an exception to allow requests with an argument that contains "passthrough".

```
PUT / waasPolicies /<policy_ocid>/wafConfig/protectionRules
```

With the body:

```
[
 {
       "key":"911100",
       "action":"BLOCK",
       "exclusions":
        [
               {
                "target":"REQUEST_COOKIES",
                "exclusions":["yourcompany.com", "Wed, 21 Oct 2015 07:28:00 GMT", "12345", "219ffwef9w0f"]
               },
               {
                              "target":"REQUEST_COOKIES_NAMES",
```

```
                                "exclusions":["OAMAuthnCookie", "JSESSIONID", "HCM-PSJSESSIONID"]
                },
                {
                 "target":"ARGS",
                 "exclusions":["passthrough"]
                }
        ]
 }
]
```

This will return a 202 Accepted HTTP status, which means the policy will enter an UPDATING state until changes are provisioned to the edge nodes.

Supported Protection Rules

The Oracle Cloud Infrastructure WAF service supports many protection rule types. The following list provides a brief explanation of the purpose of each protection rule type.

Protection Rules

Rule ID/Key	Name	Description
90001	Filter Profanity	Detects profanity used in request headers and body.
90004	Executable File Upload Attempt	Detects attempts to upload executable files though input forms.
90006	Credit Card Leakage in Request: GSA SmartPay	Detects GSA SmartPay credit card numbers in user input.
90007	Credit Card Leakage in Request: MasterCard	Detects MasterCard credit card numbers in user input.

Rule ID/Key	Name	Description
90008	Credit Card Leakage in Request: Visa	Detects Visa credit card numbers in user input.
90009	Credit Card Leakage in Request: American Express	Detects American Express credit card numbers in user input.
90010	Credit Card Leakage in Request: Diners Club	Detects Diners Club credit card numbers in user input.
90011	Credit Card Leakage in Request: enRoute	Detects enRoute credit card numbers in user input.
90012	Credit Card Leakage in Request: Discover	Detects Discover credit card numbers in user input.
90013	Credit Card Leakage in Request: JCB	Detects JCB credit card numbers in user input.
120123	Joomla! Core CVE-2015-8562 Remote Code Execution Vulnerability Prevention	Detects Joomla! Core CVE-2015-8562 Remote Code Execution Vulnerability payload.
900032	HTTP Parameter Pollution (HPP) Detection	Detects requests that have multiple arguments with the same name indicative of an HPP attack.
911100	Restrict HTTP Request Methods	Allows only request methods specified by the configurable "Allowed http methods" parameter.
920100	Invalid HTTP Request Line	Detects an invalid HTTP request line.
920280	Missing/Empty Host Header	Detects a missing/empty host header.
920350	Invalid HTTP Request Line	Detects invalid HTTP request lines.

Rule ID/Key	Name	Description
941100	Cross-Site Scripting (XSS) Attempt: Libinjection - XSS Detection	Detects XSS Libinjection attempt.
941101	Cross-Site Scripting (XSS) Attempt: SS Attack Detected via libinjection	Detects an SS attack via libinjection.
941110	Cross-Site Scripting (XSS) Attempt: XSS Filters - Category 1	Detects script tag-based XSS vectors, for example, <script> alert(1)</script>.
941120	Cross-Site Scripting (XSS) Attempt: XSS Filters - Category 2	Detects XSS vectors making use of event handlers like onerror, onload etc., for example, <body onload="alert(1)">.
941130	Cross-Site Scripting (XSS) Attempt: XSS Filters - Category 3	Detects XSS vectors making use of attribute vectors.
941140	Cross-Site Scripting (XSS) Attempt: XSS Filters - Category 4	Detects XSS vectors making use of javascript URI and tags, for example, <p style="background:url(javascript:alert(1))">.
941150	Cross-Site Scripting (XSS) Attempt: XSS Filters - Category 5	Detects HTML attributes - src, style, and href.
941160	Cross-Site Scripting (XSS) Attempt: NoScript XSS Filters	Detects NoScript InjectionChecker: HTML Injection.

Rule ID/Key	Name	Description
941170	Cross-Site Scripting (XSS) Attempt: NoScript XSS Filters	Detects NoScript InjectionChecker: Attributes injection.
941180	Cross-Site Scripting (XSS) Attempt: Blacklist Keywords from Node-Validator	Detects Blacklist Keywords from Node-Validator.
941190	Cross-Site Scripting (XSS) Attempt: XSS Filters from Internet Explorer	Detects XSS Filters from IE.
941200	Cross-Site Scripting (XSS) Attempt: XSS Filters from Internet Explorer	Detects XSS Filters from IE.
941210	Cross-Site Scripting (XSS) Attempt: XSS Filters from Internet Explorer	Detects XSS Filters from IE.
941220	Cross-Site Scripting (XSS) Attempt: XSS Filters from Internet Explorer	Detects XSS Filters from IE.
941230	Cross-Site Scripting (XSS) Attempt: XSS Filters from Internet Explorer	Detects XSS Filters from IE.
941240	Cross-Site Scripting (XSS) Attempt: XSS Filters from Internet Explorer	Detects XSS Filters from IE.

Rule ID/Key	Name	Description
941250	Cross-Site Scripting (XSS) Attempt: XSS Filters from Internet Explorer	Detects XSS Filters from IE.
941260	Cross-Site Scripting (XSS) Attempt: XSS Filters from Internet Explorer	Detects XSS Filters from IE.
941270	Cross-Site Scripting (XSS) Attempt: XSS Filters from Internet Explorer	Detects XSS Filters from IE.
941280	Cross-Site Scripting (XSS) Attempt: XSS Filters from Internet Explorer	Detects XSS Filters from IE.
941300	Cross-Site Scripting (XSS) Attempt: XSS Filters from Internet Explorer	Detects XSS Filters from IE.
941310	Cross-Site Scripting (XSS) Attempt: US-ASCII encoding bypass listed on XSS filter evasion	Cross-Site Scripting (XSS) Attempt: US-ASCII encoding bypass listed on XSS filter evasion
941320	Cross-Site Scripting (XSS) Attempt: HTML Tag Handler	Cross-Site Scripting (XSS) Attempt: HTML Tag Handler
941330	Cross-Site Scripting (XSS) Attempt: XSS Filters from Internet Explorer	Detects XSS Filters from IE.

Rule ID/Key	Name	Description
941340	Cross-Site Scripting (XSS) Attempt: XSS Filters from Internet Explorer	Detects XSS Filters from IE.
941350	Cross-Site Scripting (XSS) Attempt: UTF-7 encoding XSS filter evasion for IE	Cross-Site Scripting (XSS) Attempt: UTF-7 encoding XSS filter evasion for IE.
950002	Common System Command Access Attempt	Detects access attempts to common system commands, such as map, telnet, ftp, rcms, cmd.
950005	Common System Files Access Attempt	Detects access attempts to common system files, such as access, passwd, groupm global.asa, httpd.conf, boot.ini, /etc.
950006	Injection for Common System Commands	Detects injections for common system commands such as telnet, map, blocalgroup, ftp, rcmd, echo, cmd, chmod, passwd, mail.
950007	Blind SQL Injection	Detects common blind SQL injection attacks.

Rule ID/Key	Name	Description
950009	Session Fixation	Detects Session Fixation, an attack technique that forces a user's session ID to an explicit value. Depending on the functionality of the target website, several techniques can be utilized to "fix" the session ID value. These techniques range from Cross-site Scripting exploits to peppering the website with previously made HTTP requests. After a user's session ID has been fixed, the attacker will wait for that user to log in. Once the user does so, the attacker uses the predefined session ID value to assume the same online identity.
950010	LDAP Injection	Detects common LDAP data constructions injections.
950011	SSI Injection	Detects common Server-Side-Include format data injections.
950012	HTTP Request Smuggling	Detects specially crafted requests that under certain circumstances could be seen by the attacked entities as two different sets of requests. This allows certain requests to be smuggled through to a second entity without the first one realizing it.
950018	UPDF XSS Injection	Detects submitted links that contains the # fragment in a query_string.

Rule ID/Key	Name	Description
950019	Email Injection	Detects mail command injections targeting mail servers and webmail applications that construct IMAP/SMTP statements from user-supplied input that is not properly sanitized.
950103	Path/Directory Traversal	Detects path traversal attempts, also known as directory traversal or "../" attacks.
950107	URL Encodings Validation	Detects URL encoding inconsistencies, encoding abuse, and invalid formatting.
950116	Unicode Encoding/Decoding Validation	blocks full-width Unicode encoding as decoding evasions could be possible.
950117	URL Contains an IP Address	Detects a common RFI attack, when a URL contains an IP address.
950118	PHP Include() Function	Detects a common RFI php include() function attacks.
950119	Data Ends with Question Mark (s) (?)	Detects a common RFI attack, when data ends with question mark(s) (?).
950120	Host Doesn't Match Localhost	Detects a common RFI attack, when host doesn't match localhost.
950801	UTF Encoding Validation	Detects UTF encoding inconsistencies and invalid formatting.

Rule ID/Key	Name	Description
950907	OS Command Injection	Detects OS command injection in an application to elevate privileges, execute arbitrary commands, compromise the underlying operating system and install malicious toolkits such as those to participate in botnet attacks.
950910	HTTP Response Splitting	Detects Carriage Return + Linefeed characters in the response header that could cause attacked entities to interpret it as two separate responses instead of one.
958000	Addimport XSS Attack	Detects usage of addimport in request, cookies, or arguments.
958001	document Cookie XSS Attack	Detects usage of document.cookie in request, cookies, or arguments.
958002	execscript XSS Attack	Detects usage of execscript in request, cookies, or arguments.
958003	fromcharcode XSS Attack	Detects usage of fromcharcode in request, cookies, or arguments.
958004	innerhtml XSS Attack	Detects usage of innerhtml in request, cookies, or arguments.
958005	cdata XSS Attack	Detects usage of cdata in request, cookies, or arguments.
958006	body background XSS Attack	Detects usage of <body background in request, cookies, or arguments.

Rule ID/Key	Name	Description
958007	onload XSS Attack	Detects usage of onload in request, cookies, or arguments.
958008	input type image XSS Attack	Detects usage of <input type image in request, cookies, or arguments.
958009	import XSS Attack	Detects usage of import in request, cookies, or arguments.
958010	activexobject XSS Attack	Detects usage of activexobject in request, cookies, or arguments.
958011	background-image: XSS Attack	Detects usage of background-image: in request, cookies, or arguments.
958012	copyparentfolder XSS Attack	Detects usage of copyparentfolder in request, cookies, or arguments.
958013	createtextrange XSS Attack	Detects usage of createtextrange in request, cookies, or arguments.
958016	getparentfolder XSS Attack	Detects usage of getparentfolder in request, cookies, or arguments.
958017	getspecialfolder XSS Attack	Detects usage of getspecialfolder in request, cookies, or arguments.
958018	href javascript: XSS Attack	Detects usage of href javascript: in request, cookies, or arguments.
958019	href schell XSS Attack	Detects usage of href schell in request, cookies, or arguments.

Rule ID/Key	Name	Description
958020	href vbscript: XSS Attack	Detects usage of href vbscript: in request, cookies, or arguments.
958022	livescript: XSS Attack	Detects usage of livescript: in request, cookies, or arguments.
958023	lowsrc javascript: XSS Attack	Detects usage of lowsrc javascript: in request, cookies, or arguments.
958024	lowsrc shell XSS Attack	Detects usage of lowsrc shell in request, cookies, or arguments.
958025	lowsrc vbscript XSS Attack	Detects usage of lowsrc vbscript in request, cookies, or arguments.
958026	mocha: XSS Attack	Detects usage of mocha: in request, cookies, or arguments.
958027	onabort XSS Attack	Detects usage of onabort in request, cookies, or arguments.
958028	settimeout XSS Attack	Detects usage of settimeout in request, cookies, or arguments.
958030	src http: XSS Attack	Detects usage of src http: in request, cookies, or arguments.
958031	javascript: XSS Attack	Detects usage of javascript: in request, cookies, or arguments.
958032	src and shell XSS Attack	Detects usage of src and shell in request, cookies, or arguments.

Rule ID/Key	Name	Description
958033	vbscript: XSS Attack	Detects usage of vbscript: in request, cookies, or arguments.
958034	style bexpression XSS Attack	Detects usage of style bexpression in request, cookies, or arguments.
958036	type application x-javascript XSS Attack	Detects usage of type application x-javascript in request, cookies, or arguments.
958037	type application x-vbscript XSS Attack	Detects usage of type application x-vbscript in request, cookies, or arguments.
958038	type text ecmascript XSS Attack	Detects usage of type text ecmascript in request, cookies, or arguments.
958039	type text javascript XSS Attack	Detects usage of type text javascript in request, cookies, or arguments.
958040	type text jscript XSS Attack	Detects usage of type text jscript in request, cookies, or arguments.
958041	type text vbscript XSS Attack	Detects usage of type text vbscript in request, cookies, or arguments.
958045	url javascript: XSS Attack	Detects usage of url javascript: in request, cookies, or arguments.
958046	url shell XSS Attack	Detects usage of <url shell in request, cookies, or arguments.
958047	url vbscript: XSS Attack	Detects usage of url vbscript: in request, cookies, or arguments.

Rule ID/Key	Name	Description
958049	?meta XSS Attack	Detects usage of ?meta in request, cookies, or arguments.
958051	?script XSS Attack	Detects usage of < ?script in request, cookies, or arguments.
958052	alert XSS Attack	Detects usage of alert in request, cookies, or arguments.
958054	lowsrc and http: XSS Attack	Detects usage of lowsrc and http: in request, cookies, or arguments.
958056	iframe src XSS Attack	Detects usage of iframe src in request, cookies, or arguments.
958057	?iframe XSS Attack	Detects usage of ?iframe in request, cookies, or arguments.
958059	asfunction: XSS Attack	Detects usage of asfunction: in request, cookies, or arguments.
958291	Range Header Validation	Detects range header inconsistencies and invalid formatting.
958295	Connection Header Validation	Detects connection header inconsistencies and invalid formatting.
958404	onerror XSS Attack	Detects usage of onerror in request, cookies, or arguments.
958405	onblur XSS Attack	Detects usage of onblur in request, cookies, or arguments.

Rule ID/Key	Name	Description
958406	onchange XSS Attack	Detects usage of onchange in request, cookies, or arguments.
958407	onclick XSS Attack	Detects usage of onclick in request, cookies, or arguments.
958408	ondragdrop XSS Attack	Detects usage of ondragdrop in request, cookies, or arguments.
958409	onfocus XSS Attack	Detects usage of onfocus in request, cookies, or arguments.
958410	onkeydown XSS Attack	Detects usage of onkeydown in request, cookies, or arguments.
958411	onkeypress XSS Attack	Detects usage of onkeypress in request, cookies, or arguments.
958412	onkeyup XSS Attack	Detects usage of onkeyup in request, cookies, or arguments.
958413	onload XSS Attack	Detects usage of onload in request, cookies, or arguments.
958414	onmousedown XSS Attack	Detects usage of onmousedown in request, cookies, or arguments.
958415	onmousemove XSS Attack	Detects usage of onmousemove in request, cookies, or arguments.
958416	bonmouseout XSS Attack	Detects usage of bonmouseout in request, cookies, or arguments.

Rule ID/Key	Name	Description
958417	bonmouseover XSS Attack	Detects usage of bonmouseover in request, cookies, or arguments.
958418	onmouseup XSS Attack	Detects usage of onmouseup in request, cookies, or arguments.
958419	onmove XSS Attack	Detects usage of onmove in request, cookies, or arguments.
958420	onresize XSS Attack	Detects usage of onresize in request, cookies, or arguments.
958421	onselect XSS Attack	Detects usage of onselect in request, cookies, or arguments.
958422	onsubmit XSS Attack	Detects usage of onsubmit in request, cookies, or arguments.
958423	onunload XSS Attack	Detects usage of onunload in request, cookies, or arguments.
959151	php Code Injection	Detects a common injections attack, when request contain any php code e.g. "<\?>".
960000	File Name Validation	Detects multipart/form-data file name evasion attempts.
960007	Missing Host Header	Detects missing request host header.
960009	Missing User-Agent Header	Detects missing request user-agent header.
960011	GET/HEAD Requests Validation	Detects if GET/HEAD requests contain request body since it is not a common practice.

Rule ID/Key	Name	Description
960012	Content-Length Header Validation	Detects if content-length header is provided with every POST request.
960013	Require Content-Length to be provided with every HTTP/1.1 POST request that has no Transfer-Encoding header	Detects HTTP/1.1 requests that do not comply with HTTP 1.1 spec by having no content-length header when transfer-encoding is also absent.
960014	URI Validation	Ensures that URI and canonical server name are matching.
960015	Missing Accept Header	Detects missing request accept header.
960016	Content-Length Header Validation	Detects if content-length HTTP header is not numeric.
960017	Host Header Is IP Address	Detects if host header is a numeric IP address as it could be indicative of automated client access.
960020	Pragma Header Validation	Ensures that pragma, cache-control headers and HTTP protocol version supplied by the client are matching.
960022	Expect Header Validation	Ensures that expect header and HTTP protocol version supplied by the client are matching.
960024	Repetitive Non-Word Chars	Attempts to identify when 4 or more non-word characters are repeated in sequence.
960208	Values Limits	Detects HTTP requests with value length exceeding the configurable "Max length of argument" parameter.

Rule ID/Key	Name	Description
960209	Arguments Limits	Detects HTTP requests with argument name length exceeding the 100 symbols.
960335	Number of Arguments Limits	Detects HTTP requests with number of arguments exceeding the configurable "Max amount of arguments" value.
960341	Total Arguments Limits	Detects HTTP requests with total length of all arguments exceeding the configurable "Max total argument length" parameter.
960901	Character Set Validation	Ensures that only a specific character set(s) is used.
960902	Content-Encoding Header Validation	Ensures that identity is not specified in content-encoding header.
960904	Missing Content-Type Header	Detects missing content-type header or if combination of content-length and content-type headers is invalid.
960911	Request Line Format Validation Against the HTTP RFC	Uses rule negation against the regex for positive security. The regex specifies the proper construction of URI request lines such as: "http:" "//" host [":" port] [abs_path ["?" query]]. It also outlines proper construction for CONNECT, OPTIONS, and GET requests.
960912	Malformed request bodies	Checks for request body parsing errors.

Rule ID/Key	Name	Description
960914	Strict Multipart Parsing Checks	Uses strict checks for what is accepted in the multipart/form-data request body. If the rule proves to be too strict for your environment consider changing it to Off.
960915	Multipart Unmatched Boundary Check	Checks for signs of evasions during file upload requests.
970901	5XX Status Code Information Leakage	Detects if an application generates 500-level status code. For example, 500 Internal Server Error, 501 Not Implemented...505 HTTP Version Not Supported.
973300	Common Direct HTML Injection	Detects tags that are the most common direct HTML injection points.
973306	Embedded JavaScript in Style Attribute	Detects embedded JavaScript in style attribute.
973307	Embedded Scripts Within JavaScript Fragments	Detects common JavaScript fragments like fromcharcode, alert, eval that can be used for attacks.
973309	CSS Fragments Attacks	Detects common CSS fragments attacks like or <img style="x:expression (document.write(1))">.
973310	Embedded Scripts Within Alert Fragments	Detects attacks like alert('xss'), alert("xss"), alert(/xss/).

Rule ID/Key	Name	Description
973311	String.fromCharCode (88,83,83) attacks	Detects String.fromCharCode(88,83,83) attacks.
973312	'';!--"<XSS>=&{()} Attacks	Detects '';!--"<XSS>=&{()} attacks.
973313	&{alert('xss')} Attacks	Detects &{alert('xss')} attacks.
973314	Doctype Entity Inject	Detects Doctype Entity inject attacks.
973331	Internet Explorer XSS Filters	Detects common IE XSS attacks.
973336	Embedding Scripts Within Scripts	Detects script tag-based XSS vectors. For example, <script> alert(1)</script>.
973337	Embedded Scripts Within Event Handlers	Detects event handler based XSS vectors. For example, <body onload="alert(1)">.
973338	Embedded Scripts Within URI Schemes	Detects "data", "javascript", "src" or other URI schemes/attributes based XSS vectors. For example, <p style="background:url (javascript:alert(1))">.
981136	Generic XSS Attacks	Detects common XSS attacks embedded within non-script elements. For example, jscript onsubmit copyparentfolder document javascript meta onchange onmove onkeydown onkeyup activexobject onerror onmouseup ecmascript bexpression onmouseover vbscript.
981172	SQL Character Anomaly Scoring	Attempts to gauge when there is an excessive use of meta-characters within a single parameter payload.

Rule ID/Key	Name	Description
981227	Request URI Validation	Detects invalid URI in request.
981242	–°lassic SQL Injection Probings	Detects classic SQL injection probings.
981244	SQL Authentication Bypass Attempts	Detects basic SQL authentication bypass attempts.
981245	SQL Authentication Bypass Attempts	Detects basic SQL authentication bypass attempts.
981246	SQL Authentication Bypass Attempts	Detects basic SQL authentication bypass attempts.
981272	SQL Injection Using sleep() or benchmark()	Detects blind SQL injection tests using sleep() or benchmark() functions.
981300	SQL Keyword Anomaly Scoring	Detects common SQL keywords anomalies.
981318	String Termination/Statement Ending	Identifies common initial SQLi probing requests where attackers insert/append quote characters to the existing normal payload to see how the app/db responds.
1000000	Shellshock Exploit Attempt	Detects the ability to unintentionally execute commands in Bash (CVE-2014-6271).
2017100	Apache Struts 2 Multipart Parser CVE-2017-5638 Remote Code Execution Vulnerability Prevention	Detects Apache Jakarta CVE-2017-5638 Remote Code Execution Vulnerability Payload.

Rule ID/Key	Name	Description
2018100	CVE-2018-6389 WordPress Parameter Resource Consumption Remote DoS	Detects WordPress parameter resource consumption remote DoS on jquery-ui-core .
2100019	/_layouts/scriptresx.ashx sections Parameter XSS	Detects Microsoft SharePoint /_ layouts/scriptresx.ashx sections parameter XSS attacks.
2100023	/owssrv.dll List Parameter XSS	Detects Microsoft SharePoint /owssrv.dll List Parameter XSS attacks.
2100026	_ layouts/Chart/WebUI/WizardList.aspx skey Parameter XSS	Detects Microsoft SharePoint _ layouts/Chart/WebUI/WizardList.aspx skey Parameter XSS attacks.
2100027	_layouts/themeweb.aspx XSS	Detects Microsoft SharePoint _ layouts/themeweb.aspx ctl00$PlaceHolderMain$ctl82 $customizeThemeSection$accent6 Parameter XSS attacks.
2100028	_layouts/inplview.aspx ListViewPageUrl Parameter XSS	Detects Microsoft SharePoint _ layouts/inplview.aspx ListViewPageUrl Parameter XSS attacks.
2100032	owssrv.dll View Parameter XSS	Detects Microsoft SharePoint owssrv.dll View Parameter XSS attacks.
2100033	NewForm.aspx TextField_ spSave Parameter XSS	Detects Microsoft SharePoint NewForm.aspx TextField_spSave Parameter XSS attacks.

Rule ID/Key	Name	Description
2100034	/Lists/Calendar/calendar.aspx CalendarDate Parameter XSS	Detects Microsoft SharePoint /Lists/Calendar/calendar.aspx CalendarDate Parameter XSS attacks.
2100035	_layouts/Picker.aspx XSS	Detects Microsoft SharePoint _ layouts/Picker.aspx ctl00$PlaceHolderDialogBodySection$ctl04$hiddenSpanData Parameter XSS attacks.
2100048	_layouts/help.aspx cid0 Parameter XSS	Detects Microsoft SharePoint _layouts/help.aspx cid0 Parameter XSS attacks.
2100062	_layouts/ScriptResx.ashx name Parameter LFI	Detects Microsoft SharePoint _ layouts/ScriptResx.ashx name Parameter LFI attacks.
2100063	_ layouts/OSSSearchResults.aspx k Parameter XSS	Detects Microsoft SharePoint _ layouts/OSSSearchResults.aspx k Parameter XSS attacks.
2100069	wiki pages multiple Parameter XSS	Detects Microsoft SharePoint wiki pages multiple Parameter XSS (CVE-2013-3180) attacks.
2100070	/Lists/Links/AllItems.aspx XSS	Detects Microsoft SharePoint /Lists/Links/AllItems.aspx ctl00mg_2085a732_4692_4d3e_99d2_4d90ea5108d2$ctl00$ctl05$ctl00$ctl00$ctl00$ctl04$ctl00$ctl00$UrlFieldUrl Parameter XSS attacks.

Rule ID/Key	Name	Description
2100082	Drupal - pre-auth SQL Injection Vulnerability	Detects Drupal pre-auth SQL injection vulnerability. A malicious user can inject arbitrary SQL queries and thereby control the complete Drupal site. This leads to a code execution as well. Drupal 7.32 fixed this bug.
2100083	Gerber WebPDM XSS Vulnerability	Detects cross-site scripting vulnerability in Gerber WebPDM Product Data Management System.
2100084	Gerber WebPDM SQL Injection Vulnerability	Detects SQL Injection Vulnerability in Gerber WebPDM Product Data Management System.
2100085	High X-SharePointHealthScore	Detects Microsoft SharePoint High X-SharePointHealthScore - potential DoS attack/availability risk.
2100086	Response Header Found	Detects Microsoft SharePoint SharePointError Response Header Found.
2100087	x-virus-infected Response Header Found	Detects x-virus-infected Response Header Found.
2100088	Rights Management (IRM) Error Response Header Found	Detects Microsoft SharePoint Information Rights Management (IRM) Error Response Header Found.
2100089	/_ layouts/mobile/editform.aspx XSS	Detects Microsoft SharePoint /_ layouts/mobile/editform.aspx XSS attacks.
2200924	IRC Botnet Attacks	Detects common IRC Botnet attack commands.

Rule ID/Key	Name	Description
2200925	Detects HOIC DoS Tool Requests	Detects HOIC DoS tool requests.
2250117	Common RFI Attacks	Detects common types of Remote File Inclusion (RFI) attacks.
2250120	Local File Inclusion Attacks	Detects common local file inclusion attacks like my $dir = "../../../../../../../../../../../../"; or "http://".$site.$bug.$dir."/proc/self/environ%0000";.
2250121	Local File Inclusion ENV Attack in User-Agent	Detects Local File Inclusion ENV Attack in User-Agent
2250122	PHP Injection Attack	Detects common php injection attacks like "send-contactus=1&author_name=[php]eval (base64_decode ('".$code."'))%3Bdie%28%29%3B%5B%2Fphp%5D"
2250123	XML-RPC PHP Injection Attack	Detects common XML-RPC PHP Injections like $exploit .= "echo'j13mb0t';".$code."echo'j13mb0t';exit;/* </name> </value></param></params></methodCall>";
2250125	osCommerce File Upload	Detects osCommerce file upload attacks like "http://".$site."admin/file_ manager.php/login.php";.
2250126	Oscommerce File Disclosure and Admin ByPass	Detects Oscommerce File Disclosure and Admin ByPass.

Rule ID/Key	Name	Description
2250127	e107 Plugin my_gallery Exploit	Detects e107 Plugin my_gallery Exploit "http://".$site."e107_plugins/my_ gallery/image.php?file=../../e107_config.php".
2250128	Opencart Remote File Upload Vulnerability	Detects Opencart remote file upload vulnerability.
2250129	Zen Cart Local File Disclosure Vulnerability	Detects Zen Cart local file disclosure vulnerability.
20182056	CVE-2003-1567 CVE-2004-2320 CVE-2010-0360 TRACE & CONNECT Attempts	Detects TRACE method attempts.
201821375	CVE-2012-0209, Remote Execution Backdoor Attempt Against Horde	Detects remote execution backdoor attempt against Horde.
201821438	CVE-2012-1723, CVE-2012-1889, CVE-2012-4681, Blackhole Exploit Kit JavaScript Carat String Splitting with Hostile Applet	Detects Blackhole exploit kit JavaScript carat string splitting with hostile applet.
201822063	CVE-2012-1823, CVE-2012-2311, CVE-2012-2335, CVE-2012-2336, PHP-CGI Remote File Include Attempt	Detects PHP-CGI remote file include attempts.
201826834	CVE-2012-4681, CVE-2012-5076, CVE-2013-2423, Sweet Orange Exploit Kit Landing Page in.php base64 uri	Detects Sweet Orange exploit kit landing page in.php base64 uri attacks.

Rule ID/Key	Name	Description
201826947	CVE-2013-2423, DotkaChef/Rmayana/DotCache Exploit Kit Inbound Java Exploit Download	Detects DotkaChef/Rmayana/DotCache exploit kit inbound java exploit download attacks.
201826948	CVE-2013-1493, DotkaChef/Rmayana/DotCache Exploit Kit Inbound Java Exploit Download	Detects DotkaChef/Rmayana/DotCache exploit kit inbound java exploit download attacks.
201827040	CVE-2013-0422, CVE-2013-2423, Styx Exploit Kit Plugin Detection Connection Jorg	Detects Styx exploit kit plugin detection connection jorg attacks.
201841409	CVE-2017-3823, CVE-2017-6753, Cisco WebEx Explicit Use of Web Plugin	Detects Cisco WebEx explicit use of web plug-in.
201843811	CVE-2017-9812, Kaspersky Linux File Server WMC Directory Traversal Attempt	Detects Kaspersky Linux file server WMC directory traversal attempts.

Custom Protection Rules

The WAF service allows you to define and apply custom protection rules from open source firewall modules to your WAF configurations, such as ModSecurity modules. This topic describes how to format, create, and implement custom protection rules in your WAF policies using the WAAS API. For a list of protection rules already available in the service, see Supported Protection Rules.

Note

Custom protection rules can only be created using the WAAS API.

Custom Protection Rule Syntax

All custom protection rules are expressed in ModSecurity Rule Language. For more information about ModSecurity syntax, see Making Rules: The Basic Syntax.

Additionally, each rule must include two placeholder variables that are updated by the WAF service upon publication of the rule.

id: {{id_1}} - This field is updated with a unique rule ID generated by the WAF service which identifies a `SecRule`. More than one `SecRule` can be defined in the `template` field of a CreateCustomProtectionRule call. The value of the first `SecRule` must be `id: {{id_1}}` and the `id` field of each subsequent `SecRule` should increase by one, as shown in the example.

ctl:ruleEngine={{mode}} - The action to be taken when the criteria of the `SecRule` are met, either `OFF`, `DETECT` or `BLOCK`. This field is updated with the corresponding value of the `action` field of the `CustomProtectionRuleSetting` object when using the UpdateWafConfig operation.

Example of a custom protection rule format:

```
SecRule REQUEST_COOKIES "regex matching SQL injection - part 1/2" \
       "phase:2,                                                  \
       msg:'Detects chained SQL injection attempts 1/2.',         \
       id: {{id_1}},                                              \
       ctl:ruleEngine={{mode}},                                   \
       deny"
       SecRule REQUEST_COOKIES "regex matching SQL injection - part 2/2" \
       "phase:2,                                                  \
       msg:'Detects chained SQL injection attempts 2/2.',         \
       id: {{id_2}},                                              \
       ctl:ruleEngine={{mode}},                                   \
       deny"
```

Actions

The WAF service can take an action on an HTTP request when the criteria of a custom protection rule are met.

- **DETECT** - Logs the request when the criteria of the custom protection are met.
- **BLOCK** - Blocks the request when the criteria of the custom protection rule are met.
- **OFF** - The custom protection rule is inactive and will take no action.

Create a Custom Protection Rule

Custom protection rules can be created and added to a compartment using the CreateProtectionRule call in the WAAS API. Using ModSecurity Rule Language formatting, populate the `template` field with the criteria of the rule.

EXAMPLE:

```
{
  "compartmentId":
"ocid1.compartment.region1..aaaaaaaa5n4ocdo64z66dzfftcvo6ntalkpojfiiwgmxohi4tlakqosvdrmq",
  "description": "The description text for the rule being created",
  "displayName": "Custom Protection Rule Name",
  "template": "SecRule REQUEST_URI / \"phase:2, t:none, capture, msg:'Custom (XSS) Attack. Matched Data:
%{TX.0} found within %{MATCHED_VAR_NAME}: %{MATCHED_VAR}', id:{{id_1}}, ctl:ruleEngine={{mode}},
tag:'Custom', severity:'2'\""
}
```

Adding Custom Protection Rules to a WAF Configuration

Custom protection rules can be added to a WAF configuration using the UpdateWafConfig call in the WAAS API.

Add the OCID and the desired action to take to the `CustomProtectionRuleSetting` object of the UpdateWafConfig schema.

EXAMPLE:

```
[
  {
    "action": "BLOCK",
```

```
    "id":
"ocid1.waascustomprotectionrule.oc1..aaaaaaaalxd4jrws4rbbnddzlnotu3giuzo53kopbj747mbvarttr7vyy7ja"
  },
  {
    "action": "DETECT",
    "id":
"ocid1.waascustomprotectionrule.oc1..aaaaaaaamx5r72ntmmhwgeaspzpdqcwsgprpuvwsa7xoshnyo3xhtpwcobeq"
  }
]
```

To view a list of available custom protection rules in a compartment and their corresponding OCIDs, use the ListCustomProtectionRules call in the WAAS API.

Access Control

As a WAF administrator you can define explicit actions for requests that meet various conditions. Conditions use various operations and regular expressions. A rule action can be set to log and allow, detect, or block requests.

The available conditions are shown in the following table:

Criteria Type	Criteria
URL	Users shall be able to define one or more criteria based on: • URL is • URL is not • URL starts with • URL ends with • URL contains • URL regex The URL regex matching uses Perl-compatible regular expressions.
IP Address	Users shall be able to define one or more criteria based on: • Client IP Address is • Client IP Address is not These values can be a valid IPv4 address, subset, or CIDR notation for a range. IPv6 is not yet supported.
Country/Region	Users shall be able to define one or more criteria based on: • Country/Region is • Country/Region is not For the API, use a 2-letter country code.

Criteria Type	Criteria
User Agent	User Agent is a value that identifies the browser client. • User Agent is • User Agent is not
HTTP Header	HTTP Request headers can be evaluated as criteria: • HTTP Header contains The HTTP Header contains value should be entered with colon-delimited <name>:<value> .
HTTP Method	HTTP Methods can be evaluated as criteria: • HTTP method is • HTTP method is not Available methods include GET, POST, PUT, DELETE, HEAD, CONNECT, OPTIONS, TRACE, and PATCH.

You can use the IP Whitelist tab to manage whitelists containing trusted IP addresses that bypass all rules and challenges.

Using the Console

Note

The WAF uses a first-match algorithm so that once an Access Rule criteria matches, it will stop evaluating future rules. The order of rules matters. Use the API to reorder rules.

To add an access rule

1. Open the navigation menu. Under **Governance and Administration**, go to **Security** and click **WAF Policies**.
2. Click the name of the WAF Policy you want to view IP Address Whitelists for. The WAF Policy overview appears.
3. Click **Access Control**.
4. Select the **Access Rules** tab.
5. Click **Add Access Rule**.
6. In the Add Access Rule dialog box, enter the following:
    - **Name:** A unique name for the access rule. Avoid entering confidential information.
    - **Rule Condition:** Select the condition that must be met before the rule is matched and specify the details of the condition. Additional conditions can be added in this section.
    - **Rule Action:** Determines the response to a request when the rule is matched. Select one of the following options:
        - **Log and Allow**: A log will be created for all matched requests and no further action will be taken.
        - **Detect Only**: A detection alert will be created for all matched requests and no further action will be taken.
        - **Block:** All matched requests will be blocked and a browser page for the selected response code will be returned.
            - **Block Action**: Select the action that will be taken when a matching request is blocked.
            - **Block Response Code:** Select a response code that will be returned when the request has been blocked. The response code provides

information indicating why the request was blocked. The default response code is 403 "Forbidden".

7. Click **Add Access Rule**. The access rule is added to the access rule list.

To edit an access rule

1. Open the navigation menu. Under **Governance and Administration**, go to **Security** and click **WAF Policies**.
2. Click the name of the WAF Policy you want to view access rules for. The WAF Policy overview appears.
3. Click **Access Control**.
4. Select the **Access Rules** tab.
5. Select the check box for the access rule you want to update and then select **Edit** from the **Actions** drop-down menu.
6. In the Edit Access Rule dialog box, make the necessary updates and then click **Save**.

To delete an access rule

1. Open the navigation menu. Under **Governance and Administration**, go to **Security** and click **WAF Policies**.
2. Click the name of the WAF Policy you want to view access rules for. The WAF Policy overview appears.
3. Click **Access Control**.
4. Select the **Access Rules** tab.
5. Select the check box for the access rule you want to delete and then select **Delete** from the **Actions** drop-down menu.

To add an IP address whitelist

1. Open the navigation menu. Under **Governance and Administration**, go to **Security** and click **WAF Policies**.
2. Click the name of the WAF Policy you want to view IP Address Whitelists for. The WAF Policy overview appears.
3. Click **Access Control**.
4. Select the **IP Whitelist** tab.
5. Click **Add IP Address Whitelist**.
6. In the Add IP Address Whitelist dialog box, enter the following:
   - **Whitelist Name:** A name for the IP addresses used in the list.
   - **IP Addresses:** Select an IP address or enter an IP address and select it to add it. This field supports CIDR notation.
7. Click **Add IP Address Whitelist**.
   The IP Address Whitelist is added to the list of changes to be published.

To edit an IP Address Whitelist

1. Open the navigation menu. Under **Governance and Administration**, go to **Security** and click **WAF Policies**.
2. Click the name of the WAF Policy you want to view IP Address Whitelists for. The WAF Policy overview appears.
3. Click **Access Control**.
4. Select the **IP Whitelist** tab.
5. Select the check box for the IP Address Whitelist name you want to edit.
6. Click **Edit**.
7. In the Edit IP Address Whitelist dialog box, make the needed changes.
8. Click **Save**.

The IP Address Whitelist change is added to the list of changes to be published.

To delete an IP Address Whitelist

1. Open the navigation menu. Under **Governance and Administration**, go to **Security** and click **WAF Policies**.
2. Click the name of the WAF Policy you want to view alerts for. The WAF Policy overview appears.
3. Click **Access Control**.
4. Select the **IP Whitelist** tab.
5. Select the check box for the IP Address Whitelist name you want to delete.
6. Click **Delete**.
   The deleted IP Address Whitelist is added to the list of changes to be published.

To publish changes

Updates to your WAF policy appear in the list to be published in Unpublished Changes. Pending changes do not persist across browser sessions. Once you publish changes, it cannot be edited until changes propagate to the edge nodes.

1. Under WAF Policy, click **Unpublished Changes**.
2. In the Unpublished Changes list, click the drop-down arrow beside an unpublished change to review the change.
3. Click **Publish All**.
4. In the Publish Changes dialog box, click **Publish All**.

To discard changes

Updates to your WAF policy appear in the list to be published in Unpublished Changes.

1. Under WAF Policy, click **Unpublished Changes**.
2. In the Unpublished Changes list, click the drop-down arrow beside an unpublished change to review the change.
3. Select the check box for the change you want to discard.
4. Click **Discard**.
5. In the Discard Change dialog box, click **Discard**.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the following operations to get an array of all access rules in the policy:

- UpdateAccessRules
- ListAccessRules
- UpdateWhitelists
- ListWhitelists

To create an access rule:

```
PUT /waasPolicies/{waasPolicyId}/wafConfig/accessRules
```

```
[
   {
   "name": "DetectRequestsToHealthCheck",
   "criteria": [
      {
      "condition": "URL_IS",
      "value": "/health/check"
      }
               ],
   "action": "DETECT",
      }
]
```

Address Lists

Use the following API operations to create and manage address lists that can be applied to access rules:

- CreateAddressList
- ListAddressLists
- GetAddressList
- UpdateAddressList
- DeleteAddressList

Example

To create an address list:

```
POST /addressLists
{
  "addresses": [
    "198.51.100.0",
    "198.51.255.45",
    "198.51.145.55"
  ],
  "compartmentId": "ocid1.compartment.region1...",
  "displayName": "example IP addresses"
}
```

Caching Rules

Caching rules allow you to selectively cache requested content on Oracle Cloud Infrastructure's edge servers, such as web pages or certain file types.

Note

Caching rules are currently only configurable using the WAAS API.

Use the following API operations to create and manage caching rules that can be applied to your WAF configurations:

- ListCachingRules
- UpdateCachingRules
- PurgeCache

Available Cache Rules Criteria

The criteria of the caching rule determines if the requested content should be cached.

- **URL_IS** - Matches if the concatenation of requested URL path and query is identical to the contents of the `value` field. For example, if this rule is set to cache the content of `www.example.com/products`, only HTTP requests for `www.example.com/products` will cache.
- **URL_STARTS_WITH** - Matches if the concatenation of requested URL path and query starts with the contents of the `value` field. For example, if this rule is set to cache content from `www.example.com/products`, all HTTP requests requesting URLs starting with `www.example.com/products` will be cached and subsequent requests will receive content from the cache, including requests for `www.example.com/products/new-product` and `www.example.com/products/old-product`.
- **URL_PART_ENDS_WITH** - Matches if the concatenation of requested URL path and query ends with the contents of the `value` field. For example, if the rule is set to cache content from URLs that end with `/product.jpg`, HTTP requests for the URLs `www.example.com/products/new-product/product-banner.jpg` and `www.example.com/products/old-product/product-banner.jpg` will be cached and subsequent requests will receive content from the cache.

- **URL_PART_CONTAINS** - Matches if the concatenation of requested URL path and query contains the contents of the `value` field. If the rule is set to cache content from URLs that contain `/product-banner`, HTTP requests for the URLs `www.example.com/products/new-product/product-banner/blue.jpg` and `www.example.com/products/new-product/product-banner/red.jpg` will be cached and subsequent requests will receive content from the cache.

Available Cache Rule Actions

A caching rule can be set to take one of two available actions when receiving a request:

- **CACHE** - Requests matching the criteria of the rule will be cached and subsequent requests will receive content from the cache.
- **BYPASS_CACHE** - Requests matching the criteria of the rule will bypass the cache and be directed to the origin.

Cache Duration

Content can be cached for a specified period of time on Oracle Cloud Infrastructure's edge servers or cached locally by the client. The duration is set in the `cachingDuration` and `clientCachingDuration` fields, in ISO 8601 extended format.

Example of a Caching Rule

```
[
  {
    "action": "CACHE",
    "cachingDuration": "PT20M",
    "clientCachingDuration": "PT20M",
    "criteria": [
      {
        "condition": "URL_IS",
        "value": "/path/to-cache"
      }
    ],
    "isClientCachingEnabled": true,
```

```
    "name": "Caching Rule 1"
  },
  {
    "action": "BYPASS_CACHE",
    "criteria": [
      {
        "condition": "URL_PART_ENDS_WITH",
        "value": "urp-part-not-to-cache"
      }
    ],
    "isClientCachingEnabled": false,
    "name": "Do not cache"
  }
]
```

Best Practices

The order the caching rules is specified in are important. The rules are processed in the order they are specified in and the first matching rule will be used when processing a request. It is best to add rules that bypass cache to the top of the order and caching rules below any bypass rules.

Purge Caches

Caches can be purged using the PurgeCache operation. Caches can either be selectively purged by specifying the URL path of a resource or all caches can be purged for the WAF by not specifying any resources to pass to the API.

EXAMPLES

Purge the cache for specified resources:

```
{
  "resources": [
    "/path/to-purge",
    "/multiple-paths"
  ]
}
```

Threat Intelligence

WAF has several sources of known IP address threats that are updated daily. The IP address threats are displayed in the following table:

Source	Description
ABUSE|ch	Blacklist of "bad" SSL certificates identified by abuse.ch to be associated with malware or botnet activities.
Bambenek Consulting	Active and non-sinkholed Command & Control (C&C) IP addresses.
BlockList.de	Includes IP addresses for hosting phishing sites and other kinds of fraud activities such as ad-click or gaming fraud.
BruteForceBlocker Project	Feed of known IP addresses from blocked SSH brute force attacks.
Proofpoint ET Labs	IP addresses involved in suspicious and malicious activity.
Feodo IP Blocklist	IP addresses used as C&C communication channel by the Feodo Trojan.
Palevo	IP addresses which are being used as botnet C&C for the Palevo crimeware.
Webroot BotNets	Botnet C&C channels and infected zombie machine controlled by Bot master.
Webroot Denial of Service	Includes DOS, DDOS, anomalous sync flood, and anomalous traffic detection.
Webroot Mobile Threats	IP addresses of malicious and unwanted mobile applications. This category leverages data from the Webroot mobile threat research tea.

Source	Description
Webroot Phishing	IP addresses hosting phishing sites and other kinds of illicit activities such as ad-click or gaming fraud.
Webroot Proxy	IP addresses providing proxy and def services.
Webroot Reputation	IP addresses currently known to be infected with malware. This category also includes IP addresses with an average low Webroot Reputation Index score.
Webroot Scanners	Includes all reconnaissance such as probes, host scan, domain scan and password brute force attacks.
Webroot Spam Sources	Includes tunneling spam messages through proxy, anomalous SMTP activities, and forum spam activities.
Webroot Tor Proxy	Includes IP addresses acting as exit nodes for the Tor Network. Exit nodes are the last point along the proxy chain and make a direct connection to the originator's intended destination.
Webroot Web Attacks	Includes known IP addresses involved in cross site scripting, iFrame injection, SQL injection, cross domain injection, or domain password brute force attacks.
Webroot Windows Exploits	Includes active IP addresses offering or distributing malware, shell code, rootkits, worms or viruses.
ZueS	IP blocklist including known C&C servers/hosts.

Using the CLI

You can use the CLI to enable threat intelligence sources to block.

Open a command prompt and run the following command to list the keys for all of the threat intelligence:

```
oci waas threat-feed list --waas-policy-id <policy_ocid>
```

Then parse the keys to block and add them to the JSON:

```
oci waas threat-feed update --threat-feeds '[{"key":"<key_id>","action":"BLOCK"}]' --waas-policy-id
<policy_ocid>
```

For example:

```
oci waas threat-feed update --threat-feeds '[{"key":"0998d237-bce8-4612-82c8-
a1ca126c0492","action":"BLOCK"}]' --waas-policy-id
ocid1.waaspolicy.oc1..aaaaaaaapfa5zrwnns75kru7mrlzkkmcdevp7w55ld3phjxtgl4s2phuepjq
```

Using the API

Enabling Threat Intelligence can only be performed by using the API at this time.

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

To return a set of keys for the threat intelligence:

- ListThreatFeeds

Note

Do not use the keys in the example below, as keys are unique across each policy.

```
{
        "8d3f7f1b-673f-4e3a-ba49-08226f385df3": "OFF",
        "0ff7b308-6afe-4b83-91e0-e3ca04afed6e": "OFF",
        "ea5d7c67-1326-43c9-ac31-1df034b9c063": "OFF",
        "87b420ca-5fbb-4ad4-aeba-1b02a9e60b30": "OFF",
        "2168fc70-2d05-466a-9db5-c13c0e32177d": "OFF",
        "7d080a4a-58ce-4370-a02c-f600b3a84e7b": "OFF",
        "a36c7c50-e99e-4b84-9140-5653fc68ce8d": "OFF",
        "5de7bbc1-313f-4995-9810-f6f77cfd30c9": "OFF",
        "fd2152cc-14f5-4471-a58b-d94cc8a61444": "OFF",
        "cfacd3d3-65d9-4368-93e0-62c906e7a748": "OFF",
```

```
        "6eb86368-01ea-4e94-ac1b-49bf0e551443": "OFF",
        "aabb45d9-0d75-481d-9568-58ecad217e1e": "OFF",
        "3805ecc2-1d6d-428b-a03e-2a0fe77fd46f": "OFF",
        "c3452861-4910-4f3a-9872-22cf92d424eb": "OFF",
        "4cf31deb-11af-460e-a46a-ecc1946a6688": "OFF",
        "eff34d63-6235-4081-976d-acd39248bdc3": "OFF",
        "1d1c94d9-038b-45eb-acd4-fb422e281f4c": "OFF",
        "687b5ff4-b1b6-4d12-8dba-3ea90b4536a1": "OFF",
        "65cf274d-991b-41f8-adda-6fe60ba2704f": "OFF"
}
```

To set all threats to DETECT:

- UpdateThreatFeeds
  With body:

```
[
{"action":"DETECT","key":"8d3f7f1b-673f-4e3a-ba49-08226f385df3"},
{"action":"DETECT","key":"0ff7b308-6afe-4b83-91e0-e3ca04afed6e"},
{"action":"DETECT","key":"ea5d7c67-1326-43c9-ac31-1df034b9c063"},
{"action":"DETECT","key":"87b420ca-5fbb-4ad4-aeba-1b02a9e60b30"},
{"action":"DETECT","key":"2168fc70-2d05-466a-9db5-c13c0e32177d"},
{"action":"DETECT","key":"7d080a4a-58ce-4370-a02c-f600b3a84e7b"},
{"action":"DETECT","key":"a36c7c50-e99e-4b84-9140-5653fc68ce8d"},
{"action":"DETECT","key":"5de7bbc1-313f-4995-9810-f6f77cfd30c9"},
{"action":"DETECT","key":"fd2152cc-14f5-4471-a58b-d94cc8a61444"},
{"action":"DETECT","key":"cfacd3d3-65d9-4368-93e0-62c906e7a748"},
{"action":"DETECT","key":"6eb86368-01ea-4e94-ac1b-49bf0e551443"},
{"action":"DETECT","key":"aabb45d9-0d75-481d-9568-58ecad217e1e"},
{"action":"DETECT","key":"3805ecc2-1d6d-428b-a03e-2a0fe77fd46f"},
{"action":"DETECT","key":"d9cfc537-dd50-427d-830e-a612f535c11f"},
{"action":"DETECT","key":"c3452861-4910-4f3a-9872-22cf92d424eb"},
{"action":"DETECT","key":"4cf31deb-11af-460e-a46a-ecc1946a6688"},
{"action":"DETECT","key":"eff34d63-6235-4081-976d-acd39248bdc3"},
{"action":"DETECT","key":"1d1c94d9-038b-45eb-acd4-fb422e281f4c"},
{"action":"DETECT","key":"687b5ff4-b1b6-4d12-8dba-3ea90b4536a1"},
{"action":"DETECT","key":"65cf274d-991b-41f8-adda-6fe60ba2704f"}
]
```

  This will return a 202 Accepted HTTP status, which means the policy will enter an UPDATING state until changes are provisioned to the edge nodes.

Settings

To use SSL with your WAF policy, you must add a certificate bundle. The certificate bundle you upload includes the public certificate and the corresponding private key. Self-signed certificates can be used for the internal communication within Oracle Cloud Infrastructure.

Working with SSL Certificates

Oracle Cloud Infrastructure accepts third-party and self-signed certificates in PEM format only. The following is an example PEM encoded certificate:

```
-----BEGIN CERTIFICATE-----
<Base64_encoded_certificate>
-----END CERTIFICATE-----
```

Obtaining Third-Party SSL Certificates

You can purchase an SSL certificate from a trusted Certificate Authority such as Symantec, Thawte, RapidSSL, or GeoTrust. The certificate issuer will provide an SSL certificate that includes a certificate, intermediate certificate, and private key. Use this information, including the intermediate certificate, when adding an SSL certificate to Oracle Cloud Infrastructure.

Converting to PEM format

If you receive your certificates and keys in formats other than PEM, you must convert them before you can upload them to the system. You can use OpenSSL to convert certificates and keys to PEM format.

Uploading Certificate Chains

If you have multiple certificates that form a single certification chain, you must include all relevant certificates in one file before you upload them to the system. The following example of a certificate chain file includes four certificates:

```
-----BEGIN CERTIFICATE-----
<Base64_encoded_certificate>
```

```
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
<Base64_encoded_certificate>
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
<Base64_encoded_certificate>
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
<Base64_encoded_certificate>
-----END CERTIFICATE-----
```

Submitting Private Keys

If your private key submission returns an error, the most common reasons are your private key is malformed or the system does not recognize the encryption method used for your key.

PRIVATE KEY CONSISTENCY

If you receive an error related to the private key, you can use OpenSSL to check its consistency:

```
openssl rsa -check -in <private_key>.pem
```

This command verifies that the key is intact, the passphrase is correct, and the file contains a valid RSA private key.

DECRYPTING A PRIVATE KEY

If the system does not recognize the encryption technology used for your private key, decrypt the key. Upload the unencrypted version of the key with your certificate bundle. You can use OpenSSL to decrypt a private key:

```
openssl rsa -in <private_key>.pem -out <decrypted_private_key>.pem
```

Using the Console

To edit WAF settings

1. Open the navigation menu. Under **Governance and Administration**, go to **Security** and click **WAF Policies**.
2. Click the name of the WAF Policy you want to view settings for. The WAF Policy overview appears.
3. Click **Settings**.
4. Click **Edit**.
5. In the **Edit Settings** dialog box, enter the following:
    - **WAF Origin:** Select the name and IP address of the origin.
    - **Enable HTTPS Support:** When enabled, all communications between the browser and web app are encrypted. Enter the following information:
        - **SSL Certificate:** Drag and drop, select, or paste a valid SSL certificate in PEM format. You must also include intermediate certificates (the website certificate must be first). The following is an example:

          ```
          -----BEGIN CERTIFICATE-----
          <Base64_encoded_certificate>
          -----END CERTIFICATE-----
          -----BEGIN CERTIFICATE-----
          <Intermediate_Base64_encoded_certificate>
          -----END CERTIFICATE-----
          ```

        - **Private Key:** Drag and drop, select, or paste a valid private key in PEM format in this field. The private key cannot be protected by a passphrase. The following is an example:

          ```
          -----BEGIN PRIVATE KEY-----
          <Base64_encoded_private_key>
          -----END PRIVATE KEY-----
          ```

        - **Self Signed Certificate:** Enable this field when using a self-signed certificate to show an SSL warning in the browser.

- **HTTP to HTTPS Redirect:** When enabled, all HTTP traffic is automatically redirected to HTTPS.

6. Click **Save**.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

- CreateCertificate
- GetCertificate
- DeleteCertificate

Logs

Logs displays log activity and the details of each logged event within a specified time frame. Logs enable you to understand what rules and countermeasures are triggered by requests and are used as a basis to move request handling into block mode. Logs can come from Access Control, Protection Rules, or Bot events.

Note

If you have concerns over General Data Protection Regulation (GDPR) requirements, Logs can be disabled for the WAF service. You can use My Oracle Support to file a service request to disable Logs.

Using the Console

To view Logs

1. Open the navigation menu. Under **Governance and Administration**, go to **Security** and click **WAF Policies**.
2. Click the name of the WAF Policy you want to view logs for. The WAF Policy overview appears.
3. Click **Logs**. Logs for the WAF policy appear.
4. To help find a log, you can use the following filter options:
    - To view alerting activity data for a specific time range, enter a **Start Date**, **Start Time**, **End Date**, or **End Time**.
    - To view logs for a URL, enter a **Request URL**.
    - To view logs for a client IP address, select an address from the **Client IP Address** drop-down menu.
    - To view logs for a country, select a country from the **Country Name** drop-down list.
    - To find a type of action, select an **Action** check box.
    - To find a type of log, select a **Log Type** check box from the following options:
        - Access Rules
        - CAPTCHA Challenge
        - JavaScript Challenge
        - Protection Rules
        - Human Interaction Challenge
        - Device Fingerprinting Challenge
        - Threat Intelligence Feeds
        - Address Rate Limiting
        - Access

5. Click the plus sign next to the Alert Type you want to view.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the ListWafLogs API operation to display log activity. You can use filters to help find a log.

Example

You can filter logs by the following logType:

- ACCESS_RULES
- CAPTCHA_CHALLENGE
- JAVASCRIPT_CHALLENGE
- PROTECTION_RULES
- HUMAN_INTERACTION_CHALLENGE
- DEVICE_FINGERPRINT_CHALLENGE
- THREAT_INTELLIGENCE_FEEDS
- ADDRESS_RATE_LIMITING
- ACCESS

Logs can be filtered by logType by making the following request:

```
GET /20181116/waasPolicies/<unique_
ID>
/wafLogs?logType=
<logType>
&timeObservedGreaterThanOrEqualTo=<timestamp>&timeObservedLessThan=<timestamp>&compartmentId=<unique_ID>
```

For example:

```
GET /20181116/waasPolicies/ocid1.waaspolicy.oc1../wafLogs?logType=PROTECTION_
RULES&timeObservedGreaterThanOrEqualTo=2019-10-24T13:00:00+00:00&timeObservedLessThan=2019-10-
24T13:47:00+00:00&compartmentId=ocid1.compartment.oc1..
```

The following response output for the filtered logs is returned:

```
[

    {

        "action": "BLOCK",

        "clientAddress": "192.0.2.0",

        "countryCode": "US",

            "X-Client-Ip": "192.0.2.0",

            "X-Country-Code": "US",

            "X-Forwarded-For": "192.0.2.0, 192.0.2.0"

        },

        "httpMethod": "GET",

        "httpVersion": "HTTP/1.1",

        "incidentKey": "2019-10-24T13:46:25Z|43bd96b710|192.0.2.0|E04WECJbcY",

        "logType": "PROTECTION_RULES",

        "protectionRuleDetections": {

            "950002": {

                "Message": "System Command Access. Matched Data: cmd.exe found within ARGS:abc:
cmd.exe",

                "Message details": "Access denied with code 403 (phase 2). Pattern match \"\\\\b(?:(?:n
(?:map|et|c)|w(?:guest|sh)|telnet|rcmd|ftp)\\\\.exe\\\\b|cmd(?:
(?:32)?\\\\.exe\\\\b|\\\\b\\\\W*?\\\\/c))\" at ARGS:abc."

            }

        },

        "requestUrl": "/?abc=cmd.exe",
```

```
        "timestamp": "Thu, 24 Oct 2019 13:46:25 GMT",

        "userAgent": "curl/7.54.0"

    }

]
```

Example

Logs can be filtered by clientAddress and time range by making the following request:

```
GET /20181116/waasPolicies/<unique_ID>/wafLogs?clientAddresss=<IP
address>
&timeObservedGreaterThanOrEqualTo=<timestamp>&timeObservedLessThan=<timestamp>&compartmentId=<unique_ID>
```

For example:

```
GET
/20181116/waasPolicies/ocid1.waaspolicy.oc1../wafLogs?clientAddresss=192.0.2.0&timeObservedGreaterThanO
rEqualTo=2019-10-24T13:26:47+00:00&timeObservedLessThan=2019-10-
24T13:26:56+00:00&compartmentId=ocid1.compartment.oc1..
```

The following response output for the filtered logs is returned:

```
[

    {

        "clientAddress": "192.0.2.0",

        "countryName": "Unknown",

        "domain": "example.com",

        "fingerprint": "-",

        "httpHeaders": {

            "Accept": "*/*",

            "Host": "example.com",
```

```
            "Referer": "",
            "User-Agent": "curl/7.54.0",
            "X-Client-Ip": "192.0.2.01",
            "X-Country-Code": "AU",
            "X-Forwarded-For": "192.0.2.0, 192.0.2.0"
        },
        "httpMethod": "GET",
        "httpVersion": "1.1",
        "incidentKey": "2019-10-24T13:26:55Z|43bd96b710|192.0.2.0|ytQbBpuerK",
        "logType": "ACCESS",
        "originAddress": "130.35.212.39:80",
        "originResponseTime": "0.2500",
        "requestUrl": "/",
        "responseCode": 200,
        "responseSize": 4978,
        "timestamp": "Thu, 24 Oct 2019 13:26:55 GMT",
        "userAgent": "curl/7.54.0"
    },
    {
        "clientAddress": "192.0.2.0",
        "countryName": "Unknown",
```

```
    "domain": "example.com",
    "fingerprint": "-",
    "httpHeaders": {
        "Accept": "*/*",

    "responseCode": 200,
    "responseSize": 4978,
    "timestamp": "Thu, 24 Oct 2019 13:26:54 GMT",
```

```
        "userAgent": "curl/7.54.0"

    }

]
```

CHAPTER 34 Developer Tools

This chapter includes general information about using the Oracle Cloud Infrastructure REST API and developer tools.

Software Development Kits and Command Line Interface

Oracle Cloud Infrastructure provides a number of Software Development Kits (SDKs) and a Command Line Interface (CLI) to facilitate development of custom solutions.

- Software Development Kits (SDKs)
  Build and deploy apps that integrate with Oracle Cloud Infrastructure services. Each SDK provides the tools you need to develop an app, including code samples and documentation to create, test, and troubleshoot. In addition, if you want to contribute to the development of the SDKs, they are all open source and available on GitHub.
  - SDK for Java
  - Python SDK
  - Ruby SDK
  - Go SDK
- Command Line Interface (CLI)
  The CLI provides the same core capabilities as the Oracle Cloud Infrastructure Console, plus additional commands that can extend the Console's functionality. Convenient for developers or anyone who prefers the command line to a GUI.

SDK for Java

The SDK for Java enables you to write code to manage Oracle Cloud Infrastructure resources.

This SDK and sample is dual-licensed under the Universal Permissive License 1.0 and the Apache License 2.0; third-party content is separately licensed as described in the code.

Download: GitHub or Maven.

Requirements

To use the SDK for Java, you must have the following:

- An Oracle Cloud Infrastructure account.
- A user created in that account, in a group with a policy that grants the desired permissions. This can be a user for yourself, or another person/system that needs to call the API. For an example of how to set up a new user, group, compartment, and policy, see Adding Users. For a list of typical policies you may want to use, see Common Policies.
- A key pair used for signing API requests, with the public key uploaded to Oracle. Only the user calling the API should be in possession of the private key. For more information, see Configuring Credentials.
- Java 8
- A TTL value of 60. For more information, see Java Virtual Machine TTL for DNS Name Lookups.

Services Supported

- Analytics Cloud
- Announcements
- Audit
- Budgets
- Container Engine for Kubernetes
- Compute Autoscaling
- Compute Work Requests
- Content and Experience
- Core Services (Networking, Compute, Block Volume)
- Data Transfer
- Database
- Digital Assistant

- DNS
- Email Delivery
- Events
- File Storage
- Functions
- Health Checks
- IAM
- Integration
- Key Management
- Limits
- Load Balancing
- Monitoring
- Notifications
- Object Storage
- Quotas
- Resource Manager
- Search
- Streaming
- Web Application Acceleration and Security

CONTRIBUTIONS

Got a fix for a bug or a new feature you'd like to contribute? The SDK is open source and accepting pull requests on GitHub.

NOTIFICATIONS

To be notified when a new version of the SDK for Java is released, subscribe to the Atom feed.

QUESTIONS OR FEEDBACK

- GitHub Issues: To file bugs and feature requests only
- Stack Overflow: Please use the oracle-cloud-infrastructure and oci-java-sdk tags in your post
- Developer Tools section of the Oracle Cloud forums
- My Oracle Support

Getting Started

This topic describes how to install and configure the Oracle Cloud Infrastructure SDK for Java.

DOWNLOADING THE SDK FROM GITHUB

You can download the SDK for Java as a zip archive from GitHub. It contains the SDK, all of its dependencies, documentation, and examples. For best compatibility and to avoid issues, use the version of the dependencies included in the archive. Some notable issues are:

- Bouncy Castle: The SDK bundles 1.60, but if you need FIPS compliance, you must download and use a FIPS-certified version. The SDK supports bc-fips 1.0.1 and bcpkix-fips 1.0.1. You can download them at: https://www.bouncycastle.org/fips-java/
- Jersey Core and Client: The SDK bundles 2.24.1, which is required to support large object uploads to Object Storage. Older versions will not support uploads greater than ~2.1 GB.
- Jax-RS API: The SDK bundles 2.0.1 of the spec. Older versions will cause issues.

Note

The SDK for Java is bundled with Jersey, but you can also use your own JAX-RS implementation. For details, see Using Your Own JAX-RS Implementation

DOWNLOADING THE SDK FROM MAVEN OR JCENTER

The SDK for Java is available on Maven Central and JCenter.

To use the Oracle Cloud Infrastructure SDK for Java in your project, import the `oci-java-sdk-bom`, followed by your project dependencies. For example:

```
<dependencyManagement>
   <dependencies>
     <dependency>
       <groupId>com.oracle.oci.sdk</groupId>
       <artifactId>oci-java-sdk-bom</artifactId>
       <!-- replace the version below with your required version -->
       <version>1.5.2</version>
       <type>pom</type>
       <scope>import</scope>
     </dependency>
   </dependencies>
 </dependencyManagement>
 <dependencies>
 <dependency>
   <groupId>com.oracle.oci.sdk</groupId>
   <artifactId>oci-java-sdk-audit</artifactId>
 </dependency>
 <dependency>
   <groupId>com.oracle.oci.sdk</groupId>
   <artifactId>oci-java-sdk-core</artifactId>
 </dependency>
 <dependency>
   <groupId>com.oracle.oci.sdk</groupId>
   <artifactId>oci-java-sdk-database</artifactId>
 </dependency>
 <!-- more dependencies if needed -->
```

CONFIGURING THE SDK

The SDK services need two types of configuration: credentials and client-side HTTP settings.

CONFIGURING CREDENTIALS

First, you need to set up your credentials and config file. For instructions, see SDK and CLI Configuration File.

Next you need to set up the client to use the credentials. The credentials are abstracted through an `AuthenticationDetailsProvider` interface. Clients can implement this however you choose. We have included a simple POJO/builder class to help with this task (`SimpleAuthenticationDetailsProvider`).

- You can load a config with or without a profile:

```
ConfigFile config
    = ConfigFileReader.parse("~/.oci/config");
ConfigFile configWithProfile
    = ConfigFileReader.parse("~/.oci/config", "DEFAULT");
```

- The private key supplier can be created with the file path directly, or using the config file:

```
Supplier<InputStream> privateKeySupplier
    = new SimplePrivateKeySupplier("~/.oci/oci_api_key.pem");
Supplier<InputStream> privateKeySupplierFromConfigEntry
    = new SimplePrivateKeySupplier(config.get("key_file"));
```

- To create an auth provider using the builder:

```
AuthenticationDetailsProvider provider
    = SimpleAuthenticationDetailsProvider.builder()
        .tenantId("myTenantId")
        .userId("myUserId")
        .fingerprint("myFingerprint")
        .privateKeySupplier(privateKeySupplier)
        .build();
```

- To create an auth provider using the builder with a config file:

```
AuthenticationDetailsProvider provider
    = SimpleAuthenticationDetailsProvider.builder()
        .tenantId(config.get("tenancy"))
        .userId(config.get("user"))
        .fingerprint(config.get("fingerprint"))
        .privateKeySupplier(privateKeySupplier)
        .build();
```

- Finally, if you use standard config file keys and the standard config file location, you can simplify this further by using `ConfigFileAuthenticationDetailsProvider`:

```
AuthenticationDetailsProvider provider
    = new ConfigFileAuthenticationDetailsProvider("ADMIN_USER");
```

CONFIGURING CLIENT-SIDE OPTIONS

Create a client-side configuration through the `ClientConfiguration` class. If you do not provide your own configuration, the SDK for Java uses a default configuration. To provide your own configuration, use the following:

```
ClientConfiguration clientConfig
    = ClientConfiguration.builder()
        .connectionTimeoutMillis(3000)
        .readTimeoutMillis(60000)
        .build();
```

After you have both a credential configuration and the optional client configuration, you can start creating service instances.

CONFIGURING CUSTOM OPTIONS

In the config file, you can insert custom key-value pairs that you define, and then reference them as necessary. For example, you could specify a frequently used compartment ID in the config file like so (highlighted in red italics):

```
[DEFAULT]
user=ocid1.user.oc1..aaaaaaaat5nvwcna5j6aqzjcmdy5eqbb6qt2jvpkanghtgdaqedqw3rynjq
fingerprint=20:3b:97:13:55:1c:5b:0d:d3:37:d8:50:4e:c5:3a:34
key_file=~/.oci/oci_api_key.pem
tenancy=ocid1.tenancy.oc1..aaaaaaaaba3pv6wkcr4jqae5f15p2bcmdyt2j6rx32uzr4h25vqstifsfdsq
custom_compartment_
id=ocid1.compartment.oc1..aaaaaaaayzfqeibduyox6iib3olcmdar3ugly4fmameq4h7lcdlihrvur7xq
```

Then you can retrieve the value like so:

```
ConfigFile config
    = ConfigFileReader.parse("~/.oci/config");

String compartmentId = config.get("custom_compartment_id");
```

Configuration

This topic provides details on compatibility, advanced configurations, and add-ons for the Oracle Cloud Infrastructure SDK for Java.

Security Manager Permissions

If your application needs to run inside the Java Security Manager, you must grant additional permissions by updating a policy file, or by specifying an additional or a different policy file at runtime.

The SDK requires the following permissions:

- Required by Jersey:

```
permission java.lang.RuntimePermission "getClassLoader";
permission java.lang.reflect.ReflectPermission "suppressAccessChecks";
permission java.lang.RuntimePermission "accessDeclaredMembers";
permission java.util.PropertyPermission "*", "read,write";
permission java.lang.RuntimePermission "setFactory";
```

- Required by the SDK to overwrite reserved headers:

```
permission java.util.PropertyPermission "sun.net.http.allowRestrictedHeaders", "write";
```

- Required by the SDK to open socket connections:

```
permission java.net.SocketPermission "*", "connect";
```

To include another policy file, in addition to Java Runtime Environment's default policy file, launch the Java Virtual Machine with:

```
java -Djava.security.manager -Djava.security.policy=</path/to/other_policy>
```

To replace the default policy file, launch the Java Virtual Machine with:

```
java -Djava.security.manager -Djava.security.policy==</path/to/other_policy>
```

Note

Use a single equals sign (=) when supplying an additional policy file. Use a double equals sign (==) only if you wish to replace the default policy file.

JAVA VIRTUAL MACHINE TTL FOR DNS NAME LOOKUPS

The Java Virtual Machine (JVM) caches DNS responses from lookups for a set amount of time, called *time-to-live* (TTL). This ensures faster response time in code that requires frequent name resolution.

The JVM uses the networkaddress.cache.ttl property to specify the caching policy for DNS name lookups. The value is an integer that represents the number of seconds to cache the successful lookup. The default value for many JVMs, `-1`, indicates that the lookup should be cached forever.

Because resources in Oracle Cloud Infrastructure use DNS names that can change, we recommend that you change the the TTL value to 60 seconds. This ensures that the new IP address for the resource is returned on next DNS query. You can change this value globally or specifically for your application:

- To set TTL globally for all applications using the JVM, add the following in the `$JAVA_HOME/jre/lib/security/java.security` file:

  ```
  networkaddress.cache.ttl=60
  ```

- To set TTL only for your application, set the following in your application's initialization code:

  ```
  java.security.Security.setProperty("networkaddress.cache.ttl" , "60");
  ```

APACHE CONNECTOR ADD-ON

The `oci-java-sdk-addons-apache` is an optional add-on to the SDK for Java that allows for configuring a client connection pool and an HTTP proxy. The add-on leverages the Jersey `ApacheConnectorProvider` instead of the SDK's default `HttpUrlConnectorProvider` when making service calls. The add-on can be found in the `bmc-addons` directory of the SDK.

For details on installation and configuration, see the Readme for the add-on.

USING YOUR OWN JAX-RS IMPLEMENTATION

The SDK for Java is bundled with Jersey, but you can also use your own JAX-RS implementation. For an example of how to configure your own implementation, see RESTEasy Client Configurator Add-On and accompanying code samples.

RESTEASY CLIENT CONFIGURATOR ADD-ON

The `oci-java-sdk-addons-resteasy-client-configurator` is provided to demonstrate how to configure an alternate JAX-RS implementation. The add-on can be found in the `bmc-addons` directory of the SDK.

For details on installation and configuration, see the Readme for the add-on.

For code samples that demonstrate how to configure the client, see:

- ResteasyClientExample.java
- ResteasyClientWithObjectStorageExample.java
- InstancePrincipalsAuthenticationDetailsProviderWithResteasyClientExample.java

USING SLF4J FOR LOGGING

Logging in the SDK is done through SLF4J. SLF4J is a logging abstraction that allows the use of a user-supplied logging library (e.g., log4j). For more information, see the SLF4J manual.

The following is an example that enables basic logging to standard out. More advanced logging options can be configured by using the log4j binding.

1. Download the SLF4J Simple binding jar: SLF4J Simple Binding
2. Add the jar to your classpath (e.g., add it to the `/third-party/lib` directory of the SDK download)
3. Add the following VM arg to enable debug level logging (by default, info level is used): `-Dorg.slf4j.simpleLogger.defaultLogLevel=debug`

Concepts

This topic explains some of the key concepts for using the Oracle Cloud Infrastructure SDK for

Java.

SYNCHRONOUS CALLS

To make synchronous calls, create an instance of the synchronous client. The general pattern for synchronous clients is that for a service named Example, there will be an interface named ExampleService, and the synchronous client implementation will be called ExampleServiceClient. Here's an example of creating an Object Storage client:

```
AuthenticationDetailsProvider provider = ...;
ObjectStorage clientWithDefaultClientConfig = new ObjectStorageClient(provider);
clientWithDefaultClientConfig.setRegion(Region.US_ASHBURN_1);

ClientConfiguration clientConfig = ...;
ObjectStorage clientWithExplicitClientConfig = new ObjectStorageClient(provider, clientConfig);
clientWithExplicitClientConfig.setRegion(Region.US_ASHBURN_1);
```

Synchronous calls will block until the response is available. All SDK APIs return a response object (regardless of whether or not the API sends any content back). The response object typically contains at least a request ID that you can use when contacting Oracle support for help on a particular request.

```
ObjectStorage client = ...;
GetBucketResponse response = client.getBucket(
    GetBucketRequest.builder().namespaceName("myNamespace").bucketName("myBucket").build());
String requestId = response.getOpcRequestId();
Bucket bucket = response.getBucket();
System.out.println(requestId);
System.out.println(bucket.getName());
```

ASYNCHRONOUS CALLS

To make asynchronous calls, create an instance of the asynchronous client. The general pattern for asynchronous clients is that for a service named Example, there will be an interface named ExampleServiceAsync, and the asynchronous client implementation will be called ExampleServiceAsyncClient. Here's an example of creating an Object Storage client:

```
AuthenticationDetailsProvider provider = ...;
ObjectStorageAsync clientWithDefaultClientConfig = new ObjectStorageAsyncClient(provider);
clientWithDefaultClientConfig.setRegion(Region.US_ASHBURN_1);
```

```
ClientConfiguration clientConfig = ...;
ObjectStorageAsync clientWithExplicitClientConfig = new ObjectStorageAsyncClient(provider,
clientConfig);
clientWithExplicitClientConfig.setRegion(Region.US_ASHBURN_1);
```

Asynchronous calls return immediately. You need to provide an AsyncHandler that will be invoked after the call completes either successfully or unsuccessfully:

```
ObjectStorageAsync client = ...;

AsyncHandler<GetBucketRequest, GetBucketResponse> handler = new AsyncHandler<GetBucketRequest,
GetBucketResponse>() {
        @Override
        public void onSuccess(GetBucketRequest request, GetBucketResponse response) {
            String requestId = response.getOpcRequestId();
            Bucket bucket = response.getBucket();
            System.out.println(requestId);
            System.out.println(bucket.getName());
        }

        @Override
        public void onError(GetBucketRequest request, Throwable error) {
            error.printStackTrace();
        }
};

Future<GetBucketResponse> future = client.getBucket(
        GetBucketRequest.builder().namespaceName("myNamespace").bucketName("myBucket").build(),
        handler);
```

POLLING WITH WAITERS

The SDK offers waiters that allow your code to wait until a specific resource reaches a desired state. A waiter can be invoked in both a blocking or a non-blocking (with asychronous callback) manner, and will wait until either the desired state is reached or a timeout is exceeded. Waiters abstract the polling logic you would otherwise have to write into an easy-to-use single method call.

Waiters are obtained through the service client (`client.getWaiters()`). Both a `Get<Resource>Request` and the desired lifecycle state are passed in to the `waiters.for<Resource>` method. For example:

```
public static Instance waitForInstanceProvisioningToComplete(  ComputeClient computeClient, String
instanceId) throws Exception {

    ComputeWaiters waiters = computeClient.getWaiters();
    GetInstanceResponse response = waiters.forInstance(
        GetInstanceRequest.builder().instanceId(instanceId).build(),
        Instance.LifecycleState.Running)
    .execute();

    return response.getInstance();
}
```

Each `waiters.for<Resource>` method has two versions:

- One version uses the default polling values. For example:

  ```
  waiters.forInstance(GetInstanceRequest, LifecycleState)
  ```

- The other version gives you full control over how long to wait and how much time between polling attempts. For example:

  ```
  waiters.forInstance(GetInstanceRequest, LifecycleState, TerminationStrategy, DelayStrategy)
  ```

THREADING MODEL

A client becomes thread-safe when it is initialized. After setting its endpoint, you can safely use a client in multiple threads and concurrently call methods on it.

You can reuse a client on multiple requests, both across concurrent threads or within a single thread. Unless the environment's resources are constrained, you should only close the client immediately before it goes out of scope.

Note

This guarantee applies only to the default JAX-RS implementation, Jersey. When using an alternate implementation, you must manage thread safety yourself. For more information, see Using Your Own JAX-RS Implementation

Uploading Large Objects

The Object Storage service supports multipart uploads to make large object uploads easier by splitting the large object into parts. The SDK for Java supports raw multipart upload operations for advanced use cases, as well as a higher level upload class that uses the multipart upload APIs. Managing Multipart Uploads provides links to the APIs used for multipart upload operations. Higher level multipart uploads are implemented using the UploadManager, which will: split a large object into parts for you, upload the parts in parallel, and then recombine and commit the parts as a single object in storage.

The UploadObject example shows how to use the UploadManager to automatically split an object into parts for upload to simplify interaction with the Object Storage service.

Raw Requests

Raw requests are useful, and in some cases necessary. Typical use cases are: when using your own HTTP client, making a OCI-authenticated request to an alternate endpoint, and making a request to a OCI API that is not currently supported in the SDK. The SDK for Java exposes the `DefaultRequestSigner` class that you can use to create a `RequestSigner` instance for non-standard requests.

The Raw Request example on GitHub shows how to:

- create an authentication provider and request signer
- integrate with an HTTP client (Jersey in this example) to authenticate requests

Setting the Endpoints

Service endpoints can be set in three ways.

- Call `setEndpoint()` on the service instance. This lets you specify a full host name (for example, https://www.example.com).
- Call `setRegion()` on the service instance. This selects the appropriate host name for the service for the given region. However, if the service is not supported in the region you set, the Java SDK returns an error.
- Pass the region in the configuration file. For more information, see SDK and CLI Configuration File.

Note that a service instance cannot be used to communicate with different regions. If you need to make requests to different regions, create multiple service instances.

Forward Compatibility and enums

If you have conditional logic based on an enum, be sure that your code handles the `UnknownEnumValue` case to ensure forward compatibility. Some response fields are of type enum, but in the future, individual services may return values not covered by existing enums for that field. To address this possibility, every response field of type enum has an additional value named `UnknownEnumValue`. If a service returns a value that is not recognized by your version of the SDK, then the response field will be set to this value.

New Region Support

If you are using a version of the SDK released prior to the announcement of a new region, you can use a workaround to reach it.

A *region* is a localized geographic area. For more information on regions and how to identify them, see Regions and Availability Domains.

A *realm* is a set of regions that share entities. You can identify your realm by looking at the domain name at the end of the network address. For example, the realm for `xyz.abc.123.oraclecloud.com` is `oraclecloud.com`.

You must first call `Region.register` to register the new region, and then you can set the region by either using the configuration file or by calling the `setRegion` method.

Note

Once a region is registered, the federation endpoint is no longer required while using instance principals. For an example, see https://github.com/oracle/oci-java-sdk/blob/master/bmc-examples/src/main/java/NewRegionAndRealmSupportWithoutSDKUpdate.java.

ORACLECLOUD.COM REALM

For regions in the `oraclecloud.com` realm, you can pass new region names just as you would pass ones that are already defined in the Region enum for your SDK version.

Note

For the following code samples, be sure to supply the appropriate endpoints for your region.

If you are using version 1.2.34 or later of the SDK for Java, you can pass the new region name as a string using one of the following methods:

- To set the region on a previously created client:

```
client.setRegion("ca-toronto-1");
```

- To set a region when building a new client:

```
Identity identityClient = IdentityClient.builder()
        .region("ca-toronto-1")
        .build(provider);
```

- You can also pass the region in the configuration file. For more information, see SDK and CLI Configuration File.

OTHER REALMS

For regions in realms other than `oraclecloud.com`, you can use the following workarounds to reach new regions with earlier versions of the SDK.

To specify the endpoint:

```
AuthenticationDetailsProvider provider =
        new ConfigFileAuthenticationDetailsProvider(configurationFilePath, profile);

IdentityClient client = IdentityClient.builder()
        .endpoint("https://identity.ca-toronto-1.oraclecloud.com")
        .build(provider);
```

If you are authenticating via instance principals, you can set the endpoint and

federationEndpoint via the following process:

```
InstancePrincipalsAuthenticationDetailsProvider provider =
InstancePrincipalsAuthenticationDetailsProvider.builder()
        .federationEndpoint("https://auth.ca-toronto-1.oraclecloud.com/v1/x509")
        .build();

IdentityClient identityClient = IdentityClient.builder()
        .endpoint("https://identity.ca-toronto-1.oraclecloud.com")
        .build(provider);
```

PAGINATED RESPONSES

Some APIs return paginated result sets, so you must check for additional items and if necessary, fetch the next page. You can do so manually or you can use an iterator.

MANUALLY FETCHING PAGES

The Response objects contain a method to fetch the next page token. If the token is null, there are no more items. If it is not null, you can make an additional request, by setting the token on the `Request` object, to get the next page of responses.

Note

Some APIs may return a token even if there are no additional results. Be sure to also check whether any items were returned and stop if there are none.

This example shows how to handle page tokens returned by the Object Storage API:

```
ObjectStorage client = ...;

ListBucketsRequest.Builder builder =
    ListBucketsRequest.builder().namespaceName(namespace);
String nextPageToken = null;
do {
    builder.page(nextPageToken);
    ListBucketsResponse listResponse = client.listBuckets(builder.build());
    List<Bucket> buckets = listResponse.getItems();
    // handle buckets
```

```
    nextPageToken = listResponse.getOpcNextPage();
} while (nextPageToken != null);
```

USING AN ITERATOR

Instead of manually working with page tokens, you can use an iterator. Each service client exposes a `getPaginators()` method that returns a `Paginator` object. This object contains methods to return objects of type Iterable. We support two approaches to using **iterable**:

- **Response Iterator**: You can iterate over the `Response` objects that are returned by the list operation. These are referred to as *ResponseIterators*, and their methods are suffixed with "ResponseIterator," for example, *listUsersResponseIterator*.

```
Iterable<ListUsersResponse> responseIterator = identityClient.getPaginators
().listUsersResponseIterator(request);
for (ListUsersResponse response : responseIterator) {
    for (User user : response.getItems()) {
        System.out.println(user);
    }
}
```

- **Record Iterator**: You can iterate over the resources/records that are listed. These are referred to as *RecordIterator*, and their methods are suffixed with "RecordIterator," for example, *listUsersRecordIterator*.

```
Iterable<User> recordIterator = identityClient.getPaginators().listUsersRecordIterator(request)
for (User user : recordIterator) {
    System.out.println(user);
}
```

EXCEPTION HANDLING

When handling an exception, you can get more information about the HTTP request that caused it, such as the status code or timeout. You can also get the request ID when handling a `BmcException` by using the `getOpcRequestId` method.

This example shows a try-catch block that handles a `BmcException`and prints the request ID.

```
ObjectStorage client = ...;
try {
    GetBucketResponse response = client.getBucket(
                GetBucketRequest.builder().namespaceName("myNamespace").bucketName("myBucket").build());
```

```
    String requestId = response.getOpcRequestId();
    System.out.println(requestId);
} catch (BmcException e) {
    String requestId = e.getOpcRequestId();
    System.out.println(requestId);
    e.printStackTrace();
}
```

Exceptions in the SDK for Java are runtime exceptions (unchecked), so they do not show up in method signatures. All APIs can throw a `BmcException`.

Examples

Examples of SDK usage can be found on GitHub, including:

- Example: Synchronous Object Storage
- Example: Asynchronous Object Storage
- Example: Create an instance
- Example: Get an instance's public IP address

The examples are also in the downloadable .zip file for the SDK. Examples for older versions of the SDK are in the downloadable .zip for the specific version, available on GitHub.

If you'd like to see another example not already covered, file a GitHub issue.

Running Examples

1. Download the SDK to a directory named `oci`. See GitHub for the download.
2. Unzip the SDK into the `oci` directory. For example: `tar -xf oci-java-sdk-dist.zip`
3. Create your configuration file in your home directory (`~/.oci/config`). See Configuring the SDK.
4. Use `javac` to compile one of the previous example classes from the `examples` directory, ex:

   ```
   javac -cp lib/oci-java-sdk-full-<version>.jar:third-party/lib/*
   examples/ObjectStorageSyncExample.java
   ```

5. You should now have a class file in the `examples` directory. Run the example:

```
java -cp examples:lib/oci-java-sdk-full-<version>.jar:third-party/lib/* ObjectStorageSyncExample
```

THIRD-PARTY DEPENDENCIES AND SHADING

The SDK requires a number of third-party dependencies, which are available in the `third-party/lib` directory. To use the SDK library `lib/oci-java-sdk-full-<version>.jar`, all of the third-party dependencies in `third-party/lib` have to be on the class path.

The SDK also includes a second version of the SDK library, `shaded/lib/oci-java-sdk-full-shaded-<version>.jar`, which contains most of the third-party dependencies already. Only a few more third-party libraries in `shaded/third-party/lib` have to be on the class path when you use this version of the SDK library.

These two versions of the SDK library are functionally the same, however the second version, `shaded/lib/oci-java-sdk-full-shaded-<version>.jar` can simplify dealing with different versions of third-party dependencies. This is because all the dependencies that are included in `shaded/lib/oci-java-sdk-full-shaded-<version>.jar` were shaded, which means they will not interfere with other versions of themselves you may want to include along with this SDK.

You can use either `lib/oci-java-sdk-full-<version>.jar` or `shaded/lib/oci-java-sdk-full-shaded-<version>.jar`, but not both. When using `lib/oci-java-sdk-full-<version>.jar`, use all the third-party libraries in `third-party/lib`. When using `shaded/lib/oci-java-sdk-full-shaded-<version>.jar`, use all the third-party libraries in `shaded/third-party/lib`.

To use the shaded version of the SDK, replace the `javac` commands in steps 4 and 5 with the following:

- **Step 4:**

```
javac -cp shaded/lib/oci-java-sdk-full-shaded-<version>.jar:shaded/third-party/lib/*
examples/ObjectStorageSyncExample.java
```

- **Step 5:**

```
java -cp examples:shaded/lib/oci-java-sdk-full-shaded-<version>.jar:shaded/third-party/lib/*
ObjectStorageSyncExample
```

Troubleshooting

This section contains troubleshooting information for the Oracle Cloud Infrastructure SDK for Java.

OBJECTSTORAGE CLIENT DOES NOT CLOSE CONNECTIONS WHEN CLIENT IS CLOSED.

Too many file descriptors are opened up, and it takes too long to close existing ones. An exception may look like this:

```
Caused by: java.io.FileNotFoundException: classes/caspertest.pem (Too many open files)
at java.io.FileInputStream.open0(Native Method)
at java.io.FileInputStream.open(FileInputStream.java:195)
at java.io.FileInputStream.<init>(FileInputStream.java:138)
```

Use one of the following workarounds to fix this issue.

- Make this call before creating a client: `System.setProperty("http.keepAlive", "false");`
- Use this command line argument when running Java: `-Dhttp.keepAlive=false`

SERIALIZATION ERRORS WHEN MAKING REQUESTS OR HANDLING RESPONSES

If you encounter an `UnrecognizedPropertyException` error when handling a response to a call against the SDK for Java, this indicates that the version of the Jackson library in use does not support a feature that was injected at runtime from another dependency in your application's class path. This happens even if the `FAIL_ON_UNKNOWN_PROPERTIES` deserialization property is set to `false` for the configured `ObjectMapper`.

Solution:

Determine which version of Jackson libraries are referenced in your application’s class path and, if necessary, upgrade to version 2.9.5. For a complete list of Jackson libraries that the SDK for Java depends on, please refer to the pom.xml file that is hosted on GitHub.

Note

If you customize a client when instantiated in your application, ensure that you reference the preconfigured `ObjectMapper`from the `RestClientFactory` using the `RestClientFactory#getObjectMapper()` method.

An alternative solution is to to use the shaded version of the SDK for Java jar file, which includes a bundled version of the Jackson libraries.

Encryption key size errors

By default, the SDK for Java can only handle keys of 128 bit or lower key length. Users get "Invalid Key Exception" and "Illegal key size" errors when they use longer keys, such as AES256.

Use one of the following workarounds to fix this issue.

- Use a 128 bit key, such as AES128.
- Install the Java Cryptography Extension (JCE) Unlimited Strength Jurisdiction from the following location: http://www.oracle.com/technetwork/java/javase/downloads/jce8-download-2133166.html

Troubleshooting Service Errors

Any operation resulting in a service error will cause an exception of type com.oracle.bmc.model.BmcException to be thrown by the SDK. For information about common service errors returned by OCI, see API Errors.

Python SDK

The Python SDK enables you to write code to manage Oracle Cloud Infrastructure resources.

This SDK and sample is dual-licensed under the Universal Permissive License 1.0 and the Apache License 2.0; third-party content is separately licensed as described in the code.

Download: The Python SDK is available on GitHub or the Python Package Index (PyPi).

Documentation: Available on readthedocs.io.

Command Line Interface (CLI)

The CLI is a small footprint tool that you can use on its own or with the Console to complete Oracle Cloud Infrastructure tasks. The CLI provides the same core functionality as the Console, plus additional commands. Some of these, such as the ability to run scripts, extend the Console's functionality.

This CLI and sample is dual-licensed under the Universal Permissive License 1.0 and the Apache License 2.0; third-party content is separately licensed as described in the code.

The CLI is built on Python (version 2.7.5 or 3.5 or later), running on Mac, Windows, or Linux. The Python code makes calls to Oracle Cloud Infrastructure APIs to provide the functionality implemented for the various services. These are REST APIs that use HTTPS requests and responses. For more information, see About the API.

Installation: See Quickstart.

Reference: For help with a specific command, you can enter `help <command>` on the command line or view the Command Line Reference. This reference is derived from the APIs and help text in the Python source code.

Requirements

To install and use the CLI, you must have:

- An Oracle Cloud Infrastructure account
- A user created in that account, in a group with a policy that grants the desired permissions. This account user can be you, another person, or a system that calls the

API. For an example of how to set up a new user, group, compartment, and policy, see Adding Users. For a list of other typical Oracle Cloud Infrastructure policies, see Common Policies.

- A keypair used for signing API requests, with the public key uploaded to Oracle. Only the user calling the API should possess the private key. See Configuring the CLI.

Note

To use the CLI without a keypair, you can use token-based authentication. For more information, see Token-based Authentication for the CLI.

- Python version 2.7.5 or 3.5 or later, running on Mac, Windows, or Linux. Note that if you use the CLI Installer and do not have Python on your machine, the Installer offers to automatically install Python for you. If you already have Python installed on your machine, you can use the `python --version` command to find out which version is installed.
- If you require FIPS-compliance, see Using FIPS-validated Libraries.

QUESTIONS OR FEEDBACK

- GitHub Issues: To file bugs and feature requests only
- Developer Tools section of the Oracle Cloud forums
- My Oracle Support

Quickstart

Using the installer script and the setup command is the fastest way to get up and running with the CLI.

Warning

Oracle recommends that you avoid using string values that include confidential information.

INSTALLING THE CLI

The installer script automatically installs the CLI and its dependencies, Python and virtualenv. Before running the installer, be sure you meet the Requirements.

MACOS, LINUX, AND UNIX

1. Open a terminal.
2. To run the installer script, run the following command.

```
bash -c "$(curl -L https://raw.githubusercontent.com/oracle/oci-
cli/master/scripts/install/install.sh)"
```

3. Respond to the Installation Script Prompts.

WINDOWS

1. Open the PowerShell console using the **Run as Administrator** option.
2. The installer enables auto-complete by installing and running a script. To allow this script to run, you must enable the RemoteSigned execution policy.
   To configure the remote execution policy for PowerShell, run the following command.

   ```
   Set-ExecutionPolicy RemoteSigned
   ```

3. To run the installer script, run the following command.

   ```
   powershell -NoProfile -ExecutionPolicy Bypass -Command "iex ((New-Object
   System.Net.WebClient).DownloadString('https://raw.githubusercontent.com/oracle/oci-
   cli/master/scripts/install/install.ps1'))"
   ```

4. Respond to the Installation Script Prompts.

INSTALLATION SCRIPT PROMPTS

The installation script prompts you for the following information.

- If you do not have a compatible version of Python installed:
  - Windows and Linux: You are prompted to provide a location for installing the binaries and executables. The script will install Python for you.
  - MacOS: You are notified that your version of Python is incompatible. You must upgrade before you can proceed with the installation. The script will not install Python for you.
- When prompted to upgrade the CLI to the newest version, respond with **Y** to overwrite an existing installation.
- When prompted to update your PATH, respond with **Y** to be able to invoke the CLI without providing the full path to the executable. This will add oci.exe to your PATH.

Setting up the Config File

Before using the CLI, you must create a config file that contains the required credentials for working with Oracle Cloud Infrastructure. You can create this file using a setup dialog or manually using a text editor.

Use the Setup Dialog

To have the CLI walk you through the first-time setup process, use the `oci setup config` command. The command prompts you for the information required for the config file and the API public/private keys. The setup dialog generates an API key pair and creates the config file.

For more information about how to find the required information, see:

- Where to Get the Tenancy's OCID and User's OCID
- Regions and Availability Domains

Manual Setup

If you want to set up the API public/private keys yourself and write your own config file, see SDK and Tool Configuration.

Tip

Use the `oci setup keys` command to generate a key pair to include in the config file.

Next Steps

- For details on starting a session, see Starting a CLI Session
- Getting Started with the Command Line Interface provides an end-to-end walk-through of using the CLI to launch an instance.

Manual Installation

Instead of using the installer script as described in the Quickstart, you can manually install the CLI and its dependencies. Before proceeding, be sure you meet the Requirements.

Warning

Oracle recommends that you avoid using string values that include confidential information.

STEP 1: INSTALLING PYTHON

Python installation instructions vary for each operating system.

Windows and Windows Server 2008 R2

WINDOWS

Install Python from the Python Windows downloads page. During installation, choose to add Python to the PATH and/or environment variables (depending on the prompt).

WINDOWS SERVER 2008 R2

To install Python on this version of Windows Server you must install Python 2.7, or install Windows 2008 R2 Service Pack 1 (SP1) to the instance before installing later versions of Python.

Oracle Linux 7.3 and Oracle Linux 6

ORACLE LINUX

Some versions of Oracle Linux come with incompatible versions of Python, and may require additional components to install the CLI.

ORACLE LINUX 7.3

Before you install the CLI, run the following command on a new Oracle Linux 7.3 image.

```
sudo yum install gcc libffi-devel python-devel openssl-devel
sudo easy_install pip
```

ORACLE LINUX 6

On Oracle Linux 6, a newer version of Python is usually required. You can install a newer version alongside the existing version by downloading from Python, and then install the CLI in a virtual environment that uses the new version. To install the new version of Python, run the following commands.

```
sudo yum install gcc libffi-devel python-devel openssl-devel
sudo easy_install pip
curl -O https://www.python.org/ftp/python/3.6.0/Python-3.6.0.tgz
tar -xvzf Python-3.6.0.tgz
cd Python-3.6.0
./configure
make
sudo make install
```

CentOS 6 and CentOS 7

CENTOS 6 AND CENTOS 7

Before you install the CLI, run the following commands on a new CentOS image.

```
sudo yum install gcc libffi-devel python-devel openssl-devel
sudo easy_install pip
```

Ubuntu 16.04

UBUNTU 16.04

Python should come installed. However, if you need to install Python, use the OS's normal package manager.

To install the additional required components, run the following commands.

```
sudo apt-get update
sudo apt-get install build-essential libssl-dev libffi-dev python-dev
sudo apt-get install python3-pippip3 install --upgrade pip
```

STEP 2: INSTALLING AND CONFIGURING VIRTUALENV

`virtualenv` is a virtual environment builder that lets you create isolated Python environments. For Linux users, `virtualenv` is usually in a separate package from the main Python package.

Download the software and documentation from:

- Software: GitHub or PyPI.
- Documentation: Docs Virtualenv

INSTALLING AND CONFIGURING VIRTUALENV

After Python is installed, install and configure `virtualenv`.

1. To set up the environment for Python 2, use the following command.

   ```
   pip install virtualenv
   ```

2. To set up the environment for Python 3, use the following command.

   ```
   pip3 install virtualenv
   ```

   `virtualenv` typically installs to your Python directory. For example:

   ```
   /usr/local/share/python3/virtualenv
   ```

3. (Optional) To create a directory for storing your virtual environments, run the following command.

   ```
   mkdir -p myvirtualspaces/virtualenvs
   ```

4. To create a new virtual environment without any packages, run the following command.

   ```
   virtualenv myvirtualspaces/virtualenvs/cli-testing --no-site-packages
   ```

If you're installing a newer version of Python to run alongside an existing version, you can create a virtual environment that uses the new version.

To reference the new version of Python, run the following command with the `-p` parameter.

```
virtualenv -p /usr/local/bin/python3.6 cli-testing
```

Step 3: Installing the Command Line Interface

You can download the CLI from GitHub or install the package from Python Package Index (PyPI).

To install using the GitHub download:

- Download and unzip **oci-cli.zip**.
- Run the following command.

  ```
  pip install oci_cli-*-py2.py3-none-any.whl
  ```

To install using PyPI, run the following command.

```
pip install oci-cli
```

For information on how to start a CLI session, see Starting a CLI Session.

Installing Without a Virtual Environment

We do not recommend installing the CLI in your system-wide Python and suggest that instead you install the CLI using the installer or virtual environment.

In cases where you are trying to install the CLI in your system-wide Python using the latest pip version, you might encounter conflicts with some `distutils` installed packages. Following is an example error message when this occurs:

```
sudo pip install oci-cli
...
...
Cannot uninstall 'requests'. It is a distutils installed project and thus we cannot accurately determine
which files belong to it which would lead to only a partial uninstall.
```

Another option is to install the CLI for the user using the following command, although this approach is not supported:

```
pip install --user oci-cli
```

Token-based Authentication for the CLI

Token-based authentication for the CLI allows customers to authenticate their session interactively, then use the CLI for a single session without an API signing key. This enables customers using an identity provider that is not SCIM-supported to use a federated user account with the CLI and SDKs.

REQUIREMENTS

The requirements are the same as those listed for the CLI in Requirements, except that instead of a SSH keypair, you need a web browser for the authentication process.

STARTING A TOKEN-BASED CLI SESSION

To use token-based authentication for the CLI on a computer with a web browser:

1. In the CLI, run the following command. This will launch a web browser.

   ```
   oci session authenticate
   ```

2. In the browser, enter your user credentials. This authentication information is saved to the `.config` file.

VALIDATING A TOKEN

To verify that a token is valid, run the following command:

```
oci session validate --config-file <path_to_config_file> --profile <profile_name> --auth security_token
```

You should receive a message showing the expiration date for the session. If you receive an error, check your profile settings.

REFRESHING A TOKEN

The default token TTL is set to 1 hour before it expires and can be refreshed within the validity period up to 24 hours.

To refresh the token, run the following command:

```
oci session refresh --profile <profile_name>
```

Starting a Token-based CLI Session without a Browser

To use token-based authentication for the CLI on a computer without a web browser, you must export a session from a web-enabled computer, then import it to the computer without a web browser.

Exporting from Source Computer

On the source computer with the browser:

1. In the CLI, run the following command:

   ```
   oci session authenticate
   ```

2. Enter the user credentials you wish to use on the target computer.
3. To export a zip file, run the following command:

   ```
   oci session export --profile <profile_name> --output-file <output_filename>
   ```

To verify the export, see Validating a Token.

Importing to Target Computer

On the target computer without the browser, run the following command in the CLI,:

```
oci session import --session-archive <path_to_exported_zip>
```

You can test the import by running the following:

```
oci iam region list --config-file <path_to_config_file> --profile <profile_name> --auth security_token
```

It should return a list of regions. Successful execution of this command verifies that the token authentication is working as expected.

Running Scripts on a Computer without a Browser

After importing the authentication to the target computer, you can run the CLI and SDKs by using the following settings.

For CLI

To run scripts on the CLI, append the following suffix:

```
--config-file <path_to_config_file> --profile <profile_name> --auth security_token
```

FOR SDKS

To run SDKs on the target computer, you must read in the token file, then use it to initialize the `SecurityTokenSigner`.

After creating a token file as shown in Starting a Token-based CLI Session, use the following process.

Note

These code samples demonstrate how to accomplish this using the Python SDK. For other SDKs, follow the same process, but adjust the syntax accordingly.

1. Read the token file from the `security_token_file` parameter of the `.config` file.

```
config = oci.config.from_file(profile_name='TokenDemo')
token_file = config['security_token_file']
token = None
with open(token_file, 'r') as f:
    token = f.read()
```

2. Read the private key specified by the `.config` file.

```
private_key = oci.signer.load_private_key_from_file(config['key_file'])
```

3. Create the initial SDK client which targets the user-specified region.

```
signer = oci.auth.signers.SecurityTokenSigner(token, private_key)
client = oci.identity.IdentityClient({'region': region}, signer=signer)
```

4. Make the identity request.

```
result = client.list_region_subscriptions(config['tenancy'])
```

Configuration

You can use these optional configurations to extend CLI functionality. The CLI supports using a file for CLI-specific configurations. You can:

- Specify a default profile.
- Set default values for command options so you don't have to type them into the command line.
- Define aliases for commands. For example, using "ls" as an alias for `list`.
- Define aliases for options. For example, using "--ad" as an alias for `--availability-domain`.
- Define named queries that are passed to the `--query` option instead of typing a JMESPath expression on the command line.

The default location and file name is `~/.oci/oci_cli_rc`. You can also explicitly specify this file with the `--cli-rc-file` option or by with the legacy `--defaults-file` option. For example:

```
# Uses the file from ~/.oci/oci_cli_rc
oci os bucket list

# Uses a custom file
oci os bucket list --cli-rc-file path/to/my/cli/rc/file
```

To set up an oci-cli-rc file, run the following command.

```
oci setup oci-cli-rc --file path/to/target/file
```

This command creates the file you specify that includes examples of default command aliases, parameter aliases, and named queries.

Note

If you are using Windows, you should use backslash as the directory separator in pathnames, instead of the forward slash.

SPECIFYING A DEFAULT PROFILE

Specify a default profile in the `OCI_CLI_SETTINGS` section of the CLI configuration file. The next example shows how to specify a default profile named IAD. The CLI looks for a profile

named IAD in your `~/.oci/config` file, or any other file that you specify using the `--config-file` option.

```
[OCI_CLI_SETTINGS]
default_profile=IAD
```

You can also specify a default value for the `--profile` option using the `OCI_CLI_PROFILE` environment variable.

If a default profile value has been specified in multiple locations, the order of precedence is:

1. The value specified in the `--profile` option.
2. The value specified in the `OCI_CLI_PROFILE` environment variable.
3. The value specified in the `default_profile` field in the `OCI_CLI_SETTINGS` section of the CLI configuration file.

SPECIFYING DEFAULT VALUES

The CLI supports using a default values file so that you don't have to keep typing them into the command line. For example, instead of typing in a `--compartment-id` on each launch instance command or having to keep specifying the `--namespace` when using Object Storage commands. You can put this information in a default values file.

Default values can be applied at different levels, from general to specific:

- Globally, across all the CLI commands.
- To a particular service, such as Compute or Object Storage.
- To a specific group, such as commands related to exporting images.
- To a specific command.

Default values are treated hierarchically, with specific values having a higher order of precedence than general values. For example, if there is a globally defined value for `compartment-id` and a specific `compartment-id` defined for the `compute instance launch` command, the CLI uses the value for the `compute instance launch` instead of the global default.

Default Values File Name and Location

When you start the CLI, the program looks for the default values file in `~/.oci/oci_cli_rc`. You can also specify a different file and location by using the `--cli-rc-file` option, as illustrated by the following:

```
# Uses the default values file from ~/.oci/oci_cli_rc
oci os bucket list

# Uses a custom default values file
oci os bucket list --cli-rc-file path/to/my/cli/custom-oci-cli-rc-file
```

Command Value Priority

If a value is provided on the command line also exists in `--cli-rc-file`, the value from the command line has priority. For a command with options that take multiple values, the values are taken entirely from the command line or from `--cli-rc-file`. The 2 sources aren't merged.

Defaults Value File Syntax

The `--cli-rc-file` file can be divided into different sections with one or more keys per section.

Sections

In the next example, the file has two sections, with a key in each section. To specify which section to use, you use the `--profile` option in the CLI.

```
[DEFAULT]
compartment-id = ocid1.compartment.oc1..aaaaaaaal5zx25nzpgeyqd3gzijdlg3ieqeyrggnx7il26astxxhqoljnhwa
[ANOTHER_SECTION]
compartment-id = ocid1.compartment.oc1..aaaaaaaal3gzieyqdrggnx7xil26astxxhqol2pgjjdlieqeyg35nz5znhwa
```

Keys

Keys are named after command line options, but do not use a leading double hyphen (--). For example, the key for `--image-id` is `image-id`. You can specify keys for single values, multiple values, and flags.

- Keys for Single Values. The next example shows how to specify key values at different levels, and with different scope.

```
[DEFAULT]
# Defines a global default for bucket-name
bucket-name = my-global-default-bucket-name

# Defines a default for bucket-name, which applies to all 'compute' commands
compute.bucket-name = bucket-name-for-image-import-export

# Defines a default for bucket-name, which applies to all 'os object' commands (e.g., os object
get)
os.object.bucket-name = bucket-name-for-object-commands

# Defines a default for bucket-name, for the 'os object multipart list' command
os.object.multipart.list.bucket-name = bucket-name-for-multipart-list
```

- Keys for Multiple Values. Some options, such as `--include` and `--exclude` on the `oci os object bulk-upload` command can be specified more than once. For example:

```
oci os object bulk-upload -ns my-namespace -bn my-bucket --src-dir my-directory --include *.txt -
-include *.png
```

  The next example shows how you would enter the `--include` values in the `--cli-rc-file` file

```
[DEFAULT]
os.object.bulk-upload.include =
                        *.txt
                        *.png
```

  In the previous example, one value is given for each line and each line must be indented underneath its key. You can use tabs or spaces and the amount of indentation doesn't matter. You can also put a value on the same line as the key, add more values on the following lines, and use a path statement for a value. For example:

```
[DEFAULT]
os.object.bulk-upload.include = *.pdf
                        *.txt
                        *.png
                        my-subfolder/*.tiff
```

- Keys for Flags. Some command options are flags, like `--force`, which uses a Boolean value. To set a flag for the `--force` option, use the following command.

```
os.object.delete.force=true
```

SPECIFYING COMMAND ALIASES

Specify named queries in the OCI_CLI_COMMAND_ALIASES section of the CLI configuration file. There are two types of aliases, global aliases and command sequence aliases. The following example shows each type of alias.

```
[OCI_CLI_COMMAND_ALIASES]
# This is a global alias that lets you use "ls" instead of "list" for any list command in the CLI.
#
ls = list

# Command examples:
# oci os object ls or oci os compute ls

# This is a command sequence alias that lets you use "oci os object rm" instead of "oci os
# object delete".
# <alias> = <dot-separated sequence of groups and sub-groups>.<command or group to alias>
#
rm = os.object.delete

# Command example:
# <alias> = rm, <sequence of groups and sub-groups> = os object, <command or group to alias> = delete
```

If you want to define default values for options in your CLI configuration file, you can use the alias names you have defined. For example, if you have `-ls` as an alias for `--list`, you can define a default for an availability domain when listing instances by using the following command.

```
[DEFAULT]
compute.instance.ls.compartment-
id=ocid1.compartment.oc1..aaaaaaaal5zx25nzpgeyqd3gzijdlg3ieqeyrggnx7il26astxxhqoljnhwa
```

SPECIFYING OPTION ALIASES

Specify option aliases in the OCI_CLI_PARAM_ALIASES section of the CLI configuration file. Option aliases are applied globally. The following example shows some aliases for command

options.

```
[OCI_CLI_PARAM_ALIASES]
# Option aliases either start with a double hyphen (--) or are a single hyphen (-) followed by a #
single letter. For example: --example-alias, -e
#
--ad = --availability-domain
--dn = --display-name
--egress-rules = --egress-security-rules
--ingress-rules = --ingress-security-rules
```

If you want to define default values for options in your CLI configuration file, you can use the alias names you have defined. For example, if you have `-ad` as an alias for `--availability-domain`, you can define a default for an availability domain when listing instances by using the following command.

```
[DEFAULT]
compute.instance.list.ad=xyx:PHX-AD-1
```

SPECIFYING NAMED QUERIES

If you use the `--query` parameter to filter or manipulate output, you can define named queries instead of using a JMESPath expression on the command line.

Specify named queries in the OCI_CLI_CANNED_QUERIES section of the CLI configuration file.

Examples of Named Queries

```
[OCI_CLI_CANNED_QUERIES]
#  For list results, this gets the ID and display-name of each item in the list.
#  Note that when the names of attributes have dashes in them they need to be surrounded
#  with double quotes. This query knows to look for a list because of the [*] syntax

get_id_and_display_name_from_list=data[*].{id: id, "display-name": "display-name"}

get_id_and_display_name_from_single_result=data.{id: id, "display-name": "display-name"}

#  Retrieves a comma separated string, for example:
#  ocid1.instance.oc1.phx.xyz....,cli_test_instance_675195,RUNNING
#
get_id_display_name_and_lifecycle_state_from_single_result_as_csv=data.[id, "display-name", "lifecycle-
```

```
state"] | join(`,`, @)

#  Retrieves comma separated strings from a list of results
#
get_id_display_name_and_lifecycle_state_from_list_as_csv=data[*].[join(`,`, [id, "display-name",
"lifecycle-state"])][]

#  Filters where the display name contains some text
#
filter_by_display_name_contains_text=data[?contains("display-name", `your_text_here`)]

#  Filters where the display name contains some text and pull out certain attributes(id and time-
created)
#
filter_by_display_name_contains_text_and_get_attributes=data[?contains("display-name", `your_text_
here`)].{id: id, timeCreated: "time-created"}

#  Get the top 5 results from a list operation
#
get_top_5_results=data[:5]

#  Get the last 2 results from a list operation
#
get_last_2_results=data[-2:]
```

You can reference any of these queries using this syntax: `query://<query name>`.

For example, to get id and display name from a list, run the following command.

```
oci compute instance list -c $C --query query://get_id_and_display_name_from_list
```

ENABLING AUTO-COMPLETE

If you used the CLI installer, you don't have to configure auto-complete because it's enabled automatically.

To enable auto-complete (tab completion) for a manual CLI installation, run the following command.

```
oci setup autocomplete
```

To enable auto-complete on a session by session basis, run the following command.

```
eval "$(_OCI_COMPLETE=source oci)"
```

Note

Support for Auto-complete on Windows

Auto-complete on Windows is only supported if you're using PowerShell. A script runs to enable this feature. However, you must change the PowerShell execution policy to RemoteSigned. To configure this policy, run the following command at the PowerShell command line.

```
Set-ExecutionPolicy RemoteSigned
```

USING FIPS-VALIDATED LIBRARIES

The CLI can be configured to use FIPS-validated libraries on Linux. The CLI is built on the Python SDK and leverages operating system level cryptographic libraries.

CONFIGURING THE ENVIRONMENT

1. Verify the installed version of OpenSSL is FIPS-compliant. Run the following command:

   ```
   openssl version
   ```

   If "fips" is not part of the version name, you should upgrade OpenSSL to a FIPS-compliant version. You can download the latest versions of OpenSSL at: https://www.openssl.org/source/

2. Determine the location of the FIPS-compliant version of libcrypto:

   ```
   ls -l /usr/lib64/libcrypto*
   ```

3. Set the environment variable OCI_CLI_FIPS_LIBCRYPTO_FILE to the location of libcrypto:

   ```
   export OCI_CLI_FIPS_LIBCRYPTO_FILE=</path/to/libcrypto.x.x.x>
   ```

If you do not want to run this command at the start of every session, you can add it to your.bashrc or .bash_profile file.

You can confirm that the environment variable is set properly with this command:

```
set | grep OCI_CLI_FIPS_LIBCRYPTO_FILE
```

You can now proceed to the standard installation process outlined in Quickstart

VERIFYING THE CONFIGURATION

To verify that the CLI is using the library that you specified during Configuring the Environment, execute the following commands in Python. Be sure to do so in the same environment that the CLI uses.

```
import ssl
ssl.FIPS_mode()
```

This should return 1, indicating that SSL is using the library specified by the OCI_CLI_FIPS_ LIBCRYPTO_FILE environment variable.

Using the CLI

This topic describes how to use the CLI to access Oracle Cloud Infrastructure and carry out service-related tasks. This topic assumes that you have configured the CLI and are ready to start using it.

Tip

Getting Started with the Command Line Interface provides an end-to-end walk-through of using the CLI to launch an instance.

STARTING A CLI SESSION

MACOS, LINUX, AND UNIX

To start a CLI session, run the following commands.

1. Open a terminal.
2. Change the working directory.

```
cd myvirtualspaces/virtualenvs/cli-testing/bin
```

3. Run the activate batch file.

```
source activate
```

To stop using the CLI, run the following command in a terminal.

```
deactivate
```

Windows

To start a CLI session, run the following commands.

1. Open the Command Prompt using the **Run as administrator** option.
2. Change the working directory.

```
cd myvirtualspaces/virtualenvs/cli-testing/Scripts
```

3. Run the activate batch file.

```
activate
```

To stop using the CLI, run the following command from the command line.

```
deactivate
```

Warning

Avoid entering confidential information when providing resource names, descriptions, or other values that may expose sensitive information.

Command Line Syntax

Most commands must specify a service, followed by a resource type and then an action. The basic command line syntax is:

```
oci <service> <type> <action> <options>
```

For example, this syntax is applied as follows:

- `compute` is the <service>
- `instance` is the resource <type>
- `launch` is the <action>, and
- the rest of the command string consists of <options>.

The following command to launch an instance shows a typical command line construct.

```
oci compute instance launch --availability-domain "EMIr:PHX-AD-1" -c
ocid1.compartment.oc1..aaaaaaaal3gzijdlieqeyg35nz5zxil26astxxhqol2pgeyqdrggnx7jnhwa --shape
"VM.Standard1.1"   --display-name "Instance 1 for sandbox" --image-id
ocid1.image.oc1.phx.aaaaaaaaqutj4qjxihpl4mboabsa27mrpusygv6gurp47kat5z7vljmq3puq --subnet-id
ocid1.subnet.oc1.phx.aaaaaaaaypsr25bzjmjyn6xwgkcrgxd3dbhiha6lodzus3gafscirbhj5bpa
```

Warning

In the previous example, you can provide a friendly name for the instance using the `--display-name` option. Avoid entering confidential information when providing resource names or descriptions.

BASIC EXAMPLES

This section provides examples of basic operations using the CLI.

Note

Using Environment Variables for OCIDs

Several of the CLI examples use environment variables for OCIDs, such as:

- $T for a tenancy OCID
- $C for a compartment OCID

For example:

```
T=ocid1.tenancy.oc1..aaaaaaaaba3pv6wm2ytdrwrx32uzr4h25vkcr4jqae5f15p2b2qstifsfdsq

C=ocid1.compartment.oc1..aaaaaaaarhifmvrvuqtye5q66rck6copzqck3ukc5fldrwpp2jojdcypxfga
```

To get a namespace, run the following command.

```
oci os ns get
```

To list compartments, run the following command.

```
oci iam compartment list -c $T
```

To get a list of buckets, run the following command.

```
oci os bucket list -ns mynamespace --compartment-id $C
```

To list users and limit the output, run the following command.

```
oci iam user list --compartment-id $T --limit 5
```

To add a user to a group, run the following command.

```
oci iam group add-user --user-id
ocid1.user.oc1..aaabcaaaxkkhhtmghvqqq7rgvzwuj3drwmtlsgz6sbfo7y4uc5sprzli377q --group-id
ocid1.group.oc1..aaabcaaa66plootq6uuwwxhfdw2lsdqtgeb6l4pjsv5eeuenxrauujj35b7b
```

GETTING HELP WITH COMMANDS

You can get help for any command using `--help`, `-h`, or `-?`. For example:

```
oci --help
```

```
oci os bucket -h
```

```
oci os bucket create -?
```

VIEWING ALL THE CLI HELP

You can view the command line help.

DETERMINING THE INSTALLED VERSION OF THE CLI

To get the installed version of the CLI, run the following command.

```
oci --version
```

USING DATES AND TIMES IN CLI COMMANDS

The CLI supports the following accepted date formats.

- UTC with milliseconds

  ```
  Format: YYYY-MM-DDTHH:mm:ss.sssTZD, Example: 2017-09-15T20:30:00.123Z
  ```

- UTC without milliseconds

  ```
  Format: YYYY-MM-DDTHH:mm:ssTZD, Example: 2017-09-15T20:30:00Z
  ```

- UTC with minute precision

  ```
  Format: YYYY-MM-DDTHH:mmTZD, Example: 2017-09-15T20:30Z
  ```

- Timezone with milliseconds

  ```
  Format: YYYY-MM-DDTHH:mm:ss.sssTZD, Example: 2017-09-15T12:30:00.456-08:00
  ```

- Timezone without milliseconds

  ```
  Format: YYYY-MM-DDTHH:mm:ssTZD, Example: 2017-09-15T12:30:00-08:00
  ```

- Timezone with offset with minute precision

  ```
  Format: YYYY-MM-DDTHH:mmTZD, Example: 2017-09-15T12:35-08:00
  ```

- Date Only (This date will be taken as midnight UTC of that day)

  ```
  Format: YYYY-MM-DD, Example: 2017-09-15
  ```

- Epoch seconds

```
Example: 1412195400
```

Note

In our datetime formats, the `T` can be replaced with a space. For example, both `"2017-09-15 20:30:00.123Z"` and `2017-09-15T20:30:00.123Z` are acceptable. (Note that if you do not include the `T`, you must wrap the value in quotes.) We also support time zones with and without the colon. Both `+10:00` and `+1000` are acceptable.

MANAGING CLI INPUT AND OUTPUT

The CLI provides several options for managing command input and output.

PASSING COMPLEX INPUT

Complex input, such as arrays and objects with more than one value, are passed in JSON format and can be provided as a string at the command line, as a file, or as a command line string and as a file.

MacOS, Linux, or Unix

The following command shows how to pass two values for the `--metadata` object.

```
oci os bucket create -ns mynamespace --name mybucket --metadata '{"key1":"value1","key2":"value2"}' --
compartment-id ocid1.compartment.oc1..aaaaaaaarhifmvrvuqtye5q66rck6copzqck3ukc5fldrwpp2jojdcypxfga
```

Windows

On Windows, to pass complex input to the CLI as a JSON string, you must enclose the entire block in double quotes. Inside the block, each double quote for the key and value strings must be escaped with a backslash (\) character.

The following command shows how to pass two values for the `--metadata` object on Windows.

```
oci os bucket create -ns mynamespace --name mybucket --metadata "
{\"key1\":\"value1\",\"key2\":\"value2\"}" --compartment-id
ocid1.compartment.oc1..aaaaaaaarhifmvrvuqtye5q66rck6copzqck3ukc5fldrwpp2jojdcypxfga
```

Note

JSON Errors

The error message "Parameter '<PARAMETER NAME>' must be in JSON format." indicates that the value you passed for the parameter with name "PARAMETER NAME" was not valid JSON. This error is typically a result of the JSON string not being escaped correctly.

For more information about using JSON strings, see Advanced JSON Options

FORMAT OUTPUT AS A TABLE

By default, all responses to a command are returned in JSON format. For example, a response like the following is returned when you issue the command to get a list of regions.

```
{
  "data": [
    {
      "key": "FRA",
      "name": "eu-frankfurt-1"
    },
    {
      "key": "IAD",
      "name": "us-ashburn-1"
    },
    {
      "key": "ICN",
      "name": "ap-seoul-1"
    },
    {
      "key": "PHX",
      "name": "us-phoenix-1"
    },
    {
```

```
      "key": "LHR",
      "name": "uk-london-1"
    },
    {
      "key": "NRT",
      "name": "ap-tokyo-1"
    },
    {
      "key": "YYZ",
      "name": "ca-toronto-1"
    }
  ]
}
```

In some cases, readability can become an issue, which is easily resolved by formatting a response as a table. To get a response to a command formatted as a table, run the following command.

```
oci iam region list --output table
```

The following sample list of regions is returned as a two column table.

```
+-----+----------------+
| key | name           |
+-----+----------------+
| FRA | eu-frankfurt-1 |
| IAD | us-ashburn-1   |
| ICN | ap-seoul-1     |
| PHX | us-phoenix-1   |
| NRT | ap-tokyo-1     |
| LHR | uk-london-1    |
| YYZ | ca-toronto-1   |
+-----+----------------+
```

FILTER OUTPUT

You can filter output using the JMESPath query option for JSON. Filtering is very useful when dealing with large amounts of output. For example, run the following command with the output table option to get a list of images.

```
oci compute image list -c
ocid1.compartment.oc1..aaaaaaaapxgklgmujxjzx2ypptfjrcieq7rrob2u2zbesh3wlafsgthhqtea --output table
```

The image information is returned in table format, but too much data is returned, which overflows the width of the terminal. In addition, you might not need all the information that's returned.

```
| base-image-id | compartment-id | create-image-allowed | display-name
         | id | lifecycle-state | operating-system | operating-system-version | time-created
        |

```

You can limit the amount of data returned by combining the `--query` option with `--output table` to get the information you want from a command.

To get filtered image information returned in a table format, run the following command.

```
oci compute image list -c
ocid1.compartment.oc1..aaaaaaaapxgklgmujxjzx2ypptfjrcieq7rrob2u2zbesh3wlafsgthhqtea --output table --
query "data [*].{ImageName:\"display-name\", OCID:id}"
```

The previous command returns the following image information, formatted as a two column table.

```
+-----------------------------------------------------------+-----------------------------------------
-------------------------------------+
| ImageName                                                 | OCID

```

For more information about the JMESPath query language for JSON, see JMESPath.

ADVANCED JSON OPTIONS

You can get the correct JSON format for command options and commands.

- For a command option, use `--generate-param-json-input` and specify the command option that you want to get the JSON for. To generate the JSON for creating or updating a security rule, run the following command.

  ```
  oci network security-list create --generate-param-json-input ingress-security-rules
  ```

Response from the Command

```
[
  {
    "icmpOptions": {
      "code": 0,
      "type": 0
      },
    "isStateless": true,
    "protocol": "string",
    "source": "string",
    "tcpOptions": {
    "destinationPortRange": {
      "max": 0,
      "min": 0
      },
    "sourcePortRange": {
      "max": 0,
      "min": 0
      }
    },
    "udpOptions": {
    "destinationPortRange": {
      "max": 0,
      "min": 0
      },
    "sourcePortRange": {
      "max": 0,
      "min": 0
      }
    }
    },
    {
    "icmpOptions": {
      "code": 0,
      "type": 0
      },
    "isStateless": true,
    "protocol": "string",
```

```
    "source": "string",
    "tcpOptions": {
    "destinationPortRange": {
      "max": 0,
      "min": 0
      },
    "sourcePortRange": {
      "max": 0,
      "min": 0
      }
    },
    "udpOptions": {
    "destinationPortRange": {
      "max": 0,
      "min": 0
      },
    "sourcePortRange": {
      "max": 0,
      "min": 0
      }
    }
  }
]
```

- For an entire command, use `--generate-full-command-json-input`. To generate the JSON for launching an instance, run the following command.

```
oci compute instance launch --generate-full-command-json-input
```

Response from the Command

```
{
  "assignPublicIp": true,
  "availabilityDomain": "string",
  "compartmentId": "string",
  "displayName": "string",
  "extendedMetadata": {
  "string1": {
    "string1": "string",
    "string2": "string"
```

```
   },
  "string2": {
    "string1": "string",
    "string2": "string"
   }
  },
  "hostnameLabel": "string",
  "imageId": "string",
  "metadata": {
    "string1": "string",
    "string2": "string"
    },
  "privateIp": "string",
  "shape": "string",
  "skipSourceDestCheck": true,
  "subnetId": "string",
  "vnicDisplayName": "string"
}
```

ORDER OF PRECEDENCE FOR JSON INPUT

The CLI supports combining arguments on the command line with file input. However, if the same values are provided in a file and on the command line, the command line takes precedence.

USING A JSON FILE FOR COMPLEX INPUT

You can pass complex input from a file by referencing it from the command line. For Windows users, this removes the requirement of having to escape JSON text. You provide a path to the file using the `file://` prefix.

Path Types

Using `testfile.json` as an example, the following types of paths are supported.

- Relative paths from the same directory, for example: `file://testfile.json` and `file://relative/path/to/testfile.json`
- Absolute paths on Linux, MacOS or Unix, for example:

`file:///absolute/path/to/testfile.json`

- Full file paths on Windows, for example: `file://C:\path\to\testfile.json`

Note

File Path Expansions

File path expansions, such as "~/", "./", and "../", are supported. On Windows, the "~/" expression expands to your user directory, which is stored in the %USERPROFILE% environment variable. Using environment variables in paths is also supported.

File Locations

The following file locations are supported.

- Your home directory.

```
oci os bucket create -ns mynamespace --name mybucket --compartment-id
ocid1.compartment.oc1..aaaaaaaarhifmvrvuqtye5q66rck6copzqck3ukc5fldrwpp2jojdcypxfga --metadata
file://~/testfile.json
```

- The current directory.

```
oci os bucket create -ns mynamespace --name mybucket --compartment-id
ocid1.compartment.oc1..aaaaaaaarhifmvrvuqtye5q66rck6copzqck3ukc5fldrwpp2jojdcypxfga --metadata
file://testfile.json
```

- The /tmp directory (Linux, Unix, or MacOS).

```
oci os bucket create -ns mynamespace --name mybucket --compartment-id
ocid1.compartment.oc1..aaaaaaaarhifmvrvuqtye5q66rck6copzqck3ukc5fldrwpp2jojdcypxfga --metadata
file:///tmp/testfile.json
```

- The C:\temp directory (Windows).

```
oci os bucket create -ns mynamespace --name mybucket --compartment-id
ocid1.compartment.oc1..aaaaaaaarhifmvrvuqtye5q66rck6copzqck3ukc5fldrwpp2jojdcypxfga --metadata
file://C:\temp\testfile.json
```

EXAMPLES OF USING A JSON FILE AS INPUT

The examples in this section use JSON that's generated for a command option and an entire command. The JSON is saved in a file, edited, and then used as command line input.

Use File Input for a Command Option

This end-to-end example shows how to generate the JSON for a security list id option used to create a subnet. The JSON is saved in a file, edited, and then used as command line input.

Use a JSON File as Input for a Security List Option

1. To generate the JSON for the `security-list-ids` option, run the following command.

```
oci network subnet create --generate-param-json-input security-list-ids
```

2. Create a file and add the following content, which was returned in step 1. This content doesn't have to be escaped or on a single line, it just has to contain valid JSON.

```
[
  "string",
  "string"
]
```

3. Edit the file and replace the "string" values with values, as shown in the following example.

```
[
  "ocid1.securitylist.oc1.phx.aaaaaaaaw7c62ybv4676muq5tdrwup3v2maiquhbkbh4sf75tjcf5dm6kvlq",
  "ocid1.securitylist.oc1.phx.aaaaaaaa7snx4jh5drwo2h33rwcdqev6elir55hnrhi2yfndjfons5rcqk4q"
]
```

4. Save the file as "security-list.json".
5. To create the subnet using "security-list.json" as input, run the following command.

```
oci network subnet create --vcn-id
ocid1.vcn.oc1.phx.aaaaaaaa6wmuahgxejkv7ukyruqdrwlmrumtl6vyisxxxavagiqw2eeet2sa -c
ocid1.compartment.oc1..aaaaaaaal3gzijdliedxxhqol2rggndrwyg35nz5zxil26astpgeyq7jnhwa  --
availability-domain "EMIr:PHX-AD-1" --display-name TESTSUB --dns-label "testinstances" --cidr-
block "10.0.0.0/16" --security-list-ids file://security-list.json
```

Use File Input for an Entire Command

This end-to-end example shows how to generate the JSON to create a virtual cloud network (VCN). The JSON is saved in a file, edited, and then used as command line input.

Use a JSON File as Input to Create a VCN

1. To generate the JSON needed to create a VCN, run the following command.

```
oci network vcn create --generate-full-command-json-input
```

2. Create a file and add the following content, which was returned in step 1. This content doesn't have to be escaped or on a single line, it just has to contain valid JSON.

```
{
  "cidrBlock": "string",
  "compartmentId": "string",
  "displayName": "string",
  "dnsLabel": "string"
}
```

3. Edit the file and replace the "string" values with values, as shown in the following example.

```
{
  "cidrBlock": "10.0.0.0/16",
  "compartmentId":
"ocid1.compartment.oc1..aaaaaaaal3gzijdliedxxhqol2rggndrwyg35nz5zxil26astpgeyq7jnhwa",
  "displayName": "TestVCN",
  "dnsLabel": "testdns"
}
```

4. Save the file and name it "create-vcn.json"
5. To create the VCN using "create-vcn.json" as input, run the following command.

```
oci network vcn create --from-json file://create-vcn.json
```

Advanced Examples

The following examples show how you can use the CLI to complete complex tasks in Oracle Cloud Infrastructure.

WORKING WITH OBJECT STORAGE

You can use the CLI for several object operations with the Object Storage service.

Uploading and Downloading Files

Objects can be uploaded from a file or from the command line (STDIN), and can be downloaded to a file or to the command line (STDOUT).

Upload an object:

```
oci os object put -ns mynamespace -bn mybucket --name myfile.txt --file /Users/me/myfile.txt --metadata
'{"key1":"value1","key2":"value2"}'
```

Upload object contents from the command line (STDIN):

```
oci os object put -ns mynamespace -bn mybucket --name myfile.txt --file <--'object content'
```

Download an object:

```
oci os object get -ns mynamespace -bn mybucket --name myfile.txt --file /Users/me/myfile.txt
```

Print object contents to the command line (STDOUT):

```
oci os object get -ns mynamespace -bn mybucket --name myfile.txt --file -
```

Bulk Operations in Object Storage

The CLI supports the following bulk operations in Object Storage:

- Uploading files in a directory and all its subdirectories to a bucket

  ```
  # Upload all the files in a directory.
  oci os object bulk-upload -ns mynamespace -bn mybucket --src-dir path/to/upload/directory
  ```

- Downloading all objects, or all the objects that match a specified prefix, in a bucket

  ```
  # Download all the objects.
  oci os object bulk-download -ns mynamespace -bn mybucket --download-dir
  path/to/download/directory

  # Download all the objects that match the specified prefix.
  ```

```
oci os object bulk-download -ns mynamespace -bn mybucket --download-dir
path/to/download/directory --prefix myprefix
```

- Deleting all objects, or all the objects that match a specified prefix, in a bucket

```
# Delete all the objects.
oci os object bulk-delete -ns mynamespace -bn mybucket

# Delete objects that match the specified prefix.
oci os object bulk-delete -ns mynamespace -bn mybucket --prefix myprefix
```

Bulk operations support several options that let you:

- Overwrite or skip files/objects using `--overwrite` or `--no-overwrite`. (**Note**: If you pass neither of these options you are prompted for confirmation every time there is something to overwrite.)
- Limit delete, upload, or download operations using `--prefix` and/or `--delimiter`
- Preview a bulk deletion with `--dry-run`

To get more information about the commands for bulk operations, run the following help commands:

```
# bulk-upload
oci os object bulk-upload -h

# bulk-download
oci os object bulk-download -h

# bulk-delete
oci os object bulk-delete -h
```

Multipart Operations in Object Storage

Multipart operations for Object Storage include object uploads and downloads.

MULTIPART UPLOADS

Large files can be uploaded to Object Storage in multiple parts to speed up the upload. By default, files larger than 128 MiB are uploaded using multipart operations. You can override this default by using the `--no-multipart` option.

You can configure the following options for the `oci os object put` command:

- `--no-multipart` overrides an automatic multipart upload if the object is larger than 128 MiB. The object is uploaded as a single part, regardless of size.
- `--part-size` in MiB, to use in a multipart operation. The default part size is 128 MiB and a part size that you specify must be greater than 10 MiB. If the object is larger than the `--part-size`, it is uploaded in multiple parts.
- `--parallel-upload-count`, to specify the number of parallel operations to perform. You can use this value to balance resources and upload times. A higher value may improve times but consume more system resources and network bandwidth. The default value is 10.

The `--resume-put` command allows you to resume a large file upload in cases where the upload was interrupted.

Note

Multipart Uploads from STDIN

Objects uploaded from STDIN are uploaded in multiple parts. If the object content is smaller than 10 MiB, the upload is only 1 part, and the MultipartUpload API is used for the upload. Specifying `--no-multipart` when uploading from STDIN will result in an error.

The following example shows the command for a multipart upload if the object is larger than 200 MiB.

```
oci os object put -ns my-namespace -bn my-bucket --file path/to/large/file --part-size 200
```

For more information about multipart uploads, see Using Multipart Uploads.

MULTIPART DOWNLOADS

Large files can be downloaded from Object Storage in multiple parts to speed up the download.

You can configure the following options for the `oci os object get` command:

- `--multipart-download-threshold` lets you specify the size, in MiB at which an object should be downloaded in multiple parts. This size must be at least 128 MiB.
- `--part-size`, in MiB, to use for a download part. This gives you the flexibility to use more (smaller size) or fewer (larger size) parts as appropriate for your requirements. For example, compute power and network bandwidth. The default minimum part size is 120 MiB.
- `--parallel-download-count` lets you specify how many parts are downloaded at the same time. A higher value may improve times but consume more system resources and network bandwidth. The default value is 10.

The following example shows the command to download any object with a size greater than 500 MiB. The object is downloaded in 128 MiB parts.

```
oci os object get -ns my-namespace -bn my-bucket --name my-large-object --multipart-download-threshold
500 --part-size 128
```

Upgrading the CLI

If you installed the CLI manually, use one of the following commands to upgrade the CLI.

- To upgrade a standard installation, run the following command.

  ```
  pip install oci-cli --upgrade
  ```

- To upgrade a standard virtualenv installation, run the following command.

  ```
  cli-testing/bin/pip install oci-cli --upgrade
  ```

If you installed the CLI using the install script, use the following process to upgrade the CLI:

- Run the install script and specify the same install directory.
- When prompted, reply **Y** to overwrite the existing installation.

Uninstalling the CLI

FOR MANUAL INSTALLATIONS

If you manually installed the CLI using pip, run the following command:

```
pip uninstall oci-cli
```

If you manually installed the CLI in a virtualenv, run the following command:

```
<path/to/virtualenv>/bin/pip uninstall oci-cli
```

FOR SCRIPT INSTALLATIONS

If you used the install script and the default installation location, you should delete the following directories.

On Windows:

- %USERPROFILE%/lib
- %USERPROFILE%/bin

On Mac:

- $HOME/lib
- $HOME/bin

If you used the install script, but installed to a custom location, you should delete the directories at that location.

UNINSTALLING PYTHON

The script also installs Python as a dependency if it was not already installed. In Windows 10, you can uninstall Python in Control Panel or at the command line.

USING CONTROL PANEL

To uninstall Python in Control Panel, select **Programs and Features**. Right-click Python and select **Uninstall**.

For more information, see Repair or remove programs in Windows 10.

USING THE COMMAND LINE

To uninstall Python at the command line, run the following command:

```
msiexec /x python<version>.msi
```

If you do not have the MSI file, you can also use the package or product code. For more information, see Using the Windows Installer.

Troubleshooting the CLI

This topic describes how to resolve issues that you might encounter when installing Python or the CLI, or when using the CLI.

Service Errors

Any operation resulting in a service error causes an error of type "ServiceError" to be returned by the CLI. For information about common service errors that Oracle Cloud Infrastructure returns, see API Errors.

Oracle Linux Permissions Issues

On Oracle Linux 7.3, if you encounter permission issues when running `pip install`, you might need to use `sudo`.

oci Command Not Found

If the `oci` command isn't found, this can be caused by one of the following reasons:

- pip installed the package to a different virtual environment than your active one.
- You switched to a different active virtual environment after you installed the CLI.

To determine where the CLI is installed, run the `which pip` and `which oci` commands.

Wheel File Won't Install

If the wheel file won't install, verify that pip is up to date. To update pip, run the `pip install -U pip` command. Try to install the wheel again.

Windows Issues

If the `oci` command isn't found, make sure that the `oci.exe` location is in your path (for example, the `Scripts` directory in your Python installation).

CONTACT INFORMATION

If you want to contribute ideas, report a bug, get notified about updates, have questions, or want to give feedback, use one of the following links.

CONTRIBUTIONS

Got a fix for a bug, or a new feature you'd like to contribute? The CLI is open source and accepting pull requests on GitHub.

NOTIFICATIONS

To be notified when a new version of the CLI is released, subscribe to the Atom feed.

QUESTIONS OR FEEDBACK

Ways to get in touch:

- GitHub: To file bugs and feature requests only.
- Stack Overflow: Use the oracle-cloud-infrastructure and oci-cli tags in your post.

Other Tools and Plug-ins

Tools and Plug-ins for SDKs and CLI

Oracle Cloud Infrastructure provides additional developer tools for automating processes and facilitating development.

Toolkit for Eclipse - The toolkit is an open source plug-in for the Eclipse Integrated Development Environment (IDE) that enables Java developers to code and deploy applications more quickly and efficiently.

- **Documentation**: Toolkit for Eclipse
- **Download**: To build and install the Toolkit, clone the GitHub repository then follow instructions in Getting Started with Toolkit for Eclipse.

HDFS Connector for Object Storage - Read and write data with your Apache Hadoop application to and from the Oracle Cloud Infrastructure Object Storage service. Building the connector relies on Maven artifacts that are provided by the SDK for Java.

- **Documentation**: Properties
- **Download**: GitHub

DevOps Tools and Plug-ins

Oracle Cloud Infrastructure provides a number of DevOps tools and plug-ins for working with Oracle Cloud Infrastructure services. These can simplify provisioning and managing infrastructure or enable automated testing and continuous delivery.

Terraform Provider - Manage "infrastructure as code" with this component that connects Terraform to a given Oracle Cloud Infrastructure service.

- **Documentation**: Terraform Provider
- **Download**: GitHub

Ansible Modules - Automate provisioning and configuring of Oracle Cloud Infrastructure resources, such as Compute, Load Balancing, and Database services.

- **Documentation**: Ansible Modules
- **Download**: GitHub

Chef Knife Plug-in - Manage Oracle Cloud Infrastructure resources with Chef Knife, a command line tool that provides an interface between a local chef-repo and the Chef server.

- **Documentation**: Chef Knife Plug-in
- **Download**: GitHub

Compute Jenkins Plug-in - Bring up and down services or nodes as required to serve Jenkins Build Jobs and dynamically allocate Oracle Cloud Infrastructure resources for continuous integration tasks.

- **Documentation**: Compute Jenkins Plug-in
- **Download**: GitHub

Grafana Plug-in - Visualize metrics from the Monitoring service in your Grafana instance.

- **Documentation**: Grafana Plug-in
- **Download**: GitHub

Terraform Kubernetes Installer - Provision and configure the resources needed to run a highly available and configurable Kubernetes cluster.

- **Download**: GitHub

Kubernetes Volume Provisioner - Enable dynamic provisioning of storage resources when running Kubernetes on Oracle Cloud Infrastructure.

- **Download**: GitHub

DevOps Integrations

- Jenkins X Integration: Create a new Kubernetes cluster on Oracle Cloud Infrastructure Container Engine for Kubernetes.
- Packer Integration: Create reusable custom images.

Other Services and Features for DevOps

Oracle Cloud Infrastructure provides other services and features relevant to DevOps professionals.

- Container Engine for Kubernetes (OKE)
  Reliably build, deploy, and manage cloud-native containerized applications. You specify

the compute resources that your applications require, and Container Engine for Kubernetes provisions them on Oracle Cloud Infrastructure in an existing tenancy.

- Oracle Cloud Infrastructure Registry
  Store, share, and manage development artifacts like Docker images. As Oracle Cloud Infrastructure Registry is managed by Oracle, your applications are deployed reliably and you don't have to deal with operational issues.

Toolkit for Eclipse

The Oracle Cloud Infrastructure Toolkit for Eclipse is an open source plug-in for the Eclipse Integrated Development Environment (IDE). The toolkit provides a set of features that help developers connect to Oracle Cloud Infrastructure from within Eclipse. For example, by using the toolkit, you can deploy a project to the cloud by using the Object Storage feature to upload multiple files in one click. The Compute feature enables you to start a compute instance or restart it if needed. You can also switch between multiple accounts and regions from the Eclipse IDE.

Download: To install the Toolkit, download the `com.oracle.oci.eclipse.zip` toolkit from the releases section on GitHub, then follow the instructions in Getting Started with Toolkit for Eclipse.

Requirements

To use the Oracle Cloud Infrastructure Toolkit for Eclipse, you must have the following:

- An Oracle Cloud Infrastructure account
- A user created in that account, in a group with a policy that grants the desired permissions. This can be a user for yourself, or another person/system that needs to call the API. For an example of how to set up a new user, group, compartment, and policy, see Adding Users. For a list of typical policies you may want to use, see Common Policies.
- A key pair used for signing API requests, with the public key uploaded to Oracle. For more information on generating and uploading keys, see Required Keys and OCIDs.
- Java 8

- Maven
- SDK for Java
- Eclipse IDE for Java Developers 4.3 or later

Services Supported

- Compute
- Object Storage

Getting Started with Toolkit for Eclipse

DOWNLOADING THE TOOLKIT

You can download the `com.oracle.oci.eclipse.zip` toolkit from the releases section on GitHub.

INSTALLING THE TOOLKIT

After building the toolkit, launch the Eclipse IDE.

1. From the top navigation bar, select **Help > Install New Software...**
2. In Install dialog, click **Add...**
3. In the Add Repository dialog, click **Archive...**
4. In the right pane of the Repository Archive window, select the zip file containing the toolkit. Click **Open**.
5. In the Add Repository dialog click **Add**.
6. In the Available Software dialog, select **Oracle Cloud Infrastructure Toolkit for Eclipse**, then click **Next**.
7. In the Install Details dialog, click **Finish**.

CONFIGURING THE TOOLKIT

ORACLE CLOUD INFRASTRUCTURE PREFERENCES

Before you can use the toolkit, you must configure the Oracle Cloud Infrastructure Preferences in the Eclipse IDE. This process will provide the necessary identifiers and credentials so the toolkit can connect to your Oracle Cloud Infrastructure account. For more information, see Required Keys and OCIDs.

1. From the top navigation bar, select **Preferences > Oracle Cloud Infrastructure Preferences** .
2. For **Profile Name**, provide a short descriptive name.
3. From the **Region** dropdown, select your region.
4. Enter your **User OCID** and **Tenancy OCID**. For information on how to locate this information, see Where to Get the Tenancy's OCID and User's OCID.
5. For **Key File**, click **Browse** and select the appropriate file. For more information, see How to Generate an API Signing Key.
6. Enter the **Fingerprint** for the Key File. For more information, see How to Get the Key's Fingerprint.
7. Enter the **Passphrase**, if you created one for the key pair. If not, leave this field blank.

8. Click **Save Profile**.
9. Click **Apply and Close**.

Proxy Settings

If you are on a network that uses a proxy to connect to the internet, you must configure Eclipse proxy settings. For more information, see Network Connections in the Eclipse IDE Documentation.

Uninstalling the Toolkit

Launch the Eclipse IDE.

1. From the top navigation bar, select **Help > About Eclipse IDE**
2. Click **Installation Details**.
3. In the Installation Details window, select the Installed Software tab.
4. Select Oracle Cloud Infrastructure Toolkit for Eclipse and click **Uninstall...**
5. In the Uninstall dialog, confirm the items to be uninstalled then click **Finish**.
6. Click **Restart**.

Using Toolkit for Eclipse

After configuring the Oracle Cloud Infrastructure Preferences, you can connect to your tenancy via Eclipse and use the Oracle Cloud Infrastructure Explorer to view and update your resources. You can also switch between different accounts saved in the profile.

To change the region, click the region icon in the Explorer navigation bar and select from the dropdown.

To change the compartment, click the compartment icon and select from the dropdown.

Using the Toolkit for Eclipse with Compute Instances

In the Oracle Cloud Infrastructure Explorer, double-click **Compute** to view available resources.

Double-click **Instances** to display a list of instances. You can right-click each one in the list to start, stop, or reboot it.

You can also double-click **Block Volumes** to view a list of block volumes.

USING THE TOOLKIT FOR ECLIPSE WITH OBJECT STORAGE

In the Oracle Cloud Infrastructure Explorer, double-click Object Storage to view available resources.

WORKING WITH BUCKETS

To create a bucket, right-click **Object Storage** and select **Create New Bucket**.

To view content and details, double-click or right-click the bucket and select **Open Bucket**.

To delete a bucket, view the bucket's details and click **Delete Bucket**.

WORKING WITH OBJECTS

To upload an object, select the destination bucket and view its details. Right-click the Object list and select **Upload Object**. You can also drag one or more files to the Object list to upload.

To download one or more objects, right-click and select **Download Object**.

To delete one or more objects, right-click and select **Delete Object**.

HDFS Connector for Object Storage

The Hadoop Distributed File System (HDFS) Connector lets your Apache Hadoop application read and write data to and from the Oracle Cloud Infrastructure Object Storage service.

This SDK and sample is dual-licensed under the Universal Permissive License 1.0 and the Apache License 2.0; third-party content is separately licensed as described in the code.

- **Services supported:** Object Storage
- **Download:** GitHub or Maven
- **API Documentation:** HDFS Connector API Reference

Requirements

To use the HDFS connector, you must have:

- An Oracle Cloud Infrastructure account.
- A user created in that account, in a group with a policy that grants the desired permissions for any bucket you want to use. This can be a user for yourself, or another person/system that needs to call the API. For an example of how to set up a new user, group, compartment, and policy, see Adding Users. For a basic Object Storage policy, see Let Object Storage admins manage buckets and objects.
- Java 8
- A TTL value of 60. For more information, see Configuring JVM TTL for DNS Name Lookups.

Credentials and Passwords

If you use an encrypted PEM file for credentials, the passphrase will be read from configuration using the `getPassword` Hadoop Configuration method. The `getPassword` option checks for a password in a registered security provider. If the security provider doesn't contain the requested key, it will fallback to reading the plaintext passphrase directly from the configuration file.

Configuring JVM TTL for DNS Name Lookups

The Java Virtual Machine (JVM) caches DNS responses from lookups for a set amount of time, called *time-to-live* (TTL). This ensures faster response time in code that requires frequent name resolution.

The JVM uses the networkaddress.cache.ttl property to specify the caching policy for DNS name lookups. The value is an integer that represents the number of seconds to cache the successful lookup. The default value for many JVMs, `-1`, indicates that the lookup should be cached forever.

Because resources in Oracle Cloud Infrastructure use DNS names that can change, we recommend that you change the the TTL value to 60 seconds. This ensures that the new IP address for the resource is returned on next DNS query. You can change this value globally or specifically for your application:

- To set TTL globally for all applications using the JVM, add the following in the `$JAVA_HOME/jre/lib/security/java.security` file:

```
networkaddress.cache.ttl=60
```

- To set TTL only for your application, set the following in your application's initialization code:

```
java.security.Security.setProperty("networkaddress.cache.ttl" , "60");
```

Installation

Copy the bundled jars from lib and third-party/lib the to each node of the Hadoop cluster so that they are included in Hadoop's CLASSPATH.

SDK for Java and Maven Artifacts

Building an HDFS connector relies on Maven artifacts that are provided by the SDK for Java. To obtain the artifacts, you must download the SDK for Java and build it locally. You can then build the HDFS connector.

Important

The SDK for Javafile version that you download from the Oracle Releases page must match the HDFS connector version, which you can find in the `hdfs-connector/pom.xml` file in the dependency tag block that has the `groupId` attribute.

HDFS Connector and Maven Artifacts

The HDFS Connector is available on Maven Central and JCenter.

To use the HDFS Connector in your project, import the following project dependency. For example:

```
<dependency>
  <groupId>com.oracle.oci.sdk</groupId>
  <artifactId>oci-hdfs-connector</artifactId>
```

```
  <!-- Replace the version below with your required version -->
  <version>2.9.2.0</version>
</dependency>
```

PROPERTIES

You can set the following HDFS Connector properties in the `core-site.xml` file. The BmcProperties page lists additional properties that you can configure for a connection to Object Storage.

Property	Description	Type	Required
`fs.oci.client.hostname`	URL of the host endpoint. For example, `https://www.foo.com`.	String	Yes
`fs.oci.client.auth.tenantId`	OCID of your tenancy. To get the value, see Required Keys and OCIDs.	String	Yes
`fs.oci.client.auth.userId`	OCID of the user calling the API. To get the value, see Required Keys and OCIDs.	String	Yes

Property	Description	Type	Required
`fs.oci.client.auth.fingerprint`	Fingerprint for the key pair being used. To get the value, see Required Keys and OCIDs.	String	Yes, unless you provide a custom authenticator.
`fs.oci.client.auth.pemfilepath`	Full path and file name of the private key used for authentication. The file should be on the local file system.	String	Yes, unless you provide a custom authenticator
`fs.oci.client.auth.passphrase`	Passphrase used for the key, if it is encrypted.	String	Only if your key is encrypted

You can specify that a property value applies to a specific bucket by appending `.<bucket_name>.<namespace_name>` to the property name.

This example shows how properties can be configured in a `core-site.xml` file (the OCIDs are shortened for brevity):

```
<configuration>
...
  <property>
    <name>fs.oci.client.hostname</name>
    <value>https://objectstorage.us-ashburn-1.oraclecloud.com</value>
  </property>
  <property>
    <name>fs.oci.client.hostname.myBucket.myNamespace</name>
    <value>https://objectstorage.phoenix-1.oraclecloud.com</value><!-- Use Phoenix for
myBucket@myNamespace -->
  </property>
  <property>
    <name>fs.oci.client.auth.tenantId</name>
    <value>ocid1.tenancy.oc1..aaaaaaaaba3pv6wkcr4j...stifsfdsq</value>
```

```
  </property>
  <property>
    <name>fs.oci.client.auth.userId</name>
    <value>ocid1.user.oc1..aaaaaaaat5nvwcnazjc...aqw3rynjq</value>
  </property>
  <property>
    <name>fs.oci.client.auth.fingerprint</name>
    <value>20:3b:97:13:55:1c:5b:0d:d3:37:d8:50:4e:c5:3a:34</value>
  </property>
  <property>
    <name>fs.oci.client.auth.pemfilepath</name>
    <value>~/.oci/oci_api_key.pem</value>
  </property>
...
</configuration>
```

Using Instance Principals for Authentication

Oracle provides *instance principals* so that you no longer need to configure user credentials or provide PEM files on services running on instances. Each of these instances has its own identity and authenticates by using certificates added to the instance by instance principals.

To use instance principals authentication with the HDFS connector, simply provide the property `fs.oci.client.custom.authenticator` and set the value to `com.oracle.bmc.hdfs.auth.InstancePrincipalsCustomAuthenticator`.

Because using instance principals provides your instance with a custom authenticator, it is no long necessary to configure the following properties:

- `fs.oci.client.auth.tenantId`
- `fs.oci.client.auth.userId`
- `fs.oci.client.auth.fingerprint`
- `fs.oci.client.auth.pemfilepath`
- `fs.oci.client.auth.passphrase`

The following example code illustrates using instance principals for authentication with the HDFS connector:

```
<?xml version="1.0"?>
<configuration>
  <property>
    <name>fs.oci.client.hostname</name>
    <value>https://objectstorage.us-phoenix-1.oraclecloud.com</value>
  </property>
  <property>
    <name>fs.oci.client.custom.authenticator</name>
    <value>com.oracle.bmc.hdfs.auth.InstancePrincipalsCustomAuthenticator</value>
  </property>
</configuration>
```

For more information about instance principals, see Announcing Instance Principals for Identity and Access Management.

Configuring a HTTP Proxy

You can set the following optional properties in the `core-site.xml` file to configure a HTTP proxy:

Property	Description	Type	Required
`fs.oci.client.proxy.uri`	The URI of the proxy endpoint. For example, `http://proxy.mydomain.com:80`.	String	No
`fs.oci.client.proxy.username`	The username to authenticate with the proxy.	String	No
`fs.oci.client.proxy.password`	The password to authenticate with the proxy.	String	No
`fs.oci.client.multipart.allowed`	Enables the upload manager to support multipart uploads	Boolean	No

Property	Description	Type	Required
`fs.oci.client.multipart.minobjectsize.mb`	Specifies the minimum object size in mebibytes in order to use the upload manager.	Integer	No
`fs.oci.client.multipart.partsize.mb`	Specifies the part size in mebibytes for the upload manager.	Integer	No

Note

Configuring a proxy enables use of the `ApacheConnectorProvider` when making connections to Object Storage. It buffers requests into memory and can impact memory utilization when uploading large objects. It is recommended to enable multipart uploads and adjust the multipart properties to manage memory consumption.

Large Object Uploads

Large objects are uploaded to Object Storage using multipart uploads. The file is split into smaller parts that are uploaded in parallel, which reduces upload times. This also enables the HDFS connector to retry uploads of failed parts instead of failing the entire upload. However, uploads may transiently fail, and the connector will attempt to abort partially uploaded files. Because these files accumulate (and you will be charged for storage), list the uploads periodically and then after a certain number of days abort them manually using the SDK for Java.

Information about using the Object Storage API for managing multipart uploads can be found in API Documentation.

Note

If you prefer not to use multipart uploads, you can disable them by setting the `fs.oci.client.multipart.allowed` property to `false`.

Best Practices

The following sections contain best practices to optimize usage and performance.

Directory Names

There are no actual directories in Object Storage. Directory grouping is a function of naming convention, where objects use `/` delimiters in their names. For example, an object named `a/example.json` implies there is a directory named `a`. However, if that object is deleted, the `a` directory is also deleted implicitly. To preserve filesystem semantics where the directory can exist without the presence of any files, the HDFS connector creates an actual object whose name ends in `/` with a path that represents the directory, (e.g., create an object named `a/`). Now, deleting `a/example.json` doesn't affect the existence of the `a` directory, because the `a/` object maintains its presence. However, it's entirely possible that somebody could delete that `a/` object without deleting the files/directories beneath it. The HDFS connector will only delete the folder object if there are no objects beneath that path. The folder object itself is zero bytes.

Inconsistent Filesystem

Deleting a directory means deleting all objects that start with the prefix representing that directory. HDFS allows you to query for the file status of a file or a directory. The file status of a directory is implemented by verifying that the folder object for that directory exists. However, it's possible that the folder object has been deleted, but some of the objects with that prefix still exist. For example, in a situation with these objects:

- a/b/example.json
- a/b/file.json
- a/b/

HDFS would know that directory /a/b/ exists and is a directory, and scanning it would result in example.json and file.json. However, if object a/b/ was deleted, the filesystem would appear to be in an inconsistent state. You could query it for all files in directory /a/b/ and find the two entries, but querying for the status of the actual /a/b/ directory would result in an exception because the directory doesn't exist. The HDFS connector does not attempt to fix up the state of the filesystem.

File Creation

Object Storage supports objects that can be many gigabytes in size. Creating files will normally be done by writing to a temp file and then uploading the contents of the file when the stream is closed. The temp space must be large enough to handle multiple uploads. The temp directory used is controlled by the hadoop.tmp.dir configuration property.

Read/Seek Support

When in-memory buffers are enabled (fs.oci.io.read.inmemory), seek is fully supported because the entire file is buffered into a byte array. When in-memory buffer is not enabled (likely because object sizes are large), seek is implemented by closing the stream and making a new range request starting at the specified offset.

Directory Listing

Listing a directory is essentially a List bucket operation with a prefix and delimiter specified. To create an HDFS FileStatus instance for each key, the connector performs an additional HEAD request to get ObjectMetadata for each individual key. This will be required until Object Storage supports richer list operation data.

URI Format for Filesystems and Files

HDFS filesystems and files are referenced through URIs. The scheme specifies the type of filesystem, and the remaining part of the URI is largely free for the filesystem

implementation to interpret as it wants.

Because Object Storage is an object store, its ability to name objects as if they were files in a filesystem is used to mimic an actual filesystem.

ROOT

The root of Object Storage filesystem is denoted by a path where the authority component includes the bucket name and the namespace name, as shown:

Note

In the examples, "`MyBucket`" and "`MyNamespace`" are placeholders and should be replaced with appropriate values.

```
oci://MyBucket@MyNamespace/
```

This is always the root of the filesystem. The reason for using authority for both bucket and namespace is that HDFS only allows the authority portion to determine where the filesystem is; the path portion denotes just the path to the resource (so "oci//MyNamespace/MyBucket" won't work, for example). Note that the `@` character is not a valid character for buckets or namespaces, and should allow the authority to be parsed correctly.

SUB-DIRECTORIES

Sub-directories do not actually exist, but can be mimicked by creating objects with `/` characters. For example, two files named `a/b/c/example.json` and `a/b/d/path.json` would appear as if they were in a common directory `a/b`. This would be achieved by using the Object Storage prefix- and delimiter-based querying. In the given example, referencing a sub-directory as a URI would be:

```
oci://MyBucket@MyNamespace/a/b/
```

OBJECTS/FILES

An object named `a/b/c/example.json` is referenced as:

```
oci://MyBucket@MyNamespace/a/b/c/example.json
```

Logging

Logging in the connector is done through SLF4J. SLF4J is a logging abstraction that allows the use of a user-supplied logging library (e.g., log4j). For more information, see, the SLF4J manual.

The following example shows how to enable basic logging to standard output.

1. Download the SLF4J Simple binding jar: SLF4J Simple Binding
2. Add the jar to your classpath
3. Add the following VM arg to enable debug level logging (by default, info level is used): `-Dorg.slf4j.simpleLogger.defaultLogLevel=debug`

You can configure more advanced logging options by using the log4j binding.

Sample Hadoop Job

hadoop_sample_hdfs:

```
package com.oracle.oci.hadoop.example;

import java.io.ByteArrayOutputStream;
import java.io.IOException;
import java.net.URI;
import java.net.URISyntaxException;

import org.apache.commons.io.IOUtils;
import org.apache.hadoop.conf.Configuration;
import org.apache.hadoop.fs.FSDataInputStream;
import org.apache.hadoop.fs.FSDataOutputStream;
import org.apache.hadoop.fs.Path;
import org.apache.hadoop.io.IntWritable;
```

```
import org.apache.hadoop.io.Text;
import org.apache.hadoop.mapreduce.Job;
import org.apache.hadoop.mapreduce.lib.input.FileInputFormat;
import org.apache.hadoop.mapreduce.lib.output.FileOutputFormat;
import org.slf4j.Logger;
import org.slf4j.LoggerFactory;

import com.oracle.oci.hdfs.BmcFilesystem;

import lombok.RequiredArgsConstructor;

@RequiredArgsConstructor
public class SampleOracleBmcHadoopJob
{
    private static final String SAMPLE_JOB_PATH = "/samplehadoopjob";
    private static final String INPUT_FILE = SAMPLE_JOB_PATH + "/input.dat";
    private static final String OUTPUT_DIR = SAMPLE_JOB_PATH + "/output";

    // non-static since this is the runner class it needs to initialize after we set the properties
    private final Logger log = LoggerFactory.getLogger(SampleOracleBmcHadoopJob.class);

    /**
     * Runner for sample hadoop job. This expects 3 args: path to configuration file, Object Store
namespace, Object
     * Store bucket. To run this, you must:
     *{@code

         *
    Create a standard hadoop configuration file

         *
    Create the bucket ahead of time.

         *}

     * This runner will create a test input file in a file '/samplehadoopjob/input.dat', and job results
will be written
     * to '/samplehadoopjob/output'.
     *
     * @param args
```

```
     *            1) path to configuration file, 2) namespace, 3) bucket
     * @throws Exception
     */
    public static void main(final String[] args) throws Exception
    {
        if (args.length != 3)
        {
            throw new IllegalArgumentException(
                    "Must have 3 args: 1) path to config file, 2) object storage namespace, 3) object
storage bucket");
        }

        // redirect all logs to sysout
        System.setProperty("org.slf4j.simpleLogger.logFile", "System.out");
        System.setProperty("org.slf4j.simpleLogger.defaultLogLevel", "debug");

        final SampleOracleBmcHadoopJob job = new SampleOracleBmcHadoopJob(args[0], args[1], args[2]);
        System.exit(job.execute());
    }

    private final String configurationFilePath;
    private final String namespace;
    private final String bucket;

    public int execute() throws IOException, ClassNotFoundException, InterruptedException,
URISyntaxException
    {
        log.info("Creating hadoop configuration");

        for (final IntWritable val : values)
        {
            sum += val.get();
        }
        this.result.set(sum);
        context.write(key, this.result);
    }
}
```

Troubleshooting

This section contains troubleshooting information for the HDFS Connector.

Troubleshooting Service Errors

Any operation resulting in a service error will cause an exception of type com.oracle.bmc.model.BmcException to be thrown by the HDFS Connector. For information about common service errors returned by OCI, see API Errors.

Java Encryption Key Size Errors

The HDFS Connector can only handle keys of 128 bit or lower key length. Users get "Invalid Key Exception" and "Illegal key size" errors when they use longer keys, such as AES256. Use one of the following workarounds to fix this issue:

- Use a 128 bit key, such as AES128.
- Install the Java Cryptography Extension (JCE) Unlimited Strength Jurisdiction from the following location: http://www.oracle.com/technetwork/java/javase/downloads/jce8-download-2133166.html

Contributions

Got a fix for a bug, or a new feature you'd like to contribute? The SDK is open source and accepting pull requests on GitHub.

Notifications

If you wish to be notified when a new version of the HDFS connector is released, subscribe to the Atom feed.

Questions or Feedback

Ways to get in touch:

- GitHub Issues: To file bugs and make feature requests
- Stack Overflow: Please use the oracle-cloud-infrastructure and oci-hdfs-connector tags in your post

- Oracle Cloud Infrastructure Forum: Threads tagged with Developer Tools

Using the HDFS Connector with Spark

Introduction

This article provides a walk through that illustrates using the HDFS connector with the Spark application framework. For the walkthrough, we use the Oracle Linux 7.4 operating system, and we run Spark as a standalone on a single computer.

Prerequisites

Following are prerequisites for completing the walkthrough:

- You must have permission to launch a Compute instance. For guidance, see Launching an Instance.
- You must be able to connect to the service instance that you've launched. For guidance, see Connecting to an Instance.
- You must have the appropriate OCID, fingerprint, and private key for the Identity and Access Management (IAM) user that you will use to interact with an Object Storage. For guidance, see SDK and Tool Configuration; see also Resource Identifiers.
- You must have an Object Storage bucket that you can connect to.
- The IAM user must be able to read and write to that bucket using the Console.

Using Spark

Install Spark and Dependencies

Note

For the purpose of this example, install Spark into the current user's home directory. Note that for production scenarios, you would not do this.

Note

Versions 2.7.7.0 and later no longer install all of the required third party dependencies. Required third party dependencies are bundled under the `third-party/lib` folder in the zip archive and should be installed manually.

1. Launch an instance of your Compute service. For guidance, see Launching an Instance.
2. Ensure that your service instance has a public IP address so that you can connect using a Secure Shell (SSH) connection. For guidance, see Instance Console Connections.
3. Connect to your service instance using an SSH connection.
4. Install Spark and its dependencies, Java and Scala, by using the code examples that follow.

```
# We'll use wget to download some of the artifacts that need to be installed
sudo yum install wget

# First install Java
sudo yum install java-1.8.0-openjdk.x86_64
export JAVA_HOME=/usr/lib/jvm/jre-1.8.0-openjdk
# Should be something like: OpenJDK Runtime Environment (build 1.8.0_161-b14)
java -version

# Then install Scala
wget https://downloads.lightbend.com/scala/2.12.4/scala-2.12.4.rpm
sudo yum install scala-2.12.4.rpm
# Should be something like: Scala code runner version 2.12.4 -- Copyright 2002-2017, LAMP/EPFL and
Lightbend, Inc.
scala -version

# Then download Spark
wget https://archive.apache.org/dist/spark/spark-2.2.1/spark-2.2.1-bin-hadoop2.7.tgz
tar xvf spark-2.2.1-bin-hadoop2.7.tgz
export SPARK_HOME=$HOME/spark-2.2.1-bin-hadoop2.7
export PATH=$PATH:$SPARK_HOME/bin
```

```
# Start a Spark master
cd $SPARK_HOME
./sbin/start-master.sh
```

DOWNLOAD THE HDFS CONNECTOR AND CREATE CONFIGURATION FILES

Note

For the purposes of this example, place the JAR and key files in the current user's home directory. For production scenarios you would instead put these files in a common place that enforces the appropriate permissions (that is, readable by the user under which Spark and Hive are running).

Download the HDFS connector to the service instance and add the relevant configuration files by using the following code example. For additional information, see HDFS Connector for Object Storage.

```
wget https://github.com/oracle/oci-hdfs-connector/releases/download/v2.9.2.1/oci-hdfs.zip
unzip oci-hdfs.zip -d oci-hdfs

cd $HOME
mkdir .oci
# Create or copy your API key into the $HOME/.oci directory

cd $SPARK_HOME/conf
# Create a core-site.xml (e.g. by transferring one you have, using vi etc.). Consult
# https://docs.cloud.oracle.com/Content/API/SDKDocs/hdfsconnector.htm#two
# for what this should look like

# Create a spark-defaults.conf file from the template
cp spark-defaults.conf.template spark-defaults.conf
```

In the `spark-defaults.conf` file, add the following at the bottom:

```
spark.sql.hive.metastore.sharedPrefixes= shaded.oracle,com.oracle.bmc
```

PREPARE DATA

For testing data, we will use the MovieLens data set.

1. Download the latest data set at https://grouplens.org/datasets/movielens/latest/. Be sure to download the "Small" data set.
2. Unzip the download file.
3. Upload the `movies.csv` file to your Object Storage bucket.

TEST USING THE SPARK SHELL

With the data ready, we can now launch the Spark shell and test it using a sample command:

```
cd $SPARK_HOME
./bin/spark-shell

scala> sc.wholeTextFiles("oci://PipedUploadTest@sampletenancy/")
java.io.IOException: No FileSystem for scheme: oci
```

You receive an error at this point because the oci:// file system schema is not available. We need to reference the JAR file before starting the Spark shell. Here's an example for doing so:

```
./bin/spark-shell --jars $HOME/oci-hdfs/lib/oci-hdfs-full-1.2.7.jar

scala> sc.wholeTextFiles("oci://PipedUploadTest@sampletenancy/")
res0: org.apache.spark.rdd.RDD[(String, String)] = oci://PipedUploadTest@sampletenancy/
MapPartitionsRDD[1] at wholeTextFiles at <console>:25

scala> sc.textFile("oci://PipedUploadTest@sampletenancy/movies.csv").take(20).foreach(println)
movieId,title,genres
1,Toy Story (1995),Adventure|Animation|Children|Comedy|Fantasy
2,Jumanji (1995),Adventure|Children|Fantasy
3,Grumpier Old Men (1995),Comedy|Romance
4,Waiting to Exhale (1995),Comedy|Drama|Romance
5,Father of the Bride Part II (1995),Comedy
6,Heat (1995),Action|Crime|Thriller
7,Sabrina (1995),Comedy|Romance
8,Tom and Huck (1995),Adventure|Children
9,Sudden Death (1995),Action
10,GoldenEye (1995),Action|Adventure|Thriller
11,"American President, The (1995)",Comedy|Drama|Romance
12,Dracula: Dead and Loving It (1995),Comedy|Horror
```

```
13,Balto (1995),Adventure|Animation|Children
14,Nixon (1995),Drama
15,Cutthroat Island (1995),Action|Adventure|Romance
16,Casino (1995),Crime|Drama
17,Sense and Sensibility (1995),Drama|Romance
18,Four Rooms (1995),Comedy
19,Ace Ventura: When Nature Calls (1995),Comedy
```

The command is successful so we are able to connect to Object Storage. Note that if you do not wish to pass the `--jars` argument each time the command executes, you can instead copy the `oci-hdfs-full` JAR file into the `$SPARK_HOME/jars` directory.

START THE SPARK THRIFT SERVER

Start the Spark Thrift Server on port 10015 and use the Beeline command line tool to establish a JDBC connection and then run a basic query, as shown here:

```
cd $SPARK_HOME
./sbin/start-thriftserver.sh --hiveconf hive.server2.thrift.port=10015
```

Once the Spark server is running, we can launch Beeline, as shown here:

```
cd $SPARK_HOME
./bin/beeline
Beeline version 1.2.1.spark2 by Apache Hive
beeline>
```

Next, connect to the server, as shown here:

Note

For the purposes of this example, we have not configured any security, so any user name and password will be accepted. For production scenarios you would not do this.

```
beeline> !connect jdbc:hive2://localhost:10015 testuser testpass
Connecting to jdbc:hive2://localhost:10015
log4j:WARN No appenders could be found for logger (org.apache.hive.jdbc.Utils).
log4j:WARN Please initialize the log4j system properly.
```

```
log4j:WARN See http://logging.apache.org/log4j/1.2/faq.html#noconfig for more info.
Connected to: Spark SQL (version 2.2.1)
Driver: Hive JDBC (version 1.2.1.spark2)
Transaction isolation: TRANSACTION_REPEATABLE_READ
0: jdbc:hive2://localhost:10015>
```

If we now check to see what tables exist, we see the following:

```
0: jdbc:hive2://localhost:10015> show tables;
+-----------+------------+--------------+--+
| database  | tableName  | isTemporary  |
+-----------+------------+--------------+--+
+-----------+------------+--------------+--+
No rows selected (0.724 seconds)
```

None exist presently; however, we can create a table and link it to the `movies.csv` file that we downloaded and placed in the Object Storage bucket, as shown here:

```
0: jdbc:hive2://localhost:10015> create table test_table (movieId integer, title string, genres
string) using csv options (path "oci://myBucket@myTenant/movies.csv", header "true", delimiter ",");

0: jdbc:hive2://localhost:10015> describe formatted test_table;
+-------------------------------+--------------------------------------------------------------------+------

   |
| Table Properties              | [transient_lastDdlTime=1519937118]                            |
   |
| Location                      | oci://PipedUploadTest@sampletenancy/movies.csv    |          |
| Serde Library                 | org.apache.hadoop.hive.serde2.lazy.LazySimpleSerDe            |
   |
| InputFormat                   | org.apache.hadoop.mapred.SequenceFileInputFormat              |
   |
| OutputFormat                  | org.apache.hadoop.hive.ql.io.HiveSequenceFileOutputFormat     |
   |
| Storage Properties            | [delimiter=,, header=true, serialization.format=1]            |
   |
+-------------------------------+---------------------------------------------------------------+------
----+--+
```

Note that the table stores its data externally in Object Storage and the data can be accessed using the HDFS connector (the `oci://` file system scheme). Now that we have a table, we can query it:

```
0: jdbc:hive2://localhost:10015> select * from test_table limit 10;
+----------+--------------------------------------+-----------------------------------------------+--+
| movieId  |                title                 |                    genres                     |
+----------+--------------------------------------+-----------------------------------------------+--+
| 1        | Toy Story (1995)                     | Adventure|Animation|Children|Comedy|Fantasy  |
| 2        | Jumanji (1995)                       | Adventure|Children|Fantasy                     |
| 3        | Grumpier Old Men (1995)              | Comedy|Romance                                  |
| 4        | Waiting to Exhale (1995)             | Comedy|Drama|Romance                            |
| 5        | Father of the Bride Part II (1995)   | Comedy                                        |
| 6        | Heat (1995)                          | Action|Crime|Thriller                         |
| 7        | Sabrina (1995)                       | Comedy|Romance                                  |
| 8        | Tom and Huck (1995)                  | Adventure|Children                           |

Terraform Provider

This topic provides information about installing, configuring, and using the Terraform provider with Oracle Cloud Infrastructure.

Terraform is a tool that allows you to programmatically manage, version, and persist your IT infrastructure as "infrastructure as code." Terraform uses declarative syntax to describe your infrastructure and then persist it in configuration files that can be shared, reviewed, edited, versioned, preserved, and reused.

The Oracle Cloud Infrastructure Terraform provider is a component that connects Terraform to the service infrastructure that you wish to manage.

- **Services supported:**
  - Analytics Cloud
  - Audit
  - Budgets
  - Container Engine for Kubernetes
  - Compute Autoscaling
  - Content and Experience
  - Core Services (Networking, Compute, Block Volume)
  - Database
  - Digital Assistant
  - DNS Service
  - Email Delivery

  - Events
  - FastConnect
  - File Storage
  - Functions
  - Health Checks
  - IAM
  - Integration Cloud
  - Key Management
  - Limits
  - Load Balancing
  - Monitoring
  - Notifications
  - Object Storage
  - Streaming
  - Web Application Firewall (WAF)
- **Licensing:** This provider and sample is licensed under the Mozilla Public License 2.0; third-party content is separately licensed as described in the code.
- **Documentation:** Oracle Cloud Infrastructure Provider

Note

For troubleshooting, see Terraform state drift with tag defaults and tags for secondary resources for a known issue with tags related to Terraform.

Contributions

Got a fix for a bug, or a new feature you'd like to contribute? The Terraform provider is open source and accepting pull requests on GitHub.

Notifications

To be notified when a new version of the Terraform provider is released, subscribe to the Atom feed.

Questions or Feedback

Ways you can get in touch:

- GitHub: To file bugs and feature requests only.
- Stack Overflow: Please use the oci-terraform and oracle-cloud-infrastructure tags in your post.
- Developer Tools section of the Oracle Cloud forums.

Getting Started with the Terraform Provider

This topic provides instructions for downloading and installing both Terraform and the Oracle Cloud Infrastructure Terraform provider, and provides a brief introduction to the key concepts for understanding and using the Oracle Cloud Infrastructure Terraform provider.

Terraform Overview

Terraform is "infrastructure-as-code" software that allows you to define your infrastructure resources in files that you can persist, version, and share. These files describe the steps required to provision your infrastructure and maintain its desired state; it then executes these steps and builds out the described infrastructure.

Terraform’s configuration and execution building blocks are modules, which are self-contained configuration packages. You can use these modules to organize your code and to create reusable components. HashiCorp, the developer of Terraform, provides a library of open-source Terraform modules “out of the box” to support many common tasks.

To use Terraform for Oracle Cloud Infrastructure, you must download two components - Terraform from HashiCorp, and then the Oracle Cloud Infrastructure Terraform provider.

Download and Install Terraform

Download Terraform from the HashiCorp download page. Ensure that you download the correct binary file for your system.

Important

The Oracle Cloud Infrastructure Terraform provider version 2.2.0 and greater requires Terraform version 0.10.1 or greater.

Download the Oracle Cloud Infrastructure Terraform Provider

Prerequisites for Installing and Using the Terraform Provider

- An Oracle Cloud Infrastructure account that has user credentials sufficient to execute a Terraform plan.
- A user in that account.
- Required keys and Oracle Cloud Infrastructure IDs (OCIDs). For guidance, see "Required Keys and OCIDs" in the *Oracle Cloud Infrastructure User Guide*.
- The correct Terraform binary file for your operating system (version 0.10.1 or greater).

Installing and Configuring the Terraform Provider

- For guidance on installing or on upgrading a previous version of the Oracle Cloud Infrastructure Terraform provider, see Terraform Provider Version 3.
- For guidance on setting up the Terraform provider, see Oracle Cloud Infrastructure Provider.

- Terraform Configuration Syntax

Writing Terraform Configurations

OVERVIEW

Using Terraform, you can describe your Oracle Cloud Infrastructure using the HashiCorp Configuration Language format (HCL) in Terraform configuration files (see Configuration Syntax). Terraform configuration files can use either of two formats: Terraform domain-specific language (HashiCorp Configuration Language format [HCL]), which is the recommended approach, or JSON format if the files need to be machine-readable. Configuration files that use the HCL format end with the `.tf` file extension; those using JSON format end with the `.tf.json` file extension. The Terraform format is human-readable, while the JSON format is machine readable.

Use Terraform configurations to define your Oracle Cloud Infrastructure resources, variable definitions, data sources, and a great deal more. Terraform, then, converts your Oracle Cloud Infrastructure configurations into a set of API calls against Oracle Cloud Infrastructure API endpoints. The key to writing Terraform configuration is understanding how to abstract the desired infrastructure conceptually into Terraform configuration syntax.

Important

While the Oracle Cloud Infrastructure API uses camelCase extensively, Terraform does not support camelCase in configuration files. For this reason, in the configurations you see underscores rather than capitalization as separators. For example, where the API uses `availabilityDomain`, the Terraform configuration uses `availability_domain`.

CONFIGURATION FILE REQUIREMENTS

Terraform configuration (`.tf`) files have specific requirements, depending on the components that are defined in the file. For example, you might have your Terraform provider defined in one file (provider.tf), your variables defined in another (variables.tf), your data sources defined in yet another.

Note

We provide a great many example configuration files in the Terraform Provider Examples on our Oracle Cloud Infrastructure GitHub.

PROVIDER DEFINITIONS

The following example using Terraform syntax illustrates the requirements for an Oracle Cloud Infrastructure Terraform provider definition, and also shows associated variable definitions. The provider definition relies on variables so that the configuration file itself does not contain sensitive data. Including sensitive data creates a security risk when exchanging or sharing configuration files.

```
variable "tenancy_ocid" {}
variable "user_ocid" {}
variable "fingerprint" {}
```

```
variable "private_key_path" {}
variable "region" {}

provider "oci" {
   tenancy_ocid = "${var.tenancy_ocid}"
   user_ocid = "${var.user_ocid}"
   fingerprint = "${var.fingerprint}"
   private_key_path = "${var.private_key_path}"
   region = "${var.region}"
}
```

The `region` attribute specifies the geographical region in which your provider resources are created. To target multiple regions in a single configuration, you simply create a provider definition for each region and then differentiate by using a provider alias, as shown in the following example. Notice that only one provider, named "oci" is defined, and yet the `oci` provider definition is entered twice, once for the `us-phoenix-1` region (with the alias "phx"), and once for the region `us-ashburn-1` (with the alias "iad").

```
variable "tenancy_ocid" {}
variable "user_ocid" {}
variable "fingerprint" {}
variable "private_key_path" {}
variable "compartment_ocid" {}

provider "oci" {
   region = "us-phoenix-1"
   alias = "phx"
   tenancy_ocid = "${var.tenancy_ocid}"
   user_ocid = "${var.user_ocid}"
   fingerprint = "${var.fingerprint}"
   private_key_path = "${var.private_key_path}"
}

provider "oci" {
   region = "us-ashburn-1"
   alias = "iad"
   tenancy_ocid = "${var.tenancy_ocid}"
   user_ocid = "${var.user_ocid}"
   fingerprint = "${var.fingerprint}"
   private_key_path = "${var.private_key_path}"
}
```

For more information, see Provider Configuration.

Variable Definitions

Variables in Terraform represent parameters for Terraform modules. In variable definitions, each block configures a single input variable, and each definition can take any or all of three optional arguments:

- `type` (optional): Defines the variable type as one of three allowed values: `string`, `list`, and `map`. If this argument is not used, the variable type is inferred based on `default`. If no `default` is provided, the type is assumed to be `string`.
- `default` (optional): Sets the default value for the variable. If no default value is provided, the caller must provide a value or Terraform throws an error.
- `description` (optional): A human-readable description of the variable.

Following are examples of several variable definitions. Some definitions include optional parameters.

```
variable "tenancy_ocid" {}
variable "user_ocid" {}
variable "fingerprint" {}
variable "private_key_path" {}
variable "region" {}

variable "AD" {
    default     = "1"
    description = "Availability Domain"
}

variable "CPUCoreCount" {
    default = "2"
    type    = "string"
}
```

For more information, see Input Variable Configuration. See also Input Variables.

Output Configuration

Output variables provide a means to support Terraform end-user queries. This allows users to extract meaningful data from among the potentially massive amount of data associated with a complex infrastructure. For example, you might be interested only in a handful of key values

at any given time and defining output variables allows you to extract exactly the information that you need.

Following is a simple example in which only a few output variables (instance IP addresses and boot volume IDs) are defined:

```
# Output the private and public IPs of the instance
output "InstancePrivateIPs" {
value = ["${oci_core_instance.TFInstance.*.private_ip}"]
}

output "InstancePublicIPs" {
value = ["${oci_core_instance.TFInstance.*.public_ip}"]
}

# Output the boot volume IDs of the instance
output "BootVolumeIDs" {
  value = ["${oci_core_instance.TFInstance.*.boot_volume_id}"]
}
```

For more information, see Output Variables. See also Output Configuration.

RESOURCE CONFIGURATION

Resources are components of your Oracle Cloud Infrastructure. These resources include everything from low-level components such as physical and virtual servers, to higher-level components such as email and database providers, your DNS record.

Declaring Resources

Following is a simple example of a resource definition that illustrates their basic structure.

```
resource "oci_core_virtual_network" "vcn1" {
   cidr_block = "10.0.0.0/16"
   dns_label = "vcn1"
   compartment_id = "${var.compartment_ocid}"
   display_name = "vcn1"
}
```

The resource declaration on the first line of the example uses the keyword "resource" and takes two parameters, resource `type` and resource `name` ("oci_core_virtual_network" and "vcn1" in the example). Inside the code block, then, is the resource configuration.

For more information, see Resource Configuration.

Referencing Resources in Another Stack

You can reference resources that exist in other stacks. The Terraform remote_state data source allows you to read output variables from state files.

For example, when writing a Terraform configuration for a new web application, you can make the web application use the subnet previously created from your network stack, as long as the required subnet values were output in the network stack state file. In the Terraform configuration for your new web application, do the following:

- Pull the state file of the existing network stack into the context of your current Terraform configuration.
- Load the pulled state file to a data source for remote state files.
- Populate the subnet data source in your current configuration with values from the relevant output variables of the referenced state file.
- Optionally print the identifying information for the populated data source to confirm expected values.

Note

In addition to permissions required for Resource Manager operations, you'll need appropriate permissions for resource types you're referencing, in the compartment that you're referencing them. In this example, you need read permissions for network resources in the compartment where they're located.

The following Terraform configuration excerpt references a subnet in another stack.

```
# The following example assumes that the source stack (defined by `stack_id`) has output a value named
`subnet_id`
# Terraform v0.12 is assumed
```

```
variable "stack_id" {}

# Pull the state file of the existing Resource Manager stack (the network stack) into this context
data "oci_resourcemanager_stack_tf_state" "stack1_tf_state" {
  stack_id   = "${var.stack_id}"
  local_path = "stack1.tfstate"
}

# Load the pulled state file into a remote state data source
data "terraform_remote_state" "external_stack_remote_state" {
  backend = "local"
  config = {
    path = "${data.oci_resourcemanager_stack_tf_state.stack1_tf_state.local_path}"
  }
}

# Populate a data source in this configuration using a value from the remote state data source
data "oci_core_subnet" "subnet1" {
  subnet_id = "${data.terraform_remote_state.external_stack_remote_state.outputs.subnet_id}"
}

# Print the values of the populated data source
output "print-subnet1" {
  value = "${data.oci_core_subnet.subnet1}"
}
```

DATA SOURCE CONFIGURATION

Data sources represent read-only views of existing infrastructure intended for semantic use in Terraform configurations. Following is a simple example of a data source configuration to illustrate its basic structure:

```
# Gets a list of Availability Domains
data "oci_identity_availability_domains" "ADs" {
  compartment_id = "${var.tenancy_ocid}"
}

# Get DB node list
data "oci_database_db_nodes" "DBNodeList" {
  compartment_id = "${var.compartment_ocid}"
  db_system_id = "${oci_database_db_system.TFDBNode.id}"
```

```
}

# Get DB node details
data "oci_database_db_node" "DBNodeDetails" {
  db_node_id = "${lookup(data.oci_database_db_nodes.DBNodeList.db_nodes[0], "id")}"
}

# Gets the OCID of the first (default) vNIC
data "oci_core_vnic" "DBNodeVnic" {
  vnic_id = "${data.oci_database_db_node.DBNodeDetails.vnic_id}"
}
```

For more information, see Data Source Configuration.

ENABLING INSTANCE PRINCIPAL AUTHORIZATION

Instance principal authorization allows your provider to make API calls from an Oracle Cloud Infrastructure compute instance without needing the `tenancy_ocid`, `user_ocid`, `fingerprint`, and `private_key_path` attributes in your provider definition.

Note

Instance principle authorization applies only to instances that are running in the Oracle Cloud Infrastructure.

To enable instance principal authorization for Oracle Cloud Infrastructure Terraform providers, set the `auth` attribute to "InstancePrincipal" in your provider definition, as shown in the following example:

```
variable "region" {}

provider "oci" {
   auth = "InstancePrincipal"
   region = "${var.region}"
}
```

Example Terraform Providers

To see examples of the Oracle Cloud Infrastructure Terraform provider, see Terraform Provider Examples. Several examples are provided and are grouped by service, including Compute, Database, Networking, Load Balancing, and several others.

For More Information

- Configuration
- Configuration Syntax
- Terraform Provider Examples

Using the Object Store for Terraform State Files

You can store Terraform state files in the Oracle Cloud Infrastructure Object Storage. Doing so requires that you configure a backend using one of the Terraform backend types.

Terraform supports various backend types to allow flexibility in how state files are loaded into Terraform. (For more information, see Terraform Backend Types.) For our purposes, we address two of these approaches:

- Using an HTTP remote state backend
- Using an S3-compatible remote state backend

Using an HTTP Backend

Using the HTTP backend type allows you to store state using a simple REST client. With the HTTP backend type, you can easily fetch, update, and purge state using the `HTTP GET`, `POST`, and `DELETE` methods.

To configure the HTTP backend to store your Oracle Cloud Infrastructure Terraform state files, do the following:

Create a Pre-Authenticated Request

Creating a pre-authenticated request in Oracle Object Storage enables accessing a bucket or object in the Oracle Cloud Infrastructure without needing to provide credentials. To do so, you must create a pre-authenticated request that has read/write permissions to the object store

where you intend to save the Terraform state file. You can do so in any of three ways: by using the Console UI, by using the command line interface (CLI), or by using the REST APIs.

Note

A state file must exist in the bucket before you create the pre-authenticated request. This file can be an existing state file, or an empty file for the initial state.

For guidance, see Using Pre-Authenticated Requests.

UPLOAD EXISTING STATE

If you have an existing state file, you can upload it using Curl to make an `HTTP Put` request to the object store URL, as shown here:

```
curl -X PUT -H "Content-Type: text/plain" --data-binary "@path/to/local/tfstate" http://<prefix>/<my-access-uri>
```

CONFIGURE HTTP AS A TERRAFORM BACKEND

The HTTP backend type stores state using a simple REST client and allows you to easily fetch, update, and purge state using the `HTTP GET`, `POST`, and `DELETE` methods.

The access URI for addressing Oracle Cloud Infrastructure Terraform configurations must be of the form : `https://objectstorage.us-phoenix-1.oraclecloud.com/my-access-uri` (where region and access URI are specific to you).

For more example configuration and state files that reference code, and a summary of configuration variables, see Standard Backends: HTTP.

Following is an example Terraform configuration. The region in the URL can be something other than the Phoenix region.

```
terraform {
   backend "http" {
     address = "https://objectstorage.us-phoenix-1.oraclecloud.com/<my-access-uri>" update_method = "PUT" }
}
```

REINITIALIZE TERRAFORM

Finally, you must reinitialize Terraform and then run the `apply` command, as shown following.

```
terraform init
terraform apply
```

After completing these steps,, you are able to use Oracle Cloud Infrastructure as the backend for storing Terraform state files.

USING AN S3-COMPATIBLE BACKEND

Configuring the S3-compatible backend requires that the account be enabled with S3 authentication keys, which are set on a per-user basis.

1. In the Console, open the navigation menu, then, under **Governance and Administration**, navigate to **Identity**, then **Users**. Under **User Details**, click **Customer Secret Key**. For guidance, see Working with Amazon S3 Compatibility API Keys.
2. Set the location for the credentials file. The default location is `~/.aws/credentials`. You can set an alternate location by using the S3 backend `shared_credentials_file` option.

   

   Warning

   Never set the `access_key` and the `secret_key` attributes in the same Terraform backend configuration, since this creates a security risk.

3. Configure the `[default]` entry in the credentials file with the appropriate object storage credentials. The file can contain any number of credential profiles. If you provide a different profile name, you must also update the backend `profile` option in your Terraform configuration file.

   Following is an example of Object Storage credentials:

```
[default]
aws_access_key_
id=ocid1.credential.oc1..aaaaaaaasbmhehdmefolvqwtbdjgwfsxjsgxgipdbph7odn2brgurgsyztca
aws_secret_access_key=mSTdaWhlbWj3ty4JZXlm0NUZV52xlImWjayJLJ6OH9A=
```

Where `aws_access_key_id` and `aws_secret_access_key` are user-specific values provided from the Console. The key values provided in the example are not valid and provided as examples only.

4. Set the object storage `endpoint` value in the following format:

   `https://{namespace}.compat.objectstorage.{region}.oraclecloud.com`

Following is a full example of an Object Storage backend configuration:

```
terraform {
  backend "s3" {
    bucket   = "terraform-state"
    key      = "terraform.tfstate"
    region   = "us-phoenix-1"
    endpoint = "https://acme.compat.objectstorage.us-phoenix-1.oraclecloud.com"

    skip_region_validation      = true
    skip_credentials_validation = true
    skip_requesting_account_id  = true
    skip_get_ec2_platforms      = true
    skip_metadata_api_check     = true
    force_path_style            = true
  }
}
```

Note

The S3 backend configuration can also be used for the `terraform_remote_state` data source to enable sharing state across Terraform projects.

Once you have configured the backend, you must run `terraform init` to finish the setup. If you already have an existing `terraform.tfstate` file, then Terraform prompts you to confirm that the current state file is the one to upload to the remote state.

- State Files
- Terraform Backend Types

Terraform Provider Best Practices

Following are recommended best practices for writing configurations for the Oracle Cloud Infrastructure Terraform provider.

- Referencing Images
- Availability Domains

REFERENCING IMAGES

When launching Compute instances, your Terraform configuration should use the same image every time you run a Terraform Apply job.

To ensure this, specify the image OCID directly, rather than locating it using the `oci_core_image` data source. This is because the `oci_core_image` data source calls into the `ListImages` API, whose return values can change over time because over time images are added and older ones deleted. For a list of Oracle-Provided images and their OCIDs, see Oracle-Provided Images. For more information, see Results of oci_core_images will change over time for Oracle-provided images.

We recommend the following pattern for specifying an image for a given region:

```
variable "image_id" {
  type = "map"
  default = {
    // See https://docs.cloud.oracle.com/iaas/images/
    // Oracle-provided image "Oracle-Linux-7.4-2018.02.21-1"
    us-phoenix-1 = "ocid1.image.oc1.phx.aaaaaaaaupbfz5f5hdvejulmalhyb6goieolullgkpumorbvxlwkaowglslq"
    us-ashburn-1 = "ocid1.image.oc1.iad.aaaaaaaajlw3xfie2t5t52uegyhiq2npx7bqyu4uvi2zyu3w3mqayc2bxmaa"
    eu-frankfurt-1 = "ocid1.image.oc1.eu-frankfurt-
1.aaaaaaaa7d3fsb6272srnftyi4dphdgfjf6gurxqhmv6ileds7ba3m2gltxq"
    uk-london-1 = "ocid1.image.oc1.uk-london-
1.aaaaaaaaa6h6gj6v4n56mqrbgnosskq63blyv2752g36zerymy63cfkojiiq"
```

```
  }
}
```

A Compute instance can use this in the following way:

```
resource "oci_core_instance" "TFInstance" {
  image = "${var.image_id[var.region]}"
  ...
}
```

AVAILABILITY DOMAINS

With respect to Availability Domains, we caution against a common pattern, as shown here:

```
// Get all availability domains for the region
data "oci_identity_availability_domains" "ads" {
  compartment_id = "${var.tenancy_ocid}"
}

// Then either use it to get a single AD name based on the index:
resource "oci_core_instance" "nat" {
  availability_domain = "${lookup(data.oci_identity_availability_domains.ads.availability_domains
[var.nat_instance_ad],"name")}"
  ...
}

// Or iterate through all the ADs:
resource "oci_core_subnet" "nat" {
  count = "${length(data.oci_identity_availability_domains.ads.availability_domains)}"
  availability_domain = "${lookup(data.oci_identity_availability_domains.ad.availability_domains
[count.index], "name")}"
  ...
}
```

The recommendation, then, is to explicitly list the Availability Domain names for the regions in your configuration. To do so, use a variable that you have defined as follows:

```
variable "ad_list" {
  type = "list"
}
```

You can then use the variable as shown here:

```
// Index:
resource "oci_core_instance" "nat" {
```

```
  availability_domain = "${var.ad_list[var.nat_instance_ad_index]}"
  ...
}

// Or iterate through all the ADs:
resource "oci_core_subnet" "nat" {
  count = "${length(var.ad_list)}"
  availability_domain = "${var.ad_list[count.index]}"
  ...
}
```

You can then set the `ad_list` variable directly by using the availability domain names for your tenant and region, as shown here:

```
variable "ad_list" {
  type = "list"
  default = ["kIdk:PHX-AD-1","kIdk:PHX-AD-2","kIdk:PHX-AD-3"]
}
```

The advantage of using this method is that it gives you control over your availability domain usage and prevents unexpected changes over time. However, this approach is problematic when configurations are shared between tenancies and regions, since availability domain names are tenancy- and region-specific.

A convenient alternative is to instead set the `ad_list` value by using the `oci_identity_availability_domains` data source. You should do this in the configuration, then pass them into the modules. This effectively centralizes the list of ADs, making it is easy to switch to an explicit list later, should that become necessary: Note that the modules themselves should not use the `oci_identity_availability_domains` data source.

```
data "oci_identity_availability_domains" "ad" {
  compartment_id = "${var.tenancy_ocid}"
}

data "template_file" "ad_names" {
  count = "${length(data.oci_identity_availability_domains.ad.availability_domains)}"
  template = "${lookup(data.oci_identity_availability_domains.ad.availability_domains[count.index],
"name")}"
}

module "ssm_network" {
  ad_list = "${data.template_file.ad_names.*.rendered}"
```

```
  ...
}
```

Ansible Modules

This topic provides information about installing, configuring, and using Ansible and the Oracle Cloud Infrastructure Ansible modules.

Oracle supports the use of Ansible for cloud infrastructure provisioning, orchestration, and configuration management. Ansible allows you to automate configuring and provisioning your cloud infrastructure, deploying and updating software assets, and orchestrating your complex operational processes.

What enables orchestrating, provisioning, and configuration management tasks are the Ansible modules for Oracle Cloud Infrastructure. Ansible provides a library of these Ansible modules "out of the box" for managing common tasks, and libraries of custom modules from cloud providers like AWS and Azure (see the Module Index). Oracle also provides a library of Ansible cloud modules that support provisioning and managing Oracle Cloud Infrastructure services.

Ansible playbooks automate configuration, deployment, and orchestration tasks using a declarative language (YAML), which allows you to describe infrastructure configuration, deployment policy, and orchestrating complex process steps, either synchronously or asynchronously. Ansible playbooks can be thought of as automation instruction manuals; Ansible modules, then, are your task execution tools.

Ansible modules allow you to author Ansible playbooks that enable automating the provisioning and configuring of Oracle Cloud Infrastructure services and resources, such as Compute, Load Balancing, Database, and other Oracle Cloud Infrastructure services.

- **Services supported:**
  - Block Volume
  - Compute
  - Container Engine for Kubernetes
  - Database
  - DNS
  - Email Delivery
  - File Storage
  - IAM
  - Load Balancing
  - Networking
  - Object Storage
  - Search
  - WAF
- **Licensing:** Copyright © 2018, Oracle and/or its affiliates. This software is made available to you under the terms of the GPL 3.0 license or the Apache 2.0 license. See LICENSE.TXT for details.
- **Download:** You can download the Oracle Cloud Infrastructure Ansible Module from the Oracle GitHub repository. Please follow guidance in Getting Started with Ansible for Oracle Cloud Infrastructure, in the section "Installing the Oracle Cloud Infrastructure Ansible Modules."
- **Documentation:** Getting Started with Ansible for Oracle Cloud Infrastructure

Requirements

To use Ansible, you must have the following prerequisites on your controller computer, that is, the computer from which Ansible playbooks are executed. For more information, see the Ansible Installation Guide.

- An Oracle Cloud Infrastructure account.
- A user created in that account, in a security group with a policy that grants the necessary permissions for working with resources in those compartments. For guidance, see How Policies Work.
- The necessary credentials and OCID information.
- The Oracle Cloud Infrastructure Python SDK. To download and install the SDK, see the topic Python SDK.
- Install the Ansible modules by following guidance in Getting Started with Ansible for Oracle Cloud Infrastructure, in the section "Installing the Oracle Cloud Infrastructure Ansible Modules."

Ansible Key Concepts

MODULES

Modules represent discrete provisioning tasks or operations that you can invoke individually from the command line, or else run individually or in sequence from a playbook. Ansible provides a large library of out-of-box modules that are listed in the Module Index. Other Ansible providers like Microsoft Azure and Amazon Web Services (AWS) also provide libraries of Ansible modules. Oracle also provides a library of Ansible modules that interact with services. For more information, see Working with Modules.

PLAYBOOKS

Playbooks provide a declarative language that allows you to create and persist your Ansible cloud infrastructure provisioning tasks. Playbooks are coded sets of instructions that you create to manage cloud infrastructure provisioning, and more advanced processes. For more information, see Working with Playbooks. See also a set of available Example Playbooks.

ROLES

Ansible roles are units of organization that allows you to abstract configuration, orchestration, and provisioning tasks into roles that you can save and share among playbooks and other users, and that are useful for organizing functionality in playbooks. In a sense, playbooks are

minimalist playbooks that encapsulate common configuration steps so you can share them across users or playbooks. For more information, see Ansible Roles.

INVENTORY

Ansible inventory is a means for describing hosts and groups. The inventory can be static (as a simple .ini file), or dynamic, where a look-up script assembles an up-to-date infrastructure inventory. For more information about Ansible inventory, see Working with Inventory.

Important

When using Ansible to work with Oracle Cloud Infrastructure hosts, we recommend using the Oracle dynamic inventory script to obtain a dynamic inventory list. For more information, see Using the Dynamic Inventory Script.

Notifications

To be notified when new Ansible modules are released, subscribe to the Ansible Atom Feed.

Questions or Feedback

Ways to get in touch:

- GitHub: To file bugs and feature requests only.
- Stack Overflow: Use the oci-ansible and oracle-cloud-infrastructure tags in your post.
- Developer Tools section of the Oracle Cloud forums.

Getting Started with Ansible for Oracle Cloud Infrastructure

This topic discusses how to get started with downloading and using Ansible with the Oracle Cloud Infrastructure. There are four initial steps for getting started with Ansible:

- Ensure that you have all of the prerequisites
- Download and install the Oracle Cloud Infrastructure Python SDK
- Download and install Ansible
- Download and install the Ansible modules for Oracle Cloud Infrastructure

Prerequisites for Using Ansible for Oracle Cloud Infrastructure

- You must have an Oracle Cloud Infrastructure account.
- Create a user in that account, in a security group with a policy that grants necessary permissions for working with resources in the account compartments.
- You must have the necessary credentials and OCID information.

Installing the Oracle Cloud Infrastructure Python SDK

1. Download and install the Python SDK by following instructions in the topic, Python SDK. For additional guidance, see Downloading and Installing the SDK.
2. After installing the Python SDK, you must configure it using instructions in the topic Configuring the SDK.

Installing and Configuring Ansible

- To install Ansible, follow the instructions provided in the Ansible Installation Guide.
- For guidance configuring Ansible, see Configuring Ansible.

Installing Oracle Cloud Infrastructure Ansible Modules on an Oracle Linux image

Oracle Cloud Infrastructure Ansible Modules come pre-installed on the Oracle Cloud Developer image.

Note

For more information on Oracle Cloud Infrastructure-provided images, see Oracle-Provided Images.

To install Oracle Cloud Infrastructure Ansible Modules on an Oracle Linux image:

1. `$ yum install oci-ansible-modules`

Installing Oracle Cloud Infrastructure Ansible Modules on a non-Oracle Linux image

1. `$ git clone https://github.com/oracle/oci-ansible-modules.git`
2. `$ cd oci-ansible-modules`
3. Run one of the following commands:
    a. If Ansible is installed as a user:
    `$ ./install.py`
    b. If Ansible is installed as root:
    `$ sudo ./install.py`

Sample Ansible Modules

Sample modules are available in the Oracle Cloud Infrastructure Ansible Module GitHub project. The samples library is updated regularly with the addition of new samples. You can access the samples at https://github.com/oracle/oci-ansible-modules.

Writing a Sample Playbook

You can now write a sample playbook that uses Ansible modules. Following is an example playbook (named `list_buckets.yml`) that uses the `oci_bucket_facts` module to fetch all of the facts pertaining to all of the buckets in your compartment.

```
---
- name : List summary of existing buckets in OCI object storage
  connection: local
  hosts: localhost
  tasks:
    - name: List bucket facts
      oci_bucket_facts:
         namespace_name: '<yournamespace>'
```

```
        compartment_id: '<yourcompartmentocid>'
    register: result
  - name: Dump result
    debug:
      msg: '{{result}}'
```

Executing the Playbook

Execute the Ansible playbook using Python by invoking this command:

```
$ ansible-playbook list_buckets.yml
```

How to Obtain Module Documentation

To obtain access to detailed information about using Ansible modules in the CLI, including documentation of a module's configurable options, samples, return values, and so forth, use the `ansible-doc` command on the module's name. For example, to get the documentation for the `oci_bucket_facts` module, execute the following command:

```
$ ansible-doc oci_bucket_facts
```

Documentation of the Oracle Cloud Infrastructure Ansible modules is also available in the Cloud Modules page of the Oracle Cloud Infrastructure Ansible Modules site.

Configuring Authentication

When creating and configuring Oracle Cloud Infrastructure resources, Ansible modules use authentication information that is outlined in SDK and CLI Configuration File.

Warning

IAM credentials that are referenced in Oracle Cloud Infrastructure SDK configuration files grant access to Oracle Cloud Infrastructure resources. Because of this, it is important to secure the credentials to prevent unauthorized access to these resources. To secure the credentials on the controller node where your Ansible playbooks run, follow guidelines outlined in the document Securing IAM (see section entitled "IAM Credentials").

Ansible modules permit you to override authentication information specified in the SDK configuration file by using module options and environment variables. Documentation for this is provided internally, as described in the preceding section, **How to Obtain Module Documentation**. However, using environment variables and Ansible module options to override authentication information must be avoided in production scenarios.

We recommend using Oracle Cloud Infrastructure SDK configuration files to specify authentication information. Use the "profiles" feature in the SDK configuration file to support different users. When distributing roles that use Ansible modules, ensure that no IAM credentials are included with the roles.

- Get Started with Ansible
- How Ansible Works
- Ansible for DevOps

Using the Dynamic Inventory Script

Ansible tracks configuration resources by preserving lists, called inventory lists, as simple list files (also sometimes called a *hostfile*). These inventory files can be either simple static lists,

or they can be dynamic lists that automatically update when inventory resources are added, deleted, or moved. For more information about Ansible inventory files, see Working with Inventory. See also, Working with Dynamic Inventory.

When using Ansible to work with hosts that you have provisioned in Oracle Cloud Infrastructure, static inventory lists can cause problems because Compute instances are added and deleted over time. They can also be affected by external tools such as Terraform, or by the Oracle Cloud Infrastructure SDKs.

Having up-to-date and accurate inventory lists is essential for running Ansible playbooks. Oracle Cloud Infrastructure provides you with a script that you can download and run to ensure that your instance inventory list is always up-to-date. The script ensures that you always have the current set of Oracle Cloud Infrastructure compute instances available to your playbooks.

Download and Configure the Dynamic Inventory Script

Download the dynamic inventory script (`oci_inventory.py`) and the default configuration file (`oci_inventory.ini`) from the following:

- https://github.com/oracle/oci-ansible-modules/blob/master/inventory-script/oci_inventory.py
- https://github.com/oracle/oci-ansible-modules/blob/master/inventory-script/oci_inventory.ini

Important

Before you can use the script, ensure that you have a valid Oracle Cloud Infrastructure configuration. For guidance configuring `~/.oci/config`, see SDK and CLI Configuration File.

Script and Configuration Details

The Python script, `oci_inventory.py`, uses the Oracle Cloud Infrastructure Python SDK to query compute instances in your Oracle Cloud Infrastructure tenancy and then uses this

information to create a dynamic inventory that you can use with your Ansible playbooks. Use arguments in the Python script to control the configuration profile and the tenancy compartment that you query against.

You can use the configuration file, `oci_inventory.ini`, to control how inventory details are cached, and to control which Oracle Cloud Infrastructure profile to use. This file allows you to modify host names, and to control how hosts are named in the inventory list that is generated.

Arguments and Environment Variables

For a complete list of command-line arguments and environment variables that the script accepts, see Dynamic Inventory Script.

Order of Precedence

Following is the order of precedence for configurations that are used by the dynamic inventory script:

1. Command-line arguments.
2. Environment variables.
3. Configuration settings in the selected `profile` in your Oracle Cloud Infrastructure configuration file.

Note

The default configuration file used by the inventory script is `./oci_inventory.ini`. The Oracle Cloud Infrastructure SDK configuration file, however, defaults to `~/.oci/config`. The script reads the `DEFAULT` profile from the `config` file if no profile name is specified.

Important

By default, the inventory is generated for all the compartments in the tenancy. You must have `COMPARTMENT_INSPECT` permission on the root compartment for this script to be able to access all compartments. However, when `compartment_ocid` is specified, the inventory is generated for only the specific compartment, so you only need `COMPARTMENT_INSPECT` permission on the specified compartment.

The inventory list that is generated by the dynamic inventory script is grouped using the following attributes:

- The region in which the compute instance resides.
- The name of the compartment the compute instance belongs to.
- The Availability Domain the compute instance is in.
- The vcn_id of the vcn the compute instance is in.
- The subnet_id of the subnet the compute instance is in.
- The security_list_ids of the subnet the compute instance is in.
- The image_id of the image used to launch the compute instance.
- Shape of the compute instance.
- The instance's free-form tags, with the group name set to tag_<tag_name>=<tag_value>.
- The instance's defined tags, with the group name set to <tag_namespace>#<tag_name>=<tag_value>.
- Oracle Cloud Infrastructure compute instance metadata (key-value pairs), with the group name set to <metadata-key>=<metadata-value>.
- Oracle Cloud Infrastructure compute instance extended metadata (key-value pairs), with the group name set to <metadata-key>=<metadata-value>.

Important

By default, all non-alphanumeric characters in group names and host names are replaced with an underscore (_) when the inventory is generated *except* hash (#), equals (=), period (.) and dash (-) . This allows you to use these names as Ansible group names. To disable this default substitution, set `sanitize_names` to `False` in the dynamic inventory settings file, whose default location is `./oci_inventory.ini`). To also replace the dash (-) when `sanitize_names` is `True`, set `replace_dash_in_names` to `True` in the settings file.

How to Use Dynamic Inventory

Using Dynamic Inventory During Playbook Execution

To use your dynamic inventory, first ensure that you have a correct Oracle Cloud Infrastructure SDK configuration file. Optionally, you can also have an `oci_inventory.ini` file.

Invoke `ansible-playbook` using the following command:

```
$ ansible-playbook -i <path-to-inventory-file>/oci_inventory.py <your-playbook-using-the-generated-inventory>
```

Alternatively, use the `ANSIBLE_HOSTS` environment variable by using the following command:

```
$ ANSIBLE_HOSTS=<path-to-inventory-file>/oci_inventory.py ansible-playbook <your-playbook-using-the-generated-inventory>
```

Disabling the Cache and Fetching the Latest Inventory List

If you are running the dynamic inventory script in a stand-alone manner, you can ignore the cached inventory list and fetch the most current inventory list by using the `--refresh` (`-r`) argument, as shown in the following example:

```
$ \<path-to-inventory-file\>/oci_inventory.py --refresh
```

If instead you use the inventory script during an Ansible playbook invocation, set the `OCI_CACHE_MAX_AGE` environment variable to `0` (zero) to ignore the cached list, and fetch the latest compute instance, as shown in the following example:

```
$ OCI_CACHE_MAX_AGE=0 ansible-playbook -i <path-to-inventory-file>/oci_inventory.py <your-playbook-using-the-generated-inventory>
```

DEBUGGING THE INVENTORY LIST

To examine the inventory list, run the dynamic inventory script using the `--list` argument, as shown here:

```
$ \<path-to-inventory-file\>/oci_inventory.py --list
```

If you wish to print additional debug information to `STDERR`, use the `--debug` argument, as shown:

```
$ \<path-to-inventory-file\>/oci_inventory.py --debug
```

RETRIEVE INFORMATION ABOUT A HOST

You can configure the inventory script to provide information about a specified host by using the `--host` argument and providing the host's IP address, as shown:

```
$ \<path-to-inventory-file\>/oci_inventory.py --host <host IP address>
```

The command returns the following set of variables and values:

```
{
  "availability_domain": "IwGV:US-ASHBURN-AD-1",
  "compartment_id": "ocid1.compartment.oc1..<xxxxxEXAMPLExxxxx>",
  "defined_tags": {},
  "display_name": "ansible-test-instance",
  "extended_metadata": {},
  "freeform_tags": {},
  "id": "ocid1.instance.oc1.iad.<xxxxxEXAMPLExxxxx>",
  "image_id": "ocid1.image.oc1.iad.<xxxxxEXAMPLExxxxx>",
  "ipxe_script": null,
  "launch_mode": "CUSTOM",
  "launch_options": {
     "boot_volume_type": "ISCSI",
     "firmware": "UEFI_64",
     "network_type": "VFIO",
     "remote_data_volume_type": "ISCSI"
```

```
  },
  "lifecycle_state": "AVAILABLE",
  "metadata": {
     "baz": "quux",
     "foo": "bar"
  },
  "region": "iad",
  "shape": "VM.Standard1.1",
  "source_details": {
    "image_id": "ocid1.image.oc1.iad.<xxxxxEXAMPLExxxxx>",
  "source_type": "image"
  },
  "time_created": "2018-01-16T12:13:35.336000+00:00"
}
```

TROUBLESHOOTING THE DYNAMIC INVENTORY SCRIPT

If the inventory list generated by the inventory script does not include all of the compute instances in your tenancy, review the following information.

USER PERMISSIONS

Ensure that the user OCID (specified using either the `OCI_USER` environment variable, or the `profile` section in your SDK configuration file) has the policy permissions to list the compute instances. To see a list of permissions for API operations, see Details for the Core Services.

The inventory script makes API calls for the following operations:

- ListCompartments
- ListVNICAttachments
- GetSubnet
- GetVCN
- GetVNIC
- GetInstance

HOSTNAME FORMAT

The default for `OCI_HOSTNAME_FORMAT` is `public_ip`. The dynamic inventory generated using `OCI_HOSTNAME_FORMAT` set to `public_ip` contains only compute instances that have a public

IP address. This can be useful in cases where the Ansible controller node is outside the VCN, since Ansible can only reach instances that have public IP addresses.

However, if running Ansible in a compute instance within your VCN, and it has access to all of the subnets within your VCN, including compute instances that have private IP addresses, you must set the `OCI_HOSTNAME_FORMAT` to `private_ip` to list compute instances using their private IP addresses.

Sample Ansible Playbooks

Provided here is a catalog of sample Ansible playbooks for Oracle Cloud Infrastructure that illustrate how to carry out common infrastructure provisioning and configuration tasks. The samples are organized in groups associated with Oracle Cloud Infrastructure services:

- Block Volume
- Compute
- Container Engine for Kubernetes
- Database
- File Storage
- IAM
- Load Balancing
- Object Storage
- Deployment Solution (MongoDB)

You find a brief description of each playbook in the sections that follow, along with links to each sample on the Oracle GitHub repository. Begin by reviewing the Readme.md file that you find in each playbook's root directory.

BLOCK VOLUME

ATTACH A BLOCK VOLUME TO A COMPUTE INSTANCE

This sample playbook shows how to attach a block volume to a compute instance using the iSCSI volume attachment type, and then connect it to the compute instance using `iscsiadm`. The sample shows how to do the following:

- Generate a temporary, host-specific SSH key pair.
- Specify the public key from the key pair for connecting to the instance, and then launch the instance.
- Create a new Block Volume for the instance, attach the volume to the instance, and specify `iSCSI` as the volume attachment type.
- Connect to and then mount the volume from the compute instance by executing `iscsiadm` commands over SSH using an Ansible module.

Go to the sample on Oracle GitHub.

COMPUTE

LAUNCH A COMPUTE INSTANCE

This sample playbook shows how to launch a public Compute instance and then access the instance from an Ansible module over an SSH connection. The sample illustrates how to do the following:

- Generate a temporary, host-specific SSH key pair.
- Specify the public key from the key pair for connecting to the instance, and then launch the instance.
- Connect to the newly launched instance using SSH.

Go to the sample on Oracle GitHub.

USE NAT TO ENABLE INTERNET ACCESS FROM A COMPUTE INSTANCE

This sample playbook shows how to enable internet access from a Compute instance in a private subnet. The example uses a network address translation (NAT) instance in a public

subnet through an Ansible module. The sample illustrates how to do the following:

Note

For guidance setting up the network topology to support a NAT instance, see the white paper NAT Instance Configuration: Enabling Internet Access for Private Subnets. See also Tutorial: Automatically Set Up a NAT Instance in Oracle Cloud Infrastructure with Terraform.

- Set up the applicable network topology, including creating the VCN, internet gateway, public and private subnets, and required security lists and route rules.
- Provision a NAT instance in the public subnet, and a private instance in the private subnet.
- Enable outbound internet access for the private instance through the NAT instance on the public subnet.

Go to the sample on Oracle GitHub.

ENABLE INTERNET ACCESS FROM A COMPUTE INSTANCE USING THE ORACLE CLOUD INFRASTRUCTURE NAT GATEWAY

This sample is similar to the previous sample except that while the previous sample configures a compute instance to operate as a NAT Gateway, the present sample employes the Oracle Cloud Infrastructure NAT Gateway service.

Note

For more information about the Oracle Cloud Infrastructure NAT Gateway service, see NAT Gateway. For a blog post discussing how to use the Oracle Cloud Infrastructure NAT Gateway, see Access Resources on the Public Internet Through an Oracle Cloud Infrastructure NAT Gateway.

The sample show how to complete the following:

- Set up the VCN, the NAT Gateway, the Internet Gateway, the public and private subnets, and the necessary security lists and route rules.
- Provision a bastion instance in the public subnet and a private instance in the private subnet.

Once set up, the private instance will have outbound Internet access through the Oracle Cloud Infrastructure NAT Gateway, and will be accessible using SSH from the bastion instance.

Go to the sample on Oracle GitHub

CREATE AN INSTANCE POOL

This sample shows how to manage your Compute instances using resources such as instance configurations and instance pools that are provided using Oracle Cloud Infrastructure Ansible modules. Instance pools help you create and provision multiple Compute instances within the same region based on a single instance configuration.

The sample illustrated completing the following tasks:

- Generate a temporary, host-specific SSH key pair.
- From the SSH key pair, specify the public key for connecting to the instance during launch.
- Create an instance configuration that defines settings for creating a Compute instance as part of the instance pool. The configuration provides details such as base image, shape, and metadata.
- Demonstrates how the Compute instances based on the instance configuration can be launched using instance pools.
- Connect to one of the Compute instances using SSH.

Go to the sample on Oracle GitHub

CREATE INSTANCE CONSOLE CONNECTIONS AND CAPTURE CONSOLE HISTORY

This sample shows you can create VNC and serial console connections to a Compute instance, and how you can fetch and capture the serial Console data from the instance. For more

information about Console connections, see Instance Console Connections.

This sample illustrates completing the following tasks:

- Generate a temporary SSH key pair for the serial Console connection.
- Create an instance Console connection for a Compute instance.
- Capture serial Console data for a Compute instance, and then save the data to a local machine so you can troubleshoot and debug issues.

Go to the sample on Oracle GitHub

ACCESS OBJECT STORAGE FROM A PRIVATE INSTANCE USING SERVICE GATEWAY

This sample playbook hows how you can enable private access to anObject Storage from a Compute instance using a service gateway.

Note

For more information about service gateways, see Access to Oracle Services: Service Gateway. To read a blog post discussing how to connect Compute instances using the service gateway, see Connect Private Instances with Oracle Services Through an Oracle Cloud Infrastructure Service Gateway.

The sample shows how to complete the following tasks:

- Set up a user, group, and policies required for managing buckets.
- Create and upload the required API keys to the user.
- Set up the VCN, the NAT gateway, the Internet gateway, the public and private subnets, as well as the required security lists and route tables. Note that a bastion instance is provisioned in the public subnet, and a private instance is provisioned in the private subnet.
- Provision a Compute instance in the private subnet,

- Install the Oracle Cloud Infrastructure command line interface (CLI) and configure the CLI using the cloud init script.
- Disable the NAT gateway to restrict public access to the private instance.
- Create a bucket from the private instance using the Oracle Cloud Infrastructure CLI, then verify that the bucket is created.

Following this setup, the private instnace will have private access to Object Storage.

Go to the sample on Oracle GitHub

CONTAINER ENGINE FOR KUBERNETES

CREATE A CLUSTER USING CONTAINER ENGINE FOR KUBERNETES

This sample playbook uses Container Engine for Kubernetes (OKE) to create a cluster and deploys a sample application on the cluster. This sample complements an existing example, Creating a Cluster with Oracle Cloud Infrastructure Container Engine for Kubernetes.

This sample illustrates how to do the following:

- Creates and configures a VCN and related resources required for setting up an OKE cluster.
- Creates a cluster.
- Creates a node pool.
- Downloads the kubeconfig file for the cluster.
- Deploys a sample application on the cluster.
- Verifies a successful deployment.

Go to the sample on Oracle GitHub.

DATABASE

BARE METAL/VM DATABASE PROVISIONING

This sample playbook shows how to retrieve the public and private IP addresses of a database system node so that you can access it through an Ansible module. The sample illustrates how

to do the following:

- Collect database node VNIC information for a specified database.
- Extract public and private IP addresses of the database node from the VNIC.

Go to the sample on Oracle GitHub.

AUTONOMOUS DATA WAREHOUSE

This sample playbook shows how to create an Autonomous Data Warehouse and manage its lifecycle. The sample shows how to do the following:

- Set up an Autonomous Data Warehouse.
- List all of the Autonomous Data Warehouse instances available in a compartment, filtered by display name.
- Get the "facts" for a specified Autonomous Data Warehouse.
- Stop and start an Autonomous Data Warehouse instance.
- Delete an Autonomous Data Warehouse instance.

Go to the sample on Oracle GitHub.

AUTONOMOUS TRANSACTION PROCESSING

This sample playbook shows how to create an Autonomous Transaction Processing database and manage its lifecycle. The sample shows how to do the following:

- Set up an Autonomous Transaction Processing database instance.
- List all of the Autonomous Transaction Processing instances in a compartment, filtered by display name.
- Get the "facts" for a specified Autonomous Transaction Processing instance.
- Delete an Autonomous Transaction Processing database instance.

Go to the sample on Oracle GitHub.

File Storage

Create and Mount a File System

The sample shows how to create a file system that you can access through an Oracle Cloud Infrastructure Compute instance using Ansible cloud modules. The sample illustrates completing the following tasks:

- Creates network dependencies like VCNs, subnets, and so forth, as well as a security list that is configured as required by the File Systems service.
- Generates the certificates required by the Compute instances.
- Demonstrates how to create File Storage service components, such as mount targets, file systems, exports, and snapshots.
- Demonstrates how to mount the file system using a Compute instance, and how to then access the file system content from a different Compute instance.

Go to the sample on Oracle GitHub

Multiple File Systems with Mount Targets

This sample shows how one you can export one file system using two different export paths located on two different mount targets. It also shows how a single mount target can export paths from two different file systems. The sample illustrates completing the following tasks:

- Creates network dependencies like VCNs, subnets, and so forth, as well as a security list that is configured as required by the File Systems service.
- Generates the certificates required by the Compute instances.
- Demonstrates how to create File Storage service components, such as mount targets, file systems, exports, and snapshots.
- Demonstrates how one file system can be exported onto two different mount targets.
- Demonstrates how a single mount target can export paths from two different file systems.
- Demonstrates how to mount the file system using an Oracle Cloud Infrastructure Compute instance.

Go to the sample on Oracle GitHub

IAM

Use Ansible Modules to Perform IAM Tasks

This sample shows how to perform basic identity and access management (IAM) tasks using Ansible modules. The sample also shows how to execute an Ansible playbook or execute individual tasks as a different user. The sample illustrates how to do the following:

- Create groups (**ObjectReaders** and **ObjectWriters**).
- Create an IAM policy the enables the following:
  - **ObjectReaders** to list and read buckets and objects.
  - **ObjectWriters** to create, update, list, and read buckets and objects in a specified compartment.
  - Assign the policy to groups.
- Create users (**alice** and **bob**) and then do the following:
  - Add **alice** to the **ObjectWriters** group.
  - Add **bob** to the **ObjectReaders** group.
  - Run as **alice** to create a bucket, then upload objects to the bucket.
  - Run as **bob** to list all objects in a bucket.

Go to the sample on Oracle GitHub.

Load Balancing

This sample playbook shows how to create a public load balancer using an Ansible module. The sample illustrates the following:

- Generating network-related artifacts, such as subnets and VCNs, for example.
- Generating the required certificates for the load balancer.
- Using an Ansible playbook to create a public load balancer.

Go to the sample on Oracle GitHub.

OBJECT STORAGE

LIST OBJECTS AND BUCKETS

This sample playbook shows how to list all objects and buckets in a namespace.

Go to the sample on Oracle GitHub.

DELETE OBJECTS

This sample playbook shows how to delete objects created within a specified range of days from the specified the buckets. You can also modify the sample so it deletes objects older than a specified number of days, which helps you prune old or unwanted objects that are stored in the service.

Go to the sample on Oracle GitHub.

MONGODB DEPLOYMENT

USE ANSIBLE MODULES TO DEPLOY A MONGODB DATABASE

This sample playbook shows how to deploy a MongoDB database in the securely in the cloud using Ansible modules. The sample implements security measures using the Castle strategy ("defense in depth"), which is discussed in the article Secure MongoDB on Oracle Bare Metal Cloud Services.

Go to the sample on Oracle GitHub.

NETWORKING

USE ANSIBLE MODULES TO PROVISION A VCN

This sample playbook shows how to provision a virtual cloud network (VCN) with two private subnets in different availability domains, and an IPSec VPN.The sample provisions infrastructure resources that are illustrated in the knowledge base article Scenario B: Private Subnet with a VPN. The sample provisions the following resources:

- A VCN.
- Two private subnets.

- A dynamic routing gateway (DRG).
- Customer premises equipment (CPE).
- An IPSec connection between the DRG and the CPE, and retrieves IPSec configuration information and status.

Go to the sample on Oracle GitHub.

Chef Knife Plug-in

Grafana Plug-in

This topic provides instructions for installing, configuring, and using Oracle Cloud Infrastructure Data Source for Grafana, otherwise referenced as the Grafana Plug-in.

Grafana Plug-in Overview

Grafana is an open-source visualization and alerting tool that you can use for analytics and monitoring of time-series data (metrics). While metrics from Oracle Cloud Infrastructure Monitoring are visible in metrics charts through the Console, you can use Oracle Cloud Infrastructure Data Source for Grafana ("the Grafana Plug-in") to view metrics from resources across providers on a single Grafana dashboard.

Prerequisites for Using the Grafana Plug-in

- An Oracle Cloud Infrastructure account.
- A user in that account, in a security group with an IAM policy that grants necessary permissions for working with resources in the account compartments. The policy must give you access to the metric namespaces emitting metrics (such as Compute) as well as the related resources (such as a set of Compute instances). If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in. Administrators: For common policies that give groups access to metrics, see Let users view metric definitions in a compartment and Restrict user access to a specific metric namespace. To authorize resources, such as instances, to make API calls, add the resources to a dynamic group through its matching rules, and then create a policy that allows that dynamic group access to metrics. To allow access across compartments, create the policy in the tenancy. Because of the concept of policy inheritance, instances in the indicated dynamic group can then access metrics in any compartment. To reduce the scope of access to a particular compartment, specify that compartment instead of the tenancy. See Let instances make API calls to access monitoring metrics in the tenancy.

- Compute instances: To emit metrics, Compute instances must be monitoring-enabled. OracleCloudAgent software installation may also be required. For more information, see Enabling Monitoring for Compute Instances.
- Required keys and Oracle Cloud Infrastructure IDs (OCIDs). For guidance, see "Required Keys and OCIDs" in the *Oracle Cloud Infrastructure User Guide*.

Download and Install the Grafana Plug-in

This section provides instructions for downloading and installing the Grafana Plug-in, either locally (Linux or Mac) or by Terraform script. Use Terraform script to provision a Compute instance that runs Grafana in Oracle Cloud Infrastructure.

Authentication for metric access depends on where Grafana is running. If you are running Grafana on a local machine outside Oracle Cloud Infrastructure, you must call the Monitoring API using the Command Line Interface (CLI). If you are running Grafana on the new Compute instance created by the Terraform script, use the script-generated dynamic group. If you are running Grafana on an Oracle Cloud Infrastructure Compute instance that you created, then you can add the instance to a dynamic group by configuring a matching rule. In all scenarios, you have the option of calling the API using the CLI.

Local: Download and Install the Plug-in

Local Installation Prerequisites

Grafana installation. Version 3.0 or later required.

To install the Grafana Plug-in (Oracle Cloud Infrastructure Data Source for Grafana), see https://grafana.com/plugins/oci-datasource/installation. After installation, you're ready to configure the Grafana Plug-in.

Terraform Script: Create a Grafana environment

This section describes how to use Terraform scripts to create a Grafana environment on your virtual machine.

The Terraform scripts create a dynamic group using the name you specify, configure an IAM policy named "grafana_policy," provision a Compute instance named "TFInstance0" (in

the compartment and VCN that you specify), and download and install both Grafana and the Grafana Plug-in onto the instance.

Terraform Script Prerequisites

Before running the Terraform scripts, make sure you have the following:

- Terraform and Oracle Cloud Infrastructure Terraform Provider must both be installed on your development machine. See Getting Started with the Terraform Provider.
- A Virtual Cloud Network (VCN) with access to the Internet.
  For reference, see the Linux Tutorial for creating a VCN.
- Values for the following variables. You can pass the values to your .bashrc or .bash_profile, or note them somewhere for entering when needed. These variables are required for creating the Grafana environment and using the Grafana Plug-in.

Required variables

```
variable "tenancy_ocid" {}
variable "user_ocid" {}
variable "fingerprint" {}
variable "private_key_path" {}
variable "region" {}
variable "compartment_ocid" {}
variable "ssh_public_key" {}
variable "ssh_private_key" {}
variable "subnet_id" {}
variable "availability_domain" {}
variable "dynamic_group_name" {}
```

Note

For help on getting the tenancy OCID and other values needed for these variables, see Required Keys and OCIDs.

To download and run the Terraform scripts

Make sure you satisfy the prerequisites before running the scripts.

1. Download the Terraform scripts using the following command.
   `wget https://objectstorage.us-ashburn-1.oraclecloud.com/n/oracle-cloudnative/b/GrafanaTerraform/o/terraform_grafana.tar && tar -xvf terraform_grafana.tar`
2. Change to the terraform_grafana directory using the following command.
   `cd /terraform_grafana`
3. Initialize a new Terraform configuration using the following command.
   `terraform init`
   Initialization creates the files `terraform.tfstate` and `terraform.tfstate.backup`.
4. Generate an execution plan using the following command.
   `terraform plan`
   Generating a plan can help you validate your Terraform script before you apply it to your environment.
5. Run the scripts using the following command, using the same availability domain and dynamic group variables passed in with `terraform plan`.
   `terraform apply`
   On completion, the "Apply complete!" message appears. You're now ready to configure the Grafana Plug-in.

Configure the Grafana Plug-in

This section describes how to add the Grafana Plug-in and set up a dashboard.

To configure the Grafana Plug-in

Local installation

Note

When installed locally, the Grafana plug-in accesses metrics using calls to the Monitoring API.

1. Set up the CLI for accessing Oracle Cloud Infrastructure APIs.
   You'll need to access the Monitoring API for authentication.
2. Navigate to the Grafana homepage at the following URL.
   http://localhost:3000
3. Add the Grafana Plug-In (Oracle Cloud Infrastructure Data Source for Grafana).
   In addition to the steps below, see the Grafana instructions for adding data sources at http://docs.grafana.org/guides/getting_started/.
   a. In Grafana, on the Home Dashboard, click the gear icon on the left.
   b. Click **Add data source**.
   c. In the Filter text box, type: `oracle-oci-datasource`
   d. In the filtered list, select **oracle-oci-datasource**.
   e. In the Settings page, fill in your **Tenancy OCID**, **Default Region**, and **Environment**. For **Environment** choose **local**.

Environment options

local is for Grafana deployments outside Oracle Cloud Infrastructure.

OCI Instance is for Grafana deployments on Oracle Cloud Infrastructure resources.

The data source is now added, enabling you to set up a dashboard showing metrics from Oracle Cloud Infrastructure.

4. Set up a dashboard of the type "Graph."
5. (Optional) To confirm access to metrics from Oracle Cloud Infrastructure, update your dashboard query ("Metrics") with a specific region, compartment, namespace, metric. You can also add one or more dimensions.
   Congratulations. You can now view your Oracle Cloud Infrastructure metrics in Grafana!

Terraform environment

Note

When installed by Terraform script, the Grafana plug-in accesses metrics using the script-generated dynamic group.

1. Connect to the new instance "TFInstance0."
   For instructions, see Connecting to an Instance.
2. Navigate to the Grafana homepage by running the following command, where *[Instance Public IP]* is the IP address of your new instance "TFInstance0."
   `ssh opc@[Instance Public IP] -L 3000:localhost:3000`

Note

You can get the address from the list of instances in the Console. Click **Compute**, choose your **Compartment**, and then find your instance in the list. Alternatively, you can use the Core Services API`ListVnicAttachments` and `GetVnic` operations.

3. Add the Grafana Plug-In (Oracle Cloud Infrastructure Data Source for Grafana).
   In addition to the steps below, see the Grafana instructions for adding data sources at http://docs.grafana.org/guides/getting_started/.
   a. In Grafana, on the Home Dashboard, click the gear icon on the left.
   b. Click **Add data source**.
   c. In the Filter text box, type: `oracle-oci-datasource`
   d. In the filtered list, select **oracle-oci-datasource**.
   e. In the Settings page, fill in your **Tenancy OCID**, **Default Region**, and **Environment**. For **Environment** choose **OCI Instance**.

      Environment options

      local is for Grafana deployments outside Oracle Cloud Infrastructure.
      OCI Instance is for Grafana deployments on Oracle Cloud Infrastructure resources.

      The data source is now added, enabling you to set up a dashboard showing metrics from Oracle Cloud Infrastructure.
4. Set up a dashboard of the type "Graph."
5. (Optional) To confirm access to metrics from Oracle Cloud Infrastructure, update your dashboard query ("Metrics") with a specific region, compartment, namespace, metric.

You can also add one or more dimensions.

Congratulations. You can now view your Oracle Cloud Infrastructure metrics in Grafana!

Troubleshoot the Plug-In

If the dashboard query ("Metrics") fails to populate with options, or if you have other issues accessing metrics, then the IAM policy used to access metrics may be malformed, or it may not include all required matching rules for your dynamic group (Terraform script).

To resolve this issue, do the following.

- Review your IAM policy to ensure that it matches prerequisites.
- For Terraform, consider adding the following matching rule to your dynamic group: `matching_rule = "ANY {instance.compartment.id = '${var.compartment_ocid}'}"`
- If you updated your IAM policy, then restart the Grafana server and refresh the Grafana homepage.

Terraform: Remove the environment

If you ran the Terraform script to create a Grafana environment on your virtual machine, you may want to remove the environment after your work is done. Follow the instructions in this section to do so.

To remove your Grafana environment

Run the following command, using the same availability domain and dynamic group variables passed in with `terraform apply`.

```
terraform destroy
```

Tools Configuration

This general reference shows how to configure the SDKs and other developer tools to integrate with Oracle Cloud Infrastructure services.

- Required Keys and OCIDs - Details on identity and access management
- SDK and CLI Configuration File - Methods for providing configuration information when using the SDKs or CLI.

Required Keys and OCIDs

Whether you're using an Oracle client (see Software Development Kits and Command Line Interface) or a client you built yourself, you need to do the following:

1. Create a user in IAM for the person or system who will be calling the API, and put that user in at least one IAM group with any desired permissions. See "Adding Users" in the *Oracle Cloud Infrastructure Getting Started Guide*. You can skip this if the user exists already.
2. Get these items:
    - RSA key pair **in PEM format** (minimum 2048 bits). See How to Generate an API Signing Key.
    - Fingerprint of the public key. See How to Get the Key's Fingerprint.
    - Tenancy's OCID and user's OCID. See Where to Get the Tenancy's OCID and User's OCID.
3. Upload the public key from the key pair in the Console. See How to Upload the Public Key.
4. If you're using one of the Oracle SDKs or tools, supply the required credentials listed above in either a configuration file or a config object in the code. See SDK and CLI Configuration File. If you're instead building your own client, see Request Signatures.

Important

This key pair is **not** the SSH key that you use to access compute instances. See Security Credentials.

Both the private key and public key must be in PEM format (not SSH-RSA format). The public key in PEM format looks something like this:

```
-----BEGIN PUBLIC KEY-----
MIIBIjANBgkqhkiG9w0BAQE...
...
-----END PUBLIC KEY-----
```

How to Generate an API Signing Key

You can use the following OpenSSL commands to generate the key pair in the required PEM format. If you're using Windows, you'll need to install Git Bash for Windows and run the commands with that tool.

1. If you haven't already, create a `.oci` directory to store the credentials:

   ```
   mkdir ~/.oci
   ```

2. Generate the private key with one of the following commands.

   - Recommended: To generate the key, encrypted with a passphrase you provide when prompted:

     ```
     openssl genrsa -out ~/.oci/oci_api_key.pem -aes128 2048
     ```

     Note: For Windows, you may need to insert `-passout stdin` to be prompted for a passphrase. The prompt will just be the blinking cursor, with no text.

     ```
     openssl genrsa -out ~/.oci/oci_api_key.pem -aes128 -passout stdin 2048
     ```

   - To generate the key with no passphrase:

     ```
     openssl genrsa -out ~/.oci/oci_api_key.pem 2048
     ```

3. Ensure that only you can read the private key file:

```
chmod go-rwx ~/.oci/oci_api_key.pem
```

4. Generate the public key:

```
openssl rsa -pubout -in ~/.oci/oci_api_key.pem -out ~/.oci/oci_api_key_public.pem
```

Note: For Windows, if you generated the private key with a passphrase, you may need to insert `-passin stdin` to be prompted for the passphrase. The prompt will just be the blinking cursor, with no text.

```
openssl rsa -pubout -in ~/.oci/oci_api_key.pem -out ~/.oci/oci_api_key_public.pem -passin stdin
```

5. Copy the contents of the public key to the clipboard using pbcopy, xclip or a similar tool (you'll need to paste the value into the Console later). For example:

```
cat ~/.oci/oci_api_key_public.pem | pbcopy
```

Your API requests will be signed with your private key, and Oracle will use the public key to verify the authenticity of the request. You must upload the public key to IAM (instructions below).

How to Get the Key's Fingerprint

You can get the key's fingerprint with the following OpenSSL command. If you're using Windows, you'll need to install Git Bash for Windows and run the command with that tool.

```
openssl rsa -pubout -outform DER -in ~/.oci/oci_api_key.pem | openssl md5 -c
```

When you upload the public key in the Console, the fingerprint is also automatically displayed there. It looks something like this: 12:34:56:78:90:ab:cd:ef:12:34:56:78:90:ab:cd:ef

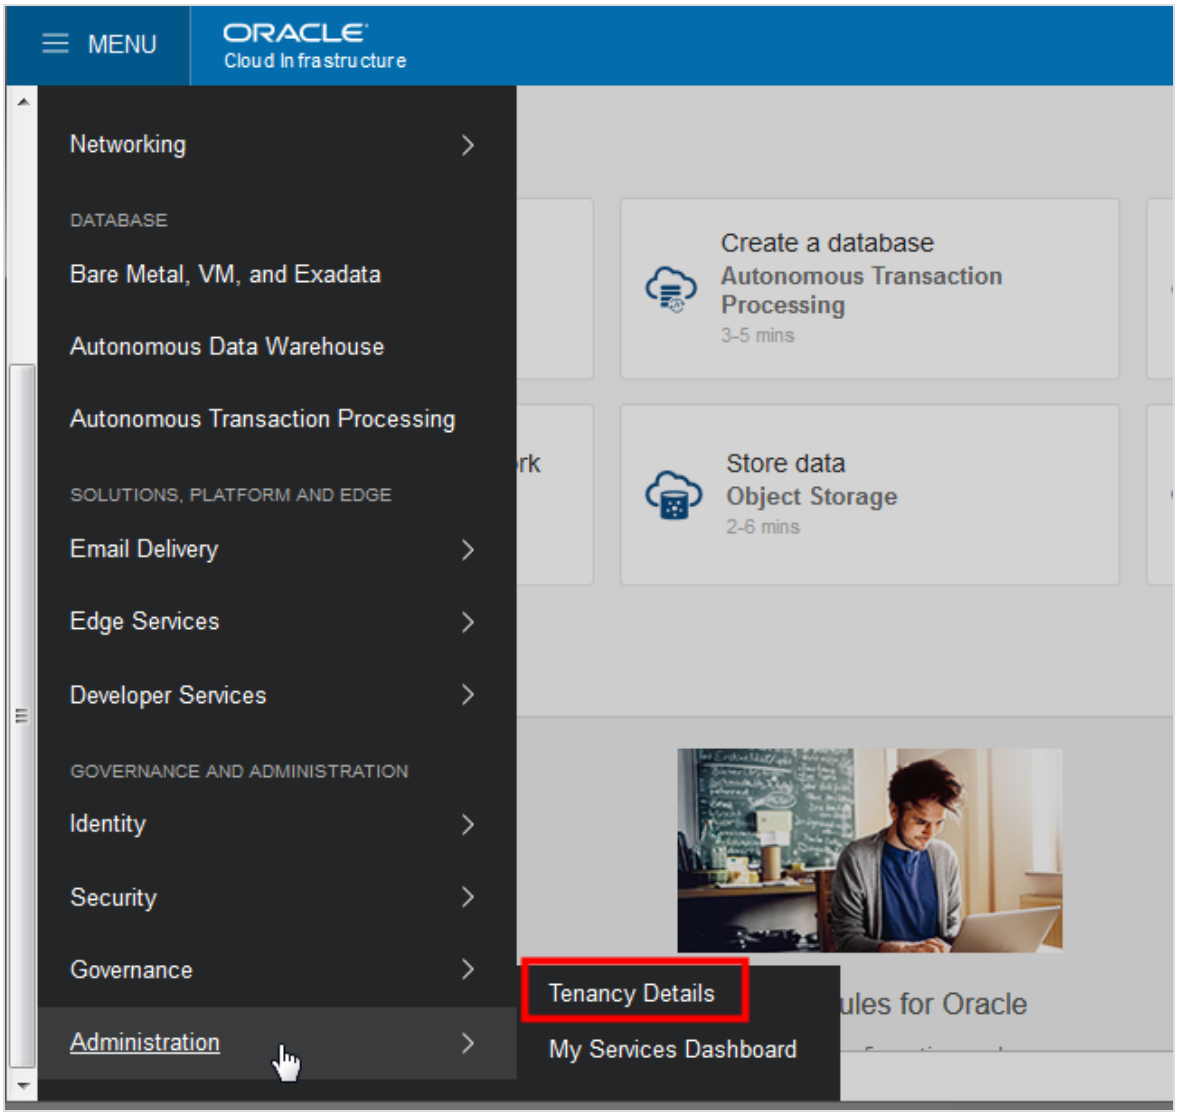
Where to Get the Tenancy's OCID and User's OCID

Both OCIDs are in the Console, which is located at https://console.us-ashburn-1.oraclecloud.com. If you don't have a login and password for the Console, contact an administrator. If you're not familiar with OCIDs, see Resource Identifiers.

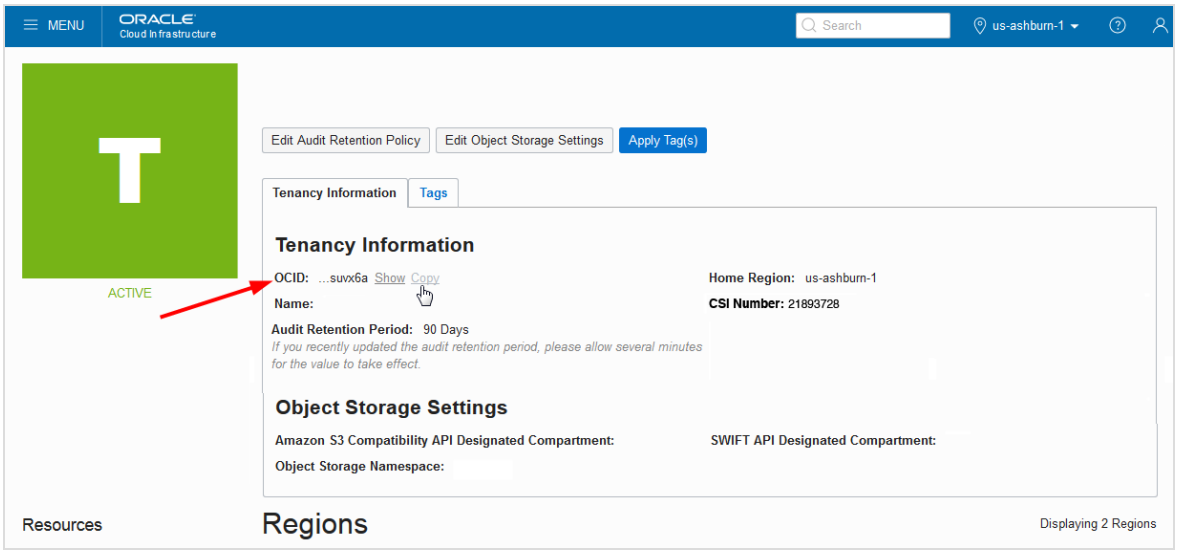
TENANCY'S OCID

Get the tenancy OCID from the Oracle Cloud Infrastructure Console on the **Tenancy Details** page:

1. Open the navigation menu, under Governance and Administration, go to **Administration** and click **Tenancy Details**.



2. The tenancy OCID is shown under **Tenancy Information**. Click **Copy** to copy it to your clipboard.



USER'S OCID

Get the user's OCID in the Console on the page showing the user's details. To get to that page:

- If you're signed in as the user: Open the **Profile** menu ( ) and click **User Settings**.
- If you're an administrator doing this for another user: Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Users**. Select the user from the list.

How to Upload the Public Key

You can upload the PEM public key in the Console, located at https://console.us-ashburn-1.oraclecloud.com. If you don't have a login and password for the Console, contact an administrator.

1. Open the Console, and sign in.
2. View the details for the user who will be calling the API with the key pair:
    - If you're signed in as this user, click your username in the top-right corner of the Console, and then click **User Settings**.

- If you're an administrator doing this for another user, instead click **Identity**, click **Users**, and then select the user from the list.

3. Click **Add Public Key**.
4. Paste the contents of the PEM public key in the dialog box and click **Add**.

The key's fingerprint is displayed (for example, 12:34:56:78:90:ab:cd:ef:12:34:56:78:90:ab:cd:ef).

Notice that after you've uploaded your first public key, you can also use the UploadApiKey API operation to upload additional keys. You can have up to three API key pairs per user. In an API request, you specify the key's fingerprint to indicate which key you're using to sign the request.

SDK and CLI Configuration File

Oracle Cloud Infrastructure SDKs and CLI require basic configuration information, like user credentials and tenancy OCID. You can provide this information by:

- Using a configuration file
- Declaring a configuration at runtime

The SDKs fully support both options. Refer to the documentation for each SDK for information about the config object and any exceptions when using a configuration file:

- SDK for Java Configuration
- Python SDK Configuration
- Ruby SDK Configuration
- Go SDK Configuration

The CLI requires a configuration file. `--region` is the only configuration value that can be passed as a parameter for a CLI operation.

File Name and Location

The default configuration file name and location is `~/.oci/config`.

Note

On Windows, you can use PowerShell to create the folder with the following command: `mkdir ~/.oci`. File Explorer does not support creating folder names that start with a period.

File Entries

The following table lists the basic entries that are required for the configuration file, as well as where to get the required information.

Entry	Description and Where to Get the Value	Required?
`user`	OCID of the user calling the API. To get the value, see Required Keys and OCIDs. Example: `ocid1.user.oc1..aaaaaaaa65vwl75tewwm32rgqvm6i34unq` (shortened for brevity)	Yes
`fingerprint`	Fingerprint for the key pair being used. To get the value, see Required Keys and OCIDs. Example: `20:3b:97:13:55:1c:5b:0d:d3:37:d8:50:4e:c5:3a:34`	Yes

Entry	Description and Where to Get the Value	Required?
`key_file`	Full path and filename of the private key. **Important:** The key pair must be in PEM format. For instructions on generating a key pair in PEM format, see Required Keys and OCIDs. If you encrypted the key with a passphrase, you must also include the `pass_phrase` entry in the config file. Example: `~/.oci/oci_api_key.pem`	Yes
`pass_phrase`	Passphrase used for the key, if it is encrypted. Example: `examplephrase`	If key is encrypted
`tenancy`	OCID of your tenancy. To get the value, see Required Keys and OCIDs. Example: `ocid1.tenancy.oc1..aaaaaaaaba3pv6wuzr4h25vqstifsfdsq` (shortened for brevity)	Yes
`region`	An Oracle Cloud Infrastructure region. See Regions and Availability Domains. Example: `us-ashburn-1`	Yes

CUSTOM VALUES

Some Oracle Cloud Infrastructure SDKs support defining custom values in the configuration file. Refer to the documentation for each SDK for more information.

Warning

Avoid saving confidential information in the configuration file.

PROFILES AND INHERITANCE

You can create multiple profiles with different values for these entries, then you can specify which profile to load.

Some Oracle Cloud Infrastructure SDKs require a DEFAULT profile and support profile inheritance. This means that any value that isn't explicitly defined for a given profile is inherited from the DEFAULT profile. Refer to the documentation for each SDK for more information.

Example Configuration

The following example shows key values in a configuration file and how to set profiles for a SDK that supports profile inheritance.

```
[DEFAULT]
user=ocid1.user.oc1..aaaaaaaat5nvwcna5j6aqzjcaty5eqbb6qt2jvpkanghtgdaqedqw3rynjq
fingerprint=20:3b:97:13:55:1c:5b:0d:d3:37:d8:50:4e:c5:3a:34
key_file=~/.oci/oci_api_key.pem
tenancy=ocid1.tenancy.oc1..aaaaaaaaba3pv6wkcr4jqae5f15p2b2m2yt2j6rx32uzr4h25vqstifsfdsq
region=us-ashburn-1

[ADMIN_USER]
user=ocid1.user.oc1..aaaaaaaa65vwl7zut55hiavppn4nbfwyccuecuch5tewwm32rgqvm6i34unq
fingerprint=72:00:22:7f:d3:8b:47:a4:58:05:b8:95:84:31:dd:0e
key_file=keys/admin_key.pem
pass_phrase=mysecretphrase
```

REST APIs

The Oracle Cloud Infrastructure APIs are typical REST APIs that use HTTPS requests and responses. This topic describes basic information about using the APIs.

Warning

Oracle recommends that you avoid using string values that include confidential information in the Oracle Cloud Infrastructure API.

API Reference and Endpoints

For links to the Oracle Cloud Infrastructure API reference and a list of the regional API endpoints, see API Reference and Endpoints.

API Version

The base path of the endpoint includes the desired API version (for example, 20160918). Here's an example for a POST request to create a new VCN in the Ashburn region:

```
POST https://iaas.us-ashburn-1.oraclecloud.com/20160918/vcns
```

Request Signing Required

All Oracle Cloud Infrastructure API requests must be signed for authentication purposes. For information about the required credentials and how to sign the requests, see Request Signatures.

HTTPS and TLS 1.2 Required

All Oracle Cloud Infrastructure API requests must support HTTPS and SSL protocol TLS 1.2.

Maximum Allowed Client Clock Skew

HTTP status code 401 (NotAuthenticated) is returned if the client's clock is skewed more than 5 minutes from the server's. To determine the server's clock time, use this curl command

with the API endpoint:

```
curl -s --head <endpoint> | grep Date
```

For example:

```
curl -s --head https://iaas.us-phoenix-1.oraclecloud.com | grep Date
```

Request and Response Format

The Oracle Cloud Infrastructure APIs use standard HTTP requests and responses. Each may contain Oracle-specific headers for pagination, entity tags (ETags), and so on as described elsewhere in this topic and in the API documentation.

Each response includes a unique Oracle-assigned request ID (for example, bb3f3275-f356-462a-93c4-bf40fb82bb02) in the `opc-request-id` response header. If you need to contact Oracle about a particular request, please provide this request ID.

Many of the API operations require JSON in the request body or return JSON in the response body. The specific contents of the JSON are described in the API documentation for the individual operation. Notice that the JSON is not wrapped or labeled according to the operation's name or the object's name or type.

Note

Make sure to set the `Content-Type` header to `application/json` in your POST and PUT requests that contain JSON in the body.

Example CreateVcn Request

```
POST https://iaas.us-phoenix-1.oraclecloud.com/20160918/vcns
host: iaas.us-phoenix-1.oraclecloud.com
opc-retry-token: 239787fs987
Content-Type: application/json
HTTP headers required for authentication
Other HTTP request headers per the HTTP spec
```

```
{
  "compartmentId":
"ocid1.compartment.oc1..aaaaaaaauwjnv47knr7uuuvqar5bshnspi6xoxsfebh3vy72fi4swgrkvuvq",
  "displayName": "Apex Virtual Cloud Network",
  "cidrBlock": "172.16.0.0/16"
}
```

Example CreateVcn Response

```
200 OK
opc-request-id: 6c4d01a6-f764-4325-a3f8-720c8b5cae7b

{
   "id": "ocid1.vcn.oc1.phx.aaaaaaaa4ex5pqjtkjhdb4h4gcnko7vx5uto5puj5noa5awznsqpwjt3pqyq",
   "compartmentId":
"ocid1.compartment.oc1..aaaaaaaauwjnv47knr7uuuvqar5bshnspi6xoxsfebh3vy72fi4swgrkvuvq",
   "displayName": "Apex Virtual Cloud Network",
   "cidrBlock": "172.16.0.0/16"
   "defaultRouteTableId":
"ocid1.routetable.oc1.phx.aaaaaaaaba3pv6wkcr4jqae5f44n2b2m2yt2j6rx32uzr4h25vqstifsfdsq",
   "defaultSecurityListId":
"ocid1.securitylist.oc1.phx.aaaaaaaac6h4ckr3ncbxmvwinfvzxjbr7owu5hfzbvtu33kfe7hgscs5fjaq"
   "defaultDhcpOptionsId":
"ocid1.dhcpoptions.oc1.phx.aaaaaaaawglzn7s5sogyfznl25a4vxgu76c2hrgvzcd3psn6vcx33lzmu2xa"
   "state": "PROVISIONING",
   "timeCreated": "2016-07-22T17:43:01.389+0000"
}
```

Error Format

If a request results in an error, the response contains a standard HTTP response code with 4xx for client errors and 5xx for server errors. The body also includes JSON with an error code and a description of the error. For example:

```
{
    "code": "InvalidParameter",
    "message": "Description may not be empty; description size must be between 1 and 400"
}
```

For a list of common errors across all services, see API Errors.

Request Throttling

Oracle Cloud Infrastructure applies throttling to many API requests to prevent accidental or abusive use of resources. If you make too many requests too quickly, you might see some succeed and others fail. Oracle recommends that you implement an exponential back-off, starting from a few seconds to a maximum of 60 seconds. When a request fails due to throttling, the system returns response code 429 and the following error code and description:

```
{
      "code": "TooManyRequests",
      "message": "User-rate limit exceeded."
}
```

Polling for Resource Status

Most Oracle Cloud Infrastructure resources, such as compute instances, have lifecycles. In many cases, you want your code to wait until a resource or work request reaches a specific state, or a timeout is exceeded, before taking further action.

You can poll a resource to determine its state. For example, when you call GetInstance, the response body contains an instance resource that includes the `lifecycleState` attribute. You might want your code to wait until the instance's `lifecycleState` is RUNNING before proceeding.

Different resources take different amounts of time to transition between states. Therefore, the optimal frequency and duration parameters for a polling strategy can vary among resources. The Oracle Cloud Infrastructure SDK waiters use the following default strategy:

- Use an exponential back-off, starting from a few seconds to a maximum of 30 seconds between poll attempts.
- Poll up to 20 minutes, and then stop.

Or more information on waiters, see:

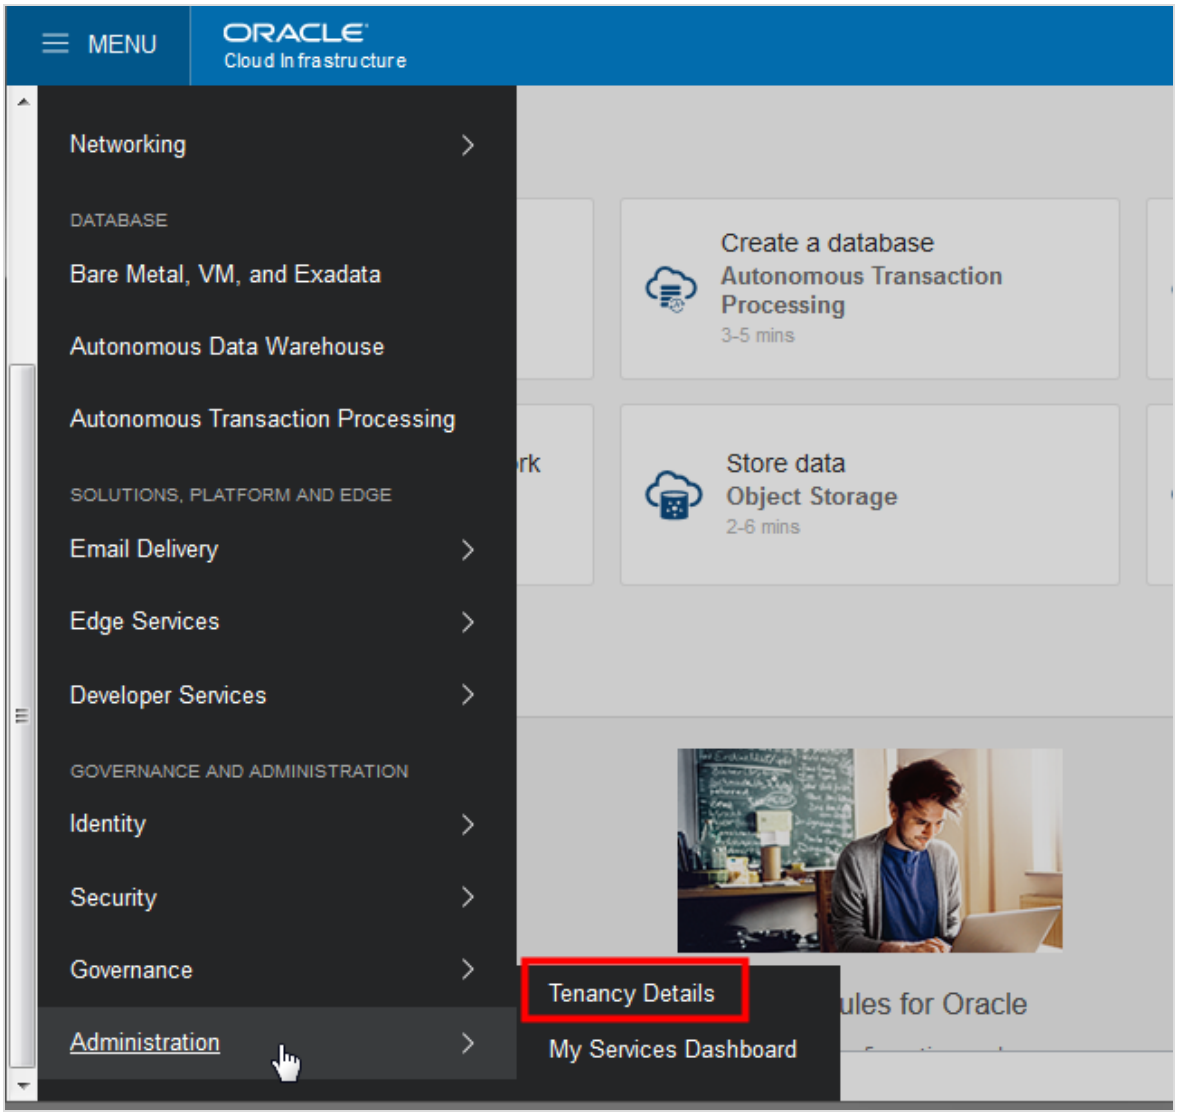
- SDK for Java waiters documentation
- Ruby SDK waiters documentation

Where to Find Your Tenancy's OCID

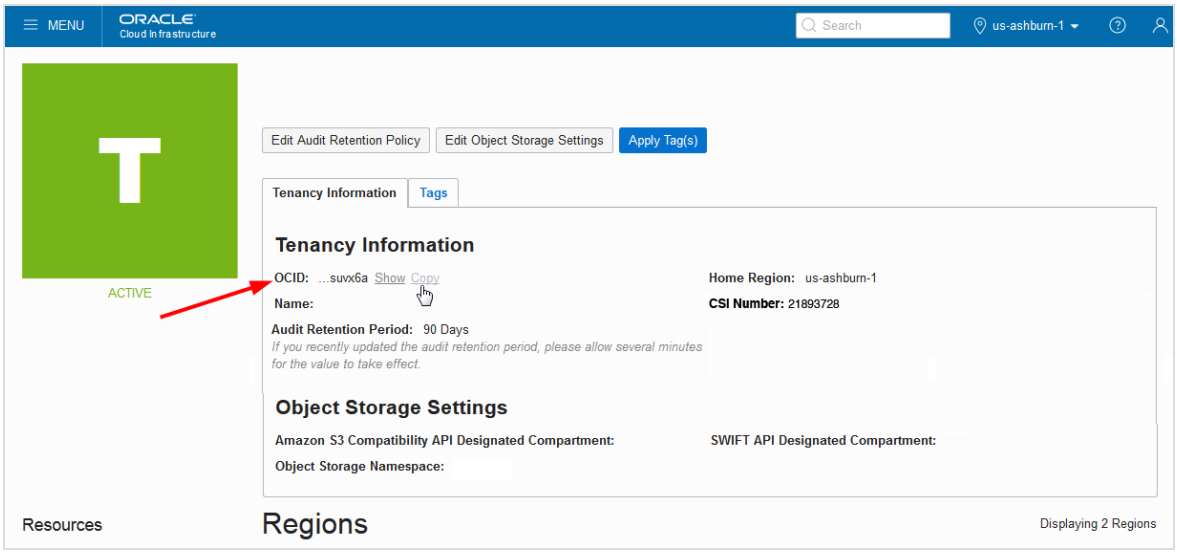
If you use the API, you'll need your tenancy's OCID in order to sign the requests (see Request Signatures). You'll also need it for some of the IAM API operations. An OCID is an Oracle Cloud ID (see Resource Identifiers).

Get the tenancy OCID from the Oracle Cloud Infrastructure Console on the **Tenancy Details** page:

1. Open the navigation menu, under Governance and Administration, go to **Administration** and click **Tenancy Details**.



2. The tenancy OCID is shown under **Tenancy Information**. Click **Copy** to copy it to your clipboard.



The tenancy OCID looks something like this (notice the word "tenancy" in it): `ocid1.tenancy.oc1..<unique_ID>`.

List Pagination

Most List operations paginate results. For example, results are paginated for the ListInstances operation in the Core Services API. When you call a paginated List operation, the response indicates additional pages of results by including the `opc-next-page` header.

> **Note**
>
> A page can be empty even when more results remain. Any time the `opc-next-page` header appears, there are more list items to get. For more information about resource list control, see Overview of Search.

To get the next page of results

Make a new GET request against the same URL, modified by setting the page query parameter to the value from the `opc-next-page` header. Repeat this process until you get a response without an `opc-next-page` header. The absence of this header indicates that you have reached the last page of the list.

Note

For an alternative to writing pagination code, see the functions in the pagination module provided with the Python SDK.

To get the previous page of results

(Available with some APIs.) Make a new GET request against the same URL, modified by setting the page query parameter to the value from the `opc-prev-page` header. Repeat this process until you get a response without an `opc-prev-page` header. The absence of this header indicates that you have reached the first page of the list.

Note

For an alternative to writing pagination code, see the functions in the pagination module provided with the Python SDK.

To change the maximum number of results per page

In the GET request, set the `limit` to the number of items you want returned in the response.

Note

The service will return no more than the number specified as `limit`, but might not return that exact number.

Retry Token

For some operations you can provide a unique retry token (`opc-retry-token`) so the request can be retried in case of a timeout or server error without the risk of executing that same action again. The token expires after 24 hours, but can be invalidated before then due to conflicting operations (for example, if a resource has been deleted and purged from the system, then a retry of the original creation request may be rejected).

ETags for Optimistic Concurrency Control

The API supports etags for the purposes of optimistic concurrency control. The GET and POST calls return an `etag` response header with a value you should store. When you later want to update or delete the resource, set the `if-match` header to the ETag you received for the resource. The resource will then be updated or deleted *only* if the ETag you provide matches the current value of that resource's ETag.

Null vs. Empty Strings for Optional Parameters

If you send an empty string ("") as the value of an optional parameter, the API validates the value as normal (for example, checks against minimum and maximum allowed length, and so on). Often the minimum allowed length is 1, so an error would be returned. If you don't set the value (it's null), the API performs no validation, and some other action may occur. For example: if you don't set a value for the `displayName` when creating a new VCN object, the service will auto-generate a value.

API Reference and Endpoints

Oracle Cloud Infrastructure has these APIs and corresponding regional endpoints:

Analytics Cloud API

- https://identity.eu-frankfurt-1.oraclecloud.com
- https://identity.eu-zurich-1.oraclecloud.com
- https://identity.sa-saopaulo-1.oraclecloud.com
- https://identity.uk-london-1.oraclecloud.com
- https://identity.us-ashburn-1.oraclecloud.com
- https://identity.us-phoenix-1.oraclecloud.com

Note

Use the Endpoint of Your Home Region for All IAM API Calls

When you sign up for Oracle Cloud Infrastructure, Oracle creates a tenancy for you in one region. This is your home region. Your home region is where your IAM resources are defined. When you subscribe to a new region, your IAM resources are replicated in the new region, however, the master definitions reside in your home region and can only be changed there. Make all IAM API calls against your home region endpoint. The changes automatically replicate to all regions. If you try to make an IAM API call against a region that is not your home region, you will receive an error.

Integration API

Oracle Integration Service Instance REST API

Use this API to create, modify, delete, get information about an Oracle Integration instance, and list Oracle Integration instances in a compartment.

API Errors

Common Errors Returned by All Services

The following table lists the common errors returned by all the services for Oracle Cloud Infrastructure.

HTTP Status Code	Error Code	Description	Retry
400	`CannotParseRequest`	The request is incorrectly formatted.	No.
400	`InvalidParameter`	A parameter is invalid or incorrectly formatted.	No.
400	`LimitExceeded`	Fulfilling this request exceeds the Oracle-defined limit for this tenancy for this resource type.	No.
400	`MissingParameter`	A required parameter is missing.	No.
400	`QuotaExceeded`	Fulfilling this request exceeds the administrator-defined quota for this compartment for this resource.	No.
400	`RelatedResourceNotAuthorizedOrNotFound`	A resource specified in the body of the request was not found, or you do not have authorization to access that resource.	Yes, with backoff.
401	`NotAuthenticated`	The required authentication information was not provided or was incorrect. There are other reasons why this error code is generated. For more information, see HTML Status Code 401.	Yes, with backoff.
402	`SignUpRequired`	This operation requires opt-in before it may be called.	No.
403	`NotAuthorized`	You do not have authorization to update one or more of the fields included in this request.	No.

HTTP Status Code	Error Code	Description	Retry
404	`NotAuthorizedOrNotFound`	A resource specified via the URI (path or query parameters) of the request was not found, or you do not have authorization to access that resource. For more information, see HTML Status Code 404.	Yes, with backoff.
404	`NotFound`	There is no operation supported at the URI path and HTTP method you specified in the request.	No.
405	`MethodNotAllowed`	The target resource does not support the HTTP method.	No.
409	`IncorrectState`	The requested state for the resource conflicts with its current state.	Yes, with backoff.
409	`InvalidatedRetryToken`	The provided retry token was used in an earlier request that resulted in a system update, but a subsequent operation invalidated the token. This can happen, for example, in cases where an entity created with the same token has since been deleted. If the system state change that is associated with this request should be performed again, retry it using a different token.	No.

HTTP Status Code	Error Code	Description	Retry
409	`NotAuthorizedOr ResourceAlreadyExists`	You do not have authorization to perform this request, or the resource you are attempting to create already exists. This error code is returned only from **create** operations, where it is returned instead of the more general **NotAuthorizedOrNotFound** error code.”	Yes, with backoff.
412	`NoEtagMatch`	The ETag specified in the request does not match the ETag for the resource.	No.
429	`TooManyRequests`	You have issued too many requests to the Oracle Cloud Infrastructure APIs in too short of an amount of time.	Yes, with backoff.
500	`InternalServerError`	An internal server error occurred.	Yes, with backoff.
501	`MethodNotImplemented`	The HTTP request target does not recognize the HTTP method.	No.

Error Details and Troubleshooting

HTTP STATUS CODE: 401

- **Missing or incorrect authentication information.** Verify that all the required information (tenant OCID, user OCID, fingerprint, and private key) is provided and accurate. Verify that the public key corresponding to the fingerprint has been

uploaded for the user. For more information, see Required Keys and OCIDs.

- **Clock skew.** This status code is returned if the client's clock is skewed more than five (5) minutes from the server's clock. For more information, see Maximum Allowed Client Clock Skew.
- **API request signature error.** This status code is returned if a required header is missing from a signing string. For more information, see Request Signatures.

ERROR CODES: NOTAUTHORIZEDORNOTFOUND, RELATEDRESOURCENOTAUTHORIZEDORNOTFOUND , NOTAUTHORIZEDORRESOURCEALREADYEXISTS

- **Authorization error.** Verify that the user is in a group that has the permissions to work with resources in a compartment.
- **Compartment or resource not found.** Verify that the compartment or resource exist and is referenced correctly. For example, this status code is returned for either of the following errors:
  - `CompartmentNotFound` if a compartment doesn't exist
  - `VolumeNotFound` if a volume doesn't exist

Asynchronous Work Requests

This topic describes asynchronous work requests for long-running operations against Oracle Cloud Infrastructure services. It also provides guidance on obtaining request status, and for inspecting the request response to enable filtering for affected resources.

Overview

API calls to Oracle Cloud Infrastructure services can launch long-running operations that do not complete the client's request before a response is returned. In these cases, the service spawns an *asynchronous work request* that allows for visibility into the progress of long-running, asynchronous operations. The response to the REST API call contains a work request ID in the `opc-work-request-id` header, which allows you to monitor its progress and status. The work request itself remains in a queue until the operation has completed.

You can monitor the status of the work request at any time by calling `GetWorkRequest` and passing in the work request ID.

Note

The Compute and Database services support work requests using Work Requests API, which contains the `GetWorkRequest` operation.

The Container Engine for Kubernetes, Load Balancing, Object Storage and IAM services each support work requests through the service APIs. These service APIs each include operations that work in a similar manner to the `GetWorkRequest` operation used by the Work Requests API.

Two features of the request response are of particular interest: the status of the work request, and a list of the resources that are affected by the work request. The status is important because asynchronous work requests must know when an operation has completed, is still running, or whether it has failed altogether.

To retrieve information about work request failures or errors, each service provides APIs for fetching information about errors, and logs. For links to API reference documentation for each of the service, see the section For More Information.

Also important in cases where a work request operation affects several resources is having a list of the resources that a work request affects, along with each one's `entityType` and `actionType` attributes.

Work Request Status

Asynchronous work requests allow you to monitor their progress by providing a status attribute on the `WorkRequest` object. Each of the supported services provides its own API for obtaining status, as listed in the following sections.

Note

There is a ContainerEngineWaiters class that allows you to create a callback using the `forWorkRequest` method. Use this API to forward a notification when an operation's status changes, for example, from `IN_PROGRESS` to `COMPLETED`.

The following table lists status attributes that are supported by the `WorkRequest` object on the respective services.

Service	Status Attributes
Compute	• `ACCEPTED` • `IN_PROGRESS` • `FAILED` • `SUCCEEDED` • `CANCELING` • `CANCELED`
Container Engine for Kubernetes	• `ACCEPTED` • `IN_PROGRESS` • `FAILED` • `SUCCEEDED` • `CANCELING` • `CANCELED`

Service	Status Attributes
Database	• ACCEPTED • IN_PROGRESS • FAILED • SUCCEEDED
IAM	• ACCEPTED • IN_PROGRESS • FAILED • SUCCEEDED • CANCELING • CANCELED
Load Balancing	• CREATING • FAILED • ACTIVE • DELETING • DELETED
Object Storage	• ACCEPTED • IN_PROGRESS • FAILED • COMPLETED • CANCELING • CANCELED

Filtering the Request Response

You sometimes need to know which resources are affected by a given asynchronous work request. In cases where the request response includes just one or two affected resources, the body of the request response is probably sufficient. However, in cases where a request response affects a great many resources, you must filter the response to identify the resources that you're interested in.

Filtering of resources listed in a work request response relies on two attributes of the `WorkRequestResource` type: `entityType` and `actionType`.

- **entityType:** Represents the resource type which the work request affects. This is an optional attribute, but each resource can have only one `entityType`.
- **actionType:** Represents how the specified resource is affected by the operation associated with the work request. Each service specifies a fixed list of allowable `actionType` values (shown in the sections following).

To obtain resource information on a work request, call `GetWorkRequest` and pass in the work request ID. The call returns a response in JSON format. Following is an example from calling `GetWorkRequest` on the Object Storage service.

```
{
    operationType: "COPY_OBJECT",
    status: "IN_PROGRESS",
    id: "f54527d6-029b-4221-9046-a811b7686202",
    resources: [
        {
            entityType: "object",
            actionType: "READ",
            entityUri: "/n/mynamespace/b/backups/o/myobject"
        },
        {
            entityType: "object",
            actionType: "WRITTEN",
            entityUri: "/n/mynamespace/b/backups/o/copyofmyobject"
        },
    ],
    timeAccepted: 2017-10-13T17:23:46.000Z,
    timeStarted: 2017-10-13T17:23:52.198Z,
```

```
    percentComplete: 10.0
}
```

Note

Different services provide slightly different responses. See the reference documentation for each service's work request API for details. Links to each are provided in the For More Information section.

The following table lists the entity types and action types that are supported by Oracle Cloud Infrastructure services.

Service Name	Operation	entityType	actionType
Container Engine for Kubernetes	CreateCluster DeleteCluster UpdateCluster CreateNodePool DeleteNodePool UpdateNodePool	cluster nodepool	ACCEPTED IN_PROGRESS FAILED SUCCEEDED CANCELING CANCELED
Load Balancing	CreateLoadBalancer UpdateLoadBalancer DeleteLoadBalancer	LoadBalancer	ACCEPTED IN_PROGRESS FAILED SUCCEEDED
Object Storage	CopyObject	object	READ WRITTEN

Request/Response Sample

Following is a sequence of REST API calls to create a cluster, which is a common long-running operation. The caller retrieves the work request ID from the response to the initial `POST` call and then periodically polls the `WorkRequest` to determine the status of the operation. The request/response sequence that follows depicts this workflow:

1. The user issues a `CreateCluster` API call.
2. The service responds with status code 202, indicating that the request has been accepted and returns a work request ID in the `Opc-Work-Request-Id` header.
3. Next, the user issues a `GET` call on the work request ID to obtain the status of the work request.
4. The service responds with status code 200, indicating in the response body that the `CLUSTER_CREATE` operation has the status `ACCEPTED`.
5. With continued polling, we see another `GET` call for the work request.
6. The service responds with status code 200. The response body reports that the operation `SUCCEEDED`.

Step 1. Initial API call to initiate a `CLUSTER_CREATE` operation.

x-content-sha256: S8U8OKQHyTLNViAzgexkjxvF4ctncJJHTjuRfXn0ya4={
   "name":"JavaSDK.CRUD",
   "compartmentId":"ocid1.compartment.oc1..<unique_ID>",
   "vcnId":"ocid1.vcn.oc1.eu-frankfurt-1.<unique_ID>",
   "kubernetesVersion":"v1.10.3",
   "options":{"serviceLbSubnetIds":["ocid1.subnet.oc1.eu-frankfurt-1.<unique_ID>",
   "ocid1.subnet.oc1.eu-frankfurt-1.<unique_ID>"]}}
```

Step 2. The response to the initial API call, which contains the work request ID in the `Opc-Work-Request-Id header`.

```
202
Access-Control-Allow-Methods: DELETE, GET, HEAD, OPTIONS, PATCH, POST, PUT
Access-Control-Allow-Origin: *
Access-Control-Expose-Headers: opc-work-request-id
Content-Length: 0
Date: Mon, 02 Jul 2018 18:20:04 GMT
Opc-Request-Id:
D7A390ED909C47038C438BA3629FB612/33EEDCAAB2E84508B34AA75CD0FD86F4/8261D1CC89814E9BB934440A1F43DA09
Opc-Work-Request-Id: ocid1.clustersworkrequest.oc1.eu-frankfurt-1.exampleuniqueID
Uri: /20180222/clusters
Vary: Accept-Encoding
X-Rate-Limit-Duration: 1
X-Rate-Limit-Limit: 16.70
X-Rate-Limit-Request-Forwarded-For: 10.237.10.0, 10.237.9.51
X-Rate-Limit-Request-Remote-Addr: 10.237.9.51:53077
```

Step 3. Because this is a long-running operation, the user periodically polls the work request using a `GET` call to determine its status.

```
GET https://containerengine.eu-frankfurt-1.oraclecloud.com/20180222/workRequests/<clusters_work_request_
OCID>
Accept: application/json
authorization: <Redacted>
date: Mon, 02 Jul 2018 18:20:04 GMT
host: containerengine.eu-frankfurt-1.oraclecloud.com
opc-client-info: Oracle-JavaSDK/1.2.42-preview1-SNAPSHOT
opc-request-id: E8F20DAC443346B3B0EA599F367EE294
User-Agent: Oracle-JavaSDK/1.2.42-preview1-SNAPSHOT (Mac OS X/10.13.5; Java/1.8.0_172; Java HotSpot(TM)
64-Bit Server VM/25.172-b11)
```

Step 4. The `GET` call returns the following response, which indicates in the response body that the `CLUSTER_CREATE` operation has a status of `ACCEPTED`.

```
200
Access-Control-Allow-Methods: DELETE, GET, HEAD, OPTIONS, PATCH, POST, PUT
Access-Control-Allow-Origin: *
Access-Control-Expose-Headers: opc-work-request-id
Content-Length: 717
Content-Type: application/json
Date: Mon, 02 Jul 2018 18:20:05 GMT
```

```

Retry-After: 30
Uri: /20180222/workRequests/_id_
Vary: Accept-Encoding
X-Rate-Limit-Duration: 1
X-Rate-Limit-Limit: 16.70
X-Rate-Limit-Request-Forwarded-For: 10.237.10.0, 10.237.9.51
X-Rate-Limit-Request-Remote-Addr: 10.237.9.51:43533
{
  "id": "ocid1.clustersworkrequest.oc1.eu-frankfurt-1.exampleuniqueID",
  "operationType": "CLUSTER_CREATE",
  "status": "ACCEPTED",
  "compartmentId": "ocid1.compartment.oc1..exampleuniqueID",
  "resources": [
    {
      "actionType": "IN_PROGRESS",
      "entityType": "cluster",
      "identifier": "ocid1.cluster.oc1.eu-frankfurt-1.exampleuniqueID",
      "entityUri": "/clusters/ocid1.cluster.oc1.eu-frankfurt-1.exampleuniqueID"
    }
  ],
  "timeAccepted": "2018-07-02T18:20:05Z",
  "timeStarted": null,
  "timeFinished": null
}
```

Step 5. The operation continues, and the user continues to poll the work request using the `GET` method.

```
GET https://containerengine.eu-frankfurt-1.oraclecloud.com/20180222/workRequests/<clusters_work_request_
OCID>
Accept: application/json
authorization: <Redacted>
date: Mon, 02 Jul 2018 18:24:13 GMT
host: containerengine.eu-frankfurt-1.oraclecloud.com
opc-client-info: Oracle-JavaSDK/1.2.42-preview1-SNAPSHOT
opc-request-id: 64595B97E39A471A886DA29966BB6B1D

Request Signatures

This topic describes how to sign Oracle Cloud Infrastructure API requests.

Signing samples are included for the following:

- Bash
- PowerShell
- C#
- Java
- NodeJS
- Perl
- PHP
- Python

- Ruby
- Go

Signature Version 1

The signature described here is *version 1* of the Oracle Cloud Infrastructure API signature. In the future, if Oracle modifies the method for signing requests, the version number will be incremented and your company will be notified.

Required Credentials and OCIDs

You need an API signing key in the correct format. See Required Keys and OCIDs.

Warning

Client Clock Skew

If the client's clock is skewed more than 5 minutes, a 401 (NotAuthenticated) HTTP status code is returned. This will affect your API requests. For more information, see Maximum Allowed Client Clock Skew.

You also need the OCIDs for your tenancy and user. See Where to Get the Tenancy's OCID and User's OCID.

Summary of Signing Steps

In general, these are the steps required to sign a request:

1. Form the HTTPS request (SSL protocol TLS 1.2 is required).
2. Create the signing string, which is based on parts of the request.
3. Create the signature from the signing string, using your private key and the RSA-SHA256 algorithm.

4. Add the resulting signature and other required information to the `Authorization` header in the request.

See the remaining sections in this topic for details about these steps.

Specification You Need to Be Familiar With

To learn how to perform steps 2-4 in the process above, refer to draft-cavage-http-signatures-08. It's a draft specification that forms the basis for how Oracle handles request signatures. It describes generally how to form the signing string, how to create the signature, and how to add the signature and required information to the request. The remaining sections in this topic assume you're familiar with it. Important details of the Oracle Cloud Infrastructure implementation of the reference are listed in the next section.

Special Implementation Details

The following sections describe important items to note about the Oracle Cloud Infrastructure implementation of the spec.

Authorization Header

The Oracle Cloud Infrastructure signature uses the "Signature" Authentication scheme (with an `Authorization` header), and not the Signature HTTP header.

Required Headers

This section describes the headers that must be included in the signing string.

Note

Error if Required Header is Missing

If a required header is missing, your client will receive a 401 "Unauthorized" response.

For GET and DELETE requests (when there's no content in the request body), the signing string must include at least these headers:

- `(request-target)` (as described in draft-cavage-http-signatures-08)
- `host`
- `date` or `x-date` (if both are included, Oracle uses `x-date`)

For PUT and POST requests (when there's content in the request body), the signing string must include at least these headers:

- `(request-target)`
- `host`
- `date` or `x-date` (if both are included, Oracle uses `x-date`)
- `x-content-sha256` (except for Object Storage PUT requests; see the next section)
- `content-type`
- `content-length`

Warning

For PUT and POST requests, your client must compute the `x-content-sha256` and include it in the request and signing string, even if the body is an empty string. Also, the `content-length` is always required in the request and signing string, even if the body is empty. Some HTTP clients will not send the `content-length` if the body is empty, so you must explicitly ensure your client sends it. If `date` and `x-date` are both included, Oracle uses `x-date`. The `x-date` is used to protect against the reuse of the signed portion of the request (replay attacks).

The one exception is for Object Storage PUT requests on objects (see the next section).

Special Instructions for Object Storage PUT

For Object Storage PutObject and UploadPart PUT requests, the signing string must include at least these headers:

- `(request-target)`
- `host`
- `date` or `x-date` (if both are included, Oracle uses `x-date`)

If the request also includes any of the other headers that are normally required for PUT requests (see the list above), then those headers must also be included in the signing string.

Case and Order of Headers

The headers must be all lowercase in the signing string.

The order of the headers in the signing string does not matter. Just make sure to specify the order in the `headers` parameter in the `Authorization` header, as described in the draft-cavage-http-signatures-05.

Warning

The `(request-target)` includes the path and query string from the request. Oracle expects that you will create the signing string with the query parameters in the *same order* as they appear in the request. If the request query parameters change order after signing occurs, authentication will fail.

URL Encoding of Path and Query String

When forming the signing string, you must URL encode all parameters in the path and query string (but not the headers) according to RFC 3986.

KEY IDENTIFIER

You must set `keyId="<TENANCY OCID>/<USER OCID>/<KEY FINGERPRINT>"` in the `Authorization` header that you add to the request. To get those values, see Where to Get the Tenancy's OCID and User's OCID. An example `keyId` looks like this (wrapped to better fit the page):

```
ocid1.tenancy.oc1..exampleuwjnv47knr7uuuvqar5bshnspi6xoxsfebh3vy72fi4swgrkvuvq/ocid1.user.oc1..exampleb
a3pv6wkcr4jqae5f44n2b2m2yt2j6rx32uzr4h25vqstifsfdsq/40:a4:f8:a0:40:4f:a3:2f:e0:fd:4e:b9:25:72:81:5f
```

SIGNING ALGORITHM

The signing algorithm must be RSA-SHA256, and you must set `algorithm="rsa-sha256"` in the `Authorization` header (notice the quotation marks).

SIGNATURE VERSION

You should include `version="1"` in the `Authorization` header (notice the quotation marks). If you do not, it's assumed that you're using whatever the current version is (which is version 1 at this time).

EXAMPLE HEADER

Here's an example of the general syntax of the `Authorization` header (for a request with content in the body):

```
Authorization: Signature version="1",keyId="<tenancy_ocid>/<user_ocid>/<key_
fingerprint>",algorithm="rsa-sha256",headers="(request-target) date x-content-sha256 content-type
content-length",signature="Base64(RSA-SHA256(<signing_string>))"
```

Test Values

Here's an example key pair, two example requests, and the resulting `Authorization` header for each.

Warning

The example signatures use the RSA 2048-bit keys below. Use these keys only for testing your signing code, not for sending production requests.

```

```

Sample Code

This section shows the basic code for signing API requests.

BASH

.

```
# Version: 1.0.2
# Usage:
# oci-curl <host> <method> [file-to-send-as-body] <request-target> [extra-curl-args]
#
# ex:
# oci-curl iaas.us-ashburn-1.oraclecloud.com get "/20160918/instances?compartmentId=some-compartment-
ocid"
# oci-curl iaas.us-ashburn-1.oraclecloud.com post ./request.json "/20160918/vcns"

function oci-curl {
       # TODO: update these values to your own
               local tenancyId="ocid1.tenancy.oc1..aaaaaaaaba3pv6wkcr4jqae5f15p2b2m2yt2j6rx32uzr4h25vqstifsfdsq";
               local authUserId="ocid1.user.oc1..aaaaaaaat5nvwcna5j6aqzjcaty5eqbb6qt2jvpkanghtgdaqedqw3rynjq";
               local keyFingerprint="20:3b:97:13:55:1c:5b:0d:d3:37:d8:50:4e:c5:3a:34";
               local privateKeyPath="/Users/someuser/.oci/oci_api_key.pem";

       local alg=rsa-sha256
       local sigVersion="1"
```

```
    local now="$(LC_ALL=C \date -u "+%a, %d %h %Y %H:%M:%S GMT")"
    local host=$1
    local method=$2
    local extra_args
    local keyId="$tenancyId/$authUserId/$keyFingerprint"

    case $method in

            "get" | "GET")
            local target=$3
            extra_args=("${@: 4}")
            local curl_method="GET";
            local request_method="get";
            ;;

            "delete" | "DELETE")
            local target=$3
            extra_args=("${@: 4}")
            local curl_method="DELETE";

An example of a request.json file that could be used with the preceding Bash code is shown next:

```
{
   "compartmentId": "some-compartment-id",
   "displayName": "some-vcn-display-name",
   "cidrBlock": "10.0.0.0/16"
}
```

POWERSHELL

The following is an example for creating a request signature for an Oracle Cloud Infrastructure REST API call using a PowerShell script (`oci-rest.ps1`). The example uses the Bouncy Castle library .dll file to enable crypto functionality. Download the DLL from https://www.bouncycastle.org and place it in the same directory as the PowerShell script file.

.

```
param (
    [Parameter(Mandatory=$true)][string]$method,
    [Parameter(Mandatory=$true)][string]$ocihost,
    [Parameter(Mandatory=$true)][string]$target,

    [bool]$echo_debug = $false,

    # TODO: Update these defaults or override them on the command line.
    [string]$tenancyId =
'ocid1.tenancy.oc1..aaaaaaaaba3pv6wkcr4jqae5f15p2b2m2yt2j6rx32uzr4h25vqstifsfdsq',
    [string]$authUserId= 'ocid1.user.oc1..aaaaaaaalj3z3isgtuqd5uqft424he7r3cuqfr3e5gpidgnmqsxwd5qevkha',
    [string]$keyFingerprint = '29:f3:01:46:07:b8:dc:8c:16:c3:2b:b3:8d:dc:26:c5',
    [string]$privateKeyPath = $PSScriptRoot + '/oci_api_key.pem',

    [Parameter(Mandatory=$false)][string]$body,
    [Parameter(Mandatory=$false)][string]$bouncycastlelib
)

#############################################################################
# This is a powershell example of how to create request signatures for an
# Oracle Cloud Infra REST API call.  It was modeled after the bash example.
#
# Note that it utilizes the Bouncy Castle library dll for crypto functionality.
# It is assumed to be in the same directory as this script,
# but can be changed via commandline argument.
# See https://www.bouncycastle.org for more details.
#
# Usage:
# oci-rest.ps1 -host <host> -method <method> -body [file-to-send-as-body] -target <request-target> -
bouncycastlelib [BouncyCastle.Crypto.dll]
#
# Examples:
# ./oci-rest.ps1 -method get -ocihost iaas.us-ashburn-1.oraclecloud.com -target
"/20160918/instances?compartmentId=ocid1.compartment.oc1..aaaaaaaam3we6vgnherjq5q2idnccdflvjsnog7mlr6rt
db25gilchfeyjxa"
# ./oci-rest.ps1 -method post -ocihost iaas.us-ashburn-1.oraclecloud.com -target "/20160918/vcns" -body
./request.json

Go

The following example shows how to create a default signer.

Note

The Go SDK exposes a stand-alone signer that you can use to sign custom requests. You can find related code at http_signer.go.

```
client := http.Client{}
var request http.Request
request = ... // some custom request

// Set the Date header
request.Header.Set("Date", time.Now().UTC().Format(http.TimeFormat))

// And a provider of cryptographic keys
provider := common.DefaultConfigProvider()

// Build the signer
signer := common.DefaultSigner(provider)

// Sign the request
```

```
signer.Sign(&request)

// Execute the request
client.Do(request)
```

The following example shows how the signer can allow more granular control on the headers used for signing:

```
client := http.Client{}
var request http.Request
request = ... // some custom request

// Set the Date header
request.Header.Set("Date", time.Now().UTC().Format(http.TimeFormat))

// Mandatory headers to be used in the sign process
defaultGenericHeaders    = []string{"date", "(request-target)", "host"}

// Optional headers
optionalHeaders = []string{"content-length", "content-type", "x-content-sha256"}

// A predicate that specifies when to use the optional signing headers
optionalHeadersPredicate := func (r *http.Request) bool {
       return r.Method == http.MethodPost
}

// And a provider of cryptographic keys
provider := common.DefaultConfigProvider()

// Build the signer
signer := common.RequestSigner(provider, defaultGenericHeaders, optionalHeaders,
optionalHeadersPredicate)

// Sign the request
signer.Sign(&request)

// Execute the request
c.Do(request)
```

GLOSSARY

A

AD-specific subnet

A subnet that is specific to a particular availability domain (AD). Historically all subnets were AD-specific. Compare with regional subnets, which Oracle recommends over AD-specific subnets.

alarm

The trigger rule and query to evaluate and related configuration, such as notification details to use when the trigger is breached. Alarms passively monitor your cloud resources using metrics in Monitoring.

API key

A credential for securing requests to the Oracle Cloud Infrastructure REST API.

attach

Link a volume and instance together. Allows an instance to connect and mount the volume as a hard drive.

auth token

Oracle Cloud Infrastructure-generated token you use to authenticate with third-party APIs, such as a Swift client.

availability domain

One or more isolated, fault-tolerant Oracle data centers that host cloud resources such as instances, volumes, and subnets. A region contains one or more availability domains.

B

backend set

A logical entity defined by a list of backend servers, a load balancing policy, and a health check policy.

bare metal IaaS

A cloud infrastructure that allows you to utilize hosted physical hardware, as opposed to traditional software-based virtual machines, ensuring a high level of security and performance.

block storage volume

A virtual disk that provides persistent storage space for instances in the cloud.

bucket

A logical container for storing objects.

C

CHAP

Stands for Challenge-Handshake-Authentication-Protocol. It is a security protocol used by iSCSI for authentication between a volume and an instance.

Cloud Block Storage

A service that allows you to add block storage volumes to an instance in order to expand the available storage on that resource.

cloud network

A virtual version of a traditional network—including CIDRs, subnets, route tables, and gateways—on which your instance runs.

cluster network

A pool of high performance computing (HPC) instances that are connected with a high-bandwidth, ultra low-latency network.

compartment

A collection of related resources that can be accessed only by certain groups that have been given permission by an administrator in your organization.

Compute

A service that lets you provision and manage compute hosts, known as instances.

connect

Make an attached volume usable by an instance's guest OS.

CPE

The router at the edge of your on-premises network. The Networking service also has an object called a CPE, which is a virtual representation of your edge router. You create that object when setting up VPN Connect (an IPSec VPN) between Oracle and your on-premises network.

cross-connect

Used with Oracle Cloud Infrastructure FastConnect, specifically if you're using a third-party provider or colocated with Oracle in a FastConnect location. A cross-connect is the physical cable connecting your existing network to Oracle in the FastConnect location.

cross-connect group

Used with Oracle Cloud Infrastructure FastConnect, specifically if you're using a third-party provider or colocated with Oracle in a FastConnect location. A cross-connect group is a link aggregation group (LAG) that contains at least one cross-connect.

customer-premises equipment

The router at the edge of your on-premises network. The Networking service also has an object called a CPE, which is a virtual representation of your edge router. You create that object when setting up VPN Connect (an IPSec VPN) between Oracle and your on-premises network.

D

data point

(Monitoring service) A timestamp-value pair for the specified metric. Example: 2018-05-10T22:19:00Z, 10.4

DB System

A dedicated bare metal instance running Oracle Linux, optimized for running one or more Oracle databases. A DB System is a Database Service resource.

DHCP options

Configuration information that is automatically provided to the instances when they boot up.

dimension

(Monitoring service) A qualifier provided in a metric definition. Example: Resource identifier (resourceId), provided in the definitions of oci_computeagent metrics.

display name

A friendly name or description that helps you easily identify the resource.

DRG

An optional virtual router that you can add to your VCN to provide a path for private network traffic between your VCN and on-premises network.

DRG attachment

When you attach a dynamic routing gateway (DRG) to a virtual cloud network (VCN), the result is a DRG attachment object. To detach the DRG, you delete that attachment object.

dynamic group

A special type of IAM group that contains instances that match rules that you define (thus the membership can change dynamically as matching instances are terminated or launched). These instances act as "principal" actors and can make API calls to Oracle Cloud Infrastructure services according to IAM policies that you write for the dynamic group.

dynamic routing gateway

An optional virtual router that you can add to your VCN to provide a path for private network traffic between your VCN and on-premises network.

E

ephemeral public IP

A public IP address (and related properties) that is temporary and exists for the life of the instance it's assigned to. It can be assigned only to the primary private IP on a VNIC. Compare with reserved public IP.

Export

Controls how file systems are accessed by NFS clients when they connect to a mount target.

Export Options

A set of parameters that specify the level of access granted to NFS clients when they connect to a mount target.

F

FastConnect

FastConnect provides an easy way to create a dedicated, private connection between your data center or existing network and Oracle Cloud Infrastructure. FastConnect provides higher-bandwidth options, and a more reliable and consistent networking experience compared to internet-based connections.

FastConnect location

A specific data center where you can connect to Oracle Cloud Infrastructure by using FastConnect.

fault domain

A logical grouping of hardware and infrastructure within an availability domain to provide isolation of resources in case of hardware failure or unexpected software changes.

File System

An organized system of directories and folders where data is stored.

frequency

(Monitoring service) The time period between each posted raw data point for a given metric. (Raw data points are posted by the metric namespace to the Monitoring service.)

G

group

A collection of users who all need a particular type of access to a set of resources or compartment.

guest operating system

An operating system installed on a cloud instance.

guest OS

An operating system installed on a cloud instance.

H

health check

A test to confirm the availability of backend servers.

I

IaaS

A service that allows customers to rapidly scale up or down their computer infrastructure (computing, storage, or network).

IAM

The service for controlling authentication and authorization of users who need to use your cloud resources. Also called "IAM".

Identity and Access Management Service

The service for controlling authentication and authorization of users who need to use your cloud resources. Also called "IAM".

identity provider

A service that provides identifying credentials and authentication for federated users.

IdP

Short for "identity provider", which is a service that provides identifying credentials and authentication for federated users.

image

A template of a virtual hard drive that determines the operating system and other software for an instance.

Infrastructure-as-a-Service

A service that allows customers to rapidly scale up or down their computer infrastructure (computing, storage, or network).

instance

A bare metal or virtual machine (VM) compute host. The image used to launch the instance determines its operating system and other software. The shape specified during the launch process determines the number of CPUs and memory allocated to the instance.

instance wallet

An Autonomous Database instance wallet contains only credentials and keys for a single database instance.

internet gateway

An optional virtual router that you can add to your VCN. It provides a path for network traffic between your VCN and the internet.

interval

(Monitoring service) The time window used to convert the given set of raw data points. Example: 5 minutes

IPSec connection

The secure connection between a dynamic routing gateway (DRG) and customer-premises equipment (CPE), consisting of multiple IPSec tunnels. The IPSec connection is one of the components forming a site-to-site VPN between a virtual cloud network (VCN) and your on-premises network.

IPv6

An object that contains an IPv6 address and related properties. Currently IPv6 addressing is supported only in the US Government Cloud. Only instances in IPv6-enabled VCNs and IPv6-enabled subnets can have IPv6 addresses.

IQN

A unique ID assigned to an iSCSI device. Used when connecting a volume to an instance.

iSCSI

A TCP/IP based standard used for communication between a volume and attached instance.

iSCSI Qualified Name

A unique ID assigned to an iSCSI device. Used when connecting a volume to an instance.

K

key pair

A security mechanism consisting of a public key and a private key. Required (for example) for Secure Shell (SSH) access to an instance.

L

listener

An entity that checks for incoming traffic on the load balancer's public floating IP address.

local peering gateway

A component on a VCN for routing traffic to a locally peered VCN. "Local" peering means the two VCNs are in the same region. Compare with a remote peering connection.

local VCN peering

The process of connecting two VCNs in the same region so that their resources can communicate without routing the traffic over the internet or through your on-premises network.

LPG

A component on a VCN for routing traffic to a locally peered VCN. "Local" peering means the two VCNs are in the same region. Compare with a remote peering connection.

M

message

(Notifications and Monitoring services) An alert published to all subscriptions in the specified topic. Each message is delivered at least once per subscription.

metric

(Monitoring service) A measurement related to health, capacity, or performance of a given resource. Example: CpuUtilization

metric definition

(Monitoring service) A set of references, qualifiers, and other information provided by a metric namespace for a given metric.

metric namespace

(Monitoring service) Indicator of the resource, service, or application that emits the metric. Provided in the metric definition. Example: oci_computeagent

metric stream

(Monitoring service) An individual set of aggregated data for a metric. Typically specific to a resource.

Monitoring Query Language

(Monitoring service) The syntax used for metric and alarm queries.

Mount Point

A directory from which a client may access a remote File Storage Service file system.

Mount Target

An NFS endpoint that allows a file system to be accessed by clients.

MQL

(Monitoring service) Monitoring Query Language. The syntax used for metric and alarm queries. In the Console, MQL syntax of queries is displayed in Advanced Mode.

N

NAT gateway

An optional virtual router that you can add to your VCN to perform Network Address Translation (NAT). A NAT gateway gives cloud resources without public IP addresses access to the internet without exposing those resources to incoming internet connections.

network security group

One method for implementing security rules in a VCN. A network security group consists of a set of resources (VNICs or resources with VNICs) and security rules that apply to those resources. See also security rules and security lists.

notification destination

(Monitoring service) Protocol and other details for sending messages when the alarm transitions to another state, such as from "OK" to "FIRING."

NSG

One method for implementing security rules in a VCN. A network security group consists of a set of resources (VNICs or resources with VNICs) and security rules that apply to those resources. See also security rules and security lists.

O

object

Any type of data, regardless of content type, is stored as an object. The object is composed of the object itself and metadata about the object. Each object is stored in a bucket.

OCID

An Oracle-assigned unique ID called an Oracle Cloud Identifier (OCID). This ID is included as part of the resource's information in both the Console and API.

one-time password

A single-use Console password that Oracle assigns to a new user, or to an existing user who requested a password reset.

Oracle Cloud Identifier

An Oracle-assigned unique ID called an Oracle Cloud Identifier (OCID). This ID is included as part of the resource's information in both the Console and API.

OTP

A single-use Console password that Oracle assigns to a new user, or to an existing user who requested a password reset.

P

policy

An IAM document that specifies who has what type of access to your resources. It is used in different ways: to mean an individual statement written in the policy language; to mean a collection of statements in a single, named "policy" document (which has an Oracle Cloud ID (OCID) assigned to it); and to mean the overall body of policies your organization uses to control access to resources.

policy statement

Policies can contain one or more individual statements. Each statement gives a group a certain type of access to certain resources in a particular compartment.

primary IP

The private IP that is automatically created and assigned to a VNIC during creation.

primary VNIC

The VNIC that is automatically created and attached to an instance during launch.

private IP

An object that contains a private IPv4 address and related properties such as a hostname for DNS. Each instance automatically comes with a primary private IP, and you can add secondary ones.

private peering

One of the ways to use FastConnect. Private peering lets you extend your existing infrastructure into a virtual cloud network (VCN) in Oracle Cloud Infrastructure (for example, to implement a hybrid cloud, or a lift and shift scenario). Communication across the connection is with IPv4 private addresses (typically RFC 1918).

private subnet

A subnet in which instances are not allowed to have public IP addresses

private virtual circuit

A FastConnect virtual circuit that supports private peering.

public IP

An object that contains a public IP address and related properties. You control whether each private IP on an instance has an assigned public IP. There are two types: reserved public IPs and ephemeral public IPs.

public peering

One of the way to use FastConnect. Public peering lets your on-premises network access public services in Oracle Cloud Infrastructure without using the internet. For example, Object Storage, the Oracle Cloud Infrastructure Console and APIs, or public load balancers in your VCN. Communication across the connection is with IPv4 public IP addresses. Without FastConnect, the traffic destined for public IP addresses would be routed over the internet. With FastConnect, that traffic goes over your private physical connection.

public subnet

A subnet in which instances are allowed to have public IP addresses. When you launch an instance in a public subnet, you specify whether the instance should have a public IP address.

public virtual circuit

A FastConnect virtual circuit that supports public peering.

Q

query

(Monitoring service) The expression to evaluate for returning aggregated data. A valid query includes a metric, statistic, and interval. In the Console, you can view a query in Basic Mode or Advanced Mode. The latter displays the Monitoring Query Language (MQL) syntax.

R

realm

A logical collection of regions. Realms are isolated from each other and do not share any data. Your tenancy exists in a single realm and can access the regions that belong to that realm.

region

A collection of availability domains located in a single geographic location.

regional subnet

A subnet that spans all availability domains (ADs) in the region. Oracle recommends using regional subnets because they are more flexible and make it easier to implement failover across ADs. Compare with AD-specific subnets.

regional wallet

An Autonomous Database regional wallet contains credentials and keys for all Autonomous Databases in a specified region.

remote peering connection

A component on a dynamic routing gateway (DRG) for routing traffic to a remotely peered VCN. "Remote" peering means the two VCNs are in different regions. Compare with a local peering gateway.

remote VCN peering

The process of connecting two VCNs in different regions so that their resources can communicate without routing their traffic over the internet or through your on-premises network.

reserved public IP

A public IP address (and related properties) that you create in your tenancy and assign to your instances in a given region as you like. It persists in your tenancy until you delete it. It can be assigned to any private IP on a given VNIC, not just the primary private IP. Compare with ephemeral private IP.

resolution

(Monitoring service) The period between time windows, or the regularity at which time windows shift. Example: 1 minute

resource

The cloud objects that your company's employees create and use when interacting with Oracle Cloud Infrastructure.

route table

Virtual route table for your VCN that provides mapping for the traffic from subnets via gateways to external destinations.

RPC

A component on a dynamic routing gateway (DRG) for routing traffic to a remotely peered VCN. "Remote" peering means the two VCNs are in different regions. Compare with a local peering gateway.

S

secondary IP address

An additional private IP you've added to a VNIC on an instance. Each VNIC automatically comes with a primary private IP that cannot be removed.

secondary VNIC

An additional VNIC you've added to an instance. Each instance automatically comes with a primary VNIC that cannot be removed.

security list

One method for implementing security rules in a VCN. A security list consists of security rules that apply to all resources in any subnet that uses the security list. See also security rules and network security groups.

security rule

Virtual firewall rules for your VCN. Each security rule specifies a type of ingress or egress traffic allowed in or out of a resource or VNIC. Also see network security groups and security lists.

service gateway

An optional virtual router that you can add to your VCN. The gateway enables on-premises hosts or VCN hosts to privately access Oracle services (such as Object Storage and Autonomous Database) without exposing the resources to the public internet.

shape

A template that determines the number of CPUs and the amount of memory allocated to a newly created instance.

statement

Policies can contain one or more individual statements. Each statement gives a group a certain type of access to certain resources in a particular compartment.

statistic

The aggregation function applied to the given set of raw data points. Example: SUM

subnet

Subdivision of your VCN used to separate your network into multiple smaller, distinct networks.

subscription

(Notifications service) An endpoint for a topic; typically a URL or email address. Published messages are sent to each subscription for a topic.

suppression

(Monitoring service) A configuration to avoid publishing messages during the specified time range. Useful for suspending alarm notifications during system maintenance.

Swift password

(Deprecated. Use an auth token to authenticate with your Swift client.) Swift is the OpenStack object store service. A Swift password enables you to use an existing Swift client with Oracle Cloud Infrastructure Object Storage.

T

tenancy

The root compartment that contains all of your organization's compartments and other Oracle Cloud Infrastructure cloud resources.

tenant

The name assigned to a particular company's or organization's overall environment. Users provide their tenant when signing in to the Console.

topic

(Notifications service) A communication channel for sending messages to the subscriptions in the topic.

transit routing

A network setup in which your on-premises network uses a connected virtual cloud network (VCN) to reach Oracle resources or services beyond that VCN. You connect the on-premises network to the VCN with a FastConnect private virtual circuit or VPN Connect, and then configure the VCN routing so that traffic transits through the VCN to its destination beyond the VCN. You can use transit routing to access multiple VCNs from your on-premises network over a single FastConnect or VPN Connect. Or you can use it to give your on-premises network private access to Oracle services so that on-premises hosts use their private IP addresses and the traffic does not go over the internet.

trigger rule

(Monitoring service) The condition that must be met for the alarm to be in the firing state. A trigger rule can be based on a threshold or absence of a metric.

U

user

An individual employee or system that needs to manage or use your company's Oracle Cloud Infrastructure resources.

V

VCN

A virtual version of a traditional network—including CIDRs, subnets, route tables, and gateways—on which your instance runs.

virtual circuit

Used with Oracle Cloud Infrastructure FastConnect. An isolated network path that runs over one or more physical network connections to provide a single, logical connection between the edge of

your existing network and Oracle Cloud Infrastructure.

virtual cloud network

A virtual version of a traditional network—including CIDRs, subnets, route tables, and gateways—on which your instance runs.

virtual machine

A software-based emulation of a full computer that runs within a physical host computer.

virtual network interface card

A VNIC enables an instance to connect to a VCN and determines how the instance connects with endpoints inside and outside the VCN. Each instance automatically comes with a primary VNIC, and you can add secondary ones. Other types of cloud resources also automatically get a VNIC upon creation (examples: load balancers, DB systems).

VM

A software-based emulation of a full computer that runs within a physical host computer.

VNIC

A VNIC enables an instance to connect to a VCN and determines how the instance connects with endpoints inside and outside the VCN. Each instance automatically comes with a primary VNIC, and you can add secondary ones. Other types of cloud resources also automatically get a VNIC upon creation (examples: load balancers, DB systems).

volume

A detachable block storage device that allows you to dynamically expand the storage capacity of an instance.

W

work request

An object that reports on the current state of an asynchronous service request.

RELEASE NOTES

You can find the Oracle Cloud Infrastructure Release Notes online.
