    - **Database version:** The version of the database. You can mix database versions on the DB system, but not editions.
    - **PDB name** (Optional) For version 12.1.0.2 and later, you can specify the name of the pluggable database. The PDB name must begin with an alphabetic character, and can contain a maximum of 8 alphanumeric characters. The only special character permitted is the underscore (_).
    - **Create administrator credentials:** A database administrator `SYS` user will be created with the password you supply.
        - **Username:** SYS
        - **Password:** Supply the password for this user. The password must meet the following criteria:

          A strong password for SYS, SYSTEM, TDE wallet, and PDB Admin. The password must be 9 to 30 characters and contain at least 2 uppercase, 2 lowercase, 2 numeric, and 2 special characters. The special characters must be _, #, or -. The password must not contain the username (SYS, SYSTEM, and so on) or the word "oracle" either in forward or reversed order and regardless of casing.
        - **Confirm password:** Re-enter the SYS password you specified.
    - **Select workload type:** Choose the workload type that best suits your application:
        - **Online Transactional Processing (OLTP)** configures the database for a transactional workload, with a bias towards high volumes of random data access.

    - **Decision Support System (DSS)** configures the database for a decision support or data warehouse workload, with a bias towards large data scanning operations.
- **Configure database backups:** Specify the settings for backing up the database to Object Storage:
    - **Enable automatic backup:** Check the check box to enable automatic incremental backups for this database.
    - **Backup Retention Period:** If you enable automatic backups, you can choose one of the following preset retention periods: 7 days, 15 days, 30 days, 45 days, or 60 days. The default selection is 30 days.
    - **Backup Scheduling:** If you enable automatic backups, you can choose a two-hour scheduling window to control when backup operations begin. If you do not specify a window, the six-hour default window of 00:00 to 06:00 (in the time zone of the DB system's region) is used for your database. See Backup Scheduling for more information.

6. Click **Show Advanced Options** to specify advanced options for the database:
    - **Character set:** The character set for the database. The default is AL32UTF8.
    - **National character set:** The national character set for the database. The default is AL16UTF16.
    - Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.
7. Click **Create Database**.

When the database creation is complete, the status changes from Provisioning to Available.

To create a database from a backup in an existing DB system

Before you begin, note the following:

- When you create a database from a backup, you can choose a different DB system and compartment. However, the availability domain will be the same as where the source database is hosted.

  Tip

  You can use the GetBackup API to obtain information about the availability domain of the backup.

- The DB system you specify must support the same type as the system from which the backup was taken. For example, if the backup is from a single-node database, then the target DB system must be a single-node shape.
- The version of the target DB system must be the same or higher than the version of the backup.

1. Open the navigation menu. Under **Database**, click **Bare Metal, VM, and Exadata**.
2. Choose your **Compartment**.
   A list of DB systems is displayed.
3. Navigate to the backup you wish to use to create a new database. You can select a backup from a database details page, or select a backup that appears in your compartment's list of standalone backups.

Tip

If you are creating a database from an automatic backup, you may choose any level 0 weekly backup, or a level 1 incremental backup created after the most recent level 0 backup. For more information on automatic backups, see Automatic Incremental Backups.

To navigate to a database's list of backups

a. Find the DB system where the database is located, and click the system name to display details about it.
   A list of databases is displayed.

b. Find the database associated with the backup you wish to use, and click its name to display details about it.
   A list of backups is displayed in the default view of the database details. You can also access the list of backups for a database by clicking on **Backups** under **Resources**.

To navigate to the list of standalone backups for your current compartment

a. Click **Standalone Backups** under **Bare Metal, VM, and Exadata**.

b. In the list of standalone backups, find the backup you want to use to create the database.

4. Click the Actions icon (three dots) for the backup you are interested in, and then click **Create Database**.

5. In the **Create Database from Backup** dialog, enter the following:
    - **DB System:** The DB system in which you want to create the database. You must have the **Use Existing DB System** radio button selected to see the drop-down list of DB system choices.

      Note

      You cannot create a new database in the same DB system in which the database used to create the backup resides.

    - **Database Name:** The name for the database. The database name must begin with an alphabetic character and can contain a maximum of eight alphanumeric characters. Special characters are not permitted.
    - **Database Admin Password:** A strong password for SYS, SYSTEM, TDE wallet, and PDB Admin. The password must be 9 to 30 characters and contain at least 2 uppercase, 2 lowercase, 2 numeric, and 2 special characters. The special characters must be _, #, or -. The password must not contain the username (SYS, SYSTEM, and so on) or the word "oracle" either in forward or reversed order and regardless of casing.
    - **Confirm Database Admin Password:** Re-enter the Database Admin Password you specified.
    - **Password for Transparent Data Encryption (TDE) Wallet or RMAN Encryption:**
      Enter either the TDE wallet password or the RMAN encryption password for the backup, whichever is applicable. The TDE wallet password is the SYS password provided when the database was created by using the Oracle Cloud Infrastructure Console, API, or CLI. The RMAN encryption password is typically required instead if the password was subsequently changed manually.
6. Click **Create Database**.

To terminate a database

You'll get the chance to back up the database prior to terminating it. This creates a standalone backup that can be used to create a database later. Oracle recommends that you create this final backup for any production (non-test) database.

Note

Terminating a database removes all automatic incremental backups of the database from Oracle Cloud Infrastructure Object Storage. However, all full backups that were created on demand, including your final backup, will persist as standalone backups.

You cannot terminate a database that is assuming the primary role in a Data Guard association. To terminate it, you can switch it over to the standby role.

1. Open the navigation menu. Under **Database**, click **Bare Metal, VM, and Exadata**.
2. Choose your **Compartment**.
   A list of DB systems is displayed.
3. In the list of DB systems, find the DB system that contains the database you want to terminate, and then click its name to display details about it.
4. In the list of databases, find the database you want to terminate, and then click its name to display details about it.
5. Click **Actions**, and then click **Terminate**.
6. In the confirmation dialog, indicate whether you want to back up the database before terminating it, and type the name of the database to confirm the termination.
7. Click **Terminate Database**.
   The database's status indicates Terminating.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use these API operations to manage databases.

Database homes:

- ListDbHomes
- GetDbHome
- CreateDbHome
- DeleteDbHome

Databases:

- ListDatabases
- GetDatabase

For the complete list of APIs for the Database service, see Database Service API.

Monitoring a Database

This topic explains how to set up an:

- Enterprise Manager Express console to monitor a version 12.1.0.2 or later database
- Enterprise Manager Database Control console to monitor a version 11.2.0.4 database

Each console is a web-based database management tool inside the Oracle database. You can use the console to perform basic administrative tasks such as managing user security, memory, and storage, and view performance information.

Required IAM Policy

Some of the procedures below require permission to create or update security lists. For more information about security list policies, see Security Lists.

Monitoring a Database with Enterprise Manager Express

On 1- and 2-node RAC DB Systems, by default, the EM Express console is not enabled on version 18.1.0.0, 12.2.0.1, and 12.1.0.2 databases. You can enable it for an existing database as described below, or you can enable it when you create a database by using the dbcli create-database command with the `-co` parameter.

You must also update the security list and iptables for the DB system as described later in this topic.

When you enable the console, you'll set the port for the console. The procedure below uses port 5500, but each additional console enabled on the same DB system will have a different port.

To enable the EM Express console and determine its port number

1. SSH to the DB system, log in as opc, sudo to the oracle user, and log in to the database as SYS.

   ```
   sudo su - oracle
   . oraenv
    <provide the database SID at the prompt>
   sqlplus / as sysdba
   ```

2. Do one of the following:

   - To enable the console and set its port, use the following command.

     ```
     exec DBMS_XDB_CONFIG.SETHTTPSPORT(<port>);
     ```

     For example:

     ```
     SQL> exec DBMS_XDB_CONFIG.SETHTTPSPORT(5500);

     PL/SQL procedure successfully completed.
     ```

   - To determine the port for a previously enabled console, use the following command.

     ```
     select dbms_xdb_config.getHttpsPort() from dual;
     ```

For example:

```
SQL> select dbms_xdb_config.getHttpsPort() from dual;

DBMS_XDB_CONFIG.GETHTTPSPORT()
------------------------------
                          5500
```

3. Return to the operating system by typing `exit` and then confirm that the listener is listening on the port:

```
lsnrctl status | grep HTTP

(DESCRIPTION=(ADDRESS=(PROTOCOL=tcps)(HOST=xxx.us.oracle.com)(PORT=5500))(Security=(my_wallet_
directory=/u01/app/oracle/admin/prod/xdb_wallet))(Presentation=HTTP)(Session=RAW))
```

4. If you're using a 2-node RAC DB system, see To set the required permissions on a 2-node RAC DB system.
5. Open the console's port as described in Opening Ports on the DB System.
6. Update the security list for the console's port as described in Updating the Security List for the DB System.

To set the required permissions on a 2-node RAC DB system

If you're using a 2-node RAC DB system, you'll need to add read permissions for the asmadmin group on the wallet directory on *both* nodes in the system.

1. SSH to one of the nodes in the DB system, log in as opc, sudo to the grid user.

```
[opc@dbsysHost1 ~]$ sudo su - grid
[grid@dbsysHost1 ~]$ . oraenv
ORACLE_SID = [+ASM1] ?
The Oracle base has been set to /u01/app/grid
```

2. Get the location of the wallet directory, shown in red below in the command output.

```
[grid@dbsysHost1 ~]$ lsnrctl status | grep xdb_wallet

(DESCRIPTION=(ADDRESS=(PROTOCOL=tcps)(HOST=dbsysHost1.sub04061528182.dbsysapril6.oraclevcn.com)
```

```
(PORT=5500))(Security=(my_wallet_directory=/u01/app/oracle/admin/dbsys12_phx3wm/xdb_wallet))
(Presentation=HTTP)(Session=RAW))
```

3. Return to the opc user, switch to the oracle user, and change to the wallet directory.

```
[opc@dbsysHost1 ~]$ sudo su - oracle
[oracle@dbsysHost1 ~]$ cd /u01/app/oracle/admin/dbsys12_phx3wm/xdb_wallet
```

4. List the directory contents and note the permissions.

```
[oracle@dbsysHost1 xdb_wallet]$ ls -ltr
total 8
-rw------- 1 oracle asmadmin 3881 Apr  6 16:32 ewallet.p12
-rw------- 1 oracle asmadmin 3926 Apr  6 16:32 cwallet.sso
```

5. Change the permissions:

```
[oracle@dbsysHost1 xdb_wallet]$ chmod 640 /u01/app/oracle/admin/dbsys12_phx3wm/xdb_wallet/*
```

6. Verify that read permissions were added.

```
[oracle@dbsysHost1 xdb_wallet]$ ls -ltr
total 8
-rw-r----- 1 oracle asmadmin 3881 Apr  6 16:32 ewallet.p12
-rw-r----- 1 oracle asmadmin 3926 Apr  6 16:32 cwallet.sso
```

7. **Important!** Repeat the steps above on the other node in the cluster.

To connect to the EM Express console

After you've enabled the console and opened its port in the security list and iptables, you can connect as follows:

1. From a web browser, connect to the console using the following URL format:

```
https://<ip_address>:<port>/em
```

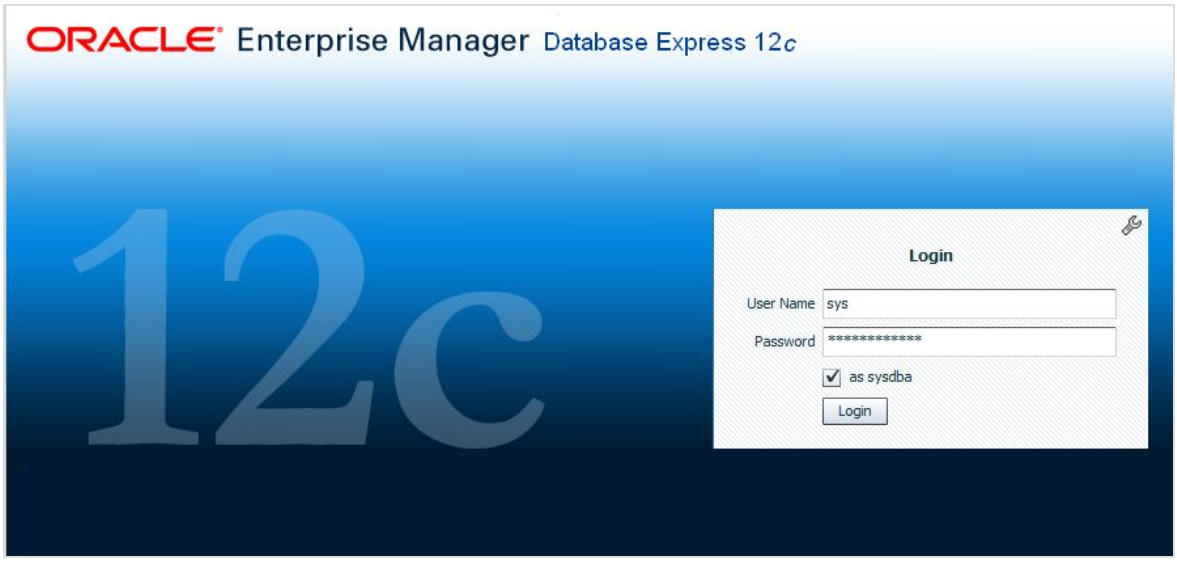
   For example, `https://129.145.0.164:5500/em`
   Use the DB system's private or public IP address depending on your network configuration.

Use the private IP address to connect to the DB system from your on-premises network, or from within the virtual cloud network (VCN). This includes connecting from a host located on-premises connecting through a VPN or FastConnect to your VCN, or from another host in the same VCN.

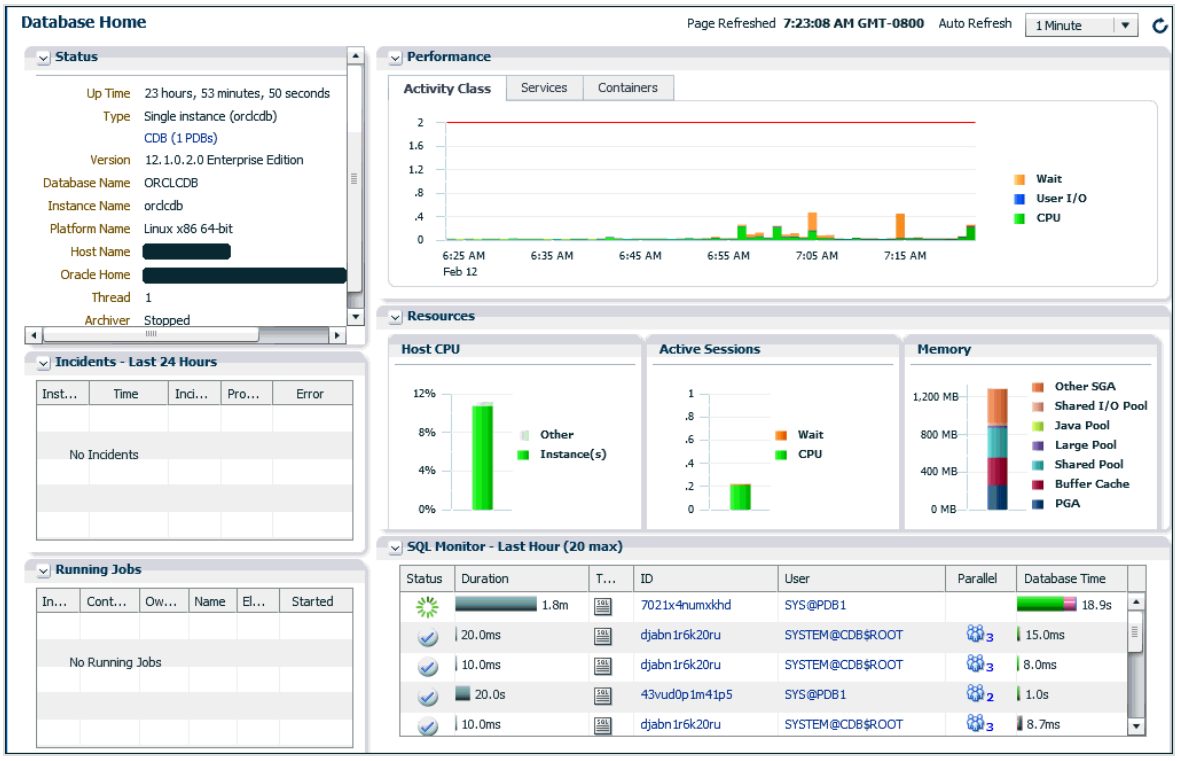
Use the DB System's public IP address to connect to the system from outside the cloud (with no VPN).

You can find the IP addresses in the Oracle Cloud Infrastructure Console on the **Database** page.

2. A login page is displayed and you can log in with any valid database credentials.



The Database Home page is displayed.



To learn more about EM Express, see Introduction to Oracle Enterprise Manager Database Express.

Note

If you're using a 1-node DB system, and you are unable to connect to the EM Express console, see Database Known Issues.

Monitoring a Database with Enterprise Manager Database Control

By default, the Enterprise Manager Database Control console is not enabled on version 11.2.0.4 databases. You can enable the console:

- when you create a database by using the dbcli create-database with the `-co` parameter
- for an existing database as described here.

Port 1158 is the default port used for the first console enabled on the DB system, but each additional console enabled on the DB system will have a different port.

Note

For a version 11.2.0.4 database on a 2-node RAC DB system, see To enable the console for a version 11.2.0.4 database on a multi-node DB system .

To determine the port for the Enterprise Manager Database Control console

1. SSH to the DB system, log in as opc, and sudo to the oracle user.

```
sudo su - oracle
. oraenv
 <provide the database SID at the prompt>
```

2. Use the following command to get the port number.

```
emctl status dbconsole
```

The port is in the URL, as shown in the following example:

```
[oracle@dbsys ~]$ emctl status dbconsole
Oracle Enterprise Manager 11g Database Control Release 11.2.0.4.0
Copyright (c) 1996, 2013 Oracle Corporation.  All rights reserved.
https://dbprod:1158/em/console/aboutApplication
Oracle Enterprise Manager 11g is running.
------------------------------------------------------------------
```

```
Logs are generated in directory /u01/app/oracle/product/11.2.0.4/dbhome_2/dbprod_db11/sysman/log
```

3. Open the console's port as described in Opening Ports on the DB System.
4. Update the security list for the console's port as described in Updating the Security List for the DB System.

To connect to the Enterprise Manager Database Control console

After you've enabled the console and opened its port in the security list and iptables, you can connect as follows:

1. From a web browser, connect to the console using the following URL format:

   ```
   https://<ip_address>:<port>/em
   ```

   For example, `https://129.145.0.164:1158/em`

   Use the DB system's private or public IP address depending on your network configuration.

   Use the private IP address to connect to the DB system from your on-premises network, or from within the virtual cloud network (VCN). This includes connecting from a host located on-premises connecting through a VPN or FastConnect to your VCN, or from another host in the same VCN.

   Use the DB System's public IP address to connect to the system from outside the cloud (with no VPN).

   You can find the IP addresses in the Oracle Cloud Infrastructure Console on the **Database** page.
2. A login page will be displayed and you can log in with any valid database credentials.

To learn more about Enterprise Manager Database Control, see Introduction to Oracle Enterprise Manager Database Control.

To enable the console for a version 11.2.0.4 database on a multi-node DB system

A few extra steps are required to enable the console for a version 11.2.0.4 database on a

multi-node DB system.

Configure SSH Equivalency Between the Two Nodes

You'll create SSH keys on each node and copy the key to the other node, so that each node has the keys for both nodes. The following procedure uses the sample names node1 and node2.

1. SSH to node1, log in as opc, and sudo to the oracle user.

   ```
   sudo su - oracle
   ```

2. Create a directory called .ssh, set its permissions, create an RSA key, and add the public key to the `authorized_keys` file.

   ```
   mkdir .ssh
   chmod 755 .ssh
   ssh-keygen -t rsa
   cat id_rsa.pub > authorized_keys
   ```

3. Repeat the previous steps on the other node in the cluster.
4. On each node, add the `id_rsa.pub` key for the *other* node to the `authorized_keys` file. When you're done, you should see both keys in `authorized_keys` on each node.
5. On node1, create the `known_hosts` file by doing the following:
   - SSH to node1 and reply yes to the authentication prompt.
   - SSH to node2 and reply yes to the authentication prompt.
6. On node2, create the `known_hosts` file by doing the following:
   - SSH to node2 and reply yes to the authentication prompt.
   - SSH to node1 and reply yes to the authentication prompt.
7. On node1, verify that SSH equivalency is now configured by using the following Cluster Verification Utility (CVU) command.

   ```
   cluvfy stage -pre crsinst -n all -verbose
   ```

Configure the Console

1. On node1, create a file called emca.rsp with the following entries.

```
DB_UNIQUE_NAME=<pdb_unique_name>
SERVICE_NAME=<db_unique_name>.<db_domain>
PORT=<scan listener port>
LISTENER_OH=$GI_HOME
SYS_PWD=<admin password>
DBSNMP_PWD=<admin password>
SYSMAN_PWD=<admin password>
CLUSTER_NAME=<cluster name>     <=== to get the cluster name, run: $GI_HOME/bin/cemutlo -n
ASM_OH=$GI_HOME
ASM_SID=+ASM1
ASM_PORT=<asm listener port>
ASM_USER_NAME=ASMSNMP
ASM_USER_PWD=<admin password>
```

2. On node1, run Enterprise Manager Configuration Assistant (EMCA) using the emca.rsp file as input.

```
$ORACLE_HOME/bin/emca -config dbcontrol db -repos create -cluster -silent -respFile  <location of response file above>
```

3. On node2, configure the console so the agent in node1 reports to the console in node1, and the agent in node2 reports to the console in node2.

```
$ORACLE_HOME/bin/emca -reconfig dbcontrol -silent -cluster -EM_NODE <node2 host> -EM_NODE_LIST <node2 host> -DB_UNIQUE_NAME <db_unique_name>
 -SERVICE_NAME <db_unique_name>.<db_domain>
```

4. On each node, verify that console is working properly.

```
$ export ORACLE_UNQNAME=<db_unique_name>

$ emctl status agent

---------------------------------------------------------------
```

Update iptables and Security List

1. On each node, edit iptables to open the console's port as described in Opening Ports on the DB System.
2. Update the security list for the console's port as described in Updating the Security List for the DB System.

Opening Ports on the DB System

Open the following ports as needed on the DB system:

- 6200 - For Oracle Notification Service (ONS).
- 5500 - For EM Express. 5500 is the default port, but each additional EM Express console enabled on the DB system will have a different port. If you're not sure which port to open for a particular console, see Monitoring a Database with Enterprise Manager Express.
- 1158 - For Enterprise Manager Database Control. 1158 is the default port, but each additional console enabled on the DB system will have a different port. If you're not sure which port to open for a particular console, see Monitoring a Database with Enterprise Manager Database Control.

For important information about critical firewall rules, see Essential Firewall Rules.

To open ports on the DB system

1. SSH to the DB System.

   ```
   ssh -i <private_key_path> opc@<db_system_ip_address>
   ```

2. Log in as opc and then sudo to the root user.

   ```
   login as: opc

   [opc@dbsys ~]$ sudo su -
   ```

3. Save a copy of iptables as a backup.

   ```
   [root@dbsys ~]# iptables-save > /tmp/iptables.orig
   ```

   (If necessary, you can restore the original file by using the command `iptables-restore < /tmp/iptables.orig`.)

4. Dynamically add a rule to iptables to allow inbound traffic on the console port, as shown in the following sample. Change the port number and comment as needed.

   ```
   [root@dbsys ~]# iptables -I INPUT 8 -p tcp -m state --state NEW -m tcp --dport 5500 -j ACCEPT -m comment --comment "Required for EM Express."
   ```

5. Make sure the rule was added.

   ```
   [root@dbsys ~]# service iptables status
   ```

6. Save the updated file to `/etc/sysconfig/iptables`.

   ```
   [root@dbsys ~]# /sbin/service iptables save
   ```

   The change takes effect immediately and will remain in effect when the node is rebooted.

7. Update the DB system's security list as described in Updating the Security List for the DB System.

Updating the Security List for the DB System

Review the list of ports in Opening Ports on the DB System and for every port you open in iptables, update the security list used for the DB system, or create a new security list.

Note that port 1521 for the Oracle default listener is included in iptables, but should also be added to the security list.

To update an existing security list

1. Open the navigation menu. Under **Database**, click **Bare Metal, VM, and Exadata**.
2. Choose your **Compartment**.
   A list of DB systems is displayed.
3. Locate the DB system in the list.
4. Note the DB system's **Subnet** name and click its **Virtual Cloud Network**.
5. Locate the subnet in the list, and then click its security list under **Security Lists**.
6. Click **Edit All Rules** and add an ingress rule with source type = CIDR, source CIDR=*<source CIDR>*, protocol=TCP, and port=*<port number or port range>*.
   The source CIDR should be the CIDR block that includes the ports you open for the client connection.

For detailed information about creating or updating a security list, see Security Lists.

Backing Up a Database

Backing up your DB System is a key aspect of any Oracle database environment. You can store backups in the cloud or in local storage. Each backup destination has advantages, disadvantages, and requirements that you should consider, as described below.

Object Storage (Recommended)

- Backups are stored in the Oracle Cloud Infrastructure Object Storage.
- Durability: High

- Availability: High
- Back Up and Recovery Rate: Medium
- Advantages: High durability, performance, and availability.

Local Storage

- Backups are stored locally in the Fast Recovery Area of the DB System.
- Durability: Low
- Availability: Medium
- Back Up and Recovery Rate: High
- Advantages: Optimized back up and fast point-in-time recovery.
- Disadvantages: If the DB System becomes unavailable, the backup is also unavailable.

Currently, Oracle Cloud Infrastructure does not provide the ability to attach block storage volumes to a DB System, so you cannot back up to network attached volumes.

For 1- and 2-node RAC DB Systems, see:

- Backing Up a Database to Oracle Cloud Infrastructure Object Storage
- Backing Up a Database to Local Storage Using the Database CLI

Backing Up a Database to Oracle Cloud Infrastructure Object Storage

Note

This topic is not applicable to Exadata DB systems. For Exadata DB systems, see Managing Exadata Database Backups.

This topic explains how to work with backups managed by Oracle Cloud Infrastructure. You do this by using the Console or the API. (For unmanaged backups, you can use `RMAN` or `dbcli`,

and you must create and manage your own Object Storage buckets for backups. See Backing Up a Database to Object Storage Using RMAN.)

Warning

If you previously used `RMAN` or `dbcli` to configure backups and then you switch to using the Console or the API for backups, a new backup configuration is created and associated with your database. This means that you can no longer rely on your previously configured unmanaged backups to work.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don't have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

If you're new to policies, see Getting Started with Policies and Common Policies.

Prerequisites

The DB system requires access to the Oracle Cloud Infrastructure Object Storage service, including connectivity to the applicable Swift endpoint for Object Storage. Oracle recommends using a service gateway with the VCN to enable this access. For more information, see these topics:

- Network Setup for DB Systems: For information about setting up your VCN for the DB system, including the service gateway.
- https://cloud.oracle.com/infrastructure/storage/object-storage/faq: For information about the Swift endpoints to use.

Important

Note that your database and DB system must be in an "Available" state for a backup operation to run successfully. Oracle recommends that you avoid performing actions that could interfere with availability (such as patching and Data Guard operations) while a backup operation is in progress. If an automatic backup operation fails, the Database service retries the operation during the next day's backup window. If an on-demand full backup fails, you can try the operation again when the DB system and database availability are restored.

In addition to the prerequisites listed, ensure that the following conditions are met to avoid backup failures:

- The database's archiving mode is set to `ARCHIVELOG` (the default).
- The `/u01` directory on the database host file system has sufficient free space for the execution of backup processes.
- The .bash_profile file for the oracle user does not include any interactive commands (such as `oraenv` or one that could generate an error or warning message).
- (For automatic backups) No changes were made to the default `WALLET_LOCATION` entry in the sqlnet.ora file.
- No changes were made to `RMAN` backup settings by using standard `RMAN` commands.

> See Backup Failures on Bare Metal and Virtual Machine DB Systems for details on problems that can result from not following these guidelines.

ORACLE CLOUD INFRASTRUCTURE MANAGED BACKUP FEATURES

The following information applies to managed backups configured using the Oracle Cloud Infrastructure Console or API.

AUTOMATIC INCREMENTAL BACKUPS

When you enable the Automatic Backup feature, the service creates daily incremental backups of the database to Object Storage. The first backup created is a level 0 backup. Then, level 1 backups are created every day until the next weekend. Every weekend, the cycle repeats, starting with a new level 0 backup.

Backup Retention

If you choose to enable automatic backups, you can choose one of the following preset retention periods: 7 days, 15 days, 30 days, 45 days, or 60 days. The system automatically deletes your incremental backups at the end of your chosen retention period.

Backup Scheduling

The automatic backup process starts at any time during your daily backup window. You can optionally specify a 2-hour scheduling window for your database during which the automatic backup process will begin. There are 12 scheduling windows to choose from, each starting on an even-numbered hour (for example, one window runs from 4:00-6:00 AM, and the next from 6:00-8:00 AM). Backups jobs do not necessarily complete within the scheduling window

The default backup window of 00:00 to 06:00 in the time zone of the DB system's region is assigned to your database if you do not specify a window. Note that the default backup scheduling window is six hours long, while the windows you specify are two hours long. See note for backup window time zone information.

Note

- **Backup Window Time Zone** - Automatic backups enabled for the first time after November 20, 2018 on any database will run between midnight and 6:00 AM in the time zone of the DB system's region. If you have enabled automatic backups on a database before this date, the backup window for the database will continue to be between midnight and 6:00 AM **UTC**. You can create a My Oracle Support service request to have your automatic backups run in a backup window of your choice.
- **Data Guard** - You can enable the Automatic Backup feature on a database with the standby role in a Data Guard association. However, automatic backups for that database will not be created until it assumes the primary role.
- **Retention Period Changes** - If you shorten your database's automatic backup retention period in the future, existing backups falling outside the updated retention period are deleted by the system.
- **Object Storage Costs** - Automatic backups incur Object Storage usage costs.

ON-DEMAND FULL BACKUPS

You can create a full backup of your database at any time unless your database is assuming the standby role in a Data Guard association.

STANDALONE BACKUPS

When you terminate a DB system or a database, all of its resources are deleted, along with any automatic backups. Full backups remain in Object Storage as standalone backups. You can use a standalone backup to create a new database.

USING THE CONSOLE

You can use the Console to enable automatic incremental backups, create full backups on demand, and view the list of managed backups for a database. The Console also allows you to delete full backups.

Note

The list of backups you see in the Console does not include any unmanaged backups (backups created directly by using `RMAN` or `dbcli`).

All backups are encrypted with the same master key used for Transparent Data Encryption (TDE) wallet encryption.

To navigate to the list of standalone backups for your current compartment

1. Open the navigation menu. Under **Database**, click **Bare Metal, VM, and Exadata**.
2. Click **Standalone Backups** under **Bare Metal, VM, and Exadata**.

To configure automatic backups for a database

When you launch a DB system, you can optionally enable automatic backups for the initial database. Use this procedure to configure or disable automatic backups after the database is created.

1. Open the navigation menu. Under **Database**, click **Bare Metal, VM, and Exadata**.
2. Choose your **Compartment**.
   A list of DB systems is displayed.
3. Find the DB system where the database is located, and click the system name to display details about it.
   A list of databases is displayed.
4. Find the database for which you want to enable or disable automatic backups, and click its name to display database details. The details indicate whether automatic backups are enabled. When backups are enabled, the details also indicate the chosen backup retention period .
5. Click **Configure Automatic Backups**.
6. In the **Configure Automatic Backups** dialog, check or uncheck **Enable Automatic Backup**, as applicable.
   If you are enabling automatic backups, you can choose to configure the following:
   - **Backup Retention Period:** If you enable automatic backups, you can choose one of the following preset retention periods: 7 days, 15 days, 30 days, 45 days, 60 days, or 90 days. The default selection is 30 days.
   - **Backup Scheduling:** If you enable automatic backups, you can choose a two-hour scheduling window to control when backup operations begin. If you do not specify a window, the six-hour default window of 00:00 to 06:00 (in the time zone of the DB system's region) is used for your database. See Backup Scheduling for more information.
7. Click **Save Changes**.

To create an on-demand full backup of a database

1. Open the navigation menu. Under **Database**, click **Bare Metal, VM, and Exadata**.
2. Choose your **Compartment**.
   A list of DB systems is displayed.

3. Find the DB system where the database is located, and click the system name to display details about it.
   A list of databases is displayed.
4. Find the database for which you want to create an on-demand full backup and click its name to display database details.
5. Under **Resources**, click **Backups**.
   A list of backups is displayed.
6. Click **Create Backup**.

To delete full backups from Object Storage

Note

You cannot explicitly delete automatic backups. Unless you terminate the database, automatic backups remain in Object Storage for 30 days, after which time they are automatically deleted.

1. Open the navigation menu. Under **Database**, click **Bare Metal, VM, and Exadata**.
2. Choose your **Compartment**.
   A list of DB systems is displayed.
3. Find the DB system where the database is located and click the DB system name to display details.
   A list of databases is displayed.
4. Find the database you are interested in and click its name to display database details.
5. Under **Resources**, click **Backups**.
   A list of backups is displayed.

6. Click the Actions icon (three dots) for the backup you are interested in, and then click **Delete**.
7. Confirm when prompted.

USING THE API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use these API operations to manage database backups:

- ListBackups
- GetBackup
- CreateBackup
- DeleteBackup
- UpdateDatabase - To enable and disable automatic backups.

For the complete list of APIs for the Database service, see Database Service API.

WHAT'S NEXT?

See Recovering a Database from Object Storage.

Backing Up a Database to Object Storage Using RMAN

Note

This topic is not applicable to Exadata DB systems. For Exadata DB systems, see Managing Exadata Database Backups by Using bkup_api.

This topic explains how to use Recovery Manager (RMAN) to manage backups of your Bare Metal or Virtual Machine DB system database to your own Object Storage. For backups

managed by Oracle Cloud Infrastructure, see Backing Up a Database to Oracle Cloud Infrastructure Object Storage.

To back up to the service you'll need to create an Object Storage bucket for the backups, generate a password for the service, install the Oracle Database Cloud Backup Module, and then configure RMAN to send backups to the service. The backup module is a system backup to tape (SBT) interface that's tightly integrated with RMAN, so you can use familiar RMAN commands to perform backup and recovery operations.

You'll notice *Swift* mentioned in the Console and in the endpoint URL for the service. That's because the backup module is typically used to back up to the Oracle Database Backup Cloud Service, which is an OpenStack Swift object store.

Tip

On a 1-node DB system, you can use the database command line interface (`dbcli`)to back up to Object Storage. This is an alternative to installing the backup module and using RMAN for backups. For more information, see Objectstoreswift Commands. Note that the `dbcli` commands are not available for a 2-node RAC DB system.

PREREQUISITES

You'll need the following:

- A DB system and a database to back up. For more information, see Creating Bare Metal and Virtual Machine DB Systems.
- The DB system's cloud network (VCN) must be configured with access to Object Storage:
    - For Object Storage access in the same region as the DB system: Oracle recommends using a service gateway. For more information, see Service Gateway for the VCN.

    - For Object Storage access in a different region than the DB system: Use an internet gateway. Note that the network traffic between the DB system and Object Storage does not leave the cloud and never reaches the public internet. For more information, see Internet Gateway.
- An existing Object Storage bucket to use as the backup destination. You can use the Console or the Object Storage API to create the bucket. For more information, see Managing Buckets.
- An auth token generated by Oracle Cloud Infrastructure. You can use the Console or the IAM API to generate the password. For more information, see Working with Auth Tokens.
- The user name (specified when you install and use the backup module) must have tenancy-level access to Object Storage. An easy way to do this is to add the user name to the Administrators group. However, that allows access to *all* of the cloud services. Instead, an administrator should create a policy like the following that limits access to only the required resources in Object Storage for backing up and restoring the database:

  ```
  Allow group <group_name> to manage objects in compartment <compartment_name> where
  target.bucket.name = '<bucket_name>'

  Allow group <group_name> to read buckets in compartment <compartment_name>
  ```

  For more information about adding a user to a group, see Managing Groups. For more information about policies, see Getting Started with Policies.

Installing the Backup Module on the DB System

1. SSH to the DB system, log in as opc, and sudo to the oracle user.

   ```
   ssh -i <SSH_key_used_when_launching_the_DB_system> opc@<DB_system_IP_address_or_hostname>
   login as: opc
   sudo su - oracle
   ```

2. Change to the directory that contains the backup module `opc_install.jar` file.

   ```
   cd /opt/oracle/oak/pkgrepos/oss/odbcs
   ```

3. Use the following command syntax to install the backup module.

```
java -jar opc_install.jar -opcId <user_id> -opcPass '<auth_token>' -container <bucket_name> -
walletDir ~/hsbtwallet/ -libDir ~/lib/ -configfile ~/config -host
https://swiftobjectstorage.<region_name>.oraclecloud.com/v1/<tenant>
```

The parameters are:

Parameter	Description
-opcId	The user name for the Oracle Cloud Infrastructure user account, for example: `-opcId <username>@<example>.com` This is the user name you use to sign in to the Console. The user name must be a member of the Administrators group, as described in Prerequisites. You can also specify the user name in single quotes. This might be necessary if the name contains special characters, for example: `-opcId 'j~smith@<example>.com'` Make sure to use straight single quotes and not slanted apostrophes.
-opcPass	The auth token generated by using the Console or IAM API, in single quotes, for example: `-opcPass '<password>'` Make sure to use straight single quotes and not slanted apostrophes. For more information, see Managing User Credentials. This is **not** the password for the Oracle Cloud Infrastructure user.
-container	The name of an existing bucket in Object Storage to use as the backup destination, for example: `-container DBBackups`
-walletDir	The directory where the install tool will create an Oracle Wallet containing the Oracle Cloud Infrastructure user name and auth token. `-walletDir ~/hsbtwallet` creates the wallet in the current user (oracle) home directory.

Parameter	Description
-libDir	The directory where the SBT library is stored. The directory must already exist before you run the command. This parameter causes the latest SBT library to be downloaded. `-libDir ~/lib/` downloads the `libopc.so` file to the current user's home directory, for example, `/home/oracle/lib/libopc.so`.
-configfile	The name of the initialization parameter file that will be created by the install tool. This file will be referenced by your RMAN jobs. `-configfile ~/config` creates the file in the current user's home directory, for example, `/home/oracle/config`.
-host	The endpoint URL to which backups are to be sent: `https://swiftobjectstorage.<region_name>.oraclecloud.com/v1/<tenant>` where *<tenant>* is the *lowercase* tenant name (even if it contains uppercase characters) that you specify when signing in to the Console, for example: `https://swiftobjectstorage.<region_name>.oraclecloud.com/v1/companyabc` Do not add a slash after the tenant name. See Regions and Availability Domains to look up the region name.

CONFIGURING RMAN

This section describes how to configure RMAN to use the bucket as the default backup destination. The following assumes you are still logged in to the DB system.

1. On the DB system, set the ORACLE_HOME and ORACLE_SID environment variables using the oraenv utility.

```
. oraenv
```

2. Connect to the database using RMAN.

```
rman target /
```

3. Configure RMAN to use the SBT device and point to the `config` file that was created when you installed the backup module. A sample command for a version 12 database is shown here.

```
RMAN> CONFIGURE CHANNEL DEVICE TYPE 'SBT_TAPE' PARMS 'SBT_LIBRARY=/home/oracle/lib/libopc.so,
SBT_PARMS=(OPC_PFILE=/home/oracle/config)';
```

4. Configure RMAN to use SBT_TAPE by default. The following sample enables the controlfile and spfile autobackup to SBT_TAPE and configures encryption (recommended). There are other settings that may apply to your installation such as compression, number of backup and recovery channels to use, backup retention policy, archived log deletion policy, and more. See the Oracle Backup and Recovery documentation for your version of Oracle for more information on choosing the appropriate settings.

```
RMAN> CONFIGURE DEFAULT DEVICE TYPE TO SBT_TAPE;
RMAN> CONFIGURE BACKUP OPTIMIZATION ON;
RMAN> CONFIGURE CONTROLFILE AUTOBACKUP ON;
RMAN> CONFIGURE CONTROLFILE AUTOBACKUP FORMAT FOR DEVICE TYPE SBT_TAPE TO '%F';
RMAN> CONFIGURE ENCRYPTION FOR DATABASE ON;
```

Once the RMAN configuration is complete, you can use the same RMAN commands that you regularly use for tape backups.

Backing up the Database

This section provides examples of commonly used backup commands.

1. Set the database encryption:

```
RMAN> SET ENCRYPTION IDENTIFIED BY "password" ONLY;
```

   Note that this setting is not permanent; you must set it for each new RMAN session.

2. Back up the database and archivelogs. Below are some example commands. See the Oracle Backup and Recovery documentation for your version of Oracle for more information about choosing a back up procedure that meets your needs. Be sure to back up regularly to minimize potential data loss and always include a copy of the spfile and controlfile. Note that the example below uses multi-section incremental backups, which

is a feature introduced in 12c. When using 11g, omit the `section size` clause.

```
RMAN> BACKUP INCREMENTAL LEVEL 0 SECTION SIZE 512M DATABASE PLUS ARCHIVELOG;
```

```
RMAN> BACKUP INCREMENTAL LEVEL 1 SECTION SIZE 512M DATABASE PLUS ARCHIVELOG;
```

```
RMAN> BACKUP INCREMENTAL LEVEL 1 CUMULATIVE SECTION SIZE 512M DATABASE PLUS ARCHIVELOG;
```

3. Backup archivelogs frequently to minimize potential data loss, and keep multiple backup copies as a precaution.

```
RMAN> BACKUP ARCHIVELOG ALL NOT BACKED UP 2 TIMES;
```

When the backup job completes, you can display the backup files in your bucket in the Console on the **Storage** page, by selecting **Object Storage**.

WHAT'S NEXT?

See Recovering a Database from Object Storage.

Backing Up a Database to Local Storage Using the Database CLI

Note

This topic is not applicable to virtual machine DB systems because they have no local storage. For Exadata DB systems, see Managing Exadata Database Backups.

This topic explains how to back up to the local Fast Recovery Area on a bare metal DB system by using the database CLI (dbcli). Some sample dbcli commands are provided below. For complete command syntax, see the Oracle Database CLI Reference.

Note

Backing up to local storage is fast and provides for fast point-in-time recovery, however, if the DB system becomes unavailable, the backup also becomes unavailable. For information about more durable backup destinations, see Backing Up a Database.

BACKING UP THE DATABASE TO LOCAL STORAGE

You'll use the dbcli commands to create a backup configuration, associate the backup configuration with the database, initiate the backup operation, and then review the backup job.

1. SSH to the DB System.

```
ssh -i <private_key_path> opc@<db_system_ip_address>
```

2. Log in as opc and then sudo to the root user. Use `sudo su -` with a hyphen to invoke the root user's profile, which will set the PATH to the dbcli directory (`/opt/oracle/dcs/bin`).

```
login as: opc

[opc@dbsys ~]$ sudo su -
```

3. Create a backup configuration by using the dbcli update-backupconfig command and specify local disk storage as the backup destination.
   The following example creates a backup configuration named prodbackup and specifies a disk backup destination and a disk recovery window of 5 (backups and archived redo logs will be maintained in local storage for 5 days).

```
[root@dbsys ~]# dbcli create-backupconfig --name prodbackup --backupdestination disk  --
recoverywindow 5
{
  "jobId" : "e7050756-0d83-48ce-9336-86592be59827",
  "status" : "Success",
```

```
  "message" : null,
  "reports" : [ {
    "taskId" : "TaskParallel_471",
    "taskName" : "persisting backup config metadata",
    "taskResult" : "Success",
    "startTime" : 1467774813141,
    "endTime" : 1467774813207,
    "status" : "Success",
    "taskDescription" : null,
    "parentTaskId" : "TaskSequential_467",
    "jobId" : "e7050756-0d83-48ce-9336-86592be59827",
    "reportLevel" : "Info",
    "updatedTime" : 1467774813207
  } ],
  "createTimestamp" : 1467774781851,
  "description" : "create backup config:prodbackup",
  "updatedTime" : 1467774813236
}
```

The example above uses full parameter names for demonstration purposes, but you can abbreviate the parameters like this:

```
dbcli create-backupconfig -n prodbackup -d disk  -w 5
```

4. Get the ID of the database you want to back up by using the dbcli list-databases command.

```
[root@dbsys ~]# dbcli list-databases

ID                                       DB Name    DB Version CDB        Class    Shape
Storage    Status
---------------------------------------- ---------- ---------- ---------- -------- -------- -----
----- ----------
71ec8335-113a-46e3-b81f-235f4d1b6fde     prod       12.1.0.2   true       OLTP     odb1     ACFS
     Configured
```

5. Get the ID of the backup configuration by using the dbcli list-backupconfigs command.

```
[root@dbbackup backup]# /opt/oracle/dcs/bin/dbcli list-backupconfigs
ID                                       Name                 DiskRecoveryWindow
BackupDestination createTime
---------------------------------------- -------------------- ----- ------ ----------------------
```

```
-------------

78a2a5f0-72b1-448f-bd86-cf41b30b64ee     prodbackup           5     Disk    July 6, 2016 3:13:01
AM UTC
```

6. Associate the backup configuration ID with the database ID by using the dbcli update-database command.

```
[root@dbsys ~]# dbcli update-database  --backupconfigid 78a2a5f0-72b1-448f-bd86-cf41b30b64ee --
dbid 71ec8335-113a-46e3-b81f-235f4d1b6fde
{
  "jobId" : "2b104028-a0a4-4855-b32a-b97a37f5f9c5",
  "status" : "Created",
  "message" : null,
  "reports" : [ ],
  "createTimestamp" : 1467775842977,
  "description" : "update database id:71ec8335-113a-46e3-b81f-235f4d1b6fde",
  "updatedTime" : 1467775842978
}
```

   You can view details about the update job by using the dbcli describe-job command and specifying the job ID from the `dbcli update-database` command output, for example:

```
dbcli describe-job --jobid 2b104028-a0a4-4855-b32a-b97a37f5f9c5
```

7. Initiate the database backup by using the dbcli create-backup command. The backup operation is performed immediately.

   The following example creates a backup of the specified database.

```
[root@dbsys ~]# dbcli create-backup --dbid 71ec8335-113a-46e3-b81f-235f4d1b6fde
{
    "createTimestamp": 1467792576854,
    "description": "Backup service creation with db name: prod",
    "jobId": "d6c9edaa-fc80-40a9-bcdd-056430cdc56c",
    "message": null,
    "reports": [],
    "status": "Created",
    "updatedTime": 1467792576855
}
```

   Or you can abbreviate the command parameters like this:

```
dbcli create-backup -i 71ec8335-113a-46e3-b81f-235f4d1b6fde
```

You can view details about the back up job by using the dbcli describe-job command and specifying the job ID from the `dbcli create-backup` command output, for example:

```
dbcli describe-job --jobid d6c9edaa-fc80-40a9-bcdd-056430cdc56c
```

8. **Important!** Manually back up any TDE password-based wallets to your choice of a safe location, preferably not on the DB system. The wallets are required to restore the backup to a new host.
9. Optionally, you can review the backup report. Use the Oracle Database CLI Reference command to create a report, then use Oracle Database CLI Reference to get the report ID, and then use Oracle Database CLI Reference with the report ID to get the report location, as shown in the following example.

```
[root@dbsys ~]# dbcli create-backupreport --dbid 71ec8335-113a-46e3-b81f-235f4d1b6fde --
reporttype summary

{
       "jobId" : "65ce79fe-4ef4-4d7d-8020-e56a5390026d",
       "status" : "Created",
       "message" : null,
       "reports" : [ ],
       "createTimestamp" : "July 6, 2016 23:06:11 PM UTC",
       "description" : "Creating a report for database 71ec8335-113a-46e3-b81f-235f4d1b6fde",
       "updatedTime" : "July 6, 2016 23:06:11 PM UTC"
}

[root@dbsys ~]# dbcli list-backupreports

ID                                       Name                 ReportType DbId
                createTime                          updatedTime
---------------------------------------- -------------------- ---------- ------------------------
---------------- ---------------------------------- ----------------------------------
c0e0a16a-485f-4176-ab73-5b30ccf5c560                          summary    71ec8335-113a-46e3-b81f-
235f4d1b6fde     July 6, 2016 11:04:05 PM UTC        July 6, 2016 11:04:17 PM UTC

[root@dbsys ~]# dbcli describe-backupreport --id c0e0a16a-485f-4176-ab73-5b30ccf5c560

Backup Report details
```

```
------------------------------------------------------------------
                     ID: ed67a2cf-fe63-4755-a5d6-7eda5b669837
                   Name:
            Report Type: summary
               Location:
/opt/oracle/dcs/log/LrbvevghazqOGpbatvbpMRZJeVCzaW/rman/bkup/hhUiFnBz/rman_list_backup_
summary/2016-07-06/rman_list_backup_summary_2016-07-06_09-49-20.0832.log
            Database ID: 71ec8335-113a-46e3-b81f-235f4d1b6fde
            CreatedTime: July 6, 2016 3:49:12 AM UTC
            UpdatedTime: July 6, 2016 3:49:24 AM UTC
```

After the backup command completes, the database backup files are available in the Fast Recovery Area on the DB system.

WHAT'S NEXT?

See Recovering a Database from a CLI Backup.

Recovering a Database

For information on restoring a database on a bare metal or virtual machine DB system, see the following topics:

- Recovering a Database from Object Storage
- Recovering a Database from a CLI Backup
- Recovering a Database from the Oracle Cloud Infrastructure Classic Object Store

Recovering a Database from Object Storage

Note

This topic is not applicable to Exadata DB systems.

This topic explains how to recover a database from a backup stored in Object Storage. The service is a secure, scalable, on-demand storage solution in Oracle Cloud Infrastructure. For

information on using Object Storage as a backup destination, see Backing Up a Database to Oracle Cloud Infrastructure Object Storage.

You can recover a database using the Console, API, or by using RMAN.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don't have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

If you're new to policies, see Getting Started with Policies and Common Policies.

Prerequisites

The DB system requires access to the Oracle Cloud Infrastructure Object Storage service, including connectivity to the applicable Swift endpoint for Object Storage. Oracle recommends using a service gateway with the VCN to enable this access. For more information, see these topics:

- Network Setup for DB Systems: For information about setting up your VCN for the DB system, including the service gateway.
- https://cloud.oracle.com/infrastructure/storage/object-storage/faq: For information about the Swift endpoints to use.

Using the Console

You can use the Console to restore the database from a backup in the Object Storage that was

created by using the Console or the API. You can restore to the last known good state of the database, or you can specify a point in time or an existing System Change Number (SCN). You can also create a new database by using a standalone backup.

Note

The list of backups you see in the Console does not include any unmanaged backups (backups created directly by using `RMAN` or `dbcli`).

Restoring a database with Data Guard enabled is not supported. You must first remove the Data Guard association by terminating the standby database before you can restore the database.

RESTORING AN EXISTING DATABASE

To restore a database

1. Open the navigation menu. Under **Database**, click **Bare Metal, VM, and Exadata**.
2. Choose your **Compartment**.
   A list of DB systems is displayed.
3. Find the DB system where the database is located, and click the system name to display details about it.
   A list of databases is displayed.
4. Find the database you want to restore, and click its name to display details about it.
   A list of backups is displayed in the default view of the database details. You can also access the list of backups for a database by clicking on **Backups** under **Resources**.
5. Click **Restore**.
6. Select one of the following options, and then click **Restore Database**:

- **Restore to the latest:** Restores the database to the last known good state with the least possible data loss.
- **Restore to the timestamp:** Restores the database to the timestamp specified.
- **Restore to System Change Number (SCN):** Restores the database using the SCN specified. This SCN must be valid.

Tip

You can determine the SCN number to use either by accessing and querying your database host, or by accessing any online or archived logs.

7. Confirm when prompted.
   If the restore operation fails, the database will be in a "Restore Failed" state. You can try restoring again using a different restore option. However, Oracle recommends that you review the `RMAN` logs on the host and fix any issues before reattempting to restore the database.

To restore a database using a specific backup from Object Storage

1. Open the navigation menu. Under **Database**, click **Bare Metal, VM, and Exadata**.
2. Choose your **Compartment**.
   A list of DB systems is displayed.
3. Find the DB system where the database is located, and click the system name to display details about it.
   A list of databases is displayed.
4. Find the database you want to restore, and click its name to display details about it.
5. Under **Resources**, click **Backups**.

A list of backups is displayed.

6. Click the Actions icon (three dots) for the backup you are interested in, and then click **Restore**.
7. Confirm when prompted.

Creating a New Database from a Backup

You can use a backup to create a database in an existing DB system or to launch a new DB system. See the following procedures for more information:

- To create a database from a backup in an existing DB system
- To launch a new DB system from a backup

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use these API operations to recover a database:

- ListBackups
- GetBackup
- RestoreDatabase
- CreateDbHome - For creating a DB system database from a standalone backup.

For the complete list of APIs for the Database service, see Database Service API.

Using an RMAN Backup

This topic explains how to recover a Recovery Manager (RMAN) backup stored in Object Storage.

Prerequisites

You'll need the following:

- A new DB system to restore the database to (see assumptions below). For more information, see Creating Bare Metal and Virtual Machine DB Systems.
- The Oracle Database Cloud Backup Module must be installed on the DB system. For more information, see Installing the Backup Module on the DB System.

ASSUMPTIONS

The procedures below assume the following:

- A new DB system has been created to host the restored database and no other database exists on the new DB system. It is possible to restore to a DB system that has existing databases, but that is beyond the scope of this topic.
- The original database is lost and all that remains is the latest RMAN backup. For virtual machine DB systems, the procedure assumes the DB system (inclusive of the database) no longer exists.

Warning

Any data not included in the most recent backup will be lost.

- The Oracle Wallet and/or encryption keys used by the original database at the time of the last backup is available.
- The RMAN backup contains a copy of the control file and spfile as of the most recent backup as well as all of the datafile and archivelog backups needed to perform a complete database recovery.
- An RMAN catalog will not be used during the restore.

SETTING UP STORAGE ON THE DB SYSTEM

1. SSH to the DB System.

```
ssh -i <private_key_path> opc@<db_system_ip_address>
```

2. Log in as opc and then sudo to the root user. Use `sudo su -` with a hyphen to invoke the root user's profile, which will set the PATH to the dbcli directory (`/opt/oracle/dcs/bin`).

```
login as: opc

[opc@dbsys ~]$ sudo su -
```

3. You can use an existing empty database home or create a new one for the restore. Use the applicable commands to help you complete this step.

   If you will be using an existing database home:

   - Use the dbcli list-dbhomes command to list the database homes.

```
[root@dbsys ~]# dbcli list-dbhomes
ID                                       Name                 DB Version Home Location
---------------------------------------- -------------------- ---------- -----------------
----------------------------
2e743050-b41d-4283-988f-f33d7b082bda     OraDB12102_home1     12.1.0.2
/u01/app/oracle/product/12.1.0.2/dbhome_1
```

   - Use the dbcli list-databases command to ensure the database home is not associated with any database.

   If necessary, use the dbcli create-dbhome command to create a database home for the restore.

4. Use the dbcli create-dbstorage to set up directories for DATA, RECO, and REDO storage. The following example creates 10GB of ACFS storage for the rectest database.

```
[root@dbsys ~]# dbcli create-dbstorage --dbname rectest --dataSize 10 --dbstorage ACFS
```

Note

When restoring a version 11.2 database, ACFS storage must be specified.

PERFORMING THE DATABASE RESTORE AND RECOVERY

1. SSH to the DB system, log in as opc, and then become the oracle user.

   ```
   sudo su - oracle
   ```

2. Create an entry in `/etc/oratab` for the database. Use the same SID as the original database.

   ```
   db1:/u01/app/oracle/product/12.1.0.2/dbhome_1:N
   ```

3. Set the ORACLE_HOME and ORACLE_SID environment variables using the oraenv utility.

   ```
   . oraenv
   ```

4. Obtain the DBID of the original database. This can be obtained from the file name of the `controlfile` autobackup on the backup media. The file name will include a string that contains the DBID. The typical format of the string is `c-DDDDDDDDDDDD-YYYYMMDD-NN` where `DDDDDDDDDDDD` is the DBID, `YYYYMMDD` is the date the backup was created, and `NN` is a sequence number to make the file name unique. The DBID in the following examples is 1508405000. Your DBID will be different.

   Use the following curl syntax to perform a general query of Object Storage. The parameters in red are the same parameters you specified when installing the backup module as described in Installing the Backup Module on the DB System.

   ```
   curl -u '<user_ID>.com:<auth_token>' -v https://swiftobjectstorage.<region_
   name>.oraclecloud.com/v1/<tenant_name>
   ```

   See Regions and Availability Domains to look up the region name.

   For example:

   ```
   curl -u 'djones@mycompany.com:1cnk!d0++ptETd&C;tHR' -v https://swiftobjectstorage.<region_
   name>.oraclecloud.com/v1/mycompany
   ```

   To get the DBID from the control file name, use the following syntax:

   ```
   curl -u '<user_id>.com:<auth_token>' -v https://swiftobjectstorage.<region_
   name>.oraclecloud.com/v1/<tenant_name>/<bucket_name>?prefix=sbt_catalog/c-
   ```

   For example:

```
curl -u 'djones@mycompany.com:1cnk!d0++ptETd&C;tHR' -v https://swiftobjectstorage.<region_
name>.oraclecloud.com/v1/mycompany/dbbackups/?prefix=sbt_catalog/c-
```

In the sample output below, 1508405000 is the DBID.

```
{
    "bytes": 1732,
    "content_type": "binary/octet-stream",
    "hash": "f1b61f08892734ed7af4f1ddaabae317",
    "last_modified": "2016-08-11T20:28:34.438000",
    "name": "sbt_catalog/c-1508405000-20160811-00/metadata.xml"
}
```

5. Run RMAN and connect to the target database. There is no need to create a `pfile` or `spfile` or use a backup `controlfile`. These will be restored in the following steps. Note that the target database is `(not started)`. This is normal and expected at this point.

```
rman target /

Recovery Manager: Release 12.1.0.2.0 - Production on Wed Jun 22 18:36:40 2016

Copyright (c) 1982, 2014, Oracle and/or its affiliates.  All rights reserved.

connected to target database (not started)
```

6. Set the DBID using the value obtained above.

```
RMAN> set dbid 1508405000;

executing command: SET DBID
```

7. Run the `STARTUP NOMOUNT` command. If the server parameter file is not available, RMAN attempts to start the instance with a dummy server parameter file. The ORA-01078 and LRM-00109 errors are normal and can be ignored.

```
RMAN> STARTUP NOMOUNT

startup failed: ORA-01078: failure in processing system parameters
LRM-00109: could not open parameter file '/u01/app/oracle/product/12.1.0.2/dbhome_
1/dbs/initdb1.ora'
```

```
starting Oracle instance without parameter file for retrieval of spfile
Oracle instance started

Total System Global Area    2147483648 bytes

Fixed Size                     2944952 bytes
Variable Size                847249480 bytes
Database Buffers            1254096896 bytes
Redo Buffers                  43192320 bytes
```

8. Restore the server parameter file from autobackup.
   The SBT_LIBRARY is the same library specified with the `-libDir` parameter when the Backup Module was installed, for example `/home/oracle/lib/`.
   The OPC_PFILE is the same file specified with the `-configfile` parameter when the Backup Module was installed, for example `/home/oracle/config`.

```
set controlfile autobackup format for device type sbt to '%F';
run {
  allocate channel c1 device type sbt PARMS  'SBT_LIBRARY=/home/oracle/lib/libopc.so, SBT_PARMS=
(OPC_PFILE=/home/oracle/config)';
  restore spfile from autobackup;
}
```

9. Create the directory for audit_file_dest. The default is `/u01/app/oracle/admin/$ORACLE_SID/adump`. You can see the setting used by the original database by searching the spfile for the string, `audit_file_dest`.

```
strings ${ORACLE_HOME}/dbs/spfile${ORACLE_SID}.ora | grep audit_file_dest
*.audit_file_dest='/u01/app/oracle/admin/db1/adump'

mkdir -p /u01/app/oracle/admin/db1/adump
```

10. If block change tracking was enabled on the original database, create the directory for the block change tracking file. This will be a directory under `db_create_file_dest`. Search the `spfile` for the name of the directory.

```
strings ${ORACLE_HOME}/dbs/spfile${ORACLE_SID}.ora | grep db_create_file_dest
*.db_create_file_dest='/u02/app/oracle/oradata/db1'

mkdir -p /u02/app/oracle/oradata/db1/<$ORA_UNQNAME if available or database name>/changetracking
```

11. Restart the instance with the restored server parameter file.

```
STARTUP FORCE NOMOUNT;
```

12. Restore the controlfile from the RMAN autobackup and mount the database.

```
set controlfile autobackup format for device type sbt to '%F';
run {
  allocate channel c1 device type sbt PARMS 'SBT_LIBRARY=/home/oracle/lib/libopc.so, SBT_PARMS=
(OPC_PFILE=/home/oracle/config)';
  restore controlfile from autobackup;
  alter database mount;
    }
```

13. Restore and recover the database.

```
RESTORE DATABASE;
RECOVER DATABASE;
```

14. RMAN will recover using archived redo logs until it can't find any more. It is normal for an error similar to the one below to occur when RMAN has applied the last archived redo log in the backup and can't find any more logs.

```
unable to find archived log
archived log thread=1 sequence=29
RMAN-00571: ===========================================================
RMAN-00569: =============== ERROR MESSAGE STACK FOLLOWS ===============
RMAN-00571: ===========================================================
RMAN-03002: failure of recover command at 06/28/2016 00:57:35
RMAN-06054: media recovery requesting unknown archived log for thread 1 with sequence 29 and
starting SCN of 2349563
```

15. Open the database with resetlogs.

```
ALTER DATABASE OPEN RESETLOGS;
```

The recovery is complete. The database will have all of the committed transactions as of the last backed up archived redo log.

Recovering a Database from a CLI Backup

Note

This topic is not applicable to Exadata DB Systems.

This topic explains how to perform a complete or point-in-time recovery of an existing database from a backup created with the dbcli create-backup command. The backup resides in the local Fast Recovery Area on the DB System.

To initiate the recovery, you'll use the Oracle Database CLI Reference command and specify the recovery type parameter (either `--recoverytype` or just `-t`). You can specify the following types of recovery:

- `-t Latest` for a complete recovery
- `-t SCN -s <scn>` for a recovery using a system change number (SCN) as the end point of the recovery
- `-t PITR <mm/dd/yyyy hh:mm:ss>` for a database point-in-time (incomplete) recovery based on a time stamp

The `dbcli create-recovery` attempts to perform a full recovery of the database. For information on performing a partial recovery (datafile, tablespace and PDB), see the *Oracle Database Backup Recovery Guide* for version 18.1, 12.2, 12.1, or 11.2.

PREREQUISITES

- The backup must have been created with the `dbcli create-backup` command.
- If the database is configured with Transparent Data Encryption (TDE), make sure the password-based and autologin TDE wallets are present in the following location:

```
/opt/oracle/dcs/commonstore/wallets/tde/<db_unique_name>
```

RECOVERING THE DATABASE

1. SSH to the DB System.

```
ssh -i <private_key_path> opc@<db_system_ip_address>
```

2. Log in as opc and then sudo to the root user. Use `sudo su -` with a hyphen to invoke the root user's profile, which will set the PATH to the dbcli directory (`/opt/oracle/dcs/bin`).

```
login as: opc

[opc@dbsys ~]$ sudo su -
```

3. Find the ID of database you want to recover by using the dbcli list-databases command. You'll need the ID for the following step.

```
[root@dbsys ~]# dbcli list-databases
ID                                       DB Name     DB Version CDB        Class     Shape
Storage    Status
---------------------------------------- ---------- ---------- ---------- -------- -------- -----
----- ----------
5a3e980b-e0fe-4909-9628-fcefe43b3326     prod       12.1.0.2   true       OLTP     odb1     ACFS
     Configured
```

4. Initiate the recovery by using the Oracle Database CLI Reference command and specifying the database ID, recovery type parameter (`-t`), and any parameter required for the recover type, like the time stamp or system change number.
   The following example initiates a complete recovery.

```
[root@dbsys ~]# dbcli create-recovery --dbid 5a3e980b-e0fe-4909-9628-fcefe43b3326 --recoverytype
Latest
{
  "jobId" : "c9f81228-2ce9-43b4-88f6-b260d398cf06",
  "status" : "Created",
  "message" : null,
  "reports" : [ ],
  "createTimestamp" : "August 08, 2016 18:20:47 PM UTC",
  "description" : "Create recovery for database id :5a3e980b-e0fe-4909-9628-fcefe43b3326",
  "updatedTime" : "August 08, 2016 18:20:47 PM UTC"
}
```

   The following example initiates a point-in-time recovery of the specified database:

```
[root@dbsys ~]# dbcli create-recovery --dbid d4733796-dbea-4155-8606-24a85d64bd74 --recoverytype
PITR --recoveryTimeStamp 08/09/2016 5:12:15
```

Note the job ID in the command output.

5. Check the status of the recovery by using the dbcli describe-job command with the job ID from the previous step.

```
[root@dbsys ~]# dbcli describe-job -i c9f81228-2ce9-43b4-88f6-b260d398cf06

Job details
----------------------------------------------------------------
                     ID:  c9f81228-2ce9-43b4-88f6-b260d398cf06
            Description:  Create recovery for database id :5a3e980b-e0fe-4909-9628-fcefe43b3326
                 Status:  Success
                Created:  August 8, 2016 6:20:47 PM UTC
                Message:

Open database                            August 8, 2016 6:22:35 PM UTC       August 8, 2016
6:22:44 PM UTC       Success
Restart database                         August 8, 2016 6:22:44 PM UTC       August 8, 2016
6:23:41 PM UTC       Success
Persist Recovery Metadata                August 8, 2016 6:23:41 PM UTC       August 8, 2016
6:23:41 PM UTC       Success
```

You can also check the database restore report logs on the DB System at:

`/opt/oracle/dcs/log/<nodename>/rman/bkup/<db_unique_name>`

Recovering a Database from the Oracle Cloud Infrastructure Classic Object Store

Note

This topic is not applicable to Exadata DB systems.

This topic explains how to recover a database using a backup created by the Oracle Database Backup Module and stored in Oracle Cloud Infrastructure Object Storage Classic.

The following terms are used throughout this topic:

- Source database: The database backup in Object Storage Classic.
- Target database: The new database on a DB system in Oracle Cloud Infrastructure.

Prerequisites

You'll need the following:

- The service name, identity name, container, user name, and password for Oracle Cloud Infrastructure Object Storage Classic.
- The backup password if password-based encryption was used when backing up to Object Storage Classic.
- The source database ID, database name, database unique name (required for setting up storage).
- If the source database is configured with Transparent Data Encryption (TDE), you'll need a backup of the wallet and the wallet password.
- Tnsnames to setup for any database links.
- The output of `Opatch lsinventory` for the source database Oracle_home, for reference.
- A copy of the sqlpatch directory from the source database home. This is required for rollback in case the target database does not include these patches.

Setting Up Storage on the DB System

1. SSH to the DB System.

```
ssh -i <private_key_path> opc@<db_system_ip_address>
```

2. Log in as opc and then sudo to the root user. Use `sudo su -` with a hyphen to invoke the root user's profile, which will set the PATH to the dbcli directory (`/opt/oracle/dcs/bin`).

```
login as: opc

[opc@dbsys ~]$ sudo su -
```

3. Use the dbcli create-dbstorage to set up directories for DATA, RECO, and REDO storage. The following example creates 10GB of ACFS storage for the tdetest database.

```
[root@dbsys ~]# dbcli create-dbstorage --dbname tdetest --dataSize 10 --dbstorage ACFS
```

Note

When migrating a version 11.2 database, ACFS storage must be specified.

4. Use the dbcli list-dbstorages command to list the storage ID. You'll need the ID for the next step.

```
[root@dbsys ~]# dbcli list-dbstorages
ID                                       Type   DBUnique Name        Status
---------------------------------------- ------ -------------------- ----------
9dcdfb8e-e589-4d5f-861a-e5ba981616ed     Acfs   tdetest              Configured
```

5. Use the dbcli describe-dbstorage command with the storage ID from the previous step to list the DATA, RECO and REDO locations.

```
[root@dbsys ~]# dbcli describe-dbstorage --id 9dcdfb8e-e589-4d5f-861a-e5ba981616ed
DBStorage details
----------------------------------------------------------------
                     ID: 9dcdfb8e-e589-4d5f-861a-e5ba981616ed
                DB Name: tdetest
```

```
          DBUnique Name: tdetest
         DB Resource ID:
           Storage Type: Acfs
          DATA Location: /u02/app/oracle/oradata/tdetest
          RECO Location: /u03/app/oracle/fast_recovery_area/
          REDO Location: /u03/app/oracle/redo/
                  State: ResourceState(status=Configured)
                Created: August 24, 2016 5:25:38 PM UTC
            UpdatedTime: August 24, 2016 5:25:53 PM UTC
```

6. Note the DATA, RECO and REDO locations. You'll need them later to set the `db_create_file_dest`, `db_create_online_log_dest`, and `db_recovery_file_dest` parameters for the database.

CHOOSING AN ORACLE_HOME

Decide which ORACLE_HOME to use for the database restore and then switch to that home with the correct ORACLE_BASE, ORACLE_HOME, and PATH settings. The ORACLE_HOME must not already be associated with a database.

To get a list of existing ORACLE_HOMEs and to ensure that the ORACLE_HOME is empty, use the dbcli list-dbhomes and the dbcli list-databases commands, respectively. To create a new ORACLE_HOME, use the dbcli create-dbhome command.

COPYING THE SOURCE DATABASE WALLETS

Skip this section if the source database is **not** configured with TDE.

1. On the DB system, become the oracle user:

```
sudo su - oracle
```

2. Create the following directory, if it does not already exist:

```
mkdir /opt/oracle/dcs/commonstore/wallets/tde/<db_unique_name>
```

3. Copy the ewallet.p12 file from the source database to the directory you created in the previous step.
4. On the target host, make sure that `$ORACLE_HOME/network/admin/sqlnet.ora` contains the following line:

```
ENCRYPTION_WALLET_LOCATION=(SOURCE=(METHOD=FILE)(METHOD_DATA=
(DIRECTORY=/opt/oracle/dcs/commonstore/wallets/tde/$ORACLE_UNQNAME)))
```

Add the line if it doesn't exist in the file. (The line might not be there if this is a new home and no database has been created yet on this host.)

5. Create the autologin wallet from the password-based wallet to allow auto-open of the wallet during restore and recovery operations.

   For a version 12.1 or later database, use the `ADMINISTER KEY MANAGEMENT` command:

```
$cat create_autologin_12.sh

#!/bin/sh
if [ $# -lt 2 ]; then
        echo "Usage: $0 <dbuniquename><remotewalletlocation>"
        exit 1;
fi

mkdir /opt/oracle/dcs/commonstore/wallets/tde/$1
cp $2/ewallet.p12* /opt/oracle/dcs/commonstore/wallets/tde/$1
rm -f autokey.ora
echo "db_name=$1"  > autokey.ora
autokeystoreLog="autologinKeystore_`date +%Y%m%d_%H%M%S_%N`.log"
echo "Enter Keystore Password:"
read -s keystorePassword
echo "Creating AutoLoginKeystore -> "
sqlplus "/as sysdba"  <<EOF
spool $autokeystoreLog
set echo on
startup nomount pfile=autokey.ora
ADMINISTER KEY MANAGEMENT CREATE AUTO_LOGIN KEYSTORE
FROM KEYSTORE '/opt/oracle/dcs/commonstore/wallets/tde/$1' -- Keystore location
IDENTIFIED BY "$keystorePassword";
shutdown immediate;
EOF
```

Adjust the `cwallet.sso` permissions from `oracle:asmadmin` to `oracle:oinstall`.

```
$ ls -ltr /opt/oracle/dcs/commonstore/wallets/tde/<db_unique_name>

total 20
```

```
-rw-r--r-- 1 oracle oinstall 5680 Jul  6 11:39 ewallet.p12

-rw-r--r-- 1 oracle asmadmin 5725 Jul  6 11:39 cwallet.sso
```

For a version 11.2 database, use the `orapki` command:

```
orapki wallet create -wallet wallet_location -auto_login [-pwd password]
```

INSTALLING THE ORACLE DATABASE BACKUP MODULE

The backup module JAR file is included on the DB system but you need to install it.

1. SSH to the DB system, log in as opc, and then become the oracle user.

```
ssh -i <path to SSH key used when launching the DB System> opc@<DB System IP address or hostname>

sudo su - oracle
```

2. Change to the directory that contains the backup module `opc_install.jar` file.

```
cd /opt/oracle/oak/pkgrepos/orapkgs/oss/<version>/
```

3. Use the command syntax described in Installing the Oracle Database Cloud Backup Module to install the backup module.

SETTING ENVIRONMENT VARIABLES

Set the following environment variables for the RMAN and SQL*Plus sessions for the database:

```
ORACLE_HOME=<path of Oracle Home where the database is to be restored>
ORACLE_SID=<database instance name>
ORACLE_UNQNAME=<db_unique_name in lower case>
NLS_DATE_FORMAT="mm/dd/yyyy hh24:mi:ss"
```

ALLOCATING AN RMAN SBT CHANNEL

For each restore operation, allocate an SBT channel and set the SBT_LIBRARY parameter to the location of the `libopc.so` file and the OPC_FILE parameter to the location of the `opc_sbt.ora` file, for example:

```
ALLOCATE CHANNEL c1 DEVICE TYPE sbt MAXPIECESIZE 2 G FORMAT '%d_%I_%U' PARMS 'SBT_
LIBRARY=/tmp/oss/libopc.so ENV=(OPC_PFILE=/<ORACLE_HOME>/dbs/opc_sbt.ora)';
```

(For more information about these files, see Files Created When the Backup Module is Installed.)

Ensuring Decryption is Turned On

Make sure that decryption is turned on for all the RMAN restore sessions.

```
set decryption wallet open identified by <keystore password>;
```

For more information, see Providing Password Required to Decrypt Encrypted Backups.

Restoring Spfile

The following sample shell script restores the spfile. Set the `$dbID` variable to the dbid of the database being restored. By default, spfile is restored to `$ORACLE_HOME/dbs/spfile<sid>.ora`.

```
rman target / <<EOF

spool log to "`date +%Y%m%d_%H%M%S_%N`_dbid_${dbID}_restore_spfile.log"
startup nomount
set echo on
run {
ALLOCATE CHANNEL c1 DEVICE TYPE sbt MAXPIECESIZE 2 G FORMAT '%d_%I_%U' PARMS 'SBT_
LIBRARY=/tmp/oss/libopc.so ENV=(OPC_PFILE=/tmp/oss/opc_sbt.ora)';
SET DBID=$dbID;
RESTORE SPFILE FROM AUTOBACKUP;
shutdown immediate;
EOF
```

Setting the Database Parameters

1. Start the database in nomount mode.

   ```
   startup nomount
   ```

2. Update spfile and modify the following parameters.

   - If the database storage type is ACFS, use the DATA, RECO, and REDO locations obtained from the `dbcli describe-dbstorage` command output, as described in Setting Up Storage on the DB System:

```
alter system set db_create_file_dest='/u02/app/oracle/oradata/' scope = spfile;
alter system set db_create_online_log_dest_1='/u03/app/oracle/redo' scope = spfile;
alter system set db_recovery_file_dest='/u03/app/oracle/fast_recovery_area' scope =
spfile;
```

- If the database storage type is ASM:

```
alter system set db_create_file_dest='+DATA' scope = spfile;
alter system set db_create_online_log_dest_1='+RECO' scope = spfile;
alter system set db_recovery_file_dest='+RECO' scope = spfile;
```

- Set `db_recovery_file_dest_size` is not set or is set incorrectly:

```
alter system set db_recovery_file_dest_size=<sizeG> scope=spfile;
```

- Set `audit_file_dest` to the correct value:

```
alter system set audit_file_dest=/u01/app/oracle/admin/<db_unique_name in lower
case>/adump
```

3. Remove the `control_files` parameter. The Oracle Managed Files (OMF) parameters will be used to create the control file.

```
alter system reset control_files scope=spfile;
```

4. Restart the database in nomount mode using the newly added parameters.

```
shutdown immediate
startup nomount
```

RESTORING THE CONTROL FILE

Modify the following sample shell script for your environment to restore the control file. Set the `$dbID` variable to the dbid of the database being restored. Set SBT_LIBRARY to the location specified in the `-libDir` parameter when you installed the Backup Module. Set OPC-PFILE to the location specified in the `-configFile` parameter, which defaults to *ORACLE_HOME*/dbs/opc*SID*.ora.

```
rman target / <<EOF

spool log to "`date +%Y%m%d_%H%M%S_%N`_dbid_${dbID}_restore_controlfile.log"
set echo on
run {
ALLOCATE CHANNEL c1 DEVICE TYPE sbt MAXPIECESIZE 2 G FORMAT '%d_%I_%U' PARMS 'SBT_LIBRARY=/<Backup
Module libDir>/libopc.so ENV=(OPC_PFILE=/<Backup Module configFile>/opcSID.ora)';
```

```
SET DBID=$dbID;
RESTORE CONTROLFILE FROM AUTOBACKUP;
alter database mount;
}

exit;
EOF
```

RESTORING THE DATABASE

1. Preview and validate the backup. The database is now mounted and RMAN should be able to locate the backup from the restored controlfile. This step helps ensure that the list of archivelogs is present and that the backup components can be restored .
   In the following examples, modify SBT_LIBRARY and OPC_PFILE as needed for your environment.

   ```
   rman target / <<EOF

   spool log to "`date +%Y%m%d_%H%M%S_%N`_restore_database_preview.log"
   set echo on
   run {
   ALLOCATE CHANNEL c1 DEVICE TYPE sbt MAXPIECESIZE 2 G FORMAT '%d_%I_%U' PARMS 'SBT_
   LIBRARY=/tmp/oss/libopc.so ENV=(OPC_PFILE=/tmp/oss/opc_sbt.ora)';
   ALLOCATE CHANNEL c2 DEVICE TYPE sbt MAXPIECESIZE 2 G FORMAT '%d_%I_%U' PARMS 'SBT_
   LIBRARY=/tmp/oss/libopc.so ENV=(OPC_PFILE=/tmp/oss/opc_sbt.ora)';
   ALLOCATE CHANNEL c3 DEVICE TYPE sbt MAXPIECESIZE 2 G FORMAT '%d_%I_%U' PARMS 'SBT_
   LIBRARY=/tmp/oss/libopc.so ENV=(OPC_PFILE=/tmp/oss/opc_sbt.ora)';
   restore database validate header preview;
   }
   ```

   Review the output and if there are error messages, investigate the cause of the problem.
2. Redirect the restore using `set newname` to restore the data files in OMF format and use `switch datafile all` to allow the control file to update with the new data file copies.

   ```
   rman target / <<EOF

   spool log to "`date +%Y%m%d_%H%M%S_%N`_restore_database_preview.log"
   set echo on
   run {
   ```

```
ALLOCATE CHANNEL c1 DEVICE TYPE sbt MAXPIECESIZE 2 G FORMAT '%d_%I_%U' PARMS 'SBT_
LIBRARY=/tmp/oss/libopc.so ENV=(OPC_PFILE=/tmp/oss/opc_sbt.ora)';
ALLOCATE CHANNEL c2 DEVICE TYPE sbt MAXPIECESIZE 2 G FORMAT '%d_%I_%U' PARMS 'SBT_
LIBRARY=/tmp/oss/libopc.so ENV=(OPC_PFILE=/tmp/oss/opc_sbt.ora)';
ALLOCATE CHANNEL c3 DEVICE TYPE sbt MAXPIECESIZE 2 G FORMAT '%d_%I_%U' PARMS 'SBT_
LIBRARY=/tmp/oss/libopc.so ENV=(OPC_PFILE=/tmp/oss/opc_sbt.ora)';
set newname for database to new;
restore database;
switch datafile all;
switch tempfile all;
recover database;
}
```

This recovery will attempt to use the last available archive log backup and then fail with an error, for example:

```
RMAN-00571: ===========================================================
RMAN-00569: =============== ERROR MESSAGE STACK FOLLOWS ===============
RMAN-00571: ===========================================================
RMAN-03002: failure of recover command at 07/20/2016 12:09:02
RMAN-06054: media recovery requesting unknown archived log for thread 1 with sequence 22 and
starting SCN of 878327
```

3. To complete the incomplete recovery, run a recovery using the sequence number and thread number shown in the RMAN-06054 message, for example:

```
Recover database until sequence 22 thread 1;
```

RESETTING THE LOGS

Reset the logs.

```
alter database open resetlogs;
```

PREPARING TO REGISTER THE DATABASE

Before you register the database:

1. Make sure the database COMPATIBLE parameter value is acceptable. If the value is less than the minimum, the database cannot be registered until you upgrade the database compatibility.

   The minimum compatibility values are as follows:

- For a version 18.1 database - 18.0.0.0
- For a version 12.2 or 12.1 database - 12.1.0.2
- For a version 11.2 database - 11.2.0.4

2. Verify that the database has registered with the listener and the service name.

```
lsnrctl services
```

3. Make sure the password file was restored or created for the new database.

```
ls -ltr $ORACLE_HOME/dbs/orapw<oracle sid>
```

If the file does not exist, create it using the orapwd utility.

```
orapwd file=<$ORACLE_HOME/dbs/orapw<$ORACLE_SID>> password=<sys password>
```

4. Make sure the restored database if open in read write mode.

```
select open_mode from v$database;
```

The command output should indicate read write mode. The `dbcli register-database` command will attempt to run datapatch, which requires read write mode. If there are PDBs, they should also be in read write mode to ensure that datapatch runs on them.

5. From oracle home on the restored database, use the following command verify the connection to SYS:

```
conn sys/<password>@//<hostname>:1521/<database service name>
```

This connection is required to register the database later. Fix any connection issues before continuing.

6. Make sure the database is running on spfile by using the SQL*Plus command.

```
SHOW PARAMETERS SPFILE
```

7. (Optional) If you would like to manage the database backup with the dbcli command line interface, you can associate a new or existing backup configuration with the migrated database when you register it or after you register it. A backup configuration defines the backup destination and recovery window for the database. Use the following commands to create, list, and display backup configurations:

- dbcli update-backupconfig
- dbcli list-backupconfigs
- dbcli describe-backupconfig

8. Copy the folder `$ORACLE_HOME/sqlpatch` from source database to the target database. This will enable the `dbcli register-database` command to roll back any conflicting patches.

Note

If you are migrating a version 11.2 database, additional steps are required after you register the database. For more information, see Rolling Back Patches on a Version 11.2 Database.

Registering the Database on the DB System

The dbcli register-database command registers the restored database to the dcs-agent so it can be managed by the dcs-agent stack.

Note

The `dbcli register-database` command is not available on 2-node RAC DB systems.

As the root user, use the `dbcli register-database` command to register the database on the DB system, for example:

```
[root@dbsys ~]# dbcli register-database --dbclass OLTP --dbshape odb1 --servicename tdetest --
syspassword
Password for SYS:
{
  "jobId" : "317b430f-ad5f-42ae-bb07-13f053d266e2",
  "status" : "Created",
  "message" : null,
```

```
  "reports" : [ ],
  "createTimestamp" : "August 08, 2016 05:55:49 AM EDT",
  "description" : "Database service registration with db service name: tdetest",
  "updatedTime" : "August 08, 2016 05:55:49 AM EDT"
}
```

UPDATING TNSNAMES.ORA

Check the `tnsnames.ora` in the backup location, check the database links used in the cloned database, and then add any relevant connection strings to the cloned database file at `$ORACLE_HOME/network/admin/tnsnames.ora`.

ROLLING BACK PATCHES ON A VERSION 11.2 DATABASE

For version 11.2 databases, the sqlpatch application is not automated, so any interim patches (previously known as a "one-off" patches) applied to the source database that are not part of the installed PSU must be rolled back manually in the target database. After registering the database, execute the `catbundle.sql` script and then the `postinstall.sql` script with the corresponding PSU patch (or the overlay patch on top of the PSU patch), as described below.

Tip

Some interim patches may include files written to the $ORACLE_HOME/rdbms/admin directory as well as the $ORACLE_HOME/sqlpatch directory. Oracle recommends that you roll back these patches in the source database using the instructions in the patch read-me prior to migrating the database to OCI environment. Contact Oracle Support if you need assistance with rolling back these patches.

1. On the DB System, use the `dbcli list-dbhomes` command to find the PSU patch number for the version 11.2 database home. In the following sample command output, the PSU patch number is the second number in the DB Version column:

```
[root@dbsys ~]# dbcli  list-dbhomes
ID                                   Name                DB Version
Home Location                                Status
------------------------------------ ------------------  ----------------------------------  --
---------------------------------------- ----------
59d9bc6f-3880-4d4f-b5a6-c140f16f8c64 OraDB11204_home1  11.2.0.4.160719 (23054319, 23054359)
/u01/app/oracle/product/11.2.0.4/dbhome_1 Configured
```

(The first patch number, 23054319 in the example above, is for the OCW component in the database home.)

2. Find the overlay patch, if any, by using the `lsinventory` command. In the following example, patch number *24460960* is the overlay patch on top of the 23054359 PSU patch.

```
$ $ORACLE_HOME/OPatch/opatch lsinventory
...
Installed Top-level Products (1):

Oracle Database 11g                                                  11.2.0.4.0
There are 1 products installed in this Oracle Home.

Interim patches (5) :

Patch  24460960     : applied on Fri Sep 02 15:28:17 UTC 2016
Unique Patch ID:  20539912
   Created on 31 Aug 2016, 02:46:31 hrs PST8PDT
   Bugs fixed:
     23513711, 23065323, 21281607, 24006821, 23315889, 22551446, 21174504
   This patch overlays patches:
     23054359
   This patch needs patches:
     23054359
   as prerequisites
```

3. Start SQL*Plus and execute the `catbundle.sql` script, for example:

```
SQL> startup
SQL> connect / as sysdba
```

```
SQL> @$ORACLE_HOME/rdbms/admin/catbundle.sql psu apply
exit
```

4. Apply the sqlpatch, using the overlay patch number from the previous step, for example:

```
SQL> connect / as sysdba
SQL> @$ORACLE_HOME/sqlpatch/24460960/postinstall.sql
exit
```

Note

If the source database has one-off patches installed and those patches are **not** part of the installed PSU in the cloud environment, then the SQL changes that correspond to those one-off patches need to be rolled back. To rollback the SQL changes, copy the `$ORACLE_HOME/sqlpatch/<patch#>/postdeinstall.sql` script from the source environment to the cloud environment and execute the `postdeinstall.sql` script.

POST RESTORE CHECKLIST

After the database is restored and registered on the DB system, use the following checklist to verify the results and perform any post-restore customizations.

1. Make sure the database files were restored in OMF format.
2. Make sure the database is listed in the dbcli list-databases command output.
3. Check for the following external references in the database and update them if necessary:
    - External tables: If the source database uses external tables, back up that data and migrate it to the target host.

- Directories: Customize the default directories as needed for the restored database.
- Database links: Make sure all the required TNS entries are updated in the `tnsnames.ora` file in ORACLE_HOME.
- Email and URLs: Make sure any email addresses and URLs used in the database are still accessible from the DB system.
- Scheduled jobs: Review the jobs scheduled in source database and schedule similar jobs as needed in the restored database.

4. If you associated a backup configuration when you registered the database, run a test back up using the dbcli create-backup command.
5. If the restored database contains a CDB and PDBs, verify that patches have been applied to all PDBs.

Using Oracle Data Guard

Note

This topic is not applicable to Exadata DB systems.

This topic explains how to use the Console to manage Data Guard associations in your DB system. To configure a Data Guard system across regions or between on-premises and Oracle Cloud Infrastructure DB systems, you must access the database host directly and use the DGMGRL utility.

For complete information on Oracle Data Guard, see the Data Guard Concepts and Administration documentation on the Oracle Document Portal.

Required IAM Service Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK,

CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

If you're new to policies, see Getting Started with Policies and Common Policies.

Prerequisites

A Data Guard implementation requires two DB systems, one containing the primary database and one containing the standby database. When you enable Data Guard for a virtual machine DB system database, a new DB system with the standby database is created and associated with the primary database. For a bare metal DB system, the DB system with the database to be used as the standby must already exist before you enable Data Guard.

Tip

A Data Guard configuration on the Oracle Cloud Infrastructure is limited to one standby database per primary database.

Requirement details are as follows:

- Both DB systems must be in the same compartment, and they must be the same shape.
- The database versions and editions must be identical. Data Guard does not support Standard Edition. (Active Data Guard requires Enterprise Edition - Extreme Performance.)
- The database version determines whether Active Data Guard is enabled. If you are using the BYOL licensing model and if your license does not include Active Data Guard, you must either use Enterprise Edition - High Performance or set up Data Guard manually. See Using Oracle Data Guard with the Database CLI.
- Both DB systems must use the same VCN, and port 1521 must be open.
- **Important!** Properly configure the security list ingress and egress rules for the subnets of both DB systems in the Data Guard association to allow TCP traffic to flow between

the applicable ports. Ensure that the rules you create are stateful (the default).
For example, if the subnet of the primary DB System uses the source CIDR 10.0.0.0/24 and the subnet of the standby DB system uses the source CIDR 10.0.1.0/24, create rules as shown in the following example.

Note

The egress rules in the example show how to enable TCP traffic only for port 1521, which is a minimum requirement for Data Guard to work. If TCP traffic is already enabled on all of your outgoing ports (0.0.0.0/0), then you need not explicitly add these specific egress rules.

Security List for Primary DB System's Subnet

```
Ingress Rules:

Stateless: No
Source: 10.0.1.0/24
IP Protocol: TCP
Source Port Range: All
Destination Port Range: 1521
Allows: TCP traffic for ports: 1521

Egress Rules:

Stateless: No
Destination: 10.0.1.0/24
IP Protocol: TCP
Source Port Range: All
Destination Port Range: 1521
Allows: TCP traffic for ports: 1521
```

Security List for Standby DB System's Subnet

```
Ingress Rules:
```

```
Stateless: No
Source: 10.0.0.0/24
IP Protocol: TCP
Source Port Range: All
Destination Port Range: 1521
Allows: TCP traffic for ports: 1521

Egress Rules:

Stateless: No
Destination: 10.0.0.0/24
IP Protocol: TCP
Source Port Range: All
Destination Port Range: 1521
Allows: TCP traffic for ports: 1521
```

For information about creating and editing rules, see Security Lists.

Availability Domain and Fault Domain Considerations for Data Guard

Oracle recommends that the DB system of the standby database be in a different availability domain from the DB system of the primary database to improve availability and disaster recovery. If you enable Data Guard for a database and your standby database is in the same availability domain as the primary (either by choice, or because you are working in a single availability domain region), Oracle recommends that you place the standby database in a different fault domain from that of the primary database. Note that if your primary and standby databases are 2-node RAC databases and both are in the same availability domain, only one of the two nodes of the standby database can be in a fault domain that does not include any other nodes from either the primary or standby database. This is because each availability domain has only three fault domains, and the primary and standby databases have a combined total of 4 nodes. For more information on availability domains and fault domains, see Regions and Availability Domains.

Working with Data Guard

Oracle Data Guard ensures high availability, data protection, and disaster recovery for enterprise data. The Oracle Cloud Infrastructure Database Data Guard implementation requires two databases, one in a primary role and one in a standby role. The two databases

compose a Data Guard association. Most of your applications access the primary database. The standby database is a transactionally consistent copy of the primary database.

Data Guard maintains the standby database by transmitting and applying redo data from the primary database. If the primary database becomes unavailable, you can use Data Guard to switch or fail over the standby database to the primary role.

Tip

The standby databases in Oracle Cloud Infrastructure Database are physical standbys.

SWITCHOVER

A switchover reverses the primary and standby database roles. Each database continues to participate in the Data Guard association in its new role. A switchover ensures no data loss. Performing planned maintenance on a DB system with a Data Guard association is typically done by switching the primary to the standby role, performing maintenance on the standby, and then switching it back to the primary role.

FAILOVER

A failover transitions the standby database into the primary role after the existing primary database fails or becomes unreachable. A failover might result in some data loss when you use **Maximum Performance** protection mode.

REINSTATE

Reinstates a database into the standby role in a Data Guard association. You can use the reinstate command to return a failed database into service after correcting the cause of failure.

Note

You can't terminate a primary database that has a Data Guard association with a peer (standby) database. Delete the standby database first. Alternatively, you can switch over the primary database to the standby role, and then terminate it.

You can't terminate a DB system that includes Data Guard enabled databases. To remove the Data Guard association:

- For a bare metal DB system database - terminate the standby database.
- For a virtual machine DB system database - terminate the standby DB system.

Using the Console

The Console allows you to enable a Data Guard association between databases, change the role of a database in a Data Guard association using either a *switchover* or a *failover* operation, and *reinstate* a failed database.

When you enable Data Guard, a separate Data Guard association is created for the primary and the standby database.

To enable Data Guard on a bare metal DB system

If you don't already have bare metal DB systems with the databases that will assume the primary and standby roles, create them as described in Creating Bare Metal and Virtual Machine DB Systems. A new DB system includes an initial database.

1. Open the navigation menu. Under **Database**, click **Bare Metal, VM, and Exadata**.
2. Choose the **Compartment** that contains the DB system with the database for which you want to enable Data Guard.
3. Click the name of the DB system that contains the database you want to assume the primary role, and then click the name of that database.

Tip

If Data Guard is already enabled, a shield icon appears next to the database name.

4. Under **Resources**, click **Data Guard Associations**.
5. Click **Enable Data Guard**.
6. In the **Enable Data Guard** dialog box, configure your Data Guard association.
   - **Protection Mode:** (Informational) The protection mode used for this Data Guard association. The Console supports only **Maximum Performance**.
   - **Availability Domain:** The availability domain of the peer DB system. If your database is in a single availability domain region, or if you choose to provision your peer (standby) database in the same availability domain as your primary database, the system provides a fault domain selector for your peer database. Oracle recommends that your peer DB system be in a different fault domain from your primary DB system in such cases. For more information on fault domains, see Regions and Availability Domains.
   - **Peer DB System:** Select the DB system that contains the peer (standby) database.
   - **Transport Type:** (Informational) The redo transport type used for this Data Guard association. The Console supports only **Async**.
   - **Database Admin Password:** Enter the primary database admin password. The same password is used for the standby database.

7. Click **Enable**.
   When the association is created, a shield icon appears next to the name of this database and its peer, and their respective roles (primary or standby) are displayed.

To enable Data Guard on a virtual machine DB system

If you don't already have a virtual machine DB system with the database that will assume the primary role, create it as described in Creating Bare Metal and Virtual Machine DB Systems. The new DB system will include the initial database. When you enable Data Guard on the primary database, a new virtual machine DB system will be launched for the standby database.

1. Open the navigation menu. Under **Database**, click **Bare Metal, VM, and Exadata**.
2. Choose the **Compartment** that contains the DB system with the database for which you want to enable Data Guard.
3. Click the name of the DB system that contains the database you want to assume the primary role, and then click the name of that database.

Tip

If Data Guard is already enabled, a shield icon appears next to the database name.

4. Under **Resources**, click **Data Guard Associations**.
5. Click **Enable Data Guard**.
6. In the **Enable Data Guard** dialog box, configure your Data Guard association.
   Display Name: A friendly, display name for the DB system. The name doesn't need to be unique. An Oracle Cloud Identifier (OCID) will uniquely identify the DB system.
   Availability Domain: The availability domain in which the DB system resides.

- **Virtual Cloud Network:** (Informational) Shows the VCN in which the DB system will be launched. The VCN of the primary database and the standby database must be the same.
- **Client Subnet:** The subnet to which the DB system should attach.
  Do not use a subnet that overlaps with 192.168.16.16/28, which is used by the Oracle Clusterware private interconnect on the database instance. Specifying an overlapping subnet will cause the private interconnect to malfunction.
- **Network Security Groups:** Optionally, you can specify one or more network security groups (NSGs) for your standby database's DB system. NSGs function as virtual firewalls, allowing you to apply a set of ingress and egress security rules to your DB system. A maximum of five NSGs can be specified. For more information, see Network Security Groups and Network Setup for DB Systems.
  Note that if you choose a subnet with a security list, the security rules for the DB system will be a union of the rules in the security list and the NSG.

  To use network security groups

  a. Check the **Use Network Security Groups to Control Traffic** check box. Note that you must have a virtual cloud network selected to be able to assign NSGs to your DB system.
  b. Specify the NSG to use with the DB system. You might need to specify more than one NSG. If you're not sure, contact your network administrator.
  c. To use additional NSGs, click **+ Another Network Security Group**.

- **Hostname Prefix:** Your choice of host name for the DB system. The host name must begin with an alphabetic character, and can contain only alphanumeric characters and hyphens (-). The maximum number of characters allowed for a virtual machine DB system is 16.

Important

The host name must be unique within the subnet. If it is not unique, the DB system will fail to provision.

- **Host Domain Name:** The domain name for the DB system. If the selected subnet uses the Oracle-provided Internet and VCN Resolver for DNS name resolution, this field displays the domain name for the subnet and it can't be changed. Otherwise, you can provide your choice of a domain name. Hyphens (-) are not permitted.

  Host and Domain URL: Combines the host and domain names to display the fully qualified domain name (FQDN) for the database. The maximum length is 64 characters.
- **Protection Mode:** (Informational) The protection mode used for this Data Guard association. The Console supports only **Maximum Performance**.
- **Transport Type:** (Informational) The redo transport type used for this Data Guard association. The Console supports only **Async**.
- **Database Admin Password:** Enter the primary database admin password. The same password is used for the standby database.

  Confirm Database Admin Password: Re-enter the Database Admin Password you specified.

7. Click **Enable**.
   When the association is created, a shield icon appears next to the name of this database and its peer, and their respective roles (primary or standby) are displayed.

To perform a database switchover

You initiate a switchover operation by using the Data Guard association of the primary

database.

1. Open the navigation menu. Under **Database**, click **Bare Metal, VM, and Exadata**.
2. Choose the **Compartment** that contains the DB system with the primary database you want to switch over.
3. Click the DB system name, and then click the name of the primary database.
4. Under **Resources**, click **Data Guard Associations**.
5. For the Data Guard association on which you want to perform a switchover, click the Actions icon (three dots), and then click **Switchover**.
6. In the **Switchover Database** dialog box, enter the database admin password, and then click **OK**.
   This database should now assume the role of the standby, and the standby should assume the role of the primary in the Data Guard association.

To perform a database failover

You initiate a failover operation by using the Data Guard association of the standby database.

1. Open the navigation menu. Under **Database**, click **Bare Metal, VM, and Exadata**.
2. Choose the **Compartment** that contains the DB system with the primary database's peer standby you want to fail over to.
3. Click the DB system name, and then click the name of the standby database.
4. Under **Resources**, click **Data Guard Associations**.
5. For the Data Guard association on which you want to perform a failover, click **Failover**.
6. In the **Failover Database** dialog box, enter the database admin password, and then click **OK**.
   This database should now assume the role of the primary, and the old primary's role should display as **Disabled Standby**.

To reinstate a database

After you fail over a primary database to its standby, the standby assumes the primary role and the old primary is identified as a disabled standby. After you correct the cause of failure, you can reinstate the failed database as a functioning standby for the current primary by using its Data Guard association.

Note

Before you can reinstate a version 12.2 database, you must perform some steps on the database host to stop the database or start it in `MOUNT` mode.

Set your ORACLE_UNQNAME environment variable to the value of the Database Unique Name (as seen in the Console), and then run these commands:

```
srvctl stop database -d db-unique-name -o abort
srvctl start database -d db-unique-name -o mount
```

1. Open the navigation menu. Under **Database**, click **Bare Metal, VM, and Exadata**.
2. Choose the **Compartment** that contains the DB system with the failed database you want to reinstate.
3. Click the DB system name, and then click the database name.
4. Under **Resources**, click **Data Guard Associations**.
5. For the Data Guard association on which you want to reinstate this database, click the Actions icon (three dots), and then click **Reinstate**.
6. In the **Reinstate Database** dialog box, enter the database admin password, and then click **OK**.
   This database should now be reinstated as the standby in the Data Guard association.

To terminate a Data Guard association on a bare metal DB system

On a bare metal DB system, you remove a Data Guard association by terminating the standby database.

1. Open the navigation menu. Under **Database**, click **Bare Metal, VM, and Exadata**.
2. Choose the **Compartment** that contains the DB system that includes the standby database you want to terminate.
3. Click the DB system name.
4. For the standby database you want to terminate, click the Actions icon (three dots), and then click **Terminate**.
5. In the **Terminate Database** dialog box, enter the name of the database, and then click **OK**.

To terminate a Data Guard association on a virtual machine DB system

On a virtual machine DB system, you remove a Data Guard association by terminating the standby DB system.

1. Open the navigation menu. Under **Database**, click **Bare Metal, VM, and Exadata**.
2. Choose the **Compartment** that contains the standby DB system that you want to terminate.
3. Click the DB system name, click the Actions icon (three dots), and then click **Terminate**.
4. Confirm when prompted.
   The DB system's icon indicates Terminating.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use these API operations to manage Data Guard associations:

- CreateDataGuardAssociation
- GetDataGuardAssociation
- ListDataGuardAssociations
- SwitchoverDataGuardAssociation
- FailoverDataGuardAssociation
- ReinstateDataGuardAssociation
- DeleteDbHome - To terminate a bare metal DB system Data Guard association, delete the standby database.
- TerminateDbSystem - To terminate a virtual machine DB system Data Guard association, terminate the standby DB system.

For the complete list of APIs for the Database service, see Database Service API.

Using Oracle Data Guard with the Database CLI

Oracle recommends that you use the Console instead of the database CLI to set up and work with Data Guard in Oracle Cloud Infrastructure. See Using Oracle Data Guard for information and instructions.

Note

This topic is not applicable to Exadata DB systems. You can manually configure Data Guard on Exadata DB systems using native Oracle Database utilities and commands, however this topic explains how set up primary and standby databases using `dbcli`, which is not available on Exadata DB systems. For more information, see *Data Guard Concepts and Administration* for version 18.1, 12.2, 12.1, or 11.2.

This topic explains how to use the database CLI to set up Data Guard with Fast-Start Failover (FSFO) in Oracle Cloud Infrastructure. The following sections explain how to prepare the primary and standby databases, and then configure Data Guard to transmit redo data from the primary database and apply it to the standby database.

Note

This topic assumes that you are familiar with Data Guard and FSFO. To learn more about them, see documentation at the Oracle Document Portal.

Prerequisites

To perform the procedures in this topic, you'll need the following information for the primary and standby databases.

- db_name (or oracle_sid)
- db_unique_name
- oracle home directory (or database home)

To find the database information

After you've launched the primary and standby DB systems and created databases as described later in this topic, you can use the CLI on those systems to find the needed database information.

1. SSH to the DB System.

   ```
   ssh -i <private_key_path> opc@<db_system_ip_address>
   ```

2. Log in as opc and then sudo to the root user. Use `sudo su -` with a hyphen to invoke the root user's profile, which will set the PATH to the dbcli directory (`/opt/oracle/dcs/bin`).

```
login as: opc

[opc@dbsys ~]$ sudo su -
```

3. To find the db_name (or oracle_sid) and db_uniqueName, run the `dbcli list-databases -j` command.

```
[root@dbsys ~]# dbcli list-databases -j
[ {
  "id" : "80ad855a-5145-4f8f-a08f-406c5e4684ff",
  "name" : "dbtst",
  "dbName" : "dbtst",
  "databaseUniqueName" : "dbtst_phx1cs",
  "dbVersion" : "12.1.0.2",
  "dbHomeId" : "2efe7af7-0b70-4e9b-ba8b-71f11c6fe287",
  "instanceOnly" : false,
   .
   .
   .
```

4. To find the oracle home directory (or database home), run the `dbcli list-dbhomes` command. If there are multiple database homes on the DB system, use the one that matches the "dbHomeId" in the `dbcli list-databases -j` command output shown above.

```
[root@dbtst ~]# dbcli list-dbhomes

ID                                       Name                 DB Version
     Home Location                                Status
---------------------------------------- -------------------- ----------------------------------
----- ---------------------------------------------- ----------
2efe7af7-0b70-4e9b-ba8b-71f11c6fe287     OraDB12102_home1     12.1.0.2.160719 (23739960,
23144544)     /u01/app/oracle/product/12.1.0.2/dbhome_1     Configured
33ae99fe-5413-4392-88da-997f3cd24c0f     OraDB11204_home1     11.2.0.4.160719 (23054319,
23054359)     /u01/app/oracle/product/11.2.0.4/dbhome_1     Configured
```

Creating a Primary DB System

If you don't already have a primary DB system, create one as described in Creating Bare Metal and Virtual Machine DB Systems. The DB system will include an initial database. You

can create additional databases by using the dbcli create-database command available on the DB system.

Creating a Standby DB System

Note

The standby database must have the same db_name as the primary database, but it must have a different db_unique_name. If you use the same database name for the standby and primary, you will have to delete the database from the standby DB system by using the `dbcli delete-database` command before you can run the `dbcli create-database` command described below. Deleting and creating the database will take several minutes to complete. The `dbcli` commands must be run as the root user.

1. Create a standby DB system as described in Creating Bare Metal and Virtual Machine DB Systems and wait for the DB system to finish provisioning and become available.
   You can create the standby DB system in a different availability domain from the primary DB system for availability and disaster recovery purposes (this is strongly recommended). You can create the standby DB system in the primary DB system's cloud network so that both systems are in a single, routable network.
2. SSH to the DB System.

   ```
   ssh -i <private_key_path> opc@<db_system_ip_address>
   ```

3. Log in as opc and then sudo to the root user. Use `sudo su -` with a hyphen to invoke the root user's profile, which will set the PATH to the dbcli directory (`/opt/oracle/dcs/bin`).

```
login as: opc

[opc@dbsys ~]$ sudo su -
```

4. The DB system will include an initial database, but you'll need to create a standby database by using the `dbcli create-database` command with the `--instanceonly` parameter. This parameter creates only the database storage structure and starts the database in nomount mode (no other database files are created).

   When using `--instanceonly`, both the `--dbname` and `--adminpassword` parameters are required and they should match the dbname and admin password of the primary database to avoid confusion.

   The following sample command prompts for the admin password and then creates a storage structure for a database named dbname.

   ```
   [root@dbsys ~]# dbcli create-database --dbname <same as primary dbname> --databaseUniqueName
   <different from primary uniquename> --instanceonly --adminpassword
   ```

   If you are using pluggable databases, also specify the `--cdb` parameter.

   For complete command syntax, see dbcli create-database.

5. Wait a few minutes for the `dbcli create-database` command to create the standby database.

   You can use the `dbcli list-jobs` command to verify that the creation job ran successfully, and then the `dbcli list-databases` command verify that the database is configured.

Preparing the Primary DB System

To prepare the primary DB system, you'll need to configure static listeners, update tnsnames.ora, and configure some database settings and parameters.

Configuring the Static Listeners

Create static listeners to be used by RMAN and Data Guard Broker.

1. SSH to the primary DB system, log in as the opc or root user, and sudo to the grid OS user.

```
sudo su - grid
```

2. Edit `/u01/app/<version>/grid/network/admin/listener.ora` and add the following content to it. The first static listener shown here is optional. The second `DGMGRL` static listener is optional for version 12.1 or later databases, but required for version 11.2 databases.

```
SID_LIST_LISTENER=
  (SID_LIST=
    (SID_DESC=
    (SDU=65535)
    (GLOBAL_DBNAME = <primary_db_unique_name>.<primary_db_domain>)
    (SID_NAME = <primary_oracle_sid>)
    (ORACLE_HOME=<oracle_home_directory>)
    (ENVS="TNS_ADMIN=<oracle_home_directory>/network/admin")
    )
    (SID_DESC=
    (SDU=65535)
       (GLOBAL_DBNAME = <primary_db_unique_name>_DGMGRL.<primary_db_domain>)
    (SID_NAME = <primary_oracle_sid>)
    (ORACLE_HOME=<oracle_home_directory>)
    (ENVS="TNS_ADMIN=<oracle_home_directory>/network/admin")
    )
  )
```

3. Save your changes and then restart the listener.

```
$ srvctl stop listener
$ srvctl start listener
```

Adding Net Service Names to tnsnames.ora

As the oracle user, edit `$ORACLE_HOME/network/admin/tnsnames.ora` and add the standby database net service name to it.

```
<standby db_unique_name> =
  (DESCRIPTION =
    (SDU=65535)
    (ADDRESS = (PROTOCOL = TCP)(HOST = <standby_server>.<domain>) (PORT = 1521))
    (CONNECT_DATA =
      (SERVER = DEDICATED)
      (SERVICE_NAME = <standby db_unique_name>.<standby db_domain>)
```

```
    )
  )
```

The sample above assumes that name resolution is working and that the *<standby_server>*.*<domain>* is resolvable at the primary database. You can also use the private IP address of the standby server if the IP addresses are routable within a single cloud network (VCN).

Configuring Primary Database Parameters

Tip

If the primary and standby hosts have different directory structures, you might need to set additional parameters that are not discussed here, such as the `log_file_name_convert` parameter. See the RMAN documentation for more information about how to create standbys for hosts with different directory structures.

1. As the oracle user, enable automatic standby file management.

   ```
   SQL> alter system set standby_file_management=AUTO;
   ```

2. Identify the Broker configuration file names and locations. The commands used for this depend on the type of database storage. If you're not sure of the database storage type, use the dbcli list-databases command on the DB system.

   For ACFS database storage, use the following commands to set the Broker configuration files.

   ```
   SQL> alter system set dg_broker_config_file1='/u02/app/oracle/oradata/<Primary db_unique_
   name>/dbs/dr1<Primary db_unique_name>.dat';
   SQL> alter system set dg_broker_config_file2='/u02/app/oracle/oradata/<Primary db_unique_
   name>/dbs/dr2<Primary db_unique_name>.dat';
   ```

   For ASM database storage, use the following commands to set the Broker configuration files.

```
SQL> alter system set dg_broker_config_file1='+DATA/<Primary db_unique_name>/dr1<db_unique_
name>.dat';
SQL> alter system set dg_broker_config_file2='+DATA/<Primary db_unique_name>/dr2<db_unique_
name>.dat';
```

3. Enable Broker DMON process for the database.

```
SQL> alter system set dg_broker_start=true;
```

4. Force database logging for all database transactions.

```
SQL> alter database force logging ;
```

5. Add Standby Redo Logs (SRLs), based on the Online Redo Logs (ORLs). On a newly launched DB system, there will be three ORLs of size 1073741824, so create four SRLs of the same size.

   You can use the query below to determine the number and size (in bytes) of the ORLs.

```
SQL> select group#, bytes from v$log;

    GROUP# BYTES
---------- ----------
         1 1073741824
         2 1073741824
         3 1073741824
```

   All of the ORLs must be the same size.

   The SRLs must be the same size as the ORLs, but there must be at least one more SRL than the ORLs. In the example above, there are three ORLs, so four SRLs are required. So specify the current redo logs plus one, and use the same size as the redo logs.

```
SQL> alter database add standby logfile thread 1 size <size>;
```

   There should be only one member in the SRL group (by default, a DB system is created with only one member per SRL group). To ensure this, you can name the file with the following syntax.

```
alter database add standby logfile thread 1 group 4 (<logfile name with full path>) size
1073741824, group 5(<logfile name with full path>) size 1073741824 ...
```

   For ASM/OMF configurations, the above command uses the diskgroup instead of *<logfile name with full path>*.

```
alter database add standby logfile thread 1 group 4 (+RECO) size 1073741824, group 5(+RECO) size
1073741824 ...
```

Tip

ORLs and SRLs should be sized so that log switches do not occur more frequently than every 10 minutes. This requires knowledge of the application and may need to be adjusted after deployment. For more information, see Use Standby Redo Logs and Configure Size Appropriately.

6. Verify that you created the correct number of SRLs.

```
SQL> select group#, bytes from v$standby_log;
```

7. Make sure the database is in ARCHIVELOG mode.

```
SQL> archive log list
```

8. Enable database FLASHBACK. The minimum recommended value for db_flashback_ retention_target is 120 minutes.

```
SQL> alter database flashback on ;
SQL> alter system set db_flashback_retention_target=120;
```

9. Perform a single switch redo log to activate archiving if database is newly created. (At least one log must be archived prior to running the RMAN duplicate.)

```
SQL> alter system switch logfile;
```

Preparing the Standby Database

Before you prepare the standby database, make sure the database home on the standby is the same version as on the primary. (If the primary and standby databases are both newly created with the same database version, the database homes will be the same.) If it is not, create a database home that is the same version. You can use the dbcli list-dbhomes command to verify the versions and the dbcli create-dbhome command to create a new database home as needed.

To prepare the standby DB system, you'll need to configure static listeners, update tnsnames.ora, configure TDE Wallet, create a temporary password file, verify connectivity, run RMAN DUPLICATE, enable FLASHBACK, and then create the database service.

CONFIGURING THE STATIC LISTENERS

Create static listeners to be used by RMAN and Data Guard Broker.

1. SSH to the standby DB system, log in as the opc or root user, and sudo to the grid OS user.

   ```
   sudo su - grid
   ```

2. Append the following content to `/u01/app/<db_version>/grid/network/admin/listener.ora`.

   The first static listener shown below is required for RMAN DUPLICATE. The second DGMGRL static listener is optional for database versions 12.2.0.1 and 12.1.0.2, but required for database version 11.2.0.4.

   ```
   SID_LIST_LISTENER=
     (SID_LIST=
       (SID_DESC=
       (SDU=65535)
       (GLOBAL_DBNAME = <standby db_unique_name>.<standby db_domain>)
       (SID_NAME = <standby oracle_sid>)
       (ORACLE_HOME=<oracle home directory>)
       (ENVS="TNS_ADMIN=<oracle home directory>/network/admin")
       )
       (SID_DESC=
       (SDU=65535)
       (GLOBAL_DBNAME = <standby db_unique_name>_DGMGRL.<standby db_domain>)
       (SID_NAME = <standby oracle_sid>)
       (ORACLE_HOME=<oracle home directory>)
       (ENVS="TNS_ADMIN=<oracle home directory>/network/admin")
       )
     )
   ```

3. Restart the listener.

   ```
   $ srvctl stop listener
   $ srvctl start listener
   ```

4. Verify that the static listeners are available. The sample output below is for database version 12.1.0.2. Note that the `...status UNKNOWN` messages are expected at this point.

```
$ lsnrctl status

LSNRCTL for Linux: Version 12.1.0.2.0 - Production on 29-SEP-2016 21:09:25

```

ADDING NET SERVICE NAMES TO TNSNAMES.ORA

As the oracle user, add the standby database net service name to `$ORACLE_HOME/network/admin/tnsnames.ora`. $ORACLE_HOME is the database home where the standby database is running.

```
<Primary db_unique_name> =
  (DESCRIPTION =
    (SDU=65535)
    (ADDRESS = (PROTOCOL = TCP)(HOST = <primary_server>.<domain>) (PORT = 1521))
```

```
    (CONNECT_DATA =
      (SERVER = DEDICATED)
      (SERVICE_NAME = <primary db_unique_name).<primary db_domain>)
    )
  )

<Standby db_unique_name> =
  (DESCRIPTION =
    (SDU=65535)
    (ADDRESS = (PROTOCOL = TCP)(HOST = <standby_server>.<domain>) (PORT = 1521))
    (CONNECT_DATA =
      (SERVER = DEDICATED)
      (SERVICE_NAME = <standby db_unique_name>.<db_domain>)
    )
  )
```

Copying the TDE Wallets to the Standby System

Copy the TDE wallet files from the primary DB system to standby DB system using SCP. The following sample command assumes the SCP command is being run by the oracle OS user and that the private key for oracle has been created and exists on the host where SCP is being run.

```
$ scp -i <private key> primary_server:/opt/oracle/dcs/commonstore/wallets/tde/<primary db_unique_name>/*
standby_server:/opt/oracle/dcs/commonstore/wallets/tde/<standby db_unique_name>
```

Setting Up the Standby System Configuration

As the oracle user, create the following directory for database version 11.2.0.4. This step is optional for version 12.2.0.1 and version 12.1.0.2.

```
[oracle@dbsys ~]$ mkdir  -pv /u03/app/oracle/redo/<standby db_unique_name uppercase>/controlfile
```

Creating the Audit File Destination

As the oracle user, create the following directory to use as the audit file destination.

```
[oracle@dbsys ~]$ mkdir -p /u01/app/oracle/admin/<db_name>/adump
```

Otherwise, the RMAN duplicate command used later will fail.

Creating a Temporary Password File

As the oracle user, create a temporary password file.

```
[oracle@dbsys ~]$ orapwd file=$ORACLE_HOME/dbs/orapw<standby oracle_sid>    password=<admin password for primary> entries=5
```

The password **must** be the same as the admin password of the primary database. Otherwise, the RMAN duplicate step below will fail with: RMAN-05614: Passwords for target and auxiliary connections must be the same when using active duplicate.

VERIFYING THE STANDBY DATABASE IS AVAILABLE

1. As the oracle user, set the environment variables.

   ```
   [oracle@dbsys ~]$ . oraenv
   <enter the db_name>
   ```

2. Replace $ORACLE_HOME/dbs/init<*standby sid_name*>.ora with the following content:

   ```
   db_name=<Primary db_name>
   db_unique_name=<standby db_unique_name>
   db_domain=<standby db_domain>
   ```

3. Remove the spfile from the standby.

   ```
   /u02/app/oracle/oradata/<standby db_unique_name>/dbs/spfile$ORACLE_SID.ora
   ```

   The database needs to be started in nomount mode with no spfile specified, but the original init file contains an spfile parameter which will prevent the RMAN duplicate step from working.

4. Set the ORACLE_UNQNAME environment variable to point to your DB_UNIQUE_NAME.

   ```
   $ export ORACLE_UNQNAME =db_unique_name
   ```

   > **Important**
   >
   > If you do not perform this step, the wallet will not be opened, and running the RMAN DUPLICATE command in the subsequent step will fail.

5. The dbcli create-database --instanceonly command used earlier opens the

standby database as a primary in read/write mode, so the database needs to be brought down before proceeding to the nomount step below.

```
$ sqlplus / as sysdba
SQL> shutdown immediate
```

6. Start the database in nomount mode.

```
SQL> startup nomount
```

VERIFYING THE DATABASE CONNECTIONS

Verify the connection between the primary and standby databases.

1. Make sure that the listener port 1521 is open in the security list(s) used for the primary and standby DB systems. For more information, see Updating the Security List for the DB System.
2. From the primary database, connect to standby database.

```
$ sqlplus sys/<password>@<standby net service name> as sysdba
```

3. From standby database, connect to primary database.

```
$ sqlplus sys/<password>@<primary net service name> as sysdba
```

RUNNING THE RMAN DUPLICATE COMMAND

Run the RMAN DUPLICATE command on the standby DB system, as the oracle user.

If the primary database is large, you can allocate additional channels to improve performance. For a newly installed database, one channel typically runs the database duplication in a couple of minutes.

Make sure that there are no errors generated by the RMAN DUPLICATE command. If errors occur, restart the database using the `init.ora` file (not spfile) in case it is generated under `$ORACLE_HOME/dbs` as part of RMAN DUPLICATE.

In the following examples, use lowercase for the *<Standby db_unique_name>* unless otherwise specified.

For ACFS storage layout, run the following commands.

```
$ rman target sys/<password>@<primary alias>  auxiliary sys/<password>@<standby alias> log=rman.out

RMAN> run { allocate channel prim1 type disk;
            allocate auxiliary channel sby type disk;
            duplicate target database for standby from active database
            dorecover
            spfile
            parameter_value_convert '/<Primary db_unique_name>/','/<Standby db_unique_name>/','/<Primary
db_unique_name uppercase>/','/<Standby db_unique_name uppercase >/'
            set db_unique_name='<Standby db_unique_name>'
            set db_create_file_dest='/u02/app/oracle/oradata/<Standby db_unique_name>'
            set dg_broker_config_file1='/u02/app/oracle/oradata/<Standby db_unique_name>/dbs/dr1<Standby
db_unique_name>.dat'
            set dg_broker_config_file2='/u02/app/oracle/oradata/<Standby db_unique_name>/dbs/dr2<Standby
db_unique_name>.dat'
            set dispatchers ='(PROTOCOL=TCP) (SERVICE=<Standby db_unique_name>XDB)'
            set instance_name='<Standby db_unique_name>'
            ;
           }
```

For ASM storage layout, run the following commands.

```
$ rman target sys/<password>@<primary alias>  auxiliary sys/<password>@<standby alias> log=rman.out

RMAN> run { allocate channel prim1 type disk;
            allocate auxiliary channel sby type disk;
            duplicate target database for standby from active database
            dorecover
            spfile
            parameter_value_convert '/<Primary db_unique_name>/','/<Standby db_unique_name>/','/<Primary
db_unique_name uppercase>/','/<Standby db_unique_name uppercase>/'
            set db_unique_name='<Standby db_unique_name>'
            set dg_broker_config_file1='+DATA/<Standby db_unique_name>/dr1<Standby db_unique_name>.dat'
            set dg_broker_config_file2='+DATA/<Standby db_unique_name>/dr2<Standby db_unique_name>.dat'
            set dispatchers ='(PROTOCOL=TCP) (SERVICE=<Standby db_unique_name>XDB)'
            set instance_name='<Standby db_unique_name>'
            ;
          }
```

Enabling Database FLASHBACK

1. As a Data Guard best practice, enable flashback and set `db_flashback_retention_target` to at least 120 minutes on both the primary and standby databases.

```
SQL> alter database flashback on;
SQL> alter system set db_flashback_retention_target=120;
```

2. Verify that the standby database is created properly.

```
SQL> select FORCE_LOGGING, FLASHBACK_ON, OPEN_MODE, DATABASE_ROLE,SWITCHOVER_STATUS, DATAGUARD_
BROKER, PROTECTION_MODE from v$database ;
```

Creating a Database Service

Oracle recommends creating a database service for the standby database by using srvctl.

For ACFS storage layout.

1. Create a shared directory and copy the spfile file to it.

```
$ mkdir -pv /u02/app/oracle/oradata/<Standby db_unique_name>/dbs
$ cp $ORACLE_HOME/dbs/spfile<standby oracle_sid>.ora /u02/app/oracle/oradata/<Standby db_unique_
name>/dbs
```

2. Stop and remove the existing database service.

```
$ srvctl stop database -d <standby db_unique_name>
$ srvctl remove database -d <standby db_unique_name>
```

3. Create the database service.

```
$ srvctl add database -d <standby db_unique_name> -n <standby db_name> -o $ORACLE_HOME -c SINGLE
-p '/u02/app/oracle/oradata/<standby db_unique_name>/dbs/spfile<standby db_name>.ora'
-x <standby hostname> -s "READ ONLY" -r PHYSICAL_STANDBY -i <db_name>
$ srvctl setenv database -d <standby db_unique_name> -t "ORACLE_
UNQNAME=<standby db_unique_name>"
$ srvctl config database -d <standby db_unique_name>
```

4. Start the database service.

```
$ srvctl start database -d <standby db_unique_name>
```

5. Clean up the files from `$ORACLE_HOME/dbs`.

```
$ rm $ORACLE_HOME/dbs/spfile<standby oracle_sid>.ora
$ rm $ORACLE_HOME/dbs/init<standby oracle_sid>.ora
```

6. Create the $ORACLE_HOME/dbs/init*<standby oracle_sid>*.ora file to reference the new location of the spfile file.

```
SPFILE='/u02/app/oracle/oradata/<standby db_unique_name>/dbs/spfile<standby db_name>.ora'
```

7. Stop the standby database and then start it by using srvctl.

```
srvctl stop database -d <standby db_unique_name>
srvctl start database -d <standby db_unique_name>
```

For ASM storage layout.

1. Consider generating the spfile file under +DATA.

```
SQL> create pfile='init<standby oracle_sid>.ora' from spfile ;
SQL> create spfile='+DATA' from pfile='init<standby oracle_sid>.ora' ;
```

2. Stop and remove the existing database service.

```
$ srvctl stop database -d <standby db_unique_name>
$ srvctl remove database -d <standby db_unique_name>
```

3. Create the database service.

```
$ srvctl add database -d <standby db_unique_name> -n <standby db_name>   -o $ORACLE_HOME -c
SINGLE  -p '+DATA/<standby db_unique_name>/PARAMETERFILE/spfile.xxx.xxxxxx'
-x <standby hostname> -s "READ ONLY" -r PHYSICAL_STANDBY -i <db_name>
$ srvctl setenv database -d <standby db_unique_name> -t "ORACLE_UNQNAME=<standby db_unique_name>"
$ srvctl config database -d <standby db_unique_name>
```

4. Start the database service.

```
$ srvctl start database -d <standby db_unique_name>
```

5. Clean up the files from $ORACLE_HOME/dbs.

```
$ rm $ORACLE_HOME/dbs/init<standby oracle_sid>.ora
$ rm $ORACLE_HOME/dbs/spfile<standby oracle_sid>.ora
```

6. Create $ORACLE_HOME/dbs/init*<standby oracle_sid>*.ora file to reference the new location of the spfile file.

```
SPFILE='+DATA/<standby db_unique_name>/PARAMETERFILE/spfile.xxx.xxxxxx'
```

7. Stop the database and start the standby database by using srvctl.

```
$ srvctl start database -d <standby db_unique_name>
```

Configuring Data Guard

Perform the following steps to complete the configuration of Data Guard and enable redo transport from the primary database and redo apply in the standby database.

1. Run the dgmgrl command line utility from either the primary or standby DB system and connect to the primary database using sys credentials.

```
DGMGRL> connect sys/<sys password>@<primary tns alias>
```

2. Create the Data Guard configuration and identify for the primary and standby databases.

```
DGMGRL> create configuration mystby as primary database is <primary db_unique_name> connect
identifier is <primary tns alias>;
add database  <standby db_unique_name> as connect identifier is <standby tns alias>  maintained
as physical;
```

3. Enable Data Guard configuration.

```
DGMGRL> enable configuration;
```

4. Verify that Data Guard setup was done properly. Run the following SQL in **both** the primary and standby databases.

```
SQL> select FORCE_LOGGING, FLASHBACK_ON, OPEN_MODE, DATABASE_ROLE, SWITCHOVER_STATUS, DATAGUARD_
BROKER, PROTECTION_MODE from v$database;
```

5. Verify that Data Guard processes are initiated in the standby database.

```
SQL> select PROCESS,PID,DELAY_MINS from V$MANAGED_STANDBY;
```

6. Verify parameter configuration on primary and standby.

```
SQL> show parameter log_archive_dest_
SQL> show parameter log_archive_config
SQL> show parameter fal_server
SQL> show parameter log_archive_format
```

7. Verify that the Data Guard configuration is working. Specifically, make sure redo

shipping and redo apply are working and that the standby is not unreasonably lagging behind the primary.

```
DGMGRL> show configuration verbose
DGMGRL> show database verbose <standby db_unique_name>
DGMGRL> show database verbose <primary db_unique_name>
```

Any discrepancies, errors, or warnings should be resolved. You can also run a transaction on the primary and verify that it's visible in the standby.

8. Verify that the Data Guard configuration is functioning as expected by performing switchover and failover in both directions. Run `show configuration` after each operation and make sure there are no errors or warnings.

Warning

This step is optional, based on your discretion. If for any reason the configuration is not valid, the switchover and/or failover will fail and it might be difficult or impossible to start the primary database. A recovery of the primary might be required, which will affect availability.

```
DGMGRL> switchover to <standby db_unique_name>
DGMGRL> switchover to <primary db_unique_name>

#connect to standby before failover:

DGMGRL> connect sys/<sys password>@<standby db_unique_name>
DGMGRL> failover to <standby db_unique_name>
DGMGRL> reinstate database <primary db_unique_name>

#connect to primary before failover:

DGMGRL> connect sys/<sys password>@<primary db_unique_name>
DGMGRL> failover to <primary db_unique_name>
DGMGRL> reinstate database <standby db_unique_name>
```

Configuring Observer (Optional)

The best practice for high availability and durability is to run the primary, standby, and observer in separate availability domains. The observer determines whether or not to failover to a specific target standby database. The server used for observer requires the Oracle Client Administrator software, which includes the Oracle SQL NET and Broker.

1. Configure TNS alias names for both the primary and standby databases as described previously, and verify the connection to both databases.
2. Change protection mode to either maxavailability or maxperformance (maxprotection is not supported for FSFO).

   To enable maxavailability:

   ```
   DGMGRL> edit database <standby db_unique_name> set property 'logXptMode'='SYNC';
   DGMGRL> edit database <primary db_unique_name> set property 'logXptMode'='SYNC';
   DGMGRL> edit configuration set protection mode as maxavailability;
   ```

   To enable maxperformance:

   ```
   DGMGRL> edit configuration set protection mode as maxperformance;
   DGMGRL> edit database <standby db_unique_name> set property 'logXptMode'='ASYNC';
   DGMGRL> edit database <primary db_unique_name> set property 'logXptMode'='ASYNC';
   ```

   For maxperformance, the FastStartFailoverLaglimit property limits the maximum amount of permitted data loss to 30 seconds by default.
3. The following properties should also be considered. Run `show configuration verbose` to see their current values.
   - FastStartFailoverPmyShutdown
   - FastStartFailoverThreshold
   - FastStartFailoverTarget
   - FastStartFailoverAutoReinstate

   (Running `show configuration` will result in the following error until the observer is started: `Warning : ORA-16819: fast-start failover observer not started`.)
4. Enable fast-start failover from Broker:

   ```
   DGMGRL> Enable fast_start failover
   ```

5. Verify the fast-start failover and associated settings.

```
DGMGRL> show fast_start failover
```

6. Start the observer from Broker (it will run in the foreground, but can also be run in the background).

```
DGMGRL> start observer
```

7. Verify fast-start failover is enabled and without errors or warnings.

```
DGMGRL> show configuration verbose
```

8. Always test failover in both directions to ensure that everything is working as expected. Verify that FSFO is running properly by performing a shutdown abort of the primary database.

   The observer should start the failover to the standby database. If protection mode is set to maxprotection, some loss of data can occur, based on the FastStartFailoverLaglimit value.

Oracle Database CLI Reference

The database CLI (dbcli) is a command line interface available on bare metal and virtual machine DB systems. After you connect to the DB system, you can use the database CLI to perform tasks such as creating Oracle database homes and databases.

Note

The database CLI is **not** for use on Exadata DB systems.

Operational Notes

- The database CLI commands must be run as the root user.
- `dbcli` is in the `/opt/oracle/dcs/bin/` directory.

  This directory is included in the path for the root user's environment.

- Oracle Database maintains logs of the `dbcli` command output in the `dcscli.log` and `dcs-agent.log` files in the `/opt/oracle/dcs/log/` directory.
- The database CLI commands and most parameters are case sensitive and should be typed as shown. A few parameters are not case sensitive, as indicated in the parameter descriptions, and can be typed in uppercase or lowercase.

Warning

Oracle recommends that you avoid specifying parameter values that include confidential information when you use the database CLI commands.

Syntax

The database CLI commands use the following syntax:

```
dbcli command [parameters]
```

where:

- `command` is a verb-object combination such as `create-database`.
- `parameters` include additional options for the command. Most parameter names are preceded with two dashes, for example, `--help`. Abbreviated parameter names are preceded with one dash, for example, `-h`.
- User-specified parameter values are shown in red text within angle brackets, for example, *<db_home_id>*. Omit the angle brackets when specifying these values.
- The help parameter is available with every command.

The remainder of this topic contains syntax and other details about the commands.

CLI Update Command

Occasionally, new commands are added to the database CLI and other commands are updated to support new features. You can use the following command to update the database CLI:

CLIADM UPDATE-DBCLI

Use the `cliadm update-dbcli` command to update the database CLI with the latest new and updated commands.

Note

The `cliadm update-dbcli` command is not available on 2-node RAC DB systems.

SYNTAX

```
cliadm update-dbcli [-h] [-j]
```

PARAMETERS

Parameter	Full Name	Description
-h	--help	(Optional) Displays help for using the command.
-j	--json	(Optional) Displays JSON output.

EXAMPLE

The following command updates the `dbcli`:

```
[root@dbsys ~]# cliadm update-dbcli
{
  "jobId" : "dc9ce73d-ed71-4473-99cd-9663b9d79bfd",
  "status" : "Created",
  "message" : "Dcs cli will be updated",
  "reports" : [ ],
  "createTimestamp" : "January 18, 2017 10:19:34 AM PST",
  "resourceList" : [ ],
  "description" : "dbcli patching",
  "updatedTime" : "January 18, 2017 10:19:34 AM PST"
}
```

Agent Commands

The following commands are available to manage agents:

- dbcli ping-agent
- dbcli list-agentConfigParameters
- dbcli update-agentConfigParameters

DBCLI PING-AGENT

Use the `dbcli ping-agent` command to test the reachability of an agent.

SYNTAX

```
dbcli ping-agent [-h] [-j]
```

PARAMETERS

Parameter	Full Name	Description
-h	--help	(Optional) Displays help for using the command.
-j	--json	(Optional) Displays JSON output.

DBCLI LIST-AGENTCONFIGPARAMETERS

Use the `dbcli list-agentConfigParameters` command to list agent configuration parameters.

SYNTAX

```
dbcli list-agentConfigParameters [-n] [-h] [-j]
```

PARAMETERS

Parameter	Full Name	Description
-h	--help	(Optional) Displays help for using the command.
-j	--json	(Optional) Displays JSON output.
-n	-name	(Optional) Parameter name.

DBCLI UPDATE-AGENTCONFIGPARAMETERS

Use the `dbcli update-agentConfigParameters` command to update agent configuration parameters.

SYNTAX

```
dbcli update-agentConfigParameters -n <parameter> [-v <value>] [-a] [-c] [-d] [-u] [-r] [-h] [-j]
```

PARAMETERS

Parameter	Full Name	Description
-a	--append	(Optional) Appends the specified values to the specified parameters. Example with multiple parameter names and values: `-n p1 -v v1 -n p2 -v v2 -a`
-c	--comment	(Optional) Adds a comment for the parameter. Default: [ ]
-d	--description	(Optional) Adds a description for the parameter. Default: [ ]
-h	--help	(Optional) Displays help for using the command.
-j	--json	(Optional) Displays JSON output.
-n	--name	Parameter name. Example with multiple parameter names and values: `-n p1 -v v1 -n p2 -v v2` Default: [ ]

Parameter	Full Name	Description
-r	--reset	(Optional) Resets the parameter to the default value. Example resetting multiple parameters: `-n p1 -n p2 -r` Default: false
-u	--update	(Optional) Replaces the specified parameter values as directed. Example with multiple parameter names and values: `-n p1 -v v1 -n p2 -v v2 -u` Default: false
-v	--value	(Optional) Parameter value. Example with multiple parameter names and values: `-n p1 -v v1 -n p2 -v v2` Default: [ ]

Autologcleanpolicy Commands

The following commands are available to manage policies for automatic cleaning (purging) of logs.

- dbcli create-autoLogCleanPolicy
- dbcli list-autoLogCleanPolicy

DBCLI CREATE-AUTOLOGCLEANPOLICY

Use the `dbcli create-autoLogCleanPolicy` command to create policies for automatic cleaning (purging) of logs.

SYNTAX

```
dbcli create-autoLogCleanPolicy [-c {gi|database|dcs}] [-f <number>] [-o <number>] [-u
{Day|Hour|Minute}] [-uMB <number>] [-uPer <number>] [-h] [-j]
```

PARAMETERS

Parameter	Full Name	Description
-c	--components	(Optional) Components to purge. Possible values are gi, database, and dcs. Separate multiple values with commas. Example: `gi,dcs`
-f	--freeSpaceBelowPercentage	(Optional) Purges logs when the free disk space is below the specified percentage of the total partition size. Valid range: 20-50. Default: 20.
-h	--help	(Optional) Displays help for using the command.
-j	--json	(Optional) Displays JSON output.
-o	--olderthan	(Optional) Quantity portion of time interval. Default: 30. Cleans logs older than the specified time interval (`-o` and `-u`).
-u	--olderThanUnit	(Optional) Unit portion of time interval. Possible values: Day, Hour, or Minute. Default: Day. Cleans logs older than the specified time interval (`-o` and `-u`).
-uMB	--usageOverMB	(Optional) Purges logs when log usage exceeds the specified number of MegaBytes (MB). Valid range: 10 to 50% of total partition size.
-uPer	--usageOverPercentage	(Optional) Purges logs when log usage exceeds the specified percentage of the total partition size. Valid range: 10-50.

DBCLI LIST-AUTOLOGCLEANPOLICY

Use the `dbcli list-autoLogCleanPolicy` command to list policies for automatic cleaning of logs.

SYNTAX

```
dbcli list-autoLogCleanPolicy [-c {gi|database|dcs}] [-h] [-j]
```

PARAMETERS

Parameter	Full Name	Description
-c	--components	(Optional) Components. Possible values are gi, database, and dcs. Separate multiple values with commas. Example: `gi,dcs`
-h	--help	(Optional) Displays help for using the command.
-j	--json	(Optional) Displays JSON output.

Backup Commands

The following commands are available to back up databases:

- dbcli create-backup
- dbcli getstatus-backup
- dbcli schedule-backup

Note

Instead of using `dbcli`, you can use the Console or the API to manage backing up your bare metal or virtual machine DB system databases to Object Storage. However, if you switch from using `dbcli` to using managed backups, a new backup configuration is created and associated with your database, and backups you created by using `dbcli` will not be accessible from the managed backup interfaces. For information about managed backups, see Backing Up a Database to Oracle Cloud Infrastructure Object Storage.

Before you can back up a database by using the dbcli create-backup command, you'll need to:

1. Create a backup configuration by using the dbcli create-backupconfig command.
2. Associate the backup configuration with the database by using the dbcli update-database command.

After a database is associated with a backup configuration, you can use the `dbcli create-backup` command in a `cron` job to run backups automatically. You can use a cron utility such as CronMaker to help build expressions. For more information, see http://www.cronmaker.com.

DBCLI CREATE-BACKUP

Use the `dbcli create-backup` command to create a backup of a database.

SYNTAX

```
dbcli create-backup -in <db_name> -i <db_id> [-bt {Regular-L0|Regular-L1|Longterm|ArchiveLog}] [-c
{Database|TdeWallet}] [-k <n>] [-t <tag>] [-h] [-j]
```

PARAMETERS

Parameter	Full Name	Description
-bt	--backupType	(Optional) Backup type. Possible values are Regular-L0, Regular-L1, Longterm, and ArchiveLog. Regular-L0 and Regular L1 correspond to incremental L0 and L1 backups. Longterm corresponds to Full backup. ArchiveLog corresponds to archived redo logs backup. The default value is Regular-L1. Values are not case-sensitive. If omitted, the default value is used.

Parameter	Full Name	Description
-c	--component	(Optional) Component. Possible values are Database and TdeWallet. The default value is Database. The value TdeWallet backs up TDE wallets. Values are not case-sensitive. If omitted, the default value is used.  **Note** TDE wallets are automatically backed up in the following situations: • A database is created with an Object Storage backup configuration. • A database that has an Object Storage backup configuration is updated. • An Object Storage backup configuration is updated. • A backup of the type Longterm is created. • The TDE key for a database is rotated. • A database is backed up and no TDE wallet backups exist yet.
-h	--help	(Optional) Displays help for using the command.

Parameter	Full Name	Description
-i	--dbid	The ID of the database to back up. Use the `dbcli list-databases` command to get the database's ID.
-in	--dbName	The name of the database to back up. Use the `dbcli list-databases` command to get the database's name.
-j	--json	(Optional) Displays JSON output.
-k	--keepDays	(Optional) Specifies the time until which the backup or copy must be kept. After this time the backup is obsolete, regardless of the backup retention policy settings. For Longterm backup type only.
-t	--tag	(Required for Longterm backup type) Specifies a user-specified tag name for a backup set and applies this tag to the output files generated by the command. This value is not case sensitive. Valid number of characters: 1 to 30. The characters are limited to the characters that are valid in file names on the target file system. For example, ASM does not support the use of the hyphen (-) character in the file names it uses internally, so weekly-incremental is not a valid tag name for backups in ASM disk groups. Environment variables are not valid in the TAG parameter.

EXAMPLES

The following command creates a backup of the specified database using the database ID.

```
[root@dbsys ~]# dbcli create-backup -i 573cadb2-0cc2-4c1c-9c31-595ab8963d5b
```

The following command creates a backup of the specified database using the database name ("mydb").

```
[root@dbsys ~]# dbcli create-backup -in mydb
```

DBCLI GETSTATUS-BACKUP

Use the `dbcli getstatus-backup` command to display the status of a backup.

SYNTAX

```
dbcli getstatus-backup -t <backup_type> [i <id>] [-in <name>] [-l] [-h] [-j]
```

PARAMETERS

Parameter	Full Name	Description
-h	--help	(Optional) Displays help for using the command.
-i	--dbId	(Optional) Database Resource ID.
-in	--dbName	(Optional) Database Resource Name.
-j	--json	(Optional) Displays JSON output.
-l	--isLatestBackupReport	(Optional) Latest backup report. Default: true.
-t	--backupType	Backup type.

DBCLI SCHEDULE-BACKUP

Use the `dbcli schedule-backup` command to schedule a backup of a database.

SYNTAX

```
dbcli schedule-backup -t <backup_type> -f <number> [i <id>] [-in <name>] [-h] [-j]
```

PARAMETERS

Parameter	Full Name	Description
-f	--frequency	Frequency in minutes.
-h	--help	(Optional) Displays help for using the command.

Parameter	Full Name	Description
-i	--dbId	(Optional) Database Resource ID.
-in	--dbName	(Optional) Database Resource Name.
-j	--json	(Optional) Displays JSON output.
-t	--backupType	Backup type.

Backupconfig Commands

A backup configuration determines the backup destination and recovery window for database backups. You create the backup configuration and then associate it with a database by using the `dbcli update-database` command.

Warning

Backups that were configured using the Console may become unusable if you make changes using these commands. For backups configured using the Console, use these commands with support guidance only.

Note

Instead of using `dbcli`, you can use the Console or the API to manage backing up your bare metal or virtual machine DB system databases to Object Storage. For information about managed backups, see Backing Up a Database to Oracle Cloud Infrastructure Object Storage.

After a database is associated with a backup configuration, you can use the `dbcli create-backup` command in a `cron` job to run backups automatically. You can use a cron utility such

as CronMaker to help build expressions. For more information, see http://www.cronmaker.com.

The following commands are available to manage backup configurations:

- dbcli create-backupconfig
- dbcli list-backupconfigs
- dbcli describe-backupconfig
- dbcli update-backupconfig
- dbcli delete-backupconfig

DBCLI CREATE-BACKUPCONFIG

Use the `dbcli create-backupconfig` command to create a backup configuration that defines the backup destination and recovery windows.

SYNTAX

```
dbcli create-backupconfig -d {DISK|OBJECTSTORE|NONE} -c <bucket>  -o <object_store_swift_id> -on
<object_store_swift_name> -w <n> -n <name> [-cr|-no-cr] [-h] [-j]
```

PARAMETERS

Parameter	Full Name	Description
-c	--container	The name of an existing bucket in the Oracle Cloud Infrastructure Object Storage service. You can use the Console or the Object Storage API to create the bucket. For more information, see Managing Buckets. You must also specify `--backupdestination objectstore` and the `--objectstoreswiftId` parameter.
-cr -no-cr	--crosscheck --no-crosscheck	(Optional) Indicates whether to enable the crosscheck operation. This operation determines if the files on the disk or in the media management catalog correspond to data in the RMAN repository. If omitted, the default setting is used (crosscheck is enabled by default).
-d	--backupdestination	The backup destination as one of the following (these values are **not** case sensitive): DISK - The local Fast Recovery Area. OBJECTSTORE - The Oracle Cloud Infrastructure Object Storage service. You must also specify the `--container` and `--objectstoreswiftId` parameters. NONE - Disables the backup.
-h	--help	(Optional) Displays help for using the command.
-j	--json	(Optional) Displays JSON output.
-n	--name	The name of the backup configuration.

Parameter	Full Name	Description
-o	--objectstoreswiftId	The ID of the object store that contains the endpoint and credentials for the Oracle Cloud Infrastructure Object Storage service. Use the dbcli list-objectstoreswifts command to get the object store ID. Use the dbcli create-objectstoreswift command to create an object store. You must also specify `--backupdestination objectstore` and the `--container` parameter.
-on	--objectstoreswiftName	The name of the object store that contains the endpoint and credentials for the Oracle Cloud Infrastructure Object Storage service. Use the dbcli list-objectstoreswifts command to get the object store name. Use the dbcli create-objectstoreswift command to create an object store. You must also specify `--backupdestination objectstore` and the `--container` parameter.
-w	--recoverywindow	The number of days for which backups and archived redo logs are maintained. The interval always ends with the current time and extends back in time for the number of days specified. For a DISK backup destination, specify 1 to 14 days. For an OBJECTSTORE backup destination, specify 1 to 30 days.

EXAMPLE

The following command creates a backup configuration named dbbkcfg1:

```
[root@dbsys ~]# dbcli create-backupconfig -d Disk -w 7 -n dbbkcfg1
{
```

```
  "jobId" : "4e0e6011-db53-4142-82ef-eb561658a0a9",
  "status" : "Success",
  "message" : null,
  "reports" : [ {
    "taskId" : "TaskParallel_919",
    "taskName" : "persisting backup config metadata",
    "taskResult" : "Success",
    "startTime" : "November 18, 2016 20:21:25 PM UTC",
    "endTime" : "November 18, 2016 20:21:25 PM UTC",
    "status" : "Success",
    "taskDescription" : null,
    "parentTaskId" : "TaskSequential_915",
    "jobId" : "4e0e6011-db53-4142-82ef-eb561658a0a9",
    "tags" : [ ],
    "reportLevel" : "Info",
    "updatedTime" : "November 18, 2016 20:21:25 PM UTC"
  } ],
  "createTimestamp" : "November 18, 2016 20:21:25 PM UTC",
  "description" : "create backup config:dbbkcfg1",
  "updatedTime" : "November 18, 2016 20:21:25 PM UTC"
}
```

DBCLI LIST-BACKUPCONFIGS

Use the `dbcli list-backupconfigs` command to list all the backup configurations in the DB system.

SYNTAX

```
dbcli list-backupconfigs [-h] [-j]
```

PARAMETERS

Parameter	Full Name	Description
-h	--help	(Optional) Displays help for using the command.
-j	--json	(Optional) Displays JSON output.

EXAMPLE

The following command lists a backup configuration:

```
[root@dbsys ~]# dbcli list-backupconfigs

ID                                       Name                 RecoveryWindow     BackupDestination
CreateTime
---------------------------------------- -------------------- ------------------ ----------------- -----
------------------------
ccdd56fe-a40b-4e82-b38d-5f76c265282d     dbbkcfg1             7                  Disk              July

```

DBCLI DESCRIBE-BACKUPCONFIG

Use the `dbcli describe-backupconfig` command to show details about a specific backup configuration.

SYNTAX

```
dbcli describe-backupconfig -i <id> -in <name> [-h] [-j]
```

PARAMETERS

Parameter	Full Name	Description
-h	--help	(Optional) Displays help for using the command.
-i	--backupconfigid	The backup configuration ID. Use the `dbcli list-backupconfigs` command to get the ID.
-in	--backupconfigname	The backup configuration name. Use the `dbcli list-backupconfigs` command to get the name.
-j	--json	(Optional) Displays JSON output.

EXAMPLE

The following command displays details about a backup configuration:

```
[root@dbsys ~]# dbcli describe-backupconfig -i ccdd56fe-a40b-4e82-b38d-5f76c265282d

Backup Config details
----------------------------------------------------------------
```

```
                    ID: ccdd56fe-a40b-4e82-b38d-5f76c265282d
                  Name: dbbkcfg1
        RecoveryWindow: 7
     BackupDestination: Disk
           CreatedTime: July 10, 2016 12:24:08 PM UTC
           UpdatedTime: July 10, 2016 12:24:08 PM UTC
```

DBCLI UPDATE-BACKUPCONFIG

Use the `dbcli update-backupconfig` command to update an existing backup configuration.

SYNTAX

```
dbcli update-backupconfig -i <id> -in <name> -w <n> -c <bucket> -o <object_store_swift_id> -on <object_store_swift_name> [-cr|-no-cr] [-h] [-j]
```

PARAMETERS

Parameter	Full Name	Description
-c	--container	The name of an existing bucket in the Oracle Cloud Infrastructure Object Storage service. You can use the Console or the Object Storage API to create the bucket. For more information, see Managing Buckets. You must also specify `--backupdestination objectstore` and the `--objectstoreswiftId` parameter.
-cr -no-cr	--crosscheck --no-crosscheck	(Optional) Indicates whether to enable the crosscheck operation. This operation determines if the files on the disk on in the media management catalog correspond to data in the RMAN repository. If omitted, the default setting is used (crosscheck is enabled by default).
-h	--help	(Optional) Displays help for using the command.

Parameter	Full Name	Description
-i	--backupconfigid	The ID of the backup configuration to update. Use the `dbcli list-backupconfigs` command to get the ID.
-in	--backupconfigname	The name of the backup configuration to update. Use the `dbcli list-backupconfigs` command to get the name.
-j	--json	(Optional) Displays JSON output.
-o	--objectstoreswiftId	The ID of the object store that contains the endpoint and credentials for the Oracle Cloud Infrastructure Object Storage service. Use the dbcli list-objectstoreswifts command to get the object store ID. Use the dbcli create-objectstoreswift command to create an object store. You must also specify `--backupdestination objectstore` and the `--container` parameter.
-on	--objectstoreswiftname	The name of the object store that contains the endpoint and credentials for the Oracle Cloud Infrastructure Object Storage service. Use the dbcli list-objectstoreswifts command to get the object store name. Use the dbcli create-objectstoreswift command to create an object store. You must also specify `--backupdestination objectstore` and the `--container` parameter.
-w	--recoverywindow	The new disk recovery window. For a DISK backup destination, specify 1 to 14 days. For an OBJECTSTORE backup destination, specify 1 to 30 days.

EXAMPLE

The following command updates the recovery window for a backup configuration:

```
[root@dbsys ~]# dbcli update-backupconfig -i ccdd56fe-a40b-4e82-b38d-5f76c265282d -w 5
{
  "jobId" : "0e849291-e1e1-4c7a-8dd2-62b522b9b807",
  "status" : "Created",
  "message" : null,
  "reports" : [ ],
  "createTimestamp" : 1468153731699,
  "description" : "update backup config: dbbkcfg1",
  "updatedTime" : 1468153731700
}
```

DBCLI DELETE-BACKUPCONFIG

Use the `dbcli delete-backupconfig` command to delete a backup configuration.

SYNTAX

```
dbcli delete-backupconfig -i <id> -in <name> [-h] [-j]
```

PARAMETERS

Parameter	Full Name	Description
-h	--help	(Optional) Displays help for using the command.
-i	--id	The backup configuration ID to delete. Use the `dbcli list-backupconfigs` command to get the ID.
-in	--backupconfigname	The name of the backup configuration to delete. Use the `dbcli list-backupconfigs` command to get the name.
-j	--json	(Optional) Displays JSON output.

EXAMPLE

The following command deletes the specified backup configuration:

```
[root@dbsys ~]# dbcli delete-backupconfig -i ccdd56fe-a40b-4e82-b38d-5f76c265282d
```

Bmccredential Commands

The following commands are available to manage credentials configurations, which are required for downloading DB system patches from the Oracle Cloud Infrastructure Object Storage service. For more information, see Patching a DB System.

- dbcli create-bmccredential
- dbcli list-bmccredentials
- dbcli describe-bmccredential
- dbcli delete-bmccredential
- dbcli update-bmccredential

Note

The `bmccredential` commands are not available on 2-node RAC DB systems.

DBCLI CREATE-BMCCREDENTIAL

Use the `dbcli create-bmccredential` command to create a credentials configuration.

PREREQUISITES

Before you can create a credentials configuration, you'll need these items:

- An RSA key pair **in PEM format** (minimum 2048 bits). See How to Generate an API Signing Key.
- The fingerprint of the public key. See How to Get the Key's Fingerprint.
- Your tenancy's OCID and user name's OCID. See Where to Get the Tenancy's OCID and User's OCID.

Then you'll need to upload the public key in the Console. See How to Upload the Public Key.

SYNTAX

```
dbcli create-bmccredential -c [backup|patching|other] -t <tenant_ocid> -u <user_ocid>  -f <fingerprint>
-k <private_key_path> -p|-hp <passphrase> [-n <credentials_name>] [-e <object_store_url>] [-h] [-j]
```

PARAMETERS

Parameter	Full Name	Description
-c	--credentialsType	The type of Object Storage credentials configuration to create (these values are **not** case sensitive): BACKUP - Reserved for the future use. PATCHING - For downloading patches from the service. OTHER - Reserved for the future use.
-e	--objectStoreUrl	(Optional) The Object Storage endpoint URL. Omit this parameter when `--credentialsType PATCHING` is specified. The following URL is assumed: https://objectstorage.*<region_name>*.oraclecloud.com See Regions and Availability Domains for region name strings.
-f	--fingerPrint	The public key fingerprint. You can find the fingerprint in the Console by clicking your user name in the upper right corner and then clicking **User Settings**. The fingerprint looks something like this: `-f 61:9e:52:26:4b:dd:46:dc:8c:a8:05:6b:9f:0a:30:d2`
-k	--privateKey	The path to the private key file in PEM format, for example: `-k /root/.ssh/privkey`
-h	--help	(Optional) Displays help for using the command.

Parameter	Full Name	Description
-j	--json	(Optional) Displays JSON output.
-n	--name	(Optional) The name for the new credentials configuration. The name is useful for tracking the configuration.
-p -hp	--passPhrase	The passphrase for the public/private key pair, if you specified one when creating the key pair. Specify `-p` (with no passphrase) to be prompted. Specify `-hp` *<passphrase>* to provide the passphrase in the command.
-t	--tenantOcid	Your tenancy OCID. See Where to Find Your Tenancy's OCID. The tenancy OCID looks something like this: `ocid1.tenancy.oc1..<unique_ID>`
-u	--userOcid	The user name OCID for your Oracle Cloud Infrastructure user account. You can find the OCID in the Console: Open the **Profile** menu () and click **User Settings**. The user name OCID looks something like this: `ocid1.user.oc1..<unique_ID>`

EXAMPLE

The following command creates a credentials configuration:

```
[root@dbsys ~]# dbcli create-bmccredential -c patching -hp mypass -t
ocid1.tenancy.oc1..aaaaaaaaba3pv6wkcr4jqae5f44n2b2m2yt2j6rx32uzr4h25vqstifsfdsq -u
ocid1.user.oc1..aaaaaaaalhdxviuxqi7xevqskscc16edokgldvuf6raskcioq4x2z7watsfa -f
60:9e:56:26:4b:dd:46:dc:8c:a8:05:6d:9f:0a:30:d2 -k /root/.ssh/privkey

{
  "jobId" : "f8c80510-b717-4ee2-a47e-cd380480b28b",
  "status" : "Created",
  "message" : null,
  "reports" : [ ],
```

```
  "createTimestamp" : "December 26, 2016 22:46:38 PM PST",
  "resourceList" : [ ],
  "description" : "BMC Credentials Creation",
  "updatedTime" : "December 26, 2016 22:46:38 PM PST"
}
```

DBCLI LIST-BMCCREDENTIALS

Use the `dbcli list-bmccredentials` command to list the credentials configurations on the DB system.

SYNTAX

```
dbcli list-bmccredentials [-h] [-j]
```

PARAMETERS

Parameter	Full Name	Description
-h	--help	(Optional) Displays help for using the command.
-j	--json	(Optional) Displays JSON output.

EXAMPLE

The following command lists the credentials configurations on the DB system:

```
[root@dbsys ~]# dbcli list-bmccredentials
    ID                                       Name           Type          End Point
                              Status
    ---------------------------------------- -------------  ----------    ------------------------------
----------------------------- ----------
    f19d7c8b-d0d5-4jhf-852b-eb2a81cb7ce5     patch1         Patching      https://objectstorage.us-
phoenix-1.oraclecloud.com           Configured
    f1a8741c-b0c4-4jhf-239b-ab2a81jhfde4     patch2         Patching      https://objectstorage.us-
phoenix-1.oraclecloud.com           Configured
```

DBCLI DESCRIBE-BMCCREDENTIAL

Use the `dbcli describe-bmccredential` command to display details about a credentials configuration.

SYNTAX

```
dbcli describe-bmccredential -i <credentials_id> [-h] [-j]
```

PARAMETERS

Parameter	Full Name	Description
-h	--help	(Optional) Displays help for using the command.
-i	--id	The ID for the credentials configuration. Use the dbcli list-bmccredentials command to get the ID.
-j	--json	(Optional) Displays JSON output.

EXAMPLE

The following command displays details about the specified credentials configuration:

```
[root@dbsys ~]# dbcli describe-bmccredential -i 09f9988e-eed5-4dde-8814-890828d1c763

BMC Credentials details
----------------------------------------------------------------
                     ID: 09f9988e-eed5-4dde-8814-890678d1c763
                   Name: patch23
           Tenant OCID: ocid1.tenancy.oc1..aaaaaaaaba3pv6wkcr4jqae5f44n2b2m2yt2j6rx32uzr4h25vqstifsfdsq
             User OCID: ocid1.user.oc1..aaaaaaaalhjhfiuxqi7xevqskscc16edokgldvuf6raskcioq4x2z7watjhf
      Credentials Type: Patching
       objectStore URL: https://objectstorage.us-phoenix-1.oraclecloud.com
                Status: Configured
               Created: January 9, 2017 1:19:11 AM PST
           UpdatedTime: January 9, 2017 1:41:46 AM PST
```

DBCLI DELETE-BMCCREDENTIAL

Use the `dbcli delete-bmccredential` command to delete a credentials configuration.

SYNTAX

```
dbcli delete-bmccredential -i <credentials_id> [-h] [-j]
```

PARAMETERS

Parameter	Full Name	Description
-h	--help	(Optional) Displays help for using the command.
-i	--id	The ID for the credentials configuration. Use the dbcli list-bmccredentials command to get the ID.
-j	--json	(Optional) Displays JSON output.

EXAMPLE

The following command deletes the specified credentials configuration:

```
[root@dbsys ~]# dbcli delete-bmccredential -i f19d7c8b-d0d5-4jhf-852b-eb2a81cb7ce5
```

DBCLI UPDATE-BMCCREDENTIAL

Use the `dbcli update-bmccredential` command to update a credentials configuration.

SYNTAX

```
dbcli update-bmccredential -i <credentials_id> -n <credentials_name> -c [backup|patching|other] -p|-hp
<passphrase> -f <fingerprint> -k <private_key_path> [-h] [-j]
```

PARAMETERS

Parameter	Full Name	Description
-c	--credentialsType	The type of Object Storage credentials configuration (these values are **not** case sensitive): BACKUP - Reserved for the future use. PATCHING - For downloading patches from the service. OTHER - Reserved for the future use.
-i	--id	The ID for the credentials configuration. Use the dbcli list-bmccredentials command to get the ID.
-f	--fingerPrint	The public key fingerprint, for example: `-f 61:9e:52:26:4b:dd:46:dc:8c:a8:05:6b:9f:0a:30:d2`
-k	--privateKey	The path to the private key file in PEM format, for example: `-k /root/.ssh/privkey`
-h	--help	(Optional) Displays help for using the command.
-j	--json	(Optional) Displays JSON output.
-n	--name	(Optional) The name for the credentials configuration. Use the dbcli list-bmccredentials command to get the name.
-p -hp	--passPhrase	The passphrase for the public/private key pair, if you specified one when creating the key pair. Specify `-p` (with no passphrase) to be prompted. Specify `-hp` *<passphrase>* to provide the passphrase in the command.

EXAMPLE

The following command updates a credentials configuration:

```
[root@dbsys ~]# dbcli update-bmccredential -c OTHER -i 6f921b29-61b6-56f4-889a-ce9270621956
{
  "jobId" : "6e95a69e-cf73-4e51-a444-c7e4b9631c27",
  "status" : "Created",
  "message" : null,
  "reports" : [ ],
  "createTimestamp" : "January 19, 2017 12:01:10 PM PST",
  "resourceList" : [ ],
  "description" : "Update BMC Credentials of object 6f921b29-61b6-48f4-889a-ce9270621945",
  "updatedTime" : "January 19, 2017 12:01:10 PM PST"
```

Component Command

DBCLI DESCRIBE-COMPONENT

Tip

Your DB system might not include this newer command. If you have trouble running the command, use the cliadm update-dbcli command to update the database CLI and then retry the command.

Note

The `dbcli describe-component` command is not available on 2-node RAC DB systems. Patching 2-node systems from Object Storage is not supported.

Use the `dbcli describe-component` command to show the installed and available patch versions for the server, storage, and/or database home components in the DB system.

This command requires a valid Object Storage credentials configuration. Use the dbcli create-bmccredential command to create the configuration if you haven't already done so. If the

configuration is missing or invalid, the command fails with the error: `Failed to connect to the object store. Please provide valid details.`

For more information about updating the CLI, creating the credentials configuration, and applying patches, see Patching a DB System.

SYNTAX

```
dbcli describe-component [-s <server_group>] [-d <db_group>] [-h] [-j]
```

PARAMETERS

Parameter	Full Name	Description
-d	--dbhomes	(Optional) Lists the installed and available patch versions for only the database home components.
-h	--help	(Optional) Displays help for using the command.
-j	--json	(Optional) Displays JSON output.
-s	--server	(Optional) Lists the installed and available patch versions for only the server components.

EXAMPLE

The following command to show the current component versions and the available patch versions in the object store:

```
[root@dbsys ~]# dbcli describe-component
System Version
---------------
12.1.2.10.0

Component                                Installed Version    Available Version
---------------------------------------- -------------------- --------------------
OAK                                      12.1.2.10.0          up-to-date
GI                                       12.1.0.2.161018      up-to-date
ORADB12102_HOME1                         12.1.0.2.161018      up-to-date
ORADB12102_HOME2, ORADB12102_HOME3       12.1.0.2.160719      12.1.0.2.161018
```

Database Commands

The following commands are available to manage databases:

- dbcli clone-database
- dbcli create-database
- dbcli delete-database
- dbcli describe-database
- dbcli list-databases
- dbcli modify-database
- dbcli recover-database
- dbcli register-database
- dbcli update-database

DBCLI CLONE-DATABASE

Use the `dbcli clone-database` command to clone a database.

SYNTAX

```
dbcli clone-database -f <name> -u <name> -n <name> [-s <shape>] [-t <type>] [m <sys_password>] [-p <tde_password>] [-h] [-j]
```

PARAMETERS

Parameter	Full Name	Description
-f	--sourcedbname	Source database name.
-h	--help	(Optional) Displays help for using the command.
-j	--json	(Optional) Displays JSON output.
-m	--syspassword	(Optional) Password for SYS.
-n	--dbname	Database name.

Parameter	Full Name	Description
-p	--tdepassword	(Optional) Password for source TDE wallet.
-s	--dbshape	(Optional) Database shape. Examples: odb1, odb2.
-t	--dbtype	(Optional) Database Type: SI
-u	--databaseUniqueName	Database unique name.

DBCLI CREATE-DATABASE

Use the `dbcli create-database` command to create a new database. You can create a database with a new or existing Oracle Database home, however each database home can have only one database.

It takes a few minutes to create the database. After you run the `dbcli create-database` command, you can use the `dbcli list-jobs` command to check the status of the database creation job.

Tip

Wait for the database creation job to complete before you attempt to create another database. Running multiple `dbcli create-database` commands at the same time can result in some of the creation jobs not completing.

Once the database is created, you can use the `dbcli list-databases -j` command to see additional information about the database.

Note

The `dbcli create-database` command is available on bare metal DB systems only.

You must create and activate a master encryption key for any PDBs that you create. After creating or plugging in a new PDB on a 1- or 2-node RAC DB System, use the `dbcli update-tdekey` command to create and activate a master encryption key for the PDB. Otherwise, you might encounter the error `ORA-28374: typed master key not found in wallet` when attempting to create tablespaces in the PDB. In a multitenant environment, each PDB has its own master encryption key which is stored in a single keystore used by all containers. For more information, see "Overview of Managing a Multitenant Environment" in the Oracle Database Administrator's Guide.

SYNTAX

```
dbcli create-database -dh <db_home_id> -cl {OLTP|DSS|IMDB} -n <db_name> -u <unique_name> -bi <bkup_
config_id> -bn <bkup_config_name> -m -s <db_shape> -r {ACFS|ASM} -y {SI|RAC|RACOne} [-dn <name>] -io -d
<pdb_admin_user> [-p <pdb>] [-ns <nlcharset>] [-cs <charset>] [-l <language>] [-dt <territory>] -v
<version> [-c|-no-c] [-co|-no-co] [-h] [-j]
```

PARAMETERS

Parameter	Full Name	Description
-bi	--backupconfigid	Defines the backup configuration identifier for future use. Use the `dbcli list-backupconfigs` command to get the ID.
-bn	--backupconfigname	Defines the backup configuration name for future use. Use the `dbcli list-backupconfigs` command to get the name.
-c -no-c	--cdb --no-cdb	(Optional) Indicates whether to create a Container Database. If omitted, a Container Database is not created.
-cs	--characterset	(Optional) Defines the character set for the database. The default is AL32UTF8.
-cl	--dbclass	Defines the database class. The options are OLTP, DSS, or IMDB. The default is OLTP. For Enterprise Editions, all three classes are supported. For Standard Edition, only OLTP is supported.
-co -no-co	--dbconsole --no-dbconsole	(Optional) Indicates whether the Database Console is enabled. If omitted, the console is not enabled. This parameter is not available for a version 11.2.0.4 database on a 2-node RAC DB system. For more information, see To enable the console for a version 11.2.0.4 database on a multi-node DB system .
-d	--pdbadmin	Defines the name of the Pluggable Database (PDB) Admin User. The default value is pdbadmin.

Parameter	Full Name	Description
-dn	--dbdomainname	(Optional) Database domain name (indicates the logical location of the database within the network structure).
-dt	--dbterritory	(Optional) Defines the territory for the database. The default is AMERICA.
-dh	--dbhomeid	Identifies the database home in which to create the database. The database home must be empty because each database home can have only one database. You can use the `dbcli list dbhomes` command to get the DB home ID. If this parameter is omitted, the database is created with a new Oracle home.
-h	--help	(Optional) Displays help for the command.
-j	--json	(Optional) Displays JSON output.
-l	--dblanguage	(Optional) Defines the language for the database. The default is AMERICAN.
-m	--adminpassword	A strong password for SYS, SYSTEM, TDE wallet, and PDB Admin. The password must be 9 to 30 characters and contain at least 2 uppercase, 2 lowercase, 2 numeric, and 2 special characters. The special characters must be _, #, or -. The password must not contain the username (SYS, SYSTEM, and so on) or the word "oracle" either in forward or reversed order and regardless of casing. Specify `-m` (with no password) to be prompted for the password.

Parameter	Full Name	Description
-n	--dbname	Defines the name given to the new database. The database name must begin with an alphabetic character and can contain a maximum of eight alphanumeric characters. Special characters are not permitted.
-ns	--nationalscharacterset	(Optional) Defines the national character set for the database. The default is AL16UTF16.
-p	--pdbname	(Optional) Defines a unique name for the PDB. The PDB name must begin with an alphabetic character and can contain a maximum of 30 alphanumeric characters. The only special character permitted is the underscore (_). The default value is pdb1. PDB names must be unique within a CDB and within the listener to which they are registered. Make sure the PDB name is unique on the system. To ensure uniqueness, do not use the default name value (pdb1).
-r	--dbstorage	Defines the database storage, either ACFS or ASM. The default value is ASM. See Usage Notes for more information.
-s	--dbshape	Identifies the database sizing template to use for the database. For example, odb1, odb2, or odb3. The default is odb1. For more information, see Database Sizing Templates.

Parameter	Full Name	Description
-u	--databaseUniqueName	Defines a unique name for the database to ensure uniqueness within an Oracle Data Guard group (a primary database and its standby databases). The unique name can contain only alphanumeric and underscore (_) characters. The unique name cannot be changed. The unique name defaults to the name specified in the `--dbname` parameter.
-v	--version	Defines the database version as one of the following: • 18.1.0.0 • 12.2.0.1 • 12.1.0.2 (the default) • 11.2.0.4
-y	--dbtype	Defines the database type. Specify SI for a 1-node instance, RAC for a 2-node cluster, or RACOne for 1-node instance with a second node in cold standby mode. The default value is RAC. These values are not case sensitive.

USAGE NOTES

- You cannot mix Oracle Database Standard Edition and Enterprise Edition databases on the same DB system. (You can mix supported database versions on the DB system, but not editions.)
- When `--dbhomeid` is not provided, the `dbcli create-database` command will create a new Oracle Database home.

Note

Bare metal DB systems allow only one database per database home.

- When `--dbhomeid` is provided, the `dbcli create-database` command creates the database using the Oracle home specified. Use the `dbcli list-dbhomes` command to get the dbhomeid. The database home you specify must be empty.
- Oracle Database 12.1 or later databases are supported on both Oracle Automatic Storage Management (ASM) and Oracle ASM Cluster file system (ACFS). The default is Oracle ACFS.
- Oracle Database 11.2 is supported on Oracle ACFS.
- Each database is configured with its own Oracle ACFS file system for the datafiles and uses the following naming convention: `/u02/app/db user/oradata/db` name. The default size of this mount point is 100G.
- Online logs are stored in the `/u03/app/db user/redo/` directory.
- The Oracle Fast Recovery Area (FRA) is located in the `/u03/app/db user/fast_recovery_area` directory.

EXAMPLES

To create a database and be prompted for the password interactively:

```
[root@dbsys ~]# dbcli create-database -n hrdb -c -m -cl OLTP -s odb2 -p pdb1

Password for SYS,SYSTEM and PDB Admin:
{
   "jobId" : "f12485f2-dcbe-4ddf-aee1-de24d37037b6",
   "status" : "Created",
   "message" : null,
   "reports" : [ ],
   "createTimestamp" : "August 08, 2016 03:54:03 AM EDT",
   "description" : "Database service creation with db name: hrdb",
   "updatedTime" : "August 08, 2016 03:54:03 AM EDT"
}
```

To create a database non-interactively, providing the password on the command line:

```
[root@dbsys ~]# dbcli create-database -n crmdb -hm <password> -cl OLTP -s odb2
{
   "jobId" : "30b5e2a6-493b-4461-98b8-78e9a15f8cdd",
   "status" : "Created",

```

DBCLI DELETE-DATABASE

Use the `dbcli delete-database` command to delete a database.

Note

The `dbcli create-database` command is available on bare metal DB systems only.

SYNTAX

```
dbcli  delete-database -i <db_id> -in <db_name> [-fd] [-j] [-h]
```

PARAMETERS

Parameter	Full Name	Description
-h	--help	(Optional) Displays help for using the command.
-fd	--force	(Optional) Forces the delete operation.
-i	--dbid	The ID of the database to delete. Use the `dbcli list-databases` command to get the database ID.

Parameter	Full Name	Description
-in	--dbName	The name of the database to delete. Use the `dbcli list-databases` command to get the database name.
-j	--json	(Optional) Displays JSON output.

EXAMPLE

The following command deletes the database named 625d9b8a-baea-4994-94e7-4c4a857a17f9:

```
[root@dbsys ~]# dbcli delete-database -i 625d9b8a-baea-4994-94e7-4c4a857a17f9
```

DBCLI DESCRIBE-DATABASE

Use the `dbcli describe-database` command to display database details.

SYNTAX

```
dbcli describe-database -i <db_id> -in <db_name> [-h] [-j]
```

PARAMETERS

Parameter	Full Name	Description
-h	--help	(Optional) Displays help for using the command.
-i	--dbid	The ID of the database to display. Use the `dbcli list-databases` command to get the database ID.
-in	--dbName	The name of the database to display. Use the `dbcli list-databases` command to get the database name.
-j	--json	(Optional) Displays JSON output.

EXAMPLE

The following command displays information for a database named b727bf80-c99e-4846-ac1f-28a81a725df6:

```
[root@dbsys ~]# dbcli describe-dbhome -i b727bf80-c99e-4846-ac1f-28a81a725df6

DB Home details
------------------------------------------------------------
                     ID: b727bf80-c99e-4846-ac1f-28a81a725df6
                   Name: OraDB12102_home1
                Version: 12.1.0.2
          Home Location: /u01/app/orauser/product/12.1.0.2/dbhome_1
                Created: Jun 2, 2016 10:19:23 AM
```

DBCLI LIST-DATABASES

Use the `dbcli list-databases` command to list all databases on the DB system.

SYNTAX

```
dbcli  list-databases [-h] [-j]
```

PARAMETERS

Parameter	Full Name	Description
-h	--help	(Optional) Displays help for using the command.
-j	--json	(Optional) Displays JSON output.

EXAMPLE

The following command displays a list of databases:

```
[root@dbsys ~]# dbcli  list-databases

ID                                       DB Name    DB Version           CDB        Class    Shape
Storage    Status
---------------------------------------- ---------- -------------------- ---------- -------- -------- --
-------- ----------
80ad855a-5145-4f8f-a08f-406c5e4684ff     dbst       12.1.0.2             true       OLTP     odb2
ACFS       Configured
6f4e36ae-120b-4436-b0bf-d0c4aef9f7c9     db11tsta   11.2.0.4             false      OLTP     odb1
ACFS       Configured
d8e31790-84e6-479c-beb0-ef97207091a2     db11tstb   11.2.0.4             false      OLTP     odb1
ACFS       Configured
```

```
cce096c7-737b-447a-baa1-f4c2a330c030     pdbtst     12.1.0.2            true       OLTP     odb1
ACFS       Configured
```

The following command displays the JSON output for a database:

```
[root@dbsys ~]# dbcli list-databases -j
[ {
  "id" : "80ad855a-5145-4f8f-a08f-406c5e4684ff",
  "name" : "dbtst",
  "dbName" : "dbtst",
  "databaseUniqueName" : "dbtst_phx1cs",
  "dbVersion" : "12.1.0.2",
  "dbHomeId" : "2efe7af7-0b70-4e9b-ba8b-71f11c6fe287",
  "instanceOnly" : false,
  "registerOnly" : false,
  "dbId" : "167525515",

    "status" : "CONFIGURED"
  },
  "createTime" : "November 09, 2016 17:23:05 PM UTC",
  "updatedTime" : "November 09, 2016 18:00:47 PM UTC"
}
```

DBCLI MODIFY-DATABASE

Use the `dbcli modify-database` command to modify a database.

SYNTAX

```
dbcli modify-database -i <db_id> -dh <destination_db_home_id> [-h] [-j]
```

PARAMETERS

Parameter	Full Name	Description
-dh	--destdbhomeid	Destination database home ID.
-h	--help	(Optional) Displays help for using the command.
-i	--databaseid	Database ID.
-j	--json	(Optional) Displays JSON output.

DBCLI RECOVER-DATABASE

Use the `dbcli recover-database` command to recover a database.

SYNTAX

```
dbcli recover-database [-br <json>] [-in <db_name>] [-i <db_id>] [-r <time>] [-t {Latest|PITR|SCN}] [-s]
[-l <location>] [-tp <tde_password>] [-h] [-j]
```

PARAMETERS

Parameter	Full Name	Description
-br	--backupReport	(Optional) JSON input for backup report.
-h	--help	(Optional) Displays help for using the command.
-i	--dbid	(Optional) Database resource ID.
-in	--dbName	(Optional) Database name.

Parameter	Full Name	Description
-j	--json	(Optional) Displays JSON output.
-l	--tdeWalletLocation	(Optional) TDE wallet backup location. TDE wallet should be backed up in tar.gz format.
-r	--recoveryTimeStamp	(Required when recovery type is PITR) Recovery timestamp in the format mm/dd/yyyy hh:mi:ss. Default: [ ]
-s	--scn	(Required when recovery type is SCN) SCN.
-t	--recoverytype	(Required when backup report is provided) Recovery type. Possible values are Latest, PITR, and SCN.
-tp	--tdeWalletPassword	(Optional) TDE wallet password.

DBCLI REGISTER-DATABASE

Use the `dbcli register-database` command to register a database that has been migrated to Oracle Cloud Infrastructure. The command registers the database to the dcs-agent so it can be managed by the dcs-agent stack.

Note

The `dbcli register-database` command is not available on 2-node RAC DB systems.

SYNTAX

```
dbcli  register-database -bi <bkup_config_id> -c {OLTP|DSS|IMDB} [-co|-no-co] -s {odb1|odb2|...} -t SI
[-o <db_host_name>] [-tp <password>] -sn <service_name> -p [-h] [-j]
```

PARAMETERS

Parameter	Full Name	Description
-bi	--backupconfigid	Defines the backup configuration ID. Use the `dbcli list-backupconfigs` command to get the ID.
-c	--dbclass	Defines the database class. The options are OLTP, DSS, or IMDB. The default is OLTP. For Enterprise Editions, all three classes are supported. For Standard Edition, only OLTP is supported.
-co -no-co	--dbconsole --no-dbconsole	(Optional) Indicates whether the Database Console is enabled or not. If omitted, the console is not enabled.
-h	--help	(Optional) Displays help for using the command.
-j	--json	(Optional) Displays JSON output.
-o	--hostname	(Optional) Defines the database host name. The default is `Local host name`.
-p	--syspassword	Defines a strong password for SYS. Specify `-p` with no password. You will be prompted for the password. If you must provide the password in the command, for example in a script, use `-hp <password>` instead of `-p`.
-s	--dbshape	Defines the database sizing template to use for the database. For example, odb1, odb2, and odb3. For more information, see Database Sizing Templates.
-sn	--servicename	Defines the database service name used to build the EZCONNECT string for connecting to the database. The connect string format is `hostname:port/servicename`.

Parameter	Full Name	Description
-t	--dbtype	(Optional) Defines the Database Type as single node (SI). The default value is SI.
-tp	--tdeWalletPassword	(Optional) Password for TDE wallet. Required if TDE is enabled on the migrated database.

EXAMPLE

The following command registers the database with the specified database class, service name, and database sizing template.

```
[root@dbsys ~]# dbcli register-database -c OLTP -s odb1 -sn crmdb.example.com -p
Password for SYS:
{
  "jobId" : "317b430f-ad5f-42ae-bb07-13f053d266e2",
  "status" : "Created",
  "message" : null,
  "reports" : [ ],
  "createTimestamp" : "August 08, 2016 05:55:49 AM EDT",
  "description" : "Database service registration with db service name: crmdb.example.com",
  "updatedTime" : "August 08, 2016 05:55:49 AM EDT"
}
```

DBCLI UPDATE-DATABASE

Use the `dbcli update-database` command to associate a backup configuration with a database.

SYNTAX

```
dbcli update-database -i <db_id> -bi <bkup_config_id> -bin <bkup_config_name> [-id <id>] -in <name> [-
no-ab] [-h] [-j]
```

PARAMETERS

Parameter	Full Name	Description
-bi	--backupconfigid	Defines the backup configuration ID. Use the `dbcli list-backupconfigs` command to get the ID.
-bin	--backupconfigname	Defines the backup configuration name for future use. Use the `dbcli list-backupconfigs` command to get the name.
-id	--databaseid	(Optional.) Specifies the DBID, which is a unique 32-bit identification number computed when the database is created. RMAN displays the DBID upon connection to the target database. You can obtain the DBID by querying the V$DATABASE view or the RC_DATABASE and RC_DATABASE_INCARNATION recovery catalog views.
-in	--dbName	Defines the database name to be updated. Use the `dbcli list-databases` command to get the database name.
-h	--help	(Optional) Displays help for using the command.
-i	--dbid	Defines the database ID to be updated. Use the `dbcli list-databases` command to get the database ID.

Parameter	Full Name	Description
-j	--json	(Optional) Displays JSON output.
-no-ab	--noautobackup	(Optional) Disables automatic backups for the specified database. **Note** Once disabled, automatic backup cannot be re-enabled using the CLI. To re-enable automatic backup, use the Console.

EXAMPLE

The following command associates a backup configuration file with a database:

```
[root@dbsys ~]# dbcli update-database -bi 78a2a5f0-72b1-448f-bd86-cf41b30b64ee -i 71ec8335-113a-46e3-b81f-235f4d1b6fde
{
  "jobId" : "2b104028-a0a4-4855-b32a-b97a37f5f9c5",
  "status" : "Created",
  "message" : null,
  "reports" : [ ],
  "createTimestamp" : 1467775842977,
  "description" : "update database id:71ec8335-113a-46e3-b81f-235f4d1b6fde",
  "updatedTime" : 1467775842978
}
```

Dbhome Commands

The following commands are available to manage database homes:

- dbcli create-dbhome
- dbcli describe-dbhome

- dbcli delete-dbhome
- dbcli list-dbhomes
- dbcli update-dbhome

DBCLI CREATE-DBHOME

Use the `dbcli create-dbhome` command to create an Oracle Database Home.

SYNTAX

```
dbcli create-dbhome -v <version> [-h] [-j]
```

PARAMETERS

Parameter	Full Name	Description
-h	--help	(Optional) Displays help for using the command.
-j	--json	(Optional) Displays JSON output.
-v	--version	Defines the Database Home version. Specify one of the supported versions: • 18.1.0.0 • 12.2.0.1 • 12.1.0.2 • 11.2.0.4

EXAMPLE

The following command creates an Oracle Database Home version 12.1.0.2:

```
[root@dbsys ~]# dbcli  create-dbhome -v 12.1.0.2
```

DBCLI DESCRIBE-DBHOME

Use the `dbcli describe-dbhome` command to display Oracle Database Home details.

SYNTAX

```
dbcli describe-dbhome -i <db_home_id> [-h] [-j]
```

PARAMETERS

Parameter	Full Name	Description
-h	--help	(Optional) Displays help for using the command.
-i	--dbhomeid	Identifies the database home ID. Use the `dbcli list-dbhomes` command to get the ID.
-j	--json	(Optional) Displays JSON output.

EXAMPLE

The following output is an example of using the display Oracle Database Home details command.

```
[root@dbsys ~]# dbcli describe-dbhome -i 52850389-228d-4397-bbe6-102fda65922b

DB Home details
------------------------------------------------------------
                     ID: 52850389-228d-4397-bbe6-102fda65922b
                   Name: OraDB12102_home1
                Version: 12.1.0.2
          Home Location: /u01/app/oracle/product/12.1.0.2/dbhome_1
                Created: June 29, 2016 4:36:31 AM UTC
```

DBCLI DELETE-DBHOME

Use the `dbcli delete-dbhome` command to delete a database home from the DB system.

SYNTAX

```
dbcli delete-dbhome -i <db_home_id> [-h] [-j]
```

PARAMETERS

Parameter	Full Name	Description
-h	--help	(Optional) Displays help for using the command.
-i	--dbhomeid	Identifies the database home ID to be deleted. Use the `dbcli list-dbhomes` command to get the ID.
-j	--json	(Optional) Displays JSON output.

DBCLI LIST-DBHOMES

Use the `dbcli list-dbhomes` command to display a list of Oracle Home directories.

SYNTAX

```
dbcli list-dbhomes [-h] [-j]
```

PARAMETER

Parameter	Full Name	Description
-h	--help	(Optional) Displays help for using the command.
-j	--json	(Optional) Displays JSON output.

EXAMPLE

The following command displays a list of Oracle Home directories.

```
[root@dbsys ~]# dbcli  list-dbhomes
ID                                   Name                DB Version Home Location
------------------------------------ ------------------  ---------- ------------------------------------
-----
b727bf80-c99e-4846-ac1f-28a81a725df6 OraDB12102_home1   12.1.0.2
/u01/app/orauser/product/12.1.0.2/dbhome_1
```

DBCLI UPDATE-DBHOME

Tip

Your DB system might not include this newer command. If you have trouble running the command, use the cliadm update-dbcli command to update the database CLI and then retry the command.

Use the `dbcli update-dbhome` command to apply the DBBP bundle patch to a database home. For more information about applying patches, see Patching a DB System.

SYNTAX

```
dbcli update-dbhome -i <db_home_id> -n <node> [--local] [--precheck] [-h] [-j]
```

PARAMETERS

Parameter	Full Name	Description
-h	--help	(Optional) Displays help for using the command.
-i	--dbhomeid	The ID of the database home. Use the `dbcli list-dbhomes` command to get the ID.
-j	--json	(Optional) Displays JSON output.
-n	--node	(Optional) Node number to be updated. Use the `dbcli list-nodes` command to get the node number.
	--local	(Optional) Performs the operation on the local node of a multi-node high availability (HA) system. This parameter is not needed to perform the operation on a single-node system.
	--precheck	(Optional) Runs precheck operations to check prerequisites.

EXAMPLE

The following commands update the database home and show the output from the update job:

```
[root@dbsys ~]# dbcli update-dbhome -i e1877dac-a69a-40a1-b65a-d5e190e671e6
{
  "jobId" : "493e703b-46ef-4a3f-909d-bbd123469bea",
  "status" : "Created",
  "message" : null,
  "reports" : [ ],
  "createTimestamp" : "January 19, 2017 10:03:21 AM PST",
  "resourceList" : [ ],
  "description" : "DB Home Patching: Home Id is e1877dac-a69a-40a1-b65a-d5e190e671e6",
  "updatedTime" : "January 19, 2017 10:03:21 AM PST"
}

# dbcli describe-job -i 493e703b-46ef-4a3f-909d-bbd123469bea

Job details
----------------------------------------------------------------
                     ID:  493e703b-46ef-4a3f-909d-bbd123469bea

Dbstorage Commands

The following commands are available to manage database storage:

- dbcli list-dbstorages
- dbcli describe-dbstorage
- dbcli create-dbstorage
- dbcli delete-dbstorage

DBCLI LIST-DBSTORAGES

Use the `dbcli list-dbstorages` command to list the database storage in the DB system.

SYNTAX

```
dbcli list-dbstorages [-h] [-j]
```

PARAMETERS

Parameter	Full Name	Description
-h	--help	(Optional) Displays help for using the command.
-j	--json	(Optional) Displays JSON output.

EXAMPLE

The following command displays details about database storage:

```
[root@dbsys ~]# dbcli list-dbstorages

ID                                       Type   DBUnique Name        Status
---------------------------------------- ------ -------------------- ----------
afb4a1ce-d54d-4993-a149-0f28c9fb33a4     Acfs   db1_2e56b3a9b815     Configured
d81e8013-4551-4d10-880b-d1a796bca1bc     Acfs   db11xp               Configured
```

DBCLI DESCRIBE-DBSTORAGE

Use the `dbcli describe-dbstorage` command to show detailed information about a specific database storage resource.

SYNTAX

```
dbcli describe-dbstorage -i <db_storage_id> [-h] [-j]
```

PARAMETERS

Parameter	Full Name	Description
-h	--help	(Optional) Displays help for using the command.
-i	--id	Defines the database storage ID. Use the `dbcli list-dbstorages` command to get the database storage ID.
-j	--json	(Optional) Displays JSON output.

EXAMPLE

The following command displays the database storage details for 105a2db2-625a-45ba-8bdd-ee46da0fd83a:

```
[root@dbsys ~]# dbcli describe-dbstorage -i 105a2db2-625a-45ba-8bdd-ee46da0fd83a

DBStorage details
----------------------------------------------------------------

                     ID: 105a2db2-625a-45ba-8bdd-ee46da0fd83a
                DB Name: db1
          DBUnique Name: db1
         DB Resource ID: 439e7bd7-f717-447a-8046-08b5f6493df0
           Storage Type:
          DATA Location: /u02/app/oracle/oradata/db1
          RECO Location: /u03/app/oracle/fast_recovery_area/
          REDO Location: /u03/app/oracle/redo/
                  State: ResourceState(status=Configured)
                Created: July 3, 2016 4:19:21 AM UTC
            UpdatedTime: July 3, 2016 4:41:29 AM UTC
```

DBCLI CREATE-DBSTORAGE

Use the `dbcli create-dbstorage` command to create the database storage layout without creating the complete database. This is useful for database migration and standby database

creation.

SYNTAX

```
dbcli create-dbstorage -n <db_name> [-u <db_unique_name>] [-r {ACFS|ASM}] [-s <datasize>] [-h] [-j]
```

PARAMETERS

Parameter	Full Name	Description
-h	--help	(Optional) Displays help for using the command.
-j	--json	(Optional) Displays JSON output.
-n	--dbname	Defines the database name. The database name must begin with an alphabetic character and can contain a maximum of eight alphanumeric characters. Special characters are not permitted.
-r	--dbstorage	(Optional) Defines the type of database storage as ACFS or ASM. The default value is ASM.
-s	--dataSize	(Optional) Defines the data size in GBs. The minimum size is 10GB. The default size is 100GB.
-u	--databaseUniqueName	(Optional) Defines the unique name for the database. The default is the database name specified in `--dbname`.

EXAMPLE

The following command creates database storage with a storage type of ACFS:

```
[root@dbsys ~]# dbcli create-dbstorage -r ACFS -n testdb -u testdbname

{
  "jobId" : "5884a77a-0577-414f-8c36-1e9d8a1e9cee",
  "status" : "Created",
  "message" : null,
  "reports" : [ ],
```

```
  "createTimestamp" : 1467952215102,
  "description" : "Database storage service creation with db name: testdb",
  "updatedTime" : 1467952215103
}
```

DBCLI DELETE-DBSTORAGE

Use the `dbcli delete-dbstorage` command to delete database storage that is not being used by the database. A error occurs if the resource is in use.

SYNTAX

```
dbcli delete-dbstorage -i <dbstorageID> [-h] [-j]
```

PARAMETERS

Parameter	Parameter	Description
-h	--help	(Optional) Displays help for using the command.
-i	--id	The database storage ID to delete. Use the `dbcli list-dbstorages` command to get the database storage ID.
-j	--json	(Optional) Displays JSON output.

EXAMPLE

The following command deletes the specified database storage:

```
[root@dbsys ~]# dbcli delete-dbstorage -i f444dd87-86c9-4969-a72c-fb2026e7384b

{
  "jobId" : "467c9388-18c6-4e1a-8655-2fd3603856ef",
  "status" : "Running",
  "message" : null,
  "reports" : [ ],
  "createTimestamp" : 1467952336843,
  "description" : "Database storage service deletion with id: f444dd87-86c9-4969-a72c-fb2026e7384b",
  "updatedTime" : 1467952336856
}
```

Dgconfig Commands

DBCLI LIST-DGCONFIGS

Use the `dbcli list-dgconfigs` command to list DG configurations.

SYNTAX

```
dbcli list-dgconfigs [-h] [-j]
```

PARAMETERS

Parameter	Full Name	Description
-h	--help	(Optional) Displays help for using the command.
-j	--json	(Optional) Displays JSON output.

Featuretracking Commands

DBCLI LIST-FEATURETRACKING

Use the `dbcli list-featuretracking` command to list tracked features.

SYNTAX

```
dbcli list-featuretracking[-h] [-j]
```

PARAMETERS

Parameter	Full Name	Description
-h	--help	(Optional) Displays help for using the command.
-j	--json	(Optional) Displays JSON output.

Job Commands

The following commands are available to manage jobs:

- dbcli describe-job
- dbcli list-jobs

DBCLI DESCRIBE-JOB

Use the `dbcli describe-job` command to display details about a specific job.

SYNTAX

```
dbcli describe-job -i <job_id> [-h] [-j]
```

PARAMETERS

Parameter	Full Name	Description
-h	--help	(Optional) Displays help for using the command.
-i	--jobid	Identifies the job. Use the `dbcli list-jobs` command to get the jobid.
-j	--json	(Optional) Displays JSON output.

EXAMPLE

The following command displays details about the specified job ID:

```
[root@dbsys ~]# dbcli describe-job -i 74731897-fb6b-4379-9a37-246912025c17

Job details
----------------------------------------------------------------
                     ID:  74731897-fb6b-4379-9a37-246912025c17
            Description:  Backup service creation with db name: dbtst
                 Status:  Success
                Created:  November 18, 2016 8:33:04 PM UTC
                Message:

Task Name                                Start Time                          End Time
        Status
---------------------------------------- ----------------------------------- ---------------------------

PM UTC    Success
```

DBCLI LIST-JOBS

Use the `dbcli list-jobs` command to display a list of jobs, including the job IDs, status, and the job

created date and time stamp.

SYNTAX

```
dbcli list-jobs [-h] [-j]
```

PARAMETERS

Parameter	Full Name	Description
-h	--help	(Optional) Displays help for using the command.
-j	--json	(Optional) Displays JSON output.

EXAMPLE

The following command displays a list of jobs:

```
[root@dbsys ~]# dbcli list-jobs

ID                                       Description
            Created                             Status
---------------------------------------- --------------------------------------------------------------------
------------ ---------------------------------- ----------

```

Latestpatch Command

DBCLI DESCRIBE-LATESTPATCH

Tip

Your DB system might not include this newer command. If you have trouble running the command, use the cliadm update-dbcli command to update the database CLI and then retry the command.

Note

The `dbcli describe-latestpatch` command is not available on 2-node RAC DB systems. Patching 2-node systems from Object Storage is not supported.

Use the `dbcli describe-latestpatch` command show the latest patches applicable to the DB system and available in Oracle Cloud Infrastructure Object Storage.

This command requires a valid Object Storage credentials configuration. Use the dbcli create-bmccredential command to create the configuration if you haven't already done so. If the configuration is missing or invalid, the command fails with the error: `Failed to connect to the object store. Please provide valid details.`

For more information about updating the CLI, creating the credentials configuration, and applying patches, see Patching a DB System.

SYNTAX

```
dbcli describe-latestpatch [-h] [-j]
```

PARAMETERS

Parameter	Full Name	Description
-h	--help	(Optional) Displays help for using the command.
-j	--json	(Optional) Displays JSON output.

EXAMPLE

The following command displays patches available in the object store:

```
[root@dbsys ~]# dbcli describe-latestpatch

componentType   availableVersion
--------------- --------------------
gi              12.1.0.2.161018
db              11.2.0.4.161018
db              12.1.0.2.161018
oak             12.1.2.10.0
```

Logcleanjob Commands

The following commands are available to manage log cleaning jobs:

- dbcli create-logCleanJob
- dbcli describe-logCleanJob
- dbcli list-logCleanJobs

DBCLI CREATE-LOGCLEANJOB

Use the `dbcli create-logCleanJob` command to create a log cleaning job.

SYNTAX

```
dbcli create-logCleanJob [-c {gi|database|dcs}] [-o <number>] [u {Day|Hour|Minute}] [-h] [-j]
```

PARAMETERS

Parameter	Full Name	Description
-c	--components	(Optional) Components. Possible values are gi, database, and dcs. Separate multiple values by commas.
-h	--help	(Optional) Displays help for using the command.
-j	--json	(Optional) Displays JSON output.
-o	--olderThan	(Optional) Quantity portion of time interval. Default: 30. Cleans logs older than the specified time interval (`-o` and `-u`).
-u	--unit	(Optional) Unit portion of time interval. Possible values: Day, Hour, or Minute. Default: Day. Cleans logs older than the specified time interval (`-o` and `-u`).

DBCLI DESCRIBE-LOGCLEANJOB

Use the `dbcli describe-logCleanJob` command to display the summary for a log cleaning job.

SYNTAX

```
dbcli describe-logCleanJob -i <job_id> [-h] [-j]
```

PARAMETERS

Parameter	Full Name	Description
-h	--help	(Optional) Displays help for using the command.
-i	--jobid	ID of log cleaning job for which to display the summary.
-j	--json	(Optional) Displays JSON output.

DBCLI LIST-LOGCLEANJOBS

Use the `dbcli list-logCleanJobs` command to list log cleaning jobs.

SYNTAX

```
dbcli list-logCleanJobs [-h] [-j]
```

PARAMETERS

Parameter	Full Name	Description
-h	--help	(Optional) Displays help for using the command.
-j	--json	(Optional) Displays JSON output.

Logspaceusage Command

DBCLI LIST-LOGSPACEUSAGE

Use the `dbcli list-logSpaceUsage` command to list log space usage.

SYNTAX

```
dbcli list-logSpaceUsage [-c {gi|database|dcs}] [-h] [-j]
```

PARAMETERS

Parameter	Full Name	Description
-c	--components	(Optional) Components. Possible values: gi, database, and dcs. Separate multiple values by commas.
-h	--help	(Optional) Displays help for using the command.
-j	--json	(Optional) Displays JSON output.

Netsecurity Commands

The following commands are available to manage network encryption on the DB system:

- dbcli describe-netsecurity
- dbcli update-netsecurity

DBCLI DESCRIBE-NETSECURITY

Use the `dbcli describe-netsecurity` command to display the current network encryption setting for a database home.

SYNTAX

```
dbcli describe-netsecurity -H <db_home_id> [-h] [-j]
```

PARAMETERS

Parameter	Full Name	Description
-H	--dbHomeId	Defines the database home ID. Use the `dbcli list-dbhomes` command to get the dbhomeid.
-h	--help	(Optional) Displays help for using the command.
-j	--json	(Optional) Displays JSON output.

EXAMPLE

The following command displays the encryption setting for specified database home:

```
[root@dbsys ~]# dbcli describe-netsecurity -H 16c96a9c-f579-4a4c-a645-8d4d22d6889d

NetSecurity Rules
-----------------------------------------------------------------
         DatabaseHomeID: 16c96a9c-f579-4a4c-a645-8d4d22d6889d

                   Role: Server
   EncryptionAlgorithms: AES256 AES192 AES128
    IntegrityAlgorithms: SHA1
         ConnectionType: Required

                   Role: Client
   EncryptionAlgorithms: AES256 AES192 AES128
```

```
    IntegrityAlgorithms: SHA1
         ConnectionType: Required
```

DBCLI UPDATE-NETSECURITY

Use the `dbcli update-netsecurity` command to update the Oracle Net security configuration on the DB system.

SYNTAX

```
dbcli update-netsecurity {-c|-s} -t {REJECTED|ACCEPTED|REQUESTED|REQUIRED} -H db_home_id> -e
{AES256|AES192|AES128} -i {SHA1|SHA512|SHA384|SHA256} [-h] [-j]
```

PARAMETERS

Parameter	Full Name	Description
-c	--client	Indicates that the specified data encryption or data integrity configuration is for the client. (`--client` and `--server` are mutually exclusive.)
-e	--encryptionAlgorithms	Defines the algorithm to be used for encryption. Specify either AES256, AES192, or AES128.
-H	--dbHomeId	Defines the database home ID. Use the `dbcli list-dbhomes` command to get the dbHomeId.
-h	--help	(Optional) Displays help for using the command.
-i	--integrityAlgorithms	Defines the algorithm to be used for integrity. Specify either SHA1, SHA512, SHA384, or SHA256. For Oracle Database 11g, the only accepted value is SHA1.
-j	--json	(Optional) Displays JSON output.

Parameter	Full Name	Description
-s	--server	Indicates that the specified data encryption or data integrity configuration is for the server. (`--client` and `--server` are mutually exclusive.)
-t	--connectionType	Specifies how Oracle Net Services data encryption or data integrity is negotiated with clients. The following values are listed in the order of increasing security: REJECTED - Do not enable data encryption or data integrity, even if required by the client. ACCEPTED - Enable data encryption or data integrity if required or requested by the client. REQUESTED - Enable data encryption or data integrity if the client permits it. REQUIRED - Enable data encryption or data integrity or preclude the connection. For detailed information about network data encryption and integrity, see https://docs.oracle.com/database/121/DBSEG/asoconfg.htm#DBSEG1047.

EXAMPLE

The following command updates the connection type to ACCEPTED:

```
[root@dbsys ~]# dbcli update-netsecurity -H a2ffbb07-c9c0-4467-a458-bce4d3b76cd5 -t ACCEPTED
```

Node Command

DBCLI LIST-NODES

Use the `dbcli list-nodes` command to display a list of nodes, including the node numbers.

SYNTAX

```
dbcli list-nodes [-h] [-j]
```

PARAMETERS

Parameter	Full Name	Description
-h	--help	(Optional) Displays help for using the command.
-j	--json	(Optional) Displays JSON output.

EXAMPLE

The following command displays a list of nodes:

```
[root@dbsys ~]# dbcli list-nodes
node Number node Name                                ilom Name            IP Address          Subnet              Mask Gate
---------- ---------------------------------------- -------------------- ------------------- ------------
------ ------------------
0          rac21                                     N/A                  N/A                 N/A                 N/A
1          rac22                                     N/A                  N/A                 N/A                 N/A
```

Objectstoreswift Commands

You can back up a database to an existing bucket in the Oracle Cloud Infrastructure Object Storage service by using the dbcli create-backup command, but first you'll need to:

1. Create an object store on the DB system, which contains the endpoint and credentials to access Object Storage, by using the dbcli create-objectstoreswift command.
2. Create a backup configuration that refers to the object store ID and the bucket name by using the dbcli create-backupconfig command.
3. Associate the backup configuration with the database by using the dbcli update-database command.

The following commands are available to manage object stores.

- dbcli create-objectstoreswift
- dbcli describe-objectstoreswift
- dbcli list-objectstoreswifts

DBCLI CREATE-OBJECTSTORESWIFT

Use the `dbcli create-objectstoreswift` command to create an object store.

SYNTAX

```
dbcli create-objectstoreswift -n <object_store_name> -t <tenant_name> -u <user_name> -e
https://swiftobjectstorage.<region_name>.oraclecloud.com/v1 -p [-h] [-j]
```

PARAMETERS

Parameter	Full Name	Description
-e	--endpointurl	The following endpoint URL. `https://swiftobjectstorage.<region_name>.oraclecloud.com/v1` See Regions and Availability Domains for region name strings.
-h	--help	(Optional) Displays help for using the command.
-j	--json	(Optional) Displays JSON output.
-n	--name	The name for the object store to be created.

Parameter	Full Name	Description
-p	--swiftpassword	The auth token that you generated by using the Console or IAM API. For information about generating an auth token for use with Swift, see Managing User Credentials. This is **not** the password for the Oracle Cloud Infrastructure user. Specify `-p` (with no password) to be prompted. Specify `-hp "<password>"` in quotes to provide the password (auth token) in the command.
-t	--tenantname	The case-sensitive tenant name that you specify when signing in to the Console.
-u	--username	The user name for the Oracle Cloud Infrastructure user account, for example: `-u djones@example.com` This is the user name you use to sign in to the Console. The user name must have tenancy-level access to the Object Storage. An easy way to do this is to add the user name to the Administrators group. However, that allows access to *all* of the cloud services. Instead, an administrator can create a policy that allows tenancy-level access to just Object Storage. The following is an example of such a policy. `Allow group DBAdmins to manage buckets in tenancy` `Allow group DBAdmins to manage objects in tenancy` For more information about adding a user to a group, see Managing Groups. For more information about policies, see Getting Started with Policies.

EXAMPLE

The following command creates an object store and prompts for the Swift password:

```
[root@dbsys ~]# dbcli create-objectstoreswift -n r2swift -t CompanyABC -u djones@example.com -e
https://swiftobjectstorage.<region_name>.oraclecloud.com/v1 -p
Password for Swift:
{
  "jobId" : "c565bb71-f67b-4fab-9d6f-a34eae36feb7",
  "status" : "Created",
  "message" : "Create object store swift",
  "reports" : [ ],
  "createTimestamp" : "January 19, 2017 11:11:33 AM PST",
  "resourceList" : [ {
    "resourceId" : "8a0fe039-f5d4-426a-8707-256c612b3a30",
    "resourceType" : "ObjectStoreSwift",
    "jobId" : "c565bb71-f67b-4fab-9d6f-a34eae36feb7",
    "updatedTime" : "January 19, 2017 11:11:33 AM PST"
  } ],
  "description" : "create object store:biyanr2swift",
  "updatedTime" : "January 19, 2017 11:11:33 AM PST"
}
```

DBCLI DESCRIBE-OBJECTSTORESWIFT

Use the `dbcli describe-objectstoreswift` command to display details about an object store.

SYNTAX

```
dbcli describe-objectstoreswift -i <object_store_swift_id> -in <object_store_swift_name> [-h] [-j]
```

PARAMETERS

Parameter	Full Name	Description
-h	--help	(Optional) Displays help for using the command.
-i	--objectstoreswiftid	The object store ID. Use the `dbcli list-objectstoreswifts` command to get the ID.

Parameter	Full Name	Description
-in	--objectstoreswiftName	The object store name. Use the `dbcli list-objectstoreswifts` command to get the name.
-j	--json	(Optional) Displays JSON output.

EXAMPLE

The following command displays details about an object store:

```
[root@dbsys ~]# dbcli describe-objectstoreswift -i 910e9e2d-25b4-49b4-b88e-ff0332f7df87
Object Store details
----------------------------------------------------------------
                     ID: 910e9e2d-25b4-49b4-b88e-ff0332f7df87
                   Name: objstrswift15
               UserName: djones@example.com
             TenantName: CompanyABC
           endpoint URL: https://swiftobjectstorage.<region_name>.oraclecloud.com/v1
            CreatedTime: November 16, 2016 11:25:34 PM UTC
            UpdatedTime: November 16, 2016 11:25:34 PM UTC
```

DBCLI LIST-OBJECTSTORESWIFTS

Use the `dbcli list-objectstoreswifts` command to list the object stores on a DB system.

SYNTAX

```
dbcli list-objectstoreswifts [-h] [-j]
```

PARAMETERS

Parameter	Full Name	Description
-h	--help	(Optional) Displays help for using the command.
-j	--json	(Optional) Displays JSON output.

EXAMPLE

The following command lists the object stores on the DB system:

```
[root@dbsys ~]# dbcli list-objectstoreswifts

ID                                       Name                 UserName              TenantName     Url
                                                          createTime
---------------------------------------- -------------------- --------------------  -------------- -----
- -------------------------------------------------- ----------------------------------

https://swiftobjectstorage.<region_name>.oraclecloud.com/v1 November 10, 2016 8:42:18 PM UTC
910e9e2d-25b4-49b4-b88e-ff0332f7df87     objstrswift15        djones@example.com    LargeComputers
https://swiftobjectstorage.<region_name>.oraclecloud.com/v1 November 16, 2016 11:25:34 PM UTC
```

Pendingjob Command

DBCLI LIST-PENDINGJOBS

Use the `dbcli list-pendingjobs` command to display a list of pending jobs.

SYNTAX

```
dbcli list-pendingjobs [-h] [-j]
```

PARAMETERS

Parameter	Full Name	Description
-h	--help	(Optional) Displays help for using the command.
-j	--json	(Optional) Displays JSON output.

Rmanbackupreport Commands

The following commands are available to manage RMAN backup reports:

- dbcli create-rmanbackupreport
- dbcli delete-rmanbackupreport
- dbcli describe-rmanbackupreport
- dbcli list-rmanbackupreports

DBCLI CREATE-RMANBACKUPREPORT

Use the `dbcli create-rmanbackupreport` command to create an RMAN backup report.

SYNTAX

```
dbcli create-rmanbackupreport -w {summary|detailed} -rn <name> [-i <db_id>] [-in <db_name>] [-h] [-j]
```

PARAMETERS

Parameter	Full Name	Description
-h	--help	(Optional) Displays help for using the command.
-i	--dbid	(Optional) Database resource ID.
-in	--dbname	(Optional) Database resource name.
-j	--json	(Optional) Displays JSON output.
-rn	--rptname	RMAN backup report name. Maximum number of characters: 30. Wrap name in single quotes when special characters are used.
-w	--reporttype	RMAN backup report type. Possible values: summary or detailed.

DBCLI DELETE-RMANBACKUPREPORT

Use the `dbcli delete-rmanbackupreport` command to delete an RMAN backup report.

SYNTAX

```
dbcli delete-rmanbackupreport [-d <db_id>] [-dn <db_name>] [-n <number>] [-i <rpt_id>] [-in <rpt_name>]
[-h] [-j]
```

PARAMETERS

Parameter	Full Name	Description
-d	--dbid	(Optional) Database resource ID.
-dn	--dbname	(Optional) Database resource name.
-h	--help	(Optional) Displays help for using the command.
-i	--reportid	(Optional) RMAN backup report ID
-in	--rptname	(Optional) RMAN backup report name
-j	--json	(Optional) Displays JSON output.
-n	--numofday	(Optional) Number of days since created (provided with Database ID/Database Name)

DBCLI DESCRIBE-RMANBACKUPREPORT

Use the `dbcli describe-rmanbackupreport` command to

SYNTAX

```
dbcli describe-rmanbackupreport [-i <rpt_id>] [-in <rpt_name>] [-h] [-j]
```

PARAMETERS

Parameter	Full Name	Description
-h	--help	(Optional) Displays help for using the command.
-i	--id	(Optional) RMAN backup report ID
-in	--name	(Optional) RMAN backup report name
-j	--json	(Optional) Displays JSON output.

DBCLI LIST-RMANBACKUPREPORTS

Use the `dbcli list-rmanbackupreports` command to

SYNTAX

```
dbcli list-rmanbackupreports [-i <db_id>] [-in <db_name>] [-h] [-j]
```

PARAMETERS

Parameter	Full Name	Description
-h	--help	(Optional) Displays help for using the command.
-i	--dbid	(Optional) Database resource ID.
-in	--dbName	(Optional) Database resource name.
-j	--json	(Optional) Displays JSON output.

Schedule Commands

The following commands are available to manage schedules:

- dbcli describe-schedule
- dbcli list-schedules
- dbcli update-schedule

DBCLI DESCRIBE-SCHEDULE

Use the `dbcli describe-schedule` command to describe a schedule.

SYNTAX

```
dbcli describe-schedule -i <id> [-h] [-j]
```

PARAMETERS

Parameter	Full Name	Description
-h	--help	(Optional) Displays help for using the command.
-i	--scheduleid	Schedule ID.
-j	--json	(Optional) Displays JSON output.

DBCLI LIST-SCHEDULES

Use the `dbcli list-schedules` command to list schedules.

SYNTAX

```
dbcli list-schedules [-h] [-j]
```

PARAMETERS

Parameter	Full Name	Description
-h	--help	(Optional) Displays help for using the command.
-j	--json	(Optional) Displays JSON output.

DBCLI UPDATE-SCHEDULE

Use the `dbcli update-schedule` command to update a schedule.

SYNTAX

```
dbcli update-schedule -i <id> [-x <expression>] [-t <description>] [-d] [-e] [-h] [-j]
```

PARAMETERS

Parameter	Full Name	Description
-d	--disable	(Optional) Disables the schedule.
-e	--enable	(Optional) Enables the schedule.
-h	--help	(Optional) Displays help for using the command.
-i	--scheduleid	Schedule ID.
-j	--json	(Optional) Displays JSON output.
-t	--description	(Optional) Description
-x	--cronExpression	(Optional) Cron expression. Use cronmaker.com to generate a valid cron expression.

Scheduledexecution Command

DBCLI LIST-SCHEDULEDEXECUTIONS

Use the `dbcli list-scheduledExecutions` command to list scheduled executions.

SYNTAX

```
dbcli list-scheduledExecutions [-e <execution_id>] [-i <schedule_id>] [-h] [-j]
```

PARAMETERS

Parameter	Full Name	Description
-e	--executionid	(Optional) Execution ID.
-h	--help	(Optional) Displays help for using the command.

Parameter	Full Name	Description
-i	--scheduleid	(Optional) Schedule ID.
-j	--json	(Optional) Displays JSON output.

Server Command

DBCLI UPDATE-SERVER

Tip

Your DB system might not include this newer command. If you have trouble running the command, use the cliadm update-dbcli command to update the database CLI and then retry the command.

Use the `dbcli update-server` command to apply patches to the server components in the DB system. For more information about applying patches, see Patching a DB System.

SYNTAX

```
dbcli update-server [-n <number>] [--local] [--precheck] [-h] [-j]
```

PARAMETERS

Parameter	Full Name	Description
-h	--help	(Optional) Displays help for using the command.
-j	--json	(Optional) Displays JSON output.

Parameter	Full Name	Description
-l	--local	(Optional) Performs the operation on the local node of a multi-node high availability (HA) system. This parameter is not needed to perform the operation on a single-node system.
-n	--node	(Optional) Node number to be updated. Use the `dbcli list-nodes` command to get the node number.
-p	--precheck	(Optional) Runs precheck operations to check prerequisites.

EXAMPLES

The following commands update the server and show the output from the update job:

```
[root@dbsys ~]# dbcli update-server
{
  "jobId" : "9a02d111-e902-4e94-bc6b-9b820ddf6ed8",
  "status" : "Created",

  "description" : "Server Patching Prechecks",
  "updatedTime" : "April 26, 2019 06:07:27 AM UTC"
}
```

System Command

DBCLI DESCRIBE-SYSTEM

Use the `dbcli describe-system` command to display details about the system. On a 2-node RAC DB system, the command provides information about the local node.

SYNTAX

```
dbcli describe-system [-b] [-d] [-h] [-j]
```

PARAMETERS

Parameter	Full Name	Description
-b	--bom	(Optional) Displays BOM information.
-d	--details	(Optional) Displays additional information about the DB system, including dcs CLI and agent version information.
-h	--help	(Optional) Displays help for using the command.
-j	--json	(Optional) Displays JSON output.

TDE Commands

The following commands are available to manage TDE-related items (backup reports, keys, and wallets):

- dbcli list-tdebackupreports
- dbcli update-tdekey
- dbcli recover-tdewallet

DBCLI LIST-TDEBACKUPREPORTS

Use the `dbcli list-tdebackupreports` command to list backup reports for TDE wallets.

SYNTAX

```
dbcli  list-tdebackupreports [-i <db_id>] [-in <db_name>] [-h] [-j]
```

PARAMETERS

Parameter	Full Name	Description
-h	--help	(Optional) Displays help for using the command.
-i	--dbResid	(Optional) Displays the TDE Wallet backup reports for the specified database resource ID. Use the `dbcli list-databases` command to get the database resource ID.
-in	--dbResname	(Optional) Displays the TDE Wallet backup reports for the specified database resource name. Use the `dbcli list-databases` command to get the database resource name.
-j	--json	(Optional) Displays JSON output.

EXAMPLE

The following command lists the backup reports for TDE wallets:

```
[root@dbsys ~]# dbcli list-tdebackupreports
DbResID                                  OraDbId                 BackupLocation

DBCLI UPDATE-TDEKEY

Use the `dbcli update-tdekey` command to update the TDE encryption key inside the TDE wallet. You can update the encryption key for Pluggable Databases (if -pdbNames are

specified), and/or the Container Database (if -rootDatabase is specified).

SYNTAX

```
dbcli update-tdekey -i <db_id> -p [-all] -n <pdbname1,pdbname2> [-r|-no-r] -t <tag_name> [-h] [-j]
```

PARAMETERS

Parameter	Full Name	Description
-all	--allPdbNames	(Optional) Flag to rotate (update) all PDB names. To update all instead of specified PDB names, use this parameter instead of `-n`. Default: false.
-i	--databaseId	Defines the database ID for which to update the key.
-p	--password	Defines the TDE Admin wallet password. Specify `-p` with no password. You will be prompted for the password. If you must provide the password in the command, for example in a script, use `-hp <password>` instead of `-p`.
-n	--pdbNames	Defines the PDB names to be rotated (updated).
-r -no-r	--rootDatabase --no-rootDatabase	Indicates whether to rotate the key for the root database if it is a container database.
-t	-tagName	Defines the TagName used to backup the wallet. The default is OdaRotateKey.
-h	--help	(Optional) Displays help for using the command.
-j	--json	(Optional) Displays JSON output.

EXAMPLE

The following command updates the key for pdb1 and pdb2 only:

```
[root@dbsys ~]# dbcli update-tdekey -dbid ee3eaab6-a45b-4e61-a218-c4ba665503d9 -p -n pdb1,pdb2

TDE Admin wallet password:
{
  "jobId" : "08e5edb1-42e1-4d16-a47f-783c0afa4778",
  "status" : "Created",
  "message" : null,
  "reports" : [ ],
  "createTimestamp" : 1467876407035,
  "description" : "TDE update",
  "updatedTime" : 1467876407035
}
```

The following command updates pdb1, pdb2, and the container database:

```
[root@dbsys ~]# dbcli update-tdekey -dbid ee3eaab6-a45b-4e61-a218-c4ba665503d9 -p -n pdb1,pdb2 -r

TDE Admin wallet password:
{
  "jobId" : "c72385f0-cd81-42df-a8e8-3a1e7cab1278",
  "status" : "Created",
  "message" : null,
  "reports" : [ ],
  "createTimestamp" : 1467876433783,
  "description" : "TDE update",
  "updatedTime" : 1467876433783
}
```

DBCLI RECOVER-TDEWALLET

Use the `dbcli recover-tdewallet` command to recover a TDE wallet.

SYNTAX

```
dbcli recover-tdewallet -in <db_name> -tp <password> [-l <location>] [-h] [-j]
```

PARAMETERS

Parameter	Full Name	Description
-h	--help	(Optional) Displays help for using the command.
-in	--dbName	Database name.
-j	--json	(Optional) Displays JSON output.
-l	--tdeWalletBackuplocation	(Optional) TDE wallet backup location. TDE wallet should b ebacked up in tar.gz format.
-tp	--tdeWalletPassword	Defines the TDE Admin wallet password.

Admin Commands

The following commands are to perform administrative actions on the DB system:

- dbadmcli manage diagcollect
- dbadmcli power
- dbadmcli power disk status
- dbadmcli show controller
- dbadmcli show disk
- dbadmcli show diskgroup
- dbadmcli show env_hw (environment type and hardware version)
- dbadmcli show fs (file system details)
- dbadmcli show storage
- dbadmcli stordiag

DBADMCLI MANAGE DIAGCOLLECT

Use the `dbadmcli manage diagcollect` command to collect diagnostic information about a DB system for troubleshooting purposes, and for working with Oracle Support Services.

SYNTAX

```
dbadmcli manage diagcollect --storage [-h]
```

PARAMETERS

Parameter	Description
-h	(Optional) Displays help for using the command.
--storage	Collects all of the logs for any storage issues.

EXAMPLE

```
[root@dbsys ~]# dbadmcli manage diagcollect --storage
Collecting storage log data. It will take a while, please wait...
Collecting oak data. It will take a while, please wait...
tar: Removing leading `/' from member names
tar: /opt/oracle/oak/onecmd/tmp/OakCli-Command-Output.log: file changed as we read it

Logs are collected to : /opt/oracle/oak/log/dbsys/oakdiag/oakStorage-dbsys-20161118_2101.tar.gz
```

DBADMCLI POWER

Use the `dbadmcli power` command to power a disk on or off.

Note

The `dbadmcli power` command is not available on 2-node RAC DB systems.

SYNTAX

```
dbadmcli power {-on|-off} <name> [-h]
```

PARAMETERS

Parameter	Description
-h	(Optional) Displays help for using the command.
name	Defines the disk resource name. The resource name format is pd_[0..3]. Use the `dbadmcli show disk` command to get the disk resource name.
-off	Powers off the disk.
-on	Powers on the disk.

DBADMCLI POWER DISK STATUS

Use the `dbadmcli power disk status` command to display the current power status of a disk.

SYNTAX

```
dbadmcli power disk status <name> [-h]
```

PARAMETERS

Parameter	Description
-h	(Optional) Displays help for using the command.
name	Identifies a specific disk resource name. The resource name format is pd_[0..3]. For example, pd_01.

EXAMPLE

```
[root@dbsys ~]# dbadmcli power disk status pd_00

The disk is powered ON
```

DBADMCLI SHOW CONTROLLER

Use the `dbadmcli show controller` command to display details of the controller.

SYNTAX

```
dbadmcli show controller <controller_id> [-h]
```

PARAMETER

Parameter	Description
controller_id	The ID number of the controller. Use the `dbadmcli show storage` command to get the ID.
-h	(Optional) Displays help for using the command.

DBADMCLI SHOW DISK

Use the `dbadmcli show disk` command to display the status of a single disk or all disks on the DB system.

SYNTAX

```
dbadmcli show disk [<name>] [-shared] [-all] [-getlog] [-h]
```

PARAMETERS

Parameter	Description
-all	(Optional) Displays detailed information for the named disk.
-h	(Optional) Displays help for using the command.
-getlog	(Optional) Displays all the SMART log entries for an NVMe disk.
name	(Optional) Identifies a specific disk resource name. The resource name format is pd_[0..3]. If omitted, the command displays information about all disks on the system.
-shared	(Optional) Displays all the shared disks.

EXAMPLES

To display the status of all the disks on the system:

```
[root@dbsys ~]# dbadmcli show disk
       NAME            PATH            TYPE            STATE           STATE_DETAILS

       pd_00           /dev/nvme2n1    NVD             ONLINE          Good
       pd_01           /dev/nvme3n1    NVD             ONLINE          Good
       pd_02           /dev/nvme1n1    NVD             ONLINE          Good
       pd_03           /dev/nvme0n1    NVD             ONLINE          Good
```

To display the status of a disk named pd_00:

```
[root@dbsys ~]# dbadmcli show disk pd_00
The Resource is : pd_00
       ActionTimeout   :       1500
       ActivePath      :       /dev/nvme2n1
       AsmDiskList     :       |data_00||reco_00|
       AutoDiscovery   :       1
       AutoDiscoveryHi :       |data:70:NVD||reco:30:NVD|
       CheckInterval   :       300
       ColNum          :       0
       CriticalWarning :       0
       DependListOpr   :       add
       Dependency      :       |0|
       DiskId          :       360025380144d5332
       DiskType        :       NVD
       Enabled         :       1
       ExpNum          :       29
       HbaPortNum      :       10
       IState          :       0
       Initialized     :       0

```

DBADMCLI SHOW DISKGROUP

Use the `dbadmcli show diskgroup` command to list configured diskgroups or display a specific diskgroup configuration.

SYNTAX

To list configured diskgroups:

```
dbadmcli show diskgroup [-h]
```

To display DATA configurations:

```
dbadmcli show diskgroup [DATA] [-h]
```

To display RECO configurations:

```
dbadmcli show diskgroup [RECO] [-h]
```

PARAMETERS

Parameter	Description
DATA	(Optional) Displays the DATA diskgroup configurations.
-h	(Optional) Displays help for using the command.
RECO	(Optional) Displays the RECO diskgroup configurations.

EXAMPLES

To list all diskgroups:

```
[root@dbsys ~]# dbadmcli show diskgroup

DiskGroups
----------
DATA
RECO
```

To display DATA configurations:

```
[root@dbsys ~]# dbadmcli show diskgroup DATA

ASM_DISK       PATH                            DISK    STATE   STATE_DETAILS
data_00        /dev/NVD_S00_S2LHNAAH101026p1   pd_00   ONLINE  Good
data_01        /dev/NVD_S01_S2LHNAAH101008p1   pd_01   ONLINE  Good
```

DBADMCLI SHOW ENV_HW

Use the `dbadmcli show env_hw` command to display the environment type and hardware version of the current DB system.

SYNTAX

```
dbadmcli show env_hw [-h]
```

PARAMETER

Parameter	Description
-h	(Optional) Displays help for using the command.

DBADMCLI SHOW FS

Use the `dbadmcli show fs` command to display file system details.

SYNTAX

```
dbadmcli show fs [-h]
```

PARAMETER

Parameter	Description
-h	(Optional) Displays help for using the command.

DBADMCLI SHOW STORAGE

Use the `dbadmcli show storage` command to show the storage controllers, expanders, and disks.

SYNTAX

```
dbadmcli show storage [-h]
```

To show storage errors:

```
dbadmcli show storage -errors [-h]
```

PARAMETERS

Parameter	Description
-errors	(Optional) Shows storage errors.
-h	(Optional) Displays help for using the command.

EXAMPLE

To display storage devices:

```
[root@dbsys ~]# dbadmcli show storage
==== BEGIN STORAGE DUMP ========
Host Description: Oracle Corporation:ORACLE SERVER X5-2
Total number of controllers: 5
        Id          = 4
        Pci Slot    = -1
        Serial Num  =
        Vendor      =
        Model       =
        FwVers      =
        strId       = iscsi_tcp:00:00.0
        Pci Address = 00:00.0

        Id          = 0
        Pci Slot    = 13
        Serial Num  = S2LHNAAH504431
        Vendor      = Samsung
        Model       = MS1PC2DD3ORA3.2T
        FwVers      = KPYA8R3Q
        strId       = nvme:25:00.00
        Pci Address = 25:00.0

        Id          = 1
        Pci Slot    = 12
        Serial Num  = S2LHNAAH505449
        Vendor      = Samsung

        /dev/nvme0n1    Samsung           NVD 3200gb slot:  3  pci : 25
==== END STORAGE DUMP =========
```

DBADMCLI STORDIAG

Use the `dbadmcli stordiag` command to collect detailed information for each disk or NVM Express (NVMe).

SYNTAX

```
dbadmcli stordiag <name> [-h]
```

PARAMETERS

Parameter	Description
name	Defines the disk resource name. The resource name format is pd_[0..3].
-h	(Optional) Displays help for using the command.

EXAMPLE

To display detailed information for NVMe pd_00:

```
[root@dbsys ~]# dbadmcli stordiag pd_0
```

Database Sizing Templates

When you create a database using the `dbcli create-database` command, you can specify a database sizing template with the `--dbshape` parameter. The sizing templates are configured for different types of database workloads. Choose the template that best matches the most common workload your database performs:

- Use the OLTP templates if your database workload is primarily online transaction processing (OLTP).
- Use the DSS templates if your database workload is primarily decision support (DSS) or data warehousing.
- Use the in-memory (IMDB) templates if your database workload can fit in memory, and can benefit from in-memory performance capabilities.

The following tables describe the templates for each type of workload.

OLTP Database Sizing Templates

Template	CPU Cores	SGA (GB)	PGA (GB)	Flash (GB)	Processes	Redo Log File Size (GB)	Log Buffer (MB)
odb1s	1	2	1	6	200	1	16
odb1	1	4	2	12	200	1	16
odb2	2	8	4	24	400	1	16
odb4	4	16	8	48	800	1	32
odb6	6	24	12	72	1200	2	64
odb8	8	32	16	n/a	1600	2	64
odb10	10	40	20	n/a	2000	2	64
odb12	12	48	24	144	2400	4	64
odb16	16	64	32	192	3200	4	64
odb20	20	80	40	n/a	4000	4	64
odb24	24	96	48	192	4800	4	64
odb32	32	128	64	256	6400	4	64
odb36	36	128	64	256	7200	4	64

DSS Database Sizing Templates

Template	CPU Cores	SGA (GB)	PGA (GB)	Processes	Redo Log File Size (GB)	Log Buffer (MB)
odb1s	1	1	2	200	1	16
odb1	1	2	4	200	1	16
odb2	2	4	8	400	1	16
odb4	4	8	16	800	1	32
odb6	6	12	24	1200	2	64
odb8	8	16	32	1600	2	64
odb10	10	20	40	2000	2	64
odb12	12	24	48	2400	4	64
odb16	16	32	64	3200	4	64
odb20	20	40	80	4000	4	64
odb24	24	48	96	4800	4	64
odb32	32	64	128	6400	4	64
odb36	36	64	128	7200	4	64

IN-MEMORY DATABASE SIZING TEMPLATES

Template	CPU Cores	SGA (GB)	PGA (GB)	In-Memory (GB)	Processes	Redo Log Lile Size (GB)	Log Buffer (MB)
odb1s	1	2	1	1	200	1	16
odb1	1	4	2	2	200	1	16
odb2	2	8	4	4	400	1	16
odb4	4	16	8	8	800	1	32
odb6	6	24	12	12	1200	2	64
odb8	8	32	16	16	1600	2	64
odb10	10	40	20	20	2000	2	64
odb12	12	48	24	24	2400	4	64
odb16	16	64	32	32	3200	4	64
odb20	20	80	40	40	4000	4	64
odb24	24	96	48	48	4800	4	64
odb32	32	128	64	64	6400	4	64
odb36	36	128	64	64	7200	4	64

Storage Scaling Considerations for Virtual Machine Databases Using Fast Provisioning

Note

This topic applies only to 1-node virtual machine DB systems.

When you provision a virtual machine DB system using the fast provisioning option, the **Available storage (GB)** value you specify during provisioning determines the maximum total storage available through scaling. The following table details the maximum storage value available through scaling for each setting offered in the provisioning workflow:

Initial storage specified during provisioning (GB)	Maximum storage available through scaling (GB)
256	2560
512	2560
1024	5120
2048	10240
4096	20480
8192	40960

For more information on creating a virtual machine DB system, see Creating Bare Metal and Virtual Machine DB Systems.

Database Metrics

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure Database service resources by using metrics, alarms, and notifications. For more

information, see Monitoring Overview and Notifications Overview.

Note

Database metrics are currently available only for Autonomous Databases in serverless deployments.

This topic describes the metrics emitted by the Database service in the `oci_autonomous_database` namespace.

Resources: Autonomous Databases.

Overview of the Autonomous Database Metrics

The Database service metrics help you measure useful quantitative data about your Autonomous Databases, such as CPU and storage utilization, the number of successful and failed database logon and connection attempts, database operations, SQL queries, and transactions, and so on. You can use metrics data to diagnose and troubleshoot problems with Autonomous Databases. For a complete list of available metrics for Autonomous Databases, see Available Metrics: oci_autonomous_database.

To view a default set of metrics charts in the Console, navigate to the Autonomous Database that you're interested in, and then click **Metrics**. You also can use the Monitoring service to create custom queries.

Prerequisites

IAM policies: To monitor resources, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in. For more information on

user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.

Available Metrics: oci_autonomous_database

The metrics listed in the following table are automatically available for any Autonomous Database that you create. You do not need to enable monitoring on the resource to get these metrics.

Database service metrics for Autonomous Databases include the following dimensions:

AUTONOMOUSDBTYPE

The type of Autonomous Database, Autonomous Data Warehouse (ADW) or Autonomous Transaction Processing (ATP).

DISPLAYNAME

The friendly name of the Autonomous Database.

REGION

The region in which the Autonomous Database resides.

RESOURCEID

The OCID of the Autonomous Database.

RESOURCENAME

The name of the Autonomous Database.

In the following table, metrics that are marked with an asterisk (*) can be viewed only on the **Service Metrics** page of the Oracle Cloud Infrastructure Console.

Metric	Metric Display Name	Unit	Description	Dimensions
`CurrentLogons`*	**Current Logons**	count	The number of successful logons during the selected interval.	`AutonomousDBType` `displayName` `region` `resourceId` `resourceName`
`CpuUtilization`	**CPU Utilization**	percent	The CPU utilization expressed as a percentage, aggregated across all consumer groups. The utilization percentage is reported with respect to the number of CPUs the database is allowed to use, which is two times the number of OCPUs.	
`ExecuteCount`	**Execute Count**	count	The number of user and recursive calls that executed SQL statements during the selected interval.	
`FailedConnections`*	**Failed Connections**	count	The number of failed database connections.	

Metric	Metric Display Name	Unit	Description	Dimensions
FailedLogons	**Failed Logons**	count	The number of logons that failed because of an invalid username and/or password, during the selected interval.	
ParseCount*	**Parse Count (Total)**	count	The number of hard and soft parses during the selected interval.	
QueuedStatements	**Queued Statements**	count	The number of queued SQL statements, aggregated across all consumer groups, during the selected interval.	
RunningStatements	**Running Statements**	count	The number of running SQL statements, aggregated across all consumer groups, during the selected interval.	

Metric	Metric Display Name	Unit	Description	Dimensions
`Sessions`	**Sessions**	count	The number of sessions in the database.	
`StorageUtilization`	**Storage Utilization**	percent	The percentage of provisioned storage capacity currently in use. Represents the total allocated space for all tablespaces.	
`TransactionCount`*	**Transaction Count**	count	The combined number of user commits and user rollbacks during the selected interval.	
`UserCalls`*	**User Calls**	count	The combined number of logons, parses, and execute calls during the selected interval.	

Using the Console

To view default metric charts for a single Autonomous Database

1. Open the navigation menu. Under **Database**, click **Autonomous Transaction**

Processing or **Autonomous Data Warehouse**.

2. Choose the **Compartment** that contains the Autonomous Database you want to view, and then click display name of the database to view its details.
3. Under **Resources**, click **Metrics**.
   The **Metrics** page displays a default set of charts for the current Autonomous Database. See Available Metrics: oci_autonomous_database for information about the default charts.

For more information about monitoring metrics and using alarms, see Monitoring Overview. For information about notifications for alarms, see Notifications Overview.

To view default metric charts for multiple Autonomous Databases

1. Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Service Metrics**.
2. For **Compartment**, select the compartment that contains the Autonomous Databases that you're interested in.
3. For **Metric Namespace**, select **oci_autonomous_database**.
   The **Service Metrics** page dynamically updates the page to show charts for each metric that is emitted by the selected metric namespace.

Tip

If there are multiple Autonomous Databases in the compartment, the charts default to show a separate line for each master encryption key. You can instead show a single line aggregated across all Autonomous Databases in the compartment by selecting the **Aggregate Metric Streams** check box.

For more information about monitoring metrics and using alarms, see Monitoring Overview. For information about notifications for alarms, see Notifications Overview.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the following APIs for monitoring:

- Monitoring API for metrics and alarms
- Notifications API for notifications (used with alarms)

Using Performance Hub to Analyze Database Performance in Oracle Cloud Infrastructure

Note

Performance Hub is currently available for Autonomous Databases.

This topic describes how to use Oracle Cloud Infrastructure's Performance Hub tool for Oracle Database performance analysis and tuning. Performance Hub offers two performance monitoring tools in the Console, Active Session History (ASH) Analytics and SQL Monitoring.

You can view real-time and historical performance data in Performance Hub. When you view historical data in the Performance Hub, you are viewing statistics collected as part of the hourly snapshots of your database.

The Performance Hub page consists of the following sections:

- **Time Range** field and time slider:

  The **Time Range** selector is displayed on the top of the Performance Hub page. Use the **Select Duration** field to set the time duration. By default, **Last 60 mins** is selected. You can choose to view **Last 8 hours**, **Last 24 hours**, **Last week**, or specify a custom time range using the **Custom** option.

  The Time Range field shows active sessions in chart form for the time period selected. The active sessions chart displays the average number of active sessions broken down by **CPU**, **User I/O**, and **Wait**.

  The sliding box on the time range chart is known as the **time slider**. Use the time slider to select the exact period of time for which data is displayed in the Performance Hub tables and graphs. This is a subsection of the period of time shown in the **Time Range** field. In the image that follows, red and blue arrows point to the vertical 'handlebar' elements on the left and right boundaries of the slider box.

  You can slide the box to the left or the right to shift the time period under analysis. To slide the entire box, left-click anywhere inside the box and drag the box to the left or the right.You can widen or narrow the box to increase or decrease the length of time under analysis. To widen or narrow the box, left-click and hold the handlebar on either side of the box, then drag to the left or the right to increase or decrease the size of the box.

  To refresh the data in Performance Hub according to the time range chosen, click the **Refresh** button.

- **Active Session History (ASH) Analytics** tab:
  Displayed by default. The ASH Analytics tab shows Active Session History (ASH) analytics charts to explore ASH data. It allows you to drill down into database performance across multiple dimensions such as **Consumer Group**, **Wait Class**, **SQL ID**, and **User Name**. On the ASH Analytics tab, you can select an Average Active Sessions dimension and view the top activity for that dimension for the selected time period. For information on ASH, see Active Session History (ASH) in *Oracle Database Concepts*.
- **SQL Monitoring** tab:
  The SQL Monitoring tab is not displayed by default. To view it, click **SQL Monitoring** on the Performance Hub page.
  SQL statements are only monitored if they've been running for at least five seconds or if they're run in parallel. The table in this section displays monitored SQL statement executions by dimensions including **Last Active Time**, **CPU Time**, and **Database Time**. The table displays currently running SQL statements and SQL statements that completed, failed, or were terminated. The columns in the table provide information for monitored SQL statements including **Status**, **Duration**, and **SQL ID**.
  The **Status** column has the following icons:
  - A spinning icon indicates that the SQL statement is executing.
  - A green check mark icon indicates that the SQL statement completed its execution during the specified time period.
  - A red cross icon indicates that the SQL statement did not complete, either due to an error, or due to the session being terminated.
  - A clock icon indicates that the SQL statement is queued.

  To terminate a running or queued SQL statement, click **Kill Session**.
  You can also click an SQL ID to go to the corresponding **Real-time SQL Monitoring** page. This page provides additional details to help you tune the selected SQL statement.

Using the Oracle Cloud Infrastructure Console

To navigate to Performance Hub in the Oracle Cloud Infrastructure Console interface of an Autonomous Database

1. Open the navigation menu. Under **Database**, click **Autonomous Transaction Processing** or **Autonomous Data Warehouse**.
2. Choose your **Compartment**.
3. In the list of Autonomous Databases, click on the display name of the database you wish to analyze using Performance Hub reports.
4. Click **Performance Hub**.

To view the average active session data by a selected dimension

1. Go to the **Performance Hub** page of the Oracle Cloud Infrastructure Console for the database which you wish to manage. See To navigate to Performance Hub in the Oracle Cloud Infrastructure Console interface of an Autonomous Database for more information.
   - The database name is displayed at the top of the Performance Hub page.
   - The time period for which information is available on the Performance Hub is displayed in the **Time Range** field. The selected time period is indicated on the time slider graph by the adjustable blue-colored block.

     The **ASH Analytics** tab is displayed with the top activity for a selected dimension in the selected time period.
2. Use the **Select Duration** selector to set the exact period of time for which data is displayed in the ASH Analytics tables and graphs. By default, the last hour is selected. The time duration is the total amount of time available for analysis.
3. Use the blue box on the **time slider** to further narrow down the time period for which performance data is displayed on the **ASH Analytics** tab.

4. Select a dimension in the **Average Active Sessions** drop-down list to display ASH analytics by that particular dimension. By default, the **Consumer Group** dimension is selected and the data is categorized by the **High**, **Medium**, or **Low** service name associated with the Autonomous Database.

   Optionally, you can:

   - Click the **Max Threads** check box to view the number of Max CPU Threads. These are denoted by a red line on the chart.
   - Click the **Total Activity** check box to view a black border that denotes total activity of all the components of the selected dimension on the chart. This option is selected by default when you use the filtering capabilities to only view the data for a particular component within a dimension. For information on filtering Average Active Sessions data, see Filter Average Active Sessions Data.

5. For the dimension selected in the **Average Active Sessions** drop-down list, you can further drill down into session details by selecting dimensions in the two sections at the bottom of the **ASH Analytics** tab. By default, the following dimensions are selected:

   - **SQL ID by Consumer Group**, which displays the SQL statements with the top average active sessions activity for consumer groups for the selected time period. You can right-click the bar charts to sort the SQL statements in ascending or descending order or click the SQL ID to go the SQL Details page.
   - **User Session by Consumer Group**, which displays the user sessions with the top average active sessions activity for consumer groups for the selected time period. You can right-click the bar charts to sort the user sessions in ascending or descending order or click the user session to go to the User Session page.

To filter average active sessions data

1. Go to the **Performance Hub** page of the Oracle Cloud InfrastructureConsole for the database which you wish to manage. See To navigate to Performance Hub in the Oracle Cloud Infrastructure Console interface of an Autonomous Database for more information.

- The database name is displayed a the top of the Performance Hub page.
- The time period for which information is available on the Performance Hub is displayed in the **Time Range** field. The selected time period is indicated on the time slider graph by the adjustable blue-colored block.

  The **ASH Analytics** tab is displayed with the top activity for a selected dimension in the selected time period.

2. Use the **Select Duration** selector to set the the exact period of time for which data is displayed in the ASH Analytics tables and graphs. By default, the last hour is selected. The time duration is the total amount of time available for analysis.
3. Use the blue box on the **time slider** to further narrow down the time period for which performance data is displayed on the **ASH Analytics** tab.
4. In the **ASH Analytics** tab, select a dimension in the Average Active Sessions by drop-down list. By default, **Consumer Group** is selected.

   The chart is displayed. Each color in the chart denotes a component of the selected dimension.For example, the Consumer Group dimension has **High**, **Medium**, and **Low**, which are predefined service names assigned to your Autonomous Database to provide different levels of concurrency and performance.
5. Click a component in the legend. The selected component is displayed in the **Applied Filters** field and the chart is updated to only display data pertaining to that component. The total activity, which includes all the components of the dimension, is denoted by a black outline and is displayed by default when you filter data.

To view the SQL Monitoring report

1. Go to the **Performance Hub** page of the Oracle Cloud InfrastructureConsole for the database which you wish to manage. See To navigate to Performance Hub in the Oracle Cloud Infrastructure Console interface of an Autonomous Database for more information.

- The database name is displayed a the top of the Performance Hub page.
- The time period for which information is available on the Performance Hub is displayed in the **Time Range** field. The selected time period is indicated on the time slider graph by the adjustable blue-colored block.

2. Click **SQL Monitoring** to view the SQL monitoring tab.
3. Optionally, you can get detailed information on a specific SQL statements by clicking an ID number in the **SQL ID column**. When you click an ID number, the Real-time SQL Monitoring page is displayed.
4. Click **Download Report** to download the report data for your selected SQL statement.

Migrating Databases to the Cloud

You can migrate your on-premises Oracle Database to an Oracle Cloud Infrastructure Database service database using a number of different methods that use several different tools. The method that applies to a given migration scenario depends on several factors, including the version, character set, and platform endian format of the source and target databases.

Choosing a Migration Method

Not all migration methods apply to all migration scenarios. Many of the migration methods apply only if specific characteristics of the source and destination databases match or are compatible. Moreover, additional factors can affect which method you choose for your migration from among the methods that are technically applicable to your migration scenario.

Some of the characteristics and factors to consider when choosing a migration method are:

- On-premises database version
- Database service database version
- On-premises host operating system and version
- On-premises database character set
- Quantity of data, including indexes

- Data types used in the on-premises database
- Storage for data staging
- Acceptable length of system outage
- Network bandwidth

To determine which migration methods are applicable to your migration scenario, gather the following information.

1. Database version of your on-premises database:
    - Oracle Database 12c Release 2 version 12.2.0.1
    - Oracle Database 12c Release 1 version 12.1.0.2 or higher
    - Oracle Database 12c Release 1 version lower than 12.1.0.2
    - Oracle Database 11g Release 2 version 11.2.0.3 or higher
    - Oracle Database 11g Release 2 version lower than 11.2.0.3
2. For on-premises Oracle Database 12c Release 2 and Oracle Database 12c Release 1 databases, the architecture of the database:
    - Multitenant container database (CDB)
    - Non-CDB
3. Endian format (byte ordering) of your on-premises database's host platform
   Some platforms are little endian and others are big endian. Query V$TRANSPORTABLE_PLATFORM to identify the endian format, and to determine whether cross-platform tablespace transport is supported.
   The Oracle Cloud Infrastructure Database uses the Linux platform, which is little endian.
4. Database character set of your on-premises database and the Oracle Cloud Infrastructure Database database.
   Some migration methods require that the source and target databases use compatible database character sets.
5. Database version of the Oracle Cloud Infrastructure Database database you are migrating to:

- Oracle Database 12c Release 2
- Oracle Database 12c Release 1
- Oracle Database 11g Release 2

Oracle Database 12c Release 2 and Oracle Database 12c Release 1 databases created on the Database service use CDB architecture. Databases created using the Enterprise Edition software edition are single-tenant, and databases created using the High Performance or Extreme Performance software editions are multitenant.

After gathering this information, use the "source" and "destination" database versions as your guide to see which migration methods apply to your migration scenario:

- Migrating from Oracle Database 11g to Oracle Database 11g in the Cloud
- Migrating from Oracle Database 11g to Oracle Database 12c in the Cloud
- Migrating from Oracle Database 12c CDB to Oracle Database 12c in the Cloud
- Migrating from Oracle Database 12c Non-CDB to Oracle Database 12c in the Cloud

Migration Connectivity Options

You have several connectivity options when migrating your on-premises databases to the Oracle Cloud Infrastructure. The options are listed below in order of preference.

1. **FastConnect:** Provides a secure connection between your existing network and your virtual cloud network (VCN) over a private physical network instead of the internet. For more information, see FastConnect.
2. **IPSec VPN:** Provides a secure connection between a dynamic routing gateway (DRG) and customer-premise equipment (CPE), consisting of multiple IPSec tunnels. The IPSec connection is one of the components forming a site-to-site VPN between a VCN and your on-premises network. For more information, see VPN Connect.
3. **Internet gateway:** Provides a path for network traffic between your VCN and the internet. For more information, see Internet Gateway.

Migration Methods

Many methods exist to migrate Oracle databases to the Oracle Cloud Infrastructure Database service. Which of these methods apply to a given migration scenario depends on several factors, including the version, character set, and platform endian format of the source and target databases.

- Data Pump Conventional Export/Import
- Data Pump Full Transportable
- Data Pump Transportable Tablespace
- Remote Cloning a PDB
- Remote Cloning Non-CDB
- RMAN Cross-Platform Transportable PDB
- RMAN Cross-Platform Transportable Tablespace Backup Sets
- RMAN Transportable Tablespace with Data Pump
- RMAN DUPLICATE from an Active Database
- RMAN CONVERT Transportable Tablespace with Data Pump
- SQL Developer and INSERT Statements to Migrate Selected Objects
- SQL Developer and SQL*Loader to Migrate Selected Objects
- Unplugging/Plugging a PDB
- Unplugging/Plugging Non-CDB

Migrating an On-Premises Database to Oracle Cloud Infrastructure by Creating a Backup in the Cloud

Note

This topic is not applicable to Exadata DB systems.

You can migrate an on-premises database to Oracle Cloud Infrastructure by creating a backup of your on-premises database in Oracle Cloud Infrastructure's Database service.

Oracle provides a Python script to create a backup of your database. The script invokes an API call to create the backup and then places the backup in Oracle Cloud Infrastructure. You can then use the Console or the API to create a new database or DB system from that backup. Backups created using the instructions in this topic appear under Standalone Backups in the console.

The Python script is bundled as a part of the Oracle Cloud Infrastructure CLI installation. Oracle provides the migration script and associated files at no cost. Normal Object Storage charges apply for the storage of your backup in Oracle Cloud Infrastructure.

Compatibility

The scripted migration process is compatible with the following bare metal and virtual machine DB system configurations:

Configuration	Version or Type	Notes
Database Version	18.x 12.2.0.1 12.1.0.2 11.2.0.4	• For versions 18c, 12.2.0.1, and 12.1.0.2: ◦ Only Container Databases (CDBs) are supported. The scripted migration process may work with non-CDB databases for these database versions, but Oracle does not provide support for the migration of non-CDB databases using the script described in this topic. For information on creating an on-premises pluggable database (PDB) by cloning a non-CDB in Oracle Database 18c, see About Cloning a Non-CDB. For an overview of multitenant architecture in Oracle Database 18c, see Introduction to the Multitenant Architecture. For information on creating an on-premises pluggable database (PDB) from a non-CDB database in Oracle Database 12c Release 2 (12.2), see Upgrading a Non-CDB Oracle Database To a PDB on a CDB. For an overview of multitenant architecture in 12c Release 2, see Overview of Managing a Multitenant Environment. ◦ The Oracle Cloud Infrastructure Database service will attempt to run datapatch, which requires read/write mode. If there are pluggable databases (PDBs), they should also be in read/write mode to ensure that datapatch runs on them. • For version 11.2.0.4, depending on the source

Configuration	Version or Type	Notes
		database patch level, you may need to roll back patches prior to migrating. See Rolling Back Patches on a Version 11.2 Database for more information. • If your on-premises database has an interim patch (previous known as a one-off patch), see Applying Interim Patches for details on applying the patch in Oracle Cloud Infrastructure.
Source Database Platform	Oracle Enterprise Linux / Red Hat Enterprise Linux 5.x Oracle Linux / Red Hat Enterprise Linux 6.x Oracle Linux / Red Hat Enterprise 7.x	• The scripted migration described in this topic may work in Microsoft Windows environments, but Oracle currently does not provide support for this script in Windows. • For Oracle Linux 6.x users, see Configuring Oracle Linux 6 to install Python for details on configuring the operating system to install a compatible version of Python. See Installing the CLI for more information regarding Oracle Linux 6.
Encryption	TDE Non-TDE	• In a non-TDE configuration, the RMAN encryption password is required. • Unencrypted on-premises databases remain unencrypted when restored to Oracle Cloud Infrastructure. The stored RMAN standalone backups are always encrypted.

Configuration	Version or Type	Notes
Target Database Edition	Standard Edition Enterprise Edition Enterprise Edition - High Performance Enterprise Edition - Extreme Performance	
Cluster	Single RAC	

Prerequisites

On the source database host:

- Outbound internet connectivity for installing Python packages, running yum install, and access to the Oracle Cloud Infrastructure API and Object Storage.
- RMAN configuration to autobackup `controlfile` and `spfile`:

```
RMAN> CONFIGURE CONTROLFILE AUTOBACKUP ON;
```

Note

RMAN configuration changes must be completed prior to running the script. The script may modify RMAN parameters as required to complete the backup and migration tasks.

To Migrate an On-Premises Database Using a Standalone Backup

Perform the following tasks on the source database host:

1. Create a directory named `/home/oracle/migrate`.

Tip

You can name the `migrate` portion of the directory path anything you want. If you use a different name, you must adjust all of the paths that appear in this task accordingly. The following examples assume the name `migrate` for simplicity and clarity.

2. As *root*, run the CLI installer in the directory you created in step 1. (For example, `/home/oracle/migrate`.) See Installing the CLI: Windows for instructions on running the installer script in Windows. See Installing the CLI: MacOS, Linux, and Unix for instructions on running the installer script in the Bash environment.
   The installer installs Python 3.6.0 if either Python 2.7 or Python 3.6 does not exist on the machine. The installer also installs the Python script required to create and migrate a standalone backup from an on-premises database.

On Oracle Linux 6, a newer version of Python (such as Python 3.6.0) is usually required. **Use the following instructions to configure Oracle Linux 6 before running the backup script.**

Configuring Oracle Linux 6 to install Python

In Oracle Linux 6 use the following `/etc/yum.repos.d/ol6.repo` file to ensure that a compatible version of Python is installed by the script if a compatible version is not already installed. Include this file before attempting to run the script with the `./install.sh` command.

```
[ol6_latest]
name=Oracle Linux $releasever Latest ($basearch)
baseurl=http://yum.oracle.com/repo/OracleLinux/OL6/latest/$basearch/
gpgkey=file:///etc/pki/rpm-gpg/RPM-GPG-KEY-oracle
gpgcheck=1
enabled=1
```

3. Copy the following files into the new directory:
   - Oracle Database Backup Module (`opc_install.jar`)
   - Your API `*.pem` key file.
4. Respond to the prompts as follows:

```
(yum install)
Is this ok [y/N]: y

===> Missing native dependencies. Continue and install the following dependencies: gcc, libffi-
devel, python36u-devel, openssl-devel? (Y/n): Y

===> In what directory would you like to place the install? (leave blank to use
'/root/lib/oracle-cli'): /home/oracle/migrate/lib/oracle-cli

===> In what directory would you like to place the 'oci' executable? (leave blank to use
'/root/bin'): /home/oracle/migrate/bin

===> In what directory would you like to place the OCI scripts? (leave blank to use
'/root/bin/oci-cli-scripts'): /home/oracle/migrate/bin/oci-cli-scripts
```

```
===> Currently supported optional packages are: ['db (will install cx_Oracle)'] What optional CLI
packages would you like to be installed (comma separated names; press enter if you don't need any
optional packages)?: db

===> Modify profile to update your $PATH and enable shell/tab completion now? (Y/n): Y

===> Enter a path to an rc file to update (leave blank to use '/root/.bashrc'):
/home/oracle/.bashrc
```

5. Perform the following file operations:

```
# chown -R oracle:oinstall /home/oracle/migrate
```

6. Edit the `/home/oracle/migrate/config.txt` file

```
[DEFAULT]
tenancy=<your_tenancy_OCID>
user=<your_user_OCID>
fingerprint=<fingerprint>
key_file=/home/oracle/migrate/<your_api_key>.pem
region=<region>
```

   If you do not know your API signing key's fingerprint, see How to Get the Key's Fingerprint.

7. As *oracle user* (not *root*), run one of the following sets of commands, depending on the type of database you are migrating.

   For a non-TDE database:

```
export AD=<destination_availability_domain>
export C=<destination_compartment_OCID>
export ORACLE_SID=<ORACLE_SID>
export ORACLE_HOME=<ORACLE_HOME>
export PATH=$PATH:$ORACLE_HOME/bin
export LC_ALL=en_US.UTF-8
export ORACLE_UNQNAME=<source_DB_unique_name>
rm -rf /home/oracle/migrate/onprem_upload
cd /home/oracle/migrate/bin/oci-cli-scripts/
./create_backup_from_onprem --config-file /home/oracle/migrate/config.txt --display-name
<example_display_name> --availability-domain $AD --edition ENTERPRISE_EDITION_EXTREME_PERFORMANCE
```

```
--opc-installer-dir /home/oracle/migrate --tmp-dir /home/oracle/migrate/onprem_upload --
compartment-id $C --rman-password <password>
```

For a TDE-enabled database:

```
export AD=<destination_availability_domain>
export C=<destination_compartment_OCID>
export ORACLE_SID=<ORACLE_SID>
export ORACLE_HOME=<ORACLE_HOME>
export PATH=$PATH:$ORACLE_HOME/bin
rm -rf /home/oracle/migrate/onprem_upload
cd /home/oracle/migrate/bin/oci-cli-scripts/
./create_backup_from_onprem --config-file /home/oracle/migrate/config.txt --display-name
<example_display_name> --availability-domain $AD --edition ENTERPRISE_EDITION_EXTREME_PERFORMANCE
--opc-installer-dir /home/oracle/migrate --tmp-dir /home/oracle/migrate/onprem_upload --
compartment-id $C
```

See the following list of parameters used by the script for more details.

Parameters used by the script

Parameter	Description	Required
`--config-file`	The path to the oci-cli config file. The default path is as follows: `~/.oci/config`	No
`--profile`	The profile in the config file to load. This profile will also be used to locate any default parameter values which have been specified in the OCI CLI-specific configuration file. The default value is `DEFAULT`.	No
`--compartment-id`	The compartment OCID of the Oracle Cloud Infrastructure compartment that will contain your standalone backup.	Yes

Parameter	Description	Required
`--display-name`	The name of the backup, as you wish it to be displayed in the OCI Console under Standalone Backups.	Yes
`--availability-domain`	The availability domain where the backup is to be stored.	Yes
`--edition`	The edition of the Oracle Cloud Infrastructure DB system that will contain the database created from the standalone backup. You can choose the same edition as the on-premises database, or any addition above the on-premises database. The choices, listed from lowest to highest, are the following: • STANDARD_EDITION • ENTERPRISE_EDITION • ENTERPRISE_EDITION_HIGH_PERFORMANCE • ENTERPRISE_EDITION_EXTREME_PERFORMANCE	Yes
`--opc-installer-dir`	The directory containing the `opc_installer.jar` file. This is the directory you created in step 1 of this procedure.	Yes
`--additional-opc-args`	Optional additional arguments for the opc installer.	No
`--tmp-dir`	Optional temporary directory for intermediate files.	No

Parameter	Description	Required
`--rman-password`	The RMAN password to use for the standalone backup.	Required if TDE is not enabled
`--rman-channels`	RMAN channels. The default value is 5.	No
`--help`	Displays in-line help for the script in the OCI-CLI environment.	No

The script will produce a standalone backup of your on-premises database in your Oracle Cloud Infrastructure tenancy. You can check the Console for your backup by viewing the **Standalone Backups** page in the Database service, under **Bare Metal, VM, and Exadata**.

Tip

To access command line help for the backup script, run the following command in the /home/oracle/migrate/bin/oci-cli-scripts/ directory:

```
create_backup_from_onprem --help
```

8. Create a new database or launch a new DB system using the backup you created in the preceding step. See the following instructions to perform these tasks:
   - Recovering a Database from Object Storage
   - Recovering a Database from Object Storage

Migrating from Oracle Database 11g to Oracle Database 11g in the Cloud

You can migrate Oracle Database 11g databases from on-premises to Oracle Database 11g databases in the Database service using several different methods.

The applicability of some of the migration methods depends on the on-premises database's character set and platform endian format.

If you have not already done so, determine the database character set of your on-premises database, and determine the endian format of the platform your on-premises database resides on. Use this information to help you choose an appropriate method.

- Data Pump Conventional Export/Import
  This method can be used regardless of the endian format and database character set of the on-premises database.
  For the steps this method entails, see Data Pump Conventional Export/Import.
- Data Pump Transportable Tablespace
  This method can be used only if the on-premises platform is little endian, and the database character sets of your on-premises database and the Oracle Cloud Infrastructure Database database are compatible.
  For the steps this method entails, see Data Pump Transportable Tablespace.
- RMAN Transportable Tablespace with Data Pump
  This method can be used only if the on-premises platform is little endian, and the database character sets of your on-premises database and the Oracle Cloud Infrastructure Database database are compatible.
  For the steps this method entails, see RMAN Transportable Tablespace with Data Pump.
- RMAN `CONVERT` Transportable Tablespace with Data Pump
  This method can be used only if the database character sets of your on-premises database and the Oracle Cloud Infrastructure Database database are compatible.
  This method is similar to the Data Pump Transportable Tablespace method, with the addition of the RMAN `CONVERT` command to enable transport between platforms with different endianness. Query `V$TRANSPORTABLE_PLATFORM` to determine if the on-premises database platform supports cross-platform tablespace transport and to

determine the endian format of the platform. The Database service platform is little-endian format.

For the steps this method entails, see RMAN CONVERT Transportable Tablespace with Data Pump.

Migrating from Oracle Database 11g to Oracle Database 12c in the Cloud

You can migrate Oracle Database 11g databases from on-premises to Oracle Database 12c databases in the Database service using several different methods.

The applicability of some of the migration methods depends on the on-premises database's version, database character set and platform endian format.

If you have not already done so, determine the database version and database character set of your on-premises database, and determine the endian format of the platform your on-premises database resides on. Use this information to help you choose an appropriate method.

- Data Pump Conventional Export/Import

  This method can be used regardless of the endian format and database character set of the on-premises database.

  For the steps this method entails, see Data Pump Conventional Export/Import.
- Data Pump Transportable Tablespace

  This method can be used only if the on-premises platform is little endian, and the database character sets of your on-premises database and the Databaseservice database are compatible.

  For the steps this method entails, see Data Pump Transportable Tablespace.
- RMAN Transportable Tablespace with Data Pump

  This method can be used only if the on-premises platform is little endian, and the database character sets of your on-premises database and the Database service database are compatible.

  For the steps this method entails, see RMAN Transportable Tablespace with Data Pump.
- RMAN `CONVERT` Transportable Tablespace with Data Pump

This method can be used only if the database character sets of your on-premises database and the Database service database are compatible.

This method is similar to the Data Pump Transportable Tablespace method, with the addition of the RMAN `CONVERT` command to enable transport between platforms with different endianness. Query `V$TRANSPORTABLE_PLATFORM` to determine if the on-premises database platform supports cross-platform tablespace transport and to determine the endian format of the platform. The Database service platform is little-endian format.

For the steps this method entails, see RMAN CONVERT Transportable Tablespace with Data Pump.

- Data Pump Full Transportable

  This method can be used only if the source database release version is 11.2.0.3 or later, and the database character sets of your on-premises database and the Database service database are compatible.

  For the steps this method entails, see Data Pump Full Transportable.

Migrating from Oracle Database 12c CDB to Oracle Database 12c in the Cloud

You can migrate Oracle Database 12c CDB databases from on-premises to Oracle Database 12c databases in the Oracle Cloud Infrastructure Database service using several different methods.

The applicability of some of the migration methods depends on the on-premises database's character set and platform endian format.

If you have not already done so, determine the database character set of your on-premises database, and determine the endian format of the platform your on-premises database resides on. Use this information to help you choose an appropriate method.

- Data Pump Conventional Export/Import

  This method can be used regardless of the endian format and database character set of the on-premises database.

  For the steps this method entails, see Data Pump Conventional Export/Import.

- Data Pump Transportable Tablespace
  This method can be used only if the on-premises platform is little endian, and the database character sets of your on-premises database and the Database database are compatible.
  For the steps this method entails, see Data Pump Transportable Tablespace.
- RMAN Transportable Tablespace with Data Pump
  This method can be used only if the on-premises platform is little endian, and the database character sets of your on-premises database and the Oracle Cloud Infrastructure Database service database are compatible.
  For the steps this method entails, see RMAN Transportable Tablespace with Data Pump.
- RMAN `CONVERT` Transportable Tablespace with Data Pump
  This method can be used only if the database character sets of your on-premises database and the Database database are compatible.
  This method is similar to the Data Pump Transportable Tablespace method, with the addition of the RMAN `CONVERT` command to enable transport between platforms with different endianness. Query `V$TRANSPORTABLE_PLATFORM` to determine if the on-premises database platform supports cross-platform tablespace transport and to determine the endian format of the platform. The Database service platform is little-endian format.
  For the steps this method entails, see RMAN CONVERT Transportable Tablespace with Data Pump.
- RMAN Cross-Platform Transportable Tablespace Backup Sets
  This method can be used only if the database character sets of your on-premises database and the Database service database are compatible.
  For the steps this method entails, see RMAN Cross-Platform Transportable Tablespace Backup Sets.
- Data Pump Full Transportable
  This method can be used only if the database character sets of your on-premises database and the Database service database are compatible.
  For the steps this method entails, see Data Pump Full Transportable.

- Unplugging/Plugging (CDB)
  This method can be used only if the on-premises platform is little endian, and the on-premises database and Database database have compatible database character sets and national character sets.
  For the steps this method entails, see Unplugging/Plugging a PDB.
- Remote Cloning (CDB)
  This method can be used only if the on-premises platform is little endian, the on-premises database release is 12.1.0.2 or higher, and the on-premises database and Database service database have compatible database character sets and national character sets.
  For the steps this method entails, see Remote Cloning a PDB.
- RMAN Cross-Platform Transportable PDB
  This method can be used only if the on-premises platform is little endian, and the database character sets of your on-premises database and the Database service database are compatible.
  For the steps this method entails, see RMAN Cross-Platform Transportable PDB.
- SQL Developer and SQL*Loader to Migrate Selected Objects
  You can use SQL Developer to create a cart into which you add selected objects to be loaded into your Oracle Database 12c database on the cloud. In this method, you use SQL*Loader to load the data into your cloud database.
  For the steps this method entails, see SQL Developer and SQL*Loader to Migrate Selected Objects.
- SQL Developer and `INSERT` Statements to Migrate Selected Objects
  You can use SQL Developer to create a cart into which you add selected objects to be loaded into your Oracle Database 12c database on the cloud. In this method, you use SQL `INSERT` statements to load the data into your cloud database.
  For the steps this method entails, see SQL Developer and INSERT Statements to Migrate Selected Objects.

Migrating from Oracle Database 12c Non-CDB to Oracle Database 12c in the Cloud

You can migrate Oracle Database 12c non-CDB databases from on-premises to Oracle Database 12c databases in Oracle Cloud Infrastructure Database service using several different methods.

The applicability of some of the migration methods depends on the on-premises database's character set and platform endian format.

If you have not already done so, determine the database character set of your on-premises database, and determine the endian format of the platform your on-premises database resides on. Use this information to help you choose an appropriate method.

- Data Pump Conventional Export/Import
  This method can be used regardless of the endian format and database character set of the on-premises database.
  For the steps this method entails, see Data Pump Conventional Export/Import.
- Data Pump Transportable Tablespace
  This method can be used only if the on-premises platform is little endian, and the database character sets of your on-premises database and the Database database are compatible.
  For the steps this method entails, see Data Pump Transportable Tablespace.
- RMAN Transportable Tablespace with Data Pump
  This method can be used only if the on-premises platform is little endian, and the database character sets of your on-premises database and the Database service database are compatible.
  For the steps this method entails, see RMAN Transportable Tablespace with Data Pump.
- RMAN `CONVERT` Transportable Tablespace with Data Pump
  This method can be used only if the database character sets of your on-premises database and the Database service database are compatible.
  This method is similar to the Data Pump Transportable Tablespace method, with the addition of the RMAN `CONVERT` command to enable transport between platforms with

different endianness. Query `V$TRANSPORTABLE_PLATFORM` to determine if the on-premises database platform supports cross-platform tablespace transport and to determine the endian format of the platform. The Database service platform is little-endian format.

For the steps this method entails, see RMAN CONVERT Transportable Tablespace with Data Pump.

- RMAN Cross-Platform Transportable Tablespace Backup Sets

  This method can be used only if the database character sets of your on-premises database and the Database database are compatible.

  For the steps this method entails, see RMAN Cross-Platform Transportable Tablespace Backup Sets.

- Data Pump Full Transportable

  This method can be used only if the database character sets of your on-premises database and the Database service database are compatible.

  For the steps this method entails, see Data Pump Full Transportable.

- Unplugging/Plugging (non-CDB)

  This method can be used only if the on-premises platform is little endian, and the on-premises database and Database service database have compatible database character sets and national character sets.

  You can use the unplug/plug method to migrate an Oracle Database 12c non-CDB database to Oracle Database 12c in the cloud. This method provides a way to consolidate several non-CDB databases into a single Oracle Database 12c CDB on the cloud.

  For the steps this method entails, see Unplugging/Plugging Non-CDB.

- Remote Cloning (non-CDB)

  This method can be used only if the on-premises platform is little endian, the on-premises database release is 12.1.0.2 or higher, and the on-premises database and Database service database have compatible database character sets and national character sets.

You can use the remote cloning method to copy an Oracle Database 12c non-CDB on-premises database to your Oracle Database 12c database in the cloud.
For the steps this method entails, see Remote Cloning Non-CDB.

- SQL Developer and SQL*Loader to Migrate Selected Objects
  You can use SQL Developer to create a cart into which you add selected objects to be loaded into your Oracle Database 12c database on the cloud. In this method, you use SQL*Loader to load the data into your cloud database.
  For the steps this method entails, see SQL Developer and SQL*Loader to Migrate Selected Objects.
- SQL Developer and `INSERT` Statements to Migrate Selected Objects
  You can use SQL Developer to create a cart into which you add selected objects to be loaded into your Oracle Database 12c database on the cloud. In this method, you use SQL `INSERT` statements to load the data into your cloud database.
  For the steps this method entails, see SQL Developer and INSERT Statements to Migrate Selected Objects.

Data Pump Conventional Export/Import

You can use this method regardless of the endian format and database character set of the on-premises database.

To migrate an on-premises source database, tablespace, schema, or table to the database on a Database service database deployment using Data Pump Export and Import, you perform these tasks:

1. On the on-premises database host, invoke Data Pump Export and export the on-premises database.
2. Use a secure copy utility to transfer the dump file to the Database service compute node.
3. On the Database service compute node, invoke Data Pump Import and import the data into the database.
4. After verifying that the data has been imported successfully, you can delete the dump file.

For information about Data Pump Import and Export, see these topics:

- "Data Pump Export Modes" in *Oracle Database Utilities* for Release 12.2, 12.1 or 11.2.
- "Data Pump Import Modes" in *Oracle Database Utilities* for Release 12.2, 12.1 or 11.2.

Data Pump Conventional Export/Import: Example

This example provides a step-by-step demonstration of the tasks required to migrate a schema from an on-premises Oracle database to a Database service database.

This example illustrates a schema mode export and import. The same general procedure applies for a full database, tablespace, or table export and import.

In this example, the on-premises database is on a Linux host.

1. On the on-premises database host, invoke Data Pump Export to export the schemas.
    a. On the on-premises database host, create an operating system directory to use for the on-premises database export files.

    ```
    $ mkdir /u01/app/oracle/admin/orcl/dpdump/for_cloud
    ```

    b. On the on-premises database host, invoke SQL*Plus and log in to the on-premises database as the `SYSTEM` user.

    ```
    $ sqlplus system
    Enter password: <enter the password for the SYSTEM user>
    ```

    c. Create a directory object in the on-premises database to reference the operating system directory.

    ```
    SQL> CREATE DIRECTORY dp_for_cloud AS '/u01/app/oracle/admin/orcl/dpdump/for_cloud';
    ```

    d. Exit from SQL*Plus.
    e. On the on-premises database host, invoke Data Pump Export as the `SYSTEM` user or another user with the `DATAPUMP_EXP_FULL_DATABASE` role and export the on-premises schemas. Provide the password for the user when prompted.

    ```
    $ expdp system SCHEMAS=fsowner DIRECTORY=dp_for_cloud
    ```

2. Use a secure copy utility to transfer the dump file to the Database service compute

node.

In this example the dump file is copied to the `/u01` directory. Choose the appropriate location based on the size of the file that will be transferred.

a. On the Database service compute node, create a directory for the dump file.

```
$ mkdir /u01/app/oracle/admin/ORCL/dpdump/from_onprem
```

b. Before using the `scp` command to copy the export dump file, make sure the SSH private key that provides access to the Database service compute node is available on your on-premises host.

c. On the on-premises database host, use the SCP utility to transfer the dump file to the Databaseservice compute node.

```
$ scp –i private_key_file \
/u01/app/oracle/admin/orcl/dpdump/for_cloud/expdat.dmp \
oracle@IP_address_DBaaS_VM:/u01/app/oracle/admin/ORCL/dpdump/from_onprem
```

3. On the Database service compute node, invoke Data Pump Import and import the data into the database.

a. On the Database service compute node, invoke SQL*Plus and log in to the database as the `SYSTEM` user.

```
$ sqlplus system
Enter password: <enter the password for the SYSTEM user>
```

b. Create a directory object in the Database service database.

```
SQL> CREATE DIRECTORY dp_from_onprem AS '/u01/app/oracle/admin/ORCL/dpdump/from_onprem';
```

c. If they do not exist, create the tablespace(s) for the objects that will be imported.

d. Exit from SQL*Plus.

e. On the Database service compute node, invoke Data Pump Import and connect to the database. Import the data into the database.

```
impdp system SCHEMAS=fsowner DIRECTORY=dp_from_onprem
```

4. After verifying that the data has been imported successfully, you can delete the `expdat.dmp` file.

Data Pump Full Transportable

You can use this method only if the source database release version is 11.2.0.3 or later, and the database character sets of your on-premises database and the Oracle Cloud Infrastructure Database service database are compatible.

You can use the Data Pump full transportable method to copy an entire database from your on-premises host to the database on a Database service database deployment.

To migrate an Oracle Database 11g on-premises database to the Oracle Database 12c database on a Database service database deployment using the Data Pump full transportable method, you perform these tasks:

1. On the on-premises database host, prepare the database for the Data Pump full transportable export by placing the user-defined tablespaces in `READ ONLY` mode.
2. On the on-premises database host, invoke Data Pump Export to perform the full transportable export.
3. Use a secure copy utility to transfer the Data Pump Export dump file and the datafiles for all of the user-defined tablespaces to the Database service compute node.
4. Set the on-premises tablespaces back to `READ WRITE`.
5. On the Database service compute node, prepare the database for the tablespace import.
6. On the Database service compute node, invoke Data Pump Import and connect to the database.
7. After verifying that the data has been imported successfully, you can delete the dump file.

Data Pump Full Transportable: Example

This example provides a step-by-step demonstration of the tasks required to migrate an Oracle Database 11g database to a Database service 12c database.

In this example, the source database is on a Linux host.

1. On the source database host, prepare the database for the Data Pump full transportable export.
    a. On the source database host, create a directory in the operating system to use for the source export.

```
$ mkdir /u01/app/oracle/admin/orcl/dpdump/for_cloud
```

    b. On the source database host, invoke SQL*Plus and log in to the source database as the `SYSTEM` user.

```
$ sqlplus system
Enter password: <enter the password for the SYSTEM user>
```

    c. Create a directory object in the source database to reference the operating system directory.

```
SQL> CREATE DIRECTORY dp_for_cloud AS '/u01/app/oracle/admin/orcl/dpdump/for_cloud';
```

    d. Determine the name(s) of the tablespaces and data files that belong to the user-defined tablespaces by querying `DBA_DATA_FILES`. These files will also be listed in the export output.

```
SQL> SELECT tablespace_name, file_name FROM dba_data_files;
TABLESPACE_NAME  FILE_NAME
---------------  --------------------------------------------------
USERS            /u01/app/oracle/oradata/orcl/users01.dbf
UNDOTBS1         /u01/app/oracle/oradata/orcl/undotbs01.dbf
SYSAUX           /u01/app/oracle/oradata/orcl/sysaux01.dbf
SYSTEM           /u01/app/oracle/oradata/orcl/system01.dbf
EXAMPLE          /u01/app/oracle/oradata/orcl/example01.dbf
FSDATA           /u01/app/oracle/oradata/orcl/fsdata01.dbf
FSINDEX          /u01/app/oracle/oradata/orcl/fsindex01.dbf
SQL>
```

    e. On the source database host, set all tablespaces that will be transported (the transportable set) to `READ ONLY` mode.

```
SQL> ALTER TABLESPACE example READ ONLY;
Tablespace altered.
SQL> ALTER TABLESPACE fsindex READ ONLY;
Tablespace altered.
```

```
SQL> ALTER TABLESPACE fsdata READ ONLY;
Tablespace altered.
SQL> ALTER TABLESPACE users READ ONLY;
Tablespace altered.
SQL>
```

f. Exit from SQL*Plus.

2. On the source database host, invoke Data Pump Export to perform the full transportable export. Specify `FULL=y` and `TRANSPORTABLE=always`. Because this is an Oracle Database 11g database and full transportable is an Oracle Database 12c feature, specify `VERSION=12`. Provide the password for the `SYSTEM` user when prompted.

```
$ expdp system FULL=y TRANSPORTABLE=always VERSION=12 DUMPFILE=expdat.dmp DIRECTORY=dp_for_cloud
```

3. Use a secure copy utility to transfer the Data Pump Export dump file and the datafiles for all of the user-defined tablespaces to the Database service compute node.
   In this example the dump file is copied to the `/u01` directory. Choose the appropriate location based on the size of the file that will be transferred.

   a. On the Database service compute node, create a directory for the dump file.

```
$ mkdir /u01/app/oracle/admin/ORCL/dpdump/from_source
```

   b. Before using the `scp` utility to copy files, make sure the SSH private key that provides access to the Database service compute node is available on your source host.

   c. On the source database host, use the `scp` utility to transfer the dump file and all datafiles of the transportable set to the Database service compute node.

```
$ scp -i private_key_file \
/u01/app/oracle/admin/orcl/dpdump/for_cloud/expdat.dmp \
oracle@compute_node_IP_address:/u01/app/oracle/admin/ORCL/dpdump/from_source

$ scp -i private_key_file \
/u01/app/oracle/oradata/orcl/example01.dbf \
oracle@compute_node_IP_address:/u02/app/oracle/oradata/ORCL/PDB2

$ scp -i private_key_file \
/u01/app/oracle/oradata/orcl/fsdata01.dbf \
oracle@compute_node_IP_address:/u02/app/oracle/oradata/ORCL/PDB2
```

```
$ scp -i private_key_file \
/u01/app/oracle/oradata/orcl/fsindex01.dbf \
oracle@compute_node_IP_address:/u02/app/oracle/oradata/ORCL/PDB2

$ scp -i private_key_file \
/u01/app/oracle/oradata/orcl/users01.dbf \
oracle@compute_node_IP_address:/u02/app/oracle/oradata/ORCL/PDB2
```

4. Set the source tablespaces back to `READ WRITE`.
    a. Invoke SQL*Plus and log in as the `SYSTEM` user.
    b. Set the user-defined tablespaces back to `READ WRITE` mode.

```
SQL> ALTER TABLESPACE example READ WRITE;
Tablespace altered.
SQL> ALTER TABLESPACE fsdata READ WRITE;
Tablespace altered.
SQL> ALTER TABLESPACE fsindex READ WRITE;
Tablespace altered.
SQL> ALTER TABLESPACE users READ WRITE;
Tablespace altered.
```

    c. Exit from SQL*Plus.
5. On the Database service compute node, prepare the PDB for the tablespace import.
    a. On the Database service compute node, invoke SQL*Plus and log in to the PDB as the `SYSTEM` user.
    b. Create a directory object in the PDB.

```
SQL> CREATE DIRECTORY dp_from_source AS '/u01/app/oracle/admin/ORCL/dpdump/from_source';
```

6. On the Database service compute node, invoke Data Pump Import and connect to the PDB.

    Import the data into the database using the `TRANSPORT_DATAFILES` option.

```
$ impdp system@PDB2 FULL=y DIRECTORY=dp_from_source \
TRANSPORT_
DATAFILES='/u02/app/oracle/oradata/ORCL/PDB2/example01.dbf',\
'/u02/app/oracle/oradata/ORCL/PDB2/fsdata01.dbf',\
```

```
'/u02/app/oracle/oradata/ORCL/PDB2/fsindex01.dbf,'\
'/u02/app/oracle/oradata/ORCL/PDB2/users01.dbf'
```

7. After verifying that the data has been imported successfully, you can delete the `expdat.dmp` dump file.

Data Pump Transportable Tablespace

You can use this method only if the on-premises platform is little endian, and the database character sets of your on-premises database and the Oracle Cloud Infrastructure Database service database are compatible.

The Transportable Tablespace method is generally much faster than a conventional export/import of the same data because the data files containing all of the actual data are simply copied to the destination location. You use Data Pump to transfer only the metadata of the tablespace objects to the new database.

To migrate an on-premises source database to the database deployment on the Database service using the Data Pump Transportable Tablespace method, you perform these tasks:

1. On the on-premises database host, prepare the database for the Data Pump transportable tablespace export.
2. On the on-premises database host, invoke Data Pump Export to perform the transportable tablespace export.
3. Use a secure copy utility to transfer the Data Pump Export dump file and the tablespace datafiles to the Database service compute node.
4. Set the on-premises tablespaces back to `READ WRITE`.
5. On the Databaseservice compute node, prepare the database for the tablespace import.
6. On the Database service compute node, invoke Data Pump Import and connect to the database.
7. Set the tablespaces on the Database service database to `READ WRITE` mode.
8. After verifying that the data has been imported successfully, you can delete the dump file.

Data Pump Transportable Tablespace: Example

This example provides a step-by-step demonstration of the tasks required to migrate tablespaces in an on-premises Oracle database to a Database service database.

This example performs a migration of the `FSDATA` and `FSINDEX` tablespaces.

In this example, the on-premises database is on a Linux host.

1. On the on-premises database host, prepare the database for the Data Pump transportable tablespace export.
    a. On the on-premises database host, create a directory in the operating system to use for the on-premises export.

    ```
    mkdir /u01/app/oracle/admin/orcl/dpdump/for_cloud
    ```

    b. On the on-premises database host, invoke SQL*Plus and log in to the on-premises database as the `SYSTEM` user.

    ```
    sqlplus system
    Enter password: <enter the password for the SYSTEM user>
    ```

    c. Create a directory object in the on-premises database to reference the operating system directory.

    ```
    SQL> CREATE DIRECTORY dp_for_cloud AS '/u01/app/oracle/admin/orcl/dpdump/for_cloud';
    ```

    d. Determine the name(s) of the datafiles that belong to the `FSDATA` and `FSINDEX` tablespaces by querying DBA_DATA_FILES. These files will also be listed in the export output.

    ```
    SQL> SELECT file_name FROM dba_data_files
      2  WHERE tablespace_name = 'FSDATA';

    FILE_NAME
    ----------------------------------------------------------------
    /u01/app/oracle/oradata/orcl/fsdata01.dbf

    SQL> SELECT file_name FROM dba_data_files
      2  WHERE tablespace_name = 'FSINDEX';

    FILE_NAME
    ```

```
---------------------------------------------------------------
/u01/app/oracle/oradata/orcl/fsindex01.dbf
```

e. On the on-premises database host, set all tablespaces that will be transported (the transportable set) to `READ ONLY` mode.

```
SQL> ALTER TABLESPACE fsindex READ ONLY;
Tablespace altered.
SQL> ALTER TABLESPACE fsdata READ ONLY;
Tablespace altered.
```

f. Exit from SQL*Plus.

2. On the on-premises database host, invoke Data Pump Export to perform the transportable tablespace export.

   On the on-premises database host, invoke Data Pump Export and connect to the on-premises database. Export the on-premises tablespaces using the `TRANSPORT_TABLESPACES` option. Provide the password for the `SYSTEM` user when prompted.

```
expdp system TRANSPORT_TABLESPACES=fsdata,fsindex TRANSPORT_FULL_CHECK=YES DIRECTORY=dp_for_cloud
```

3. Use a secure copy utility to transfer the Data Pump Export dump file and the tablespace datafiles to the Database service compute node.

   In this example the dump file is copied to the `/u01` directory. Choose the appropriate location based on the size of the file that will be transferred.

   a. On the Database service compute node, create a directory for the dump file.

```
mkdir /u01/app/oracle/admin/ORCL/dpdump/from_onprem
```

   b. Before using the `scp` utility to copy files, make sure the SSH private key that provides access to the Database service compute node is available on your on-premises host.

   c. On the on-premises database host, use the `scp` utility to transfer the dump file and all datafiles of the transportable set to the Database service compute node.

```
scp -i private_key_file \
/u01/app/oracle/admin/orcl/dpdump/for_cloud/expdat.dmp \
oracle@IP_address_DBaaS_VM:/u01/app/oracle/admin/ORCL/dpdump/from_onprem

$ scp -i private_key_file \/u01/app/oracle/oradata/orcl/fsdata01.dbf \
```

```
oracle@IP_address_DBaaS_VM:/u02/app/oracle/oradata/ORCL

$ scp -i private_key_file \/u01/app/oracle/oradata/orcl/fsindex01.dbf \
oracle@IP_address_DBaaS_VM:/u02/app/oracle/oradata/ORCL
```

4. Set the on-premises tablespaces back to `READ WRITE`.
    a. Invoke SQL*Plus and log in as the `SYSTEM` user.
    b. Set the `FSDATA` and `FSINDEX` tablespaces back to `READ WRITE` mode.

```
SQL> ALTER TABLESPACE fsdata READ WRITE;
Tablespace altered.
SQL> ALTER TABLESPACE fsindex READ WRITE;
Tablespace altered.
```

    c. Exit from SQL*Plus.
5. On the Database service compute node, prepare the database for the tablespace import.
    a. On the Database service compute node, invoke SQL*Plus and log in to the database as the `SYSTEM` user.
    b. Create a directory object in the Database service database.

```
SQL> CREATE DIRECTORY dp_from_onprem AS '/u01/app/oracle/admin/ORCL/dpdump/from_onprem';
```

    c. If the owners of the objects that will be imported do not exist in the database, create them before performing the import. The transportable tablespace mode of import does not create the users.

```
SQL> CREATE USER fsowner
  2  PROFILE default
  3  IDENTIFIED BY fspass
  4  TEMPORARY TABLESPACE temp
  5  ACCOUNT UNLOCK;
```

6. On the Database service compute node, invoke Data Pump Import and connect to the database.
   Import the data into the database using the `TRANSPORT_DATAFILES` option.

```
impdp system DIRECTORY=dp_from_onprem \
TRANSPORT_DATAFILES='/u02/app/oracle/oradata/ORCL/fsdata01.dbf', \
'/u02/app/oracle/oradata/ORCL/fsindex01.dbf'
```

7. Set the tablespaces on the Database service database to `READ WRITE` mode.
    a. Invoke SQL*Plus and log in as the `SYSTEM` user.
    b. Set the `FSDATA` and `FSINDEX` tablespaces to `READ WRITE` mode.

    ```
    SQL> ALTER TABLESPACE fsdata READ WRITE;
    Tablespace altered.
    SQL> ALTER TABLESPACE fsindex READ WRITE;
    Tablespace altered.
    ```

    c. Exit from SQL*Plus.
8. After verifying that the data has been imported successfully, you can delete the `expdat.dmp` dump file.

Remote Cloning a PDB

You can use this method only if the on-premises platform is little endian, the on-premises database release is 12.1.0.2 or higher, and the on-premises database and Database service database have compatible database character sets and national character sets.

You can use the remote cloning method to copy a PDB from your on-premises Oracle Database 12c database to a PDB in an Oracle Database 12c database on the Database service.

Migration Tasks

To migrate an Oracle Database 12c PDB to a PDB in a Database service database deployment using the remote cloning method, you perform these tasks:

1. On the on-premises database host, invoke SQL*Plus and close the on-premises PDB and then reopen it in `READ ONLY` mode.
2. On the Database service compute node, invoke SQL*Plus and create a database link that enables a connection to the on-premises database.

3. On the Database service compute node, execute the `CREATE PLUGGABLE DATABASE` command to clone the on-premises PDB.
4. On the Database compute node, open the new PDB by executing the `ALTER PLUGGABLE DATABASE OPEN` command.
5. Optionally, on the on-premises database host invoke SQL*Plus and set the on-premises PDB back to `READ WRITE` mode.

For more information, see "Cloning a Remote PDB or Non-CDB" in *Oracle Database Administrator's Guide* for Release 12.2 or 12.1.

Remote Cloning Non-CDB

You can use this method only if the on-premises platform is little endian, the on-premises database release is 12.1.0.2 or higher, and the on-premises database and Database service database have compatible database character sets and national character sets.

You can use the remote cloning method to copy an Oracle Database 12c non-CDB on-premises database to a PDB in an Oracle Database 12c database on the Databaseservice.

Migration Tasks

To migrate an Oracle Database 12c non-CDB database to a Database service database deployment using the remote cloning method, you perform these tasks:

1. On the on-premises database host, invoke SQL*Plus and set the on-premises database to `READ ONLY` mode.
2. On the Database service compute node, invoke SQL*Plus and create a database link that enables a connection to the on-premises database.
3. On the Database service compute node, execute the `CREATE PLUGGABLE DATABASE` command to clone the on-premises non-CDB database.
4. On the Database service compute node, execute the `$ORACLE_HOME/rdbms/admin/noncdb_to_pdb.sql` script.
5. On the Database service compute node, open the new PDB by executing the `ALTER`

`PLUGGABLE DATABASE OPEN` command.

6. Optionally, on the on-premises database host invoke SQL*Plus and set the on-premises database back to `READ WRITE` mode.

For more information, see "Cloning a Remote PDB or Non-CDB" in *Oracle Database Administrator's Guide* for Release 12.2 or 12.1.

RMAN Cross-Platform Transportable PDB

This method can be used only if the on-premises platform is little endian, and the database character sets of your on-premises database and the Database service database are compatible.

To migrate an Oracle Database 12c PDB to a PDB in an Oracle Database 12c database on a Database service deployment using the RMAN cross-platform transportable PDB method, you perform these tasks:

1. On the on-premises database host, invoke SQL*Plus and close the on-premises PDB.
2. On the on-premises database host, execute the `ALTER PLUGGABLE DATABASE UNPLUG` command to generate an XML file containing the list of datafiles that will be plugged in on the cloud database.
3. On the on-premises database host, invoke RMAN and connect to the root. Execute the `BACKUP FOR TRANSPORT PLUGGABLE DATABASE` command.
4. Use a secure copy utility to transfer the XML file and the backup set to the Database service compute node.
5. On the Database service compute node, invoke RMAN and connect to the root. Execute the `RESTORE ALL FOREIGN DATAFILES` command.
6. the Database service compute node, invoke SQL*Plus and connect to the root. Execute the `CREATE PLUGGABLE DATABASE` command.
7. the Database service compute node, execute the `ALTER PLUGGABLE DATABASE OPEN` command.

For more information, see " Performing Cross-Platform Data Transport in CDBs and PDBs" in *Oracle Database Backup and Recovery User's Guide* for Release 12.2 or 12.1.

RMAN Cross-Platform Transportable Tablespace Backup Sets

You can use this method only if the database character sets of your on-premises database and the Database service database are compatible.

Note

For detailed information on a similar method that enables you to perform a cross-platform transport of an entire database, see the *Oracle Database 12c Backup and Recovery User's Guide* for Release 12.2 or 12.1 . When you transport an entire database to a different platform, the source platform and the destination platform must use the same endian format.

To migrate Oracle Database 12c on-premises tablespaces to an Oracle Database 12c database on a Database service deployment using the RMAN cross-platform transportable backup sets method, you perform these tasks:

1. On the on-premises database host, prepare the database by placing the user-defined tablespaces that you intend to transport in `READ ONLY` mode.
2. On the on-premises database host, invoke RMAN and use the `BACKUP` command with the `TO PLATFORM` or `FOR TRANSPORT` clause and the `DATAPUMP` clause to create a backup set for cross-platform transport. See in "BACKUP" in *Oracle Database Backup and Recovery Reference* for Release 12.2 or 12.1 for more information on the `BACKUP` command.
3. Use a secure copy utility to transfer the backup sets, including the Data Pump export dump file, to the Database service compute node.
4. Set the on-premises tablespaces back to `READ WRITE`.
5. On the Database service compute node, prepare the database by creating the required

schemas.

6. On the Database service compute node, invoke RMAN and use the `RESTORE` command with the `foreignFileSpec` subclause to restore the cross-platform backup.
7. On the Database service compute node, set the tablespaces on the database to `READ WRITE` mode.

For more information, see "Overview of Cross-Platform Data Transport Using Backup Sets" in *Oracle Database Backup and Recovery User's Guide* for Release 12.2 or 12.1.

RMAN Cross-Platform Transportable Tablespace Backup Sets: Example

This example provides a step-by-step demonstration of the tasks required to migrate tablespaces in an Oracle Database PDB to a Database service database.

This example performs a migration of the `FSDATA` and `FSINDEX` tablespaces.

In this example, the on-premises database is on a Linux host.

1. On the on-premises database host, prepare the database by creating a directory for the export dump file and placing the user-defined tablespaces that you intend to transport in READ ONLY mode..
    a. On the on-premises database host, create a directory in the operating system to use for the export dump.

    ```
    mkdir /u01/app/oracle/admin/orcl/dpdump/for_cloud
    ```

    b. On the on-premises data host, invoke SQL*Plus and log in to the PDB as the `SYSTEM` user..

    ```
    sqlplus system@pdb_servicename
    Enter password: enter the password for the SYSTEM user
    ```

    c. Create a directory object in the on-premises database to reference the operating system directory.

    ```
    SQL> CREATE DIRECTORY dp_for_cloud AS '/u01/app/oracle/admin/orcl/dpdump/for_cloud';
    ```

    d. On the on-premises database host, set all tablespaces that will be transported

(the transportable set) to READ ONLY mode.

```
SQL> ALTER TABLESPACE fsindex READ ONLY;
SQL> ALTER TABLESPACE fsdata READ ONLY;
```

e. Exit from SQL*Plus.

2. On the on-premises database host, invoke RMAN and use the `BACKUP` command with the `TO PLATFORM` or `FOR TRANSPORT` clause and the `DATAPUMP` clause to create a backup set for cross-platform transport.

   a. On the on-premises database host, create an operating system directory for the datafiles.

   ```
   mkdir /u01/app/oracle/admin/orcl/rman_transdest
   ```

   b. Invoke RMAN and log in as a user that has been granted the `SYSDBA` or `SYSBACKUP` privilege.

   ```
   rman target username@pdb_servicename
   ```

   c. Execute the `BACKUP` command.

   ```
   RMAN> BACKUP FOR TRANSPORT
   2> FORMAT '/u01/app/oracle/admin/orcl/rman_transdest/fs_tbs.bck'
   3> TABLESPACE fsdata,fsindex
   4> DATAPUMP FORMAT '/u01/app/oracle/admin/orcl/rman_transdest/fs_tbs.dmp';
   ```

   d. Log out of RMAN.

   e. Optionally, navigate to the directory you specified in the `BACKUP` command to view the files that were created.

   ```
   cd /u01/app/oracle/admin/orcl/rman_transdest
   $ ls
   fs_tbs.bck  fs_tbs.dmp
   ```

3. Use a secure copy utility to transfer the backup set, including the Data Pump export dump file, to the Database service compute node.

   a. On the Database service compute node, create a directory for the backup set and dump file.

   ```
   mkdir /tmp/from_onprem
   ```

b. Before using the `scp` command to copy files, make sure the SSH private key that provides access to the Database service compute node is available on your on-premises host.

c. On the on-premises database host, use the SCP utility to transfer the backup set and the dump file to the Database service compute node.

```
scp -i private_key_file \
/u01/app/oracle/admin/orcl/rman_transdest/fs_tbs.bck \
oracle@IP_address_DBaaS_VM:/tmp/from_onprem

$ scp -i private_key_file \
/u01/app/oracle/admin/orcl/rman_transdest/fs_tbs.dmp \
oracle@IP_address_DBaaS_VM:/tmp/from_onprem

$
```

4. Set the on-premises tablespaces back to READ WRITE.

a. Invoke SQL*Plus and log in to the PDB as the `SYSTEM` user.

b. Set the `FSDATA` and `FSINDEX` tablespaces back to READ WRITE mode.

```
SQL> ALTER TABLESPACE fsdata READ WRITE;
SQL> ALTER TABLESPACE fsindex READ WRITE;
```

c. Exit from SQL*Plus.

5. On the Database service compute node, prepare the database by creating the required schemas.

a. On the Database service compute node, invoke SQL*Plus and log in to the PDB as the `SYSTEM` user.

b. If the owners of the objects that will be imported do not exist in the database, create them before performing the `RESTORE`.

```
SQL> CREATE USER fsowner
  2  PROFILE default
  3  IDENTIFIED BY fspass
  4  TEMPORARY TABLESPACE temp
  5  ACCOUNT UNLOCK;
```

6. On the Database service compute node, invoke RMAN and use the `RESTORE` command with the `foreignFileSpec` subclause to restore the cross-platform backup.
    a. Create an operating system directory for the Data Pump Dump file.

    ```
    mkdir /tmp/from_onprem
    ```

    b. Invoke RMAN and log in to the PDB as a user that has been granted the `SYSDBA` or `SYSBACKUP` privilege.

    ```
    rman target username@pdb_servicename
    ```

    c. Execute the `RESTORE` command.

    ```
    RMAN> RESTORE FOREIGN TABLESPACE fsdata,fsindex TO NEW
    2> FROM BACKUPSET '/tmp/from_onprem/fs_tbs.bck'
    3> DUMP FILE DATAPUMP DESTINATION '/tmp/datapump'
    4> FROM BACKUPSET '/tmp/from_onprem/fs_tbs.dmp';
    ```

    d. Exit from RMAN.
7. On the Database service compute node, set the tablespaces to READ WRITE mode.
    a. Invoke SQL*Plus and log in to the PDB as the `SYSTEM` user.
    b. Set the `FSDATA` and `FSINDEX` tablespaces to READ WRITE.

    ```
    SQL> ALTER TABLESPACE fsdata READ WRITE;
    SQL> ALTER TABLESPACE fsindex READ WRITE;
    ```

    c. Exit from SQL*Plus.
8. After verifying that the data has been imported successfully, you can delete the backup set files that were transported from the on-premises host.

RMAN Transportable Tablespace with Data Pump

You can use this method only if the on-premises platform is little endian, and the database character sets of your on-premises database and the Databaseservice database are compatible.

You can use this method to eliminate placing the tablespaces in `READ ONLY` mode, as required by the Data Pump Transportable Tablespace method.

To migrate an on-premises source database to a database deployment on the Database service using the RMAN Transportable Tablespace with Data Pump method, you perform these tasks:

1. On the on-premises database host, invoke RMAN and create the transportable tablespace set.
2. Use a secure copy utility to transfer the Data Pump Export dump file and the tablespace datafiles to the Database service compute node.
3. On the Database service compute node, prepare the database for the tablespace import.
4. On the Database service compute node, invoke Data Pump Import and connect to the database. Import the data into the database using the `TRANSPORT_DATAFILES` option.
5. After verifying that the data has been imported successfully, you can delete the dump file.

RMAN Transportable Tablespace with Data Pump: Example

This example provides a step-by-step demonstration of the tasks required to migrate tablespaces in an on-premises Oracle database to a Database service database.

This example performs a migration of the `FSDATA` and `FSINDEX` tablespaces.

In this example, the on-premises database is on a Linux host.

1. On the on-premises database host, invoke RMAN and create the transportable tablespace set.
    a. On the on-premises database host, create an operating system directory for the datafiles.

    ```
    mkdir /u01/app/oracle/admin/orcl/rman_transdest
    ```

    b. On the on-premises data host, create an operating system directory for the RMAN auxiliary instance files.

    ```
    mkdir /u01/app/oracle/admin/orcl/rman_auxdest
    ```

c. Invoke RMAN and log in as the `SYSTEM` user. Enter the password for the `SYSTEM` user when prompted.

```
rman target system
```

d. Execute the `TRANSPORT TABLESPACE` command.

```
RMAN> TRANSPORT TABLESPACE fsdata, fsindex
2> TABLESPACE DESTINATION '/u01/app/oracle/admin/orcl/rman_transdest'
3> AUXILIARY DESTINATION '/u01/app/oracle/admin/orcl/rman_auxdest';
```

e. Log out of RMAN.

f. Optionally, navigate to the directory you specified for the `TABLESPACE DESTINATION` and view the files that were created by the `TRANSPORT TABLESPACE` operation.

```
cd /u01/app/oracle/admin/orcl/rman_transdest
$ ls
dmpfile.dmp  fsdata01.dbf  fsindex01.dbf  impscrpt.sql
```

2. Use a secure copy utility to transfer the Data Pump Export dump file and the tablespace datafiles to the Database service compute node.

   In this example the dump file is copied to the `/u01` directory. Choose the appropriate location based on the size of the file that will be transferred.

   a. On the Database service compute node, create a directory for the dump file.

```
mkdir /u01/app/oracle/admin/ORCL/dpdump/from_onprem
```

   b. Before using the `scp` command to copy files, make sure the SSH private key that provides access to the Database service compute node is available on your on-premises host.

   c. On the on-premises database host, use the SCP utility to transfer the dump file and all datafiles of the transportable set to the Database service compute node.

```
scp -i private_key_file \
/u01/app/oracle/admin/orcl/rman_transdest/dmpfile.dmp \
oracle@IP_address_DBaaS_VM:/u01/app/oracle/admin/ORCL/dpdump/from_onprem

$ scp -i private_key_file \
/u01/app/oracle/admin/orcl/rman_transdest/fsdata01.dbf \
```

```
oracle@IP_address_DBaaS_VM:/u02/app/oracle/oradata/ORCL

$ scp -i private_key_file \
/u01/app/oracle/admin/orcl/rman_transdest/fsindex01.dbf \
oracle@IP_address_DBaaS_VM:/u02/app/oracle/oradata/ORCL
```

3. On the Database service compute node, prepare the database for the tablespace import.

    a. On the Database service compute node, invoke SQL*Plus and log in to the database as the `SYSTEM` user.

    b. Create a directory object in the Database service database.

    ```
    SQL> CREATE DIRECTORY dp_from_onprem AS '/u01/app/oracle/admin/ORCL/dpdump/from_onprem';
    ```

    c. If the owners of the objects that will be imported do not exist in the database, create them before performing the import. The transportable tablespace mode of import does not create the users.

    ```
    SQL> CREATE USER fsowner
      2  PROFILE default
      3  IDENTIFIED BY fspass
      4  TEMPORARY TABLESPACE temp
      5  ACCOUNT UNLOCK;
    ```

4. On the Database service compute node, invoke Data Pump Import and connect to the database.

    Import the data into the database using the `TRANSPORT_DATAFILES` option.

    ```
    impdp system DIRECTORY=dp_from_onprem DUMPFILE='dmpfile.dmp' \
    TRANSPORT_DATAFILES='/u02/app/oracle/oradata/ORCL/fsdata01.dbf', \
    '/u02/app/oracle/oradata/ORCL/fsindex01.dbf'
    ```

5. After verifying that the data has been imported successfully, you can delete the `dmpfile.dmp` dump file.

RMAN CONVERT Transportable Tablespace with Data Pump

You can use this method only if the database character sets of your on-premises database and the Database service database are compatible.

This method is similar to the Data Pump Transportable Tablespace method, with the addition of the RMAN `CONVERT` command to enable transport between platforms with different endianness. Query `V$TRANSPORTABLE_PLATFORM` to determine if the on-premises database platform supports cross-platform tablespace transport and to determine the endian format of the platform. The Database service platform is little-endian format.

To migrate tablespaces from your on-premises Oracle database to a database deployment on the Database service using RMAN, you perform these tasks:

1. On the on-premises database host, prepare the database for the Data Pump transportable tablespace export.
2. On the on-premises database host, invoke Data Pump Export to perform the transportable tablespace export.
3. On the on-premises database host, invoke RMAN and use the `CONVERT TABLESPACE` command to convert the tablespace datafile to the Database service platform format. Refer to the Oracle Database Backup and Recovery Reference for more information on the `CONVERT` command.
4. Use a secure copy utility to transfer the Data Pump Export dump file and the converted tablespace datafiles to the Database service compute node.
5. Set the on-premises tablespaces back to `READ WRITE`.
6. On the Database service compute node, prepare the database for the tablespace import.
7. On the Database service compute node, invoke Data Pump Import and connect to the database.
8. On the Database service compute node, set the tablespaces in the database to `READ WRITE` mode.
9. After verifying that the data has been imported successfully, you can delete the dump file.

RMAN CONVERT Transportable Tablespace with Data Pump: Example

This example provides a step-by-step demonstration of the tasks required to migrate tablespaces in an on-premises Oracle database to a Database service database.

In this example, the on-premises database is on a Linux host.

1. On the on-premises database host, prepare the database for the Data Pump transportable tablespace export.
    a. On the on-premises database host, create a directory in the operating system to use for the on-premises export.

    ```
    mkdir /u01/app/oracle/admin/orcl/dpdump/for_cloud
    ```

    b. On the on-premises database host, invoke SQL*Plus and log in to the on-premises database as the `SYSTEM` user.

    ```
    sqlplus system
    Enter password: <enter the password for the SYSTEM user>
    ```

    c. Create a directory object in the on-premises database to reference the operating system directory.

    ```
    SQL> CREATE DIRECTORY dp_for_cloud AS '/u01/app/oracle/admin/orcl/dpdump/for_cloud';
    ```

    d. On the on-premises database host, set all tablespaces that will be transported (the transportable set) to `READ ONLY` mode.

    ```
    SQL> ALTER TABLESPACE fsindex READ ONLY;
    Tablespace altered.
    SQL> ALTER TABLESPACE fsdata READ ONLY;
    Tablespace altered.
    ```

    e. Exit from SQL*Plus.
2. On the on-premises database host, invoke Data Pump Export to perform the transportable tablespace export.
    On the on-premises database host, invoke Data Pump Export and connect to the on-premises database. Export the on-premises tablespaces using the `TRANSPORT_TABLESPACES` option. Provide the password for the `SYSTEM` user when prompted.

    ```
    expdp system TRANSPORT_TABLESPACES=fsdata,fsindex TRANSPORT_FULL_CHECK=YES DIRECTORY=dp_for_cloud
    ```

3. On the on-premises database host, invoke RMAN and use the `CONVERT TABLESPACE` command to convert the tablespace datafile to the Database service platform format.

a. Invoke RMAN.

```
rman target /
```

b. Execute the RMAN `CONVERT TABLESPACE` command to convert the datafiles and store the converted files in a temporary location on the on-premises database host.

```
RMAN> CONVERT TABLESPACE fsdata, fsindex
   2> TO PLATFORM 'Linux x86 64-bit'
   3> FORMAT '/tmp/%U ';
…
input datafile file number=00006 name=/u01/app/oracle/oradata/orcl/fsdata01.dbf
converted datafile=/tmp/data_D-ORCL_I-1410251631_TS-FSDATA_FNO-6_0aqc9un3
…
input datafile file number=00007 name=/u01/app/oracle/oradata/orcl/fsindex01.dbf
converted datafile=/tmp/data_D-ORCL_I-1410251631_TS-FSINDEX_FNO-7_0bqc9un6
…
```

c. Take note of the names of the converted files. You will copy these files to the Database service compute node in the next step.

d. Exit RMAN.

4. Use a secure copy utility to transfer the Data Pump Export dump file and the converted tablespace datafiles to the Database service compute node.

   In this example the dump file is copied to the `/u01` directory. Choose the appropriate location based on the size of the file that will be transferred.

   a. On the Databaseservice compute node, create a directory for the dump file.

   ```
   mkdir /u01/app/oracle/admin/ORCL/dpdump/from_onprem
   ```

   b. Before using the `scp` command to copy files, make sure the SSH private key that provides access to the Database service compute node is available on your on-premises host.

   c. On the on-premises database host, use the `scp` utility to transfer the dump file and all data files of the transportable set to the Database service compute node.

   ```
   scp -i private_key_file \
   /u01/app/oracle/admin/orcl/dpdump/for_cloud/expdat.dmp \
   oracle@IP_address_DBaaS_VM:/u01/app/oracle/admin/ORCL/dpdump/from_onprem
   ```

```
$ scp -i private_key_file \
/tmp/data_D-ORCL_I-1410251631_TS-FSDATA_FNO-6_0aqc9un3 \
oracle@IP_address_DBaaS_VM:/u02/app/oracle/oradata/ORCL/fsdata01.dbf

$ scp -i private_key_file \
/tmp/data_D-ORCL_I-1410251631_TS-FSINDEX_FNO-7_0bqc9un6 \
oracle@IP_address_DBaaS_VM:/u02/app/oracle/oradata/ORCL/fsindex01.dbf
```

5. Set the on-premises tablespaces back to `READ WRITE`.
    a. Invoke SQL*Plus and log in as the `SYSTEM` user.
    b. Set the `FSDATA` and `FSINDEX` tablespaces back to `READ WRITE` mode.

    ```
    SQL> ALTER TABLESPACE fsdata READ WRITE;
    Tablespace altered.
    SQL> ALTER TABLESPACE fsindex READ WRITE;
    Tablespace altered.
    ```

    c. Exit from SQL*Plus.
6. On the Database service compute node, prepare the database for the tablespace import.

    a. On the Database service compute node, invoke SQL*Plus and log in to the database as the `SYSTEM` user.
    b. Create a directory object in the Database service database.

    ```
    SQL> CREATE DIRECTORY dp_from_onprem AS '/u01/app/oracle/admin/ORCL/dpdump/from_onprem';
    ```

    c. If the owners of the objects that will be imported do not exist in the database, create them before performing the import. The transportable tablespace mode of import does not create the users.

    ```
    SQL> CREATE USER fsowner
      2  PROFILE default
      3  IDENTIFIED BY fspass
      4  TEMPORARY TABLESPACE temp
      5  ACCOUNT UNLOCK;
    ```

7. On the Database service compute node, invoke Data Pump Import and connect to the database.

Import the data into the Database service database using the `TRANSPORT_DATAFILES` option

```
impdp system DIRECTORY=dp_from_onprem \
TRANSPORT_DATAFILES='/u02/app/oracle/oradata/ORCL/fsdata01.dbf', \
'/u02/app/oracle/oradata/ORCL/fsindex01.dbf'
```

8. On the Database service compute node, set the tablespaces in the database to `READ WRITE` mode.
    a. Invoke SQL*Plus and log in as the `SYSTEM` user.
    b. Set the `FSDATA` and `FSINDEX` tablespaces to `READ WRITE` mode.

    ```
    SQL> ALTER TABLESPACE fsdata READ WRITE;
    Tablespace altered.
    SQL> ALTER TABLESPACE fsindex READ WRITE;
    Tablespace altered.
    ```

    c. Exit from SQL*Plus.
9. After verifying that the data has been imported successfully, you can delete the `expdat.dmp` dump file.

RMAN DUPLICATE from an Active Database

This topic explains how to migrate an entire, active container database (CDB) or non-CDB database to Oracle Cloud Infrastructure by using RMAN Active Duplication. The database to be migrated can reside on-premises or in Oracle Cloud Infrastructure Classic. This topic does not cover duplicating a pluggable database, or migrating a pluggable database or non-CDB to a CDB in the cloud.

The following terms are used throughout this topic:

- Source database: The active database to be migrated.
- Target database: The new database (duplicated from the source database) on a DB system in the Oracle Cloud Infrastructure.

Note

Version 11.2.0.4 databases will be migrated to a DB system using a ACFS storage.

Prerequisites

For the source database to be migrated, you'll need:

- The source database name, database unique name, listener port, service name, database home patch level, and the password for SYS.
- A copy of the sqlpatch directory from the source database home. This is required for rollback in case the target DB system does not include these patches.
- If the source database is configured with Transparent Data Encryption (TDE), you'll need a backup of the wallet and the wallet password to allow duplication of a database with encrypted data.

When migrating a source database to an existing target database, Oracle recommends that you patch the source environment to the same database bundle patch level as the target database home. If the source environment has an interim patch (previously known as a "one-off" patch) that includes a sqlpatch component, and that sqlpatch is missing from the target environment (or a different cumulative patch is applied), the interim patch should be rolled back in the source environment before the migration, if possible.

Tip

To check for interim patches installed on the source or target database, use the `$ORACLE_HOME/OPatch/opatch lspatches` command. To roll back SQL changes in the target database, copy the `$ORACLE_HOME/sqlpatch/<patch#>/postdeinstall.sql` script from the source environment to the cloud environment and execute the `postdeinstall.sql` script.

For the target database, you'll need:

- A target DB system that supports the same database edition as the source database edition. When you launch a DB system, an initial database is created on it. If necessary, you can delete that database and create a new one by using the dbcli command line interface. For more information on creating a DB system, see Creating Bare Metal and Virtual Machine DB Systems. For information about creating a database with the DBCLI, see Database Commands.
- The target database name, database unique name, auxiliary service name, and database home patch level.
- A free TCP port in the target database to setup the auxiliary instance.

If you need to roll back interim patches in the target environment so that the patch level matches that of the source environment, copy the source DB $ORACLE_HOME/sqlpatch/*<patch_number>* directory to the target database home.

Migrating Source Databases That Include Patch Set Updates (PSUs)

In Oracle Cloud Infrastructure DB systems, the database home includes an installation of Database Proactive Bundle Patches. If the source DB uses Patch Set Updates (PSUs), follow the instructions in MOS Note:1962125.1 (Oracle Database - Overview of Database Patch Delivery Methods) for migrating the DB into Oracle Cloud Infrastructure.

Verifying the Environment

Perform the following steps before you begin the migration:

1. Make sure the source DB system is reachable from the target DB system. You should be able to SSH between the two hosts.
2. On the target host, use the TNSPING utility to make sure the source host listener port works. For example:

   ```
   tnsping <source_host>:1521
   ```

3. On the target host, use Easy Connect to verify the connection to the source database:

   ```
   <host>:<port>/<service_name>
   ```

   For example:

   ```
   sqlplus system@129.145.0.164:1521/proddb
   ```

   Make sure the connection string does not exceed 64 characters.
4. Copy the required sqlpatch files (for rollback) from the source database home to the target database.
5. Make sure at least one archivelog has been created on the source database, otherwise, the RMAN duplication will fail with an error.
6. If the source database uses wallets, back up the password-based wallet and copy it to the standard location in the DB system:

   ```
   /opt/oracle/dcs/commonstore/wallets/tde/<db_unique_name>/
   ```

7. Make sure the compatibility parameters in the source database are set to at least:
   - 18.0.0.0.0 for an 18.1.0.0 database
   - 12.1.0.2.0 for a 12.1.0.2 or a 12.2.0.1 database
   - 11.2.0.4.0 for an 11.2.0.4 database

Setting Up Storage on the DB System

1. SSH to the DB System.

```
ssh -i <private_key_path> opc@<db_system_ip_address>
```

2. Log in as opc and then sudo to the root user. Use `sudo su -` with a hyphen to invoke the root user's profile, which will set the PATH to the dbcli directory (`/opt/oracle/dcs/bin`).

```
login as: opc

[opc@dbsys ~]$ sudo su -
```

3. Use the dbcli create-dbstorage to set up directories for DATA, RECO, and REDO storage. The following example creates 10GB of ACFS storage for the tdetest database.

```
[root@dbsys ~]# dbcli create-dbstorage --dbname tdetest --dataSize 10 --dbstorage ACFS
```

Note

When migrating a version 11.2 database, ACFS storage must be specified.

4. Use the dbcli list-dbstorages command to list the storage ID. You'll need the ID for the next step.

```
[root@dbsys ~]# dbcli list-dbstorages
ID                                       Type   DBUnique Name        Status
---------------------------------------- ------ -------------------- ----------
9dcdfb8e-e589-4d5f-861a-e5ba981616ed     Acfs   tdetest              Configured
```

5. Use the dbcli describe-dbstorage command with the storage ID from the previous step to list the DATA, RECO and REDO locations.

```
[root@dbsys ~]# dbcli describe-dbstorage --id 9dcdfb8e-e589-4d5f-861a-e5ba981616ed
DBStorage details
----------------------------------------------------------------
                     ID: 9dcdfb8e-e589-4d5f-861a-e5ba981616ed
                DB Name: tdetest
          DBUnique Name: tdetest
```

```
        DB Resource ID:
          Storage Type: Acfs
         DATA Location: /u02/app/oracle/oradata/tdetest
         RECO Location: /u03/app/oracle/fast_recovery_area/
         REDO Location: /u03/app/oracle/redo/
                State: ResourceState(status=Configured)
              Created: August 24, 2016 5:25:38 PM UTC
           UpdatedTime: August 24, 2016 5:25:53 PM UTC
```

Note the locations. You'll use them later to set the `db_create_file_dest`, `db_create_online_log_dest`, and `db_recovery_file_dest` parameters for the database.

Choosing an ORACLE_HOME

Decide which ORACLE_HOME to use for the database restore and then switch to that home with the correct ORACLE_BASE, ORACLE_HOME, and PATH settings.

To get a list of existing ORACLE_HOMEs, use the dbcli list-dbhomes command. To create a new ORACLE_HOME, use the dbcli create-dbhome command.

Copying the Source Database Wallets

Skip this section if the source database is **not** configured with TDE.

1. On the DB system, become the oracle user:

   ```
   sudo su - oracle
   ```

2. Create the following directory if it does not already exist:

   ```
   mkdir /opt/oracle/dcs/commonstore/wallets/tde/<db_unique_name>
   ```

3. Copy the ewallet.p12 file from the source database to the directory you created in the previous step.
4. On the target host, make sure that `$ORACLE_HOME/network/admin/sqlnet.ora` contains the following line:

   ```
   ENCRYPTION_WALLET_LOCATION=(SOURCE=(METHOD=FILE)(METHOD_DATA=
   (DIRECTORY=/opt/oracle/dcs/commonstore/wallets/tde/$ORACLE_UNQNAME)))
   ```

Add the line if it doesn't exist in the file. (The line might not be there if this is a new home and no database has been created yet on this host.)

5. Create the autologin wallet from the password-based wallet to allow auto-open of the wallet during restore and recovery operations.

   For version 12c, use the `ADMINISTER KEY MANAGEMENT` command:

```
$cat create_autologin_12.sh

#!/bin/sh
if [ $# -lt 2 ]; then
        echo "Usage: $0 <db_unique_name> <remote_wallet_location>"
        exit 1;
fi

mkdir /opt/oracle/dcs/commonstore/wallets/tde/$1
cp $2/ewallet.p12* /opt/oracle/dcs/commonstore/wallets/tde/$1
rm -f autokey.ora
echo "db_name=$1"  > autokey.ora
autokeystoreLog="autologinKeystore_`date +%Y%m%d_%H%M%S_%N`.log"
echo "Enter Keystore Password:"
read -s keystorePassword
echo "Creating AutoLoginKeystore -> "
sqlplus "/as sysdba"  <<EOF
spool $autokeystoreLog
set echo on
startup nomount pfile=autokey.ora
ADMINISTER KEY MANAGEMENT CREATE AUTO_LOGIN KEYSTORE
FROM KEYSTORE '/opt/oracle/dcs/commonstore/wallets/tde/$1' -- Keystore location
IDENTIFIED BY "$keystorePassword";
shutdown immediate;
EOF
```

   For version 11g, use the `orapki` command:

```
orapki wallet create -wallet wallet_location -auto_login [-pwd <password>]
```

Setting Up the Static Listener

Set up the static listener for the auxiliary instance for RMAN duplication.

1. On the DB system, create `$ORACLE_HOME/network/admin/listener.ora` and add the following content to it.

```
LISTENER_aux_<db_unique_name>=
  (DESCRIPTION=
    (ADDRESS_LIST=
      (ADDRESS=(PROTOCOL=TCP)(HOST=<hostname> or <ip_address>)(PORT=<available_TCP_port>))
    )
   )
SID_LIST_LISTENER_aux_<db_unique_name>=
  (SID_LIST=
    (SID_DESC=
      (GLOBAL_DBNAME=<auxServiceName_with_domain>)
       (ORACLE_HOME=<Oracle_home_for_target_database>)
       (SID_NAME=<database_name>)
       (ENVS="TNS_ADMIN=<path_to_tnsnames.ora>")
       (ENVS="ORACLE_UNQNAME=<db_unique_name(in lower case)>"))
)
```

2. Make sure the port specified in `(PORT=<available_TCP_port>)` is open in the DB system's iptables and in the DB system's cloud network Security List.

Using the RMAN Duplicate Command to Migrate the Database

1. Set the following environment variables for RMAN and SQL Plus sessions for the database:

```
ORACLE_HOME=<path_of_Oracle_home_where_the database_is_to_be_restored>
ORACLE_SID=<database_name>
ORACLE_UNQNAME=<db_unique_name(in lower case)>
NLS_DATE_FORMAT="mm/dd/yyyy hh24:mi:ss"
```

2. Start the listener:

```
lsnrctl start listener_aux_<db_unique_name>
```

3. Create an `init.ora` file with the minimal required parameters as described in Creating an Initialization Parameter File and Starting the Auxiliary Instance and use it for the auxiliary instance.
4. Start the auxiliary instance in nomount mode:

```
startup nomount
```

5. Run the following commands to duplicate the database. Note that the example below uses variables to indicate the values to be specified:

```
rman target sys/$sourceSysPassword@$sourceNode:$sourceListenerPort/$sourceDb auxiliary
sys/$auxSysPassword@$targetNode:$targetListenerPort/$auxService<<EOF

spool log to "`date +%Y%m%d_%H%M%S_%N`_duplicate_${targetDbUniqueName}_from_${sourceDb}.log"
set echo on

duplicate target database to $targetDb from active database
password file
spfile
 PARAMETER_VALUE_CONVERT $sourceDb $targetDb $sourceDbUniqueNameCaps $targetDbUniqueNameCaps
 set cluster_database='false'
 set db_name='$targetDb'
 set db_unique_name='$targetDbUniqueName'
 set db_create_file_dest='$dataLoc'
 set db_create_online_log_dest_1='$redoLoc'
 set db_recovery_file_dest='$recoLoc'
 set audit_file_dest = '$auditFileDest'
 reset control_files
nofilenamecheck
;
EOF
```

Preparing to Register the Database

Before you register the database:

1. Make sure the database COMPATIBLE parameter value is acceptable.
   For a 11.2 database, the minimum compatibility value is 11.2.0.4.
   For a 12c database, the minimum compatibility value is 12.1.0.2.
   If the value is less than the minimum, the database cannot be registered until you upgrade the database compatibility.
2. Use the following command to verify that the database has registered with the local listener and service name.

```
lsnrctl services
```

3. Use the following command to verify that the password file was restored or created for a new database.

```
ls -ltr $ORACLE_HOME/dbs/orapw<$ORACLE_SID>
```

   If the file does not exist, create it using the orapwd command.

```
orapwd file=<$ORACLE_HOME/dbs/orapw<$ORACLE_SID>> password=<sys_password>
```

4. Use the following command to verify that the restored database is open in read write mode.

```
select open_mode from v$database;
```

   Read write mode is required to register the database later. Any PDBs must also be in read write mode.

5. From oracle home on the migrated database host, use the following command verify the connection to SYS.

```
conn sys/<password>@<service_name> as sysdba
```

   This connection is required to register the database later. Fix any connection issues before continuing.

6. Copy the folder `$ORACLE_HOME/sqlpatch` from source database to the target database. This will enable the `dbcli register-database` command to rollback any conflicting patches.

Note

If you are migrating a version 11.2 database, additional steps are required after you register the database. For more information, see Rolling Back Patches on a Version 11.2 Database.

7. Use the following SQL*Plus command to make sure the database is using the spfile.

```
SHOW PARAMETERS SPFILE
```

Registering the Database on the DB System

The dbcli register-database command registers the migrated database to the dcs-agent so it can be managed by the dcs-agent stack.

Note

The `dbcli register-database` command is not available on 2-node RAC DB Systems.

As the root user, use the `dbcli register-database` command to register the database on the DB system, for example:

```
[root@dbsys ~]# dbcli register-database --dbclass OLTP --dbshape odb1 --servicename crmdb.example.com --
syspassword
Password for SYS:
{
  "jobId" : "317b430f-ad5f-42ae-bb07-13f053d266e2",
  "status" : "Created",
  "message" : null,
  "reports" : [ ],
  "createTimestamp" : "August 08, 2016 05:55:49 AM EDT",
  "description" : "Database service registration with db service name: crmdb.example.com",
  "updatedTime" : "August 08, 2016 05:55:49 AM EDT"
}
```

Migrating a Version 12.1 or Later Database That Includes SQL Patch Components

For a 1-node DB system at version 12.1 or higher, the `dbcli register-database` command automates the datapatch execution. Before executing the `dbcli register-database` command, open all PDBs in read-write mode. If you have already run the `dbcli register-database` command and did not open all PDBs, or did not copy the $ORACLE_HOME/sqlpatch directory from the source database home, manually rerun the datapatch utility to configure the SQL portion of existing interim patches. This can be done by executing the command `$ORACLE_HOME/OPatch/opatch datapatch`.

Tip

If the source database includes patch 23170620 and the target database is running with the October 2017 patch or a later one, the $ORACLE_HOME/sqlpatch directory does not need to be copied to the target database, because the contents of the patch are already installed in the target database.

Rolling Back Patches on a Version 11.2 Database

For version 11.2 databases, the sqlpatch application is not automated, so any interim patches (previously known as a "one-off" patches) applied to the source database that are not part of the installed PSU must be rolled back manually in the target database. After registering the database, execute the `catbundle.sql` script and then the `postinstall.sql` script with the corresponding PSU patch (or the overlay patch on top of the PSU patch), as described below.

Tip

Some interim patches may include files written to the $ORACLE_HOME/rdbms/admin directory as well as the $ORACLE_HOME/sqlpatch directory. Oracle recommends that you roll back these patches in the source database using the instructions in the patch read-me prior to migrating the database to OCI environment. Contact Oracle Support if you need assistance with rolling back these patches.

1. On the DB System, use the `dbcli list-dbhomes` command to find the PSU patch number for the version 11.2 database home. In the following sample command output, the PSU patch number is the second number in the DB Version column:

```
[root@dbsys ~]# dbcli  list-dbhomes
ID                                   Name                DB Version
Home Location                                Status
------------------------------------ ------------------  ------------------------------------  --
---------------------------------------- ----------
59d9bc6f-3880-4d4f-b5a6-c140f16f8c64 OraDB11204_home1  11.2.0.4.160719 (23054319, 23054359)
/u01/app/oracle/product/11.2.0.4/dbhome_1 Configured
```

(The first patch number, 23054319 in the example above, is for the OCW component in the database home.)

2. Find the overlay patch, if any, by using the `lsinventory` command. In the following example, patch number *24460960* is the overlay patch on top of the 23054359 PSU patch.

```
$ $ORACLE_HOME/OPatch/opatch lsinventory
...
Installed Top-level Products (1):

Oracle Database 11g                                                  11.2.0.4.0
There are 1 products installed in this Oracle Home.

Interim patches (5) :

Patch  24460960     : applied on Fri Sep 02 15:28:17 UTC 2016
Unique Patch ID:  20539912
   Created on 31 Aug 2016, 02:46:31 hrs PST8PDT
   Bugs fixed:
     23513711, 23065323, 21281607, 24006821, 23315889, 22551446, 21174504
   This patch overlays patches:
     23054359
   This patch needs patches:
     23054359
   as prerequisites
```

3. Start SQL*Plus and execute the `catbundle.sql` script, for example:

```
SQL> startup
SQL> connect / as sysdba
```

```
SQL> @$ORACLE_HOME/rdbms/admin/catbundle.sql psu apply
exit
```

4. Apply the sqlpatch, using the overlay patch number from the previous step, for example:

```
SQL> connect / as sysdba
SQL> @$ORACLE_HOME/sqlpatch/24460960/postinstall.sql
exit
```

Creating a Backup Configuration (Optional)

If you would like to manage the database backup with the dbcli command line interface, you can associate a new or existing backup configuration with the migrated database when you register it or after you register it. A backup configuration defines the backup destination and recovery window for the database. As the root user, use the following commands to create, list, and display backup configurations:

- dbcli update-backupconfig
- dbcli list-backupconfigs
- dbcli describe-backupconfig

Post Migration Checklist

After the database is migrated and registered on the DB system, use the following checklist to verify the results of the migration and perform any post-migration customizations.

1. Make sure the database files were restored in OMF format.
2. Make sure the database is listed in the dbcli list-databases command output.
3. Check for the following external references in the database and update them if necessary:
    - External tables: If the source database uses external tables, back up that data and migrate it to the target host.
    - Directories: Customize the default directories as needed for the migrated database.

- Database links: Make sure all the required TNS entries are updated in the tnsnames.ora file in ORACLE_HOME.
- Email and URLs: Make sure any email addresses and URLs used in the database are still accessible from the DB system.
- Scheduled jobs: Review the jobs scheduled in source database and schedule similar jobs as needed in the migrated database.

4. If you associated a backup configuration when you registered the database, run a test back up using the dbcli create-backup command.
5. Verify that patches have been applied to all PDBs if the migrated database contains CDB and PDBs.
6. Validate the database performance by using Database Replay and SQL Performance Analyzer for SQL. For more information, see the Database Testing Guide.

SQL Developer and INSERT Statements to Migrate Selected Objects

You can use SQL Developer to create a cart into which you add selected objects to be loaded into an Oracle Database 12c database in the Oracle Cloud Infrastructure Database service.

In this method, you use SQL `INSERT` statements to load the data into your cloud database.

To migrate selected objects to an Oracle Database 12c database in a Database service deployment using SQL Developer and `INSERT` statements, you perform these tasks:

1. Launch SQL Developer, connect to your on-premises database and create a cart containing the objects you want to migrate.
2. In SQL Developer, click the Export Cart icon and select “Insert” in the Format menu.
3. In SQL Developer, open a connection to the Oracle Database 12c database in the Database service and execute the generated script to create the database objects.
4. In SQL Developer, open a connection to the Oracle Database 12c database in the Database service and run the generated script to create the objects and load the data.

SQL Developer and SQL*Loader to Migrate Selected Objects

You can use SQL Developer to create a cart into which you add selected objects to be loaded into an Oracle Database 12c database in the Oracle Cloud Infrastructure Database.

In this method, you use SQL*Loader to load the data into your cloud database.

To migrate selected objects to an Oracle Database 12c database in the Database service deployment using SQL Developer and SQL*Loader, you perform these tasks:

1. Launch SQL Developer, connect to your on-premises database and create a cart containing the objects you want to load into your cloud database.
2. In SQL Developer, click the Export Cart icon and select "loader" in the Format menu.
3. In SQL Developer, open a connection to the Oracle Database 12c database on the Database service and execute the generated script to create the database objects.
4. Use a secure copy utility to transfer the SQL*Loader control files and the SQL*Loader data files to the Database service compute node.
5. On the Database service compute node, invoke SQL*Loader to load the data using the SQL*Loader control files and data files for each object.

Unplugging/Plugging a PDB

You can use this method only if the on-premises platform is little endian, and the on-premises database and the Oracle Cloud Infrastructure Database service database have compatible database character sets and national character sets.

You can use the unplug/plug method to migrate an Oracle Database 12c PDB to a PDB in an Oracle Database 12c database on a Database service database deployment.

To migrate an Oracle Database 12c PDB to a PDB in the Oracle Database 12c database on an Oracle Cloud Infrastructure Database service database deployment using the plug/unplug method, you perform these tasks:

1. On the on-premises database host, invoke SQL*Plus and close the on-premises PDB.
2. On the on-premises database host, execute the `ALTER PLUGGABLE DATABASE UNPLUG`

command to generate an XML file containing the list of datafiles that will be plugged in to the database on the Database service.

3. Use a secure copy utility to transfer the XML file and the datafiles to the Databaseservice compute node.
4. On the Database service compute node, invoke SQL*Plus and execute the `CREATE PLUGGABLE DATABASE` command to plug the database into the CDB.
5. On the Database service compute node, open the new PDB by executing the `ALTER PLUGGABLE DATABASE OPEN` command.

For more information, see "Creating a PDB by Plugging an Unplugged PDB into a CDB" in *Oracle Database Administrator's Guide* for Release 12.2 or 12.1.

Unplugging/Plugging Non-CDB

You can use this method only if the on-premises platform is little endian, and the on-premises database and the Oracle Cloud Infrastructure Database database have compatible database character sets and national character sets.

You can use the unplug/plug method to migrate an Oracle Database 12c non-CDB database to a PDB in an Oracle Database 12c database on a Database service database deployment. This method provides a way to consolidate several non-CDB databases into a single Oracle Database 12c multitenant database on the Database service.

To migrate an Oracle Database 12c non-CDB database to the Oracle Database 12c database on a Database service deployment using the plug/unplug method, you perform these tasks:

1. On the on-premises database host, invoke SQL*Plus and set the on-premises database to `READ ONLY` mode.
2. On the on-premises database host, execute the `DBMS_PDB.DESCRIBE` procedure to generate an XML file containing the list of datafiles that will be plugged in on the cloud database.
3. Use a secure copy utility to transfer the XML file and the datafiles to the Database service compute node.

4. On the Database service compute node, invoke SQL*Plus and execute the `CREATE PLUGGABLE DATABASE` command to plug the database into the CDB.
5. On the Database service compute node, execute the `$ORACLE_HOME/rdbms/admin/noncdb_to_pdb.sql` script to delete unnecessary metadata from the `SYSTEM` tablespace of the new PDB.
6. On the Database service compute node, open the new PDB by executing the `ALTER PLUGGABLE DATABASE OPEN` command.
7. Optionally, on the on-premises database host invoke SQL*Plus and set the on-premises database back to `READ WRITE` mode.

For more information, see "Creating a PDB Using a Non-CDB" in *Oracle Database Administrator's Guide* for Release 12.2 or 12.1.

Troubleshooting

These topics cover some common issues you might run into and how to address them.

- Backup Failures on Bare Metal and Virtual Machine DB Systems
- Patching Failures on Bare Metal and Virtual Machine DB Systems

Backup Failures on Bare Metal and Virtual Machine DB Systems

Database backups can fail for various reasons. Typically, a backup fails because either the database host cannot access the object store, or there are problems on the host or with the database configuration.

This topic includes information to help you determine the cause of the failure and fix the problem. The information is organized into several sections, based on the error condition. If you already know the cause, you can skip to the section with the suggested solution. Otherwise, use the procedure in Determining the Problem to get started.

Determining the Problem

In the Console, a failed database backup either displays a status of **Failed** or hangs in the **Backup in Progress** or **Creating** state. If the error message does not contain enough information to point you to a solution, you can use the database CLI and log files to gather more data. Then, refer to the applicable section in this topic for a solution.

To identify the root cause of the backup failure

1. Log on to the host as the root user and navigate to the `/opt/oracle/dcs/bin/` directory.
2. Determine the sequence of operations performed on the database.

   ```
   dbcli list-jobs | grep -i <dbname>
   ```

   Note the last job ID listed with a status other than **Success**.
3. With the job ID you noted from the previous step, use the following command to check the details of that job:

   ```
   dbcli describe-job -i <job_ID> -j
   ```

   Typically, running this command is enough to reveal the root cause of the failure.
4. If you require more information, review the `/opt/oracle/dcs/log/dcs-agent.log` file.
   You can find the job ID in this file by using the timestamp returned by the job report in step 2.
5. If the problem details suggest an RMAN issue, review the RMAN logs in the `/opt/oracle/dcs/log/<hostname>/rman/bkup/<db_unique_name>/rman_backup/<yyyy-mm-dd>` directory.

Note

If the database failure is on a 2-node RAC database, perform steps 3 and 4 on both nodes.

Database Service Agent Issues

Your Oracle Cloud Infrastructure Database makes use of an agent framework to allow you to manage your database through the cloud platform. Occasionally you might need to restart the dcsagent program if it has the status of **stop/waiting** to resolve a backup failure.

To restart the database service agent

1. From a command prompt, check the status of the agent:

```
initctl status initdcsagent
```

2. If the agent is in the **stop/waiting** state, try to restart the agent:

```
initctl start initdcsagent
```

3. Check the status of the agent again to confirm that it has the **start/running** status:

```
initctl status initdcsagent
```

Oracle Clusterware Issues

Oracle Clusterware enables servers to communicate with each other so that they can function as a collective unit. Occasionally you might need to restart the Clusterware program to resolve a backup failure.

To restart the Oracle Clusterware

1. From command prompt, check the status of Oracle Clusterware:

```
crsctl check crs
```

```
crsctl stat res -t
```

2. If Oracle Clusterware is not online, try to restart the program:

```
crsctl start crs
```

3. Check the status of Oracle Clusterware to confirm that it is online:

```
crsctl check crs
```

Object Store Connectivity Issues

Backing up your database to Oracle Cloud Infrastructure Object Storage requires that the host can connect to the applicable Swift endpoint. You can test this connectivity by using a Swift user.

To ensure your database host can connect to the object store

1. Create a Swift user in your tenancy. See Working with Auth Tokens.
2. With the user you created in the previous step, use the following command to verify the host can access the object store.

```
curl -v -X HEAD -u <user_ID>:'<auth_token>' https://swiftobjectstorage.<region_
name>.oraclecloud.com/v1/<tenant>
```

   See Object Storage FAQ for the correct region to use.

3. If you cannot connect to the object store, refer to Prerequisites for how to configure object store connectivity.

Host Issues

One or more of the following conditions on the database host can cause backups to fail:

Interactive Commands in the Oracle Profile

If an interactive command such as `oraenv`, or any command that might return an error or warning message, was added to the `.bash_profile` file for the grid or oracle user, Database service operations like automatic backups can be interrupted and fail to complete. Check the `.bash_profile` file for these commands, and remove them.

The File System Is Full

Backup operations require space in the `/u01` directory on the host file system. Use the `df -h` command on the host to check the space available for backups. If the file system has insufficient space, you can remove old log or trace files to free up space.

Incorrect Version of the Oracle Database Cloud Backup Module

Your system might not have the required version of the backup module (opc_installer.jar). See Unable to use Managed Backups in your DB System for details about this known issue. To fix the problem, you can follow the procedure in that section or simply update your DB system and database with the latest bundle patch.

Changes to the Site Profile File (glogin.sql)

Customizing the site profile file (`$ORACLE_HOME/sqlplus/admin/glogin.sql`) can cause managed backups to fail in Oracle Cloud Infrastructure. In particular, interactive commands can lead to backup failures. Oracle recommends that you not modify this file for databases hosted in Oracle Cloud Infrastructure.

Database Issues

An improper database state or configuration can lead to failed backups.

Database Not Running During Backup

The database must be active and running while the backup is in progress.

To check that the database is active and running

Use the following command to check the state of your database, and ensure that any

problems that might have put the database in an improper state are resolved:

```
srvctl status database -d <db_unique_name> -verbose
```

The system returns a message including the database's instance status. The instance status must be **Open** for the backup to succeed. If the database is not running, use the following command to start it:

```
srvctl start database -d <db_unique_name> -o open
```

If the database is mounted but does not have the **Open** status, use the following commands to access the SQL*Plus command prompt and set the status to **Open**:

```
sqlplus / as sysdba
```

```
alter database open;
```

ARCHIVING MODE SET TO NOARCHIVELOG

When you provision a new database, the archiving mode is set to `ARCHIVELOG` by default. This is the required archiving mode for backup operations. Check the archiving mode setting for the database and change it to `ARCHIVELOG`, if applicable.

To check and set the archiving mode

Open an SQL*Plus command prompt and enter the following command:

```
select log_mode from v$database;
```

If you need to set the archiving mode to `ARCHIVELOG`, start the database in **Mount** status (and not **Open** status), and use the following command at the SQL*Plus command prompt:

```
alter database archivelog;
```

Be sure to confirm that the `db_recovery_file_dest` parameter points to `+RECO`, and that the `log_archive_dest_1` parameter is set to `USE_DB_RECOVERY_FILE_DEST`.

For RAC databases, one instance must have the **Mount** status when enabling archivelog mode. To enable archivelog mode for a RAC database, perform the following steps:

1. Shutdown all database instances:

```
srvctl stop database -d
```

2. Start one of the database instances in mount state:

```
srvctl start instance -d <db_unique_name> -i <instance_name> -o mount
```

3. Access the SQL*Plus command prompt:

```
sqlplus / as sysdba
```

4. Enable archive log mode:

```
alter database archivelog;
```

```
exit;
```

5. Stop the database:

```
srvctl stop instance -d <db_unique_name> -i <instance_name>
```

6. Re-start all database instances:

```
srvctl start database -d <db_unqiue_name>
```

7. At the SQL*Plus command prompt, confirm the archiving mode is set to `ARCHIVELOG`:

```
select log_mode from v$database;
```

Stuck Database Archiver Process and Backup Failures

Backups can fail when the database instance has a stuck archiver process. For example, this can happen when the flash recovery area (FRA) is full. You can check for this condition using the `srvctl status database -db <db_unique_name> -v` command. If the command returns the following output, you must resolve the stuck archiver process issue before backups will succeed:

```
Instance <instance_identifier> is running on node *<node_identifier>. Instance status: Stuck Archiver
```

Refer to ORA-00257:Archiver Error (Doc ID 2014425.1) for information on resolving a stuck archiver process.

After resolving the stuck process, the command should return the following output :

```
Instance <instance_identifier> is running on node *<node_identifier>. Instance status: Open
```

If the instance status does not change after you resolve the underlying issue with the device or resource being full or unavailable, try one of the following workarounds:

- Restart the database using the `srvctl` command to update the status of the database in the clusterware
- Upgrade the database to the latest patchset levels

TEMPORARY TABLESPACE ERRORS

If fixed table statistics are not up to date on the database, backups can fail with errors referencing temporary tablespace present in the `dcs-agent.log` file. For example:

```
select status from v$rman_status where COMMAND_ID=<backup_id>

ERROR at line 1:
ORA-01652: unable to extend temp segment by 128 in tablespace TEMP
```

Gather your fixed table statics as follows to resolve this issue:

```
conn / as sysdba

exec dbms_stats.gather_fixed_objects_stats();
```

RMAN CONFIGURATION AND BACKUP FAILURES

Editing certain RMAN configuration parameters can lead to backup failures in Oracle Cloud Infrastructure. To check your RMAN configuration, use the `show all` command at the RMAN command line prompt.

See the following list of parameters for details about RMAN the configuration settings that should not be altered for databases in Oracle Cloud Infrastructure.

RMAN configuration settings that should not be altered

```
CONFIGURE RETENTION POLICY TO RECOVERY WINDOW OF 30 DAYS;
```

```
CONFIGURE CONTROLFILE AUTOBACKUP ON;

CONFIGURE DEVICE TYPE 'SBT_TAPE' PARALLELISM 5 BACKUP TYPE TO COMPRESSED BACKUPSET;

CONFIGURE CHANNEL DEVICE TYPE DISK MAXPIECESIZE 2 G;

CONFIGURE CHANNEL DEVICE TYPE 'SBT_TAPE' MAXPIECESIZE 2 G FORMAT   '%d_%I_%U_%T_%t' PARMS  'SBT_
LIBRARY=/opt/oracle/dcs/commonstore/pkgrepos/oss/odbcs/libopc.so ENV=(OPC_
PFILE=/opt/oracle/dcs/commonstore/objectstore/opc_pfile/1578318329/opc_tiger_iad3c8.ora)';

CONFIGURE ARCHIVELOG DELETION POLICY TO BACKED UP 1 TIMES TO 'SBT_TAPE';

CONFIGURE CHANNEL DEVICE TYPE DISK MAXPIECESIZE 2 G;

CONFIGURE ENCRYPTION FOR DATABASE ON;
```

RMAN Retention Policy and Backup Failures

The RMAN retention policy configuration can be the source of backup failures. Using the REDUNDANCY retention policy configuration instead of the RECOVERY WINDOW policy can lead to backup failures. Be sure to use the RECOVERY WINDOW OF 30 DAYS configuration.

To configure the RMAN retention policy setting

1. Find the database ID using the following command:

   ```
   dbcli list-databases
   ```

2. Find the `BackupConfigId` value for the database using the following command:

   ```
   dbcli describe-database -i <database_id>
   ```

3. Update the retention policy configuration to `RECOVERY WINDOW OF 30 DAYS`:

   ```
   dbcli update-backupconfig -i <backup_config_id> --recoverywindow 30
   ```

Loss of Objectstore Wallet File and Backup Failures

RMAN backups fail when an objectstore wallet file is lost. The wallet file is necessary to enable connectivity to the object store.

To confirm that the objectstore wallet file exists and has the correct permissions

1. Find the database ID using the following command:

   ```
   dbcli list-databases
   ```

2. Find the `BackupConfigId` value for the database using the following command:

   ```
   dbcli describe-database -i <database_id>
   ```

3. Find the `BackupLocation` value for the database using the following command:

   ```
   dbcli describe-backupconfig <backup_config_id>
   ```

4. Find the file path of the backup config parameter file (`opc_<backup_location_value>_BC.ora`) using the following command:

   ```
   locate opc_<backup_location_value>_BC.ora
   ```

   For example:

   ```
   [root@orcl 13aef284-9d6b-4eb6-8751-2988aexample]# locate opc_b9naijWMAXzi9example_BC.ora

   /opt/oracle/dcs/commonstore/objectstore/opc_pfile/13aef284-9d6b-4eb6-8751-2988a9example/opc_
   b9naijWMAXzi9example_BC.ora
   ```

5. Find the file path to the wallet file in the backup config parameter file by inspecting the value stored in the `OPC_WALLET` parameter. To do this, navigate to the directory containing the backup config parameter file and use the following `cat` command:

   ```
   cat <backup_config_parameter_file>
   ```

   For example:

   ```
   [root@orcl 13aef284-9d6b-4eb6-8751-2988aexample]# cat opc_b9naijWMAXzi9example_BC.ora
   OPC_HOST=https://swiftobjectstorage.us-ashburn-1.oraclecloud.com/v1/dbbackupiad
   OPC_WALLET='LOCATION=file:/opt/oracle/dcs/commonstore/objectstore/wallets/13aef284-9d6b-4eb6-
   8751-2988aexample CREDENTIAL_ALIAS=alias_opc'
   OPC_CONTAINER=b9naijWMAXzi9example
   ```

6. Confirm that the `cwallet.sso` file exists in the directory specified in the `OPC_WALLET` parameter, and confirm that the file has the correct permissions. The file permissions should have the octal value of "600" (`-rw-------`). Use the following command:

   ```
   ls -ltr /opt/oracle/dcs/commonstore/objectstore/wallets/<backup_config_id>
   ```

   For example:

   ```
   [root@orcl 13aef284-9d6b-4eb6-8751-2988aexample]# ls -ltr
   /opt/oracle/dcs/commonstore/objectstore/wallets/13aef284-9d6b-4eb6-8751-2988aexample

   total 4

   -rw------- 1 oracle oinstall    0 Apr 20 06:45 cwallet.sso.lck

   -rw------- 1 oracle oinstall 1941 Apr 20 06:45 cwallet.sso
   ```

TDE Wallet and Backup Failures

Incorrect TDE Wallet Location Specification

For backup operations to work, the `$ORACLE_HOME/network/admin/sqlnet.ora` file must contain the ENCRYPTION_WALLET_LOCATION parameter formatted exactly as follows:

```
ENCRYPTION_WALLET_LOCATION=(SOURCE=(METHOD=FILE)(METHOD_DATA=
(DIRECTORY=/opt/oracle/dcs/commonstore/wallets/tde/$ORACLE_UNQNAME)))
```

> **Important**
>
> In this wallet location entry, `$ORACLE_UNQNAME` is an environment variable and should not be replaced with an actual value.

To check the TDE wallet location specification

Use the `cat` command to check the TDE wallet location specification. For example:

```
[oracle@orcl tde]$ cat $ORACLE_HOME/network/admin/sqlnet.ora

ENCRYPTION_WALLET_LOCATION=(SOURCE=(METHOD=FILE)(METHOD_DATA=
(DIRECTORY=/opt/oracle/dcs/commonstore/wallets/tde/$ORACLE_UNQNAME)))
```

INCORRECT STATE OF THE TDE WALLET

Database backups fail if the TDE wallet is not in the proper state. The following scenarios can cause this problem:

The ORACLE_UNQNAME environment variable was not set when the database was started using SQL*Plus

If the database was started using SQL*Plus, and the `ORACLE_UNQNAME` environment variable was not set, the wallet is not opened correctly.

To fix the problem, start the database using the `srvctl` utility:

```
srvctl start database -d <db_unique_name>
```

A pluggable database was added with an incorrectly configured master encryption key

In a multitenant environment, each pluggable database (PDB) has its own master encryption key, which is stored in a single keystore used by all containers. After you create or plug in a new PDB, you must create and activate a master encryption key for it. If you do not do so, the `STATUS` column in the `v$encryption_wallet` view shows the value `OPEN_NO_MASTER_KEY`.

To check the master encryption key status and create a master key, do the following:

1. Review the the `STATUS` column in the `v$encryption_wallet` view, as shown in the following example:

   ```
   SQL> alter session set container=pdb2;

   Session altered.

   SQL> select WRL_TYPE,WRL_PARAMETER,STATUS,WALLET_TYPE from v$encryption_wallet;
   ```

```
WRL_TYPE         WRL_PARAMETER                                          STATUS
WALLET_TYPE

--------------- ------------------------------------------------------ ------------------
------

FILE             /opt/oracle/dcs/commonstore/wallets/tde/example_iadxyz/ OPEN_NO_MASTER_KEY
AUTOLOGIN
```

2. Confirm that the PDB is in READ WRITE open mode and is not restricted, as shown in the following example:

```
SQL> show pdbs

CON_ID CON_NAME     OPEN MODE              RESTRICTED

------ ------------ ---------------------- ---------------

2      PDB$SEED     READ ONLY              NO

3      PDB1         READ WRITE             NO

4      PDB2         READ WRITE             NO
```

   The PDB cannot be open in restricted mode (the `RESTRICTED` column must show `NO`). If the PDB is currently in restricted mode, review the information in the PDB_PLUG_IN_VIOLATIONS view and resolve the issue before continuing. For more information on the PDB_PLUG_IN_VIOLATIONS view and the restricted status, review the documentation on pluggable database for your Oracle database version.

3. Run the following `DBCLI` commands to change the status to `OPEN`:

```
$ sudo su -
 # dbcli list-database
 # dbcli update-tdekey -i <database_ID> -n <PDB_name> -p
```

   The `update-tdekey` command shown will prompt you for the admin password.

   a. Confirm that the status of the wallet has changed from OPEN_NO_MASTER_KEY to OPEN by querying the `v$encryption_wallet` view as shown in step 1.

INCORRECT CONFIGURATION RELATED TO THE TDE WALLET

Several configuration parameters related to the TDE wallet can cause backups to fail.

To check configuration related to the TDE wallet

- Check that the environment's database unique name parameter (ORACLE_UNQNAME) is set correctly using the following command:

  ```
  srvctl getenv database -d <db_unique_name>
  ```

  For example:

  ```
  [oracle@orcl tde]$ srvctl getenv database -d orclbkp_iadxyz

  orclbkp_iadxyz:

  ORACLE_UNQNAME=orclbkp_iadxyz

  TZ=UTC
  ```

- Check your `sqlnet.ora` settings to confirm that the file has an ENCRYPTION_WALLET_LOCATION parameter with the correct DIRECTORY value. Use the following command: `cat $ORACLE_HOME/network/admin/sqlnet.ora`

  For example:

  ```
  [oracle@orcl tde]$ cat $ORACLE_HOME/network/admin/sqlnet.ora

  ENCRYPTION_WALLET_LOCATION=(SOURCE=(METHOD=FILE)(METHOD_DATA=
  (DIRECTORY=/opt/oracle/dcs/commonstore/wallets/tde/$ORACLE_UNQNAME)))
  ```

- Confirm that the wallet status is **open** and the wallet type is **auto login** by checking the `v$encryption_wallet` view. For example:

  ```
  SQL> select status, wrl_parameter,wallet_type from v$encryption_wallet;

  STATUS                         WRL_PARAMETER                                          WALLET_TYPE

  ------------------------------ ------------------------------------------------------ ------------
  --------
  ```

```
OPEN                           /opt/oracle/dcs/commonstore/wallets/tde/example_iadxyz/ AUTOLOGIN
```

For pluggable databases (PDBs), be sure that you switch to the appropriate container before querying `v$encryption_wallet` view. For example:

```
[oracle@paulo ~]$ sqlplus / as sysdba

SQL> alter session set container=pdb1;

Session altered.

SQL> select WRL_TYPE,WRL_PARAMETER,STATUS,WALLET_TYPE from v$encryption_wallet;

WRL_TYPE   WRL_PARAMETER                                            STATUS     WALLET_TYPE

---------- ---------------------------------------------------------- ---------- --------------------
--

FILE       /opt/oracle/dcs/commonstore/wallets/tde/tiger_iad3c8/     OPEN       AUTOLOGIN
```

MISSING TDE WALLET FILE

The TDE wallet file (`ewallet.p12`) can cause backups to fail if it is missing, or if it has incompatible file system permissions or ownership. Check the file as shown in the following example:

```
[oracle@orcl tde]$ ls -ltr /opt/oracle/dcs/commonstore/wallets/tde/$ORACLE_UNQNAME/ewallet.p12

-rwx------ 1 oracle oinstall 5680 Apr 18 13:09 /opt/oracle/dcs/commonstore/wallets/tde/orclbkp_
iadxzy/ewallet.p12
```

The TDE wallet file should have file permissions with the octal value "700" (`-rwx------`), and the owner of this file should be a part of the `oinstall` operating system group.

MISSING AUTO LOGIN WALLET FILE

The auto login wallet file (`cwallet.sso`) can cause backups to fail if it is missing, or if it has incompatible file system permissions or ownership. Check the file as shown in the following example:

```
[oracle@orcl tde]$ ls -ltr /opt/oracle/dcs/commonstore/wallets/tde/$ORACLE_UNQNAME/cwallet.sso

-rwx------ 1 oracle oinstall 5725 Apr 18 13:09 /opt/oracle/dcs/commonstore/wallets/tde/orclbkp_
iadxyz/cwallet.sso
```

The auto login wallet file should have file permissions with the octal value "700" (`-rwx------`), and the owner of this file should be a part of the `oinstall` operating system group.

Other Causes of Backup Failures

Unmounted Commonstore Mount Point

The mount point `/opt/oracle/dcs/commonstore` must be mounted, or backups will fail.

To check the commonstore mount point

Confirm that the mount point `/opt/oracle/dcs/commonstore` is mounted, as shown in the following example:

```
[root@orcl ~]# srvctl config filesystem -volume commonstore -diskgroup data

Volume device: /dev/asm/commonstore-5

Diskgroup name: data

Volume name: commonstore

Canonical volume device: /dev/asm/commonstore-5

Accelerator volume devices:

Mountpoint path: /opt/oracle/dcs/commonstore

Mount point owner: oracle

Mount users:

Type: ACFS
```

To confirm that ora.data.commonstore.acfs is online

The state for ora.data.commonstore.acfs must be online, or backups will fail. Confirm as shown in the following example:

```
[root@orcl ~]# crsctl stat resource ora.data.commonstore.acfs -v

NAME=ora.data.commonstore.acfs

TYPE=ora.acfs.type

LAST_SERVER=orcl

STATE=OFFLINE

TARGET=OFFLINE
...

STATE_DETAILS=admin unmounted /opt/oracle/dcs/commonstore

...

[root@orcl ~]# ls -ltr /opt/oracle/dcs/commonstore

total 0
```

If the STATE_DETAILS value is `unmounted`, mount the file system as shown in the following example:

```
[root@orcl ~]# srvctl start filesystem -volume commonstore -diskgroup data
```

Confirm that the change was successful as shown in the following example:

```
[root@orcl ~]# crsctl stat resource ora.data.commonstore.acfs -v

NAME=ora.data.commonstore.acfs

TYPE=ora.acfs.type

LAST_SERVER=orcl
```

```
STATE=ONLINE on orcl

TARGET=ONLINE

CARDINALITY_ID=ONLINE

...

STATE_DETAILS=mounted on /opt/oracle/dcs/commonstore
```

List the contents of the `commonstore` directory to confirm that it is mounted, as shown in the following example:

```
[root@orcl ~]# ls -ltr /opt/oracle/dcs/commonstore

total 220

drwx------ 2 root   root     65536 Apr 18 10:50 lost+found

drwx------ 3 oracle oinstall 20480 Apr 18 11:02 wallets

drwxr-xr-x 3 root   root     20480 Apr 20 06:41 pkgrepos

drwxr-xr-x 4 oracle oinstall 20480 Apr 20 06:41 objectstore
```

THE DATABASE IS NOT PROPERLY REGISTERED

Database backups fail if the database is not registered with the dcs-agent. This scenario can occur if you manually migrate the database to Oracle Cloud Infrastructure and do not run the `dbcli register-database` command.

To check whether the database is properly registered, review the information returned by running the `srvctl config database` command and the `dbcli list-databases` command. If either command does not return a record of the database, contact Oracle Support Services.

For instructions on how to register the database, refer to the following topics:

- Registering the Database on the DB System
- dbcli register-database

Obtaining Further Assistance

If you were unable to resolve the problem using the information in this topic, follow the procedures below to collect relevant database and diagnostic information. After you have collected this information, contact Oracle Support.

To collect database information for use in problem reports

Use the following commands to collect details about your database. Record the output of each command for reference:

```
dbcli list-databases
```

```
dbcli describe-database -i <database_id>
```

```
dbcli describe-component
```

To collect diagnostic information regarding failed jobs

1. Log on to the host as the root user and navigate to the `/opt/oracle/dcs/bin/` directory.
2. Run the following two commands to generate information about the failed job:

   ```
   dbcli list-jobs |grep -i <dbname>
   ```

   ```
   dbcli describe-job -i <job_ID> -j
   ```

   The *<job_ID>* in the second command should be the ID of the latest failed job reported from the first command.
3. Run the diagnostics collector script to create a zip file with the diagnostic information for Oracle Support Services.

   ```
   diagcollector.py
   ```

   This command creates a file named `diagLogs-<timestamp>.zip` in the `/tmp` directory.

To collect DCS agent log files

To collect DCS agent log files, do the following:

1. Log in as opc user.
2. Run the following command:

```
sudo /opt/oracle/dcs/bin/diagcollector.py
```

3. The system returns a message indicating that agent logs are available in a zip file at a specified directory. For example:

```
[opc@prodpr ~]$ sudo /opt/oracle/dcs/bin/diagcollector.py

Log files collected to :/tmp/dcsdiag/diagLogs-1234567890.zip

Logs are being collected to:

/tmp/dcsdiag/diagLogs-1234567890.zip
```

To collect TDE configuration details

1. Run the `srvctl getenv database -d` *<db_unique_name>* command and record the output for reference.
2. Record the output of the view `v$encryption_wallet`. For example:

```
SQL> select status, wrl_parameter,wallet_type from v$encryption_wallet;

STATUS          WRL_PARAMETER                                             WALLET_TYPE

--------------- --------------------------------------------------------- ---------

OPEN            /opt/oracle/dcs/commonstore/wallets/tde/example_iadxyz/ AUTOLOGIN
```

3. Record the output of the output of the `ls -ltr` *<wrl_parameter>* command. For example:

```
[oracle@patchtst ~]$ ls -ltr /opt/oracle/dcs/commonstore/wallets/tde/example_iadxyz/
```

```
total 28

-rw------- 1 oracle asmadmin 2400 May  2 09:42 ewallet_2018050209420381_defaultTag.p12

-rw------- 1 oracle asmadmin 5680 May  2 09:42 ewallet.p12

-rw------- 1 oracle asmadmin 5723 May  2 09:42 cwallet.sso
```

To collect the RMAN backup report file

Generate RMAN Backup Report File using the following command:

```
dbcli create-rmanbackupreport -i <db_id> -w detailed -rn <report_name>
```

For example:

```
[root@patchtst ~]# dbcli create-rmanbackupreport -i 57fvwxyz-9dc4-45d3-876b-5f850example -w detailed -rn
bkpreport1
```

Locate the report file using the `dbcli describe-rmanbackupreport -in <report_name>` command. The location of the report is given in output. For example:

```
[root@patchtst ~]# dbcli describe-rmanbackupreport -in bkpreport1

Backup Report details

------------------------------------------------------------------

ID: b55vwxyz-c49f-4af3-a956-acccdexample

Report Type: detailed

Location: Node patchtst: /opt/oracle/dcs/log/patchtst/rman/bkup/example_iadxyz/rman_list_backup_
detail/2018-05-02/rman_list_backup_detail_2018-05-02_11-46-51.0359.log

Database ID: 57fvwxyz-9dc4-45d3-876b-5f850example

CreatedTime: May 2, 2018 11:46:38 AM UTC
```

Patching Failures on Bare Metal and Virtual Machine DB Systems

Patching operations can fail for various reasons. Typically, an operation fails because a database node is down, there is insufficient space on the file system, or the database host cannot access the object store.

This topic includes information to help you determine the cause of the failure and fix the problem. The information is organized into several sections, based on the error condition. If you already know the cause, you can skip to the section with the suggested solution. Otherwise, use the procedure in Determining the Problem to get started.

Determining the Problem

In the Console, you can identify a failed patching operation by viewing the patch history of a DB system or an individual database. A patch that was not successfully applied displays a status of **Failed** and includes a brief description of the error that caused the failure. If the error message does not contain enough information to point you to a solution, you can use the database CLI and log files to gather more data. Then, refer to the applicable section in this topic for a solution.

To identify the root cause of the patching operation failure

1. Log on to the host as the root user and navigate to the `/opt/oracle/dcs/bin/` directory.
2. Determine the sequence of operations performed on the database.

   ```
   dbcli list-jobs
   ```

   Note the last job ID listed with a status other than **Success**.
3. With the job ID you noted from the previous step, use the following command to check the details of that job:

   ```
   dbcli describe-job -i <job_ID> -j
   ```

   Typically, running this command is enough to reveal the root cause of the failure.

4. If you require more information, review the `/opt/oracle/dcs/log/dcs-agent.log` file.
   You can find the job ID in this file by using the timestamp returned by the job report in step 2.

Note

If the patching failure is on a 2-node RAC database, perform steps 3 and 4 on both nodes.

Database Service Agent Issues

Your Oracle Cloud Infrastructure Database makes use of an agent framework to allow you to manage your database through the cloud platform.

Resolving Patching Failures Caused By a Stopped Agent

Occasionally you might need to restart the dcsagent program if it has the status of **stop/waiting** to resolve a patching failure.

To restart the database service agent

1. From a command prompt, check the status of the agent:

```
initctl status initdcsagent
```

2. If the agent is in the **stop/waiting** state, try to restart the agent:

```
initctl start initdcsagent
```

3. Check the status of the agent again to confirm that it has the **start/running** status:

```
initctl status initdcsagent
```

Resolving Patching Failures Caused By an Agent That Needs to Be Updated

Patching can also fail if your agent needs to be updated. The system gives the following error message for this failure:

```
Current DcsAgent version is less than or equal to minimum required version.
```

To resolve this issue, perform the steps in To have Oracle Support update the Oracle Cloud Infrastructure Database service agent.

To have Oracle Support update the Oracle Cloud Infrastructure Database service agent

1. Confirm that the agent (dcsagent) and DCS Admin program (dcsadmin) are running using the following commands:

   ```
   initctl status initdcsagent
   ```

   ```
   initctl status initdcsadmin
   ```

   If these programs are not running, use the following commands to restart them:

   ```
   initctl start initdcsagent
   ```

   ```
   initctl start initdcsadmin
   ```

2. Follow the instructions in Obtaining Further Assistance to collect your DCS agent log files.
3. Contact Oracle Support for assistance with updating the agent.

Object Store Connectivity Issues

Oracle Cloud Infrastructure DB system and database patches are stored in Oracle Cloud Infrastructure Object Storage. Therefore, successful patching operations require connectivity between the DB system host and the Object Storage location from which the patches are downloaded.

To ensure your database host can connect to Oracle Cloud Infrastructure Object Storage

1. Use the following command to verify the host can access Oracle Cloud Infrastructure Object Storage:

   ```
   dbcli describe-latestpatch
   ```

   Example output indicating success:

   ```
   [root@<host> ~]# dbcli describe-latestpatch

   componentType availableVersion
   --------------- --------------------
   gi 12.2.0.1.180417
   gi 12.1.0.2.180417
   gi 18.2.0.0.180417
   db 11.2.0.4.180417
   db 12.2.0.1.180417
   db 12.1.0.2.180417
   db 18.2.0.0.180417
   oak 12.1.2.11.3
   oak 12.2.1.1.0
   ```

   Example output indicating failure:

   ```
   [root@<host> ~]# dbcli describe-latestpatch

   DCS-10032:Resource patch metadata is not found.Failed to download patchmetadata from
   objectstore
   ```

2. If you cannot connect to the object store, refer to Prerequisites for how to configure object store connectivity.

Host and Oracle Clusterware Issues

One or more of the following conditions on the database host can cause patching operations to fail:

Database Node Not Running During the Patching Operation

All nodes of the database must be active and running while a patching operation is in progress, whether you are patching the DB system or the database home. Use the Console to check that the status of each node is AVAILABLE, and start the node, if needed.

The File System Is Full

Patching operations require a minimum of 15 GB of free space in the `/u01` directory on the host file system. Use the `df -h` command on the host to check the available space. If the file system has insufficient space, you can remove old log or trace files to free up space.

The Oracle Clusterware Is Not Running

Oracle Clusterware enables servers to communicate with each other so that they can function as a collective unit. The cluster software program must be up and running on the DB system for patching operations to complete. Occasionally you might need to restart the Oracle Clusterware to resolve a patching failure.

To restart the Oracle Clusterware

1. From command prompt, check the status of Oracle Clusterware:

   ```
   crsctl check crs
   ```

   Example output:

   ```
   [grid@<host> ~]$ crsctl check crs
   CRS-4638: Oracle High Availability Services is online
   CRS-4537: Cluster Ready Services is online
   CRS-4529: Cluster Synchronization Services is online
   CRS-4533: Event Manager is online
   ```

   For more detailed status information, you can run `crsctl stat res -t`.

2. If Oracle Clusterware is not online, try to restart the program:

   ```
   crsctl start crs
   ```

3. Check the status of Oracle Clusterware to confirm that it is online:

   ```
   crsctl check crs
   ```

The Oracle Grid Infrastructure (GI) Is Not Updated

This problem occurs when you try to patch a database before you patch the DB system of that database. The error description indicates that the Oracle Grid Infrastructure must be updated

first. To resolve this issue, patch the DB system to latest available version. After you patch the DB system, you can retry the database patching operation.

To get the current and latest-available GI versions for the DB system, use the following command:

```
dbcli describe-component
```

Database Issues

An improper database state can lead to patching failures.

Database Not Running During the Patching Operation

The database must be active and running for all of the patching tasks to complete. Otherwise, you must run the datapatch task manually.

To check that the database is active and running

Use the following command to check the state of your database, and ensure that any problems that might have put the database in an improper state are resolved:

```
srvctl status database -d <db_unique_name> -verbose
```

The system returns a message including the database instance status. The instance status must be **Open** for the patching operation to succeed.

If the database is not running, use the following command to start it:

```
srvctl start database -d <db_unique_name> -o open
```

If the database is mounted but does not have the **Open** status, use the following commands to access the SQL*Plus command prompt and set the status to **Open**:

```
sqlplus / as sysdba
```

```
alter database open;
```

To run the datapatch task

Before you run the `datapatch` command, ensure that all pluggable databases (PDBs) are open. To open a PDB, you can use SQL*Plus to execute `ALTER PLUGGABLE DATABASE <pdb_name> OPEN READ WRITE;` against the PDB.

```
$ORACLE_HOME/OPatch/datapatch
```

The datapatch command should be run on each database home.

Obtaining Further Assistance

If you were unable to resolve the problem using the information in this topic, follow the procedures below to collect relevant database and diagnostic information. After you have collected this information, contact Oracle Support.

To collect diagnostic information regarding failed jobs

1. Log on to the host as the root user and navigate to the `/opt/oracle/dcs/bin/` directory.
2. Run the following two commands to generate information about the failed job:

   ```
   dbcli list-jobs
   ```

   ```
   dbcli describe-job -i <job_ID> -j
   ```

   The *<job_ID>* in the second command should be the ID of the latest failed job reported from the first command.
3. Run the diagnostics collector script to create a zip file with the diagnostic information for Oracle Support Services.

   ```
   diagcollector.py
   ```

   This command creates a file named `diagLogs-<timestamp>.zip` in the `/tmp` directory.

To collect DCS agent log files

To collect DCS agent log files, do the following:

1. Log in as opc user.
2. Run the following command:

```
sudo /opt/oracle/dcs/bin/diagcollector.py
```

3. The system returns a message indicating that agent logs are available in a zip file at a specified directory. For example:

```
[opc@prodpr ~]$ sudo /opt/oracle/dcs/bin/diagcollector.py

Log files collected to :/tmp/dcsdiag/diagLogs-1234567890.zip

Logs are being collected to:

/tmp/dcsdiag/diagLogs-1234567890.zip
```

To collect Oracle Grid Infrastructure and Database log files

If an Oracle Grid Infrastructure or Oracle Database patch failed, you can find log files for these failures in the following locations:

Oracle Grid Infrastructure

```
$GI_HOME/cfgtoollogs/
```

Oracle Database

```
$ORACLE_HOME/cfgtoollogs/
```

CHAPTER 12 DNS and Traffic Management

This chapter explains how to create and manage your DNS zones and guide traffic to your endpoints based on various conditions.

Overview of the DNS Service

The Oracle Cloud Infrastructure Domain Name System (DNS) service lets you create and manage your DNS zones. You can create zones, add records to zones, and allow Oracle Cloud Infrastructure's edge network to handle your domain's DNS queries.

See Supported Resource Records for additional information.

DNS Service Components

The following list describes the components used to build a DNS zone and make it accessible from the internet.

DOMAIN

Domain names identify a specific location or group of locations on the Internet as a whole. A common definition of "domain" is the complete portion of the DNS tree that has been delegated to a user's control. For example, *example.com* or *oracle.com*.

ZONE

A zone is a portion of the DNS namespace. A Start of Authority record (SOA) defines a zone. A zone contains all labels underneath itself in the tree, unless otherwise specified.

LABEL

Labels are prepended to the zone name, separated by a period, to form the name of a subdomain. For example, the "www" section of www.example.com or the "docs" and "us-ashburn-1" sections of docs.us-ashburn-1.oraclecloud.com are labels. Records are associated with these domains.

CHILD ZONE

Child zones are independent subdomains with their own Start of Authority and Name Server (NS) records. The parent zone of a child zone must contain NS records that refer DNS queries to the name servers responsible for the child zone. Each subsequent child zone creates another link in the delegation chain.

RESOURCE RECORDS

A record contains specific domain information for a zone. Each record type contains information called record data (RDATA). For example, the RDATA of an A or AAAA record contains an IP address for a domain name, while MX records contain information about the mail server for a domain. OCI normalizes all RDATA into the most machine readable format. The returned presentation of your RDATA may differ from its initial input. For more information about RDATA, please see Supported DNS Resource Record Types.

DELEGATION

The name servers where your DNS is hosted and managed.

Ways to Access the DNS Service

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide.

To access the Console, you must use a supported browser. You can use the Console link at the top of this page to go to the sign-in page. Enter your tenancy, user name, and your password.

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see

Getting Started with Policies. For specific details about writing policies for each of the different services, see Policy Reference.

If you're a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

DNS Service Capabilities and Limits

The Oracle Cloud Infrastructure DNS service is limited to 1000 zones per account and 25,000 records per zone. Customers with zone and record size needs exceeding these values are encouraged to contact support at support.oracle.com. Zone file uploads are limited to 1 megabyte (MB) in size per zone file. If your zone file is larger than 1 MB, you will need to split the zone file into smaller batches to upload all of the zone information.

Required IAM Service Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don't have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

If you're new to policies, see Getting Started with Policies and Common Policies. For more details about policies for DNS, see Details for the DNS Service.

Getting Started with DNS

If you're new to Oracle Cloud Infrastructure DNS, this topic gives guidance on how to proceed.

What is DNS?

The Domain Name System (DNS) translates human-readable domain names to machine-readable IP addresses. A DNS nameserver stores the DNS records for a zone, and responds

with answers to queries against its database. When you type a domain name into your browser, your operating system queries several DNS nameservers until it finds the authoritative nameserver for that domain. The authoritative nameserver then responds with an IP address or other requested record data. The answer is then relayed back to your browser and the DNS record is resolved to the web page.

Creating a Zone

In this step, you will create a zone. A zone holds the trusted DNS records that will reside on Oracle Cloud Infrastructure's nameservers.

To add a zone

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **DNS Zone Management**.
2. Click **Create Zone**.
3. In the **Create Zone** dialog box, choose one of the following methods:
    - **Manual** - Enter the following:
        - **Zone Name**: Enter the name of a zone you want to create. Avoid entering confidential information.
        - **Zone Type**: If you want to control the zone contents directly within Oracle Cloud Infrastructure, select **Primary**. If you want Oracle Cloud Infrastructure to pull zone contents from an external server, select **Secondary** and enter your **Zone Master Server IP** address.
    - **Import** - Drag and drop, select, or paste a valid zone file into the Import Zone File window. The zone is imported as a primary zone. For information about formatting a zone file, see Formatting a Zone File.
4. Click **Submit**.

The system creates and publishes the zone, complete with the necessary SOA and NS records. For more information on adding a record to your zone, see To add a zone record.

Delegating Your Zone

In this step, you will delegate your domain with your registrar. Delegating your domain with your domain's registrar makes your Oracle Cloud Infrastructure hosted zone accessible through the internet.

To delegate a zone

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **DNS Zone Management**.
2. Click the Zone Name for the zone you want to delegate. Zone details and a list of records appear.
3. Use the **Type** sort filter to locate the NS records for your zone.
4. Note the name servers in the RDATA field within each NS record.
5. You can use the noted name servers to change your domain's DNS delegation. Refer to your registrar's documentation for instructions.

Note

Once delegation has completed, allow 24 hours for your delegation to propagate across the internet.

To add a zone record

Tip

There are many record types you can add to your zone, depending on your goals for the zone and its DNS management.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **DNS Zone Management**.
2. Click the **Zone Name** in which you want to add a record. Zone details and a list of records appear.

Tip

You can use the Zone Name sort filter to list to sort zone names alphanumerically in ascending or descending order.

3. Click **Add Record**.
4. In the **Add Record** dialog box, select a record type from the drop-down list, and then enter the information for the record. Avoid entering confidential information. For more information about record types, see Supported Resource Records.
5. (Optional) Click the **Add Another Record** check box to add multiple records in succession.
6. Click **Submit**.
7. Once your records have been added, click **Publish Changes**.
8. In the confirmation dialog box, click **Publish Changes**.

Common DNS Zone Record Types

For a complete list of records supported by Oracle Cloud Infrastructure DNS, see Supported Resource Records.

A

An address record used to point a hostname to an IPv4 address. For more information about A records, see RFC 1035.

AAAA

An address record used point a hostname at an IPv6 address. For more information about AAAA records, see RFC 3596.

CNAME

A Canonical Name record identifies the canonical name for a domain. For more information about CNAME records, see RFC 1035.

Note

Per RFC 1912, CNAMES cannot be placed at the apex of the zone.

MX

A Mail Exchanger record defines the mail server accepting mail for a domain. MX records must point to a hostname. MX records must not point to a CNAME or IP address. For more information about MX records, see RFC 1035.

TXT

A Text record holds descriptive, human readable text, and can also include non-human readable content for specific uses. It is commonly used for SPF records and DKIM records that require non-human readable text items. For more information about TXT records, see RFC 1035.

Testing DNS Using BIND's dig Tool

Using the Domain Information Groper (dig) command line tool, you can test against the delegation where your domain is hosted, and you will immediately see whether the change took place without accounting for the cache or TTL (Time to Live) that you have configured.

For more information on using dig to test your DNS, see Testing DNS Using BIND'S dig Tool.

Managing DNS Service Zones

The Oracle Cloud Infrastructure DNS service enables you to manage zones and view zone reports within the Console.

Using the Console

MANAGING ZONES AND ZONE RECORDS

To add a zone

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **DNS Zone Management**.
2. Click **Create Zone**.
3. In the **Create Zone** dialog box, choose one of the following methods:
    - **Manual** - Enter the following:
        - **Zone Name**: Enter the name of a zone you want to create. Avoid entering confidential information.
        - **Zone Type**: If you want to control the zone contents directly within OCI, select **Primary**. If you want OCI to pull zone contents from an external server, select **Secondary** and enter your **Zone Master Server IP** address.
    - **Import** - Drag and drop, select, or paste a valid zone file into the Import Zone File window. The zone is imported as a primary zone. For information about formatting a zone file or how to amend a zone file exported from GoDaddy.com, please see Formatting a Zone File.
4. Click **Submit**.

The system creates and publishes the zone, complete with the necessary SOA and NS records. For more information on adding a record to your zone, see To add a zone record.

To update a secondary zone

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **DNS Zone Management**.
2. Click the secondary **Zone Name** you want to update. Zone details and a list of master server IPs appear.

Tip

You can use the Zone Type sort filter to sort zone type alphanumerically in ascending or descending order.

3. Select the checkbox for the Master Server IP you want to update, and then select **Edit** from the **Actions** drop-down menu.
4. Make the needed changes, and then click **Submit**.
5. (Optional) Click **Add Master Server** to add another Master Server IP address.
6. Click **Publish Changes**.
7. In the confirmation dialog box, click **Publish Changes**.

Tip

For OCI to transfer data from your zone, your nameservers must be able to accept a transfer request from the following IP addresses: 208.78.68.65, 204.13.249.65, 2600:2001:0:1::65, 2600:2003:0:1::65

To delete a zone

Warning

Deletion permanently removes a zone from your DNS service.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **DNS Zone Management**.
2. Select the checkbox for the zone you want to delete.
3. Click **Delete**. The zone is staged for deletion.
4. Click **Publish Changes** to delete the zone.
5. In the confirmation dialog box, click **Publish Changes**.

To add a zone record

Tip

There are many record types you can add to your zone, depending on your goals for the zone and its DNS management.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **DNS Zone Management**.
2. Click the **Zone Name** in which you want to add a record. Zone details and a list of records appear.

Tip

You can use the Zone Name sort filter to list to sort zone names alphanumerically in ascending or descending order.

3. Click **Add Record**.
4. In the **Add Record** dialog box, select a record type from the drop-down list, and then enter the information for the record. Avoid entering confidential information. For more information about record types, see Supported Resource Records.
5. (Optional) Click the **Add Another Record** check box to add multiple records in succession.
6. Click **Submit**.
7. Once your records have been added, click **Publish Changes**.
8. In the confirmation dialog box, click **Publish Changes**.

To update a zone record

Note

Protected Records

You can change various components of the records within your zones, such as time-to-live (TTL) and

relevant RDATA. However, some records contain information that cannot be changed. A lock symbol indicates a protected record. You can attempt changes to such records through the **Actions** menu, but the system might not permit updates to some fields.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **DNS Zone Management**.
2. Click the **Zone Name** in which you want to update a record. Zone details and a list of records appear.

Tip

You can use the Zone Name sort filter to sort zone names alphanumerically in ascending or descending order.

3. To help find a record, you can use the following filter options:
   - Enter the name of the record's domain in the **Search** field.
   - To find unpublished records, select the **Staged** check box.
   - To find published records, select the **Unstaged** check box.
   - Use the **Domain**, **TTL**, or **Type** sort filter to sort records.
4. Select the checkbox for the record you want to update, and select **Edit** from the **Actions** drop-down menu.
5. In the **Edit Record** dialog box, make the needed changes, and then click **Submit**.
6. Click **Publish Changes**.
7. In the confirmation dialog box, click **Publish Changes**.

Reverting Changes Before Publishing

You can revert records to their current published state before you publish changes. Once a record has been published, it cannot be reverted. Select the checkbox for the record you want to revert, and then select **Revert** from the **Actions** drop-down menu.

To delete a zone record

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **DNS Zone Management**.
2. Click the **Zone Name** in which you want to delete a record. Zone details and a list of records appear.

Tip

You can use the Zone Name sort filter to sort zone names alphanumerically in ascending or descending order.

3. Select the checkbox for the record you want to delete, and then select **Delete** from the **Actions** drop-down menu.
4. Click **Publish Changes**.
5. In the confirmation dialog box, click **Publish Changes**.

To delegate a zone

To make your Oracle Cloud Infrastructure hosted zone accessible through the internet, you must delegate your domain with your domain's registrar.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **DNS Zone Management**.
2. Click the Zone Name for the zone you want to delegate. Zone details and a list of records appear.
3. Use the **Type** sort filter to locate the NS records for your zone.
4. Note the name servers in the RDATA field within each NS record.
5. You can use the noted name servers to change your domain's DNS delegation. Refer to your registrar's documentation for instructions.

To move a zone to a different compartment

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **DNS Zone Management**.
2. In the **List Scope** section, select a compartment.
3. Find the zone in the list, click the the Actions icon (three dots), and then click **Choose New Compartment**.
4. Choose the destination compartment from the list.
5. Click **Move Resource**.
   For more information, see Managing Compartments.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the following operations to manage your DNS zones:

- GetZone
- ListZones
- CreateZone

- UpdateZone
- DeleteZone
- PatchZoneRecords (add or delete records)
- UpdateZoneRecords

Setting Up Reverse DNS Zones

Reverse DNS, or rDNS, maps an IP address to a hostname. Reverse DNS serves a number of different purposes from email to network troubleshooting. Some of the benefits include:

- Adding a label for network troubleshooting tools such as traceroute.
- Populating the "Received:" header field in an SMTP email.
- Checking for generic reverse DNS such as 1-2-3-4.example.com to identify spammers.
- Verifying a relationship between the owner of a domain name and the owner of the server (IP address).
- Writing a human readable hostname to the log files for system monitoring tools.
- Determining which hostname is affected when maintenance is performed on an IP address.

Before getting started with setting up reverse DNS within your Oracle Cloud Infrastructure account, contact your IP provider and confirm that they allow delegation of your reverse DNS zone. If they do not allow delegation, typically they can host your pointer record (PTR) for you and no reverse DNS configurations are required within your Oracle Cloud Infrastructure account. If they do allow delegation, confirm the exact syntax of the reverse DNS hostname with them, as some providers use slashes and some use dashes. Additionally, if you are delegating a reverse DNS zone, confirm that this zone matches exactly what you configure in your Oracle Cloud Infrastructure account as this is necessary in order for delegation to work properly.

After you create and publish your reverse DNS zone and PTR records, you can update your reverse DNS zone delegation with your IP provider. Delegation changes are not required with your domain registrar with a reverse DNS zone.

Setting up a reverse DNS zone is different for the two types of IP address blocks. Use the following procedures to set up a reverse DNS zone for your IP address block type.

Using the Console

Setting Up Reverse DNS for Classless Address Block (Partial Range of IP Addresses)

To find your reverse DNS zone name using classless address block

1. Make a note of your network IP address. For example, **192.168.15.224/27**.
2. Remove the netmask portion of the address. This is the number after the slash (/). For example, remove the '27' after your IP address, **192.168.15.224/27**.
3. Reverse the order of the remaining octets. For example, **224.15.168.192**.
4. Append '**in-addr.arpa**' to the end of the IP address. For example, **224.15.168.192.in-addr.arpa**.

Note

Some assigning authorities require you to use a slash (/) instead of a dash (-) in the reverse address. Ask which character to use when you contact your assigning authority to delegate the reverse address.

5. Add the netmask back into the address. For example, **224-27.15.168.192.in-addr.arpa**.

In this example, **224-27.15.168.192.in-addr.arpa** is your reverse DNS zone name.

To create your DNS zone

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click

DNS Zone Management.

2. Click **Create Zone**.
3. In the Create Zone dialog box, choose one of the following methods:
    - **Manual** - Enter the following:
        a. **Zone Name:** Enter the name of a zone you want to create. Avoid entering confidential information.
        b. **Zone Type:** If you want to control the zone contents directly within OCI, select **Primary**. If you want OCI to pull zone contents from an external server, select **Secondary** and enter your **Zone Master Server IP** address.
    - **Import** - Drag and drop, select, or paste a valid zone file into the Import Zone File window. The zone is imported as a primary zone. For information about formatting a zone file or how to amend a zone file exported from GoDaddy.com, see Formatting a Zone File.
4. Click **Submit**.

The system creates and publishes the zone, complete with the necessary SOA and NS records.

To create a pointer record (PTR) for each host address

As part of the process of setting up a reverse DNS zone, you need to add a PTR record for each host address. This is done specifically for reverse DNS zones to ensure requests are properly routed for resolution.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **DNS Zone Management**.
2. Click the Zone Name in which you want to add the PTR record. Zone details and a list of records appear.

Tip

You can use the Zone Name sort filter to list to sort zone names alphanumerically in ascending or descending order.

3. Click **Add Record**.
4. In the Add Record dialog box, select the **PTR – Pointer** record type from the drop-down list. Enter the following information:
    a. **Name:** Optional. Name of the subdomain.
    b. **TTL:** Click the lock icon to unlock this field. All PTR records in the zone will be updated to reflect the last changes to TTL. This value indicates how long you want to allow external nameservers to cache the information about a given DNS record.
    c. **TTL Unit:** Select the unit of time used for the TTL value.
    d. **RData Mode:** Select Basic or Advanced format. If you select Advanced, enter the canonical hostname (for example, *example.com*) that the record is going to point to in the RDATA field.
    e. **Hostname:** The web address of your zone.

    For more information about the PTR record type, see Supported Resource Records.
5. Click **Submit**.
6. Once your record has been added, click **Publish Changes**.
7. In the confirmation dialog box, click **Publish Changes**.

To add CNAME records for each host at your ISP

If your IP provider does not automatically configure the CNAME record on your behalf, you will need to add a CNAME record for each host at your ISP. This is done specifically for

reverse DNS zones to ensure requests are properly routed for resolution.

1. Make a note of the IP address and your desired CNAME for each host in your new reverse DNS zone.
2. Contact your ISP and request that they append a CNAME record for each host in your Oracle Cloud Infrastructure DNS zone to your account with them.
3. Test the reverse DNS path by running the following command:

   ```
   dig -x <insert any regular forward-formatted IP address from the zone> +trace
   ```

   See Testing DNS Using BIND'S dig Tool for more information.

The returned information should show that your reverse domain is now being resolved.

To update your zone delegation

To make your Oracle Cloud Infrastructure hosted zone accessible through the internet, you must delegate your domain with your domain's registrar (usually the website where you purchased your domain, such as GoDaddy.com or Bluehost.com).

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **DNS Zone Management**.
2. Click the Zone Name for the zone you want to delegate. Zone details and a list of records appear.
3. Use the **Type** sort filter to locate the NS records for your zone.
4. Note the name servers in the RDATA field within each NS record.

You can use the noted name servers to change your domain's DNS delegation. Refer to your registrar's documentation for instructions.

SETTING UP REVERSE DNS FOR FULL ADDRESS BLOCK

To find your reverse DNS zone name using full address block

1. Make a note of your network IP address. For example, **192.168.15.0**.
2. Remove the netmask portion of the address (the last number in the set of 4). For example, **192.168.15**.
3. Reverse the order of the remaining three octets. For example, **15.168.192**.
4. Append '**in-addr.arpa**' to the end. For example, **15.168.192.in-addr.arpa**

In this example, **15.168.192.in-addr.arpa** is your reverse DNS zone name.

To create your DNS zone

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **DNS Zone Management**.
2. Click **Create Zone**.
3. In the Create Zone dialog box, choose one of the following methods:
    - **Manual** - Enter the following:
        a. **Zone Name:** Enter the name of a zone you want to create. Avoid entering confidential information.
        b. **Zone Type:** If you want to control the zone contents directly within OCI, select **Primary**. If you want OCI to pull zone contents from an external server, select **Secondary** and enter your **Zone Master Server IP** address.
    - **Import** - Drag and drop, select, or paste a valid zone file into the Import Zone File window. The zone is imported as a primary zone. For information about formatting a zone file or how to amend a zone file exported from GoDaddy.com, see Formatting a Zone File.
4. Click **Submit**.

The system creates and publishes the zone, complete with the necessary SOA and NS records.

To create a pointer record (PTR) for each host address

As part of the process of setting up a reverse DNS zone, you need to add a PTR record for each host address. This is done specifically for reverse DNS zones to ensure requests are properly routed for resolution.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **DNS Zone Management**.
2. Click the Zone Name in which you want to add the PTR record. Zone details and a list of records appear.

Tip

You can use the Zone Name sort filter to list to sort zone names alphanumerically in ascending or descending order.

3. Click **Add Record**.
4. In the Add Record dialog box, select the **PTR – Pointer** record type from the drop-down list. Enter the following information:
    a. **Name:** Optional. Name of the subdomain.
    b. **TTL:** Click the lock icon to unlock this field. All PTR records in the zone will be updated to reflect the last changes to TTL. This value indicates how long you want to allow external nameservers to cache the information about a given DNS record.
    c. **TTL Unit:** Select the unit of time used for the TTL value.
    d. **RData Mode:** Select Basic or Advanced format. If you select Advanced, enter the canonical hostname (for example, *example.com*) that the record is going to point

to in the RDATA field.

e. **Hostname:** The web address of your zone.

For more information about the PTR record type, see Supported Resource Records.

5. Click **Submit**.
6. Once your record has been added, click **Publish Changes**.
7. In the confirmation dialog box, click **Publish Changes**.

To update your zone delegation

To make your Oracle Cloud Infrastructure hosted zone accessible through the internet, you must delegate your domain with your domain's registrar.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **DNS Zone Management**.
2. Click the Zone Name for the zone you want to delegate. Zone details and a list of records appear.
3. Use the **Type** sort filter to locate the NS records for your zone.
4. Note the name servers in the RDATA field within each NS record.

You can use the noted name servers to change your domain's DNS delegation. Refer to your registrar's documentation for instructions.

Supported Resource Records

The Oracle Cloud Infrastructure DNS service supports many resource record types. The following list provides a brief explanation of the purpose of each supported record type. Avoid entering confidential information when entering record data. The RFC links direct you to further information about the record types and data structure.

Note About RDATA

OCI normalizes all RDATA into the most machine readable format. The returned presentation of your RDATA may differ from its initial input.

Example:

The RDATA for the ALIAS, CNAME, DNAME, MX, and NS record types may contain one or more absolute domain names. If the specified RDATA for one of these record types does not end in a dot or period to represent the root, the period will be added.

```
www.example.com --> www.example.com.
```

You can use various DNS libraries to normalize your RDATA before input.

Programming Language	Library
Go	DNS Library in Go
Java	dnsjava
Python	dnspython

DNS Resource Record Types

A

An address record used to point a hostname to an IPv4 address. For more information about A records, see RFC 1035.

AAAA

An address record used point a hostname at an IPv6 address. For more information about AAAA records, see RFC 3596.

ALIAS

A private pseudo-record that allows CNAME functionality at the apex of a zone. You can view and read ALIAS records in Oracle Cloud Infrastructure DNS, but you cannot create them.

CAA

A Certification Authority Authorization record allows a domain name holder to specify one or more Certification Authorities authorized to issue certificates for that domain. For more information about CAA records, see RFC 6844.

CDNSKEY

A Child DNSKEY moves a CDNSSEC key from a child zone to a parent zone. The information provided in this record must match the CDNSKEY information for your domain at your other DNS provider. This record is automatically created if you enable DNSSEC on a primary zone in Oracle Cloud Infrastructure DNS. For more information about CDNSKEY, see RFC 7344.

CDS

A Child Delegation Signer record is a child copy of a DS record, for transfer to a parent zone. For more information about CDS records, see RFC 7344.

CERT

A Certificate record stores public key certificates and related certificate revocation lists in the DNS. For more information about CERT records, see RFC 2538 and RFC 4398.

CNAME

A Canonical Name record identifies the canonical name for a domain. For more information about CNAME records, see RFC 1035.

CSYNC

A Child-to-Parent Synchronization record syncs records from a child zone to a parent zone. For more information about CNAME records, see RFC 7477.

DHCID

A DHCP identifier record provides a way to store DHCP client identifiers in the DNS to eliminate potential hostname conflicts within a zone. For more information about DHCID, see RFC 4701.

DKIM

A Domain Keys Identified Mail is a special TXT record set up specifically to supply a public key used to authenticate arriving mail for a domain. For more information about DKIM records, see RFC 6376.

DNAME

A Delegation Name record has similar behavior to a CNAME record, but allows you to map an entire subtree beneath a label to another domain. For more information about DNAME records, see RFC 6672.

DNSKEY

A DNS Key record documents public keys used for DNSSEC. The information in this record must match the DNSKEY information for your domain at your other DNS provider. For more information about DNSKEY records, see RFC 4034.

DS

A Delegation Signer record resides at the top-level domain and points to a child zone's DNSKEY record. DS records are created when DNSSEC security authentication is added to the zone. For more information about DS records, see RFC 4034.

IPSECKEY

An IPSec Key record stores public keys for a host, network, or application to connect to IP security (IPSec) systems. For more information on IPSECKEY records, see RFC 4025.

KEY

A Key record stores a public key that is associated with a domain name. Currently only used by SIG and TKEY records. IPSECKEY and DNSKEY have replaced key for use in IPSec and DNSSEC, respectively. For more information about KEY records, see RFC 4025.

KX

A Key Exchanger record identifies a key management agent for the associated domain name with some cryptographic systems (not including DNSSEC). For more information about KX records, see RFC 2230.

LOC

A Location record stores geographic location data of computers, subnets, and networks within the DNS. For more information about LOC records, see RFC 1876.

MX

A Mail Exchanger record defines the mail server accepting mail for a domain. MX records must point to a hostname. MX records must not point to a CNAME or IP address. For more information about MX records, see RFC 1035.

NS

A Nameserver record lists the authoritative nameservers for a zone. Oracle Cloud Infrastructure DNS automatically generates NS records at the apex of each new primary zone. For more information about NS records, see RFC 1035.

PTR

A Pointer record reverse maps an IP address to a hostname. This behavior is the opposite of an A Record, which forward maps a hostname to an IP address. PTR records are commonly found in reverse DNS zones. For more information about PTR records, see RFC 1035.

PX

A resource record used in X.400 mapping protocols. For more information about PX records, see RFC 822 and RFC 2163.

SOA

A Start of Authority record specifies authoritative information about a DNS zone, including:

- The primary nameserver.
- The email of the domain administrator.

- The domain serial number.
- Several timers relating to refreshing the zone.

The Oracle Cloud Infrastructure DNS automatically generates an SOA record when a zone is created. For more information about SOA records, see RFC 1035.

SPF

A Sender Policy Framework record is a special TXT record used to store data designed to detect email spoofing. For more information about SPF records, see RFC 4408.

SRV

A Service Locator record allows administrators to use several servers for a single domain. For more information about SRV records, see RFC 2782.

SSHFP

An SSH Public Key Fingerprint record publishes SSH public host key fingerprints using the DNS. For more information about SSHFP records, see RFC 6594.

TLSA

A Transport Layer Security Authentication record associates a TLS server certificate, or public key, with the domain name where the record is found. This relationship is called a TLSA certificate association. For more information about TLSA records, see RFC 6698.

TXT

A Text record holds descriptive, human readable text, and can also include non-human readable content for specific uses. It is commonly used for SPF records and DKIM records that require non-human readable text items. For more information about TXT records, see RFC 1035.

Formatting a Zone File

A zone file is a text file that describes a DNS zone. The BIND file format is the industry preferred zone file format and has been widely adopted by DNS server software. The format is defined in RFC 1035.

Example of a Zone File

This is an example of a zone file downloaded from Oracle Cloud Infrastructure DNS.

```
$ORIGIN example.com.
                        @                    3600 SOA   ns1.p30.oraclecloud.net. (
                        zone-admin.dyndns.com.     ; address of responsible party
                        2016072701                 ; serial number
                        3600                       ; refresh period
                        600                        ; retry period
                        604800                     ; expire time
                        1800                     ) ; minimum ttl
                        86400 NS    ns1.p68.dns.oraclecloud.net.
                        86400 NS    ns2.p68.dns.oraclecloud.net.
                        86400 NS    ns3.p68.dns.oraclecloud.net.
                        86400 NS    ns4.p68.dns.oraclecloud.net.
                        3600 MX    10 mail.example.com.
                        3600 MX    20 vpn.example.com.
                        3600 MX    30 mail.example.com.
                        60 A     204.13.248.106
                        3600 TXT   "v=spf1 includespf.oraclecloud.net ~all"
                        mail                  14400 A     204.13.248.106
                        vpn                      60 A     216.146.45.240
                        webapp                   60 A     216.146.46.10
                        webapp                   60 A     216.146.46.11
                www                   43200 CNAME example.com.
```

Note

Record Classes

In the example zone file above, no record classes are displayed. Oracle Cloud Infrastructure DNS only works with Internet (IN) class records but omits the class information in zone files for efficiency purposes.

Anatomy of a Zone File

`$ORIGIN` indicates a DNS node tree and will typically start a DNS zone file. Any host labels below the origin will append the origin hostname to assemble a fully qualified hostname. Any host label within a record that uses a fully qualified domain terminating with an ending period will not append the origin hostname.

Example: With `$ORIGIN example.com.`, any record where the host label field is not followed by a period, `example.com`. will be appended to them.

The "@" symbol is a special label that indicates the `$ORIGIN` should replace the "@" symbol. This is typically used for the apex of a zone.

SOA Record – The `$ORIGIN` is followed by the zone's Start Of Authority (SOA) record. An SOA record is required for each zone. It contains the name of the zone, the e-mail address of the party responsible for administering the domain's zone file, the current serial number of the zone, the primary nameserver of the zone, and various timing elements (measured in seconds).

SOA Record Format

```
@     IN     SOA    {primary-name-server}     {hostmaster-email} (
                           {serial-number}
                           {time-to-refresh}
                           {time-to-retry}
                           {time-to-expire}
                      {minimum-TTL} )
```

- **Primary Name Server** – The nameserver that contains the original zone file and not an AXFR transferred copy.
- **Hostmaster Email** – Address of the party responsible for the zone. A period "." is used in place of an "@" symbol. For email addresses that contain periods, replace the periods with a slash "/".
- **Serial Number** – Version number of the zone. The serial number will increase with each subsequent update to your zone.
- **Time To Refresh** – How long a nameserver should wait prior to checking for a serial number increase within the primary zone file, in seconds. An increased serial number

detected by a secondary DNS nameserver means a transfer is needed to sync your records. Only applies to zones using secondary DNS.

- **Time To Retry** – How long a nameserver should wait prior to retrying to update a zone after a failed attempt, in seconds. Only applies to zones using secondary DNS.
- **Time To Expire** – How long a nameserver should wait prior to considering data from a secondary zone invalid and stop answering queries for that zone, in seconds. Only applies to zones using secondary DNS.
- **Minimum TTL** – Minimum Time To Live (TTL). How long a nameserver or resolver should cache a negative response, in seconds.

Anatomy of a Record Within a Zone File

A zone file is a collection of resource records with each record entry described in the following sequence:

Format:	Host Label	TTL	Record Class	Record Type	Record Data
Example:	example.com.	60	IN	A	104.255.228.125

- **Host Label** – A host label helps to define the hostname of a record and whether the `$ORIGIN` hostname will be appended to the label. Fully qualified hostnames terminated by a period will not append the origin.
- **TTL** – The Time To Live (TTL) is the amount of time that a DNS record will be cached by an outside DNS server or resolver, in seconds.
- **Record Class** – There are three classes of DNS records: IN (Internet), CH (Chaosnet), and HS (Hesiod). Oracle Cloud Infrastructure DNS only uses the IN class of records.
- **Record Type** – The type of a record, such as CNAME, AAAA, or TXT.
- **Record Data** – The data within a DNS answer, such as an IP address, hostname, or other information. Different record types will contain different types of record data.

Amending Zone Files Exported from GoDaddy.com for Import

GoDaddy.com exports zone files in a proprietary format. To get the Oracle Cloud Infrastructure DNS service to correctly import a zone file exported from GoDaddy.com, you must directly alter the file. Follow these instructions to update the zone file.

1. Export your zone file from GoDaddy.com. Reference GoDaddy.com's documentation to see how this is done.
2. Open the file in your preferred text editor.
3. Prepend a new line to the file before the SOA record with the following information, including the trailing period: `$ORIGIN [yourdomain].`
4. Once the file has been amended, save the changes to the file and use the zone import function to import the file into your DNS configuration. For more information about zone import, see Managing DNS Zones.

Note

If your zone file includes includes dynamic A records, such as `@ 600 IN A GoCentral Published Site`, you will need to amend these records with the correct IP addresses of your website. Please contact GoDaddy.com for information about how to obtain this information.

Example: `@ 600 IN A 192.0.2.255`

Example:

This is an example of a zone file exported from GoDaddy.com. The code in bold is the code that needs to be removed from the file for it to be eligible for import into Oracle Cloud Infrastructure DNS.

Tip

Placing a semi-colon at the beginning of a line is valid comment syntax for a zone file, per RFC 1035, but for ease of use and formatting it is recommended to remove the large section of comments from the beginning of the zone file provided by GoDaddy.com, as shown below.

```
Domain: example.com
; Exported (y-m-d hh:mm:ss): 2019-01-10 13:05:04
;
; This file is intended for use for informational and archival
; purposes ONLY and MUST be edited before use on a production
; DNS server.
;
; In particular, you must update the SOA record with the correct
; authoritative name server and contact e-mail address information,
; and add the correct NS records for the name servers which will
; be authoritative for this domain.
;
; For further information, please consult the BIND documentation
; located on the following website:
;
; http://www.isc.org/
;
; And RFC 1035:
;
; http://www.ietf.org/rfc/rfc1035.txt
;
; Please note that we do NOT offer technical support for any use
; of this zone data, the BIND name server, or any other third-
; party DNS software.
;
; Use at your own risk.
; SOA Record

Setting Up HTTP Redirect

The HTTP Redirect service allows you to redirect HTTP traffic to another URL. You can use HTTP Redirect to:

- Redirect all HTTP traffic for an entire zone to another zone. For example, if a company owns example.net and example.com, HTTP Redirect lets the company redirect all HTTP traffic for example.net to example.com. This is a one-to-one mapping; wildcards are not supported.
- Redirect a specific subdomain to an HTTP URL. For example, test.example.com can be redirected to http://example.net/test/test.php.
- Redirect a subdomain to a URL with a port number. For example, camera.example.com can be redirected to http://office.example.com:8080 so a user can view their camera system without typing in the port number each time.
- Permanently redirect a domain name that has been deprecated by displaying a 301 response code. Permanently redirecting a domain name informs search engines and browsers what to do with the information.

Using the Console

To create an HTTP redirect

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **HTTP Redirects**.
2. Select a zone.
3. Click **Create HTTP Redirect**.
4. In the Create Redirect dialog box, enter the following information:
    - **Name:** (Optional) Enter the name of the redirect zone you want to create. Avoid entering confidential information.
    - **Select a Zone:** (Optional) Select a zone from a list of configured zones. If the **Create DNS Record** check box is selected, the zone will be used to build an alias record for the redirect.
    - **Domain:** Enter the domain name from which traffic is redirected.
    - **Target -** Enter the following information for the endpoint where the traffic will be redirected:
        - **Protocol:** The network protocol used to interact with the target.
        - **Host:** The hostname of the target.
        - **Port:** (Optional) The port used to connect to the endpoint. The default is 80 for HTTP and 443 for HTTPS.
        - **Path:** (Optional) The specific path on the target for the redirect. A value of {path} will copy the path from the incoming request.
        - **Query:** (Optional) The query component of the target URL (for example, "?redirected" in "https://target.example.com/path/to/resource?redirected"). Use of the "\" character is not permitted except to escape a following "\", "{", or "}". An empty value results in a redirection target URL with no query component. A static value must begin with a leading "?", optionally followed by other query characters. A request-copying value must exactly match "{query}",

and will be replaced with the query component of the request URL (including a leading "?" if the request URL includes a query component).

- **Response Code:** The response code that is returned with the redirect. If your website was permanently moved to the redirection URL and you want it to be indexed by search engines, select **301 - Moved Permanently**. If you want to indicate that the URL has been temporarily changed to a different address, select **302 - Found**.
- **Create DNS Record:** Select this check box to create an associated ALIAS record for the redirect in the specified zone. If a record for the zone specified already exists, the DNS record will not be created.
- **ALIAS TTL in Seconds** - The Time to Live for the ALIAS record before a new ALIAS record is retrieved. The default value is 300.
- **Tags:** Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.

5. Click **Create**. The redirect zone is added to the redirects list.

To edit an HTTP redirect

1. Open the navigation menu. **Under Core Infrastructure**, go to **Networking** and click **HTTP Redirects**.
2. Click the name of a redirect zone.
3. Click **Edit**.
4. In the Edit Redirect dialog box, make the needed changes and then click **Save Changes**.

To delete an HTTP redirect

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **HTTP Redirects**.
2. Select a redirect zone.
3. Click **Delete**.
4. In the Delete Resource dialog box, click **Delete HTTP Redirect**. Any attached records will need to be managed in DNS Zone Management.

To move an HTTP redirect to another compartment

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **HTTP Redirects**.
2. Click the name of a redirect zone.
3. Click **Move Resource**.
4. Choose the destination compartment from the list.
5. Click **Move Resource**.

Using the API

Use the following operations to manage your HTTP redirect zones:

- GetHttpRedirect
- ListHttpRedirects
- CreateHttpRedirect
- UpdateHttpRedirect
- DeleteHttpRedirect
- ChangeHttpRedirectCompartment

Testing DNS Using BIND'S dig Tool

Using the Domain Information Groper (dig) command line tool, you can test against the delegation where your domain is hosted, and you will immediately see whether the change took place without accounting for the cache or TTL (Time to Live) that you have configured.

Note

Windows users can download the tool from BIND's website. Use Terminal to access dig on Linux and Macintosh systems.

Using dig

Before using BIND's dig tool, you must access or install dig on your system. Once you have access to dig, you can use dig to test your DNS.

To access dig (Mac)

1. From your Applications folder, open the Utilities folder, and then select **Terminal**.
2. When Terminal is open, type a dig command using a hostname you want to look up.

To Install dig (Windows)

1. Go to BIND's website and download the most current, stable version of BIND.

Note

BIND supports both 32 and 64 bit Windows systems. Confirm which version of Windows you are using and download the correct version of BIND. View Microsoft's documentation to determine which version of Windows you are using.

2. Extract the downloaded file and install BIND in the following directory: **C:\Program Files\ISC BIND 9**. Select the **Tools Only** check box.
3. Once BIND is installed, on the Windows menu open the Control Panel, and then open your System properties.
4. On the **Advanced** tab, click **Environment Variables**.
5. Under **System Variables**, select **Path**, and then click **Edit**.
6. At the end of the path in the Edit System Variable window, add **C:\Program Files\ISC BIND 9\bin**, and then click **OK**.
7. In the Edit Variables window, click **OK**. In the System properties window, click **OK**.

To open the Command Prompt

For Windows versions 8 -10:

1. Click the Windows menu icon.
2. In the **Search** field, type **CMD**.
3. Click **Command Prompt**.

For Windows version 7:

1. On the **Start** menu click **Run**.
2. Enter **CMD**, and then click **OK**.

To use dig to test your DNS

1. Open Terminal (Mac and Linux) or Command Prompt (Windows).
2. Type `dig <any hostname>`, and then press **Enter**.

The following information is returned:

```
$ dig oracle.com

; <<>> DiG 9.10.6 <<>> oracle.com

```

- **Question section**: The query made to the DNS. In this example, we asked for the first available A record for the hostname, oracle.com.

- **Answer section**: The first available answer for the query made to the DNS. In this example, we received the A record for the IP address 137.254.16.101.
- **Authority section**: The authoritative nameservers from which the answer to the query was received. These nameservers house the zones for a domain.
- **Additional section**: Additional information the resolver may need but not the answer to the query.

DIG COMMANDS

Command	Description	Example
`dig [hostname]`	Returns any A record found within the queried hostname's zone.	`dig oracle.com`
`dig [hostname] [record type]`	Returns the records of that type found within the queried hostname's zone.	`dig oracle.com MX`
`dig [hostname] +short`	Provides a brief answer, usually just an IP address.	`dig oracle.com +short`
`dig @[nameserver address] [hostname]`	Queries the nameserver directly instead of your ISP's resolver.	`dig @dnsmaster6.oracle.com`
`dig [hostname] +trace`	Adding `+trace` instructs dig to resolve the query from the root nameserver downwards and to report the results from each query step.	`dig dyn.com +trace`

Command	Description	Example
`dig -X [IP address]`	Reverse lookup for IP addresses.	`dig -X 137.254.16.101`
`dig [hostname] any`	Returns all records for a hostname.	`dig oracle.com any`

Overview of the Traffic Management Steering Policies Service

The Oracle Cloud Infrastructure Traffic Management Steering Policies service is a critical component of DNS. Traffic Management Steering Policies enables you to configure policies to serve intelligent responses to DNS queries, meaning different answers (endpoints) may be served for the query depending on the logic the customer defines in the policy. Traffic Management Steering Policies can account for health of answers to provide failover capabilities, provide the ability to load balance traffic across multiple resources, and account for the location where the query was initiated to provide a simple, flexible and powerful mechanism to efficiently steer DNS traffic.

Traffic Management Steering Policies Service Components

The following list describes the components used to build a traffic management steering policy.

STEERING POLICIES

A framework to define the traffic management behavior for your zones. Steering policies contain rules that help to intelligently serve DNS answers.

ATTACHMENTS

Allows you to link a steering policy to your zones. An attachment of a steering policy to a zone occludes all records at its domain that are of a covered record type, constructing DNS responses from its steering policy rather than from those domain's records. A domain can have at most one attachment covering any given record type.

RULES

The guidelines steering policies use to filter answers based on the properties of a DNS request, such as the requests geo-location or the health of your endpoints.

ANSWERS

Answers contain the DNS record data and metadata to be processed in a steering policy.

Ways to Access the Traffic Management Steering Policies Service

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide.

To access the Console, you must use a supported browser. You can use the Console link at the top of this page to go to the sign-in page. Enter your tenancy, user name, and your password.

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies. For specific details about writing policies for each of the different services, see Policy Reference.

If you're a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

Traffic Management Steering Policies Service Capabilities and Limits

The Oracle Cloud Infrastructure Traffic Management Steering Policies service is limited to 100 policies and 1,000 attachments per tenant. See Service Limits for a list of applicable limits and instructions for requesting a limit increase.

Required IAM Service Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don't have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

If you're new to policies, see Getting Started with Policies and Common Policies. For more details about policies for Traffic Management Steering Policies, see Details for the Traffic Management Steering Policies Service.

Traffic Management Steering Policies API Guide

Traffic Management Steering Policies allows you to build and configure traffic management policies using the Oracle Cloud Infrastructure DNS REST API. Use the following guide to learn how policies are constructed using the REST API.

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies. For specific details about writing policies for each of the different services, see Policy Reference.

If you're a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

Traffic Management Steering Policy Components

The following list describes the components used to build a Traffic Management Steering Policy.

STEERING POLICIES

An overall framework to define the traffic management behavior for your zones. Steering policies contain rules that help to intelligently serve DNS answers.

ATTACHMENTS

Allows you to link a steering policy to your zones. An attachment of a steering policy to a zone occludes all records at its domain that are of a covered record type, constructing DNS responses from its steering policy rather than from those domain's records. A domain can have at most one attachment covering any given record type.

RULES

The guidelines steering policies use to filter answers based on the properties of a DNS request, such as the requests geo-location or the health of your endpoints.

ANSWERS

Answers contain the DNS record data and metadata to be processed in a steering policy.

TEMPLATES

Templates are predefined rule sequences that create a policy type and its intended behavior. Example: The `FAILOVER` template determines answers by checking DNS query against a `FILTER` rule first, then the following rules in succession: `HEALTH`, `PRIORITY`, and `LIMIT`. This gives the domain dynamic failover capability. Policies that define the `template` field with any policy other than `CUSTOM`, must follow the rule sequence outlined for that policy type, otherwise, a `400` status code error will be returned upon policy creation.

CASES

A rule may optionally include a sequence of cases defining alternate configurations for how it should behave during processing for any given DNS query. When a rule has no sequence of cases, it is always evaluated with the same configuration during processing. When a rule has an empty sequence of cases, it is always ignored during processing. When a rule has a non-empty sequence of cases, its behavior during processing is configured by the first matching case in the sequence. A rule case with no `caseCondition` always matches. A rule case with a `caseCondition` matches only when that expression evaluates to true for the given query.

Create Steering Policies Using Templates

The following section explains the rule configuration for each type of steering policy template followed by an example POST request (CreateSteeringPolicy) displaying how to configure each template.

FAILOVER

Failover policies allow you to prioritize the order in which you want answers served in a policy (for example, Primary and Secondary). Oracle Cloud Infrastructure Health Checks are leveraged to determine the health of answers in the policy. If the Primary Answer is determined to be unhealthy, DNS traffic will automatically be steered to the Secondary Answer. Each of the following rules must be defined in the order specified below in the `rules` field of your request body when using a `FAILOVER` template:

Order	Rule	Restrictions	Comments
1	FILTER	• No cases are allowed. • Answer data must be defined in `defaultAnswerData` using the following JSON: `{ "answerCondition": "answer.isDisabled != true", "shouldKeep": true }`	
2	HEALTH	• No cases are allowed.	Only included if `healthCheckMonitorId` is defined for the policy.

Example of a POST /steeringPolicies policy using the `FAILOVER` template:

```
{
  "compartmentId": "ocid1...",
  "displayName": "failover between endpoints",
  "ttl": 30,
  "healthCheckMonitorId": "ocid1...",
  "template": "FAILOVER",
  "answers": [
    {
      "name": "server-primary",
      "rtype": "A",
      "rdata": "192.0.2.1",
      "pool": "primary"
    },
    {
      "name": "server-secondary",
      "rtype": "A",
      "rdata": "192.1.2.1",
      "pool": "secondary"
    }
  ],
```

```
  "rules": [
    {
      "ruleType": "FILTER",
      "defaultAnswerData": [
        {
          "answerCondition": "answer.isDisabled != true",
          "shouldKeep": true
        }
      ]
    },
    {
      "ruleType": "HEALTH"
    },
    {
      "ruleType": "PRIORITY",
      "defaultAnswerData": [
        {
          "answerCondition": "answer.pool == 'primary'",
          "value": 1
        },
        {
          "answerCondition": "answer.pool == 'secondary'",
          "value": 99
        }
      ]
    },
    {
      "ruleType": "LIMIT",
      "defaultCount": 1
    }
  ]
}
```

LOAD_BALANCE

Load Balancer policies allow distribution of traffic across multiple endpoints. Endpoints can be assigned equal weights to distribute traffic evenly across the endpoints or custom weights may be assigned for ratio load balancing. Oracle Cloud Infrastructure Health Checks are leveraged to determine the health of the endpoint. DNS traffic will be automatically distributed to the other endpoints, if an endpoint is determined to be

unhealthy. Each of the following rules must be defined in the order specified below in the `rules` field of your request body when using a `LOAD_BALANCE` template:

Order	Rule	Restrictions	Comments
1	`FILTER`	• No cases are allowed. • Answer data must be defined in `defaultAnswerData` using the following JSON: `{ "answerCondition": "answer.isDisabled != true", "shouldKeep": true }`	
2	`HEALTH`	• No cases are allowed.	Only included if `healthCheckMonitorId` is defined for the policy.

Example of a `POST /steeringPolicies` request body using the `LOAD_BALANCE` template:

```
{
  "compartmentId": "ocid1...",
  "displayName": "Weighted load balance for a set of answers with health checks",
  "ttl": 30,
  "healthCheckMonitorId": "ocid1...",
  "template": "LOAD_BALANCE",
  "answers": [
    {
      "name": "server1",
      "rtype": "A",
      "rdata": "192.0.2.1"
    },
    {
      "name": "server2",
      "rtype": "A",
      "rdata": "198.51.100.1"
    }
```

```
  ],
  "rules": [
    {
      "ruleType": "FILTER",
      "defaultAnswerData": [
        {
          "answerCondition": "answer.isDisabled != true",
          "shouldKeep": true
        }
      ]
    },
    {
      "ruleType": "HEALTH"
    },
    {
      "ruleType": "WEIGHTED",
      "defaultAnswerData": [
        {
          "answerCondition": "answer.name == 'server1'",
          "value": 99
        },
        {
          "answerCondition": "answer.name == 'server2'",
          "value": 1
        }
      ]
    },
    {
      "ruleType": "LIMIT",
      "defaultCount": 1
    }
  ]
}
```

ROUTE_BY_GEO

Geolocation-based steering policies distribute DNS traffic to different endpoints based on the location of the end user. Customers can define geographic regions composed of originating continent, countries or states/provinces (North America) and define a separate endpoint or set of endpoints for each region. Each of the following rules must be defined in

the order specified below in the `rules` field of your request body when using a `ROUTE_BY_GEO` template:

Order	Rule	Restrictions	Comments
1	`FILTER`	• No cases are allowed. • Answer data must be defined in `defaultAnswerData` using the following JSON: `{ "answerCondition": "answer.isDisabled != true", "shouldKeep": true }`	
2	`HEALTH`	• No cases are allowed.	Only included if `healthCheckMonitorId` is defined for the policy.

Example of a `POST /steeringPolicies` request body using the `ROUTE_BY_GEO` template:

```
{
  "compartmentId": "ocid1...",
  "displayName": "Geolocations mapped to answer pools",
  "ttl": 30,
  "healthCheckMonitorId": "ocid1...",
  "template": "ROUTE_BY_GEO",
  "answers": [
    {
      "name": "US Server 1",
      "rtype": "A",
      "rdata": "10.10.10.10",
      "pool": "US"
    },
    {
      "name": "US Server 2",
      "rtype": "A",
      "rdata": "10.10.10.11",
```

```
      "pool": "US"
    },
    {
      "name": "EU Server 1",
      "rtype": "A",
      "rdata": "10.10.1.1",
      "pool": "EU"
    },
    {
      "name": "EU Server 2",
      "rtype": "A",
      "rdata": "10.10.1.2",
      "pool": "EU"
    },
    {
      "name": "rest of world 1",
      "rtype": "A",
      "rdata": "203.0.113.1",
      "pool": "Global"
    },
    {
      "name": "rest of world 2",
      "rtype": "A",
      "rdata": "203.0.113.2",
      "pool": "Global"
    }
  ],
  "rules": [
    {
      "ruleType": "FILTER",
      "defaultAnswerData": [
        {
          "answerCondition": "answer.isDisabled != true",
          "shouldKeep": true
        }
      ]
    },
    {
      "ruleType": "HEALTH"
    },
```

```
{
  "ruleType": "PRIORITY",
  "cases": [
    {
      "caseCondition": "query.client.geoKey in (geoKey '6255149')",
      "answerData": [
        {
          "answerCondition": "answer.pool == 'US'",
          "value": 1
        },
        {
          "answerCondition": "answer.pool == 'EU'",
          "value": 2
        },
        {
          "answerCondition": "answer.pool == 'Global'",
          "value": 3
        }
      ]
    },
    {
      "caseCondition": "query.client.geokey in (geokey '6255148')",
      "answerdata": [
        {
          "answerCondition": "answer.pool == 'EU'",
          "value": 1
        },
        {
          "answerCondition": "answer.pool == 'US'",
          "value": 2
        },
        {
          "answerCondition": "answer.pool == 'Global'",
          "value": 3
        }
      ]
    },
    {
      "answerData": [
        {
```

```
            "answerCondition": "answer.pool == 'Global'",
            "value": 1
          },
          {
            "answerCondition": "answer.pool == 'US'",
            "value": 2
          },
          {
            "answerCondition": "answer.pool == 'EU'",
            "value": 3
          }
        ]
      }
    ]
  },
  {
    "ruleType": "LIMIT",
    "defaultCount": 1
  }
 ]
}
```

For a list of geographic keys to use in the `geokey` field, see Traffic Management Steering Policy geokeys.

ROUTE_BY_ASN

ASN-based steering policies enable you to steer DNS traffic based on Autonomous System Numbers (ASN). DNS queries originating from a specific ASN or set of ASNs can be steered to a specified endpoint. Each of the following rules must be defined in the order specified below in the `rules` field of your request body when using a `ROUTE_BY_ASN` template:

Order	Rule	Restrictions	Comments
1	FILTER	• No cases are allowed. • Answer data must be defined in `defaultAnswerData` using the following JSON: `{ "answerCondition": "answer.isDisabled != true", "shouldKeep": true }`	
2	HEALTH	• No cases are allowed.	Only included if `healthCheckMonitorId` is defined for the policy.

Example of a `POST /steeringPolicies` request body using the `ROUTE_BY_ASN` template:

```
{
  "compartmentId": "ocid1...",
  "displayName": "ASNs mapped to pools",
  "ttl": 30,
  "template": "ROUTE_BY_ASN",
  "answers": [
    {
      "name": "MIT Server",
      "rtype": "A",
      "rdata": "10.10.10.10",
      "pool": "MIT"
    },
    {
      "name": "Google Fiber Server",
      "rtype": "A",
      "rdata": "10.10.1.1",
      "pool": "Google Fiber"
    },
    {
      "name": "Other",
```

```
    "rtype": "A",
    "rdata": "203.0.113.1",
    "pool": "Other"
  }
],
"rules": [
  {
    "ruleType": "FILTER",
    "defaultAnswerData": [
      {
        "answerCondition": "answer.isDisabled != true",
        "shouldKeep": true
      }
    ]
  },
  {
    "ruleType": "PRIORITY",
    "cases": [
      {
        "caseCondition": "query.client.asn == 3",
        "answerData": [
          {
            "answerCondition": "answer.pool == 'MIT'",
            "value": 1
          },
          {
            "answerCondition": "answer.pool == 'Google Fiber'",
            "value": 2
          },
          {
            "answerCondition": "answer.pool == 'Other'",
            "value": 3
          }
        ]
      },
      {
        "caseCondition": "query.client.asn == 16591",
        "answerdata": [
          {
            "answerCondition": "answer.pool == 'Google Fiber'",
```

```
            "value": 1
          },
          {
            "answerCondition": "answer.pool == 'MIT'",
            "value": 2
          },
          {
            "answerCondition": "answer.pool == 'Other'",
            "value": 3
          }
        ]
      },
      {
        "answerData": [
          {
            "answerCondition": "answer.pool == 'Other'",
            "value": 1
          },
          {
            "answerCondition": "answer.pool == 'MIT'",
            "value": 2
          },
          {
            "answerCondition": "answer.pool == 'Google Fiber'",
            "value": 3
          }
        ]
      }
    ]
  },
  {
    "ruleType": "LIMIT",
    "defaultCount": 1
  }
 ]
}
```

ROUTE_BY_IP

IP Prefix-based steering policies enable customers to steer DNS traffic based on the IP Prefix of the originating query. Each of the following rules must be defined in the order

specified below in the `rules` field of your request body when using a `ROUTE_BY_IP` template:

Order	Rule	Restrictions	Comments
1	`FILTER`	• No cases are allowed. • Answer data must be defined in `defaultAnswerData` using the following JSON: `"answer.isDisabled != true",`	`{ "answerCondition": "shouldKeep": true }`
2	`HEALTH`	• No cases are allowed.	Only included if `healthCheckMonitorId` is defined for the policy.

Example of a `POST /steeringPolicies` request body using the `ROUTE_BY_IP` template:

```
{
  "compartmentId": "ocid1...",
  "displayName": "IP subnets mapped to answer pools",
  "ttl": 30,
  "template": "ROUTE_BY_IP",
  "answers": [
    {
      "name": "MIT Server",
      "rtype": "A",
      "rdata": "10.10.10.10",
      "pool": "MIT"
    },
    {
      "name": "Google Fiber Server",
      "rtype": "A",
      "rdata": "10.10.1.1",
```

```
      "pool": "Google Fiber"
    },
    {
      "name": "Other",
      "rtype": "A",
      "rdata": "203.0.113.1",
      "pool": "Other"
    }
  ],
  "rules": [
    {
      "ruleType": "FILTER",
      "defaultAnswerData": [
        {
          "answerCondition": "answer.isDisabled != true",
          "shouldKeep": true
        }
      ]
    },
    {
      "ruleType": "PRIORITY",
      "cases": [
        {
          "caseCondition": "query.client.address in (subnet '18.0.0.0/9')",
          "answerData": [
            {
              "answerCondition": "answer.pool == 'MIT'",
              "value": 1
            },
            {
              "answerCondition": "answer.pool == 'Google Fiber'",
              "value": 2
            },
            {
              "answerCondition": "answer.pool == 'Other'",
              "value": 3
            }
          ]
        },
        {
```

```
        "caseCondition": "query.client.address in (subnet '136.32.0.0/11')",
        "answerdata": [
          {
            "answerCondition": "answer.pool == 'Google Fiber'",
            "value": 1
          },
          {
            "answerCondition": "answer.pool == 'MIT'",
            "value": 2
          },
          {
            "answerCondition": "answer.pool == 'Other'",
            "value": 3
          }
        ]
      },
      {
        "answerData": [
          {
            "answerCondition": "answer.pool == 'Other'",
            "value": 1
          },
          {
            "answerCondition": "answer.pool == 'MIT'",
            "value": 2
          },
          {
            "answerCondition": "answer.pool == 'Google Fiber'",
            "value": 3
          }
        ]
      }
    ]
  },
  {
    "ruleType": "LIMIT",
    "defaultCount": 1
  }
 ]
}
```

CUSTOM

Custom policies allow you to create complex policies combining the capabilities of failover, load balancing, geolocation, ASN and IP prefix steering. Custom templates to not require a regimented sequence of rules and it is recommended to contact Oracle Cloud Infrastructure support before creating a custom policy.

Rule Types

FILTER

Uses boolean data associated with answers, keeping answers only if the rule's `shouldKeep` value is `true`.

HEALTH

Utilizes Oracle Cloud Health Check monitors to determine the health of your endpoints and add and remove answers from your policy as needed. A health check monitor must be referenced in a health rule to have an effect on the policy. For more information about Health Checks, see Health Checks.

WEIGHTED

Uses a number between 0 and 255 used to determine how often an answer will be served in relation to other answers. Answers with higher values are more likely to be returned.

PRIORITY

Uses an integer associated with each answer to sort answers from lowest to highest value. Example: An answer with a priority value of 1 would be returned before an answer with a priority value of 10 in the list of answers. Answers that do not have a priority value assigned to them will be moved to the end of the list of answers.

LIMIT

Uses a count property to filter away all but the first answers in the list.

Managing Traffic Management Steering Policies

Policy Types

FAILOVER

Failover policies allow you to prioritize the order in which you want answers served in a policy (for example, Primary and Secondary). Oracle Cloud Infrastructure Health Checks are leveraged to determine the health of answers in the policy. If the Primary Answer is determined to be unhealthy, DNS traffic will automatically be steered to the Secondary Answer.

LOAD BALANCER

Load Balancer policies allow distribution of traffic across multiple endpoints. Endpoints can be assigned equal weights to distribute traffic evenly across the endpoints or custom weights may be assigned for ratio load balancing. Oracle Cloud Infrastructure Health Checks are leveraged to determine the health of the endpoint. DNS traffic will be automatically distributed to the other endpoints, if an endpoint is determined to be unhealthy.

GEOLOCATION STEERING

Geolocation steering policies distribute DNS traffic to different endpoints based on the location of the end user. Customers can define geographic regions composed of originating continent, countries or states/provinces (North America) and define a separate endpoint or set of endpoints for each region.

ASN STEERING

ASN steering policies enable you to steer DNS traffic based on Autonomous System Numbers (ASN). DNS queries originating from a specific ASN or set of ASNs can be steered to a specified endpoint.

IP PREFIX STEERING

IP Prefix steering policies enable customers to steer DNS traffic based on the IP Prefix of the originating query.

Typical Traffic Steering Scenarios

This section describes several typical scenarios for using Traffic Management Steering Policies.

Basic Failover

You can leverage Traffic Management Steering Policies to provide automated failover between primary and secondary servers.

Cloud Migration

Weighted load balancing supports controlled migration from your data center to Oracle Cloud Infrastructure servers. You can steer a small amount of traffic (1%) to your new resources in the cloud to verify everything is working as expected. You can then increase the ratios until you are comfortable with fully migrating all DNS traffic to the cloud.

Load Balancing Across Multiple Servers for Scale

You can configure load balancing pools of multiple servers. Traffic Management Steering Policies can automatically distribute DNS traffic across the set of servers. Health Checks may also be used and traffic will be automatically redirected to healthy servers, if a server is determined to be unhealthy.

Hybrid Environments

Since Traffic Management Steering Policies is an agnostic service, it may be used to not only steer traffic to Oracle Cloud Infrastructure resources, but can also be used to steer traffic to any publicly exposed (internet resolvable) resources, including other cloud providers and enterprise data centers.

Worldwide Geolocation Treatment

You can divide your global users into geographically defined regions (for example, state/province level in NA, country level for rest of world) and steer customers to specified resources based on their location. This helps to ensure global, high performing internet resolution, and supports functions such as ring fencing. For example, keeping traffic from China in China and block traffic outside of China into China.

CANARY TESTING

Leveraging IP Prefix steering, you can configure policies to serve different responses for your internal users versus external users.

ZERO-RATING SERVICES

ASN steering conditional steering based on the originating enterprise, mobile operator or other communications provider in support of various commercial agreements that may be in place. Essentially, preferred ASNs can be directed to free resources, while all other traffic can be directed to paid resources.

Using the Console

MANAGING TRAFFIC MANAGEMENT STEERING POLICIES

To create a Load Balancer policy

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Traffic Management Steering Policies**.
2. Click **Create Traffic Management Steering Policy**.
3. In the **Create Traffic Management Steering Policy** dialog box, select **Load Balancer**.
4. Enter the following information:
    - **Policy Name:** The unique name that identifies policy.
    - **Policy TTL**: The Time to Live for responses from the steering policy. If not specified, the system will set this value on the steering policy.
    - **Maximum Answer Count**: The maximum number of answers returned for the policy.
    - **Answer(s):** Answer pools contain the group of answers that will be served in response to DNS queries.

        - **Name**: A unique name to identify the answer. Avoid entering confidential information.
        - **Type**: The record type that will be provided as the answer.
        - **RDATA**: A valid domain name or IP address to add as an answer.
        - **Weight**: A number between 0 and 255 used to determine how often an answer is served in relation to other answers. Answers with higher values are more likely to be served.
        - **Eligible**: Select the check box to indicate that the answer is available within the pool to be used in response to queries. Alternatively, select **Mark pool answers eligible** or **Mark pool answers ineligible** from the **Actions** drop-down menu.
    - **Attach Health Check:** Select an existing Health Check to be included as part of the policy, add a new one, or select **None**.
    - **Attach Domain(s):** (Optional) The domain name and domain OCID you want to attach to the policy. Additional domains can be added in this section.
5. Click **Create Policy**.

The system creates and publishes the policy.

To create a Failover policy

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Traffic Management Steering Policies**.
2. Click **Create Traffic Management Steering Policy**.
3. In the **Create Traffic Management Steering Policy** dialog box, select **Failover**.
4. Enter the following information:
    - **Policy Name:** The unique name that identifies policy. Avoid entering confidential information.

- **Policy TTL**: The Time to Live for responses from the steering policy. If not specified, the system will set this value on the steering policy.
- **Maximum Answer Count**: The maximum number of answers returned for the policy. For priority-based policies, the first valid answer is returned.
- **Answer Pool(s):** Answer pools contain the group of answers that will be served in response to DNS queries.
    - **Answer Pool Name**: A user-friendly name for the answer pool, unique within the steering policy. Avoid entering confidential information.
    - **Name**: A unique name to identify the answer. Avoid entering confidential information.
    - **Type**: The record type that will be provided as the answer.
    - **RDATA**: A valid domain name or IP address to add as an answer.
    - **Weight**: A number between 0 and 255 used to determine how often an answer is served in relation to other answers. Answers with higher values are more likely to be served.
    - **Eligible**: Select the check box to indicate that the answer is available within the pool to be used in response to queries. Alternatively, select **Mark pool answers eligible** or **Mark pool answers ineligible** from the **Actions** drop-down menu.
- **Pool Priority**: Failover priority rules specify the priority of answers that are served in a policy. If the primary answer is unavailable, traffic is steered to the next answer in the list.
    - **Pool**: Select the priority in which the answers are served.
- **Attach Health Check**: Select an existing Health Check to be included as part of the policy, add a new one, or select **None**.
- **Attach Domain(s)**: The domain name and domain OCID you want to attach to the policy. Additional domains can be added in this section.

5. Click **Create Policy**.

The system creates and publishes the policy.

To create a Geolocation Steering policy

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Traffic Management Steering Policies**.
2. Click **Create Traffic Management Steering Policy**.
3. In the **Create Traffic Management Steering Policy** dialog box, select **Geolocation Steering**.
4. Enter the following information:
    - **Policy Name:** The unique name that identifies policy. Avoid entering confidential information.
    - **Policy TTL**: The Time to Live for responses from the steering policy. If not specified, the system will set this value on the steering policy.
    - **Maximum Answer Count**: The maximum number of answers returned for the policy. For priority-based policies, the first valid answer is returned.
    - **Answer Pool(s):** Answer pools contain the group of answers that will be served in response to DNS queries.
        - **Answer Pool Name**: A user-friendly name for the answer pool, unique within the steering policy. Avoid entering confidential information.
        - **Name**: A unique name to identify the answer. Avoid entering confidential information.
        - **Type**: The record type that will be provided as the answer.
        - **RDATA**: A valid domain name or IP address to add as an answer.
        - **Eligible**: Select the check box to indicate that the answer is available within the pool to be used in response to queries. Alternatively, select **Mark pool answers eligible** or **Mark pool answers ineligible** from the **Actions** drop-down menu.

- **Geolocation Steering Rules**: Geolocation steering rules specify the priority of answers that are served in a policy. If the primary answer is unavailable, traffic is steered to the next answer in the list. Additional rules and priorities can be added in this section.
    - **Geolocation**: Select a location that will be used to distribute DNS traffic.
    - **Pool Priority**: Select the priority in which the answers are served.
    - **Global Catch-all**: Adding a global catch-all allows you to specify answer pools for queries that do not match any of the specified rules you have added. Click **Add Global Catch-all** and select the pool priorities.
- **Attach Health Check**: Select an existing Health Check to be included as part of the policy, add a new one, or select **None**.
- **Attach Domain(s)**: The domain name and domain OCID you want to attach to the policy. Additional domains can be added in this section.

5. Click **Create Policy**.

The system creates and publishes the policy.

To create an ASN Steering policy

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Traffic Management Steering Policies**.
2. Click **Create Traffic Management Steering Policy**.
3. In the **Create Traffic Management Steering Policy** dialog box, select **ASN Steering**.
4. Enter the following information:
    - **Policy Name:** The unique name that identifies policy. Avoid entering confidential information.
    - **Policy TTL**: The Time to Live for responses from the steering policy. If not specified, the system will set this value on the steering policy.

- **Maximum Answer Count**: The maximum number of answers returned for the policy. For priority-based policies, the first valid answer is returned.
- **Answer Pool(s):** Answer pools contain the group of answers that will be served in response to DNS queries.
    - **Answer Pool Name**: A user-friendly name for the answer pool, unique within the steering policy. Avoid entering confidential information.
    - **Name**: A unique name to identify the answer. Avoid entering confidential information.
    - **Type**: The record type that will be provided as the answer.
    - **RDATA**: A valid domain name or IP address to add as an answer.
    - **Eligible**: Select the check box to indicate that the answer is available within the pool to be used in response to queries. Alternatively, select **Mark pool answers eligible** or **Mark pool answers ineligible** from the **Actions** drop-down menu.
- **ASN Steering Rules**: ASN steering rules specify the priority of answers that are served in a policy. If the primary answer is unavailable, traffic is steered to the next answer in the list.
    - **ASN**: Enter an Autonomous System Number (ASN) that will be used to distribute DNS traffic.
    - **Pool Priority**: Select the priority in which the answers are served.
    - **Global Catch-all**: Adding a global catch-all allows you to specify answer pools for queries that do not match any of the specified rules you have added. Click **Add Global Catch-all** and select the pool priorities.
- **Attach Health Check**: Select an existing Health Check to be included as part of the policy, add a new one, or select **None**.
- **Attach Domain(s)**: The domain name and domain OCID you want to attach to the policy. Additional domains can be added in this section.

5. Click **Create Policy**.

The system creates and publishes the policy.

To create an IP Prefix Steering policy

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Traffic Management Steering Policies**.
2. Click **Create Traffic Management Steering Policy**.
3. In the **Create Traffic Management Steering Policy** dialog box, select **IP Prefix Steering**.
4. Enter the following information:
    - **Policy Name:** The unique name that identifies policy. Avoid entering confidential information.
    - **Policy TTL**: The Time to Live for responses from the steering policy. If not specified, the system will set this value on the steering policy.
    - **Maximum Answer Count**: The maximum number of answers returned for the policy. For priority-based policies, the first valid answer is returned.
    - **Answer Pool(s):** Answer pools contain the group of answers that will be served in response to DNS queries.
        - **Answer Pool Name**: A user-friendly name for the answer pool, unique within the steering policy. Avoid entering confidential information.
        - **Name**: A unique name to identify the answer. Avoid entering confidential information.
        - **Type**: The record type that will be provided as the answer.
        - **RDATA**: A valid domain name or IP address to add as an answer.
        - **Eligible**: Select the check box to indicate that the answer is available within the pool to be used in response to queries. Alternatively, select **Mark pool answers eligible** or **Mark pool answers ineligible** from the **Actions** drop-down menu.

- **IP Prefix Steering Rules**: IP prefix steering rules specify the priority of answers that are served in a policy. If the primary answer is unavailable, traffic is steered to the next answer in the list.
    - **Subnet Address**: Enter a subnet address that will be used to distribute DNS traffic.
    - **Pool Priority**: Select the priority in which the answers are served.
    - **Global Catch-all**: Adding a global catch-all allows you to specify answer pools for queries that do not match any of the specified rules you have added. Click **Add Global Catch-all** and select the pool priorities.
- **Attach Health Check**: Select an existing Health Check to be included as part of the policy, add a new one, or select **None**.
- **Attach Domain(s)**: The domain name and domain OCID you want to attach to the policy. Additional domains can be added in this section.

5. Click **Create Policy**.

The system creates and publishes the policy.

To update a policy

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Traffic Management Steering Policies**.
2. Click the **Policy Name** you want to update. Policy information and a list of attached domains appear.

Tip

You can use search for a policy by name in the **Search** field. You can also use the **Time Created** sort filter to sort the policies chronologically in ascending or descending order.

3. Click **Edit**.
4. Make the needed changes, and then click **Save**.

To attach a domain to an existing policy

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Traffic Management Steering Policies**.
2. Click the **Policy Name** you want to update. Policy information and a list of attached domains appear.

Tip

You can use search for a policy by name in the **Search** field. You can also use the **Time Created** sort filter to sort the policies chronologically in ascending or descending order.

3. Click **Add Attached Domain(s)**.
4. In the Add Attached Domain(s) dialog box, enter the domain and select a zone.
5. Click **Submit**.

To edit an attached domain

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Traffic Management Steering Policies**.
2. Click the **Policy Name** you want to update. Policy information and a list of attached domains appear.

Tip

You can use search for a policy by name in the **Search** field. You can also use the **Time Created** sort filter to sort the policies chronologically in ascending or descending order.

3. For the attached domain you want to edit, click the Actions icon (three dots), and then click **Edit Attached Domain**.
4. In the Attached Domain(s) dialog box, enter the domain and select a zone.
5. Click **Save**.

To delete a policy

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Traffic Management Steering Policies**.
2. Select the check box for the policy you want to delete.
3. Click **Delete**. The policy is staged for deletion.
4. Click **Publish Changes** to delete the policy.
5. In the confirmation dialog box, click **Publish Changes**.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

For more information about managing steering policies using the API, see Traffic Management Steering Policies API Guide.

Use the following operations to manage your steering policies:

- CreateSteeringPolicy
- ListSteeringPolicies
- GetSteeringPolicy
- UpdateSteeringPolicy
- DeleteSteeringPolicy

Use the following operations to manage your steering policy attachments:

- CreateSteeringPolicyAttachment
- ListSteeringPolicyAttachments
- GetSteeringPolicyAttachment
- UpdateSteeringPolicyAttachment
- DeleteSteeringPolicyAttachment

Traffic Management Steering Policy geokeys

Use these keys as values for the `geokey` fields of `caseConditions` in `ROUTE_BY_GEO` steering policies.

CHAPTER 13 Email Delivery

This chapter explains how to send large volume email.

Overview of the Email Delivery Service

Oracle Cloud Infrastructure Email Delivery is an email sending service that provides a fast and reliable managed solution for sending high-volume emails that need to reach your recipients' inbox. Email Delivery provides the tools necessary to send application-generated email for mission-critical communications such as receipts, fraud detection alerts, multi-factor identity verification, and password resets.

Oracle Cloud Infrastructure's Email Deliverability team manages the platform using key deliverability metrics to ensure the best sending reputation possible for your emails.

The following items are provided to you when you send email using the Email Delivery service:

- Unique mailbox provider SMTP configurations on our Mail Transfer Agents (MTA)
- Bounce collection
- User complaint collection
- Email authentication standards
- Deliverability performance

Email Delivery Service Components

Email Delivery uses the components described in this section.

APPROVED SENDERS

An Approved Sender is a resource that equates to the "From" address. An approved sender is associated with a compartment and only exists in the region where the approved sender was configured. If you need to have the same approved sender in another region,

it must be created in the other region. For example, if you create an approved sender in the US West (Phoenix) region, you cannot send email through the US East (Ashburn) region.

SUPPRESSION LIST

The Suppression List is included on your Email Delivery console user interface and from the API. Email Delivery automatically adds email addresses with bounce codes showing permanent failures or user complaints to the suppression list to protect your sender reputation. Email Delivery will not send any messages to these recipients in the future.

Reasons for suppression currently include:

- Complaints
- Hard bounces
- Repetitive soft bounces
- Manual entries
- List-unsubscribe requests

SPF AUTHENTICATION

Sender Policy Framework (SPF) is used by email receivers to detect email spoofing. Using SPF, an email receiver can check if the Internet Protocol (IP) is explicitly authorized to send for that domain.

SPF is implemented by publishing a special TXT record to a domain's DNS records. The TXT record declares which hosts are allowed to send mail on behalf of this domain.

Receiving mail servers check the SPF records of sending domains to verify that the email's source IP address is authorized to send from that domain. Without SPF, a spam or phishing email can be “spoofed” to appear that the email comes from a legitimate domain. Domains that implement SPF are much more likely to block emails attempting to spoof your domain.

For an overview of how SPF works, see Sender Policy Framework. For details on SPF record syntax, see SPF Record Syntax.

Regions and Availability Domains

Email Delivery is available in the US West (Phoenix), US East (Ashburn), and UK South (London) regions. For more information, see Regions and Availability Domains.

The sending application is not required to be located in the region where email is sent. For example, if your sending application is located in a region where Email Delivery is not currently available, you would configure email from one of the regions where it is available. In the Console, change your region to US West (Phoenix), US East (Ashburn), or UK South (London) and create an approved sender. When creating SMTP credentials, any region can be used, as identities are global assets. Configure your application to send email to the region where you created the approved sender (US West (Phoenix), US East (Ashburn), or UK South (London) endpoint) using the SMTP credentials.

When Email Delivery is available in more regions, you can configure Email Delivery in the same region as the sending application to improve performance.

Configuring a New Region

If you want to start sending email from a new region, keep the following in mind:

- An approved sender must be created in the new region.
- SMTP credentials are global, however, it is recommended that you generate SMTP credentials for a new user (without console access) in the new region so that the credentials are not shared with other regions. Ensure that the user has the correct privileges.
- Email must be sent to the new regional SMTP connection endpoint.
- The suppression list and approved senders are regional Email Delivery assets. For example, if an email sent from the US West (Phoenix) region bounces, the recipient email address will be added to the US West (Phoenix) region suppression list. This recipient would not be added to other region suppression lists. If you are sending email from different regions, approved senders must be created in each region.
- SPF must be set up on each subdomain. For example, in your DNS setup, create a TXT record for notification.eu-frankfurt-1.oraclecloud.com and paste the following

information from the dialog box into the record: `v=spf1 include:spf.oracleemaildelivery.com -all`

Ways to Access Oracle Cloud Infrastructure

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. For a list of available SDKs, see SDKs and Other Tools.

To access the Console, you must use a supported browser. You can use the Console link at the top of this page to go to the sign-in page. You are prompted to enter your cloud tenant, your user name, and your password. For general information about using the API, see About the API.

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies. For specific details about writing policies for each of the different services, see Policy Reference.

If you're a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

Email Delivery supports the following authentication types for control plane operations (management endpoint):

- **Instance Authorization:** The IAM service feature that enables instances to be authorized actors (or principals) to perform actions on service resources. Each compute instance has its own identity, and it authenticates using the certificates that are added to it. These certificates are automatically created, assigned to instances and rotated, preventing the need for you to distribute credentials to your hosts and rotate them.
- **Cross-Tenancy:** Cross-tenancy authorization allows customers to share resources between tenancies. To authorize a cross-tenancy request, the request must be endorsed by the requester's tenancy and permitted by the target tenancy.
- **Federated:** Federated authentication enables an administrator to configure a relationship between an identity provider and a service provider. When you federate Oracle Cloud Infrastructure with an identity provider, you manage users and groups in the identity provider. You manage authorization in Oracle Cloud Infrastructure's IAM service. Oracle Cloud Infrastructure tenancies are federated with Oracle Identity Cloud Service by default.

Note

Instance authorization, cross-tenancy, and federated authentication types do not apply to SMTP email sending. An approved sender and SMTP credentials are required and must be associated with the same tenancy for SMTP email sending.

SMTP Authentication and Connection Endpoints

Email Delivery only supports the AUTH PLAIN command when using SMTP authentication. If the sending application is not flexible with the AUTH command, an SMTP proxy/relay can be used. For more information about the AUTH command, see AUTH Command and its Mechanisms.

Use the following regional endpoints for establishing SMTP connections for sending.

- US West (Phoenix): smtp.us-phoenix-1.oraclecloud.com
- US East (Ashburn): smtp.us-ashburn-1.oraclecloud.com
- UK South (London): smtp.email.uk-london-1.oci.oraclecloud.com

Monitoring Resources

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications. For more information, see Monitoring Overview and Notifications Overview.

For information about available Email Delivery service metrics and how to view them, see Email Delivery Metrics.

Email Delivery Service Capabilities and Limits

See Service Limits for a list of applicable limits and instructions for requesting a limit increase. To set compartment-specific limits on a resource or resource family, administrators can use compartment quotas.

Customers that sign up for a free Oracle Cloud trial are limited to:

- A volume of 200 emails a day.
- Five approved senders.
- Each user is limited to a maximum of two SMTP credentials.
- Sending rates are limited to ten emails per minute.
- Inline attachments.

Enterprise accounts are limited to:

- A volume of 50,000 emails a day.
- 10,000 approved senders.
- Sending rates are limited to 18,000 emails per minute.
- Inline attachments.

Note

The Email Delivery platform supports higher volumes. Limits are set as a safeguard for our customers' reputation. To file a service request to increase the email sending limit, open the navigation menu. Under **Governance and Administration**, go to **Service Limits**. Click **Request a service limit increase**.

Note

Currently, Email Delivery supports messages up to 2 MB, inclusive of message headers, body, and attachments. This is not a limit set per tenant. Larger message sizes will be available in the future.

Required IAM Service Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

If you're new to policies, see Getting Started with Policies and Common Policies. For more details about policies for Email Delivery, see Details for the Email Service.

Permissions are required for managing and using approved senders and the suppression list. For example:

- To enable all operations on approved senders for a specific user group:

```
Allow group <Your Group Name> to manage approved-senders in tenancy
```

- To enable all operations on suppressions for a specific user group:

```
Allow group <Your Group Name> to manage suppressions in tenancy
```

Tagging Resources

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the desired tags. For general information about applying tags, see Resource Tags.

Email Delivery supports applying tags to approved senders.

Integration with Oracle Cloud Infrastructure Services

Email Delivery audits the following events:

- Creating a sender (CreateSender)
- Deleting a sender (DeleteSender)
- Retrieving details about a sender (ListSenders)

To view logs for events in the Email Delivery service, your user must be in a group with the ability to view all of the Audit event logs in the tenancy. For more information, see Viewing Audit Log Events.

Getting Started with Email Delivery

You can set up the Email Delivery service within the Console. To begin sending email with Email Delivery, complete the following steps:

1. Generate SMTP credentials for a user.
2. Set up permissions.
3. Create an approved sender.

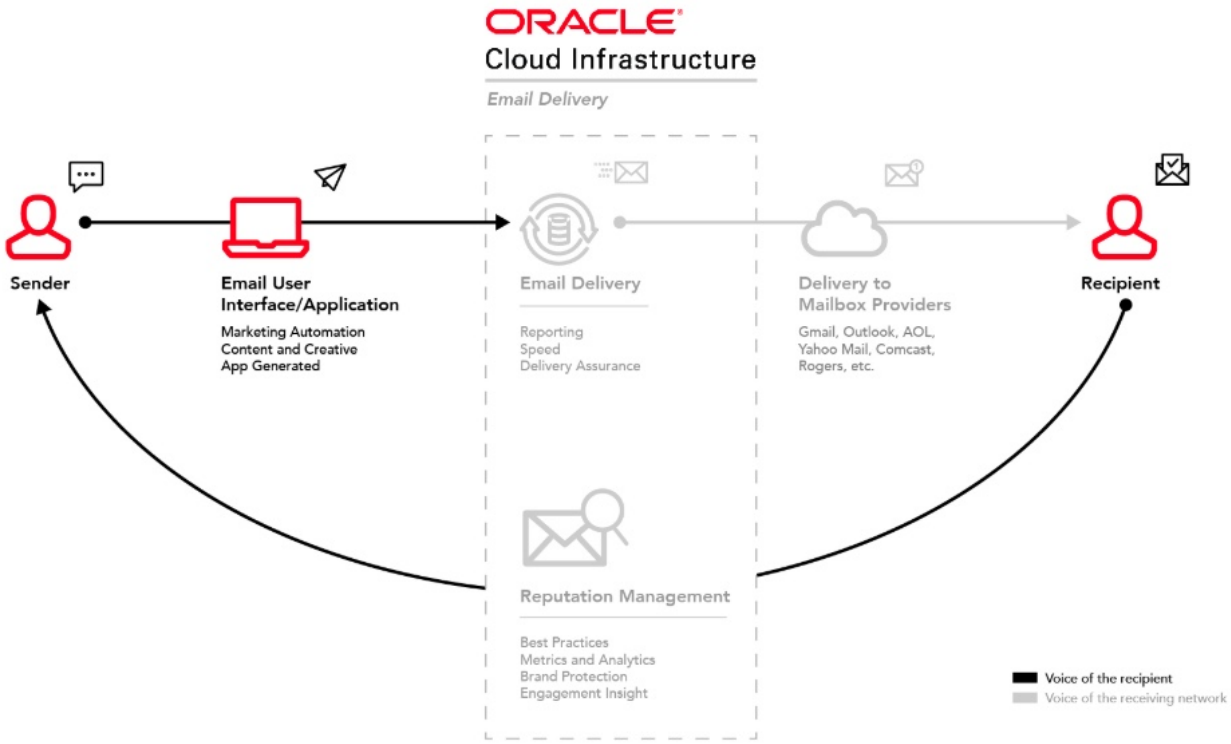
4. Configure SPF on the approved sender domain.
5. Configure the SMTP connection.
6. Begin sending email.

For more information, see Getting Started with Email Delivery.

Getting Started with Email Delivery

Email Delivery provides a highly scalable, cost effective, and reliable way to send email from your applications. Email Delivery includes developer-friendly tools to quickly send application-generated email for mission-critical communications such as receipts, programmatic notifications, or password reset emails.

Email Delivery Basics



When you use Email Delivery, we become your outbound email server. If you have an existing email server, you can keep it and configure it to send through Email Delivery. The Email Delivery service will take care of the feedback loops and platform reputation automatically.

Getting Started

This topic gives guidance on how to get started with Email Delivery. For complete details about the service and its components, see Overview of the Email Delivery Service.

Email Configuration Options

You can configure Oracle Cloud Infrastructure using the Console (a browser-based interface), REST API, SDKs, CLI or Terraform.

Using the Email Delivery SDK

The Email Delivery SDK is available in several programming languages. For information on installing and configuring the Oracle Cloud Infrastructure SDKs, see Developer Tools.

Examples of SDK usage can be found on GitHub, including:

- Example: Email Delivery SDK for Java
- Example: Email Delivery SDK for Python
- Example: Email Delivery SDK for Ruby
- Example: Email Delivery SDK for Go

Configuring Third-Party Applications

The following information describes how you can configure third-party applications to send email through Email Delivery:

- Integrating Oracle Application Express with Email Delivery
- Integrating Postfix with Email Delivery
- Integrating Oracle Enterprise Manager with Email Delivery
- Integrating Mailx with Email Delivery
- Integrating Swaks with Email Delivery
- Integrating Sendmail with Email Delivery
- Integrating JavaMail with Email Delivery
- Integrating PeopleSoft with Email Delivery
- Integrating Python with Email Delivery

Sending Email

To begin sending email with Email Delivery, complete the following steps:

Generate SMTP credentials for a user.

Simple Mail Transfer Protocol (SMTP) credentials are necessary to send email through Email Delivery. Each user is limited to a maximum of two SMTP credentials. If more than two are required, SMTP credentials must be generated that are associated with another existing user or more users must be created.

Best Practice: A security best practice is to generate SMTP credentials for a new user instead of your Console user that already has permissions assigned to it. For detailed instructions on creating a user, see Adding Users.

To generate SMTP credentials for a user.

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Users**. Locate the user in the list that has permissions to manage email, and then click the user's name to view the details.

> **Tip**
>
> If your user does not have permissions to view or create users, you can create SMTP credentials under your user. Open the **Profile** menu ( ) and click **User Settings**.

2. Click **SMTP Credentials**.
3. Click **Generate SMTP Credentials**.
4. Enter a **Description** of the SMTP Credentials in the dialog box.
5. Click **Generate SMTP Credentials**. A user name and password is displayed.

6. Copy the user name and password for your records and click **Close**.

Set up permissions.

The new user must be assigned to a group with permissions to manage `approved-senders` and `suppressions`.

To create a policy to allow a group to manage approved senders and suppressions

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Policies**.
   A list of the policies in the compartment you're viewing is displayed.
2. If you want to attach the policy to a compartment other than the one you're viewing, select the desired compartment from the list on the left. Where the policy is attached controls who can later modify or delete it (see Policy Attachment).
3. Click **Create Policy**.
4. Enter the following:
   - **Name:** A unique name for the policy. The name must be unique across all policies in your tenancy. You cannot change this later.
   - **Description:** A friendly description. You can change this later if you want to.
   - **Policy Versioning:** Select **Keep Policy Current** if you'd like the policy to stay current with any future changes to the service's definitions of verbs and resources. Or if you'd prefer to limit access according to the definitions that were current on a specific date, select **Use Version Date** and enter that date in format YYYY-MM-DD format. For more information, see Policy Language Version.
   - **Statement:** Enter the following policy statement:

     ```
     Allow group <group name> to use approved-senders in compartment <compartment name>
     ```

For more information about policies and policy syntax, see Policy Basics.

- **Tags:** Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.

5. Click **Create**.

The new policy will go into effect typically within 10 seconds.

To add the new user to the group

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Users**.
   A list of the users in your tenancy is displayed.
2. Locate the user in the list.
3. Click the user.
   Its details are displayed.
4. Click **Groups**.
5. Click **Add User to Group**.
6. Select the group from the drop-down list, and then click **Add**.

Make sure to let the user know which compartment(s) they have access to.

Create an approved sender.

You must set up an approved sender for all "From:" addresses sending mail via Oracle Cloud Infrastructure or mail will be rejected. An approved sender is associated with a compartment and only exists in the region where the approved sender was configured. That is, if you create

an approved sender in the Phoenix (PHX) region, you cannot send email through the Ashburn (IAD) region.

Best Practice: Approved senders should not be created in the root compartment. If approved senders exist in the root compartment, you are required to create a policy to manage approved senders in the entire tenant. Creating approved senders in a compartment other than the root allows the policy to be specific to that compartment.

To create an approved sender using the Console

1. Open the navigation menu. Under **Solutions and Platform**, go to **Email Delivery** and click **Email Approved Senders**. Ensure that you are in the correct compartment. Your user must be in a group with permissions to manage `approved-senders` in this compartment.
2. Click **Create Approved Sender** within the **Approved Senders** view.
3. Enter the email address you want to list as an approved sender in the **Add Sender** dialog box.
4. Click **Add**. The email address is added to your Approved Senders list.

Tip

Approved senders are unique to tenancies. If an attempt is made to create a duplicate approved sender within a tenancy, the service will return a 409 Conflict error.

To create an approved sender using the API

The following example shows how to create an approved sender. For more information about creating an approved sender, see CreateSender.

```
POST /20170907/senders

                                {
                                "compartmentId":
"ocid1.compartment.oc1..aaaaaaaat7uqcb6zoxvzoga4d4vh4dtweciavepacd3skz56atf3qp73d7fx",
                                "emailAddress": "user@example.com",

               }
```

Configure SPF on the approved sender domain.

Sender Policy Framework (SPF) is used by email receivers to detect email spoofing. Using SPF, an email receiver can check if the Internet Protocol (IP) is explicitly authorized to send for that domain.SPF is implemented by publishing a special TXT record to a domain's DNS records. The TXT record declares which hosts are allowed to send mail on behalf of this domain. Receiving mail servers check the SPF records of sending domains to verify that the email's source IP address is authorized to send from that domain. Without SPF, a spam or phishing email can be “spoofed” to appear that the email comes from a legitimate domain. Domains that implement SPF are much more likely to block emails attempting to spoof your domain.For an overview of how SPF works, see Sender Policy Framework. For details on SPF record syntax, see SPF Record Syntax.

The Approved Senders section within the Console provides validation of an SPF record for each of your approved senders.

To configure SPF

1. Open the navigation menu. Under **Solutions and Platform**, go to **Email Delivery** and click **Email Approved Senders**.
2. Select the checkbox for the approved sender you want to view SPF details for and click **View SPF**.

Tip

You can search for an approved sender by using the Search field. Addresses can be sorted alphanumerically or by creation date in ascending or descending order.

3. The Manage SPF dialog box appears indicating whether an SPF record for the approved sender exists.
    - If your domain does not currently have an SPF record, the information necessary to add an SPF record in your DNS setup is displayed. See Managing DNS Service Zones for instructions on adding a zone record in Oracle Cloud Infrastructure. If your DNS setup resides with another provider, please reference their documentation for adding a TXT record to your domain.
        - In your DNS setup, create a TXT record and paste the following information from the dialog box into the record: `v=spf1 include:spf.oracleemaildelivery.com -all`
    - If your domain currently has an SPF record, add the following information to the record to add Oracle Cloud Infrastructure Email Delivery: `include:spf.oracleemaildelivery.com`

Configure the SMTP connection.

Set up and test your SMTP connection using an SMTP library or product such, as Postfix or Sendmail, to send email through Oracle Cloud Infrastructure Email Delivery.

SMTP Connection Endpoints

Use the following regional endpoints for establishing SMTP connections for sending.

- PHX: smtp.us-phoenix-1.oraclecloud.com
- IAD: smtp.us-ashburn-1.oraclecloud.com
- LHR: smtp.email.uk-london-1.oci.oraclecloud.com

TLS Requirements

Oracle maintains strict security policies and only accepts email traffic using Transport Layer Security (TLS). Use of TLS 1.2 is mandatory to send email using Oracle Cloud Infrastructure.

The approved TLS 1.2 ciphers are:

- TLS_DHE_RSA_WITH_AES_256_CBC_SHA256
- TLS_DHE_DSS_WITH_AES_256_CBC_SHA256
- TLS_RSA_WITH_AES_256_CBC_SHA256
- TLS_DHE_DSS_WITH_AES_128_CBC_SHA256
- TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256
- TLS_ECDHE_ECDSA_WITH_AES_256_GCM_SHA384
- TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256
- TLS_ECDHE_ECDSA_WITH_AES_128_CBC_SHA256
- TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA256

To access SMTP sending information to configure the connection in your system

Open the navigation menu. Under **Solutions and Platform**, go to **Email Delivery** and click **Email Configuration**. The following information is displayed:

- **Manage SMTP Credentials:** Access your user credentials. Use the SMTP user credentials (in plain text) when validating your connection.
- **Server Name:** Regional SMTP endpoint
- **Port:** Email Delivery supports TLS on port 25 or 587.
- **Use Transport Layer Security (TLS):** This field indicates if TLS, the standard means of performing encryption in transit for email, is being used. Customers must encrypt

email while it is in transit to the Oracle Cloud Infrastructure Email Delivery service. Encrypted emails are protected from being read during transit.

Tip

Java applications (including JavaMail) must be updated to the latest version to ensure the latest protocols, ciphers, and security patches are in compliance with Oracle's supported security policies and ciphers.

Begin sending email.

Use Email Delivery to begin sending email.

Suppression List

As you begin to send email, Email Delivery automatically adds email addresses with bounce codes showing permanent failures or user complaints to the suppression list to protect your sender reputation. Email Delivery will not send any messages to these recipients in the future. Reasons for suppression currently include:

- Complaints
- Hard bounces
- Repetitive soft bounces
- Manual entries
- List-unsubscribe requests

To manually add an email address to the suppression list using the Console

1. Open the navigation menu. Under **Solutions and Platform**, go to **Email Delivery** and

click **Email Suppression List**.

2. Click **Add Suppression**.
3. In the Add Suppression dialog box, enter the email address.
4. Click **Add**. The email address is added to the suppression list.

For more information, see Managing the Suppression List.

To manually add an email address to the suppression list using the API

The following example shows how to add an email address to the suppression list. For more information about managing the suppressions list, see GetSuppression and DeleteSuppression.

```
POST /20170907/suppressions

                                {
                                "compartmentId":
"ocid1.compartment.oc1..aaaaaaaat7uqcb6zoxvzoga4d4vh4dtweciavepacd3skz56atf3qp73d7fx",
                                "emailAddress": "user@example.com",

               }
```

Using the API

You can access Oracle Cloud Infrastructure using the REST API. Instructions for the API are included in topics throughout this guide. For a list of available SDKs, see SDKs and Other Tools.

Regions

See Regions and Availability Domains for information on regions Email Delivery is available in.

Limits

See Email Delivery Service Capabilities and Limits for information on new account and enterprise account limits.

Best Practices

This section describes best practices for using Email Delivery.

Volume Testing - In order to maintain our sender reputation and yours, testing at volume needs to be done using the following best practice.

- Use a recipient address at the email-blackhole.com domain, such as example@email-blackhole.com. Email Delivery will accept the mail but will not deliver it to an inbox.
- If large volume emails are sent to valid email addresses, these will get rejected by receivers and will result in a large amount of hard bounces. This will negatively affect IP reputation. For testing bounce processing, send small amounts of emails to a domain that does not have an MX record, in other words, the domain does not exist.

Deliverability - To help you learn and manage the habits that affect your sending reputation, see Deliverability Best Practices.

Sending to Email Aliases - When sending email to an alias, the alias is considered one recipient. When sending email to a distribution group or list set up in an email client such as Apple Mail or Outlook, a separate email is sent for each recipient in the group.

Generate SMTP Credentials for a User

Simple Mail Transfer Protocol (SMTP) credentials are necessary to send email through Email Delivery. Each user is limited to a maximum of two SMTP credentials. If more than two are required, SMTP credentials must be generated on other existing users or more users must be created.

A security best practice is to generate SMTP credentials for a new user instead of your Console user that already has permissions assigned to it. For detailed instructions on creating

a user, see Adding Users. The new user must be assigned to a group with permissions to manage `approved-senders` and `suppressions`. For example:

```
Allow group <group name> to use approved-senders in compartment <compartment name>
```

Using the Console

To generate SMTP credentials for a user

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Users**. Locate the user in the list that has permissions to manage email, and then click the user's name to view the details.

   Tip

   If your user does not have permissions to view or create users, you can create SMTP credentials under your user. Open the **Profile** menu () and click **User Settings**.

2. Click **SMTP Credentials**.
3. Click **Generate SMTP Credentials**.
4. Enter a **Description** of the SMTP Credentials in the dialog box.
5. Click **Generate SMTP Credentials**. A user name and password is displayed.
6. Copy the user name and password for your records and click **Close**.

Managing Approved Senders

You must set up an approved sender for all “From:” addresses sending mail via Oracle Cloud Infrastructure or mail will be rejected. An approved sender is associated with a compartment and only exists in the region where the approved sender was configured. That is, if you create

an approved sender in the US West (Phoenix) region, you cannot send email through the US East (Ashburn) region.

Approved senders should not be created in the root compartment. If approved senders exist in the root compartment, you are required to create a policy to manage approved senders in the entire tenant. Creating approved senders in a compartment other than the root allows the policy to be specific to that compartment.

Moving Approved Senders to a Different Compartment

You can move approved senders from one compartment to another. To manage approved senders and use approved senders to send mail, user groups must have an associated identity policy in the new compartment. For more information, see Managing Compartments.

Using the Console

To create an approved sender

1. Open the navigation menu. Under **Solutions and Platform**, go to **Email Delivery** and click **Email Approved Senders**. Ensure that you are in the correct compartment. Your user must be in a group with permissions to manage `approved-senders` in this compartment.
2. Click **Create Approved Sender** within the **Approved Senders** view.
3. Enter the email address you want to list as an approved sender in the **Create Approved Sender** dialog box.

   Tags: Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.

4. Click **Create Approved Sender**. The email address is added to your Approved Senders list.

Tip

Approved senders are unique to tenancies. If an attempt is made to create a duplicate approved sender within a tenancy, the service will return a 409 Conflict error.

To delete an approved sender

1. Open the navigation menu. Under **Solutions and Platform**, go to **Email Delivery** and click **Email Approved Senders**.
2. Find the approved sender you're interested in, click the Actions icon (three dots), and then click **Delete**.
3. In the confirmation dialog box, click **Confirm**. The email address is removed from the Approved Senders list.

To move an approved sender to a different compartment

1. Open the navigation menu. Under **Solutions and Platform**, go to **Email Delivery** and click **Email Approved Senders**.
2. In the **List Scope** section, select a compartment.
3. Find the approved sender in the list, click the the Actions icon (three dots), and then click **Choose New Compartment**.
4. Choose the destination compartment from the list.
5. Click **Move Approved Sender**.

   For more information, see Managing Compartments.

To manage tags for an approved sender

1. Open the navigation menu. Under **Solutions and Platform**, go to **Email Delivery** and click **Email Approved Senders**.
2. Find the approved sender you're interested in, click the Actions icon (three dots), and then click **View Tags** to view or edit existing tags. Or click **Apply tag(s)** to add new ones.

   For more information, see Resource Tags.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the following operations to manage your approved senders:

- CreateSender
- GetSender
- ListSenders
- DeleteSender

Configure SPF

The Approved Senders section within the Console provides validation of an SPF record for each of your approved senders.

Using the Console

To configure SPF

1. Open the navigation menu. Under **Solutions and Platform**, go to **Email Delivery** and click **Email Approved Senders**.
2. Select the checkbox for the approved sender you want to view SPF details for and click **View SPF**.

Tip

You can search for an approved sender by using the Search field. Addresses can be sorted alphanumerically or by creation date in ascending or descending order.

3. The Manage SPF dialog box appears indicating whether an SPF record for the approved sender exists.
    - If your domain does not currently have an SPF record, the information necessary to add an SPF record in your DNS setup is displayed. See Managing DNS Service Zones for instructions on adding a zone record in Oracle Cloud Infrastructure. If your DNS setup resides with another provider, please reference their documentation for adding a TXT record to your domain.
        - In your DNS setup, create a TXT record and paste the following information from the dialog box into the record: `v=spf1 include:spf.oracleemaildelivery.com -all`
    - If your domain currently has an SPF record, add the following information to the record to add Oracle Cloud Infrastructure Email Delivery: `include:spf.oracleemaildelivery.com`

Configure SMTP Connection

Set up and test your SMTP connection using an SMTP library or product, such as Postfix or Sendmail, to send email through Oracle Cloud Infrastructure Email Delivery.

To access SMTP sending information to configure the connection in your system, open the navigation menu. Under **Solutions and Platform**, go to **Email Delivery** and click **Email Configuration**. The following information is displayed:

- **Manage SMTP Credentials:** Access your user credentials. Use the SMTP user credentials (in plain text) when validating your connection.
- **Server Name:** The Email Delivery service hostname.
- **Port:** Email Delivery supports TLS on port 25 or 587.
- **Use Transport Layer Security (TLS):** This field indicates if TLS, the standard means of performing encryption in transit for email, is being used. Customers must encrypt email while it is in transit to the Oracle Cloud Infrastructure Email Delivery service. Encrypted emails are protected from being read during transit.

Important

Java applications (including JavaMail) must be updated to the latest version to ensure the latest protocols, ciphers, and security patches are in compliance with Oracle's supported security policies and ciphers.

SMTP Connection Endpoints

Use the following regional endpoints for establishing SMTP connections for sending.

- PHX: smtp.us-phoenix-1.oraclecloud.com
- IAD: smtp.us-ashburn-1.oraclecloud.com

- LHR: smtp.email.uk-london-1.oci.oraclecloud.com

TLS Requirements

Oracle maintains strict security policies and only accepts email traffic using Transport Layer Security (TLS). Use of TLS 1.2 is mandatory to send email using Oracle Cloud Infrastructure.

The approved TLS 1.2 ciphers are:

- TLS_DHE_RSA_WITH_AES_256_CBC_SHA
- TLS_DHE_RSA_WITH_AES_256_CBC_SHA256
- TLS_DHE_DSS_WITH_AES_256_CBC_SHA256
- TLS_RSA_WITH_AES_256_CBC_SHA
- TLS_RSA_WITH_AES_256_CBC_SHA256
- TLS_DHE_RSA_WITH_AES_128_CBC_SHA
- TLS_DHE_DSS_WITH_AES_128_CBC_SHA256
- TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256
- TLS_ECDHE_ECDSA_WITH_AES_256_GCM_SHA384
- TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256
- TLS_ECDHE_ECDSA_WITH_AES_128_CBC_SHA256
- TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA256

Managing the Suppression List

Manually add an email address to the suppression list to prevent it from being part of your sending list.

Users are required to have correct permissions to manage the suppression list. Currently, identity policies for suppression must be at the tenant level (not at the compartment level). The following is an example of the permission policy statement.

```
Allow group <group name> to manage suppressions in tenancy
```

Suppressions are stored at the tenancy level. Therefore any request requiring a `compartmentId` must provide the `tenancyId` as the `compartmentId`. For example:

```
Allow group <ordinary users> to inspect approved-senders in tenancy
Allow group <power users> to read approved-senders in tenancy
Allow group <sender admins> to manage approved-senders in tenancy
Allow user <mail user> to use approved-senders in tenancy where target.approved-sender.senderId =
<senderId>

Allow group <ordinary users> to inspect suppressions in tenancy
Allow group <power users> to read suppressions in tenancy
Allow group <sender admins> to manage suppressions in tenancy
```

Using the Console

To manually add an email address to the suppression list

1. Open the navigation menu. Under **Solutions and Platform**, go to **Email Delivery** and click **Email Suppression List**.
2. Click **Add Suppression**.
3. In the Add Suppression dialog box, enter the email address.
4. Click **Add**. The email address is added to the Suppression List.

To delete an email address from the suppression list

1. Open the navigation menu. Under **Solutions and Platform**, go to **Email Delivery** and click **Email Suppression List**.
2. Select the checkbox for the email address you want to delete and then click **Delete**.

Tip

You can search for an email address by using the Search field. Addresses can be sorted alphanumerically or by creation date in ascending or descending order.

3. In the confirmation dialog box, click **OK**. The email address is removed from the Suppression List.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the following operations to manage your suppressions:

- CreateSuppression
- GetSuppression
- ListSuppressions
- DeleteSuppression

Email Delivery Metrics

You can monitor the health, capacity, and performance of your Email Delivery by using metrics, alarms, and notifications.

This topic describes the metrics emitted by the metric namespace `oci_emaildelivery` (the Email Delivery service).

Overview of the Email Delivery Service Metrics

Oracle Cloud Infrastructure Email Delivery (Email Delivery) is an email sending service that provides a fast and reliable managed solution for sending high-volume emails that need to reach your recipients' inbox. The Email Delivery service metrics help you measure counts for accepted mail, which consists of the unique emails accepted by the Email Delivery service to send. Emails are defined by the number of unique emails, as well as the number of unique recipients per message attempted to be delivered, resulting in successful delivery and blocked email. For example, sending an email with 10 recipients means 10 emails accepted.

Note

Email Delivery is billed for every 1,000 emails accepted.

For more information, see Overview of the Email Delivery Service.

Prerequisites

- IAM policies: To monitor resources, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.

Available Metrics: oci_emaildelivery

The metrics listed in the following table are automatically available for any policies you create. You do not need to enable monitoring on the resource to get these metrics. However,

your tenancy must have Email Delivery configured and must send mail to make the `oci_emaildelivery` metric space available in the Metrics Explorer feature.

Each metric includes the following dimensions:

RESOURCEID

The OCID of the policy to which the metric applies.

Metric	Metric Display Name	Unit	Description	Dimensions
`EmailsAccepted`	**EmailsAccepted**	count	The number of unique emails accepted by the Email Delivery service.	`resourceID`

Using the Console

Email Delivery service metrics are currently only available using the Metrics Explorer feature in the Console. For more information about metrics, see Viewing Metric Charts.

To view Email Delivery metric charts

1. Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Metrics Explorer**.
   For **Metric Namespace**, select **oci_emaildelivery**.
2. Select a metric to view from the **Metric Name** field.
3. Select a qualifier specified in the **Dimension Name** field. For example, the dimension `resourceId` is specified in the metric definition for `EmailsAccepted`.
4. Select the value you want to use for the specified dimension in the **Dimension Value** field. For example, the resource identifier for your instance of interest.
5. Click **Update Chart**.

The chart will be updated with the metrics that have been requested.

For more information about monitoring metrics and using alarms, see Monitoring Overview. For information about notifications for alarms, see Notifications Overview.

Using the API

Use the following APIs for monitoring:

- Monitoring API for metrics and alarms
- Notifications API for notifications (used with alarms)

Integrating Oracle Application Express with Email Delivery

Configure Oracle Application Express to Send Email Through Email Delivery

You can use the `APEX_MAIL` package to send emails from Oracle Application Express applications deployed in Autonomous Transaction Processing. See Creating an Autonomous Database and Autonomous Transaction Processing for more information.

Before you use `APEX_MAIL` you must configure Oracle Cloud Infrastructure Email Delivery in your Application Express instance.

To enable `APEX_MAIL` functionality in your Application Express instance in Autonomous Transaction Processing:

1. Identify the SMTP connection endpoint for Email Delivery. You configure the endpoint as the SMTP Host in your Application Express instance in Step 4. See Configure SMTP Connection for more information.
2. Generate SMTP credentials for Email Delivery. Your Application Express instance uses credentials to authenticate with Email Delivery servers when you send email. See Generate SMTP Credentials for a User for more information.

3. Create an approved sender for Email Delivery. You need to complete this step for all email addresses you use as the "From" with `APEX_MAIL.SEND` calls, as the Application Email From Address in your apps, or in the `SMTP_FROM` instance parameter. See Managing Approved Senders for more information.
4. Connect to your Autonomous Transaction Processing as ADMIN user using a SQL client and configure the following SMTP parameters using `APEX_INSTANCE_ADMIN.SET_PARAMETER`:
   - `SMTP_HOST_ADDRESS`: Specifies the SMTP connection endpoint from Step 1.
   - `SMTP_USERNAME` Specifies the SMTP credential user name from Step 2.
   - `SMTP_PASSWORD` Specifies the SMTP credential password from Step 2.

   For example:

```
BEGIN
       APEX_INSTANCE_ADMIN.SET_PARAMETER('SMTP_HOST_ADDRESS', 'smtp.us-phoenix-1.oraclecloud.com');
       APEX_INSTANCE_ADMIN.SET_PARAMETER('SMTP_USERNAME', 'ocid1.user.oc1.username');
       APEX_INSTANCE_ADMIN.SET_PARAMETER('SMTP_PASSWORD', 'password');
       COMMIT;
END;
/
```

5. Send a test email using APEX SQL Workshop, SQL Commands specifying one of the approved senders from Step 3 as "From". For example:

```
BEGIN
       APEX_MAIL.SEND(p_from => 'alice@example.com',
                      p_to   => 'bob@example.com',
                      p_subj => 'Email from Oracle Autonomous Database',
                      p_body => 'Sent using APEX_MAIL');
END;
/
```

6. To monitor email delivery in your Application Express instance:
   a. Sign in to APEX Administration Services.
   b. Open the Manage Instance page.
   c. Click the Mail Queue link in the Manage Meta Data section.

Alternatively, query `APEX_MAIL_QUEUE` and `APEX_MAIL_LOG` views using a SQL client.

More Information

- Creating Applications with Oracle Application Express in Autonomous Database
- APEX_MAIL in Oracle Application Express API Reference
- APEX_INSTANCE_ADMIN in Oracle Application Express API Reference

Integrating Postfix with Email Delivery

Configure Postfix to Send Email Through Email Delivery

You can use Postfix to send emails through Email Delivery. Before you use Postfix you must configure Oracle Cloud Infrastructure Email Delivery in your Postfix application.

Note

The paths and commands used below for specifying file locations are specific to Ubuntu/Debian; your file paths or editing commands may differ depending on the operating system you are using. The changes to the configuration files are the same.

To enable Postfix to integrate with Email Delivery:

1. Make sure Email Delivery is configured to send email. See Getting Started with Email Delivery.

Note

The SMTP credentials are required to configure Postfix to use Email Delivery. Be sure to note the user name and password when you generate the SMTP credentials.

2. Update the Postfix `main.cf` file.
   To open the `main.cf` file, run the following command:

   ```
   sudo vi /etc/postfix/main.cf
   ```

   Add the following information to the end of the file:

   ```
   smtp_tls_security_level = may
   smtp_sasl_auth_enable = yes
   smtp_sasl_password_maps = hash:/etc/postfix/sasl_passwd
   smtp_sasl_security_options =
   ```

   If the following line is present, either remove the line or turn it off:

   ```
   smtpd_use_tls = yes
   ```

3. Update `relayhost` to include your SMTP connection endpoint and port. For example:

   ```
   relayhost = smtp.us-ashburn-1.oraclecloud.com:587
   ```

4. Create the `sasl_passwd` file in the same directory as `main.cf`.
   Run the following command:

   ```
   sudo vi /etc/postfix/sasl_passwd
   ```

5. Add your relay host and port by entering:

   ```
   server:port user:pass
   ```

   where:

   - `server` is your relay host and `port` is 25 or 587.
   - `user` is the user name and `pass` is the password you received when you generated your SMTP credentials.

6. Enter the permissions in the password file.
   Run the following command:

   ```
   sudo chown root:root /etc/postfix/sasl_passwd && sudo chmod 600 /etc/postfix/sasl_passwd
   ```

7. Generate the password hash.
   Run the following command:

   ```
   sudo postmap hash:/etc/postfix/sasl_passwd
   ```

8. Reload Postfix.
   Run the following command:

   ```
   sudo postfix reload
   ```

9. Test the configuration by sending a test email.
   Run the following command:

   ```
   echo "This is a test message" | mail -s "Test" -r "<approved sender email address>" <recipient email address>
   ```

   If you want to monitor the log while you send the test email, open a separate Terminal window and run the following command before running the test command:

   ```
   log stream --predicate '(process == "smtpd") || (process == "smtp")' --info
   ```

   A `status=sent (250 Ok)` message in the log indicates the email was sent successfully.

Note

If you are using SASL authentication, you must use the following RPM package: `cyrus-sasl-plain`. See the PostFix website for further documentation on configuring SASL authentication.

More Information

- See the Postfix website for more information on Postfix configuration.
- See TLS errors when integrating with Postfix for troubleshooting techniques related to Email Delivery.

Integrating Oracle Enterprise Manager with Email Delivery

Configure Oracle Enterprise Manager to Send Email Through Email Delivery

You can use Oracle Enterprise Manager to send emails through Email Delivery. Before you use Oracle Enterprise Manager, you must configure Oracle Cloud Infrastructure Email Delivery in your Oracle Enterprise Manager application.

Note

For information on installing Oracle Enterprise Manager, see Setting Up Oracle Enterprise Manager on Oracle Cloud Infrastructure.

To enable Oracle Enterprise Manager to integrate with Email Delivery:

1. Make sure Email Delivery is configured to send email. See Getting Started with Email Delivery.

Note

The SMTP credentials are required to configure Oracle Enterprise Manager to use Email Delivery. Be sure to note the user name and password when you generate the SMTP credentials.

2. In Oracle Enterprise Manager, go to the **Setup** menu and click **Initial Setup Console**.
3. In the **Initial Setup Console** section, click **Configure Mail Servers** in the navigation pane.
4. In the **Sender Identify** section, click **Edit**.
5. Enter the name of the administrator or system that should send the email notifications and the email address from which the notifications should be sent, and then click **OK**.
6. In the **Outgoing Mail (SMTP) Servers** section, click **Create**.
7. Enter the mail server host name, the mail server credentials, and the encryption method to be used, and then click **OK**.
8. Select the outgoing mail server you wish to test and select **Test Mail Server**. Note the confirmation message in the console and verify that you received the test email in your inbox.

Note

If you configure multiple outgoing mail servers, automatic failover and load balancing is performed in round robin fashion.

Integrating Mailx with Email Delivery

Configure Mailx to Send Email Through Email Delivery

You can use Mailx to send emails through Email Delivery. Before you use Mailx you must configure Oracle Cloud Infrastructure Email Delivery in your Mailx application.

> **Note**
>
> These steps assume you are logged into an Oracle Linux instance. Other distributions of Linux may have different commands and file locations.

To enable Mailx to integrate with Email Delivery:

1. Make sure Email Delivery is configured to send email. See Getting Started with Email Delivery.

   > **Note**
   >
   > The SMTP credentials are required to configure Mailx to use Email Delivery. Be sure to note the user name and password when you generate the SMTP credentials.

2. Update the Mailx `mail.rc` file.
   To open the `mail.rc` file, run the following command:

   ```
   sudo vi ~/etc/mail.rc
   ```

   Add the following information to the end of the file:

   ```
   #smtp config

   set nss-config-dir=/etc/pki/nssdb/
   set smtp-use-starttls
   ```

```
set smtp-auth=plain
set smtp=<SMTP connection endpoint>:25
set from=<from_email_address>
set smtp-auth-user=<OCID from smtp credentials>
set smtp-auth-password=<password from smtp credentials>

#write and quit file
:wq!
```

3. Test the configuration by sending a test email.
   Run the following command:

```
echo "Test Email" | mail -v -s "Send an email via mailx" -r "from_name<from_email_address>" -S
replyto="from_name><from_email_address>" -S smtp="SMTP connection endpoint:25" -S smtp-use-
starttls -S smtp-auth=plain -S smtp-auth-user='<ocid from smtp credentials>' -S smtp-auth-
password='<password from smtp credentials>' -S ssl-verify=ignore <recipient_email_address>
```

More Information

- For network security services, see the Mailx documentation.

Integrating Swaks with Email Delivery

Swaks (Swiss Army Knife SMTP) is a transaction-based tool you can use to test SMTP configurations in Email Delivery. Before you use Swaks, you must configure Email Delivery and take note of your SMTP sending information and SMTP credentials.

Note

Many options and parameters can be used to test various scenarios with Swaks. When Swaks evaluates an option (that is, a flag with parameters), it does so in three steps:

- First, it looks for a configuration file (default location or specified with `--config`).
- Next, it looks for options in environment variables.
- Finally, it looks at command line options. At each step, any options set earlier are overridden.

Assumptions

The following procedures assume the following:

- The following example supplies options to Swaks via the command line in long form, for example, `--server` as opposed to the short form, `-s`.
- The following example assumes the default behavior to connect through network sockets.
- A local certificate is not required for a TLS connection to be negotiated. The following example assumes the default behavior where Swaks does not attempt certificate verification.
- Swaks is primarily intended for use on UNIX-like operating systems with functionality based on known standards so it should work on most modern mail servers.

Configure Swaks to Send Email Through Email Delivery

To enable Swaks to test the configuration of Email Delivery:

1. Ensure Email Delivery is configured to send email. See Getting Started with Email Delivery.

   Note

   The SMTP credentials are required to configure Swaks to use Email Delivery. Be sure to note the user name and password when you generate the SMTP credentials.

2. Ensure Swaks is installed. The installation process differs depending on which operating system you are using. For example, run the following command to install Swaks on Oracle Linux:

   ```
   sudo yum install swaks -y
   ```

3. To send a test email with Swaks, run the following command:

   ```
   swaks --pipeline -tls --server <smtp.region.oraclecloud.com> --port <587 or 25> --auth-user
   '<username OCID from SMTP credentials>' --auth-pass '<password>' --from '<sender email
   address>' --to '<recipient email address>' --data '<email message>'
   ```

   For example:

   ```
   swaks --pipeline -tls --server smtp.us-ashburn-1.oraclecloud.com --port 25 --auth-user
   'ocid1.user.oc1..<unique_ID>' --auth-pass '<password>' --from 'sender@example.com' --to
   'recipient@example.com' --data 'From: sender@example.com\nDate: Thu, 13 Sep 2019\nSubject: Test
   Send\n\nTest email'
   ```

   Note the following when sending email with Swaks:

   - The `-tls` parameter is required.
   - The `--pipeline` parameter is supported to make use of SMTP pipelining.
   - The `--port <number>` parameter or `:<port number>` syntax can be used to specify the port.

More Information

- See the Swaks documentation for more information.

Integrating JavaMail with Email Delivery

JavaMail provides a platform-independent and protocol-independent framework to build mail and messaging applications. Before you use JavaMail, you must configure Email Delivery and take note of your SMTP sending information and SMTP credentials. This guide uses the Eclipse IDE and the JavaMail API to send email through Email Delivery.

Important

Java applications (including JavaMail) must be updated to the latest version to ensure that the latest protocols, ciphers, and security patches are in compliance with Oracle's supported security policies and ciphers.

Configure JavaMail to Send Email Through Email Delivery

To enable JavaMail to test the configuration of Email Delivery:

1. Ensure Email Delivery is configured to send email. See Getting Started with Email Delivery.

Note

The SMTP credentials are required to configure JavaMail to use Email Delivery. Be sure to note the user name and password when you generate the SMTP credentials.

2. Open a browser and go to https://github.com/javaee/javamail/releases.
3. Under **Downloads**, select **javax.mail.jar** to download the latest version of JavaMail.

4. Create a project in Eclipse by performing the following steps:
    a. In Eclipse, open the **File** menu. Select **New**, and then click **Java Project**.
    b. In the Create a Java Project dialog box, enter a project name, and then click **Next**.
    c. In the Java Settings dialog box, select the **Libraries** tab.
    d. Click **Add External JARs**.
    e. In the JAR Selection dialog box, browse to the folder in which you downloaded JavaMail. Select the **javax.mail.jar** file, and then click **Open**.
    f. In the Java Settings dialog box, click **Finish**.
5. In Eclipse, in the Package Explorer window, expand your project.
6. Under your project, right-click the src directory, select **New**, and then click **Class**.
7. In the New Java Class dialog box, enter "OCIemail" in the **Name** field and then click **Finish**.
8. Enter the following code in **OCIemail.java** to send a test email with JavaMail:

```
import java.util.Properties;
import javax.mail.Message;
import javax.mail.Session;
import javax.mail.Transport;
import javax.mail.internet.InternetAddress;
import javax.mail.internet.MimeMessage;

public class OCIemail {

    // Replace FROM with your "From" address.
    // This address must be added to Approved Senders in the console.
    static final String FROM = "<sender email address>";
    static final String FROMNAME = "<sender name>";

    // Replace TO with a recipient address.
    static final String TO = "<recipient email address>";

    // Replace smtp_username with your Oracle Cloud Infrastructure SMTP username generated in
console.
```

```
    static final String SMTP_USERNAME = "<username OCID from SMTP credentials>";

    // Replace smtp_password with your Oracle Cloud Infrastructure SMTP password generated in
console.
    static final String SMTP_PASSWORD = "<SMTP password>";

    // Oracle Cloud Infrastructure Email Delivery hostname.
    static final String HOST = "<SMTP endpoint>";

    // The port you will connect to on the SMTP endpoint. Port 25 or 587 is allowed.
    static final int PORT = 587;

       static final String SUBJECT = "<subject of your email>";
       static final String BODY = String.join(

           System.getProperty("line.separator"),
           "<h1>OCI Email Delivery test</h1>",
           "<p>This email was sent with OCI Email Delivery using the ",
           "<a href='Javamail'>https://github.com/javaee/javamail'>Javamail Package</a>",
          " for <a href='Javahttps://www.java.com'>Java</a>."

       );

    public static void main(String[] args) throws Exception {

        // Create a Properties object to contain connection configuration information.

       Properties props = System.getProperties();
       props.put("mail.transport.protocol", "smtp");
       props.put("mail.smtp.port", PORT);

       //props.put("mail.smtp.ssl.enable", "true"); //the default value is false if not set
       props.put("mail.smtp.auth", "true");
       props.put("mail.smtp.auth.login.disable", "true");  //the default authorization order is
"LOGIN PLAIN DIGEST-MD5 NTLM". 'LOGIN' must be disabled since Email Delivery authorizes as
'PLAIN'
       props.put("mail.smtp.starttls.enable", "true");   //TLSv1.2 is required
       props.put("mail.smtp.starttls.required", "true");  //Oracle Cloud Infrastructure required

        // Create a Session object to represent a mail session with the specified properties.
```

```
Session session = Session.getDefaultInstance(props);

 // Create a message with the specified information.
 MimeMessage msg = new MimeMessage(session);
 msg.setFrom(new InternetAddress(FROM,FROMNAME));
 msg.setRecipient(Message.RecipientType.TO, new InternetAddress(TO));
 msg.setSubject(SUBJECT);
 msg.setContent(BODY,"text/html");

 // Create a transport.
 Transport transport = session.getTransport();

 // Send the message.

 try
 {

     System.out.println("Sending Email now...standby...");

     // Connect to OCI Email Delivery using the SMTP credentials specified.
     transport.connect(HOST, SMTP_USERNAME, SMTP_PASSWORD);

     // Send email.
     transport.sendMessage(msg, msg.getAllRecipients());
     System.out.println("Email sent!");

 }

 catch (Exception ex) {

     System.out.println("The email was not sent.");
     System.out.println("Error message: " + ex.getMessage());

 }

 finally

 {
```

```
            // Close & terminate the connection.
            transport.close();

        }

    }
}
```

9. In the **OCIemail.java** file, replace the following with your own values:

Note

Email addresses are case-sensitive. Ensure that the addresses are the same as the ones you entered in Approved Senders in the console.

   - **FROM** - Replace with your sender email address. This email address must be added to the Approved Senders list in Email Delivery first.
   - **TO** - Replace with your recipient email address.
   - **SMTP credentials** - Replace smtp_username and smtp_password with your Oracle Cloud Infrastructure SMTP username and password generated in the console.
   - **HOST** - Replace with the Email Delivery SMTP endpoint. For example, smtp.us-ashburn-1.oraclecloud.com.
10. Refer to the requirements for configuring an SMTP connection with Email Delivery. TLSv1.2 is required for Email Delivery. Some default settings of Javamail need to be disabled. For example, JavaMail authorizes in a certain order. The default authorization order is "LOGIN PLAIN DIGEST-MD5 NTLM". Since Email Delivery authorizes as "PLAIN", "LOGIN" needs to be disabled. For example, the following code is entered in **OCIemail.java** file to configure the SMTP connection:

```
//props.put("mail.smtp.ssl.enable", "true"); //default is false if not set
     props.put("mail.smtp.auth", "true");
     props.put("mail.smtp.auth.login.disable", "true");
     props.put("mail.smtp.starttls.enable", "true");
     props.put("mail.smtp.starttls.required", "true");
```

11. Open the **File** menu and click **Save**.
12. To build the project, open the **Project** menu and then select **Build Project**. If this option is disabled, you may have automatic building enabled.
13. To start the program and send the email, open the **Run** menu and then click **Run**.
14. Review the output. If the email was successfully sent, the console displays "Email sent successfully!" Otherwise, it displays an error message.
15. Log into the recipient inbox to verify receipt of the email.

More Information

- See the JavaMail documentation for more information.

Integrating Sendmail with Email Delivery

Configure Sendmail to Send Email Through Email Delivery

You can use Sendmail to send emails through Email Delivery. Before you use Sendmail you must configure Oracle Cloud Infrastructure Email Delivery in your Sendmail application.

Note

The steps below are for configuring Sendmail to send email via Oracle Cloud Infrastructure Email Delivery. These steps were tested on an Ubuntu 18.04 compute instance.

To enable Sendmail to integrate with Email Delivery:

1. Make sure Email Delivery is configured to send email. See Getting Started with Email Delivery.

   Note

   SMTP credentials are required to configure Sendmail to use Email Delivery. Be sure to note the user name and password when you generate the SMTP credentials.

2. Run the following update and install commands:

   ```
   sudo apt update
   sudo apt install sendmail
   sudo apt install m4
   ```

3. In a file editor such as `vi`, update `/etc/mail/authinfo`.
   Run the following command:

   ```
   sudo vi /etc/mail/authinfo
   ```

   Note

   If `/etc/mail/authinfo` doesn't exist, you can create it by running the command `sudo vi /etc/mail/authinfo`.

   Add the following line:

   ```
   AuthInfo:<SMTP connection endpoint> "U:root" "I:<username from smtp credentials>" "P:<password from smtp credentials>" "M:PLAIN"

   #write and quit file
   :wq!
   ```

4. Generate the `/etc/mail/authinfo.db` file.

Run the following command:

```
sudo sh -c 'makemap hash /etc/mail/authinfo.db < /etc/mail/authinfo'
```

5. Add support for relaying to the Oracle Cloud Infrastructure Email Delivery SMTP endpoint.
   Run the following command:

   ```
   sudo sh -c 'echo "Connect:<SMTP connection endpoint> RELAY" >> /etc/mail/access'
   ```

6. Regenerate `/etc/mail/access.db`.
   Run the following command:

   ```
   sudo sh -c 'makemap hash /etc/mail/access.db < /etc/mail/access'
   ```

7. Create a backup of the `sendmail.cf` and `sendmail.mc` files.
   Run the following command:

   ```
   sudo sh -c 'cp /etc/mail/sendmail.cf /etc/mail/sendmail_cf.backup && cp /etc/mail/sendmail.mc
   /etc/mail/sendmail_mc.backup'
   ```

8. Update the `/etc/mail/sendmail.mc` file.
   Run the following command:

   ```
   sudo vi /etc/mail/sendmail.mc
   ```

   Find the `MAILER()` definitions.
   Type `/MAILER` and press `ENTER`.
   In Insert mode, add the following settings before any `MAILER()` definitions:

   ```
   define(`SMART_HOST', `<SMTP connection endpoint>')dnl
   define(`RELAY_MAILER_ARGS', `TCP $h 25')dnl
   define(`confAUTH_MECHANISMS', `LOGIN PLAIN')dnl
   FEATURE(`authinfo', `hash -o /etc/mail/authinfo.db')dnl
   MASQUERADE_AS(`<sending_domain>')dnl
   FEATURE(masquerade_envelope)dnl
   FEATURE(masquerade_entire_domain)dnl
   ```

   Disable Insert mode.
   Run the following command:

   ```
   #write and quit file
   :wq!
   ```

9. Make Sendmail writeable.
   Run the following command:

   ```
   sudo chmod 666 /etc/mail/sendmail.cf
   ```

10. Regenerate `sendmail.cf`.
    Run the following command:

    ```
    sudo sh -c 'm4 /etc/mail/sendmail.mc > /etc/mail/sendmail.cf'
    ```

    Note

    If you receive an error, such as "Command not found" or "No such file or directory," confirm that the m4 and sendmail packages are installed on your system.

11. Reset permissions for sendmail.cf to read only.
    Run the following command:

    ```
    sudo chmod 644 /etc/mail/sendmail.cf
    ```

12. Restart Sendmail.
    Run the following command:

    ```
    sudo /etc/init.d/sendmail restart
    ```

13. Test the configuration by sending a test email.
    Run the following command:

    ```
    /usr/sbin/sendmail -vf <from_email_address> <recipient_email_address>
    ```

    Enter the details of the email. After each line press `Enter`.
    For example:

    ```
    From: <from_email_address>
    To: <recipient_email_address>
    Subject: OCI Email Delivery test email
    This is a test message sent from OCI Email Delivery using Sendmail.
    ```

Press `Ctrl + D` to send the email.

14. Verify receipt of the test email.

Note

You can troubleshoot an issue by reviewing the Sendmail log on your mail server, located at `/var/log/mail.log`.

More Information

- For more information, see the Sendmail Installation and Operation Guide.

Integrating PeopleSoft with Email Delivery

Configure PeopleSoft to Send Email Through Email Delivery

You can use PeopleSoft to send emails through Email Delivery. Before you use PeopleSoft, you must configure Oracle Cloud Infrastructure Email Delivery in your PeopleSoft application.

Note

The following steps require familiarity with PeopleSoft documentation. (This link points to PeopleTools 8.57, which is the latest version at the time this article was published. Please refer to the documentation for your specific PeopleTools version.)

To enable PeopleSoft to integrate with Email Delivery:

1. Make sure Email Delivery is configured to send email. See Getting Started with Email Delivery.

Note

SMTP credentials are required to configure PeopleSoft to use Email Delivery. Be sure to note the user name and password when you generate the SMTP credentials.

2. Open a Chrome browser and navigate to the SMTP connection endpoint (for example, https://smtp.us-phoenix-1.oraclecloud.com).
    a. Click the certificate, and then click the **Certification Path** tab.
    b. Select the **DigiCert** root certificate.
    c. Click **View Certificate**.
    d. Click the **Details** tab for the Digitrust certificate, and then select **Copy to File**.
    e. Select **Base-64 X-509**.
    f. Save the certificate.
3. Repeat the steps above for the **Digicert SHA2 Secure Server CA** intermediate certificate.
4. Add the certificates to the PeopleSoft application.
   Log into the Pure Internet Architecture (PIA) as user "PS" and import the certificates into the target environment. See Installing Application Server-Based Digital Certificates and refer to the **Adding CA Authorities and Installing Root Certificates** section.
5. Encrypt the SMTP password in the config file.
   You can encrypt the SMTP password using the PIA or the PSCipher utility.
   Using the PIA
    a. Open the navigation menu on the PeopleSoft dashboard. Go to **PeopleTools**, and then select **Integration Broker**.

b. Select **Configuration**, and then click **Gateways**. Select the default LOCAL gateway.

c. Click **Gateway Setup Properties**. The default user ID is administrator and the default password is the password selected during setup.

d. Click the **Advanced Properties Page** link.

e. Click **Password Encryption** at the bottom of the page. This is where you will encrypt your password.

Using PSCipher

The PSCipher utility can be found under `$PS_CFG_HOME/webserv/<DOMAIN>/piabin` where `<DOMAIN>` is your web server domain.

Run the following command:

```
./PSCipher.sh <password>
```

Note

The password can have special characters so you will need to enclose the password in single quotes. For example:

```
./PSCipher.sh '#rpassword$){'
```

6. Update the SMTP settings on the PeopleSoft Application server. For more information, see SMTP Settings in the PeopleSoft documentation.

   Establish an ssh connection to the PeopleSoft Application server machine (as username "opc") and do the following:

   a. Switch user to `psadm2` (for example, `sudo su - psadm2`).

Note

`psadm2` is the PeopleTools domain user who creates and configures the Application Server domain.

b. Navigate to the Appserver configuration directory.
Run the following command:

```
$ cd $PS_CFG_HOME/appserv/APPDOM
```

c. Back up the original `psappsrv.cfg` file.

d. Add the following information to the `psappsrv.cfg` file:

```
SMTPServer=<SMTP connection endpoint>
SMTPUserName=<username from SMTP credentials>
SMTPUserPassword=<encrypted SMTP password>
SMTPPort=587
SMTPUseSSL=N
SMTPSSLPort=587
SMTPTLSEnable=true
SMTPTLSRequired=true
```

Note

Do not include a space between the "=" and the values because the space could be counted in the value for the password, causing an authentication failure.

7. Add the primary email address for the PeopleSoft application user who is trying to send notification from within the application. In this example, the user is "PS".
Log in as "PS" and do the following:

a. Open the navigation menu on the PeopleSoft dashboard. Go to **PeopleTools**, and then select **Security**.

b. Select **User Profiles**, and then click **user Profiles**. Find the profile for "PS".

c. On the **General** tab, click **Edit Email Addresses**.

d. Enter the approved sender email address as the primary email address.

8. Log out of the PeopleSoft application.
9. Reboot the application server using the `PSADMIN` utility. See Using the Application Server Administration Menu.
10. Test the email notification delivery.
    Log into the PIA as "PS", and select **Notify** anywhere in the console. For example, you can do the following:
    a. Go to **Peopletools**, and then select **Web Profile**.
    b. Select **Web Profile Configuration**.
    c. Click **Search**, and then click **PROD** in the search results.
    d. Click **Notify**, enter the notification details, and then click **OK**.
    Confirm receipt of the test email.

To debug SMTP errors (optional):

1. You can add the following parameter to help with SMTP debugging: `SMTPTrace=1`
   LogFence should be set to 5 to use this parameter. The system writes the log information to `SMTP<DDMM>.log` in `%PS_SERVDIR%/LOGS` by default, or the custom value set for Log Directory.
   For example:
   ```
   $PS_CFG_HOME\APPSERV\domain\LOGS\SMTP6_27.log
   ```
2. After you set this parameter, you will need to reboot the Application server. Once this parameter is set, you can monitor the SMTP log.
3. Type `ls` and find the SMTP file for the date you sent the email.
4. Run the following command:
   ```
   tail -f <smtp log file and date>
   ```
   For example,

```
tail -f SMTP9_17.log
```

Search for any errors in the output.

- My Oracle Support: Is There a Way to Both Authenticate And Secure Emails From PeopleSoft?

Integrating Python with Email Delivery

You can use Python to send emails through Email Delivery. Before you can send email you must configure Email Delivery in Python.

Note

These steps assume you are logged into an Oracle Linux instance. Other distributions of Linux may have different commands and file locations.

Configure Python to Send Email Through Email Delivery

To enable Python to test the configuration of Email Delivery:

1. Ensure Email Delivery is configured to send email. See Getting Started with Email Delivery.

Note

The SMTP credentials are required to configure Python to use Email Delivery. Be sure to note the user name and password when you generate the SMTP credentials.

2. Ensure Python is installed. The installation process differs depending on which operating system you are using. For example, run the following command to install Python on Oracle Linux:

```
sudo yum install python3 -y
```

3. In a file editor such as vi, create a python script to test Email Delivery.
   Run the following command:

```
sudo vi ociemail.py
```

4. In the **ociemail.py** file, replace the variables with your own values.
   For example:

```
---------------------------------------------------------------------------------------------------
#python script for sending SMTP configuration with Oracle Cloud Infrastructure Email Delivery
import smtplib
import email.utils
from email.mime.multipart import MIMEMultipart
from email.mime.text import MIMEText

# Replace sender@example.com with your "From" address.
# This address must be verified.
SENDER = 'sender@example.com'
SENDERNAME = 'Sender Name'

# Replace recipient@example.com with a "To" address. If your account
# is still in the sandbox, this address must be verified.
RECIPIENT  = 'recipient@example.com'

# Replace the USERNAME_SMTP value with your Email Delivery SMTP username.
USERNAME_SMTP = 'ocid1.user.oc1..<unique_ID>@ocid1.tenancy.oc1..<unique_ID>.vf.com'
```

```
# Replace the PASSWORD_SMTP value with your Email Delivery SMTP password.
PASSWORD_SMTP = '<password>'

# If you're using Email Delivery in a different region, replace the HOST value with an SMTP
endpoint. Use port 25 or 587 to connect to the SMTP endpoint.
HOST = "smtp.us-ashburn-1.oraclecloud.com"
PORT = 587

# The subject line of the email.
SUBJECT = 'Email Delivery Test (Python smtplib)'

# The email body for recipients with non-HTML email clients.
BODY_TEXT = ("Email Delivery Test\r\n"
             "This email was sent through the Email Delivery SMTP "
             "Interface using the Python smtplib package."
            )

# The HTML body of the email.
BODY_HTML = """<html>
<head></head>
<body>
  <h1>Email Delivery SMTP Email Test</h1>
  <p>This email was sent with Email Delivery using the
    <a href='https://www.python.org/'>Python</a>
    <a href='https://docs.python.org/3/library/smtplib.html'>
    smtplib</a> library.</p>
</body>
</html>"""

# Create message container - the correct MIME type is multipart/alternative.
msg = MIMEMultipart('alternative')
msg['Subject'] = SUBJECT
msg['From'] = email.utils.formataddr((SENDERNAME, SENDER))
msg['To'] = RECIPIENT

# Record the MIME types of both parts - text/plain and text/html.
part1 = MIMEText(BODY_TEXT, 'plain')
part2 = MIMEText(BODY_HTML, 'html')
```

```
# Attach parts into message container.
# According to RFC 2046, the last part of a multipart message, in this case
# the HTML message, is best and preferred.
msg.attach(part1)
msg.attach(part2)

# Try to send the message.
try:
    server = smtplib.SMTP(HOST, PORT)
    server.ehlo()
    server.starttls()
    #smtplib docs recommend calling ehlo() before & after starttls()
    server.ehlo()
    server.login(USERNAME_SMTP, PASSWORD_SMTP)
    server.sendmail(SENDER, RECIPIENT, msg.as_string())
    server.close()
# Display an error message if something goes wrong.
except Exception as e:
    print ("Error: ", e)
else:
    print ("Email successfully sent!")
```

5. To send a test email with Python, run the following command from the directory the script is located in:

```
python3 ociemail.py
```

More Information

- More Python script examples can be found on GitHub.

Troubleshooting Email Delivery

This topic provides troubleshooting solutions for problems you might encounter using Email Delivery.

TLS errors when integrating with Postfix

- If you are encountering TLS errors when attempting to integrate Postfix with Email Delivery, ensure that the following setting is removed from the Postfix `main.cf` file, as it has been deprecated:

  ```
  smtp_use_tls = yes
  ```

- Use the following setting instead to turn on TLS:

  ```
  smtp_tls_security_level = may
  ```

  Using this setting, the Postfix SMTP server announces STARTTLS support to remote SMTP clients, but does not require that clients use TLS encryption.

- If you want to enforce the use of TLS, so that the Postfix SMTP server announces STARTTLS and accepts no mail without TLS encryption, use the following setting:

  ```
  smtp_tls_security_level = encrypt
  ```

For more information, see Postfix TLS Support.

Connectivity Issues

Note

Email Delivery does not prohibit connectivity from any source IP range. Any IP that attempts to connect to Email Delivery will be accepted.

Refer to SMTP Connection Endpoints for a list of regional endpoints to establish SMTP connections for sending.

To troubleshoot a problem connecting to endpoint network ports

- Ensure that you have the correct endpoint DNS name or IP address for the region and

that you have been whitelisted to use the endpoint.

- Ping the endpoint to ensure that you can reach the endpoint.
  1. Open a command prompt.
  2. Use the following command to ensure you can reach the endpoint.

     ```
     ping <SMTP endpoint>
     ```

     For example, `ping smtp.us-ashburn-1.oraclecloud.com`

     If you are unable to ping the endpoint successfully, you are experiencing a network connectivity issue. If you are able to ping the SMTP endpoint, you will now need to test connectivity on ports 25 or 587.
- Test connectivity to the endpoint using port 25 or 587. Use a utility such as Telnet or netcat to attempt to connect to the port manually.
  1. Open a command prompt.
  2. Use the following command to test the network connection.

     ```
     telnet <SMTP endpoint> <port>
     ```

     For example, `telnet smtp.us-ashburn-1.oraclecloud.com 25`

     The port is open and the test is successful if a blank screen appears. If you are unable to connect to the ports using telnet, you are experiencing a network connectivity issue.

To troubleshoot a problem connecting to an external mail transfer agent (MTA)

Use the following steps to determine whether you are able to communicate with an external service on the required ports 25 or 587. If you are unable to connect successfully, you are experiencing a network connectivity issue. If you are able to connect to an external MTA, the network connectivity issue is within Oracle Cloud Infrastructure.

- Connect to an external MTA such as Google's mail exchangers.
    1. Open a command prompt.
    2. Use the following command to retrieve one of Google's MX server records.

        ```
        dig MX google.com
        ```

    3. Use the following command to test connectivity to the endpoint port 25 or 587 against Google's MX servers.

        ```
        telnet <IP address> <port>
        ```

        If you are unable to connect to Google's MX servers, this confirms that you are having issues connecting to mail servers (port 25 or 587). It is possible that your egress rules are filtering traffic at the VCN.

        If you can connect to an external MTA (that is, you are able to communicate with a public SMTP endpoint on the correct ports) but you cannot connect to Email Delivery public SMTP endpoints on those ports, create a service request with My Oracle Support with this information.

Common Errors Returned by Email Delivery

API Errors

For a complete list of common errors returned by all the services for Oracle Cloud Infrastructure, see API Errors.

Common SMTP Errors Returned by Email Delivery

The following table lists the common errors returned by the Email Delivery SMTP service.

HTTP Status Code	Error Code	Description
451	`Server error`	An unexpected error has occurred during the SMTP conversation.
451	`Error in Processing`	An unexpected error has occurred during the SMTP conversation.
452	`System storage error`	The server is unable to persist the message in its delivery queue.
455	`Maximum messages sent per minute reached : limit is <limit>`	The SMTP send burst rate (of messages accepted per minute period) has been exceeded.
455	`Maximum messages sent per day reached : limit is <limit>`	The SMTP daily send rate (of messages accepted per 24 hour period) has been exceeded.
471	`Authorization failed: address <address> not authorized`	Authorization of the address (either in the envelope or message) has failed for the SMTP user.
501	`Invalid command argument, not a valid Base64 string`	The base64 encoded AUTH (PLAIN) secret is invalid.
501	`Invalid command argument, does not contain NUL`	The base64 encoded AUTH (PLAIN) secret does not contain NUL field separator(s).

HTTP Status Code	Error Code	Description
501	`Invalid command argument, does not contain the second NUL`	The base64 encoded AUTH (PLAIN) secret does not contain NUL field separator(s).
504	`Method not supported`	The client has attempted to use an unsupported AUTH mechanism with our service.
504	`AUTH mechanism mismatch`	The client has sent an invalid AUTH command to our service.
523	`Exceeds byte limit`	The message has exceeded the size limit enforced by the service (see server response to EHLO for size restriction).
535	`Authentication credentials invalid`	Authentication of the SMTP user has failed.
535	`Authentication required`	The client has sent commands that require SMTP authentication succeeded before the service is able to process (that is, commands are being sent out of order).
553	`<address> Invalid email address`	The RFC-822 Internet Address sent by the client is invalid.
554	`Message parse error`	The RFC-2822 Internet Message is invalid (and unable to be parsed by the server).

Deliverability Best Practices

Deliverability Best Practices help you to learn and manage the habits that affect your sending reputation. These six recommendations can help lower your email bounce rate, stay off blacklists, lower your complaint rate, and improve your email sender reputation.

Implement an Opt-in Process

An opt-in process is a method for your users to subscribe to your mailing list, which gives you permission to send messages. Only send messages to subscribers who have opted-in to your mailing list. There are two types of opt-in procedures.

- **Single opt-in (unconfirmed):** A user provides their email address and gives permission to receive relevant messages. Once the address is provided, messages can be sent without confirming the email address belongs to the user who provided it.
- **Double opt-in (confirmed):** A user provides their email address, but before the first mailing, a confirmation email is sent to the account owner. The email requires action from the account owner to confirm that future messages are wanted. An account can be verified by having the owner click a link for reply to the email. The confirmation email ensures that the address was not added to a third-party mailing list without consent.

Purge Unengaged Users

Remove unengaged users by implementing a process. If a recipient is not engaging with your mail by either opening or clicking the email, this might be an indication that the email account is not in use or that the recipient is no longer interested in your content. If the recipient does not use the email account, eventually the mailbox provider terminates the account or transforms the account into a spam trap. Remove recipients who have not engaged with your email in a time frame defined by your business model. Purging unengaged users helps your deliverability by increasing your user engagement rate.

Review Your Subscriber List

When reviewing your subscriber list, keep these things in mind:

- Eliminate duplicate addresses before sending. If addresses that do not exist are mailed to multiple times, your hard bounce rate could be inflated.
- Ensure that a previous suppression list (possibly from another email service provider) was not accidentally included.
- Verify that subscribers have opted-in. Do not send to an old list that you found.
- Restrict users from uploading their email client's contact list in a "select all" fashion. Forcing users to select addresses individually prevents users from accidentally including potentially out of date or expired addresses.

Evaluate Your Sending Frequency

Sending too many emails in a short time might aggravate recipients, causing the recipients to mark your messages as spam. This is called list fatigue. Ensure that your message cadence aligns with the expected frequency of your content. Reducing frequency might reduce spam complaints. Ensure that your content is relevant to your subscribers. Keep your email messages consistent to your audience. A person who subscribed to a list for coupon updates might not want regular emails about auto loan finance rates. These unexpected messages are likely to be marked as spam, which decreases your sender reputation.

Easily Accessible Unsubscribe URL

Unsubscribing helps your inbox success by sending only to recipients that engage by opening or clicking. When people complain, your sending reputation is harmed. Make it easy for recipients to be removed from the list. Do not hide the unsubscribe URL at the bottom of the message. A small percentage of users scroll to the bottom of the email and search for a small URL. Most users mark the email as spam.

Canadian Anti-Spam Law (CASL) Guide

Canada's Anti-Spam Law (CASL) is one of the best guides to ensuring your compliance with the law, users' desire, and the intended filtering that most mailbox providers use. If you are a Canadian email sender or you send email to Canadian residents, you must comply with CASL. The following information is intended to help provide you with some guidance for complying

with CASL. This article does not constitute legal advice, nor is it intended supplement or otherwise affect your rights or obligations under your service agreement with Oracle, including your obligations under Oracle's Acceptable Use Policy. If you have questions about CASL or the legality of your sending practices, we encourage you to speak with an attorney who specializes in that subject matter.

What is covered by CASL?

CASL and its related regulations apply to any "commercial electronic message" sent from or to Canadian computers and devices in Canada. Electronic messages that are merely routed through Canadian computer systems are not subject to CASL.

A "commercial electronic message" is any message that:

- Is in an electronic format, including emails, instant messages, text messages, and some social media communications.
- Is sent to an electronic address, including email addresses, instant message accounts, phone accounts, and social media accounts; and
- Contains a message encouraging recipients to take part in some type of commercial activity, including the promotion of products, services, people/personas, companies, or organizations.

Are there any types of messages that are exempt from CASL?

These types of electronic messages are exempt from CASL for various reasons.

- Messages to family or a person with established personal relationship.
- Messages to an employee, consultant, or person associated with your business.
- Responses to a current customer, or someone who has inquired in the last six months.
- Messages that will be opened or accessed in a foreign country, including the U.S., China, and most of Europe.
- Messages sent on behalf of a charity or political organization for the purposes of raising funds or soliciting contributions.
- Messages attempting to enforce a legal right or court order.

- Messages that provide warranty, recall, safety, or security information about a product or service purchased by the recipient.
- Messages that provide information about a purchase, subscription, membership, account, loan, or other ongoing relationship, including delivery of product updates or upgrades.
- A single message to a recipient without an existing relationship based on a referral. The full name of the referring person must be disclosed in the message. The referrer might be family or have another relationship with the person to whom you are sending.

If your message does not meet one of these criteria, consent is required under CASL. Not all of the previous messages listed are permitted under the Oracle Cloud Hosting and Delivery Policy.

What is "express consent"?

Under CASL, "express consent" means a written or oral agreement to receive specific types of messages. For example, "You want to receive monthly newsletters and weekly discount notifications from Oracle".

Express consent is only valid if your request for consent clearly and simply describes the following information:

- Your purpose in obtaining consent.
- A description of messages you will be sending.
- The name and contact information (physical mailing address and telephone number, email address, or website URL) of the requestor.
- A statement that the recipient can unsubscribe at any time.

The requestor can be you or someone for whom you are asking. If you are requesting consent on behalf of a client, the name and contact information of the client must be included with the consent request.

What is "implied consent"?

Under CASL, you can only obtain implied consent when certain circumstances exist, including when:

- A recipient has purchased a product, service or made another business deal, contract, or membership with your organization in the last 24 months.
- You are a registered charity or political organization, and the recipient has made a donation or gift, has volunteered, or attended a meeting organized by you.
- A professional message is sent to someone whose email address was given to you, or is conspicuously published, and who has not published or told you that unsolicited messages are not wanted.

What type of consent is required?

After July 1, 2017, you can only send to recipients with express consent or whose implied consent is valid under CASL.

Some additional requirements

In addition to understanding what qualifies as CASL-regulated message, and what type of consent is needed, there are a few other details to keep in mind.

- Retention of a record of consent confirmations is required.
- When requesting consent, checkboxes cannot be pre-filled to suggest consent. Each subscriber must check the box themselves for consent to be valid.
- All messages sent must include the following:
    - your name
    - the person on whose behalf you are sending (if any)
    - your physical mailing address and telephone number
    - your email address or website URL
- All messages sent after consent must also include an unsubscribe mechanism, and unsubscribes must be processed within ten days.

Where can I find more information on CASL?

The full text of the law can be found on the website for the Canadian Justice Department. The Canadian Radio and Telecommunications Commission has also set up an FAQ page and some guidelines for obtaining consent. If you have any questions, we encourage you to contact an attorney who is familiar with the law.

Oracle Cloud Hosting and Delivery Policy

Often, the Oracle Cloud Hosting and Delivery Policy is more stringent than CASL requirements. It is important that you review Oracle policies before using the service.

Troubleshooting Undelivered Emails

The following issues can cause an email to be undelivered:

- The recipient is on the Suppression List.
- An authentication failure or an issue with the format of the email message occurred. For example, if the SMTP "From" address is not the same as the "From" address in the email body, the email is rejected. The addresses must match and be an Approved Sender. Refer to your sending application's logs to review any issues.

If you are unable to resolve the issue, you can go to My Oracle Support and create a service request. See Creating a Service Request for more information.

CHAPTER 14 Events

This chapter explains how to create automation in your tenancy.

Overview of Events

Oracle Cloud Infrastructure Events enables you to create automation based on the state changes of resources throughout your tenancy. Use Events to allow your development teams to automatically respond when a resource changes its state.

Here are some examples of how you might use Events:

- Send a notification to a DevOps team when a database backup completes.
- Convert files of one format to another when files are uploaded to an Object Storage bucket.

Note

Events is not available in Oracle Cloud Infrastructure Government Cloud.

How Events Works

Oracle Cloud Infrastructure services emit *events*, which are structured messages that indicate changes in resources. Events (the messages, not the service) follow the CloudEvents industry standard format hosted by the Cloud Native Computing Foundation (CNCF). This standard allows for interoperability between various cloud providers or on-premises systems and cloud providers. An event could be a create, read, update, or delete (CRUD) operation, a resource lifecycle state change, or a system event impacting a resource. For example, an event can be emitted when a backup completes or fails, or a file in an Object Storage bucket is added, updated, or deleted.

Services emit events for resources or data. For example, Object Storage emits events for buckets and objects. Services emit different types of events for resources, which are distinguished as *event types*. Buckets and objects have event types of create, update, and delete, for example. Event types are the changes that produce events by a given resource. For a list of services that produce events and the event types that those services track, see Services that Produce Events.

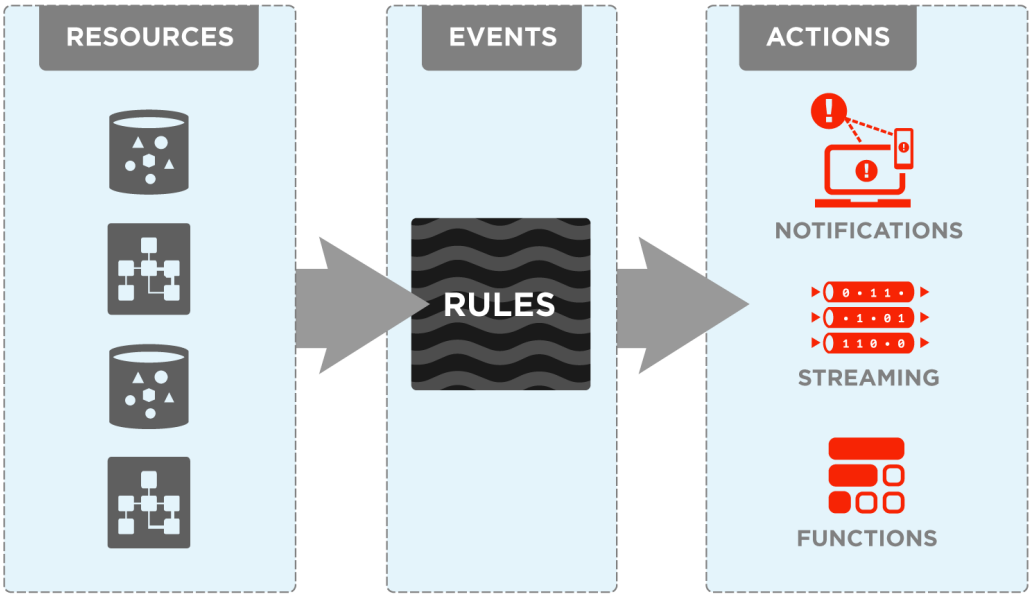
You work with events by creating *rules*. Rules include a filter you define to specify events produced by the resources in your tenancy. The filter is flexible:

- You can define filters that match only certain events or all events.
- You can define filters based on the way resources are tagged or the presence of specific values in attributes from the event itself.

Rules must also specify an *action* to trigger when the filter finds a matching event. Actions are responses you define for event matches. You set up select Oracle Cloud Infrastructure services that the Events service has established as actions (more on these select services follows). The resources for these services act as destinations for matching events. When the filter in the rule finds a match, the Events service delivers the matching event to one or more of the destinations you identified in the rule. The destination service that receives the event then processes the event in whatever manner you defined. This delivery provides the automation in your environment.

You can only deliver events to certain Oracle Cloud Infrastructure services with a rule. Use the following services to create actions:

- Notifications
- Streaming
- Functions



Events Concepts

The following concepts are essential to working with Events.

EVENTS

An automatic notification of a state change as reported by an event-emitting Oracle Cloud Infrastructure resource. For example, an database resource emits a `backup.begin` event when a backup begins.

EVENT TYPES

A distinction between the different types of events. For more information, see Services that Produce Events.

RULES

A JSON object you create to subscribe to an event type and trigger an action should that event occur. For example, a rule might specify that `backup.end` event types from databases trigger the Notifications service to send an email to a particular DevOps engineer. For more information, see Matching Events with Filters.

ACTIONS

Rules must also specify an *action* to trigger when the filter finds a matching event. Actions are responses you define for event matches. You set up select Oracle Cloud Infrastructure services that the Events service has established as actions. The resources for these services act as destinations for matching events. When the filter in the rule finds a match, the Events service delivers the matching event to one or more of the destinations you identified in the rule. The destination service that receives the event then processes the event in whatever manner you defined. This delivery provides the automation in your environment.

You can only deliver events to certain Oracle Cloud Infrastructure services with a rule. Use the following services to create actions:

- Notifications
- Streaming
- Functions

Region Availability

Events is currently available in all regions of the commercial realm. Events is currently not available in regions within the Government Cloud realm.

Ways to Access Oracle Cloud Infrastructure

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. For a list of available SDKs, see Software Development Kits and Command Line Interface.

To access the Console, you must use a supported browser. Oracle Cloud Infrastructure supports the latest desktop versions of Google Chrome, Microsoft Edge, Internet Explorer 11, Safari, Firefox, and Firefox ESR. Note that private browsing mode is not supported for Firefox, Internet Explorer, or Edge. Mobile browsers are not supported.

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies. For specific details about writing policies for each of the different services, see Policy Reference.

If you're a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

Administrators: You must write IAM policy that authorize users to work with rules. For more information, see Events and IAM Policies.

Limits on Events Resources

The Events service has a limitation of 50 rules per tenancy.

See Service Limits for a list of applicable limits and instructions for requesting a limit increase.

Service Gateway and Events

The Events service also supports private access from Oracle Cloud Infrastructure resources in a VCN through a service gateway. A service gateway allows connectivity to the Events public endpoints from private IP addresses in private subnets. For example, you can manage rules over the Oracle Cloud Infrastructure backbone instead of over the internet. You can optionally use IAM policies to control which VCNs or ranges of IP addresses can access Events. See Access to Oracle Services: Service Gateway for details.

Getting Started with Events

This topic introduces you to creating automation with Events. You create a simple rule that sends a notification whenever someone creates a bucket in a particular compartment in your tenancy.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Setting Up for Events

To try out the Events service for this tutorial, you must have these things set up first:

- Create IAM policy for Events
- Create a topic and subscription to use as an action

Important

A tenancy administrator must configure your tenancy for Events. These configurations give you access to an Oracle Cloud Infrastructure tenancy with the necessary IAM policy and a resource to use as an action.

Create Users, Groups, and Compartments

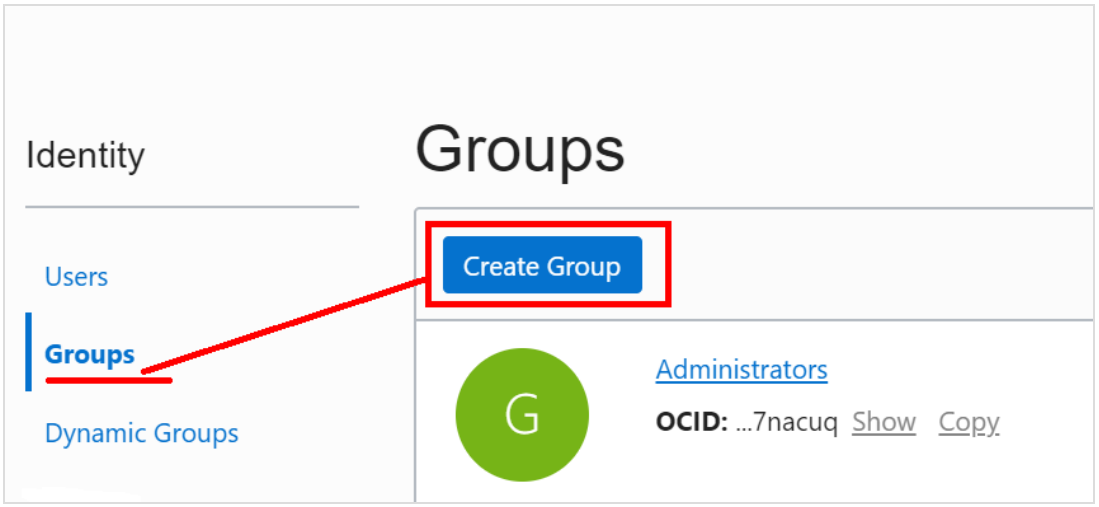
You can use existing users, groups, and compartments or make new ones.

To create groups and users

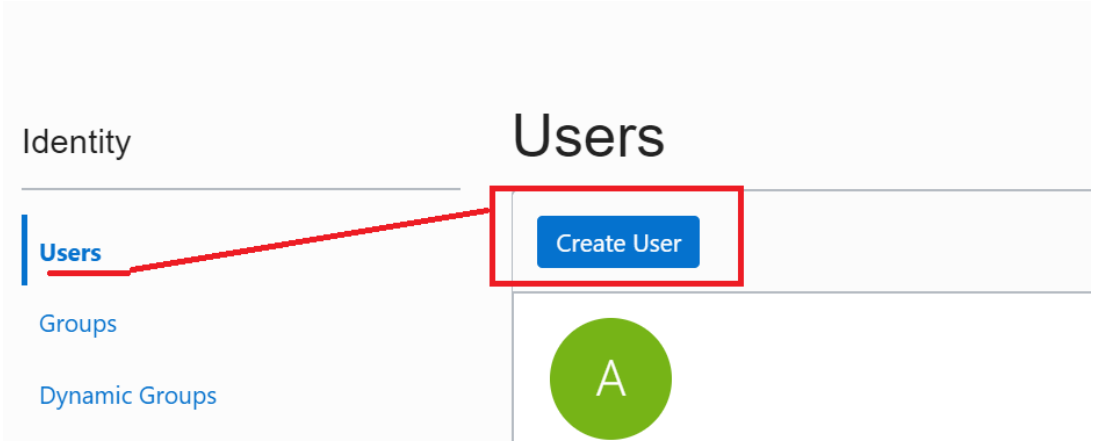
If suitable users and groups for assigning users permissions to work with rules don't already exist, log in to the Console as a tenancy administrator and create them.

1. Log in to the Console as a tenancy administrator.
2. If you need a group for Events, perform these steps:
    a. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Groups**. A list of the groups in your tenancy is displayed.
    b. Click **Create Group** and create a new group (see To create a group). Give the group a meaningful name and description. Avoid entering confidential

information.



3. If you need user accounts for Events, perform these steps:
   a. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Users**. A list of the users in your tenancy is displayed.
   b. Click **Create User** and create one or more new users (see To create a user).



4. If users haven't been added to groups already, perform these steps:
    a. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Groups**. A list of the groups in your tenancy is displayed.
    b. Click the group you want to use for Events.
    c. Click **Add User to Group**.

    d. Select the users from the drop-down list, and then click **Add**.

To create a compartment

If suitable compartment for rules and the resources that emit events doesn't already exist, log in to the Console as a tenancy administrator and create it.

1. Log in to the Console as a tenancy administrator.
2. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Compartments**. A list of the compartments in your tenancy is displayed.
3. Click **Create Compartment** and create a new compartment (see To create a compartment). Give the compartment a meaningful name and description. Avoid

entering confidential information.

Create IAM Policy for Events

Before users can start using Events to create automation, as a tenancy administrator you must create IAM policy:

To create a policy that allows users to create and manage rules

1. Log in to the Console as a tenancy administrator.
2. In the Console, open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Policies**. A list of the policies in the compartment you're viewing is displayed.
3. Select the root compartment.
4. Click **Create Policy**.
5. Enter the following:
   - **Name:** A meaningful name for the policy. The name must be unique across all policies in your tenancy. You cannot change this later. Avoid entering confidential information.

- **Description:** A meaningful description. You can change this later if you want to. Avoid entering confidential information.
- **Statement:** Enter the following policy statements to give users in the group the ability to manage and create rules:

  This line gives the user inspect access to resources in compartments to select actions.

  ```
  allow group <RuleAdmins> to inspect compartments in tenancy
  ```

  This line gives the user access to defined tags to apply filter tags to rules.

  ```
  allow group <RuleAdmins> to use tag-namespaces in tenancy
  ```

  These lines give the user access to Streaming resources for actions

  ```
  allow group <RuleAdmins> to inspect streams in tenancy
  allow group <RuleAdmins> to use stream-push in tenancy
  allow group <RuleAdmins> to use stream-pull in tenancy
  ```

  These lines give the user access to Functions resources for actions.

  ```
  allow group <RuleAdmins> to use virtual-network-family in tenancy
  allow group <RuleAdmins> to manage function-family in tenancy
  ```

  This line give the user access to Notifications topics for actions.

  ```
  allow group <RuleAdmins> to use ons-topic in tenancy
  ```

  This line gives the user manage access to rules for Events.

  ```
  allow group <RuleAdmins> to manage cloudevents-rules in tenancy
  ```

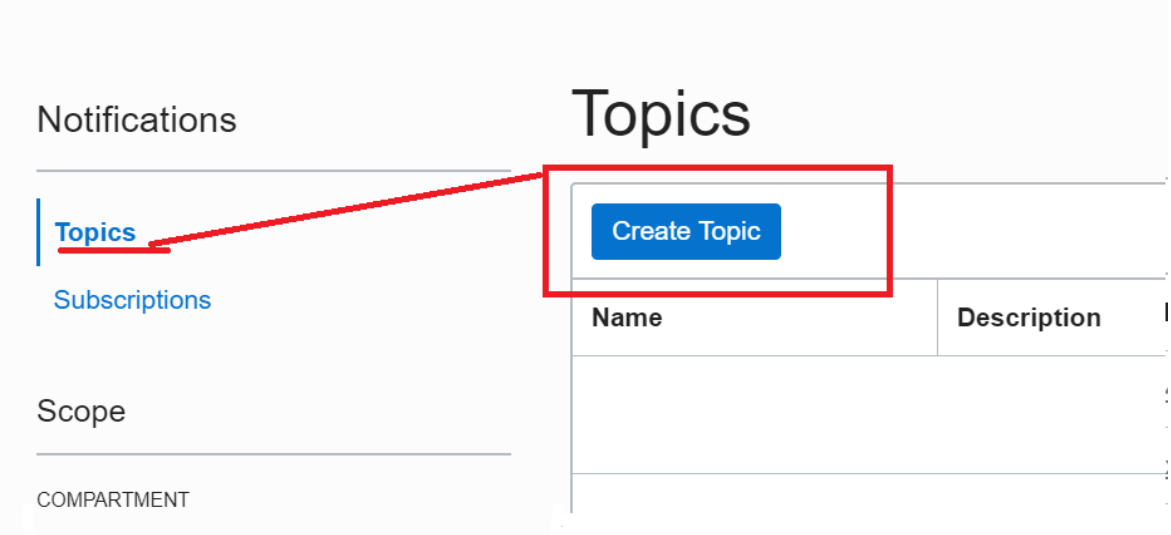
6. Click **Create**.

Create Notifications Topic and Subscription

If a suitable Notifications topic doesn't already exist, then you must log in to the Console as a tenancy administrator and create it. Whether you use an existing topic or create a new one, add an email address as a subscription so that you can monitor that email account for notifications.

To create a topic

1. Open the navigation menu. Under **Solutions and Platform**, go to **Application Integration** and click **Notifications**.
2. Click **Create Topic** at the top of the topic list.

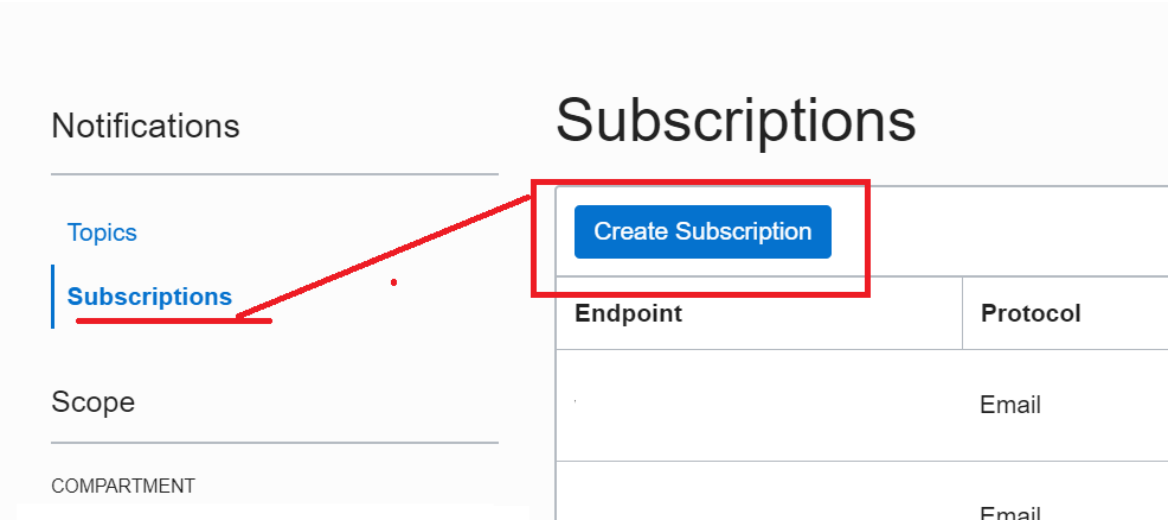


3. In the **Create Topic** dialog box, configure your topic.
   - **Name**: Required. Specify a friendly name for the topic. It must be unique; validation is case-sensitive. Avoid entering confidential information.
   - **Description**: Optional. Enter a description for the topic. Avoid entering confidential information.
4. Click **Create**.

To create a subscription

1. Open the navigation menu. Under **Solutions and Platform**, go to **Application Integration** and click **Notifications**.

2. Click the name of the topic that you created in the previous step or the topic you intend to use for this tutorial.
3. On the topic detail page, click **Create Subscription**.



4. In the **Create Subscription** dialog box, select **Email**, and then type an email address.

5. Click **Create**.
   The subscription has been created and a subscription confirmation URL will be sent. The subscription remains in "Pending" status until it has been confirmed.

To confirm a subscription

- In the confirmation email sent to the address you specified in the previous procedure, click the confirmation URL.

Using the Console to Create a Rule

Use the Console to create a rule with a pattern that matches bucket creation events emitted by Object Storage. Specify the Notifications topic you created as an action to deliver matching events. To test your rule, create a bucket. Object Storage emits an event which triggers the action. Check the email specified in the subscription to receive your notification.

To create a rule

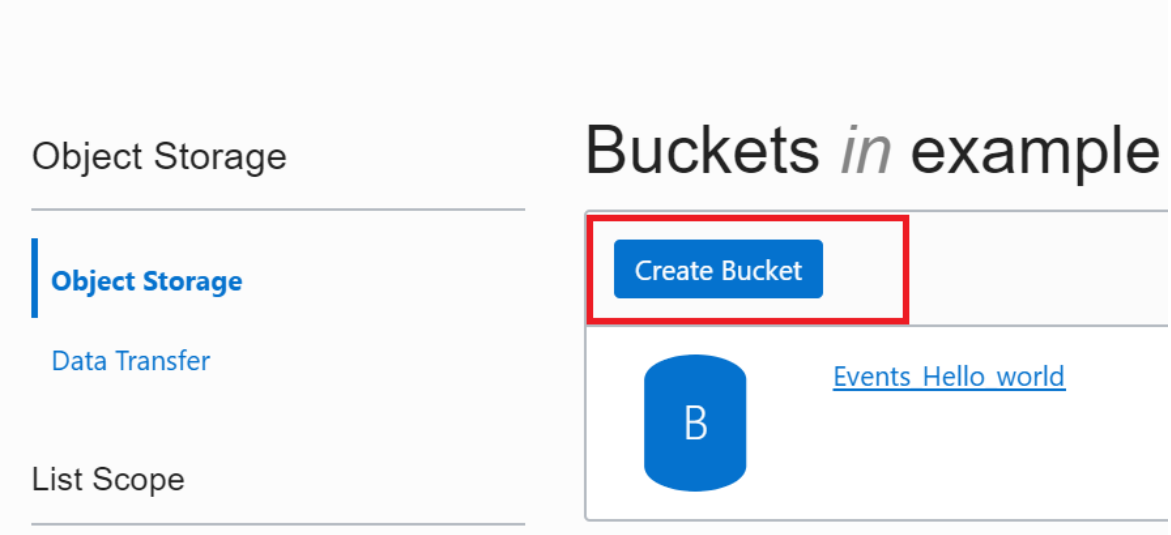
1. Open the navigation menu. Under the **Solutions and Platform** group, go to **Application Integration** and click **Events Service**.
2. Choose a **Compartment** you have permission to work in, and then click **Create Rule**.
   Events compares the rules you create in this compartment to event messages emitted from resources in this compartment and any child compartments.
3. Enter the following.
   - **Display Name:** Specify a friendly name for the rule. You can change this name later. Avoid entering confidential information.
   - **Description:** Specify a description of what the rule does. You can change this description later. Avoid entering confidential information.
4. In **Event Matching**, select **Event Type**.

a. In **Service Name**, select **Object Storage**.
b. In **Event Type**, select **Object Storage - Create Bucket**.

5. In **Actions**, specify the actions to trigger when the filter finds a match:
   a. In **Action Type**, select **Notifications**.
   b. In **Notifications Compartment**, select the compartment that contains the topic.
   c. In **Topic**, select the topic.
6. Click **Create Rule**.

To create a bucket

1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.
2. Select the compartment where you created your rule (or any of its subordinate compartments).
3. Click **Create Bucket**.



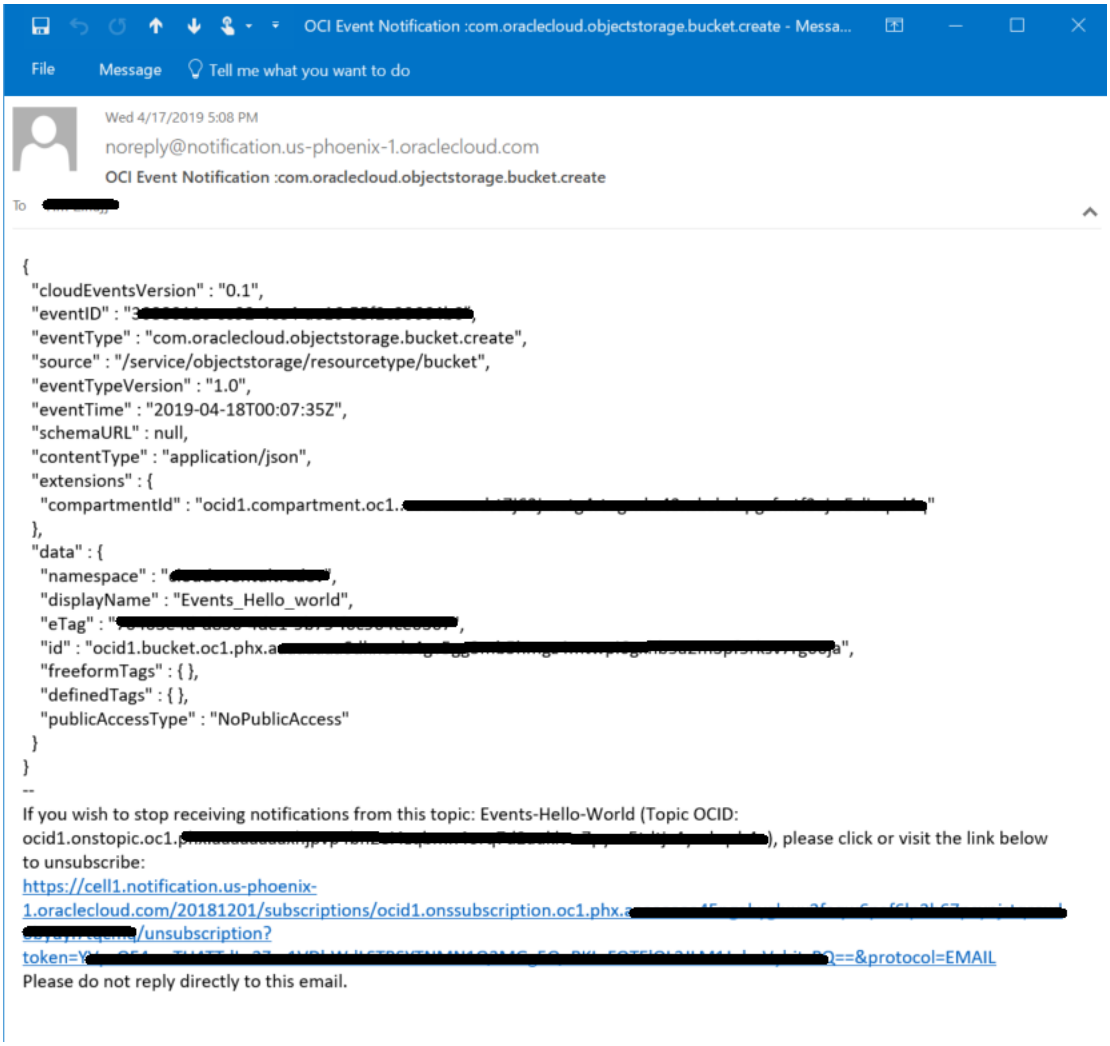
4. In the **Create Bucket** dialog, specify the attributes of the bucket:

- **Name**: Required. A user-friendly name or description. Avoid entering confidential information.
- **Storage Tier**: Select the tier in which you want to store your data. Available tiers include:
  - **Standard** is the primary default Object Storage tier for storing data that is accessed frequently and requires fast and immediate access.
  - **Archive** is a special tier for storing data that is accessed infrequently and requires long retention periods. Access to data in the **Archive** tier is not immediate. You must restore archived data before it's accessible.

5. Click **Create Bucket**.

To receive your notification

- Log in to the email account you specified in the previous procedure to receive the notification about the bucket being created.



OCI Event Notification :com.oraclecloud.objectstorage.bucket.create - Messa...

File Message Tell me what you want to do

Wed 4/17/2019 5:08 PM

noreply@notification.us-phoenix-1.oraclecloud.com

OCI Event Notification :com.oraclecloud.objectstorage.bucket.create

To [redacted]

```
{
 "cloudEventsVersion" : "0.1",
 "eventID" : "[redacted]",
 "eventType" : "com.oraclecloud.objectstorage.bucket.create",
 "source" : "/service/objectstorage/resourcetype/bucket",
 "eventTypeVersion" : "1.0",
 "eventTime" : "2019-04-18T00:07:35Z",
 "schemaURL" : null,
 "contentType" : "application/json",
 "extensions" : {
  "compartmentId" : "ocid1.compartment.oc1.[redacted]"
 },
 "data" : {
  "namespace" : "[redacted]",
  "displayName" : "Events_Hello_world",
  "eTag" : "[redacted]",
  "id" : "ocid1.bucket.oc1.phx.a[redacted]",
  "freeformTags" : { },
  "definedTags" : { },
  "publicAccessType" : "NoPublicAccess"
 }
}
```

--

If you wish to stop receiving notifications from this topic: Events-Hello-World (Topic OCID: ocid1.onstopic.oc1.[redacted]), please click or visit the link below to unsubscribe:

https://cell1.notification.us-phoenix-1.oraclecloud.com/20181201/subscriptions/ocid1.onssubscription.oc1.phx.a[redacted]/unsubscription?token=[redacted]==&protocol=EMAIL

Please do not reply directly to this email.

Tip

You will receive notifications each time a bucket is created in the compartment (or any of its sub compartments) until you disable the rule.

Using the CLI to Create a Rule

When you use the CLI to create a rule, you work a little differently than using the Console.

- To specify the actions for your rule, use a JSON formatted file. You create this file before you create the rule, and the file simplifies the amount of information you must type at the command line.
- To specify an event to match, use a JSON formatted string. You type this right into the console as you create the rule.

To create an action file

1. Create a file and add the following content.

```
{
  "actions": [
      {
        "actionType": "ONS",
        "description": "string",
        "isEnabled": true,
        "topicId": "<topic_OCID>"
      }
  ]
}
```

Tip: You can specify functions, streams, or topics as an action.

Example action file template

```
{
```

```
  "actions": [
      {
        "actionType": "FAAS",
        "description": "string",
        "functionId": "<function_OCID>",
        "isEnabled": true
      },
      {
        "actionType": "ONS",
        "description": "string",
        "isEnabled": true,
        "topicId": "<topic_OCID>"
      },
      {
        "actionType": "OSS",
        "description": "string",
        "isEnabled": true,
        "streamId": "<stream_OCID>"
      }
  ]
}
```

2. Fill in *<topic_OCID>* with actual topic OCID value from your tenancy.
3. Add a description.
4. Save the file with *action.json* as the file name.

To create a rule

Open a command prompt and run `oci events rule create` to create a rule.

Use the following options:

- `display-name` indicates the name of the rule in the Console
- `is-enabled` indicates whether the rule is evaluated.
- `condition` a JSON formatted string used to indicate a pattern for event matching (see Examples for usage).

Examples

The following example shows how to pass a simple condition that matches all events. Everything between the double quotes (`" "`) is a string, while the brackets `{ }` indicate JSON:

```
oci events rule create --display-name <friendly_name> --is-enabled true --condition "{}" --
compartment-id <compartment_OCID> --actions file://action.json --wait-for-state=ACTIVE
```

To pass complex input to the CLI as a JSON string, you must enclose the entire block in double quotes. Inside the block, each double quote for the key and value strings must be escaped with a backslash (\) character.

For example:

```
oci events rule create --display-name <friendly_name> --is-enabled true --condition "
{\"eventType\":[\"com.oraclecloud.objectstorage.createbucket\"]}" --compartment-id <compartment_
OCID> --actions file://action.json --wait-for-state=ACTIVE
```

In PowerShell, to escape double quotes, you must use two characters: The backslash (\) and the back tick (`).

For example (Windows PowerShell):

```
oci events rule create --display-name <friendly_name> --is-enabled true --condition "
{\`"eventType\`":[\`"com.oraclecloud.objectstorage.createbucket\`"]}" --compartment-id
<compartment_OCID> --actions file://action.json --wait-for-state=ACTIVE
```

Tip

The `condition` option does not support using a file to pass the JSON formatted string.

- `compartment-id` indicates the compartment where the rule applies. Events evaluates messages from resources in this compartment and any child compartments.
- `actions` indicates the location in the local file system of the JSON formatted file you created to specify the actions for a rule.
- `wait-for-state=` when used with ACTIVE indicates that the CLI should wait for the service to create the rule, do another GET operation, and then display the rule in the active state. Without the option, the CLI displays the rule immediately in the creating state.

For example:

```
oci events rule create --display-name CLI-created_rule --is-enabled true --condition "{\"eventType\":
[\"com.oraclecloud.objectstorage.createbucket\"]}" --compartment-id <compartment_OCID> --actions <path_
to_json_formatted_actions_file> --wait-for-state=ACTIVE
```

Note

Replace the values in *<compartment_OCID>* and *<path_to_json_formatted_actions_file>* with the actual values from your tenancy and local file system.

When you run the preceding command, the CLI prompts you about the rule and its display:

```
 Action completed. Waiting until the resource has entered state: ACTIVE
{
  "data": {
    "actions": {
      "actions": [
        {
          "action-type": "ONS",
          "description": "Notifications action",
          "id": "ocid1.eventaction.oc1.phx.<unique_ID>",
          "lifecycle-message": null,
          "lifecycle-state": "ACTIVE",
          "topic-id": "ocid1.onstopic.oc1.phx.<unique_ID>"
        }
      ]
    },
    "compartment-id": "ocid1.compartment.oc1..<unique_ID>",
    "condition": "{\"eventType\":[\"com.oraclecloud.objectstorage.createbucket\"]}",
    "defined-tags": {},
    "description": null,
    "display-name": "CLI-created_rule",
    "freeform-tags": {},
    "id": "ocid1.eventrule.oc1.phx.<unique_ID>",
    "is-enabled": true,
    "lifecycle-message": null,
    "lifecycle-state": "ACTIVE",
    "time-created": "2019-04-25T01:32:56.855000+00:00"
  },
```

```
  "etag": "<unique_ID>--gzip"
}
```

To create a bucket

1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.
2. Select the compartment where you created your rule (or any of its subordinate compartments).
3. Click **Create Bucket**.
4. In the **Create Bucket** dialog, specify the attributes of the bucket:
    - **Name**: Required. A user-friendly name or description. Avoid entering confidential information.
    - **Storage Tier**: Select the tier in which you want to store your data. Available tiers include:
        - **Standard** is the primary default Object Storage tier for storing data that is accessed frequently and requires fast and immediate access.
        - **Archive** is a special tier for storing data that is accessed infrequently and requires long retention periods. Access to data in the **Archive** tier is not immediate. You must restore archived data before it's accessible.
5. Click **Create Bucket**.

To receive your notification

- Log in to the email account you specified in the previous procedure to receive the notification about the bucket being created.

Tip

You receive notifications each time a bucket is created in the compartment (or any of its sub compartments) until you disable the rule.

Matching Events with Filters

This topic describes how to match events with pattern filters in rules to build automation.

Background

To understand filtering, it's helpful to review the structure of an actual event message. Events uses JSON objects to represent events. This is an event:

```
{
	"cloudEventsVersion": "0.1",
	"eventID": "<unique_ID>",
	"eventType": "com.oraclecloud.objectstorage.deletebucket",
	"source": "objectstorage",
	"eventTypeVersion": "1.0",
	"eventTime": "2019-01-10T21:19:24Z",
	"contentType": "application/json",
	"extensions": {
		"compartmentId": "ocid1.compartment.oc1..<unique_ID>"
	},
	"data": {
		"compartmentId": "ocid1.compartment.oc1..<unique_ID>",
		"compartmentName": "example_name",
		"resourceName": "my_bucket",
		"resourceId": "ocid1.compartment.oc1..<unique_ID>",
		"availabilityDomain": "NfHZ:PHX-AD-2",
		"freeFormTags": {
			"Department": "Finance"
		},
		"definedTags": {
```

```
                        "Operations": {
                                "CostCenter": "42"
                        }
                },
                "additionalDetails": {
                        "namespace": "example_namespace",
                        "publicAccessType": "NoPublicAccess",
                        "eTag": "f8ffb6e9-f602-460f-a6c0-00b5abfa24c7"
                }
        }
}
```

Two key points to remember about all events:

- Events all have the same set of top-level attributes, which are known as the event envelope. With one exception, most of these top-level attributes are not that useful for creating filters. The exception is `eventType`, which identifies the type of event included in the payload.
- The payload of the event appears within the `data` attribute. The information in this field depends on which service produced the event and the event type requested. The information in the payload is useful for isolating one event from another with a filter.

For more information about the envelope, see Contents of an Event Message. For a list of all the services that produce events, see Services that Produce Events.

Event Matching with Filters

Rules use filters to select events and route them for delivery to action resources. A rule is represented as a JSON object, similar to an event. The filter is an attribute of the rule, and the attribute is named `condition`. A filter either matches an event or it does not.

A few important things to remember about filters:

- Fields not mentioned in a filter are ignored. You can create a valid filter that matches all event messages with two curly brackets.

- For a filter to match an event, the event must contain all the field names listed in the filter. Field names must appear in the filter with the same nesting structure used in the event.
- Rules apply to events in the compartment in which you create them and any child compartments. This means that a filter specified by a rule only matches events emitted from resources in the same compartment or any child compartments.
- Wildcard matching is supported with the asterisk (*) character. See Examples of Wildcard Matching in Filters.

Examples of Simple Filters

The following filter matches every event in the compartment and any child compartments where you create the rule.

```
{
...

       "condition": "{ }"

}
```

When you add fields to the filter, you limit the events that the filter can match. For example, the following filter matches only `deletebucket` events.

```
{
...

       "condition": "{
              "eventType": "com.oraclecloud.objectstorage.deletebucket"
       }"
}
```

To create a filter for more than one event type, use an array in `eventType`. The following filter matches `deletebucket` and `createbucket` events.

```
{
...

       "condition": "{
```

```
                "eventType": [
                        "com.oraclecloud.objectstorage.deletebucket",
                        "com.oraclecloud.objectstorage.createbucket"
                ]
        }"
}
```

Examples of Filters with Event Payload Attributes

Both of the following filters would match the event at the top of the page. The first because filter specifies two fields and both fields appear in the event, the second because the "NoPublicAccess" type appears in the event.

The important thing to note is how the field names in the filter match the nesting structure of the event.

```
{
...

        "condition": "{
                "data": {
                        "compartmentName": "example_name",
                        "resourceName": "my_bucket"
                }
        }"
}
```

```
{
...

        "condition": "{
                "data": {
                        "additionalDetails": {
                                "publicAccessType": "NoPublicAccess"
                        }
                }
        }"
}
```

Neither of the following filters would match the event at the top of this page. The first because the filter specifies a PublicAccessType not found in the event. The second because the event specifies a name for different bucket.

```
{
...

       "condition": "{
               "data": {
                       "compartmentName": "example_name",
                       "resourceName": "my_bucket",
                       "additionalDetails": {
                               "publicAccessType": "PublicAccess"
                       }
               }
       }"
}
```

```
{
...

       "condition": "{
               "data": {
                       "additionalDetails": {
                               "publicAccessType": "NoPublicAccess"
                       }
               }
       }"
}
```

Examples of Arrays in Filters

Arrays in filters match events if any of the values in the filter match a value in an event. The following filter would match the event at the top of the page because the name of the bucket in the event is included in an array in the filter.

```
{
...

       "condition": "{
               "data": {
```

```
                        "resourceName": [
                                "my_bucket_2",
                                "my_bucket_1",
                                "my_bucket"
                        ],
                        "additionalDetails": {
                                "namespace": "example_namespace",
                                "publicAccessType": "NoPublicAccess"
                        }
                }
        }"
}
```

You can use an array in `eventType` (or any of the top-level fields), the event payload as shown in the preceding example, or both the event payload and a top-level field.

```
{
...

        "condition": "{
                "eventType": [
                        "com.oraclecloud.objectstorage.deletebucket",
                        "com.oraclecloud.objectstorage.createbucket"
                ],
                "data": {
                        "resourceName": [
                                "my_bucket_2",
                                "my_bucket_1",
                                "my_bucket"
                        ],
                        "additionalDetails": {
                                "namespace": "example_namespace",
                                "publicAccessType": "NoPublicAccess"
                        }
                }
        }"
}
```

Examples of Wildcard Matching in Filters

The following are a few things to consider about wildcard matching with filters.

- Use the wildcard only in attribute values. You cannot use the asterisk for matching in keys.
- An attribute value with only an asterisk matches all values for the associated attribute name, but *not* null.
- The period character has no special meaning in a filter.

You can add the asterisk at the start of a string, in the middle, or at the end. All of the filters that follow match the event at the top of the page.

- The first matches because the wildcard in `displayName` matches the bucket naming pattern.
- The second one matches because the `publicAccessType` uses a wildcard. Because of the use of the wildcard, these first two filters would also match events from buckets with a similar naming pattern and would include events from buckets with or without public access.
- The third one matches because the event type includes all types of bucket events.

```
{

...
       "condition": "{

               "data": {
                       "resourceName": "my_bucket*",
                       "additionalDetails": {
                               "namespace": "example_namespace",
                               "publicAccessType": "NoPublicAccess"
                       }
               }
       }"
}
```

```
{
...

       "condition": "{

               "data": {
                       "resourceName": [
```

```
                                "my_bucket_2",
                                "my_bucket_1",
                                "my_bucket"
                        ],
                        "additionalDetails": {
                                "namespace": "example_namespace",
                                "publicAccessType": "*"
                        }
                }
        }"
}
```

```
{
...

        "condition": "{
                "eventType": "com.oraclecloud.objectstorage.*bucket",

                "data": {
                        "resourceName": [
                                "my_bucket_2",
                                "my_bucket_1",
                                "my_bucket"
                        ],
                        "additionalDetails": {
                                "namespace": "example_namespace",
                                "publicAccessType": "NoPublicAccess"
                        }
                }
        }"
}
```

Events and IAM Policies

This topic describes how an administrator must write IAM policy for the Events service. If you're new to policies, see Getting Started with Policies and Common Policies. For more details about how to write IAM policy for Events, see Details for the Events Service.

Allow Users to Work with Rules

These IAM policies allow users to manage or list rules.

Let users list rules in a compartment

Type of access: Ability to list Events rules.

Where to create the policy: In the tenancy.

```
Allow group RuleReaders to read cloudevents-rules in tenancy
```

The preceding policy allows RuleReaders to list rules in the tenancy.

Let admins manage rules in a compartment

Type of access: Ability to manage Events rules, including creating, deleting, updating or moving rules to a different compartment.

Where to create the policy: In the tenancy.

This line gives the user inspect access to resources in compartments to select actions.

```
allow group <RuleAdmins> to inspect compartments in tenancy
```

This line gives the user access to defined tags to apply filter tags to rules.

```
allow group <RuleAdmins> to use tag-namespaces in tenancy
```

These lines give the user access to Streaming resources for actions

```
allow group <RuleAdmins> to inspect streams in tenancy
allow group <RuleAdmins> to use stream-push in tenancy
allow group <RuleAdmins> to use stream-pull in tenancy
```

These lines give the user access to Functions resources for actions.

```
allow group <RuleAdmins> to use virtual-network-family in tenancy
allow group <RuleAdmins> to manage function-family in tenancy
```

This line give the user access to Notifications topics for actions.

```
allow group <RuleAdmins> to use ons-topic in tenancy
```

This line gives the user manage access to rules for Events.

```
allow group <RuleAdmins> to manage cloudevents-rules in tenancy
```

Managing Rules for Events

This topic describes how to manage rules for the Events service. For more information about Events, see Overview of Events.

Prerequisites for Creating Rules

- Action resources: You must have resources already set up to specify as an action. The Events service invokes the action specified in the rule by delivering the event message to action resources, which can include topics, streams, or functions. Every rule must have at least one action. The Events service can invoke any of the following services by delivering an event message for processing:
    - Notifications
    - Streaming
    - Functions
- IAM policies: To manage or list rules, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform a task and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in. For more information, see Events and IAM Policies.
- Event messages: To create rules, the resources you want to monitor with the rule must emit events. For more information, see Services that Produce Events.

Working with Rules

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

A typical workflow for setting up rule might follow this pattern:

1. **Identify action resources**
   Set up or identify whatever action resources you intend to use with the rule. For example, you might set up a Notifications topic and create subscriptions for the DevOps team so that they are notified when backups complete. If a topic already exists, you can use it instead of creating a topic. The resources you specify for actions do not have to be in the same compartment as the rule.
2. **Plan filtering**
   Ensure the resources that you want to monitor emit events to the Events service and plan your pattern matching strategy. For example, you might want to monitor backups on Autonomous Data Warehouse instances in the ABC compartment. Ensure Autonomous Data Warehouse instances emit an event type you can use to create the automation you require. Review the example JSON event to determine the best way to identify those resources in filters. See Matching Events with Filters and Services that Produce Events.
3. **Create the rule**
   Rules apply to events in the compartment in which you create them and any child compartments. Create a rule in the compartment with the resource you want to monitor and specify where to deliver matching events. For example, in the ABC compartment, you might create a rule that filters for Autonomous Data Warehouse backup events.

Since Events has no requirement about the location of action resources, you could specify a topic in the XYZ compartment as the resource to deliver any matching events.

Managing Tags for Rules

You can add tags to your resources to help you organize them according to your business needs. You can add tags at the time you create a resource, or you can update the resource later with the desired tags. For general information about applying tags, see Resource Tags.

Tags and Event Filtering

With Events, you can also use tags to target resources in your tenancy. You target resources by adding the tag to a filter in a rule. A *filter tag* helps you hone automation by targeting only resources that contain a particular tag. For example, let's say you have dozens of Database instances in your tenancy, but only a few of the most critical of these instances have the tag "Operations." You could create a rule that triggers a particular action for resources that only contain the "Operations" tag.

Policy for working with filter tags is no different from policy for working with tags.

To manage filter tags

1. Open the navigation menu. Under the **Solutions and Platform** group, go to **Application Integration** and click **Events Service**.
2. Choose a **Compartment** you have permission to work in, and then click rule's name.
3. In the **Resources** menu, click **Event Matching**.
4. In the **Filter Tags** section, you can view or edit existing filter tags, or click **Add Filter Tag** to add new ones.

To manage tags for rules

1. Open the navigation menu. Under the **Solutions and Platform** group, go to **Application Integration** and click **Events Service**.
2. Choose a **Compartment** you have permission to work in, and then click rule's name.
3. Click the **Tags** tab to view or edit existing tags, or click **Add Tags** to add new ones.

For more information, see Resource Tags.

Move Rules to a Different Compartment

You can move rules from one compartment to another. When you move a rule to a new compartment, you stop monitoring events from resources in the current compartment and begin monitoring events in the new compartment (and any child compartments). After you move the rule to the new compartment, inherent policies apply immediately and affect access to the rules through the Console. Moving rules doesn't affect access by the Events service to actions defined in rules. For more information, see Moving Resources to a Different Compartment.

Monitoring Rules

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications. For more information, see Monitoring Overview and Notifications Overview.

For more information about monitoring the rules you create, see Events Metrics.

Object Events and the Events Service

Events for objects are handled differently than other resources. Objects do not emit events by default. Use the Console, CLI, or API to enable a bucket to emit events for object state changes. You can enable events for object state changes during or after bucket creation.

Using the Console

To create a rule

1. Open the navigation menu. Under the **Solutions and Platform** group, go to **Application Integration** and click **Events Service**.
2. Choose a **Compartment** you have permission to work in, and then click **Create Rule**.
   Events compares the rules you create in this compartment to event messages emitted from resources in this compartment and any child compartments.
3. Enter the following.
   - **Display Name:** Specify a friendly name for the rule. You can change this name later. Avoid entering confidential information.
   - **Description:** Specify a description of what the rule does. You can change this description later. Avoid entering confidential information.
4. In **Rule Conditions**, create a filter:

To add an event type

a. Select **Event Type**.
b. Select a **Service Name**.
c. In **Event type**, select one or more event types for this service.
d. Click **+ Another Condition** and select **Event Type** to add event types for a different service.
   This filter will match events of the event types you specify.

To add an attribute

You must first select an event type to add an attribute.

a. Select **Attribute**.
b. Select an **Attribute Name**.
c. Enter an **Attribute Value**. Attribute values are optional.
d. Click **+ Another Condition** and select **Attribute** to add another attribute.
This filter will match events of the events types with the attributes you specify.

To add a filter tag

a. Select **Filter Tag**
b. Select a **Tag Namespace.**
To specify a free-form tag, select **None (apply a free-form tag)**.
c. Select a **Tag Key**.
d. Enter a **Tag Value**. Tag values are optional.
e. Click **+ Another Condition** and select **Filter Tag** to add another filter tag.
This filter will match events with the tags you specify.

Filter tags help you to hone automation by targeting only resources that contain a particular tag. If you want to use tags to organize your rules, use resource tags instead. For more information, see Tags and Event Filtering.

Tip

You can leave this field entirely blank to match all events. See Matching Events with Filters.

To validate this rule

You can only evaluate a rule against one event type at a time. To test different event

types, repeat these steps as necessary.

a. Click **Validate Rule**.
   The **Test Rule** panel opens.
b. In **Service Name**, select a service if necessary.
c. In **Event Type**, select an event type, if necessary.
   A example event appears based on the selections you made. Edit the values in the event to match the values for any attributes and tags you added to your rule. For more information, see Contents of an Event Message.
d. Click **Check if Example Event Matches Rule**.
   If the rule doesn't match, use the rule editor to modify any of the following:
   - Add or remove event types
   - Add or remove values or attributes
   - Add or remove tags
   - Insert wildcards

   For more information, see Matching Events with Filters.
e. Click **Close**.

To view reference events

a. Click **View example events (JSON)**.
   The **View Example Events** panel opens.
b. In **Service Name**, select a service if necessary.
c. In **Event Type**, select an event type, if necessary.
   A example event appears based on the selections you made. Use the events viewer to browse reference events.
d. Click **Done**.

For more information, see Contents of an Event Message and Matching Events with Filters.

5. In **Actions**, specify the actions resources to trigger when the filter finds a match:

To select a topic

a. Select **Notifications**.
b. Select the **Notifications Compartment**.
c. Select the **Topic**.
d. Click **+ Another Action** and select **Notifications** to add another topic.

To select a stream

a. Select **Streaming**.
b. Select the **Stream Compartment**.
c. Select the **Stream**.
d. Click **+ Another Action** and select **Streaming** to add another stream.

To select a function

a. Select **Functions**.
b. Select the **Functions Compartment**.
c. Select a **Functions Application**.
d. Select the **Functions ID**.
e. Click **+ Another Action** and select **Functions** to add another function.

6. Click **Create Rule**.

To edit a rule

1. Open the navigation menu. Under the **Solutions and Platform** group, go to **Application Integration** and click **Events Service**.
2. Choose a **Compartment** that has the rule you want to edit.
3. For the rule you want to edit, click the Actions icon (three dots), and then click **Edit**.
4. Make your changes and click **Save Changes**.

To disable or enable a rule

1. Open the navigation menu. Under the **Solutions and Platform** group, go to **Application Integration** and click **Events Service**.
2. Choose a **Compartment** that has the rule you want to work with.
3. For the rule, you want change, click the Actions icon (three dots), and then take one of the following actions:
    - Click **Disable**
    - Click **Enable**
4. Confirm when prompted.

To move a rule to a different compartment

1. Open the navigation menu. Under the **Solutions and Platform** group, go to **Application Integration** and click **Events Service**.
2. In the **Scope** section, select a compartment.
3. Find the rule in the list, click the the Actions icon (three dots), and then click **Move Resource**.
4. Choose the destination compartment from the list.
5. Click **Move Resource**.

To validate a rule

You can only evaluate a rule against one event type at a time. Repeat as necessary to test different event types.

1. Open the navigation menu. Under the **Solutions and Platform** group, go to **Application Integration** and click **Events Service**.
2. Choose a **Compartment** you have permission to work in, and then click the **Name** of the rule you want to test.
3. Click **Validate Rule**.
4. Take one or more of the following actions:
    - If there are no event types in the rule, select the service and event type you want to test.
    - If you want to test a different event type than the one selected by default, select the service and event type you want to test.
    - If you added attribute values or filter tags to the rule, edit the example data in the event to match the values in your rule.
5. Click **Check if Example Event Matches Rule**.

For more information, see Matching Events with Filters and Contents of an Event Message.

To delete a rule

1. Open the navigation menu. Under the **Solutions and Platform** group, go to **Application Integration** and click **Events Service**.
2. Choose the **Compartment** that has rule you want to delete.
3. For the rule you want to delete, click the Actions icon (three dots) , and then click **Delete**.
4. Confirm when prompted.

To add an action to a rule

1. Open the navigation menu. Under the **Solutions and Platform** group, go to **Application Integration** and click **Events Service**.
2. Choose a **Compartment** you have permission to work in, and then click the **Name** of the rule you want to update.
3. In the **Resources** menu, click **Actions**.
4. Click **Add**.
    - The **Add Action** box appears. Configure the action resources:

      ### To select a topic

      a. Select **Notifications**.
      b. Select the **Notifications Compartment**.
      c. Select the **Topic**.

      ### To select a stream

      a. Select **Streaming**.
      b. Select the **Stream Compartment**.
      c. Select the **Stream**.

      ### To select a function

      a. Select **Functions**.
      b. Select the **Functions Compartment**.
      c. Select a **Functions Application**.
      d. Select the **Functions ID**.

    - **Action State:** Select to enable the action. Clear to disable.

5. Click **Add Action**.

To edit an action

1. Open the navigation menu. Under the **Solutions and Platform** group, go to **Application Integration** and click **Events Service**.
2. Choose a **Compartment** you have permission to work in, and then click the **Name** of the rule you want to update.
3. In the **Resources** menu, click **Actions**.
4. Select an action.
5. Go to **Actions** and click **Edit**.
   The **Edit Action** box appears.
6. Make your changes and click **Save Changes**.

To enable or disable an action

1. Open the navigation menu. Under the **Solutions and Platform** group, go to **Application Integration** and click **Events Service**.
2. Choose a **Compartment** you have permission to work in, and then click the **Name** of the rule you want to update.
3. In the **Resources** menu, click **Actions**.
4. Select an action.
5. Go to **Actions** and specify **Enable** or **Disable**.
6. Confirm when prompted.

To remove an action

1. Open the navigation menu. Under the **Solutions and Platform** group, go to

Application Integration and click **Events Service**.

2. Choose a **Compartment** you have permission to work in, and then click the **Name** of the rule you want to update.
3. In the **Resources** menu, click **Actions**.
4. Select an action.
5. Go to **Actions** and click **Remove**.
6. Confirm when prompted.
   Each rule must have one action.

To add event types to a rule

1. Open the navigation menu. Under the **Solutions and Platform** group, go to **Application Integration** and click **Events Service**.
2. Choose a **Compartment** you have permission to work in, and then click the **Name** of the rule you want to update.
3. In the **Resources** menu, click **Event Matching**.
4. Click **Add Event Type**.
5. In **Service Name**, select a service.
6. In **Event Type**, select an event type for this service.
7. Click **Add Event Type**.

To edit event types for a rule

1. Open the navigation menu. Under the **Solutions and Platform** group, go to **Application Integration** and click **Events Service**.
2. Choose a **Compartment** you have permission to work in, and then click the **Name** of the rule you want to update.
3. In the **Resources** menu, click **Event Matching**.

4. Select an event type.
5. Click **Edit**.
   The **Edit Event Type** box appears.
6. Make your changes and click **Save Changes**.

To remove event types for a rule

1. Open the navigation menu. Under the **Solutions and Platform** group, go to **Application Integration** and click **Events Service**.
2. Choose a **Compartment** you have permission to work in, and then click the **Name** of the rule you want to update.
3. In the **Resources** menu, click **Event Matching**.
4. Select the check box next to the event types you want to remove.
   Tip: To select the entire list, select the check box in the header row.
5. Click **Remove**.
6. Confirm when prompted.

To add attributes to a rule

1. Open the navigation menu. Under the **Solutions and Platform** group, go to **Application Integration** and click **Events Service**.
2. Choose a **Compartment** you have permission to work in, and then click the **Name** of the rule you want to update.
3. In the **Resources** menu, click **Event Matching**.
4. Click **Add Attribute**.
   The **Add Attribute** box appears. Configure the attribute:

- **Attribute Name:** Specify an attribute or tag to narrow matching results.
  - Select an attribute name. The list of attribute names is based on the event types you selected. If you select no event types, you cannot add an attribute.
  - If you specify an attribute here, you limit the events that match this rule.
- **Attribute Values**: Specify one or more values for the attribute name.
  a. Enter a value. As you type, the value appears under the field with (New) appended. Select the value with (New) appended to add the value to **Attribute Values**.

  b. Enter more values for attribute name in the same manner as before.

  Here are some things to consider about attribute values:
  - Use an asterisk to create a wildcard. See Examples of Wildcard Matching in Filters.
  - Multiple values for an attribute name broaden your results. If any of the values you enter here match a value in an event, the rule matches. See Examples of Arrays in Filters.

5. Click **Add attribute**.

To edit attributes for a rule

1. Open the navigation menu. Under the **Solutions and Platform** group, go to **Application Integration** and click **Events Service**.
2. Choose a **Compartment** you have permission to work in, and then click the **Name** of the rule you want to update.
3. In the **Resources** menu, click **Event Matching**.
4. Select an attribute.
5. Click **Edit**.
   The **Edit Attribute** box appears.
6. Make your changes and click **Save Changes**.

To remove attributes for a rule

1. Open the navigation menu. Under the **Solutions and Platform** group, go to **Application Integration** and click **Events Service**.
2. Choose a **Compartment** you have permission to work in, and then click the **Name** of the rule you want to update.
3. In the **Resources** menu, click **Event Matching**.
4. Select the check box next to the attributes you want to remove.
   Tip: To select the entire list, select the check box in the header row.
5. Click **Remove**.
6. Confirm when prompted.

To add filter tags to a rule

1. Open the navigation menu. Under the **Solutions and Platform** group, go to **Application Integration** and click **Events Service**.

2. Choose a **Compartment** you have permission to work in, and then click the **Name** of the rule you want to update.
3. In the **Resources** menu, click **Event Matching**.
4. Click **Add Filter Tag**.
5. In **Tag Namespace**, do one of the following:
   - Select a namespace to add a defined tag as a filter.
   - Select **None (apply a free-form tag)** to add a free-form tag as a filter.
6. In **Tag Key**, do one of the following:
   - Select the tag key for the defined tag.
   - Enter the tag key for the free-form tag.
7. Enter a **Value**.
8. Click **Add Filter Tag**.

To edit filter tags for a rule

1. Open the navigation menu. Under the **Solutions and Platform** group, go to **Application Integration** and click **Events Service**.
2. Choose a **Compartment** you have permission to work in, and then click the **Name** of the rule you want to update.
3. In the **Resources** menu, click **Event Matching**.
4. Select a filter tag.
5. Click **Edit**.
   The **Edit Attribute** box appears.
6. Make your changes and click **Save Changes**.

To remove filter tags for a rule

1. Open the navigation menu. Under the **Solutions and Platform** group, go to **Application Integration** and click **Events Service**.
2. Choose a **Compartment** you have permission to work in, and then click the **Name** of the rule you want to update.
3. In the **Resources** menu, click **Event Matching**.
4. Select the check box next to the filter tags you want to remove.
   Tip: To select the entire list, select the check box in the header row.
5. Click **Remove**.
6. Confirm when prompted.

Using the Command Line Interface (CLI)

When you use the CLI to create a rule, you work a little differently than using the Console.

- To specify the actions for your rule, use a JSON formatted file. You create this file before you create the rule, and the file simplifies the amount of information you must type at the command line.
- To specify an event to match, use a JSON formatted string. You type this right into the console as you create the rule.

For information about using the CLI, see Command Line Interface (CLI). For a complete list of flags and options available for CLI commands, see CLI Help.

To create an action JSON file

To specify the actions for your rule, use a JSON formatted file. For more information, see Using a JSON File for Complex Input.

1. Create a file and add the following content. This content doesn't have to be escaped or on a single line, it just has to contain valid JSON.

```
{
  "actions": [
       {
         "actionType": "FAAS",
         "description": "string",
         "functionId": "<function_OCID>",
         "isEnabled": true
       },
       {
         "actionType": "ONS",
         "description": "string",
         "isEnabled": true,
         "topicId": "<topic_OCID>"
       },
       {
         "actionType": "OSS",
         "description": "string",
         "isEnabled": true,
         "streamId": "<stream_OCID>"
       }
  ]
}
```

2. Edit the file and remove any objects you don't want to use as an action. For example, if you wanted to only use Notifications as an action, then you would delete all the other objects.

```
{
  "actions": [
       {
         "actionType": "ONS",
         "description": "string",
         "isEnabled": true,
         "topicId": "<topic_OCID>"
       }
  ]
}
```

3. Edit the file and fill in any *variables* with actual values from your tenancy, as shown in the following example.

```
{
  "actions": [
       {
         "actionType": "ONS",
         "description": "string",
         "isEnabled": true,
         "topicId": "<topic_OCID>"
       }
```

```
  ]
}
```

4. Add a description.
5. Save the file as action.json
6. To create a rule and specify Notifications as an action, run the following command.

```
oci events rule create --display-name <friendly_name> --is-enabled true --condition "{}" --
compartment-id <compartment_OCID> --actions file://action.json
```

To create a rule

Open a command prompt and run `oci events rule create` to create a rule.

Use the following options:

- `display-name` indicates the name of the rule in the Console
- `is-enabled` indicates whether Events should evaluate the rule.
- `condition` a JSON formatted string used to indicate a pattern for event matching (see Examples for usage).

Examples

The following example shows how to pass a simple condition that matches all events. Everything between the double quotes (`" "`) is a string, while the brackets `{ }` indicate JSON:

```
oci events rule create --display-name <friendly_name> --is-enabled true --condition "{}" --
compartment-id <compartment_OCID> --actions file://action.json --wait-for-state=ACTIVE
```

To pass complex input to the CLI as a JSON string, you must enclose the entire block in double quotes. Inside the block, each double quote for the key and value strings must be escaped with a backslash (`\`) character.

For example:

```
oci events rule create --display-name <friendly_name> --is-enabled true --condition "
{\"eventType\":[\"com.oraclecloud.objectstorage.createobject\"]}" --compartment-id <compartment_
OCID> --actions file://action.json --wait-for-state=ACTIVE
```

In PowerShell, to escape double quotes, you must use two characters: The backslash (\) and the back tick (`).
For example, in Windows PowerShell:

```
oci events rule create --display-name <friendly_name> --is-enabled true --condition "
{\`"eventType\`":[\`"com.oraclecloud.objectstorage.createobject\`"]}" --compartment-id
<compartment_OCID> --actions file://action.json --wait-for-state=ACTIVE
```

Tip

The `condition` option does not support using a file to pass the JSON formatted string.

For information on creating filters, see Matching Events with Filters.

- `compartment-id` indicates the compartment where the rule applies. Events evaluates messages from resources in this compartment *and any subordinate compartments*.
- `actions` indicates the location in the local file system of the JSON formatted file you created to specify the actions for a rule.
- `wait-for-state=` when used with ACTIVE indicates that the CLI should wait for the service to create the rule, do another GET operation, and then display the rule in the active state. Without the option, the CLI displays the rule immediately in the creating state.

For example:

```
oci events rule create --display-name <friendly_name> --is-enabled true --condition <json_formatted_
string> --compartment-id <compartment_OCID> --actions <json_formatted_file> --wait-for-state=ACTIVE
```

Note

Replace the values in *<compartment_OCID>* and *<json_formatted_file>* with the actual values from your tenancy and the local file system.

To delete a rule

Open a command prompt and run `oci events rule delete` to delete a single rule. For example:

```
oci events rule delete --rule-id <rule_OCID>
```

The command returns a prompt, asking for confirmation. Type `y` to delete the rule.

To get rule metadata

You can get rule metadata using the CLI. The Console displays this metadata in the **Rule Details** tab.

Open a command prompt and run `oci events rule get` to get information about a single rule. For example:

```
oci events rule get --rule-id <rule_OCID>
```

The command returns the following information:

```
{
  "data": {
    "actions": {
      "actions": [
        {
          "action-type": "ONS",
          "description": null,
          "id": "ocid1.eventaction.oc1.phx.<unique_ID>",
          "lifecycle-message": null,
```

```
          "lifecycle-state": "ACTIVE",
          "topic-id": "ocid1.onstopic.oc1.phx.<unique_ID>"
        }
      ]
    },
    "compartment-id": "ocid1.compartment.oc1..<unique_ID>",
    "condition": "{\n  \"eventType\": [\n
\"com.oraclecloud.databaseservice.autonomous.datawarehouse.backup.end\",\n    \"CustomEventType\"\n
]\n}",
    "defined-tags": null,
    "description": null,
    "display-name": "rule_name",
    "freeform-tags": null,
    "id": "ocid1.eventrule.oc1.phx.<unique_ID>",
    "is-enabled": true,
    "lifecycle-message": null,
    "lifecycle-state": "ACTIVE",
    "time-created": "2019-01-23T00:48:20.155000+00:00"
  },
  "etag": "<unique_ID>--gzip"
}
```

To get a list of rules

Open a command prompt and run `oci events rule list` to list the rules in a compartment. For example:

```
oci events rule list --compartment-id <compartment_OCID>
```

The command returns the following information:

```
{
  "data": [
    {
      "compartment-id": "ocid1.compartment.oc1..<unique_ID>",
      "condition": "{}",
      "description": "Example_Rule",
      "display-name": "rule_1",
      "id": "ocid1.eventrule.oc1.phx.<unique_ID>",
      "is-enabled": true,
      "lifecycle-state": "ACTIVE",
```

```
      "time-created": "2019-01-22T20:10:53.562000+00:00"
    },
    {
      "compartment-id": "ocid1.compartment.oc1..<unique_ID>",
      "condition": "{}",
      "description": null,
      "display-name": "rule_2",
      "id": "ocid1.eventrule.oc1.phx.<unique_ID>",
      "is-enabled": true,
      "lifecycle-state": "ACTIVE",
      "time-created": "2019-01-22T20:27:25.099000+00:00"
    },

    ...

    {
      "compartment-id": "ocid1.compartment.oc1..<unique_ID>",
      "condition": "{\"eventType\":[\"com.oraclecloud.objectstorage.createobject\"]}",
      "description": null,
      "display-name": "rule_75",
      "id": "ocid1.eventrule.oc1.phx.<unique_ID>",
      "is-enabled": true,
      "lifecycle-state": "ACTIVE",
      "time-created": "2019-01-22T23:08:12.379000+00:00"
    }
  ]
}
```

To update a rule

Open a command prompt and run `oci events rule update` to update a rule.

To update the condition for a rule:

```
oci events rule update --rule-id <rule_OCID> --condition <json_formatted_string>
```

For example:

```
oci events rule update --rule-id ocid1.eventrule.oc1.phx.<unique_ID> --condition "{}" --wait-for-
state=ACTIVE
```

The previous command would update the condition of the rule to use an empty JSON string. The CLI updates the rule, waits for the rule to update and change to the active state (only if you used the `--wait-for-state` option), then displays the updated rule.

Use the following options to update a rule:

- `display-name`
- `description`
- `is-enabled`
- `condition`
- `actions`
- `freeform-tags`
- `defined-tags`

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the following operations to manage rules:

- ChangeRuleCompartment
- CreateRule
- DeleteRule
- GetRule
- UpdateRule
- ListRules

Contents of an Event Message

This topic describes the contents of an event message. Every event message includes two main parts:

- Envelope: a container for all event messages
- Payload: the data from the resource emitting the event message

Event Envelope

These attributes for an event envelope are the same for all events. The structure of the envelope follows the CloudEvents industry standard format hosted by the Cloud Native Computing Foundation (CNCF).

Property	Description
`cloudEventsVersion`	The version of the CloudEvents specification.  **Note** Events uses version 0.1 specification of the CloudEvents event envelope.
`contentType`	Set to `application/json`. The content type of the data contained in the `data` attribute.
`data`	The payload of the event. All of the information within `data` comes from the resource emitting the event. See the following table for more detail on the structure of the payload.
`eventID`	The UUID of the event. This identifier is not an OCID, but just a unique ID for the event.
`eventTime`	The time of the event, expressed in RFC 3339 timestamp format.

Property	Description
`eventType`	The type of event that happened. For a list of all services that produce events and the even types that those services track, see Services that Produce Events. **Note** The service that produces the event can also add, remove, or change the meaning of a field by publishing a new version of an `eventType` and revising the `eventTypeVersion` field.
`eventTypeVersion`	The version of the event type.
`extensions`	The OCID of the compartment from which the event originates. If the event originates from the root compartment of the tenancy, then this attribute specifies a tenancy OCID. This attribute is mandatory in the Oracle Cloud Infrastructure implementation of the CloudEvents specification.
`source`	The resource that produced the event. For example, an Autonomous Database or an Object Storage bucket.

Payload

The data in these fields depends on which service produced the event and the event type it defines.

Property	Description
`compartmentId`	The OCID of the compartment of the resource emitting the event.
`compartmentName`	The name of the compartment of the resource emitting the event.
`resourceName`	The name of the resource emitting the event.
`resourceId`	An OCID or an ID for the resource emitting the event.
`availabilityDomain`	The availability domain of the resource emitting the event.
`freeFormTags`	Free-form tags added to the resource emitting the event.
`definedTags`	Defined tags added to the resource emitting the event.
`additionalDetails`	A container for attributes unique to the resource emitting the event. In the example bucket event that follows, the payload includes three Object Storage attributes: • `namespace` • `publicAccessType` • `eTag` To determine what attributes are included for other resources, retrieve an event or consult the reference samples listed on Services that Produce Events.

Resource Identifiers

Most types of Oracle Cloud Infrastructure resources have a unique, Oracle-assigned identifier called an Oracle Cloud ID (OCID). For information about the OCID format and other ways to identify your resources, see Resource Identifiers.

An Example Event

The following is an example bucket event emitted by Object Storage.

```
{
       "cloudEventsVersion": "0.1",
       "eventID": "<unique_ID>",
       "eventType": "com.oraclecloud.objectstorage.deletebucket",
       "source": "objectstorage",
       "eventTypeVersion": "1.0",
       "eventTime": "2019-01-10T21:19:24Z",
       "contentType": "application/json",
       "extensions": {
              "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
       },
       "data": {
              "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
              "compartmentName": "example_name",
              "resourceName": "my_bucket",
              "resourceId": "ocid1.compartment.oc1..<unique_ID>",
              "availabilityDomain": "NfHZ:PHX-AD-2",
              "freeFormTags": {
                     "Department": "Finance"
              },
              "definedTags": {
                     "Operations": {
                            "CostCenter": "42"
                     }
              },
              "additionalDetails": {
                     "namespace": "example_namespace",
                     "publicAccessType": "NoPublicAccess",
                     "eTag": "f8ffb6e9-f602-460f-a6c0-00b5abfa24c7"
              }
       }
}
```

Services that Produce Events

This topic lists the Oracle Cloud Infrastructure services that emit events:

- Analytics Cloud
- Block Volume
- Compute
- Database
- File Storage
- Functions
- IAM
- Integration
- Networking
- Notifications
- Object Storage
- Resource Manager

About Event Types and Example Reference Events

Services emit event messages by resource type. Event messages use a combination of an event type and a data payload (from the resource) to identify state changes.

In this section:

- Event types are organized by service, then by resource type
- There is one reference example per resource type if the payload contains the same attributes for all event types

See Matching Events with Filters and Contents of an Event Message.

Analytics Cloud

For details about events emitted by Analytics Cloud, see Service Events.

Block Volume

Block Volume resources that emit events:

- Block Volumes and Block Volume Backups
- Boot Volumes and Boot Volume Backups
- Volume Groups and Volume Group Backups

Block Volume Event Types

These are the event types that block volumes emit:

Friendly Name	Event Type
Change Volume Compartment Begin	`com.oraclecloud.blockvolumes.changevolumecompartment.begin`
Change Volume Compartment End	`com.oraclecloud.blockvolumes.changevolumecompartment.end`
Create Volume Begin	`com.oraclecloud.blockvolumes.createvolume.begin`
Create Volume End	`com.oraclecloud.blockvolumes.createvolume.end`
Delete Volume Begin	`com.oraclecloud.blockvolumes.deletevolume.begin`
Delete Volume End	`com.oraclecloud.blockvolumes.deletevolume.end`
Delete Volume Kms Key Begin	`com.oraclecloud.blockvolumes.deletevolumekmskey.begin`
Update Volume	`com.oraclecloud.blockvolumes.updatevolume`
Update Volume Begin	`com.oraclecloud.blockvolumes.updatevolume.begin`
Update Volume End	`com.oraclecloud.blockvolumes.updatevolume.end`
Update Volume Kms Key Begin	`com.oraclecloud.blockvolumes.updatevolumekmskey.begin`
Update Volume Kms Key End	`com.oraclecloud.blockvolumes.updatevolumekmskey.end`

Block Volume Example

This is a reference event for block volumes:

```
{
   "eventType": "com.oraclecloud.blockvolumes.createvolume.begin",
   "cloudEventsVersion": "0.1",
   "eventTypeVersion": "2.0",
   "source": "BlockVolumes",
   "eventTime": "2019-01-10T21:19:24Z",
   "contentType": "application/json",
   "data": {
      "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
      "compartmentName": "example_name",
      "resourceName": "my_volume",
      "resourceId": "ocid1.volume.oc1..<unique_ID>",
      "availabilityDomain": "<availability_domain>",
   }
   "eventID": "<unique_ID>",
   "extensions": {
      "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
   }
}
```

Block Volume Backup Event Types

These are the event types that block volume backups emit:

Friendly Name	Event Type
Change Volume Backup Compartment	`com.oraclecloud.blockvolumes.changevolumebackupcompartment`
Copy Volume Backup Begin	`com.oraclecloud.blockvolumes.copyvolumebackup.begin`
Copy Volume Backup End	`com.oraclecloud.blockvolumes.copyvolumebackup.end`
Create Volume Backup Begin	`com.oraclecloud.blockvolumes.createvolumebackup.begin`

Friendly Name	Event Type
Create Volume Backup End	`com.oraclecloud.blockvolumes.createvolumebackup.end`
Create Volume Backup Policy Assignment	`com.oraclecloud.blockvolumes.createvolumebackuppolicyassignment`
Delete Volume Backup Begin	`com.oraclecloud.blockvolumes.deletevolumebackup.begin`
Delete Volume Backup End	`com.oraclecloud.blockvolumes.deletevolumebackup.end`
Delete Volume Backup Policy Assignment	`com.oraclecloud.blockvolumes.deletevolumebackuppolicyassignment`
Update Volume Backup	`com.oraclecloud.blockvolumes.updatevolumebackup`
Update Volume Backup Policy	`com.oraclecloud.blockvolumes.updatevolumebackuppolicy`

Block Volume Backup Example

This is a reference event for block volume backups:

```
{
   "eventType": "com.oraclecloud.blockvolumes.createvolumebackup.end",
   "cloudEventsVersion": "0.1",
   "eventTypeVersion": "2.0",
   "source": "BlockVolumes",
   "eventTime": "2019-01-10T21:19:24Z",
   "contentType": "application/json",
   "data": {
      "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
      "compartmentName": "example_name",
      "resourceName": "my_volumebackup via policy:gold",
      "resourceId": "ocid1.volumebackup.oc1..<unique_ID>",
      "additionalDetails": {
         "sourceType": "SCHEDULED",
         "volumeId": ""ocid1.volume.oc1..<unique_ID>"
      }
   }
   "eventID": "<unique_ID>",
   "extensions": {
```

```
      "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
   }
}
```

Boot Volume Event Types

These are the event types that boot volumes emit:

Friendly Name	Event Type
Change Boot Volume Compartment Begin	`com.oraclecloud.blockvolumes.changebootvolumecompartment.begin`
Change Boot Volume Compartment End	`com.oraclecloud.blockvolumes.changebootvolumecompartment.end`
Create Boot Volume Begin	`com.oraclecloud.blockvolumes.createbootvolume.begin`
Create Boot Volume End	`com.oraclecloud.blockvolumes.createbootvolume.end`
Delete Boot Volume Begin	`com.oraclecloud.blockvolumes.deletebootvolume.begin`
Delete Boot Volume End	`com.oraclecloud.blockvolumes.deletebootvolume.end`
Delete Boot Volume Kms Key Begin	`com.oraclecloud.blockvolumes.deletebootvolumekmskey.begin`
Update Boot Volume	`com.oraclecloud.blockvolumes.updatebootvolume`
Update Boot Volume Begin	`com.oraclecloud.blockvolumes.updatebootvolume.begin`
Update Boot Volume End	`com.oraclecloud.blockvolumes.updatebootvolume.end`
Update Boot Volume Kms Key Begin	`com.oraclecloud.blockvolumes.updatebootvolumekmskey.begin`
Update Boot Volume Kms Key End	`com.oraclecloud.blockvolumes.updatebootvolumekmskey.end`

Boot Volume Example

This is a reference event for boot volumes:

```
{
   "eventType": "com.oraclecloud.blockvolumes.createbootvolume.begin",
   "cloudEventsVersion": "0.1",
   "eventTypeVersion": "2.0",
   "source": "BlockVolumes",
   "eventTime": "2019-01-10T21:19:24Z",
   "contentType": "application/json",
   "data": {
               "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
               "compartmentName": "example_name",
               "resourceName": "my_volume",
               "resourceId": "ocid1.volume.oc1..<unique_ID>",
               "availabilityDomain": "<availability_domain>",
       }
   "eventID": "<unique_ID>",
   "extensions": {
      "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
   }
}
```

Boot Volume Backup Event Types

These are the event types that boot volume backups emit:

Friendly Name	Event Type
Change Boot Volume Backup Compartment	`com.oraclecloud.blockvolumes.changebootvolumebackupcompartment`
Create Boot Volume Backup Begin	`com.oraclecloud.blockvolumes.createbootvolumebackup.begin`
Create Boot Volume Backup End	`com.oraclecloud.blockvolumes.createbootvolumebackup.end`

Friendly Name	Event Type
Delete Boot Volume Backup Begin	`com.oraclecloud.blockvolumes.deletebootvolumebackup.begin`
Delete Boot Volume Backup End	`com.oraclecloud.blockvolumes.deletebootvolumebackup.end`
Update Boot Volume Backup	`com.oraclecloud.blockvolumes.updatebootvolumebackup`

Boot Volume Backup Example

This is a reference event for boot volume backups:

```
{
   "eventType": "com.oraclecloud.blockvolumes.createbootvolume.end",
   "cloudEventsVersion": "0.1",
   "eventTypeVersion": "2.0",
   "source": "BlockVolumes",
   "eventTime": "2019-01-10T21:19:24Z",
   "contentType": "application/json",
   "data": {
      "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
      "compartmentName": "example_name",
      "resourceName": "my_volumebackup via policy:gold",
      "resourceId": "ocid1.volumebackup.oc1..<unique_ID>",
      "additionalDetails": {
         "sourceType": "SCHEDULED",
         "volumeId": ""ocid1.volume.oc1..<unique_ID>"
      }
   }
   "eventID": "<unique_ID>",
   "extensions": {
      "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
   }
}
```

Volume Groups and Volume Group Backups

These are the event types that volume groups and volume group backups emit:

Friendly Name	Event Type
Change Volume Group Compartment	`com.oraclecloud.blockvolumes.changevolumegroupcompartment`
Change Volume Group Backup Compartment	`com.oraclecloud.blockvolumes.changevolumegroupbackupcompartment`
Create Volume Group	`com.oraclecloud.blockvolumes.createvolumegroup`
Create Volume Group Begin	`com.oraclecloud.blockvolumes.createvolumegroup.begin`
Create Volume Group End	`com.oraclecloud.blockvolumes.createvolumegroup.end`
Create Volume Group Backup Begin	`com.oraclecloud.blockvolumes.createvolumegroupbackup.begin`
Create Volume Group Backup End	`com.oraclecloud.blockvolumes.createvolumegroupbackup.end`
Delete Volume Group Begin	`com.oraclecloud.blockvolumes.deletevolumegroup.begin`
Delete Volume Group End	`com.oraclecloud.blockvolumes.deletevolumegroup.end`
Delete Volume Group Backup Begin	`com.oraclecloud.blockvolumes.deletevolumegroupbackup.begin`
Delete Volume Group Backup End	`com.oraclecloud.blockvolumes.deletevolumegroupbackup.end`
Update Volume Group	`com.oraclecloud.blockvolumes.updatevolumegroup`
Update Volume Group Backup	`com.oraclecloud.blockvolumes.updatevolumegroupbackup`

Volume Group Example

This is a reference event for volume groups:

```
{
  "eventType": "com.oraclecloud.blockvolumes.createvolumegroup",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "BlockVolumes",
  "eventTime": "2019-01-10T21:19:24Z",
  "contentType": "application/json",
  "data": {
    "resourceName": "my_volumegroup",
    "resourceId": "ocid1.volumegroup.oc1..<unique_ID>",
     "availabilityDomain": "<availability_domain>",
   }
   "eventID": "<unique_ID>",
   "extensions": {
      "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
   }
}
```

Compute

Compute resources that emit events:

- Autoscaling configurations and autoscaling policies
- Cluster networks
- Console histories
- Images
- Instances and instance attachments
- Instance configurations
- Instance console connections
- Instance pools

Autoscaling Event Types

These are the event types that autoscaling configurations and autoscaling policies emit:

Friendly Name	Event Type
Change Autoscaling Configuration Compartment	`com.oraclecloud.autoscaling.changeautoscalingconfigurationcompartment`
Create Autoscaling Configuration	`com.oraclecloud.autoscaling.createautoscalingconfiguration`
Delete Autoscaling Configuration	`com.oraclecloud.autoscaling.deleteautoscalingconfiguration`
Scaling Action	`com.oraclecloud.autoscaling.scalingaction`
Update Autoscaling Configuration	`com.oraclecloud.autoscaling.updateautoscalingconfiguration`
Update Autoscaling Policy	`com.oraclecloud.autoscaling.updateautoscalingpolicy`

Autoscaling Example

This is a reference event for autoscaling:

```
{
  "eventType": "com.oraclecloud.autoscaling.scalingaction",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "autoscaling",
  "eventTime": "2019-08-21T04:00:10.046Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_compartment",
    "resourceName": "example autoscaling configuration",
    "resourceId": "ocid1.autoscalingconfiguration.oc1.phx.<unique_ID>",
```

```
    "additionalDetails": {
      "policyName": "my_policy_name",
      "ruleName": "my_scale_up_condition",
      "actionType": "SCALE_OUT",
      "previousSize": 1,
      "newSize": 2
    }
  },
  "eventID": "<unique_ID>",
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
  }
```

Cluster Network Event Types

These are the event types that cluster networks emit:

Friendly Name	Event Type
Change Cluster Network Compartment	`com.oraclecloud.computemanagement.changeclusternetworkcompartment`
Create Cluster Network Begin	`com.oraclecloud.computemanagement.createclusternetwork.begin`
Create Cluster Network End	`com.oraclecloud.computemanagement.createclusternetwork.end`
Terminate Cluster Network Begin	`com.oraclecloud.computemanagement.terminateclusternetwork.begin`
Terminate Cluster Network End	`com.oraclecloud.computemanagement.terminateclusternetwork.end`

Cluster Networks Example

This is a reference event for most cluster network events:

```
{
  "eventType": "com.oraclecloud.computemanagement.createclusternetwork.begin",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
```

```
  "source": "ComputeManagement",
  "eventTime": "2019-09-12T21:45:09.036Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_compartment",
    "resourceName": "my_cluster_network",
    "resourceId": "ocid1.clusternetwork.oc1.uk-london-1.<unique_ID>",
    "availabilityDomain": "<availability_domain>"
  },
  "eventID": "<unique_ID>",
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
  }
}
```

Create cluster network end and terminate cluster network end don't include the availability domain.

Console History Event Types

These are the event types that console histories emit:

Friendly Name	Event Type
Capture Console History Begin	`com.oraclecloud.computeapi.captureconsolehistory.begin`
Capture Console History End	`com.oraclecloud.computeapi.captureconsolehistory.end`
Delete Console History	`com.oraclecloud.computeapi.deleteconsolehistory`
Update Console History	`com.oraclecloud.computeapi.updateconsolehistory`

Console History Example

This is a reference event for console histories:

```
{
  "eventType": "com.oraclecloud.computeapi.captureconsolehistory.begin",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
```

```
"source": "ComputeApi",
"eventTime": "2019-08-20T21:58:13.554Z",
"contentType": "application/json",
"data": {
  "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
  "compartmentName": "example_compartment",
  "resourceId": "ocid1.consolehistory.oc1.iad.<unique_ID>",
  "availabilityDomain": "SoSC:PHX-AD-3"
},
"eventID": "<unique_ID>",
"extensions": {
  "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
}
```

Image Event Types

These are the event types that images emit:

Friendly Name	Event Type
Add Image Shape Compatibility	`com.oraclecloud.computeapi.addimageshapecompatibility`
Change Image Compartment	`com.oraclecloud.computeapi.moveimage`
Create Image Begin	`com.oraclecloud.computeapi.createimage.begin`
Create Image End	`com.oraclecloud.computeapi.createimage.end`
Delete Image	`com.oraclecloud.computeapi.deleteimage`
Export Image Begin	`com.oraclecloud.computeapi.exportimage.begin`
Export Image End	`com.oraclecloud.computeapi.exportimage.end`
Remove Image Shape Compatibility	`com.oraclecloud.computeapi.removeimageshapecompatibility`
Update Image	`com.oraclecloud.computeapi.updateimage`

Image Example

This is a reference event for most image events:

```
{
  "eventType": "com.oraclecloud.computeapi.exportimage.begin",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "ComputeApi",
  "eventTime": "2019-08-27T04:12:37.397Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.tenancy.oc1..<unique_ID>",
    "compartmentName": "example_compartment",
    "resourceName": "my_image",
    "resourceId": "ocid1.image.oc1.iad.<unique_ID>",
    "availabilityDomain": "SoSC:PHX-AD-3"
  },
  "eventID": "<unique_ID>",
  "extensions": {
    "compartmentId": "ocid1.tenancy.oc1..<unique_ID>"
  }
}
```

Change image compartment doesn't include the resource name or availability domain.

Instance Event Types

These are the event types that Compute instances and instance attachments emit:

Friendly Name	Event Type
Attach Boot Volume Begin	`com.oraclecloud.computeapi.attachbootvolume.begin`
Attach Boot Volume End	`com.oraclecloud.computeapi.attachbootvolume.end`
Attach Secondary VNIC Begin	`com.oraclecloud.computeapi.attachvnic.begin`
Attach Secondary VNIC End	`com.oraclecloud.computeapi.attachvnic.end`
Attach Volume Begin	`com.oraclecloud.computeapi.attachvolume.begin`

Friendly Name	Event Type
Attach Volume End	`com.oraclecloud.computeapi.attachvolume.end`
Change Instance Compartment Begin	`com.oraclecloud.computeapi.changeinstancecompartment.begin`
Change Instance Compartment End	`com.oraclecloud.computeapi.changeinstancecompartment.end`
Detach Boot Volume Begin	`com.oraclecloud.computeapi.detachbootvolume.begin`
Detach Boot Volume End	`com.oraclecloud.computeapi.detachbootvolume.end`
Detach Secondary VNIC Begin	`com.oraclecloud.computeapi.detachvnic.begin`
Detach Secondary VNIC End	`com.oraclecloud.computeapi.detachvnic.end`
Detach Volume Begin	`com.oraclecloud.computeapi.detachvolume.begin`
Detach Volume End	`com.oraclecloud.computeapi.detachvolume.end`
Instance Action Begin	`com.oraclecloud.computeapi.instanceaction.begin`
Instance Action End	`com.oraclecloud.computeapi.instanceaction.end`
Launch Instance Begin	`com.oraclecloud.computeapi.launchinstance.begin`
Launch Instance End	`com.oraclecloud.computeapi.launchinstance.end`
Terminate Instance Begin	`com.oraclecloud.computeapi.terminateinstance.begin`
Terminate Instance End	`com.oraclecloud.computeapi.terminateinstance.end`
Update Instance	`com.oraclecloud.computeapi.updateinstance`

Compute Instance Example

This is a reference event for most instance events (attach/detach volume and boot volume events don't include additional details):

```
{
  "eventType": "com.oraclecloud.computeapi.launchinstance.begin",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "ComputeApi",
  "eventTime": "2019-08-15T21:21:48.586Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_compartment",
    "resourceName": "my_instance",
    "resourceId": "ocid1.instance.oc1.phx.<unique_ID>",
    "availabilityDomain": "SoSC:PHX-AD-3",
    "additionalDetails": {
      "imageId": "ocid1.image.oc1.phx.<unique_ID>",
      "shape": "VM.Standard2.1",
      "type": "CustomerVmi"
    }
  },
  "eventID": "<unique_ID>",
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
  }
}
```

This is a reference event for attach/detatch VNIC events:

```
{
  "eventType": "com.oraclecloud.computeapi.attachvnic.end",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "ComputeApi",
  "eventTime": "2019-08-15T21:21:48.586Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_compartment",
    "resourceName": "my_instance",
    "resourceId": "ocid1.instance.oc1.phx.<unique_ID>",
```

```
    "availabilityDomain": "SoSC:PHX-AD-3",
    "additionalDetails": {
      "subnetId": "ocid1.subnet.oc1.phx.<unique_ID>"
    }
  },
  "eventID": "<unique_ID>",
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
  }
}
```

Instance Configuration Event Types

These are the event types that Compute instance configurations emit:

Friendly Name	Event Type
Change Instance Configuration Compartment	`com.oraclecloud.computemanagement.changeinstanceconfigurationcompartment`
Create Instance Configuration	`com.oraclecloud.computemanagement.createinstanceconfiguration`
Delete Instance Configuration	`com.oraclecloud.computemanagement.deleteinstanceconfiguration`
Launch Instance Configuration Begin	`com.oraclecloud.computemanagement.launchinstanceconfiguration.begin`
Launch Instance Configuration End	`com.oraclecloud.computemanagement.launchinstanceconfiguration.end`
Update Instance Configuration	`com.oraclecloud.computemanagement.updateinstanceconfiguration`

Compute Instance Configuration Example

This is a reference event for most instance configuration events:

```
{
  "eventType": "com.oraclecloud.computemanagement.createinstanceconfiguration",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "ComputeManagement",
  "eventTime": "2019-08-12T22:52:01.062Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_compartment",
    "resourceName": "my_instance_configuration",
    "resourceId": "ocid1.instanceconfiguration.oc1.phx.<unique_ID>",
    "availabilityDomain": "<availability_domain>"
  },
  "eventID": "<unique_ID>",
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
  }
```

Launch instance configuration end doesn't include the availability domain.

Instance Console Connection Event Types

These are the event types that Compute instance console connections emit:

Friendly Name	Event Type
Create Instance Console Connection Begin	`com.oraclecloud.computeapi.createinstanceconsoleconnection.begin`
Create Instance Console Connection End	`com.oraclecloud.computeapi.createinstanceconsoleconnection.end`
Delete Instance Console Connection Begin	`com.oraclecloud.computeapi.deleteinstanceconsoleconnection.begin`
Delete Instance Console Connection End	`com.oraclecloud.computeapi.deleteinstanceconsoleconnection.end`

Compute Instance Console Connection Example

This is a reference event for instance console connections:

```
{
  "eventType": "com.oraclecloud.computeapi.createinstanceconsoleconnection.begin",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "ComputeApi",
  "eventTime": "2019-08-12T14:47:35.762Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_compartment",
    "resourceId": "ocid1.instanceconsoleconnection.oc1.phx.<unique_ID>",
    "availabilityDomain": "SoSC:PHX-AD-3"
  },
  "eventID": "<unique_ID>",
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
  }
}
```

Instance Pool Event Types

These are the event types that Compute instance pools emit:

Friendly Name	Event Type
Attach Load Balancer Begin	`com.oraclecloud.computemanagement.attachloadbalancer.begin`
Attach Load Balancer End	`com.oraclecloud.computemanagement.attachloadbalancer.end`
Change Instance Pool Compartment	`com.oraclecloud.computemanagement.changeinstancepoolcompartment`
Create Instance Pool Begin	`com.oraclecloud.computemanagement.createinstancepool.begin`
Create Instance Pool End	`com.oraclecloud.computemanagement.createinstancepool.end`

Friendly Name	Event Type
Detach Load Balancer Begin	`com.oraclecloud.computemanagement.detachloadbalancer.begin`
Detach Load Balancer End	`com.oraclecloud.computemanagement.detachloadbalancer.end`
Reset Instance Pool Begin	`com.oraclecloud.computemanagement.resetinstancepool.begin`
Reset Instance Pool End	`com.oraclecloud.computemanagement.resetinstancepool.end`
Soft Reset Instance Pool Begin	`com.oraclecloud.computemanagement.softresetinstancepool.begin`
Soft Reset Instance Pool End	`com.oraclecloud.computemanagement.softresetinstancepool.end`
Start Instance Pool Begin	`com.oraclecloud.computemanagement.startinstancepool.begin`
Start Instance Pool End	`com.oraclecloud.computemanagement.startinstancepool.end`
Stop Instance Pool Begin	`com.oraclecloud.computemanagement.stopinstancepool.begin`
Stop Instance Pool End	`com.oraclecloud.computemanagement.stopinstancepool.end`
Terminate Instance Pool Begin	`com.oraclecloud.computemanagement.terminateinstancepool.begin`
Terminate Instance Pool End	`com.oraclecloud.computemanagement.terminateinstancepool.end`
Update Instance Pool Begin	`com.oraclecloud.computemanagement.updateinstancepool.begin`
Update Instance Pool End	`com.oraclecloud.computemanagement.updateinstancepool.end`

Compute Instance Pools Example

This is a reference event for most instance pool events:

```
{
  "eventType": "com.oraclecloud.computemanagement.createinstancepool.begin",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "ComputeManagement",
  "eventTime": "2019-08-12T22:52:01.343Z",
  "contentType": "application/json",
```

```
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_compartment",
    "resourceName": "my_instance_pool",
    "resourceId": "ocid1.instancepool.oc1.phx.<unique_ID>",
    "availabilityDomain": "<availability_domain>"
  },
  "eventID": "<unique_id>",
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
  }
}
```

These instance pool events don't include the availability domain: create instance pool end, detach load balancer end, reset instance pool end, soft reset instance pool end, start instance pool end, stop instance pool end, terminate instance pool end, and update instance pool end.

Database

Database resources that emit events:

- **Autonomous Database Resources:**
  - Autonomous Databases
  - Autonomous Container Databases
  - Autonomous Exadata Infrastructure instances
- **Exadata Cloud at Customer Resources:**
  - Exadata Infrastructure
  - VM cluster networks
  - VM clusters
  - Backup destinations
  - Database nodes
  - Database Homes
  - Databases

- **Bare metal, virtual machine, and Exadata DB system resources**
  - DB systems
  - Database nodes
  - Database Homes
  - Databases
  - Data Guard associations

Autonomous Database Event Types

These are the event types that Autonomous Databases emit:

Friendly Name	Event Type
Change Compartment Begin	`com.oraclecloud.databaseservice.changeautonomousdatabasecompartment.begin`
Change Compartment End	`com.oraclecloud.databaseservice.changeautonomousdatabasecompartment.end`
Create Backup Begin	`com.oraclecloud.databaseservice.autonomous.database.backup.begin`
Create Backup End	`com.oraclecloud.databaseservice.autonomous.database.backup.end`
Create Begin	`com.oraclecloud.databaseservice.autonomous.database.instance.create.begin`
Create End	`com.oraclecloud.databaseservice.autonomous.database.instance.create.end`
Restore Begin	`com.oraclecloud.databaseservice.autonomous.database.restore.begin`
Restore End	`com.oraclecloud.databaseservice.autonomous.database.restore.end`
Start Begin	`com.oraclecloud.databaseservice.startautonomousdatabase.begin`
Start End	`com.oraclecloud.databaseservice.startautonomousdatabase.end`

Friendly Name	Event Type
Stop Begin	`com.oraclecloud.databaseservice.stopautonomousdatabase.begin`
Stop End	`com.oraclecloud.databaseservice.stopautonomousdatabase.end`
Terminate Begin	`com.oraclecloud.databaseservice.deleteautonomousdatabase.begin`
Terminate End	`com.oraclecloud.databaseservice.deleteautonomousdatabase.end`

Autonomous Database Example

This is a reference event for Autonomous Databases:

```
{
  "cloudEventsVersion": "0.1",
  "eventID": "<unique_ID>",
  "eventType": "com.oraclecloud.databaseservice.autonomous.database.backup.begin",
  "source": "databaseservice",
  "eventTypeVersion": "<version>",
  "eventTime": "2019-07-10T14:06:23Z",
  "contentType": "application/json",
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
  },
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_name",
    "resourceName": "my_database",
    "resourceId": "ocid1.autonomousdatabase.oc1.phx.<unique_ID>",
    "availabilityDomain": "SoSC:PHX-AD-3",
    "freeFormTags": {},
    "definedTags": {},
    "additionalDetails": {
      "cpuCoreCount": 1,
      "lifecycleState": "PROVISIONING",
      "dataStorageSizeInTBs": 1,
      "timeCreated": "2019-07-10T14:06:10.905Z",
      "timeUpdated": "2019-07-10T14:06:10.905Z",
      "serviceConsoleUrl": null,
      "licenseType": null,
```

```
      "workloadType": "<Data Warehouse | Transaction Processing>",
      "autonomousDatabaseType": "<Dedicated Infrastructure | Severless>"
    }
  }
}
```

Autonomous Container Database Event Types

These are the event types that Autonomous Container Databases emit:

Friendly Name	Event Type
Change Compartment	`com.oraclecloud.databaseservice.changeautonomouscontainerdatabasecompartment`
Create Backup Begin	`com.oraclecloud.databaseservice.autonomous.container.database.backup.begin`
Create Backup End	`com.oraclecloud.databaseservice.autonomous.container.database.backup.end`
Create Begin	`com.oraclecloud.databaseservice.autonomous.container.database.instance.create.begin`
Create End	`com.oraclecloud.databaseservice.autonomous.container.database.instance.create.end`
Maintenance Begin	`com.oraclecloud.databaseservice.autonomous.container.database.maintenance.begin`
Maintenance End	`com.oraclecloud.databaseservice.autonomous.container.database.maintenance.end`
Maintenance Reminder	`com.oraclecloud.databaseservice.autonomous.container.database.maintenance.reminder`
Maintenance Scheduled	`com.oraclecloud.databaseservice.autonomous.container.database.maintenance.scheduled`

Friendly Name	Event Type
Restart Begin	`com.oraclecloud.databaseservice.restartautonomouscontainerdatabase.begin`
Restart End	`com.oraclecloud.databaseservice.restartautonomouscontainerdatabase.end`
Restore Begin	`com.oraclecloud.databaseservice.autonomous.container.database.restore.begin`
Restore End	`com.oraclecloud.databaseservice.autonomous.container.database.restore.end`
Terminate Begin	`com.oraclecloud.databaseservice.terminateautonomouscontainerdatabase.begin`
Terminate End	`com.oraclecloud.databaseservice.terminateautonomouscontainerdatabase.end`
Update Begin	`com.oraclecloud.databaseservice.autonomous.container.database.instance.update.begin`
Update End	`com.oraclecloud.databaseservice.autonomous.container.database.instance.update.begin`

Autonomous Container Database Example

This is a reference event for Autonomous Container Databases:

```
{
  "cloudEventsVersion": "0.1",
  "eventID": "<unique_ID>",
  "eventType": "com.oraclecloud.databaseservice.autonomous.container.database.backup.begin",
  "source": "databaseservice",
  "eventTypeVersion": "<version>",
  "eventTime": "2019-06-27T21:16:04Z",
  "contentType": "application/json",
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
  },
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_name",
    "resourceName": "my_container_database",
```

```
    "resourceId": "<unique_ID>",
    "availabilityDomain": "all",
    "freeFormTags": {},
    "definedTags": {},
    "additionalDetails": {
      "cpuCoreCount": null,
      "lifecycleState": "ACTIVE",
      "dataStorageSizeInTBs": null,
      "timeCreated": "2019-06-27T21:15:59.000Z",
      "timeUpdated": "2019-06-27T21:16:04.389Z",
      "dbUniqueName": "dwrrdtsr_phx289",
      "dbHomeId": "ocid1.autonomoushome.oc1.phx.<unique_ID>",
      "dbName": "dwrrdtsr"
      "autonomousContainerDatabaseId": "ocid1.autonomouscontainerdatabase.oc1.phx.<unique_ID>"
    }
  }
}
```

Autonomous Exadata Infrastructure Event Types

These are the event types that Autonomous Exadata Infrastructure instances emit:

Friendly Name	Event Type
Change Compartment	`com.oraclecloud.databaseservice.changeautonomousexadatainfrastructurecompartment`
Create Begin	`com.oraclecloud.databaseservice.autonomous.exadata.infrastructure.instance.create.begin`
Create End	`com.oraclecloud.databaseservice.autonomous.exadata.infrastructure.instance.create.end`
Maintenance Begin	`com.oraclecloud.databaseservice.autonomous.exadata.infrastructure.maintenance.begin`

Friendly Name	Event Type
Maintenance End	`com.oraclecloud.databaseservice.autonomous.exadata.infrastructure.maintenance.end`
Maintenance Reminder	`com.oraclecloud.databaseservice.autonomous.exadata.infrastructure.maintenance.reminder`
Maintenance Scheduled	`com.oraclecloud.databaseservice.autonomous.exadata.infrastructure.maintenance.scheduled`
Terminate Begin	`com.oraclecloud.databaseservice.terminateautonomousexadatainfrastructure.begin`
Terminate End	`com.oraclecloud.databaseservice.terminateautonomousexadatainfrastructure.end`

Autonomous Exadata Infrastructure Example

This is a reference event for Autonomous Exadata Infrastructure instances:

```
{
  "cloudEventsVersion": "0.1",
  "eventID": "<unique_ID>",
  "eventType":
"com.oraclecloud.databaseservice.autonomous.exadata.infrastructure.instance.create.begin",
  "source": "databaseservice",
  "eventTypeVersion": "<version>",
  "eventTime": "2019-07-10T23:28:12Z",
  "contentType": "application/json",
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
  },
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_name",
    "resourceName": "my_exadata_instance",
    "resourceId": "ocid1.autonomousexainfrastructure.oc1.phx.<unique_ID>",
    "availabilityDomain": "XXIT:PHX-AD-3",
```

```
    "freeFormTags": {},
    "definedTags":{},
    "additionalDetails":{
      "cpuCoreCount": 92,
      "lifecycleState": "TERMINATED",
      "dataStorageSizeInTBs": null,
      "timeCreated": "2019-07-10T23:13:43.136Z",
      "timeUpdated": "2019-07-10T23:28:12.390Z",
      "serviceConsoleUrl": null,
      "licenseType": null,
      "dbName": null
    }
  }
}
```

Exadata Infrastructure Event Types

These are the event types that Exadata Infrastructure instances emit:

Friendly Name	Event Type
Activate Begin	`com.oraclecloud.databaseservice.activateexadatainfrastructure.begin`
Activate End	`com.oraclecloud.databaseservice.activateexadatainfrastructure.end`
Change Compartment	`com.oraclecloud.databaseservice.changeexadatainfrastructurecompartment`
Configuration File Download	`com.oraclecloud.databaseservice.downloadexadatainfrastructureconfigfile`
Create Begin	`com.oraclecloud.databaseservice.createexadatainfrastructure.begin`
Create End	`com.oraclecloud.databaseservice.createexadatainfrastructure.end`
Delete Begin	`com.oraclecloud.databaseservice.deleteexadatainfrastructure.begin`
Delete End	`com.oraclecloud.databaseservice.deleteexadatainfrastructure.end`

Friendly Name	Event Type
Update Begin	`com.oraclecloud.databaseservice.updateexadatainfrastructure.begin`
Update End	`com.oraclecloud.databaseservice.updateexadatainfrastructure.end`

Exadata Infrastructure Example

This is a reference event for Exadata Infrastructure instances:

```
{
   "cloudEventsVersion": "0.1",
   "eventID": "60600c06-d6a7-4e85-b56a-1de3e6042f57",
   "eventType": "com.oraclecloud.databaseservice.createexadatainfrastructure.begin",
   "source": "databaseservice",
   "eventTypeVersion": "<version>",
   "eventTime": "2019-08-29T21:16:04Z",
   "contentType": "application/json",
   "extensions": {
     "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
   },
   "data": {
     "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
     "compartmentName": "example_name",
     "resourceName": "my_exadata_infra",
     "resourceId": "ExadataInfra-unique_ID",
     "availabilityDomain": "all",
     "freeFormTags": {},
     "definedTags": {},
     "additionalDetails": {
       "id": "ocid1.id..oc1...<unique_ID>",
       "lifecycleState": "AVAILABLE",
       "timeCreated": "2019-08-29T12:00:00.000Z",
       "timeUpdated": "2019-08-29T12:30:00.000Z",
       "lifecycleDetails": "detail message",
       "shape": "ExadataCC.Base3.48",
       "timeZone": "US/Pacific",
       "displayName": "testDisplayName"
     }
   }
 }
```

VM Cluster Network Event Types

These are the event types that VM cluster networks emit:

Friendly Name	Event Type
Create Begin	`com.oraclecloud.databaseservice.createvmclusternetwork.begin`
Create End	`com.oraclecloud.databaseservice.createvmclusternetwork.end`
Network Validation File Download	`com.oraclecloud.databaseservice.downloadvmclusternetworkconfigfile`
Terminate Begin	`com.oraclecloud.databaseservice.deletevmclusternetwork.begin`
Terminate End	`com.oraclecloud.databaseservice.deletevmclusternetwork.end`
Update Begin	`com.oraclecloud.databaseservice.createvmclusternetwork.begin`
Update End	`com.oraclecloud.databaseservice.createvmclusternetwork.end`
Validate Begin	`com.oraclecloud.databaseservice.validatevmclusternetwork.begin`
Validate End	`com.oraclecloud.databaseservice.validatevmclusternetwork.end`

VM Cluster Network Example

This is a reference event for VM cluster networks:

```
{
   "cloudEventsVersion": "0.1",
   "eventID": "60600c06-d6a7-4e85-b56a-1de3e6042f57",
   "eventType": "com.oraclecloud.databaseservice.createvmclusternetwork.begin",
   "source": "databaseservice",
   "eventTypeVersion": "<version>",
   "eventTime": "2019-08-29T21:16:04Z",
   "contentType": "application/json",
   "extensions": {
     "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
   },
   "data": {
```

```
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_name",
    "resourceName": "my_vmcluster_network",
    "resourceId": "VmClusterNetwork-unique_ID",
    "availabilityDomain": "all",
    "freeFormTags": {},
    "definedTags": {},
    "additionalDetails": {
      "id": "ocid1.id..oc1...<unique_ID>",
      "lifecycleState": "AVAILABLE",
      "timeCreated": "2019-08-29T12:00:00.000Z",
      "timeUpdated": "2019-08-29T12:30:00.000Z",
      "lifecycleDetails": "detail message",
      "exadataInfrastructureId": "ExadataInfra-unique_ID",
      "displayName": "testDisplayName"
    }
  }
}
```

VM Cluster Event Types

These are the event types that VM clusters emit:

Friendly Name	Event Type
Change Compartment	`com.oraclecloud.databaseservice.changevmclustercompartment`
Create Begin	`com.oraclecloud.databaseservice.createvmcluster.begin`
Create End	`com.oraclecloud.databaseservice.createvmcluster.end`
Terminate Begin	`com.oraclecloud.databaseservice.deletevmcluster.begin`
Terminate End	`com.oraclecloud.databaseservice.deletevmcluster.end`
Update Begin	`com.oraclecloud.databaseservice.updatevmcluster.begin`
Update End	`com.oraclecloud.databaseservice.updatevmcluster.end`

VM Cluster Example

This is a reference event for VM clusters:

```
{
   "cloudEventsVersion": "0.1",
   "eventID": "60600c06-d6a7-4e85-b56a-1de3e6042f57",
   "eventType": "com.oraclecloud.databaseservice.createvmclusternetwork.begin",
   "source": "databaseservice",
   "eventTypeVersion": "<version>",
   "eventTime": "2019-08-29T21:16:04Z",
   "contentType": "application/json",
   "extensions": {
     "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
   },
   "data": {
     "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
     "compartmentName": "example_name",
     "resourceName": "my_vmcluster_network",
     "resourceId": "VmClusterNetwork-unique_ID",
     "availabilityDomain": "all",
     "freeFormTags": {},
     "definedTags": {},
     "additionalDetails": {
       "id": "ocid1.id..oc1...<unique_ID>",
       "lifecycleState": "AVAILABLE",
       "timeCreated": "2019-08-29T12:00:00.000Z",
       "timeUpdated": "2019-08-29T12:30:00.000Z",
       "lifecycleDetails": "detail message",
       "exadataInfrastructureId": "ExadataInfra-unique_ID",
       "displayName": "testDisplayName"
     }
   }
 }
```

Backup Destination Event Types

These are the event types that backup destinations emit:

Friendly Name	Event Type
Change Compartment	`com.oraclecloud.databaseservice.changebackupdestinationcompartment`
Create	`com.oraclecloud.databaseservice.createbackupdestination`
Terminate	`com.oraclecloud.databaseservice.deletebackupdestination`
Update	`com.oraclecloud.databaseservice.updatebackupdestination`

Backup Destination Example

This is a reference event for backup destinations:

```
{
    "cloudEventsVersion": "0.1",
    "eventID": "60600c06-d6a7-4e85-b56a-1de3e6042f57",
    "eventType": "com.oraclecloud.databaseservice.createbackupdestination",
    "source": "databaseservice",
    "eventTypeVersion": "<version>",
    "eventTime": "2019-08-29T21:16:04Z",
    "contentType": "application/json",
    "extensions": {
      "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
    },
    "data": {
      "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
      "compartmentName": "example_name",
      "resourceName": "my_backupdestination",
      "resourceId": "BackupDestination-unique_ID",
      "availabilityDomain": "all",
      "freeFormTags": {},
      "definedTags": {}
    }
  }
```

Database Node Event Types (Cloud at Customer)

These are the event types that database nodes emit:

Friendly Name	Event Type
Update Begin	`com.oraclecloud.databaseservice.dbnodeaction.begin`
Update End	`com.oraclecloud.databaseservice.dbnodeaction.end`

Database Node Example

This is a reference event for database nodes:

```
{
  "cloudEventsVersion": "0.1",
  "eventID": "60600c06-d6a7-4e85-b56a-1de3e6042f57",
  "eventType": "com.oraclecloud.databaseservice.dbnodeaction.begin",
  "source": "databaseservice",
  "eventTypeVersion": "<version>",
  "eventTime": "2019-06-27T21:16:04Z",
  "contentType": "application/json",
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
  },
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_name",
    "resourceName": "my_dbnode",
    "resourceId": "DbNode-unique_ID",
    "availabilityDomain": "all",
    "freeFormTags": {},
    "definedTags": {},
    "additionalDetails": {
      "id": "ocid1.id..oc1...<unique_ID>",
      "lifecycleState": "AVAILABLE",
      "timeCreated": "2019-08-26T12:00:00.000Z",
      "timeUpdated": "2019-08-26T12:30:00.000Z",
      "dbSystemId": "ocid1.dbsystem.oc1.phx.<unique_ID>",
      "lifecycleDetails": "detail message",
      "vmClusterId": "VmCluster-unique_ID",
      "dbHostId": "dbHost-unique_ID",
      "nodeNumber": 2,
      "powerAction": "HardReset",
      "hostName": "testHostName"
    }
```

```
  }
}
```

Database Home Event Types (Cloud at Customer)

These are the event types that Database Homes emit:

Friendly Name	Event Type
Create Begin	`com.oraclecloud.databaseservice.createdbhome.begin`
Create End	`com.oraclecloud.databaseservice.createdbhome.end`
Terminate Begin	`com.oraclecloud.databaseservice.deletedbhome.begin`
Terminate End	`com.oraclecloud.databaseservice.deletedbhome.end`

Database Home Example

This is a reference event for Database Homes:

```
{
    "cloudEventsVersion": "0.1",
    "eventID": "60600c06-d6a7-4e85-b56a-1de3e6042f57",
    "eventType": "com.oraclecloud.databaseservice.createdbhome.begin",
    "source": "databaseservice",
    "eventTypeVersion": "<version>",

      "dbHostId": "DbHost-<unique_ID>",
      "nodeNumber": null
    }
  }
}
```

Database Home Types (DB Systems)

These are the event types that Database Homes emit:

Friendly Name	Event Type
Create Begin	`com.oraclecloud.databaseservice.createdbhome.begin`
Create End	`com.oraclecloud.databaseservice.createdbhome.end`
Terminate Begin	`com.oraclecloud.databaseservice.deletedbhome.begin`
Terminate End	`com.oraclecloud.databaseservice.deletedbhome.end`

Database Home Example

This is a reference event for Database Homes:

```
{
    "cloudEventsVersion": "0.1",
    "eventID": "60600c06-d6a7-4e85-b56a-1de3e6042f57",
    "eventType": "com.oraclecloud.databaseservice.createdbhome.begin",
    "source": "databaseservice",
    "eventTypeVersion": "<version>",
    "eventTime": "2019-08-29T21:16:04Z",
    "contentType": "application/json",
    "extensions": {
      "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
    },
    "data": {
      "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
      "compartmentName": "example_name",
      "resourceName": "my_dbhome",
      "resourceId": "DbHome-unique_ID",
      "availabilityDomain": "all",
      "freeFormTags": {},
      "definedTags": {},
      "additionalDetails": {
        "id": "ocid1.id..oc1...<unique_ID>",
        "lifecycleState": "AVAILABLE",
        "timeCreated": "2019-08-29T12:00:00.000Z",
        "timeUpdated": "2019-08-29T12:30:00.000Z",
        "lifecycleDetails": "detail message",
        "dbSystemId": "DbSystem-unique_ID",
        "dbVersion": "19.0.0.0",
        "recordVersion": 4,
        "displayName": "testDisplayName"
      }
    }
  }
```

Database Event Types (DB Systems)

These are the event types that databases emit:

Friendly Name	Event Type
Automatic Backup Begin	`com.oraclecloud.databaseservice.automaticbackupdatabase.begin`
Automatic Backup End	`com.oraclecloud.databaseservice.automaticbackupdatabase.end`
Create Backup Begin	`com.oraclecloud.databaseservice.backupdatabase.begin`
Create Backup End	`com.oraclecloud.databaseservice.backupdatabase.end`
Restore Begin	`com.oraclecloud.databaseservice.restoredatabase.begin`
Restore End	`com.oraclecloud.databaseservice.restoredatabase.end`
Update Begin	`com.oraclecloud.databaseservice.updatedatabase.begin`
Update End	`com.oraclecloud.databaseservice.updatedatabase.end`

Database Example

This is a reference event for databases:

```
{
  "cloudEventsVersion": "0.1",
  "eventID": "<unique_ID>",
  "eventType": "com.oraclecloud.databaseservice.database.backup.begin",
  "source": "databaseservice",

    },
    "source": "DatabaseService"
}
```

File Storage

File Storage resources that emit events:

- File Systems and Snapshots
- Mount Targets
- Exports and Export Sets

File System Event Types

These are the event types that file systems emit:

Friendly Name	Event Type
Change File System Compartment	`com.oraclecloud.filestorage.changefilesystemcompartment`
Create File System	`com.oraclecloud.filestorage.createfilesystem`
Delete File System	`com.oraclecloud.filestorage.deletefilesystem`
Update File System	`com.oraclecloud.filestorage.updatefilesystem`

File System Example

This is a reference event for file systems:

```
{
  "eventType": "com.oraclecloud.filestorage.createfilesystem",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "filestorage",
  "eventTime": "2019-08-12T17:51:42.789Z",
  "contentType": "application/json",
  "data": {
```

```
    "compartmentId": "ocid1.compartment.oc1..<unique_id>",
    "compartmentName": "example_name",
    "resourceName": "my_filesystem",
    "resourceId": "ocid1.filesystem.oc1..<unique_id>",
    "availabilityDomain": "availability_domain",
    "freeFormTags": {
      "Department": "Finance"
    },
    "definedTags": {
      "Operations": {
        "CostCenter": "42"
      }
    }
  },
  "eventID": "unique_ID",
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_id>"
  }
}
```

Snapshot Event Types

These are the event types that snapshots emit:

Friendly Name	Event Type
Create Snapshot	`com.oraclecloud.filestorage.createsnapshot`
Delete Snapshot	`com.oraclecloud.filestorage.deletesnapshot`

Snapshot Example

This is a reference event for snapshots:

```
{
  "eventType": "com.oraclecloud.filestorage.createsnapshot",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "filestorage",
  "eventTime": "2019-08-12T17:51:42.789Z",
  "contentType": "application/json",
```

```
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_id>",
    "compartmentName": "example_name",
    "resourceName": "my_snapshot",
    "resourceId": "ocid1.snapshot.oc1..<unique_id>",
    "availabilityDomain": "availability_domain",
    "freeFormTags": {
      "Department": "Finance"
    },
    "definedTags": {
      "Operations": {
        "CostCenter": "42"
      }
    }
  },
  "eventID": "unique_ID",
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_id>"
  }
}
```

Mount Target Event Types

These are the event types that mount targets emit:

Friendly Name	Event Type
Change Mount Target Compartment	`com.oraclecloud.filestorage.changemounttargetcompartment`
Create Mount Target	`com.oraclecloud.filestorage.createmounttarget`
Delete Mount Target	`com.oraclecloud.filestorage.deletemounttarget`
Update Mount Target	`com.oraclecloud.filestorage.updatemounttarget`

Mount Target Example

This is a reference event for mount targets:

```
{
  "eventType": "com.oraclecloud.filestorage.createmounttarget",
```

```
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "filestorage",
  "eventTime": "2019-08-12T17:51:42.789Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_id>",
    "compartmentName": "example_name",
    "resourceName": "my_mounttarget",
    "resourceId": "ocid1.mounttarget.oc1..<unique_id>",
    "availabilityDomain": "availability_domain",
    "freeFormTags": {
      "Department": "Finance"
    },
    "definedTags": {
      "Operations": {
        "CostCenter": "42"
      }
    }
  },
  "eventID": "unique_ID",
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_id>"
  }
}
```

Export Event Types

These are the event types that exports emit:

Friendly Name	Event Type
Create Export	`com.oraclecloud.filestorage.createexport`
Delete Export	`com.oraclecloud.filestorage.deleteexport`
Update Export	`com.oraclecloud.filestorage.updateexport`

Export Example

This is a reference event for exports:

```
{
  "eventType": "com.oraclecloud.filestorage.createexport",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "filestorage",
  "eventTime": "2019-08-12T17:51:42.789Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_id>",
    "compartmentName": "example_name",
    "resourceName": "my_export",
    "resourceId": "ocid1.export.oc1..<unique_id>",
    "availabilityDomain": "availability_domain",
    "freeFormTags": {
      "Department": "Finance"
    },
    "definedTags": {
      "Operations": {
        "CostCenter": "42"
      }
    }
  },
  "eventID": "unique_ID",
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_id>"
  }
}
```

Export Set Event Types

These are the event types that export sets emit:

Friendly Name	Event Type
Delete Export Set	`com.oraclecloud.filestorage.deleteexportset`
Update Export Set	`com.oraclecloud.filestorage.updateexportset`

Export Set Example

This is a reference event for export sets :

```
{
  "eventType": "com.oraclecloud.filestorage.updateexportset",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "filestorage",
  "eventTime": "2019-08-12T17:51:42.789Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_id>",
    "compartmentName": "example_name",
    "resourceName": "my_exportset",
    "resourceId": "ocid1.exportset.oc1..<unique_id>",
    "availabilityDomain": "availability_domain",
    "freeFormTags": {
      "Department": "Finance"
    },
    "definedTags": {
      "Operations": {
        "CostCenter": "42"
      }
    }
  },
  "eventID": "unique_ID",
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_id>"
  }
}
```

Functions

Functions resources that emit events:

- Application Event Types
- Function Event Types

Application Event Types

These are the event types that applications emit:

Friendly Name	Event Type
Change Application Compartment	`com.oraclecloud.functions.changeapplicationcompartment`
Create Application	`com.oraclecloud.functions.createapplication`
Delete Application	`com.oraclecloud.functions.deleteapplication`
Update Application	`com.oraclecloud.functions.updateapplication`

Application Example

This is an example event for applications:

```
{
  "eventType": "com.oraclecloud.functions.createapplication",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "functions",
  "eventTime": "2019-07-22T09:33:44.754Z",
  "contentType": "application/json",
  "data":{
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "my_compartment",
    "resourceName": "my-application",
    "resourceId": "ocid1.fnapp.oc1.phx.<unique_ID>",
    "availabilityDomain": "AD3"
  },
  "eventID": "<unique_ID>",
  "extensions":{
    "compartmentId":"ocid1.compartment.oc1..<unique_ID>"
  }
}
```

Function Event Types

These are the event types that functions emit:

Friendly Name	Event Type
Create Function	`com.oraclecloud.functions.createfunction`
Delete Function	`com.oraclecloud.functions.deletefunction`
Update Function	`com.oraclecloud.functions.updatefunction`

Function Example

This is an example event for functions:

```
{
  "eventType": "com.oraclecloud.functions.createfunction",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "functions",
  "eventTime": "2019-07-22T09:33:44.754Z",
  "contentType": "application/json",
  "data":{

```

IAM

IAM resources that emit events:

- Authentication Policy Event Types
- Credentials Event Types
- Dynamic Group Event Types

- Group Event Types
- Identity Provider Event Types
- Multi-Factor Authentication TOTP Device Event Types
- Policy Event Types
- User Event Types

Authentication Policy Event Types

This is the event type that authentication policies emit:

Friendly Name	Event Type
Update Authentication Policy	`com.oraclecloud.identityControlPlane.UpdateAuthenticationPolicy`

Authentication Policy Example

This is a reference event for authentication policy events:

```
{
  "eventType": "com.oraclecloud.identityControlPlane.UpdateAuthenticationPolicy",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "identityControlPlane",
  "eventID": "<unique_ID>",
  "eventTime": "2019-10-21T17:23:54.095Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_name",
    "resourceName": "my_compartment",
    "resourceId": "ocid1.compartment.oc1..<unique_ID>",
    "availabilityDomain": "availability_domain",
    "freeFormTags": {
      "Department": "Finance"
    },
    "definedTags": {
      "Operations": {
        "CostCenter": "42"
      }
```

```
    }
  },
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
  }
}
```

Credentials Event Types

These are the event types that credentials emit.

Friendly Name	Event Type
Create Auth Token	com.oraclecloud.identityControlPlane.CreateAuthToken
Create Customer Secret Key	com.oraclecloud.identityControlPlane.CreateCustomerSecretKey
Create or Reset Password	com.oraclecloud.identityControlPlane.CreateOrResetPassword
Create SMTP Credential	com.oraclecloud.identityControlPlane.CreateSmtpCredential
Create Swift Password	com.oraclecloud.identityControlPlane.CreateSwiftPassword
DeleteAPI Key	com.oraclecloud.identityControlPlane.DeleteApiKey
Delete Auth Token	com.oraclecloud.identityControlPlane.DeleteAuthToken
Delete Customer Secret Key	com.oraclecloud.identityControlPlane.DeleteCustomerSecretKey
Delete SMTP Credential	com.oraclecloud.identityControlPlane.DeleteSmtpCredential
Delete Swift Password	com.oraclecloud.identityControlPlane.DeleteSwiftPassword
Update Auth Token	com.oraclecloud.identityControlPlane.UpdateAuthToken
Update Authentication Policy	com.oraclecloud.identityControlPlane.UpdateAuthenticationPolicy
Update Customer Secret Key	com.oraclecloud.identityControlPlane.UpdateCustomerSecretKey

Friendly Name	Event Type
Update SMTP Credential	`com.oraclecloud.identityControlPlane.UpdateSmtpCredential`
UpdateSwift Password	`com.oraclecloud.identityControlPlane.UpdateSwiftPassword`
Upload API KEY	`com.oraclecloud.identityControlPlane.UploadApiKey`

Credentials Example

This is a reference event for most credential events (create or reset password don't include additional details):

```
{
  "eventType": "com.oraclecloud.identityControlPlane.DeleteApiKey",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "identityControlPlane",
  "eventID": "<unique_ID>",
  "eventTime": "2019-10-21T17:23:54.095Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_name",
    "resourceName": "my_user",
    "resourceId": "<unique_ID>",
    "availabilityDomain": "availability_domain",
    "freeFormTags": {
      "Department": "Finance"
    },
    "definedTags": {
      "Operations": {
        "CostCenter": "42"
      }
    },
    "additionalDetails": {
      "userId": "ocid1.user.oc1..<unique_ID>"
    }
  },
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
```

```
  }
}
```

Dynamic Group Event Types

These are the event types that dynamic groups emit.

Friendly Name	Event Type
Create Dynamic Group	`com.oraclecloud.identityControlPlane.CreateDynamicGroup`
Delete Dynamic Group	`com.oraclecloud.identityControlPlane.DeleteDynamicGroup`
Update Dynamic Group	`com.oraclecloud.identityControlPlane.UpdateDynamicGroup`

Dynamic Group Example

This is a reference event for dynamic groups:

```
{
  "eventType": "com.oraclecloud.identityControlPlane.CreateDynamicGroup",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "identityControlPlane",
  "eventID": "<unique_ID>",
  "eventTime": "2019-10-21T17:23:54.095Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_name",
    "resourceName": "my_dynamicgroup",
    "resourceId": "ocid1.dynamicgroup.oc1..<unique_ID>",
    "availabilityDomain": "availability_domain",
    "freeFormTags": {
      "Department": "Finance"
    },
    "definedTags": {
      "Operations": {
        "CostCenter": "42"
      }
    }
```

```
  },
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
  }
}
```

Group Event Types

These are the event types that groups emit.

Friendly Name	Event Type
Add User to Group	`com.oraclecloud.identityControlPlane.AddUserToGroup`
Create Group	`com.oraclecloud.identityControlPlane.CreateGroup`
Delete Group	`com.oraclecloud.identityControlPlane.DeleteGroup`
Remove User From Group	`com.oraclecloud.identityControlPlane.RemoveUserFromGroup`
Update Group	`com.oraclecloud.identityControlPlane.UpdateGroup`

Group Example

This is a reference event for some groups (create, delete, and update events don't include additional details):

```
{
  "eventType": "com.oraclecloud.identityControlPlane.AddUserToGroup",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "identityControlPlane",
  "eventID": "<unique_ID>",
  "eventTime": "2019-10-21T17:23:54.095Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_name",
    "resourceName": "my_group",
    "resourceId": "ocid1.groupmembership.oc1.<unique_ID>",
    "availabilityDomain": "availability_domain",
```

```
    "freeFormTags": {
      "Department": "Finance"
    },
    "definedTags": {
      "Operations": {
        "CostCenter": "42"
      }
    },
    "additionalDetails": {
      "userId": "ocid1.user.oc1..<unique_ID>",
      "groupId": "ocid1.group.oc1..<unique_ID>"
    }
  },
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
  }
}
```

Identity Provider Event Types

These are the event types that identity providers emit.

Friendly Name	Event Type
Add User to IdP Group	`com.oraclecloud.identityControlPlane.AddUserToIdpGroup`
Create Identity Provider	`com.oraclecloud.identityControlPlane.CreateIdentityProvider`
Create Identity Provider Group	`com.oraclecloud.identityControlPlane.CreateIdentityProviderGroup`
Create IdP Group Mapping	`com.oraclecloud.identityControlPlane.CreateIdpGroupMapping`
Create IdP User	`com.oraclecloud.identityControlPlane.CreateIdpUser`
Delete Identity Provider	`com.oraclecloud.identityControlPlane.DeleteIdentityProvider`
Delete Identity Provider Group	`com.oraclecloud.identityControlPlane.DeleteIdentityProviderGroup`

Friendly Name	Event Type
Delete IdP Group Mapping	`com.oraclecloud.identityControlPlane.DeleteIdpGroupMapping`
Delete IdP User	`com.oraclecloud.identityControlPlane.DeleteIdpUser`
Remove User From IdP Group	`com.oraclecloud.identityControlPlane.RemoveUserFromIdpGroup`
Reset IdP SCIM Client	`com.oraclecloud.identityControlPlane.ResetIdpScimClient`
Update Identity Provider	`com.oraclecloud.identityControlPlane.UpdateIdentityProvider`
Update IdP Group Mapping	`com.oraclecloud.identityControlPlane.UpdateIdpGroupMapping`

Identity Provider Example

The following reference events are for identity provider events that include additional details. Some identity providers events do not include additional details. These events are create, delete, and update identity providers, as well as delete identity provider group, delete IdP user, and reset IdP SCIM.

This is a reference event for adding and removing users from IdP groups:

```
{
  "eventType": "com.oraclecloud.identityControlPlane.AddUserToIdpGroup",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "identityControlPlane",
  "eventID": "<unique_ID>",
  "eventTime": "2019-10-21T17:23:54.095Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_name",
    "resourceName": "my_group",
    "resourceId": "ocid1.idpgroup.oc1..<unique_ID>",
    "availabilityDomain": "availability_domain",
    "freeFormTags": {
      "Department": "Finance"
    },
    "definedTags": {
```

```
      "Operations": {
        "CostCenter": "42"
      }
    },
    "additionalDetails": {
      "userId": "ocid1.user.oc1..<unique_ID>"
    }
  },
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
  }
}
```

This is a reference event for create, update, and delete IdP group mapping:

```
{
  "eventType": "com.oraclecloud.identityControlPlane.CreateIdpGroupMapping",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "identityControlPlane",
  "eventID": "<unique_ID>",
  "eventTime": "2019-10-21T17:23:54.095Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_name",
    "resourceName": "my_identityprovider",
    "resourceId": "ocid1.idpgroupmapping.oc1..<unique_ID>",
    "availabilityDomain": "availability_domain",
    "freeFormTags": {
      "Department": "Finance"
    },
    "definedTags": {
      "Operations": {
        "CostCenter": "42"
      }
    },
    "additionalDetails": {
      "idpGroupName": "my_group",
      "groupId": "ocid1.group.oc1..<unique_ID>"
    }
  },
  "extensions": {
```

```
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
  }
}
```

This is a reference event for create IdP user and create IdP group:

```
{
  "eventType": "com.oraclecloud.identityControlPlane.CreateIdentityProviderGroup",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "identityControlPlane",
  "eventID": "<unique_ID>",
  "eventTime": "2019-10-21T17:23:54.095Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_name",
    "resourceName": "my_idpgroup",
    "resourceId": "ocid1.idpgroup.oc1..<unique_ID>",
    "availabilityDomain": "availability_domain",
    "freeFormTags": {
      "Department": "Finance"
    },
    "definedTags": {
      "Operations": {
        "CostCenter": "42"
      }
    },
    "additionalDetails": {
      "externalIdentifier": "my_externalidentifier"
    }
  },
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
  }
}
```

Multi-Factor Authentication TOTP Device Event Types

These are the event types that MFA TOTP devices emit.

Friendly Name	Event Type
Activate MFA TOTP Device	`com.oraclecloud.identityControlPlane.ActivateMfaTotpDevice`
Create MFA TOTP Device	`com.oraclecloud.identityControlPlane.CreateMfaTotpDevice`
Delete MFA TOTP Device	`com.oraclecloud.identityControlPlane.DeleteMfaTotpDevice`
Generate MFA TOTP Device Seed	`com.oraclecloud.identityControlPlane.GenerateTotpSeed`

Multi-Factor Authentication TOTP Devices Example

This is a reference event for MFA TOTP Devices:

```
{
  "eventType": "com.oraclecloud.identityControlPlane.CreateMfaTotpDevice",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "identityControlPlane",
  "eventID": "<unique_ID>",
  "eventTime": "2019-10-21T17:23:54.095Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_name",
    "resourceName": "my_user",
    "resourceId": "ocid1.credential.oc1..<unique_ID>",
    "availabilityDomain": "availability_domain",
    "freeFormTags": {
      "Department": "Finance"
    },
    "definedTags": {
      "Operations": {
        "CostCenter": "42"
      }
    },
    "additionalDetails": {
      "userId": "ocid1.user.oc1..<unique_ID>"
    }
  },
  "extensions": {
```

```
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
  }
}
```

Policy Event Types

These are the event types that policies emit.

Friendly Name	Event Type
Create Policy	`com.oraclecloud.identityControlPlane.CreatePolicy`
Delete Policy	`com.oraclecloud.identityControlPlane.DeletePolicy`
Update Policy	`com.oraclecloud.identityControlPlane.UpdatePolicy`

Policy Example

This is a reference event for policies:

```
{
  "eventType": "com.oraclecloud.identityControlPlane.CreatePolicy",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "identityControlPlane",
  "eventID": "<unique_ID>",
  "eventTime": "2019-10-21T17:23:54.095Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_name",
    "resourceName": "my_policy",
    "resourceId": "ocid1.policy.oc1..<unique_ID>",
    "availabilityDomain": "availability_domain",
    "freeFormTags": {
      "Department": "Finance"
    },
    "definedTags": {
      "Operations": {
        "CostCenter": "42"
      }
```

```
    }
  },
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
  }
}
```

User Event Types

These are the event types that users emit.

Friendly Name	Event Type
Create User	`com.oraclecloud.identityControlPlane.CreateUser`
Delete User	`com.oraclecloud.identityControlPlane.DeleteUser`
Update User	`com.oraclecloud.identityControlPlane.UpdateUser`
Update User Capabilities	`com.oraclecloud.identityControlPlane.UpdateUserCapabilities`
Update User State	`com.oraclecloud.identityControlPlane.UpdateUserState`

User Example

This is a reference event for users:

```
{
  "eventType": "com.oraclecloud.identityControlPlane.CreateUser",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "identityControlPlane",
  "eventID": "<unique_ID>",
  "eventTime": "2019-10-21T17:23:54.095Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_name",
    "resourceName": "my_user",
    "resourceId": "ocid1.user.oc1..<unique_ID>",
    "availabilityDomain": "availability_domain",
```

```
    "freeFormTags": {
      "Department": "Finance"
    },
    "definedTags": {
      "Operations": {
        "CostCenter": "42"
      }
    }
  },
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
  }
}
```

Integration

For details about events emitted by Oracle Integration, see Automating with Events.

Networking

Networking resources that emit events:

- NAT gateways
- Route tables
- Security lists
- Service gateways
- Virtual cloud networks (VCNs)

NAT Gateway Event Types

These are the event types that NAT gateways emit:

Friendly Name	Event Type
Create NAT Gateway	`com.oraclecloud.natgateway.createnatgateway`
Delete NAT Gateway	`com.oraclecloud.natgateway.deletenatgateway`
Update NAT Gateway	`com.oraclecloud.natgateway.updatenatgateway`
Change NAT Gateway Compartment	`com.oraclecloud.natgateway.changenatgatewaycompartment`

NAT Gateway Example

This is a reference event for NAT gateways:

```
{
  "eventType": "com.oraclecloud.natgateway.createnatgateway",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "natgateway",
  "eventTime": "2019-08-12T17:51:42.789Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oci..<unique_ID>",
    "compartmentName": "example_name",
    "resourceName": "example_name",
    "resourceId": "ocid1.natgateway.oci.phx.<unique_ID>",
    "availabilityDomain": "XXIT:PHX-AD-1",
    "freeFormTags": {
      "Department": "Finance"
    },
    "definedTags": {
      "Operations": {
        "CostCenter": "42"
      }
    }
  },
  "eventID": "<unique_ID>",
  "extensions": {
```

```
    "compartmentId": "ocid1.compartment.oci..<unique_ID>"
  }
}
```

Route Table Event Types

These are the event types that route tables emit:

Friendly Name	Event Type
Create Route Table	`com.oraclecloud.virtualnetwork.createroutetable`
Delete Route Table	`com.oraclecloud.virtualnetwork.deleteroutetable`
Update Route Table	`com.oraclecloud.virtualnetwork.updateroutetable`
Change Route Table Compartment	`com.oraclecloud.virtualnetwork.changeroutetablecompartment`

Route Table Example

This is a reference event for route tables:

```
{
  "eventType": "com.oraclecloud.virtualnetwork.createroutetable",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "virtualNetwork",
  "eventTime": "2019-08-12T17:51:42.789Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oci..<unique_ID>",
    "compartmentName": "example_name",
    "resourceName": "example_name",
    "resourceId": "ocid1.routetable.oci.phx.<unique_ID>",
    "availabilityDomain": "XXIT:PHX-AD-1",
    "freeFormTags": {
      "Department": "Finance"
    },
    "definedTags": {
      "Operations": {
        "CostCenter": "42"
```

```
      }
    }
  },
  "eventID": "<unique_ID>",
  "extensions": {
    "compartmentId": "ocid1.compartment.oci..<unique_ID>"
  }
}
```

Security List Event Types

These are the event types that security lists emit:

Friendly Name	Event Type
Create Security List	`com.oraclecloud.virtualnetwork.createsecuritylist`
Delete Security List	`com.oraclecloud.virtualnetwork.deletesecuritylist`
Update Security List	`com.oraclecloud.virtualnetwork.updatesecuritylist`
Change Security List Compartment	`com.oraclecloud.virtualnetwork.changesecuritylistcompartment`

Security List Example

This is a reference event for security lists:

```
{
  "eventType": "com.oraclecloud.virtualnetwork.createsecuritylist",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "virtualNetwork",
  "eventTime": "2019-08-12T17:51:42.789Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oci..<unique_ID>",
    "compartmentName": "example_name",
    "resourceName": "example_name",
    "resourceId": "ocid1.securitylist.oci.phx.<unique_ID>",
    "availabilityDomain": "XXIT:PHX-AD-1",
    "freeFormTags": {
```

```
      "Department": "Finance"
    },
    "definedTags": {
      "Operations": {
        "CostCenter": "42"
      }
    }
  },
  "eventID": "<unique_ID>",
  "extensions": {
    "compartmentId": "ocid1.compartment.oci..<unique_ID>"
  }
}
```

Service Gateway Event Types

These are the event types that service gateways emit:

Friendly Name	Event Type
Create Service Gateway	`com.oraclecloud.servicegateway.createservicegateway`
Delete Service Gateway Start	`com.oraclecloud.servicegateway.deleteservicegateway.begin`
Delete Service Gateway End	`com.oraclecloud.servicegateway.deleteservicegateway.end`
Update Service Gateway	`com.oraclecloud.servicegateway.updateservicegateway`
Change Service Gateway Compartment	`com.oraclecloud.servicegateway.changeservicegatewaycompartment`
Attach Service	`com.oraclecloud.servicegateway.attachserviceid`
Detach Service	`com.oraclecloud.servicegateway.detachserviceid`

Service Gateway Example

This is a reference event for service gateways:

```
{
  "eventType": "com.oraclecloud.servicegateway.createservicegateway",
```

```
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "servicegateway",
  "eventTime": "2019-08-12T17:51:42.789Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oci..<unique_ID>",
    "compartmentName": "example_name",
    "resourceName": "example_name",
    "resourceId": "ocid1.servicegateway.oci.phx.<unique_ID>",
    "availabilityDomain": "XXIT:PHX-AD-1",
    "freeFormTags": {
      "Department": "Finance"
    },
    "definedTags": {
      "Operations": {
        "CostCenter": "42"
      }
    }
  },
  "eventID": "<unique_ID>",
  "extensions": {
    "compartmentId": "ocid1.compartment.oci..<unique_ID>"
  }
}
```

VCN Event Types

These are the event types that VCNs emit:

Friendly Name	Event Type
Create VCN	`com.oraclecloud.virtualnetwork.createvcn`
Delete VCN	`com.oraclecloud.virtualnetwork.deletevcn`
Update VCN	`com.oraclecloud.virtualnetwork.updatevcn`

VCN Example

This is a reference event for VCNs:

```
{
  "eventType": "com.oraclecloud.virtualnetwork.createvcn",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "virtualNetwork",
  "eventTime": "2019-08-12T17:51:42.789Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oci..<unique_ID>",
    "compartmentName": "example_name",
    "resourceName": "example_name",
    "resourceId": "ocid1.vcn.oci.phx.<unique_ID>",
    "availabilityDomain": "XXIT:PHX-AD-1",
    "freeFormTags": {
      "Department": "Finance"
    },
    "definedTags": {
      "Operations": {
        "CostCenter": "42"
      }
    }
  },
  "eventID": "<unique_ID>",
  "extensions": {
    "compartmentId": "ocid1.compartment.oci..<unique_ID>"
  }
}
```

Notifications

Notifications resources that emit events:

- Subscriptions
- Topics

Subscriptions Event Types

These are the event types that subscriptions emit:

Friendly Name	Event Type
Create Subscription	`com.oraclecloud.notification.createsubscription`
Delete Subscription	`com.oraclecloud.notification.deletesubscription`
Move Subscription	`com.oraclecloud.notification.movesubscription`
Resend Subscription Confirmation	`com.oraclecloud.notification.resendsubscriptionconfirmation`
Update Subscription	`com.oraclecloud.notification.updatesubscription`

Subscription Example

This is a reference event for subscriptions:

```
{
  "eventType": "com.oraclecloud.notification.createsubscription",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "notification",
  "eventTime": "2019-01-10T21:19:24Z",
  "contentType": "application/json",
  "data":{
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "my_compartment",
    "resourceName": "ons-subscription",
    "resourceId": "ocid1.onssubscription.oc1..<unique_ID>",
    "availabilityDomain": "AD3"
  },
  "eventID": "<unique_ID>",
  "extensions":{
    "compartmentId":"ocid1.compartment.oc1..<unique_ID>"
  }
}
```

Topics Event Types

These are the event types that topics emit:

Friendly Name	Event Type
Create Topic	`com.oraclecloud.notification.createtopic`
Delete Topic	`com.oraclecloud.notification.deletetopic`
Move Topic	`com.oraclecloud.notification.movetopic`
Update Topic	`com.oraclecloud.notification.updatetopic`

Topic Example

This is a reference event for topics:

```
{
  "eventType": "com.oraclecloud.notification.createtopic",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "notification",
  "eventTime": "2019-01-10T21:19:24Z",
  "contentType": "application/json",
  "data":{
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "my_compartment",
    "resourceName": "my_topic",
    "resourceId": "ocid1.onstopic.oc1..<unique_ID>",
    "availabilityDomain": "AD3"
  },
  "eventID": "<unique_ID>",
  "extensions":{
    "compartmentId":"ocid1.compartment.oc1..<unique_ID>"
  }
}
```

Object Storage

Object Storage resources that emit events:

- Buckets
- Objects

Buckets Event Types

These are the event types that buckets emit:

Friendly Name	Event Type
Create Bucket	`com.oraclecloud.objectstorage.createbucket`
Delete Bucket	`com.oraclecloud.objectstorage.deletebucket`
Update Bucket	`com.oraclecloud.objectstorage.updatebucket`

Bucket Example

This is an example event for buckets:

```
{
  "cloudEventsVersion": "0.1",
  "eventID": "<unique_ID>",
  "eventType": "com.oraclecloud.objectstorage.createbucket",
  "source": "objectstorage",
  "eventTypeVersion": "2.0",
  "eventTime": "2019-01-10T21:19:24Z",
  "contentType": "application/json",
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
  },
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_name",
    "resourceName": "my_bucket",
    "resourceId": "ocid1.compartment.oc1..<unique_ID>",
    "availabilityDomain": "all",
    "freeFormTags": {
      "Department": "Finance"
    },
    "definedTags": {
      "Operations": {
        "CostCenter": "42"
      }
    },
    "additionalDetails": {
```

```
      "namespace": "example_namespace",
      "publicAccessType": "NoPublicAccess",
      "eTag": "f8ffb6e9-f602-460f-a6c0-00b5abfa24c7"
    }
  }
}
```

Objects Event Types

Events for objects are handled differently than other resources. Objects do not emit events by default. Use the Console, CLI, or API to enable a bucket to emit events for object state changes. You can enable events for object state changes during or after bucket creation.

These are the event types that objects emit:

Friendly Name	Event Type
Create Object	`com.oraclecloud.objectstorage.createobject`
Delete Object	`com.oraclecloud.objectstorage.deleteobject`
Update Object	`com.oraclecloud.objectstorage.updateobject`

Object Example

This is an example event for objects:

```
{
  "cloudEventsVersion": "0.1",
  "eventID": "<unique_ID>",
  "eventType": "com.oraclecloud.objectstorage.createobject",
  "source": "objectstorage",
  "eventTypeVersion": "2.0",
  "eventTime": "2019-07-10T13:37:11Z",
  "contentType": "application/json",
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
  },
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "Example_Compartment,
```

```
    "resourceName": "v1/log/10.0.6.166",
    "resourceId": "",
    "availabilityDomain": "all",
    "additionalDetails": {
      "eTag": "8162db5b-50d7-4947-a576-4401798ed2fa",
      "namespace": "my_namespace",
      "archivalState": null,
      "bucketName": "my_bucket",
      "bucketId": "ocid1.bucket.oc1.<unique_ID>"
    }
  }
}
```

Resource Manager

Resource Manager resources that emit events:

- Jobs
- Stacks

Job Event Types

These are the event types that jobs emit:

Friendly Name	Event Type
Cancel Job	`com.oraclecloud.oracleresourcemanager.canceljob`
Create Job Begin	`com.oraclecloud.oracleresourcemanager.createjob.begin`
Create Job End	`com.oraclecloud.oracleresourcemanager.createjob.end`
Update Job	`com.oraclecloud.oracleresourcemanager.updatejob`

This is a reference event for jobs:

```
{
  "eventType": "com.oraclecloud.oracleresourcemanager.updateJob",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
```

```
  "source": "OracleResourceManager",
  "eventTime": "2019-07-23T01:46:37.606Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_compartment",
    "resourceName": "example_name",
    "resourceId": "ocid1.ormjob.oc1.phx.<unique_ID>",
    "availabilityDomain": "availability_domain"
  },
  "eventID": "<unique_ID>",
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
  }
}
```

Stack Event Types

These are the event types that stacks emit:

Friendly Name	Event Type
Change Compartment Begin	`com.oraclecloud.oracleresourcemanager.changestackcompartment.begin`
Change Compartment End	`com.oraclecloud.oracleresourcemanager.changestackcompartment.end`
Create Stack	`com.oraclecloud.oracleresourcemanager.createstack`
Delete Stack	`com.oraclecloud.oracleresourcemanager.deletestack`
Update Stack	`com.oraclecloud.oracleresourcemanager.updatestack`

This is a reference event for stacks:

```
{
  "eventType": "com.oraclecloud.oracleresourcemanager.createstack",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "OracleResourceManager",
  "eventTime": "2019-07-23T01:32:10.866Z",
```

```
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_compartment",
    "resourceName": "example_name",
    "resourceId": "ocid1.ormstack.oc1.phx.<unique_ID>",
    "availabilityDomain": "availability_domain"
  },
  "eventID": "<unique_ID>",
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
  }
}
```

Events Metrics

You can monitor performance of your rules by using metrics, alarms, and notifications. This topic describes the metrics emitted by the metric namespace `oci_cloudevents` (the Events service).

Resources: rules. Also measures data for events, which are not resources.

Prerequisites

IAM policies: To monitor resources, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.

Overview of the Events Service Metrics

You create rules that specify which events should be delivered to other services for processing. This delivery creates the automation in your tenancy. A rule identifies an event

pattern to match and specifies other services to deliver matching events to. Metrics help you measure the success of the rules you create (in terms of pattern matching and delivery) and the quality and scope of the emitted events in your tenancy. For more information, see Overview of Events.

Available Metrics: oci_cloudevents

The metrics listed in the following table are automatically available for rules you create. You do not need to enable monitoring to get these metrics.

Each metric includes one or more of the following dimensions:

RESOURCEID

The OCID of the rule or compartment to which the metric applies.

EVENTTYPE

The type of event emitted by a resource.

RESOURCEDISPLAYNAME

The name of the rule.

ACTIONTYPE

One or more of the following types of resources that receives an event from the Events service.

- Notifications
- Streaming
- Functions

Metric	Metric Display Name	Unit	Description	Dimensions
`PublishedEvents`	Events Emitted	`count`	Total number of events emitted by resources in a compartment.	`eventType` `resourceId`
`MatchedEvents`	Events Matched	`count`	If you view the default chart from a rule, this metric provides the total number of events matched for the rule. If you view the chart from the Service Metrics page, this metric gives a total number of matched events for all the rules in a compartment.	`resourceDisplayName` `resourceId`

Metric	Metric Display Name	Unit	Description	Dimensions
`DeliverySucceedEvents`	Events Delivered	`count`	If you view the default chart from a rule, this metric provides the total number of successful deliveries to actions for the rule. If you view the chart from the Service Metrics page, this metric gives a total number of successful deliveries to actions for all the rules in a compartment.	`actionType` `resourceDisplayName` `resourceId`

Metric	Metric Display Name	Unit	Description	Dimensions
DeliveryFailedEvents	Delivery Failure	count	If you view the default chart from a rule, this metric provides the total number of unsuccessful deliveries to actions for the rule. If you view the chart from the Service Metrics page, this metric gives a total number of unsuccessful deliveries to actions for all the rules in a compartment.	

Using the Console

To view default metric charts for a rule

1. Open the navigation menu. Under the **Solutions and Platform** group, go to **Application Integration** and click **Events Service**.

2. Choose the **Compartment** that contains the rule you want to view, and then click the rule's name.
3. Click **Metrics**.
   The **Metrics** page displays a default set of charts for the current rule.

For more information about monitoring metrics and using alarms, see Monitoring Overview. For information about notifications for alarms, see Notifications Overview.

To view default metric charts for a compartment

1. Open the navigation menu. Under the **Solutions and Platform** group, go to **Application Integration** and click **Events Service**.
2. Choose the **Compartment** that contains the rules you want to monitor.
3. Click **Metrics**.
   The **Metrics** page displays a default set of charts for the current compartment.

For more information about monitoring metrics and using alarms, see Monitoring Overview. For information about notifications for alarms, see Notifications Overview.

Using the API

Use the following APIs for monitoring:

- Monitoring API for metrics and alarms
- Notifications API for notifications (used with alarms)

CHAPTER 15 File Storage

This chapter explains how to create file systems, how to manage them, and how to mount them to write files.

Overview of File Storage

Oracle Cloud Infrastructure File Storage service provides a durable, scalable, secure, enterprise-grade network file system. You can connect to a File Storage service file system from any bare metal, virtual machine, or container instance in your Virtual Cloud Network (VCN). You can also access a file system from outside the VCN using Oracle Cloud Infrastructure FastConnect and Internet Protocol security (IPSec) virtual private network (VPN).

Large Compute clusters of thousands of instances can use the File Storage service for high-performance shared storage. Storage provisioning is fully managed and automatic as your use scales from a single byte to exabytes without upfront provisioning. You have redundant storage for resilient data protection.

The File Storage service supports the Network File System version 3.0 (NFSv3) protocol. The service supports the Network Lock Manager (NLM) protocol for file locking functionality.

Use the File Storage service when your application or workload includes big data and analytics, media processing, or content management, and you require Portable Operating System Interface (POSIX)-compliant file system access semantics and concurrently accessible storage. The File Storage service is designed to meet the needs of applications and users that need an enterprise file system across a wide range of use cases, including the following:

- **General Purpose File Storage:** Access to an unlimited pool of file systems to manage growth of structured and unstructured data.
- **Big Data and Analytics:** Run analytic workloads and use shared file systems to store persistent data.

- **Lift and Shift of Enterprise Applications:** Migrate existing Oracle applications that need NFS storage, such as Oracle E-Business Suite and PeopleSoft.
- **Databases and Transactional Applications:** Run test and development workloads with Oracle, MySQL, or other databases.
- **Backups, Business Continuity, and Disaster Recovery:** Host a secondary copy of relevant file systems from on premises to the cloud for backup and disaster recovery purposes.
- **MicroServices and Docker:** Deliver stateful persistence for containers. Easily scale as your container-based environments grow.

Tip

Watch a video introduction to the service and its capabilities.

Note

File Storage is not available in Oracle Cloud Infrastructure Government Cloudrealms.

File Systems Concepts

Using the File Storage service requires an understanding of the following concepts, including some that pertain to Oracle Cloud Infrastructure Networking:

Mount Target

An NFS endpoint that lives in a subnet of your choice and is highly available. The mount target provides the IP address or DNS name that is used in the mount command when connecting NFS clients to a file system. A single mount target can export many file systems. By default, you can create two mount targets per account per availability domain, but you can request an increase. See Service Limits for a list of applicable limits and instructions for requesting a limit increase. See Managing Mount Targets for more information about working with this resource.

Export

Exports control how NFS clients access file systems when they connect to a mount target. File systems are exported (made available) through mount targets. Each mount target maintains an export set which contains one or many exports. A file system must have at least one export in one mount target in order for instances to mount the file system. The information used by an export includes the file system OCID, mount target OCID, export set OCID, export path, and client export options. For more information, see Managing Mount Targets.

Export Set

Collection of one or more exports that control what file systems the mount target exports using NFSv3 protocol and how those file systems are found using the NFS mount protocol. Each mount target has an export set. Each file system associated with the mount target has at least one export in the export set.

Export Path

A path that is specified when an export is created. It uniquely identifies the file system within the mount target, letting you associate up to 100 file systems to a single mount target. This path is unrelated to any path within the file system itself, or the client mount point path.

The File Storage service adds an export that pairs the file system's Oracle Cloud Identifier (OCID) and path.

See Paths in File Systems for more information.

Export Options

NFS export options are a set of parameters within the export that specify the level of access granted to NFS clients when they connect to a mount target. An NFS export options entry within an export defines access for a single IP address or CIDR block range. For more information, see Working with NFS Export Options.

Virtual Cloud Network (VCN)

A private network that you set up in the Oracle data centers, with firewall rules and specific types of communication gateways that you can choose to use. A VCN covers a single, contiguous IPv4 CIDR block of your choice. For more information about VCNs, see VCNs and Subnets in the Oracle Cloud Infrastructure Networking documentation.

You can set up a service gateway and give your VCN private access to the File Storage service. A service gateway can be used only by resources in the gateway's own VCN. Traffic to the service will not travel through the internet. When creating the service gateway, enable the service label called **All <region> Services in Oracle Services Network**. It includes the File Storage service. Be sure to update route tables for any subnets that need to access File Storage through the service gateway.

For more information and detailed instructions, see Setting Up a Service Gateway in the Console

Subnets

Subdivisions you define in a VCN (for example, 10.0.0.0/24 and 10.0.1.0/24). Subnets contain virtual network interface cards (VNICs), which attach to instances. A subnet can span a region or exist in a single availability domain . A subnet consists of a contiguous range of IP addresses that do not overlap with other subnets in the VCN. For each subnet, you specify the routing rules and security lists that apply to it. For more information about subnets, see VCNs and Subnets in the Oracle Cloud Infrastructure Networking documentation.

SECURITY LISTS

Virtual firewall rules for your VCN. Your VCN comes with a default security list, and you can add more. These security lists provide ingress and egress rules that specify the types of traffic allowed in and out of the instances. You can choose whether a given rule is stateful or stateless. Security list rules must be set up so that clients can connect to file system mount targets. For more information about how security lists work in Oracle Cloud Infrastructure, see Security Lists in the Networking documentation. For information about setting up specific security list rules required for mount target traffic, see Configuring VCN Security List Rules for File Storage. About Security explains how security lists interact with other types of security in your file system.

SNAPSHOTS

Snapshots provide a consistent, point-in-time view of your file system, and you can take as many snapshots as you need. You pay only for the storage used by your data and metadata, including storage capacity used by snapshots. Each snapshot reflects only data that changed from the previous snapshot. For more information, see Managing Snapshots.

Encryption

The File Storage service encrypts all data at rest. By default all file systems are encrypted using Oracle-managed encryption keys. You have the option to encrypt all of your file systems using the keys that you own and manage using the Key Management service. For more information, see Overview of Key Management.

For how to use your own key for new file systems, see Creating File Systems. See To assign a key to a file system for how to assign or change the key for an existing file system.

Data Transfers

FastConnect offers you the ability to accelerate data transfers. You can leverage the integration between FastConnect and the File Storage service to perform initial data migration, workflow data transfers for large files, and disaster recovery scenarios between two regions, among other things.

File Storage Space Allocation

The File Storage service allocates space in blocks of variable size in a way that is fine-tuned to minimize total customer cost and optimize performance for modern workloads. The minimum block size used is 8192 bytes. For example, if you create a 1-byte file, we allocate 8192 bytes. We use larger blocks to store larger files. This method of allocation might cause a different block count for files than expected after they are copied from another storage device to your Oracle Cloud Infrastructure file system.

How File Storage Permissions Work

File Storage service resources include file systems, mount targets, and export sets. The AUTH_UNIX style of authentication and permission checking is supported for remote NFS client requests. You use Oracle Cloud Infrastructure Identity and Access Management (IAM) policy language to define access to Oracle Cloud Infrastructure resources. You can consider exports and snapshots subsidiary resources of export sets and file systems, respectively. As such, they do not need their own permissions. Related resources include Oracle Cloud Infrastructure Compute instances and Oracle Cloud Infrastructure Networking virtual cloud networks (VCNs).

Oracle Cloud Infrastructure users require resource permissions to create, delete, and manage resources. Without the appropriate IAM permissions, you cannot export a file system through a mount target. Until a file system has been exported, Compute instances cannot mount it. For more information about creating an IAM policy, see Let users create, manage, and delete file systems.

If you have successfully exported a file system on a subnet, then you use Networking security lists to control traffic to and from the subnet and, therefore, the mount target. Security lists act as a virtual firewall, allowing only the network traffic you specify to and from the IP addresses and port ranges configured in your ingress and egress rules. The security list you create for the subnet lets hosts send and receive packets and mount the file system. If you have firewalls on individual instances, use FastConnect, or use a virtual private network (VPN), the settings for those might also impact security at the networking layer. For more information about creating a security list for the File Storage service, see Creating File

Systems. See About Security for more information on how different types of security work together in your file system.

Regions and Availability Domains

You can use the File Storage service in all regions. For a list of supported regions, see Regions and Availability Domains.

When you create file systems and mount targets, you specify the availability domain they are created in. All file system data is then stored entirely within the availability domain the file system resides in. Within an availability domain, the File Storage service uses synchronous replication and high availability failover to keep your data safe and available.

You cannot move a file system to a different availability domain or region. However, you can take a snapshot of your data and use a tool such as `rsync` to copy your data to a different availability domain or region. See Managing Snapshots for more information on using snapshots to protect your data.

While it is possible to access mount targets from any availability domain in a region, for optimal performance, place File Storage resources in the same availability domain as the Compute instances that access them.

Subnets can be either AD-specific or regional. You can create File Storage resources in either type of subnet. Regional subnets allow Compute instances to connect to any mount target in the subnet regardless of AD, with no additional routing configuration. However, to minimize latency, place mount targets in the same AD as Compute instances just as you would in an AD-specific subnet. For more information, see About Regional Subnets.

Creating Automation with Events

You can create automation based on state changes for your Oracle Cloud Infrastructure resources by using event types, rules, and actions. For more information, see Overview of Events.

The following File Storage resources emit events:

- File systems
- Snapshots
- Mount targets
- Exports
- Export sets

Resource Identifiers

Most types of Oracle Cloud Infrastructure resources have a unique, Oracle-assigned identifier called an Oracle Cloud ID (OCID). For information about the OCID format and other ways to identify your resources, see Resource Identifiers.

Ways to Access Oracle Cloud Infrastructure

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. For a list of available SDKs, see Software Development Kits and Command Line Interface.

To access the Console, you must use a supported browser. Oracle Cloud Infrastructure supports the latest desktop versions of Google Chrome, Microsoft Edge, Internet Explorer 11, Safari, Firefox, and Firefox ESR. Note that private browsing mode is not supported for Firefox, Internet Explorer, or Edge. Mobile browsers are not supported.

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see

Getting Started with Policies. For specific details about writing policies for each of the different services, see Policy Reference.

If you're a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

Limits on Your File Storage Components

See Service Limits for a list of applicable limits and instructions for requesting a limit increase.

You can use the "Classic View" of the **Service Limits** page in the Console to see File Storage service **Limit** and **Usage** data for your tenancy.

To view Limit and Usage data for File Storage

1. Open the navigation menu. Under Governance and Administration, click Governance, then click **Limits, Quotas and Usage**.
2. Click **Switch Back to Classic View**.
3. In Service Limits, click on **File Storage** to expand.

About Security

This topic discusses different methods you can use to secure your file systems.

Tip

Watch a video about security in File Storage.

Access Control

Oracle Cloud Infrastructure (OCI) Identity and Access Management (IAM) uses policies to control what users can do within Oracle Cloud Infrastructure, such as creating instances, a VCN and its security rules, mount targets, and file systems.

Network security controls which instance IP addresses or CIDR blocks can connect to a host file system. It uses VCN security list rules to allow or deny traffic to the mount target, and therefore access to any associated file system.

NFS export options apply access control on each file system export based on source IP address.

NFS v.3 Unix security controls what users can do on the instance, such as installing applications, creating directories, mounting external file systems by a local mount point, and reading and writing files.

This security layer...	Uses these...	To control actions like...
Oracle Cloud Infrastructure (Oracle Cloud Infrastructure)	OCI Users and policies	Creating instances and VCNs. Creating, listing, and associating file systems and mount targets.
Network security	IP addresses, CIDR blocks, security lists	Connecting the client instance to the mount target.

This security layer...	Uses these...	To control actions like...
NFS export options	File system exports, IP addresses, Unix users	Privileged source port connection, reading and writing files, and limiting root user access on a per-file system basis.
NFS v.3 Unix security	Unix users, file mode bits	Mounting file systems, reading and writing files.

You create users and groups in Oracle Cloud Infrastructure. Then, you can use policies to specify which users and groups can create, access, or modify resources such as file systems, mount targets, and export options.

The network security layer allows you to use VCN security lists to block the appropriate ports from specific IP addresses and CIDR blocks and restrict host access. However, it's on an 'all or nothing' basis - the client either can or cannot access the mount target, and therefore all file systems associated with it. See Working with NFS Export Options to specify granular controls on a per-file system basis.

File Storage service supports the AUTH_UNIX style of authentication and permission checking for remote NFS client requests. When mounting file systems, we recommend that you use the `-nosuid` option. This option disables set-user-identifier or set-group-identifier bits. Remote users are prevented from gaining higher privileges using a `setuid` program. For more information, see Mounting File Systems.

Remember that users in UNIX aren't the same as users in Oracle Cloud Infrastructure - they're not linked or associated in any way. The Oracle Cloud Infrastructure policy layer doesn't govern anything that happens inside the file system, the UNIX security layer does. Conversely, the UNIX security layer doesn't govern creating file systems or mount targets in Oracle Cloud Infrastructure.

NFS export options are a method of applying access control at the network security layer and the NFS v.3 Unix security layer. You can use NFS export options to limit access levels by IP addresses or CIDR blocks connecting to multiple file systems through exports of an associated mount target. Access can be restricted so that each client's file system is inaccessible and invisible to the other, allowing for managed hosted environment security. Moreover, you can set permissions for read-only, read/write, or root-squash for your file systems. See Working with NFS Export Options for more information.

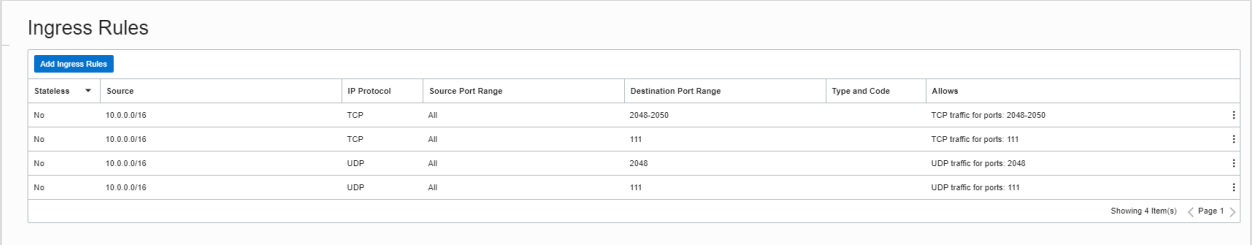
Encryption

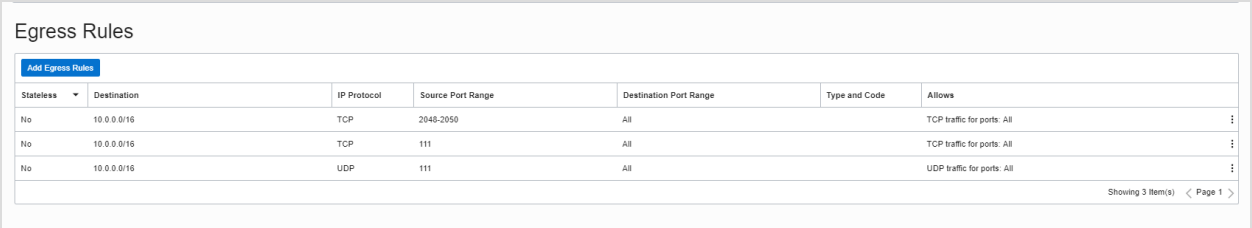
The Oracle Cloud Infrastructure File Storageservice always encrypts all file systems at rest. By default all file systems are encrypted using the Oracle-provided encryption keys.

You have the option to encrypt all of your file systems using the keys that you own and manage using the Key Management service. For more information, see Overview of Key Management. If you do not configure a file system to use the Key Management service or you later unassign a key from the file system, the File Storage service uses the Oracle-provided encryption key instead. For how to use your own key for new file systems, see Creating File Systems. See To assign a key to a file system for instructions about how to assign or change the key for an existing file system.

Configuring VCN Security List Rules for File Storage

When you create a VCN, a default security list is also created. Rules in the security list are used to allow or deny traffic to a subnet. Before you can mount a file system, you must configure security list rules to allow traffic to the mount target subnet. File Storage requires stateful ingress to TCP ports 111, 2048, 2049, and 2050 and stateful ingress to UDP ports 111 and 2048. File storage also requires stateful egress from TCP ports 111, 2048, 2049, and 2050 and stateful egress from UDP port 111.





See Security Lists for more information about how security lists work in Oracle Cloud Infrastructure. See About Security for information about how security lists work with other types of security in File Storage.

Required IAM Service Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: The policy in Let network admins manage a cloud network covers management of all networking components, including security lists. See the Policy Reference for more information.

If you're new to policies, see Getting Started with Policies and Common Policies.

Using the Console

To configure security list rules for mount target traffic

Security list rules allow ingress and egress for the following:

- Open Network Computing Remote Procedure Call (ONC RPC) rpcbind utility protocol
- Network File System (NFS) protocol
- Network File System (MOUNT) protocol
- Network Lock Manager (NLM) protocol

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
2. In the **Scope** section, select the compartment that contains the subnet associated with your file system.
3. Click the name of the cloud network associated with your file system.
4. On the details page for the cloud network, in **Resources**, and then click **Security Lists**.
5. Click the name of the security list used by the subnet associated with your file system.
6. In **Resources**, click **Ingress Rules**.
7. Click **Add Ingress Rules** and add the following ingress rule allowing **TCP** traffic.
    - Specify that it's a stateful rule by leaving the check box clear. (For more information about stateful and stateless rules, see Stateful Versus Stateless Rules). By default, rules are stateful unless you specify otherwise.
    - To allow traffic from the subnet of the cloud network, click **Source Type**, choose **CIDR**, and then enter the CIDR block for the subnet.
    - Click **IP Protocol**, and then click **TCP**.
    - In **Source Port Range**, specify the range of ports that you want to allow traffic from. Alternatively, accept the default of **All** to allow traffic from any source port.

Important

We recommend that NFS clients be limited to reserved ports. To do this, set the **Source Port** range to **1-1023**. You can also set export options for a file system to require clients to connect from a privileged source port. For more information, see Working with NFS Export Options.

- Click **Destination Port Range**, and then enter **2048-2050**.

8. Click **+ Additional Ingress Rule** and create a second stateful ingress rule allowing **TCP** traffic to a **Destination Port Range** of **111**.
9. Click **+ Additional Ingress Rule** and create a third stateful ingress rule allowing **UDP** traffic to a **Destination Port Range** of **2048**.
10. Click **+ Additional Ingress Rule** and create a fourth stateful ingress rule allowing **UDP** traffic to a **Destination Port Range** of **111**.
11. When you're done, click **Add Ingress Rules**.
12. Next, create the egress rules. In **Resources**, click **Egress Rules**.
13. Click **Add Egress Rules** and add the following egress rule allowing **TCP** traffic:
    - Specify that it's a stateful rule by leaving the check box clear.
    - Click **Destination Type**, choose **CIDR**, and then enter the CIDR block for the subnet.
    - Click **IP Protocol**, and then click **TCP**.
    - In **Source Port Range**, enter **2048-2050**.
    - In **Destination Port Range**, accept the default of **All** to allow traffic to any destination port.

14. Click **+ Additional Egress Rule** and add a second stateful egress rule allowing **TCP** traffic from a **Source Port Range** of **111**.
15. Click **+ Additional Egress Rule** and add a third stateful egress rule allowing **UDP** traffic from a **Source Port Range of 111**.
16. When you're done, click **Add Egress Rules**.

Next steps:

- Create a mount target and associated file system
- Mount a file system

Working with NFS Export Options

This topic describes the basic features of NFS export options, and how to control client access to your file system.

Overview

NFS export options enable you to create more granular access control than is possible using just security list rules to limit VCN access. You can use NFS export options to specify access levels for IP addresses or CIDR blocks connecting to file systems through exports in a mount target. Access can be restricted so that each client's file system is inaccessible and invisible to the other, providing better security controls in multi-tenant environments.

Using NFS export option access controls, you can limit clients' ability to connect to the file system and view or write data. For example, if you want to allow clients to consume but not update resources in your file system, you can set access to Read Only. You can also reduce client root access to your file systems and map specified User IDs (UIDs) and Group IDs (GIDs) to an anonymous UID/GID of your choice. For more information about how NFS export options work with other security layers, see About Security.

Tip

Watch a video about working with NFS export options in File Storage.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: The policy in Let users create, manage, and delete file systems allows users to manage NFS export options.

If you're new to policies, see Getting Started with Policies and Common Policies.

Exports

Exports control how NFS clients access file systems when they connect to a mount target. File systems are exported (made available) through mount targets. Each mount target maintains an export set which contains one or many exports. A file system may be exported through one or more mount targets. A file system must have at least one export in one mount target in order for instances to mount the file system. The information used by an export includes the file system OCID, mount target OCID, export set OCID, export path, and client export options. Typically, an export is created in a mount target when the file system is created. Thereafter, you can create additional exports for a file system in any mount target that resides in the same availability domain as the file system.

See To create an export for a file system for more information.

NFS Export Options

NFS export options are a set of parameters within the export that specify the level of access granted to NFS clients when they connect to a mount target. An NFS export options entry within an export defines access for a single IP address or CIDR block range.

Each separate client IP address or CIDR block you want to define access for needs a separate export options entry in the export. For example, if you want to set options for NFS client IP addresses 10.0.0.6, 10.0.08, and 10.0.0.10, you need to create three separate entries, one for each IP address.

File Storage service considers the listed order of each export options entry for the export. During an NFS request by a client, File Storage service applies the first set of options that matches the client Source IP address. Only the first set is applied; the rest are ignored.

For example, consider the following two export options entries specifying access for an export:

Entry 1: Source: 10.0.0.0/16, Access: Read Only

Entry 2: Source: 10.0.0.8, Access: Read/Write

In this case, clients who connect to the export from IP address 10.0.0.8 have Read Only access. The request Source IP address is contained in the CIDR block specified in the first entry, and File Storage Service applies the options in the first match.

Important

File systems can be associated with one or more exports, contained within one or more mount targets. If the client **source** IP address does not match any entry on the list for a single export, then that export is not visible to the client. However, the file system could be accessed through other exports on the same or other mount targets. **To completely deny client access to a file system, be sure that the client source IP address or CIDR block is not included in any export for any mount target associated with the file system.**

The following options can be set to control export access:

- **Source**: The IP address or CIDR block of a connecting NFS client.
- **Require Privileged Source Port (true/false):** This setting determines whether the NFS clients specified in **source** are required to connect from a privileged source port. Privileged ports are any port including 1-1023. On Unix-like systems, only the root user can open privileged ports. Setting this value to **true** disallows requests from unprivileged ports. The default for this setting is different depending on how the export is created. Creating an export without an explicit `ClientOption` array sets the `requirePrivilegedSourcePort` attribute of the client option to **false**. When you create a `ClientOption` array explicitly , `requirePrivilegedSourcePort` defaults to **true**. For example, creating an export in the Console using the default selections sets `requirePrivilegedSourcePort` to **false**. Creating an export in the API along with a `ClientOption` array sets `requirePrivilegedSourcePort` to **true**.

Important

When **Require Privileged Source Port** is set to **true**, you also have to follow these additional configuration steps:

1. When mounting the file system from a Unix-like system, include the `resvport` option in your mount command when mounting. For example:

   ```
   sudo mount -o resvport 10.x.x.x:/fs-export-path
   /mnt/yourmountpoint
   ```

   For more information, see Mounting File Systems From Unix-Style Instances.
2. When mounting the file system from a Windows system, be sure the **UseReserverdPort**s registry key value is set to **1**.
   For more information, see Mounting File Systems From Windows Instances.

- **Access (Read_Only, Read_Write):** This setting specifies the **source** NFS client access. If unspecified, defaults to **Read_Write**.
- **Identity Squash: (All, Root, None):** This setting determines whether the **source** clients accessing the file system have their User ID (UID) and Group ID (GID) remapped to **anonymousUid** and **anonymousGid**. If you choose **All**, all users and groups are remapped. If **Root**, only the root user UID/GID combination 0/0 is remapped. If **None**, no users are remapped. If unspecified, defaults to **None**.
- **anonymousUid:** This setting is used along with the **Identity Squash** option. When remapping users, you can use this setting to change the default anonymousUid of **65534** to any user ID of your choice.

- **anonymousGid**: This setting is used along with the **Identity Squash** option. When remapping groups, you can use this setting to change the default anonymousGid of **65534** to any group ID of your choice.

Typical Access Control Scenarios

When you create file system and export, the NFS export options for that file system are set to the following defaults, which allow full access for all NFS client source connections. These defaults must be changed if you want to restrict access:

- **Source:** 0.0.0.0/0 (All)
- **Require Privileged Source Port:** False
- **Access:** Read_Write
- **Identity Squash:** None

Scenario A: Control Host Based Access

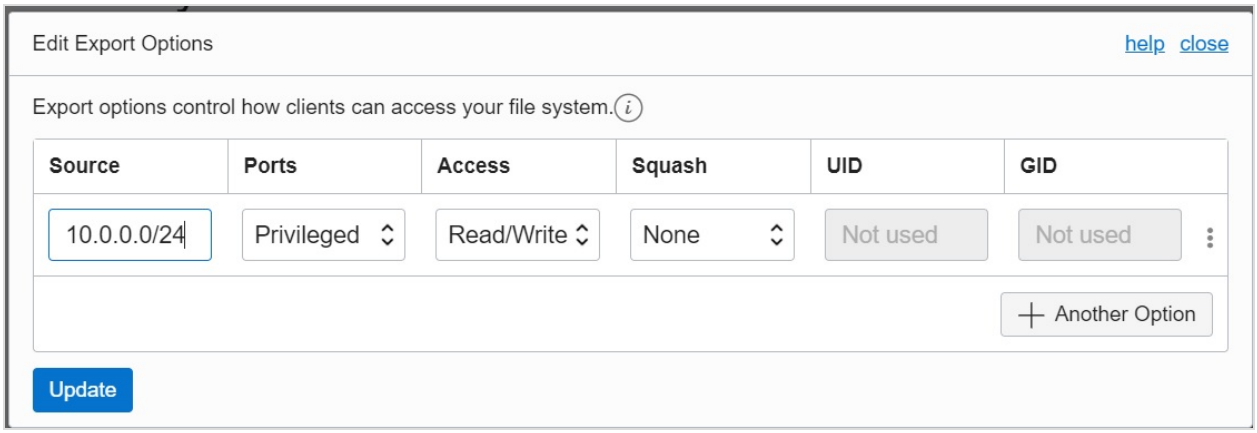
Provide a managed hosted environment for two clients. The clients share a mount target, but each has their own file system, and cannot access each other's data. For example:

- Client A, who is assigned to CIDR block 10.0.0.0/24, requires Read/Write access to file system A, but not file system B.
- Client B, who is assigned to CIDR block 10.1.1.0/24, requires Read/Write access to file system B, but not file system A.
- Client C, who is assigned to CIDR block 10.2.2.0/24, has no access of any kind to file system A or file system B.
- Both file systems A and B are associated to a single mount target, MT1. Each file system has an export contained in the export set of MT1.

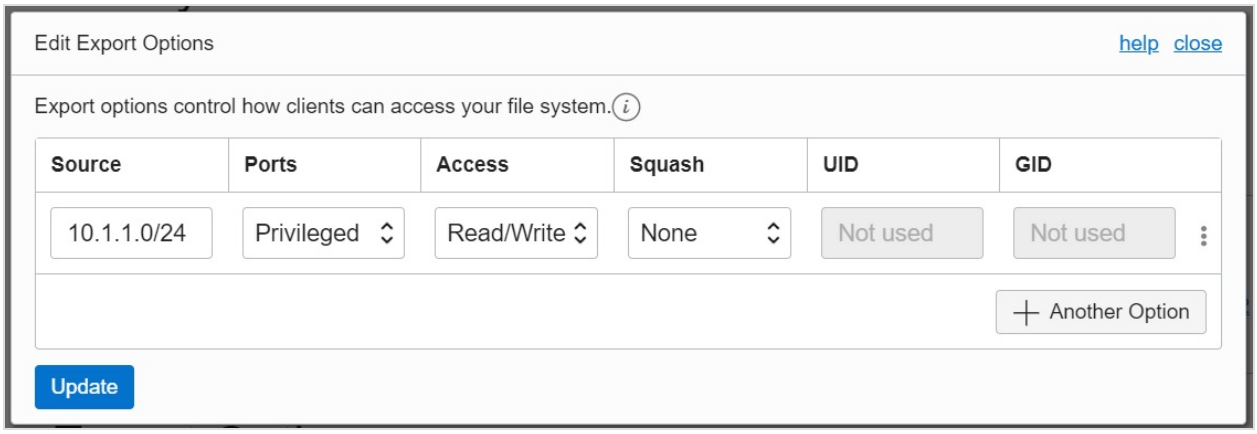
Since Client A and Client B access the mount target from different CIDR blocks, you can set the client options for both file system exports to allow access to only a single CIDR block. Client C is denied access by not including its IP address or CIDR block in the NFS export options for any export of either file system.

Console Example

Set the export options for file system A to allow Read/Write access only to Client A, who is assigned to CIDR block 10.0.0.0/24. Client B and Client C are not included in this CIDR block, and cannot access the file system.



Set the export options for file system B to allow Read/Write access only to Client B, who is assigned to CIDR block 10.1.1.0/24. Client A and Client C are not included in this CIDR block, and cannot access the file system.



CLI Example

Set the export options for file system A to allow Read_Write access only to Client A, who is assigned to CIDR block 10.0.0.0/24. Client B and Client C are not included in this CIDR block, and cannot access the file system.

```
oci fs export update --export-id <File_system_A_export_ID> --export-options '
[{"source":"10.0.0.0/24","require-privileged-source-port":"true","access":"READ_WRITE","identity-
squash":"NONE","anonymous-uid":"65534","anonymous-gid":"65534"}]'
```

Set the export options for file system B to allow Read_Write access only to Client B, who is assigned to CIDR block 10.1.1.0/24. Client A and Client C are not included in this CIDR block, and cannot access the file system.

```
oci fs export update --export-id <File_system_B_export_ID> --export-options '[{"source":"10.1.1.0/24
","require-privileged-source-port":"true","access":"READ_WRITE","identity-squash":"NONE","anonymous-
uid":"65534","anonymous-gid":"65534"}]'
```

API Example

Set the export options for file system A to allow READ_WRITE access only to Client A, who is assigned to CIDR block 10.0.0.0/24. Client B and Client C are not included in this CIDR block, and cannot access the file system.

```
PUT/<Current_API_Version>/exports/<File_System_A_export_OCID>
Host: filestorage.us-phoenix-1.oraclecloud.com
<authorization and other headers>
{
    "exportOptions": [
        {
          "source": "10.0.0.0/24",
          "requirePrivilegedSourcePort": true,
          "access": "READ_WRITE",
          "identitySquash": "NONE",
          "anonymousUid": 65534,
          "anonymousGid": 65534
        }
    ]
}
```

Set the export options for file system B to allow READ_WRITE access only to Client B, who is assigned to CIDR block 10.1.1.0/24. Client A and Client C are not included in this CIDR block, and cannot access the file system.

```
PUT/<Current_API_Version>/exports/<File_System_B_export_OCID>
Host: filestorage.us-phoenix-1.oraclecloud.com
<authorization and other headers>
{
    "exportOptions": [
        {
          "source": "10.1.1.0/24",
          "requirePrivilegedSourcePort": true,
          "access": "READ_WRITE",
          "identitySquash": "NONE",
          "anonymousUid": 65534,
          "anonymousGid": 65534
        }
    ]
}
```

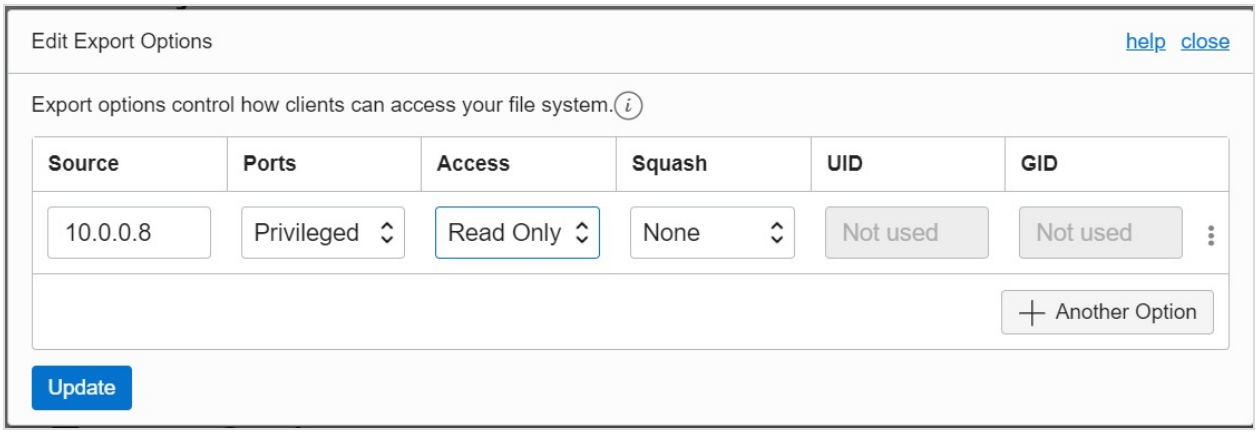
Scenario B: Limit the Ability to Write Data

Provide data to customers for consumption, but don't allow them to update the data.

For example, you'd like to publish a set of resources in file system A for an application to consume, but not change. The application connects from IP address 10.0.0.8.

Console Example

Set the source IP address 10.0.0.8 to Read Only in the export for file system A:



CLI Example

Set the source IP address 10.0.0.8 to READ_ONLY in the export for file system A:

```
oci fs export update --export-id <File_System_A_export_OCID> --export-options '
[{"source":"10.0.0.8","require-privileged-source-port":"true","access":"READ_
ONLY","identitysquash":"NONE","anonymousuid":"65534","anonymousgid":"65534"}]'
```

API Example

Set the source IP address 10.0.0.8 to READ_ONLY in the export for file system A:

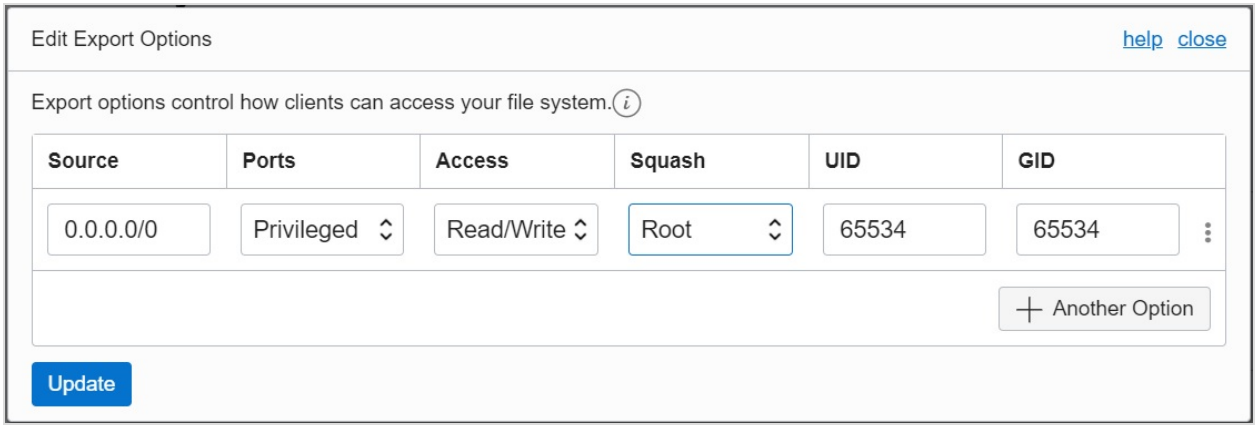
```
PUT/<Current_API_Version>/exports/<File_System_A_export_OCID>
Host: filestorage.us-phoenix-1.oraclecloud.com
<authorization and other headers>
{
    "exportOptions": [
        {
          "source": "10.0.0.8",
          "requirePrivilegedSourcePort": true,
```

```
          "access": "READ_ONLY",
          "identitySquash": "NONE",
          "anonymousUid": 65534,
          "anonymousGid": 65534
        }
    ]
}
```

SCENARIO C: IMPROVE FILE SYSTEM SECURITY

To increase security, you'd like to limit the root user's privileges when connecting to File System A. Use Identity Squash to remap root users to UID/GID 65534. In Unix-like systems, this UID/GID combination is reserved for '*nobody*', a user with no system privileges.

Console Example



CLI Example

```
oci fs export update --export-id <File_System_A_export_OCID> --export-options '
[{"source":"0.0.0.0/0","require-privileged-source-port":"true","access":"READ_
WRITE","identitysquash":"ROOT","anonymousuid":"65534","anonymousgid":"65534"}]'
```

API Example

```
PUT/<Current_API_Version>/exports/<File_System_A_export_OCID>
Host: filestorage.us-phoenix-1.oraclecloud.com
<authorization and other headers>
{
    "exportOptions": [
        {
          "source": "0.0.0.0/0",
          "requirePrivilegedSourcePort": true,
          "access": "READ_WRITE",
          "identitySquash": "ROOT",
          "anonymousUid": 65534,
          "anonymousGid": 65534
        }
    ]
}
```

Tip

If you don't want a file system to be visible to any clients, you can set all of the properties in the `exportOptions` array to empty values. For example,

```
{
   "exportOptions": [
     {
      "source":"",
      "requirePrivilegedSourcePort":"",
      "access": "",
      "identitySquash":""}
]
```

Using the Console

To set export options for a file system

1. Open the navigation menu. Under **Core Infrastructure**, click **File Storage** and then click **File Systems**.
2. In the **List Scope** section, select a compartment. All of the file systems in the selected compartment are displayed.
3. Find the file system you want to set export options for, click the the Actions icon (three dots), and then click **View File System Details**.
4. In the **Exports** list, find the export you want to set export options in, click the the Actions icon (three dots), and then click **View Export Details**. If there is no export listed for the file system, you can create one. See To create an export for a file system for more information.

Tip

To be sure you be sure that you select export, check the following:

- **The export path:** This path uniquely identifies the file system within the mount target. No two exports in a mount target can have the same export path, even if the exports are for the same file system.
- **The mount target name:** File systems can be exported through more than one mount target. Be sure that you've selected the export for the correct mount target.

5. Click **Edit Export Options**.
6. Make one or more of these changes:

- Change an export option entry in the list.
- Click **+Another Option** to create a new export option entry.
- Click the Actions icon (three dots) for an entry and move it up or down in the list.

7. When you're done, click **Update**.

Using the CLI

For information about using the CLI, see Command Line Interface (CLI).

To create an export

Open a command prompt and run `oci fs export create` to create an export for a specified file system within a specified export set. This example creates an export along with its NFS export options.

For example:

```
oci fs export create --export-set-id <export_set_OCID> --file-system-id <file_system_OCID> --path
"</pathname>" --export-options '
[{"source":"10.0.0.0/16","requireprivilegedsourceport":"true","access":"READWRITE","identitysquash":"NO
NE","anonymousuid":"0","anonymousgid":"0"}]'
```

Important

Export Path Names

The path must start with a slash (/) followed by a sequence of zero or more slash-separated elements. For any two export resources associated with the same export set, the path sequence for the first export resource can’t contain the complete path element sequence of the second export sequence. Paths can't end in a slash. No path element can be a period (.) or two periods in sequence (..). Lastly, no path can exceed 255 bytes.

Examples:

Acceptable:

`/example` and `/path`

`/example1` and `/example2`

Not Acceptable:

`/example` and `/example/path`

`/` and `/example`

`/example/`

`/example/path/../example1`

To update export options

Open a command prompt and run `oci fs export update`. To update export options for a specified file system, use `--export-options`.

For example:

```
oci fs export update --export-id <export_OCID> --export-options '[{"source":"<0.0.0.0/0>","require-privileged-source-port":"true","access":"READ_ONLY","identity-squash":"ROOT","anonymous-uid":"65534","anonymous-gid":"65534"}]'

WARNING: Updates to export-options will replace any existing values. Are you sure you want to continue? [y/N]: y
```

Tip

If you don't want a file system to be visible to any clients, you can set all of the properties in Client Options to empty values. For example,

```
oci fs export update --export-id <export_OCID> --export-options '[{"source":"","require-privileged-source-port":"true","access":"READ_ONLY","identity-squash":"ROOT","anonymous-uid":"65534","anonymous-gid":"65534"}]'
```

To list exports

Open a command prompt and run `oci fs export list` to list all exports in a specified compartment.

For example:

```
oci fs export list --compartment-id target_compartment_id
```

To delete an export

Open a command prompt and run `oci fs export delete` to delete an export.

For example:

```
oci fs export delete --export-id export_OCID
```

Warning

When you delete an export, you can no longer mount the file system using the file path specified in the deleted export.

Using the API

- CreateExport
- UpdateExport
- ListExports
- GetExport
- DeleteExport

Creating File Systems

You can create a shared file system in the cloud using the File Storage service. Network access to your file system is provided through a mount target. Exports control how NFS clients access file systems when they connect to a mount target. File systems must have at least one export in one mount target for any instance to mount and use the file system. Typically, you create your first mount target when you create your first file system.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Required IAM Service Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: The policy in Let users create, manage, and delete file systems allows users to create file systems. Since mount targets are network endpoints, users must also have "use" permissions for VNICs, private IPs, private DNS zones, and subnets to create or delete a mount target. See the Policy Reference for more information.

If you're new to policies, see Getting Started with Policies and Common Policies.

Prerequisites

Before you create a file system, you need:

- At least one Virtual Cloud Network (VCN) in a compartment. For more information, see VCNs and Subnets.
- Correctly configured security list rules in the VCN subnet where you plan to create the file system's associated mount target. See Security Lists for information about how security lists work in Oracle Cloud Infrastructure. Use the instructions in Configuring VCN Security List Rules for File Storage to set up security lists for your file systems.

Using the Console

To create a file system

1. Open the navigation menu. Under **Core Infrastructure**, click **File Storage** and then click **File Systems**.

2. In the left-hand navigation, in the **List Scope** section, under **Compartment**, select a compartment.
3. Click **Create File System**.

Note

File systems are encrypted by default. You cannot turn off encryption.

4. You can choose to accept the system defaults, or change them by clicking **Edit Details**.
    - **File System Information:**
        - **Name:**File Storage service creates a default name using "FileSystem-YYMMDD-HHMM". Optionally, change the default name for the file system. It doesn't have to be unique; an Oracle Cloud Identifier (OCID) uniquely identifies the file system.
        - **Availability Domain:** The first availability domain selected in the left panel list is used as default.
        - **Encryption:** File systems use Oracle-managed keys by default, which leaves all encryption-related matters to Oracle. Optionally, you can encrypt the data in this file system using your own Key Management encryption key. To use Key Management for your encryption needs, select **Encrypt using customer-managed keys** check box. Then, select the **Vault Compartment** and **Vault** that contain the master encryption key you want to use. Also select the **Master Encryption Key Compartment** and **Master Encryption Key**. For more information about encryption, see Overview of Key Management.
        - **Tags:** Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you

are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.

- **Export Information**
  Mount targets use exports to manage access to file systems. The path name uniquely identifies the file system within the mount target, and is used by an instance to mount the file system.
  - **Export Path:** The File Storage service creates a default export path using the file system name. Optionally, replace the default export path name with a new path name, preceded by a forward slash (/). For example, /fss. This value specifies the mount path to the file system (relative to the mount target IP address or hostname). Avoid entering confidential information.

Important

The path must start with a slash (/) followed by a sequence of zero or more slash-separated elements. For multiple file systems associated with a single mount target, the path sequence for the first file system cannot contain the complete path element sequence of the second file system path sequence. Paths cannot end in a slash. No path element can be a period (.) or two periods in sequence (..). Lastly, no path can exceed 255 bytes. For example:

Acceptable:

`/example` and `/path`

`/example` and `/example2`

Not Acceptable:

`/example` and `/example/path`

`/` and `/example`

`/example/`

`/example/path/../example1`

Warning

If one file system associated to a mount target has '/' specified as an export path, you can't associate another file system with that mount target.

Note

Export paths cannot be edited after the export is created. If you want to use a different export path, you must create a new export with the desired path. Optionally, you can then delete the export with the old path.

For more information, see Paths in File Systems.

- **Use Secure Export Options:** Select to set the export options to require NFS clients to use a privileged port (1-1023) as its source port. This option enhances security because only a client with root privileges can use a privileged source port. After the export is created, you can edit the export options to adjust security. See Working with NFS Export Options for more information.

Warning

Leaving the "Use Secure Export Options" setting disabled allows unprivileged users to read and modify any file or directory on the target file system.

- **Mount Target Information:**
  File systems must be associated with a mount target to be mounted by an instance.
  If you have one or more previously created mount targets in the availability domain, the File Storage service automatically chooses the most recently created mount target in the list. If you don't have a mount target in the selected availability domain, the File Storage service creates one using the following defaults.
  - **Mount Target Name:** File Storage service creates a default mount target name using "Mount-YYYYMMDD-HHMM".
  - **Compartment:** The compartment you're currently working in.
  - **Virtual Cloud Network:** The first VCN listed in the current compartment is used as default.
  - **Subnet:** The most recently created subnet listed in the selected availability domain is used as default. Subnets can be either AD-specific or regional (regional ones have "*regional*" after the name). For more information, see About Regional Subnets.

5. If you want to *accept the defaults* for the mount target, click **Create**. *The file system is created with the information displayed*. If you want to choose another mount target or change the default information, click the **Edit Details** link.
6. In the **Mount Target Information** section, specify details for the mount target that is associated with the file system:

- **Select an Existing Mount Target:** Choose this option if you want to associate the file system with a mount target you already created. Choose the **Mount Target** from the list. Click the **click here** link in the dialog box if you want to enable compartment selection for the mount target.

  Tip

  If there aren't any mount targets in the current combination of availability domain and compartment, this option is disabled. You can:

  - Choose a different compartment.
  - Choose a different availability domain in the *File System Information* section.
  - Create a new mount target.

- **Create a New Mount Target:** Choose this option if you want to create a new mount target associated with this file system. By default, the mount target is created in your current compartment and you can use network resources in that compartment. Click the **click here** link in the dialog box if you want to enable compartment selection for the mount target, its VCN, or subnet resources.

Important

The mount target is always in the same availability domain as the file system. While it is possible to access mount targets from any AD in a region, for optimal performance, your mount target and file system should be in the same availability domain as the Compute instances that access them. For more information, see Regions and Availability Domains.

- **Create in Compartment:** Specify the compartment you want to create the mount target in.
- **New Mount Target Name:** Optionally, replace the default with a friendly name for the mount target. It doesn't have to be unique; an Oracle Cloud Identifier (OCID) uniquely identifies the mount target. Avoid entering confidential information.

Note

The mount target name is different than the DNS hostname, which is specified in step 7.

- **Virtual Cloud Network Compartment:** The compartment containing the cloud network (VCN) in which to create the mount target.
- **Virtual Cloud Network:** Select the cloud network (VCN) where you want to create the new mount target.

- **Subnet Compartment:** Specify the compartment containing a subnet within the VCN to attach the mount target to.
- **Subnet:** Select a subnet to attach the mount target to. Subnets can be either AD-specific or regional (regional ones have "*regional*" after the name). For more information, see About Regional Subnets.

Warning

Each mount target requires three internal IP addresses in the subnet to function. Do not use /30 or smaller subnets for mount target creation because they do not have sufficient available IP addresses. Two of the IP addresses are used during mount target creation. The third IP address must remain available for the mount target to use for high availability failover.

- **Tags**:Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.

7. Optionally, click **Show Advanced Options** to configure the mount target's advanced options.
   - **IP Address:** You can specify an unused IP address in the subnet you selected for the mount target.
   - **Hostname:** You can specify a hostname you want to assign to the mount target.

Note

The File Storage service constructs a fully qualified domain name (FQDN) by combining the hostname with the FQDN of the subnet the mount target is located in.

For example, `myhostname.subnet123.dnslabel.oraclevcn.com`.

Once created, the hostname may be changed in the mount target's Details page. See Managing Mount Targets for more information.

8. Click **Create**.

The File Storage service typically creates the file system and mount target within seconds. Next, mount the file system from an instance so that you can read and write directories and files in your file system. See Mounting File Systems for instructions about obtaining mount commands for your operating system type and mounting your file system.

Using the command line interface (CLI)

For information about using the CLI, see Command Line Interface (CLI).

To create a file system

Open a command prompt and run `oci fs file-system create` to create a file system. For example:

```
oci fs file-system create --availability-domain <target_availability_domain> --display-name "<My File System>" --compartment-id <target_compartment_id>
```

Warning

Avoid entering confidential information in the file system `display-name`.

The file system is created.

File systems use Oracle-managed keys by default, which leaves all encryption-related matters to Oracle. Optionally, you can encrypt the data in this file system using your own Key Management encryption key. For more information, see Overview of Key Management.

For example:

```
oci fs file-system create --availability-domain AAbC:US-ASHBURN-AD-1 --display-name "My File System" --
compartment-id ocid1.compartment.oc1..<unique_id> --kms-key-id --kms-key-id ocid1.key.oc1.phx.<unique_
id>
```

To create a mount target

You can create a mount target for file systems in a specified compartment and subnet. A file system can only be associated with a mount target in the same availability domain.

Warning

Each mount target requires three internal IP addresses in the subnet to function. Do not use /30 or smaller subnets for mount target creation because they do not have sufficient available IP addresses. Two of the IP addresses are used during mount target creation. The third IP address must remain available for the mount target to use for high availability failover.

Open a command prompt and run `oci fs mount-target create` to create a mount target.

For example:

```
oci fs mount-target create --availability-domain <target_availability domain> --compartment-id <target_
compartment_id> --subnet-id <subnet_OCID> --display-name "<My Mount Target>"
```

Warning

Avoid entering confidential information in the mount target `display-name`.

To create an export

An export is a file system together with the path that can be used to mount it. Each export resource belongs to one export set.

Open a command prompt and run `oci fs export create` to create an export for a specified file system within a specified export set.

For example:

```
oci fs export create --export-set-id <export_set_OCID> --file-system-id <file_system_OCID> --path
"</pathname>"
```

Important

The path must start with a slash (/) followed by a sequence of zero or more slash-separated elements. For multiple file systems associated with a single mount target, the path sequence for the first file system cannot contain the complete path element sequence of the second file system path sequence. Paths cannot end in a slash. No path element can be a period (.) or two periods in sequence (..). Lastly, no path can exceed 255 bytes. For example:

Acceptable:

`/example` and `/path`

`/example` and `/example2`

Not Acceptable:

`/example` and `/example/path`

`/` and `/example`

`/example/`

`/example/path/../example1`

Warning

If one file system associated to a mount target has '/' specified as an export path, you can't associate another file system with that mount target.

Note

Export paths cannot be edited after the export is created. If you want to use a different export path, you must create a new export with the desired path. Optionally, you can then delete the export with the old path.

For more information, see Paths in File Systems.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the following operations to create file systems:

- CreateFileSystem
- CreateMountTarget
- CreateExport

Mounting File Systems

Users of Unix-style operating systems and Windows Server 2008 R2, 2012 R2, or 2016 can connect to a file system and write files. Mount targets serve as file system network access points for file systems. After your mount target is assigned an IP address, you can use it together with the file system export path to mount the file system. On the instance from which you want to mount the file system, you need to install an NFS client. For Unix-style operating systems, you create a mount point. When you mount the file system, the mount point effectively represents the root directory of the File Storage file system, allowing you to write

files to the file system from the instance. Windows operating systems use a drive letter assignment instead of a mount point to represent root access.

Prerequisites

- The file system must have at least one export in at least one mount target. When you create a new file system, an export for the file system is created at the same time. See Creating File Systems for more information.
- Correctly configured security list rules in the VCN subnet where the file system's associated mount target resides. See Security Lists for information about how security lists work in Oracle Cloud Infrastructure. Use the instructions in Configuring VCN Security List Rules for File Storage to set up security lists for your file systems.

Mounting File Systems From an Instance

Mounting File Systems From Unix-Style Instances (Including Oracle Linux DB instances)

Mounting File Systems From Windows Instances

Obtaining Mount Command Samples

You can use the Console to get mount command samples that include all the information for a specific mount target and file system. Samples are available for the following operating system images:

- Oracle Linux
- CentOS
- Debian
- Red Hat Linux
- Ubuntu

Warning

When mounting file systems, the following mount option combination is **not supported** by the File Storage service:

- `soft` when the file system is mounted with the read/write mount option (`-o rw`). **This combination can cause corruption of your data**.

The following mount options or mount option combinations are **not recommended** for use with the File Storage service:

- `soft` when the file system is mounted with the read-only mount option (`-o ro`) and the `timeo` has been specified as less than `300` seconds. **This combination can cause a profusion of I/O error responses.**
- `rsize`, or `wsize`. **These options cause issues with performance.**

Note

When mounting file systems, Network Lock Manager (NLM) is enabled for file locking by default. The default requires no specified mount option. Typical NFS workloads function normally using the default.

Some applications might require you to specify the `nolock` mount option. Refer to your application documentation for best practices regarding this mount option.

Required IAM Service Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: The policy in Let users create, manage, and delete file systems allows users to obtain mount commands.

If you're new to policies, see Getting Started with Policies and Common Policies.

Using the Console

To get mount command samples

1. Open the navigation menu. Under **Core Infrastructure**, click **File Storage** and then click **File Systems**.
2. In the **List Scope** section, select a compartment.

The Console displays a list of file systems that have already been created in the compartment, if any.

3. Find the file system you want to mount, click the Actions icon (three dots), and then click **View File System Details**.
4. In **Resources**, click **Exports**.
5. Find the export in the mount target you want to use to mount the file system, click the Actions icon (three dots), and then click **Mount Commands**.

Tip

To be sure that you select the correct export, check the following:

- **The export path:** This path uniquely identifies the file system within the mount target. No two exports in a mount target can have the same export path, even if the exports are for the same file system.
- **The mount target name:** File systems can be exported through more than one mount target. Be sure that you've selected the export for the correct mount target.

6. In **Image**, choose the image of the Compute instance you want to mount the file system to.
7. Click the **Copy** link to copy the commands.

Next, mount the file system from a Unix-style or Windows instance.

Mounting File Systems From Unix-Style Instances

Users of Ubuntu and Linux operating systems can use the command line to connect to a file system and write files. Mount targets serve as network access points for file systems. After your mount target is assigned an IP address, you can use it together with the export path to mount the file system. On the instance from which you want to mount the file system, you need to install an NFS client and create a mount point. When you mount the file system, the mount point effectively represents the root directory of the File Storage file system, allowing you to write files to the file system from the instance.

Prerequisites

- The file system must have at least one export in at least one mount target. When you create a new file system, an export for the file system is created at the same time. See Creating File Systems for more information.
- Correctly configured security list rules in the VCN subnet where the file system's associated mount target resides. See Security Lists for information about how security lists work in Oracle Cloud Infrastructure. Use the instructions in Configuring VCN Security List Rules for File Storage to set up security lists for your file systems.

Mounting File Systems

You can use the following instructions to construct your mount commands, or use the Console to get mount command samples that include all the information for a specific mount target and file system. For more information, see To get mount command samples.

Warning

When mounting file systems, the following mount option combination is **not supported** by the File Storage service:

- `soft` when the file system is mounted with the read/write mount option (`-o rw`). **This combination can cause corruption of your data**.

The following mount options or mount option combinations are **not recommended** for use with the File Storage service:

- `soft` when the file system is mounted with the read-only mount option (`-o ro`) and the `timeo` has been specified as less than `300` seconds. **This combination can cause a profusion of I/O error responses.**
- `rsize`, or `wsize`. **These options cause issues with performance.**

Note

When mounting file systems, Network Lock Manager (NLM) is enabled for file locking by default. The default requires no specified mount option. Typical NFS workloads function normally using the default.

Some applications might require you to specify the `nolock` mount option. Refer to your application documentation for best practices regarding this mount option.

To mount a file system from Ubuntu or Debian

1. Open a command window. Then, get the NFS client by copying and pasting the **Install Command** from the Console or type the following:

   ```
   sudo apt-get install nfs-common
   ```

2. Create a mount point by copying and pasting the **Create Mount Point Command** from the Console or type the following, replacing `yourmountpoint` with the local directory from which you want to access your file system.

   ```
   sudo mkdir -p /mnt/yourmountpoint
   ```

3. Mount the file system by copying and pasting the **Mount Command** from the Console or type the following. Replace `10.x.x.x:` with the local subnet IP address assigned to your mount target, `fs-export-path` with the export path you specified when associating the file system with the mount target, and `yourmountpoint` with the path to the local mount point. The export path is the path to the file system (relative to the mount target IP address or hostname). If you did not specify a path when you associated the file system and mount target, then `10.x.x.x:/` represents the full extent of the mount target.

Tip

IP address and export path information is available in the **Details** page of the mount target associated with your file system. See To view details of a mount target for more information.

```
sudo mount -o nosuid,resvport 10.x.x.x:/fs-export-path /mnt/yourmountpoint
```

Warning

Omitting the `-o nosuid` option may allow unprivileged users to escalate their permissions to 'root'. The `nosuid` option disables set-user-identifier or set-group-identifier bits within the mounted system, which are rarely used.

Note

The `-o resvport` option is required when the "Require Privileged Source Port" export option is used and otherwise optional. It causes the mounting filesystem to connect from a privileged source port (1-1023). See Working with NFS Export Options for more information.

4. View the file system.

```
df -h
```

5. Write a file to the file system by typing the following. Replace `yourmountpoint` with the

path to the local mount point and `helloworld` with your file name.

```
sudo touch /mnt/yourmountpoint/helloworld
```

6. Verify that you can view the file by typing the following. Replace `yourmountpoint` with the path to the local mount point.

```
cd /mnt/yourmountpoint
```

```
ls
```

See Mount Command Fails in Troubleshooting Your File System for more information about common issues you may encounter.

To mount a file system from Linux, Red Hat, or CentOS

1. Open a command window. Then, get the NFS client by copying and pasting the **Install Command** from the Console or typing the following:

```
sudo yum install nfs-utils
```

2. Create a mount point by copying and pasting the **Create Mount Point Command** from the Console or type the following, replacing `yourmountpoint` with the local directory from which you want to access your file system.

```
sudo mkdir -p /mnt/yourmountpoint
```

3. Mount the file system by copying and pasting the **Mount Command** from the Console or type the following. Replace `10.x.x.x:` with the local subnet IP address assigned to your mount target, `fs-export-path` with the export path you specified when associating the file system with the mount target, and `yourmountpoint` with the path to the local mount point. The export path is the path to the file system (relative to the mount target's IP address or hostname). If you did not specify a path when you associated the file system and mount target, then `10.x.x.x:/` represents the full extent of the mount target.

Tip

IP address and export path information is available in the **Details** page of the mount target associated with your file system. See To view details of a mount target for more information.

```
sudo mount -o nosuid,resvport 10.x.x.x:/fs-export-path /mnt/yourmountpoint
```

Warning

Omitting the `-o nosuid` option may allow unprivileged users to escalate their permissions to 'root'. The `nosuid` option disables set-user-identifier or set-group-identifier bits within the mounted system, which are rarely used.

Note

The `-o resvport` option is required when the "Require Privileged Source Port" export option is used and otherwise optional. It causes the mounting filesystem to connect from a privileged source port (1-1023). See Working with NFS Export Options for more information.

4. View the file system.

```
df -h
```

5. Write a file to the file system by typing the following. Replace `yourmountpoint` with the

path to the local mount point and `helloworld` with your file name.

```
sudo touch /mnt/yourmountpoint/helloworld
```

6. Verify that you can view the file by typing the following. Replace `yourmountpoint` with the path to the local mount point.

```
cd /mnt/yourmountpoint
```

```
ls
```

See Mount Command Fails in Troubleshooting Your File System for more information about common issues you may encounter.

To mount a file system from a Database VM instance

Database VM instances are built on Oracle Linux 6.8, unlike Oracle Linux Compute instances, which run on version 7.4. The NFS Utilities package is pre-installed on DB instances, but the Open Network Computing Remote Procedure Call (ONC RPC) rpcbind utility is disabled by default. Oracle Linux 6.8 does not have systemd, so DB instances are managed differently than OL compute instances. An Oracle DB instance comes with a set of iptables rules that excludes any non-database ports and need to be updated to allow mount target traffic.

1. SSH to the DB system.

```
ssh -i <private_key_path> opc@<db_system_ip_address>
```

2. Start the rpcbind service by typing the following:

```
sudo service rpcbind start
```

3. Use the chkconfig command to enable starting rpcbind service at system startup.

```
sudo chkconfig rpcbind on
```

4. Change the default configuration of iptables to include the mount target IP address and allow traffic by typing the following. Replace `10.x.x.x` with the local subnet address assigned to the mount target for the file system. Save the new iptables entries.

```
sudo iptables -A INPUT -p tcp -s 10.x.x.x -j ACCEPT
```

```
sudo iptables -A OUTPUT -p tcp -s 10.x.x.x -j ACCEPT
```

```
sudo service iptables save
```

5. Create a mount point by typing the following, replacing `yourmountpoint` with the local directory from which you want to access your file system.

```
sudo mkdir -p /mnt/yourmountpoint
```

6. Mount the file system by typing the following. Replace `10.x.x.x:` with the local subnet IP address assigned to your mount target, `fs-export-path` with the export path you specified when associating the file system with the mount target, and `yourmountpoint` with an absolute path to a local mount point. The export path is the path to the file system (relative to the mount target IP address or hostname). If you did not specify a path when you associated the file system and mount target, then `10.x.x.x:/` represents the full extent of the mount target.

Tip

IP address and export path information is available in the **Details** page of the mount target associated with your file system. See To view details of a mount target for more information.

```
sudo mount -t nfs -o nosuid,resvport,tcp,vers=3 10.x.x.x:/fs-export-path /mnt/yourmountpoint
```

Warning

Omitting the `-o nosuid` option may allow unprivileged users to escalate their permissions to 'root'. The `nosuid` option disables set-user-identifier or set-group-identifier bits within the mounted system, which are rarely used.

Note

The `-o resvport` option is required when the "Require Privileged Source Port" export option is used and otherwise optional. It causes the mounting filesystem to connect from a privileged source port (1-1023). See Working with NFS Export Options for more information.

See Mount Command Fails in Troubleshooting Your File System for more information about common issues you may encounter.

To auto-mount a shared file system

Auto-mount ensures that a file system is automatically re-mounted on an instance if it is rebooted.

1. Open a command window. Then, mount the file system using the steps described in the previous section.
2. Type the following command to get the file system entry point:

```
sudo cat /etc/mtab |grep -i nfs
```

3. Copy the file system entry point, and open the /etc/fstab file:

```
cd /etc
```

```
vi fstab
```

4. Add the following line to the fstab file:

```
<file_system_ip_address>:<file_system_path_name><your_local_mount_point> nfs
defaults,nofail,nosuid,resvport 0 0
```

Warning

Omitting the `-o nosuid` option may allow unprivileged users to escalate their permissions to 'root'. The `nosuid` option disables set-user-identifier or set-group-identifier bits within the mounted system, which are rarely used.

Important

Be sure to add the `nofail` option to each entry. This option ensures that an unavailable file system does not cause the instance reboot process to fail.

Note

The `-o resvport` option is required when the "Require Privileged Source Port" export option is used and otherwise optional. It causes the mounting filesystem to connect from a privileged source port (1-1023). See Working with NFS Export Options for more information.

5. Save the fstab file.

See Mount Command Fails in Troubleshooting Your File System for more information about common issues you may encounter.

Mounting File Systems From Windows Instances

Users of Windows Server 2008 R2, 2012 R2, or 2016 can mount a file system on any available drive letter using the mount target IP address and the file system export path.

The Windows NFS client must be installed on the instance from which you want to mount the file system.

Warning

Installing the Windows NFS client may require a restart of your system.

Access to NFS file systems requires UNIX-style user and group identities, which are not the same as Windows user and group identities. To enable users to access NFS shared resources, Windows client for NFS accesses file systems anonymously, using `AnonymousGid` and `AnonymousUid`. On brand new file systems, write permissions are only granted to the root user. The `AnonymousGid` and `AnonymousUid` identity values must be configured to allow write access.

Warning

Updating the 'AnonymousGid' and 'AnonymousUid' values require registry changes to your system.

After you have installed the NFS client and correctly mapped user identities, you can mount the file system to any available drive letter using the command line or **Map network drive**. You can access your file system through the chosen drive letter to write files.

Prerequisites

- The file system must have at least one export in at least one mount target. When you create a new file system, an export for the file system is created at the same time. See

Creating File Systems for more information.

- Correctly configured security list rules in the VCN subnet where the file system's associated mount target resides. See Security Lists for information about how security lists work in Oracle Cloud Infrastructure. Use the instructions in Configuring VCN Security List Rules for File Storage to set up security lists for your file systems.

Warning

When mounting file systems, the following mount option combination is **not supported** by the File Storage service:

- `soft` when the file system is mounted with the read/write mount option (`-o rw`). **This combination can cause corruption of your data**.

The following mount options or mount option combinations are **not recommended** for use with the File Storage service:

- `soft` when the file system is mounted with the read-only mount option (`-o ro`) and the `timeo` has been specified as less than `300` seconds. **This combination can cause a profusion of I/O error responses.**
- `rsize`, or `wsize`. **These options cause issues with performance.**

Note

When mounting file systems, Network Lock Manager (NLM) is enabled for file locking by default. The default requires no specified mount option. Typical NFS workloads function normally using the default.

Some applications might require you to specify the `nolock` mount option. Refer to your application documentation for best practices regarding this mount option.

Using Windows Command Prompt

To mount a file system from Windows Server 2008 R2 Command Prompt

If you are using Oracle-provided Windows images, the NFS client is already installed, and the correct user identities are mapped. Skip to step 7.

1. Install Services for NFS components.
    a. Click **Start** go to **Administrative Tools**, then click **Server Manager**.
    b. In the left pane, click **Roles**.
    c. Under **Roles Summary** in the right pane, click **Add Roles**. The **Add Roles Wizard** appears. Click **Next**.
    d. Select the **File Services** check box from the list and click **Next**. Review the information and click **Next**.
    e. Select the **Services for Network File System** check box from the list, and click **Next**.

f. Confirm your selections, then click **Install**. Click **Close** when the installation is complete.

2. Open the registry editor (regedit) and map the AnonymousGid and AnonymousUid to the root user.

> **Warning**
>
> User identity mapping requires changes to your system registry.

a. Click **Windows Search.**

b. Enter `regedit` in the **Search** field and press **Enter**.

c. Click **Yes** to allow changes to your device.

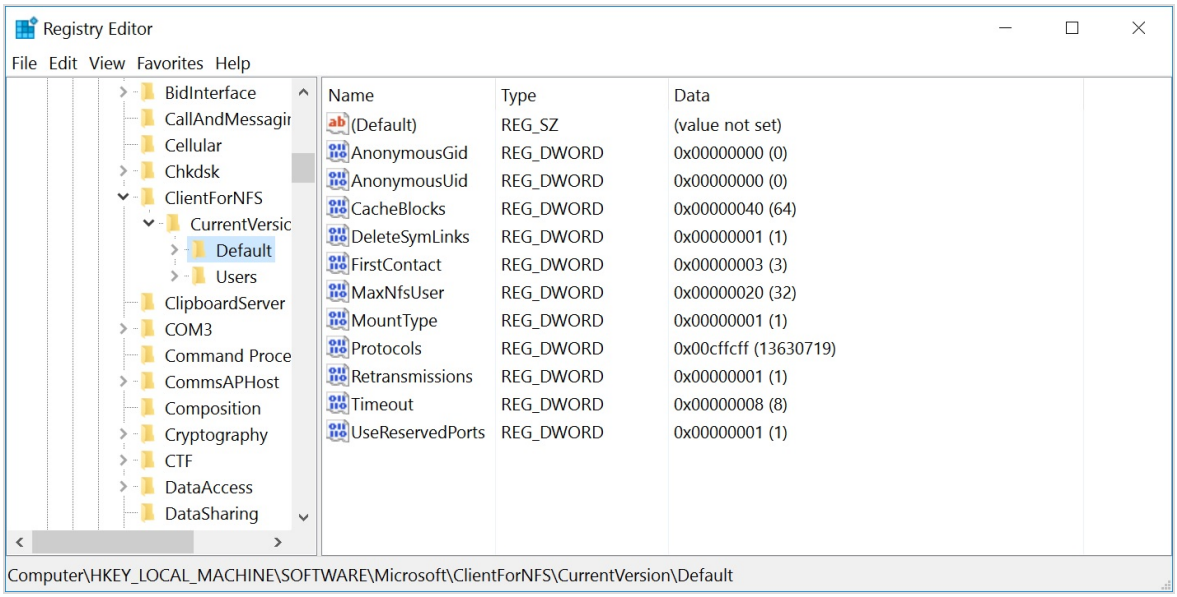
d. Click `HKEY_LOCAL_MACHINE`. Then, browse to: `Software\Microsoft\ClientForNFS\CurrentVersion\Default`.

3. Add a new DWORD32 registry entry for `AnonymousGid`:

a. Click **Edit**, and select **New DWORD (32 bit) Value**.

b. In the **Name** field, enter `AnonymousGid`. Leave the value at `0`.

4. Repeat step 3 to add a second DWORD32 registry entry named `AnonymousUid` with a value of `0`.



5. Open Windows Command Line (CMD) and run as **Administrator**:
    a. Click **Start** .
    b. Press **Ctrl+Shift** and click **Command Prompt**.
    c. Click **Yes**.

> **Important**
>
> If you've set export options for your file system to require clients to connect from a privileged source port (1-1023), then you must set the **UseReserverdPorts** registry key to **1**.
> For more information, see Working with NFS Export Options.

6. In the Administrator: Windows Command Prompt (CMD) window, restart the NFS Client by typing the following:

```
nfsadmin client stop
```

```
nfsadmin client start
```

7. Close the Administrator: Windows Command Prompt (CMD) window. Open a **standard** Command Prompt Window:
   a. Click **Start**, then click **Command Prompt**.

Important

NFS file systems mounted as Administrator are not available to standard users.

8. In the standard Windows Command Line (CMD) window, mount the file system by typing the following. Replace `10.x.x.x:` with the local subnet IP address assigned to your mount target, `fs-export-path` with the export path you specified when associating the file system with the mount target, and `X` with the drive letter of any available drive you want to map the file system to.

Tip

IP address and export path information is available in the **Details** page of the mount target associated with your file system. See To view details of a mount target for more information.

```
mount 10.x.x.x:/fs-export-path X:
```

> **Important**
>
> The export path is the path to the file system (relative to the mount target IP address or hostname). If you did not specify a path when you associated the file system and mount target, then "/" represents the full extent of the mount target. In that case, you must use a "!" when mounting the file system. For example: `mount 10.0.0.0:/! X:`

9. Write a file to the file system by typing the following. Replace `X` with the drive letter you used in step 8 and `helloworld` with your file name.

```
X:
```

```
echo > helloworld.txt
```

10. Verify that you can view the file by typing the following.

```
dir
```

See Troubleshooting Windows NFS Client Connections for more information on common issues you may encounter.

To mount a file system from Windows Server 2012 R2 or 2016 Command Prompt

If you are using Oracle-provided Windows images, the NFS client is already installed, and the correct user identities are mapped. Skip to step 4.

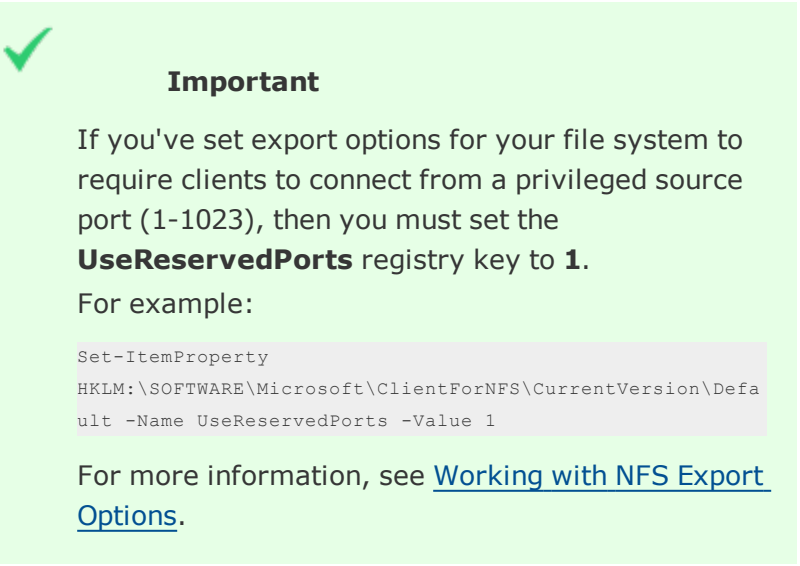
1. Open **Windows PowerShell** and run as **Administrator**:
    a. Go to **Start** and click the **Windows PowerShell** icon.
    b. In Windows PowerShell, type the following to run as Administrator:

```
Start-Process powershell -Verb runAs
```

c. In the **User Account Control** window, click **Yes**. A new Administrator: PowerShell window opens. You can close the standard PowerShell window to avoid confusing them.

2. In Administrator: PowerShell, get the NFS client by typing the following:

```
Install-WindowsFeature -Name NFS-Client
Set-ItemProperty HKLM:\SOFTWARE\Microsoft\ClientForNFS\CurrentVersion\Default -Name AnonymousUid
-Value 0
Set-ItemProperty HKLM:\SOFTWARE\Microsoft\ClientForNFS\CurrentVersion\Default -Name AnonymousGid
-Value 0
Stop-Service -Name NfsClnt
Restart-Service -Name NfsRdr
Start-Service -Name NfsClnt
```



Important

If you've set export options for your file system to require clients to connect from a privileged source port (1-1023), then you must set the **UseReservedPorts** registry key to **1**.

For example:

```
Set-ItemProperty
HKLM:\SOFTWARE\Microsoft\ClientForNFS\CurrentVersion\Defa
ult -Name UseReservedPorts -Value 1
```

For more information, see Working with NFS Export Options.

3. Close the Administrator: PowerShell window. Open a **standard** Command Prompt Window:

a. Click **Start**, then click **Command Prompt**.

Important

NFS file systems mounted as Administrator are not available to standard users.

4. In the standard Windows Command Line (CMD) window, mount the file system by typing the following. Replace `10.x.x.x:` with the local subnet IP address assigned to your mount target, `fs-export-path` with the export path you specified when associating the file system with the mount target, and `X` with the drive letter of any available drive you want to map the file system to.

Tip

IP address and export path information is available in the **Details** page of the mount target associated with your file system. See To view details of a mount target for more information.

```
mount 10.x.x.x:/fs-export-path X:
```

Important

The export path is the path to the file system (relative to the mount target IP address or hostname). If you did not specify a path when you associated the file system and mount target, then "/" represents the full extent of the mount target. In that case, you must use a "!" when mounting the file system. For example: `mount 10.0.0.0:/! X:`

5. Write a file to the file system by typing the following. Replace `X` with the drive letter you used in step 10 and `helloworld` with your file name.

```
X:
```

```
echo > helloworld.txt
```

6. Verify that you can view the file by typing the following.

```
dir
```

See Troubleshooting Windows NFS Client Connections for more information on common issues you may encounter.

Using Windows File Explorer

To mount a file system from Windows Server 2008 R2 File Explorer

If you are using Oracle-provided Windows images, the NFS client is already installed, and the correct user identities are mapped. Skip to step 7.

1. Install Services for NFS components.
    a. Click **Start** go to **Administrative Tools**, then click **Server Manager**.
    b. In the left pane, click **Roles**.
    c. Under **Roles Summary** in the right pane, click **Add Roles**. The **Add Roles Wizard** appears. Click **Next**.
    d. Select the **File Services** check box from the list and click **Next**. Review the information and click **Next**.
    e. Select the **Services for Network File System** check box from the list, and click **Next**.
    f. Confirm your selections, then click **Install**. Click **Close** when the installation is complete.
2. Open the registry editor (regedit) to map the AnonymousGid and AnonymousUid to the root user.

Warning

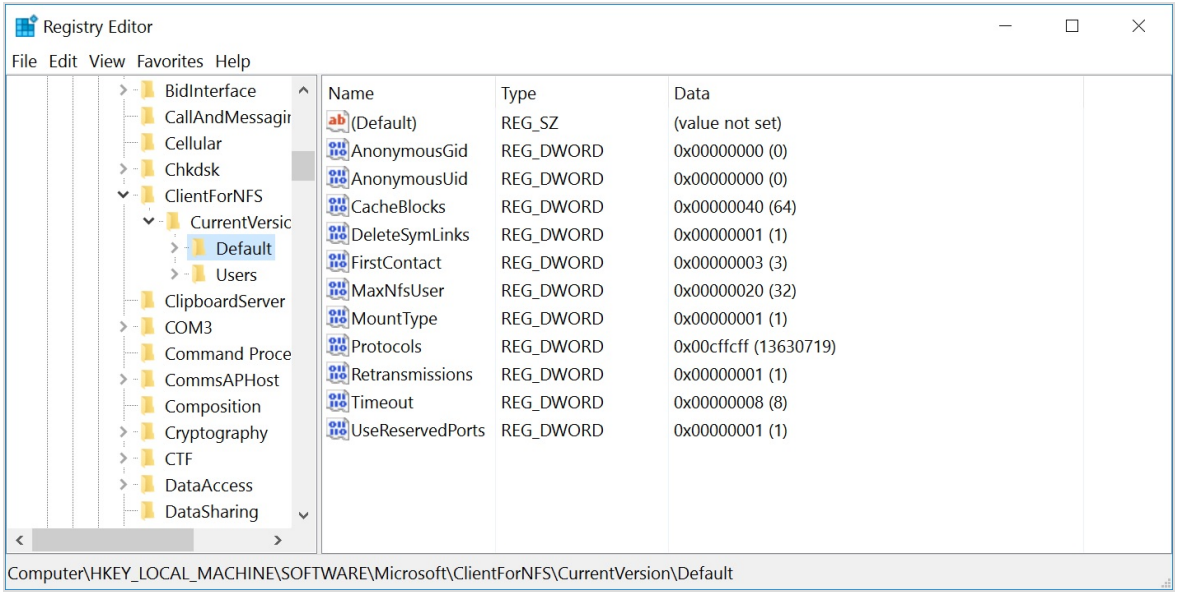
User identity mapping requires changes to your system registry.

    a. Click **Windows Search.**
    b. Enter `regedit` in the **Search** field and press **Enter**.
    c. Click **Yes** to allow changes to your device.
    d. Click `HKEY_LOCAL_MACHINE`. Then, browse to: `Software\Microsoft\ClientForNFS\CurrentVersion\Default`.
3. Add a new DWORD32 registry entry for `AnonymousGid`:

a. Click **Edit**, and select **New DWORD (32 bit) Value**.

b. In the **Name** field, enter `AnonymousGid`. Leave the value at `0`.

4. Repeat step 3 to add a second DWORD32 registry entry named `AnonymousUid` with a value of `0`.



Important

If you've set export options for your file system to require clients to connect from a privileged source port (1-1023), then you must set the **UseReserverdPorts** registry key to **1**.

For more information, see Working with NFS Export Options.

5. Open Windows Command Line (CMD) and run as **Administrator**:
    a. Click **Start** .
    b. Press **Ctrl+Shift** and click **Command Prompt**.
    c. Click **Yes**.
6. In the Administrator: Windows Command Prompt (CMD) window, restart the NFS Client by typing the following:

```
nfsadmin client stop
```

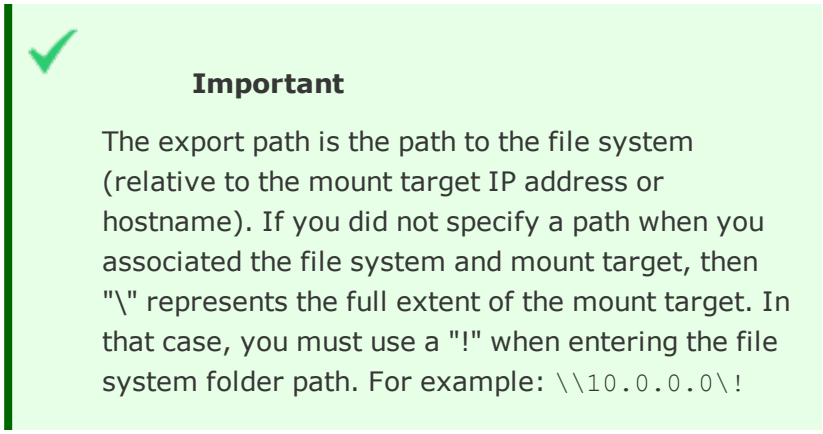
```
nfsadmin client start
```

7. Open **File Explorer** and select **Computer**. Click the **Map network drive** tab.
8. Select the **Drive** letter that you want to assign to the file system.
9. In the **Folder** field, enter the following. Replace `10.x.x.x` with the local subnet IP address assigned to your mount target, and `fs-export-path` with the export path you specified when associating the file system with the mount target.

Tip

IP address and export path information is available in the **Details** page of the mount target associated with your file system. See To view details of a mount target for more information.

```
\\10.x.x.x\fs-export-path
```



Important

The export path is the path to the file system (relative to the mount target IP address or hostname). If you did not specify a path when you associated the file system and mount target, then "\" represents the full extent of the mount target. In that case, you must use a "!" when entering the file system folder path. For example: `\\10.0.0.0\!`

10. Click the **Finish** button when complete.

See Troubleshooting Windows NFS Client Connections for more information on common issues you may encounter.

To mount a file system from Windows Server 2012 R2 or 2016 File Explorer

If you are using Oracle-provided Windows images, the NFS client is already installed, and the correct user identities are mapped. Skip to step 9.

1. Open **Windows PowerShell** and run as **Administrator**:
    a. Go to **Start** and click the **Windows PowerShell** icon.
    b. In Windows PowerShell, type the following to run as Administrator:

    ```
    Start-Process powershell -Verb runAs
    ```

    c. In the **User Account Control** window, click **Yes**. A new Administrator: PowerShell window opens. You can close the standard PowerShell window to avoid confusing them.
2. In Administrator: PowerShell, get the NFS client by typing the following:

    ```
    Install-WindowsFeature -Name NFS-Client
    ```

3. If necessary, restart your system.

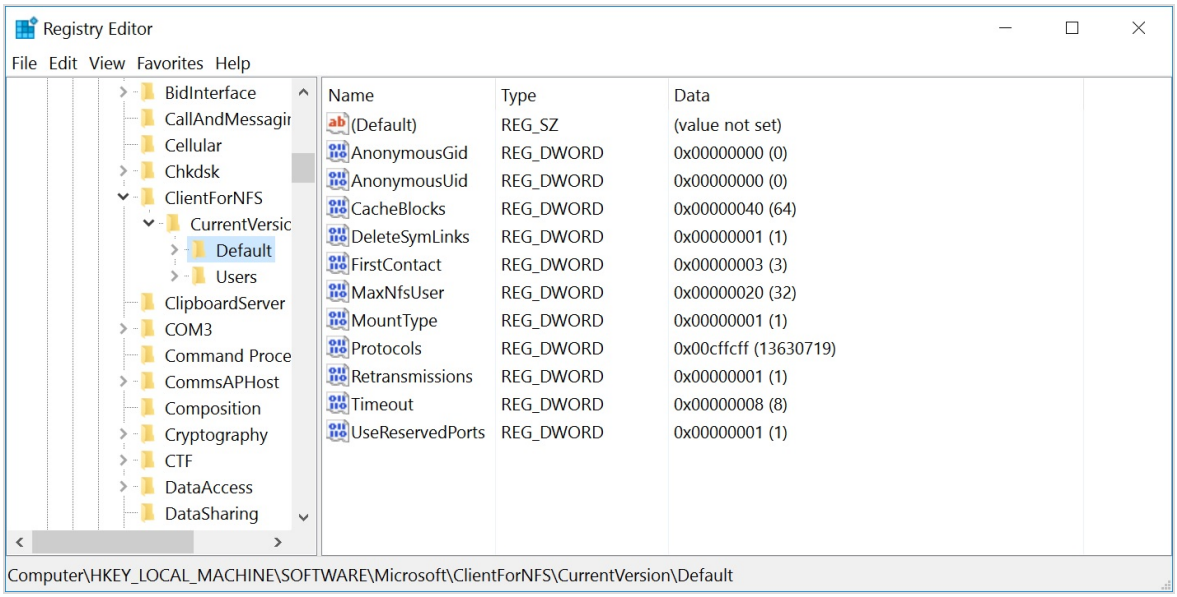
4. Open the registry editor (regedit) to map the AnonymousGid and AnonymousUid to the root user.

Warning

User identity mapping requires changes to your system registry.

   a. Click **Windows Search.**
   b. Enter `regedit` in the **Search** field and press **Enter**.
   c. Click **Yes** to allow changes to your device.
   d. Click `HKEY_LOCAL_MACHINE`. Then, browse to: `Software\Microsoft\ClientForNFS\CurrentVersion\Default`.

5. Add a new DWORD32 registry entry for `AnonymousGid`:
   a. Click **Edit**, and select **New DWORD (32 bit) Value**.
   b. In the **Name** field, enter `AnonymousGid`. Leave the value at `0`.
6. Repeat step 5 to add a second DWORD32 registry entry named `AnonymousUid` with a value of `0`.



Important

If you've set export options for your file system to require clients to connect from a privileged source port (1-1023), then you must set the **UseReserverdPorts** registry key to **1**.

For more information, see Working with NFS Export Options.

7. Open Windows Command Line (CMD) and run as Administrator:
   a. Go to **Start** and scroll down to **Apps**.
   b. In the **Windows System** section, press **Ctrl+Shift** and click **Command Prompt**.
8. In the Windows Command Line (CMD) window, restart the NFS Client by typing the

following:

```
nfsadmin client stop
```

```
nfsadmin client start
```

9. Open **File Explorer** and select **This PC**. In the **Computer** tab, select **Map network drive**.
10. Select the **Drive** letter that you want to assign to the file system.
11. In the **Folder** field, enter the following. Replace `10.x.x.x` with the local subnet IP address assigned to your mount target, and `fs-export-path` with the export path you specified when associating the file system with the mount target.

Tip

IP address and export path information is available in the **Details** page of the mount target associated with your file system. See To view details of a mount target for more information.

```
\\10.x.x.x\fs-export-path
```

Important

The export path is the path to the file system (relative to the mount target IP address or hostname). If you did not specify a path when you associated the file system and mount target, then "\" represents the full extent of the mount target. In that case, you must use a "!" when entering the file system folder path. For example: `\\10.0.0.0\!`

12. Click the **Finish** button when complete.

See Troubleshooting Windows NFS Client Connections for more information on common issues you may encounter.

Managing File Systems

In the File Storage service, file systems are associated with a single compartment. When you select a compartment, the Console displays all file systems in the compartment. You can also see exports and snapshots associated with each file system. If there are no file systems in the compartment, see Creating File Systems for instructions about creating one.

The compartment has policies that indicate what actions a user can take to manage file system. UNIX permissions control what actions a user can take on the files stored in the file system. See About Security for more information.

Actions you can take to manage a file system include:

- Viewing file system details
- Editing file system settings
- Viewing associated file system resources
- Creating an export for the file system
- Deleting a file system

You can perform most administrative tasks for your file systems using the Console, Command Line Interface (CLI), or API. You can use the Console to list mount targets exporting a specific file system. Use the API or CLI if you want to list all mount targets in a compartment.

To access a file system, it must have at least one export in one mount target. Next, mount the file system from an instance, and then you can create directories and read and write files. For more information about creating an export for a file system, see To create an export for a file system in this topic. For more information about accessing your file system, see Mounting File Systems.

Required IAM Service Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: The policy in Let users create, manage, and delete file systems allows users to manage file systems.

If you're new to policies, see Getting Started with Policies and Common Policies.

Tagging Resources

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the desired tags. For general information about applying tags, see Resource Tags.

Moving File Systems to a Different Compartment

You can move file systems from one compartment to another. When you move a file system to a new compartment, its associated snapshots move with it. After you move the file system to the new compartment, inherent policies apply immediately and affect access to the file system and snapshots through the Console. Moving these resources doesn't affect access to file systems and snapshots from mounted instances. For more information, see Managing Compartments.

Details About Your File System

The file system details page provides the following information about your file system:

File System OCID

Every Oracle Cloud Infrastructure resource has an Oracle-assigned unique ID called an Oracle Cloud Identifier (OCID). You need your file system's OCID to use the Command Line Interface (CLI) or the API. You also need the OCID when contacting support.

Availability Domain

When you create a file system, you specify the availability domain that it resides in. An availability domain is one or more data centers located within a region. You need your file system's availability domain to use the Command Line Interface (CLI) or the API. For more information, see Regions and Availability Domains.

Created

The date and time that the file system was created.

Compartment

When you create a file system, you specify the compartment that it resides in. A compartment is a collection of related resources (such as cloud networks, compute instances, or file systems) that are only accessible to those groups that have been given permission by an administrator in your organization. You need your file system's compartment to use the Command Line Interface (CLI) or the API. For more information, see Managing Compartments.

Utilization

Metered size of the file system that gets updated hourly.

Important

There can be a delay of up to 1 hour when reporting file system usage.

You can use `df` or `du` commands from your mounted instance command line application to view usage information about your file system.

- `df` provides the amount of storage metered for your file system. Results are returned quickly, but can be up to 1 hour out of date.
- `du` provides the storage used by a directory hierarchy. The `du` command walks the directory tree, and if your hierarchy is large, it can take a long time to run and return results.

The results provided by `df` and `du` can differ for several reasons:

- `df` and `du` report snapshot utilization differently. Snapshots are copy-on-write, so each snapshot shares the blocks used by the unchanged data. The `df` command retrieves information provided by the File Storage service using the NFS FSSTAT call, which accounts correctly for the shared utilization. The `du` command can't detect this sharing, and reports the shared utilization once for each snapshot.
- `df` counts each file only once. `du` may count files with hard links more than once.
- File Storage needs 512 bytes for each directory entry and 8192 bytes for each symlink for metadata cost. `df` reports this cost usage, even on empty files. `du` reports empty files as using zero bytes.

RESOURCES

Resources such as exports and snapshots that are associated with the file system are listed here. Click the resource type link to see a list of each individual resource. Each export in the list shows the file system's export path and mount target. You need the export path to mount a file system.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Using the Console

To view file system details

The File Storage service displays a list of file systems in each compartment.

1. Open the navigation menu. Under **Core Infrastructure**, click **File Storage** and then click **File Systems**.
2. In the **List Scope** section, select a compartment.
3. To view information about a file system, find the file system, click the Actions icon (three dots), and then click **View File System Details**.

   The Console displays metadata for the file system, exports and snapshots for the file system, and status for the file system and its exports in associated mount targets.

To change the file system name

You can change the display name of the file system.

1. Open the navigation menu. Under **Core Infrastructure**, click **File Storage** and then click **File Systems**.
2. In the **List Scope** section, select a compartment.
3. To view information about a file system, find the file system, click the Actions icon (three dots), and then click **View File System Details**.
4. Click **Rename**.
5. Enter the new file system name, and click **Rename**.

To create an export for a file system

Exports control how NFS clients access file systems when they connect to a mount target. File systems are exported (made available) through mount targets. Each mount target maintains an export set which contains one or many exports. A file system may be exported through one

or more mount targets. A file system must have at least one export in one mount target in order for instances to mount the file system. The information used by an export includes the file system OCID, mount target OCID, export set OCID, export path, and client export options. Typically, an export is created in a mount target when the file system is created. Thereafter, you can create additional exports for a file system in any mount target that resides in the same availability domain as the file system.

1. Open the navigation menu. Under **Core Infrastructure**, click **File Storage** and then click **File Systems**.
2. In the left-hand navigation, in the **List Scope** section, under **Compartment**, select a compartment.
3. Click the name of the file system you want to create an export for, and click **Create Export**.

Note

File systems are encrypted by default. You cannot turn off encryption.

4. You can choose to accept the system defaults, or change them by clicking **Edit Details**.
5. If you want to *accept the defaults* for the mount target, click **Create**. *The file system is created with the information displayed*. If you want to choose another mount target or change the default information, click the **Edit Details** link.
6. In the **Mount Target Information** section, specify details for the mount target that is associated with the file system:
   - **Select an Existing Mount Target:** Choose this option if you want to associate the file system with a mount target you already created. Choose the **Mount Target** from the list. Click the **click here** link in the dialog box if you want to enable compartment selection for the mount target.

Tip

If there aren't any mount targets in the current combination of availability domain and compartment, this option is disabled. You can:

- Choose a different compartment.
- Create a new mount target.

- **Create a New Mount Target:** Choose this option if you want to create a new mount target associated with this file system. By default, the mount target is created in your current compartment and you can use network resources in that compartment. Click the **click here** link in the dialog box if you want to enable compartment selection for the mount target, its VCN, or subnet resources.

Important

The mount target is always in the same availability domain as the file system. While it is possible to access mount targets from any AD in a region, for optimal performance, your mount target and file system should be in the same availability domain as the Compute instances that access them. For more information, see Regions and Availability Domains.

- **Create in Compartment:** Specify the compartment you want to create the mount target in.
- **New Mount Target Name:** Optionally, replace the default with a friendly name

for the mount target. It doesn't have to be unique; an Oracle Cloud Identifier (OCID) uniquely identifies the mount target. Avoid entering confidential information.

Note

The mount target name is different than the DNS hostname, which is specified in step 7.

- **Virtual Cloud Network Compartment:** The compartment containing the cloud network (VCN) in which to create the mount target.
- **Virtual Cloud Network:** Select the cloud network (VCN) where you want to create the new mount target.
- **Subnet Compartment:** Specify the compartment containing a subnet within the VCN to attach the mount target to.
- **Subnet:** Select a subnet to attach the mount target to. Subnets can be either AD-specific or regional (regional ones have "*regional*" after the name). For more information, see About Regional Subnets.

Warning

Each mount target requires three internal IP addresses in the subnet to function. Do not use /30 or smaller subnets for mount target creation because they do not have sufficient available IP addresses. Two of the IP addresses are used during mount target creation. The third IP address must remain available for the mount target to use for high availability failover.

- **Tags**:Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.

7. Optionally, click **Show Advanced Options** to configure the mount target's advanced options.
   - **IP Address:** You can specify an unused IP address in the subnet you selected for the mount target.
   - **Hostname:** You can specify a hostname you want to assign to the mount target.

Note

The File Storage service constructs a fully qualified domain name (FQDN) by combining the hostname with the FQDN of the subnet the mount target is located in.

For example, `myhostname.subnet123 .dnslabel.oraclevcn.com`.

Once created, the hostname may be changed in the mount target's Details page. See Managing Mount Targets for more information.

8. Click **Create**.

Next, mount the file system from an instance so that you can read and write directories and files in your file system. See Mounting File Systems for instructions about obtaining mount commands for your operating system type and mounting your file system.

To set the file system reported size

The File Storage service reports file system capacity as 8589934592 gibibytes (GiB) and 8589934592 gibiinodes (GiI) by default. Sometimes, application installers perform a space requirement check prior to running an installation process but cannot correctly interpret the reported size or reported inodes of the file system. When this occurs, you can define the file system size reported to the operating system by setting the **Reported Size** or **Reported Inodes** value in the file system's mount target. Typically, setting the size to 1024 GiB and the inodes to 1024 GiI permits successful installation.

Important

Changing the **Reported Size** or **Reported Inodes** for a mount target affects all file systems exported by the mount target. **Changing these values does not limit the amount of data you can store.**

1. Open the navigation menu. Under **Core Infrastructure**, click **File Storage** and then click **File Systems**.
2. In the **List Scope** section, select a compartment.
3. Find the mount target you're interested in, click the Actions icon (three dots), and then click **View File System Details**.
4. In **Exports**, click on the mount target name.
5. Click the **Reported Size (in GiB) Edit** or the **Reported Inodes (in Gil)** icon.
6. Enter the maximum free space in gibibytes or the maximum inodes in gibinodes you want the File Storage service to report.
7. Click the **Save** icon.

Important

There can be a delay of up to 1 hour when reporting file system usage, either in the console or by using the `df` command.

To manage tags for a file system

1. Open the navigation menu. Under **Core Infrastructure**, click **File Storage** and then click **File Systems**.

2. In the **List Scope** section, select a compartment.
3. Find the file system you're interested in, click the Actions icon (three dots), and then click **View File System Details**.
4. Click the **Tags** tab to view or edit the existing tags. Or click **Apply tag(s)** to add new ones.

For more information, see Resource Tags.

To move a file system to a different compartment

1. Open the Console,
2. Open the navigation menu. Under **Core Infrastructure**, click **File Storage** and then click **File Systems**.
3. In the **List Scope** section, select a compartment.
4. Find the file system in the list, click the the Actions icon (three dots), and then click **Change Compartment**.
5. Choose the destination compartment from the list.
6. Click **Change Compartment**.

The file system is moved immediately. Moving a file system doesn't affect mounted instances.

To assign a key to a file system

File systems use Oracle-managed keys by default, which leaves all encryption-related matters to Oracle. Optionally, you can encrypt the data in this file system using your own Key Management encryption key. For more information, see Overview of Key Management.

1. Open the navigation menu. Under **Core Infrastructure**, click **File Storage** and then click **File Systems**.
2. Under **List Scope**, in the **Compartment** list, choose the compartment that contains the file system that you want to encrypt with a Key Management master encryption key.

3. From the list of file systems, click the file system name.
4. Next to **Encryption Key**, click **Edit**.
5. In **Encryption Type,** select **Encrypt using customer-managed keys**.
6. Choose the vault compartment, vault, key compartment, and key.
7. When you are finished, click **Save Changes**.

To specify Oracle-managed keys for a file system

File systems use Oracle-managed keys by default, which leaves all encryption-related matters to Oracle. However, if you assign a Key Management key to a file system, you can later return the file system to using Oracle-managed keys for encryption. For more information, see Overview of Key Management.

1. Open the navigation menu. Under **Core Infrastructure**, click **File Storage** and then click **File Systems**.
2. Under **List Scope**, in the **Compartment** list, choose the compartment that contains the file system that you want to encrypt with a Key Management master encryption key.
3. From the list of file systems, click the file system name.
4. Next to **Encryption Key**, click **Edit**.
5. In **Encryption Type,** select **Encrypt using Oracle-managed keys**.
6. When you are finished, click **Save Changes**.

To delete a file system

You can permanently delete a file system.

Warning

You cannot undo this operation. Any data in a file system is permanently deleted with the file system. Snapshots of the file system are permanently deleted with the file system. You cannot recover a deleted file system or its snapshots.

1. Open the navigation menu. Under **Core Infrastructure**, click **File Storage** and then click **File Systems**.
2. In the **List Scope** section, select a compartment.
3. Find the file system you want to delete.
4. Click the Actions icon (three dots), and then click **View File System Details**.
5. Delete all of the file system's exports:
    - In **Exports**, select the check box for all exports listed, and then click **Delete**.
6. When all of the exports are deleted, click **Delete** to delete the file system.

The file system is deleted immediately, along with all of its snapshots.

Using the Command Line Interface (CLI)

For information about using the CLI, see Command Line Interface (CLI).

To list file systems

Open a command prompt and run `oci fs file-system list` to list all the file systems in a specified availability domain and compartment.

For example:

```
oci fs file-system list --availability-domain <target_availability_domain> --compartment-id <target_
compartment_id>
```

To get a specific file system

Open a command prompt and run `oci fs file-system get` to retrieve information about a specific file system.

For example:

```
oci fs file-system get --file-system-id <file_system_OCID>
```

To update a file system

Open a command prompt and run `oci fs file-system update` to update a specific file system's information.

For example:

```
oci fs file-system update --file-system-id <file_system_OCID> --display-name "<New File System Name>"
```

Warning

Avoid entering confidential information in the file system `display-name`.

To create an export for a file system

Exports control how NFS clients access file systems when they connect to a mount target. File systems are exported (made available) through mount targets. Each mount target maintains an export set which contains one or many exports. A file system may be exported through one or more mount targets. A file system must have at least one export in one mount target in order for instances to mount the file system. The information used by an export includes the file system OCID, mount target OCID, export set OCID, export path, and client export options.

Typically, an export is created in a mount target when the file system is created. Thereafter, you can create additional exports for a file system in any mount target that resides in the same availability domain as the file system.

Open a command prompt and run `oci fs export create` to create an export for a specified file system within a specified export set.

For example:

```
oci fs export create --export-set-id <export_set_OCID> --file-system-id <file_system_OCID> --path
"</pathname>"
```

Important

The path must start with a slash (/) followed by a sequence of zero or more slash-separated elements. For multiple file systems associated with a single mount target, the path sequence for the first file system cannot contain the complete path element sequence of the second file system path sequence. Paths cannot end in a slash. No path element can be a period (.) or two periods in sequence (..). Lastly, no path can exceed 255 bytes. For example:

Acceptable:

`/example` and `/path`

`/example` and `/example2`

Not Acceptable:

`/example` and `/example/path`

`/` and `/example`

`/example/`

`/example/path/../example1`

Warning

If one file system associated to a mount target has '/' specified as an export path, you can't associate another file system with that mount target.

Note

Export paths cannot be edited after the export is created. If you want to use a different export path, you must create a new export with the desired path. Optionally, you can then delete the export with the old path.

For more information, see Paths in File Systems.

To set the file system reported free space

Some existing application installers perform a capacity check before running an installation process. Sometimes an installation fails because of too much available capacity. The File Storage service currently reports 8 exabytes of available capacity by default for each file system.

Customers can define how much free capacity is reported as available to the operating system.

Open a command prompt and type in the following command:

```
oci fs export-set update --export-set-id <export_set_ OCID> --max-fs-stat-bytes <number_of_bytes>
```

Important

The maximum free space setting affects each export in the export set. Setting the maximum free space does not limit the amount of data you can store.

To move a file system to a different compartment

```
oci fs file-system change-file-system-compartment --file-system-id <file_system_OCID> --compartment-id
<destination_compartment_OCID>
```

To update the key for a file system

Open a command prompt and run `oci fs file-system update` to update the file system with a new key.

```
oci fs file-system update --file-system-id <file_system_OCID> --kms-key-id <target_key_id>
```

For example:

```
oci fs file-system update --file-system-id ocid1.filesystem.oc1.phx.<unique_id> --kms-key-id
ocid1.key.oc1.phx.<unique_id>
```

To specify Oracle-managed keys for a file system

File systems use Oracle-managed keys by default, which leaves all encryption-related matters to Oracle. However, if you assign a Key Management key to a file system, you can later return the file system to using Oracle-managed keys for encryption.

Open a command prompt and run `oci fs file-system update`. Leave the `--kms-key-id` value **unspecified**.

```
oci fs file-system update --file-system-id <file_system_OCID> --kms-key-id ""
```

For example:

```
oci fs file-system update --file-system-id ocid1.filesystem.oc1.phx.<unique_id> --kms-key-id ""
```

To delete a file system

You can delete a file system if no non-deleted export resources reference it. Deleting a file system also deletes all its snapshots.

Open a command prompt and run `oci fs file-system delete` to delete a file system.

For example:

```
oci fs file-system delete --file-system-id <file_system_OCID>
```

Warning

You cannot undo this operation. Any data in a file system is permanently deleted with the file system. Snapshots of the file system are permanently deleted with the file system. You cannot recover a deleted file system or its snapshots.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the following operations to manage file systems:

- ListFileSystems
- GetFileSystem
- UpdateFileSystem
- ChangeFileSystemCompartment
- DeleteFileSystem

Managing Mount Targets

This topic describes the basics of managing mount targets.

Overview

Actions you can take to manage a mount target include:

- Viewing mount target details
- Obtaining mount command samples
- Creating a new export and file system
- Editing exports and export options
- Change the reported size of exported file systems
- Deleting a mount target

You can perform most administrative tasks for your mount targets using the Console, Command Line Interface (CLI), or API. You can use the Console to list mount targets exporting a specific file system. Use the API or CLI if you want to list all mount targets in a compartment.

Mount Target

A mount target is an NFS endpoint that lives in a VCN subnet of your choice and provides network access for file systems. The mount target provides the IP address or DNS name that is used together with a unique export path to mount the file system. A single mount target can export many file systems. Typically, you create your first mount target and export when you create your first file system. The mount target maintains an export set which contains all of the exports for its associated file systems.

Exports

Exports control how NFS clients access file systems when they connect to a mount target. File systems are exported (made available) through mount targets. Each mount target maintains an export set which contains one or many exports. A file system may be exported through one or more mount targets. A file system must have at least one export in one mount target in order for instances to mount the file system. The information used by an export includes the file system OCID, mount target OCID, export set OCID, export path, and client export options. Typically, an export is created in a mount target when the file system is created. Thereafter, you can create additional exports for a file system in any mount target that resides in the same availability domain as the file system.

NFS Export Options

NFS export options are a set of parameters within the export that specify the level of access granted to NFS clients when they connect to a mount target. An NFS export options entry within an export defines access for a single IP address or CIDR block range.

For more information, see Working with NFS Export Options.

Limitations and Considerations

- Each availability domain is limited to two mount targets by default. However, you can export up to 100 file systems through each mount target.

  See Service Limits for a list of applicable limits and instructions for requesting a limit increase.

- Each mount target requires three internal IP addresses in the subnet to function. Two of the IP addresses are used during mount target creation. The third IP address must remain available for the mount target to use for high availability failover.
- The File Storage service doesn't "reserve" the third IP address required for high availability failover. Use care when designing your subnets and file systems to ensure that sufficient IP addresses remain available for your mount targets.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: The policy in Let users create, manage, and delete file systems allows users to manage mount targets. Since mount targets are network endpoints, users must also have "use" permissions for VNICs, private IPs, private DNS zones, and subnets to create or delete a mount target. See the Policy Reference for more information.

If you're new to policies, see Getting Started with Policies and Common Policies.

Tagging Resources

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the desired tags. For general information about applying tags, see Resource Tags.

Moving Mount Targets to a Different Compartment

You can move mount targets from one compartment to another. When you move a mount target to a new compartment, its associated export set and exports move with it. After you move the mount target to the new compartment, inherent policies apply immediately and affect access to the mount target, export set, and exports through the Console. Moving these resources doesn't affect access to file systems and snapshots from mounted instances. For more information, see Managing Compartments.

Details About Your Mount Target

The mount target details page provides the following information about your mount target:

MOUNT TARGET OCID

Every Oracle Cloud Infrastructure resource has an Oracle-assigned unique ID called an Oracle Cloud Identifier (OCID). You need your mount target's OCID to use the Command Line Interface (CLI) or the API. You also need the OCID when contacting support.

CREATED

The date and time that the mount target was created.

AVAILABILITY DOMAIN

When you create a mount target, you specify the availability domain that it resides in. An availability domain is one or more data centers located within a region. You need your mount target's availability domain to use the Command Line Interface (CLI) or the API. For more information, see Regions and Availability Domains.

COMPARTMENT

When you create a mount target, you specify the compartment that it resides in. A compartment is a collection of related resources (such as cloud networks, compute instances, or file systems) that are accessible only to those groups that have been given permission by an administrator in your organization. You need your mount target's compartment to use the Command Line Interface (CLI) or the API. For more information, see Managing Compartments.

REPORTED SIZE (GIB)

The maximum capacity in gibibytes reported by the file systems exported through this mount target. The File Storage service currently reports 8589934592 gibibytes (GiB) of available capacity by default. If you are installing an application that requires a specific reported size, you can change the reported size. Typically, setting the size to 1024 GiB is sufficient for most applications. This value is updated hourly. See To set the file system reported size for more information.

REPORTED INODES (GII)

The maximum capacity in gibiinodes reported by the file systems exported through this mount target. The File Storage service currently reports gibiinodes (GiI) of available inodes by default. If you are installing an application that requires specific reported inodes, you can change the reported inodes. Typically, setting the inodes to 1024 GiI is sufficient for most applications. This value is updated hourly. See To set the file system reported size for more information.

VIRTUAL CLOUD NETWORK

The VCN that contains the subnet where the mount target VNIC resides.

SUBNET

The subnet within the VCN where the mount target VNIC resides. Subnets can be either AD-specific or regional (regional ones have "*regional*" after the name). For more information, see About Regional Subnets.

IP Address

The IP address that was assigned to the mount target when it was created. You need your mount target's IP address to mount associated file systems.

Hostname

The hostname that was assigned to the mount target, if any. For more information about hostnames, see DNS in Your Virtual Cloud Network.

Fully Qualified Domain Name

The hostname together with the subnet domain name. For more information, see DNS in Your Virtual Cloud Network. If you specify a hostname, you can use the FDQN to mount the file system.

Export Set OCID

The OCID of the mount target's export set resource. Each mount target has one export set, which contains all of the exports for the mount target. You need your mount target's export set OCID when you perform export-related tasks in the Command Line Interface (CLI) or the API.

Exports

All of the mount target's exports are listed here. The export path and name of each file system is also listed. You need the export path to mount a file system.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Using the Console

To create a mount target

Important

While it is possible to access mount targets from any AD in a region, for optimal performance, your mount targets should be in the same availability domain as the Compute instances that access them. For more information, see Regions and Availability Domains.

1. Open the navigation menu. Under **Core Infrastructure**, click **File Storage** and then click **Mount Targets**.
2. In the **List Scope** section, select a compartment.
   The Console displays a list of mount targets that have already been created in the compartment, if any.
3. Click **Create Mount Target**.
4. Enter the required mount target information. Click the **click here** link in the dialog box if you want to enable compartment selection for the mount target, its VCN, or subnet resources:
   - **New Mount Target Name:** Optionally, replace the default with a friendly name for the mount target. It doesn't have to be unique; an Oracle Cloud Identifier (OCID) uniquely identifies the mount target. Avoid entering confidential information.

Note

The mount target name is different than the DNS hostname, which is specified in step 5.

- **Virtual Cloud Network Compartment:** The compartment containing the cloud network (VCN) in which to create the mount target.
- **Virtual Cloud Network:** Select the cloud network (VCN) where you want to create the new mount target.
- **Subnet Compartment:** Specify the compartment containing a subnet within the VCN to attach the mount target to.
- **Subnet:** Select a subnet to attach the mount target to. Subnets can be either AD-specific or regional (regional ones have "*regional*" after the name). For more information, see About Regional Subnets.

Warning

Each mount target requires three internal IP addresses in the subnet to function. Do not use /30 or smaller subnets for mount target creation because they do not have sufficient available IP addresses. Two of the IP addresses are used during mount target creation. The third IP address must remain available for the mount target to use for high availability failover.

5. Optionally, click **Show Advanced Options** to configure the mount target's advanced options.

- **IP Address:** You can specify an unused IP address in the subnet you selected for the mount target.
- **Hostname:** You can specify a hostname you want to assign to the mount target.

Note

The File Storage service constructs a fully qualified domain name (FQDN) by combining the hostname with the FQDN of the subnet the mount target is located in.

For example, `myhostname.subnet123.dnslabel.oraclevcn.com`.

Once created, the hostname may be changed in the mount target's Details page. See Managing Mount Targets for more information.

6. Click **Create**.

To view details of a mount target

1. Open the navigation menu. Under **Core Infrastructure**, click **File Storage** and then click **Mount Targets**.
2. In the **List Scope** section, select a compartment.
   The Console displays a list of mount targets that have already been created in the compartment, if any.
3. Find the mount target you're interested in, click the Actions icon (three dots), and then click **View Mount Target Details**.

To change the mount target name

You can change the display name of the mount target.

Note

Changing the display name doesn't affect mounting file systems exported through the mount target.

1. Open the navigation menu. Under **Core Infrastructure**, click **File Storage** and then click **Mount Targets**.
2. In the **List Scope** section, select a compartment.
3. To view information about a file system, find the file system, click the Actions icon (three dots), and then click **View Mount Target Details**.
4. Click **Rename**.
5. Enter the new mount target name, and click **Rename**.

To create an export and a new file system

Exports control how NFS clients access file systems when they connect to a mount target. File systems must have at least one export in at least one mount target in order for instances to mount the file system. The following steps create an export and a new file system. If you want to create an export for an *existing* file system, see To create an export for a file system.

1. Open the navigation menu. Under **Core Infrastructure**, click **File Storage** and then click **Mount Targets**.
2. In the left-hand navigation, in the **List Scope** section, under **Compartment**, select a compartment.
3. Click the name of the mount target you want to create an export for, and click **Create Export**.

Note

File systems are encrypted by default. You cannot turn off encryption.

4. You can choose to accept the system defaults, or change them by clicking **Edit Details**.
5. Click **Create**.

Next, mount the file system from an instance so that you can read and write directories and files in your file system. See Mounting File Systems for instructions about obtaining mount commands for your operating system type and mounting your file system.

To set the file system reported size

The File Storage service reports file system capacity as 8589934592 gibibytes (GiB) and 8589934592 gibiinodes (GiI) by default. Sometimes, application installers perform a space requirement check prior to running an installation process but cannot correctly interpret the reported size or reported inodes of the file system. When this occurs, you can define the file system size reported to the operating system by setting the **Reported Size** or **Reported Inodes** value in the file system's mount target. Typically, setting the size to 1024 GiB and the inodes to 1024 GiI permits successful installation.

Important

Changing the **Reported Size** or **Reported Inodes** for a mount target affects all file systems exported by the mount target. **Changing these values does not limit the amount of data you can store.**

1. Open the navigation menu. Under **Core Infrastructure**, click **File Storage** and then click **Mount Targets**.
2. In the **List Scope** section, select a compartment.
3. Find the mount target you're interested in, click the Actions icon (three dots), and then click **View Mount target Details**.
4. Click the **Reported Size (in GiB) Edit** or the **Reported Inodes (in Gil)** icon.
5. Enter the maximum size in gibibytes or the maximum inodes in gibiinodes you want the File Storage service to report.
6. Click the **Save** icon.

Important

There can be a delay of up to 1 hour when reporting file system usage, either in the console or by using the `df` command.

To delete an export

Note

Deleting an export does not impact the data stored in the associated file system. Deleting an export disconnects any instance that mounts the file system with the deleted export path. Mount targets that have no exports still count toward your service limit.

1. Open the navigation menu. Under **Core Infrastructure**, click **File Storage** and then click **Mount Targets**.

2. In the **List Scope** section, select a compartment.
3. Find the mount target you're interested in, click the Actions icon (three dots), and then click **View Mount target Details**.
4. In **Exports**, find the export you want to delete.
5. Click the Actions icon (three dots), and then click **Delete**.

To manage tags for a mount target

1. Open the navigation menu. Under **Core Infrastructure**, click **File Storage** and then click **Mount Targets**.
2. In the **List Scope** section, select a compartment.
3. Find the mount target you're interested in, click the Actions icon (three dots), and then click **View Mount Target Details**.
4. Click the **Tags** tab to view or edit the existing tags. Or click **Apply tag(s)** to add new ones.

For more information, see Resource Tags.

To move a mount target to a different compartment

1. Open the Console,
2. Open the navigation menu. Under **Core Infrastructure**, click **File Storage** and then click **Mount Targets**.
3. In the **List Scope** section, select a compartment.
4. Find the mount target in the list, click the the Actions icon (three dots), and then click **Change Compartment**.
5. Choose the destination compartment from the list.
6. Click **Change Compartment**.

To delete a mount target

1. Open the navigation menu. Under **Core Infrastructure**, click **File Storage** and then click **Mount Targets**.
2. In the **List Scope** section, select a compartment.
3. Find the mount target you want to delete.
4. Click the Actions icon (three dots), and then click **Delete**.

Warning

Deleting the mount target also deletes all of its exports of associated file systems. File systems are no longer available through the deleted mount target.

Deleting a mount target has no effect on file system data or file system snapshots.

Using the Command Line

For information about using the CLI, see Command Line Interface (CLI).

To create a mount target

You can create a mount target for file systems in a specified compartment and subnet. A file system can only be associated with a mount target in the same availability domain.

Warning

Each mount target requires three internal IP addresses in the subnet to function. Do not use /30 or smaller subnets for mount target creation because they do not have sufficient available IP addresses. Two of the IP addresses are used during mount target creation. The third IP address must remain available for the mount target to use for high availability failover.

Open a command prompt and run `oci fs mount-target create` to create a mount target.

For example:

```
oci fs mount-target create --availability-domain <target_availability domain> --compartment-id <target_
compartment_id> --subnet-id <subnet_OCID> --display-name "<My Mount Target>"
```

Warning

Avoid entering confidential information in the mount target `display-name`.

To update a mount target

Open a command prompt and run `oci fs mount-target update` to update a specific mount target's information.

For example:

```
oci fs mount-target update --mount-target-id <mount_target_OCID> --display-name "<New Mount Target
Name>"
```

Warning

Avoid entering confidential information in the mount target `display-name`.

To delete a mount target

Open a command prompt and run `oci fs mount-target delete` to delete a mount target. Deleting a mount target also deletes the mount target's VNICs.

For example:

```
oci fs mount-target delete --mount-target-id <mount_target_OCID>
```

Warning

Deleting a mount target can cause any clients that have mounted an associated file system to hang. Be sure to have all clients unmount the file systems before deleting the mount target.

To list mount targets

You cannot use the Console to list mount targets. Use the command line interface or the API from a host machine running a UNIX-style operating system.

Open a command prompt and run `oci fs mount-target list` to list all mount targets in a specified availability domain and compartment.

For example:

```
oci fs mount-target list --availability-domain <target_availability_domain> --compartment-id <target_compartment_OCID>
```

To get a specific mount target

Open a command prompt and run `oci fs mount-target get` to retrieve information about a specific mount target.

For example:

```
oci fs mount-target get --mount-target-id <mount_target_OCID>
```

To create an export

Exports control how NFS clients access file systems when they connect to a mount target. File systems are exported (made available) through mount targets. Each mount target maintains an export set which contains one or many exports. A file system may be exported through one or more mount targets. A file system must have at least one export in one mount target in order for instances to mount the file system. The information used by an export includes the file system OCID, mount target OCID, export set OCID, export path, and client export options. Typically, an export is created in a mount target when the file system is created. Thereafter, you can create additional exports for a file system in any mount target that resides in the same availability domain as the file system.

Open a command prompt and run `oci fs export create` to create an export for a specified file system within a specified export set.

For example:

```
oci fs export create --export-set-id <export_set_OCID> --file-system-id <file_system_OCID> --path
"</pathname>"
```

Important

The path must start with a slash (/) followed by a sequence of zero or more slash-separated elements. For multiple file systems associated with a single mount target, the path sequence for the first file system cannot contain the complete path element sequence of the second file system path sequence. Paths cannot end in a slash. No path element can be a period (.) or two periods in sequence (..). Lastly, no path can exceed 255 bytes. For example:

Acceptable:

`/example` and `/path`

`/example` and `/example2`

Not Acceptable:

`/example` and `/example/path`

`/` and `/example`

`/example/`

`/example/path/../example1`

Warning

If one file system associated to a mount target has '/' specified as an export path, you can't associate another file system with that mount target.

Note

Export paths cannot be edited after the export is created. If you want to use a different export path, you must create a new export with the desired path. Optionally, you can then delete the export with the old path.

For more information, see Paths in File Systems.

To list exports

Open a command prompt and run `oci fs export list` to list all exports in a specified compartment.

For example:

```
oci fs export list --compartment-id <target_compartment_id>
```

To get a specific export

Open a command prompt and run `oci fs export get` to retrieve information about a specific export.

For example:

```
oci fs export get --export-id <export_OCID>
```

To delete an export

Open a command prompt and run `oci fs export delete` to delete an export.

For example:

```
oci fs export delete --export-id <export_OCID>
```

Warning

When you delete an export, any file system referenced by the export is no longer accessible through the associated mount target.

To list export sets

Open a command prompt and run `oci fs export-set list` to list all export sets in a specified availability domain and compartment.

For example:

```
oci fs export-set list --availability-domain <target_availability_domain> --compartment-id <target_compartment_OCID>
```

To get a specific export set

Open a command prompt and run `oci fs export-set get` to retrieve information about a specific export set.

For example:

```
oci fs export-set get --export-set-id <export_set_OCID>
```

To update an export set

Open a command prompt and run `oci fs export-set update` to update a specific export set's information.

For example:

```
oci fs export-set update --export-set-id <export_set_OCID> --display-name "<New Export Set Name>"
```

To set the file system reported size

The File Storage service reports file system capacity as 8589934592 gibibytes (GiB) and 8589934592 gibiinodes (GiI) by default. Sometimes, application installers perform a space requirement check prior to running an installation process but cannot correctly interpret the reported size or reported inodes of the file system. When this occurs, you can define the file system size reported to the operating system by setting the **Reported Size** or **Reported Inodes** value in the export set of the file system's mount target. Typically, setting the size to 1024 GiB and the inodes to 1024 GiI permits successful installation.

Important

Changing the **Reported Size** or **Reported Inodes** for a mount target affects all file systems exported by the mount target. **Changing these values does not limit the amount of data you can store.**

Important

There can be a delay of up to 1 hour when reporting file system usage, either in the console or by using the `df` command.

Open a command prompt and type in the following command:

```
oci fs export-set update --export-set-id <export_set_ OCID> --max-fs-stat-bytes <number_of_bytes>
```

To move a mount target to a different compartment

```
oci fs mount-target change-mount-target-compartment --mount-target-id <mount_target_OCID> --compartment-id <destination_compartment_OCID>
```

Using the API

- CreateMountTarget
- UpdateMountTarget
- DeleteMountTarget
- GetMountTarget
- ListMountTargets
- ChangeMountTargetCompartment
- CreateExport
- DeleteExport
- GetExport
- ListExports
- UpdateExportSet
- GetExportSet
- ListExportSets

Working with NFS Export Options

This topic describes the basic features of NFS export options, and how to control client access to your file system.

Overview

NFS export options enable you to create more granular access control than is possible using just security list rules to limit VCN access. You can use NFS export options to specify access levels for IP addresses or CIDR blocks connecting to file systems through exports in a mount target. Access can be restricted so that each client's file system is inaccessible and invisible to the other, providing better security controls in multi-tenant environments.

Using NFS export option access controls, you can limit clients' ability to connect to the file system and view or write data. For example, if you want to allow clients to consume but not

update resources in your file system, you can set access to Read Only. You can also reduce client root access to your file systems and map specified User IDs (UIDs) and Group IDs (GIDs) to an anonymous UID/GID of your choice. For more information about how NFS export options work with other security layers, see About Security.

Tip

Watch a video about working with NFS export options in File Storage.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: The policy in Let users create, manage, and delete file systems allows users to manage NFS export options.

If you're new to policies, see Getting Started with Policies and Common Policies.

Exports

Exports control how NFS clients access file systems when they connect to a mount target. File systems are exported (made available) through mount targets. Each mount target maintains an export set which contains one or many exports. A file system may be exported through one or more mount targets. A file system must have at least one export in one mount target in order for instances to mount the file system. The information used by an export includes the file system OCID, mount target OCID, export set OCID, export path, and client export options. Typically, an export is created in a mount target when the file system is created. Thereafter, you can create additional exports for a file system in any mount target that resides in the same availability domain as the file system.

See To create an export for a file system for more information.

NFS Export Options

NFS export options are a set of parameters within the export that specify the level of access granted to NFS clients when they connect to a mount target. An NFS export options entry within an export defines access for a single IP address or CIDR block range.

Each separate client IP address or CIDR block you want to define access for needs a separate export options entry in the export. For example, if you want to set options for NFS client IP addresses 10.0.0.6, 10.0.08, and 10.0.0.10, you need to create three separate entries, one for each IP address.

File Storage service considers the listed order of each export options entry for the export. During an NFS request by a client, File Storage service applies the first set of options that matches the client Source IP address. Only the first set is applied; the rest are ignored.

For example, consider the following two export options entries specifying access for an export:

Entry 1: Source: 10.0.0.0/16, Access: Read Only

Entry 2: Source: 10.0.0.8, Access: Read/Write

In this case, clients who connect to the export from IP address 10.0.0.8 have Read Only access. The request Source IP address is contained in the CIDR block specified in the first entry, and File Storage Service applies the options in the first match.

Important

File systems can be associated with one or more exports, contained within one or more mount targets. If the client **source** IP address does not match any entry on the list for a single export, then that export is not visible to the client. However, the file system could be accessed through other exports on the same or other mount targets. **To completely deny client access to a file system, be sure that the client source IP address or CIDR block is not included in any export for any mount target associated with the file system.**

The following options can be set to control export access:

- **Source**: The IP address or CIDR block of a connecting NFS client.
- **Require Privileged Source Port (true/false):** This setting determines whether the NFS clients specified in **source** are required to connect from a privileged source port. Privileged ports are any port including 1-1023. On Unix-like systems, only the root user can open privileged ports. Setting this value to **true** disallows requests from unprivileged ports. The default for this setting is different depending on how the export is created. Creating an export without an explicit `ClientOption` array sets the `requirePrivilegedSourcePort` attribute of the client option to **false**. When you create a `ClientOption` array explicitly , `requirePrivilegedSourcePort` defaults to **true**. For example, creating an export in the Console using the default selections sets `requirePrivilegedSourcePort` to **false**. Creating an export in the API along with a `ClientOption` array sets `requirePrivilegedSourcePort` to **true**.

Important

When **Require Privileged Source Port** is set to **true**, you also have to follow these additional configuration steps:

1. When mounting the file system from a Unix-like system, include the `resvport` option in your mount command when mounting. For example:

   ```
   sudo mount -o resvport 10.x.x.x:/fs-export-path
   /mnt/yourmountpoint
   ```

   For more information, see Mounting File Systems From Unix-Style Instances.
2. When mounting the file system from a Windows system, be sure the **UseReserverdPort**s registry key value is set to **1**.
   For more information, see Mounting File Systems From Windows Instances.

- **Access (Read_Only, Read_Write):** This setting specifies the **source** NFS client access. If unspecified, defaults to **Read_Write**.
- **Identity Squash: (All, Root, None):** This setting determines whether the **source** clients accessing the file system have their User ID (UID) and Group ID (GID) remapped to **anonymousUid** and **anonymousGid**. If you choose **All**, all users and groups are remapped. If **Root**, only the root user UID/GID combination 0/0 is remapped. If **None**, no users are remapped. If unspecified, defaults to **None**.
- **anonymousUid:** This setting is used along with the **Identity Squash** option. When remapping users, you can use this setting to change the default anonymousUid of **65534** to any user ID of your choice.

- **anonymousGid**: This setting is used along with the **Identity Squash** option. When remapping groups, you can use this setting to change the default anonymousGid of **65534** to any group ID of your choice.

Typical Access Control Scenarios

When you create file system and export, the NFS export options for that file system are set to the following defaults, which allow full access for all NFS client source connections. These defaults must be changed if you want to restrict access:

- **Source:** 0.0.0.0/0 (All)
- **Require Privileged Source Port:** False
- **Access:** Read_Write
- **Identity Squash:** None

Scenario A: Control Host Based Access

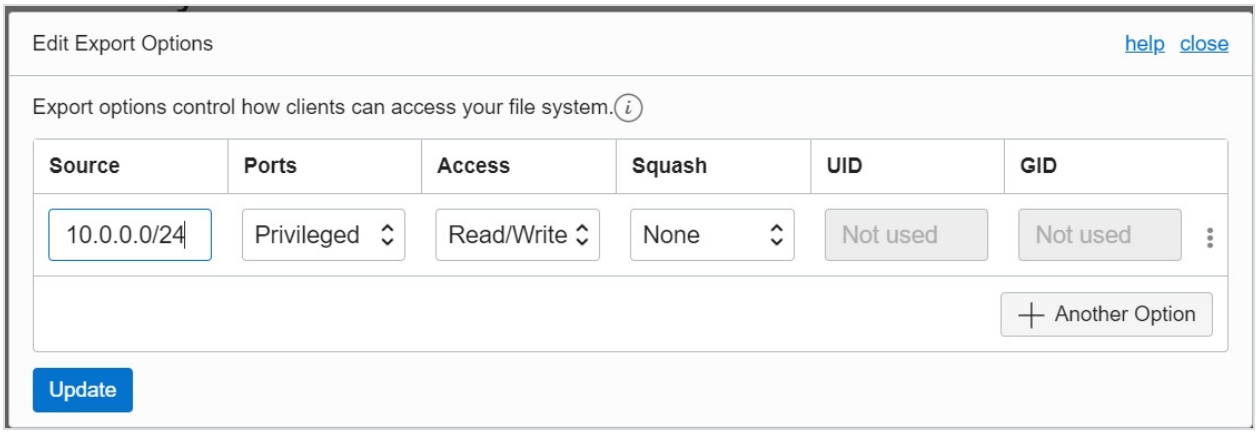
Provide a managed hosted environment for two clients. The clients share a mount target, but each has their own file system, and cannot access each other's data. For example:

- Client A, who is assigned to CIDR block 10.0.0.0/24, requires Read/Write access to file system A, but not file system B.
- Client B, who is assigned to CIDR block 10.1.1.0/24, requires Read/Write access to file system B, but not file system A.
- Client C, who is assigned to CIDR block 10.2.2.0/24, has no access of any kind to file system A or file system B.
- Both file systems A and B are associated to a single mount target, MT1. Each file system has an export contained in the export set of MT1.

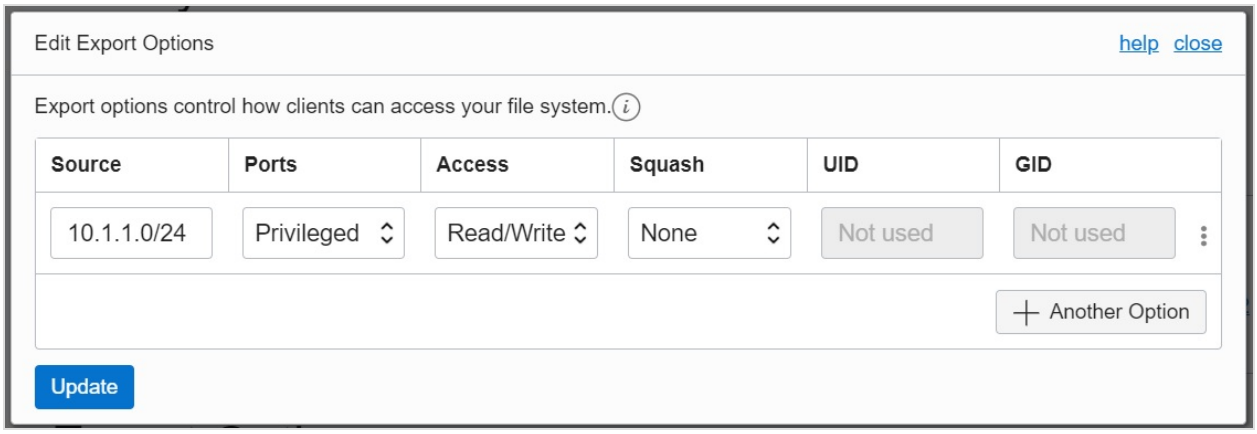
Since Client A and Client B access the mount target from different CIDR blocks, you can set the client options for both file system exports to allow access to only a single CIDR block. Client C is denied access by not including its IP address or CIDR block in the NFS export options for any export of either file system.

Console Example

Set the export options for file system A to allow Read/Write access only to Client A, who is assigned to CIDR block 10.0.0.0/24. Client B and Client C are not included in this CIDR block, and cannot access the file system.



Set the export options for file system B to allow Read/Write access only to Client B, who is assigned to CIDR block 10.1.1.0/24. Client A and Client C are not included in this CIDR block, and cannot access the file system.



CLI Example

Set the export options for file system A to allow Read_Write access only to Client A, who is assigned to CIDR block 10.0.0.0/24. Client B and Client C are not included in this CIDR block, and cannot access the file system.

```
oci fs export update --export-id <File_system_A_export_ID> --export-options '
[{"source":"10.0.0.0/24","require-privileged-source-port":"true","access":"READ_WRITE","identity-
squash":"NONE","anonymous-uid":"65534","anonymous-gid":"65534"}]'
```

Set the export options for file system B to allow Read_Write access only to Client B, who is assigned to CIDR block 10.1.1.0/24. Client A and Client C are not included in this CIDR block, and cannot access the file system.

```
oci fs export update --export-id <File_system_B_export_ID> --export-options '[{"source":"10.1.1.0/24
","require-privileged-source-port":"true","access":"READ_WRITE","identity-squash":"NONE","anonymous-
uid":"65534","anonymous-gid":"65534"}]'
```

API Example

Set the export options for file system A to allow READ_WRITE access only to Client A, who is assigned to CIDR block 10.0.0.0/24. Client B and Client C are not included in this CIDR block, and cannot access the file system.

```
PUT/<Current_API_Version>/exports/<File_System_A_export_OCID>
Host: filestorage.us-phoenix-1.oraclecloud.com
<authorization and other headers>
{
    "exportOptions": [
        {
          "source": "10.0.0.0/24",
          "requirePrivilegedSourcePort": true,
          "access": "READ_WRITE",
          "identitySquash": "NONE",
          "anonymousUid": 65534,
          "anonymousGid": 65534
        }
    ]
}
```

Set the export options for file system B to allow READ_WRITE access only to Client B, who is assigned to CIDR block 10.1.1.0/24. Client A and Client C are not included in this CIDR block, and cannot access the file system.

```
PUT/<Current_API_Version>/exports/<File_System_B_export_OCID>
Host: filestorage.us-phoenix-1.oraclecloud.com
<authorization and other headers>
{
    "exportOptions": [
        {
          "source": "10.1.1.0/24",
          "requirePrivilegedSourcePort": true,
          "access": "READ_WRITE",
          "identitySquash": "NONE",
          "anonymousUid": 65534,
          "anonymousGid": 65534
        }
    ]
}
```

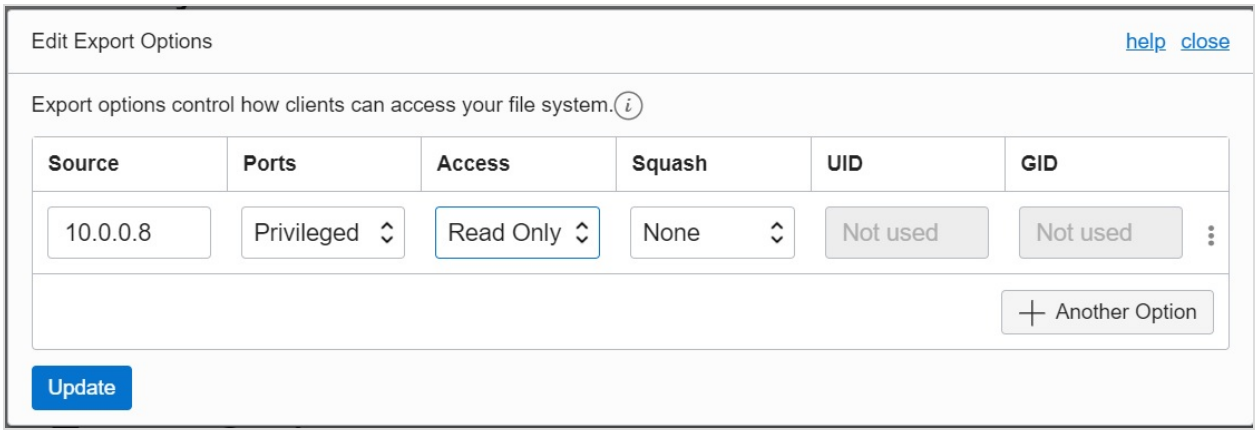
Scenario B: Limit the Ability to Write Data

Provide data to customers for consumption, but don't allow them to update the data.

For example, you'd like to publish a set of resources in file system A for an application to consume, but not change. The application connects from IP address 10.0.0.8.

Console Example

Set the source IP address 10.0.0.8 to Read Only in the export for file system A:



CLI Example

Set the source IP address 10.0.0.8 to READ_ONLY in the export for file system A:

```
oci fs export update --export-id <File_System_A_export_OCID> --export-options '
[{"source":"10.0.0.8","require-privileged-source-port":"true","access":"READ_
ONLY","identitysquash":"NONE","anonymousuid":"65534","anonymousgid":"65534"}]'
```

API Example

Set the source IP address 10.0.0.8 to READ_ONLY in the export for file system A:

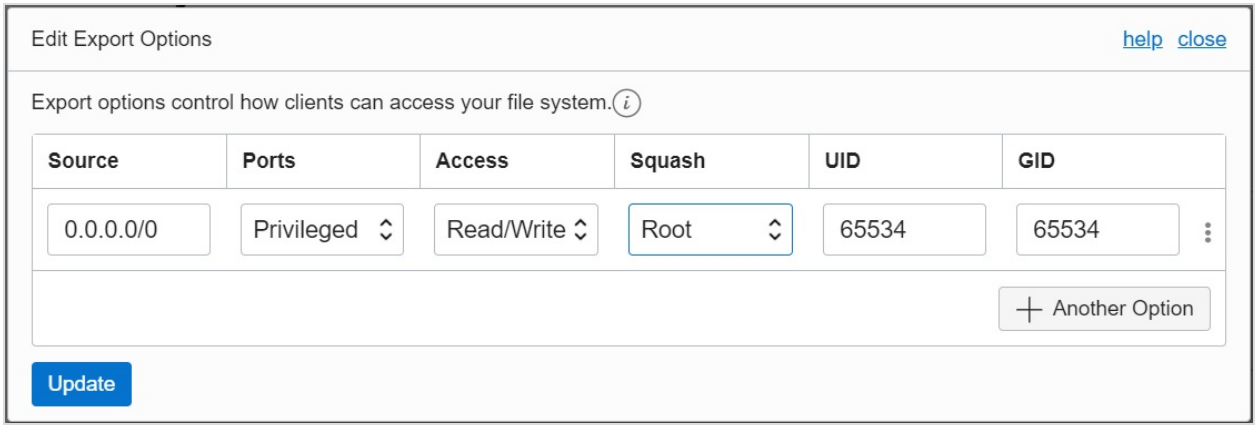
```
PUT/<Current_API_Version>/exports/<File_System_A_export_OCID>
Host: filestorage.us-phoenix-1.oraclecloud.com
<authorization and other headers>
{
    "exportOptions": [
        {
          "source": "10.0.0.8",
          "requirePrivilegedSourcePort": true,
```

```
          "access": "READ_ONLY",
          "identitySquash": "NONE",
          "anonymousUid": 65534,
          "anonymousGid": 65534
        }
    ]
}
```

SCENARIO C: IMPROVE FILE SYSTEM SECURITY

To increase security, you'd like to limit the root user's privileges when connecting to File System A. Use Identity Squash to remap root users to UID/GID 65534. In Unix-like systems, this UID/GID combination is reserved for '*nobody*', a user with no system privileges.

Console Example



CLI Example

```
oci fs export update --export-id <File_System_A_export_OCID> --export-options '
[{"source":"0.0.0.0/0","require-privileged-source-port":"true","access":"READ_
WRITE","identitysquash":"ROOT","anonymousuid":"65534","anonymousgid":"65534"}]'
```

API Example

```
PUT/<Current_API_Version>/exports/<File_System_A_export_OCID>
Host: filestorage.us-phoenix-1.oraclecloud.com
<authorization and other headers>
{
    "exportOptions": [
        {
          "source": "0.0.0.0/0",
          "requirePrivilegedSourcePort": true,
          "access": "READ_WRITE",
          "identitySquash": "ROOT",
          "anonymousUid": 65534,
          "anonymousGid": 65534
        }
    ]
}
```

Tip

If you don't want a file system to be visible to any clients, you can set all of the properties in the `exportOptions` array to empty values. For example,

```
{
   "exportOptions": [
     {
      "source":"",
      "requirePrivilegedSourcePort":"",
      "access": "",
      "identitySquash":""}
]
```

Using the Console

To set export options for a file system

1. Open the navigation menu. Under **Core Infrastructure**, click **File Storage** and then click **File Systems**.
2. In the **List Scope** section, select a compartment. All of the file systems in the selected compartment are displayed.
3. Find the file system you want to set export options for, click the the Actions icon (three dots), and then click **View File System Details**.
4. In the **Exports** list, find the export you want to set export options in, click the the Actions icon (three dots), and then click **View Export Details**. If there is no export listed for the file system, you can create one. See To create an export for a file system for more information.

Tip

To be sure you be sure that you select export, check the following:

- **The export path:** This path uniquely identifies the file system within the mount target. No two exports in a mount target can have the same export path, even if the exports are for the same file system.
- **The mount target name:** File systems can be exported through more than one mount target. Be sure that you've selected the export for the correct mount target.

5. Click **Edit Export Options**.
6. Make one or more of these changes:

- Change an export option entry in the list.
- Click **+Another Option** to create a new export option entry.
- Click the Actions icon (three dots) for an entry and move it up or down in the list.

7. When you're done, click **Update**.

Using the CLI

For information about using the CLI, see Command Line Interface (CLI).

To create an export

Open a command prompt and run `oci fs export create` to create an export for a specified file system within a specified export set. This example creates an export along with its NFS export options.

For example:

```
oci fs export create --export-set-id <export_set_OCID> --file-system-id <file_system_OCID> --path
"</pathname>" --export-options '
[{"source":"10.0.0.0/16","requireprivilegedsourceport":"true","access":"READWRITE","identitysquash":"NO
NE","anonymousuid":"0","anonymousgid":"0"}]'
```

Important

Export Path Names

The path must start with a slash (/) followed by a sequence of zero or more slash-separated elements. For any two export resources associated with the same export set, the path sequence for the first export resource can’t contain the complete path element sequence of the second export sequence. Paths can't end in a slash. No path element can be a period (.) or two periods in sequence (..). Lastly, no path can exceed 255 bytes.

Examples:

Acceptable:

`/example` and `/path`

`/example1` and `/example2`

Not Acceptable:

`/example` and `/example/path`

`/` and `/example`

`/example/`

`/example/path/../example1`

To update export options

Open a command prompt and run `oci fs export update`. To update export options for a specified file system, use `--export-options`.

For example:

```
oci fs export update --export-id <export_OCID> --export-options '[{"source":"<0.0.0.0/0>","require-privileged-source-port":"true","access":"READ_ONLY","identity-squash":"ROOT","anonymous-uid":"65534","anonymous-gid":"65534"}]'

WARNING: Updates to export-options will replace any existing values. Are you sure you want to continue? [y/N]: y
```

Tip

If you don't want a file system to be visible to any clients, you can set all of the properties in Client Options to empty values. For example,

```
oci fs export update --export-id <export_OCID> --export-options '[{"source":"","require-privileged-source-port":"true","access":"READ_ONLY","identity-squash":"ROOT","anonymous-uid":"65534","anonymous-gid":"65534"}]'
```

To list exports

Open a command prompt and run `oci fs export list` to list all exports in a specified compartment.

For example:

```
oci fs export list --compartment-id target_compartment_id
```

To delete an export

Open a command prompt and run `oci fs export delete` to delete an export.

For example:

```
oci fs export delete --export-id export_OCID
```

Warning

When you delete an export, you can no longer mount the file system using the file path specified in the deleted export.

Using the API

- CreateExport
- UpdateExport
- ListExports
- GetExport
- DeleteExport

Managing Snapshots

The File Storage service supports snapshots for data protection of your file system. Snapshots are a consistent, point-in-time view of your file systems. Snapshots are copy-on-write, and scoped to the entire file system. You can take as many snapshots as you need. Data usage is metered against differentiated snapshot data. If nothing has changed within the file system since the last snapshot was taken, the new snapshot does not consume more storage.

Snapshots are accessible under the root directory of the file system at `.snapshot/name`. For data protection, you can use a tool that supports NFSv3 to copy your data to a different availability domain, region, file system, object storage, or remote location.

For best performance, we recommend that you use the parallel tar (`partar`) and parallel copy (`parcp`) tools provided in the File Storage Parallel File Toolkit for this purpose. These tools work best with parallel workloads and requests. The Parallel File Toolkit is available for Oracle Linux, Red Hat Enterprise Linux, and CentOS. You can use `rsync` or regular `tar` for other operating system types. See To install the Parallel File Tools suite for more information.

Tip

Watch a video about protecting data with snapshots in File Storage.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Required IAM Service Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: The policy in Let users create, manage, and delete file systems allows users to create and delete snapshots.

If you're new to policies, see Getting Started with Policies and Common Policies.

Tagging Resources

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the desired tags. For general information about applying tags, see Resource Tags.

Using the Console

To create a snapshot

1. Open the navigation menu. Under **Core Infrastructure**, click **File Storage** and then click **File Systems**.
2. In the **List Scope** section, select a compartment.
3. In the **File Systems** list, locate the file system you want to take a snapshot of. Click the Actions icon (three dots), and then click **View File System Details**.
4. In **Resources**, click **Snapshots**.
5. Click **Create Snapshot**.
6. Fill out the required information:
   - **Name**: Enter a name for the snapshot. It must be unique among all other snapshots for this file system. The name can't be changed. Avoid entering confidential information.
7. Click **Create Snapshot**.

   The snapshot is accessible under the root directory of the file system at `.snapshot/`*`name`*.

To view details of a snapshot

1. Open the navigation menu. Under **Core Infrastructure**, click **File Storage** and then click **File Systems**.
2. In the **List Scope** section, select a compartment.
3. In the **File Systems** list, locate the file system you took the snapshot of. Click the Actions icon (three dots), and then click **View File System Details**.
4. In **Resources**, click **Snapshots**.

5. In the **Snapshots** list, locate the snapshot you're interested in. Click the Actions icon (three dots), and then click **View Snapshot Details**.

To create a snapshot from a Unix-style instance

You can create a snapshot from an instance that you've mounted the file system to. Snapshots are created under the root folder of your file system, in a hidden directory named `.snapshot`.

1. Connect to your instance and open a command window.
2. Navigate to your file system's hiden `.snapshot` directory. Type the following, replacing `yourmountpoint` with the name of the directory where you mounted the file system.

   ```
   cd /mnt/yourmountpoint/.snapshot
   ```

3. Use the `mkdir` command to create a directory in the hidden `.snapshot` directory. The directory you create is the snapshot. Give the snapshot a name that will help you identify it. Avoid using confidential information in the snapshot name. For example:

   ```
   mkdir snapshot-Jan1
   ```

4. Use the `ls` command to verify that your snapshot has been created in the `.snapshot` directory.

   ```
   ls
   ```

To install the Parallel File Tools suite

The Parallel File Tools suite provides parallel versions of `tar`, `rm`, and `cp`. These tools can run requests on large file systems in parallel, maximizing performance for data protection operations.

The tool suite is distributed as an RPM for Oracle Linux, Red Hat Enterprise Linux, and CentOS.

The toolkit includes:

- `partar`: Use this command to create and extract `tarballs` in parallel.
- `parrm`: You can use this command to recursively `remove` a directory in parallel.

- `parcp`: Use this command to recursively `copy` a directory in parallel.

To install Parallel File Tools on Oracle Linux:

```
sudo yum install -y fss-parallel-tools
```

To install Parallel File Tools on CentOS and Red Hat 6.x:

```
sudo wget http://yum.oracle.com/public-yum-ol6.repo -O /etc/yum.repos.d/public-yum-ol6.repo
sudo wget http://yum.oracle.com/RPM-GPG-KEY-oracle-ol6 -O /etc/pki/rpm-gpg/RPM-GPG-KEY-oracle
sudo yum --enablerepo=ol6_developer install fss-parallel-tools
```

To install Parallel File Tools on CentOS and Red Hat 7.x:

```
sudo wget http://yum.oracle.com/public-yum-ol7.repo -O /etc/yum.repo.d/public-yum-ol7.repo
sudo wget http://yum.oracle.com/RPM-GPG-KEY-oracle-ol7 -O /etc/pki/rpm-gpg/RPM-GPG-KEY-oracle
sudo yum --enablerepo=ol7_developer install fss-parallel-tools
```

To display manual pages for each tool:

```
man partar
```

```
man parcp
```

```
man parrm
```

To restore a snapshot

Snapshots are created under the root folder of your file system, in a hidden directory named `.snapshot`.

You can restore a file within the snapshot, or an entire snapshot using the `cp` command. Use the `-r` option when restoring a snapshot that contains subdirectories.

For example:

```
cp -r .snapshot/snapshot_name/* destination_directory_name
```

Optionally, you can use `rsync`, `tar`, or another tool that supports NFSv3 to copy your data to another remote location. For optimal performance, use the Parallel File Tools.

For example:

```
parcp .snapshot/snapshot_name/* destination_directory_name
```

To manage tags for a snapshot

1. Open the navigation menu. Under **Core Infrastructure**, click **File Storage** and then click **File Systems**.
2. In the **List Scope** section, select a compartment.
3. In the **File Systems** list, locate the file system you took the snapshot of. Click the Actions icon (three dots), and then click **View File System Details**.
4. In **Resources**, click **Snapshots**.
5. In the **Snapshots** list, locate the snapshot you're interested in. Click the Actions icon (three dots), and then click **View Snapshot Details**.
6. Click the **Tags** tab to view or edit the existing tags. Or click **Apply tag(s)** to add new ones.

For more information, see Resource Tags.

To delete a snapshot

1. Open the navigation menu. Under **Core Infrastructure**, click **File Storage** and then click **File Systems**.
2. In the **List Scope** section, select a compartment.
3. Find the file system with the snapshot you want to delete.
4. Click the Actions icon (three dots), and then click **View File System Details**.
5. In **Resources**, click **Snapshots**.
6. Find the snapshot you want to delete.
7. Click **Delete.**

Using the Command Line Interface (CLI)

For information about using the CLI, see Command Line Interface (CLI).

To create a snapshot

You can create a snapshot of a file system. A snapshot is a point-in-time view of the file system. The snapshot is accessible at ./shapshot/*name*.

Open a command prompt and run `oci fs snapshot create` to create a snapshot of a file system.

For example:

```
oci fs snapshot create --file-system-id <file_system_OCID> --name "<January1>"
```

Warning

Avoid entering confidential information in the snapshot `name`.

To list snapshots

Open a command prompt and run `oci fs snapshot create` to list all snapshots associated with a specific file system.

For example:

```
oci fs snapshot list --file-system-id <file_system_OCID>
```

To get a specific snapshot

Open a command prompt and run `oci fs snapshot get` to retrieve information about a specific snapshot.

For example:

```
oci fs snapshot get --snapshot-id <snapshot_OCID>
```

To delete a snapshot

Open a command prompt and run `oci fs snapshot delete` to delete a snapshot.

For example:

```
oci fs snapshot delete --snapshot-id <snapshot_OCID>
```

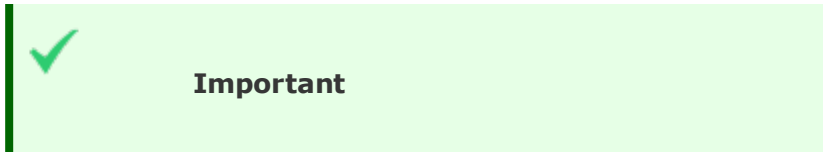
Using the API

- CreateSnapshot
- ListSnapshots
- GetSnapshot
- DeleteSnapshot

Paths in File Systems

TheFile Storage service uses three kinds of paths :

1. **Export Paths** are part of the information contained in an export that makes a file system available through a mount target. The export path uniquely identifies the file system within the mount target, letting you associate up to 100 file systems behind a single mount target. The export path is used by an instance to mount (logically attach to) the file system. This path is unrelated to any path within the file system or the client instance. It exists solely as a way to distinguish one file system from another within a single mount target.
   In this mount command example, `10.0.0.6` is the mount target IP address.`/example/path` is the unique export path that was specified when the file system was associated with a mount target during creation.
   ```
   sudo mount 10.0.0.6:/example/path /mnt/mountpointA
   ```



The path must start with a slash (/) followed by a sequence of zero or more slash-separated elements. For multiple file systems associated with a single mount target, the path sequence for the first file system cannot contain the complete path element sequence of the second file system path sequence. Paths cannot end in a slash. No path element can be a period (.) or two periods in sequence (..). Lastly, no path can exceed 255 bytes. For example:

Acceptable:

`/example` and `/path`

`/example` and `/example2`

Not Acceptable:

`/example` and `/example/path`

`/` and `/example`

`/example/`

`/example/path/../example1`

Warning

If one file system associated to a mount target has '/' specified as an export path, you can't associate another file system with that mount target.

Note

Export paths cannot be edited after the export is created. If you want to use a different export path, you must create a new export with the desired path. Optionally, you can then delete the export with the old path.

See Managing Mount Targets for more information about mount targets and exports.

2. **Mount Point Paths** are paths within a client instance to a locally accessible directory to which the remote file system is mounted.
   In this mount command example, `/mnt/mountpointA` is the path to the directory on the client instance on which the external file system is mounted.
   ```
   sudo mount 10.0.0.6:/example/path /mnt/mountpointA
   ```
   See Mounting File Systems for more information.
3. **File System Paths** are paths to directories within the file system, and contain the contents of the file system. When the file system is mounted, you can create any directory structure within it you like. Snapshots of the file system can be accessed using the file system path, under the file system's root directory at `.snapshot/name`.
   The following example shows the path to a snapshot called 'January 1' when navigating from the instance:
   ```
   /mountpointA/.snapshot/January1
   ```

Troubleshooting Your File System

These topics cover some common issues you may run into and how to address them.

File System Setup

- Mount Command Fails
- Mount Target Creation Fails

- Mount Target is in a Failed State

File System Management

- Showmount Command Fails
- Symbolic Links (Symlinks) Produce Errors
- Removing File Locks from a Host that is No Longer Available
- Cannot Delete VCN - Mount Target VNIC Still Attached

Application Installation

- Application Installation Fails Due to Too Much or Too Little Available Capacity
- Application Performance is Not as Expected

Windows NFS Connections

- Create and Write to File System Fails using Windows NFS
- Mounted Drive is Not Visible in File Explorer
- Windows 2008 R2: UNC Access Delayed; "Network Error 53 Network path not found"
- Mounting from File Explorer Fails With "An Unexpected Error Occurred."

Application Installation Fails Due to Too Much or Too Little Available Capacity

The File Storage service reports file system capacity as 8589934592 gibibytes (GiB) and 8589934592 gibiinodes (GiI) by default. Sometimes, application installers perform a space requirement check prior to running an installation process but cannot correctly interpret the reported size or reported inodes of the file system. When this occurs, you can define the file system size reported to the operating system by setting the **Reported Size** or **Reported Inodes** value in the export set of the file system's mount target.

Important

Changing the **Reported Size** or **Reported Inodes** for a mount target affects all file systems exported by the mount target. **Changing these values does not limit the amount of data you can store.**

If your application installation is failing because of too little available space, you can expand the reported available free space. If your application installation is failing because of too much reported available free space, you can reduce it. Typically, setting the size to 1024 GiB and the inodes to 1024 GiI permits successful installation.

Important

There can be a delay of up to 1 hour when reporting file system usage, either in the console or by using the `df` command.

To set the file system reported size in the Console

To set the file system reported size in the CLI

To set the reported free space in the API

You can use the UpdateExportSet operation to update the `MaxFsStatBytes`.

See REST APIs for more information.

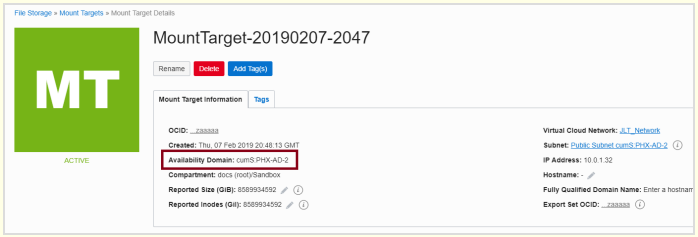
Application Performance is Not as Expected

Several factors can impact application performance:

- **Available bandwidth**
  We recommend that you use bare metal Compute instances because instance bandwidth scales with the number of oCPU's. Bare metal Compute instances provide the greatest bandwidth. Virtual machines (VMs) are bandwidth limited based on the number of CPUs consumed. Single oCPU VM Compute instances provide the least bandwidth.
- **Latency**
  Subnets can be either AD-specific or regional. The type of subnet you choose to create your File Storage resources in can affect latency. You can create File Storage resources in either type of subnet.
  Regional subnets allow Compute instances to connect to any mount target in the subnet regardless of AD, with no additional routing configuration. However, to minimize latency, place mount targets in the same AD as Compute instances just as you would in an AD-specific subnet.
  For more information, see About Regional Subnets.

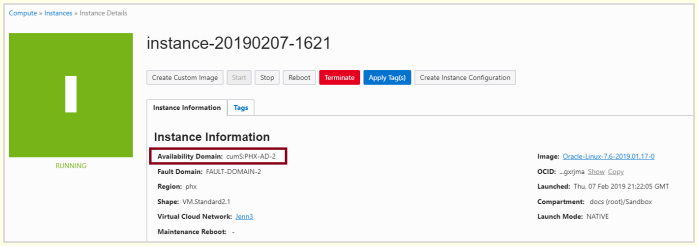
Tip

If you want to verify that your instance and mount target are in the same availability domain, you can view the availability domain for any mount target in its **Details** page, in the **Mount Target Information** tab:



A file system is always in the same subnet as its associated mount target.

You can also view the availability domain for any instance in its **Details** page, in the **Instance Information** tab:



- **Mount options**

By not providing explicit values for mount options such as rsize and wsize, the client and server can negotiate the window size for read and write operations that provide the best performance.

Cannot Delete VCN- Mount Target VNIC Still Attached

A mount target is an NFS endpoint that lives in a VCN subnet of your choice and provides network access for the file systems that it exports. Each mount target has a VNIC to enable network access. Mount target VNICs that remain in a VCN must be deleted before you can delete the VCN.

Deleting a mount target also deletes all of the exports of associated file systems that exist in its export set. Data in the file systems is not affected, but the file systems are no longer available through the deleted mount target. You can create new exports for the file system in a different mount target and subnet.

For more information, see Managing Mount Targets.

To resolve this issue using the Console

1. Note the OCID in the error message you receive when you attempt to delete the VCN. Mount target OCIDs contain the identifier `mounttarget`. For example:

   ```
   ocid1.mounttarget.oc1.phx.examplemounttargetid
   ```

2. Note the **Compartment** and **Subnet** information of the **VCN** you want to delete, and to assist navigation and choosing the correct mount target to delete.
3. Delete the mount target using the following steps:
   a. Open the navigation menu. Under **Core Infrastructure**, click **File Storage** and then click **Mount Targets**.
   b. In the **List Scope** section, select a compartment.
   c. Find the mount target you want to delete.
   d. Click the Actions icon (three dots), and then click **Delete**.

Warning

Deleting the mount target also deletes all of its exports of associated file systems. File systems are no longer available through the deleted mount target.

Tip

In the Console, the mount target OCID can be seen in the mount target details page in the **Mount Target Information** tab. See Managing Mount Targets for more information about how to view the mount target details page. Be sure the mount target OCID seen on the details page matches the mount target OCID provided by the VCN delete process error message.

4. Delete the VCN.

To resolve this issue using the API

1. Note the OCID in the error message you receive when you attempt to delete the VCN. Mount target OCIDs contain the identifier `mounttarget`. For example:

```
ocid1.mounttarget.oc1.phx.examplemounttargetid
```

2. Delete the mount target using the following steps:
   a. Use DeleteMountTarget to delete the mount target. For example:

```
DELETE /20171215/mountTargets/ocid1.mounttarget.oc1.phx.examplemounttargetid
Host: filestorage.us-phoenix-1.oraclecloud.com
<authorization and other headers
```

b. You can use GetMountTarget to verify that the mount target has been deleted. For example:

```
GET
/20171215/mountTargets/ocid1.mounttarget.oc1.phx.examplemounttargetid?compartmentId=
<compartmentId>
Host: filestorage.us-phoenix-1.oraclecloud.com
<authorization and other headers>
```

The API should return `Status 404 Not Found`.

To resolve this issue using the CLI

For general information about using the CLI, see Command Line Interface (CLI).

1. Note the OCID in the error message you receive when you attempt to delete the VCN. Mount target OCIDs contain the identifier `mounttarget`. For example:

```
ocid1.mounttarget.oc1.phx.examplemounttargetid
```

2. Delete the mount target using the following steps:

   a. Use `oci fs mount-target delete` to delete the mount target. For example:

```
oci fs mount-target delete --mount-target-id
ocid1.mounttarget.oc1.phx.examplemounttargetid
```

   b. You can use `oci fs export get` to verify that the mount target has been deleted. For example:

```
oci fs export get --export-id ocid1.mounttarget.oc1.phx.examplemounttargetid
```

   The CLI should return a message indicating the mount target is not found. For example:

```
{
    "code": "NotAuthorizedOrNotFound",
    "message": "Authorization failed or requested resource not found.",
    "opc-request-id": "<requestID>",
    "status": 404
}
```

If you still can't delete the VCN, be sure there are no other resources remaining in the VCN that might prevent it. For more information, see Subnet or VCN Deletion.

Mount Command Fails

The export path of a file system must be correctly represented in your mount command, or the mount will fail.

The export path is specified when you create an export for the file system in a mount target. It uniquely identifies the file system within the mount target, letting you associate multiple file systems to a single mount target. The export path is appended to the mount target IP address, and used to mount the file system.

```
sudo mount 10.0.0.6:/example/path /mnt/mountpointA
```

In this example, `10.0.0.6:` is the mount target IP address, and `/example/path` is the export path. `/mnt/mountpointA` is the path to the directory on the client instance on which the external file system is mounted.

Tip

You can find all the export paths for a file system in the **Exports** list shown in its Details page, together with associated mount target information.

- You can obtain the correct export path by copying mount commands directly from the file system export. These commands minimize the chance of a typing error. See To get mount command samples for more information.
- If one file system associated with a mount target uses an export path of '/' , it will prevent you from associating more file systems with that mount target. No two file systems associated with the same mount target can have an export path that contains a complete path of the other.

See Paths in File Systems for more information.

Mount Target Creation Fails

Mount target creation can fail for various reasons:

- **You've exceeded your mount target limit.**
  Each availability domain is limited to two mount targets by default. If you create both a file system and a mount target at the same time, it is possible for the file system to be successfully created but the mount target creation to fail because of this limitation.
  You can create an export for the file system in a previously existing mount target. For more information, see To create an export for a file system.
  See Service Limits for a list of applicable limits and instructions for requesting a limit increase.
- **There aren't enough available IP addresses in your subnet.**
  Each mount target requires three internal IP addresses in the subnet to function. Two of the IP addresses are used during mount target creation. The third IP address must remain available for the mount target to use for high availability failover.
  Do not use /30 or smaller subnets for mount target creation because they do not have sufficient available IP addresses for mount target creation.
  The File Storage service doesn't "reserve" the third IP address required for high availability failover, so use care when designing your subnets and file systems to ensure that sufficient IP addresses remain available for your mount targets in the future.

Mount Target is in a Failed State

Symptom: A mount target reports a **Failed** state. File systems are not accessible using the mount target's IP address.

Possible Cause: There are insufficient unallocated IP addresses in the subnet. The mount target cannot fail over successfully.

Each mount target requires three internal IP addresses in the subnet to function. Two of the IP addresses are used during mount target creation. The third IP address must remain available for the mount target to use for high availability failover. The File Storage service doesn't "reserve" the third IP address required for high availability failover. Use care to ensure that

enough unallocated IP addresses remain available for your mount targets to use during failover.

Solution:

1. Delete the failed mount target.
   To delete a mount target
2. Export the file system through an active mount target. You can create a replacement mount target and then create an export for the file system, or create an export for the file system in a pre-existing mount target.
   - You can use the same export paths for the associated file systems as the previous mount target. However, the export path must be unique for each file system within the mount target.
   - If you create a replacement mount target, you can use the same IP address as the previous mount target, if available. Be sure to explicitly specify the desired IP address when you create the mount target.

   To create a mount target
   To create an export for a file system
3. If necessary, mount the file systems again.
   Mounting File Systems

   Note

   If a replacement mount target uses *exactly the same* IP address and export paths as previously existed in the deleted mount target, mounted instances reconnect automatically.
4. To prevent a recurrence of this issue, ensure that sufficient unallocated IP addresses remain available in the subnet.

Removing File Locks from a Host that is No Longer Available

The File Storage service supports the removal of file locks from any file system. To request the removal of file locks on a file system:

1. Go to My Oracle Support and sign in.
   If you are not signed in directly to Oracle Cloud Support, click **Switch to Cloud Support** at the top of the page.
2. Click **Create Service Request**.
3. Select the following from the displayed menus:
   - **Service Type:** Select Oracle Cloud Infrastructure from the list.
   - **Service Name:** Select the appropriate option for your organization.
   - **Problem Type:** FSS File System Lock Removal Request.
4. Enter your contact information.
5. Enter a **Description**, and then enter the following required fields specific to your issue. For most Oracle Cloud Infrastructure issues you need to include the OCID (Oracle Cloud Identifier) for each resource you need help with. See Locating IDs for Your Oracle Cloud Infrastructure Resources for instructions on locating these.
   - Tenancy OCID
   - File System OCID
   - Mount Target OCID
   - Host IP Address

   For help with any of the general fields in the service request or for information on managing your service requests, click **Help** at the top of the Oracle Cloud Support page.

Showmount Command Fails

The File Storage service supports the `showmount -e` command. You can use the `showmount -e` command to show a list of NFS exports available from a specific mount target IP address.

For example, `$ showmount -e 10.0.0.0`

To enable the command, you must create a security list rule in the subnet containing the mount target. The rule must be a **stateful ingress** rule for **UDP** traffic with a **Destination Port Range** of **111**.

Click here for instructions about Configuring VCN Security List Rules for File Storage.

For more information about this command, see the Linux manual page about showmount.

Important

Only `showmount -e` is supported. No other options are supported, and the `-e` option must be included.

Symbolic Links (Symlinks) Produce Errors

The File Storage service fully supports the use of symbolic links. However, symbolic links are interpreted by the client and symlinks that point outside of the mounted File Storage system may be interpreted differently by each client and lead to unexpected results, such as broken links or pointing to the wrong file. Symbolic link targets that work on one client might be broken on another due to differences in file system layout or because clients mounted the file system using different mount targets.

Snapshots can also break symbolic links that point to a target outside the file system's root directory. This is because when you create a snapshot of a file system, it becomes available as a subdirectory of the .snapshot directory.

To minimize these potential issues, use a relative path as the target path when creating a symbolic link to a file in the network file system. Also, ensure that relative paths do not point to a target path outside the File Storage service root directory except when the target is on the local machine. If you must use a symbolic link that points to a target path outside the file system, use an absolute path starting with the client's root directory.

For example:

- Pointing to "/user/bin/example" **works**.
- Pointing to "/yourmountpoint/..." does **not** work.
- Pointing to "/home/user/yourmountpoint/..." does **not** work.

Create and Write to File System Fails using Windows NFS

Important

To connect to file systems from Windows instances, the NFS Client must first be installed. Be sure to follow the installation procedure found in Mounting File Systems From Windows Instances before proceeding with troubleshooting.

Symptom: After installing Windows NFS client, you can successfully mount the file system from Windows, but any attempt to create or update a file in the file system fails.

Cause 1: Registry entries that map the `AnonymousGid` and `AnonymousUid` to the root user are missing or in the wrong place.

Access to NFS file systems requires UNIX-style user and group identities, which are not the same as Windows user and group identities. To enable users to access NFS shared resources, Windows client for NFS accesses file systems anonymously, using `AnonymousGid` and `AnonymousUid`. On brand new file systems, write permissions are only granted to the root user.

Solution: Verify that the correct registry entries are located in `HKEY_LOCAL_MACHINE\Software\Microsoft\ClientForNFS\CurrentVersion\Default`. If not, add the `AnonymousGid` and `AnonymousUid` registry entries to map them to the root user, and then remount the file system with the new user privileges.

Tip

You can verify the `AnonymousGid` and `AnonymousUid` are correctly set for a mounted file system by opening a Windows Command Line (CMD) window and typing the `mount` command without any arguments. A list of all mounted file systems and their properties is shown. The `AnonymousGid (GID)` and `AnonymousUid (UID)` values should appear as `0`.

For example:

```
C:\>mount

Local     Remote                                    Properties
-------------------------------------------------------------------
-----------------
X:        \\10.0.1.0\FileSystem                     UID=0, GID=0
                                                    rsize=1048576,
wsize=1048576
                                                    mount=soft,
timeout=0.8
                                                    retry=1,
locking=yes

fileaccess=755, lang=ANSI

casesensitive=no
                                                    sec=sys
```

If they appear as `-2`, they have not been correctly set. Proceed to the instructions below.

To map the AnonymousGid and AnonymousUid to the root user

1. In the Windows Command Line (CMD) window, unmount the file system by typing the following. Replace `10.x.x.x:` with the local subnet IP address assigned to your mount target, `fs-export-path` with the export path you specified when associating the file system with the mount target, and `X` with the drive letter of any available drive you want to map the file system to.

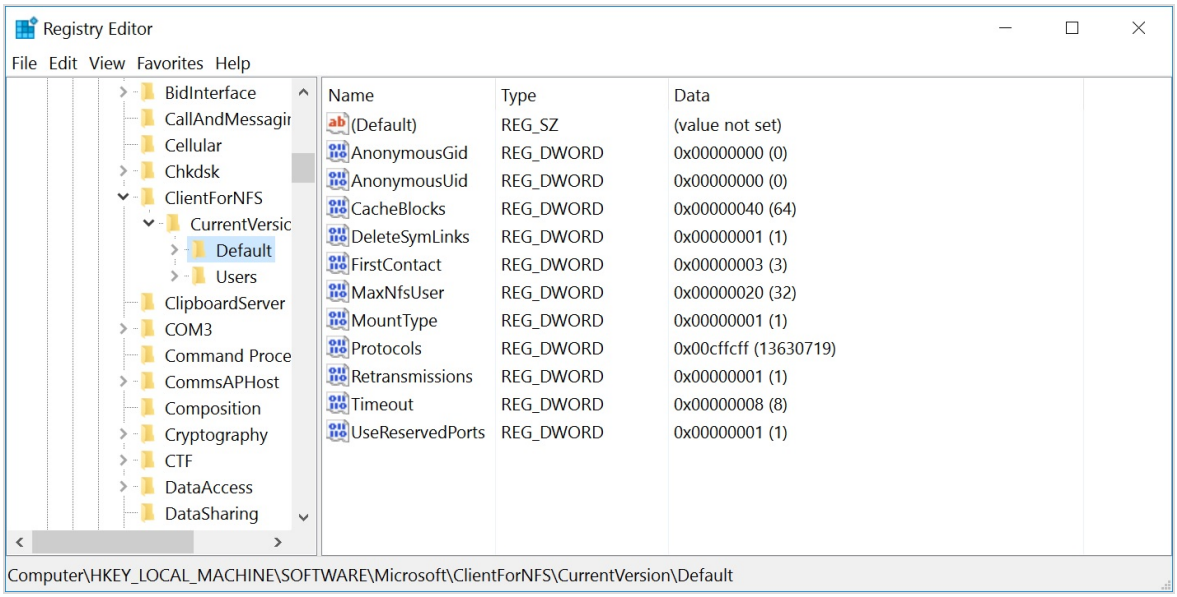
   

   Tip

   IP address and export path information is available in the **Details** page of the mount target associated with your file system. See To view details of a mount target for more information.

   ```
   umount 10.x.x.x:/fs-export-path X:
   ```

2. Open the registry editor (regedit):
   - Click **Windows Search.**
   - Enter `regedit` in the **Search** field and press **Enter**.
   - Click **Yes** to allow changes to your device.
3. Click `HKEY_LOCAL_MACHINE`. Then, browse to: `Software\Microsoft\ClientForNFS\CurrentVersion\Default`.
4. Add a new DWORD32 registry entry for `AnonymousGid`:
   - Click **Edit**, and select **New DWORD (32 bit) Value**.
   - In the Name field, enter `AnonymousGid`. Leave the value at `0`.
5. Repeat step 3 to add a second DWORD32 registry entry named `AnonymousUid` with a value of `0`.



6. Open Windows Command Line (CMD) and run as Administrator:
    - Go to **Start** and scroll down to **Apps**.
    - In the **Windows System** section, press **Ctrl+Shift** and click **Command Prompt**.
7. In the Windows Command Line (CMD) window, restart the NFS Client by typing the following:

```
nfsadmin client stop
```

```
nfsadmin client start
```

8. Close the Administrator: Windows Command Prompt (CMD) window. Open a **standard** Command Prompt Window:
    - Click **Start**, then click **Command Prompt**.

> **Important**
>
> NFS file systems mounted as Administrator are not available to standard users.

9. In the standard Windows Command Line (CMD) window, mount the file system by typing the following. Replace `10.x.x.x:` with the local subnet IP address assigned to your mount target, `fs-export-path` with the export path you specified when associating the file system with the mount target, and `X` with the drive letter of any available drive you want to map the file system to.

```
mount 10.x.x.x:/fs-export-path X:
```

Cause 2: A standard user is trying to access a file system that was mounted using the Administrator: Command Prompt (CMD). When mounting file systems, it isn't necessary to run the Command Prompt as Administrator.

Solution: Unmount the file system and then remount the file system using a standard Command Prompt. (CMD)

To remount a file system with a standard Command Prompt (CMD)

1. Open Windows Command Line (CMD) and run as Administrator:
   - Go to **Start** and scroll down to **Apps**.
   - In the **Windows System** section, press **Ctrl+Shift** and click **Command Prompt**.
2. In the Administrator: Windows Command Line (CMD) window, **unmount** the file system by typing the following. Replace `10.x.x.x:` with the local subnet IP address assigned to your mount target, `fs-export-path` with the export path you specified when associating the file system with the mount target, and `X` with the drive letter of any available drive you want to map the file system to.

Tip

IP address and export path information is available in the **Details** page of the mount target associated with your file system. See To view details of a mount target for more information.

```
umount 10.x.x.x:/fs-export-path X:
```

3. **Close** the Administrator: Windows Command Line (CMD) window.
4. Open a **standard** Command Prompt Window:
   - Click **Start**, then click **Command Prompt**.
5. In the **standard** Command Line (CMD) window, mount the file system by typing the following. Replace `10.x.x.x:` with the local subnet IP address assigned to your mount target, `fs-export-path` with the export path you specified when associating the file system with the mount target, and `X` with the drive letter of any available drive you want to map the file system to.

```
mount 10.x.x.x:/fs-export-path X:
```

Mounted Drive is Not Visible in File Explorer

Important

To connect to file systems from Windows instances, the NFS Client must first be installed. Be sure to follow the installation procedure found in Mounting File Systems From Windows Instances before proceeding with troubleshooting.

Symptom: After installing Windows NFS client, you can successfully mount the file system from Windows, but the file system drive is not visible in File Explorer.

Cause: A standard user is trying to access a file system that was mounted using the Administrator: Command Prompt (CMD). When mounting file systems, it isn't necessary to run the Command Prompt as Administrator.

Solution: Unmount the file system and then remount the file system using a standard Command Prompt. (CMD) See To remount a file system with a standard Command Prompt (CMD).

Mounted Drive is Not Visible in PowerShell

Important

To connect to file systems from Windows instances, the NFS Client must first be installed. Be sure to follow the installation procedure found in Mounting File Systems From Windows Instances before proceeding with troubleshooting.

Symptom: After installing Windows NFS client, you can successfully mount the file system from either Windows File Explorer or the Command Prompt (CMD) using `mount` or `net use` commands. However, the file system drive is not visible in PowerShell.

Cause: A known issue exists where drives mapped from outside PowerShell aren't visible from within PowerShell.

Solution: Unmount the file system and remount the file system within PowerShell, using options to make it visible in File Explorer and in the CMD application.

To unmount a file system using the CMD prompt

1. Open Windows Command Line (CMD) and run as Administrator:

- Go to **Start** and scroll down to **Apps**.
- In the **Windows System** section, press **Ctrl+Shift** and click **Command Prompt**.

2. In the Administrator: Windows Command Line (CMD) window, **unmount** the file system by typing the following. Replace `10.x.x.x:` with the local subnet IP address assigned to your mount target, `fs-export-path` with the export path you specified when associating the file system with the mount target, and `X` with the drive letter of any available drive you want to map the file system to.

Tip

IP address and export path information is available in the **Details** page of the mount target associated with your file system. See To view details of a mount target for more information.

```
umount 10.x.x.x:/fs-export-path X:
```

3. **Close** the Administrator: Windows Command Line (CMD) window.

To map a drive in PowerShell and make it visible

You can map a drive in PowerShell and then use options to make it visible from File Explorer and the Windows Command Line (CMD).

1. Open **Windows PowerShell** and run as **Administrator**:
   a. Go to **Start** and click the **Windows PowerShell** icon.
   b. In Windows PowerShell, type the following to run as Administrator:

```
Start-Process powershell -Verb runAs
```

c. In the **User Account Control** window, click **Yes**. A new Administrator: PowerShell window opens. You can close the standard PowerShell window to avoid confusing them.

2. Type the following cmdlet. Replace `10.x.x.x:` with the local subnet IP address assigned to your mount target, `fs-export-path` with the export path you specified when associating the file system with the mount target, and `X` with the drive letter of any available drive you want to map the file system to:

```
New-PSDrive X -PsProvider FileSystem -Root \\10.x.x.x:\fs-export-path -Persist
```

Windows 2008 R2: UNC Access Delayed; "Network Error 53 Network path not found"

Important

To connect to file systems from Windows instances, the NFS Client must first be installed. Be sure to follow the installation procedure found in Mounting File Systems From Windows Instances before proceeding with troubleshooting.

Symptom1 : After installing NFS client on Windows 2008 R2 servers, mount fails with "Network Error 53 "Network path not found".

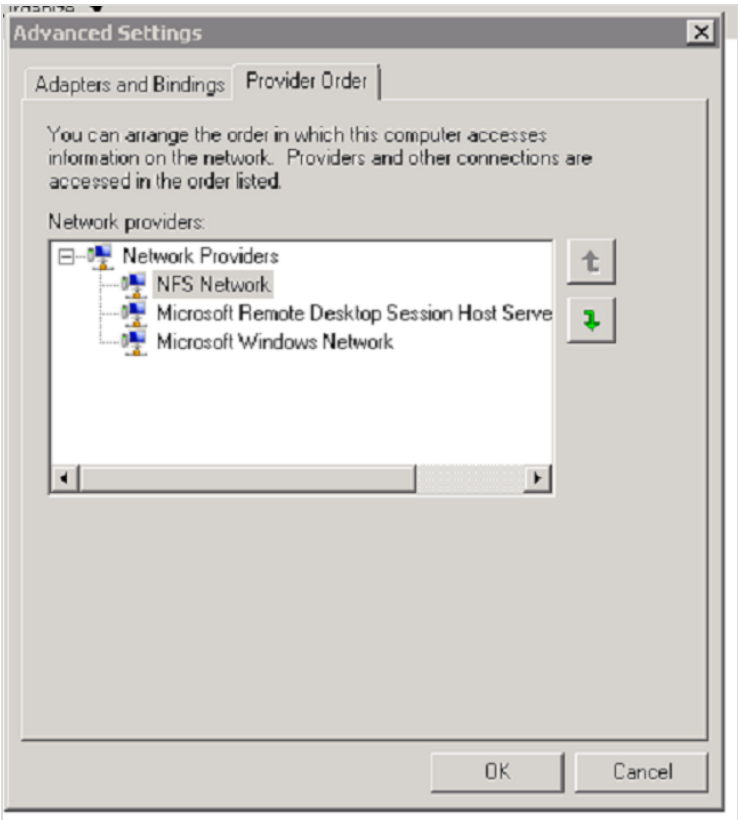
Symptom 2: After installing NFS client, connection to a file system using a Universal Naming Convention (UNC) path, is significantly delayed on Windows 2008 R2 servers.

Cause 1: Windows Network Provider has higher priority than Client for NFS Network Provider.

Solution 1: Change the Network Provider Order so that Client for NFS Network Provider is tried first.

To change the Network Provider Order on Windows 2008 R2

1. Click **Start**, and then click **Network**.
2. **Right-click** or press **Shift+F10** and click **Properties**.
3. Click **Change Adapter Settings**. Press **Alt** and click **Advanced** in the menu.
4. In the **Advanced** menu, click **Advanced Settings**.
5. Click the **Provider Order** tab.
6. Select the **NFS Network** from the list of Network providers.
7. Click the **Up Arrow** to move the NFS Network provider to the top of the list.
8. Click **OK**.



Cause 2: The security list rules for the subnet where the mount target resides are not correctly set up.

Mounting a file system requires stateful **ingress** TCP ports 111, 2048, 2049, and 2050 as well as stateful **ingress** UDP ports 111 and 2048.

Stateful **egress** from TCP ports 111, 2048, 2049, and 2050 and stateful **egress** from UDP port 111 is also required.

Solution 2: Use the instructions in Configuring VCN Security List Rules for File Storage to set up the correct security list rules.

Mounting from File Explorer Fails With "An Unexpected Error Occurred."

Important

To connect to file systems from Windows instances, the NFS Client must first be installed. Be sure to follow the installation procedure found in Mounting File Systems From Windows Instances before proceeding with troubleshooting.

Symptom: The IP address and export path are correctly represented in the **Folder** field. When you click **Finish**, the system attempts to connect to the file system, but fails with an error: "The mapped network drive could not be created because the following error has occurred: An unexpected error occurred."

Solution 1: Reboot the instance, and mount the file system again using File Explorer.

Solution 2: Mount the file system using the Command Prompt.

CHAPTER 16 Functions

This chapter explains how to create, deploy, and invoke functions using Oracle Functions.

Overview of Functions

Oracle Functions is a fully managed, highly scalable, on-demand, Functions-as-a-Service platform, built on enterprise-grade Oracle Cloud Infrastructure and powered by the Fn Project open source engine. Use Oracle Functions (sometimes abbreviated to just Functions) when you want to focus on writing code to meet business needs. You don't have to worry about the underlying infrastructure because Oracle Functions will ensure your app is highly-available, scalable, secure, and monitored. With Oracle Functions, you can deploy your code, call it directly or trigger it in response to events, and get billed only for the resources consumed during the execution.

Oracle Functions is based on Fn Project. Fn Project is an open source, container native, serverless platform that can be run anywhere - any cloud or on-premises. Fn Project is easy to use, supports every programming language, and is extensible and performant. You can download and install the open source distribution of Fn Project, develop and test a function locally, and then use the same tooling to deploy that function to Oracle Functions.

You can access Oracle Functions using the Console, a CLI, and a REST API. You can invoke the functions you deploy to Oracle Functions using the CLI or by making signed HTTP requests.

Oracle Functions is integrated with Oracle Cloud Infrastructure Identity and Access Management (IAM), which provides easy authentication with native Oracle Cloud Infrastructure identity functionality. See Overview of Oracle Cloud Infrastructure Identity and Access Management.

To get set up and running quickly with Oracle Functions, see the Quick Start Guide.

Ways to Access Oracle Cloud Infrastructure

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. For a list of available SDKs, see Software Development Kits and Command Line Interface.

To access the Console, you must use a supported browser. Oracle Cloud Infrastructure supports the latest desktop versions of Google Chrome, Microsoft Edge, Internet Explorer 11, Safari, Firefox, and Firefox ESR. Note that private browsing mode is not supported for Firefox, Internet Explorer, or Edge. Mobile browsers are not supported.

For general information about using the REST API, see REST APIs.

Creating Automation with Events

You can create automation based on state changes for your Oracle Cloud Infrastructure resources by using event types, rules, and actions. For more information, see Overview of Events.

The following Oracle Functions resources emit events:

- applications
- functions

You can also have events in other services invoke functions in Oracle Functions. See Invoking Oracle Functions from Other Oracle Cloud Infrastructure Services.

Resource Identifiers

Most types of Oracle Cloud Infrastructure resources have a unique, Oracle-assigned identifier called an Oracle Cloud ID (OCID). For information about the OCID format and other ways to identify your resources, see Resource Identifiers.

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies. For specific details about writing policies for each of the different services, see Policy Reference.

If you're a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

Oracle Functions Capabilities and Limits

In your tenancy you can create a maximum of:

- 10 applications
- 20 functions

See Service Limits for a list of applicable limits and instructions for requesting a limit increase.

The maximum amount of data you can send to a function (the function's request payload) is 6MB. The maximum amount of data a function can return in response to a request (the function's response payload) is 6MB. These limits are fixed and cannot be changed.

Some other Oracle Functions capabilities and limits are also fixed. However, there are also a number that you can change. See Changing Oracle Functions Default Behavior.

Required IAM Service Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

If you're new to policies, see Getting Started with Policies and Common Policies.

For more information about policies for Oracle Functions, see:

- Create Policies to Control Access to Network and Function-Related Resources
- Details for Functions

Oracle Functions Concepts

This topic describes key concepts you need to understand when using Oracle Functions.

Functions Developers

Oracle Cloud Infrastructure users who use Oracle Functions to create and deploy functions are referred to as 'functions developers'. To use Oracle Functions, functions developers must have Oracle Cloud Infrastructure user accounts. Their user accounts must belong to groups to which appropriate policies grant access to function-related resources.

See Create Groups and Users to use with Oracle Functions, if they don't exist already.

Applications

In Oracle Functions, an application is:

- a logical grouping of functions
- a common context to store configuration variables that are available to all functions in the application

When you define an application in Oracle Functions, you specify the subnets in which to run the functions in the application.

Oracle Functions shows applications and their functions in the Console.

See Creating Applications.

Functions

In Oracle Functions, functions are:

- small but powerful blocks of code that generally do one simple thing
- grouped into applications
- stored as Docker images in a specified Docker registry
- invoked in response to a CLI command or signed HTTP request

When you deploy a function to Oracle Functions using the Fn Project CLI, the function is built as a Docker image and pushed to a specified Docker registry.

A definition of the function is stored as metadata in the Oracle Functions server. The definition describes how the function is to be executed and includes:

- the Docker image to pull when the function is invoked
- the maximum length of time the function is allowed to execute for
- the maximum amount of memory the function is allowed to consume

Oracle Functions shows functions, and the applications into which they are grouped, in the Console.

See Creating, Deploying, and Invoking a Helloworld Function.

Invocations

In Oracle Functions, a function's code is run (or executed) when the function is called (or invoked). You can invoke a function that you've deployed to Oracle Functions from:

- The Fn Project CLI.
- The Oracle Cloud Infrastructure SDKs.
- Signed HTTP requests to the function's invoke endpoint. Every function has an invoke endpoint.
- Other Oracle Cloud services (for example, triggered by an event in the Events service) or from external services.

When a function is invoked for the first time, Oracle Functions pulls the function's Docker image from the specified Docker registry, runs it as a Docker container, and executes the function. If there are subsequent requests to the same function, Oracle Functions directs those requests to the same container. After a period being idle, the Docker container is removed.

Oracle Functions shows information about function invocations in metric charts.

See Invoking Functions.

Triggers

A trigger is the result of an action elsewhere in the system, that sends a request to invoke a function in Oracle Functions. For example, an event in the Events service might cause a trigger to send a request to Oracle Functions to invoke a function. Alternatively, a trigger might send regular requests to invoke a function on a defined, time-based schedule.

A function might not be associated with any triggers, or it can be associated with one or multiple triggers.

How Oracle Functions Works

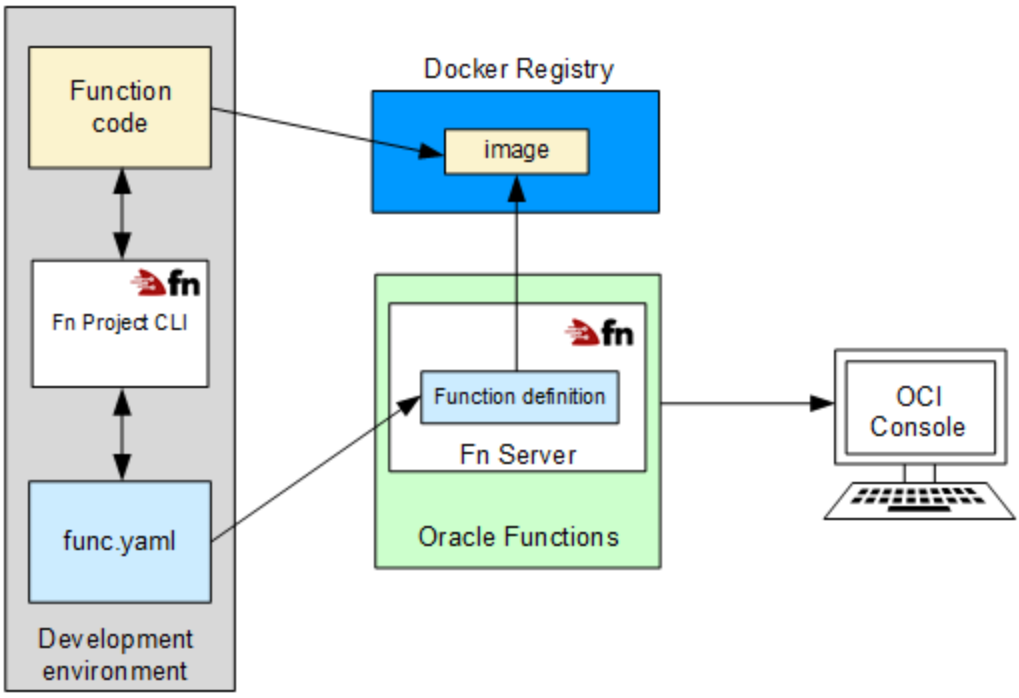
This topic describes how Oracle Functions works when you deploy a function, and when you invoke a function.

What Happens When You Deploy a Function to Oracle Functions?

When you have written the code for a function and it's ready to deploy, you can use a single Fn Project CLI command to perform all the deploy operations in sequence:

- building a Docker image from the function
- providing a definition of the function in a func.yaml file that includes:
    - the maximum length of time the function is allowed to execute for
    - the maximum amount of memory the function is allowed to consume
- pushing the image to the specified Docker registry
- uploading function metadata (including the memory and time restrictions, and a link to the image in the Docker registry) to the Fn Server
- adding the function to the list of functions shown in the Console

The above process of deploying a function to Oracle Functions is shown in the diagram.



What Happens When You Invoke a Function?

You can invoke a function that you've deployed to Oracle Functions from:

- The Fn Project CLI.
- The Oracle Cloud Infrastructure SDKs.
- Signed HTTP requests to the function's invoke endpoint. Every function has an invoke endpoint.
- Other Oracle Cloud services (for example, triggered by an event in the Events service) or from external services.

When a function is invoked for the first time, Oracle Functions first verifies the request with the IAM service. Assuming the request passes authentication and authorization checks, Oracle Functions then passes the request to the Fn Server, which uses the function definition to:

- identify the Docker image of the function to pull from the Docker registry
- execute the function by running the function's image as a container on an instance in a subnet associated with the application to which the function belongs

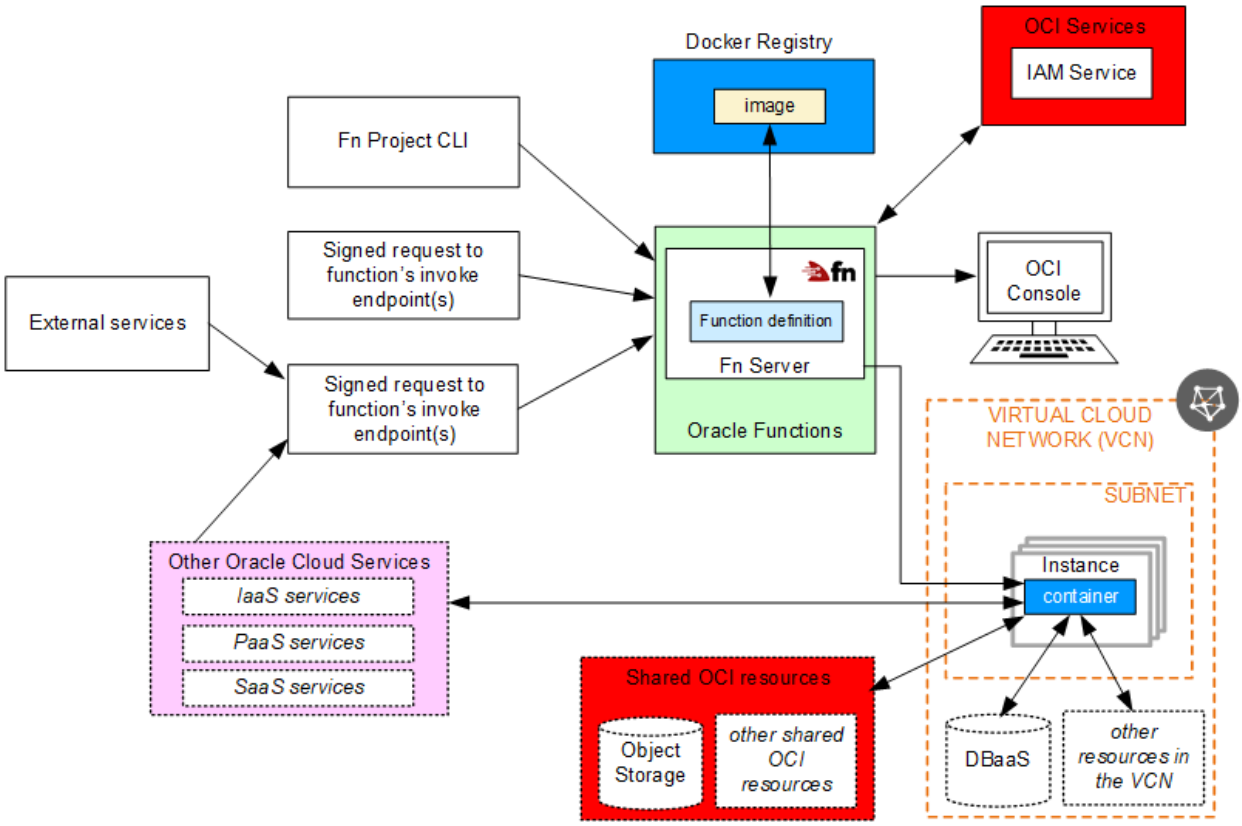
When the function is executing inside the container, the function can read from and write to other resources and services running in the same subnet (for example, Database as a Service). The function can also read from and write to other shared resources (for example, Object Storage), and other Oracle Cloud Services. You can specify the maximum length of time the function is allowed to execute by setting a timeout in the func.yaml file or in the Console.

Oracle Functions stores the function's logs in Oracle Cloud Infrastructure or in an external logging destination.

When the function has finished executing and after a period being idle, the Docker container is removed. If Oracle Functions receives another call to the same function before the container is removed, the second request is routed to the same running container. If Oracle Functions receives a call to a function that is currently executing inside a running container, Oracle Functions scales horizontally to serve both incoming requests and a second Docker container is started.

Oracle Functions shows information about function invocations in metric charts.

The above process of invoking a function is shown in the diagram.



Preparing for Oracle Functions

Before you can deploy functions to Oracle Functions:

- A tenancy administrator must have configured your Oracle Cloud Infrastructure tenancy for function development. There are a number of different tenancy configuration tasks to complete. For more information, see Configuring Your Tenancy for Function Development.

  When your tenancy is configured, you will have access, via a suitable policy and user account, to a compartment that has a VCN with at least one public subnet (and an

internet gateway) or at least one private subnet (and a service gateway). For more information about these network components, see Overview of Networking.

You will also have access to a Docker registry in which to store images. This documentation assumes you will be using Oracle Cloud Infrastructure Registry as your Docker registry and provides instructions accordingly. For more information, see Overview of Registry .

- You must have configured your client environment for functions development. There are a number of different client environment configuration tasks to complete. For more information, see Configuring Your Client Environment for Function Development.

To get set up and running quickly with Oracle Functions, see the Quick Start Guide.

Availability by Region Name and Region Code

Oracle Functions is available in the following regions. Note that you have to use region name and region code in some commands. In some cases, you might have to use shortened versions of availability domain names.

Region	Region Identifier	Region Code	Shortened Availability Domain Names
US East (Ashburn)	`us-ashburn-1`	`iad`	• `US-ASHBURN-AD-1` • `US-ASHBURN-AD-2` • `US-ASHBURN-AD-3`
Germany Central (Frankfurt)	`eu-frankfurt-1`	`fra`	• `EU-FRANKFURT-1-AD-1` • `EU-FRANKFURT-1-AD-2` • `EU-FRANKFURT-1-AD-3`
UK South (London)	`uk-london-1`	`lhr`	• `UK-LONDON-1-AD-1` • `UK-LONDON-1-AD-2` • `UK-LONDON-1-AD-3`

Region	Region Identifier	Region Code	Shortened Availability Domain Names
India West (Mumbai)	ap-mumbai-1	bom	• AP-MUMBAI-1-AD-1
US West (Phoenix)	us-phoenix-1	phx	• PHX-AD-1 • PHX-AD-2 • PHX-AD-3
Brazil East (Sao Paulo)	sa-saopaulo-1	gru	• SA-SAOPAULO-1-AD-1
South Korea Central (Seoul)	ap-seoul-1	icn	• AP-SEOUL-1-AD-1
Australia East (Sydney)	ap-sydney-1	syd	• AP-SYDNEY-1-AD-1
Japan East (Tokyo)	ap-tokyo-1	nrt	• AP-TOKYO-1-AD-1
Canada Southeast (Toronto)	ca-toronto-1	yyz	• CA-TORONTO-1-AD-1
Switzerland North (Zurich)	eu-zurich-1	zrh	• EU-ZURICH-1-AD-1

Configuring Your Tenancy for Function Development

Before you can start using Oracle Functions to create and deploy functions, you have to set up your tenancy for function development.

When a tenancy is created, an Administrators group is automatically created for the tenancy. Users that are members of the Administrators group can perform any operation on resources in the tenancy. Oracle Functions users are typically not members of the Administrators group, and do not have to be. However, a member of the Administrators group does need to perform a number of administrative tasks to enable users to use Oracle Functions.

To set up your tenancy for function development, you have to complete the following tasks in the order shown in this checklist (the instructions in the topics below assume that you are a tenancy administrator):

Task #	Tenancy Configuration Task	Done?
1	Create Groups and Users to use with Oracle Functions, if they don't exist already	
2	Create Compartments to Own Network Resources and Oracle Functions Resources in the Tenancy, if they don't exist already	
3	Create the VCN and Subnets to Use with Oracle Functions, if they don't exist already	
4	Create Policies to Control Access to Network and Function-Related Resources, and more specifically: • Create a Policy to Give Oracle Functions Users Access to Oracle Cloud Infrastructure Registry Repositories • Create a Policy to Give Oracle Functions Users Access to Function-Related Resources • Create a Policy to Give Oracle Functions Users Access to Network Resources • Create a Policy to Give the Oracle Functions Service Access to Network Resources • Create a Policy to Give the Oracle Functions Service Access to Repositories in Oracle Cloud Infrastructure Registry	

Click each of the links in turn, and follow the instructions.

When you have set up your tenancy for function development, the next step is to set up your client development environment (see Configuring Your Client Environment for Function Development).

Create Groups and Users to use with Oracle Functions, if they don't exist already

Before users can start using Oracle Functions to create and deploy functions, as a tenancy administrator you have to create Oracle Cloud Infrastructure user accounts, along with a group to which the user accounts belong. Later on, you'll define policies to give the group (and the user accounts that belong to it) access to function-related resources. If a suitable group and user accounts already exist, there's no need to create new ones.

To create groups and users to use with Oracle Functions:

1. Log in to the Console as a tenancy administrator.
2. If a suitable group for Oracle Functions users doesn't exist already, create such a group as follows:
    a. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Groups**. A list of the groups in your tenancy is displayed.
    b. Click **Create Group** and create a new group (see To create a group). Give the group a meaningful name (for example, `acme-functions-developers`) and description. Avoid entering confidential information.
3. If suitable user accounts for Oracle Functions users don't exist already, create users as follows:
    a. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Users**. A list of the users in your tenancy is displayed.
    b. Click **Create User** and create one or more new users (see To create a user).
4. If they haven't been added already, add users to the group to use Oracle Functions as follows:
    a. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Users**. A list of the users in your tenancy is displayed.
    b. Select one or more users and add them to the group authorized to use Oracle Functions (see To add a user to a group).

Create Compartments to Own Network Resources and Oracle Functions Resources in the Tenancy, if they don't exist already

Before users can start using Oracle Functions to create and deploy functions, as a tenancy administrator you have to create:

- a compartment to own network resources (a VCN, a public or private subnet, and other resources such as an internet gateway or service gateway, a route table, security lists)
- a compartment to own function-related resources (functions, applications)

Note that the same compartment can own both network resources and function-related resources. Alternatively, you can create two separate compartments for network resources and function-related resources.

If suitable compartments already exist, there's no need to create new ones.

To create a compartment to own network resources and/or function-related resources in the tenancy:

1. Log in to the Console as a tenancy administrator.
2. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Compartments**. A list of the compartments in your tenancy is displayed.
3. Click **Create Compartment** and create a new compartment (see To create a compartment). Give the compartment a meaningful name (for example, `acme-network`, `acme-functions-compartment`) and description. Avoid entering confidential information.

Create the VCN and Subnets to Use with Oracle Functions, if they don't exist already

Before users can start using Oracle Functions to create and deploy functions, a VCN containing the subnets in which to create functions and applications must already exist. The VCN can be, but need not be, owned by the same compartment to which other function-related resources will belong.

Each subnet in the VCN must have a CIDR block that provides at least a certain minimum number of free IP addresses, as follows:

- AD-specific subnets must have a minimum of 12 free IP addresses
- regional subnets must have a minimum of 32 free IP addresses

Note that Oracle strongly recommends each subnet has a CIDR block that provides more than the minimum number of free IP addresses.

To support the largest possible number of concurrent connections, Oracle also strongly recommends that the security lists used by subnets in the VCN only have stateless rules.

If a suitable VCN already exists, there's no need to create a new one.

If you do decide to create a new VCN, you have several options, including the following:

- You can create the new VCN and have related resources created automatically at the same time (as described in this topic). In this case, three public subnets and an internet gateway are created, and a new route rule is added to the default route table.
- You can create just the VCN initially, and then create the related resources yourself later (see VCNs and Subnets). In this case, you can choose whether to create public subnets and an internet gateway (see Internet Gateway), or private subnets and a service gateway (see Access to Oracle Services: Service Gateway). For example, if you don't want to expose traffic over the public internet, create private subnets and a service gateway.

Note that to use an external logging destination like Papertrail, you have to create a VCN with public subnets (see Storing and Viewing Function Logs).

To create a VCN to use with Oracle Functions (with related resources created automatically):

1. Log in to the Console as a tenancy administrator.
2. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
3. Choose the compartment that will own the network resources (on the left side of the page). For example, `acme-network`.
   The VCN can be, but need not be, owned by the same compartment to which other function-related resources will belong. The page updates to display only the resources in that compartment.

4. Click **Create Virtual Cloud Network** to create a new VCN.
5. In the **Create Virtual Cloud Network** dialog box, enter the following:
    a. **Name:** A meaningful name for the cloud network, such as `acme-functions-vcn`. The name doesn't have to be unique, but it cannot be changed later in the Console. Avoid entering confidential information.
    b. **Create Virtual Cloud Network Plus Related Resources:** For convenience, select this option to create the VCN and associated resources (all with default properties) in a single operation.
    c. **Use DNS Hostnames in this VCN:** Select this option.
6. Click **Create Virtual Cloud Network** to create the VCN, along with the related resources (three public subnets and an internet gateway).

Create Policies to Control Access to Network and Function-Related Resources

Before users can start using Oracle Functions to create and deploy functions, as a tenancy administrator you have to create a number of Oracle Cloud Infrastructure policies to grant access to function-related and network resources. You have to:

- Create a Policy to Give Oracle Functions Users Access to Oracle Cloud Infrastructure Registry Repositories
- Create a Policy to Give Oracle Functions Users Access to Function-Related Resources
- Create a Policy to Give Oracle Functions Users Access to Network Resources
- Create a Policy to Give the Oracle Functions Service Access to Network Resources
- Create a Policy to Give the Oracle Functions Service Access to Repositories in Oracle Cloud Infrastructure Registry

See Details for Functions for more information about policies.

SUMMARY OF POLICIES TO CREATE FOR ORACLE FUNCTIONS

Policy to give:	Where to create the policy:	Statement:	More information and examples:
Users access to repositories in Oracle Cloud Infrastructure Registry	Root compartment	`Allow group <group-name> to manage repos in tenancy`	Create a Policy to Give Oracle Functions Users Access to Oracle Cloud Infrastructure Registry Repositories
Users access to function-related resources	Compartment that owns function-related resources	`Allow group <group-name> to manage functions-family in compartment <compartment-name>` `Allow group <group-name> to read metrics in compartment <compartment-name>`	Create a Policy to Give Oracle Functions Users Access to Function-Related Resources
Users access to network resources	Compartment that owns network resources	`Allow group <group-name> to use virtual-network-family in compartment <compartment-name>`	Create a Policy to Give Oracle Functions Users Access to Network Resources

Policy to give:	Where to create the policy:	Statement:	More information and examples:
Oracle Functions service access to network resources	Root compartment	`Allow service FaaS to use virtual-network-family in compartment <compartment-name>`	Create a Policy to Give the Oracle Functions Service Access to Network Resources
Oracle Functions service access to repositories in Oracle Cloud Infrastructure Registry	Root compartment	`Allow service FaaS to read repos in tenancy`	Create a Policy to Give the Oracle Functions Service Access to Repositories in Oracle Cloud Infrastructure Registry

CREATE A POLICY TO GIVE ORACLE FUNCTIONS USERS ACCESS TO ORACLE CLOUD INFRASTRUCTURE REGISTRY REPOSITORIES

When Oracle Functions users work with functions, they have to access repositories in Oracle Cloud Infrastructure Registry. Users can only access repositories that the groups to which they belong have been granted access. To enable users to access a repository, you must create an identity policy to grant the groups access to that repository.

To create a policy to give Oracle Functions users access to repositories in Oracle Cloud Infrastructure Registry:

1. Log in to the Console as a tenancy administrator and create a new policy in the root compartment:
    a. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Policies**.
    b. Follow the instructions in To create a policy, and give the policy a name (for example, `acme-functions-developers-ocir-access`).

2. Specify a policy statement to give the group access to repositories in Oracle Cloud Infrastructure Registry:

   ```
   Allow group <group-name> to manage repos in tenancy
   ```

   where `<group-name>` is the name of the group to which users using Oracle Functions belong.

   For example:

   ```
   Allow group acme-functions-developers to manage repos in tenancy
   ```

   The above policy statement gives the group permission to manage all repositories in the tenancy. If you consider this to be too permissive, then you can restrict the repositories to which the group has access by including a where clause in the `manage repos` statement. Note that if you do include a where clause, you must also include a second statement in the policy to enable the group to inspect all repositories in the tenancy (when using the Console).

   For example, the following policy statements restrict the group to accessing only repositories with names that start 'acme-web-app', but also enables the group to inspect all repositories in the tenancy:

   ```
   Allow group acme-functions-developers to inspect repos in tenancy

   Allow group acme-functions-developers to manage repos in tenancy where all
   {target.repo.name=/acme-web-app*/ }
   ```

3. Click **Create**.

CREATE A POLICY TO GIVE ORACLE FUNCTIONS USERS ACCESS TO FUNCTION-RELATED RESOURCES

When Oracle Functions users create functions and applications, they have to specify a compartment for those function-related resources (including for metrics emitted by Oracle Functions). Users can only specify a compartment that the groups to which they belong have been granted access. To enable users to specify a compartment, you must create an identity policy to grant the groups access to that compartment.

To create a policy to give Oracle Functions users access to function-related resources in the compartment that will own those resources:

1. Log in to the Console as a tenancy administrator and create a new policy in the compartment that will own Oracle Functions resources:
    a. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Policies**.
    b. Follow the instructions in To create a policy, and give the policy a name (for example, `acme-functions-developers-manage-access`).
2. Specify a policy statement to give the group access to all function-related resources in the compartment:

    ```
    Allow group <group-name> to manage functions-family in compartment <compartment-name>
    ```

    For example:

    ```
    Allow group acme-functions-developers to manage functions-family in compartment acme-functions-compartment
    ```

3. Specify a second policy statement to give the group access to metrics emitted by Oracle Functions:

    ```
    Allow group <group-name> to read metrics in compartment <compartment-name>
    ```

    For example:

    ```
    Allow group acme-functions-developers to read metrics in compartment acme-functions-compartment
    ```

4. Click **Create**.

Create a Policy to Give Oracle Functions Users Access to Network Resources

When Oracle Functions users create a function or application, they have to specify a VCN and a subnet in which to create them. Users can only specify VCNs and subnets in compartments that the groups to which they belong have been granted access. To enable users to specify a VCN and subnet, you must create an identity policy to grant the groups access to the compartment.

To create a policy to give Oracle Functions users access to network resources:

1. Log in to the Console as a tenancy administrator and create a new policy in the compartment that will own network resources:

a. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Policies**.

b. Follow the instructions in To create a policy, and give the policy a name (for example, `acme-functions-developers-manage-network-access`).

2. Specify a policy statement to give the group access to the network resources in the compartment:

```
Allow group <group-name> to use virtual-network-family in compartment <compartment-name>
```

For example:

```
Allow group acme-functions-developers to use virtual-network-family in compartment acme-network
```

3. Click **Create**.

Create a Policy to Give the Oracle Functions Service Access to Network Resources

When Oracle Functions users create a function or application, they have to specify a VCN and a subnet in which to create them. To enable the Oracle Functions service to create the function or application in the specified VCN and subnet, you must create an identity policy to grant the Oracle Functions service access to the compartment to which the network resources belong.

To create a policy to give the Oracle Functions service access to network resources:

1. Log in to the Console as a tenancy administrator.
2. Create a new policy in the root compartment:
    a. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Policies**.
    b. Follow the instructions in To create a policy, and give the policy a name (for example, `functions-service-network-access`).
    c. Specify a policy statement to give the Oracle Functions service access to the network resources in the compartment:

```
Allow service FaaS to use virtual-network-family in compartment <compartment-name>
```

For example:

```
Allow service FaaS to use virtual-network-family in compartment acme-network
```

3. Click **Create**.

Create a Policy to Give the Oracle Functions Service Access to Repositories in Oracle Cloud Infrastructure Registry

The Oracle Functions service must have read access to images stored for functions in repositories in Oracle Cloud Infrastructure Registry. To enable the Oracle Functions service to access repositories in Oracle Cloud Infrastructure Registry, you must create an identity policy.

To create a policy to give the Oracle Functions service access to repositories in Oracle Cloud Infrastructure Registry:

1. Log in to the Console as a tenancy administrator.
2. Create a new policy in the root compartment:
    a. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Policies**.
    b. Follow the instructions in To create a policy, and give the policy a name (for example, `functions-service-repos-access`).
    c. Specify a policy statement to give the Oracle Functions service access to all repositories in the tenancy:

    ```
    Allow service FaaS to read repos in tenancy
    ```

    The above policy statement gives the Oracle Functions service access to all repositories in the tenancy. If you consider this to be too permissive, then you can restrict the repositories to which Oracle Functions has access by including a where clause in the `read repos` statement.
    For example, the following policy statement restricts Oracle Functions to accessing only repositories with names that start 'acme-web-app':

    ```
    Allow service FaaS to read repos in tenancy where all {target.repo.name=/acme-web-app*/ }
    ```

3. Click **Create**.

Configuring Your Client Environment for Function Development

Before you can start using Oracle Functions to create and deploy functions, you have to set up your client environment for function development. Note that prior to setting up your client environment, you must already have set up your tenancy (see Configuring Your Tenancy for Function Development).

To set up your client environment for function development, you have to complete the following tasks in the order shown in this checklist:

Task #	Development Environment Configuration Task	Done?
1	1. Set up an Oracle Cloud Infrastructure API Signing Key for Use with Oracle Functions	
2	2. Create a Profile in the Oracle Cloud Infrastructure CLI Configuration File	
3	3. Create and Configure a Copy of oci-curl	
4	4. Install Docker for Use with Oracle Functions	
5	5. Install the Fn Project CLI	
6	6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure	
7	7. Set the Context for the Fn Project CLI Using the oracle.profile Parameter	
8	8. Generate an Auth Token to Enable Login to Oracle Cloud Infrastructure Registry	
9	9. Start Docker	
10	10. Log in to Oracle Cloud Infrastructure Registry	

Click each of the links in the checklist in turn, and follow the instructions.

When you have completed all of the development environment configuration tasks, confirm your configuration is correct (see Verifying Your Configuration for Function Development).

1. Set up an Oracle Cloud Infrastructure API Signing Key for Use with Oracle Functions

Before using Oracle Functions, you have to set up an Oracle Cloud Infrastructure API signing key.

The instructions in this topic assume:

- you are using Linux
- you are following Oracle's recommendation to provide a passphrase to encrypt the private key

For more information and other options, see Required Keys and OCIDs.

The instructions below describe how to create a new ~/.oci directory, how to generate a new private key file and public key file in that ~/.oci directory, how to upload the public key to Oracle Cloud Infrastructure to create a new API signing key, and how to obtain a fingerprint for the public API key. Be aware that instructions and examples elsewhere in this documentation assume the ~/.oci directory exists and contains the private and public key files.

If your user account already has an API signing key, create the ~/.oci directory if it doesn't exist, and then go straight to 2. Create a Profile in the Oracle Cloud Infrastructure CLI Configuration File.

If your user account doesn't already have an API signing key, follow the steps below, but note the following:

- If the ~/.oci directory doesn't exist, create it.
- If the ~/.oci directory already exists, go straight to the step below that instructs you to generate a private key file.
- If the ~/.oci directory already exists and already contains a private key file and public key file, and you know the passphrase that was used to encrypt the existing private key

file, there's no need to create new private and public key files. Instead, go straight to the step below that instructs you to create a new API signing key and upload the public key value to Oracle Cloud Infrastructure to obtain a fingerprint.

- If you already have a private key file and public key file but they are not in the ~/.oci directory, and you know the passphrase that was used to encrypt the existing private key file, there's no need to create new private and public key files. Having created the ~/.oci directory if it doesn't exist, go straight to the step below that instructs you to create a new API signing key and upload the public key value to Oracle Cloud Infrastructure to obtain a fingerprint.

To set up an API signing key:

1. Log in to your development environment as a functions developer.
2. In a terminal window, confirm that the ~/.oci directory does not already exist. For example, by entering:

   ```
   ls  ~/.oci
   ```

3. Assuming the ~/.oci directory does not already exist, create it. For example, by entering:

   ```
   mkdir ~/.oci
   ```

4. Generate a private key encrypted with a passphrase that you provide by entering:

   ```
   $ openssl genrsa -out ~/.oci/<private-key-file-name>.pem -aes128 2048
   ```

   where `<private-key-file-name>` is a name of your choice for the private key file (for example, `john_api_key_private.pem`).
   For example:

   ```
   $ openssl genrsa -out ~/.oci/john_api_key_private.pem -aes128 2048

   Generating RSA private key, 2048 bit long modulus
   ....+++
   ..............................................................+++
   e is 65537 (0x10001)

   Enter pass phrase for /Users/johndoe/.oci/john_api_key_private.pem:
   ```

5. When prompted, enter a passphrase to encrypt the private key file. Be sure to make a note of the passphrase you enter, as you will need it later.
6. When prompted, re-enter the passphrase to confirm it.
7. Confirm that the private key file has been created in the directory you specified. For example, by entering:

```
$ ls -l ~/.oci/john_api_key_private.pem

-rw-r--r-- 1 johndoe staff 1766 Jul 14 00:24 /Users/johndoe/.oci/john_api_key_private.pem
```

8. Change permissions on the file to ensure that only you can read it. For example, by entering:

```
$ chmod go-rwx ~/.oci/john_api_key_private.pem
```

9. Generate a public key (in the same location as the private key file) by entering:

```
$ openssl rsa -pubout -in ~/.oci/<private-key-file-name>.pem -out ~/.oci/<public-key-file-name>.pem
```

   where:

   - `<private-key-file-name>` is what you specified earlier as the name of the private key file (for example, `john_api_key_private.pem`)
   - `<public-key-file-name>` is a name of your choice for the public key file (for example, `john_api_key_public.pem`)

   For example:

```
$ openssl rsa -pubout -in ~/.oci/john_api_key_private.pem -out ~/.oci/john_api_key_public.pem

Enter pass phrase for /Users/johndoe/.oci/john_api_key_private.pem:
```

10. When prompted, enter the same passphrase you previously entered to encrypt the private key file.
11. Confirm that the public key file has been created in the directory you specified. For example, by entering:

```
$ ls -l ~/.oci/
```

```
-rw------- 1 johndoe staff 1766 Jul 14 00:24 john_api_key_private.pem
-rw-r--r-- 1 johndoe staff 451 Jul 14 00:55 john_api_key_public.pem
```

12. Copy the contents of the public key file you just created. For example, by entering:

```
$ cat ~/.oci/john_api_key_public.pem | pbcopy
```

13. Having created the API key pair, upload the public key value to Oracle Cloud Infrastructure:
    a. Log in to the Console as the Oracle Cloud Infrastructure user who will be using Oracle Functions to create and deploy functions.
    b. In the top-right corner of the Console, open the **Profile** menu () and then click **User Settings** to view the details.
    c. On the **API Keys** page, click **Add Public Key**.
    d. Paste the public key's value into the window and click **Add**.
    The key is uploaded and its fingerprint is displayed (for example, d1:b2:32:53:d3:5f:cf:68:2d:6f:8b:5f:77:8f:07:13).
    e. (Optional) Note the fingerprint value. You'll use the fingerprint in a subsequent configuration task, so you might want to copy it to a convenient and secure location.

When you have completed the steps in this topic, go on to 2. Create a Profile in the Oracle Cloud Infrastructure CLI Configuration File.

2. Create a Profile in the Oracle Cloud Infrastructure CLI Configuration File

Before using Oracle Functions, you must have an Oracle Cloud Infrastructure CLI configuration file that contains the credentials of the user account that you will be using to create and deploy functions. These user account credentials are referred to as a 'profile'.

By default, the Oracle Cloud Infrastructure CLI configuration file is located at `~/.oci/config`. You might already have a configuration file as a result of installing the Oracle Cloud Infrastructure CLI. However, you don't need to have installed the Oracle Cloud Infrastructure CLI in order to use Oracle Functions.

The Oracle Cloud Infrastructure CLI configuration file can contain several profiles. If you already have a configuration file containing one or more profiles, you have to add a new profile to the existing file for the Oracle Cloud Infrastructure user who will be using Oracle Functions to create and deploy functions

The instructions in this topic assume:

- you are using Linux
- you have already completed the steps in 1. Set up an Oracle Cloud Infrastructure API Signing Key for Use with Oracle Functions

To create a profile in the Oracle Cloud Infrastructure CLI configuration file for the user account that you will be using to create and deploy functions:

1. Log in to your development environment as a functions developer.
2. In a terminal window, confirm the contents of the ~/.oci directory. For example, by entering:

```
$ ls -l ~/.oci/

-rw------- 1 johndoe staff 1766 Jul 14 00:24 john_api_key_private.pem
-rw-r--r-- 1 johndoe staff 451 Jul 14 00:55 john_api_key_public.pem
```

3. Do one of the following, depending on whether the ~/.oci directory already contains a file called config:
   - If the ~/.oci directory already contains a file called config, open the file in a text editor.
   - If the ~/.oci directory doesn't yet contain a file called config, create the file and open it in a text editor. For example, by entering:

     ```
     $ vim ~/.oci/config
     ```

4. Add a new profile to the ~/.oci/config file as follows:

```
[<profile-name>]
user=<user-ocid>
fingerprint=<public-key-fingerprint>
key_file=<full-path-to-private-key-pem-file>
tenancy=<tenancy-ocid>
```

```
region=<region-identifier>
pass_phrase=<passphrase>
```

where:

- `<profile-name>` is a name of your choosing for the profile.
- `<user-ocid>` is the OCID of the Oracle Cloud Infrastructure user account you will be using to create and deploy functions. See Where to Get the Tenancy's OCID and User's OCID.
- `<public-key-fingerprint>` is the fingerprint of the public API key value that you uploaded in the Console in 1. Set up an Oracle Cloud Infrastructure API Signing Key for Use with Oracle Functions.
- `<full-path-to-private-key-pem-file>` is the full path to the private key file that you created in 1. Set up an Oracle Cloud Infrastructure API Signing Key for Use with Oracle Functions.
- `<tenancy-ocid>` is the OCID of the tenancy in which you will be creating and deploying functions. See Where to Get the Tenancy's OCID and User's OCID.
- `<region-identifier>` is the identifier of the Oracle Cloud Infrastructure region in which you will be creating and deploying functions. For example, `us-phoenix-1`. See Availability by Region Name and Region Code for the list of region identifiers.
- `<passphrase>` is the passphrase you entered in 1. Set up an Oracle Cloud Infrastructure API Signing Key for Use with Oracle Functions).

For example:

```
[john-oci-profile]
user=ocid1.user.oc1..aaaaaaaas...7ap
fingerprint=d1:b2:32:53:d3:5f:cf:68:2d:6f:8b:5f:77:8f:07:13
key_file=~/.oci/john_api_key_private.pem
tenancy=ocid1.tenancy.oc1..aaaaaaaap...keq
region=us-phoenix-1
pass_phrase=<your-passphrase>
```

When you have completed the steps in this topic, go on to 3. Create and Configure a Copy of oci-curl.

3. Create and Configure a Copy of oci-curl

You can use a bash script provided by Oracle (commonly referred to as oci-curl) to invoke a function. The oci-curl script creates a signed request, based on credentials you provide in the body of the script. For more information about oci-curl, see Request Signatures - Bash.

To use oci-curl to invoke a function, you must provide the credentials of an Oracle Cloud Infrastructure user that has been granted access to resources in the same tenancy and belonging to the same compartment as the function (see Create Policies to Control Access to Network and Function-Related Resources).

Typically you'll want to invoke a function as the functions developer that's configured for your development environment. The instructions below assume that is the case.

The instructions in this topic assume you have already completed the steps in 2. Create a Profile in the Oracle Cloud Infrastructure CLI Configuration File.

To create and configure a copy of oci-curl:

1. Log in to your development environment as a functions developer.
2. Create a copy of the oci-curl script file in your development environment and add your credentials to the file as follows:
    a. In a browser navigate to https://docs.cloud.oracle.com/iaas/Content/Resources/Assets/signing_sample_bash.txt to see the oci-curl code as raw text.
    b. Select all the text and copy it.
    c. In a text editor, open a new file in a convenient location. For example, in a terminal window, you might create a new subdirectory in your home directory and open a new file in that directory by entering:

```
$ cd ~

$ mkdir oci-curl

$ vim ~/oci-curl/oci-curl.sh
```

The name and location of the new file is up to you, but the following instructions assume ~/oci-curl/oci-curl.sh.

d. Paste the oci-curl script code that you copied earlier into the new file.

e. Save the file but leave it open so you can add your credentials.

3. Replace the sample credentials in the oci-curl.sh file with those of the user account that you want to invoke functions, as follows:

   a. Locate the following lines in the oci-curl.sh file that contain sample credential values:

```
# TODO: update these values to your own
local tenancyId="ocid1.tenancy.oc1..aaaaaaaab______dsq";
local authUserId="ocid1.user.oc1..aaaaaaaas______o3r";
local keyFingerprint="20:3b:97:13:55:1c:5b:0d:d3:37:d8:50:4e:c5:3a:34";
local privateKeyPath="/Users/someuser/.oci/oci_api_key.pem";
```

Tip

Typically you'll want to invoke a function as the functions developer that's configured for your development environment. If that's the case, open the ~/.oci/config file so you can easily copy values from there to replace the sample values in the oci-curl.sh file.

   b. Change the value of the `tenancyId` parameter in the oci-curl.sh file by replacing the sample value in quotes with the OCID of the tenancy in which the function has been deployed. For example:

```
local tenancyID="ocid1.tenancy.oc1..aaaaaaaap______keq";
```

   c. Change the value of the `authUserID` parameter in the oci-curl.sh file by replacing the sample value in quotes with the OCID of the user account that you want to run the function. The user account must have access to resources in the same tenancy and belonging to the same compartment as the function. For example:

```
local authUserId="ocid1.user.oc1..aaaaaaaas_____7ap";
```

d. Change the value of the `keyFingerprint` parameter in the oci-curl.sh file by replacing the sample value in quotes with the fingerprint of the user's public key uploaded to Oracle Cloud Infrastructure. For example:

```
local keyFingerprint="d1:b2:32:53:d3:5f:cf:68:2d:6f:8b:5f:77:8f:07:";
```

e. Change the value of the `privateKeyPath` parameter in the oci-curl.sh file by replacing the sample value in quotes with the full path to the private key file that is paired with the public key for which you provided the fingerprint. For example:

```
local privateKeyPath="/Users/johndoe/.oci/john_api_key_private.pem";
```

4. Save and close the oci-curl.sh file.

Note

When you've deployed functions to Oracle Functions and you want to use oci-curl to invoke them, you will first have to run the `source` command to set up the current shell environment for oci-curl. See Invoking Functions.

When you have completed the steps in this topic, go on to 4. Install Docker for Use with Oracle Functions.

4. Install Docker for Use with Oracle Functions

Before using Oracle Functions, a version of Docker supported by Fn Project must be installed in your development environment. If Docker is not already installed, or the installed version of Docker is not supported, you'll have to install or upgrade Docker.

The instructions in this topic assume you have already completed the steps in 3. Create and Configure a Copy of oci-curl.

To confirm that a supported version of Docker is installed in your development environment:

1. Log in to your development environment as a functions developer.
2. In a terminal window, confirm that Docker is installed by entering:

   ```
   $ docker version
   ```

3. Do one of the following, depending on the message you see:
   - If you see an error message indicating that Docker is not installed, you have to install Docker before proceeding to the next step. See the Docker documentation for information about installing Docker on your platform. If your platform is Oracle Linux, see Oracle Container Runtime for Docker User's Guide.
   - If you see a message indicating the version of Docker that's installed, go to the next step.
4. Assuming Docker is installed, go to the Fn Project home page on GitHub to confirm that the installed version of Docker is at least the minimum version specified in the Pre-requisites section.
   If the installed version of Docker is not supported by Fn Project, you have to upgrade the version of Docker before proceeding. See the Docker documentation for information about upgrading Docker on your platform. If your platform is Oracle Linux, see Oracle Container Runtime for Docker User's Guide.

When you have completed the steps in this topic, go on to 5. Install the Fn Project CLI.

5. Install the Fn Project CLI

Before using Oracle Functions, the Fn Project CLI must be installed in your development environment.

You can install the Fn Project CLI in a number of different ways according to your environment.

The instructions in this topic assume you have already completed the steps in 4. Install Docker for Use with Oracle Functions.

To install the Fn Project CLI:

1. Log in to your development environment as a functions developer.
2. Open the README.md file in the fnproject/cli repository on GitHub and follow the appropriate instructions for installing the Fn Project CLI in your development environment. As a convenient overview, the instructions are summarized below:
    - In a MacOS environment using Homebrew, install the Fn Project CLI by entering:

      ```
      $ brew install fn
      ```

    - In a Linux or MacOS environment, install the Fn Project CLI by entering:

      ```
      $ curl -LSs https://raw.githubusercontent.com/fnproject/cli/master/install | sh
      ```

      If prompted for a password, enter the superuser's password.
    - In a Linux, MacOS, or Windows environment, install the Fn Project CLI by downloading the binary from the Releases page and running it.
3. In a terminal window, confirm that the CLI has been installed by entering:

    ```
    $ fn version
    ```

    Assuming the Fn Project CLI has been installed correctly, you'll see a message indicating the version of the CLI that has been installed.

When you have completed the steps in this topic, go on to 6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure.

6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure

Before using Oracle Functions, you have to configure the Fn Project CLI to connect to your Oracle Cloud Infrastructure tenancy.

When the Fn Project CLI is initially installed, it's configured for a local development 'context'. To configure Fn Project CLI to connect to your Oracle Cloud Infrastructure tenancy instead, you have to create a new context. The context specifies Oracle Functions endpoints, the OCID of the compartment to which deployed functions will belong, and the address of the Docker registry to and from which to push and pull images.

You can define multiple contexts, each stored in a different context file in .yaml format. By default, the individual context files are stored in the `~/.fn/contexts` directory. The `~/.fn/config.yaml` file specifies which context file Fn Project uses.

To create a new context, you can create a new context file manually and edit the `~/.fn/config.yaml` file by hand to point to that file. Alternatively, you can use the Fn Project CLI to interactively create the new context file and instruct the Fn Project CLI to start using that file, as described below.

The instructions in this topic assume you have already completed the steps in 5. Install the Fn Project CLI.

To create a new context file using the Fn Project CLI:

1. Log in to your development environment as a functions developer.
2. In a terminal window, create the new Fn Project CLI context for Oracle Cloud Infrastructure by entering:

   ```
   $ fn create context <my-context> --provider oracle
   ```

   where <my-context> is a name of your choosing. For example:

   ```
   $ fn create context johns-oci-context --provider oracle
   ```

3. Specify that the Fn Project CLI is to use the new context by entering:

   ```
   $ fn use context <my-context>
   ```

   where <my-context> is the name you specified in the previous step. For example:

   ```
   $ fn use context johns-oci-context
   ```

4. Configure the new context with the OCID of the compartment that you want to own the deployed functions (you might have created a new compartment specifically for this purpose, see Create Compartments to Own Network Resources and Oracle Functions Resources in the Tenancy, if they don't exist already) by entering:

   ```
   $ fn update context oracle.compartment-id <compartment-ocid>
   ```

   For example:

   ```
   $ fn update context oracle.compartment-id ocid1.compartment.oc1..aaaaaaaarvdfa72n...
   ```

5. Configure the new context with the api-url endpoint to use when calling the API by entering:

```
$ fn update context api-url <api-endpoint>
```

where <api-endpoint> is one of the endpoints in the list of Functions endpoints in Functions API, in the format https://functions.<region-identifier>.oci.oraclecloud.com. Note that this is the preferred format. An older format (https://functions.<region-identifier>.oraclecloud.com) is still supported, but is not preferred. The <region-identifier> in <api-endpoint> is the identifier of the Oracle Cloud Infrastructure region in which you'll be creating and deploying functions. For example, us-phoenix-1.

For example:

```
$ fn update context api-url https://functions.us-phoenix-1.oci.oraclecloud.com
```

6. Configure the new context with the address of the Docker registry that you want to use with Oracle Functions by entering:

```
$ fn update context registry <region-code>.ocir.io/<tenancy-namespace>/<repo-name>
```

where:

- <region-code> is the code of the Oracle Cloud Infrastructure Registry region. For example, phx for Phoenix. See Availability by Region Name and Region Code for the list of region codes.

  Oracle recommends that the Docker registry you specify is in the same region as the subnet on which you intend functions to run.
- <tenancy-namespace> is the auto-generated Object Storage namespace string of the tenancy in which to create repositories (as shown on the **Tenancy Information** page). For example, the namespace of the acme-dev tenancy might be ansh81vru1zp. Note that for some older tenancies, the namespace string might be the same as the tenancy name in all lower-case letters (for example, acme-dev).
- <repo-name> is a repository name to pre-pend to the names of functions that you deploy.

For example:

```
$ fn update context registry phx.ocir.io/ansh81vru1zp/acme-repo
```

7. (Optional) Verify the Fn Project CLI context you've created by viewing the context file. For example, by entering:

```
$ more ~/.fn/contexts/johns-oci-context.yaml

api-url: https://functions.us-phoenix-1.oci.oraclecloud.com
provider: oracle
registry: phx.ocir.io/ansh81vru1zp/acme-repo
```

When you have completed the steps in this topic, go on to 7. Set the Context for the Fn Project CLI Using the oracle.profile Parameter.

7. Set the Context for the Fn Project CLI Using the oracle.profile Parameter

Before using Oracle Functions, you have to configure the Fn Project CLI to use the new profile you added to the Oracle Cloud Infrastructure CLI configuration file `~/.oci/config` (see 2. Create a Profile in the Oracle Cloud Infrastructure CLI Configuration File). The profile you added contains the credentials of the user account you'll be using to create and deploy functions.

Note that unless you specify otherwise, the Fn Project CLI will attempt to use a profile in the `~/.oci/config` file named `default`.

The instructions in this topic assume you have already completed the steps in 6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure.

To configure the Fn Project CLI to use the profile you've created for use with Oracle Functions:

1. Log in to your development environment as a functions developer.
2. In a terminal window, configure the Fn Project CLI context with the name of the profile you've created for use with Oracle Functions by entering:

```
$ fn update context oracle.profile <profile-name>
```

For example:

```
$ fn update context oracle.profile john-oci-profile
```

When you have completed the steps in this topic, go on to 8. Generate an Auth Token to Enable Login to Oracle Cloud Infrastructure Registry.

8. Generate an Auth Token to Enable Login to Oracle Cloud Infrastructure Registry

Before using Oracle Functions, the user account you'll be using to create and deploy functions must have an Oracle Cloud Infrastructure auth token. You use the auth token as the password when logging Docker in to Oracle Cloud Infrastructure Registry

The instructions in this topic assume you have already completed the steps in 7. Set the Context for the Fn Project CLI Using the oracle.profile Parameter.

If the user account already has an auth token, go straight on to 9. Start Docker. Otherwise, if the user account does not have an auth token, generate an auth token now.

To generate an auth token for the user account you'll be using to create and deploy functions:

1. Log in to the Console as a functions developer.
2. In the top-right corner of the Console, open the **Profile** menu () and then click **User Settings** to view the details.
3. On the **Auth Tokens** page, click **Generate Token**.
4. In the **Generate Token** dialog:
    a. Enter a meaningful description for the auth token. For example, `John's auth token for use with Oracle Functions`. Avoid entering confidential information.
    b. Click **Generate Token**. The new auth token is displayed. For example, `6<!)N___ _____6MqX`.
5. Copy the auth token immediately to a secure location from where you can retrieve it later, because you won't see the auth token again in the Console.
6. Close the **Generate Token** dialog.

When you have completed the steps in this topic, go on to 9. Start Docker.

9. Start Docker

Before using Oracle Functions, Docker must be running in your development environment. If it is not running, you must start Docker before proceeding.

The instructions in this topic assume you have already completed the steps in 8. Generate an Auth Token to Enable Login to Oracle Cloud Infrastructure Registry.

To verify that Docker is running:

1. Log in to your development environment as a functions developer.
2. In a terminal window, launch the standard hello-world Docker image as a container to confirm that Docker is running by entering:

   ```
   $ docker run hello-world
   ```

3. Do one of the following, depending on the message you see:
   - If you see an error message indicating that Docker is not running, you have to start the Docker daemon before proceeding. See the Docker documentation for information about starting Docker on your platform.
   - If you see an error message indicating that the network timed out while trying to connect and advising you to check your internet connection or whether you are behind a proxy, your development environment might be behind a corporate proxy server or firewall. In which case, you will probably need to set the http_proxy, https_proxy, and no_proxy environment variables. Ask your network administrator for advice.
   - If you see a message like the one shown below, Docker is already running and you can proceed:

     ```
     Hello from Docker.

     This message shows that your installation appears to be working correctly.
     ```

When you have completed the steps in this topic, go on to 10. Log in to Oracle Cloud Infrastructure Registry.

10. Log in to Oracle Cloud Infrastructure Registry

Before using Oracle Functions, you have to log Docker in to the Docker registry in which you are going to store your functions as Docker images. This is the Docker registry specified in the Fn Project CLI context (see 6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure).

You can store functions in public and private repositories in Oracle Cloud Infrastructure Registry, an Oracle-managed registry built on top of Oracle Cloud Infrastructure.

When you log Docker into a Docker registry, you have to provide the appropriate authentication details. For example, in the case of Oracle Cloud Infrastructure Registry, you have to provide the tenancy Object Storage namespace, the user name, and the user's auth token.

The instructions in this topic assume you have already completed the steps in 9. Start Docker.

To log Docker into Oracle Cloud Infrastructure Registry:

1. Log in to your development environment as a functions developer.
2. In a terminal window, log in to Oracle Cloud Infrastructure Registry by entering:

   ```
   $ docker login <region-code>.ocir.io
   ```

   where `<region-code>` is the code for the Oracle Cloud Infrastructure Registry region specified in the Fn Project CLI context (see 6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure). For example, `phx` for Phoenix. See Availability by Region Name and Region Code for the list of region codes.
   For example:

   ```
   $ docker login phx.ocir.io
   ```

3. When prompted for **Username**, enter the name of the user you will be using with Oracle Functions to create and deploy functions, in the format:

   `<tenancy-namespace>/<username>`

   where `<tenancy-namespace>` is the auto-generated Object Storage namespace string of the tenancy in which to create repositories (as shown on the **Tenancy Information** page). For example, `ansh81vru1zp/jdoe@acme.com`.

Note that for some older tenancies, the namespace string might be the same as the tenancy name in all lower-case letters (for example, `acme-dev`).

If your tenancy is federated with Oracle Identity Cloud Service, use the format `<tenancy-namespace>/oracleidentitycloudservice/<username>`.

You must have already generated an Oracle Cloud Infrastructure auth token for the user you specify (see 8. Generate an Auth Token to Enable Login to Oracle Cloud Infrastructure Registry).

4. When prompted for **Password**, enter the user's Oracle Cloud Infrastructure auth token. Having entered the password, Docker might warn you that the password is stored unencrypted in the Docker configuration file. The warning includes a link to the Docker documentation where you can find out how to configure a credential helper. Oracle recommends you review the information in the Docker documentation and consider using an external credentials store for increased security.

When you have completed the steps in this topic, you have completed the configuration tasks for your client environment. Go on to Verifying Your Configuration for Function Development to confirm that the Fn Project CLI can communicate with the API endpoint.

Verifying Your Configuration for Function Development

Before using Oracle Functions, it's a good idea to confirm that you have successfully completed:

- the tasks for Configuring Your Tenancy for Function Development
- the tasks for Configuring Your Client Environment for Function Development

If you have successfully completed the configuration tasks, the Fn Project CLI will be able to communicate with the API endpoint.

To confirm that the Fn Project CLI can communicate with the API endpoint:

1. Log in to your development environment as a functions developer.
2. In a terminal window, try and view a list of applications that have been defined in Oracle Functions by entering:

```
$ fn list apps
```

3. If you see either of the following, you can proceed to create and deploy functions because your system is configured correctly:
    - A message indicating that no applications have been found, which is expected if this is the first time the tenancy has been configured for Oracle Functions.
    - A list of applications that have already been created, which is expected if other users are already using the tenancy for functions development.
4. If you see an error message, it's likely that the Fn Project CLI cannot communicate with the API endpoint due to some incorrect configuration. Do the following:
    - Review the configuration tasks to confirm you completed them as instructed (see Configuring Your Tenancy for Function Development and Configuring Your Client Environment for Function Development).
    - Review the solutions for common problems (see Troubleshooting Oracle Functions).

Using the Fn Project CLI with Oracle Functions

Oracle Functions is powered by the Fn Project open source engine. As a result, you can use the Fn Project CLI to perform create, read, update, and delete operations on Oracle Functions.

To enable you to use the Fn Project CLI with Oracle Functions, you perform a number of preparatory tasks. See Configuring Your Client Environment for Function Development.

Most Fn Project CLI commands have a similar syntax:

```
fn [global options] <command> [command options] [subcommands] [arguments]
```

For example, to:

- list all the available applications, use the command `fn list apps`
- create an application, use a command like `fn create app acmeapp --annotation oracle.com/oci/subnetIds='["ocid1.subnet.oc1.phx.aaaaaaaacnh..."]'`
- invoke a function, use a command like `fn invoke helloworld-app helloworld-func`

- change the profile that the Fn Project CLI uses for its context, use a command like `fn update context oracle.profile john-oci-profile`

To see a complete list of Fn Project CLI commands, you can:

- Log in to your development environment as a functions developer and enter `fn --help` or `fn -h` in a terminal window.
- In a web browser, go to the Fn Project CLI documentation.

To see detailed information about individual Fn Project CLI commands, you can:

- Log in to your development environment as a functions developer and enter `fn <command> [subcommand] --help` or `fn <command> [subcommand] -h` in a terminal window. For example:
  - `fn create --help`
  - `fn update app -h`
- In a web browser, go to the Fn Project CLI documentation and select the command from the list.

From time to time, new versions of the Fn Project CLI are released. To:

- See which version of the Fn Project CLI is currently installed and whether it is the most recent version, log in to your development environment as a functions developer and enter `fn version` in a terminal window. The Fn Project CLI version number is displayed. If a more recent version of the Fn Project CLI is available, the number of the latest available version is also displayed.
- Upgrade the Fn Project CLI to the most recent version, reinstall the Fn Project CLI by following the instructions in 5. Install the Fn Project CLI.

Creating, Deploying, and Invoking a Helloworld Function

You can start off using Oracle Functions by using Fn Project CLI commands to:

- create a simple helloworld function written in java
- push the image to the Docker registry that's configured for Oracle Functions

- deploy the function to an application in Oracle Functions
- invoke the function

Tip

If you aren't able to successfully complete one of the steps in this topic, review the solutions for common problems (see Troubleshooting Oracle Functions).

To get started with Oracle Functions:

1. Confirm that you have completed the prerequisite steps for using Oracle Functions, as described in Preparing for Oracle Functions. Specifically, that you have:
   - set up your tenancy (see Configuring Your Tenancy for Function Development)
   - set up your development environment (see Configuring Your Client Environment for Function Development)
2. Log in to the Console as a functions developer.
3. Use the Console to create a new application in Oracle Functions:
   a. In the Console, open the navigation menu. Under **Solutions and Platform**, go to **Developer Services** and click **Functions**.
   b. Select the region you intend to use for Oracle Functions. Oracle recommends that you use the same region as the Docker registry specified in the Fn Project CLI context (see 6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure).
   c. Select the compartment specified in the Fn Project CLI context (see 6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure).
      The **Applications** page shows the applications already defined in the compartment.
   d. Click **Create Application** and specify:

- The name for the new application as helloworld-app.
- The VCN and subnet (or subnets, up to a maximum of three) in which to run the function. For example, a VCN called acme-vcn-01 and a public subnet called Public Subnet IHsY:US-PHOENIX-AD-1). If a regional subnet has been defined, best practice is to select that subnet to make failover across availability domains simpler to implement. If a regional subnet has not been defined and you need to meet high availability requirements, select multiple subnets. Oracle recommends that subnets are in the same region as the Docker registry specified in the Fn Project CLI context (see 6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure).

e. Click **Create**.

4. Log in to your development environment as a functions developer.
5. In a terminal window, create a helloworld java function by entering:

```
$ fn init --runtime java helloworld-func
```

A directory called helloworld-func is created, containing:

- A function definition file called func.yaml, containing the minimum amount of information required to build and run the function. See the Fn Project documentation to find out about the additional parameters you can include in a func.yaml file.
- A /src directory containing source files and directories for the helloworld function (including /src/main/java/com/example/fn/HelloFunction.java).
- A Maven configuration file called pom.xml that specifies the project artifacts and dependencies required to compile the function from the source files.

6. Change directory to the newly created helloworld-func directory.
7. Enter the following single Fn Project command to build the function and its dependencies as a Docker image called helloworld-func, push the image to the specified Docker registry, and deploy the function to Oracle Functions in the helloworld-app:

```
$ fn -v deploy --app helloworld-app
```

The `-v` option simply shows more detail about what Fn Project commands are doing (see Using the Fn Project CLI with Oracle Functions).

8. (Optional) Assuming the specified Docker registry is Oracle Cloud Infrastructure Registry, use the Console to confirm that the helloworld-func image has been pushed to Oracle Cloud Infrastructure Registry successfully:
    a. In the Console, open the navigation menu. Under **Solutions and Platform**, go to **Developer Services** and click **Registry**.
    b. Choose the registry's region.
    You see all the repositories in the registry to which you have access. The image you pushed is in a new repository with a name constructed from:
        - the repository name in the address of the Docker registry in the Fn Project CLI context (see 6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure)
        - the name of the helloworld-func image

    For example, the new repository might be called `acme-repo/helloworld-func`.
    c. Click the name of the new repository. You see details of the helloworld-func image that's been pushed to Oracle Cloud Infrastructure Registry.
9. (Optional) Use the Console to confirm that the function has been deployed to Oracle Functions successfully:
    a. In the Console, open the navigation menu. Under **Solutions and Platform**, go to **Developer Services** and click **Functions**.
    b. Select the compartment specified in the Fn Project CLI context (see 6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure).
    The **Applications** page shows that an application called helloworld-app has been created.
    c. Click the helloworld-app application to see the functions within it.
    The **Functions** page shows that the helloworld-func function has been deployed to Oracle Functions.
10. In a terminal window, invoke the helloworld-func function by entering:

```
$ fn invoke helloworld-app helloworld-func
```

The 'Hello World !' message is displayed.

Congratulations! You've successfully created and deployed your first function to Oracle Functions!

Creating Applications

You can create applications in Oracle Functions in readiness for deploying functions. An application need not contain any functions.

You can create applications using the Console, the Fn Project CLI, and the API.

Using the Console

To create a new application in Oracle Functions using the Console:

1. Confirm that you have completed the prerequisite steps for using Oracle Functions, as described in Preparing for Oracle Functions. Specifically, that you have:
   - set up your tenancy (see Configuring Your Tenancy for Function Development)
   - set up your development environment (see Configuring Your Client Environment for Function Development)
2. Log in to the Console as a functions developer.
3. In the Console, open the navigation menu. Under **Solutions and Platform**, go to **Developer Services** and click **Functions**.
4. Select the region you are using with Oracle Functions. Oracle recommends that you use the same region as the Docker registry that's specified in the Fn Project CLI context (see 6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure).
5. Select the compartment specified in the Fn Project CLI context (see 6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure).
   The **Applications** page shows the applications already defined in the compartment.
6. Click **Create Application** and specify:

- A name for the new application (for example, acmeapp). Avoid entering confidential information.
- The VCN and subnet (or subnets, up to a maximum of three) in which to run functions. For example, a VCN called acme-vcn-01 and a public subnet called Public Subnet IHsY:US-PHOENIX-AD-1). If a regional subnet has been defined, best practice is to select that subnet to make failover across availability domains simpler to implement. If a regional subnet has not been defined and you need to meet high availability requirements, select multiple subnets. Oracle recommends that the subnets are in the same region as the Docker registry that's specified in the Fn Project CLI context (see 6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure).

7. Click **Create**.
   The new application appears in the list of applications.

Using Fn Project CLI Commands

To create a new application in Oracle Functions using the Fn Project CLI:

1. Log in to your development environment as a functions developer.
2. In a terminal window, create a new application by entering:

   ```
   $ fn create app <app-name> --annotation oracle.com/oci/subnetIds='["<subnet-ocid>"]'
   ```

   where:

   - `<app-name>` is the name of the new application. Avoid entering confidential information.
   - `<subnet-ocid>` is the OCID of the subnet (or subnets, up to a maximum of three) in which to run functions. If a regional subnet has been defined, best practice is to select that subnet to make failover across availability domains simpler to implement. If a regional subnet has not been defined and you need to meet high availability requirements, specify multiple subnets (enclose each OCID in double quotes separated by commas, in the format `'["<subnet-ocid>","<subnet-ocid>"]'`). Oracle recommends that the subnets are in the

same region as the Docker registry that's specified in the Fn Project CLI context (see 6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure).

For example:

```
 $ fn create app acmeapp --annotation oracle.com/oci/subnetIds='
["ocid1.subnet.oc1.phx.aaaaaaaacnh..."]'
```

An application is created in Oracle Functions, in the tenancy and region implied by the subnet OCID and belonging to the compartment specified in the Fn Project CLI context file.

3. Verify that the new application has been created by entering:

```
$ fn list apps
```

For example:

```
$ fn list apps

acmeapp
```

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use these API operations to manage applications:

- CreateApplication
- DeleteApplication
- GetApplication
- UpdateApplication

Creating and Deploying Functions

You use Fn Project CLI commands to create and deploy functions to Oracle Functions.

Tip

If you aren't able to successfully complete one of the steps in this topic, review the solutions for common problems (see Troubleshooting Oracle Functions).

Using Fn Project CLI Commands

To create and deploy a function to Oracle Functions using Fn Project CLI commands:

1. Confirm that you have completed the prerequisite steps for using Oracle Functions, as described in Preparing for Oracle Functions. Specifically, that you have:
   - set up your tenancy (see Configuring Your Tenancy for Function Development)
   - set up your development environment (see Configuring Your Client Environment for Function Development)
2. If the application to which you want to add the function doesn't yet exist in Oracle Functions, create it now using the Fn Project CLI or the Console. For example, you might create a new application called acmeapp. See Creating Applications.
3. Log in to your development environment as a functions developer.
4. In a terminal window, change directory to the directory containing the function code.
5. Initialize the function by entering:

   ```
   $ fn init --runtime <runtime-language> <function-name>
   ```

   where:

   - `<runtime-language>` is one of the supported runtime languages (currently go, java, node, and python are supported)
   - `<function-name>` is the name to use as the function name. If you don't specify a function name, the name of the current directory (in lower case) is used. Avoid entering confidential information.

   For example:

```
$ fn init --runtime java acme-func
```

A directory is created with the function name you specified, containing:

- A function definition file called func.yaml, containing the minimum amount of information required to build and run the function. See the Fn Project documentation to find out about the additional parameters you can include in a func.yaml file.
- A /src directory containing source files and directories.
- A Maven configuration file called pom.xml that specifies the project artifacts and dependencies required to compile the function from the source files.

Note that depending on the runtime language you specify, the `fn init` command might create an /example directory containing code for a helloworld application. As a matter of good practice, you'll probably want to delete the /example directory.

6. Change directory to the newly created directory.
7. Enter the following single Fn Project command to build the function and its dependencies as a Docker image, push the image to the specified Docker registry, and deploy the function to Oracle Functions:

```
$ fn -v deploy --app <app-name>
```

where `<app-name>` is the name of the application in Oracle Functions to which you want to add the function. For example:

```
$ fn -v deploy --app acmeapp
```

The `-v` option simply shows more detail about what Fn Project commands are doing (see Using the Fn Project CLI with Oracle Functions).

Note that you can build, push, and deploy the function using separate Fn Project commands, instead of the single `fn deploy` command.

8. (Optional) Assuming the specified Docker registry is Oracle Cloud Infrastructure Registry, use the Console to confirm that the image has been pushed to Oracle Cloud Infrastructure Registry successfully:
    a. In the Console, open the navigation menu. Under **Solutions and Platform**, go to **Developer Services** and click **Registry**.

b. Choose the registry's region.

   You see all the repositories in the registry to which you have access. The image you pushed is in a new private repository with a name constructed from:

   - the repository name in the address of the Docker registry in the Fn Project CLI context (see 6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure)
   - the name of the image you pushed

   For example, the new repository might be called `acme-repo/acme-func`.

c. Click the name of the new repository. You see details of the image that's been pushed to Oracle Cloud Infrastructure Registry

9. (Optional) Use the Console to confirm that the function has been deployed to Oracle Functions successfully:

   a. In the Console, open the navigation menu. Under **Solutions and Platform**, go to **Developer Services** and click **Functions**.

   b. Select the compartment specified in the Fn Project CLI context (see 6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure).

      The **Applications** page shows the applications in the compartment, including the one you specified in the `fn deploy` command.

   c. Click the name of the application you specified in the `fn deploy` command to see the functions within it.

      The **Functions** page shows that the function has been deployed to Oracle Functions.

Creating Functions from Existing Docker Images

You can create a new function definition in the Oracle Functions server in different ways:

- Using the Console or the Fn Project CLI command `fn create function` to create a new function based on an existing Docker image that has already been pushed to the Docker registry (as described in this topic).

- Using the single Fn Project CLI command `fn deploy` to build a new Docker image, push the image to the Docker registry, and create a new function based on the image in one step (as described in Creating and Deploying Functions).
- Using the API (see CreateFunction).

When using the Console or the `fn create function` command to create a new function based on an existing Docker image, you specify function metadata to store in the Oracle Functions server. For example, the maximum length of time the function is allowed to execute for.

The existing image on which you base a new function must be suitable for use with Oracle Functions. Typically, to build and push a suitable image, you or somebody else will use Fn Project CLI commands and/or Docker CLI commands. For example, having written your function code and a func.yaml file containing function metadata (perhaps based on the template helloworld function and func.yaml created using `fn init`), you can:

- Use `fn build` to build a new Docker image from the function.
- Use `docker push` to push the image to the Docker registry.

With the image in the Docker registry, you can then use the Console to create a function based on the image, as described in this topic.

Using the Console

To use the Console to create a new function in the Oracle Functions server from an existing Docker image that has already been pushed to the Docker registry:

1. Log in to the Console as a functions developer.
2. In the Console, open the navigation menu. Under **Solutions and Platform**, go to **Developer Services** and click **Functions**.
3. Select the region you are using with Oracle Functions. Oracle recommends that you use the same region as the Docker registry that's specified in the Fn Project CLI context (see 6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure).
4. Select the compartment specified in the Fn Project CLI context (see 6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure).

The **Applications** page shows the applications defined in the compartment.

5. Click the name of the application in which you want to create the new function.
6. Click **Create Function** and specify:
   - **Name:** A name for the new function.
   - **Image:** The existing image in the Oracle Cloud Infrastructure Registry in your currently selected region. You first select the image repository, and then the image version.
   - **Memory:** The maximum amount of memory the function can use during execution.
   - **Timeout:** The maximum amount of time the function will be allowed to run for.
   - **Tags:** Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.
7. Click **Create** to create the new function in the Oracle Functions server.

The new function is shown in the Console, in the list of functions in the application you selected.

Using Fn Project CLI Commands

To use the Fn Project CLI to create a new function in the Oracle Functions server from an existing Docker image that has already been pushed to the Docker registry:

1. Log in to your development environment as a functions developer.
2. In a terminal window, create a new function by entering:

   ```
   $ fn create function <app-name> <function-name> <image-name>
   ```

   where:

- <app-name> is the name of an existing application in which to create the new function.
- <function-name> is the name of the new function you want to create. Avoid entering confidential information.
- <image-name> is the name of the existing image in the Docker registry on which to base the new function.

For example:

```
$ fn create function acmeapp acme-func phx.ocir.io/ansh81vru1zp/acme-repo/acme-func:0.0.3
```

A new function is created in Oracle Functions, based on the existing image and with the name you specified

3. Verify that the new function has been created by entering:

```
$ fn list functions <app-name>
```

For example:

```
$ fn list functions acme-app

NAME            IMAGE
acme-func       phx.ocir.io/ansh81vru1zp/acme-repo/acme-func:0.0.3
```

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use these API operations to manage functions:

- CreateFunction
- DeleteFunction
- GetFunction
- UpdateFunction

Viewing Functions and Applications

Having deployed functions to Oracle Functions, you'll typically want to view the functions you've deployed, along with other functions in the same application and different applications. For example, you might want to see:

- all the applications in a compartment
- details of the image for a given function

You can view applications and functions using the Console, the Fn Project CLI, and the API.

Using the Console

To view details of applications and functions deployed to Oracle Functions using the Console:

1. Log in to the Console as a functions developer.
2. In the Console, open the navigation menu. Under **Solutions and Platform**, go to **Developer Services** and click **Functions**.
3. Select the region you are using with Oracle Functions. Oracle recommends that you use the same region as the Docker registry that's specified in the Fn Project CLI context (see 6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure).
4. Select the compartment containing the applications and functions that you want to see information about.

   The **Applications** page shows all the applications in the compartment you selected.
5. Click the name of an application to see the functions within it.

   The **Functions** page shows details for all the functions within the application you selected, including:

   - the Docker image created for each function
   - when the function was last updated
6. Click the name of a function on the **Functions** page to see additional information about that function, including the values of timeout and memory configuration parameters.

Using Fn Project CLI Commands

To view details of applications and functions deployed to Oracle Functions using the Fn Project CLI:

1. Log in to your development environment as a functions developer.
2. If you want to see details about applications, in a terminal window:
    - Enter the following command to see a simple list of applications:

      ```
      $ fn list apps
      ```

      For example:

      ```
      $ fn list apps

      acme-app
      ```

    - Enter the following command to see more detail about a particular application:

      ```
      $ fn inspect app <app-name>
      ```

      For example:

      ```
      $ fn inspect app acme-app

      {
          "annotations": {
              "oracle.com/oci/appCode": "fht7ns4mn2q",
              "oracle.com/oci/compartmentId": "ocid1.compartment.oc1..aaaaaaaaw______nyq",
              "oracle.com/oci/subnetIds": [
                      "ocid1.subnet.oc1.phx.aaaaaaaao..."
              ],
              "oracle.com/oci/tenantId": "ocid1.tenancy.oc1..aaaaaaaap...keq"
          },
          "created_at": "2018-07-13T17:54:34.000Z",
          "id": "ocid1.fnapp.oc1.phx.aaaaaaaaaf______r3ca",
          "name": "acme-app",
          "updated_at": "2018-07-13T17:54:34.000Z"
      }
      ```

3. If you want to see details about functions, in a terminal window:

- Enter the following command to see a simple list of functions in a particular application:

```
$ fn list functions <app-name>
```

For example:

```
$ fn list functions acme-app

NAME            IMAGE
acme-func       phx.ocir.io/ansh81vru1zp/acme-repo/acme-func:0.0.3
acme-func-dev   phx.ocir.io/ansh81vru1zp/acme-repo/acme-func-dev:0.0.7
acme-func-test  phx.ocir.io/ansh81vru1zp/acme-repo/acme-func-test:0.0.6
```

- Enter the following command to see more detail about a particular function:

```
$ fn inspect function <app-name> <function-name>
```

For example:

```
$ fn inspect function acme-app acme-func

{
    "annotations": {
        "fnproject.io/fn/invokeEndpoint": "https://fht7ns4mn2q.us-phoenix-
1.functions.oci.oraclecloud.com/20181201/functions/ocid1.fnfunc.oc1.phx.aaaa____
uxoa/actions/invoke",
        "oracle.com/oci/compartmentId": "ocid1.compartment.oc1..aaaaaaaaw______nyq"
    },
    "app_id": "ocid1.fnapp.oc1.phx.aaaaaaaaaf______r3ca",
    "created_at": "2018-07-26T12:50:53.000Z",
    "format": "default",
    "id": "ocid1.fnfunc.oc1.phx.aaaa____uxoa",
    "image": "phx.ocir.io/ansh81vru1zp/acme-repo/acme-func:0.0.3",
    "memory": 128,
    "name": "acme-func",
    "timeout": 30,
    "updated_at": "2018-07-26T13:59:18.000Z"
}
```

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use these API operations to see details about applications and functions:

- ListApplications
- ListFunctions

Invoking Functions

You can invoke a function that you've deployed to Oracle Functions in different ways:

- Using the Fn Project CLI.
- Using the Oracle Cloud Infrastructure CLI.
- Using the Oracle Cloud Infrastructure SDKs.
- Making a signed HTTP request to the function's invoke endpoint. Every function has an invoke endpoint.

Each of the above invokes the function via requests to the API. Any request to the API must be authenticated by including a signature and the OCID of the compartment to which the function belongs in the request header. Such a request is referred to as a 'signed' request. The signature includes Oracle Cloud Infrastructure credentials in an encrypted form.

If you use the Fn Project CLI or the Oracle Cloud Infrastructure CLI to invoke a function, authentication is handled for you. See Using the Fn Project CLI to Invoke Functions and Using the Oracle Cloud Infrastructure CLI to Invoke Functions.

If you use an Oracle Cloud Infrastructure SDK to invoke a function, you can use the SDK to handle authentication. See Using SDKs to Invoke Functions.

If you make a signed HTTP request to a function's invoke endpoint, you'll have to handle authentication yourself by including a signature and the OCID of the compartment to which the function belongs in the request header. You can do this in different ways:

- Using the Oracle Cloud Infrastructure CLI `raw-request` command. See Sending a Signed Request to a Function's Invoke Endpoint (using the Oracle Cloud Infrastructure CLI raw-request command).
- Using a bash script provided by Oracle (commonly referred to as oci-curl). See Sending a Signed Request to a Function's Invoke Endpoint (using oci-curl).
- Writing code to programmatically sign requests. For information about the required credentials and how to sign the requests, see Request Signatures.

Tip

If you aren't able to successfully complete one of the steps in this topic, review the solutions for common problems (see Troubleshooting Oracle Functions).

Using the Fn Project CLI to Invoke Functions

To invoke a function deployed to Oracle Functions using the Fn Project CLI:

1. Log in to your development environment as a functions developer.
2. In a terminal window, enter:

   ```
   $ fn invoke <app-name> <function-name>
   ```

   where:

   - `<app-name>` is the name of the application containing the function you want to invoke
   - `<function-name>` is the name of the function you want to invoke

   For example:

   ```
   $ fn invoke helloworld-app helloworld-func

   Hello World !
   ```

Tip

If you want to pass arguments and values to a function, prefix the `fn invoke` command with `echo -n '<argument>=<value>' |`

If the function is expecting the argument and value as JSON, use a valid JSON format. For example:

```
$ echo -n '{"name":"John"}' | fn invoke helloworld-app
helloworld-func

Hello John !
```

Using the Oracle Cloud Infrastructure CLI to Invoke Functions

If you have installed the Oracle Cloud Infrastructure CLI, you can use it to send API requests to invoke functions. Among other things, the Oracle Cloud Infrastructure CLI will facilitate Oracle Cloud Infrastructure authentication. For information about using the Oracle Cloud Infrastructure CLI, see Command Line Interface (CLI).

These instructions assume:

- you have already installed and configured the Oracle Cloud Infrastructure CLI
- you want to invoke a function as the functions developer that's configured for your development environment

To invoke a function using the Oracle Cloud Infrastructure CLI:

1. Log in to your development environment as a functions developer.
2. In a terminal window, enter:

   ```
   $ oci fn function invoke <function-ocid> --file "<output-filepath>" --body "<request-parameters>"
   ```

   where:

- `<function-ocid>` is the OCID of the function you want to invoke. To find out a function's OCID, use the `fn inspect` command to see the value of the function's `id` property (see Viewing Functions and Applications).
- `<output-filepath>` is the path and name of a file to write the response to. To write the response to stdout, specify `--file "-"`
- `<request-parameters>` are optionally arguments and values to pass to the function. If the function is expecting arguments and values as JSON, use a valid JSON format. For example, `--body '{"name":"John"}'`. Note that you must include `--body ""` in the request, even if there are no request parameters to pass.

For example:

```
$ oci fn function invoke --function-id ocid1.fnfunc.oc1.phx.aaaa____uxoa --file "-" --body
""

Hello World !
```

```
$ oci fn function invoke --function-id ocid1.fnfunc.oc1.phx.aaaa____uxoa --file "-" --body
'{"name":"John"}'

Hello John !
```

Using SDKs to Invoke Functions

If you're writing a program to invoke a function in a language for which an Oracle Cloud Infrastructure SDK exists, Oracle recommends you use that SDK to send API requests to invoke the function. Among other things, the SDK will facilitate Oracle Cloud Infrastructure authentication.

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the InvokeFunction API operation to invoke functions.

Obtaining a Function's Invoke Endpoint

When invoking a function using oci-curl or the Oracle Cloud Infrastructure CLI `raw-request` command, you have to specify the function's invoke endpoint.

To obtain a function's invoke endpoint:

1. Log in to your development environment as a functions developer.
2. In a terminal window, enter:

   ```
   $ fn inspect function <app-name> <function-name>
   ```

   where:

   - `<app-name>` is the name of the application containing the function for which you want to obtain the invoke endpoint
   - `<function-name>` is the name of the function for which you want to obtain the invoke endpoint

   For example:

   ```
   $ fn inspect function helloworld-app helloworld-func

   {
      "annotations": {
                  "fnproject.io/fn/invokeEndpoint": "https://fht7ns4mn2q.us-phoenix-
   1.functions.oci.oraclecloud.com/20181201/functions/ocid1.fnfunc.oc1.phx.aaaa____
   uxoa/actions/invoke",

   ...
   }
   ```

   The function's invoke endpoint is the value of `"fnproject.io/fn/invokeEndpoint"`. For example, `"https://fht7ns4mn2q.us-phoenix-1.functions.oci.oraclecloud.com/20181201/functions/ocid1.fnfunc.oc1.phx.aaaa____uxoa/actions/invoke"` (abbreviated for readability).

Sending a Signed Request to a Function's Invoke Endpoint (using the Oracle Cloud Infrastructure CLI `raw-request` command)

If you have installed the Oracle Cloud Infrastructure CLI, you can use it to send API requests to invoke functions. Among other things, the CLI will facilitate Oracle Cloud Infrastructure authentication. For more information about using the Oracle Cloud Infrastructure CLI, see Command Line Interface (CLI).

These instructions assume:

- you have already installed and configured the Oracle Cloud Infrastructure CLI
- you want to invoke a function as the functions developer that's configured for your development environment

To invoke a function deployed to Oracle Functions by sending a signed request to the function's invoke endpoint using the Oracle Cloud Infrastructure CLI `raw-request` command:

1. Log in to your development environment as a functions developer.
2. Obtain the function's invoke endpoint (see Obtaining a Function's Invoke Endpoint). For example, `"fnproject.io/fn/invokeEndpoint": "https://fht7ns4mn2q.us-phoenix-1.functions.oci.oraclecloud.com/20181201/functions/ocid1.fnfunc.oc1.phx.aaaa____uxoa/actions/invoke"` (abbreviated for readability).
3. Use the Oracle Cloud Infrastructure CLI `raw-request` command to invoke the function by sending a signed POST request to the function's invoke endpoint by entering:

   ```
   $ oci raw-request --http-method POST --target-uri <invoke-endpoint> --request-body "<request-parameters>"
   ```

   where:

   - `<invoke-endpoint>` is the endpoint you obtained in the earlier step.
   - `<request-parameters>` are optionally arguments and values to pass to the function. If the function is expecting arguments and values as JSON, use a valid JSON format. Note that you must include `--request-body ""` in the request, even if there are no request parameters to pass.

For example:

- ```
  $ oci raw-request --http-method POST --target-uri https://fht7ns4mn2q.us-phoenix-
  1.functions.oci.oraclecloud.com/20181201/functions/ocid1.fnfunc.oc1.phx.aaaa____
  uxoa/actions/invoke --request-body ""

  Hello World !
  ```

- ```
  $ oci raw-request --http-method POST --target-uri https://fht7ns4mn2q.us-phoenix-
  1.functions.oci.oraclecloud.com/20181201/functions/ocid1.fnfunc.oc1.phx.aaaa____
  uxoa/actions/invoke --request-body '{"name":"John"}'

  Hello John !
  ```

4. Assuming a passphrase was provided to encrypt the API signing key (as recommended by Oracle), enter the passphrase when prompted.

Sending a Signed Request to a Function's Invoke Endpoint (using oci-curl)

When you followed the instructions to prepare your client environment for Oracle Functions, you installed and configured oci-curl in readiness for using it to invoke functions. Among other things, oci-curl will facilitate Oracle Cloud Infrastructure authentication.

These instructions assume:

- you have already configured oci-curl appropriately (see 7. Set the Context for the Fn Project CLI Using the oracle.profile Parameter)
- you want to invoke a function as the functions developer that's configured for your development environment

To invoke a function deployed to Oracle Functions by sending a signed request to the function's invoke endpoint using oci-curl:

1. Log in to your development environment as a functions developer.
2. Obtain the function's invoke endpoint (see Obtaining a Function's Invoke Endpoint).
   For example, `"fnproject.io/fn/invokeEndpoint": "https://fht7ns4mn2q.us-phoenix-1.functions.oci.oraclecloud.com/20181201/functions/ocid1.fnfunc.oc1.phx.aaaa____uxoa/actions/invoke"` (abbreviated for readability).

3. In a terminal window, use the `source` command to set up the current shell environment for oci-curl by entering:

   ```
   $ source <path-to-script>/oci-curl.sh
   ```

   where `<path-to-script>` is the path to the location of the oci-curl.sh script (see 3. Create and Configure a Copy of oci-curl). For example:

   ```
   $ source ~/oci-curl/oci-curl.sh
   ```

4. In the same terminal window in which you entered the `source` command, use oci-curl to invoke the function by sending a signed POST request to the function's invoke endpoint by entering:

   ```
   oci-curl "<invoke-endpoint-host>" post <filename> "<invoke-endpoint-path>"
   ```

   where:

   - `<invoke-endpoint-host>` is the first half of the endpoint you obtained in the earlier step, excluding `https://` and up to (and including) `.oraclecloud.com`. For example, `fht7ns4mn2q.us-phoenix-1.functions.oci.oraclecloud.com`
   - `<filename>` is the name of a file containing data to pass to the function (you must specify a file, even if it's empty) . For example, `payload.json`
   - `<invoke-endpoint-path>` is the second half of the endpoint you obtained in the earlier step, from (but not including) `.oraclecloud.com` onwards. For example, `/20181201/functions/ocid1.fnfunc.oc1.phx.aaaa____uxoa/actions/invoke`

   For example, combining the previous examples, you might enter:

   ```
   $ oci-curl "fht7ns4mn2q.us-phoenix-1.functions.oci.oraclecloud.com" post payload.json
   "/20181201/functions/ocid1.fnfunc.oc1.phx.aaaa____uxoa/actions/invoke"
   ```

5. Assuming a passphrase was provided to encrypt the API signing key (as recommended by Oracle), enter the passphrase when prompted.

Storing and Viewing Function Logs

When a function you've deployed to Oracle Functions is invoked, you'll typically want to store the function's logs so that you can review them later. You specify where Oracle Functions

stores a function's logs by setting a logging policy for the application containing the function. You can specify that Oracle Functions:

- Stores logs in Oracle Cloud Infrastructure. Note that until an Oracle Cloud Infrastructure logging service is released, Oracle Functions stores logs as files in a storage bucket in Oracle Cloud Infrastructure Object Storage.
- Stores logs by exporting them to an external logging destination like Papertrail. Note that to use an external logging destination, you must have set up a VCN with public subnets and an internet gateway (see Create the VCN and Subnets to Use with Oracle Functions, if they don't exist already).

You set application logging policies in the Console.

Using the Console

To store logs for the functions in an application:

1. Log in to the Console as a functions developer.
2. In the Console, open the navigation menu. Under **Solutions and Platform**, go to **Developer Services** and click **Functions**.
3. Select the region you are using with Oracle Functions. Oracle recommends that you use the same region as the Docker registry that's specified in the Fn Project CLI context (see 6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure).
4. Select the compartment containing the application with functions for which you want to store the logs.
   The **Applications** page shows all the applications in the compartment you selected.
5. To set the logging policy:
   - for a new application, click **Create Application** and set properties for the new application
   - for an existing application, click the name of the application, and then click **Edit Application**

   By default, **Logging Policy** is set to **None**, so logs are not stored.

6. To store logs, select one of the following **Logging Policy** options:
    - Select the **Log to Object Storage** option to store logs as files in a storage bucket in Oracle Cloud Infrastructure Object Storage.
    - Select the **Syslog URL** option to store logs in an external logging destination, and enter the syslog URL to which to export the logs. For example, `tcp://my.papertrail.com:4242`
7. Click **Save**.

Whenever a function is invoked in this application, its logs are stored according to the logging policy that you specified.

To view the logs for a function that have been stored in a storage bucket in Oracle Cloud Infrastructure Object Storage:

1. Log in to the Console as a functions developer.
2. In the Console, open the navigation menu. Under **Solutions and Platform**, go to **Developer Services** and click **Functions**.
3. Select the region you are using with Oracle Functions. Oracle recommends that you use the same region as the Docker registry that's specified in the Fn Project CLI context (see 6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure).
4. Select the compartment containing the application with the function for which you want to see the logs.

   The **Applications** page shows all the applications in the compartment you selected.
5. Click the name of the application containing the function for which you want to see the logs.
6. On the **Application Information** tab, click **Logs: Object Storage** to see the **Bucket Details** page in a separate browser tab. The **Bucket Details** page shows a list of files containing the logs for functions in the compartment you selected. Each log file name includes the OCID of the associated function.

   If the storage bucket doesn't contain the log files you're expecting, or you see an error message saying that the storage bucket doesn't exist, note the following:

- A storage bucket is only created after the first log file has been written.
- After a function has been invoked, it takes around 15 minutes for the function's log files to be written to Object Storage and appear in a storage bucket. So you won't see a storage bucket for a function until around 15 minutes after the function has been invoked for the first time.
- If you have waited for longer than 15 minutes and you still don't see a storage bucket for a function, double-check that the function includes log statements.

7. (Optional) If a large number of log files are shown in the list, enter `log/<function-OCID>` in the **Search** field to reduce the list to a manageable size.
8. Click the name of a log file to download it.

Updating Functions

Having previously created a function definition in the Oracle Functions server, you can change some, but not all, of the function's properties. For example, you can change the maximum length of time a function is allowed to execute for, but you cannot change the function's name.

You can change the Docker image on which a function is based. If you do want to change the image, the replacement image must be suitable for use with Oracle Functions, and must have already been pushed to the Docker registry. With the replacement image in the Docker registry, you can then update a function's definition so that it is based on the replacement image, as described in this topic. If the replacement image has the same name and tag as the image on which the function was originally based, see Notes About Image Digests.

You can update functions using the Console, the Fn Project CLI, and the API.

Using the Console to update an existing function

To use the Console to update an existing function in the Oracle Functions server:

1. Log in to the Console as a functions developer.
2. In the Console, open the navigation menu. Under **Solutions and Platform**, go to **Developer Services** and click **Functions**.

3. Select the region you are using with Oracle Functions. Oracle recommends that you use the same region as the Docker registry that's specified in the Fn Project CLI context (see 6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure).
4. Select the compartment specified in the Fn Project CLI context (see 6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure).
   The **Applications** page shows the applications defined in the compartment.
5. Click the name of the application containing the existing function that you want to update.
6. Click the name of the function that you want to update.
7. Click **Edit** and update some or all of the following properties:
   - **Image:** The existing image in the Oracle Cloud Infrastructure Registry in your currently selected region. You first select the image repository, and then the image version. If the image has the same name and tag as the image on which the function was originally based, see Notes About Image Digests.
   - **Memory:** The maximum amount of memory the function can use during execution.
   - **Timeout:** The maximum amount of time the function will be allowed to run for.
8. Click **Save** to update the function in the Oracle Functions server.

The function's updated properties are shown in the Console.

Using Fn Project CLI Commands

To use the Fn Project CLI to update an existing function in the Oracle Functions server:

1. Log in to your development environment as a functions developer.
2. In a terminal window, update properties of an existing function by entering:

   ```
   $ fn update function <app-name> <function-name> <image-name> --<property> <value>
   ```

   where:

- `<app-name>` is the name of an existing application containing the existing function.
- `<function-name>` is the name of the existing function you want to update.
- `<image-name>` (optionally) is the name of an existing image in the Docker registry that you now want to base the function on, instead of the previously specified image. If the image has the same name and tag as the image on which the function was originally based, see Notes About Image Digests.
- `<property> <value>` (optionally) is the property you want to update, and the new value you want it to have. Enter `fn update function --help` to see a list of properties and valid values.

For example:

```
$ fn update function acmeapp acme-func phx.ocir.io/ansh81vru1zp/acme-repo/acme-func:0.0.4 --
timeout 60
```

```
$ fn update function acmeapp acme-func --memory 256
```

The properties of the existing function are updated with the values you specified.

3. Verify that the function has been updated by entering:

```
 $ fn inspect function <app-name> <function-name>
```

For example:

```
$ fn inspect function acme-app acme-func

{
    "annotations": {
        "fnproject.io/fn/invokeEndpoint": "https://fht7ns4mn2q.us-phoenix-
1.functions.oci.oraclecloud.com/20181201/functions/ocid1.fnfunc.oc1.phx.aaaa____

}
```

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the UpdateFunction API operation to update functions.

Notes About Image Digests

Images in a Docker registry are identified by repository, name, and a tag. In addition, Docker gives each version of an image a unique alphanumeric digest. When pushing an updated Docker image, it's recommended best practice to give the updated image a new tag to identify it, rather than reusing an existing tag. However, even if you push an updated image and give it the same name and tag as an earlier version, the newly pushed version will have a different digest to the earlier version.

When you create a function with Oracle Functions, you specify the name and tag of a particular version of an image on which to base the function. To avoid later inconsistencies, Oracle Functions also records the unique digest of that particular version of the image.

By default, if you push an updated version of an image to the Docker registry with the same name and tag as the original version of the image on which a function is based, Oracle Functions continues to use the original digest to pull the original version of the image. This might be the behavior you require. However, if you want Oracle Functions to pull the later version of the image, you can explicitly change the digest that Oracle Functions uses to identify which version of the image to pull in one of the following ways:

- Use the `fn update function` command and specify the original name and tag of the version of the image on which you want the function to be based. For example:

```
fn update function acmeapp acme-func phx.ocir.io/ansh81vru1zp/acme-repo/acme-func:0.0.4
```

Oracle Functions will update the digest recorded for the image on which the function is based to be the digest of the image in the Docker registry that has the name and tag you specify.

- Use the `fn update function` command and specify the digest of the version of the image on which you want the function to be based. For example:

  ```
  fn update function acmeapp acme-func --annotation oracle.com/oci/imageDigest='"sha256:8af7cb8d7______c498c0"'
  ```

  Oracle Functions will update the digest recorded for the image on which the function is based to be the digest you specify.
- Use the Console and click **Edit Function** on the **Function Information** tab, re-select the original name and tag of the version of the image on which the function is currently based, and click **Save Changes**. Oracle Functions will update the digest recorded for the image on which the function is based.
- Use the Oracle Cloud Infrastructure API or an Oracle Cloud Infrastructure SDK (for more information, see REST APIs and Software Development Kits and Command Line Interface).

Deleting Applications and Functions

You can delete applications and functions in Oracle Functions that you or other functions developers have created, provided you have been granted the necessary permission (FN_APP_DELETE or FN_FUNCTION_DELETE as appropriate).

Note the following:

- Deleting a function does not delete the Docker image on which the function is based. To delete the image, you have to delete it explicitly (see Deleting an Image).
- Deleting applications and functions is permanent. You cannot undelete an application or function that you've deleted.

- Deleting a function does not necessarily enable you to immediately delete the subnet and VCN in which the function runs. Expect to wait up to 30 minutes after the function was last invoked before you can delete the associated network resources.

You can delete applications and functions using the Console, the Fn Project CLI, and the API.

Using the Console

When using the Console to delete applications and functions, note that:

- when you delete an application, all of its functions are also deleted
- you're always prompted to confirm deletion because you cannot undelete an application or function later

To delete applications and functions in Oracle Functions using the Console:

1. Log in to the Console as a functions developer.
2. In the Console, open the navigation menu. Under **Solutions and Platform**, go to **Developer Services** and click **Functions**.
3. Select the region you are using with Oracle Functions. Oracle recommends that you use the same region as the Docker registry that's specified in the Fn Project CLI context (see 6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure).
4. Select the compartment specified in the Fn Project CLI context (see 6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure).
   The **Applications** page shows the applications defined in the compartment.
5. To delete an application, and all of its functions:
   a. Click the name of the application you want to delete.
   b. On the **Application Detail** page, click **Delete** and confirm you want to delete the application as follows:
      - If the application does not have functions within it, click **Delete** to confirm that you want to delete the application.

- If the application does have functions within it, you are shown a list of the functions in the application. To delete the application, enter `DELETE <APPLICATION-NAME>` in the text box, and click **Delete**.

Note that deleting an application and all of its functions does not delete the Docker images on which the functions are based. To delete the images, you have to delete them explicitly (see Deleting an Image).

6. To delete a function:
   a. Click the name of the application containing the function you want to delete.
   b. On the **Application Detail** page, click the name of the function you want to delete.
   c. On the **Function Detail** page, click **Delete** and confirm you want to delete the function.

   Note that deleting a function does not delete the Docker image on which the function is based. To delete the image, you have to delete it explicitly (see Deleting an Image).

Using Fn Project CLI Commands

When using the Fn Project CLI to delete applications and functions, note that you cannot delete an application if it contains functions (you must delete the functions first).

To delete applications and functions in Oracle Functions using the Fn Project CLI:

1. Log in to your development environment as a functions developer.
2. To delete an application:
   a. In a terminal window, enter:

   ```
   $ fn delete app <app-name>
   ```

   where `<app-name>` is the name of the application to delete.
   For example:

   ```
   $ fn delete app acmeapp
   ```

b. Verify that the application has been deleted by entering:

```
$ fn list apps
```

3. To delete a function:

a. In a terminal window, enter:

```
$ fn delete function <app-name> <function-name>
```

where:

- `<app-name>` is the name of the application containing the function you want to delete.
- `<function-name>` is the name of the function you want to delete.

For example:

```
$ fn delete function acmeapp acme-func
```

b. Verify that the function has been deleted by entering:

```
$ fn list functions <app-name>
```

For example:

```
$ fn list functions acmeapp
```

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use these API operations to delete applications and functions:

- DeleteApplication
- DeleteFunction

Passing Custom Configuration Parameters to Functions

The code in functions you deploy to Oracle Functions will typically require values for different parameters. Some pre-defined parameters are available to your functions as environment variables. But you'll often want your functions to use parameters that you've defined yourself. For example, you might create a function that reads from and writes to a database. The function will require a database connect string, comprising a username, password, and hostname. You'll probably want to define username, password, and hostname as parameters that are passed to the function when it's invoked.

To pass user-defined parameters to a function deployed in Oracle Functions, you create key-value pairs known as custom configuration parameters. You can create custom configuration parameters that are:

- application-wide, meaning they are passed to every function in an application
- function-specific, meaning they are passed to the particular function for which they are defined (function-specific parameters override application-wide parameters with the same name)

To create custom configuration parameters, you can use:

- the `config:` section of a function's func.yaml file, to define function-specific custom configuration parameters
- the Console and the Fn Project CLI, to define both application-wide and function-specific custom configuration parameters

Oracle Functions combines all the custom configuration parameters (both application-wide and function-specific) in the application into a single, serially-encoded configuration object with a maximum allowable size of 4Kb.

Using the Console

To specify custom configuration parameters to pass to functions using the Console:

1. Log in to the Console as a functions developer.
2. In the Console, open the navigation menu. Under **Solutions and Platform**, go to **Developer Services** and click **Functions**.
3. Select the region you are using with Oracle Functions. Oracle recommends that you use the same region as the Docker registry that's specified in the Fn Project CLI context (see 6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure).
4. Select the compartment specified in the Fn Project CLI context (see 6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure).
   The **Applications** page shows the applications defined in the compartment.
5. Click the name of the application containing functions to which you want to pass custom configuration parameters:
   - To pass one or more custom configuration parameters to every function in the application, click **Configuration** to see the **Configuration** section for the application.
   - To pass one or more custom configuration parameters to a particular function, click the function's name to see the **Configuration** section for the function.
6. In the **Configuration** section, specify details for the first custom configuration parameter:
   - **Key:** The name of the custom configuration parameter. The name must only contain alphanumeric characters and underscores, and must not start with a number. For example, `username`
   - **Value:** A value for the custom configuration parameter. The value must only contain printable unicode characters. For example, `jdoe`
7. Click the plus button to save the new custom configuration parameter.
   Oracle Functions combines the key-value pairs for all the custom configuration parameters (both application-wide and function-specific) in the application into a single, serially-encoded configuration object with a maximum allowable size of 4Kb. You

cannot save the new custom configuration parameter if the size of the serially-encoded configuration object would be greater than 4Kb.

8. (Optional) Enter additional custom configuration parameters as required.

Using Fn Project CLI Commands

To specify custom configuration parameters to pass to functions using the Fn Project CLI:

1. Log in to your development environment as a functions developer and open a terminal window.
2. To specify one or more custom configuration parameters to pass to every function in an existing application, enter:

   ```
   $ fn config app <app-name> <key> <value>
   ```

   where:

   - `<app-name>` is the name of the application containing the functions to which you want to pass the custom configuration parameter.
   - `<key>` is the name of the custom configuration parameter. The name must only contain alphanumeric characters and underscores, and must not start with a number.
   - `<value>` is the value to give to the custom configuration parameter. The value must only contain printable unicode characters.

   For example:

   ```
   $ fn config app acmeapp username jdoe
   ```

   Note the following:

   - You can also define application-wide custom configuration parameters when you create a new application using the `fn create app` command.
   - Oracle Functions combines the key-value pairs for all the custom configuration parameters (both application-wide and function-specific) in the application into a single, serially-encoded configuration object with a maximum allowable size of 4Kb.

3. To specify one or more custom configuration parameters to pass to a particular function, enter:

```
$ fn config function <app-name> <function-name> <key> <value>
```

where:

- `<app-name>` is the name of the application containing the function to which you want to pass the custom configuration parameter.
- `<function-name>` is the name of the function to which to pass the custom configuration parameter.
- `<key>` is the name of the custom configuration parameter. The name must only contain alphanumeric characters and underscores, and must not start with a number.
- `<value>` is the value to give to the custom configuration parameter. The value must only contain printable unicode characters.

For example:

```
$ fn config function acmeapp acme-func username jdoe
```

Note the following:

- You can also define function-specific custom configuration parameters when you create a new function using the `fn create function` command.
- Oracle Functions combines the key-value pairs for all the custom configuration parameters (both application-wide and function-specific) in the application into a single, serially-encoded configuration object with a maximum allowable size of 4Kb.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use these API operations to define custom configuration parameters:

- CreateFunction
- UpdateFunction
- CreateApplication
- UpdateApplication

Accessing File Systems from Running Functions

A function you've deployed to Oracle Functions can access the file system of the container in which it's running as follows:

- the function can read files from all directories
- the function can write files to the /tmp directory

For example, you might want a function to download an Excel file and then read its contents. To meet this requirement, you might create a function that writes the file to the /tmp directory in the container's filesystem, and then subsequently reads the file.

When writing files to the /tmp directory, the /tmp directory is generally always writable. However, the maximum allowable size of the /tmp directory depends on the maximum memory threshold specified for the function:

Maximum memory threshold for the function (MB)	Maximum allowed size of /tmp (MB)	Maximum allowed number of files (inodes) in /tmp
128MB	32MB	1024
256MB	64MB	2048
512MB	128MB	4096
1024MB	256MB	8192

Note that the /tmp directory might be shared by multiple invocations of the function. A file written by an earlier invocation of a function could still exist when the function is invoked a second time. It is your responsibility to delete any files to avoid unexpected behavior.

Accessing Other Oracle Cloud Infrastructure Resources from Running Functions

When a function you've deployed to Oracle Functions is running, it can access other Oracle Cloud Infrastructure resources. For example:

- You might want a function to get a list of VCNs from the Networking service.
- You might want a function to read data from an Object Storage bucket, perform some operation on the data, and then write the modified data back to the Object Storage bucket.

To enable a function to access another Oracle Cloud Infrastructure resource, you have to include the function in a dynamic group, and then create a policy to grant the dynamic group access to that resource. For more information about dynamic groups, including the permissions required to create them, see Managing Dynamic Groups.

Having set up the policy and the dynamic group, you can then include a call to a 'resource principal provider' in your function code. The resource principal provider uses a resource provider session token (RPST) that enables the function to authenticate itself with other Oracle Cloud Infrastructure services. The token is only valid for the resources to which the dynamic group has been granted access.

Note also that the token is cached for 15 minutes. So if you change the policy or the dynamic group, you will have to wait for 15 minutes to see the effect of your changes.

Oracle recommends that you use the resource principal provider included in the Oracle Cloud Infrastructure SDK. However, you might be writing a function in a language that the Oracle Cloud Infrastructure SDK does not support. Or you might simply not want to use the Oracle Cloud Infrastructure SDK. In either case, you can write your own custom resource principal provider to enable a function to authenticate itself with other Oracle Cloud Infrastructure services, using files and environment variables in the container in which the function is executing.

Using the Console

To enable a running function to access other Oracle Cloud Infrastructure resources:

1. Log in to the Console and create a new dynamic group:
    a. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Dynamic Groups**.
    b. Follow the instructions in To create a dynamic group, and give the dynamic group a name (for example, `acme-func-dyn-grp`).
    c. When specifying a rule for the dynamic group, consider the following examples:
        - If you want all functions in a compartment to be able to access a resource, enter a rule similar to the following that adds all functions in the compartment with the specified compartment OCID to the dynamic group:

          ```
          ALL {resource.type = 'fnfunc', resource.compartment.id =
          'ocid1.compartment.oc1..aaaaaaaa23______smwa'}
          ```

        - If you want a specific function to be able to access a resource, enter a rule similar to the following that adds the function with the specified OCID to the dynamic group:

          ```
          resource.id = 'ocid1.fnfunc.oc1.iad.aaaaaaaaacq______dnya'
          ```

        - If you want all functions with a specific defined tag to be able to access a resource, enter a rule similar to the following that adds all functions with the defined tag to the dynamic group :

          ```
          ALL {resource.type = 'fnfunc', tag.department.operations.value = '45'}
          ```

          Note that free-form tags are not supported. For more information about tagging, see Resource Tags.
    d. Click **Create Dynamic Group**.

    Having created a dynamic group that includes the function, you can now create a policy to give the dynamic group access to the required Oracle Cloud Infrastructure resource.
2. Create a new policy:

a. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Policies**.

b. Follow the instructions in To create a policy, and give the policy a name (for example, `acme-func-dyn-grp-policy`).

c. When specifying a policy statement, consider the following examples:

- If you want functions in the `acme-func-dyn-grp` to be able to get a list of all the VCNs in the tenancy, enter a rule similar to the following:

```
allow dynamic-group acme-func-dyn-grp to inspect vcns in tenancy
```

- If you want functions in the `acme-func-dyn-grp` to be able to read and write to a particular Object Storage bucket, enter a rule similar to the following:

```
allow dynamic-group acme-func-dyn-grp to manage objects in compartment acme-storage-compartment where all {target.bucket.name='acme-functions-bucket'}
```

- If you want functions in the `acme-func-dyn-grp` to be able to read and write to all resources in a compartment, enter a rule similar to the following:

```
allow dynamic-group acme-func-dyn-grp to manage all-resources in compartment acme-storage-compartment
```

d. Click **Create** to create the new policy.

3. Include a resource principal provider in the function code to enable the function to authenticate with other Oracle Cloud Infrastructure services. See:

- Example: Adding the Oracle Resource Principal Provider to a Python Function to Get a List of VCNs from the Networking Service
- Example: Adding a Custom Resource Principal Provider to a Function

Example: Adding the Oracle Resource Principal Provider to a Python Function to Get a List of VCNs from the Networking Service

Having added a function to a dynamic group, and created a policy that allows the dynamic group to list the VCNs in the tenancy, you could include code similar to the following example

to get a list of VCNs from the Networking service. This example uses the Oracle resource principal provider to extract credentials from the RPST token.

```
import io
import json

from fdk import response
import oci

def handler(ctx, data: io.BytesIO=None):
    signer = oci.auth.signers.get_resource_principals_signer()
    resp = do(signer)
    return response.Response(ctx,
        response_data=json.dumps(resp),
        headers={"Content-Type": "application/json"} )

def do(signer):
    # List VCNs ------------------------------------------------------
    client = oci.core.VirtualNetworkClient({}, signer=signer)
    try:
        vcns = client.list_vcns(signer.compartment_id)
        vcns = [[v.id, v.display_name] for v in vcns.data]
    except Exception as e:
        vcns = str(e)
    return {"vcns": vcns, }
```

Example: Adding a Custom Resource Principal Provider to a Function

Oracle recommends that you use the resource principal provider included in the Oracle Cloud Infrastructure SDK. However, you might be writing a function in a language that the Oracle Cloud Infrastructure SDK does not support. Or you might simply not want to use the Oracle Cloud Infrastructure SDK. In either case, you can write your own custom resource principal provider to enable a function to authenticate itself with other Oracle Cloud Infrastructure services, using files and environment variables in the container in which the function is executing.

The container in which a function executes includes a directory tree that holds Oracle Cloud Infrastructure compatible credentials, specifically:

- A resource principal session token (RPST) in a file named **rpst**. The RPST token is formatted as a JWT token, and includes claims that identify the function's host tenancy and compartment.
- A private key for use in making requests to Oracle Cloud Infrastructure services on behalf of the function, in a file named **private.pem**.

The following environment variables are set inside the container in which the function executes:

- OCI_RESOURCE_PRINCIPAL_VERSION, containing the value `2.2`.
- OCI_RESOURCE_PRINCIPAL_RPST, containing the absolute path to the **rpst** file (including the filename).
- OCI_RESOURCE_PRINCIPAL_PRIVATE_PEM, containing the absolute path to the **private.pem** file (including the filename).
- OCI_RESOURCE_PRINCIPAL_REGION, containing the region identifier in which the function is deployed (for example, `us-phoenix-1`).

To enable a function to access another Oracle Cloud Infrastructure service, add code to the function so that it can authenticate itself with the other resource:

1. Add code that loads the RPST token from the path in the OCI_RESOURCE_PRINCIPAL_RPST environment variable.
2. Add code that loads the private key from the path in the OCI_RESOURCE_PRINCIPAL_PRIVATE_PEM environment variable.
3. Add code that uses the RPST token and the private key to create an Oracle Cloud Infrastructure request signature (see Request Signatures).
4. Add code that constructs the request to the other Oracle Cloud Infrastructure resource. If necessary, you can identify:
    - The endpoints of other Oracle Cloud Infrastructure services in the same (local) region as the function, using the region identifier in the OCI_RESOURCE_PRINCIPAL_REGION environment variable.

- The function's host tenancy and compartment, using the `res_tenant` and `res_compartment` claims in the RPST token.

For example, the sample Python function below includes a custom resource principal provider that extracts credentials from the RPST token. It then submits a GET request to the IAM API's getTenancy operation to return the OCID of the function's tenancy.

```
#!/usr/bin/env python3

import base64
import email.utils
import hashlib
import httpsig_cffi.sign
import json
import logging
import os.path
import re
import requests.auth
import urllib.parse

LOG = logging.getLogger(__name__)

# The following class is derived from
https://docs.cloud.oracle.com/iaas/Content/API/Concepts/signingrequests.htm#Python

class SignedRequestAuth(requests.auth.AuthBase):
    """A requests auth instance that can be reused across requests"""
    generic_headers = [
        "date",
        "(request-target)",
        "host"
    ]
    body_headers = [
        "content-length",
        "content-type",
        "x-content-sha256",
    ]
    required_headers = {
        "get": generic_headers,
        "head": generic_headers,
```

```
        "delete": generic_headers,
        "put": generic_headers + body_headers,
        "post": generic_headers + body_headers,
    }

    def __init__(self, key_id, private_key):
        # Build a httpsig_cffi.requests_auth.HTTPSignatureAuth for each
        # HTTP method's required headers
        self.signers = {}
        for method, headers in self.required_headers.items():
            signer = httpsig_cffi.sign.HeaderSigner(

        signer, use_host = self.signers.get(verb, (None, None))
        if signer is None:
```

```
            raise ValueError(
                "Don't know how to sign request verb {}".format(verb))

        # Inject body headers for put/post requests, date for all requests
        sign_body = verb in ["put", "post"]
        self.inject_missing_headers(request, sign_body=sign_body)

        if use_host:
            host = urllib.parse.urlparse(request.url).netloc
        else:
            host = None

        signed_headers = signer.sign(
            request.headers, host=host,
            method=request.method, path=request.path_url)
        request.headers.update(signed_headers)
        return request

def rp_auther():
    if os.environ['OCI_RESOURCE_PRINCIPAL_VERSION'] != "2.2":
        raise EnvironmentError('{} must be set to the value "2.2"'.format('OCI_RESOURCE_PRINCIPAL_
VERSION'))
    rpst = os.environ['OCI_RESOURCE_PRINCIPAL_RPST']
    if os.path.isabs(rpst):
        with open(rpst) as f:
            rpst = f.read()
    private_key = os.environ['OCI_RESOURCE_PRINCIPAL_PRIVATE_PEM']
    if os.path.isabs(private_key):
        with open(private_key) as f:
            private_key = f.read()
    return get_claims(rpst), SignedRequestAuth('ST${}'.format(rpst), private_key)

def get_claims(rpst):
    """Parse an RPST as a JWT; return a dictionary of claims

    The claims that are important are: sub, res_compartment, and res_tenant.
    These carry the resource OCID together with its location.
    """
    s = rpst.split('.')[1]
    s += "=" * ((4 - len(s) % 4) % 4)  # Pad to a multiple of 4 characters
```

```
    return json.loads(base64.b64decode(s).decode('utf-8'))

# Use RP credentials to make a request
region = os.environ['OCI_RESOURCE_PRINCIPAL_REGION']
claims, rp_auth = rp_auther()

response = requests.get("https://identity.{}.oraclecloud.com/20160918/tenancies/{}".format(region,
claims['res_tenant']), auth=rp_auth)
print(response.json())
```

Permissions Granted to Containers Running Functions

When a function you've deployed to Oracle Functions is invoked, it runs inside a container. The operations that a container can perform are determined by the user ID (UID) and group ID (GID) specified when the container is started. If a UID or GID is not specified, the container runs processes as the root user, with all the default capabilities enabled.

When starting a container to run a function, Oracle Functions always specifies a user named 'fn' with a UID of 1000, and a group name 'fn' with a GID of 1000. No privileges are granted to UID 1000 and GID 1000, so the container (and the function running inside it) does not acquire the default capabilities listed in the Docker documentation. In addition, the container is prevented from gaining privileges.

As a result, do not create and deploy functions that:

- depend on capabilities that are unavailable
- depend on privilege elevation (for example, `su`, `sudo` or `setuid`)

If you are using your own Dockerfile, include the following lines:

```
groupadd --gid 1000 fn && \
adduser --uid 1000 --gid fn fn
```

For example:

```
FROM oraclelinux:7-slim

RUN  yum -y install oracle-release-el7 oracle-nodejs-release-el7 && \
     yum-config-manager --disable ol7_developer_EPEL && \
```

```
    yum -y install oracle-instantclient19.3-basiclite nodejs && \
    rm -rf /var/cache/yum && \
    groupadd --gid 1000 fn && \
    adduser --uid 1000 --gid fn fn

WORKDIR /function
ADD . /function/
RUN npm install

CMD exec node func.js
```

Note that if you do not include the `groupadd` and `adduser` lines in the above example Dockerfile, you will see the following error message:

```
cx_Oracle.DatabaseError: ORA-12560: TNS:protocol adapter error
```

Invoking Oracle Functions from Other Oracle Cloud Infrastructure Services

You can invoke functions in Oracle Functions from other Oracle Cloud Infrastructure services. Typically, you'll want an event in another service to trigger a request to invoke a function defined in Oracle Functions.

This functionality is currently available in the Events service. For more information, see Overview of Events.

Changing Oracle Functions Default Behavior

You can change several aspects of Oracle Functions default behavior using configuration parameters and environment variables.

Depending on the parameter, you can override a default value by specifying an alternative value in the following ways (note the order of precedence):

- by adding an entry to the func.yaml file (which overrides default values)
- by explicitly setting an environment variable (which overrides values set in the func.yaml file)

- by including a command option when you invoke the function using the Fn Project CLI (which overrides values set in environment variables or in the func.yaml file)

The following table indicates the parameters you can set, the default value, and where the default value can be overridden.

Parameter Description	Default Value	Units	func.yaml Parameter	Environment Variable	Fn CLI option	Notes
Maximum time a function will be allowed to run	30	Seconds	timeout	n/a	--timeout	Maximum value: 120
Maximum memory threshold for a function	128	MB	memory	FN_MEMORY	--memory	One of: • 128 • 256 • 512 • 1024 If this limit is exceeded during execution, the function is stopped and an error message is logged.

For more information about the above parameters, and other configuration parameters, see Func files in the Fn Project documentation.

Differences between Oracle Functions and Fn Project

In general, Oracle Functions and Fn Project are very similar. However there are some differences, as detailed below.

Differences in Authentication When Making API Calls

When you use the Oracle Cloud Infrastructure API with Oracle Functions, in the request header you have to provide:

- the OCID of the compartment to which the function belongs
- Oracle Cloud Infrastructure authentication details

Differences When Invoking Functions

To invoke a function deployed to Oracle Functions, you have to explicitly specify an Oracle Cloud Infrastructure endpoint (unless you're using the Fn Project CLI).

For example, when you use oci-curl to invoke a function, you have to send a request to the function's invoke endpoint (for example `https://fht7ns4mn2q.us-phoenix-1.functions.oci.oraclecloud.com/20181201/functions/ocid1.fnfunc.oc1.phx.aaaa____uxoa/actions/invoke`).

You can obtain the appropriate endpoint by making a call to the API, either directly or by using the Fn Project CLI command:

```
$ fn inspect function <app-name> <function-name>
```

Additional Context Configuration Parameters in Oracle Functions

As well as supporting Fn Project context configuration parameters, Oracle Functions also has some additional parameters, as shown in the following table.

Additional Parameter	Set in	Value	Notes
`provider`	A context configuration .yaml file in ~/.fn/contexts	`oracle`	Enables Oracle Functions rather than Fn Project functionality. When `provider` is set to `oracle`, the following parameters are valid: • `oracle.compartment-id` • `oracle.profile` See 6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure.
`oracle.compartment-id`	A context configuration .yaml file in ~/.fn/contexts	`<compartment-ocid>`	Specifies the OCID of the Oracle Cloud Infrastructure compartment that owns function-related resources. See 6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure.
`oracle.profile`	A context configuration .yaml file in ~/.fn/contexts	`<profile-name>`	Specifies which profile to use from the ~/.oci/config file. If not set, the profile named default is used. See 7. Set the Context for the Fn Project CLI Using the oracle.profile Parameter

Use of Annotations

When you're creating and viewing Oracle Functions resources using the Fn Project CLI, annotations enable you to identify and specify associated Oracle Cloud Infrastructure resources.

For example:

- When you're using the Fn Project CLI to create a new application, you use the `--annotation` parameter to specify the OCID of the subnet in which to run the function.
- When you're using the Fn Project CLI to view the properties of a function, the `annotations` element shows the OCID of the compartment that owns the function.

Note that unlike other configuration parameters and environment variables, annotation values cannot be passed as arguments to running Docker containers.

Troubleshooting Oracle Functions

This topic covers common issues related to Oracle Functions and how you can address them.

Using DEBUG=1 to see more details about an error

If you encounter an unexpected error when using an Fn Project CLI command, you can find out more about the problem by starting the command with the string `DEBUG=1` and running the command again. For example:

```
$ DEBUG=1 fn invoke helloworld-app helloworld-func
```

Note that `DEBUG=1` must appear before the command, and that `DEBUG` must be in upper case.

Using --display-call-id when invoking functions to aid issue resolution

If you encounter an issue when invoking a function, you can engage with Oracle Support. Oracle Support can investigate the issue more efficiently if you provide the call id of the function invocation. You can obtain the call id using the `--display-call-id` command option. For example:

```
$ fn invoke helloworld-app helloworld-func --display-call-id

Call ID: 01CS23SDG71BT2N9GZJ002DQM5

Hello World !
```

Creating a new application displays an error message in the New Application dialog

If you've already reached the limit for the number of applications in your tenancy, you might see a message similar to the following in the **New Application** dialog when trying to create a new application:

Unable to create your app, please try again.

Double-check how many applications already exist in your tenancy. Compare that with the number of applications you're allowed to create. See Oracle Functions Capabilities and Limits.

If you've exceeded the number of applications allowed in your tenancy, consider:

- Deleting unwanted applications (see Deleting Applications and Functions).
- Requesting an increase to the application limit (see Service Limits for instructions).

Oracle Functions attempts to interact with docker.io

If you see a message similar to the following when deploying a function, double-check that your development environment doesn't have the FN_REGISTRY environment variable set to your Docker username:

```
The push refers to repository [docker.io. ...
.
.
.
denied: requested access to the resource is denied
Fn: error running docker push, are you logged into docker?: exit status 1
See fn <command> --help’ for more information.
```

If you have used the open source Fn Project platform, you might have followed instructions in the Fn Project documentation to set the FN_REGISTRY environment variable to your Docker username to enable interaction with the official Docker registry.

The FN_REGISTRY environment variable overrides the value of the registry option in your Fn Project CLI context.

To use the Fn Project CLI with Oracle Functions, do one of the following:

- Unset the FN_REGISTRY environment variable.
- Override the FN_REGISTRY environment variable using the `--registry` global option whenever you enter an Fn Project CLI command that interacts with Oracle Cloud Infrastructure Registry.

Running `fn version` shows that a more recent version of the Fn Project CLI is available

If you see a message similar to the following when you enter the `fn version` command, a more recent version of the Fn Project CLI is available:

```
$ fn version

Client version: 0.5.33 is not latest: 0.5.34
Server version: ?
```

To upgrade the Fn Project CLI to the most recent version, reinstall the Fn Project CLI by following the instructions in 5. Install the Fn Project CLI.

Deploying a function to Oracle Functions returns "Fn: Missing subnets annotation" message

When you deploy a function to Oracle Functions, you might see the following message:

```
$ fn deploy --app joes-helloworld-app
Deploying helloworld-func to app: joes-helloworld-app
.
.
.
Fn: Missing subnets annotation
```

If you see the `Fn: Missing subnets annotation` message, confirm that you entered the correct application name. For example:

- the application might not be in the compartment currently specified by the Fn Project CLI context
- the application might have existed previously, but has subsequently been deleted

Running Fn Project CLI commands returns a 401 error

If you see a message similar to the following when running an Fn Project CLI command, double-check that the credentials specified for your current profile in the ~/.oci/config file are authenticating you correctly:

```
$ fn list apps

Fn: [GET /apps][401] ListApps default  &{Fields: Message:Not authenticated}
```

For example:

- Does `user` specify the OCID of your Oracle Cloud Infrastructure user account?
- Does `fingerprint` specify the fingerprint of the public API key value uploaded to the Console?
- Does `key_file` specify the full path to the private key file?

See 2. Create a Profile in the Oracle Cloud Infrastructure CLI Configuration File. Also see API Errors .

Running Fn Project CLI commands returns a 404 error

If you see a message similar to the following when running an Fn Project CLI command, double-check that you are authorized to access function-related and network resources:

```
$ fn list apps

Fn: [GET /apps][404] ListApps default  &{Fields: Message:Resource is not authorized or not found}
```

For example:

- Does `oracle.compartment-id` in your current context correctly specify the OCID of the compartment that owns deployed functions?
- Have policies been set up correctly to give group access to function-related and network resources?
- Does your user account belong to the group to which access to function-related and network resources has been granted?
- Has a policy been set up to give Oracle Functions access to network resources?

See 6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure and Create Policies to Control Access to Network and Function-Related Resources. Also see API Errors .

Invoking a function returns a FunctionInvokeSyslogUnavailable message and a 502 error

Oracle Functions enables you to export a function's logs to an external logging destination (like Papertrail) by setting a syslog URL for the application. See Storing and Viewing Function Logs.

If the syslog URL is invalid or unreachable, you will see the following error when you invoke the function:

```
{"code":"FunctionInvokeSyslogUnavailable","message":"Syslog endpoint unavailable"}

Fn: Error invoking function. status: 502 message: Syslog endpoint unavailable
```

To confirm that the external logging destination's URL is the cause of the error:

1. Update the application to unset the syslog URL. For example:
    - Using the Console, click **Edit Application** on the **Application Details** page and select **None** from the **Logging Policy** options.
    - Using the Fn Project CLI, enter `fn update app helloworld-app --syslog-url ""`
2. Deploy the function you want to run. See Creating and Deploying Functions.
3. Invoke the function. See Invoking Functions.

If the function runs successfully, the external logging destination's URL is not reachable from the subnet in which the function is running. Double-check that:

- The external logging destination's URL is valid.
- The external logging destination's URL is publicly accessible.
- The subnet in which the function is running has outbound access to the public internet.

Invoking a function returns a FunctionInvokeImageNotAvailable message and a 502 error

When you invoke a function, Oracle Functions pulls the corresponding image from Oracle Cloud Infrastructure Registry using the VCN and subnets specified for the application.

If Oracle Functions is unable to pull the image, the following message is returned when you invoke a function:

```
{"code":"FunctionInvokeImageNotAvailable","message":"Failed to pull function image"}

Fn: Error invoking function. status: 502 message: Failed to pull function image
```

Possible solutions:

- Double-check that the image specified for the function still exists in the specified location in Oracle Cloud Infrastructure Registry.
- Double-check that Oracle Cloud Infrastructure is available (this message is returned if Oracle Cloud Infrastructure is unexpectedly unavailable).
- Double-check that the VCN includes an internet gateway or service gateway. For Oracle Functions to be able to access Oracle Cloud Infrastructure Registry to pull an image, the VCN must include an internet gateway or a service gateway, as follows:
    - If public subnets were specified for the application, the VCN must also include an internet gateway.
    - If private subnets were specified for the application, the VCN must also include a service gateway.

  If an internet gateway or service gateway has not been defined for the VCN already, define one now.

Invoking a function returns a FunctionInvokeSubnetOutOfIPs message and a 502 error

When you invoke a function that you've deployed to Oracle Functions, you might see the following error message:

```
{"code":"FunctionInvokeSubnetOutOfIPs","message":"subnet ocid1.subnet.oc1.phx.aaaaaaaac... is out of IPs"}
Fn: Error invoking function. status: 502 message: subnet ocid1.subnet.oc1.phx.aaaaaaaac... is out of IPs
```

If you see this error, double-check that each subnet in the VCN has at least the required minimum number of free IP addresses specified in Create the VCN and Subnets to Use with Oracle Functions, if they don't exist already.

Invoking a function returns a FunctionInvokeSubnetNotAvailable message and a 502 error

When you invoke a function that you've deployed to Oracle Functions, you might see the following error message:

```
{"code":"FunctionInvokeSubnetNotAvailable","message":"subnet ocid1.subnet.oc1.phx.aaaaaaaac... does not exist or Oracle Functions is not authorized to use it"}
Fn: Error invoking function. status: 502 message: subnet ocid1.subnet.oc1.phx.aaaaaaaac... does not exist or Oracle Functions is not authorized to use it
```

If you see this error:

- Double-check that a policy has been created to give Oracle Functions access to network resources. See Create a Policy to Give the Oracle Functions Service Access to Network Resources.
- Double-check that the subnet specified for the application still exists.

Invoking a function returns a Gateway Time-out message and a 504 error

When you invoke a function that you've deployed to Oracle Functions, you might see the following error message:

```
<html>
<head><title>504 Gateway Time-out</title></head>
<body bgcolor="white">
<center><h1>504 Gateway Time-out</h1></center>
<hr><center></center>
</body>
</html>
```

If you see this error, it's likely that a policy has not been created to give Oracle Functions access to network resources. See Create a Policy to Give the Oracle Functions Service Access to Network Resources.

Invoking a function returns FunctionInvokeContainerInitFail and 'Container initialization timed out' messages, and a 504 error

When you invoke a function that you've deployed to Oracle Functions, the function execution is subject to a maximum memory threshold. If this limit is exceeded, function execution stops and the following error message is returned:

```
{"code":"FunctionInvokeContainerInitFail","message":"Container failed to initialize, please ensure you are using the latest fdk and check the logs"}

Fn: Error invoking function. status: 504 message: Container failed to initialize, please ensure you are using the latest fdk and check the logs
```

If you see this error, increase the maximum memory threshold when you invoke the function. Valid values for the maximum memory threshold are 128MB, 256MB, 512MB, and 1024MB (see Changing Oracle Functions Default Behavior).

For example, to set a function's maximum memory threshold to 256MB, do one of the following:

- Click **Edit Function** on the **Function Details** page in the Console, and select **256** from the **Memory (in MBs)** drop-down list.
- Use the following syntax when invoking the function using the Fn Project CLI. This will set the maximum memory threshold to 256MB for the current function invocation:

  ```
  $ fn invoke <app-name> <function-name> --memory 256
  ```

- Add the following line to the function's func.yaml file. This will set the maximum

memory threshold to 256MB whenever the function is invoked:

```
memory: 256
```

Note that if you edit the func.yaml file, you must re-deploy the function to Oracle Functions before invoking it again.

It's a good idea to use the latest version of the Fn Project CLI when creating a helloworld Python function. When you enter the `fn init --runtime python <function-name>` command to create the helloworld function, the line `memory: 256` is added to the func.yaml file automatically.

Invoking a function returns a FunctionInvokeTimeout message and a 504 error

When you invoke a function that you've deployed to Oracle Functions, the function is only allowed to run for a certain amount of time. If this time limit is exceeded, function execution stops and the following error message is returned:

```
{"code":"FunctionInvokeTimeout","message":"Timed out"}

Fn: Error invoking function. status: 504 message: Timed out
```

If you see this error, increase the maximum time a function is allowed to run for. For example, to set the maximum time to 120 seconds, do one of the following:

- Click **Edit Function** on the **Function Details** page in the Console, and enter **120** in the **Timeout** field.
- Use the following syntax when invoking the function using the Fn Project CLI. This will set the time limit to 120 seconds for the current function invocation:

  ```
  $ fn invoke <app-name> <function-name> --timeout 120
  ```

- Add the following line to the function's func.yaml file. This will set the maximum time limit to 120 seconds whenever the function is invoked:

  ```
  timeout: 120
  ```

  Note that if you edit the func.yaml file, you must re-deploy the function to Oracle Functions before invoking it again.

Running Fn Project CLI commands returns an X509: decryption password incorrect error

If you see a message similar to the following when running an Fn Project CLI command, double-check that the pass_phrase specified for your current profile in the ~/.oci/config file is correct:

```
$ fn list apps

Fn: x509: decryption password incorrect
```

See 2. Create a Profile in the Oracle Cloud Infrastructure CLI Configuration File.

Deploying an application returns an "unauthorized: incorrect username or password" message

When deploying an application, you might see a message similar to the following:

```
$ fn -v deploy --app acme-app

Deploying go-app to app: acme-app
Bumped to version 0.0.2
Building image phx.ocir.io/ansh81vru1zp/acme-repo/go-app:0.0.2
FN_REGISTRY: phx.ocir.io/ansh81vru1zp/acme-repo
Current Context: acme-functions-compartment
Sending build context to Docker daemon 5.12kB
Step 1/10 : FROM fnproject/go:dev as build-stage
Get https://registry-1.docker.io/v2/fnproject/go/manifests/dev: unauthorized: incorrect username or
password
```

The message indicates an unnecessary and unsuccessful attempt to log in to Docker Hub. To resolve this situation, log out from Docker using the following command:

```
$ docker logout
```

Having logged out from Docker, re-run the command to deploy the application.

When running Oracle Functions on Ubuntu, Docker login returns an "error getting credentials - err: exit status 1..." message

When you configure your development environment for Oracle Functions, you have to install Docker (see 4. Install Docker for Use with Oracle Functions). If your development environment is running Ubuntu, when you follow the subsequent instructions to log in to Oracle Cloud Infrastructure Registry using Docker (see 10. Log in to Oracle Cloud Infrastructure Registry), you might see a message similar to the following:

```
error getting credentials - err: exit status 1, out: Error spawning command line 'dbus-launch --autolaunch=d7159335070ef1c0854c75de55c8f588 --binary-syntax --close-stderr': Child process exited with code 1
```

For more information about this Docker issue, including likely causes and possible resolutions, see https://github.com/docker/docker-credential-helpers/issues/60.

Deploying a function returns a ListTriggers message and a 500 error

When deploying a function that you've previously created using an earlier version of the Fn Project CLI, you might see a message similar to the following:

```
Fn: [GET /triggers][500] ListTriggers default  &{Fields: Message:Internal server error}
```

This message indicates that the function's func.yaml file contains one or more HTTP trigger definitions. Oracle Functions does not currently support HTTP triggers. To deploy the function, remove the `triggers:` section from the func.yaml file.

To avoid creating new func.yaml files containing trigger definitions, follow the instructions in 5. Install the Fn Project CLI to upgrade the Fn Project CLI to the most recent version.

Performing Docker-related operations with the Fn Project CLI displays an "Error response from daemon... unknown: Unauthorized" message

To enable the Fn Project CLI to access the Docker registry specified in the Fn Project CLI context, the local Docker client (the Docker daemon on Linux) in your development environment must be logged in to that Docker registry. If the Docker client is not logged in to the Docker registry, you see a message similar to the following:

```
Error response from daemon: Get https://phx.ocir.io/v2/: unknown: Unauthorized
```

Follow the instructions in 10. Log in to Oracle Cloud Infrastructure Registry to log the Docker client in to the appropriate Oracle Cloud Infrastructure Registry, an Oracle-managed Docker registry available in a number of different regions.

Function Metrics

You can monitor the health, capacity, and performance of functions you've deployed to Oracle Functions by using metrics, alarms, and notifications.

This topic describes the metrics emitted by the metric namespace `oci_faas` (the Oracle Functions service).

Resources: functions

Overview of the Oracle Functions Service Metrics

Oracle Functions monitors function execution, and collects and reports metrics such as:

- The number of times a function is invoked.
- The length of time a function runs for.
- The number of times a function failed.
- The number of requests to invoke a function that returned a '429 Too Many Requests' error in the response (known as 'throttled function invocations').

Prerequisites

IAM policies: To monitor resources, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don’t

have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.

For more information about the policy statement required to access metrics emitted by Oracle Functions, see Create a Policy to Give Oracle Functions Users Access to Function-Related Resources.

Available Metrics: oci_faas

The metrics listed in the following tables are automatically available for any functions you create. You do not need to enable monitoring on the resource to get these metrics.

Oracle Functions metrics include the following dimensions:

APPLICATIONID

The OCID of the application containing functions.

RESOURCEID

The OCID of the function.

RESPONSETYPE

The response when a function is invoked (one of Success, Error, or Throttled).

Metric	Metric Display Name	Unit	Description	Dimensions
`FunctionExecutionDuration`	**Function Duration**	ms	Total function execution duration. Expressed in milliseconds.	`applicationId` `resourceId`
`FunctionInvocationCount`	**Function Invocations**	count	Total number of function invocations.	`applicationId` `resourceId`
`FunctionResponseCount`	This metric is used in the following default metric charts: **Errors** (with `responseType = "Error"`) **Throttles** (with `responseType = "Throttled"`)	count	Total number of function responses.	`applicationId` `resourceId` `responseType`

Using the Console

To view default metric charts for a single function

1. In the Console, open the navigation menu. Under **Solutions and Platform**, go to **Developer Services** and click **Functions**.
2. Select the region you are using with Oracle Functions. Oracle recommends that you use the same region as the Docker registry that's specified in the Fn Project CLI context (see 6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure).
3. Select the compartment containing the application with functions for which you want to view metrics.

   The **Applications** page shows all the applications in the compartment you selected.
4. Click the name of the application containing the function for which you want to view metrics.
5. Click the name of the function for which you want to view metrics.
6. Under **Resources**, click **Metrics**.

   The Metrics page displays a chart for each metric that is emitted by the metric namespace for Oracle Functions. For more information about the emitted metrics, see Available Metrics: oci_faas.

Not seeing the function metrics data you expect?

If you don't see the metrics data for a function that you expect, see the following possible causes and resolutions.

Problem	Possible Cause	Resolution
Missing functions: A function I invoked is missing from the **Invocations** chart.	The chart range (time period or x-axis window) does not cover the time of invocation.	Adjust the chart range or time period as necessary.
Gaps in metrics data: The chart line is discontinuous. I want to see data in the charts as a continuous line over time, but the line has gaps in it.	No metrics data exist in the times indicated by the gaps.	Smooth out the display by increasing the chart interval to see if gaps are removed.

Problem	Possible Cause	Resolution
Empty charts: The **Errors** and **Throttles** charts never show data.	No metrics data exists for these charts in the specified chart range. No errors have occurred, and no requests have been throttled. Empty **Errors** and **Throttles** charts are expected.	Not applicable.
Throttles data: The **Throttles** chart shows data. What should I do?	Data in the **Throttles** chart indicates at least one request to invoke a function returned a '429 Too Many Requests' error in the response.	Resubmit the throttled invocation requests. Submit future invocation requests less frequently.

For more information about monitoring metrics and using alarms, see Monitoring Overview. For information about notifications for alarms, see Notifications Overview.

To view default metric charts for all functions in an application

1. In the Console, open the navigation menu. Under **Solutions and Platform**, go to **Developer Services** and click **Functions**.

2. Select the region you are using with Oracle Functions. Oracle recommends that you use the same region as the Docker registry that's specified in the Fn Project CLI context (see 6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure).
3. Select the compartment containing the application for which you want to view function metrics.
   The **Applications** page shows all the applications in the compartment you selected.
4. Click the name of the application for which you want to view function metrics.
5. Under **Resources**, click **Metrics**.
   The Metrics page displays a chart for each metric that is emitted by the metric namespace for Oracle Functions. For more information about the emitted metrics, see Available Metrics: oci_faas.

For more information about monitoring metrics and using alarms, see Monitoring Overview. For information about notifications for alarms, see Notifications Overview.

To view default metric charts for all the functions in all the applications in a compartment

1. Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Service Metrics**.
2. Select the region you are using with Oracle Functions. Oracle recommends that you use the same region as the Docker registry that's specified in the Fn Project CLI context (see 6. Create an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure).
3. Select the compartment containing the applications for which you want to view function metrics.
4. For **Metric Namespace**, select **oci_faas**.
   The **Service Metrics** page dynamically updates the page to show charts for each metric that is emitted by the selected metric namespace. For more information about the emitted metrics, see Available Metrics: oci_faas.

For more information about monitoring metrics and using alarms, see Monitoring Overview. For information about notifications for alarms, see Notifications Overview.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the following APIs for monitoring:

- Monitoring API for metrics and alarms
- Notifications API for notifications (used with alarms)

CHAPTER 17 Health Checks

This chapter explains how to monitor the health of your endpoints.

Overview of the Health Checks Service

The Oracle Cloud Infrastructure Health Checks service provides users with high frequency external monitoring to determine the availability and performance of any publicly facing service, including hosted websites, API endpoints, or externally facing load balancers. By using Health Checks, users can ensure that they are immediately aware of any availability issue affecting their customers.

Health Checks Service Components

The following list describes the key components used in creating a health check.

MONITORS

Monitors allow you to continuously monitor the health of public-facing endpoints. You can configure monitors to use either HTTP and ping protocols.

ON-DEMAND PROBES

On-demand probes allow you to execute a one-time probe to assess the health of a public-facing endpoint. You can configure on-demand probes to use either or both HTTP and ping protocols. This feature is currently only available via the REST API.

VANTAGE POINTS

Vantage points are geographic locations from which monitors and probes can be executed to your specified target. Oracle Cloud Infrastructure maintains dozens of vantage points around the world.

PROTOCOLS

The Health Checks service allows you to configure both HTTP and ping type monitors. Each type has respective protocols.

Ways to Access the Health Checks Service

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide.

To access the Console, you must use a supported browser. You can use the Console link at the top of this page to go to the sign-in page. Enter your tenancy, user name, and your password.

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies. For specific details about writing policies for each of the different services, see Policy Reference.

If you're a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

Health Checks Service Capabilities and Limits

The Oracle Cloud Infrastructure Health Checks service is limited to 1000 endpoint tests per account.

See Service Limits for a list of applicable limits and instructions for requesting a limit increase. To set compartment-specific limits on a resource or resource family, administrators can use compartment quotas.

Required IAM Service Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

If you're new to policies, see Getting Started with Policies and Common Policies. For more details about policies for Health Checks, see Details for the Health Checks Service.

Policy examples:

- To enable all operations on Health Checks for all users in a tenant :

```
Allow any-user to manage health-check-family in tenancy
```

- To enable all operations on Health Checks for all users in a compartment:

```
Allow any-user to manage health-check-family in compartment <Compartment Name>
```

- To enable all operations on Health Checks for a specific user group:

```
Allow group <Your Group Name> to manage health-check-family in compartment <Compartment Name>
```

Moving Health Checks to a Different Compartment

You can move health checks from one compartment to another. When you move a health check to a new compartment, its associated monitor and test results moves with it. After the move, health checks are accessible through the SDK, CLI, and Console. For more information, see Managing Compartments.

Monitoring Resources

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications. For more information, see Monitoring Overview and Notifications Overview.

For information about available Health Checks service metrics and how to view them, see Health Checks Metrics.

Tagging Resources

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the desired tags. For general information about applying tags, see Resource Tags.

Getting Started With the Health Checks API

The Health Checks service allows you to configure and deploy monitors and on-demand probes using the Health Checks API. Use the following guide to learn how to set up monitors and probes then retrieve their results using the REST API.

Note

Monitors, metrics, and probes created with the API, SDK and CLI are associated with the region where they were configured. While using the API, you must perform monitor updates (including compartment changes), metrics retrieval, and probe results retrieval in the region where they were configured. However, you can get a list of currently configured monitors and monitor details in every region, no matter where the monitors were configured.

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies. For specific details about writing policies for each of the different services, see Policy Reference.

If you're a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

Endpoints

The Health Checks API can be accessed via the following endpoints:

- https://healthchecks.ap-mumbai-1.oraclecloud.com/20180501
- https://healthchecks.ap-seoul-1.oraclecloud.com/20180501
- https://healthchecks.ap-sydney-1.oraclecloud.com/20180501
- https://healthchecks.ap-tokyo-1.oraclecloud.com/20180501
- https://healthchecks.ca-toronto-1.oraclecloud.com/20180501
- https://healthchecks.eu-frankfurt-1.oraclecloud.com/20180501
- https://healthchecks.eu-zurich-1.oraclecloud.com/20180501
- https://healthchecks.sa-saopaulo-1.oraclecloud.com/20180501
- https://healthchecks.uk-london-1.oraclecloud.com/20180501
- https://healthchecks.us-ashburn-1.oraclecloud.com/20180501
- https://healthchecks.us-phoenix-1.oraclecloud.com/20180501

Available Protocols For Probes and Monitors

You can configure monitors and probes to use HTTP or ping requests. You will need to ensure that the endpoint being monitored is configured to accept the specified protocol.

HTTP - Configure a GET or HEAD request using HTTP/1.1 to test the target for availability. The probe results are returned in JSON and include the HTTP Status Code and DNS lookup, connection and response timings.

HTTPS - Configure an encrypted HTTPS GET or HEAD request to test the availability of any secure hosted target. Defaults to port 443. The probe results are returned in JSON and include the HTTP Status Code and DNS lookup, connection and response timings.

ICMP - Configure an ICMP echo request ping. The results include the round trip time (RTT) latency.

TCP - Configure a TCP handshake to the specified end point. You should be sure to own this endpoint as testing this connection can be costly to the recipient. The results include the round trip time (RTT) latency.

Create A Monitor

Monitors allow you to monitor the health of endpoints over time. The following example shows how to create an HTTPS monitor that checks the health of www.example.com at an interval of every 30 seconds using a GET request.

```
POST /20180501/httpMonitors
{
   "compartmentId":"ocid1.compartment.oc1..<unique_ID>",
   "protocol":"HTTPS",
   "port":443,
   "targets":[
      "www.example.com"
   ],
   "timeoutInSeconds":30,
   "method":"GET",
   "displayName":"Example HTTP monitor",
   "intervalInSeconds":30
}
```

Targets can be either hostnames or IP addresses and the `path` field can be used to specify an optional path, such as www.example.com/project/help.htm. Optionally, you can specify which geographic locations you would like the monitor to launch from by using the

`vantagePointNames` field. At least one vantage point must be listed when using this field. For a list of available vantage points, see Vantage Points.

A 200 response will be returned with the successful creation of a probe and the results of the probe can be retrieved from the URL in the `resultsUrl` field of the response.

```
{
   "id":"ocid1.httpmonitor.OC2...<unique_ID>",
   "compartmentId":"ocid1.compartment.oc1..<unique_ID>",
   "resultsUrl":"https://healthchecks.us-ashburn-
1.oraclecloud.com/20180501/httpProbeResults/ocid1.httpmonitor.OC2...<unique_ID>",
   "targets":[
      "www.example.com",
      "www.oracle.com"
   ],
   "vantagePointNames":[
      "ibm-sjc",
      "aws-dub",
      "dgo-nyc"
   ],
   "protocol":"HTTPS",
   "timeoutInSeconds":30,
   "displayName":"Example Monitor",
   "intervalInSeconds":30,
   "isEnabled":true
}
```

For more information about creating an HTTP monitor, see CreateHttpMonitor.

Note

You can configure a similar style monitors using TCP or ICMP protocols. For more information, see CreatePingMonitor.

Create An On-Demand Probe

Probes are one-off health assessments of an endpoint that can be deployed at anytime. The following example shows how to create an on-demand HTTP probe that checks the health of www.example.com with a GET request.

```
POST /20180501/httpProbeResults

{
  "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
  "protocol": "HTTP",
  "targets": [
      "www.example.com"
  ],
  "timeoutInSeconds": 30,
  "method": "GET"
}
```

Targets can be either hostnames or IP addresses and the `path` field can be used to specify an optional path, such as www.example.com/project/help.htm. Additionally, you can specify which geographic locations you would like the probe to launch from by using the `vantagePointNames` field. For a list of available vantage points, see Vantage Points.

A 200 response will be returned with the successful creation of a probe and the results of the probe can be retrieved from the URL in the `resultsUrl` field of the response. It will take a few moments for results to display once the tests have been configured.

```
{
   "id":"ocid1.pingprobe.OC2..<unique_ID>",
   "compartmentId":"ocid1.compartment.oc1..<unique_ID>",
   "resultsUrl":"https://healthchecks.us-ashburn-
1.oraclecloud.com/20180501/pingProbeResults/ocid1.pingprobe.OC2..<unique_ID>",
   "targets":[
      "www.example.com"
   ],
   "vantagePointNames":[
      "ibm-sjc",
      "aws-dub",
      "dgo-nyc"
   ],
   "protocol":"ICMP",
```

```
   "timeoutInSeconds":30
}
```

For more information about creating a probe, see CreateOnDemandHttpProbe.

Note

You can configure similar style probes using TCP or ICMP protocols. For more information, see CreateOnDemandPingProbe.

Retrieving Probe And Monitor Results

Probe and monitor results can be retrieved from URL in the `resultsUrl` field of a monitor or probe creation response. It will take a few moments for results to display once the tests have been configured. Results can also be retrieved at anytime using the following methods:

- ListPingProbeResults - For monitors or on-demand probes using TCP or ICMP protocols.
- ListHttpProbeResults - For monitors or on-demand probes using HTTP protocols.

Retrieving results for an on-demand probe or monitor requires the probe or monitor's configuration ID as a parameter. On-demand probe and configuration IDs are assigned upon their creation and are returned in the id field of the POST response. You can also use the ListHttpMonitor method to retrieve a list of currently configured monitors and probes using HTTP protocols. Use the ListPingMonitors method to retrieve a list of currently configured monitors and probes using TCP and ICMP protocols.

The following is an example of results retrieved using `GET /httpProbeResults/{probeConfigurationId}`.

```
{
  "key": "651b9f3a46041cace0530204060ae27e",
  "probeConfigurationId": "ocid1.httpmonitor.OC2..<unique_ID>",
  "startTime": 1517323711505,
  "target": "www.example.com",
  "vantagePointName": "dgo-nyc",
  "protocol": "HTTPS",
```

```
  "connection": {
    "connectDuration": 114,
    "secureConnectDuration": 99,
    "address": "93.184.216.34",
    "port": 443
    },
  "dns":{
    "domainLookupDuration": 29,
    "addresses": [
      "93.184.216.34",
      "2606:2800:220:1:248:1893:25c8:1946"
      ]
      },
  "statusCode": 200,
  "fetchStart": 1517323711505,
  "domainLookupStart": 1517323711505,
  "domainLookupEnd": 1517323711534,
  "connectStart": 1517323711535,
  "secureConnectionStart": 1517323711550,
  "connectEnd": 1517323711649,
  "requestStart": 1517323711649,
  "responseStart": 1517323711673,
  "responseEnd": 1517323711676,
  "duration": 171,
  "encodedBodySize": 1270,
  "isTimedOut": false,
  "isHealthy": true
}
```

Vantage Points

Vantage points are geographic locations from which monitors and probes can be launched. Oracle Cloud Infrastructure maintains vantage points on the infrastructure of cloud providers around the world, including AWS, IBM, and Azure. The list below is a sampling of the vantage points available. The list of vantage points is dynamic and changes frequently. Use the ListHealthChecksVantagePoints method to return a list of available vantage points.

Provider	Location	Name
Amazon	Singapore	aws-sin
Amazon	Sao Paolo	aws-sao
Amazon	Dublin	aws-dub
Amazon	San Francisco	aws-sfo
Azure	Dublin	azr-dub
Azure	Amsterdam	azr-ams
Azure	Singapore	azr-sin
Azure	Sydney	azr-syd
Digital Ocean	Toronto	dgo-yyz
Digital Ocean	Frankfurt	dgo-fra
Digital Ocean	New York City	dgo-nyc
Digital Ocean	Biratnagar, Nepal	dgo-blr
Google	Taiwan	goo-tpe
Google	Brussels	goo-bru
Google	Council Bluffs, IA	goo-cbf
Google	Charleston, SC	goo-chs
IBM	San Jose, CA	ibm-sjc
IBM	Tokyo	ibm-hnd
IBM	Dallas, TX	ibm-dfw

Provider	Location	Name
IBM	Hong Kong	ibm-hkg
Rack Space	Ashburn, VA	rck-iad
Rack Space	Dallas, TX	rck-dfw
Rack Space	London	rck-lhr
Rack Space	Sydney	rck-syd

Managing Health Checks

The Health Checks service allows you to monitor the health of IP addresses and hostnames, as measured from geographic vantage points of your choosing, using HTTP and ping probes. After configuring a health check, you can view the monitor's results. The results include the location from which the host was monitored, the availability of the endpoint, and the date and time the test was performed.

Using the Console

To add a health check

1. Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Health Checks**.
2. Click **Create Health Check**.
3. In the **Create Health Check** dialog box, enter the following:
    - **Health Check Name**: The name used for the health check. Avoid entering confidential information.
    - **Compartment**: Select the compartment the health check runs in.

- **Target(s)**: The IP address of the host being monitored. (Optional) Click **+ Add Target** to add multiple targets in succession.
- **Vantage Points**: Select the location from which the health of the target is monitored. No more than ten vantage points can be added.
- **Request Type**: Select the type of request sent to monitor the target.
- **Protocol**: The network protocol used to interact with your endpoint, such as HTTP protocol, which initializes an HTTP handshake with your endpoint.
- **Port**: The port for the monitor to look for a connection. The default is port 80 for HTTP. For HTTPS, use port 443.
- **Path**: The specific path on the target to be monitored.
- **Header Name**: (Optional) The name displayed in the request header as part of the health check. Avoid entering confidential information.
- **Header Value**: (Optional) Specifies the data requested by the header. Click **+ Add Header** to add multiple headers in succession.
- **Method**: Select the HTTP method used for the health check.
- **Timeout**: Select the maximum time to wait for a reply before marking the health check as failed.
- **Interval**: Select the period of time between health checks of the target.
- **Tags**: Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.

4. Click **Create Health Check**.

The health check is added to the health check list. To view more details, click the health check name. It will take a few moments for results to display once the tests have been configured.

To edit a health check

1. Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Health Checks**.
2. Select the check box for the health check you want to edit.

Tip

To help find a health check, you can enter the name of the health check in the **Search** field.

3. Select **Edit** from the **Actions** drop-down menu.
4. In the Edit Health Check dialog box, make the needed changes, and then click **Edit Health Check**.

To disable a health check

1. Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Health Checks**.
2. Select the check box for the health check you want to disable.

Tip

To help find a health check, you can enter the name of the health check in the **Search** field.

3. Select **Disable** from the **Actions** drop-down menu.

The status of the health check changes to **Disabled** in the health check list.

To duplicate a health check

1. Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Health Checks**.
2. Select the check box for the health check you want to duplicate.
3. Select **Duplicate** from the **Actions** drop-down menu.
4. In the Create Health Check dialog box, make any updates to the duplicated health check, and then click **Create Health Check**.

To delete a health check

1. Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Health Checks**.
2. Select the check box for the health check you want to delete.

Tip

To help find a health check, you can enter the name of the health check in the **Search** field.

3. Select **Delete** from the **Actions** drop-down menu.
4. In the confirmation dialog box, click **Delete**.

To view the history of a health check

1. Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Health Checks**.
2. Click the name of the health check you want to view.
   The Health Check history displays a list of results for the past 90 days.

Tip

To help find a result, you can use the **Start Date**, **Start Time**, **End Date**, **End Time**, and **Targets** filter options.

3. Click the drop-down arrow beside the **Timestamp** to view the monitor result details. You can use the API to download the data.

To manage tags for a health check

1. Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Health Checks**.
2. Click the name of the health check you want to view.
3. Click the **Tags** tab to view or edit the existing tags. Or click **Apply tag(s)** to add new ones.

For more information, see Resource Tags.

To move a health check to a different compartment

1. Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Health Checks**.
2. In the **Scope** section, select a compartment.
3. Find the health check in the list, click the Actions icon (three dots), and then click **Move Resource**.
4. Choose the destination compartment from the list.
5. Click **Move Resource**.

For more information, see Managing Compartments.

Tip

If your health checks are continually failing, please ensure that you have permission to monitor the host and that the ports on the host have been configured to receive traffic from Health Checks.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

- Use the CreateHTTPMonitor operation to create a Health Check monitor that uses the HTTP protocol.
- Use the CreatePingMonitor operation to create a Health Check monitor that uses the ping protocol.
- Use the ListHealthChecksVantagePoints to retrieve a list of available vantage points from which to execute monitors.
- Use the UpdateHttpMonitor operation to update the configuration of an HTTP health check monitor. You can also use this operation to disable an HTTP monitor by setting the `isEnabled` field to `false`.
- Use the UpdatePingMonitor operation to update the configuration of ping health check monitor. You can also use this operation to disable a ping monitor by setting the `isEnabled` field to `false`.
- Use the DeleteHttpMonitor operation to remove an HTTP health check monitor from your setup.
- Use the DeletePingMonitor operation to remove a ping health check monitor from your setup.

- Use the ListHttpProbeResults operation to retrieve the results of an HTTP health check monitor.
- Use the ListPingProbeResults operation to retrieve results of a ping health check monitor.

Health Checks Metrics

You can monitor the health, capacity, and performance of your health checks by using metrics, alarms, and notifications.

This topic describes the metrics emitted by the metric namespace `oci_healthchecks` (the Health Checks service).

Overview of the Health Checks Service Metrics

Oracle Cloud Infrastructure Health Checks provides users with high frequency external monitoring to determine the availability and performance of any publicly facing service, including hosted websites, API endpoints, or externally facing load balancers. The Health Checks service metrics help you monitor the performance of your endpoints over a 24 hour period.

Prerequisites

- IAM policies: To monitor resources, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.

Available Metrics: oci_healthchecks

The metrics listed in the following table are automatically available for each health check that you create. You do not need to enable monitoring on the health check to get these metrics.

Each metric includes the following dimensions:

RESOURCEID

The OCID of the policy to which the metric applies.

Metric	Metric Display Name	Unit	Description	Dimensions
`BasicCount`	**Basic Health Checks**	count	The total number of active basic health checks.	`resourceID` `resourceDisplayName`
`PremiumCount`	**Premium Health Checks**	count	The total number of active premium health checks.	

Metric	Metric Display Name	Unit	Description	Dimensions
HTTP.StatusCode	**HTTP(S) Response Status Code**	count	The HTTP response code.	target vantagePoint resourceId resourceDisplayName statusCode2xx statusCode3xx statusCode4xx statusCode5xx protocol errorMessage
PING.isHealthy	**Success Rate of Ping Test**	percent	Displays availability of end point being monitored.	target vantagePoint resourceId resourceDisplayName protocol errorMessage icmpCode

Metric	Metric Display Name	Unit	Description	Dimensions
HTTP.DNSLookupTime	**HTTP(S) DNS Lookup Time**	ms	The time taken for domain name lookup in milliseconds.	target vantagePoint resourceId resourceDisplayName protocol errorMessage
HTTP.TCPConnectTime.Full	**HTTP(S) Connection Duration**	ms	The total duration in milliseconds from start of the request until response is fully consumed or the connection is closed.	
HTTP.TCPConnectTime.SSL	**HTTP(S) Secure Connection Duration**	ms	The total duration in milliseconds from start of secure connection to end of connection.	

Metric	Metric Display Name	Unit	Description	Dimensions
HTTP.RequestTime	**HTTP(S) Request Duration**	ms	The total duration of the request in milliseconds.	
HTTP.ResponseTime	**HTTP(S) Response Duration**	ms	The total duration of response in milliseconds.	
HTTP.TotalDuration	**HTTP(S) Total Duration**	ms	The total duration of the test run in milliseconds.	

Metric	Metric Display Name	Unit	Description	Dimensions
HTTP.isHealthy	**Success Rate of HTTP(S) Test**	percent	Displays if the end point being monitored is up or down.	
PING.Latency	**Ping Latency Measurement**	ms	Latency measurement for ping test in milliseconds.	

Using the Console

To view metric charts for resources related to a health check monitor

1. Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Health Checks**.
2. Click the name of the health check you want to view metrics for.
3. Click **Metrics**.

To view health check metric charts using monitoring

1. Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Metrics Explorer**.
   For **Metric Namespace**, select **oci_healthchecks**.

2. Select a metric to view from the **Metric Name** field.
3. Select a qualifier specified in the Dimension Name field. For example, the dimension `resourceId` is specified in the metric definition for `BasicCount`.
4. Select the value you want to use for the specified dimension in the **Dimension Value** field. For example, the resource identifier for your instance of interest.
5. Click **Update Chart**.
   The chart will be updated with the metrics that have been requested.

For more information about monitoring metrics and using alarms, see Monitoring Overview. For information about notifications for alarms, see Notifications Overview.

Using the API

Use the following APIs for monitoring:

- Monitoring API for metrics and alarms
- Notifications API for notifications (used with alarms)

CHAPTER 18 IAM

This chapter explains how to set up administrators, users, and groups and specify their permissions.

Overview of Oracle Cloud Infrastructure Identity and Access Management

Oracle Cloud Infrastructure Identity and Access Management (IAM) lets you control who has access to your cloud resources. You can control what type of access a group of users have and to which specific resources. This section gives you an overview of IAM components and an example scenario to help you understand how they work together.

Note

This document uses the term "you" broadly to mean any administrator in your company who has access to work with IAM.

Components of IAM

IAM uses the components described in this section. To better understand how the components fit together, see Example Scenario.

RESOURCE

The cloud objects that your company's employees create and use when interacting with Oracle Cloud Infrastructure. For example: compute instances, block storage volumes, virtual cloud networks (VCNs), subnets, route tables, etc.

USER

An individual employee or system that needs to manage or use your company's Oracle Cloud Infrastructure resources. Users might need to launch instances, manage remote disks, work with your virtual cloud network, etc. End users of your application are not typically IAM users. Users have one or more IAM credentials (see User Credentials).

GROUP

A collection of users who all need the same type of access to a particular set of resources or compartment.

DYNAMIC GROUP

A special type of group that contains resources (such as compute instances) that match rules that you define (thus the membership can change dynamically as matching resources are created or deleted). These instances act as "principal" actors and can make API calls to services according to policies that you write for the dynamic group.

COMPARTMENT

A collection of related resources. Compartments are a fundamental component of Oracle Cloud Infrastructure for organizing and isolating your cloud resources. You use them to clearly separate resources for the purposes of measuring usage and billing, access (through the use of policies), and isolation (separating the resources for one project or business unit from another). A common approach is to create a compartment for each major part of your organization. For more information, see "Setting Up Your Tenancy" in the *Oracle Cloud Infrastructure Getting Started Guide*.

TENANCY

The root compartment that contains *all* of your organization's Oracle Cloud Infrastructure resources. Oracle automatically creates your company's tenancy for you. Directly within the tenancy are your IAM entities (users, groups, compartments, and some policies; you can also put policies into compartments inside the tenancy). You place the other types of cloud resources (e.g., instances, virtual networks, block storage volumes, etc.) inside the compartments that you create.

POLICY

A document that specifies who can access which resources, and how. Access is granted at the group and compartment level, which means you can write a policy that gives a group a specific type of access within a specific compartment, or to the tenancy itself. If you give a group access to the tenancy, the group automatically gets the same type of access to all the compartments inside the tenancy. For more information, see Example Scenario and How Policies Work. The word "policy" is used by people in different ways: to mean an individual statement written in the policy language; to mean a collection of statements in a single, named "policy" document (which has an Oracle Cloud ID (OCID) assigned to it); and to mean the overall body of policies your organization uses to control access to resources.

HOME REGION

The region where your IAM resources reside. All IAM resources are global and available across all regions, but the master set of definitions reside in a single region, the home region. You must make changes to your IAM resources in your home region. The changes will be automatically propagated to all regions. For more information, see Managing Regions.

FEDERATION

A relationship that an administrator configures between an identity provider and a service provider. When you federate Oracle Cloud Infrastructure with an identity provider, you manage users and groups in the identity provider. You manage authorization in Oracle Cloud Infrastructure's IAM service. Oracle Cloud Infrastructure tenancies are federated with Oracle Identity Cloud Service by default.

Services You Can Control Access To

You can write policies to control access to all of the services within Oracle Cloud Infrastructure.

The Administrators Group and Policy

When your company signs up for an Oracle account and Identity Domain, Oracle sets up a *default administrator* for the account. This person will be the first IAM user for your company and will be responsible for initially setting up additional administrators. Your tenancy comes with a group called *Administrators*, and the default administrator automatically belongs in this group. You can't delete this group, and there must always be at least one user in it.

Your tenancy also automatically has a policy that gives the Administrators group access to all of the Oracle Cloud Infrastructure API operations and all of the cloud resources in your tenancy. You can neither change nor delete this policy. Any other users you put into the Administrators group will have full access to all of the services. This means they can create and manage IAM resources such as, groups, policies, and compartments. And they can create and manage the cloud resources such as virtual cloud networks (VCNs), instances, block storage volumes, and any other new types of Oracle Cloud Infrastructure resources that become available in the future.

Example Scenario

The goal of this scenario is to show how the different IAM components work together, and basic features of policies.

In this scenario, Acme Company has two teams that will be using Oracle Cloud Infrastructure resources for infrastructure: Project A and Project B. In reality, your company may have many more.

Acme Company plans to use a single virtual cloud network (VCN) for both teams, and wants a network administrator to manage the VCN.

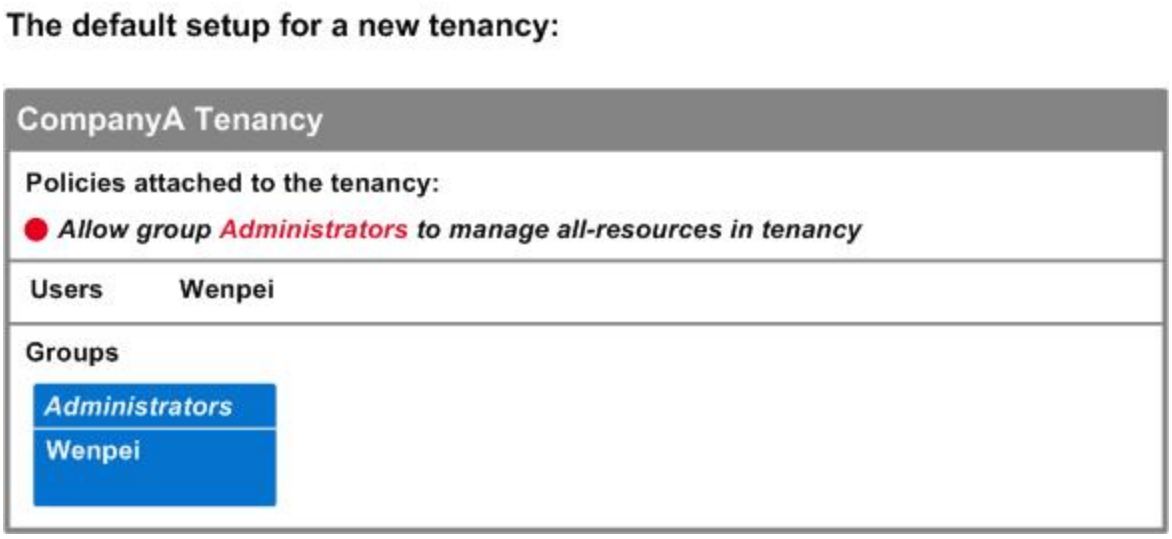
Acme Company also wants the Project A team and Project B team to *each* have their own set of instances and block storage volumes. The Project A team and Project B teams shouldn't be able to use each other's instances. These two teams also shouldn't be allowed to change anything about the VCN set up by the network administrator. Acme Company wants each team to have administrators for that team's resources. The administrators for the Project A team can decide who can use the Project A cloud resources, and how. Same for the Project B team.

Acme Company Gets Started with Oracle Cloud Infrastructure

Acme Company signs up to use Oracle Cloud Infrastructure and tells Oracle that an employee named Wenpei will be the default administrator. In response, Oracle:

- Creates a tenancy for Acme Company (see the following diagram).
- Creates an IAM user account for Wenpei in the tenancy.
- Creates the Administrators group in the tenancy and places Wenpei in that group.
- Creates a policy in Acme Company's tenancy that gives the Administrators group access to manage all of the resources in the tenancy. Here's that policy:

```
Allow group Administrators to manage all-resources in tenancy
```

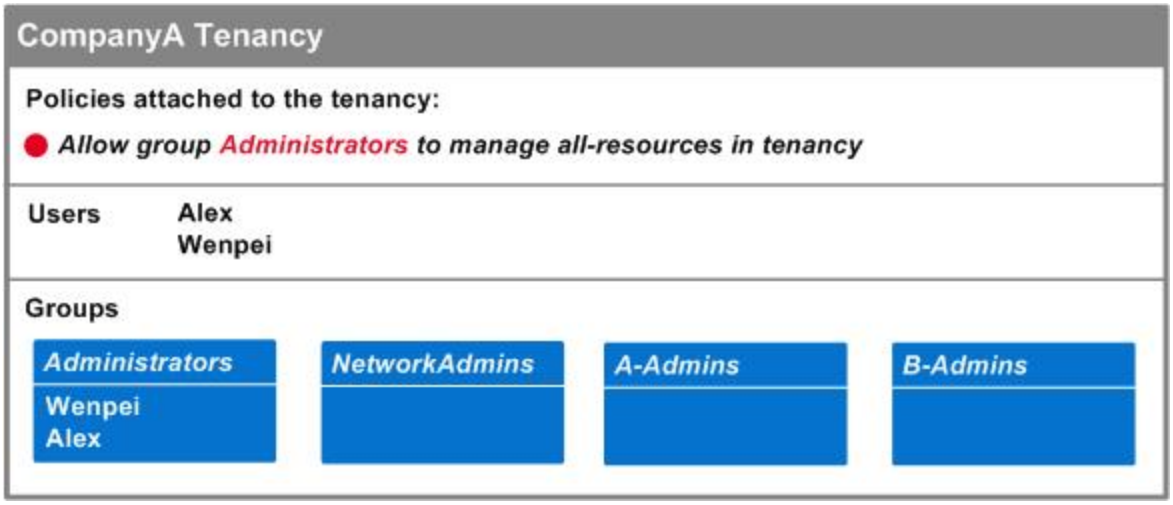


The Default Administrator Creates Some Groups and Another Administrator

Wenpei next creates several groups and users (see the following diagram). She:

- Creates groups called *NetworkAdmins*, *A-Admins*, and *B-Admins* (these last two are for Project A and Project B within the company)
- Creates a user called Alex and puts him in the Administrators group.
- Leaves the new groups empty.

To learn how to create groups, see Working with Groups. To learn how to create users and put them in groups, see Working with Users.



The Default Administrator Creates Some Compartments and Policies

Wenpei next creates compartments to group resources together (see the following diagram). She:

- Creates a compartment called *Networks* to control access to the Acme Company's VCN, subnets, IPSec VPN, and other components from Networking.
- Creates a compartment called *Project-A* to organize Project A team's cloud resources and control access to them.

- Creates a compartment called *Project-B* to organize Project B team's cloud resources and control access to them.

To learn how to manage compartments, see Working with Compartments.

Wenpei then creates a policy to give the administrators for each compartment their required level of access. She attaches the policy to the tenancy, which means that only users with access to manage policies in the tenancy can later update or delete the policy. In this scenario, that is only the Administrators group. The policy includes multiple statements that:

- Give the NetworkAdmins group access to manage networks and instances (for the purposes of easily testing the network) in the Networks compartment
- Give both the A-Admins and B-Admins groups access to use the networks in the Networks compartment (so they can create instances into the network).
- Give the A-Admins group access to manage all resources in the Project-A compartment.
- Give the B-Admins group access to manage all resources in the Project-B compartment.

Here's what that policy looks like (notice it has multiple statements in it):

```
Allow group NetworkAdmins to manage virtual-network-family in compartment Networks
Allow group NetworkAdmins to manage instance-family in compartment Networks

Allow group A-Admins,B-Admins to use virtual-network-family in compartment Networks

Allow group A-Admins to manage all-resources in compartment Project-A

Allow group B-Admins to manage all-resources in compartment Project-B
```

Notice the difference in the verbs (`manage, use`), as well as the resources (`virtual-network-family, instance-family, all-resources`). For more information about them, see Verbs and Resource-Types.To learn how to create policies, see To create a policy.

Important

A-Admins and B-Admins can *use* the virtual-network-family in the compartment Networks. However, they can't create instances in that compartment. They can only create instances in the Project-A or Project-B compartment. Remember, a compartment is a logical grouping, not a physical one, so resources that make up or reside on the same VCN can belong to different compartments.

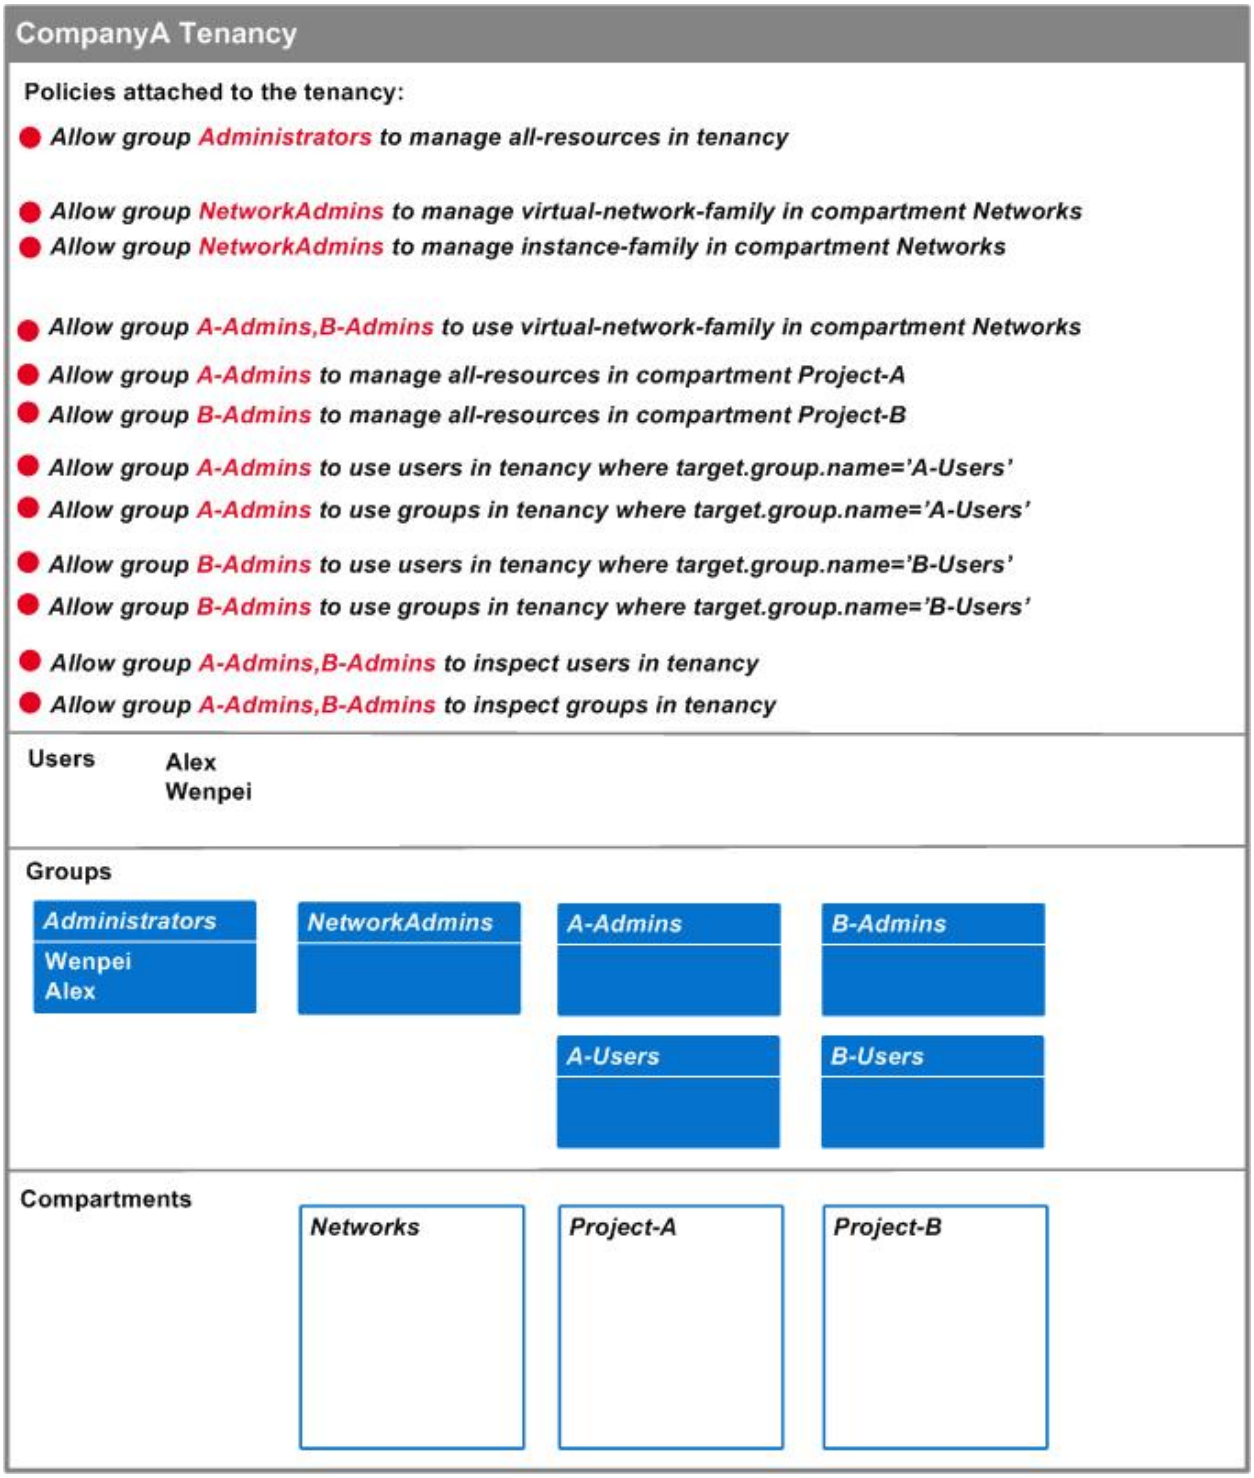
Acme Company wants to let the administrators of the Project-A and Project-B compartments decide which users can use the resources in those compartments. So Wenpei creates two more groups: A-Users and B-Users. She then adds six more statements that give the compartment admins the required access they need in order to add and remove users from those groups:

```
Allow group A-Admins to use users in tenancy where target.group.name='A-Users'
Allow group A-Admins to use groups in tenancy where target.group.name='A-Users'

Allow group B-Admins to use users in tenancy where target.group.name='B-Users'
Allow group B-Admins to use groups in tenancy where target.group.name='B-Users'

Allow group A-Admins,B-Admins to inspect users in tenancy
Allow group A-Admins,B-Admins to inspect groups in tenancy
```

Notice that this policy doesn't let the project admins *create* new users or manage credentials for the users. It lets them decide which existing users can be in the A-Users and B-Users groups. The last two statements are necessary for A-Admins and B-Admins to list all the users and groups, and confirm which users are in which groups.



CompanyA Tenancy
Policies attached to the tenancy:
Allow group Administrators to manage all-resources in tenancy
Allow group NetworkAdmins to manage virtual-network-family in compartment Networks
Allow group NetworkAdmins to manage instance-family in compartment Networks
Allow group A-Admins,B-Admins to use virtual-network-family in compartment Networks
Allow group A-Admins to manage all-resources in compartment Project-A
Allow group B-Admins to manage all-resources in compartment Project-B
Allow group A-Admins to use users in tenancy where target.group.name='A-Users'
Allow group A-Admins to use groups in tenancy where target.group.name='A-Users'
Allow group B-Admins to use users in tenancy where target.group.name='B-Users'
Allow group B-Admins to use groups in tenancy where target.group.name='B-Users'
Allow group A-Admins,B-Admins to inspect users in tenancy
Allow group A-Admins,B-Admins to inspect groups in tenancy

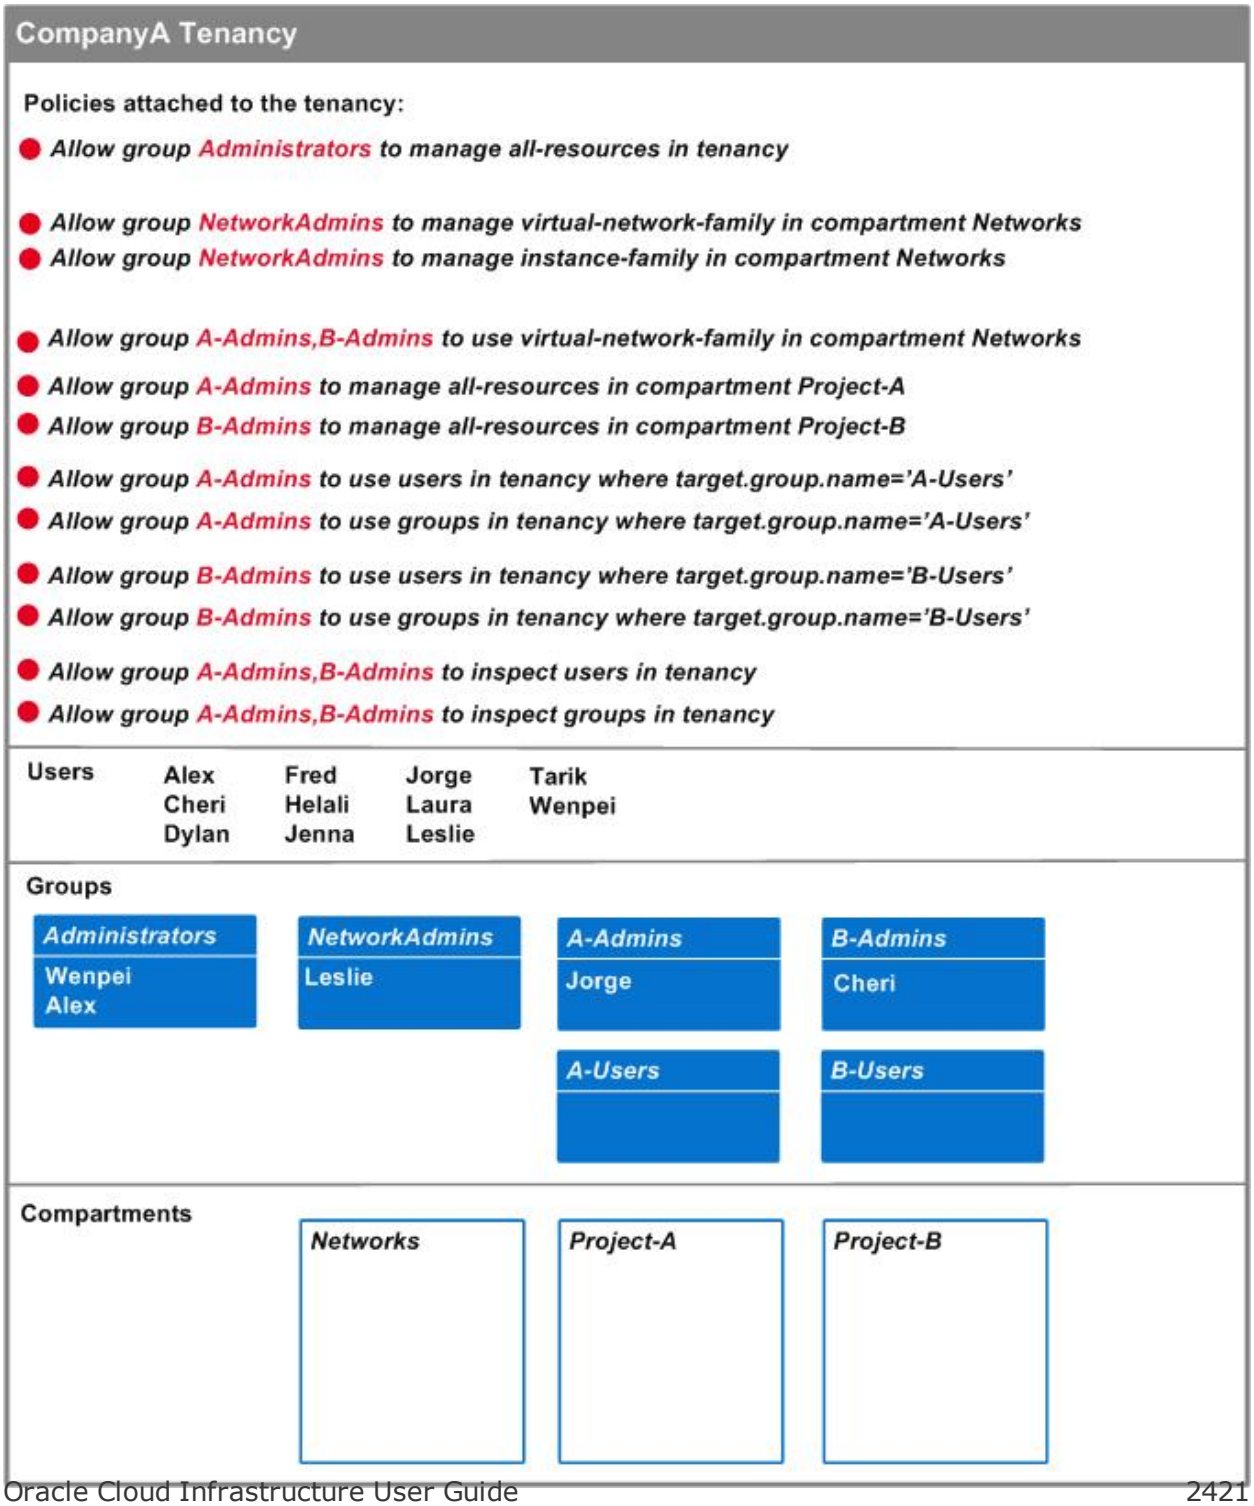
An Administrator Creates New Users

At this point, Alex is in the Administrators group and now has access to create new users. So he provisions users named Leslie, Jorge, and Cheri and places them in the NetworkAdmins, A-Admins, and B-Admins groups, respectively. Alex also creates other users who will eventually be put in the A-Users and B-Users groups by the admins for Project A and Project B.



CompanyA Tenancy
Policies attached to the tenancy:
Allow group Administrators to manage all-resources in tenancy
Allow group NetworkAdmins to manage virtual-network-family in compartment Networks
Allow group NetworkAdmins to manage instance-family in compartment Networks
Allow group A-Admins,B-Admins to use virtual-network-family in compartment Networks
Allow group A-Admins to manage all-resources in compartment Project-A
Allow group B-Admins to manage all-resources in compartment Project-B
Allow group A-Admins to use users in tenancy where target.group.name='A-Users'
Allow group A-Admins to use groups in tenancy where target.group.name='A-Users'
Allow group B-Admins to use users in tenancy where target.group.name='B-Users'
Allow group B-Admins to use groups in tenancy where target.group.name='B-Users'
Allow group A-Admins,B-Admins to inspect users in tenancy
Allow group A-Admins,B-Admins to inspect groups in tenancy

The Network Admin Sets Up the Network

Leslie (in the NetworkAdmins group) has access to manage `virtual-network-family` and `instance-family` in the Networks compartment. She creates a virtual cloud network (VCN) with a single subnet in that compartment. She also sets up an Internet gateway for the VCN, and updates the VCN's route table to allow traffic via that gateway. To test the VCN's connectivity to the on-premises network, she launches an instance in the subnet in the VCN. As part of the launch request, she must specify which compartment the instance should reside in. She specifies the Networks compartment, which is the only one she has access to. She then confirms connectivity from the on-premises network to the VCN by logging in to the instance via SSH from the on-premises network.

Leslie terminates her test instance and lets Jorge and Cheri know that the VCN is up and running and ready to try out. She lets them know that their compartments are named Project-A and Project-B respectively. For more information about setting up a cloud network, see Overview of Networking. For information about launching instances into the network, see Overview of the Compute Service.

Compartment Admins Set Up Their Compartments

Jorge and Cheri now need to set up their respective compartments. Each admin needs to do the following:

- Launch instances in their own compartment
- Put users in their "users" group (e.g., A-Users)
- Decide the type of access to give those users, and accordingly attach a policy to their compartment

Jorge and Cheri both launch instances into the subnet in the VCN, into their respective team's compartments. They create and attach block volumes to the instances. Only the compartment admins can launch/terminate instances or attach/detach block olumes in their respective team's compartments.

Important

Network Topology and Compartment Access Are Different Concepts

It's important to understand the difference between the network topology of the VCN and the access control that the compartments provide. The instances Jorge launched reside in the VCN from a network topology standpoint. But from an access standpoint, they're in the Project-A compartment, not the Networks compartment where the VCN is. Leslie (the Networks admin) can't terminate or reboot Jorge's instances, or launch new ones into the Project-A compartment. But Leslie controls the instances' network, so she controls what traffic will be routed to them. If Jorge had specified the Networks compartment instead of the Project-A compartment when launching his instances, his request would have been denied. The story is similar for Cheri and the Project-B compartment.

But it's also important to note that Wenpei and Alex in the Administrators group do have access to the resources inside the compartments, because they have access to manage all kinds of resources in the tenancy. Compartments inherit any policies attached to their parent compartment (the tenancy), so the Administrators access also applies to all compartments *within* the tenancy.

Next, Jorge puts several of the users that Alex created into the A-Users group. Cheri does the same for B-Users.

Then Jorge writes a policy that gives users the level of access they need in the Project-A compartment.

```
Allow group A-Users to use instance-family in compartment Project-A
Allow group A-Users to use volume-family in compartment Project-A
Allow group A-Users to inspect virtual-network-family in compartment Networks
```

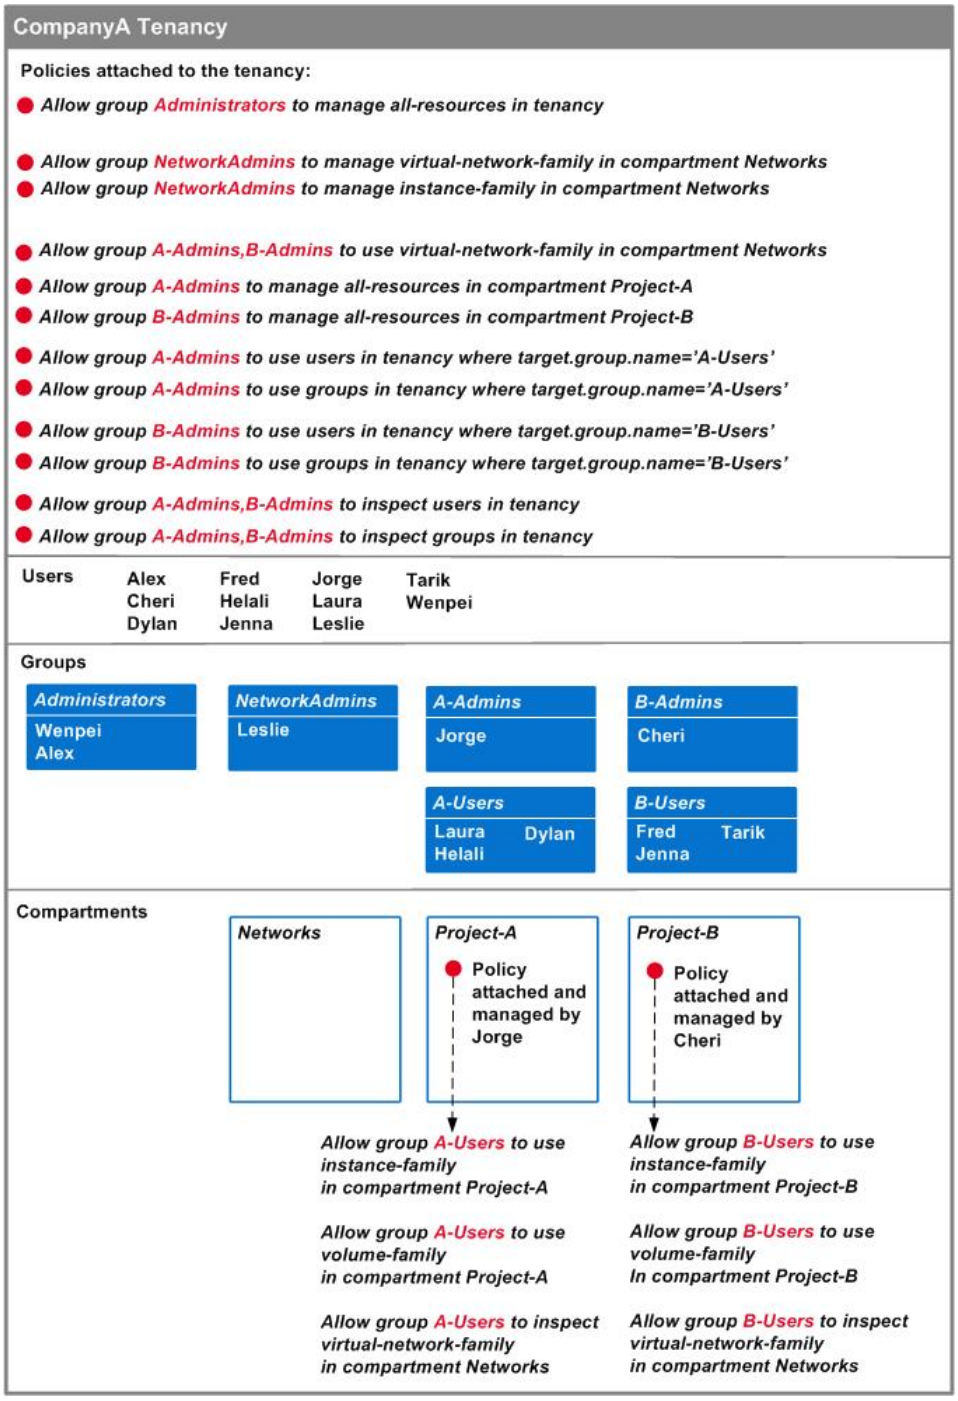
This lets them use existing instances (with attached block volumes) that the compartment admins already launched in the compartment, and stop/start/reboot them. It does not let A-Users create/delete or attach/detach any volumes. To give that ability, the policy would need to include `manage volume-family`.

Jorge attaches this policy to the Project-A compartment. Anyone with the ability to manage policies *in the compartment* can now modify or delete this policy. Right now, that is only the A-Admins group (and the Administrators group, which can do anything throughout the tenancy).

Cheri creates and attaches her own policy to the Project-B compartment, similar to Jorge's policy:

```
Allow group B-Users to use instance-family in compartment Project-B
Allow group B-Users to use volume-family in compartment Project-B
Allow group B-Users to inspect virtual-network-family in compartment Networks
```

Now the A-Users and B-Users can work with the existing instances and attached volumes in the Project-A and Project-B compartments, respectively. Here's what the layout looks like:



CompanyA Tenancy
Policies attached to the tenancy:
Allow group Administrators to manage all-resources in tenancy
Allow group NetworkAdmins to manage virtual-network-family in compartment Networks
Allow group NetworkAdmins to manage instance-family in compartment Networks
Allow group A-Admins,B-Admins to use virtual-network-family in compartment Networks
Allow group A-Admins to manage all-resources in compartment Project-A
Allow group B-Admins to manage all-resources in compartment Project-B
Allow group A-Admins to use users in tenancy where target.group.name='A-Users'
Allow group A-Admins to use groups in tenancy where target.group.name='A-Users'
Allow group B-Admins to use users in tenancy where target.group.name='B-Users'
Allow group B-Admins to use groups in tenancy where target.group.name='B-Users'

For more information about basic and advanced features of policies, see How Policies Work. For examples of other typical policies your organization might use, see Common Policies.

Viewing Resources by Compartment in the Console

In the Console, you view your cloud resources *by compartment*. This means that after you sign in to the Console, you'll choose which compartment to work in (there's a list of the compartments you have access to on the left side of the page). Notice that compartments can be nested inside other compartments. The page will update to show that compartment's resources that are within the current region. If there are none, or if you don't have access to the resource in that compartment, you'll see a message.

This experience is different when you're viewing the lists of users, groups, dynamic groups, and federation providers. Those reside in the tenancy itself (the root compartment), not in an individual compartment.

As for policies, they can reside in either the tenancy or a compartment, depending on where the policy *is attached.* Where it's attached controls who has access to modify or delete it. For more information, see Policy Attachment.

The Scope of IAM Resources

Oracle Cloud Infrastructure uses the concepts of regions and availability domains (see Regions and Availability Domains). Some resources are available regionally, whereas others are available only within a certain availability domain. IAM resources (users, groups, dynamic groups, compartments, tag namespaces, federation providers, and policies) are global and available across all regions. See Managing Regions.

Creating Automation with Events

You can create automation based on state changes for your Oracle Cloud Infrastructure resources by using event types, rules, and actions. For more information, see Overview of Events.

The following IAM resources emit events:

- Authentication policies
- Credentials
- Dynamic groups
- Groups
- Identity Providers
- Multi-factor Authentication TOTP Devices
- Policies
- Users

Resource Identifiers

Most types of Oracle Cloud Infrastructure resources have a unique, Oracle-assigned identifier called an Oracle Cloud ID (OCID). For information about the OCID format and other ways to identify your resources, see Resource Identifiers.

Ways to Access Oracle Cloud Infrastructure

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. For a list of available SDKs, see Software Development Kits and Command Line Interface.

To access the Console, you must use a supported browser. Oracle Cloud Infrastructure supports the latest desktop versions of Google Chrome, Microsoft Edge, Internet Explorer 11, Safari, Firefox, and Firefox ESR. Note that private browsing mode is not supported for Firefox, Internet Explorer, or Edge. Mobile browsers are not supported.

For general information about using the API, see REST APIs.

Limits on IAM Resources

See Service Limits for a list of applicable limits and instructions for requesting a limit increase. To set compartment-specific limits on a resource or resource family, administrators can use compartment quotas.

Getting Started with Policies

If you're new to Oracle Cloud Infrastructure Identity and Access Management (IAM) policies, this topic gives guidance on how to proceed.

If You're Doing a Proof-of-Concept

If you're just trying out Oracle Cloud Infrastructure or doing a proof-of-concept project with infrastructure resources, you may not need more than a few administrators with full access to everything. In that case, you can simply create any new users you need and add them to the Administrators group. The users will be able to do anything with any kind of resource. And you can create all your resources directly in the tenancy (the root compartment). You don't need to create any compartments yet, or any other policies beyond the Tenant Admin Policy, which automatically comes with your tenancy and can't be changed.

Note

Don't forget to add your new users to the Administrators group; it's easy to forget to do that after creating them.

If You're Past the Proof-of-Concept Phase

If you're past the proof-of-concept phase and want to restrict access to your resources, first:

- Make sure you're familiar with the basic IAM components, and read through the example scenario: Overview of Oracle Cloud Infrastructure Identity and Access

Management

- Think about how to organize your resources into compartments: See "Setting Up Your Tenancy" in the *Oracle Cloud Infrastructure Getting Started Guide*
- Learn the basics of how policies work: How Policies Work
- Check out some typical policies: Common Policies
- Read the FAQs below

Policy FAQs

Which of the services within Oracle Cloud Infrastructure can I control access to through policies?

All of them, including IAM itself. You can find specific details for writing policies for each service in the Policy Reference.

Can users do anything without an administrator writing a policy for them?

Yes. All users can automatically do these things without an explicit policy:

- Change or reset their own Console password.
- Manage their own API signing keys and other credentials.

Why should I separate resources by compartment? Couldn't I just put all the resources into one compartment and then use policies to control who has access to what?

You could put all your resources into a single compartment and use policies to control access, but then you would lose the benefits of measuring usage and billing by compartment, simple policy administration at the compartment level, and clear separation of resources between projects or business units.

Can I control or deny access to an individual user?

Yes. However, there are a couple things to know first:

- Enterprise companies typically have multiple users that need similar permissions, so policies are designed to give access to *groups* of users, not individual users. A user gains access by being in a group.
- Policies are designed to *allow* access; there's no explicit "deny" when you write a policy.

If you need to restrict a particular user's access, you can:

- Remove the user from the particular group of interest
- Delete the user entirely from IAM (you have to remove the user from all groups first)

How do I delete a user?

First ensure the user isn't in any groups. Only then can you delete the user.

How do I delete a compartment?

See Deleting Compartments.

How can I tell which policies apply to a particular group or user?

You need to look at the individual statements in all your policies to see which statements apply to which group. There's not currently an easy way to get this information.

How can I tell which policies apply to a particular compartment?

You need to look at the individual statements in all the policies in the tenancy to see if any apply to the particular compartment. You also need to look at any policies in the compartment itself. Policies in any of the sibling compartments *cannot* refer to the compartment of interest, so you don't need to check those policies.

How Policies Work

This topic describes how policies work and the basic features.

Overview of Policies

A *policy* is a document that specifies who can access which Oracle Cloud Infrastructure resources that your company has, and how. A policy simply allows a group to work in certain ways with specific types of resources in a particular compartment. If you're not familiar with users, groups, or compartments, see Overview of Oracle Cloud Infrastructure Identity and Access Management.

In general, here's the process an IAM administrator in your organization needs to follow:

1. Define users, groups, and one or more compartments to hold the cloud resources for your organization.
2. Create one or more policies, each written in the policy language. See Common Policies.
3. Place users into the appropriate groups depending on the compartments and resources they need to work with.
4. Provide the users with the one-time passwords that they need in order to access the Console and work with the compartments. For more information, see User Credentials.

After the administrator completes these steps, the users can access the Console, change their one-time passwords, and work with specific cloud resources as stated in the policies.

Policy Basics

To govern control of your resources, your company will have at least one policy. Each policy consists of one or more policy *statements* that follow this basic syntax:

```
Allow group <group_name> to <verb> <resource-type> in compartment <compartment_name>
```

Notice that the statements always begin with the word `Allow`. Policies only *allow* access; they cannot deny it. Instead there's an implicit deny, which means by default, users can do nothing

and have to be granted access through policies. (There's one exception to this rule; see Can users do anything without an administrator writing a policy for them?)

An administrator in your organization defines the groups and compartments in your tenancy. Oracle defines the possible verbs and resource-types you can use in policies (see Verbs and Resource-Types).

In some cases you'll want the policy to apply to the tenancy and not a compartment inside the tenancy. In that case, change the end of the policy statement like so:

```
Allow group <group_name> to <verb> <resource-type> in tenancy
```

For more details about the syntax, see Policy Syntax.

For information about how many policies you can have, see Service Limits.

A Few Examples

Let's say your administrator creates a group called *HelpDesk* whose job is to manage users and their credentials. Here is a policy that enables that:

```
Allow group HelpDesk to manage users in tenancy
```

Notice that because users reside in the tenancy (the root compartment), the policy simply states the word `tenancy`, without the word `compartment` in front of it.

Next, let's say you have a compartment called *Project-A*, and a group called *A-Admins* whose job is to manage all of the Oracle Cloud Infrastructure resources in the compartment. Here's an example policy that enables that:

```
Allow group A-Admins to manage all-resources in compartment Project-A
```

Be aware that the policy directly above includes the ability to write policies *for that compartment*, which means A-Admins can control access to the compartment's resources. For more information, see Policy Attachment.

If you wanted to limit A-Admins' access to only launching and managing compute instances and block storage volumes (both the volumes and their backups) in the Project-A compartment, but the network itself lives in the Networks compartment, then the policy could instead be:

```
Allow group A-Admins to manage instance-family in compartment Project-A
```

```
Allow group A-Admins to manage volume-family in compartment Project-A

Allow group A-Admins to use virtual-network-family in compartment Networks
```

The third statement with the `virtual-network-family` resource-type enables the instance launch process, because the cloud network is involved. Specifically, the launch process creates a new VNIC and attaches it to the subnet where the instance resides.

For additional examples, see Common Policies.

Details about Specifying Groups and Compartments

Typically you'll specify a group or compartment by name in the policy. However, you can use the OCID instead. Just make sure to add "`id`" before the OCID. For example:

```
Allow group

 id ocid1.group.oc1..aaaaaaaaqjihfhvxmumrl3isyrjw3n6c4rzwskaawuc7i5xwe6s7qmnsbc6a

 to manage instance-family in compartment Project-A
```

You can specify multiple groups separated by commas:

```
Allow group A-Admins, B-Admins to manage instance-family in compartment Projects-A-and-B
```

Verbs

Oracle defines the possible verbs you can use in your policies. Here's a summary of the verbs, from least amount of access to the most:

Verb	Types of Access Covered	Target User
`inspect`	Ability to list resources, without access to any confidential information or user-specified metadata that may be part of that resource. **Important:** The operation to list policies includes the contents of the policies themselves, and the list operations for the Networking resource-types return all the information (e.g., the contents of security lists and route tables).	Third-party auditors
`read`	Includes `inspect` plus the ability to get user-specified metadata and the actual resource itself.	Internal auditors
`use`	Includes `read` plus the ability to work with existing resources (the actions vary by resource type). Includes the ability to update the resource, except for resource-types where the "update" operation has the same effective impact as the "create" operation (e.g., `UpdatePolicy`, `UpdateSecurityList`, etc.), in which case the "update" ability is available only with the `manage` verb. In general, this verb does not include the ability to create or delete that type of resource.	Day-to-day end users of resources
`manage`	Includes all permissions for the resource.	Administrators

The verb gives a certain general type of access (e.g., `inspect` lets you list and get resources). When you then join that type of access with a particular resource-type in a policy (e.g., `Allow group XYZ to inspect compartments in the tenancy`), then you give that group access to a specific set of permissions and API operations (e.g., `ListCompartments`, `GetCompartment`). For more examples, see Details for Verbs + Resource-Type Combinations. The Policy Reference includes a similar table for each service, giving you a list of exactly which API operations are covered for each combination of verb and resource-type.

There are some special exceptions or nuances for certain resource-types.

Users: Access to both `manage users` and `manage groups` lets you do anything with users and groups, including creating and deleting users and groups, and adding/removing users from groups. To add/remove users from groups without access to creating and deleting users and groups, only both `use users` and `use groups` are required. See Common Policies.

Policies: The ability to update a policy is available only with `manage policies`, not `use policies`, because updating a policy is similar in effect to creating a new policy (you can overwrite the existing policy statements). In addition, `inspect policies` lets you get the full contents of the policies.

Object Storage objects: `inspect objects` lets you list all the objects in a bucket and do a HEAD operation for a particular object. In comparison, `read objects` lets you download the object itself.

Load Balancing resources: Be aware that `inspect load-balancers` lets you get *all* information about your load balancers and related components (backend sets, etc.).

Networking resources:

Be aware that the `inspect` verb not only returns general information about the cloud network's components (for example, the name and OCID of a security list, or of a route table). It also includes the contents of the component (for example, the actual rules in the security list, the routes in the route table, and so on).

Also, the following types of abilities are available only with the `manage` verb, not the `use` verb:

- Update (enable/disable) `internet-gateways`
- Update `security-lists`
- Update `route-tables`
- Update `dhcp-options`
- Attach a dynamic routing gateway (DRG) to a virtual cloud network (VCN)
- Create an IPSec connection between a DRG and customer-premises equipment (CPE)
- Peer VCNs

Important

Each VCN has various components that directly affect the behavior of the network (route tables, security lists, DHCP options, Internet Gateway, and so on). When you create one of these components, you establish a relationship between that component and the VCN, which means you must be allowed in a policy to both create the component and manage the VCN itself. However, the ability to *update* that component (to change the route rules, security list rules, and so on) does NOT require permission to manage the VCN itself, even though changing that component can directly affect the behavior of the network. This discrepancy is designed to give you flexibility in granting least privilege to users, and not require you to grant excessive access to the VCN just so the user can manage other components of the network. Be aware that by giving someone the ability to update a particular type of component, you're implicitly trusting them with controlling the network's behavior.

Resource-Types

Oracle also defines the resource-types you can use in your policies. First, there are *individual* types. Each individual type represents a specific type of resource. For example, the `vcns` resource-type is specifically for virtual cloud networks (VCNs).

To make policy writing easier, there are *family* types that include multiple individual resource-types that are often managed together. For example, the `virtual-network-family` type brings together a variety of types related to the management of VCNs (e.g., `vcns`, `subnets`, `route-tables`, `security-lists`, etc.). If you need to write a more granular policy

that gives access to only an individual resource-type, you can. But you can also easily write a policy to give access to a broader range of resources.

In another example: Block Volume has `volumes`, `volume-attachments`, and `volume-backups`. If you need to give access to only making backups of volumes, you can specify the `volume-backups` resource-type in your policy. But if you need to give broad access to all of the Block Volume resources, you can specify the family type called `volume-family`. For a full list of the resource-types, see Resource-Types.

Important

If a service introduces new individual resource-types, they will typically be included in the family type for that service. For example, if Networking introduces a new individual resource-type, it will be automatically included in the definition of the `virtual-network-family` resource type. For more information about future changes to the definitions of resource-types, see Policies and Service Updates.

Note that there are other ways to make policies more granular, such as the ability to specify conditions under which the access is granted. For more information, see Advanced Policy Features.

Access that Requires Multiple Resource-Types

Some API operations require access to multiple resource-types. For example, `LaunchInstance` requires the ability to create instances and work with a cloud network. The `CreateVolumeBackup` operation requires access to both the volume and the volume backup. That means you'll have separate statements to give access to each resource-type (for an example, see Let volume backup admins manage only backups). These individual statements do not have to be in the same policy. And a user can gain the required access from being in different groups. For example, George could be in one group that gives the required level of access to the `volumes` resource-type, and in another group that gives the required access to

the `volume-backups` resource-type. The sum of the individual statements, regardless of their location in the overall set of policies, gives George access to `CreateVolumeBackup`.

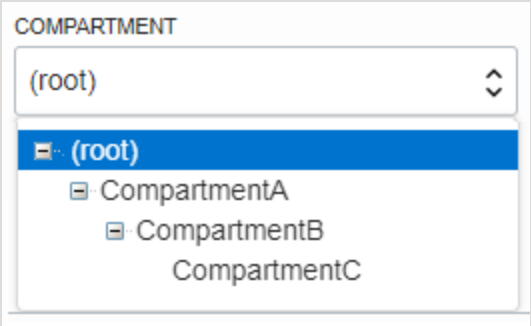
Policy Inheritance

A basic feature of policies is the concept of *inheritance*: Compartments inherit any policies from their parent compartment. The simplest example is the Administrators group, which automatically comes with your tenancy (see The Administrators Group and Policy). There's a built-in policy that enables the Administrators group to do anything in the tenancy:

```
Allow group Administrators to manage all-resources in tenancy
```

Because of policy inheritance, the Administrators group can also do anything in *any* of the compartments in the tenancy.

To illustrate further, consider a tenancy with three levels of compartments: CompartmentA, CompartmentB, and ComparmentC, shown here:



Policies that apply to resources in CompartmentA also apply to resources in CompartmentB and CompartmentC. So this policy:

```
Allow group NewtworkAdmins to manage virtual-network-family in compartment CompartmentA
```

allows the group NetworkAdmins to manage VCNs in CompartmentA, CompartmentB, and CompartmentC.

Policy Attachment

Another basic feature of policies is the concept of *attachment*. When you create a policy you must attach it to a compartment (or the tenancy, which is the root compartment). **Where you attach it controls who can then modify it or delete it.** If you attach it to the tenancy (in other words, if the policy *is in* the root compartment), then anyone with access to manage policies in the tenancy can then change or delete it. Typically that's the Administrators group or any similar group you create and give broad access to. Anyone with access only to a child compartment cannot modify or delete that policy.

If you instead attach the policy to a child compartment, then anyone with access to manage the policies *in that compartment* can change or delete it. In practical terms, this means it's easy to give compartment administrators (i.e., a group with access to `manage all-resources` in the compartment) access to manage their own compartment's policies, without giving them broader access to manage policies that reside in the tenancy. For an example that uses this kind of compartment administrator design, see Example Scenario. (Recall that because of policy inheritance, users with access to manage policies in the tenancy automatically have the ability to manage policies in compartments inside the tenancy.)

The process of attaching the policy is easy (whether attaching to a compartment or the tenancy): If you're using the Console, when you add the policy to IAM, simply make sure you're in the desired compartment when you create the policy. If you're using the API, you specify the OCID of the desired compartment (either the tenancy or other compartment) as part of the request to create the policy.

When you attach a policy to a compartment, you must be in that compartment *and* you must indicate directly in the statement which compartment it applies to. If you are not in the compartment, you'll get an error if you try to attach the policy to a different compartment. Notice that attachment occurs during policy creation, which means a policy can be attached to only one compartment. To learn how to attach a policy to a compartment, see To create a policy.

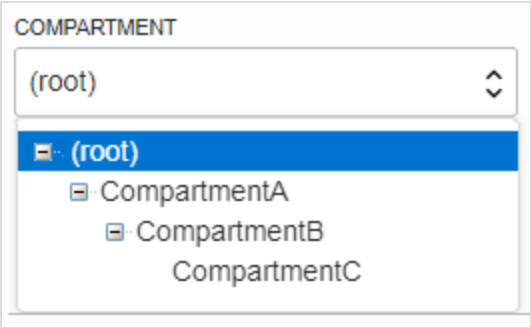
Policies and Compartment Hierarchies

As described in the previous section, a policy statement must specify the compartment for which access is being granted (or the tenancy). Where you create the policy determines who

can update the policy. If you attach the policy to the compartment or its parent, you can simply specify the compartment name. If you attach the policy further up the hierarchy, you must specify the path. The format of the path is each compartment name (or OCID) in the path, separated by a colon:

<compartment_level_1>:*<compartment_level_2>*:. . . *<compartment_level_n>*

For example, assume you have a three-level compartment hierarchy, shown here:



You want to create a policy to allow NetworkAdmins to manage VCNs in CompartmentC. If you want to attach this policy to CompartmentC or to its parent, CompartmentB, write this policy statement:

```
Allow group NewtworkAdmins to manage virtual-network-family in compartment CompartmentC
```

However, if you want to attach this policy to CompartmentA (so that only administrators of CompartmentA can modify it), write this policy statement that specifies the path:

```
Allow group NewtworkAdmins to manage virtual-network-family in compartment CompartmentB:CompartmentC
```

To attach this policy to the tenancy, write this policy statement that specifies the path from CompartmentA to CompartmentC:

```
Allow group NewtworkAdmins to manage virtual-network-family in compartment
CompartmentA:CompartmentB:CompartmentC
```

Policies and Service Updates

It's possible that the definition of a verb or resource-type could change in the future. For example, let's say that the `virtual-network-family` resource-type changes to include a new kind of resource that's been added to Networking. By default, your policies automatically stay current with any changes in service definition, so any policy you have that gives access to `virtual-network-family` would automatically include access to the newly added resource. If you'd prefer a different behavior, see Policy Language Version.

Writing Policies for Each Service

The Policy Reference includes details of the specific resource-types for each service, and which verb + resource-type combination gives access to which API operations.

Common Policies

This section includes some common policies you might want to use in your organization.

Note

These policies use example group and compartment names. Make sure to replace them with your own names.

Let the Help Desk manage users

Type of access: Ability to create, update, and delete users and their credentials. It does not include the ability to put users in groups (see Let group admins manage group membership).

Where to create the policy: In the tenancy, because users reside in the tenancy.

```
Allow group HelpDesk to manage users in tenancy
```

Let auditors inspect your resources

Type of access: Ability to list the resources in all compartments. Be aware that:

- The operation to list IAM policies includes the contents of the policies themselves
- The list operations for Networking resource-types return all the information (for example, the contents of security lists and route tables)
- The operation to list instances requires the `read` verb instead of `inspect`, and the contents include the user-provided metadata.
- The operation to view Audit service events requires the `read` verb instead of `inspect`.

Where to create the policy: In the tenancy. Because of the concept of *policy inheritance*, auditors can then inspect both the tenancy and all compartments beneath it. Or you could choose to give auditors access to only specific compartments if they don't need access to the entire tenancy.

```
Allow group Auditors to inspect all-resources in tenancy

Allow group Auditors to read instances in tenancy

Allow group Auditors to read audit-events in tenancy
```

Let network admins manage a cloud network

Type of access: Ability to manage all components in Networking. This includes cloud networks, subnets, gateways, virtual circuits, security lists, route tables, and so on. If the network admins need to launch instances to test network connectivity, see Let users launch Compute instances on this page.

Where to create the policy: In the tenancy. Because of the concept of policy inheritance, NetworkAdmins can then manage a cloud network in any compartment. To reduce the scope of access to a particular compartment, specify that compartment instead of the tenancy.

```
Allow group NetworkAdmins to manage virtual-network-family in tenancy
```

Let network admins manage load balancers

Type of access: Ability to manage all components in Load Balancing. If the group needs to launch instances, see Let users launch Compute instances on this page.

Where to create the policy: In the tenancy. Because of the concept of policy inheritance, NetworkAdmins can then manage load balancers in any compartment. To reduce the scope of access to a particular compartment, specify that compartment instead of the tenancy.

```
Allow group NetworkAdmins to manage load-balancers in tenancy
```

If the group uses the Console to manage load balancers, an additional policy to use the associated networking resources is required:

```
Allow group NetworkAdmins to manage load-balancers in tenancy

Allow group NetworkAdmins to use virtual-network-family in tenancy
```

If a particular group needs to update existing load balancers (for example, modify the backend set) but not create or delete them, use this statement:

```
Allow group LBUsers to use load-balancers in tenancy
```

Let users launch Compute instances

Type of access: Ability to do everything with instances launched into the cloud network and subnets in compartment XYZ, and attach/detach any existing volumes that already exist in compartment ABC. The first statement also lets the group create and manage instance images in compartment ABC. If the group doesn't need to attach/detach volumes, you can delete the third statement.

Where to create the policy: The easiest approach is to put this policy in the tenancy. If you want the admins of the individual compartments (ABC and XYZ) to have control over the individual policy statements for their compartments, see Policy Attachment.

```
Allow group InstanceLaunchers to manage instance-family in compartment ABC

Allow group InstanceLaunchers to read app-catalog-listing in tenancy

Allow group InstanceLaunchers to use volume-family in compartment ABC
```

```
Allow group InstanceLaunchers to use virtual-network-family in compartment XYZ
```

Let users manage Compute dedicated virtual machine hosts

Type of access: Ability to create, update, and delete dedicated virtual machine hosts as well as launch instances on dedicated virtual machine hosts.

Where to create the policy: In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the dedicated virtual machine hosts and instances in a particular compartment, specify that compartment instead of the tenancy.

```
Allow group DedicatedVMHostAdmins to manage dedicated-vm-hosts in tenancy

Allow group DedicatedVMHostAdmins to manage instances in tenancy
```

Let users launch Compute instances on dedicated virtual machine hosts

Type of access: Ability to launch instances on dedicated virtual machine hosts.

Where to create the policy: In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the dedicated virtual machine hosts and instances in a particular compartment, specify that compartment instead of the tenancy.

```
Allow group DedicatedVMHostAdmins to use dedicated-vm-hosts in tenancy

Allow group DedicatedVMHostAdmins to manage instances in tenancy
```

Let users manage Compute instance configurations, instance pools, and cluster networks

Type of access: Ability to do all things with instance configurations, instance pools, and cluster networks in all compartments.

Where to create the policy: In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the instance configurations, instance pools, and cluster networks in a particular compartment, specify that compartment instead of the tenancy.

```
Allow group InstancePoolAdmins to manage compute-management-family in tenancy
```

If a group needs to create instance configurations using existing instances as a template, and uses the API, SDKs, or command line interface (CLI) to do this, add the following statements to the policy:

```
Allow group InstancePoolAdmins to read instance-family in tenancy

Allow group InstancePoolAdmins to inspect volumes in tenancy
```

If a particular group needs to start, stop, or reset the instances in existing instance pools, but not create or delete instance pools, use this statement:

```
Allow group InstancePoolUsers to use instance-pools in tenancy
```

Let users manage Compute autoscaling configurations

Type of access: Ability to create, update, and delete autoscaling configurations.

Where to create the policy: In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the autoscaling configurations in a particular compartment, specify that compartment instead of the tenancy.

```
Allow group AutoscalingAdmins to manage auto-scaling-configurations in tenancy

Allow group AutoscalingAdmins to manage instance-pools in tenancy
```

Let users list and subscribe to images from the Partner Image catalog

Type of access: Ability to list and create subscriptions to images in the Partner Image catalog. It does not include the ability to create instances using images from the Partner Image catalog (see Let users launch Compute instances).

Where to create the policy: In the tenancy. To reduce the scope of access to just creating subscriptions in a particular compartment, specify that compartment instead of the tenancy in the third statement.

```
Allow group CatalogSubscribers to inspect app-catalog-listing in tenancy

Allow group CatalogSubscribers to read app-catalog-listing in tenancy

Allow group CatalogSubscribers to manage app-catalog-listing in tenancy
```

Let volume admins manage block volumes, backups, and volume groups

Type of access: Ability to do all things with block storage volumes, volume backups, and volume groups in all compartments with the exception of copying volume backups across regions. This makes sense if you want to have a single set of volume admins manage all the volumes, volume backups, and volume groups in all the compartments. The second statement is required in order to attach/detach the volumes from instances.

Where to create the policy: In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the volumes/backups and instances in a particular compartment, specify that compartment instead of the tenancy.

```
Allow group VolumeAdmins to manage volume-family in tenancy

Allow group VolumeAdmins to use instance-family in tenancy
```

If the group needs to also copy volume backups across regions, add the following statement to the policy:

```
Allow group VolumeAdmins to copy volume-backups in tenancy
```

Let volume backup admins manage only backups

Type of access: Ability to do all things with volume backups, but not create and manage volumes themselves. This makes sense if you want to have a single set of volume backup admins manage all the volume backups in all the compartments. The first statement gives the

required access to the volume that is being backed up; the second statement enables creation of the backup (and the ability to delete backups). The third statement enables the creation and management of user defined backup policies; the fourth statement enables assignment and removal of assignment of backup policies.

Where to create the policy: In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the volumes and backups in a particular compartment, specify that compartment instead of the tenancy.

```
Allow group VolumeBackupAdmins to use volumes in tenancy

Allow group VolumeBackupAdmins to manage volume-backups in tenancy

Allow group VolumeBackupAdmins to manage backup-policies in tenancy

Allow group VolumeBackupAdmins to manage backup-policy-assignments in tenancy
```

If the group will be using the Console, the following policy gives a better user experience:

```
Allow group VolumeBackupAdmins to use volumes in tenancy

Allow group VolumeBackupAdmins to manage volume-backups in tenancy

Allow group VolumeBackupAdmins to inspect volume-attachments in tenancy

Allow group VolumeBackupAdmins to inspect instances in tenancy

Allow group VolumeBackupAdmins to manage backup-policies in tenancy

Allow group VolumeBackupAdmins to manage backup-policy-assignments in tenancy
```

The last two statements are not necessary in order to manage volume backups. However, they enable the Console to display all the information about a particular volume and the available backup policies.

Let users create a volume group

Type of access: Ability to create a volume group from a set of volumes.

Where to create the policy: In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the volumes and volume groups in a particular compartment, specify that compartment instead of the tenancy.

```
Allow group VolumeGroupCreators to inspect volumes in tenancy
Allow group VolumeGroupCreators to manage volume-groups in tenancy
```

Let users clone a volume group

Type of access: Ability to clone a volume group from an existing volume group.

Where to create the policy: In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the volumes and volume groups in a particular compartment, specify that compartment instead of the tenancy.

```
Allow group VolumeGroupCloners to inspect volumes in tenancy
Allow group VolumeGroupCloners to manage volume-groups in tenancy
Allow group VolumeGroupCloners to manage volumes in tenancy
```

Let users create a volume group backup

Type of access: Ability to create a volume group backup.

Where to create the policy: In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the volumes/backups and volume groups/volume group backups in a particular compartment, specify that compartment instead of the tenancy.

```
Allow group VolumeGroupBackupAdmins to inspect volume-groups in tenancy
Allow group VolumeGroupBackupAdmins to manage volumes in tenancy
Allow group VolumeGroupBackupAdmins to manage volume-group-backups in tenancy
Allow group VolumeGroupBackupAdmins to manage volume-backups in tenancy
```

Let users restore a volume group backup

Type of access: Ability to create a volume group by restoring a volume group backup.

Where to create the policy: In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the volumes/backups and volume groups/volume group backups in a particular compartment, specify that compartment instead of the tenancy.

```
Allow group VolumeGroupBackupAdmins to inspect volume-group-backups in tenancy
Allow group VolumeGroupBackupAdmins to read volume-backups in tenancy
Allow group VolumeGroupBackupAdmins to manage volume-groups in tenancy
Allow group VolumeGroupBackupAdmins to manage volumes in tenancy
```

Let users create, manage, and delete file systems

Type of access: Ability to create, manage, or delete a file system. Administrative functions for a file system include the ability to rename or delete it or disconnect from it.

Where to create the policy: In the tenancy, so that the ability to create, manage, or delete a file system is easily granted to all compartments by way of policy inheritance. To reduce the scope of these administrative functions to file systems in a particular compartment, specify that compartment instead of the tenancy.

```
Allow group StorageAdmins to manage file-family in tenancy

Allow group StorageAdmins to manage file-family in compartment ABC
```

Let users create file systems

Type of access: Ability to create a file system.

Where to create the policy: In the tenancy, so that the ability to create a file system is easily granted to all compartments by way of policy inheritance. To reduce the scope of these administrative functions to file systems in a particular compartment, specify that compartment instead of the tenancy.

```
Allow group Managers to manage file-systems in tenancy

Allow group Managers to read mount-targets in tenancy
```

The second statement is required when users create a file system using the Console. It enables the Console to display a list of mount targets that the new file system can be associated with.

Let Object Storage admins manage buckets and objects

Type of access: Ability to do all things with Object Storage buckets and objects in all compartments.

Where to create the policy: In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the buckets and objects in a particular compartment, specify that compartment instead of the tenancy.

```
Allow group ObjectAdmins to manage buckets in tenancy

Allow group ObjectAdmins to manage objects in tenancy
```

Let users write objects to Object Storage buckets

Type of access: Ability to write objects to any Object Storage bucket in compartment ABC (imagine a situation where a client needs to regularly write log files to a bucket). This consists of the ability to list the buckets in the compartment, list the objects in a bucket, and create a new object in a bucket. Although the second statement gives broad access with the `manage` verb, that access is then scoped down to only the `OBJECT_INSPECT` and `OBJECT_CREATE` permissions with the condition at the end of the statement.

Where to create the policy: The easiest approach is to put this policy in the tenancy. If you want the admins of compartment ABC to have control over the policy, see Policy Attachment.

```
Allow group ObjectWriters to read buckets in compartment ABC

Allow group ObjectWriters to manage objects in compartment ABC where any {request.permission='OBJECT_
CREATE', request.permission='OBJECT_INSPECT'}
```

Access limited to a specific bucket: To limit access to a specific bucket in a particular compartment, add the condition `where target.bucket.name='<bucket_name>'`. The following policy allows the user to list all the buckets in a particular compartment, but they can only list the objects in and upload objects to BucketA:

```
Allow group ObjectWriters to read buckets in compartment ABC

Allow group ObjectWriters to manage objects in compartment ABC where all {target.bucket.name='BucketA',
any {request.permission='OBJECT_CREATE', request.permission='OBJECT_INSPECT'}}
```

For more information about using conditions, see Advanced Policy Features.

Let users download objects from Object Storage buckets

Type of access: Ability to download objects from any Object Storage bucket in compartment ABC. This consists of the ability to list the buckets in the compartment, list the objects in a bucket, and read existing objects in a bucket.

Where to create the policy: The easiest approach is to put this policy in the tenancy. If you want the admins of compartment ABC to have control over the policy, see Policy Attachment.

```
Allow group ObjectReaders to read buckets in compartment ABC

Allow group ObjectReaders to read objects in compartment ABC
```

Access limited to a specific bucket: To limit access to a specific bucket in a particular compartment, add the condition `where target.bucket.name='<bucket_name>'`. The following policy allows the user to list all buckets in a particular compartment, but they can only read the objects in and download from BucketA:

```
Allow group ObjectReaders to read buckets in compartment ABC

Allow group ObjectReaders to read objects in compartment ABC where target.bucket.name='BucketA'
```

For more information about using conditions, see Advanced Policy Features.

Let database admins manage DB systems

Type of access: Ability to do all things with the DB system resources in all compartments.

This makes sense if you want to have a single set of database admins manage all the bare metal, virtual machine, and Exadata DB systems in all the compartments.

Where to create the policy: In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the database systems in a particular compartment, specify that compartment instead of the tenancy.

```
Allow group DatabaseAdmins to manage database-family in tenancy
```

Let database admins manage Exadata Cloud at Customer instances

Type of access: Ability to do all things with the Exadata Cloud at Customer resources in all compartments. This makes sense if you want to have a single set of database admins manage all the Exadata Cloud at Customer systems in all the compartments.

Where to create the policy: In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the Exadata Cloud at Customer systems in a particular compartment, specify that compartment instead of the tenancy.

```
Allow group ExaCCAdmins to manage database-family in tenancy
```

Let database and fleet administrators manage Autonomous Databases

Type of access: Ability to do all things with Autonomous Database instances in all compartments. This makes sense if you want to have a single set of database admins manage all the Autonomous Database databases in all the compartments.

Where to create the policy: In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the Autonomous Databases databases in a particular compartment, specify that compartment instead of the tenancy.

Example 1: For fleet admins. Allows Autonomous Database fleet administrator access to **both workload types** (Autonomous Data Warehouse and Autonomous Transaction

Processing), and to dedicated deployment **infrastructure resources** (Autonomous Container Databases and Autonomous Exadata Infrastructure resources).

```
Allow group DatabaseAdmins to manage autonomous-database-family in tenancy
```

If you need to restrict access to the Autonomous Exadata Infrastructure and Autonomous Container Database resource types (applicable only to dedicated deployment instances), you can do so by creating separate policy statements for database administrators that allow access to only Autonomous Databases and their backups. Because a policy statement can only specify one resource type, you will need to create separate statements for the database and backup resources.

Example 2: For database admins. Allows Autonomous Database database administrator access to databases and backups of **both workload types**, but denies access to dedicated deployment infrastructure resources (Autonomous Container Databases and Autonomous Exadata Infrastructure resources).

```
Allow group ADB-Admins to manage autonomous-database in tenancy
```

```
Allow group ADB-Admins to manage autonomous-backup in tenancy
```

To reduce the scope of access to either the Autonomous Data Warehouse or Autonomous Transaction Processing workload types, use a `where` clause, as in the following examples:

Example 3: For Autonomous Transaction Processing database admins. Limits Autonomous Database access to **Autonomous Transaction Processing** databases and backups.

```
Allow group ADB-Admins to manage autonomous-database in tenancy where target.workloadType = 'OLTP'
```

```
Allow group ADB-Admins to manage autonomous-backup in tenancy where target.workloadType = 'OLTP'
```

Example 4: For Autonomous Data Warehouse admins. Limits Autonomous Database access to **Autonomous Data Warehouse** databases and backups.

```
Allow group ADB-Admins to manage autonomous-database in tenancy where target.workloadType = 'DW'
```

```
Allow group ADB-Admins to manage autonomous-backup in tenancy where target.workloadType = 'DW'
```

Let database admins manage Autonomous Data Warehouse databases

Deprecated. See Let database and fleet administrators manage Autonomous Databases for

sample Autonomous Database policies covering the Autonomous Data Warehouse workload type.

Let security admins manage vaults and keys

Type of access: Ability to do all things with the Key Management service in all compartments. This makes sense if you want to have a single set of security admins manage all the vaults and keys in all compartments.

Where to create the policy: In the tenancy, so that access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the keys and vaults in a particular compartment, specify that compartment instead of the tenancy.

```
Allow group SecurityAdmins to manage vaults in tenancy

Allow group SecurityAdmins to manage keys in tenancy
```

Let security admins manage all keys in a specific vault in a compartment

Type of access: Ability to do all things with keys in a specific vault in compartment ABC.

Where to create the policy: The easiest approach is to put this policy in the tenancy. If you want the admins of the individual compartment (ABC) to have control over the individual policy statements for their compartment, see Policy Attachment.

```
Allow group SecurityAdmins to manage keys in compartment ABC where target.vault.id='<vault_OCID>'
```

Let security admins use a specific key in a compartment

Type of access: Ability to list, view, and perform cryptographic operations with a specific key in a compartment.

Where to create the policy: The easiest approach is to put this policy in the tenancy. If you want the admins of the individual compartment (ABC) to have control over the individual policy statements for their compartment, see Policy Attachment.

```
Allow group SecurityAdmins to use keys in compartment ABC where target.key.id='<key_OCID>'
```

Let a user group delegate key usage in a compartment

Type of access: Ability to associate an Object Storage bucket, Block Volume volume, or a File Storage file system with a specific key authorized for use in a specific compartment. With this policy, a user in the specified group does not have permission to use the key itself. Rather, by association, the key can be used by Object Storage, Block Volume, or File Storage on behalf of the user to create or update an encrypted bucket, volume, or file system and to encrypt or decrypt data in the bucket, volume, or file system. This policy requires that you also have a companion policy that lets Object Storage, Block Volume, or File Storage use the key to perform cryptographic operations.

Where to create the policy: The easiest approach is to put this policy in the tenancy. If you want the admins of the individual compartment (ABC) to have control over the individual policy statements for their compartment, see Policy Attachment.

```
Allow group ObjectWriters, VolumeWriters, FileWriters to use key-delegate in compartment ABC where
target.key.id = '<key_OCID>'
```

Let Block Volume, Object Storage, File Storage services encrypt and decrypt volumes, volume backups, buckets, and file systems

Type of access: Ability to list, view, and perform cryptographic operations with all keys in compartment ABC. Because Object Storage is a regional service, it has regional endpoints. As such, you must specify the regional service name for each region where you're using Object Storage with Key Management encryption. This policy also requires that you have a companion policy that allows a user group to use the delegated key that Object Storage, Block Volume, or File Storage will use.

Where to create the policy: The easiest approach is to put this policy in the tenancy. If you want the admins of the individual compartment (ABC) to have control over the individual policy statements for their compartment, see Policy Attachment.

```
Allow service blockstorage, objectstorage-<region_name>, FssOc1Prod to use keys in compartment ABC where
target.key.id = '<key_OCID>'
```

For Object Storage, refer to the service in policies in the following ways, depending on your region:

- objectstorage-us-phoenix-1
- objectstorage-us-ashburn-1
- objectstorage-eu-frankfurt-1
- objectstorage-uk-london-1
- objectstorage-Japan East (Tokyo)

For File Storage, the service name used in the policy is `FssOc1Prod`.

To determine the region name value of an Oracle Cloud Infrastructure region, see Regions and Availability Domains.

Let group admins manage group membership

Type of access: Ability to manage the membership of a group. Does not include the ability to create or delete users, or manage their credentials (see Let the Help Desk manage users).

The first two statements let GroupAdmins list all the users and groups in the tenancy, list which users are in a particular group, and list what groups a particular user is in.

The last two statements together let GroupAdmins change a group's membership. The condition at the end of the last two statements lets GroupAdmins manage membership to all groups except the Administrators group (see The Administrators Group and Policy). You should protect membership to that group because it has power to do anything throughout the tenancy.

It might seem that the last two statements should also cover the basic listing functionality that the first two statements enable. To better understand how conditions work and why you also need the first two statements, see Variables that Aren't Applicable to a Request Result in a Declined Request.

Where to create the policy: In the tenancy, because users and groups reside in the tenancy.

```
Allow group GroupAdmins to inspect users in tenancy

Allow group GroupAdmins to inspect groups in tenancy
```

```
Allow group GroupAdmins to use users in tenancy where target.group.name != 'Administrators'

Allow group GroupAdmins to use groups in tenancy where target.group.name != 'Administrators'
```

Let users manage their own passwords and credentials

No policy is required to let users manage *their own* credentials. All users have the ability to change and reset their own passwords, manage their own API keys, and manage their own auth tokens. For more information, see User Credentials.

Let a compartment admin manage the compartment

Type of access: Ability to manage all aspects of a particular compartment. For example, a group called A-Admins could manage all aspects of a compartment called Project-A, including writing additional policies that affect the compartment. For more information, see Policy Attachment. For an example of this kind of setup and additional policies that are useful, see Example Scenario.

Where to create the policy: In the tenancy.

```
Allow group A-Admins to manage all-resources in compartment Project-A
```

Restrict admin access to a specific region

Type of access: Ability to manage resources in a specific region. Remember that IAM resources must be managed in the home region. If the specified region is not the home region, then the Admin will not be able to manage IAM resources. For more information about the home region, see Managing Regions.

Where to create the policy: In the tenancy.

```
Allow group PHX-Admins to manage all-resources in tenancy where request.region='phx'
```

The preceding policy allows PHX-Admins to manage all aspects of all resources in US West (Phoenix).

Members of the PHX-Admins group can only manage IAM resources if the tenancy's home region is US West (Phoenix).

Restrict user access to view only summary announcements

Type of access: Ability to view the summary versions of announcements about the operational status of Oracle Cloud Infrastructure services.

Where to create the policy: In the tenancy.

```
Allow group AnnouncementListers to inspect announcements in tenancy
```

The preceding policy allows AnnouncementListers to view a list of summary announcements.

Let users view details of announcements

Type of access: Ability to view the details of announcements about the operational status of Oracle Cloud Infrastructure services.

Where to create the policy: In the tenancy.

```
Allow group AnnouncementReaders to read announcements in tenancy
```

The preceding policy allows AnnouncementReaders to view a list of summary announcements and the details of specific announcements.

Let streaming users manage streams

Type of access: Ability to do all things with the Streaming service in all compartments.

Where to create the policy: In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the streams in a particular compartment, specify that compartment instead of the tenancy.

```
Allow group StreamAdmins to manage streams in tenancy
```

Let streaming users publish messages to streams

Type of access: Ability to produce messages to streams with the Streaming service in all compartments.

Where to create the policy: In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the streams in a particular compartment, specify that compartment instead of the tenancy.

```
Allow group StreamUsers to use stream-push in tenancy
```

Let streaming users publish messages to a specific stream

Type of access: Ability to produce messages to a stream with the Streaming service.

Where to create the policy: In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the streams in a particular compartment, specify that compartment instead of the tenancy.

```
allow group StreamUsers to use stream-pull in tenancy where target.stream.id = '<stream_OCID>'
```

Let streaming users consume messages from streams

Type of access: Ability to consume messages from streams with the Streaming service in all compartments.

Where to create the policy: In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the streams in a particular compartment, specify that compartment instead of the tenancy.

```
Allow group StreamUsers to use stream-pull in tenancy
```

Let users view metric definitions in a compartment

Type of access: Ability to view metric definitions in a specific compartment. For more information about metrics, see Metrics Feature Overview.

Where to create the policy: In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the metric definitions in a particular compartment, specify that compartment instead of the tenancy.

```
Allow group MetricReaders to inspect metrics in compartment ABC
```

Let users access monitoring metrics in a compartment

Type of access: Ability to view and retrieve monitoring metrics for supported resources in a specific compartment. For more information about metrics, see Metrics Feature Overview.

Where to create the policy: In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the metrics in a particular compartment, specify that compartment instead of the tenancy.

```
Allow group MetricReaders to read metrics in compartment ABC
```

Restrict user access to a specific metric namespace

Type of access: Ability to view and retrieve monitoring metrics for resources under a specific metric namespace. For more information about metrics, see Metrics Feature Overview.

Where to create the policy: In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to the specified metric namespace to just within a particular compartment, specify that compartment instead of the tenancy.

```
Allow group MetricReaders to read metrics in compartment ABC where target.metrics.namespace='oci_
computeagent'
```

The preceding policy allows `MetricReaders` to view and retrieve metric data points from all monitoring-enabledCompute instances in the `ABC` compartment.

Let users publish custom metrics

Type of access: Ability to publish custom metrics under a specific metric namespace to the Monitoring service. For instructions, see Publishing Custom Metrics.

Where to create the policy: In the tenancy, so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just metrics in a particular compartment, specify that compartment instead of the tenancy.

```
Allow group MetricPublishers to use metrics in tenancy where
target.metrics.namespace='mycustomnamespace'
```

The preceding policy allows `MetricPublishers` to publish data points for the custom metric namespace `mycustomnamespace` in the tenancy.

Let instances make API calls to access monitoring metrics in the tenancy

Type of access: Ability to call the Monitoring API for access to monitoring metrics. The instances on which API requests originate must be members of the dynamic group indicated in the policy. For more information, see Calling Services from an Instance and Metrics Feature Overview.

Where to create the policy: In the tenancy.

```
Allow dynamic-group MetricInstances to read metrics in tenancy
```

The preceding policy allows applications that are running on Compute instances in the dynamic group `MetricInstances` to send API requests to the Monitoring service in the tenancy.

Let users view alarms

Type of access: Ability to view alarms for supported resources in tenancy. Does not include the ability to create alarms or to create or delete topics. For more information about alarms, see Alarms Feature Overview.

Where to create the policy: In the tenancy. Because of the concept of policy inheritance, AlarmUsers can then view alarms in any compartment. To reduce the scope of access to a particular compartment, specify that compartment instead of the tenancy.

```
Allow group AlarmUsers to read alarms in tenancy

Allow group AlarmUsers to read metrics in tenancy
```

Let users manage alarms

Type of access: Ability to view and create alarms with existing notification topics for supported resources in the tenancy. Does not include the ability to create or delete topics. For more information about alarms, see Alarms Feature Overview.

All statements are required to let AlarmUsers create alarms.

Where to create the policy: In the tenancy. Because of the concept of policy inheritance, AlarmUsers can then view and create alarms in any compartment. To reduce the scope of access to a particular compartment, specify that compartment instead of the tenancy.

```
Allow group AlarmUsers to manage alarms in tenancy

Allow group AlarmUsers to read metrics in tenancy

Allow group AlarmUsers to use ons-topics in tenancy
```

Let users manage alarms and create topics

Type of access: Ability to view and create alarms (with new or existing topics) for supported resources in tenancy. Also includes the ability to create subscriptions in the tenancy, to publish messages (broadcast notification messages) to all subscriptions in the tenancy, and to move alarms to different compartments in the tenancy. For more information about alarms, see Alarms Feature Overview.

Where to create the policy: In the tenancy. Because of the concept of policy inheritance, AlarmUsers can then view and create alarms in any compartment. To reduce the scope of access to a particular compartment, specify that compartment instead of the tenancy.

```
Allow group AlarmUsers to manage alarms in tenancy

Allow group AlarmUsers to read metrics in tenancy

Allow group AlarmUsers to manage ons-topics in tenancy
```

Allow a group to manage topics

Type of access: Ability to get, create, update, and delete topics in the tenancy, as well as move topics to different compartments in the tenancy. Also includes the ability to create subscriptions in the tenancy and to publish messages (broadcast notification messages) to all subscriptions in the tenancy.

Where to create the policy: In the tenancy.

```
Allow group A-Admins to manage ons-topics in tenancy
```

Allow a group to manage topic subscriptions

Type of access: Ability to list, create, update, and delete subscriptions for topics in the tenancy. Ability to move subscriptions to different compartments in the tenancy.

Where to create the policy: In the tenancy.

```
Allow group A-Admins to manage ons-subscriptions in tenancy
```

Allow a group to publish messages to topics

Type of access: Ability to broadcast notification messages to all subscriptions in the tenancy, as well as list, create, update, and delete subscriptions in the tenancy.

Where to create the policy: In the tenancy.

```
Allow group A-Admins to use ons-topics in tenancy
```

Let users list Events rules in a compartment

Type of access: Ability to list Events rules.

Where to create the policy: In the tenancy.

```
Allow group RuleReaders to read cloudevents-rules in tenancy
```

The preceding policy allows RuleReaders to list rules in the tenancy.

Let admins manage Events rules in a compartment

Type of access: Ability to manage Events rules, including creating, deleting and updating rules.

Where to create the policy: In the tenancy.

This line gives the user inspect access to resources in compartments to select actions.

```
allow group <RuleAdmins> to inspect compartments in tenancy
```

This line gives the user access to defined tags to apply filter tags to rules.

```
allow group <RuleAdmins> to use tag-namespaces in tenancy
```

These lines give the user access to Streaming resources for actions

```
allow group <RuleAdmins> to inspect streams in tenancy
allow group <RuleAdmins> to use stream-push in tenancy
allow group <RuleAdmins> to use stream-pull in tenancy
```

These lines give the user access to Functions resources for actions.

```
allow group <RuleAdmins> to use virtual-network-family in tenancy
allow group <RuleAdmins> to manage function-family in tenancy
```

This line give the user access to Notifications topics for actions.

```
allow group <RuleAdmins> to use ons-topic in tenancy
```

This line gives the user manage access to rules for Events.

```
allow group <RuleAdmins> to manage cloudevents-rules in tenancy
```

Advanced Policy Features

This section describes policy language features that let you grant more granular access.

Conditions

As part of a policy statement, you can specify one or more *conditions* that must be met in order for access to be granted. For a simple example, see Let group admins manage group membership.

Each condition consists of one or more predefined variables that you specify values for in the policy statement. Later, when someone requests access to the resource in question, if the condition in the policy is met, it evaluates to *true* and the request is allowed. If the condition is not met, it evaluates to *false* and the request is not allowed.

There are two types of variables: those that are relevant to the request itself, and those relevant to the resource being acted upon in the request, also known as the *target*. The name of the variable is prefixed accordingly with either `request` or `target` followed by a period. For example, there's a request variable called `request.operation` to represent the API operation being requested. This variable lets you write a broad policy statement, but add a condition based on the specific API operation. For an example, see Let users write objects to Object Storage buckets.

Important

Condition matching is case insensitive. This is important to remember when writing conditions for resource types that allow case-sensitive naming. For example, the Object Storage service allows you to create both a bucket named "BucketA" and a bucket named "bucketA" in the same compartment. If you write a condition that specifies "BucketA", it will apply also to "bucketA", because the condition matching is case insensitive.

Variables that Aren't Applicable to a Request Result in a Declined Request

If the variable is *not applicable* to the incoming request, the condition evaluates to *false* and the request is declined. For example, here are the basic policy statements that together let someone add or remove users from any group except Administrators:

```
Allow group GroupAdmins to use users in tenancy
 where target.group.name != 'Administrators'

Allow group GroupAdmins to use groups in tenancy
 where target.group.name != 'Administrators'
```

Given the above policy, if GroupAdmins tried to call a general API operation for users such as `ListUsers` or `UpdateUser` (which lets you change the user's description), the request would be declined, even though those API operations are covered by `use users`.This is because the above policy statement for `use users` also includes the `target.group.name` variable, but the `ListUsers` or `UpdateUser` request doesn't involve specifying a group. There is no `target.group.name` for those requests, so the request is declined.

If you want to also grant access to general user API operations that don't involve a particular group, you would need an additional statement that gives the level of access you want to grant, *but without the condition*. For example, if you want to grant access to `ListUsers`, you need this additional statement:

```
Allow group GroupAdmins to inspect users in tenancy
```

Or if you want to grant access to `UpdateUser`, you need this additional statement (which also covers `ListUsers` because the `use` verb includes the capabilities of the `inspect` verb):

```
Allow group GroupAdmins to use users in tenancy
```

This general concept also applies to groups (e.g., `ListGroups` and `UpdateGroup`), and any other resource type with target variables.

For more information about the syntax of conditions, see Conditions. For a list of all the variables you can use in policies, see the tables in the Policy Reference.

Permissions

Permissions are the atomic units of authorization that control a user's ability to perform operations on resources. Oracle defines all the permissions in the policy language. When you write a policy giving a group access to a particular verb and resource-type, you're actually giving that group access to one or more predefined permissions. The purposes of verbs is to simplify the process of granting multiple related permissions that cover a broad set of access or a particular operational scenario. The next sections give more details and examples.

Relation to Verbs

To understand the relationship between permissions and verbs, let's look at an example. A policy statement that allows a group to `inspect volumes` actually gives the group access to a permission called VOLUME_INSPECT (permissions are always written with all capital letters and underscores). In general, that permission enables the user to get information about block volumes.

As you go from `inspect` > `read` > `use` > `manage`, the level of access generally increases, and the permissions granted are cumulative. The following table shows the permissions included with each verb for the `volumes` resource-type. Notice that no additional permissions are granted going from `inspect` to `read`.

Inspect Volumes	Read Volumes	Use Volumes	Manage Volumes
VOLUME_INSPECT	VOLUME_INSPECT	VOLUME_INSPECT VOLUME_UPDATE VOLUME_WRITE	VOLUME_INSPECT VOLUME_UPDATE VOLUME_WRITE VOLUME_CREATE VOLUME_DELETE

The policy reference lists the permissions covered by each verb for each given resource-type. For example, for block volumes and other resources covered by the Core Services, see the tables in Details for Verb + Resource-Type Combinations. The left column of each of those tables lists the permissions covered by each verb. The other sections of the policy reference include the same kind of information for the other services.

Relation to API Operations

Each API operation requires the caller to have access to one or more permissions. For example, to use either `ListVolumes` or `GetVolume`, you must have access to a single permission: VOLUME_INSPECT. To attach a volume to an instance, you must have access to multiple permissions, some of which are related to the `volumes` resource-type, some to the `volume-attachments` resource-type, and some related to the `instances` resource-type:

- VOLUME_WRITE
- VOLUME_ATTACHMENT_CREATE
- INSTANCE_ATTACH_VOLUME

The policy reference lists which permissions are required for each API operation. For example, for the Core Services API operations, see the table in Permissions Required for Each API Operation.

Understanding a User's Access

The policy language is designed to let you write simple statements involving only verbs and resource-types, without having to state the desired permissions in the statement. However, there may be situations where a security team member or auditor wants to understand the specific permissions a particular user has. The tables in the policy reference show each verb and the associated permissions. You can look at the groups the user is in and the policies applicable to those groups, and from there compile a list of the permissions granted. However, having a list of the permissions isn't the complete picture. Conditions in a policy statement can scope a user's access beyond individual permissions (see the next section). Also, each policy statement specifies a particular compartment and can have conditions that further scope the access to only certain resources in that compartment.

Scoping Access with Permissions or API Operations

In a policy statement, you can use conditions combined with permissions or API operations to reduce the scope of access granted by a particular verb.

For example, let's say you want group XYZ to be able to list, get, create, or update groups (i.e., change their description), but not delete them. To list, get, create, and update groups, you need a policy with `manage groups` as the verb and resource-type. According to the table in Details for Verbs + Resource-Type Combinations, the permissions covered are:

- GROUP_INSPECT
- GROUP_UPDATE
- GROUP_CREATE
- GROUP_DELETE

To restrict access to only the desired permissions, you could add a condition *that explicitly states the permissions you want to allow*:

```
Allow group XYZ to manage groups in tenancy

 where any {request.permission='GROUP_INSPECT',
            request.permission='GROUP_CREATE',
            request.permission='GROUP_UPDATE'}
```

An alternative would be a policy that *allows all permissions except* GROUP_DELETE:

```
Allow group XYZ to manage groups in tenancy where request.permission != 'GROUP_DELETE'
```

However, with this approach, be aware that any new permissions the service might add in the future would automatically be granted to group XYZ. Only GROUP_DELETE would be omitted.

Another alternative would be to write a condition *based on the specific API operations*. Notice that according to the table in Permissions Required for Each API Operation, both `ListGroups` and `GetGroup` require only the GROUP_INSPECT permission. Here's the policy:

```
Allow group XYZ to manage groups in tenancy

 where any {request.operation='ListGroups',
            request.operation='GetGroup',
            request.operation='CreateGroup',
            request.operation='UpdateGroup'}
```

It can be beneficial to use permissions instead of API operations in conditions. In the future, if a new API operation is added that requires one of the permissions listed in the permissions-based policy above, that policy will already control XYZ group's access to that new API operation.

But notice that you can further scope a user's access to a permission by *also* specifying a condition based on API operation. For example, you could give a user access to GROUP_INSPECT, but then only to `ListGroups`.

```
Allow group XYZ to manage groups in tenancy

 where all {request.permission='GROUP_INSPECT',
            request.operation='ListGroups'}
```

Policy Language Version

As mentioned in Policies and Service Updates, by default your policies stay current with any changes to the definitions of verbs and resources as the services change. If you'd prefer to limit access according to the definitions that were current on a specific date, you can do that. When creating a policy, you can specify a date, and that is considered its "version". You can also update the version for an existing policy. For more information, see To create a policy and also To update the version date for an existing policy.

Policy Syntax

The overall syntax of a policy statement is as follows:

```
Allow <subject> to <verb> <resource-type> in <location> where <conditions>
```

Spare spaces or line breaks in the statement have no effect.

For limits on the number of policies and statements, see Service Limits.

Subject

Specify one or more comma-separated groups by name or OCID. Or specify `any-user` to cover all users in the tenancy.

Syntax: `group <group_name> | group id <group_ocid> | dynamic-group <dynamic-group_name> | dynamic-group id<dynamic-group_ocid> | any-user`

Examples:

- To specify a single group by name:

```
Allow group A-Admins to manage all-resources in compartment Project-A
```

- To specify multiple groups by name (a space after the comma is optional):

```
Allow group A-Admins, B-Admins to manage all-resources in compartment Projects-A-and-B
```

- To specify a single group by OCID (the OCID is shortened for brevity):

```
Allow group

 id ocid1.group.oc1..aaaaaaaaqjihfhvxmum...awuc7i5xwe6s7qmnsbc6a

to manage all-resources in compartment Project-A
```

- To specify multiple groups by OCID (the OCIDs are shortened for brevity):

```
Allow group

 id ocid1.group.oc1..aaaaaaaaqjihfhvxmumrl...wuc7i5xwe6s7qmnsbc6a,
 id ocid1.group.oc1..aaaaaaaavhea5mellwzb...66yfxvl462tdgx2oecyq
```

```
to manage all-resources in compartment Projects-A-and-B
```

- To specify any user in the tenancy:

```
Allow any-user to inspect users in tenancy
```

Verb

Specify a single verb. For a list of verbs, see Verbs. Example:

```
Allow group A-Admins to manage all-resources in compartment Project-A
```

Resource-Type

Specify a single resource-type, which can be one of the following:

- An individual resource-type (e.g., `vcns`, `subnets`, `instances`, `volumes`, etc.)
- A family resource-type (e.g., `virtual-network-family`, `instance-family`, `volume-family`, etc.)
- `all-resources`: Covers all resources in the compartment (or tenancy).

A family resource-type covers a variety of components that are typically used together. This makes it easier to write a policy that gives someone access to work with various aspects of your cloud network.

For a list of the available resource-types, see Resource-Types.

Syntax: *<resource_type>* | `all-resources`

Examples:

- To specify a single resource-type:

```
Allow group HelpDesk to manage users in tenancy
```

- To specify multiple resource-types, use separate statements:

```
Allow group A-Users to manage instance-family in compartment Project-A

Allow group A-Users to manage volume-family in compartment Project-A
```

- To specify all resources in the compartment (or tenancy):

```
Allow group A-Admins to manage all-resources in compartment Project-A
```

Location

Specify a single compartment or compartment path by name or OCID. Or simply specify `tenancy` to cover the entire tenancy. Remember that users, groups, and compartments reside in the tenancy. Policies can reside in (i.e., be attached to) either the tenancy or a child compartment.

Note

Granting Access to Specific Regions or Availability Domains

To create a policy that gives access to a specific region or availability domain, use the `request.region` or `request.ad` variable with a condition. See Conditions.

The location is required in the statement. If you want to attach a policy to a compartment, you must be in that compartment when you create the policy. For more information, see Policy Attachment.

To specify a compartment that is not a direct child of the compartment you are attaching the policy to, specify the path to the compartment, using the colon (:) as a separator. For more information, see Policies and Compartment Hierarchies.

Syntax: `[ tenancy | compartment <compartment_name> | compartment id <compartment_ocid> ]`

Examples:

- To specify a compartment by name:

```
Allow group A-Admins to manage all-resources in compartment Project-A
```

- To specify a compartment by OCID:

```
Allow group
 id ocid1.group.oc1..aaaaaaaavhea5mellwzbmplwrpum46xfc73sb4rm66yfxvl462tdgx2oecyq

to manage all-resources in compartment
 id ocid1.compartment.oc1..aaaaaaaayzfq...4fmameqh7lcdlihrvur7xq
```

- To specify multiple compartments, use separate statements:

```
Allow group InstanceAdmins to manage instance-family in compartment Project-A

Allow group InstanceAdmins to manage instance-family in compartment Project-B
```

- To specify multiple compartments by OCID, use separate statements:

```
Allow group id
 ocd1.group.oc1..aaaaaaaavhea5mell...b4rm66yfxvl462tdgx2oecyq
to manage all-resources in compartment id
 ocid1.compartment.oc1..aaaaaaaayzfqei...ameq4h7lcdlihrvur7xq

Allow group id
 ocd1.group.oc1..aaaaaaaavhea5mell...b4rm66yfxvl462tdgx2oecyq
to manage all-resources in compartment id
 ocid1.compartment.oc1..aaaaaaaaphfjutov5s...vyypllbtctehnqg756a
```

- To specify a compartment that is not a direct child of the compartment where you are attaching the policy, specify the path:

```
Allow group InstanceAdmins to manage instance-family in compartment Project-A:Project-A2
```

Conditions

Specify one or more conditions. Use `any` or `all` with multiple conditions for a logical OR or AND, respectively.

Syntax for a single condition: `variable =|!= value`

Syntax for multiple conditions: `any|all {<condition>,<condition>,...}`

Important

Condition matching is case insensitive. This is important to remember when writing conditions for resource types that allow case-sensitive naming. For example, the Object Storage service allows you to create both a bucket named "BucketA" and a bucket named "bucketA" in the same compartment. If you write a condition that specifies "BucketA", it will apply also to "bucketA", because the condition matching is case insensitive.

For a list of variables supported by all the services, see General Variables for All Requests. Also see the details for each service in the Policy Reference. Here are the types of values you can use in conditions:

Type	Examples
String	`'johnsmith@example.com'` `'ocid1.compartment.oc1..aaaaaaaaph...ctehnqg756a'` (single quotation marks are required around the value)
Pattern	`/HR*/` (matches strings that start with "HR") `/*HR/` (matches strings that end with "HR") `/*HR*/` (matches strings that contain "HR")

Examples:

Note

In the following examples, the statements that specify the condition do not let GroupAdmins actually list all the users and groups, therefore statements including the `inspect` verb are added for completeness. To understand why this is required, see Variables that Aren't Applicable to a Request Result in a Declined Request.

- A single condition.
  The following policy enables the GroupAdmins group to create, update, or delete any groups with names that start with "A-Users-":

```
Allow group GroupAdmins to manage groups in tenancy where target.group.name = /A-Users-*/
Allow group GroupAdmins to inspect groups in tenancy
```

  The following policy enables the GroupAdmins group to manage the membership of any group besides the Administrators group. (Note that you must include separate statements for `inspect`access because the `target.group.name` variable is not used by the ListUsers and ListGroups operations):

```
Allow group GroupAdmins to inspect users in tenancy

Allow group GroupAdmins to use users in tenancy where target.group.name != 'Administrators'

Allow group GroupAdmins to inspect groups in tenancy

Allow group GroupAdmins to use groups in tenancy where target.group.name != 'Administrators'
```

  The following policy enables the NetworkAdmins group to manage cloud networks in any compartment except the one specified:

```
Allow group NetworkAdmins to manage virtual-network-family in tenancy where target.compartment.id
!= 'ocid1.compartment.oc1..aaaaaaaayzfqeibduyox6icmdol6zyar3ugly4fmameq4h7lcdlihrvur7xq'
```

- Multiple conditions.
  The following policy lets GroupAdmins create, update, or delete any groups whose names start with "A-", except for the A-Admins group itself:

```
Allow group GroupAdmins to manage groups in tenancy where  all {target.group.name=/A-
*/,target.group.name!='A-Admins'}

Allow group GroupAdmins to inspect groups in tenancy
```

Policy Reference

This reference includes:

- Verbs: A list of the available actions to pair with a resource-type
- Resource-Types: A list of the main resource-types
- General Variables for All Requests: Variables you can use when writing policies for any resource-type

Verbs

The verbs are listed in order of least amount of ability to most. The exact meaning of a each verb depends on which resource-type it's paired with. The tables later in this section show the API operations covered by each combination of verb and resource-type.

Verb	Types of Access Covered	Target User
`inspect`	Ability to list resources, without access to any confidential information or user-specified metadata that may be part of that resource. **Important:** The operation to list policies includes the contents of the policies themselves, and the list operations for the Networking resource-types return all the information (e.g., the contents of security lists and route tables).	Third-party auditors
`read`	Includes `inspect` plus the ability to get user-specified metadata and the actual resource itself.	Internal auditors

Verb	Types of Access Covered	Target User
`use`	Includes `read` plus the ability to work with existing resources (the actions vary by resource type). Includes the ability to update the resource, except for resource-types where the "update" operation has the same effective impact as the "create" operation (e.g., `UpdatePolicy`, `UpdateSecurityList`, etc.), in which case the "update" ability is available only with the `manage` verb. In general, this verb does not include the ability to create or delete that type of resource.	Day-to-day end users of resources
`manage`	Includes all permissions for the resource.	Administrators

Resource-Types

The family resource-types are listed below. For the individual resource-types that make up each family, follow the links.

- `all-resources`: All Oracle Cloud Infrastructure resource-types
- `cluster-family`: See Details for Container Engine for Kubernetes
- `database-family`: See Details for the Database Service
- `dns`: See Details for the DNS Service
- `file-family`: See Details for the File Storage Service
- `instance-family`: See Details for the Core Services
- `object-family`: See Details for Object Storage, Archive Storage, and Data Transfer
- `virtual-network-family`: See Details for the Core Services
- `volume-family`: See Details for the Core Services

IAM has no family resource-type, only individual ones. See Details for IAM.

General Variables for All Requests

You use variables when adding conditions to a policy. For more information, see Conditions. Here are the general variables applicable to all requests.

Name	Type	Description
`request.user.id`	Entity (OCID)	The OCID of the requesting user.
`request.user.mfaTotpVerified`	Boolean	Whether the user has been verified by multi-factor authentication (MFA). To restrict access to only MFA-verified users, add the condition `where request.user.mfaTotpVerified ='true'` See Managing Multi-Factor Authentication for information on setting up MFA.
`request.groups.id`	List of entities (OCIDs)	The OCIDs of the groups the requesting user is in.
`target.compartment.id`	Entity (OCID)	The OCID of the compartment containing the primary resource. **Note:** `target.compartment.id` and `target.compartment.name` cannot be used with a "List" API operation to filter the list based on the requesting user's access to the compartment.

Name	Type	Description
`target.compartment.name`	String	The name of the compartment specified in `target.compartment.id`.
`request.operation`	String	The API operation name being requested (for example, ListUsers).
`request.permission`	String	The underlying permission being requested (see Permissions).

Name	Type	Description
`request.region`	String	The 3-letter key for the region the request is made in. Allowed values are: • BOM - use for India West (Mumbai) • FRA - use for Germany Central (Frankfurt) • GRU - use for Brazil East (Sao Paulo) • IAD - use for US East (Ashburn) • ICN - use for South Korea Central (Seoul) • LHR - use for UK South (London) • NRT - use for Japan East (Tokyo) • PHX - use for US West (Phoenix) • SYD - use for Australia East (Sydney) • YYZ - use for Canada Southeast (Toronto) • ZRH - use for Switzerland North (Zurich)
`request.ad`	String	The name of the availability domain the request is made in. To get a list of availability domain names, use the ListAvailabilityDomains operation.

Details for Analytics Cloud

For the details for writing policies to control access to Analytics Cloud, see Details for Analytics Cloud.

Details for the Announcements Service

This topic covers details for writing policies to control access to the Announcements service.

Resource-Types

- `announcements`

Supported Variables

Only the general variables are supported (see General Variables for All Requests).

Details for Verb + Resource-Type Combinations

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from `inspect` > `read` > `use` > `manage`. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

For example, the `read` verb for the `announcements` resource-type includes the same permissions and API operations as the `inspect` verb, plus the ANNOUNCEMENT_READ permission and an additional API operation, `GetAnnouncement`. However, the `use` verb and `manage` verbs cover no extra permissions or API operations compared to `read`.

announcements

INSPECT

Permissions	APIs Fully Covered	APIs Partially Covered
ANNOUNCEMENT_LIST	`ListAnnouncements`	*none*

READ

Permissions	APIs Fully Covered	APIs Partially Covered
INSPECT + ANNOUNCEMENT_READ	*INSPECT +* `GetAnnouncement`	*none*

USE

Permissions	APIs Fully Covered	APIs Partially Covered
no extra	*no extra*	*none*

MANAGE

Permissions	APIs Fully Covered	APIs Partially Covered
no extra	*no extra*	*none*

Permissions Required for Each API Operation

The following table lists the API operations in a logical order, grouped by resource type.

For information about permissions, see Permissions.

API Operation	Permissions Required to Use the Operation
`ListAnnouncements`	ANNOUNCEMENT_LIST
`GetAnnouncement`	ANNOUNCEMENT_READ

Details for the Audit Service

This topic covers details for writing policies to control access to the Audit service.

Resource-Types

```
audit-events
```

Supported Variables

Only the general variables are supported (see General Variables for All Requests).

Details for Verb + Resource-Type Combinations

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from `inspect` > `read` > `use` > `manage`. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

For example, the `use` and `manage` verbs for the `audit-events` resource-type cover no extra permissions or API operations compared to the `read` verb.

AUDIT-EVENTS

Permissions Required for Each API Operation

The following table lists the API operations in a logical order, grouped by resource type.

For information about permissions, see Permissions.

API Operation	Permissions Required to Use the Operation
`ListEvents`	AUDIT_EVENT_READ

Details for the Core Services

This topic covers details for writing policies to control access to the Core Services (Networking, Compute, and Block Volume).

Resource-Types

Networking

AGGREGATE RESOURCE-TYPE

```
virtual-network-family
```

INDIVIDUAL RESOURCE-TYPES

```
vcns
subnets
route-tables
network-security-groups
security-lists
dhcp-options
private-ips
public-ips
ipv6s
internet-gateways
```

- `nat-gateways`
- `service-gateways`
- `local-peering-gateways` (which includes `local-peering-from`, and `local-peering-to`)
- `remote-peering-connections` (which includes `remote-peering-from`, and `remote-peering-to`)
- `drgs`
- `drg-attachments`
- `cpes`
- `ipsec-connections`
- `cross-connects`
- `cross-connect-groups`
- `virtual-circuits`
- `vnics`
- `vnic-attachments`

COMMENTS

A policy that uses `<verb> virtual-network-family` is equivalent to writing one with a separate `<verb> <individual resource-type>` statement for each of the individual resource-types.

See the table in Details for Verb + Resource-Type Combinations for a detailed breakout of the API operations covered by each verb, for each individual resource-type included in `virtual-network-family`.

Compute

INSTANCE-FAMILY AGGREGATE RESOURCE-TYPE

The `instance-family` aggregate resource-type covers these individual resource-types:

- `app-catalog-listing`
- `console-histories`
- `instances`
- `instance-console-connection`
- `instance-images`
- `volume-attachments` (includes only the permissions required for attaching volumes to instances)

COMPUTE-MANAGEMENT-FAMILY AGGREGATE RESOURCE-TYPE

The `compute-management-family` aggregate resource-type covers these individual resource-types:

- `instance-configurations`
- `instance-pools`
- `cluster-networks`

ADDITIONAL INDIVIDUAL RESOURCE-TYPES

- `auto-scaling-configurations`
- `work-requests`
- `dedicated-vm-hosts`

COMMENTS

A policy that uses `<verb> instance-family` or `<verb> compute-management-family` is equivalent to writing one with a separate `<verb> <individual resource-type>` statement for each of the individual resource-types in the family.

See the table in Details for Verb + Resource-Type Combinations for a detailed breakout of the API operations covered by each verb, for each individual resource-type.

Block Volume

AGGREGATE RESOURCE-TYPE

`volume-family`

INDIVIDUAL RESOURCE-TYPES

`volumes`

`volume-attachments`

`volume-backups`

`boot-volume-backups`

`backup-policies`

`backup-policy-assignments`

`volume-groups`

`volume-group-backups`

COMMENTS

A policy that uses `<verb> volume-family` is equivalent to writing one with a separate `<verb> <individual resource-type>` statement for each of the individual resource-types.

See the table in Details for Verb + Resource-Type Combinations for a detailed breakout of the API operations covered by each verb, for each individual resource-type included in `volume-family`.

Supported Variables

The Core Services support all the general variables, plus the ones listed here. For more information about general variables supported by Oracle Cloud Infrastructure services, see General Variables for All Requests.

Variable	Variable Type	Comments
`target.boot-volume.kms-key.id`	String	Use this variable to control whether Compute instances can be launched with boot volumes that were created without a Key Management master encryption key.

Details for Verb + Resource-Type Combinations

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from `inspect` > `read` > `use` > `manage`. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

For example, the `read` and `use` verbs for the `vcns` resource-type cover no extra permissions or API operations compared to the `inspect` verb. However, the `manage` verb includes several extra permissions and API operations.

FOR VIRTUAL-NETWORK-FAMILY RESOURCE TYPES

vcns

INSPECT

Permissions	APIs Fully Covered	APIs Partially Covered
VCN_READ	`ListVcns` `GetVcn`	`CreateNatGateway, DeleteNatGateway` (both also need `manage nat-gateways` and `manage vcns`) **Note:** The above operations in this cell are totally covered with just `manage virtual-network-family`.

FOR INSTANCE-FAMILY RESOURCE TYPES

The `instance-family` aggregate resource-type includes extra permissions beyond the sum of the permissions for the individual resource-types included in `instance-family`. For example: It includes a few permissions for `vnics` and `volumes`, even though those resource-types aren't generally considered part of the `instance-family`. Why are there extras included? So you can write fewer policy statements to cover general use cases, like working with an instance that has an attached block volume. You can write one statement for `instance-family` instead of multiple statements covering `instances`, `vnics`, and `volumes`.

Here's a list of the extra permissions:

For `inspect instance-family`:

- VNIC_READ
- VNIC_ATTACHMENT_READ
- VOLUME_ATTACHMENT_INSPECT

For `read instance-family`:

- VOLUME_ATTACHMENT_READ

For `use instance-family`:

- VNIC_ATTACH
- VNIC_DETACH
- VOLUME_ATTACHMENT_UPDATE

For `manage instance-family`:

- VOLUME_ATTACHMENT_CREATE
- VOLUME_ATTACHMENT_DELETE

The following tables list the permissions and API operations covered by each of the individual resource-types included in `instance-family`.

instances

INSPECT

Permissions	APIs Fully Covered	APIs Partially Covered
INSTANCE_INSPECT	*none*	`GetConsoleHistory`, `ListConsoleHistories` (both also need `inspect console-histories`) `ListVnicAttachments` (also need `inspect vnic-attachments`) `ListVolumeAttachments` (also need `inspect volumes` and `inspect volume-attachments`) `GetVolumeAttachments` (also need `inspect volumes` and `inspect volume-attachments`)

READ

Permissions	APIs Fully Covered	APIs Partially Covered
INSPECT + INSTANCE_READ	`ListInstances` `GetInstance` **Note:** `ListInstances` and `GetInstance` include any user-provided metadata added to the instance	*INSPECT* + `CaptureConsoleHistory` (also need `manage console-histories` and `read instance-images`) `ShowConsoleHistoryData` (also need `read console-histories` and `read instance-images`) `CreateInstanceConfiguration` (if using the `CreateInstanceConfigurationFromInstanceDetails` subtype. Also need `inspect vnics`, `inspect vnic-attachments`, `inspect volumes`, and `inspect volume-attachments`.)

USE

Permissions Required for Each API Operation

The following tables list the API operations grouped by resource type. The resource types are listed in alphabetical order.

For information about permissions, see Permissions.

CORE SERVICES API OPERATIONS

API Operation	Permissions Required to Use the Operation
CreateVolumeBackupPolicy	BACKUP_POLICIES_CREATE
DeleteVolumeBackupPolicy	BACKUP_POLICIES_DELETE
GetVolumeBackupPolicy	BACKUP_POLICIES_INSPECT
ListVolumeBackupPolicies	BACKUP_POLICIES_INSPECT
CreateVolumeBackupPolicyAssignment	BACKUP_POLICY_ASSIGNMENT_CREATE
DeleteVolumeBackupPolicyAssignment	BACKUP_POLICY_ASSIGNMENT_DELETE
GetVolumeBackupPolicyAssetAssignment	BACKUP_POLICY_ASSIGNMENT_INSPECT and VOLUME_INSPECT
GetVolumeBackupPolicyAssignment	BACKUP_POLICY_ASSIGNMENT_INSPECT
ListClusterNetworks	CLUSTER_NETWORK_INSPECT and INSTANCE_POOL_INSPECT
ListClusterNetworkInstances	CLUSTER_NETWORK_READ and INSTANCE_POOL_READ
GetClusterNetwork	CLUSTER_NETWORK_READ and INSTANCE_POOL_READ
UpdateClusterNetwork	CLUSTER_NETWORK_UPDATE

API Operation	Permissions Required to Use the Operation
`CreateClusterNetwork`	CLUSTER_NETWORK_CREATE and INSTANCE_POOL_CREATE
`ChangeClusterNetworkCompartment`	CLUSTER_NETWORK_MOVE
`TerminateClusterNetwork`	CLUSTER_NETWORK_DELETE and INSTANCE_POOL_DELETE
`ListConsoleHistories`	CONSOLE_HISTORY_READ and INSTANCE_INSPECT
`GetConsoleHistory`	CONSOLE_HISTORY_READ and INSTANCE_INSPECT
`ShowConsoleHistoryData`	CONSOLE_HISTORY_READ and INSTANCE_READ and INSTANCE_IMAGE_READ
`CaptureConsoleHistory`	CONSOLE_HISTORY_CREATE and INSTANCE_READ and INSTANCE_IMAGE_READ
`DeleteConsoleHistory`	CONSOLE_HISTORY_DELETE
`ListCpes`	CPE_READ
`GetCpe`	CPE_READ
`UpdateCpe`	CPE_UPDATE
`CreateCpe`	CPE_CREATE
`DeleteCpe`	CPE_DELETE
`ChangeCpeCompartment`	CPE_RESOURCE_MOVE

API Operation	Permissions Required to Use the Operation
`ListCrossConnects`	CROSS_CONNECT_READ
`GetCrossConnect`	CROSS_CONNECT_READ
`UpdateCrossConnect`	CROSS_CONNECT_UPDATE
`CreateCrossConnect`	CROSS_CONNECT_CREATE if not creating cross-connect in a cross-connect group. If creating the cross-connect in a cross-connect group, also need CROSS_CONNECT_CREATE and CROSS_CONNECT_ATTACH
`DeleteCrossConnect`	CROSS_CONNECT_DELETE if cross-connect is not in a cross-connect group. If the cross-connect is in a cross-connect group, also need CROSS_CONNECT_DELETE and CROSS_CONNECT_DETACH
`ChangeCrossConnectCompartment`	CROSS_CONNECT_RESOURCE_MOVE
`ListCrossConnectGroups`	CROSS_CONNECT_GROUP_READ
`GetCrossConnectGroup`	CROSS_CONNECT_GROUP_READ
`UpdateCrossConnectGroup`	CROSS_CONNECT_GROUP_UPDATE
`CreateCrossConnectGroup`	CROSS_CONNECT_GROUP_CREATE
`DeleteCrossConnectGroup`	CROSS_CONNECT_GROUP_DELETE
`ChangeCrossConnectGroupCompartment`	CROSS_CONNECT_GROUP_RESOURCE_MOVE
`ListDhcpOptions`	DHCP_READ

API Operation	Permissions Required to Use the Operation
`GetDhcpOptions`	DHCP_READ
`UpdateDhcpOptions`	DHCP_UPDATE
`CreateDhcpOptions`	DHCP_CREATE and VCN_ATTACH
`DeleteDhcpOptions`	DHCP_DELETE and VCN_DETACH
`ChangeDhcpOptionsCompartment`	DHCP_MOVE
`ListDrgs`	DRG_READ
`GetDrg`	DRG_READ
`UpdateDrg`	DRG_UPDATE
`CreateDrg`	DRG_CREATE
`DeleteDrg`	DRG_DELETE
`ChangeDrgCompartment`	DRG_MOVE
`ListDrgAttachments`	DRG_ATTACHMENT_READ
`GetDrgAttachment`	DRG_ATTACHMENT_READ
`UpdateDrgAttachment`	DRG_ATTACHMENT_UPDATE ROUTE_TABLE_ATTACH is necessary to associate a route table with the DRG attachment during the update.

API Operation	Permissions Required to Use the Operation
`CreateDrgAttachment`	DRG_ATTACH and VCN_ATTACH ROUTE_TABLE_ATTACH is necessary to associate a route table with the DRG attachment during creation.
`DeleteDrgAttachment`	DRG_DETACH and VCN_DETACH
`CreateInstanceConsoleConnection`	INSTANCE_CONSOLE_CONNECTION_CREATE and INSTANCE_READ
`DeleteInstanceConsoleConnection`	INSTANCE_CONSOLE_CONNECTION_DELETE
`GetInstanceConsoleConnection`	INSTANCE_CONSOLE_CONNECTION_READ and INSTANCE_READ
`ListInstanceConsoleConnections`	INSTANCE_CONSOLE_CONNECTION_INSPECT and INSTANCE_INSPECT and INSTANCE_READ
`ListImages`	INSTANCE_IMAGE_READ
`GetImage`	INSTANCE_IMAGE_READ
`UpdateImage`	INSTANCE_IMAGE_UPDATE
`CreateImage`	INSTANCE_IMAGE_CREATE and INSTANCE_CREATE_IMAGE The first permission is related to the `instance-image`; the second is related to the `instance`.
`ChangeImageCompartment`	INSTANCE_IMAGE_MOVE
`DeleteImage`	INSTANCE_IMAGE_DELETE

API Operation	Permissions Required to Use the Operation
`ListInstances`	INSTANCE_READ
`GetInstance`	INSTANCE_READ
`LaunchInstance`	INSTANCE_CREATE and INSTANCE_IMAGE_READ and VNIC_CREATE and VNIC_ATTACH and SUBNET_ATTACH If putting the instance in a network security group during instance creation, also need NETWORK_SECURITY_GROUP_UPDATE_MEMBERS and VNIC_ASSOCIATE_NETWORK_SECURITY_GROUP
`UpdateInstance`	INSTANCE_UPDATE
`InstanceAction`	INSTANCE_POWER_ACTIONS
`ChangeInstanceCompartment`	INSTANCE_MOVE
`TerminateInstance`	INSTANCE_DELETE and VNIC_DELETE and SUBNET_DETACH
`ListInstanceConfigurations`	INSTANCE_CONFIGURATION_INSPECT
`GetInstanceConfiguration`	INSTANCE_CONFIGURATION_READ
`LaunchInstanceConfiguration`	INSTANCE_CONFIGURATION_LAUNCH
`UpdateInstanceConfiguration`	INSTANCE_CONFIGURATION_UPDATE

API Operation	Permissions Required to Use the Operation
`CreateInstanceConfiguration`	INSTANCE_CONFIGURATION_CREATE (if using the `CreateInstanceConfigurationDetails` subtype) INSTANCE_READ and VNIC_READ and VNIC_ATTACHMENT_READ and VOLUME_INSPECT and VOLUME_ATTACHMENT_INSPECT (if using the `CreateInstanceConfigurationFromInstanceDetails` subtype)
`ChangeInstanceConfigurationCompartment`	INSTANCE_CONFIGURATION_MOVE
`DeleteInstanceConfiguration`	INSTANCE_CONFIGURATION_DELETE
`ListInstancePools`	INSTANCE_POOL_INSPECT
`ListInstancePoolInstances`	INSTANCE_POOL_READ
`GetInstancePool`	INSTANCE_POOL_READ
`UpdateInstancePool`	INSTANCE_POOL_UPDATE
`ResetInstancePool`	INSTANCE_POOL_POWER_ACTIONS
`SoftresetInstancePool`	INSTANCE_POOL_POWER_ACTIONS
`StartInstancePool`	INSTANCE_POOL_POWER_ACTIONS
`StopInstancePool`	INSTANCE_POOL_POWER_ACTIONS
`CreateInstancePool`	INSTANCE_POOL_CREATE and INSTANCE_CREATE and IMAGE_READ and VNIC_CREATE and SUBNET_ATTACH

API Operation	Permissions Required to Use the Operation
ChangeInstancePoolCompartment	INSTANCE_POOL_MOVE
TerminateInstancePool	INSTANCE_POOL_DELETE and INSTANCE_DELETE and VNIC_DELETE and SUBNET_DETACH and VOLUME_ATTACHMENT_DELETE and VOLUME_WRITE
ListInternetGateways	INTERNET_GATEWAY_READ
GetInternetGateway	INTERNET_GATEWAY_READ
UpdateInternetGateway	INTERNET_GATEWAY_UPDATE
CreateInternetGateway	INTERNET_GATEWAY_CREATE and VCN_ATTACH
DeleteInternetGateway	INTERNET_GATEWAY_DELETE and VCN_DETACH
ChangeInternetGatewayCompartment	INTERNET_GATEWAY_MOVE
ListIPSecConnections	IPSEC_CONNECTION_READ
GetIPSecConnection	IPSEC_CONNECTION_READ
UpdateIpSecConnection	IPSEC_CONNECTION_UPDATE
CreateIPSecConnection	DRG_ATTACH and CPE_ATTACH and IPSEC_CONNECTION_CREATE
DeleteIPSecConnection	DRG_DETACH and CPE_DETACH and IPSEC_CONNECTION_DELETE
GetIPSecConnectionDeviceConfig	IPSEC_CONNECTION_DEVICE_CONFIG_READ

API Operation	Permissions Required to Use the Operation
GetIPSecConnectionDeviceStatus	IPSEC_CONNECTION_READ
ListIPSecConnectionTunnels	IPSEC_CONNECTION_READ
GetIPSecConnectionTunnel	IPSEC_CONNECTION_READ
UpdateIPSecConnectionTunnel	IPSEC_CONNECTION_UPDATE
GetIPSecConnectionTunnelSharedSecret	IPSEC_CONNECTION_DEVICE_CONFIG_READ
UpdateIPSecConnectionTunnelSharedSecret	IPSEC_CONNECTION_DEVICE_CONFIG_UPDATE
ListIpv6s	IPV6_READ and SUBNET_READ (if listing by subnet) and VNIC_READ (if listing by VNIC)
GetIpv6	IPV6_READ
UpdateIpv6	IPV6_UPDATE and VNIC_UNASSIGN and VNIC_ASSIGN (if moving IPv6 to a different VNIC)
CreateIpv6	IPV6_CREATE and SUBNET_ATTACH and VNIC_ASSIGN
DeleteIpv6	IPV6_DELETE and SUBNET_DETACH and VNIC_UNASSIGN
ListLocalPeeringGateways	LOCAL_PEERING_GATEWAY_READ
GetLocalPeeringGateway	LOCAL_PEERING_GATEWAY_READ

API Operation	Permissions Required to Use the Operation
`UpdateLocalPeeringGateway`	LOCAL_PEERING_GATEWAY_UPDATE ROUTE_TABLE_ATTACH is necessary to associate a route table with the LPG during the update.
`CreateLocalPeeringGateway`	LOCAL_PEERING_GATEWAY_CREATE and VCN_ATTACH ROUTE_TABLE_ATTACH is necessary to associate a route table with the LPG during creation.
`DeleteLocalPeeringGateway`	LOCAL_PEERING_GATEWAY_DELETE and VCN_DETACH
`ConnectLocalPeeringGateway`	LOCAL_PEERING_GATEWAY_CONNECT_FROM and LOCAL_PEERING_GATEWAY_CONNECT_TO
`ChangeLocalPeeringGatewayCompartment`	LOCAL_PEERING_GATEWAY_MOVE
`ListNatGateways`	NAT_GATEWAY_READ
`GetNatGateway`	NAT_GATEWAY_READ
`UpdateNatGateway`	NAT_GATEWAY_UPDATE
`CreateNatGateway`	NAT_GATEWAY_CREATE and VCN_READ and VCN_ATTACH

API Operation	Permissions Required to Use the Operation
DeleteNatGateway	NAT_GATEWAY_DELETE and VCN_READ and VCN_DETACH
ChangeNatGatewayCompartment	NAT_GATEWAY_MOVE
ListNetworkSecurityGroups	NETWORK_SECURITY_GROUP_READ
GetNetworkSecurityGroup	NETWORK_SECURITY_GROUP_READ
UpdateNetworkSecurityGroup	NETWORK_SECURITY_GROUP_UPDATE
CreateNetworkSecurityGroup	NETWORK_SECURITY_GROUP_CREATE and VCN_ATTACH
DeleteNetworkSecurityGroup	NETWORK_SECURITY_GROUP_DELETE and VCN_DETACH
ChangeNetworkSecurityGroupCompartment	NETWORK_SECURITY_GROUP_MOVE
ListNetworkSecurityGroupSecurityRules	NETWORK_SECURITY_GROUP_LIST_SECURITY_RULES
UpdateNetworkSecurityGroupSecurityRules	NETWORK_SECURITY_GROUP_UPDATE_SECURITY_RULES and NETWORK_SECURITY_GROUP_INSPECT if writing a rule that specifies a network security group as the source (for ingress rules) or destination (for egress rules)

API Operation	Permissions Required to Use the Operation
AddNetworkSecurityGroupSecurityRules	NETWORK_SECURITY_GROUP_UPDATE_SECURITY_RULES and NETWORK_SECURITY_GROUP_INSPECT if writing a rule that specifies a network security group as the source (for ingress rules) or destination (for egress rules)
RemoveNetworkSecurityGroupSecurityRules	NETWORK_SECURITY_GROUP_UPDATE_SECURITY_RULES
ListPrivateIps	PRIVATE_IP_READ
GetPrivateIp	PRIVATE_IP_READ
UpdatePrivateIp	PRIVATE_IP_UPDATE
CreatePrivateIp	PRIVATE_IP_CREATE and PRIVATE_IP_ASSIGN and VNIC_ASSIGN and SUBNET_ATTACH
DeletePrivateIp	PRIVATE_IP_DELETE and PRIVATE_IP_UNASSIGN and VNIC_UNASSIGN and SUBNET_DETACH
ListRemotePeeringConnections	REMOTE_PEERING_CONNECTION_READ
GetRemotePeeringConnection	REMOTE_PEERING_CONNECTION_READ
UpdateRemotePeeringConnection	REMOTE_PEERING_CONNECTION_UPDATE
CreateRemotePeeringConnection	REMOTE_PEERING_CONNECTION_CREATE and DRG_ATTACH

API Operation	Permissions Required to Use the Operation
DeleteRemotePeeringConnection	REMOTE_PEERING_CONNECTION_DELETE and DRG_DETACH
ChangeRemotePeeringConnectionCompartment	REMOTE_PEERING_CONNECTION_RESOURCE_MOVE
ConnectRemotePeeringConnections	REMOTE_PEERING_CONNECTION_CONNECT_FROM and REMOTE_PEERING_CONNECTION_CONNECT_TO
ListPublicIps	For ephemeral public IPs: PRIVATE_IP_READ For reserved public IPs: PUBLIC_IP_READ
GetPublicIp	For ephemeral public IPs: PRIVATE_IP_READ For reserved public IPs: PUBLIC_IP_READ
GetPublicIpByPrivateIpId	For ephemeral public IPs: PRIVATE_IP_READ For reserved public IPs: PUBLIC_IP_READ
GetPublicIpByIpAddress	For ephemeral public IPs: PRIVATE_IP_READ For reserved public IPs: PUBLIC_IP_READ
UpdatePublicIP	For ephemeral public IPs: PRIVATE_IP_UPDATE For reserved public IPs: PUBLIC_IP_UPDATE and PRIVATE_IP_ASSIGN_PUBLIC_IP and PUBLIC_IP_ASSIGN_PRIVATE_IP and PRIVATE_IP_UNASSIGN_PUBLIC_IP and PUBLIC_IP_UNASSIGN_PRIVATE_IP

API Operation	Permissions Required to Use the Operation
`CreatePublicIp`	For ephemeral public IPs: PRIVATE_IP_ ASSIGN_PUBLIC_IP For reserved public IPs: PUBLIC_IP_CREATE and PUBLIC_IP_ASSIGN_PRIVATE_IP and PRIVATE_IP_ASSIGN_PUBLIC_IP
`DeletePublicIp`	For ephemeral public IPs: PRIVATE_IP_ UNASSIGN_PUBLIC_IP For reserved public IPs: PUBLIC_IP_DELETE and PUBLIC_IP_UNASSIGN_PRIVATE_IP and PRIVATE_IP_UNASSIGN_PUBLIC_IP
`ChangePublicIpCompartment`	PUBLIC_IP_MOVE Note: This operation applies only to reserved public IPs.
`ListRouteTables`	ROUTE_TABLE_READ
`GetRouteTable`	ROUTE_TABLE_READ

API Operation	Permissions Required to Use the Operation
`UpdateRouteTable`	ROUTE_TABLE_UPDATE and INTERNET_GATEWAY_ATTACH (if creating a route rule that uses an internet gateway as a target) and INTERNET_GATEWAY_DETACH (if deleting a route rule that uses an internet gateway as a target) and DRG_ATTACH (if creating a route rule that uses a DRG as a target) and DRG_DETACH (if deleting a route rule that uses a DRG as a target) and PRIVATE_IP_ROUTE_TABLE_ATTACH (if creating a route rule that uses a private IP as a target) and PRIVATE_IP_ROUTE_TABLE_DETACH (if deleting a route rule that uses a private IP as a target) and LOCAL_PEERING_GATEWAY_ATTACH (if creating a route rule that uses an LPG as a target) and LOCAL_PEERING_GATEWAY_DETACH (if deleting a route rule that uses an LPG as a target) and NAT_GATEWAY_ATTACH (if creating a route rule that uses a NAT gateway as a target) and NAT_GATEWAY_DETACH (if deleting a route

API Operation	Permissions Required to Use the Operation
	rule that uses a NAT gateway as a target) and SERVICE_GATEWAY_ATTACH (if creating a route rule that uses a service gateway as a target) and SERVICE_GATEWAY_DETACH (if deleting a route rule that uses a service gateway as a target)
`CreateRouteTable`	ROUTE_TABLE_CREATE and VCN_ATTACH and INTERNET_GATEWAY_ATTACH (if creating a route rule that uses an internet gateway as a target) and DRG_ATTACH (if creating a route rule that uses a DRG as a target) and PRIVATE_IP_ROUTE_TABLE_ATTACH (if creating a route rule that uses a private IP as a target) and LOCAL_PEERING_GATEWAY_ATTACH (if creating a route rule that uses an LPG as a target) and NAT_GATEWAY_ATTACH (if creating a route rule that uses a NAT gateway as a target) and SERVICE_GATEWAY_ATTACH (if creating a route rule that uses a service gateway as a target)

API Operation	Permissions Required to Use the Operation
`DeleteRouteTable`	ROUTE_TABLE_DELETE and VCN_DETACH and INTERNET_GATEWAY_DETACH (if deleting a route rule that uses an internet gateway as a target) and DRG_DETACH (if deleting a route rule that uses a DRG as a target) and PRIVATE_IP_ROUTE_TABLE_DETACH (if deleting a route rule that uses a private IP as a target) and LOCAL_PEERING_GATEWAY_DETACH (if deleting a route rule that uses an LPG as a target) and NAT_GATEWAY_DETACH (if deleting a route rule that uses a NAT gateway as a target) and SERVICE_GATEWAY_DETACH (if deleting a route rule that uses a service gateway as a target)
`ChangeRouteTableCompartment`	ROUTE_TABLE_MOVE
`ListSecurityLists`	SECURITY_LIST_READ
`GetSecurityList`	SECURITY_LIST_READ
`UpdateSecurityList`	SECURITY_LIST_UPDATE
`ChangeSecurityListCompartment`	SECURITY_LIST_MOVE
`CreateSecurityList`	SECURITY_LIST_CREATE and VCN_ATTACH

API Operation	Permissions Required to Use the Operation
`DeleteSecurityList`	SECURITY_LIST_DELETE and VCN_DETACH
`ListServiceGateways`	SERVICE_GATEWAY_READ
`GetServiceGateway`	SERVICE_GATEWAY_READ
`UpdateServiceGateway`	SERVICE_GATEWAY_UPDATE ROUTE_TABLE_ATTACH is necessary to associate a route table with the service gateway during the update.
`ChangeServiceGatewayCompartment`	SERVICE_GATEWAY_MOVE
`CreateServiceGateway`	SERVICE_GATEWAY_CREATE and VCN_READ and VCN_ATTACH ROUTE_TABLE_ATTACH is necessary to associate a route table with the service gateway during creation.
`DeleteServiceGateway`	SERVICE_GATEWAY_DELETE and VCN_READ and VCN_DETACH
`AttachServiceId`	SERVICE_GATEWAY_ADD_SERVICE
`DetachServiceId`	SERVICE_GATEWAY_DELETE_SERVICE
`ListShapes`	MACHINE_SHAPE_READ
`ListSubnets`	SUBNET_READ
`GetSubnet`	SUBNET_READ

API Operation	Permissions Required to Use the Operation
`UpdateSubnet`	SUBNET_UPDATE If changing which route table is associated with the subnet, also need ROUTE_TABLE_ATTACH and ROUTE_TABLE_DETACH If changing which security lists are associated with the subnet, also need SECURITY_LIST_ ATTACH and SECURITY_LIST_DETACH If changing which set of DHCP options are associated with the subnet, also need DHCP_ ATTACH and DHCP_DETACH
`CreateSubnet`	SUBNET_CREATE and VCN_ATTACH and ROUTE_TABLE_ATTACH and SECURITY_LIST_ ATTACH and DHCP_ATTACH
`DeleteSubnet`	SUBNET_DELETE and VCN_DETACH and ROUTE_ TABLE_DETACH and SECURITY_LIST_DETACH and DHCP_DETACH
`ChangeSubnetCompartment`	SUBNET_MOVE
`ListVcns`	VCN_READ
`GetVcn`	VCN_READ
`UpdateVcn`	VCN_UPDATE
`CreateVcn`	VCN_CREATE
`DeleteVcn`	VCN_DELETE

API Operation	Permissions Required to Use the Operation
`ChangeVcnCompartment`	VCN_MOVE
`ListVirtualCircuits`	VIRTUAL_CIRCUIT_READ
`GetVirtualCircuit`	VIRTUAL_CIRCUIT_READ
`UpdateVirtualCircuit`	VIRTUAL_CIRCUIT_UPDATE and DRG_ATTACH and DRG_DETACH If updating which cross-connect or cross-connect group the virtual circuit is using, also need CROSS_CONNECT_DETACH and CROSS_CONNECT_ATTACH
`CreateVirtualCircuit`	VIRTUAL_CIRCUIT_CREATE and DRG_ATTACH If creating the virtual circuit with a mapping to a specific cross-connect or cross-connect group, also need CROSS_CONNECT_ATTACH
`DeleteVirtualCircuit`	VIRTUAL_CIRCUIT_DELETE and DRG_DETACH If deleting a virtual circuit that's currently using a cross-connect or cross-connect group, also need CROSS_CONNECT_DETACH
`changeVirtualCircuitCompartment`	VIRTUAL_CIRCUIT_RESOURCE_MOVE
`GetVnic`	VNIC_READ

API Operation	Permissions Required to Use the Operation
`AttachVnic`	INSTANCE_ATTACH_SECONDARY_VNIC and VNIC_ATTACH and VNIC_CREATE and SUBNET_ATTACH If putting the secondary VNIC in a network security group during VNIC creation, also need NETWORK_SECURITY_GROUP_UPDATE_MEMBERS and VNIC_ASSOCIATE_NETWORK_SECURITY_GROUP
`DetachVnic`	INSTANCE_DETACH_SECONDARY_VNIC and VNIC_DETACH and VNIC_DELETE and SUBNET_DETACH
`UpdateVnic`	VNIC_UPDATE If adding or removing the VNIC from a network security group, also need NETWORK_SECURITY_GROUP_UPDATE_MEMBERS and VNIC_ASSOCIATE_NETWORK_SECURITY_GROUP
`ListVnicAttachments`	VNIC_ATTACHMENT_READ and INSTANCE_INSPECT
`GetVnicAttachment`	VNIC_ATTACHMENT_READ
`ListVolumes`	VOLUME_INSPECT
`GetVolume`	VOLUME_INSPECT
`UpdateVolume`	VOLUME_UPDATE

API Operation	Permissions Required to Use the Operation
`CreateVolume`	VOLUME_CREATE (and VOLUME_BACKUP_READ if creating volume from a backup)
`DeleteVolume`	VOLUME_DELETE
`ChangeVolumeCompartment`	VOLUME_MOVE
`ListVolumeAttachments`	VOLUME_ATTACHMENT_INSPECT and VOLUME_INSPECT and INSTANCE_INSPECT
`GetVolumeAttachment`	VOLUME_ATTACHMENT_INSPECT and VOLUME_INSPECT and INSTANCE_INSPECT **Note:** To also get the CHAP secret for the volume, then VOLUME_ATTACHMENT_READ is required instead of VOLUME_ATTACHMENT_INSPECT
`AttachVolume`	VOLUME_ATTACHMENT_CREATE and VOLUME_WRITE and INSTANCE_ATTACH_VOLUME
`DetachVolume`	VOLUME_ATTACHMENT_DELETE and VOLUME_WRITE and INSTANCE_DETACH_VOLUME
`ListVolumeBackups`	VOLUME_BACKUP_INSPECT and VOLUME_INSPECT
`GetVolumeBackup`	VOLUME_BACKUP_INSPECT and VOLUME_INSPECT
`UpdateVolumeBackup`	VOLUME_BACKUP_UPDATE and VOLUME_INSPECT
`CreateVolumeBackup`	VOLUME_BACKUP_CREATE and VOLUME_WRITE

API Operation	Permissions Required to Use the Operation
`DeleteVolumeBackup`	VOLUME_BACKUP_DELETE and VOLUME_INSPECT
`ChangeVolumeBackupCompartment`	VOLUME_BACKUP_MOVE
`GetBootVolume`	VOLUME_INSPECT
`ListBootVolumes`	VOLUME_INSPECT
`UpdateBootVolume`	VOLUME_UPDATE
`DeleteBootVolume`	VOLUME_DELETE
`ChangeBootVolumeCompartment`	BOOT_VOLUME_MOVE
`CreateBootVolumeBackup`	BOOT_VOLUME_BACKUP_CREATE, VOLUME_WRITE
`ListBootVolumeBackups`	BOOT_VOLUME_BACKUP_INSPECT, VOLUME_INSPECT
`GetBootVolumeBackup`	BOOT_VOLUME_BACKUP_INSPECT, VOLUME_INSPECT
`UpdateBootVolumeBackup`	BOOT_VOLUME_BACKUP_UPDATE, VOLUME_INSPECT
`DeleteBootVolumeBackup`	BOOT_VOLUME_BACKUP_DELETE, VOLUME_INSPECT
`ChangeBootVolumeBackupCompartment`	BOOT_VOLUME_BACKUP_MOVE

API Operation	Permissions Required to Use the Operation
`CreateVolumeGroup`	VOLUME_GROUP_CREATE, VOLUME_INSPECT if creating the volume group from a list of volumes. VOLUME_GROUP_CREATE, VOLUME_GROUP_ INSPECT, VOLUME_CREATE, VOLUME_WRITE if cloning a volume group. VOLUME_GROUP_CREATE, VOLUME_GROUP_ BACKUP_INSPECT, VOLUME_BACKUP_ READ/BOOT_VOLUME_BACKUP_READ, VOLUME_CREATE, VOLUME_WRITE if restoring from a volume group backup.
`DeleteVolumeGroup`	VOLUME_GROUP_DELETE
`GetVolumeGroup`	VOLUME_GROUP_INSPECT
`ListVolumeGroups`	VOLUME_GROUP_INSPECT
`UpdateVolumeGroup`	VOLUME_GROUP_UPDATE, VOLUME_INSPECT
`ChangeVolumegGroupCompartment`	VOLUME_GROUP_MOVE, VOLUME_MOVE/BOOT_ VOLUME_MOVE
`CreateVolumeGroupBackup`	VOLUME_GROUP_BACKUP_CREATE, VOLUME_ GROUP_INSPECT, VOLUME_WRITE, VOLUME_ BACKUP_CREATE/BOOT_VOLUME_BACKUP_ CREATE
`DeleteVolumeGroupBackup`	VOLUME_GROUP_BACKUP_DELETE, VOLUME_ BACKUP_DELETE/BOOT_VOLUME_BACKUP_ DELETE

API Operation	Permissions Required to Use the Operation
GetVolumeGroupBackup	VOLUME_GROUP_BACKUP_INSPECT
ListVolumeGroupBackups	VOLUME_GROUP_BACKUP_INSPECT
UpdateVolumeGroupBackup	VOLUME_GROUP_BACKUP_UPDATE
ChangeVolumegGroupBackupCompartment	VOLUME_GROUP_BACKUP_MOVE, VOLUME_BACKUP_MOVE/BOOT_VOLUME_BACKUP_MOVE

DEDICATED VIRTUAL MACHINE HOST API OPERATIONS

API Operation	Permissions Required to Use the Operation
CreateDedicatedVmHost	DEDICATED_VM_HOST_CREATE
ChangeDedicatedVmHostCompartment	DEDICATED_VM_HOST_MOVE
DeleteDedicatedVmHost	DEDICATED_VM_HOST_DELETE
GetDedicatedVmHost	DEDICATED_VM_HOST_READ
ListDedicatedVmHosts	DEDICATED_VM_HOST_INSPECT
ListDedicatedVmHostInstances	DEDICATED_VM_HOST_READ
ListDedicatedVmHostInstanceShapes	None
ListDedicatedVmHostShapes	None

API Operation	Permissions Required to Use the Operation
`LaunchInstance`	DEDICATED_VM_HOST_LAUNCH_INSTANCE in dedicated virtual machine host compartment INSTANCE_CREATE in compartment for the instance launched on the dedicated virtual machine host
`UpdateDedicatedVmHost`	AUTO_SCALING_CONFIGURATION_CREATE and INSTANCE_POOL_UPDATE

AUTOSCALING API OPERATIONS

API Operation	Permissions Required to Use the Operation
`ListAutoScalingConfigurations`	AUTO_SCALING_CONFIGURATION_INSPECT
`GetAutoScalingConfiguration`	AUTO_SCALING_CONFIGURATION_READ
`UpdateAutoScalingConfiguration`	AUTO_SCALING_CONFIGURATION_UPDATE and INSTANCE_POOL_UPDATE
`CreateAutoScalingConfiguration`	AUTO_SCALING_CONFIGURATION_CREATE and INSTANCE_POOL_UPDATE
`ChangeAutoScalingConfigurationCompartment`	AUTO_SCALING_CONFIGURATION_MOVE
`DeleteAutoScalingConfiguration`	AUTO_SCALING_CONFIGURATION_DELETE and INSTANCE_POOL_UPDATE

API Operation	Permissions Required to Use the Operation
`ListAutoScalingPolicies`	AUTO_SCALING_CONFIGURATION_READ
`GetAutoScalingPolicy`	AUTO_SCALING_CONFIGURATION_READ
`UpdateAutoScalingPolicy`	AUTO_SCALING_CONFIGURATION_UPDATE and INSTANCE_POOL_UPDATE
`CreateAutoScalingPolicy`	AUTO_SCALING_CONFIGURATION_CREATE and INSTANCE_POOL_UPDATE
`DeleteAutoScalingPolicy`	AUTO_SCALING_CONFIGURATION_DELETE and INSTANCE_POOL_UPDATE

WORK REQUESTS API OPERATIONS

API Operation	Permissions Required to Use the Operation
`ListWorkRequests`	WORKREQUEST_INSPECT
`GetWorkRequests`	Work requests inherit the permissions of the operation that spawns the work request. Generally, *<RESOURCE>*_CREATE permissions for the associated resource are required.
`ListWorkRequestLogs`	Work requests inherit the permissions of the operation that spawns the work request. Generally, *<RESOURCE>*_CREATE permissions for the associated resource are required.
`ListWorkRequestErrors`	Work requests inherit the permissions of the operation that spawns the work request. Generally, *<RESOURCE>*_CREATE permissions for the associated resource are required.

Details for Container Engine for Kubernetes

This topic covers details for writing policies to control access to Container Engine for Kubernetes.

Resource-Types

Aggregate Resource-Type

- `cluster-family`

Individual Resource-Types

- `clusters`
- `cluster-node-pools`
- `cluster-work-requests`

Comments

A policy that uses `<verb> cluster-family` is equivalent to writing one with a separate `<verb> <individual resource-type>` statement for each of the individual resource-types.

See the table in Details for Verb + Resource-Type Combinations for a detailed breakout of the API operations covered by each verb, for each individual resource-type included in `cluster-family`.

Supported Variables

Container Engine for Kubernetes supports all the general variables (see General Variables for All Requests), plus the ones listed here.

The `clusters` resource type can use the following variables:

Variable	Variable Type	Comments
`target.cluster.id`	Entity (OCID)	

The `cluster-node-pools` resource type can use the following variables:

Variable	Variable Type	Comments
`target.nodepool.id`	Entity (OCID)	

Details for Verb + Resource-Type Combinations

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from `inspect` > `read` > `use` > `manage`. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

For example, the `read` verb for the `clusters` resource-type includes the same permissions and API operations as the `inspect` verb, plus the CLUSTER_READ permission and a number of API operations (e.g., `GetCluster`, etc.). The `use` verb covers still another permission and API operation compared to `read`. Lastly, `manage` covers more permissions and operations compared to `use`.

`DeleteWorkRequest`	CLUSTER_WORK_REQUEST_DELETE

Details for the Database Service

See the following topics for details for writing policies to control access to Oracle Cloud Infrastructure Database service resources:

- Policy Details for Autonomous Database
- Policy Details for DB Systems
- Policy Details for Exadata Cloud at Customer

Details for the DNS Service

This topic covers details for writing policies to control access to the DNS service.

Aggregate Resource-Type

```
dns
```

Individual Resource-Types

```
dns-zones
```

```
dns-records
```

```
dns-steering-policies
```

```
dns-steering-policy-attachments
```

COMMENTS

A policy that uses `<verb> dns` is equivalent to writing one with a separate `<verb> <individual resource-type>` statement for each of the individual resource-types.

See the table in Details for Verb + Resource-Type Combinations for a detailed breakout of the API operations covered by each verb, for each individual resource-type included in `dns`.

Supported Variables

The DNS Service supports all the general variables (see General Variables for All Requests), plus the ones listed here.

The `dns-zones` resource type can use the following variables:

Variable	Variable Type	Comments
`target.dns-zone.id`	Entity (OCID)	Use this variable to control access to specific DNS zones by OCID.
`target.dns-zone.name`	String	Use this variable to control access to specific DNS zones by name.

The `dns-records` resource type can use the following variables:

Variable	Variable Type	Comments
`target.dns-zone.id`	Entity (OCID)	Use this variable to control access to specific DNS zones by OCID.
`target.dns-zone.name`	String	Use this variable to control access to specific DNS zones by name.
`target.dns-zone.scope`	String	Valid values are "public" and "private".

Variable	Variable Type	Comments
`target.dns-record.type`	List (String)	Use this variable to control access to specific DNS records by type. Valid values in the last can be any supported DNS resource type. For example, "A", "AAAA", "TXT", and so on. See .
`target.dns-domain.name`	List (String)	Use this variable to control access to specific domain names. Applicable to the following API operations: • `GetDomainRecords` • `PatchDomainRecords` • `UpdateDomainRecords` • `DeleteRRSet` • `GetRRSet` • `PatchRRSet` • `UpdateRRSet`

The `dns-steering-policies` resource type can use the following variables:

Variable	Variable Type	Comments
`target.dns-steering-policy.id`	Entity (OCID)	Use this variable to control access to specific steering policies by OCID.
`target.dns-steering-policy.display-name`	String	Use this variable to control access to specific steering policies by name.

Details for Verb + Resource-Type Combinations

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from `inspect` > `read` > `use` > `manage`. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

For example, the `manage` verb for the `dns-records` resource-type covers no extra permissions or API operations compared to the `use` verb.

`UpdateSteeringPolicyAttachment`	DNS_ZONE_UPDATE and DNS_STEERING_ POLICY_READ
`DeleteSteeringPolicyAttachment`	DNS_ZONE_UPDATE and DNS_STEERING_ POLICY_READ

Details for the Email Service

This topic covers details for writing policies to control access to the Email service.

Resource-Types

`approved-senders`

`suppressions`

Supported Variables

The Email Service supports all the general variables (see General Variables for All Requests), plus the ones listed here.

The `approved-senders` resource type can use the following variables:

Variable	Variable Type	Comments
`target.approved-sender.id`	Entity (OCID)	
`target.approved-sender.emailaddress`	String	Use this variable with the APPROVED_SENDER_USE permissions only.

Details for Verb + Resource-Type Combinations

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from `inspect` > `read` > `use` > `manage`. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

For example, the `use` verb for the `suppressions` resource-type covers no extra permissions or API operations compared to the `read` verb.

`GetSuppression`	SUPPRESSION_READ
`CreateSuppression`	SUPPRESSION_CREATE
`DeleteSuppression`	SUPPRESSION_DELETE

Details for the Events Service

This topic covers details for writing user IAM policies that control access to rules for the Events service.

Resource-Types

`cloudevents-rules`

Supported Variables

Only the general variables are supported (see General Variables for All Requests).

Details for Verb + Resource-Type Combinations

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from `inspect` > `read` > `use` > `manage`. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

For example, the `read` verb for cloudevents-rules includes the same permissions and API operations as the `inspect` verb, plus the EVENTRULE_READ permissions and the corresponding API operation `GetEventRule`. The `use` verb adds no extra permissions or API operations compared to `read`. However, `manage` adds more permissions and operations compared to `use`.

Details for the File Storage Service

This topic covers details for writing policies to control access to the File Storage Service.

Aggregate Resource-Type

- `file-family`

Individual Resource-Types

- `file-systems`
- `mount-targets`
- `export-sets`

COMMENTS

A policy that uses `<verb> file-family` is equivalent to writing one with a separate `<verb> <individual resource-type>` statement for each of the individual resource-types.

See the table in Details for Verb + Resource-Type Combinations for a detailed breakout of the API operations covered by each verb, for each individual resource-type included in `file-family`.

Supported Variables

Only the general variables are supported (see General Variables for All Requests).

Details for Verb + Resource-Type Combinations

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from `inspect` > `read` > `use` > `manage`. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

For example, the `read` verb for the `file-systems` resource-type includes the same permissions and API operations as the `inspect` verb, plus the FILE_SYSTEM_READ permission and a number of API operations (e.g., `GetFileSystem`, `ListMountTargets`, etc.). The `use` verb covers still another permission and set of API operations compared to `read`. Lastly, `manage` covers two more permissions and operations compared to `use`.

`GetSnapshot`	FILE_SYSTEM_READ
`DeleteSnapshot`	FILE_SYSTEM_DELETE_SNAPSHOT

Details for Functions

This topic covers details for writing policies to control access to Oracle Functions.

Resource-Types

Aggregate Resource-Type

- `functions-family`

Individual Resource-Types

- `fn-app`
- `fn-function`
- `fn-invocation`

Comments

A policy that uses `<verb> functions-family` is equivalent to writing one with a separate `<verb> <individual resource-type>` statement for each of the individual resource-types.

See the table in Details for Verb + Resource-Type Combinations for a detailed breakout of the API operations covered by each verb, for each individual resource-type included in `functions-family`.

Supported Variables

Oracle Functions supports all the general variables (see General Variables for All Requests).

Details for Verb + Resource-Type Combinations

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from `inspect` > `read` > `use` > `manage`. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

For example, the `read` verb for the `fn-app` resource-type includes the same permissions and API operations as the `inspect` verb, plus the FN_APP_READ permission and the `GetApp` API operation. In the case of the `fn-app` resource-type, the `use` verb covers no additional permissions or API operations compared to `read`. Lastly, `manage` covers more permissions and operations compared to `use`.

Details for the Health Checks Service

This topic covers details for writing policies to control access to the Health Checks service.

Resource-Types

`health-check-monitor`

`health-check-results`

`on-demand-probe`

`vantage-points`

`health-check-family`

Supported Variables

The Health Checks Service supports all the general variables (see General Variables for All Requests), plus the ones listed here. Values in the list can be any valid test type. For example, HTTP, HTTPS, ICMP, etc.

Variable	Variable Type	Comments
`target.health-check-monitor.test-type`	String	
`target.on-demand-probe.test-type`	String	
`target.health-check-results.test-type`	String	

Details for Verb + Resource-Type Combinations

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from `inspect` > `read` > `use` > `manage`. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

For example, the `use` verb for the `health-check-monitor` resource-type covers no extra permissions or API operations compared to the `read` verb.

Details for IAM

This topic covers details for writing policies to control access to IAM.

Resource-Types

```
authentication-policies
compartments
users
groups
dynamic-groups
policies
```

```
identity-providers
tenancies
tag-namespaces
tagdefinitions
tag-defaults
workrequest
```

Supported Variables

IAM supports all the general variables (see General Variables for All Requests), plus additional ones listed here:

Operations for This Resource-Type...	Can Use These Variables...	Variable Type	Comments
`users`	`target.user.id`	Entity (OCID)	Not available to use with CreateUser.
	`target.user.name`	String	
`groups`	`target.group.id`	Entity (OCID)	Not available to use with CreateGroup.
	`target.group.name`	String	
	`target.group.member`	Boolean	True if request.user is a member of target.group.

Operations for This Resource-Type...	Can Use These Variables...	Variable Type	Comments
policies	target.policy.id	Entity (OCID)	Not available to use with CreatePolicy.
	target.policy.name	String	
	target.policy.autoupdate	Boolean	Whether the policy being acted upon uses "Keep policy current" as its version date (i.e., either null or an empty string for the versionDate parameter in CreatePolicy and UpdatePolicy).
compartments	target.compartment.id	Entity (OCID)	For CreateCompartment, this will be the value of the parent compartment (e.g., the root compartment). This is a universal variable available to use with any request across all services (see General Variables for All Requests).
	target.compartment.name	String	

Operations for This Resource-Type...	Can Use These Variables...	Variable Type	Comments
`tag-namespace`	`target.tag-namespace.id`	Entity (OCID)	This variable is supported only in statements granting permissions for the `tag-namespaces` resource-type. For an example, see Required Permissions for Working with Defined Tags. Not available to use with CreateTagNamespace.
	`target.tag-namespace.name`	String	

Details for Verbs + Resource-Type Combinations

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from `inspect` > `read` > `use` > `manage`. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

For example, the `read` verb for compartments covers no extra permissions or API operations compared to the `inspect` verb. The `use` verb includes the same ones as the `read` verb, plus the COMPARTMENT_UPDATE permission and `UpdateCompartment` API operation. The `manage` verb includes the same permissions and API operations as the `use` verb, plus the COMPARTMENT_CREATE permission and two API operations: `CreateCompartment` and `DeleteCompartment`

Details for the Key Management Service

This topic covers details for writing policies to control access to the Key Management service.

Resource-Types

```
vaults

keys

key-delegate
```

Supported Variables

Key Management supports all the general variables, plus the ones listed here. For more information about general variables supported by Oracle Cloud Infrastructure services, see General Variables for All Requests.

Variable	Variable Type	Comments
`target.key.id`	Entity (OCID)	Use this variable to control access to specific keys by OCID.
`target.vault.id`	Entity (OCID)	Use this variable to control access to specific vaults by OCID.
`request.includePlainTextKey`	String	Use this variable to control whether to return the plaintext key in addition to the encrypted key in response to a request to generate a data encryption key.
`request.kms-key.id`	String	Use this variable to control whether block volumes or buckets can be created without a Key Management master encryption key.
`target.boot-volume.kms-key.id`	String	Use this variable to control whether Compute instances can be launched with boot volumes that were created without a Key Management master encryption key.

Details for Verb + Resource-Type Combinations

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from `inspect` > `read` > `use` > `manage`. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

For example, the `use` verb for the `keys` resource-type includes the same permissions and API operations as the `read` verb, plus the KEY_ENCRYPT and KEY_DECRYPT permissions and a number of API operations (`Encrypt`, `Decrypt`, and `GenerateDataEncryptionKey`). The `manage` verb allows even more permissions and API operations when compared to the `use` verb.

Details for Load Balancing

This topic covers details for writing policies to control access to the Load Balancing service.

Resource-Types

```
load-balancers
```

Supported Variables

Only the general variables are supported (see General Variables for All Requests).

Details for Verb + Resource-Type Combinations

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from `inspect` > `read` > `use` > `manage`. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

For example, the `read` verb for load-balancers includes the same permissions and API operations as the `inspect` verb, plus the LOAD_BALANCER_READ permission and a number of API operations (e.g., `GetLoadBalancer`, `ListWorkRequests`, etc.). The `use` verb covers still another permission and set of API operations compared to `read`. And `manage` covers two more permissions and operations compared to `use`.

Details for Monitoring

This topic covers details for writing policies to control access to the Monitoring service.

Resource-Types

```
alarms

metrics
```

Supported Variables

Monitoring supports all the general variables (see General Variables for All Requests), plus the one listed here:

Operations for This Resource-Type...	Can Use This Variable	Variable Type	Comments
`metrics`	`target.metrics.namespace`	String	Use this variable to control access to specific resource types. Surround the namespace value with single quotes. For example, to control access to metrics for Compute instances, use the following phrase: `where target.metrics.namespace='oci_computeagent'` For an example policy, see Restrict user access to a specific metric namespace. For valid namespace values, see Supported Services.

Details for Verb + Resource-Type Combinations

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from `inspect` > `read` > `use` > `manage`. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

Details for Object Storage, Archive Storage, and Data Transfer

This topic covers details for writing policies to control access to Archive Storage, Object Storage, and Data Transfer.

Tip

The object lifecycle policies feature requires that you grant permissions to the Object Storage service to archive and delete objects on your behalf. See Using Object Lifecycle Policies for more information.

Resource-Types

Individual Resource-Types

`objectstorage-namespaces`

`buckets`

`objects`

AGGREGATE RESOURCE-TYPE

`object-family`

A policy that uses `<verb> object-family` is equivalent to writing one with a separate `<verb> <individual resource-type>` statement for each of the individual resource-types.

See the table in Details for Verb + Resource-Type Combinations for a detailed breakout of the API operations covered by each verb, for each individual resource-type included in `object-family`.

ADDITIONAL INDIVIDUAL RESOURCE-TYPE FOR DATA TRANSFER

`data-transfer-jobs`

Supported Variables

Object Storage supports all the general variables (see General Variables for All Requests), plus the ones listed here:

Operations for This Resource-Type...	Can Use This Variable	Variable Type	Comments
`buckets` and `objects`	`target.bucket.name`	String	Use this variable to control access to a specific bucket. For an example policy, see Let users write objects to Object Storage buckets. **Important:** Condition matching is case insensitive. If you have a bucket named "BucketA" and a bucket named "bucketA", the condition `where target.bucket.name="BucketA"` applies to both. To avoid potential issues with resource names in policy, give your resources distinct names.
`buckets` and `objects`	`request.vcn.id`	String	If you're using a service gateway with your VCN, you can use this variable to allow access to a bucket only from a specific virtual cloud network (VCN). For an example policy, see Task 4: (Optional) Update IAM Policies to Restrict Object Storage Bucket Access.

Operations for This Resource-Type...	Can Use This Variable	Variable Type	Comments
`buckets` and `objects`	`request.ipv4.ipaddress`	String	If you're using a service gateway with your VCN, you can use this variable to allow access to a bucket only from a specific CIDR range. For an example policy, see Task 4: (Optional) Update IAM Policies to Restrict Object Storage Bucket Access.

Details for Verb + Resource-Type Combinations

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from `inspect` > `read` > `use` > `manage`. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

Permissions Required for Each API Operation

The following table lists the API operations in a logical order, grouped by resource type.

For information about permissions, see Permissions.

API Operation	Permissions Required to Use the Operation
`GetNamespace`	API requires no permissions and returns the caller's namespace. Use the API to validate your credentials. OBJECTSTORAGE_NAMESPACE_READ permission is required if you include the optional `compartmentId` parameter. Use the `compartmentId` parameter to determine the namespace for a third-party tenancy.
`GetNamespaceMetadata`	OBJECTSTORAGE_NAMESPACE_READ
`UpdateNamespaceMetadata`	OBJECTSTORAGE_NAMESPACE_UPDATE
`CreateBucket`	BUCKET_CREATE
`UpdateBucket`	BUCKET_UPDATE
`GetBucket`	BUCKET_READ
`HeadBucket`	BUCKET_INSPECT
`ListBuckets`	BUCKET_INSPECT
`DeleteBucket`	BUCKET_DELETE

API Operation	Permissions Required to Use the Operation
`ReencryptBucket`	BUCKET_UPDATE
`PutObject`	The permission required depends on whether or not the object already exists in the bucket: • OBJECT_CREATE is required when an object with that name does not already exist in the bucket. • OBJECT_OVERWRITE is required when an object with that name already exists in the bucket.
`RenameObject`	OBJECT_CREATE and OBJECT_OVERWRITE
`GetObject`	OBJECT_READ
`HeadObject`	OBJECT_READ or OBJECT_INSPECT
`DeleteObject`	OBJECT_DELETE
`ListObjects`	OBJECT_INSPECT
`RestoreObjects`	OBJECT_RESTORE
`CreateMultipartUpload`	OBJECT_CREATE and OBJECT_OVERWRITE
`UploadPart`	OBJECT_CREATE and OBJECT_OVERWRITE
`CommitMultipartUpload`	OBJECT_CREATE and OBJECT_OVERWRITE
`ListMultipartUploadParts`	OBJECT_INSPECT
`ListMultipartUploads`	BUCKET_READ
`AbortMultipartUpload`	OBJECT_DELETE
`CreatePar`	PAR_MANAGE

API Operation	Permissions Required to Use the Operation
`GetPar`	PAR_MANAGE
`ListPars`	PAR_MANAGE
`DeletePar`	PAR_MANAGE
`PutObjectLifecyclePolicy`	BUCKET_UPDATE, OBJECT_CREATE, and OBJECT_DELETE
`GetObjectLifecyclePolicy`	BUCKET_READ
`DeleteObjectLifecyclePolicy`	BUCKET_UPDATE
`CreateCopyRequest`	OBJECT_READ, OBJECT_CREATE, OBJECT_OVERWRITE, and OBJECT_INSPECT
`GetWorkRequest`	OBJECT_READ
`ListWorkRequests`	OBJECT_INSPECT
`CancelWorkRequest`	OBJECT_DELETE

Details for the Quotas Service

This topic covers details for writing policies to control access to the Quotas service.

Resource-Types

`quota`

Supported Variables

The Quotas service supports all the general variables (see General Variables for All Requests) plus the following:

Variable	Variable Type	Source
`target.quota.id`	Entity (OCID)	Request
`target.quota.name`	String	Request/Stored

Details for Verb + Resource-Type Combinations

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from `inspect` > `read` > `use` > `manage`. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

Details for Registry

This topic covers details for writing policies to control access to the Registry.

Resource-Types

- `repos`

Supported Variables

Oracle Cloud Infrastructure Registry supports all the general variables (see General Variables for All Requests), plus the ones listed here.

The `repos` resource-type can use the following variables:

Variable	Variable Type	Comments
`target.repo.name`	String	Use this variable to control access to specific repositories. For an example policy, see Policies to Control Repository Access.

Details for Verb + Resource-Type Combinations

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from `inspect` > `read` > `use` > `manage`. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

For example, the `read` verb for the `repos` resource-type includes the same permissions and API operations as the `inspect` verb, plus the REPOSITORY_READ permission and a number of API operations (e.g., `ReadDockerRepositoryMetadata`, etc.). The `use` verb covers still another permission and API operation compared to `read`. Lastly, `manage` covers more permissions and operations compared to `use`.

Note the Registry API is not currently available.

Details for Resource Manager

This topic covers details for writing policies to control access to the Resource Manager service.

Aggregate Resource-Type

```
orm-family
```

Individual Resource-Types

```
orm-stacks
```

```
orm-jobs
```

```
orm-work-requests
```

Supported Variables

Resource Manager supports all the general variables (see General Variables for All Requests), plus the ones listed here.

The `orm-jobs` resource type can use the following variables.

Variable	Variable Type	Comments
`target.job.operation`	String	Use this variable to control access for running specified job types. For example, to limit access to PLAN and APPLY jobs, use the following phrase: `where any {target.job.operation = 'PLAN', target.job.operation = 'APPLY'}`

Details for Verb + Resource-Type Combinations

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from `inspect` > `read` > `use` > `manage`. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access..

Details for Search

The Search service does not require permissions for its API operations. You do not need to write policies specifically to control access to Search. However, what you can see in search or query results depends on the permissions you have. If a policy exists to give you access to the `inspect` verb for a particular resource type, you have access to the permissions needed to view that resource type and its associated metadata in search results. If a service does not recognize the `inspect` verb or if the resource type's `inspect` verb does not fully cover list operations, permissions to view the service's supported resource types are granted by the `read` verb instead.

For more information about permissions, see the Permissions section of Advanced Policy Features.

Permissions Required to View Each Resource Type

The following table lists the resource types grouped by service, which are listed in alphabetical order. The Search API operations that can access the metadata for these resource types with these permissions are `GetResourceType`, `ListResourceTypes`, and `SearchResources`.

Service	Resource Type	Permissions Required to View in Search Results
Block Volume	`volumes`	VOLUME_INSPECT

Details for the WAF Service

This topic covers details for writing policies to control access to the WAAS service.

Aggregate Resource-Type

```
waas-family
```

Individual Resource-Types

`waas-policy`

`waas-certificate`

`waas-work-request`

`waas-metering`

COMMENTS

A policy that uses `<verb> waas` is equivalent to writing one with a separate `<verb> <individual resource-type>` statement for each of the individual resource-types.

See the table in Details for Verb + Resource-Type Combinations for a detailed breakout of the API operations covered by each verb, for each individual resource-type included in `waas`.

Supported Variables

The WAF Service supports all the general variables (see General Variables for All Requests), plus the ones listed here.

Variable	Variable Type	Comments
`target.waas-policy.id`	Entity (OCID)	Use this variable to control access to specific WAAS policies by OCID.
`target.waf-rule-key`	String	Use this variable to control access to specific WAF rules by name.

Details for Verb + Resource-Type Combinations

The following tables show the permissions and API operations covered by each verb. The level of access is cumulative as you go from `inspect` > `read` > `use` > `manage`. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

For example, the `use` and `manage` verbs for the `waas-policy` resource-type cover no extra permissions or API operations compared to the `read` verb.

User Credentials

There are several types of credentials that you manage with Oracle Cloud Infrastructure Identity and Access Management (IAM):

- **Console password:** For signing in to the Console, the user interface for interacting with Oracle Cloud Infrastructure. Note that federated users can't have Console passwords because they sign in through their identity provider. See Federating with Identity Providers.
- **API signing key (in PEM format):** For sending API requests, which require authentication.
- **Auth token:** An Oracle-generated token that you can use to authenticate with third-party APIs. For example, use an auth token to authenticate with a Swift client when using Recovery Manager (RMAN) to back up an Oracle Database System (DB System) database to Object Storage.
- **Customer Secret Keys:** For using the Amazon S3 Compatibility API with Object Storage. See Amazon S3 Compatibility API .
- **SMTP Credentials:** For using the Email Delivery service.

Important

API signing keys are different from the SSH keys you use to access a compute instance (see Security Credentials). For more information about API signing keys, see Required Keys and OCIDs. For more information about instance SSH keys, see Managing Key Pairs.

User Password

The administrator who creates a new user in IAM also needs to generate a one-time Console password for the user (see To create or reset another user's Console password). The

administrator needs to securely deliver the password to the user by providing it verbally, printing it out, or sending it through a secure email service.

When the user signs in to the Console the first time, they'll be immediately prompted to change the password. If the user waits more than 7 days to initially sign in and change the password, it will expire and an administrator will need to create a new one-time password for the user.

Once the user successfully signs in to the Console, they can use Oracle Cloud Infrastructure resources according to permissions they've been granted through policies.

Note

A user automatically has the ability to change their password in the Console. An administrator does not need to create a policy to give a user that ability.

Changing a Password

If a user wants to change their own password *sometime after* they change their initial one-time password, they can do it in the Console. Remember that a user can automatically change *their own* password; an administrator does not need to create a policy to give the user that ability.

For more information, see To change your Console password.

If a User Needs Their Console Password Reset

If a user forgets their Console password and also has no access to the API, they can use the Console's **Forgot Password** link to have a temporary password sent to them. This option is available if the user has an email address in their user profile.

If the user does not have an email address in their user profile, then they need to ask an administrator to reset their password for them. All administrators (and anyone else who has permission to the tenancy) can reset Console passwords. The process of resetting the

password generates a new one-time password that the administrator needs to deliver to the user. The user will need to change their password the next time they sign in to the Console.

If you're an administrator who needs to reset a user's Console password, see To create or reset another user's Console password.

If a User Is Blocked from Signing In to the Console

If a user tries 10 times in a row to sign in to the Console unsuccessfully, they will be automatically blocked from further attempts. They'll need to contact an administrator to get unblocked (see To unblock a user).

API Signing Keys

A user who needs to make API requests must upload an **RSA public key in PEM format (minimum 2048 bits)** to IAM and sign the API requests with the corresponding private key (see Required Keys and OCIDs).

Important

A user automatically has the ability to upload and manage *their own* API keys in the Console or API. An administrator does not need to write a policy to give the user that ability. Remember that a user can't use the API to change or delete their own credentials until they themselves upload a key in the Console, or an administrator uploads a key for that user in the Console or the API.

If you have a non-human system that needs to make API requests, an administrator needs to create a user for that system and then upload a public key to the IAM service for the system. There's no need to generate a Console password for the user.

For instructions on uploading an API key, see To upload an API signing key.

Auth Tokens

Auth tokens are authentication tokens generated by Oracle. You use auth tokens to authenticate with third-party APIs that do not support the Oracle Cloud Infrastructure signature-based authentication, for example, the Swift API. If your service requires an auth token, the service-specific documentation instructs you to generate one and how to use it.

Federating with Identity Providers

This topic describes identity federation concepts. Oracle Cloud Infrastructure supports federation with Oracle Identity Cloud Service,and Microsoft Active Directory (via Active Directory Federation Services (AD FS)), Microsoft Azure Active Directory, Okta, and other identity providers that supports the Security Assertion Markup Language (SAML) 2.0 protocol.

Overview

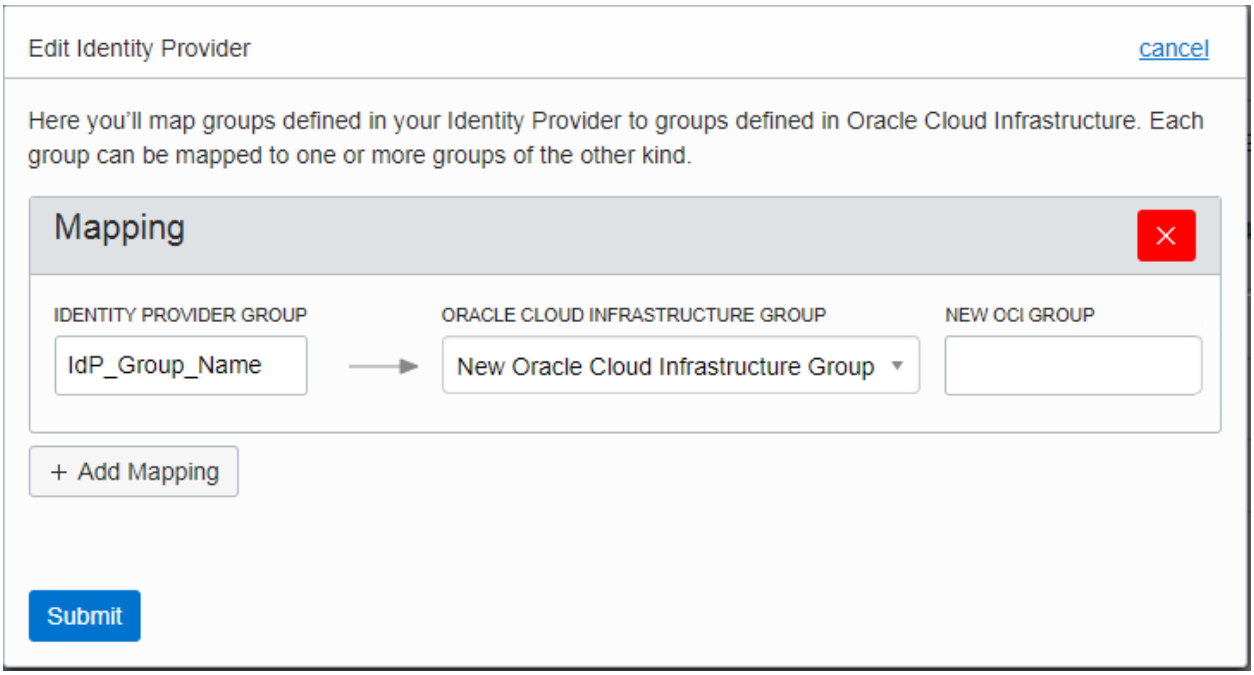
Enterprise companies commonly use an *identity provider (IdP)* to manage user login/passwords and to authenticate users for access to secure websites, services, and resources.

When someone in your company wants to use Oracle Cloud Infrastructure resources in the Console, they must sign in with a user login and password. Your administrators can federate with a supported IdP so that each employee can use an existing login and password and not have to create a new set to use Oracle Cloud Infrastructure resources.

To federate, an administrator goes through a short process to set up a relationship between the IdP and Oracle Cloud Infrastructure (commonly referred to as a *federation trust*). After an administrator sets up that relationship, any person in your company who goes to the Oracle Cloud Infrastructure Console is prompted with a "single sign-on" experience provided by the IdP. The user signs in with the login/password that they've already set up with the IdP. The IdP authenticates the user, and then that user can access Oracle Cloud Infrastructure.

When working with your IdP, your administrator defines groups and assigns each user to one or more groups according to the type of access the user needs. Oracle Cloud Infrastructure also uses the concept of groups (in conjunction with IAM policies) to define the type of access

a user has. As part of setting up the relationship with the IdP, your administrator can map each IdP group to a similarly defined IAM group, so that your company can re-use the IdP group definitions when authorizing user access to Oracle Cloud Infrastructure resources. Here's a screenshot from the mapping process:



For information about the number of federations and group mappings you can have, see Service Limits. There's no limit on the number of federated users.

Note

Any users who are in more than 50 IdP groups cannot be authenticated to use the Oracle Cloud Infrastructure Console.

Automated User Provisioning and Synchronization with SCIM

Tenancies federated with Oracle Identity Cloud Service or the third-party provider Okta, can also leverage SCIM (System for Cross-domain Identity Management) to enable provisioning of federated users in Oracle Cloud Infrastructure. Federated users that have been provisioned in Oracle Cloud Infrastructure through this process can have the additional user credentials such as API keys and auth tokens that are managed in the **User Settings** page. This enables federated users to use the SDK and CLI, and other features that require the additional user credentials. For more information, see User Provisioning for Federated Users.

General Concepts

Here's a list of the basic concepts you need to be familiar with.

IdP

IdP is short for *identity provider*, which is a service that provides identifying credentials and authentication for users.

Tenancies created after December 18, 2017 are automatically federated with Oracle Identity Cloud Service as the IdP. Oracle Cloud Infrastructure can be federated with any IdP that supports the Security Assertion Markup Language (SAML) 2.0 protocol.

SERVICE PROVIDER (SP)

A service (such as an application, website, and so on) that calls upon an IdP to authenticate users. In this case, Oracle Cloud Infrastructure is the SP.

FEDERATION TRUST

A relationship that an administrator configures between an IdP and SP. You can use the Oracle Cloud Infrastructure Console or API to set up that relationship. Then, the specific IdP is "federated" to that SP. In the Console and API, the process of federating is thought of as *adding an identity provider to the tenancy.*

SAML METADATA DOCUMENT

An IdP-provided XML-based document that provides the required information to an SP to federate with that IdP. Oracle Cloud Infrastructure supports the SAML 2.0 protocol, which is an XML-based standard for sharing required information between the IdP and SP. Depending on which idP you are federating with, you must either provide the metadata URL (see below) to this document or upload the document to Oracle Cloud Infrastructure.

METADATA URL

An IdP-provided URL that enables an SP to get required information to federate with that IdP. Oracle Cloud Infrastructure supports the SAML 2.0 protocol, which is an XML-based standard for sharing required information between the IdP and SP. The metadata URL points to the SAML metadata document the SP needs.

FEDERATED USER

Someone who signs in to use the Oracle Cloud Infrastructure Console by way of a federated IdP.

LOCAL USER

A non-federated user. In other words, someone who signs in to use the Oracle Cloud Infrastructure Console with a login and password created in Oracle Cloud Infrastructure.

GROUP MAPPING

A mapping between an IdP group and an Oracle Cloud Infrastructure group, used for the purposes of user authorization.

SCIM

SCIM (System for Cross-domain Identity Management) is an IETF standard protocol that enables user provisioning across identity systems. Oracle Cloud Infrastructure hosts a SCIM endpoint for provisioning federated users into Oracle Cloud Infrastructure. Using a SCIM client to provision users in Oracle Cloud Infrastructure enables you to assign credentials to the users in Oracle Cloud Infrastructure.

PROVISIONED (OR SYNCHRONIZED) USER

A user provisioned by the identity provider's SCIM client in Oracle Cloud Infrastructure. These users can be listed in the Oracle Cloud Infrastructure Console and can have all the Oracle Cloud Infrastructure user credentials except for a Console password.

ENCRYPT ASSERTION

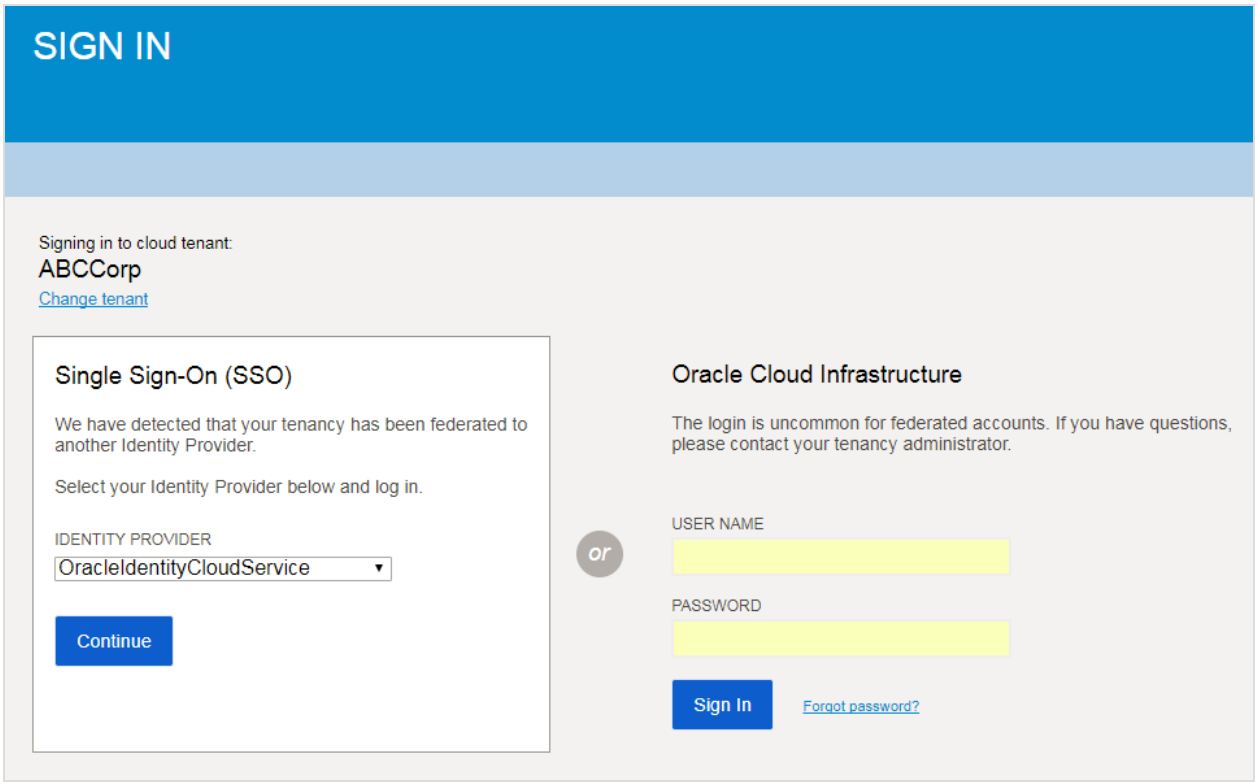
Some IdPs support the encryption of the SAML assertion. When enabled, the service provider expects the SAML assertion to be encrypted by the identity provider, using the service provider's encryption key. In this case, the service provider is Oracle Cloud Infrastructure authentication service. If you choose to enable this feature of your IdP, you must also enable the feature when you set up your Federation provider in the IAM service. Note that Microsoft AD FS enables the encryption of the SAML assertion by default. If your IdP is Microsoft AD FS, you must either enable this feature in IAM or disable it for Microsoft AD FS.

Experience for Federated Users

Federated users can use the Console to access Oracle Cloud Infrastructure (according to IAM policies for the groups the users are in).

They'll be prompted to enter their Oracle Cloud Infrastructure tenant (for example, ABCCorp).

They then see a page with two sets of sign-in instructions: one for federated users and one for non-federated (Oracle Cloud Infrastructure) users. See the following screenshot.



The tenant name is shown on the left. Directly below is the sign-in area for federated users. On the right is the sign-in area for non-federated users.

Federated users choose which identity provider to use for sign-in, and then they're redirected to that identity provider's sign-in experience for authentication. After entering their login and password, they are authenticated by the IdP and redirected back to the Oracle Cloud Infrastructure Console.

The federated users (without SCIM configuration) cannot access the "User Settings" page in the Console. This page is where a user can change or reset their Console password and manage other Oracle Cloud Infrastructure credentials such as API signing keys and auth tokens.

Experience for Federated Users with SCIM Configuration

If your IdP has also been configured with a SCIM client, a user signed in through their identity provider can access the User Settings page and have user capabilities such as API keys, auth tokens, and other user credentials. (**Note:** This is currently available for Oracle Identity Cloud Service and Okta federations only.)

Required IAM Policy

To add and manage identity providers in your tenancy, you must be authorized by an IAM policy. If you're in the Administrators group, then you have the required access.

Here's a more limited policy that restricts access to only the resources related to identity providers and group mappings:

```
Allow group IdPAdmins to manage identity-providers in tenancy

Allow group IdPAdmins to manage groups in tenancy
```

If you're new to policies, see Getting Started with Policies and Common Policies. If you want to dig deeper into writing policies for groups or other IAM components, see Details for IAM.

Supported Identity Providers

Important

Oracle Cloud Infrastructure tenancies created December 18, 2017 or later are automatically federated with Oracle Identity Cloud Service.

If your tenancy was created before December 18, 2017, and you want to set up a federation with Oracle Identity Cloud Service, see Federating with Oracle Identity Cloud Service.

For instructions for federating with other identity providers, see the following:

Federating with Microsoft Active Directory

Federating with Microsoft Azure Active Directory

Cloud Infrastructure Okta Configuration for Federation and Provisioning (white paper)

Federating with SAML 2.0 Identity Providers

Federating with Oracle Identity Cloud Service

This topic points to the appropriate topics for federating Oracle Cloud Infrastructure with Oracle Identity Cloud Service depending on when you activated your tenancy.

Tenancies created December 21, 2018 and after

These tenancies are automatically federated with Oracle Identity Cloud Service and configured to provision federated users in Oracle Cloud Infrastructure.

To manage your federated users and groups, see Managing Oracle Identity Cloud Service Users and Groups in the Oracle Cloud Infrastructure Console.

For information about the federation, see Frequently Asked Questions for Oracle Identity Cloud Service Federated Users.

Tenancies created between December 18, 2017 and December 20, 2018

These tenancies are automatically federated with Oracle Identity Cloud Service but are not configured to provision federated users in Oracle Cloud Infrastructure to allow these users to have additional credentials (API keys, auth tokens, etc.).

To enable this feature for users, you need to perform a one-time upgrade, see: User Provisioning for Federated Users.

After you have performed this upgrade, see Managing Oracle Identity Cloud Service Users and Groups in the Oracle Cloud Infrastructure Console to manage your federated users and groups.

Tenancies created before December 18, 2017

These tenancies must be manually federated with Oracle Identity Cloud Service. See Federating with Oracle Identity Cloud Service described below.

Manually Federating with Oracle Identity Cloud Service

Your organization can have multiple Oracle Identity Cloud Service accounts (e.g., one for each division of the organization). You can federate multiple Identity Cloud Service accounts with Oracle Cloud Infrastructure, but each federation trust that you set up must be for a single Identity Cloud Service account.

Note

Before following the steps in this topic, see Federating with Identity Providers to ensure that you understand general federation concepts.

Web Application and Client Credentials

For each trust, you must set up a *web application* in Oracle Identity Cloud Service (also called a *trusted application*); instructions are in Instructions for Federating with Oracle Identity Cloud Service. The resulting application has a set of client credentials (a client ID and client secret). When you federate your Identity Cloud Service account with Oracle Cloud Infrastructure, you must provide these credentials.

COMPUTEBAREMETAL application

A *trusted application* in Oracle Identity Cloud Service that contains the set of client credentials (a client ID and client secret) you'll need to provide when you federate your Identity Cloud Service account with Oracle Cloud Infrastructure.

Required URLs

The easiest way to federate with Oracle Identity Cloud Service is through the Oracle Cloud Infrastructure Console, although you could do it programmatically with the API. If you're

using the Console, you're asked to provide a *base URL* instead of the metadata URL. The base URL is the left-most part of the URL in the browser window when you're signed in to the Identity Cloud Service console:

- **Base URL:** *<Identity Cloud Service account name>*.identity.oraclecloud.com

If you're using the API to federate, you need to provide the metadata URL, which is the base URL with /fed/v1/metadata appended, like so:

- **Metadata URL:** *<Identity Cloud Service account name>*.identity.oraclecloud.com/fed/v1/metadata

The metadata URL links directly to the IdP-provided XML required to federate. If you're using the API, you need to provide both the metadata URL and the metadata itself when federating. For more information, see Managing Identity Providers in the API.

OCI-V2-<TENANCY_NAME> APP

When you manually federate an Oracle Identity Cloud Service account with Oracle Cloud Infrastructure, a new SAML application called *OCI-V2-<tenancy_name>* is automatically created in that Oracle Identity Cloud Service account. If you later need to delete the Oracle Identity Cloud Service identity provider from your Oracle Cloud Infrastructure tenancy, make sure to also delete the OCI-V2-*<tenancy_name>* from Oracle Identity Cloud Service. If you don't, and you later try to federate the same Oracle Identity Cloud Service account again, you'll get a 409 error saying that an application with the same name already exists (that is, OCI-V2-*<tenancy_name>*).

PROVISIONED USER

A provisioned user is provisioned by Oracle Identity Cloud Service in Oracle Cloud Infrastructure and is synched to a federated user that is managed in Oracle Identity Cloud Service. The provisioned user can have the special Oracle Cloud Infrastructure credentials like API keys and auth tokens to enable programmatic access. Provisioned users cannot have Console passwords.

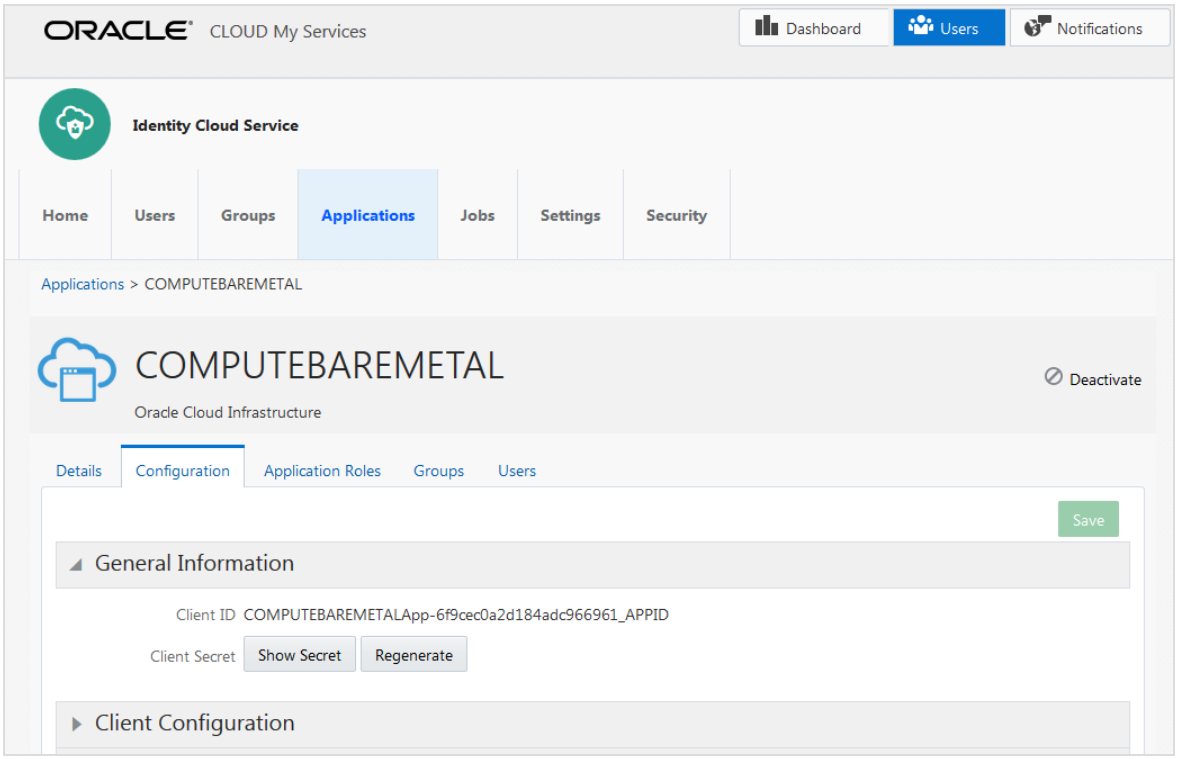
Instructions for Federating with Oracle Identity Cloud Service

Following is the general process an administrator goes through to set up the identity provider, and below are instructions for each step. It's assumed that the administrator is an Oracle Cloud Infrastructure user with the required credentials and access.

1. In Oracle Identity Cloud Service, get the required information you'll need to perform the set up steps in Oracle Cloud Infrastructure.
2. In Oracle Cloud Infrastructure, set up the federation:
    a. Set up Oracle Identity Cloud Service as an identity provider.
    b. Map Oracle Identity Cloud Service groups to IAM groups.
3. In Oracle Cloud Infrastructure, set up the IAM policies for the IAM groups to define the access you want the members of the mapped groups to have.
4. Inform your users of the name of your Oracle Cloud Infrastructure tenant and the URL for the Console (for example, https://console.us-ashburn-1.oraclecloud.com).

Step 1: Get required information from Oracle Identity Cloud Service

1. Go to the Oracle Identity Cloud Service console and sign in with admin privileges. Make sure you're viewing the Admin Console.
2. In the Identity Cloud Service console, click **Applications**. The list of trusted applications is displayed.
3. Click COMPUTEBAREMETAL.
4. Click **Configuration**.
5. Expand **General Information**. The client ID is displayed. Click **Show Secret** to display the client secret.



6. Record the Client ID and Client Secret. They look similar to this:
    - Client ID: de06b81cb45a45a8acdcde923402a9389d8
    - Client Secret: 8a297afd-66df-49ee-c67d-39fcdf3d1c31

Step 2: Add Oracle Identity Cloud Service as an identity provider in Oracle Cloud Infrastructure

1. Go to the Console and sign in with your Oracle Cloud Infrastructure login and password.
2. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Federation**.
3. Click **Add identity provider**.

4. Enter the following:
    a. **Name:** A unique name for this federation trust. This is the name federated users see when choosing which identity provider to use when signing in to the Console (for example., *ABCCorp_IDCS* as shown in the screenshot in Experience for Federated Users). The name must be unique across all identity providers you add to the tenancy. You cannot change this later.
    b. **Description:** A friendly description.
    c. **IDCS Base URL:** See Required URLs.
    d. **Client ID:** From Step 1: Get required information from Oracle Identity Cloud Service.
    e. **Client secret:** From Step 1: Get required information from Oracle Identity Cloud Service.
    f. **Encrypt Assertion:** Selecting the check box lets the IAM service know to expect the encryption from the IdP. If you select this check box, you must also set up encryption of the assertion in IDCS. For more information, see Encrypt Assertion. For information about setting this feature up in the IDCS, see Managing Oracle Identity Cloud Service Applications.
    g. **Force Authentication:** Selected by default. When selected, users are required to provide their credentials to the IdP (re-authenticate) even when they are already signed in to another session.
    h. **Authentication Context Class References:** This field is required for Government Cloud customers. When one or more values are specified, Oracle Cloud Infrastructure (the relying party), expects the identity provider to use one of the specified authentication mechanisms when authenticating the user. The returned SAML response from the IdP must contain an authentication statement with that authentication context class reference. If the SAML response authentication context does not match what is specified here, the Oracle Cloud Infrastructure auth service rejects the SAML response with a 400.

Several common authentication context class references are listed in the menu. To use a different context class, select **Custom**, then manually enter the class reference.

i. Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.

5. Click **Continue**.
6. Set up the mappings between Oracle Identity Cloud Service groups and IAM groups in Oracle Cloud Infrastructure. A given Oracle Identity Cloud Service group can be mapped to zero, one, or multiple IAM groups, and vice versa. However, each individual mapping is between only a single Oracle Identity Cloud Service group and a single IAM group. Changes to group mappings take effect typically within seconds.

Note

If you don't want to set up the group mappings now, you can simply click **Create** and come back to add the mappings later.

To create a group mapping:

a. Select the Oracle Identity Cloud Service group from the list under **Identity Provider Group**.

b. Choose the IAM group you want to map from the list under **OCI Group**. If you instead want to create a new IAM group, select **New OCI Group** and enter the name of the new group in **New OCI Group Name**. The new group is automatically created in IAM and mapped to the IdP group. It will also automatically be given this description, which you can't change: "Group created during federation".

Tip

Requirements for IAM group name: No spaces. Allowed characters: letters, numerals, hyphens, periods, underscores, and plus signs (+). The name cannot be changed later.

c. Repeat the above sub-steps for each mapping you want to create, and then click **Create**.

AFTER THE FEDERATION SET UP

The identity provider is now added to your tenancy and appears in the list on the **Federation** page. Click the identity provider to view its details and the group mappings you just set up.

Oracle assigns the identity provider and each group mapping a unique ID called an Oracle Cloud ID (OCID). For more information, see Resource Identifiers.

In the future, come to the **Federation** page if you want to edit the group mappings or delete the identity provider from your tenancy.

Users that are members of the Oracle Identity Cloud Service groups mapped to the Oracle Cloud Infrastructure groups are now listed in the Console on the Users page. See Managing User Capabilities for Federated Users for more information on assigning these users additional credentials.

Step 3: Set up IAM policies for the groups

If you haven't already, set up IAM policies to control the access the federated users have to your organization's Oracle Cloud Infrastructure resources. For more information, see Getting Started with Policies and Common Policies.

Step 4: Give your federated users the name of the tenant and URL to sign in

The federated users need the URL for the Oracle Cloud Infrastructure Console (for example, https://console.us-ashburn-1.oraclecloud.com) and the name of your tenant. They'll be prompted to provide the tenant name when they sign in to the Console.

Managing Identity Providers in the Console

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

To add an Oracle Identity Cloud Service as an identity provider

See Instructions for Federating with Oracle Identity Cloud Service.

To delete the identity provider

All the group mappings will also be deleted.

1. Delete the identity provider from your tenancy:
    a. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Federation**.
    A list of the identity providers in your tenancy is displayed.
    b. Click the identity provider to view its details.
    c. Click **Delete**.
    d. Confirm when prompted.

2. Delete the *OCI-V2-<tenancy_name>* from your Oracle Identity Cloud Service account:
    a. Go to Oracle Identity Cloud Service and sign in to the federated account.
    b. Click **Applications**. The list of applications is displayed.
    c. Locate the *OCI-V2-<tenancy_name>* and click its name to view its details page.
    d. In the upper right of the page, click **Deactivate**. Confirm when prompted.
    e. Click **Remove**. Confirm when prompted.

To add group mappings for Oracle Identity Cloud Service

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Federation**.
   A list of the identity providers in your tenancy is displayed.
2. Click the name you chose for your Oracle Identity Cloud Service federation to view its details.
3. Click **Edit Provider Details**.
4. Add at least one mapping:
    a. Click **+ Add Mapping**.
    b. Select the Oracle Identity Cloud Service group from the list under **Identity Provider Group**.
    c. Choose the IAM group you want to map from the list under **OCI Group**. If you instead want to create a new IAM group, select **New OCI Group** and enter the name of the new group in **New OCI Group Name**. The new group is automatically created in IAM and mapped to the IdP group. It will also automatically be given this description, which you can't change: "Group created during federation".
    d. Repeat the above sub-steps for each mapping you want to create, and then click **Submit**.

Your changes take effect typically within seconds in your home region. Wait several more minutes for changes to propagate to all regions.

Users that are members of the Oracle Identity Cloud Service groups mapped to the Oracle Cloud Infrastructure groups are now listed in the Console on the Users page. See Managing User Capabilities for Federated Users for more information on assigning these users additional credentials.

To update or delete a group mapping

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Federation**.
   A list of the identity providers in your tenancy is displayed.
2. Click the identity provider to view its details.
3. Click **Edit Mapping**.
4. Update the mappings (or click the X to delete a mapping), and then click **Submit**.

Your changes take effect typically within seconds in your home region. Wait several more minutes for changes to propagate to all regions.

If this action results in federated users no longer having membership in any group that is mapped to Oracle Cloud Infrastructure, the federated users' provisioned users' will also be removed from Oracle Cloud Infrastructure. Typically, this process takes several minutes.

Managing Identity Providers in the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use these API operations:

Identity providers:

- CreateIdentityProvider
- ListIdentityProviders
- GetIdentityProvider
- UpdateIdentityProvider
- DeleteIdentityProvider: Before you can use this operation, you must first use DeleteIdpGroupMapping to remove all the group mappings for the identity provider.

Group mappings:

- CreateIdpGroupMapping: Each group mapping is a separate entity with its own OCID.
- ListIdpGroupMappings
- GetIdpGroupMapping
- UpdateIdpGroupMapping
- DeleteIdpGroupMapping

Managing Oracle Identity Cloud Service Users and Groups in the Oracle Cloud Infrastructure Console

This topic describes how to use the Oracle Cloud Infrastructure Console to manage your Oracle Identity Cloud Service users and groups. Before you get started, understand basic federation concepts. See Federating with Identity Providers.

Overview of Working with Oracle Identity Cloud Service Users and Groups in the Console

The Oracle Cloud Infrastructure Console provides an integration with Oracle Identity Cloud Service (IDCS) that lets you perform many management tasks for your IDCS users and groups in the Console.

User Management Tasks

In the Console, you can do the following user management tasks:

- Add users
- Remove users

- Add users to groups
- Assign roles to users to access services and instances
- Reset user password

For information on more user management tasks, see Managing Oracle Identity Cloud Service Users in *Administering Oracle Identity Cloud Service*.

Group Management Tasks

In the Console, you can do the following group management tasks:

- Add groups
- Remove groups
- Add users to groups
- Map IDCS groups to IAM groups

For information on more group management tasks, see Managing Oracle Identity Cloud Service Groups in *Administering Oracle Identity Cloud Service*.

Required Policies and Permissions

To manage Oracle Identity Cloud Service users and groups in the Console, you'll need to be granted permissions in both the Oracle Cloud Infrastructure IAM service and in Oracle Identity Cloud Service.

Members of the OCI_Administrators group have the required permissions to create groups and policies in Oracle Cloud Infrastructure.

Important: To create users and groups in the Oracle Identity Cloud Service federation, you'll need the Identity Domain Administrator role, or be a member of a group that has been granted that role. For information on Oracle Identity Cloud Service roles, see Administering Oracle Identity Cloud Service.

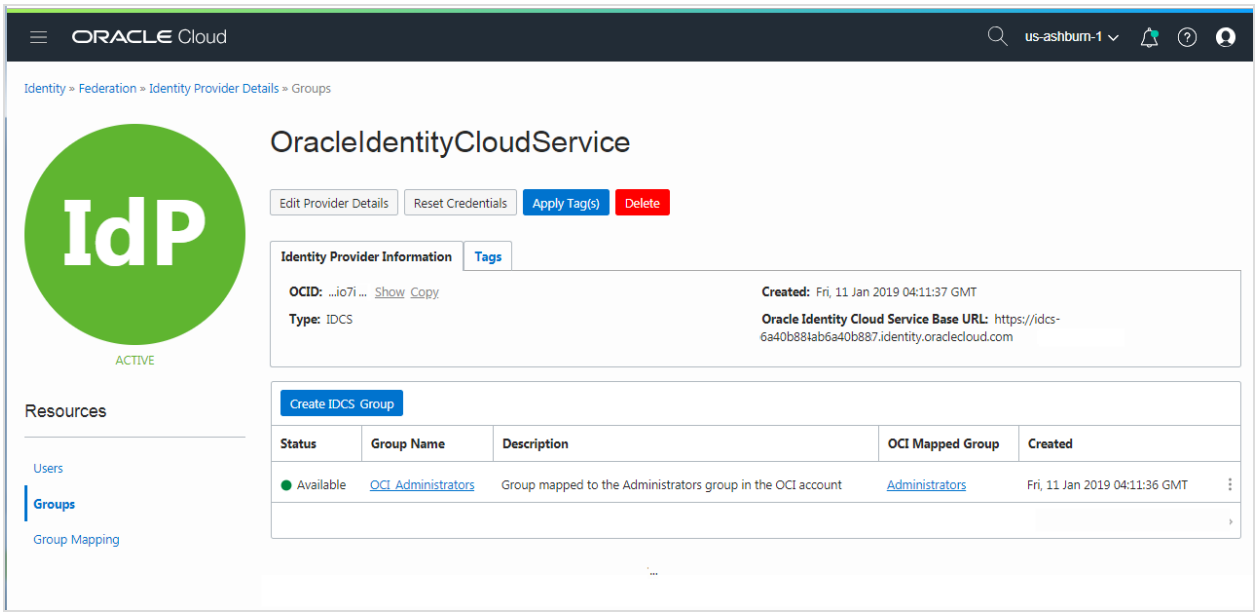
To quickly create a user with the required permissions, see Add a User with Oracle Cloud Administrator Permissions.

Navigating to Your Oracle Identity Cloud Service Users and Groups in the Console

In the Console, you can add users and groups to Oracle Identity Cloud Service from the Identity Provider Details page.

To view your identity provider details:

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Federation**.
2. Click your Oracle Identity Cloud Service federation. For most tenancies, the federation is named **OracleIdentityCloudService**.
   The identity provider details page is displayed.



From the Identity Provider Details page, click **Users** to display the users created in Oracle Identity Cloud Service. Click **Groups** to display the groups created in Oracle Identity Cloud Service.

Working with Oracle Identity Cloud Service Groups

The Console lets you perform the following tasks to manage groups in Oracle Identity Cloud Service:

- Add groups
- Delete groups
- Edit the name and description
- Add users to groups
- Remove users from groups
- Map groups to Oracle Cloud Infrastructure groups

Some tasks you can't perform in the Oracle Cloud Infrastructure Console. To add the predefined application roles for some Oracle Cloud products, you need to assign roles in the Identity Cloud Service console. For more information about using Oracle Identity Cloud Service, see Administering Oracle Identity Cloud Service.

For the members of a group in Oracle Identity Cloud Service to have permissions in Oracle Cloud Infrastructure, you must map the IDCS group to a group in IAM. Before you set up any new groups in IDCS, ensure that you understand how to assign permissions to groups in Oracle Cloud Infrastructure. See Overview of Oracle Cloud Infrastructure Identity and Access Management.

Working with Oracle Identity Cloud Service Users

The Console lets you perform the following tasks to manage users in Oracle Identity Cloud Service:

- Add users
- Delete users
- Edit user details
- Add users to groups
- Add roles to users

- Remove users from groups
- Reset user passwords

User Management Tasks You Can't Perform in the Console

The Oracle Cloud Console does not support management of the following Oracle Identity Cloud Service user features and tasks:

- Manage multi-factor authentication

For information about managing these tasks, see Administering Oracle Identity Cloud Service.

Managing Oracle Identity Cloud Service Groups in the Console

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

To create a group in Oracle Identity Cloud Service

This procedure creates a new group in Oracle Identity Cloud Service. Optionally, you can add users to the group at the time you create it. This group will not have any permissions in Oracle Cloud Infrastructure until you map it to an Oracle Cloud Infrastructure group.

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Federation**.
   A list of the federations in your tenancy is displayed.
2. Click your Oracle Identity Cloud Service federation. For most tenancies, the federation is named **OracleIdentityCloudService**.
   The identity provider details page is displayed.

3. Under **Resources**, click **Groups**.
   The list of existing groups is displayed.
4. Click **Create IDCS Group**.
5. Enter the following:
   - **Name:** A unique name for the group.
   - **Description:** A friendly description. You can change this later if you want to.
   - **Users:** Add Oracle Identity Cloud Service users to this group. You can add users when you create the group, or later. Select users from the list. To find a specific user, you can start typing the user name to filter the list as you type.
6. Click **Create**.

After you create a group in Oracle Identity Cloud Service, you'll want to give the group permissions to user services:

- To grant the group access to map it to an Oracle Cloud Infrastructure group as described in the next procedure.
- To add roles to this group, see Managing Oracle Identity Cloud Service Roles for Groups.

To map an Oracle Identity Cloud Service group to an IAM group

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Federation**.
2. Click your Oracle Identity Cloud Service federation. For most tenancies, the federation is named **OracleIdentityCloudService**.
   The identity provider details page is displayed.
3. Click **Edit Mapping**.
4. In the **Edit Identity Provider** dialog, click **+ Add Mapping**.
5. Select the **Identity Provider Group** you want to map from the list. To find a group without scrolling through the list, you can start typing the group name to filter the list as

you type.

6. Select the **OCI Group** you want to map this Identity Cloud Service group to. To find a group without scrolling through the list, you can start typing the group name to filter the list as you type.
7. To add more mappings, click **+ Add Mapping** and continue adding the mappings.
8. Select the group you want to map this group to from the list under **OCI Mapped User Group**.

Members of this group now have the permissions granted to the OCI Mapped User Group.

To add roles to a group

Oracle Cloud Infrastructure services use polices to control access to services. However, some Oracle Cloud services use roles to manage access. This procedure describes how to add roles to an IDCS group.

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Federation**.
   A list of the identity providers in your tenancy is displayed.
2. Click the **Oracle Identity Cloud Service Console** link.
   The Identity Cloud Service console is displayed.
3. In the Identity Cloud Service console, expand the **Navigation Drawer**, and then click **Applications**.
   The list of applications is displayed. Notice that the service that the application corresponds to is displayed underneath the application name. For example, underneath the JAAS application entry, you'll see Oracle Java Cloud Service.
4. Click the name of the service that you are interested in.
   The **Details** page is displayed.
5. Click **Application Roles**.
   The roles are displayed.
6. Click the menu for the role you want to assign and select **Assign Groups**.

7. Select the group you want to assign to the role, and click **OK**.
8. Click the **Applications** breadcrumb to return to the list of applications.
9. Repeat steps 4 through 7 for each role you want to assign to this group.

To remove roles from a group

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Federation**.
   A list of the identity providers in your tenancy is displayed.
2. Click the **Oracle Identity Cloud Console** link.
   The Identity Cloud Service console is displayed.
3. In the Identity Cloud Service console, expand the **Navigation Drawer**, and then click **Applications**.
   The list of applications is displayed. Notice that the service that the application corresponds to is displayed underneath the application name. For example, underneath the JAAS application entry, you'll see Oracle Java Cloud Service.
4. Click the name of the service that you are interested in.
   The **Details** page is displayed.
5. Click **Application Roles**.
   The roles are displayed.
6. Click the menu for the role you want to remove from the group and select **Revoke Groups**.
7. Select the group you want to remove the role from, and click **OK**.
8. Click the **Applications** breadcrumb to return to the list of applications.
9. Repeat steps 4 through 7 for each role you want to remove from this group.

To edit details for an Oracle Identity Cloud Service group

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Federation**.
2. Click your Oracle Identity Cloud Service federation. For most tenancies, the federation is named **OracleIdentityCloudService**.
   The identity provider details page is displayed.
3. Under **Resources**, click **Groups**.
   The list of existing groups in the federation is displayed.
4. Find the group you want to edit and click its name.
   The **Group Details** page is displayed.
5. Click **Edit**.
6. You can update the **Group Name** or the **Description**.
7. Click **Update** to save your changes.

Warning

Changing the group name will break mappings to Oracle Cloud Infrastructure (OCI) groups. If you change the group name, ensure that you delete any existing group mappings and add new mappings with the new name. See the previous task on editing mappings.

To add users to a group

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Federation**.
2. Click your Oracle Identity Cloud Service federation. For most tenancies, the federation is named **OracleIdentityCloudService**.

The identity provider details page is displayed.

3. Under **Resources**, click **Groups**.
   The list of existing groups is displayed.
4. Find the group you want add a user to.
   The **User Group Details** page is displayed.
5. Click **Add IDCS User**.
6. Select the user you want to add to this group from the **Users** list.
7. Click **Add**.

To remove users from a group

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Federation**.
2. Click your Oracle Identity Cloud Service federation. For most tenancies, the federation is named **OracleIdentityCloudService**.
   The identity provider details page is displayed.
3. Under **Resources**, click **Groups**.
   The list of existing groups is displayed.
4. Find the group you want to remove the user from.
   The list of users is displayed in the **Group Details** page.
5. Find the user you want to remove, and then click the the Actions icon (three dots).
6. Click **Remove User**.
7. Confirm when prompted.

To delete a group

Note: To delete a group, you must first remove all the users.

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity**

and click **Federation**.

2. Click your Oracle Identity Cloud Service federation. For most tenancies, the federation is named **OracleIdentityCloudService**.
   The identity provider details page is displayed.
3. Under **Resources**, click **Groups**.
   The list of existing groups is displayed.
4. Find the group you want to edit and click its name.
   The **Group Details** page is displayed.
5. Click **Delete**.
6. Confirm when prompted.

Create a policy to grant the group permissions on Oracle Cloud Infrastructure resources

The group you created in Oracle Identity Cloud Service gets permissions to access resources in Oracle Cloud Infrastructure through the policy you assign to the Oracle Cloud Infrastructure group. Before you complete this step, you need to decide what permissions you want to give your new group. For more information, see Getting Started with Policies and Common Policies.

Prerequisite: The group and compartment that you're writing the policy for must already exist.

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Policies**.
   A list of the policies in the compartment you're viewing is displayed.
2. If you want to attach the policy to a compartment other than the one you're viewing, select the desired compartment from the list on the left. Where the policy is attached controls who can later modify or delete it (see Policy Attachment).
3. Click **Create Policy**.

4. Enter the following:
    - **Name:** A unique name for the policy. The name must be unique across all policies in your tenancy. You cannot change this later.
    - **Description:** A friendly description. You can change this later if you want to.
    - **Policy Versioning:** Select **Keep Policy Current** if you'd like the policy to stay current with any future changes to the service's definitions of verbs and resources. Or if you'd prefer to limit access according to the definitions that were current on a specific date, select **Use Version Date** and enter that date in format YYYY-MM-DD format. For more information, see Policy Language Version.
    - **Statement:** A policy statement. For the correct format to use, see Policy Basics and also Policy Syntax. If you want to add more than one statement, click **+**.

      For example:

      To allow your group to manage all resources within a specified compartment enter a statement like the following:

      ```
      Allow group <OCI_group_name> to manage all-resources in compartment <compartment_name>
      ```

      For more policy examples, see Common Policies.
    - **Tags:** Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.
5. Click **Create**.

MANAGING ORACLE IDENTITY CLOUD SERVICE USERS IN THE CONSOLE

After you add a user in Oracle Identity Cloud Service, a user is also automatically provisioned in Oracle Cloud Infrastructure. This provisioned user can have the Oracle Cloud Infrastructure credentials, such as API keys and auth tokens. To understand this provisioning, see User Provisioning for Federated Users.

To create a user

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Federation**.
2. Click your Oracle Identity Cloud Service federation. For most tenancies, the federation is named **OracleIdentityCloudService**.
   The identity provider details page is displayed.
3. Click **Create IDCS User**.
4. In the **Create IDCS User** dialog enter the following:
   - **User Name**: Enter a unique name or email address for the new user.
     The value will be the user's login to the Console and must be unique across all other users in your tenancy.
   - **Email**: Enter an email address for this user. The initial sign-in credentials will be sent to this email address.
   - **First Name:** Enter the user's first name.
   - **Last Name:** Enter the user's last name.
   - **Phone Number:** Optionally, enter a phone number.
   - **Groups:** Optionally, select groups to add this user to.
5. Click **Create User**.

Important

For the user to have permissions in Oracle Cloud Infrastructure, you must assign the user to a group that is mapped to an Oracle Cloud Infrastructure group. Or, if you are also creating a new group, you can perform this mapping later. The user will not be able to sign in to the Console until the mapping is accomplished.

The user creation process generates an email that is sent to the address provided that you entered. The email includes the new user's username and password to use with the Oracle Cloud InfrastructureConsole.

To add API keys, auth tokens, customer secret keys, or SMTP credentials for this user, see Managing User Capabilities for Federated Users.

To edit a user

You can update the following fields:

- Email address
- First and last name
- Phone number

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Federation**.
2. Click your Oracle Identity Cloud Service federation. For most tenancies, the federation is named **OracleIdentityCloudService**.
   The identity provider details page is displayed.
3. Under **Resources**, click **Users**.
   The list of existing users is displayed.
4. Find the user you want to edit and click its name.
   The **User Details** page is displayed.
5. Click **Edit**.
6. Update the fields.
7. Click **Save** when finished.

To reset a user's password

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Federation**.
2. Click your Oracle Identity Cloud Service federation. For most tenancies, the federation is named **OracleIdentityCloudService**.
   The identity provider details page is displayed.
3. Under **Resources**, click **Users**.
   The list of existing user groups in the federation is displayed.
4. Find the user you want to reset the password for and click the name.
   The **User Details** page is displayed.
5. Click **Reset Password**.
   The user's password is reset. This user can't access their account until they complete the password reset steps.
6. Click **Email Password Instructions** to send the password link and instructions to the user.
   The password link is good for 24 hours. If the user does not reset their password in time, you can generate a new password link by clicking **Reset Password** for the user again.

To manage roles for services managed through IDCS

See see Managing Oracle Identity Cloud Service Roles for Users.

To add API keys, auth tokens, or other Oracle Cloud Infrastructure credentials

1. View the user's details:

- If you're adding credentials for *yourself*: Open the **Profile** menu () and click **User Settings**.
- If you're an administrator adding credentials for *another user*: Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Federation**.
  Click your Oracle Identity Cloud Service federation. For most tenancies, the federation is named **OracleIdentityCloudService**.
  The identity provider details page is displayed.
  Find the user in the list and click the **OCI Synched User** link.

2. Add the credentials for the user.

For more details about these credentials, see Managing User Credentials.

To delete a user

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Federation**.
2. Click your Oracle Identity Cloud Service federation. For most tenancies, the federation is named **OracleIdentityCloudService**.
   The identity provider details page is displayed.
3. Under **Resources**, click **Users**.
   The list of existing user groups in the federation is displayed.
4. Find the user you want to delete and click the name.
   The **User Details** page is displayed.
5. Click **Delete**.

To add group mappings for Oracle Identity Cloud Service

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Federation**.
   A list of the identity providers in your tenancy is displayed.
2. Click your Oracle Identity Cloud Service federation. For most tenancies, the federation is named **OracleIdentityCloudService**.
   The identity provider details page is displayed.
3. Click **Edit Provider Details**.
4. Add at least one mapping:
   a. Click **+ Add Mapping**.
   b. Select the Oracle Identity Cloud Service group from the list under **Identity Provider Group**.
   c. Choose the IAM group you want to map from the list under **OCI Group**. If you instead want to create a new IAM group, select **New OCI Group** and enter the name of the new group in **New OCI Group Name**. The new group is automatically created in IAM and mapped to the IdP group. It will also automatically be given this description, which you can't change: "Group created during federation".
   d. Repeat the above sub-steps for each mapping you want to create, and then click **Submit**.

Your changes take effect typically within seconds in your home region. Wait several more minutes for changes to propagate to all regions.

Users that are members of the Oracle Identity Cloud Service groups mapped to the Oracle Cloud Infrastructure groups are now listed in the Console on the Users page. See Managing User Capabilities for Federated Users for more information on assigning these users additional credentials.

To update or delete a group mapping

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Federation**.
   A list of the identity providers in your tenancy is displayed.
2. Click the identity provider to view its details.
3. Click **Edit Mapping**.
4. Update the mappings (or click the X to delete a mapping), and then click **Submit**.

If this action results in federated users no longer having membership in any group that is mapped to Oracle Cloud Infrastructure, the federated users' provisioned users' will also be removed from Oracle Cloud Infrastructure. Typically, this process takes several minutes.

Managing Oracle Identity Cloud Service Roles for Users

This topic describes managing user roles for users created in Oracle Identity Cloud Service.

About User Roles in Oracle Identity Cloud Service

You can assign roles to a user to allow access to those Oracle Cloud services that have predefined roles defined in Oracle Identity Cloud Service. You can also grant access just to service instances.

Services managed through Identity Cloud Service can have two types of predefined roles:

- Service access roles - grant access to use the service.
- Instance access roles - grant access to specific instances of a service. These can only be granted after the instances are created

For information about more complex role management including assigning other administrative privileges, see Managing Oracle Identity Cloud Service Users.

Available Roles for Each Service

Service-specific roles vary from one Oracle Cloud service to another, but they typically include at least one administrator role. See About Service Administrator Roles for more

information about administrator roles. See your service-specific documentation for a description of the predefined roles for that service.

Required Permissions to Manage Roles

Before you can manage roles using the Oracle Cloud Infrastructure Console, you must be allowed to access the Identity Provider Details page. To access this page, you must belong to a group that is allowed to inspect identity providers. If you are a Cloud Administrator or if you belong to the OCI_Administrators group, this permission is included. To give this permission to non-administrators, you'll need to write a policy like the following:

```
Allow group GroupA to inspect identity-providers in tenancy
```

where you replace GroupA with the name of the group you want to grant the permission to.

To manage the service roles for another user, you must be assigned the appropriate role in Oracle Identity Cloud Service. See Understanding Administrator Roles.

Managing Roles User Roles in the Console

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Users**.
   A list of the users in your tenancy is displayed.
   By default, users belonging to all identity providers are displayed. To view only users that belong to your Identity Cloud Service federation, clear the check boxes for any other identity providers.
2. Click the name of the user you want to edit.
3. On the user details page, click **Manage Service Roles**. The **Manage Service Roles** page displays the list of services for which you have Administrator access. The service roles that this user has already been granted are also displayed.
   Note that you won't see services that you don't have Administrator access for.
4. Find the service you want to edit this user's access to, click the Actions icon (three dots), and then click **Manage service access**. The list of roles for the selected service is displayed.
5. Edit the user's access as follows:

- Select the check box for each role you want to give to the user.
- Clear the check box for each role you want remove from the user. Note that you can't remove a role that has been granted through a group. These roles are read only.

Note

If a user is assigned the Cloud Account Administrator role, then you can't remove the individual entitlement roles for the user.

6. Click **Save Role Selections**.
7. Click **Apply Service Role Settings**.
8. If you are granting roles to a user, in the confirmation dialog, click **Send Email to User** to send an email to the user to notify them of this change.
9. Your email client launches with a default email message you can send to the user. You can send the email as shown, or make modifications before sending.
10. Return to the Console and click **Close**.

MANAGING INSTANCE ROLES IN THE CONSOLE

Some services allow you to grant access to instances of the service. After you (or someone in your organization) creates an instance, use this procedure to manage individual user access to the instance.

Managing User Access to an Instance

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Users**.
   A list of the users in your tenancy is displayed.
   By default, users belonging to all identity providers are displayed. To view only users that belong to your Identity Cloud Service federation, clear the check boxes for any other identity providers.

2. Click the name of the user you want to edit.
3. On the user details page, click **Manage Service Roles**. The **Manage Service Roles** page displays the list of services for which you have Administrator access. The service roles that this user has already been granted are also displayed.
   Note that you won't see services that you don't have Administrator access for.
4. Find the service with instances that you want to edit this user's access to, click the Actions icon (three dots), and then click **Manage instance access**. The list of instances for the selected service is displayed.
5. On the **Manage Access to Instances** page, find the name of the instance you want to edit this user's access to.
   To grant access to this instance:
   In the **Instance Role** column, select the role you want to grant to the user. You can select multiple roles from the list.
   To remove access to this instance:
   In the **Instance Role** column, click the **x** next to the role you want to remove from the user.
6. When you are finished editing roles, click **Save Instance Settings**.
7. On the **Manage Service Roles** page, click **Apply Service Role Settings**.
8. If you are granting roles to a user, in the confirmation dialog, click **Send Email to User** to send an email to the user to notify them of this change.
9. Your email client launches with a default email message you can send to the user. You can send the email as shown, or make modifications before sending.
10. Return to the Console and click **Close**.

Managing Oracle Identity Cloud Service Roles for Groups

This topic describes managing roles for groups created in Oracle Identity Cloud Service.

About Group Roles in Oracle Identity Cloud Service

You can assign roles to groups to allow access to those Oracle Cloud services that have predefined roles defined in Oracle Identity Cloud Service. You can also grant access just to

service instances.

Services managed through Identity Cloud Service can have two types of predefined roles:

- Service access roles - grant access to use the service.
- Instance access roles - grant access to specific instances of a service. These can only be granted after the instances are created.

For information about more complex role management, see Manage Oracle Identity Cloud Service Groups.

Available Roles for Each Service

Service-specific roles vary from one Oracle Cloud service to another, but they typically include at least one administrator role. See About Service Administrator Roles for more information about administrator roles. See your service-specific documentation for a description of the predefined roles for that service.

Required Permissions to Manage Roles

Before you can manage roles using the Oracle Cloud Infrastructure Console, you must be allowed to access the Identity Provider Details page. To access this page, you must belong to a group that is allowed to inspect identity providers. If you are a Cloud Administrator or if you belong to the OCI_Administrators group, this permission is included. To give this permission to non-administrators, you'll need to write a policy like the following:

```
Allow group GroupA to inspect identity-providers in tenancy
```

where you replace GroupA with the name of the group you want to grant the permission to.

To manage service roles, you must be assigned the Administrator role for that service.

Managing Group Roles in the Console

To add roles to a group

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Federation**.

2. Click your Oracle Identity Cloud Service federation. For most tenancies, the federation is named **OracleIdentityCloudService**. The identity provider details page is displayed.
3. Click **Groups**.
   The list of groups is displayed.
4. Click the name of the group you want to add roles to.
5. On the group details page, click **Manage Service Roles**. The **Manage Service Roles** page displays the list of services for which you have Administrator access. The service roles that this group has already been granted are also displayed.
   Note that you won't see services that you don't have Administrator access for.
6. Find the service you want to edit this group's access to, click the Actions icon (three dots), and then click **Manage service access**. The list of roles for the selected service is displayed.
7. Select the check box for each role you want to assign to the group.
8. Click **Save Role Selections**.
9. To add more service roles to this group, repeat steps 6 - 8.
10. Click **Apply Service Role Settings**.
11. In the confirmation dialog, click **Send Email to Group** to send an email to each member of the group to notify them of this change.
    Your email client launches with a default email message to the affected users with information about the access changes. You can send the email as written, or make modifications before sending.
12. Return to the Console and click **Close**.

To revoke roles from a group

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Federation**.
2. Click your Oracle Identity Cloud Service federation. For most tenancies, the federation

is named **OracleIdentityCloudService**. The identity provider details page is displayed.

3. Click **Groups**.
   The list of groups is displayed.
4. Click the name of the group you want to remove roles from.
5. On the group details page, click **Manage Service Roles**. The **Manage Service Roles** page displays the list of services for which you have Administrator access. The service roles that this group has already been granted are also displayed.
   Note that you won't see services that you don't have Administrator access for.
6. Find the service you want to edit this group's access to, click the Actions icon (three dots), and then click **Manage service access**. The list of roles for the selected service is displayed.
7. Clear the check box for each role you want remove from the group.
8. Click **Save Role Selections**.
9. To revoke more service roles from this group, repeat steps 6 - 8.
10. Click **Apply Service Role Settings**.
11. A confirmation dialog displays the services that you modified access to in this session. Click **Close**.

MANAGING INSTANCE ROLES IN THE CONSOLE

Some services allow you to grant access to instances of the service. After you (or someone in your organization) creates an instance, use this procedure to manage group access to the instance.

Managing Group Access to an Instance

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Federation**.
2. Click your Oracle Identity Cloud Service federation. For most tenancies, the federation is named **OracleIdentityCloudService**. The identity provider details page is displayed.

3. Click **Groups**.
   The list of groups is displayed.
4. On the group details page, click **Manage Service Roles**. The **Manage Service Roles** page displays the list of services for which you have Administrator access. The service roles that this group has already been granted are also displayed.
   Note that you won't see services that you don't have Administrator access for.
5. Find the service with instances that you want to edit this group's access to, click the Actions icon (three dots), and then click **Manage instance access**. The list of instances for the selected service is displayed.
6. On the **Manage Access to Instances** page, find the name of the instance you want to edit this group's access to.
   - To grant access to this instance: In the **Instance Role** column, select the role you want to grant to the group. You can select multiple roles from the list.
   - To remove access to this instance: In the **Instance Role** column, click the **x** next to the role you want to remove from the group.
7. When you are finished editing roles for this service, click **Save Instance Settings**.
8. To edit more instance roles for this group, repeat steps 6 - 7.
9. On the **Manage Service Roles** page, click **Apply Service Role Settings**.
10. If you added roles, in the confirmation dialog, click **Send Email to Group** to send an email to each member of the group to notify them of this change. Your email client launches with a default email message to the affected users with information about the access changes. You can send the email as written, or make modifications before sending. Return to the Console and click **Close**.
    If you revoked roles, a confirmation dialog displays the services that you modified access to in this session. Click **Close**.

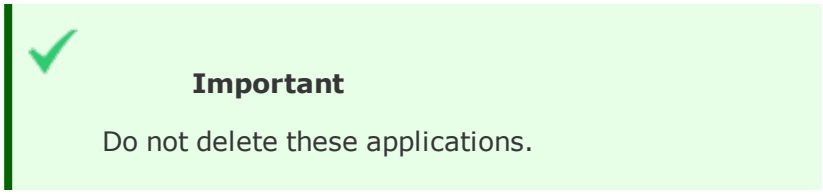
Frequently Asked Questions for Oracle Identity Cloud Service Federated Users

When you sign up for Oracle Cloud Infrastructure, your account is automatically federated with Oracle Identity Cloud Service as your identity provider. This topic answers some frequently asked questions about the federation.

What resources are created in Oracle Identity Cloud Service?

THE FOLLOWING RESOURCES ARE CREATED IN IDENTITY CLOUD SERVICE:

- **Applications:**
  - *OCI-V2-<tenancy_name>*
    This SAML application that creates the federation with Oracle Cloud Infrastructure.
  - COMPUTEBAREMETAL application
    A supporting application for the federation.



Important

Do not delete these applications.

- **Group:**
  OCI_Administrators group
  This group is mapped to the Administrators group in Oracle Cloud Infrastructure. Members of this group have full administrator privileges in Oracle Cloud Infrastructure.
- **User:**
  A default administrator user (e.g., user@example.com) who is a member of the OCI_ Administrators group.

What resources are created in Oracle Cloud Infrastructure?

THE FOLLOWING RESOURCES ARE CREATED IN ORACLE CLOUD INFRASTRUCTURE:

- **Identity Provider:** OracleIdentityCloudService
- **Group Mappings:**The federation is created with one group mapping:
  OCI_Administrators group (from Oracle Identity Cloud Service) is mapped to the Administrators group (In Oracle Cloud Infrastructure).

- **Users:**
  - The default administrator user created in Oracle Identity Cloud Service is provisioned in Oracle Cloud Infrastructure. This user can have the Oracle Cloud Infrastructure credentials, but not a Console password.
  - A default administrator local-user with the same user name (user@example.com) is also created in Oracle Cloud Infrastructure's IAM service. Customers who choose **not** to use the Oracle Identity Cloud Service federation can use this user to administer Oracle Cloud Infrastructure.

Important

The default administrator created in Oracle Identity Cloud Service and the local default administrator created in Oracle Cloud Infrastructure exist independently in their respective identity systems. Ensure that you manage passwords for them separately.

Why is my account federated with Oracle Identity Cloud Service?

Oracle Identity Cloud Service is the identity provider for multiple Oracle services. Federating Oracle Cloud Infrastructure with Oracle Identity Cloud Service allows you to have a seamless connection between services, without having to create a separate username and password for each one.

How do I know if I am signed in through Oracle Identity Cloud Service?

Click the **Profile** menu () to display your username. Users signed in through an identity provider will see their username prefaced with their identity provider name, for example:

oracleidentitycloudservice/user@example.com

How do I add a user to Oracle Identity Cloud Service (a federated user)?

See Managing Oracle Identity Cloud Service Users and Groups in the Oracle Cloud Infrastructure Console.

Can I add a user just for Oracle Cloud Infrastructure?

Yes. If you don't want to manage the user in Oracle Identity Cloud Service, you can add a user directly to the Oracle Cloud Infrastructure IAM service. See Adding Users. Using this procedure, you can create users who can sign in directly to the Oracle Cloud Infrastructure Console. Users created with this procedure do not have access to any other Oracle services.

How do I manage groups?

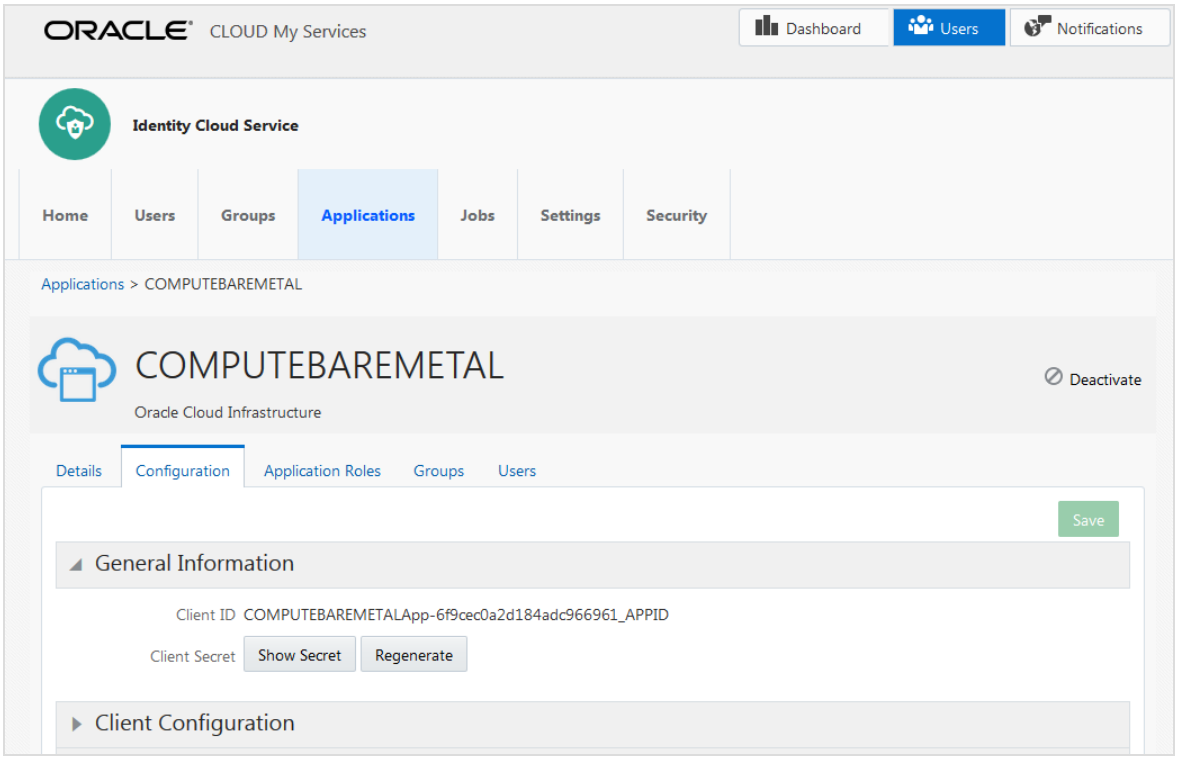
In short, managing groups requires actions in both Oracle Identity Cloud Service and Oracle Cloud Infrastructure. Groups you create in Oracle Identity Cloud Service have no privileges in Oracle Cloud Infrastructure until you map them to a group in Oracle Cloud Infrastructure. You define the policies that permit access to Oracle Cloud Infrastructure resources in the IAM service in Oracle Cloud Infrastructure. For more information, see Managing Oracle Identity Cloud Service Users and Groups in the Oracle Cloud Infrastructure Console.

How do I find the client ID and client secret?

To edit mappings of your user groups in Oracle Identity Cloud Service to user groups in Oracle Cloud Infrastructure, you'll need to supply the client ID and client secret. The client ID and client secret are stored in Oracle Identity Cloud Service. To get this information:

1. Sign in to the Oracle Identity Cloud Service console.
2. In the Identity Cloud Service console, click **Applications**. The list of trusted applications is displayed.
3. Click COMPUTEBAREMETAL.
4. Click **Configuration**.

5. Expand **General Information**. The client ID is displayed. Click **Show Secret** to display the client secret.



If I delete the federation, can I later recreate it?

Yes. To recreate the federation with Oracle Identity Cloud Service, follow the instructions in the topic Federating with Oracle Identity Cloud Service.

Federating with Microsoft Active Directory

This topic describes how to federate with Microsoft Active Directory using Microsoft Active Federation Services (AD FS).

Note

Before following the steps in this topic, see Federating with Identity Providers to ensure that you understand general federation concepts.

About Federating with Microsoft Active Directory

Your organization can have multiple Active Directory accounts (e.g., one for each division of the organization). You can federate multiple Active Directory accounts with Oracle Cloud Infrastructure, but each federation trust that you set up must be for a single Active Directory account.

To federate with Active Directory, you set up a trust between Active Directory and Oracle Cloud Infrastructure. To set up this trust, you perform some steps in the Oracle Cloud Infrastructure Console and some steps in Active Directory Federation Services.

Following is the general process an administrator goes through to set up federation with Active Directory. Details for each step are given in the sections below.

1. Get required information from Active Directory Federation Services.
2. Federate Active Directory with Oracle Cloud Infrastructure:
    a. Add the identity provider (AD FS) to your tenancy and provide the required information.
    b. Map Active Directory groups to IAM groups.
3. In Active Directory Federation Services, add Oracle Cloud Infrastructure as a trusted, relying party.
4. In Active Directory Federation Services, add the claim rules required in the authentication response by Oracle Cloud Infrastructure.
5. Test your configuration by logging in to Oracle Cloud Infrastructure with your Active Directory credentials.

Federating with Active Directory

Prerequisites

You have installed and configured Microsoft Active Directory Federation Services for your organization.

You have set up groups in Active Directory to map to groups in Oracle Cloud Infrastructure.

Tip

Consider naming Active Directory groups that you intend to map to Oracle Cloud Infrastructure groups with a common prefix, to make it easy to apply a filter rule. For example, OCI_Administrators, OCI_NetworkAdmins, OCI_InstanceLaunchers.

Step 1: Get required information from Active Directory Federation Services

Summary: Get the SAML metadata document and the names of the Active Directory groups that you want to map to Oracle Cloud Infrastructure Identity and Access Management groups.

1. Locate the SAML metadata document for your AD FS federation server. By default, it is located at this URL:

   ```
   https://<yourservername>/FederationMetadata/2007-06/FederationMetadata.xml
   ```

   Download this document and make a note of where you save it. You will upload this document to the Console in the next step.

2. Note all the Active Directory groups that you want to map to Oracle Cloud Infrastructure IAM groups. You will need to enter these in the Console in the next step.

Step 2: Add Active Directory as an identity provider in Oracle Cloud Infrastructure

Summary: Add the identity provider to your tenancy. You can set up the group mappings at the same time, or set them up later.

1. Go to the Console and sign in with your Oracle Cloud Infrastructure login and password.
2. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Federation**.
3. Click **Add identity provider**.
4. Enter the following:
    a. **Display Name:** A unique name for this federation trust. This is the name federated users see when choosing which identity provider to use when signing in to the Console. The name must be unique across all identity providers you add to the tenancy. You cannot change this later.
    b. **Description:** A friendly description.
    c. **Type:** Select Microsoft Active Directory Federation Services (ADFS) or SAML 2.0 compliant identity provider.
    d. **XML:** Upload the FederationMetadata.xml file you downloaded from Azure AD.
    e. Click **Show Advanced Options**.
    f. **Encrypt Assertion:** Selecting the check box lets the IAM service know to expect the encryption from IdP. Do not select this check box unless you have enabled assertion encryption in Azure AD.
    To enable assertion encryption for this single sign-on application in Azure AD, set up the SAML Signing Certificate in Azure AD to sign the SAML response and assertion. For more information, see the Azure AD documentation.
    g. **Force Authentication:** Selected by default. When selected, users are required to provide their credentials to the IdP (re-authenticate) even when they are already signed in to another session.
    h. **Authentication Context Class References:** This field is required for Government Cloud customers. When one or more values are specified, Oracle Cloud Infrastructure (the relying party), expects the identity provider to use one of the specified authentication mechanisms when authenticating the user. The returned SAML response from the IdP must contain an authentication statement with that authentication context class reference. If the SAML response

authentication context does not match what is specified here, the Oracle Cloud Infrastructure auth service rejects the SAML response with a 400.

Several common authentication context class references are listed in the menu. To use a different context class, select **Custom**, then manually enter the class reference.

i. Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.

5. Click **Continue**.
6. Set up the mappings between Active Directory groups and IAM groups in Oracle Cloud Infrastructure. A given Active Directory group can be mapped to zero, one, or multiple IAM groups, and vice versa. However, each individual mapping is between only a single Active Directory group and a single IAM group. Changes to group mappings take effect typically within seconds in your home region, but may take several minutes to propagate to all regions.

Note

If you don't want to set up the group mappings now, you can simply click **Create** and come back to add the mappings later.

To create a group mapping:

a. Under **Identity Provider Group**, enter the Active Directory group name. You must enter the name exactly, including the correct case.

Choose the IAM group you want to map from the list under **OCI Group**. If you instead want to create a new IAM group, select **New OCI Group** and enter the name of the new group in **New OCI Group Name**. The new group is automatically created in IAM and mapped to the IdP group. It will also

automatically be given this description, which you can't change: "Group created during federation".

Tip

Requirements for IAM group name: No spaces. Allowed characters: letters, numerals, hyphens, periods, underscores, and plus signs (+). The name cannot be changed later.

b. Repeat the above sub-steps for each mapping you want to create, and then click **Create**.

The identity provider is now added to your tenancy and appears in the list on the **Federation** page. Click the identity provider to view its details and the group mappings you just set up.

Oracle assigns the identity provider and each group mapping a unique ID called an Oracle Cloud ID (OCID). For more information, see Resource Identifiers.

In the future, come to the **Federation** page if you want to edit the group mappings or delete the identity provider from your tenancy.

STEP 3: COPY THE URL FOR THE ORACLE CLOUD INFRASTRUCTURE FEDERATION METADATA DOCUMENT

Summary: The Federation page displays a link to the Oracle Cloud Infrastructure Federation Metadata document. Before you move on to configuring Active Directory Federation Services, you need to copy the URL.

1. On the Federation page, click **Download this document**.
2. Copy the URL. The URL looks similar to:

```
https://auth.r2.oracleiaas.com/v1/saml/ocid1.tenancy.oc1..aaaaaaaaqdt2tvdmhsa3jmvc5dzulgs3pcv6imfwfgdya4aq/metadata.xml
```

STEP 4: IN ACTIVE DIRECTORY FEDERATION SERVICES, ADD ORACLE CLOUD INFRASTRUCTURE AS A TRUSTED RELYING PARTY

1. Go to the AD FS Management Console and sign in to the account you want to federate.
2. Add Oracle Cloud Infrastructure as a **trusted relying party**:
    a. From the AD FS Management Console, right-click AD FS and select **Add Relying Party Trust**.
    b. In the **Add Relying Party Trust Wizard**, click **Start**.
    c. Select **Import data about the relying party published online or on a local network**.
    Paste the Oracle Cloud Infrastructure Federation Metadata URL that you copied in Step 3. Click **Next**.
    AD FS will connect to the URL. If you get an error during the attempt to read the federation metadata, you can alternatively upload the Oracle Cloud Infrastructure Federation Metadata XML document.

    ##### To upload the federation metadata document

    i. In a web browser, paste the Oracle Cloud Infrastructure Federation Metadata URL in the address bar.
    ii. Save the XML document to a location that is accessible by your AD FS Management Console.
    iii. In the **Select Data Source** step of the **Add Relying Party Trust Wizard**, select **Import data about the relying party from a file**.
    iv. Click **Browse** and select the metadata.xml file that you saved.
    v. Click **Next**.

    d. Set the display name for the relying party (e.g., Oracle Cloud Infrastructure) and then click **Next**.
    e. Select **I do not want to configure multi-factor authentication settings for this relying party trust at this time**.

f. Choose the appropriate Issuance Authorization Rules to either permit or deny all users access to the relying party. Note that if you choose "Deny", then you must later add the authorization rules to enable access for the appropriate users. Click **Next**.

g. Review the settings and click **Next**.

h. Check **Open the Edit Claim Rules** dialog for this relying part trust when the wizard closes and then click **Close**.

STEP 5: ADD THE CLAIM RULES FOR THE ORACLE CLOUD INFRASTRUCTURE RELYING PARTY

Summary: Add the claim rules so that the elements that Oracle Cloud Infrastructure requires (Name ID and groups) are added to the SAML authentication response.

Add the Name ID rule:

1. In the **Add Transform Claim Rule Wizard**, select **Transform an Incoming Claim**, and click **Next**.
2. Enter the following:
   - **Claim rule name:** Enter a name for this rule, e.g., nameid.
   - **Incoming claim type:** Select Windows account name.
   - **Outgoing claim type:** Select Name ID.
   - **Outgoing name ID format:** Select Persistent Identifier.
   - Select **Pass through all claim value**.
   - Click **Finish**.
3. The rule is displayed in the rules list. Click **Add Rule**.

Add the groups rule:

> **Important**
>
> Any users who are in more than 100 IdP groups cannot be authenticated to use the Oracle Cloud InfrastructureConsole. To enable authentication, apply a filter to the groups rule, as described below.

If your Active Directory users are in no more than 100 groups

Add the groups rule:

1. Under Claim rule template, select **Send Claims Using a Custom Rule**. Click **Next**.
2. In the **Add Transform Claim Rule Wizard**, enter the following:
   a. **Claim rule name:** Enter groups.
   b. **Custom rule:** Enter the following custom rule:

```
c:[Type == "http://schemas.microsoft.com/ws/2008/06/identity/claims/windowsaccountname",
Issuer == "AD AUTHORITY"] => issue(store = "Active Directory", types =
("https://auth.oraclecloud.com/saml/claims/groupName"), query = ";tokenGroups;{0}", param
= c.Value);
```

   c. Click **Finish**.

If your Active Directory users are in more than 100 groups

Add the groups rule with a filter:

To limit the groups sent to Oracle Cloud Infrastructure, create two custom claim rules. The first one retrieves all groups the user belongs to directly and indirectly. The second rule applies a filter to limit the groups passed to the service provider to only those that match the filter criteria.

Add the first rule:

1. In the Edit Claim Rules dialog, click **Add Rule**.
2. Under Claim rule template, select **Send Claims Using a Custom Rule**. Click **Next**.
3. In the **Add Transform Claim Rule Wizard**, enter the following:
    a. **Claim rule name:** Enter a name, for example, groups.
    b. **Custom rule:** Enter the following custom rule:

    ```
    c:[Type == "http://schemas.microsoft.com/ws/2008/06/identity/claims/windowsaccountname",
    Issuer == "AD AUTHORITY"] => add(store = "Active Directory", types =
    ("https://auth.oraclecloud.com/saml/claims/groupName"), query = ";tokenGroups;{0}", param
    = c.Value);
    ```

    Note that in this custom rule you use `add` instead of `issue`. This command passes the results of the rule to the next rule, instead of sending the results to the service provider.
    c. Click **Finish**.
4. Now add the filter rule.
    a. In the Edit Claim Rules dialog, click **Add Rule**.
    b. Under Claim rule template, select **Send Claims Using a Custom Rule**. Click **Next**.
    c. In the **Add Transform Claim Rule Wizard**, enter the following:
        i. **Claim rule name:** Enter groups.
        ii. **Custom rule:** Enter an appropriate filter rule. For example to send only groups that begin with the string "OCI", enter the following:

        ```
        c:[Type == "https://auth.oraclecloud.com/saml/claims/groupName", Value =~ "(?i)OCI"]
        => issue(claim = c);
        ```

        This rule filters the list from the first rule to only those groups that begin with the string `OCI`. The `issue` command, sends the results of the rule to the service provider.
        You can create filters with the appropriate criteria for your organization.

For information on AD FS syntax for custom rules, see the Microsoft document: Understanding Claim Rule Language in AD FS 2.0 and Higher.

iii. Click **Finish**.

STEP 6: SET UP IAM POLICIES FOR THE GROUPS

If you haven't already, set up IAM policies to control the access the federated users have to your organization's Oracle Cloud Infrastructure resources. For more information, see Getting Started with Policies and Common Policies.

STEP 7: GIVE YOUR FEDERATED USERS THE NAME OF THE TENANT AND URL TO SIGN IN

The federated users need the URL for the Oracle Cloud Infrastructure Console (for example, https://console.us-ashburn-1.oraclecloud.com) and the name of your tenant. They'll be prompted to provide the tenant name when they sign in to the Console.

Managing Identity Providers in the Console

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

To add an identity provider

See Federating with Microsoft Active Directory.

To delete an identity provider

All the group mappings for the identity provider will also be deleted.

1. Delete the identity provider from your tenancy:
    a. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Federation**.
    A list of the identity providers in your tenancy is displayed.
    b. Click the identity provider to view its details.
    c. Click **Delete**.
    d. Confirm when prompted.

To add group mappings for an identity provider

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Federation**.
    A list of the identity providers in your tenancy is displayed.
2. Click the identity provider to view its details.
3. Click **Edit Mapping**.
4. Add at least one mapping:
    a. Click **+ Add Mapping**.
    b. Under **Identity Provider Group**, enter the Active Directory group name. The name you enter here must match exactly the name in Active Directory.
    c. Choose the IAM group you want to map from the list under **OCI Group**. If you instead want to create a new IAM group, select **New OCI Group** and enter the name of the new group in **New OCI Group Name**. The new group is automatically created in IAM and mapped to the IdP group. It will also automatically be given this description, which you can't change: "Group created during federation".
    d. Repeat the above sub-steps for each mapping you want to create, and then click **Submit**.

Your changes take effect typically within seconds.

To update a group mapping

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Federation**.
   A list of the identity providers in your tenancy is displayed.
2. Click the identity provider to view its details.
3. Click **Edit Mapping**.
4. Update the mappings (or click the X to delete a mapping), and then click **Submit**.

Your changes take effect typically within seconds.

To delete a group mapping

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Federation**.
   A list of the identity providers in your tenancy is displayed.
2. Click the identity provider to view its details.
3. For the mapping you want to delete, click **Delete** next to it.
4. Confirm when prompted.

Your changes take effect typically within seconds.

Managing Identity Providers in the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use these API operations:

Identity providers:

- CreateIdentityProvider
- ListIdentityProviders

- GetIdentityProvider
- UpdateIdentityProvider
- DeleteIdentityProvider: Before you can use this operation, you must first use DeleteIdpGroupMapping to remove all the group mappings for the identity provider.

Group mappings:

- CreateIdpGroupMapping: Each group mapping is a separate entity with its own OCID.
- ListIdpGroupMappings
- GetIdpGroupMapping
- UpdateIdpGroupMapping
- DeleteIdpGroupMapping

Federating with Microsoft Azure Active Directory

This topic describes how to federate with Microsoft Azure Active Directory (AD).

Note

Before following the steps in this topic, see Federating with Identity Providers to ensure that you understand general federation concepts.

About Federating with Azure AD

To federate with Azure AD, you set up Oracle Cloud Infrastructure as a basic SAML single sign-on application in Azure AD. To set up this application, you perform some steps in the Oracle Cloud Infrastructure Console and some steps in Azure AD.

Following is the general process an administrator goes through to set up the federation. Details for each step are given in the next section.

1. In Oracle Cloud Infrastructure, download the federation metadata document.
2. In Azure AD, set up Oracle Cloud Infrastructure Console as an enterprise application.
3. In Azure AD, configure the Oracle Cloud Infrastructure enterprise application for single sign-on.
4. In Azure AD, set up the user attributes and claims.
5. In Azure AD, download the Azure AD SAML metadata document.
6. In Azure AD, assign user groups to the application.
7. In Oracle Cloud Infrastructure, set up Azure AD as an identity provider.
8. In Oracle Cloud Infrastructure, map your Azure AD groups to Oracle Cloud Infrastructure groups.
9. In Oracle Cloud Infrastructure, set up the IAM policies to govern access for your Azure AD groups.
10. Share the Oracle Cloud Infrastructure sign-in URL with your users.

Steps to Federate with Azure AD

Prerequisites

You have an Azure tenancy with groups and users set up in Azure AD.

STEP 1: IN ORACLE CLOUD INFRASTRUCTURE, DOWNLOAD THE FEDERATION METADATA DOCUMENT

Summary: The Oracle Cloud Infrastructure Console Federation page displays a link to the Oracle Cloud Infrastructure federation metadata document. Before you set up the application in Azure AD, you need to download the document.

1. Go to the **Federation** page: Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Federation**.

   On the Federation page, click **Download this document**.

2. 
After you click the link, the metadata.xml document opens in your browser window. Use your browser's **Save page as** command to save the xml document locally where you can access it later.

Step 2: In Azure AD, add Oracle Cloud Infrastructure as an enterprise application

1. In the Azure portal, on the left navigation panel, select **Azure Active Directory**.
2. In the **Azure Active Directory** pane, select **Enterprise applications**. A sample of the applications in your Azure AD tenant is displayed.
3. At the top of the **All applications** pane, click **New application**.
4. In the **Add from gallery** region, enter **Oracle Cloud Infrastructure Console** in the search box.
5. Select the Oracle Cloud Infrastructure Console application from the results and select **Add**.
6. In the application-specific form, you can edit information about the application. For example, you can edit the name of the application.
7. When you are finished editing the properties, select **Add**.
   The getting started page is displayed with the options for configuring the application for your organization.

STEP 3: IN AZURE AD, CONFIGURE ORACLE CLOUD INFRASTRUCTURE AS AN ENTERPRISE APPLICATION

Under the **Manage** section, select **Single sign-on**.

1. 
2. Select **SAML** to configure single sign-on. The **Set up Single Sign-On with SAML - Preview** page is displayed.

   At the top of the page, click **Upload metadata file**.

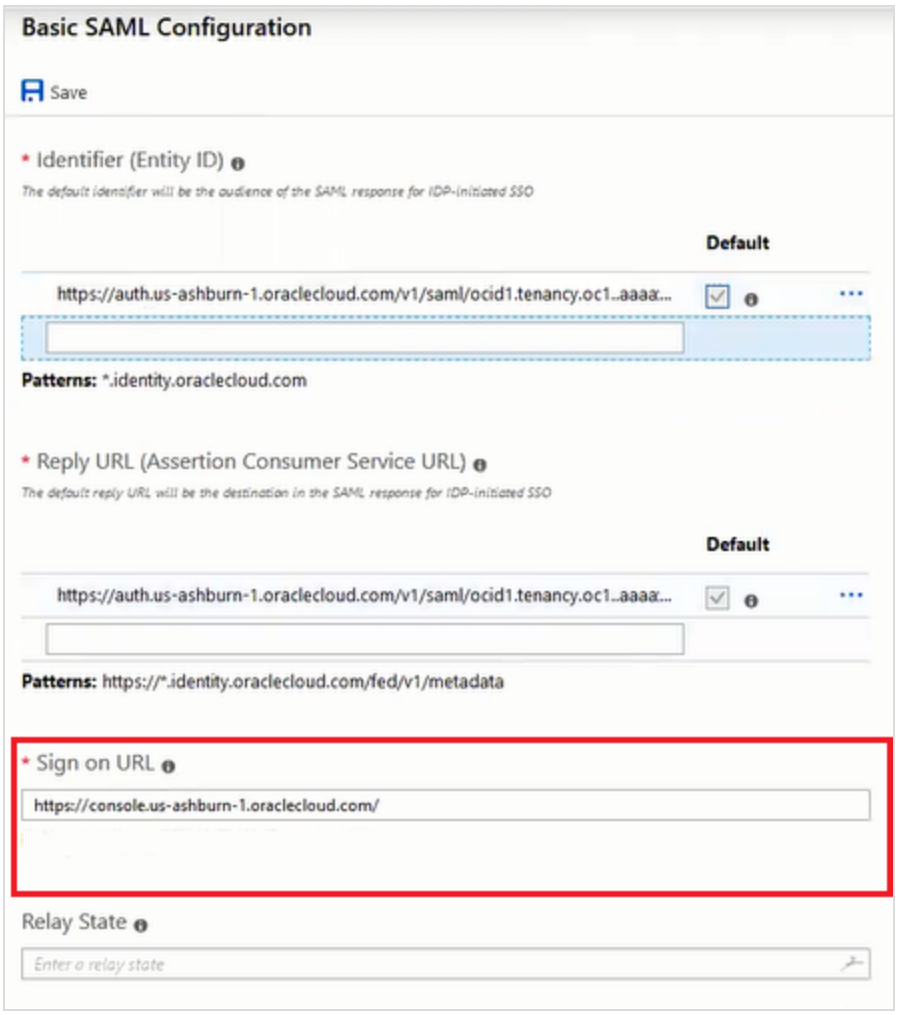
3. 
4. Locate the federation metadata file (metadata.xml) you downloaded from Oracle Cloud

Infrastructure in Step 1, and upload it here. After you upload the file, these **Basic SAML Configuration** fields are automatically populated:

- Identifier (Entity ID)
- Reply URL (Assertion Consumer Service URL)

5. In the **Basic SAML Configuration** section, click **Edit**. On the **Basic SAML Configuration** pane, enter the following required field:
   - **Sign on URL:** Enter the URL in the following format:
     `https://console.<oci_home_region>.oraclecloud.com`
     where *oci_home_region* is your tenancy's home region. For example, if you home region is Ashburn, enter:
     `https://console.us-ashburn-1.oraclecloud.com`

How do I find my home region?



6. Click **Save**.

STEP 4. CONFIGURE USER ATTRIBUTES & CLAIMS

The Oracle Cloud Infrastructure Console enterprise application template is seeded with the required attributes, so you don't need to add any. However, you do need to make the following customizations:

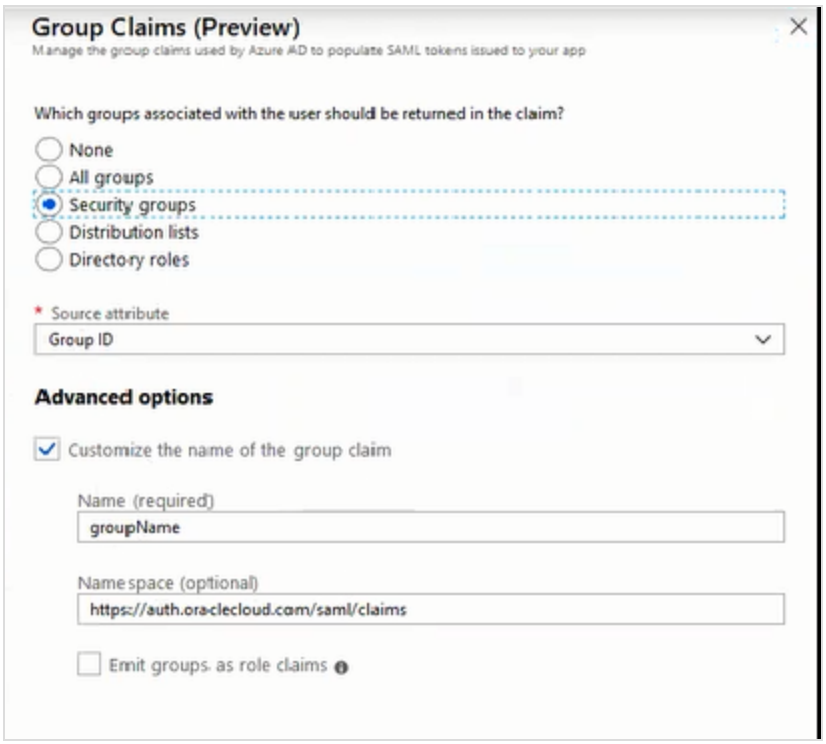
1. In the **User Attributes & Claims** section, click **Edit** in the upper-right corner. The **Manage user claims** panel is displayed.
2. Next to the **Name identifier value** field, click **Edit**.
   - Under **Choose name identifier format**, select Persistent.
   - For **Source**, select Attribute.

     For **Source attribute**, select user.userprincipalname.

     
   -
   - Click **Save**.
3. Next to the **Groups returned in claim** field, click **Edit**.
4. In the **Group Claims (Preview)** panel, configure the following:
   - Select Security groups.
   - **Source attribute:** Select Group ID.
   - Under **Advanced Options**, select **Customize the name of the group claim**.
   - In the **Name** field, enter: groupName.

     Ensure that you enter groupName with spelling and case exactly as given.

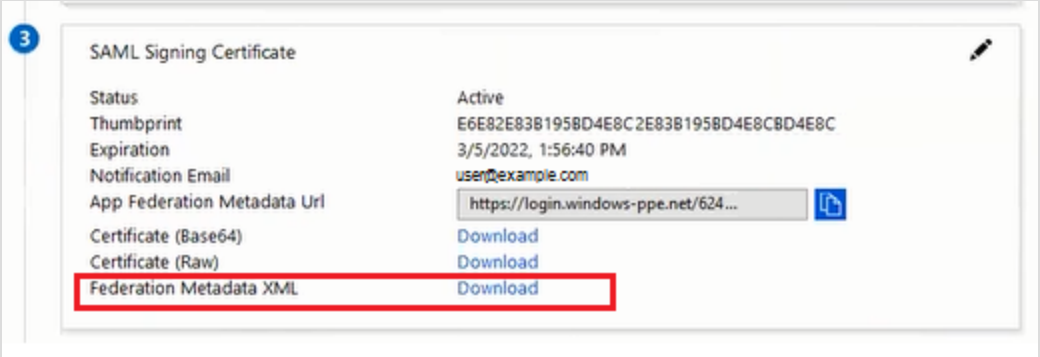
In the **Namespace** field, enter: `https://auth.oraclecloud.com/saml/claims`



-
- Click **Save**.

STEP 5: DOWNLOAD THE SAML METADATA DOCUMENT

1. On the **SAML Signing Certificate** section, click the download link next to **Federation Metadata XML**.



2. Download this document and make a note of where you save it. You will upload this document to the Console in the next step.

STEP 6. ASSIGN USER GROUPS TO THE APPLICATION

To enable Azure AD users to sign in to Oracle Cloud Infrastructure, you need to assign the appropriate user groups to your new enterprise application.

1. On the left navigation pane, under **Manage**, select **Users and Groups**.
2. Click **Add** at the top of the **Users and Groups** list to open the **Add Assignment** pane.
3. Click the **Users and groups** selector.
4. Enter the name of the group you want to assign to the application into the **Search by name or email address** search box.
5. Hover over the group in the results list to display a check box. Select the check box to add the group to the **Selected** list.
6. When you are finished selecting groups, click **Select** to add them to the list of users and groups to be assigned to the application.
7. Click **Assign** to assign the application to the selected groups.

STEP 7: ADD AZURE AD AS AN IDENTITY PROVIDER IN ORACLE CLOUD INFRASTRUCTURE

Summary: Add the identity provider to your tenancy. You can set up the group mappings at the same time, or set them up later.

1. Go to the Console and sign in with your Oracle Cloud Infrastructure username and password.
2. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Federation**.
3. Click **Add identity provider**.
4. Enter the following:
    a. **Display Name:** A unique name for this federation trust. This is the name federated users see when choosing which identity provider to use when signing in to the Console. The name must be unique across all identity providers you add to the tenancy. You cannot change this later.
    b. **Description:** A friendly description.
    c. **Type:** Select Microsoft Active Directory Federation Services (ADFS) or SAML 2.0 compliant identity provider.
    d. **XML:** Upload the FederationMetadata.xml file you downloaded from Azure AD.
    e. Click **Show Advanced Options**.
    f. **Encrypt Assertion:** Selecting the check box lets the IAM service know to expect the encryption from IdP. Do not select this check box unless you have enabled assertion encryption in Azure AD.

    To enable assertion encryption for this single sign-on application in Azure AD, set up the SAML Signing Certificate in Azure AD to sign the SAML response and assertion. For more information, see the Azure AD documentation.
    g. **Force Authentication:** Selected by default. When selected, users are required to provide their credentials to the IdP (re-authenticate) even when they are already signed in to another session.
    h. **Authentication Context Class References:** This field is required for Government Cloud customers. When one or more values are specified, Oracle Cloud Infrastructure (the relying party), expects the identity provider to use one of the specified authentication mechanisms when authenticating the user. The returned SAML response from the IdP must contain an authentication statement

with that authentication context class reference. If the SAML response authentication context does not match what is specified here, the Oracle Cloud Infrastructure auth service rejects the SAML response with a 400.

Several common authentication context class references are listed in the menu. To use a different context class, select **Custom**, then manually enter the class reference.

i. Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.

5. Click **Continue**.

Note

If you don't want to set up the group mappings now, you can simply click **Create** and come back to add the mappings later.

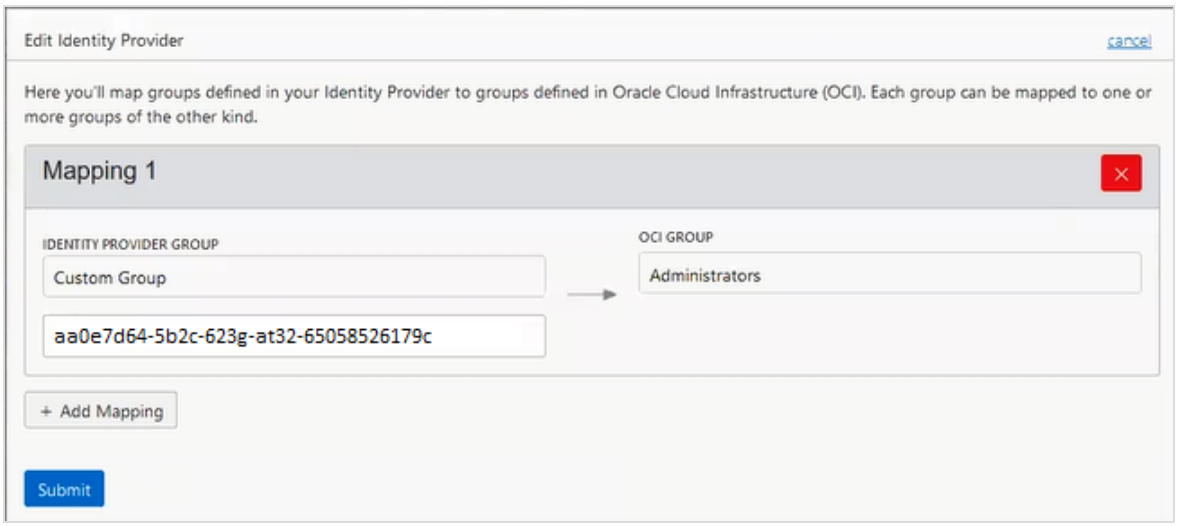
STEP 8. ADD GROUP MAPPINGS

Summary: Set up the mappings between Azure AD groups and IAM groups in Oracle Cloud Infrastructure. A given Azure AD group can be mapped to zero, one, or multiple IAM groups, and vice versa. However, each individual mapping is between only a single Azure AD group and a single IAM group. Changes to group mappings take effect typically within seconds in your home region, but may take several minutes to propagate to all regions. Note that the Azure AD groups that you choose to map must also be assigned to the enterprise application in Azure AD. See Step 6. Assign user groups to the application.

Before you begin: Have your Azure AD groups page open. From the Azure Dashboard, under **Manage**, select **Groups**. From the list of groups, select the group you want to map to an Oracle Cloud Infrastructure group. In the group's details page, click the **Copy** icon next to the Object ID for the group.

To create a group mapping:

For **Identity Provider Group**, select Custom Group. Enter (or paste) the Object ID of the Azure AD group. You must enter the Object ID exactly, including the correct case. An example Object ID looks like: aa0e7d64-5b2c-623g-at32-65058526179c



1.

2. Choose the IAM group you want to map from the list under **OCI Group**. If you instead want to create a new IAM group, select **New OCI Group** and enter the name of the new group in **New OCI Group Name**. The new group is automatically created in IAM and mapped to the IdP group. It will also automatically be given this description, which you can't change: "Group created during federation".
3. Repeat the preceding steps for each mapping you want to create, and then click **Create**.

> **Tip**
>
> Requirements for IAM group name: No spaces. Allowed characters: letters, numerals, hyphens, periods, underscores, and plus signs (+). The name cannot be changed later.

The identity provider is now added to your tenancy and appears in the list on the **Federation** page. Click the identity provider to view its details and the group mappings you just set up.

Oracle assigns the identity provider and each group mapping a unique ID called an Oracle Cloud ID (OCID). For more information, see Resource Identifiers.

In the future, come to the **Federation** page if you want to edit the group mappings or delete the identity provider from your tenancy.

STEP 9: SET UP IAM POLICIES FOR THE GROUPS

If you haven't already, set up IAM policies to control the access the federated users have to your organization's Oracle Cloud Infrastructure resources. For more information, see Getting Started with Policies and Common Policies.

STEP 10: GIVE YOUR FEDERATED USERS THE NAME OF THE TENANT AND URL TO SIGN IN

The federated users need the URL for the Oracle Cloud Infrastructure Console (for example, https://console.us-ashburn-1.oraclecloud.com) and the name of your tenant. They'll be prompted to provide the tenant name when they sign in to the Console.

Managing Identity Providers in the Console

To add an identity provider

See Federating with Microsoft Azure Active Directory.

To delete an identity provider

All the group mappings for the identity provider will also be deleted.

1. Delete the identity provider from your tenancy:
    a. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Federation**.
    A list of the identity providers in your tenancy is displayed.

b. Click the identity provider to view its details.
c. Click **Delete**.
d. Confirm when prompted.

To add group mappings for an identity provider

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Federation**.
   A list of the identity providers in your tenancy is displayed.
2. Click the identity provider to view its details.
3. Click **Edit Mapping**.
4. Add at least one mapping:
   a. Click **+ Add Mapping**.
   b. Under **Identity Provider Group**, select Custom Group. Enter (or paste) the Object ID of the Azure AD group. You must enter the Object ID exactly, including the correct case. An example Object ID looks like: aa0e7d64-5b2c-623g-at32-65058526179c. Note that for groups to be able to sign in to Oracle Cloud Infrastructure, they must also be assigned to the enterprise application in Azure AD. See Step 6. Assign user groups to the application.
   c. Choose the IAM group you want to map from the list under **OCI Group**. If you instead want to create a new IAM group, select **New OCI Group** and enter the name of the new group in **New OCI Group Name**. The new group is automatically created in IAM and mapped to the IdP group. It will also automatically be given this description, which you can't change: "Group created during federation".
   d. Repeat the preceding steps for each mapping you want to create, and then click **Submit**.

Your changes take effect typically within seconds.

To update a group mapping

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Federation**.
   A list of the identity providers in your tenancy is displayed.
2. Click the identity provider to view its details.
3. Click **Edit Mapping**.
4. Update the mappings (or click the X to delete a mapping), and then click **Submit**.

Your changes take effect typically within seconds.

To delete a group mapping

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Federation**.
   A list of the identity providers in your tenancy is displayed.
2. Click the identity provider to view its details.
3. For the mapping you want to delete, click **Delete** next to it.
4. Confirm when prompted.

Your changes take effect typically within seconds.

Managing Identity Providers in the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use these API operations:

Identity providers:

- CreateIdentityProvider
- ListIdentityProviders

- GetIdentityProvider
- UpdateIdentityProvider
- DeleteIdentityProvider: Before you can use this operation, you must first use DeleteIdpGroupMapping to remove all the group mappings for the identity provider.

Group mappings:

- CreateIdpGroupMapping: Each group mapping is a separate entity with its own OCID.
- ListIdpGroupMappings
- GetIdpGroupMapping
- UpdateIdpGroupMapping
- DeleteIdpGroupMapping

Federating with SAML 2.0 Identity Providers

This topic describes the general steps to federate Oracle Cloud Infrastructure with any identity provider that supports the Security Assertion Markup Language (SAML) 2.0 protocol. If you want specific instructions for Oracle Identity Cloud Service or Microsoft Active Directory, see Federating with Oracle Identity Cloud Service or Federating with Microsoft Active Directory.

Tip

Find detailed setup steps for more IdPs in the following white papers:

- Oracle Cloud Infrastructure Okta Configuration for Federation and Provisioning
- Federating Oracle Access Manager to Oracle Cloud Infrastructure

Instructions for Federating

Following is the general process an administrator goes through to set up the identity provider, and below are instructions for each step. It's assumed that the administrator is an Oracle Cloud Infrastructure user with the required credentials and access.

Note

Before following the steps in this topic, see Federating with Identity Providers to ensure that you understand general federation concepts.

1. In the Oracle Cloud Infrastructure Console, get the federation metadata required to establish a trust relationship with the Identity Provider (IdP).
2. In the IdP, configure Oracle Cloud Infrastructure as an application (sometimes called a trusted relying party).
3. In the IdP, assign users and groups to your new Oracle Cloud Infrastructure application.
4. In the IdP, get the required information needed by Oracle Cloud Infrastructure.
5. In Oracle Cloud Infrastructure:
    a. Add the identity provider to your tenancy and provide information you got from the IdP.
    b. Map the IdP's groups to IAM groups.
6. In Oracle Cloud Infrastructure, make sure you have IAM policies set up for the groups so you can control users' access to Oracle Cloud Infrastructure resources.
7. Inform your users of the name of your Oracle Cloud Infrastructure tenant and the URL for the Console (for example, https://console.us-ashburn-1.oraclecloud.com).

Step 1: Get information from Oracle Cloud Infrastructure

Summary: Download the federation metadata document.

The federation metadata document is a standard SAML 2.0 document, which provides information about Oracle Cloud Infrastructure you'll need to provide to your IdP. Depending

on your provider's setup requirements, you may need to upload the entire document, or you may be asked to provide only specific metadata values from the document.

1. Sign in to the Oracle Cloud Infrastructure Console as an administrator.
2. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Federation**.
3. Right-click the **Download this document** link and save the document.

Step 2: Set up Oracle Cloud Infrastructure as a trusted application

Consult your IdP documentation for how to set up a trusted application. Refer to the metadata document you downloaded for required parameters.

Step 3: Assign users and groups to the new application.

Follow your IdP's procedures for adding users and groups to the application you set up for Oracle Cloud Infrastructure.

Step 4: Download the IdP's metadata document.

Your IdP should provide a SAML 2.0 document that contains the information Oracle Cloud Infrastructure needs to complete the federation. See your IdP documentation for instructions on downloading this document.

Step 5: Federate the IdP with Oracle Cloud Infrastructure

Summary: Add the identity provider to your tenancy. You can set up the group mappings at the same time, or set them up later.

Details:

1. Go to the Console and sign in with your Oracle Cloud Infrastructure login and password.
2. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Federation**.
3. Click **Add Identity Provider**.
4. Enter the following:

a. **Name:** A unique name for this federation trust. This is the name federated users see when choosing which identity provider to use when signing in to the Console, so consider making this a friendly, intuitive name your users will understand. The name must be unique across all identity providers you add to the tenancy. You cannot change this later.

b. **Description:** A friendly description.

c. **Type:** Select **Microsoft Active Directory Federation Service (ADFS) or SAML 2.0 Compliant Identity Provider**.

d. **XML:** Upload the metadata.xml document that you downloaded from your IdP.

e. **Encrypt Assertion:** Selecting the check box lets the IAM service know to expect the encryption from the IdP. If you select this check box, you must also set up encryption of the assertion in your IdP. For more information, see Encrypt Assertion. See also your IdP's documentation.

f. **Force Authentication:** Selected by default. When selected, users are required to provide their credentials to the IdP (re-authenticate) even when they are already signed in to another session.

g. **Authentication Context Class References:** This field is required for Government Cloud customers. When one or more values are specified, Oracle Cloud Infrastructure (the relying party), expects the identity provider to use one of the specified authentication mechanisms when authenticating the user. The returned SAML response from the IdP must contain an authentication statement with that authentication context class reference. If the SAML response authentication context does not match what is specified here, the Oracle Cloud Infrastructure auth service rejects the SAML response with a 400.

   Several common authentication context class references are listed in the menu. To use a different context class, select **Custom**, then manually enter the class reference.

h. Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information

about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.

5. Click **Continue**.
6. Set up the mappings between the IdP groups and IAM groups in Oracle Cloud Infrastructure. A given IdP group can be mapped to zero, one, or multiple IAM groups, and vice versa. However, each individual mapping is between only a single IdP group and a single IAM group. Changes to group mappings take effect typically within seconds in your home region, but may take several minutes to propagate to all regions.

Note

If you don't want to set up the group mappings now, you can simply click **Create** and come back to add the mappings later.

To create a group mapping:

a. Under **Identity Provider Group**, enter the name of the group in your IdP. You must enter the name exactly, including the correct case.

Choose the IAM group you want to map from the list under **OCI Group**. If you instead want to create a new IAM group, select **New OCI Group** and enter the name of the new group in **New OCI Group Name**. The new group is automatically created in IAM and mapped to the IdP group. It will also automatically be given this description, which you can't change: "Group created during federation".

Tip

Requirements for IAM group name: No spaces. Allowed characters: letters, numerals, hyphens, periods, underscores, and plus signs (+). The name cannot be changed later.

b. Repeat the above sub-steps for each mapping you want to create, and then click **Create**.

The identity provider is now added to your tenancy and appears in the list on the **Federation** page. Click the identity provider to view its details and the group mappings you just set up.

Oracle assigns the identity provider and each group mapping a unique ID called an Oracle Cloud ID (OCID). For more information, see Resource Identifiers.

In the future, come to the **Federation** page if you want to edit or add group mappings or delete the identity provider from your tenancy.

Step 6: Set up IAM policies for the groups

If you haven't already, set up IAM policies to control the access the federated users have to your organization's Oracle Cloud Infrastructure resources. For more information, see Getting Started with Policies and Common Policies.

Step 7: Give your federated users the name of the tenant and URL to sign in

The federated users need the URL for the Oracle Cloud Infrastructure Console (for example, https://console.us-ashburn-1.oraclecloud.com) and the name of your tenant. They'll be prompted to provide the tenant name when they sign in to the Console.

Managing Identity Providers in the Console

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

To add an identity provider

See Instructions for Federating.

To delete an identity provider

All the group mappings for the identity provider will also be deleted.

1. Delete the identity provider from your tenancy:
    a. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Federation**.
    A list of the identity providers in your tenancy is displayed.
    b. Click the identity provider to view its details.
    c. Click **Delete**.
    d. Confirm when prompted.
2. Follow your IdP's documentation to delete the application from your IdP.

To add group mappings for an identity provider

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Federation**.

A list of the identity providers in your tenancy is displayed.

2. Click the identity provider to view its details.
3. Click **Edit Mapping**.
4. Add at least one mapping:
    a. Click **+ Add Mapping**.
    b. Enter the IdP group name exactly in the **Identity Provider Group** text box.
    c. Choose the IAM group you want to map from the list under **OCI Group**. If you instead want to create a new IAM group, select **New OCI Group** and enter the name of the new group in **New OCI Group Name**. The new group is automatically created in IAM and mapped to the IdP group. It will also automatically be given this description, which you can't change: "Group created during federation".
    d. Repeat the above sub-steps for each mapping you want to create, and then click **Submit**.

Your changes take effect typically within seconds in your home region. Wait several more minutes for changes to propagate to all regions

To update a group mapping

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Federation**.
   A list of the identity providers in your tenancy is displayed.
2. Click the identity provider to view its details.
3. Click **Edit Mapping**.
4. When prompted, provide the client ID and client secret for the Oracle Identity Cloud Service application, and then click **Continue**.
5. Update the mappings (or click the X to delete a mapping), and then click **Submit**.

Your changes take effect typically within seconds in your home region. Wait several more minutes for changes to propagate to all regions

To delete a group mapping

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Federation**.
   A list of the identity providers in your tenancy is displayed.
2. Click the identity provider to view its details.
3. For the mapping you want to delete, click **Delete** next to it.
4. Confirm when prompted.

Your changes take effect typically within seconds in your home region. Wait several more minutes for changes to propagate to all regions.

Managing Identity Providers in the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use these API operations:

Identity providers:

- CreateIdentityProvider
- ListIdentityProviders
- GetIdentityProvider
- UpdateIdentityProvider
- DeleteIdentityProvider: Before you can use this operation, you must first use DeleteIdpGroupMapping to remove all the group mappings for the identity provider.

Group mappings:

- CreateIdpGroupMapping: Each group mapping is a separate entity with its own OCID.
- ListIdpGroupMappings
- GetIdpGroupMapping
- UpdateIdpGroupMapping
- DeleteIdpGroupMapping

User Provisioning for Federated Users

This topic describes how you can use SCIM to provision federated users in Oracle Cloud Infrastructure. Provisioned federated users can have API keys and other service-specific credentials.

Overview

SCIM (System for Cross-domain Identity Management) is an IETF standard protocol that enables user provisioning across identity systems. Oracle Cloud Infrastructure hosts a SCIM endpoint for provisioning federated users into Oracle Cloud Infrastructure. If your IdP is Oracle Identity Cloud Service or Okta, you can set up SCIM user provisioning.

After you configure the SCIM integration between your IdP and Oracle Cloud Infrastructure, users that belong to groups mapped to Oracle Cloud Infrastructure groups are automatically provisioned in Oracle Cloud Infrastructure. Provisioned users are assigned a unique OCID, and can have API keys and other service-specific credentials.

The following functionality is supported for provisioned, federated users:

- Provisioned users are assigned a unique OCID
- Provisioned users can have API keys, auth tokens, and other service-specific credentials
- You can list the users in the Console
- Provisioned users can access the **User Settings** page to see and manage these credentials for themselves

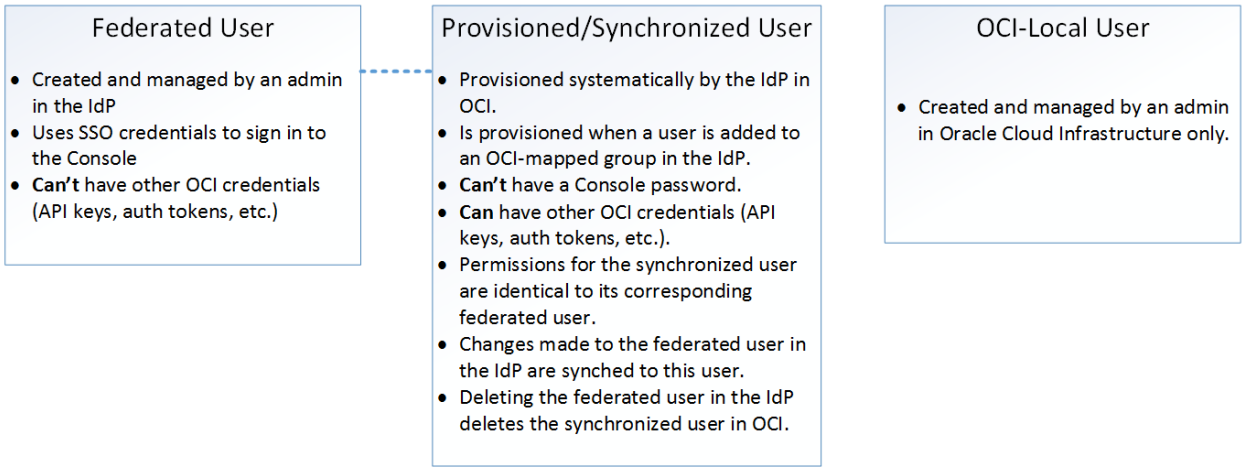
- When you add or remove users to Oracle Cloud Infrastructure-mapped groups in your IdP, the updates are automatically synched with Oracle Cloud Infrastructure

Understanding User Types

The SCIM configuration introduces the concept of the *provisioned* or *synchronized* user. The following descriptions provide details to help you understand the user types you'll be managing.

- Federated users
  A federated user is created and managed in an identity provider. Federated users can sign in to the Console using a password managed in their identity provider. Federated users are granted access to Oracle Cloud Infrastructure based on their membership in groups that are mapped to Oracle Cloud Infrastructure groups.
- Provisioned (or Synchronized) users
  A synchronized user is systematically provisioned by the identity provider in Oracle Cloud Infrastructure. Synchronized users can have Oracle Cloud Infrastructure credentials, but not Console passwords. When listing users in the Console, you can identify synchronized users using the **User Type** filter.
- Local users
  A local user is a user created and managed in Oracle Cloud Infrastructure's IAM service. Federated tenancies typically would have few, if any, local users. When listing users in the Console, you can identify local users using the **User Type** filter.

The following graphic summarizes the characteristics of the user types:



Who Should Set Up This Integration?

Set up this integration if your IdP is Oracle Identity Cloud Service or Okta and your federated users need to have the specialized credentials required by some services and features. For example, if you need your federated users to access Oracle Cloud Infrastructure through the SDK or CLI, setting up this integration enables these users to get the API keys needed for this access.

Prerequisite

Perform this synchronization setup after you have successfully set up a federation between your IdP and Oracle Cloud Infrastructure. See Supported Identity Providers.

Enabling User Provisioning

Instructions for Oracle Identity Cloud Service Federations

If your identity provider is Oracle Identity Cloud Service, you need to perform a one-time upgrade.

Important

If your tenancy was created December 21, 2018 or later, your tenancy is automatically configured to provision your Oracle Identity Cloud Service users in Oracle Cloud Infrastructure. You do not need to perform the steps in this topic. See Understanding User Types and Managing User Capabilities for Federated Users for information on managing your federated users.

Upgrading Your Oracle Identity Cloud Service Federation

If your federation with Oracle Identity Cloud service was set up before December 21, 2018, perform this one-time upgrade task.

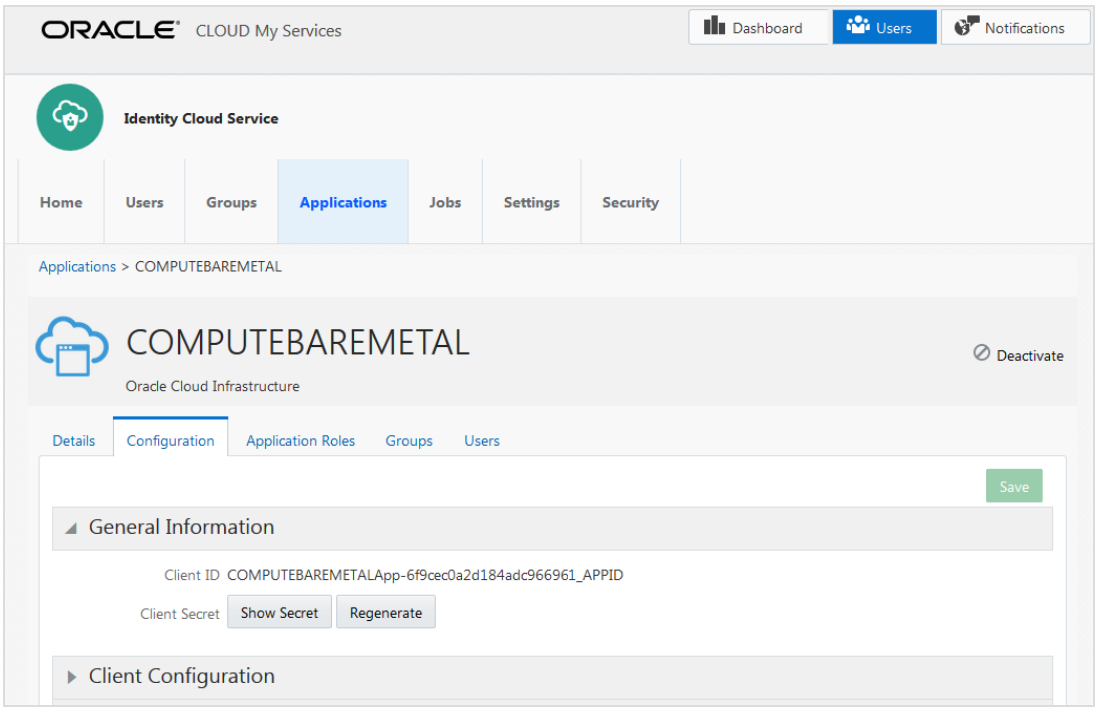
To upgrade your Oracle Identity Cloud Service federation:

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Federation**.
   A list of the identity providers in your tenancy is displayed.
2. Click your Identity Cloud Service federation to view its details. If your tenancy was auto-federated, it is listed as OracleIdentityCloudService.
3. Click **Edit Mapping**.
4. When prompted, provide the client ID and client secret for the Oracle Identity Cloud Service application, and then click **Continue**.

Where do I find the client ID and client secret?

The client ID and client secret are stored in Oracle Identity Cloud Service. To get this information:

a. Sign in to the Oracle Identity Cloud Service console.
b. In the Identity Cloud Service console, click **Applications**. The list of trusted applications is displayed.
c. Click COMPUTEBAREMETAL.
d. Click **Configuration**.
e. Expand **General Information**. The client ID is displayed. Click **Show Secret** to display the client secret.



Allow several minutes for the changes to take effect.

Instructions for Okta Federations

If you do not have an existing federation with Okta, follow the instructions in the white paper, Oracle Cloud Infrastructure Okta Configuration for Federation and Provisioning. This paper includes instructions for both setting up your federation and provisioning with SCIM.

If you have an existing federation with Okta with group mappings that you want to maintain, you can add SCIM provisioning as follows:

1. In Okta, delete the existing SAML application you originally set up to federate with Oracle Cloud Infrastructure.
2. Set up a new SAML application in Okta according to the instructions in the white paper, Oracle Cloud Infrastructure Okta Configuration for Federation and Provisioning, with the following exceptions:
    - Skip the steps to **Add Identity Provider** to Oracle Cloud Infrastructure (you already have this resource in Oracle Cloud Infrastructure).
    - Instead, click **Edit Identity Provider** and upload the new metadata.xml document from the new Okta app you created.
    - Then, in Oracle Cloud Infrastructure, ensure that you **Reset Credentials**. Add the new Client ID and Secret to the API integration settings page in Okta (Step 7 in the white paper).

What to Expect After the Upgrade

When the system has had time to synchronize, you can manage user capabilities for federated users in the Console. Users that belong to a group mapped to a group in Oracle Cloud Infrastructure are listed on the Users page in the Console. Whenever you add new users to mapped groups in Oracle Identity Cloud Service, they will be available in the Console after the system synchronizes.

By default, the following user capabilities are enabled:

- API keys
- auth tokens

- SMTP credentials
- customer secret keys

Notice that you can't enable a local password. The Oracle Cloud Infrastructure console password is still managed only in your IdP.

For more information about user capabilities, see Managing User Capabilities for Federated Users.

Resetting Credentials

Use the **Reset Credentials** button to reset your SCIM client credentials. You can perform this task periodically as a security measure to rotate your credentials. After you reset these credentials, you'll need to update the SAML app in your identity provider with the new credentials.

Note: If your IdP is Oracle Identity Cloud Service, Oracle Cloud Infrastructure automatically resets the credentials with Oracle Identity Cloud Service for you. You don't need to manually reset the configuration.

Actions You Still Perform in Your Identity Provider

After the integration is set up, continue to perform the following actions in your IdP:

- Create users and assign them to groups.
- Delete users.
  Users that you delete from your IdP are removed from Oracle Cloud Infrastructure when the next synching cycle completes.
- Query for group membership.
- Manage sign-in passwords for users.

Managing User Capabilities for Federated Users

This topic describes managing user capabilities for federated users when your tenancy is federated and configured for user provisioning with a supported identity provider.

About User Capabilities

To access Oracle Cloud Infrastructure, a user must have the required credentials. Users who need to use the Console, must have a password. Users who need access through the API need API keys. Some service features require additional credentials, such as auth tokens, SMTP credentials, and Amazon S3 Compatibility API keys. For a user to get these credentials, the user must be granted the capability to have the credential type.

User capabilities are managed by an Administrator in the user's details. Each user can see their capabilities, but only an Administrator can enable or disable them. The user capabilities available to federated users are:

- API keys
- auth tokens
- SMTP credentials
- customer secret keys

By default, these capabilities are enabled when you provision new users, allowing users to create these credentials for themselves. For information about these user credentials, see Managing User Credentials.

Important

The capability "Console password" is not available for federated users. Federated users authenticate to the Console through their IdP, where their sign-in passwords are managed.

Required IAM Policy

If you're in the Administrators group, then you have the required access for managing user capabilities. A user can't enable or disable user capabilities for themselves (except for

Administrators). However, a user can manage their own credentials that have been enabled for them.

Prerequisites

Management of user capabilities for federated users is supported for Oracle Identity Cloud Service and Okta federations only.

- Oracle Identity Cloud Service federations:
  If your tenancy was created December 21, 2018 or later, your tenancy is automatically configured to manage user capabilities. There are no prerequisites.
  If your tenancy was created before December 21, 2018, you must perform a one-time upgrade. See Instructions for Oracle Identity Cloud Service Federations.
- If your tenancy is federated with Okta, see User Provisioning for Federated Users.

Viewing Provisioned Federated Users in the Console

After the prerequisites are satisfied, you can view users that you create in your IdP that belong to groups mapped to Oracle Cloud Infrastructure groups. Whenever you add a user to a group mapped to an Oracle Cloud Infrastructure group, the user automatically displays in the Console.

To list users in the Console:

Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Users**.

Notice that you can filter the list by user type to include only users that belong to a specified identity provider. **Local Users** are users created in Oracle Cloud Infrastructure's IAM service. The filter list includes all identity providers you have set up.

Using the Console

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

To edit user capabilities

If you're an Administrator, you can edit user capabilities.

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Users**.
   A list of the users in your tenancy is displayed.
2. Click the user to see its details.
3. Click **Edit User Capabilities**.
4. Select or clear the check box to add or remove a capability.
5. Click **Save**.

To change a user's description

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Users**.
   A list of the users in your tenancy is displayed.
2. Click the user you want to update.
   The user's details are displayed. The description is displayed under the user's login.
3. Click the pencil next to the description.

4. Edit the description and save it. This description is maintained in Oracle Cloud Infrastructure and is not synched back to your identity provider.

To apply tags to a user

For instructions, see Resource Tags.

To delete a user

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Users**.
   A list of the users in your tenancy is displayed.
2. Find the user you want to delete and click the Actions icon (three dots).
3. Click **Delete**.

Important: Deleting a user here does not delete the user in your IdP. If you later want the federated user to have a provisioned user in Oracle Cloud Infrastructure, you must remove the user from all OCI-mapped groups in Oracle Identity Cloud Service and re-add the user.

For information about managing user credentials in the Console, see Managing User Credentials.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use these API operations to manage user capabilities:

- ListUsers
- GetUser
- UpdateUser: You can update the user capabilities and the user's description.

- UpdateUserCapabilities
- DeleteUser: This operation deletes the provisioned user in Oracle Cloud Infrastructure, but not the user in the identity provider.

For information about the API operations for managing user credentials, see Managing User Credentials.

The following operations are *not* supported for federated users:

- ListUserGroupMemberships
- AddUserToGroup
- GetUserGroupMembership
- RemoveUserFromGroup

Calling Services from an Instance

This topic describes how you can authorize instances to call services in Oracle Cloud Infrastructure.

Introduction

This procedure describes how you can authorize an instance to make API calls in Oracle Cloud Infrastructure services. After you set up the required resources and policies, an application running on an instance can call Oracle Cloud Infrastructure public services, removing the need to configure user credentials or a configuration file.

Concepts

DYNAMIC GROUP

Dynamic groups allow you to group Oracle Cloud Infrastructure instances as principal actors, similar to user groups. You can then create policies to permit instances in these groups to make API calls against Oracle Cloud Infrastructure services. Membership in the group is determined by a set of criteria you define, called *matching rules*.

MATCHING RULE

When you set up a dynamic group, you also define the rules for membership in the group. Resources that match the rule criteria are members of the dynamic group. Matching rules have a specific syntax you follow. See Writing Matching Rules to Define Dynamic Groups.

INSTANCE PRINCIPALS

The IAM service feature that enables instances to be authorized actors (or principals) to perform actions on service resources. Each compute instance has its own identity, and it authenticates using the certificates that are added to it. These certificates are automatically created, assigned to instances and rotated, preventing the need for you to distribute credentials to your hosts and rotate them.

Security Considerations

Any user who has access to the instance (who can SSH to the instance), automatically inherits the privileges granted to the instance. Before you grant permissions to an instance using this procedure, ensure that you know who can access it, and that they should be authorized with the permissions you are granting to the instance.

Process Overview

The following steps summarize the process flow for setting up and using instances as principals. The subsequent sections provide more details.

1. Create a dynamic group. In the dynamic group definition, you provide the matching rules to specify which instances you want to allow to make API calls against services.
2. Create a policy granting permissions to the dynamic group to access services in your tenancy (or compartment).
3. A developer in your organization configures the application built using the Oracle Cloud Infrastructure SDK to authenticate using the instance principals provider. The developer deploys the application and the SDK to all the instances that belong to the dynamic group.

4. The deployed SDK makes calls to Oracle Cloud Infrastructure APIs as allowed by the policy (without needing to configure API credentials).
5. For each API call made by an instance, the Audit service logs the event, recording the OCID of the instance as the value of `principalId` in the event log.

Steps to Enable Instances to Call Services

Perform these tasks to enable an instance to call services:

Create a Dynamic Group and Matching Rules

Write Policies for Dynamic Groups

Configure the SDK, CLI, or Terraform

Creating a Dynamic Group and Matching Rules

See Managing Dynamic Groups.

Writing Policies for Dynamic Groups

After you have created a dynamic group, you need to create policies to permit the dynamic groups to access Oracle Cloud Infrastructure services.

Policy for dynamic groups follows the syntax described in How Policies Work. Review that topic to understand basic policy features.

The syntax to permit a dynamic group access to resources in a compartment is:

```
Allow dynamic-group <dynamic_group_name> to <verb> <resource-type> in compartment <compartment_name>
```

The syntax to permit a dynamic group access to a tenancy is:

```
Allow dynamic-group <dynamic_group_name> to <verb> <resource-type> in tenancy
```

Here are a few example policies:

To allow a dynamic group (FrontEnd) to use a load balancer in a specific compartment (ProjectA):

```
Allow dynamic-group FrontEnd to use load-balancers in compartment ProjectA
```

To allow a dynamic group to launch instances in a specific compartment:

```
Allow dynamic-group FrontEnd to manage instance-family in compartment ProjectA
Allow dynamic-group FrontEnd to use volume-family in compartment ProjectA
Allow dynamic-group FrontEnd to use virtual-network-family in compartment ProjectA
```

For more sample policies, see Common Policies.

Configuring the SDK, CLI, or Terraform

For information about SDKs, see Software Development Kits and Command Line Interface.

For the SDK for Java:

In your SDK for Java, create an `InstancePrincipalsAuthenticationDetailsProvider` object. For example:

```
public static void main(String[] args) throws Exception {
   InstancePrincipalsAuthenticationDetailsProvider provider =
      InstancePrincipalsAuthenticationDetailsProvider.builder().build();
   IdentityClient identityClient = new IdentityClient(provider);
...
```

For the Python SDK:

In your Python SDK, create an `oci.auth.signers.InstancePrincipalsSecurityTokenSigner` object. For example:

```
# By default this will hit the auth service in the region returned by
http://169.254.169.254/opc/v1/instance/region on the instance.

signer = oci.auth.signers.InstancePrincipalsSecurityTokenSigner()
identity_client = oci.identity.IdentityClient(config={}, signer=signer)

...
```

To refresh the token without waiting, use the following command:

```
signer.refresh_security_token()
```

Enabling Instance Principal Authorization for the CLI

To enable instance principal authorization from the CLI, you can set the authorization option (`--auth`) for a command. For example:

```
oci os ns get --auth instance_principal
```

Alternatively, you can set the following environment variable:

```
OCI_CLI_AUTH=instance_principal
```

Note that if both are set, the value set for `--auth` takes precedence over the environment variable.

For information about using the CLI, see Getting Started with the Command Line Interface.

Enabling Instance Principal Authorization for Terraform

To enable instance principal authorization in Terraform, you can set the `auth` attribute to "InstancePrincipal" in the provider definition as shown in the following sample:

```
variable "region" {}

provider "oci" {
   auth = "InstancePrincipal"
   region = "${var.region}"

}
```

Note that when you use instance principal authorization you do not need to include the `tenancy_ocid`, `user_ocid`, `fingerprint`, and `private_key_path` attributes.

FAQs

How do I query the instance metadata service to query the certificate on the instance?

Use this curl command: `curl http://169.254.169.254/opc/v1/identity/cert.pem`

How frequently is the certificate rotated on each instance?

The certificate is rotated multiple times each day.

What happens if I try to use an expired certificate?

You will get a 401-Not Authenticated error.

Can I change the frequency at which the certificate is rotated?

No. You can't change the frequency at which the certificate is rotated. However, you can change the policy on the dynamic group. If you think an instance has been compromised, you can either change the policy on the dynamic group to revoke permissions for all members of the group, or you can remove the instance from the dynamic group. See Can I remove an instance from a dynamic group?

What happens if the certificate is rotated in the middle of a long running operation?

The token expiration is independent of the certificate expiration period. And, it also depends on the application you are interacting with. For example, if Object Storage does not have a multipart PUT operation, then it does not matter how long the operation runs.

Are the certificates accessible for all users on an instance?

Yes. Ensure that only users who should be granted the access that you have granted to the dynamic group, have access to the instance.

Are dynamic groups created at the tenancy level?

Yes.

Can I remove an instance from a dynamic group?

Yes. You can remove it by modifying the matching rule to exclude it. See below for an example.

Can I exclude specific instances in a compartment from the dynamic group?

Yes. For example, assume you want to exclude two specific instances in a compartment from the dynamic group. Write a matching rule like this:

```
All {instance.compartment.id = '<compartment_ocid>',
 instance.id != '<instance1_to_exclude_ocid>', instance.id != '<instance2_to_exclude_ocid>'}
```

The above rule includes all instances in the compartment except those with the OCIDs specified.

Managing Users

This topic describes the basics of working with users.

Important

If your tenancy is federated with Oracle Identity Cloud Service, see Managing Oracle Identity Cloud Service Users and Groups in the Oracle Cloud Infrastructure Console to manage users.

Required IAM Policy

If you're in the Administrators group, then you have the required access for managing users.

You can create a policy that gives someone power to create new users and credentials, but not control which groups those users are in. See Let the Help Desk manage users.

For the reverse: You can create a policy that gives someone power to determine what groups users are in, but not create or delete users. See Let group admins manage group membership.

If you're new to policies, see Getting Started with Policies and Common Policies. If you want to dig deeper into writing policies for users or other IAM components, see Details for IAM.

Tagging Resources

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the desired tags. For general information about applying tags, see Resource Tags.

Working with Users

When creating a user, you must provide a unique, unchangeable *name* for the user. The name must be unique across all users within your tenancy. It will be the user's login to the Console. You might want to use a name that's already in use by your company's own identity system (e.g., Active Directory, LDAP, etc.). You must also provide the user with a *description* (although it can be an empty string), which is a non-unique, changeable description for the user. This could be the user's full name, a nickname, or other descriptive information. Oracle will also assign the user a unique ID called an Oracle Cloud ID (OCID). For more information, see Resource Identifiers.

Note

If you delete a user and then create a new user with the same name, they'll be considered different users because they'll have different OCIDs.

Oracle recommends that you supply a password recovery email address for the user. If the user forgets their password, they can request to have a temporary password sent to them using the **Forgot Password** link on the sign-on page. If no email address is present for the user, an administrator must intervene to reset their password.

A new user has no permissions until you place the user in one or more groups, and there's at least one policy that gives that group permission to either the tenancy or a compartment. Exception: each user can manage *their own* credentials they have been enabled to have. An administrator does not need to create a policy to give a user that ability. For more information, see User Credentials.

Important

After creating a new user and putting them in a group, make sure to let them know which compartment(s) they have access to.

You also need to give the new user some credentials so they can access Oracle Cloud Infrastructure. A user can have one or both of the following credentials, depending on the type of access they need: A password for using the Console, and an API signing key for using the API.

About User Capabilities

To access Oracle Cloud Infrastructure, a user must have the required credentials. Users who need to use the Console, must have a password. Users who need access through the API need API keys. Some service features require additional credentials, such as auth tokens, SMTP credentials, and Amazon S3 Compatibility API keys. For a user to get these credentials, the user must be granted the capability to have the credential type.

User capabilities are managed by an Administrator in the User details. Each user can see their capabilities, but only an Administrator can enable or disable them. The user capabilities are:

- Can use Console password (native users only)
- Can use API keys
- Can use auth tokens

- Can use SMTP credentials
- Can use customer secret keys

By default, all these capabilities are enabled when you create new users, allowing users to create these credentials for themselves. For information about working with user credentials, see Managing User Credentials.

Enabling Multi-Factor Authentication for a User

See Managing Multi-Factor Authentication for details.

Unblocking a User After Unsuccessful Sign-in Attempts

If a user tries 10 times in a row to sign in to the Console unsuccessfully, they will be automatically blocked from further sign-in attempts. An administrator can unblock the user in the Console (see To unblock a user) or with the UpdateUserState API operation.

Deleting a User

You can delete a user, but only if the user is not a member of any groups.

Limits on Users

For information about the number of users you can have, see Service Limits.

Using the Console

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

To create a user

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Users**.
   A list of the users in your tenancy is displayed.
2. Click **Create User**.
3. Enter the following:
   - **Name:** A unique name or email address for the user (for tips on what value to use, see Working with Users). The name must be unique across all users in your tenancy. You cannot change this later. The name must meet the following requirements: No spaces. Only Basic Latin letters (ASCII), numerals, hyphens, periods, underscores, +, and @.
   - **Description:** This could be the user's full name, a nickname, or other descriptive information. You can change this later if you want to.
   - **Email:** Enter an email address for the user. This email address is used for password recovery. The email address must be unique in the tenancy.
     If the user forgets their password, they can click **Forgot Password** on the sign on page, and a temporary password will be automatically generated and sent to the email address provided here. The email address can also be updated later by the user or an administrator.

- **Tags:** Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.

4. Click **Create**.

Next, you need to give the user permissions by adding them to at least one group. You also need to give the user the credentials they need (see Managing User Credentials).

To add a user to a group

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Users**.
   A list of the users in your tenancy is displayed.
2. Locate the user in the list.
3. Click the user.
   Its details are displayed.
4. Click **Groups**.
5. Click **Add User to Group**.
6. Select the group from the drop-down list, and then click **Add**.

Make sure to let the user know which compartment(s) they have access to.

To remove a user from a group

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Users**.
   A list of the users in your tenancy is displayed.
2. Locate the user in the list.

3. Click the user.
   Its details are displayed.
4. Click **Groups**.
5. Click the Actions icon (three dots), and then click **Remove**.
6. Confirm when prompted.

To delete a user

Prerequisite: To delete a user, the user must not be in any groups.

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Users**.
   A list of the users in your tenancy is displayed.
2. For the user you want to delete, click **Delete**.
3. Confirm when prompted.

To unblock a user

If you're an administrator, you can use the following procedure to unblock a user who has tried 10 times in a row to sign in to the Console unsuccessfully.

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Users**.
   A list of the users in your tenancy is displayed.
2. Click the user.
   Its details are displayed, including the current status.
3. Click **Unblock**.
4. Confirm when prompted.

To change a user's description

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Users**.
   A list of the users in your tenancy is displayed.
2. Click the user you want to update.
   The user's details are displayed. The description is displayed under the user's login.
3. Click the pencil next to the description.
4. Edit the description and save it.

To edit a user's email

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Users**.
   A list of the users in your tenancy is displayed.
2. Click the user you want to update.
   The user's details are displayed.
3. Under **User Information**, click the pencil next to **Email**.
4. Enter the email address and click the save icon. The email address must be unique in the tenancy.

To edit user capabilities

If you're an Administrator, you can edit user capabilities.

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Users**.
   A list of the users in your tenancy is displayed.
2. Click the user to see its details.
3. Click **Edit User Capabilities**.

4. Select or clear the check box to add or remove a capability.
5. Click **Save**.

To apply tags to a user

For instructions, see Resource Tags.

For information about managing user credentials in the Console, see Managing User Credentials.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Note

Updates Are Not Immediate Across All Regions

Your IAM resources reside in your home region. To enforce policy across all regions, the IAM service replicates your resources in each region. Whenever you create or change a policy, user, or group, the changes take effect first in the home region, and then are propagated out to your other regions. It can take several minutes for changes to take effect in all regions. For example, assume you have a group with permissions to launch instances in the tenancy. If you add UserA to this group, UserA will be able to launch instances in your home region within a minute. However, UserA will not be able to launch instances in other regions until the replication process is complete. This process can take up to several minutes. If UserA tries to launch an instance before replication is complete, they will get a not authorized error.

Use these API operations to manage users:

- CreateUser
- ListUsers
- GetUser
- UpdateUserState: Unblocks a user who has tried to sign in 10 times in a row unsuccessfully.
- UpdateUser: You can update the user's description, email, and tags.
- UpdateUserCapabilities
- DeleteUser

- ListUserGroupMemberships: Use this operation to get a list of which users are in a group, or which groups a user is in.
- AddUserToGroup: This operation results in a `UserGroupMembership` object with its own OCID.
- GetUserGroupMembership
- RemoveUserFromGroup: This operation deletes a `UserGroupMembership` object.

For information about the API operations for managing user credentials, see Managing User Credentials.

Managing Groups

This topic describes the basics of working with groups.

Important

If your tenancy is federated with Oracle Identity Cloud Service, see Managing Oracle Identity Cloud Service Users and Groups in the Oracle Cloud Infrastructure Console to manage groups.

Required IAM Policy

If you're in the Administrators group, then you have the required access for managing groups.

For a policy that only gives someone power to determine what groups users are in, see Let group admins manage group membership.

If you're new to policies, see Getting Started with Policies and Common Policies. If you want to dig deeper into writing policies for groups or other IAM components, see Details for IAM.

Tagging Resources

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the desired tags. For general information about applying tags, see Resource Tags.

Working with Groups

When creating a group, you must provide a unique, unchangeable *name* for the group. The name must be unique across all groups within your tenancy. You must also provide the group with a *description* (although it can be an empty string), which is a non-unique, changeable description for the group. Oracle will also assign the group a unique ID called an Oracle Cloud ID (OCID). For more information, see Resource Identifiers.

Note

If you delete a group and then create a new group with the same name, they'll be considered different groups because they'll have different OCIDs.

A group has no permissions until you write at least one policy that gives that group permission to either the tenancy or a compartment. When writing the policy, you can specify the group by using either the unique name or the group's OCID. Per the preceding note, even if you specify the group name in the policy, IAM internally uses the OCID to determine the group. For information about writing policies, see Managing Policies.

You can delete a group, but only if the group is empty.

For information about the number of groups you can have, see Service Limits.

If you're federating with an identity provider, you'll create mappings between the identity provider's groups and your IAM groups. For more information, see Federating with Identity Providers.

Using the Console

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

To create a group

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Groups**.
   A list of the groups in your tenancy is displayed.
2. Click **Create Group**.
3. Enter the following:
   - **Name:** A unique name for the group. The name must be unique across all groups in your tenancy. You cannot change this later.
   - **Description:** A friendly description. You can change this later if you want to.
   - **Tags:** Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.
4. Click **Create Group**.

Next, you might want to add users to the group, or write a policy for the group. See To create a policy.

To add a user to a group

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Groups**.
   A list of the groups in your tenancy is displayed.
2. Locate the group in the list.
3. Click the group.
   Its details are displayed
4. Click **Add User to Group**.
5. Select the user from the drop-down list, and then click **Add User**.

To remove a user from a group

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Groups**.
   A list of the groups in your tenancy is displayed.
2. Locate the group in the list.
3. Click the group to display its details.
   A list of users in the group is displayed.
4. Locate the user in the list.
5. For the user you want to remove, click **Remove**.
6. Confirm when prompted.

To delete a group

Prerequisite: To delete a group, it must not have any users in it.

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Groups**.
   A list of the groups in your tenancy is displayed.

2. Locate the group in the list.
3. For the group you want to delete, click **Delete**.
4. Confirm when prompted.

To update a group's description

This is available only through the API. If you don't have access to the API and need to update a group's description, contact Oracle Support.

To apply tags to a group

For instructions, see Resource Tags.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Note

Updates Are Not Immediate Across All Regions

Your IAM resources reside in your home region. To enforce policy across all regions, the IAM service replicates your resources in each region. Whenever you create or change a policy, user, or group, the changes take effect first in the home region, and then are propagated out to your other regions. It can take several minutes for changes to take effect in all regions. For example, assume you have a group with permissions to launch instances in the tenancy. If you add UserA to this group, UserA will be able to launch instances in your home region within a minute. However, UserA will not be able to launch instances in other regions until the replication process is complete. This process can take up to several minutes. If UserA tries to launch an instance before replication is complete, they will get a not authorized error.

Use these API operations to manage groups:

- CreateGroup
- ListGroups
- GetGroup
- UpdateGroup: You can update only the group's description.
- DeleteGroup
- ListUserGroupMemberships: Use to get a list of which users are in a group, or which groups a user is in.

- AddUserToGroup: This operation results in a `UserGroupMembership` object with its own OCID.
- GetUserGroupMembership
- RemoveUserFromGroup: This operation deletes a `UserGroupMembership` object.

For API operations related to group mappings for identity providers, see Federating with Identity Providers.

Managing Dynamic Groups

This topic describes how to manage dynamic groups and define the rules to determine a dynamic group's members.

About Dynamic Groups

Dynamic groups allow you to group Oracle Cloud Infrastructure computer instances as "principal" actors (similar to user groups). You can then create policies to permit instances to make API calls against Oracle Cloud Infrastructure services. When you create a dynamic group, rather than adding members explicitly to the group, you instead define a set of *matching rules* to define the group members. For example, a rule could specify that all instances in a particular compartment are members of the dynamic group. The members can change dynamically as instances are launched and terminated in that compartment.

Required IAM Policy

If you're in the Administrators group, then you have the required access for managing dynamic groups.

If you're new to policies, see Getting Started with Policies and Common Policies. If you want to dig deeper into writing policies for dynamic groups or other IAM components, see Details for IAM.

Tagging Resources

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the desired tags. For general information about applying tags, see Resource Tags.

Working with Dynamic Groups

When creating a dynamic group, you must provide a unique, unchangeable *name* for the dynamic group. The name must be unique across all groups within your tenancy. You must also provide the dynamic group with a *description* (although it can be an empty string), which is a non-unique, changeable description for the group. Oracle will also assign the group a unique ID called an Oracle Cloud ID (OCID). For more information, see Resource Identifiers.

Note

If you delete a dynamic group and then create a new dynamic group with the same name, they'll be considered different groups because they'll have different OCIDs.

A dynamic group has no permissions until you write at least one policy that gives that dynamic group permission to either the tenancy or a compartment. When writing the policy, you can specify the dynamic group by using either the unique name or the dynamic group's OCID. Per the preceding note, even if you specify the dynamic group name in the policy, IAM internally uses the OCID to determine the dynamic group. For information about writing policies, see Managing Policies.

You can delete a dynamic group, but only if the group is empty.

Updating Dynamic Groups

You can update the matching rules that define the members of a dynamic group. For example, you might change a matching rule that includes all instances in a compartment to exclude a

particular instance. Or, you might update a rule to include a new tag value.

Important

When you make a change to a matching rule you must allow about one hour for the updated policy to take effect. For example, if you update tags on an instance to either include or exclude that instance from a dynamic group, you must wait for that policy to take effect to include or exclude the instance.

Limits on Instances in Dynamic Groups

A single compute instance can belong to a maximum of 5 dynamic groups.

Using the Console

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

To create a dynamic group

1. Open the Console, click **Identity**, and then click **Dynamic Groups**.
   A list of the dynamic groups in your tenancy is displayed.
2. Click **Create Dynamic Group**.

3. Enter the following:
    - **Name:** A unique name for the group. The name must be unique across all groups in your tenancy (dynamic groups and user groups). You can't change this later.
    - **Description:** A friendly description. You can't change this in the Console, but you can change it Using the API.
4. Enter the **Matching Rules**. Resources that meet the rule criteria are members of the group.
    - **Rule 1:** Enter a rule following the guidelines in Writing Matching Rules to Define Dynamic Groups. You can manually enter the rule in the text box or launch the rule builder.
    - Enter additional rules as needed. To add a rule, click **+Additional Rule**.
5. Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.
6. Click **Create Dynamic Group**.
   The matching rule syntax is verified, but the OCIDs are not. Be sure that the OCIDs you enter are correct.

Next, to give the dynamic group permissions, you need to write a policy. See Writing Policies for Dynamic Groups.

To delete a dynamic group

1. Open the Console, click **Identity**, and then click **Dynamic Groups**.
   A list of the dynamic groups in your tenancy is displayed.
2. Locate the dynamic group in the list.
3. For the dynamic group you want to delete, click **Delete**.
4. Confirm when prompted.

To update a dynamic group's description

This is available only through the API. If you don't have access to the API and need to update a dynamic group's description, contact Oracle Support.

To update a dynamic group's matching rules

1. Open the Console, click **Identity**, and then click **Dynamic Groups**.
   A list of the dynamic groups in your tenancy is displayed.
2. Click the dynamic group you want to update.
   The dynamic group's details are displayed.
3. Click **Edit All Matching Rules**.
4. Edit the matching rule in the text box; or, you can use the rule builder if the change is supported by the rule builder.

Writing Matching Rules to Define Dynamic Groups

Matching rules define the resources that belong to the dynamic group. In the Console, you can either enter the rule manually in the provided text box, or you can use the rule builder. The rule builder lets you make selections and entries in a dialog, then writes the rule for you, based on your entries.

You can define the members of the dynamic group based on the following:

- compartment ID - include (or exclude) the instances that reside in that compartment based on compartment OCID
- instance ID - include (or exclude) an instance based on its instance OCID
- tag namespace and tag key - include (or exclude) instances tagged with a specific tag namespace and tag key. All tag values are included. For example, include all instances tagged the with tag namespace `department` and the tag key `operations`.
- tag namespace, tag key, and tag value - include (or exclude) instances tagged with a specific value for the tag namespace and tag key. For example include all instances

tagged with the tag namespace `department` and the tag key `operations` and with the value '`45`'.

A matching rule has the following syntax:

For a single condition:

```
variable =|!= 'value'
```

For multiple conditions:

```
any|all {<condition>,<condition>,...}
```

Supported variables are:

- `instance.compartment.id` - the OCID of the compartment where the instance resides
- `instance.id` - the OCID of the instance
- `tag.`*`<tagnamespace>`*`.`*`<tagkey>`*`.value` - the tag namespace and tag key. For example, `tag.department.operations.value`.
- `tag.`*`<tagnamespace>`*`.`*`<tagkey>`*`.value='`*`<tagvalue>`*`'` - the tag namespace, tag key, and tag value. For example, `tag.department.operations.value='45'`

Here are some examples:

Include All Instances in a Specific Compartment in the Dynamic Group

To include all instances that are in a specific compartment, add a rule with the following syntax:

```
instance.compartment.id = '<compartment_ocid>'
```

You can add that rule either directly in the text box, or you can use the rule builder.

Example entry in text box:

```
instance.compartment.id = 'ocidv1:compartment:oc1:phx:samplecompartmentocid6q6igvfauxmima74jv'
```

All instances that currently exist or get created in the compartment (identified by the OCID) are members of this group.

Include All Instances in Any of Two or More Compartments

To include all instances that reside in any of two (or more) compartments, add a rule with the following syntax:

```
Any {instance.compartment.id = '<compartment_ocid>', instance.compartment.id = '<compartment_ocid>'}
```

You can add that rule either directly in the text box, or you can use the rule builder.

Example entry in the text box:

```
Any {instance.compartment.id = 'ocidv1:compartment:oc1:phx:samplecompartmentocid6q6igvfauxmima74jv',
instance.compartment.id = 'ocidv1:compartment:oc1:phx:samplecompartmentocidythksk89ekslsoelu2'}
```

Instances that currently exist or get created in either of the specified compartments are members of this group.

Include All Instances Tagged with a Specific Namespace and Tag Key

To include all instances that are tagged with a specific tag namespace and tag key, add a rule with the following syntax:

```
tag.<tagnamespace>.<tagkey>.value
```

All instances assigned the tagnamespace.tagkey combination are included. Note that the tag value is not evaluated, so all values are included.

Example: Assume you have a tag namespace called `department` and a tag key called `operations`. You want to include all instances that are tagged with the namespace and tag key.

Enter the following rule in the text box:

```
tag.department.operations.value
```

All instances that currently exist or get created with the tag namespace and tag key `department.operations` are members of this group.

Include All Instances In a Specific Compartment with a Specific Tag Namespace, Tag Key, and Tag Value

To include all instances in a specific compartment that are tagged with a specific tag namespace, key, and value, add a rule with the following syntax:

`All {instance.compartment.id = '<compartment_ocid>', tag.<tagnamespace>.<tagkey>.value='<tagvalue>'}`

All instances that are in the identified compartment and that are assigned the tagnamespace.tagkey with the specified tag value are included.

Example: Assume you have a tag namespace called `department` and a tag key called `operations`. You want to include all instances that are tagged with the value 45, that are in a particular compartment.

Enter the following statement in the text box:

```
All
{instance.compartment.id='ocidv1:compartment:oc1:phx:oc1:phx:samplecompartmentocid6q6igvfauxmima74jv,',
tag.department.operations.value='45'}
```

Include Instances in a Specific Compartment Except Those with a Specific Tag

To include all instances in a specific compartment EXCEPT those that are tagged with a specific tag namespace, key, and value, add a rule with the following syntax:

`All {instance.compartment.id = '<compartment_ocid>', tag.<tagnamespace>.<tagkey>.value!= '<tagvalue>'}`

Example: Assume you have a tag namespace called `department` and a tag key called `operations`. You want to include all instances in a specific compartment, except those that are tagged with the value 45.

Enter the following statement in the text box:

```
All
{instance.compartment.id='ocidv1:compartment:oc1:phx:oc1:phx:samplecompartmentocid6q6igvfauxmima74jv,',
tag.department.operations.value!='45'}
```

Using the Rule Builder

The rule builder is a tool available from the Console to help you write matching rules. The rule builder provides menus and text boxes for you to make entries and then writes the rule for you. The rule builder does have some limitations, so you can't use it for all cases.

LIMITATIONS OF THE RULE BUILDER

The rule builder does not support the following:

- Exclusion rules - the rule builder lets you select compartment IDs and instance IDs to include only.
- Rules based on tags - the rule builder does not allow you to select tags to include in your rule. To add a rule based on tag values, you need to enter the rule in the Rule text box using the syntax above.

LAUNCHING THE RULE BUILDER

When you click **Create Dynamic Group**, the Rule Builder is displayed in the **Create Dynamic Group** dialog.

To create a matching rule using the rule builder

1. Select **Any** or **All** from the menu.
   Any includes instances that match any of the statements in the rule.
   All includes only instances that match all of the statements in the rule.
2. Select the **Attribute** type for the statement and enter the value:
   in Compartment ID includes instances in the compartment you specify.
   with Instance ID includes instances with the OCID you specify.
3. Click **+Additional line** to add more statements to this rule.
   When you add multiple statements to a rule, remember that Any includes instances that match any of the statements. If you choose All, instances must match all of the specifications in the statements to be included in the group.

EXAMPLES USING THE RULE BUILDER

Include All Instances in a Specific Compartment in the Dynamic Group

To include all instances that are in a specific compartment, using the rule builder:

- Select ALL.
- **Attribute:** Select in Compartment ID.
- **Value:** Enter `ocidv1:compartment:oc1:yourcompartmentocid`

All instances that currently exist or get created in the compartment (identified by the OCID) are members of this group.

Include All Instances in Any of Two or More Compartments

To include all instances that reside in any of two (or more) compartments using the rule builder:

1. Select ANY.
2. Enter:
    - **Attribute:** Select in Compartment ID.
    - **Value:** Enter `ocidv1:compartment:oc1:phx:samplecompartmentocid6q6igvfauxmima74jv`
3. Click **+Additional Line**. Enter the following on the second line:
    - **Attribute:** Select in Compartment ID.
    - **Value:** Enter `ocidv1:compartment:oc1:phx:samplecompartmentocidythksk89ekslsoelu2`
4. Continue adding additional lines as needed for each compartment you want to include.

Instances that currently exist or get created in any of the specified compartments are members of this group.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use these API operations to manage dynamic groups:

- CreateDynamicGroup
- ListDynamicGroups
- GetDynamicGroup
- UpdateDynamicGroup
- DeleteDynamicGroup

Managing Compartments

This topic describes the basics of working with compartments.

Required IAM Policy

If you're in the Administrators group, then you have the required access for managing compartments.

For an additional policy related to compartment management, see Let a compartment admin manage the compartment.

If you're new to policies, see Getting Started with Policies and Common Policies. If you want to dig deeper into writing policies for compartments or other IAM components, see Details for IAM.

Tagging Resources

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource

later with the desired tags. For general information about applying tags, see Resource Tags.

Working with Compartments

When you first start working with Oracle Cloud Infrastructure, you need to think carefully about how you want to use compartments to organize and isolate your cloud resources. Compartments are fundamental to that process. Most resources can be moved between compartments. However, it's important to think through your compartment design for your organization up front, before implementing anything. For more information, see "Setting Up Your Tenancy" in the *Oracle Cloud Infrastructure Getting Started Guide*.

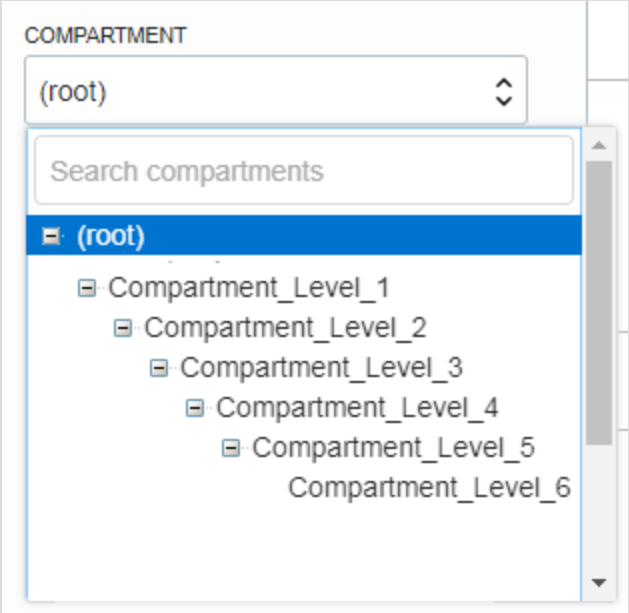
The Console is designed to display your resources by *compartment* within the current region. When you work with your resources in the Console, you must choose which compartment to work in from a list on the page. That list is filtered to show only the compartments in the tenancy that you have permission to access. If you're an administrator, you'll have permission to view all compartments and work with any compartment's resources, but if you're a user with limited access, you probably won't.

Compartments are tenancy-wide, across regions. When you create a compartment, it is available in every region that your tenancy is subscribed to. You can get a cross-region view of your resources in a specific compartment with the compartment explorer. See Viewing All Resources in a Compartment.

Creating Compartments

When creating a compartment, you must provide a *name* for it (maximum 100 characters, including letters, numbers, periods, hyphens, and underscores) that is unique within its parent compartment. You must also provide a *description*, which is a non-unique, changeable description for the compartment, from 1 through 400 characters. Oracle will also assign the compartment a unique ID called an Oracle Cloud ID. For more information, see Resource Identifiers.

You can create subcompartments in compartments to create hierarchies that are six levels deep.



For information about the number of compartments you can have, see Service Limits.

Access Control for Compartments

After creating a compartment, you need to write at least one policy for it, otherwise no one can access it (except administrators or users who have permissions set at the tenancy level). When creating a compartment inside another compartment, the compartment inherits access permissions from compartments higher up its hierarchy. For more information, see Policy Inheritance.

When you create an access policy, you need to specify which compartment to attach it to. This controls who can later modify or delete the policy. Depending on how you've designed your compartment hierarchy, you might attach it to the tenancy, a parent, or to the specific compartment itself. For more information, see Policy Attachment.

Putting Resources in a Compartment

To place a new resource in a compartment, you simply specify that compartment when creating the resource (the compartment is one of the required pieces of information to create a resource). If you're working in the Console, you just make sure you're first viewing the compartment where you want to create the resource. Keep in mind that most IAM resources reside in the tenancy (this includes users, groups, compartments, and any policies attached to the tenancy) and can't be created in or managed from a specific compartment.

Moving Resources to a Different Compartment

Most resources can be moved after they are created. There are a few resources that you can't move from one compartment to another.

Some resources have attached resource dependencies and some don’t. Not all attached dependencies behave the same way when the parent resource moves.

For some resources, the attached dependencies move with the parent resource to the new compartment. The parent resource moves immediately, but in some cases attached dependencies move asynchronously and are not visible in the new compartment until the move is complete.

For other resources, the attached resource dependencies do not move to the new compartment. You can move these attached resources independently.

After you move the resource to the new compartment, the policies that govern the new compartment apply immediately and affect access to the resource. Depending on the structure of your compartment organization, metering, billing, and alarms can also be affected.

See the service documentation for individual resources to familiarize yourself with the behavior of each resource and its attachments.

Viewing Resources in a Compartment

It's not possible to get a list of all the resources in a compartment by using a single API call. Instead you can list all the resources of a given type in the compartment (e.g., all the instances, all the block storage volumes, etc.).

Tip

In the Console, the compartment explorer allows you to get a list of resources in a compartment, across regions, with some limitations. For more information, see Viewing All Resources in a Compartment.

Deleting Compartments

To delete a compartment, it must be empty of all resources. Before you initiate deleting a compartment, be sure that all its resources have been moved, deleted, or terminated, including any policies attached to the compartment.

Important

Some resource types can't be deleted, therefore, compartments containing these resource types can't be deleted. A resource type that can't be deleted is:

- Data transfer jobs

The delete action is asynchronous and initiates a work request. The state of the compartment changes to Deleting while the work request is executing. It typically takes several minutes for the work request to complete. While it is in the Deleting state it is not displayed on the compartment picker. If the work request fails, the compartment is not deleted and it returns to the Active state.

After a compartment is deleted, its state is updated to Deleted and a random string of characters is appended to its name, for example, CompartmentA might become CompartmentA.qR5hP2BD. Renaming the compartment allows you to reuse the original name for a different compartment. The deleted compartment is displayed on the Compartments page for the number of days specified in your Audit Retention Period setting (90-365 days). The deleted compartment is removed from the compartment picker. If any policy statements

reference the deleted compartment, the name in the policy statement is updated to the new name.

Troubleshooting tips for when a compartment fails to delete

If the compartment fails to delete, verify that you have removed all the resources:

- For most resources, you can use the compartment explorer to help you locate them. See Resources Supported by the Compartment Explorer for the list of supported resources.

  ### To view resources in a compartment

  Open the navigation menu. Under **Governance and Administration**, go to **Governance** and click **Compartment Explorer**.

  When you open the compartment explorer, the list of all resources that you have permission to view is displayed. The compartment explorer opens with a view of the root compartment. The **Name** and **Description** of the compartment you are viewing are displayed at the top of the page.

  To navigate to the compartment you are interested in, use the compartment picker on the left of the Console page.

- Verify that there are no policies in the compartment (polices are not included in Search results).

  ### To find policies in a compartment

  1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Policies**.
  2. From the compartments list on the left, select the compartment you want to delete.

  Policies attached to the compartment are displayed.

- If you can't locate any resources in the compartment, check with your Administrator; you might not have permission to view all resources.

Important

There is a known issue causing deleted compartments to continue to count against your service limit of compartments. See Deleted compartments continue to count against service limits.

Adding Tag Defaults for a Compartment

Tag defaults let you specify tags to be applied automatically to all resources, at the time of creation, in the current compartment. For more information, see Managing Tag Defaults.

Moving a Compartment to a Different Parent Compartment

You can move a compartment to a different parent compartment within the same tenancy. When you move a compartment, all its contents (subcompartments and resources) are moved with it. Moving a compartment has implications for the contents. These implications are described in the following sections. Ensure that you are aware of these before you move a compartment.

- Required IAM Policy
- Restrictions on Moving Compartments
- Understanding the Policy Implications When You Move a Compartment
- Understanding Compartment Quota Implications When You Move a Compartment
- Understanding Tagging Implications When You Move a Compartment

Required IAM Policy

To move a compartment, you must belong to a group that has `manage all-resources` permissions on the lowest shared parent compartment of the current compartment and the destination compartment.

Restrictions on Moving Compartments

- You can't move a compartment to a destination compartment with the same name as the compartment being moved.
  For example, assume compartment A and compartment B are both under the root compartment. Under compartment A is a subcompartment, also called compartment B.

You cannot move the compartment B to the parent compartment B.

- Two compartments within the same parent cannot have the same name. Therefore you can't move a compartment to a destination compartment where a compartment with the same name already exists.

Understanding the Policy Implications When You Move a Compartment

After you move a compartment to a new parent compartment, the access policies of the new parent take effect and the policies of the previous parent no longer apply. Before you move a compartment, ensure that:

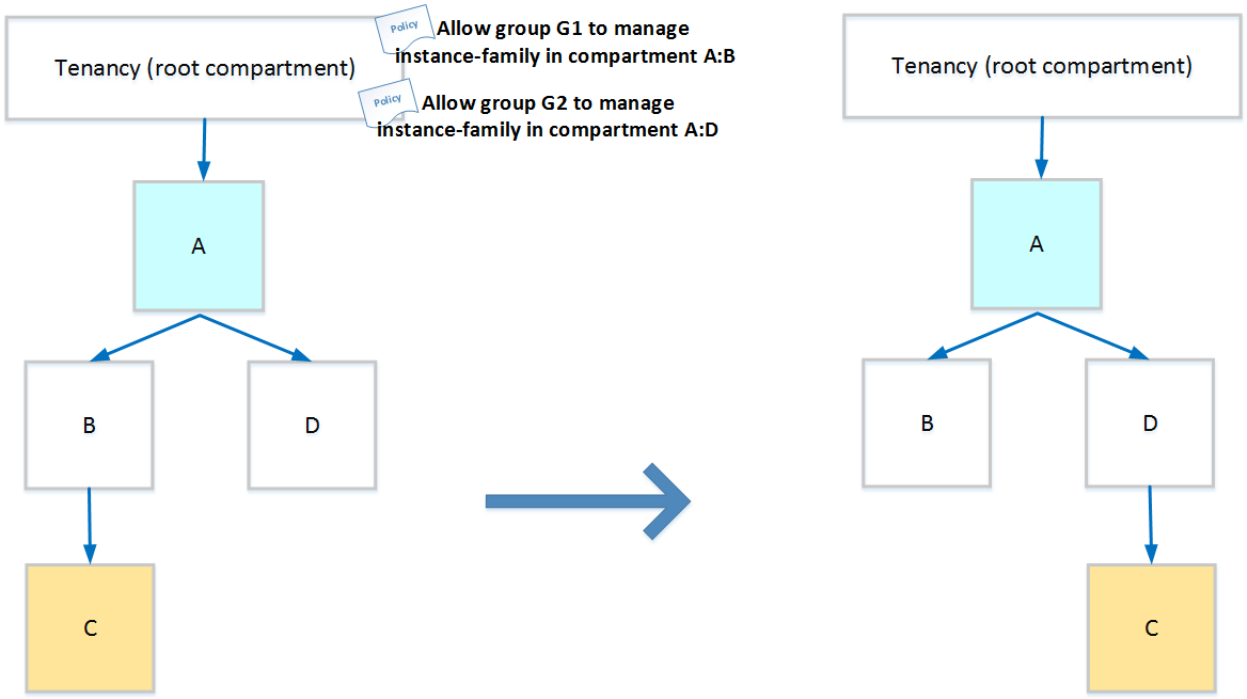
- You are aware of the policies that govern access to the compartment in its current position.
- You are aware of the polices in the new parent compartment that will take effect when you move the compartment.

In some cases, when moving nested compartments with policies that specify the hierarchy, the polices are automatically updated to ensure consistency.

Policy Examples

Groups with Permissions in the Current Compartment Lose Access; Groups with Permissions in the Destination Compartment Gain Access

The following figure shows a compartment hierarchy in which compartment C, a child of A:B is moved to the hierarchy A:D.



The tenancy has the following policies defined for compartments B and D:

Policy1: `Allow group G1 to manage instance-family in compartment A:B`

Policy2: `Allow group G2 to manage instance-family in compartment A:D`

Impact when compartment C is moved from B to D:

Group G1 can no longer manage instance-families in compartment C.

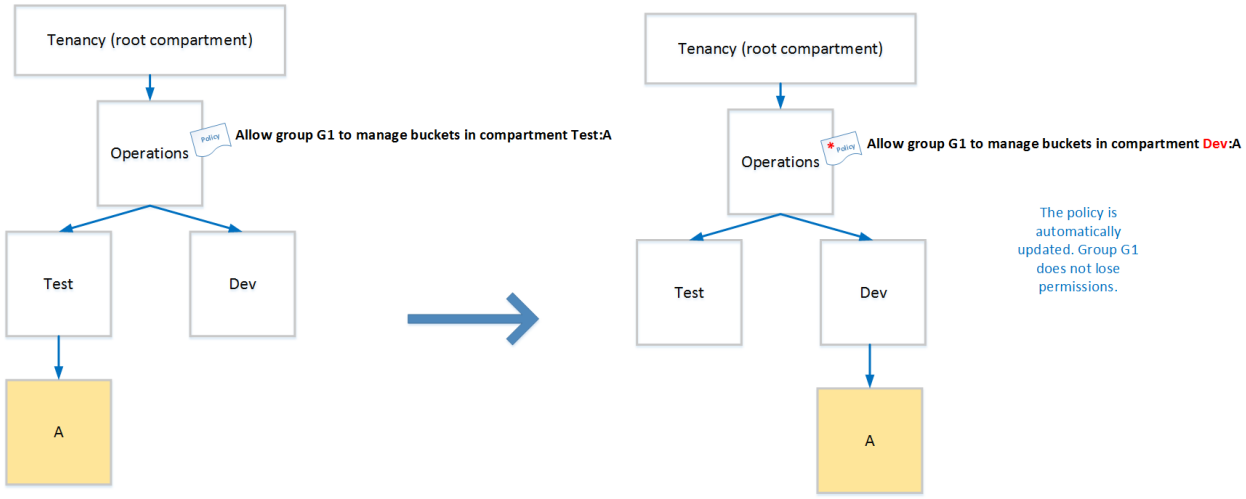
Group G2 can now manage instance-families in compartment C.

Ensure that you are aware not only of what groups lose permissions when you move a compartment, but also what groups will gain permissions.

Automatic Update of Policies

When you move a compartment, some polices will be automatically updated. Policies that specify the compartment hierarchy down to the compartment being moved will automatically be updated when the policy is attached to a shared ancestor of the current and target parent. Consider the following examples:

Example 1: Policy automatically updated



In this example, you move compartment A from Operations:Test to Operations:Dev. The policy that governs compartment A is attached to the shared parent, Operations. When the compartment is moved, the policy statement is automatically updated by the IAM service to specify the new compartment location.

The policy

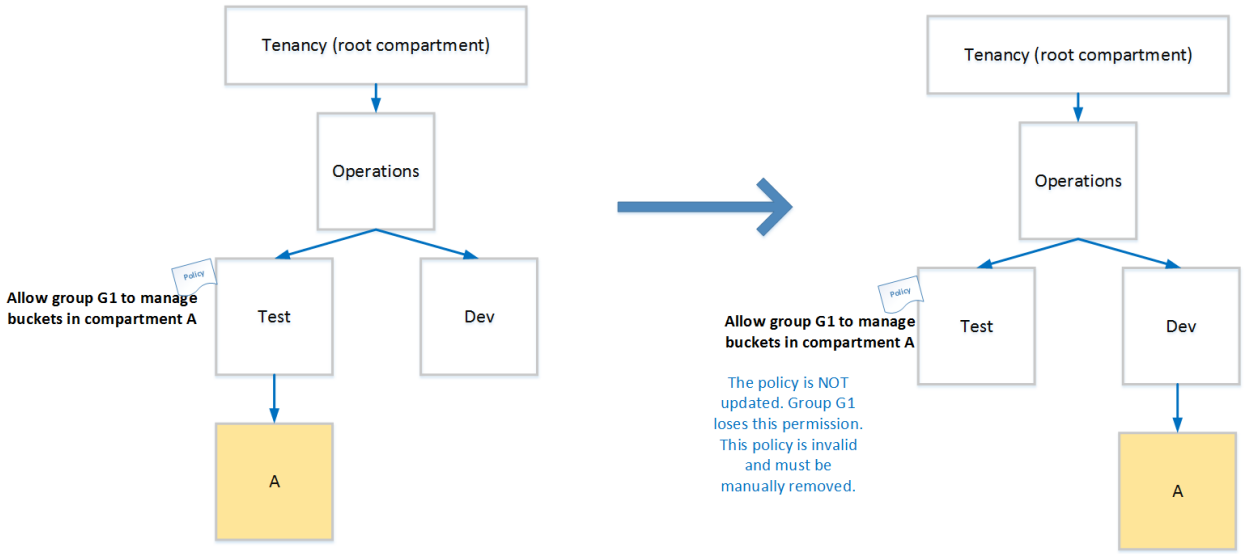
```
Allow group G1 to manage buckets in compartment Test:A
```

is updated to

```
Allow group G1 to manage buckets in compartment Dev:A
```

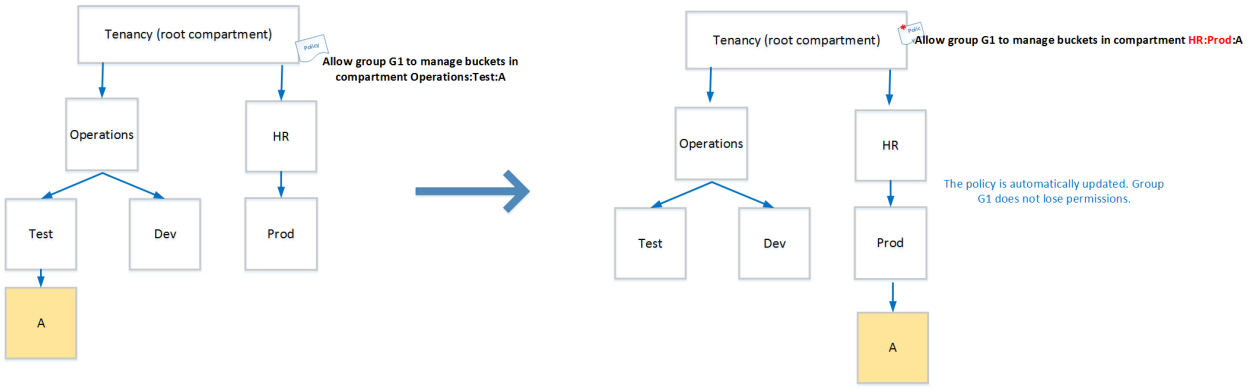
No manual intervention is required to allow group G1 to continue to access compartment A in its location.

Example 2: Policy not updated



In this example, you move compartment A from Operations:Test to Operations:Dev. However, the policy that governs compartment A here is attached directly to the Test compartment. When the compartment is moved, the policy is not automatically updated. The policy that specifies compartment A is no longer valid and must be manually removed. Group G1 no longer has access to compartment A in its new location under Dev. Unless another existing policy grants access to group G1, you must create a new policy to allow G1 to continue to manage buckets in compartment A.

Example 3: Policy attached to the tenancy is updated



In this example, you move compartment A from Operations:Test to HR:Prod. The policy that governs compartment A is attached to the tenancy, which is a shared ancestor by the original parent compartment and the new parent compartment. Therefore, when the compartment is moved, the policy statement is automatically updated by the IAM service to specify the new compartment location.

The policy statement:

```
Allow group G1 to manage buckets in compartment Operations:Test:A
```

is updated to

```
Allow group G1 to manage buckets in compartment HR:Prod:A
```

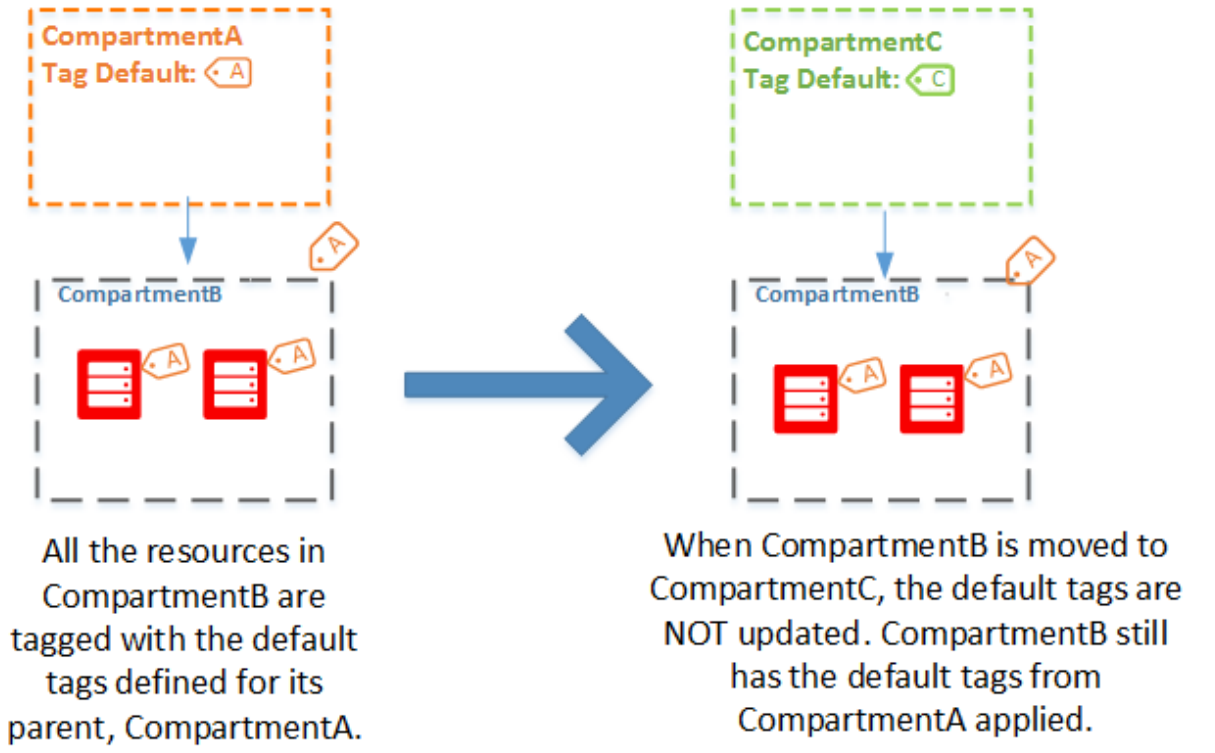
No manual intervention is required to allow group G1 to continue to access compartment A.

Understanding Compartment Quota Implications When You Move a Compartment

When you move one compartment to another, resource quotas in the destination compartment are not verified and are not enforced. Therefore, if the compartment move results in a quota violation in the destination compartment, the move is not blocked. After the move is complete, the destination compartment will be in an over-quota state. You will not be able to create new resources that are over-quota until you either adjust the quotas for the destination compartment or remove resources to comply with the existing quota. For more information on managing compartment quotas, see Compartment Quotas.

Understanding Tagging Implications When You Move a Compartment

Tags are not automatically updated after a compartment move. If you have implemented a tagging strategy based on compartment, you must update the tags on the resources after the move. For example, assume CompartmentA has a child compartment, CompartmentB. CompartmentA is set up with tag defaults so that every resource in CompartmentA is tagged with TagA. Therefore CompartmentB and all its resources are tagged with default tag, TagA. When you move CompartmentB to CompartmentC, it will still have the default tags from CompartmentA. If you have set up default tags for CompartmentC, you'll need to add those to the resources in the moved compartment.



Using the Console

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

To create a compartment

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Compartments**.
   A list of the compartments you have access to is displayed.
2. Navigate to the compartment in which you want to create the new compartment:
   - To create the compartment in the tenancy (root compartment) click **Create Compartment**.
   - Otherwise, click through the hierarchy of compartments until you reach the detail page of the compartment in which you want to create the compartment. On the **Compartment Details** page, click **Create Compartment**.
3. Enter the following:
   - **Name:** A unique name for the compartment (maximum 100 characters, including letters, numbers, periods, hyphens, and underscores). The name must be unique across all the compartments in your tenancy. Avoid entering confidential information.
   - **Description:** A friendly description. You can change this later if you want to. Avoid entering confidential information.
   - **Compartment:** The compartment you are in is displayed. To choose another compartment to create this compartment in, select it from the list.

- **Tags:** Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.

4. Click **Create Compartment**.

Next, you might want to write a policy for the compartment. See To create a policy.

To update a compartment's name

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Compartments**.
   A list of the compartments in your tenancy is displayed.
2. For the compartment you want to rename, click the Actions icon (three dots), and then click **Rename Compartment**.

Tip

You can't change the name of your root compartment.

3. Enter the new **Name**. The name must be unique across all the compartments in your tenancy. The name can have a maximum of 100 characters, including letters, numbers, periods, hyphens, and underscores. Avoid entering confidential information.
4. Click **Rename Compartment**.

To update a compartment's description

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Compartments**.
   A list of the compartments in your tenancy is displayed.
2. For the compartment you want to update, click the Actions icon (three dots), and then click **Edit Compartment Description**.
3. Enter the new description. Avoid entering confidential information.
4. Click **Save**.

To view the contents of a compartment

1. Open the Console,
2. Open the navigation menu and select the type of resource you want to view. For example, click **Compute** to view all your Compute resources.
3. Choose the compartment from the list on the left side of the page.
   The page updates to show only the resources in that compartment.

Remember that most IAM resources reside in the tenancy (this includes users, groups, and compartments). Policies can reside in either the tenancy (root compartment) or other compartments.

To move a compartment

To move a compartment, you must belong to a group that has `manage all-resources` permissions on the lowest shared parent compartment of the current compartment and the destination compartment.

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Compartments**.

A list of the compartments in your tenancy is displayed. If the compartment you want to move is not directly beneath the root compartment, click through the hierarchy of compartments to view the wanted compartment.

2. For the compartment you want to move, click the Actions icon (three dots), and then click **Move Compartment**.
3. Select the destination compartment.
4. Confirm that you are aware of the implications of the move.
5. Click **Move Compartment**.

To move a resource to a different compartment

1. Open the Console.
2. Open the navigation menu and select the type of resource you want to work with. For example, click **Compute** to view all your Compute resources.
3. In the **List Scope** section, select a compartment. Resources in the selected compartment are displayed.
4. Find the resource in the list, click the the Actions icon (three dots), and follow the prompts to move the resource to a new compartment. See the resource documentation for specific steps.

The resource is moved immediately. If attached resource dependencies move with the parent resource, the resource dependencies are moved asynchronously, and do not appear in the new compartment until the move is complete.

To apply tags to a compartment

For instructions, see Resource Tags.

To manage tag defaults for a compartment

See Managing Tag Defaults.

To delete a compartment

You must remove all resources from a compartment before you can delete it.

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Compartments**.
   A list of the compartments in your tenancy is displayed.
2. For the compartment you want to delete, click the Actions icon (three dots), and then click **Delete Compartment**.
3. At the prompt, click **OK**.

After you click **OK**, a work request is submitted to delete the compartment. The compartment state changes to Deleting. If the work request fails, the state returns to Active.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use these API operations to manage compartments:

- CreateCompartment
- ListCompartments
- GetCompartment: Returns the metadata for the compartment, not its contents.
- UpdateCompartment
- DeleteCompartment
- MoveCompartment
- GetWorkRequest: Gets the work requests spawned by the DeleteCompartment operation.

You can retrieve the contents of a compartment only by resource type. There's no API call that lists *all* resources in the compartment. For example, to list all the instances in a

compartment, call the Core Services API ListInstances operation and specify the compartment ID as a query parameter.

Managing Regions

This topic describes the basics of managing your region subscriptions. For more information about regions in Oracle Cloud Infrastructure, see Regions and Availability Domains. For information about Platform Services regions, see Managing Platform Services Regions.

Required IAM Policy

If you're in the Administrators group, then you have the required access to manage region subscriptions.

If you're new to policies, see Getting Started with Policies and Common Policies. If you want to dig deeper into writing policies for managing regions or other IAM components, see Details for IAM.

The Home Region

When you sign up for Oracle Cloud Infrastructure, Oracle creates a tenancy for you in one region. This is your *home region*. Your home region is where your IAM resources are defined. When you subscribe to another region, your IAM resources are available in the new region, however, the master definitions reside in your home region and can only be changed there.

Resources that you can create and update only in the home region are:

- Users
- Groups
- Policies
- Compartments
- Dynamic groups
- Federation resources

When you use the API to update your IAM resources, you must use the endpoint for your home region. IAM automatically propagates the updates to all regions in your tenancy.

When you use the Console to update your IAM resources, the Console sends the requests to the home region for you. You don't need to switch to your home region first. IAM then automatically propagates the updates to all regions in your tenancy.

When you subscribe your tenancy to a new region, all the policies from your home region are enforced in the new region. If you want to limit access for groups of users to specific regions, you can write policies to grant access to specific regions only. For an example policy, see Restrict admin access to a specific region.

Note

IAM Updates Are Not Immediate Across All Regions

When you create or update an IAM resource, be aware that you need to allow up to several minutes for the changes in your home region to become available in all regions.

Using the Console to Manage Infrastructure Regions

To view the list of infrastructure regions

Open the Console, open the **Region** menu, and then click **Manage Regions**.
A list of the regions offered by Oracle Cloud Infrastructure is displayed. Regions that you have not subscribed to provide a button to create a subscription.

To subscribe to an infrastructure region

1. Open the Console, open the **Region** menu, and then click **Manage Regions**.
   The list of regions available to your tenancy Oracle Cloud Infrastructure is displayed. Your home region is labeled.
2. Locate the region you want to subscribe to and click **Subscribe**.
   Note that it could take several minutes to activate your tenancy in the new region.
   Remember, your IAM resources are global, so when the subscription becomes active, all your existing policies are enforced in the new region.
   To switch to the new region, use the **Region** menu in the Console. See Switching Regions for more information.

You cannot unsubscribe from a region.

Using the API to Work with Infrastructure Regions

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use these API operations to manage infrastructure regions:

- GetTenancy
- ListRegions: Returns a list of regions offered by Oracle Cloud Infrastructure in your selected realm.
- CreateRegionSubscription
- ListRegionSubscriptions

You cannot unsubscribe from a region.

Region FAQs

Can an individual user subscribe to a region?

A region subscription is at the tenancy level. An administrator can subscribe the tenancy to a region. All IAM polices are enforced in the new region, so *all* users in the tenancy will have the same access and permissions in the new region.

Can I see my existing resources in the new region?

When you select a region in the Console, you are shown a view of the resources in your selected region. Most cloud resources (instances, VCNs, buckets, etc.) exist only in a specific region, so you only see them when you select the region where they were created. The exception is IAM resources: compartments, users, groups, and policies are global across all regions. See also Working in Multiple Regions.

How do my service limits apply to the new region?

Service limits can be scoped to the tenant level, the region level, or the availability domain level. When you subscribe to a new region, you get access to the region and its availability domains. Service limits apply accordingly. The service limits page lists the scope of each resource limit.

Can I restrict access to a specific region?

Yes. You can write policies that grant permissions in a specified region only. For an example policy, see Restrict admin access to a specific region.

Can I change my home region?

No. Oracle assigns your home region and you can't change it.

Managing Platform Services Regions

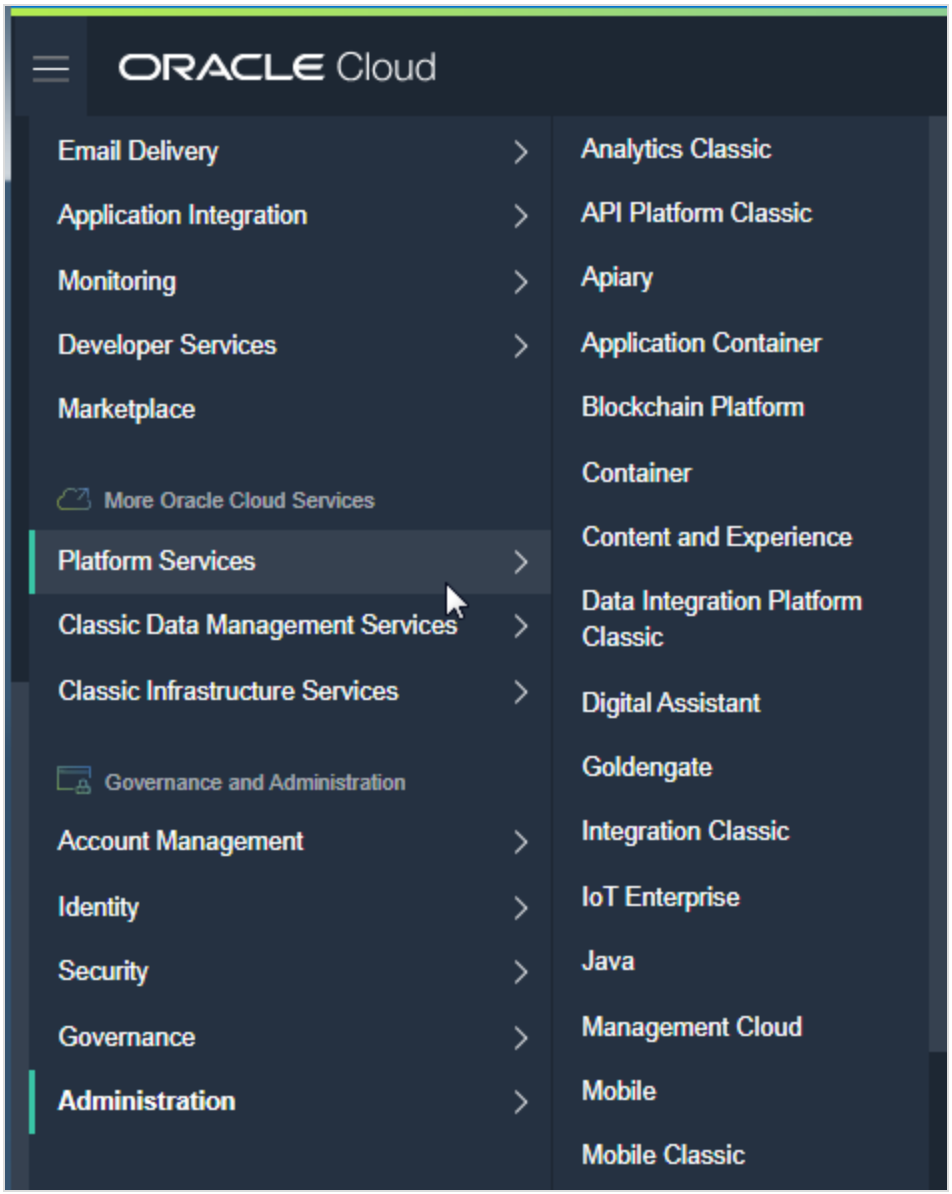
This topic describes how to manage Platform Services region subscriptions.

About the Platform Services Regions

You can manage Platform Services regions in the Console.

To use Platform Services that are not natively integrated with Oracle Cloud Infrastructure, you need to subscribe to the Platform Services region as well as the Infrastructure region. For example, to create a Platform Service instance in the Germany Central (Frankfurt) region, you need to subscribe your tenancy to both the Infrastructure region: Germany Central (Frankfurt) and to the Platform Service region: Europe and Middle East.

To know which services require the Platform Service region subscription, you can view the list under **More Oracle Services** on the Console navigation menu. A sample of the navigation to these services is shown in the following screenshot:

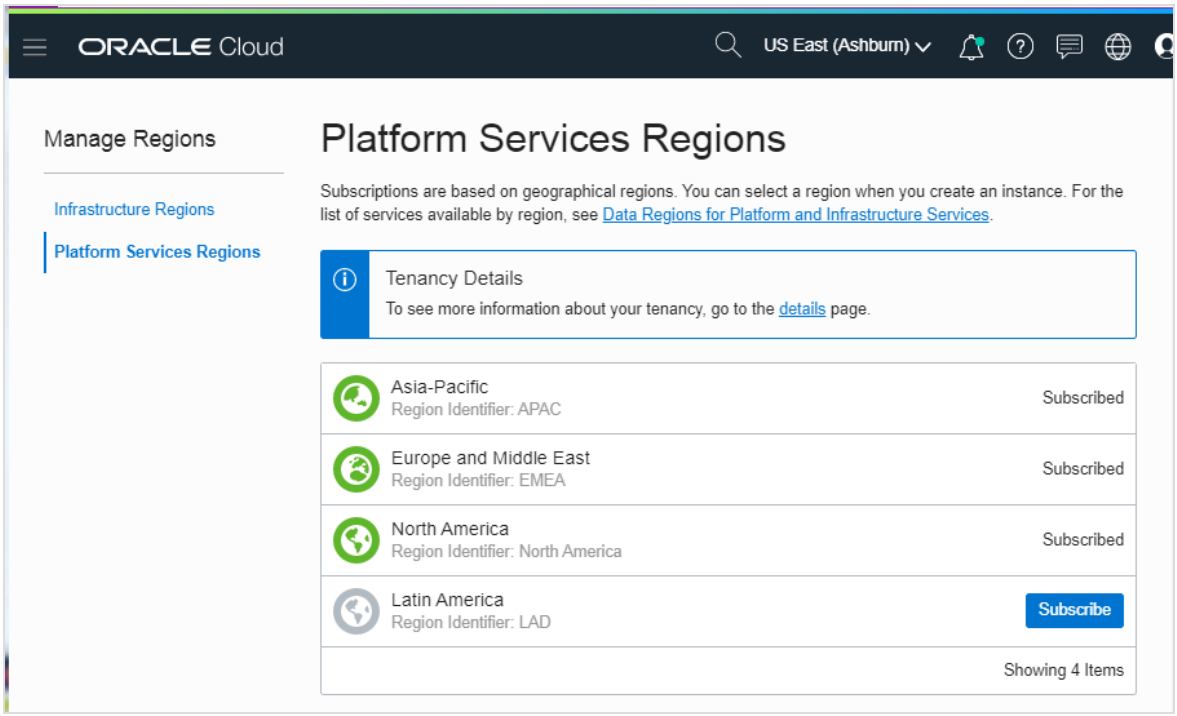


Before you can view these services in the Console or access the **Manage Platform Services Regions** page, your tenancy must have entitlements to use the Platform Services.

Managing Platform Services Regions

To view and subscribe to Platform Services regions

1. Open the Console, open the **Region** menu, and then click **Manage Regions**.
2. On the **Manage Regions** page, click **Platform Services Regions**.
   The list of geographical regions is displayed. Regions that you have not subscribed to provide a button to create a subscription. A sample of the **Platform Services Regions** page is shown in the following screenshot:



3. To subscribe to a region, locate the region in the list and click **Subscribe**.
   It might take several minutes to activate your tenancy in the new region.

You cannot unsubscribe from a region.

Managing the Tenancy

This topic describes options on the tenancy details page in the Console.

Required IAM Policy

If you're in the Administrators group, then you have the required access to manage the tenancy.

If you're new to policies, see Getting Started with Policies and Common Policies. If you want to dig deeper into writing policies for your tenancy and other IAM components, see Details for IAM.

Viewing the Tenancy Details Page

To view the tenancy details page:

Open the **Profile** menu () and click **Tenancy:** *<your_tenancy_name>*.

Details About Your Tenancy

The tenancy details page provides the following information about your tenancy:

TENANCY OCID

Every Oracle Cloud Infrastructure resource has an Oracle-assigned unique ID called an Oracle Cloud Identifier (OCID). You need your tenancy's OCID to use the API. You'll also need it when contacting support.

HOME REGION

When you sign up for Oracle Cloud Infrastructure, Oracle creates a tenancy for you in one of the available regions. This is your *home region*. Your home region is where your IAM resources are defined. For more information about the home region, see The Home Region.

NAME

Your tenancy name. Your tenancy name is typically chosen when you set up your Oracle Cloud account.

CSI NUMBER

Your Customer Service Identifier for Oracle Support.

AUDIT RETENTION PERIOD

The retention period for the Audit service logs. The value of the retention period setting affects all regions and all compartments for this tenancy. You can't set different retention periods for different regions or compartments. For more information about this setting, see Setting Audit Log Retention Period.

OBJECT STORAGE DESIGNATED COMPARTMENTS AND NAMESPACE

The Object Storage service provides API support for both Amazon S3 Compatibility API and Swift API. By default, buckets created using the Amazon S3 Compatibility API or the Swift API are created in the root compartment of the Oracle Cloud Infrastructure tenancy. You can designate a different compartment for the Amazon S3 Compatibility API or Swift API to create buckets in. For more information, see Designating Compartments for the Amazon S3 Compatibility and Swift APIs.

For information about your Object Storage namespace, see Understanding Object Storage Namespaces.

TAGS

Tagging allows you to define keys and values and associate them with resources. You can then use the tags to help you organize and list resources based on your business needs. If you have permissions to manage the tenancy, you also have permissions to apply free-form tags. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags.

SERVICE LIMITS

The limits allotted to your tenancy and usage against these limits. Not all service resources are included in the list shown here on the Console. For more information or to

request an increase, see Service Limits.

Using the API

Many of the options set on this page are managed through the owning service. For example, the Object Storage settings are managed with the Object Storage service API, and setting the Audit log retention period is handled by the Audit service API.

To get information about your tenancy use the following operation:

- GetTenancy

To tag a tenancy, use the following operations:

- GetCompartment
- UpdateCompartment

In the above operations, use the tenancy OCID for the `compartmentID` parameter.

Managing Policies

This topic describes the basics of working with policies.

Required IAM Policy

If you're in the Administrators group, then you have the required access for managing policies.

If you're new to policies, see Getting Started with Policies and Common Policies. If you want to dig deeper into writing policies to control who else can write policies or manage other IAM components, see Let a compartment admin manage the compartment, and also Details for IAM.

Tagging Resources

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the desired tags. For general information about applying tags, see Resource Tags.

Working with Policies

If you haven't already, make sure to read How Policies Work to understand the basics of how policies work.

When creating a policy, you must specify the compartment where it should be *attached*, which is either the tenancy (the root compartment) or another compartment. Where it's attached governs who can later modify or delete it. For more information, see Policy Attachment. When creating the policy in the Console, you attach the policy to the desired compartment by creating the policy *while viewing that compartment*. If you're using the API, you specify the identifier of the desired compartment in the CreatePolicy request.

Also when creating a policy, you can specify its *version date*. For more information, see Policy Language Version. You can change the version date later if you like.

When creating a policy, you must also provide a unique, non-changeable *name* for it. The name must be unique across all policies in your tenancy. You must also provide a *description* (although it can be an empty string), which is a non-unique, changeable description for the policy. Oracle will also assign the policy a unique ID called an Oracle Cloud ID. For more information, see Resource Identifiers.

Note

If you delete a policy and then create a new policy with the same name, they'll be considered different policies because they'll have different OCIDs.

For information about how to write a policy, see How Policies Work and Policy Syntax.

When you create a policy, make changes to an existing policy, or delete a policy, your changes go into effect typically within 10 seconds.

You can view a list of your policies in the Console or with the API. In the Console, the list is automatically filtered to show only the policies attached to the compartment you're viewing. To determine which policies apply to a particular group, you must view the individual statements inside all your policies. There isn't a way to automatically obtain that information in the Console or API.

For information about the number of policies you can have, see Service Limits.

Using the Console

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

To create a policy

Prerequisite: The group and compartment that you're writing the policy for must already exist.

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Policies**.
   A list of the policies in the compartment you're viewing is displayed.
2. If you want to attach the policy to a compartment other than the one you're viewing, select the desired compartment from the list on the left. Where the policy is attached controls who can later modify or delete it (see Policy Attachment).
3. Click **Create Policy**.

4. Enter the following:
    - **Name:** A unique name for the policy. The name must be unique across all policies in your tenancy. You cannot change this later.
    - **Description:** A friendly description. You can change this later if you want to.
    - **Policy Versioning:** Select **Keep Policy Current** if you'd like the policy to stay current with any future changes to the service's definitions of verbs and resources. Or if you'd prefer to limit access according to the definitions that were current on a specific date, select **Use Version Date** and enter that date in format YYYY-MM-DD format. For more information, see Policy Language Version.
    - **Statement:** A policy statement. For the correct format to use, see Policy Basics and also Policy Syntax. If you want to add more than one statement, click **+**.
    - **Tags:** Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.
5. Click **Create**.

The new policy will go into effect typically within 10 seconds.

To get a list of your policies

Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Policies**. A list of the policies in the compartment you're currently viewing is displayed. If you want to view policies attached to a different compartment, select that compartment from the list on the left. You can't get a single list of all policies; they're always displayed by compartment.

To determine which policies apply to a particular group, you must view the individual statements inside all your policies. There isn't a way to automatically obtain that information in the Console.

To update the description for an existing policy

This is available only through the API. A workaround is to create a new policy with the new description and delete the old policy.

To update the statements in an existing policy

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Policies**.
   A list of the policies in the compartment you're viewing is displayed. If you don't see the one you're looking for, verify that you're viewing the correct compartment (select from the list on the left side of the page).
2. Click the policy you want to update.
   The policy's details and statements are displayed.
3. Either delete or add new statements (for the required format for statements, see Policy Basics and Policy Syntax). If you want to update an existing statement, create a new one with your desired changes and then delete the old one.

Your changes will go into effect typically within 10 seconds.

To update the version date for an existing policy

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Policies**.
   A list of the policies in the compartment you're currently viewing is displayed. If you don't see the policy you're looking for, make sure you're viewing the correct compartment (select from the list on the left side of the page).
2. Click the policy you want to update.
   The policy's details, version date, and statements are displayed.
3. Click **Update Version Date**.

4. Select **Keep Policy Current** if you'd like the policy to stay current with any future changes to the service's definitions of verbs and resources. Or if you'd prefer to limit access according to the definitions that were current on a specific date, select **Use Version Date** and enter that date in format YYYY-MM-DD format. For more information, see Policy Language Version.
5. Click **Update Version Date**.

Your changes will go into effect typically within 10 seconds.

To delete a policy

Tip

Remember that if you delete a policy and then create a new one with the same name, they'll be considered different policies because they'll have different OCIDs.

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Policies**.
   A list of the policies in the compartment you're viewing is displayed. If you don't see the one you're looking for, verify that you're viewing the correct compartment (select from the list on the left side of the page).
2. For the policy you want to delete, click **Delete**.
3. Confirm when prompted.

Your changes will go into effect typically within 10 seconds.

To apply tags to a policy

For instructions, see Resource Tags.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Note

Updates Are Not Immediate Across All Regions

Your IAM resources reside in your home region. To enforce policy across all regions, the IAM service replicates your resources in each region. Whenever you create or change a policy, user, or group, the changes take effect first in the home region, and then are propagated out to your other regions. It can take several minutes for changes to take effect in all regions. For example, assume you have a group with permissions to launch instances in the tenancy. If you add UserA to this group, UserA will be able to launch instances in your home region within a minute. However, UserA will not be able to launch instances in other regions until the replication process is complete. This process can take up to several minutes. If UserA tries to launch an instance before replication is complete, they will get a not authorized error.

Use these API operations to manage policies:

- CreatePolicy
- ListPolicies
- GetPolicy

- UpdatePolicy
- DeletePolicy

Managing User Credentials

This topic describes the basics of working with Oracle Cloud Infrastructure Identity and Access Management (IAM) user credentials. If you're not already familiar with the available credentials, see User Credentials.

Working with Console Passwords and API Keys

Each user automatically has the ability to change or reset *their own* Console password, as well as manage *their own* API keys. An administrator does not need to create a policy to give a user those abilities.

To manage credentials for users other than yourself, you must be in the Administrators group or some other group that has permission to work with the tenancy. Having permission to work with a compartment within the tenancy is not sufficient. For more information, see The Administrators Group and Policy.

IAM administrators (or anyone with permission to the tenancy) can use either the Console or the API to manage all aspects of both types of credentials, for themselves and all other users. This includes creating an initial one-time password for a new user, resetting a password, uploading API keys, and deleting API keys.

Users who are not administrators can manage *their own* credentials. In the Console, users can:

- Change or reset their own password.
- Upload an API key in the Console for their own use (and also delete their own API keys).

And with the API, users can:

- Reset their own password with CreateOrResetUIPassword.
- Upload an additional API key to the IAM service for their own use with UploadApiKey (and also delete their own API keys with DeleteApiKey). Remember that a user can't use the API to change or delete their own credentials until they themselves upload a key in the Console, or an administrator uploads a key for that user in the Console or the API.

A user can have a maximum of three API keys at a time.

Working with Auth Tokens

Note

"Auth tokens" were previously named "Swift passwords". Any Swift passwords you had created are now listed in the Console as auth tokens. You can continue to use the existing passwords.

Auth tokens are Oracle-generated token strings that you can use to authenticate with third-party APIs that do no support Oracle Cloud Infrastructure's signature-based authentication. Each user created in the IAM service automatically has the ability to create, update, and delete their own auth tokens in the Console or the API. An administrator does not need to create a policy to give a user those abilities. Administrators (or anyone with permission to the tenancy) also have the ability to manage auth tokens for other users.

Note that you cannot change your auth token to a string of your own choice. The token is always an Oracle-generated string.

Auth tokens do not expire. Each user can have up to two auth tokens at a time. To get an auth token in the Console, see To create an auth token.

Using an Auth Token with Swift

Swift is the OpenStack object store service. If you already have an existing Swift client, you can use it with the Recovery Manager (RMAN) to back up an Oracle Database System (DB

System) database to Object Storage. You will need to get an auth token to use as your Swift password. When you sign in to your Swift client, you provide the following:

- Your Oracle Cloud Infrastructure Console user login
- Your Swift-specific auth token, provided by Oracle
- Your organization's Oracle tenant name

Any user of a Swift client that integrates with Object Storage needs permission to work with the service. If you're not sure if you have permission, contact your administrator. For information about policies, see How Policies Work. For basic policies that enable use of Object Storage, see Common Policies.

Working with Customer Secret Keys

Note

"Customer Secret keys" were previously named "Amazon S3 Compatibility API keys". Any keys you had created are now listed in the Console as Customer Secret keys. You can continue to use the existing keys.

Object Storage provides an API to enable interoperability with Amazon S3. To use this Amazon S3 Compatibility API, you need to generate the signing key required to authenticate with Amazon S3. This special signing key is an Access Key/Secret Key pair. Oracle provides the Access Key that is associated with your Console user login. You or your administrator generates the Customer Secret key to pair with the Access Key.

Each user created in the IAM service automatically has the ability to create, update, and delete their own Customer Secret keys in the Console or the API. An administrator does not need to create a policy to give a user those abilities. Administrators (or anyone with permission to the tenancy) also have the ability to manage Customer Secret keys for other users.

Any user of the Amazon S3 Compatibility API with Object Storage needs permission to work with the service. If you're not sure if you have permission, contact your administrator. For information about policies, see How Policies Work. For basic policies that enable use of Object Storage, see Common Policies.

Customer Secret keys do not expire. Each user can have up to two Customer Secret keys at a time. To create keys using the Console, see To create a Customer Secret key.

Working with SMTP Credentials

Simple Mail Transfer Protocol (SMTP) credentials are needed in order to send email through the Email Delivery service. Each user is limited to a maximum of two SMTP credentials. If more than two are required, they must be generated on other existing users or additional users must be created.

Note

You cannot change your SMTP username or password to a string of your own choice. The credentials are always Oracle-generated strings.

Each user created in the IAM service automatically has the ability to create and delete their own SMTP credentials in the Console or the API. An administrator does not need to create a policy to give a user those abilities. Administrators (or anyone with permission to the tenancy) also have the ability to manage SMTP credentials for other users.

Tip

Although each user can create and delete their own credentials, it is a security best practice to create a new user and generate SMTP credentials on this user rather than generating SMTP credentials on your Console user that already has permissions assigned to it.

SMTP credentials do not expire. Each user can have up to two credentials at a time. To get SMTP credentials in the Console, see To generate SMTP credentials.

For information about using the Email Delivery service, see Overview of the Email Delivery Service.

Using the Console

To change your Console password

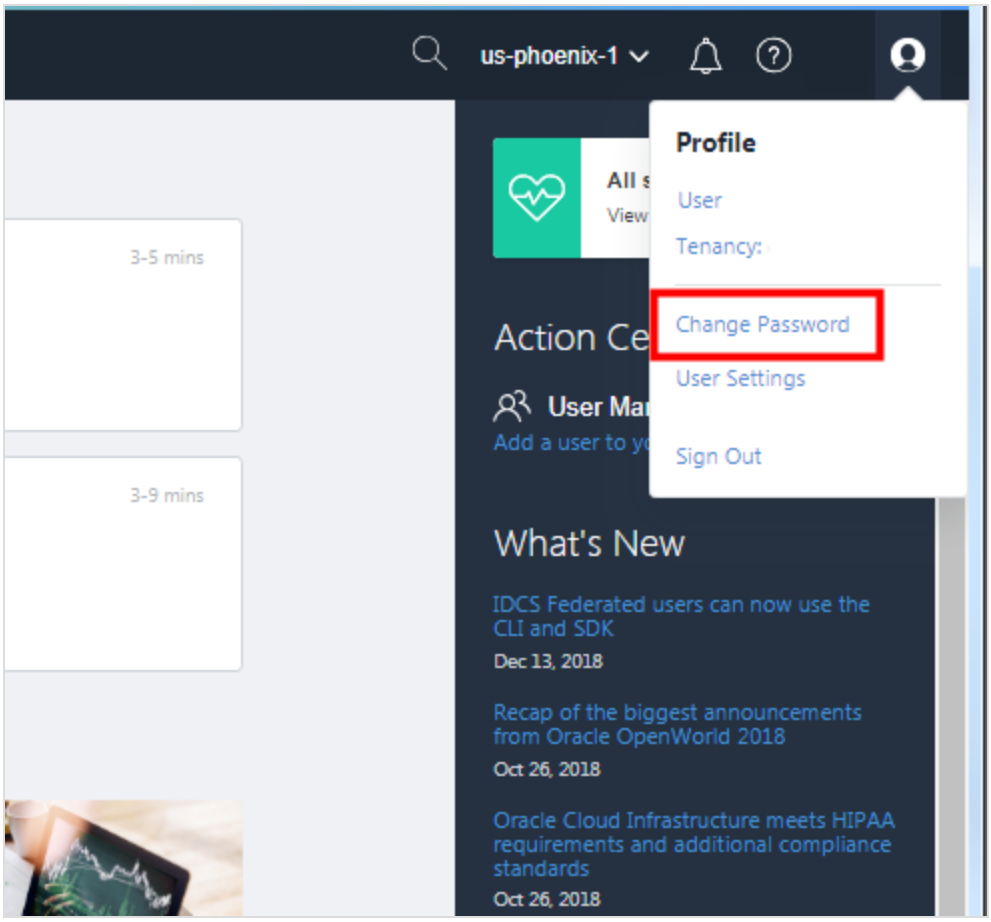
You're prompted to change your initial one-time password *the first time* you sign in to the Console. The following procedure is for changing your password again later.

Note

For Federated Users

If your company uses an identity provider (other than Oracle Identity Cloud Service) to manage user logins and passwords, you can't use the Console to update your password. You do that with your identity provider.

1. Sign in to the Console using the Oracle Cloud Infrastructure Username and Password.
2. After you sign in, go to the top-right corner of the Console, open the **Profile** menu () and then click **Change Password**.



3. Enter the current password.
4. Follow the prompts to enter the new password, and then click **Save New Password**.

To create or reset another user's Console password

If you're an administrator, you can use the following procedure to create or reset a user's password. The procedure generates a new one-time password that the user must change the next time they sign in to the Console.

1. View the user's details: In the Console, click **Identity**, and then click **Users**. Locate the user in the list, and then click the user's name to view the details.
2. Click **Create/Reset Password**.
   The new one-time password is displayed. If you're an administrator performing the task for another user, you need to securely deliver the new password to the user. The user will be prompted to change their password the next time they sign in to the Console. If they don't change it within 7 days, the password will expire and you'll need to create a new one-time password for the user.

To reset your password if you forgot it

If you have an email address in your user profile, you can use the **Forgot Password** link on the sign on page to have a temporary password sent to you. If you don't have an email address in your user profile, you must ask an administrator to reset your password for you.

To unblock a user

If you're an administrator, you can unblock a user who has tried 10 times in a row to sign in to the Console unsuccessfully. See To unblock a user.

To upload an API signing key

The following procedure works for a regular user or an administrator. Administrators can upload an API key for either another user or themselves.

Important

The API key must be an **RSA key in PEM format (minimum 2048 bits)**. The PEM format looks something like this:

```
-----BEGIN PUBLIC KEY-----
MIIBIjANBgkqhkiG9w0BAQEFAAOCAQ8AMIIBCgKCAQEAoTFqF...
...
-----END PUBLIC KEY----
```

For more information about generating a public PEM key, see Required Keys and OCIDs.

1. View the user's details:
   - If you're uploading an API key for *yourself*: Open the **Profile** menu () and click **User Settings**.
   - If you're an administrator uploading an API key for *another user*: In the Console, click **Identity**, and then click **Users**. Locate the user in the list, and then click the user's name to view the details.
2. Click **Add Public Key**.
3. Paste the key's value into the window and click **Add**.
   The key is added and its fingerprint is displayed (example fingerprint: d1:b2:32:53:d3:5f:cf:68:2d:6f:8b:5f:77:8f:07:13).

Note

When making API requests, you'll need the key's fingerprint, along with your tenancy's OCID and user OCID. See Required Keys and OCIDs.

To delete an API signing key

The following procedure works for a regular user or an administrator. Administrators can delete an API key for either another user or themselves.

1. View the user's details:
    - If you're deleting an API key for *yourself*: Open the **Profile** menu () and click **User Settings**.
    - If you're an administrator deleting an API key for *another user*: In the Console, click **Identity**, and then click **Users**. Locate the user in the list, and then click the user's name to view the details.
2. For the API key you want to delete, click **Delete**.
3. Confirm when prompted.

The API key is no longer valid for sending API requests.

To create an auth token

1. View the user's details:
    - If you're creating an auth token for yourself: Open the **Profile** menu () and click **User Settings**.
    - If you're an administrator creating an auth token for another user: In the Console, click **Identity**, and then click **Users**. Locate the user in the list, and then click the user's name to view the details.
2. On the left side of the page, click **Auth Tokens**.
3. Click **Generate Token**.
4. Enter a description that indicates what this token is for, for example, "Swift password token".
5. Click **Generate Token**.
   The new token string is displayed.

6. Copy the token string immediately, because you can't retrieve it again after closing the dialog box.

If you're an administrator creating an auth token for another user, you need to securely deliver it to the user by providing it verbally, printing it out, or sending it through a secure email service.

To delete an auth token

The following procedure works for a regular user or an administrator. Administrators can delete an auth token for either another user or themselves.

1. View the user's details:
   - If you're deleting an auth token for *yourself*: Open the **Profile** menu () and click **User Settings**.
   - If you're an administrator deleting an auth token for *another user*: In the Console, click **Identity**, and then click **Users**. Locate the user in the list, and then click the user's name to view the details.
2. On the left side of the page, click **Auth Tokens**.
3. For the auth token you want to delete, click **Delete**.
4. Confirm when prompted.

The auth token is no longer valid for accessing third-party APIs.

To create a Customer Secret key

1. View the user's details:
   - If you're creating a Customer Secret key for yourself: Open the **Profile** menu () and click **User Settings**.

- If you're an administrator creating a Customer Secret key for another user: In the Console, click **Identity**, and then click **Users**. Locate the user in the list, and then click the user's name to view the details.

2. On the left side of the page, click **Customer Secret Keys**.
   A Customer Secret key consists of an Access Key/Secret key pair. Oracle automatically generates the Access Key when you or your administrator generates the Secret Key to create the Customer Secret key.
3. Click **Generate Secret Key**.
4. Enter a friendly description for the key and click **Generate Secret Key**.
   The generated **Secret Key** is displayed in the **Generate Secret Key** dialog box. At the same time, Oracle generates the **Access Key** that is paired with the **Secret Key**. The newly generated Customer Secret key is added to the list of **Customer Secret Keys**.
5. Copy the **Secret Key** immediately, because you can't retrieve the **Secret Key** again after closing the dialog box for security reasons.
   If you're an administrator creating a Secret Key for another user, you need to securely deliver it to the user by providing it verbally, printing it out, or sending it through a secure email service.
6. Click **Close**.
7. To show or copy the **Access Key**, click the **Show** or **Copy** action to the left of the **Name** of a particular Customer Secret key.

To delete a Customer Secret key

The following procedure works for a regular user or an administrator. Administrators can delete a Customer Secret key for either another user or themselves.

1. View the user's details:
   - If you're deleting a Customer Secret key for *yourself*: Open the **Profile** menu () and click **User Settings**.

- If you're an administrator deleting a Customer Secret key for *another user*: In the Console, click **Identity**, and then click **Users**. Locate the user in the list, and then click the user's name to view the details.

2. On the left side of the page, click **Customer Secret Keys**.
3. For the Customer Secret key you want to delete, click **Delete**.
4. Confirm when prompted.

The Customer Secret key is no longer available to use with the Amazon S3 Compatibility API.

To generate SMTP credentials

1. View the user's details:
   - If you're generating SMTP credentials for *yourself*: Open the **Profile** menu () and click **User Settings**.
   - If you're an administrator generating SMTP credentials for *another user*: In the Console, click **Identity**, and then click **Users**. Locate the user in the list, and then click the user's name to view the details.
2. Click **SMTP Credentials**.
3. Click **Generate SMTP Credentials**.
4. Enter a **Description** of the SMTP Credentials in the dialog box.
5. Click **Generate SMTP Credentials**. A user name and password is displayed.
6. Copy the user name and password for your records and click **Close**. Copy the credentials immediately, because you can't retrieve the password again after closing the dialog box for security reasons.

   If you're an administrator creating the credential set for another user, you need to securely deliver it to the user by providing it verbally, printing it out, or sending it through a secure email service.

To delete SMTP credentials

The following procedure works for a regular user or an administrator. Administrators can delete SMTP credentials for either another user or themselves.

1. View the user's details:
   - If you're deleting SMTP credentials for *yourself*: Open the **Profile** menu () and click **User Settings**.
   - If you're an administrator deleting SMTP credentials for *another user*: In the Console, click **Identity**, and then click **Users**. Locate the user in the list, and then click the user's name to view the details.
2. On the left side of the page, click **SMTP Credentials**.
3. For the SMTP credentials you want to delete, click **Delete**.
4. Confirm when prompted.

The SMTP credentials are no longer available to use with the Email Delivery service.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use this API operation to manage Console passwords and access:

- CreateOrResetUIPassword: This generates a new one-time Console password for the user. The next time the user signs in to the Console, they'll be prompted to change the password.
- UpdateUserState: Unblocks a user who has tried to sign in 10 times in a row unsuccessfully.

Use these API operations to manage API signing keys:

- ListApiKeys
- UploadApiKey
- DeleteApiKey

Use these API operations to manage auth tokens:

- CreateAuthToken
- UpdateAuthToken: You can only update the auth token's description, not change the token string itself.
- ListAuthTokens
- DeleteAuthToken

Use these API operations to manage Customer Secret keys:

- CreateCustomerSecretKey
- UpdateCustomerSecretKey: You can only update the secret key's description, not change the key itself.
- ListCustomerSecretKeys
- DeleteCustomerSecretKey

Use these API operations to manage SMTP credentials:

- CreateSmtpCredential
- UpdateSmtpCredential: You can only update the description.
- ListSmtpCredentials
- DeleteSmtpCredential

Managing Authentication Settings

This topic describes how to set password policy rules for local IAM users in your tenancy.

Required IAM Policy

If you're in the Administrators group, then you have the required access for managing password policy.

To view authentication policy, you must be granted `inspect` access on the `authentication-policies` resource. For example:

```
Allow group GroupA to inspect authentication-policies in tenancy
```

To modify authentication policy, you must be granted the `AUTHENTICATION_POLICY_UPDATE` permission. This permission is included in the `manage` verb. For example:

```
Allow group GroupA to manage authentication-policies in tenancy
```

If you're new to policies, see Getting Started with Policies and Common Policies. If you want to dig deeper into writing policies for groups or other IAM components, see Details for IAM.

Working with Password Policy Rules

A password policy that you set in the IAM service is applicable for all local (or non-federated) users.

When a user is created or when a user changes their password, the IAM service validates the password that is provided against the password policy to ensure that it meets the criteria for the policy. When a user logs in for the first time to change the password, or resets the password at any time, the password policy is evaluated and enforced.

When Do Changes to Password Policy Rules Take Effect

Changes to password policy rules take effect immediately so that the next time any user changes their password they must create a password that meets the criteria. Existing passwords will continue to work even if they would be invalid under the new rules. Users are not forced to change existing passwords to meet the new criteria. Passwords are evaluated against the rules only at the time they are created or changed.

About the Password Policy Rules

The following table describes the rules that you can include in your password policy:

Rule	Setting Options	Default IAM Service Setting
Minimum password length	Minimum value is 8 (characters). Maximum value is 100.	12 characters
Special characters	Require passwords to contain at least 1 of the following special characters: !\"#$%&`()*+,-./:;<=>?@[\\]^_` {|}~	Enforced
Lowercase characters	Require passwords to contain at least 1 lowercase alphabetic character a-z.	Enforced
Uppercase characters	Require passwords to contain at least 1 uppercase alphabetic character A-Z.	Enforced
Numeric characters	Require passwords to contain at least 1 number 0-9.	Enforced

Oracle recommends that you enforce all the password rules.

Using the Console

To edit password policy rules

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Authentication Settings**.
   The authentication settings for your tenancy are displayed.

2. Click **Edit**.
3. Enter the following to set the password policy:
    - **Minimum Password Length:** Enter a number to define the minimum number of characters that a user's password must contain. Allowed values are 8 through 100.
4. Select the **Password Rules** you want to enforce:
    - **Must contain at least 1 numeric character:** Select the check box to require at least 1 number (0-9) in the password.
    - **Must contain at least 1 special character:** Select the check box to require at least 1 special character. Special characters are: !\"#$%&'()*+,-./:;<=>?@[\\]^_`{|}~
    - **Must contain at least 1 lowercase character:** Select the check box to require at least 1 lowercase alphabetic character (a-z).
    - **Must contain at least 1 uppercase character:** Select the check box to require at least 1 uppercase alphabetic character (A-Z).
5. Click **Save**.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use these API operations to manage password rules:

- GetAuthenticationPolicy
- UpdateAuthenticationPolicy

Managing Multi-Factor Authentication

This topic describes how users can manage multi-factor authentication (MFA) in Oracle Cloud Infrastructure.

Required IAM Policy

Only the user can enable multi-factor authentication (MFA) for their own account. Users can also disable MFA for their own accounts. Members of the Administrators group can disable MFA for other users, but they cannot enable MFA for another user.

About Multi-Factor Authentication

Multi-factor authentication is a method of authentication that requires the use of more than one factor to verify a user's identity.

With MFA enabled in the IAM service, when a user signs in to Oracle Cloud Infrastructure, they are prompted for their user name and password, which is the first factor (something that they know). The user is then prompted to provide a second verification code from a registered MFA device, which is the second factor (something that they have). The two factors work together, requiring an extra layer of security to verify the user's identity and complete the sign-in process.

In general, MFA may include any two of the following:

- Something that you know, like a password.
- Something that you have, like a device.
- Something that you are, like your fingerprint.

The IAM service supports two-factor authentication using a password (first factor) and a device that can generate a time-based one-time password (TOTP) (second factor).

General Concepts

Here's a list of the basic concepts you need to be familiar with.

MULTI-FACTOR AUTHENTICATION (MFA)

Multi-factor authentication (MFA) is a method of authentication that requires the use of more than one factor to verify a user's identity. Examples of authentication factors are a password (something you know) and a device (something you have).

AUTHENTICATOR APP

An app you install on your mobile device that can provide software-based secure tokens for identity verification. Examples of authenticator apps are Oracle Mobile Authenticator and Google Authenticator. To enable MFA for the IAM service, you'll need a device with an authenticator app installed. You'll use the app to register your device and then you'll use the same app (on the same device) to generate a time-based one-time passcode every time you sign in.

REGISTERED MOBILE DEVICE

Multi-factor authentication is enabled for a specific user and for a specific device. The procedure to enable MFA for a user includes the registration of the mobile device. This same device must be used to generate the time-based one-time passcode every time the user signs in. If the registered mobile device becomes unavailable, an administrator must disable MFA for the user so that MFA can be re-enabled with a new device.

TIME-BASED ONE-TIME PASSWORD (TOTP)

A TOTP is a password (or passcode) that is generated by an algorithm that computes a one-time password from a shared secret key and the current time, as defined in RFC 6238. The authenticator app on your registered mobile device generates the TOTP that you need to enter every time you sign in to Oracle Cloud Infrastructure.

Supported Authenticator Apps

The following authenticator apps have been tested with the Oracle Cloud Infrastructure IAM service:

- Oracle Mobile Authenticator
- Google Authenticator

You can find these apps in your mobile device's app store. You must install one of these apps on your mobile device before you can enable MFA.

Working with MFA

Keep the following in mind when you enable MFA:

- You must install a supported authenticator app on the mobile device you intend to register for MFA.
- Each user must enable MFA for themselves using a device they will have access to every time they sign in. An administrator *cannot* enable MFA for another user.
- To enable MFA, you use your mobile device's authenticator app to scan a QR code that is generated by the IAM service and displayed in the Console. The QR code shares a secret key with the app to enable the app to generate TOTPs that can be verified by the IAM service.
- A user can register only one device to use for MFA.
- After you add your Oracle Cloud Infrastructure account to your authenticator app, the account name displays in the authenticator app as Oracle *<tenancy_name>* - *<username>*.

Restricting Access to Only MFA-Verified Users

You can restrict access to resources to only users that have been authenticated through the IAM service's time-based one-time password authentication. You set up this restriction in the policy that allows access to the resource.

To restrict the access granted through a policy to only MFA-verified users, add the following `where clause` to the policy:

```
where request.user.mfaTotpVerified='true'
```

For example, assume your company has this policy in place to allow GroupA to manage instances:

```
allow group GroupA to manage instance-family in tenancy
```

To enhance security, you want to ensure that only users who have been verified through MFA can manage instances. To restrict access to only these users, revise the policy statement as follows:

```
allow group GroupA to manage instance-family in tenancy where request.user.mfaTotpVerified='true'
```

With this policy in place, only the members of GroupA who have successfully signed in by entering both their password and the time-based one-time passcode generated by their registered mobile device, are allowed to access and manage instances. Users who have not enabled MFA and sign in using only their password, will not be allowed access to manage instances.

For information on writing policies, see Policy Syntax.

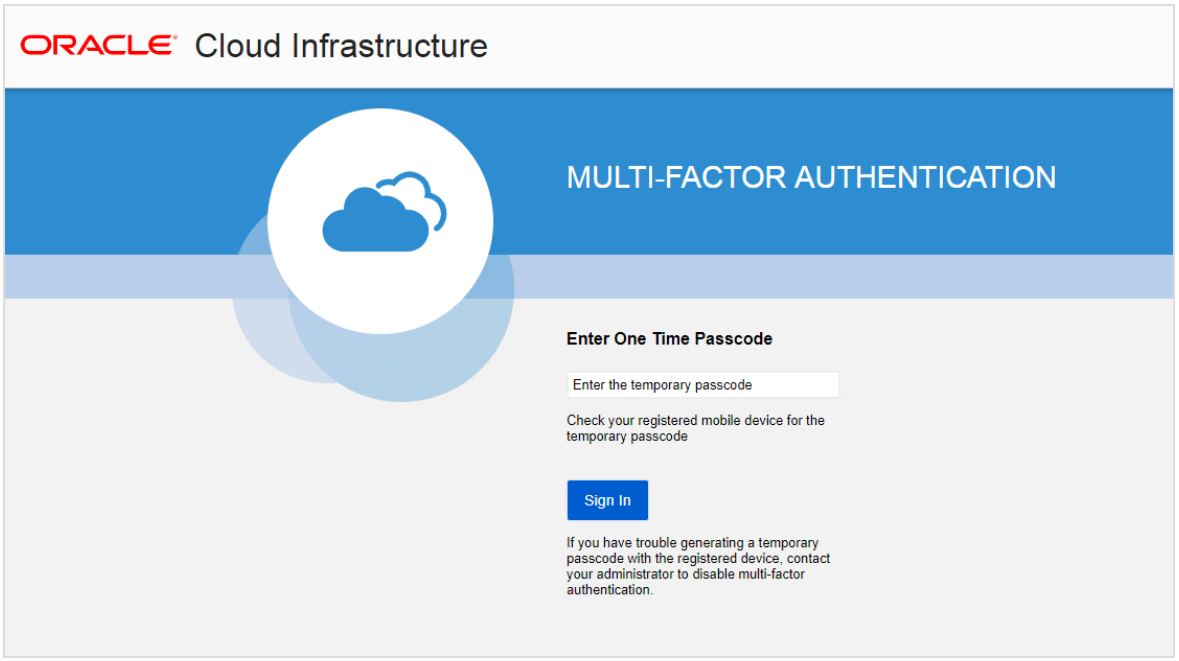
Sign in Process After Enabling MFA

After you have enabled MFA, use one of the following procedures to sign in to Oracle Cloud Infrastructure:

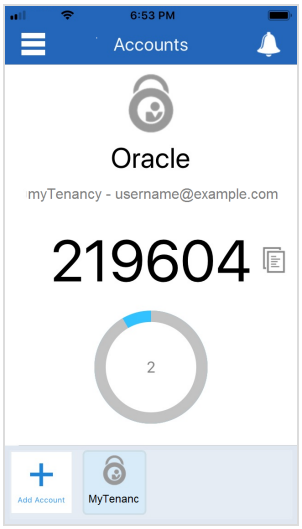
To sign in using the Console

1. Navigate to the Console sign-in page.
2. Enter your Oracle Cloud Infrastructure **User Name** and **Password** and then click **Sign In**.

After your user name and password are authenticated, you have successfully supplied the first factor for authentication. The secondary authentication page displays and prompts you to enter a one-time passcode, as shown in the following screenshot.



3. Open the authenticator app on your registered mobile device and then open the account for your Oracle Cloud Infrastructure tenancy. The following screenshot shows an example from Oracle Mobile Authenticator.



4. Enter the passcode displayed by your authenticator app (for example, 219604) and then click **Sign In**.

   Important: The authenticator app generates a new time-based one-time passcode every 30 seconds. You must enter a code while the code is still valid. If you miss the time window for one passcode, you can enter the next one that is generated. Just ensure that you enter the code that is currently displayed by your app.

To sign in using the command line interface (CLI)

1. To sign in with the CLI, run the following command:

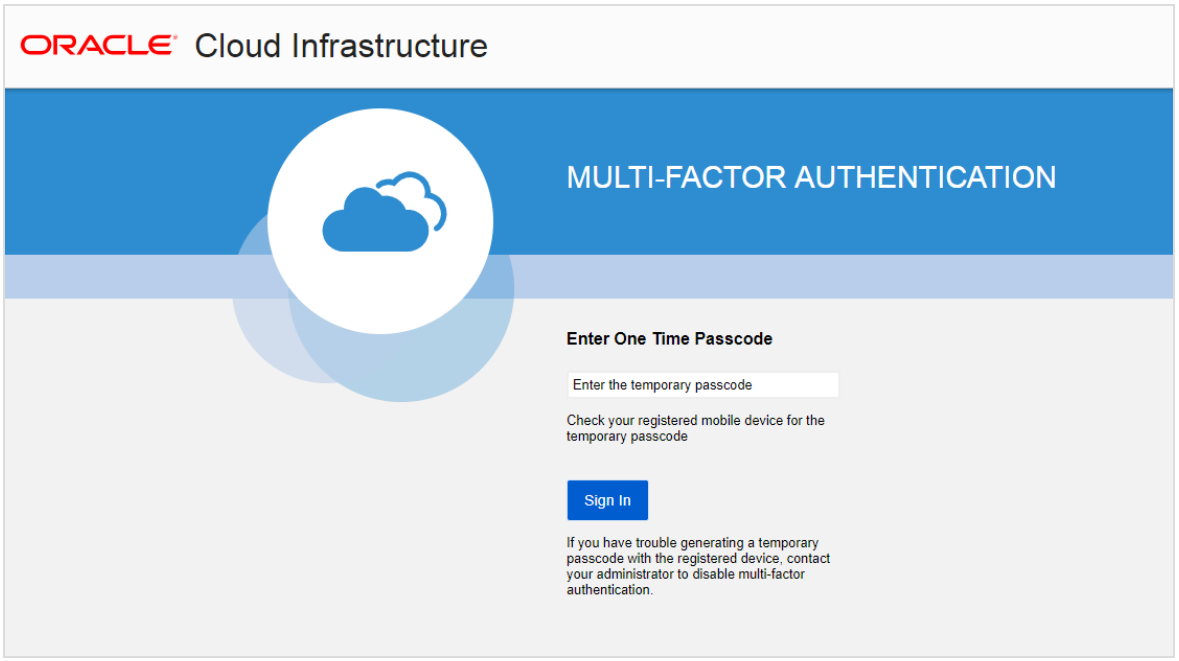
   ```
   oci session authenticate --region US East (Ashburn)
   ```

   A browser window opens, and a prompt instructs you to use the browser to sign in.

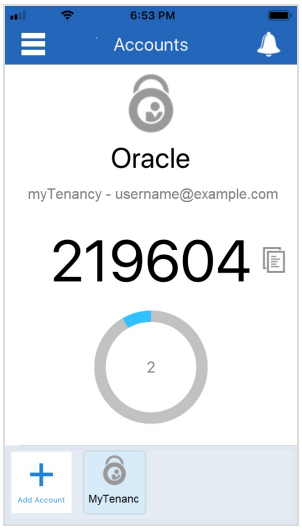
   ```
   Please switch to newly opened browser window to log in!
   ```

2. In the browser window, enter your Oracle Cloud Infrastructure **User Name** and **Password** and then click **Sign In**.

After your user name and password are authenticated, you have successfully supplied the first factor for authentication. The secondary authentication page displays and prompts you to enter a one-time passcode, as shown in the following screenshot.



3. Open the authenticator app on your registered mobile device and then open the account for your Oracle Cloud Infrastructure tenancy. The following screenshot shows an example from Oracle Mobile Authenticator.



4. Enter the passcode displayed by your authenticator app (for example, 219604) and then click **Sign In**.

   Important: The authenticator app generates a new time-based one-time passcode every 30 seconds. You must enter a code while the code is still valid. If you miss the time window for one passcode, you can enter the next one that is generated. Just ensure that you enter the code that is currently displayed by your app.

   After you authenticate, prompts instruct you to return to the CLI and enter the name of a profile.

5. In the CLI, type a name for the profile.

> **Tip**
>
> For more information about working with the CLI, see Quickstart and Getting Started with the Command Line Interface.

What To Do If You Lose Your Registered Mobile Device

If you lose your registered mobile device, you will not be able to authenticate to Oracle Cloud Infrastructure through the Console. Contact your administrator to disable multi-factor authentication for your account. You can then repeat the process to enable multi-factor authentication with a new mobile device.

Unblocking a User After Unsuccessful Sign-in Attempts

If a user tries 10 times in a row to sign in to the Console unsuccessfully, they will be automatically blocked from further sign-in attempts. An administrator can unblock the user in the Console (see To unblock a user) or with the UpdateUserState API operation.

Disabling MFA

Each user can disable MFA for themselves. An administrator can also disable MFA for another user.

Warning

Do not disable MFA unless you are instructed to by your administrator.

Using the Console

Use the following procedures to manage MFA in the Console.

To enable MFA for your user account

Prerequisite: You must install a supported authenticator app on the mobile device you intend to register for MFA.

1. In the upper-right corner of the Console, open the **Profile** menu () and then select **User Settings**. Your user details are displayed.
2. Click **Enable Multi-Factor Authentication**.
3. Scan the QR code displayed in the dialog with your mobile device's authenticator app.
   Note: If you close the browser, or if the browser crashes before you can enter the verification code, you must generate a new QR code and scan it again with your app. To generate a new QR code, click the **Enable Multi-Factor Authentication** button again.
4. In the **Verification Code** field, enter the code displayed on your authenticator app.
5. Click **Enable**.

Your mobile device is now registered with the IAM service and your account is enabled for MFA. Every time you sign in, you are prompted for your username and password first. After you provide the correct credentials, you will be prompted for a TOTP code generated by the authenticator app on your registered mobile device. *You must have your registered mobile device available every time you sign in to Oracle Cloud Infrastructure.*

To disable MFA for your user account

1. In the upper-right corner of the Console, open the **Profile** menu () and then select **User Settings**. Your user details are displayed.
2. Click **Disable Multi-Factor Authentication**.
3. Confirm when prompted.

To disable MFA for another user

1. Open the navigation menu. Under **Governance and Administration**, go to **Identity** and click **Users**.
   A list of the users in your tenancy is displayed.
2. Click the user you want to update.
   The user's details are displayed.

3. Click **Disable Multi-Factor Authentication**.
4. Confirm when prompted.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Note

Updates Are Not Immediate Across All Regions

Your IAM resources reside in your home region. To enforce policy across all regions, the IAM service replicates your resources in each region. Whenever you create or change a policy, user, or group, the changes take effect first in the home region, and then are propagated out to your other regions. It can take several minutes for changes to take effect in all regions.

Use these API operations to manage multi-factor authentication devices:

- CreateMfaTotpDevice
- ListMfaTotpDevices
- GetMfaTotpDevice
- DeleteMfaTotpDevice
- ActivateMfaTotpDevice
- GenerateTotpSeed

CHAPTER 19 Key Management

This chapter explains how to create key vaults and encryption keys and how to manage and use them.

Overview of Key Management

Oracle Cloud Infrastructure Key Management provides you with centralized management of the encryption of your data. You can use Key Management to create master encryption keys and data encryption keys, rotate keys to generate new cryptographic material, enable or disable keys for use in cryptographic operations, assign keys to resources, and use keys for encryption and decryption.

Oracle Cloud Infrastructure Object Storage, Oracle Cloud Infrastructure Block Volume, and Oracle Cloud Infrastructure File Storage integrate with Key Management to support encryption of data in buckets, block or boot volumes, and file systems. Integration with Oracle Cloud Infrastructure Identity and Access Management (IAM) lets you control who and what services can access which keys and what they can do with those keys. Oracle Cloud Infrastructure Audit integration gives you a way to monitor key usage. Audit tracks administrative actions on keys and vaults.

Keys are stored on highly available and durable hardware security modules (HSM) that meet Federal Information Processing Standards (FIPS) 140-2 Security Level 3 security certification. Key Management uses the Advanced Encryption Standard (AES) as its encryption algorithm and its keys are AES symmetric keys.

Key Management Concepts

The following concepts are integral to understanding Key Management.

KEYS

Keys are logical entities that represent one or more key versions that contain the cryptographic material used to encrypt and decrypt data, protecting the data where it is

stored. When processed as part of an encryption algorithm, a key specifies how to transform plaintext into ciphertext during encryption and how to transform ciphertext into plaintext during decryption. Conceptually, Key Management recognizes two types of encryption keys. You can create master encryption keys using the Console or API. Key Management stores those keys in a key vault. After you have a master encryption key, you can then use the API to generate data encryption keys that the service returns to you. Key Management introduces master encryption keys as an Oracle Cloud Infrastructure resource.

VAULTS

Key vaults are logical entities where Key Management creates and durably stores your keys. Vaults are partitions on a hardware security module that are isolated from one another to ensure the security and integrity of the encryption keys that are stored on them. The type of vault you have determines features and functionality such as degrees of storage isolation, access to management and encryption, scalability, and pricing. At this time, the only type of vault you can create is a virtual private vault. Key Management designates vaults as an Oracle Cloud Infrastructure resource.

KEY VERSIONS

Each master encryption key is automatically assigned a key version. When you rotate a key, Key Management generates a new key version. Periodically rotating keys limits the amount of data encrypted by one key version. Key rotation thereby reduces the risk if a key is ever compromised. A key’s unique, Oracle-assigned identifier, called an Oracle Cloud ID (OCID), remains the same across rotations, but the key version enables Key Management to seamlessly rotate keys to meet any compliance requirements you might have. Although you can't use an older key version for encryption after you rotate it, the key version remains available to decrypt any data that it previously encrypted. Key Management removes the need for you to track which key version was used to encrypt what data because the key's ciphertext contains the information that Key Management requires for decryption.

HARDWARE SECURITY MODULES

When you create a master encryption key using the Console or API, Key Management stores the key version within a hardware security module (HSM) to provide a layer of physical security. Any given key version, after it's created, is replicated within the service infrastructure as a measure of protection against hardware failures. Key versions are not otherwise stored anywhere else and cannot be exported from an HSM. Key Management uses HSMs that meet Federal Information Processing Standards (FIPS) 140-2 Security Level 3 security certification. This means that the HSM hardware is tamper-evident, has physical safeguards for tamper-resistance, requires identity-based authentication, and deletes keys from the device when it detects tampering.

ENVELOPE ENCRYPTION

The data encryption key used to encrypt your data is, itself, encrypted with a master encryption key. This concept is known as envelope encryption. Oracle Cloud Infrastructure services do not have access to the plaintext data without interacting with Key Management and without access to the master encryption key that is protected by Oracle Cloud Infrastructure Identity and Access Management (IAM). For decryption purposes, Object Storage, Block Volume, and File Storage store only the encrypted form of the data encryption key.

Regions and Availability Domains

You can use Key Management in the India West (Mumbai), South Korea Central (Seoul), Australia East (Sydney), Japan East (Tokyo), Canada Southeast (Toronto), Germany Central (Frankfurt), Switzerland North (Zurich), Brazil East (Sao Paulo), UK South (London), US East (Ashburn), and US West (Phoenix) regions. Unlike other Oracle Cloud Infrastructure services, however, Key Management does not have one regional endpoint for all API operations. The service has one regional endpoint for the provisioning service that handles create, update, and list operations for vaults. For create, update, and list operations for keys, service endpoints are distributed across multiple independent clusters.

Because Key Management has public endpoints, you can directly use data encryption keys generated by Key Management for cryptographic operations in your applications. However, if you want to use master encryption keys with a service that has integrated with Key

Management, you can do so only when the service and the key vault that holds the key both exist within the same region.

Key Management maintains copies of encryption keys across all availability domains within a region. This replication makes it possible for Key Management to generate keys even when an availability domain is unavailable.

Private Access to Key Management

Key Management supports private access from Oracle Cloud Infrastructure resources in a virtual cloud network (VCN) through a service gateway. Setting up and using a service gateway on a VCN lets resources (such as the instances that your encrypted volumes are attached to) access public Oracle Cloud Infrastructure services such as Key Management without exposing them to the public internet. No internet gateway is required and resources can be in a private subnet and use only private IP addresses. For more information, see Access to Oracle Services: Service Gateway.

Resource Identifiers

Key Management introduces keys and vaults as Oracle Cloud Infrastructure resources. Most types of Oracle Cloud Infrastructure resources have a unique, Oracle-assigned identifier called an Oracle Cloud ID (OCID). For information about the OCID format and other ways to identify your resources, see Resource Identifiers.

Ways to Access Oracle Cloud Infrastructure

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. For a list of available SDKs, see Software Development Kits and Command Line Interface. Terraform does not currently support Key Management.

To access the Console, you must use a supported browser. You can use the **Console** link at the top of this page to go to the sign-in page. You will be prompted to enter your cloud tenant, your user name, and your password.

For general information about using the API, see REST APIs.

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies. For specific details about writing policies for each of the different services, see Policy Reference.

If you're a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

Limits on Key Management Resources

See Service Limits for a list of applicable limits and instructions for requesting a limit increase. To set compartment-specific limits on a resource or resource family, administrators can use compartment quotas.

Managing Keys

This topic describes what you can do with keys and key versions in terms of managing their creation and usage. For information about how you can use keys in cryptographic operations, see Using Keys. For information about what you can do with vaults where you store keys, see Managing Vaults.

Management of keys includes the ability to do the following:

- Create keys
- View key details
- View a list of keys

- View a list of key versions for a specific key
- Update a key name
- Manage a key's tags
- Enable keys for use in cryptographic operations
- Rotate keys to generate new cryptographic material
- Disable keys to prevent their usage in cryptographic operations
- Delete keys to permanently prevent their usage in cryptographic operations or assignment to resources
- Assign keys to specific resources
- Remove keys from their assignment to specific resources
- Move a key to a new compartment

Required IAM Policy

Warning

Keys associated with volumes, buckets, and file systems will not work unless you authorize Oracle Cloud Infrastructure Block Volume, Oracle Cloud Infrastructure Object Storage, and Oracle Cloud Infrastructure File Storage to use keys on your behalf. Additionally, you must also authorize users to delegate key usage to these services in the first place. For more information, see Let a user group delegate key usage in a compartment and Let Block Volume, Object Storage, and File Storage services encrypt and decrypt volumes, buckets, and file systems in Common Policies.

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK,

CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: For typical policies that give access to keys and vaults, see Let security admins manage vaults and keys.

Also, be aware that a policy statement with `inspect vaults` gives the specified group the ability to see *all* information about the vaults. Likewise, a policy statement with `inspect keys` gives the specified group the ability to see *all* information about the keys. For more information, see Details for the Key Management Service.

If you're new to policies, see Getting Started with Policies and Common Policies.

Tagging Resources

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the desired tags. For general information about applying tags, see Resource Tags.

Monitoring Resources

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications. For more information, see Monitoring Overview and Notifications Overview.

For information about monitoring the traffic associated with your master encryption keys, see Key Management Metrics.

Moving Resources to a Different Compartment

You can move keys from one compartment to another. After you move a key to a new compartment, inherent policies apply immediately and affect access to the key and key versions. Moving a key doesn't affect access to the vault that a key is associated with. You can move a vault from one compartment to another independently of moving any of its keys. For more information, see Managing Compartments.

Using the Console

To create a new key

1. Open the navigation menu. Under the **Governance and Administration** group, go to **Security** and click **Key Management**.
2. Under **List Scope**, in the **Compartment** list, click the name of the compartment where you want to create a key.
3. From the list of vaults in the compartment, do one of the following:
   - Click the name of the vault where you want to create a key.
   - Create a new vault for the key by following the instructions in To create a new vault, and then click the name of the vault.
4. Click **Keys**, and then click **Create Key**.
5. In the **Create Key** dialog box, choose a compartment from the **Create in Compartment** list. (Keys can exist outside the compartment the vault is in.)
6. Click **Name**, and then enter a name to identify the key. Avoid entering any confidential information in this field.
7. Specify the key length, in bits, by choosing a length from the **Key Shape: Length** list.
8. Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.
9. When you are finished, click **Create Key**.

To view key details

1. Open the navigation menu. Under the **Governance and Administration** group, go to **Security** and click **Key Management**.

2. Under **List Scope**, in the **Compartment** list, click the name of the compartment that contains the vault with the key you're interested in.
3. From the list of vaults in the compartment, click the vault name.
4. Click **Keys**, and then click the name of the key for which you want to see configuration details.
5. The console displays the following information:
    - **OCID:** The unique, Oracle-assigned ID of the key.
    - **Created:** The date and time when you initially created the key.
    - **Compartment:** The unique, Oracle-assigned ID of the compartment that contains the vault that contains the key.
    - **Vault:** The unique, Oracle-assigned ID of the vault that contains the key.
    - **Key Version:** The unique, Oracle-assigned ID of the key version.
    - **Algorithm:** The encryption algorithm used by the key.
    - **Length:** The number of bits in the key length.

To view a list of keys

1. Open the navigation menu. Under the **Governance and Administration** group, go to **Security** and click **Key Management**.
2. Under **List Scope**, in the **Compartment** list, click the name of the compartment that contains the vault with the keys you're interested in.
3. From the list of vaults in the compartment, click the vault name.
4. To see a list of keys in this vault, click **Keys**.

To view a list of key versions

1. Open the navigation menu. Under the **Governance and Administration** group, go to **Security** and click **Key Management**.

2. Under **List Scope**, in the **Compartment** list, click the name of the compartment that contains the vault with the key you're interested in.
3. From the list of vaults in the compartment, click the vault name.
4. Click **Keys**, click the name of the key for which you want to see a list of key versions, and then click **Versions**.

To change the name of a key

1. Open the navigation menu. Under the **Governance and Administration** group, go to **Security** and click **Key Management**.
2. Under **List Scope**, in the **Compartment** list, click the name of the compartment that contains the vault with the key you want to rename.
3. From the list of vaults in the compartment, click the vault name.
4. Click **Keys**, locate the key you want to rename, and then click the Actions icon (three dots) for that key.
5. In the **Actions** menu, click **Edit Name**.
6. In the **Edit Key Name** dialog box, click **Name**, and then enter a new name. Avoid entering any confidential information in this field.
7. When you are finished, click **Update**.

To manage a key's tags

1. Open the navigation menu. Under the **Governance and Administration** group, go to **Security** and click **Key Management**.
2. Under **List Scope**, in the **Compartment** list, click the name of the compartment that contains the vault with the key for which you want to manage tags.
3. From the list of vaults in the compartment, click the vault name.
4. Click **Keys**, locate the key you want to manage, and then click the key name.

5. On the **Key Details** page, click the **Tags** tab to view or edit existing tags. Or, click **Add Tag(s)** to add new ones.

To enable a key

1. Open the navigation menu. Under the **Governance and Administration** group, go to **Security** and click **Key Management**.
2. Under **List Scope**, in the **Compartment** list, click the name of the compartment that contains the vault with the key you want to enable.
3. From the list of vaults in the compartment, click the vault name.
4. Click **Keys**, locate the key you want to enable, and then select the check box next to the key name.
5. In the **Actions** menu, click **Enable**.

To rotate a key

1. Open the navigation menu. Under the **Governance and Administration** group, go to **Security** and click **Key Management**.
2. Under **List Scope**, in the **Compartment** list, click the name of the compartment that contains the vault with the key you want to rotate.
3. From the list of vaults in the compartment, click the vault name.
4. Click **Keys**, locate the key you want to rotate, and then select the check box next to the key name.
5. In the **Actions** menu, click **Rotate Key**. (You can only rotate keys in an enabled state.)
6. In the **Confirm** dialog box, click **Rotate Key**.

To disable a key

1. Open the navigation menu. Under the **Governance and Administration** group, go to

Security and click **Key Management**.

2. Under **List Scope**, in the **Compartment** list, click the name of the compartment that contains the vault with the key you want to disable.
3. From the list of vaults in the compartment, click the vault name.
4. Click **Keys**, locate the key you want to disable, and then click the Actions icon (three dots) for that key.
5. In the **Actions** menu, click **Disable**.

To delete a key

Warning

When you set a key to the Pending Deletion state, anything encrypted by that key immediately becomes inaccessible. The key also cannot be assigned or unassigned to any resources or otherwise updated. When the key is deleted, all key material and metadata is irreversibly destroyed. Before you delete a key, either assign a new key to resources currently encrypted by the key or preserve your data another way. If you want to restore use of a key before it is permanently deleted, you can cancel its deletion.

1. Open the navigation menu. Under the **Governance and Administration** group, go to **Security** and click **Key Management**.
2. Under **List Scope**, in the **Compartment** list, click the name of the compartment that contains the vault with the key you want to delete.
3. From the list of vaults in the compartment, click the vault name.

4. Click **Keys**, locate the key you want to delete, and then click the Actions icon (three dots) for that key.
5. In the **Actions** menu, click **Delete Key**.
6. Confirm that you want to delete the key by clicking the box and then typing the key name.
7. Schedule when you want Key Management to delete the key. By default, the service schedules keys for deletion 30 days from the current date and time. You can set a range between 7 days and 30 days.
8. When you're ready, click **Delete Key**. If needed, you can restore use of the key and access to encrypted resources and data by canceling the scheduled deletion.

To cancel the deletion of a key

Tip

You can only cancel the deletion of a key that's in a Pending Deletion state.

1. Open the navigation menu. Under the **Governance and Administration** group, go to **Security** and click **Key Management**.
2. Under **List Scope**, in the **Compartment** list, click the name of the compartment that contains the vault with the key you want to delete.
3. From the list of vaults in the compartment, click the vault name.
4. Click **Keys**, locate the key you want to delete, and then click the Actions icon (three dots) for that key.
5. In the **Actions** menu, click **Cancel Deletion**.
6. Confirm that you want to cancel the key's deletion by clicking **Cancel Deletion**. Access to the key and any resources or data encrypted by the key are restored when key returns to an Enabled state.

To assign a key to a new Object Storage bucket

1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.
2. Under **List Scope**, in the **Compartment** list, choose the compartment where you want to create a bucket that's encrypted with a Key Management master encryption key.
3. Click **Create Bucket**, and then follow the instructions in To create a bucket in Managing Buckets.

To assign a key to an existing Object Storage bucket

1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.
2. Under **List Scope**, in the **Compartment** list, choose the compartment that contains the bucket that you want to encrypt with a Key Management master encryption key.
3. From the list of buckets, click the bucket name.
4. Do one of the following:
   - If the bucket already has a key assigned to it, next to **Encryption Key**, click **Edit** to assign a different key.
   - If the bucket does not already have a key assigned to it, next to **Encryption Key**, click **Assign**.
5. Choose the vault compartment, vault, key compartment, and key.
6. When you are finished, click **Assign** or **Update**, as appropriate.

To assign a key to a new Block Volume

1. Open the navigation menu. Under **Core Infrastructure**, go to **Block Storage** and click **Block Volumes**.
2. Under **List Scope**, in the **Compartment** list, choose the compartment where you want to create a block volume that's encrypted with a Key Management master encryption key.

3. Click **Create Block Volume**, and then follow the instructions in Creating a Volume.

To assign a key to an existing Block Volume

1. Open the navigation menu. Under **Core Infrastructure**, go to **Block Storage** and click **Block Volumes**.
2. Under **List Scope**, in the **Compartment** list, choose the compartment that contains the block volume that you want to encrypt with a Key Management master encryption key.
3. From the list of volumes, click the volume name.
4. If the volume is currently attached to an instance, click **Detach from Instance**. Follow the instructions in the **Detach Block Volume** dialog box as appropriate, click **Continue Detachment**, and then click **OK**.
5. Then, do one of the following:
   - If the volume already has a key assigned to it, next to **Encryption Key**, click **Edit** to assign a different key.
   - If the volume does not already have a key assigned to it, next to **Encryption Key**, click **Assign**.
6. Choose the vault compartment, vault, key compartment, and key.
7. When you are finished, click **Assign** or **Update**, as appropriate.

To assign a key to a new file system

1. Open the navigation menu. Under **Core Infrastructure**, click **File Storage** and then click **File Systems**.
2. Under **List Scope**, in the **Compartment** list, choose the compartment where you want to create a file system that's encrypted with a Key Management master encryption key.
3. Click **Create File System**, and then follow the instructions in Creating File Systems.

To create a Compute instance with an encrypted boot volume

Note

These instructions assume you have already fulfilled the prerequisites for creating an instance.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Instances**.
2. Under **List Scope**, in the **Compartment** list, choose the compartment where you want to create an instance with a boot volume that's encrypted with a Key Management master encryption key.
3. Click **Create Instance**, and then follow the instructions under Using the Console in Launching an Instance.

To assign a key to an existing boot volume

Note

To assign a key to an existing boot volume, you must first detach the boot volume from any instance. However, you can only detach a boot volume from an instance when the instance is stopped. For more information, see Detaching a Boot Volume and Stopping and Starting an Instance.

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Boot Volumes**.
2. Under **List Scope**, in the **Compartment** list, choose the compartment that contains the boot volume that you want to encrypt with a Key Management master encryption key.

3. From the list of volumes, click the volume name.
4. Do one of the following:
    - If the volume already has a key assigned to it, next to **Encryption Key**, click **Edit** to assign a different key.
    - If the volume does not already have a key assigned to it, next to **Encryption Key**, click **Assign**.
5. Choose the vault compartment, vault, key compartment, and key.
6. When you are finished, click **Assign** or **Update**, as appropriate.

To remove a key assignment from a bucket

1. Open the navigation menu. Under **Core Infrastructure**, click **Object Storage**.
2. Under **List Scope**, in the **Compartment** list, choose the compartment that contains the bucket from which you want to remove a Key Management key assignment.
3. From the list of buckets, click the bucket name.
4. Next to **Encryption Key**, click **Unassign**.
5. In the **Confirm** dialog box, click **OK** to remove the key assignment from the bucket.

To remove a key assignment from a Block Volume

1. Open the navigation menu. Under **Core Infrastructure**, go to **Block Storage** and click **Block Volumes**.
2. Under **List Scope**, in the **Compartment** list, choose the compartment that contains the block volume from which you want to remove a Key Management key assignment.
3. From the list of volumes, click the volume name.
4. Next to **Encryption Key**, click **Unassign**.
5. In the **Confirm** dialog box, click **OK** to remove the key assignment from the volume.

To remove a key assignment from a boot volume

1. Open the navigation menu. Under **Core Infrastructure**, go to **Compute** and click **Boot Volumes**.
2. Under **List Scope**, in the **Compartment** list, choose the compartment that contains the boot volume from which you want to remove a Key Management key assignment.
3. From the list of volumes, click the volume name.
4. Next to **Encryption Key**, click **Unassign**.
5. In the **Confirm** dialog box, click **OK** to remove the key assignment from the volume.

To change a key assignment for a file system

1. Open the navigation menu. Under **Core Infrastructure**, click **File Storage** and then click **File Systems**.
2. Under **List Scope**, in the **Compartment** list, choose the compartment that contains the file system from which you want to remove or change a Key Management key assignment.
3. From the list of file systems, click the file system name.
4. Next to **Encryption Key**, click **Edit**.
5. If you want to use Oracle-managed keys:
    - In **Encryption Type,** select **Encrypt using Oracle-managed keys**.
6. If you want to assign a different customer-managed key:
    - In **Encryption Type**, select **Encrypt using customer-manged keys**.
    - Choose the vault compartment, vault, key compartment, and key.
7. When you are finished, click **Save Changes**.

To move a key to a different compartment

1. Open the navigation menu. Under the **Governance and Administration** group, go to

Security and click **Key Management**.

2. Under **Table Scope**, in the **Compartment** list, choose the compartment that contains the master encryption key that you want to move.
3. Find the key in the list, click the the Actions icon (three dots), and then click **Move Resource**.
4. Choose the destination compartment from the list.
5. Click **Move Resource**.
6. If there are alarms monitoring the key, update the alarms to reference the new compartment. See To update an alarm after moving a resource for more information.

Using the Command Line Interface (CLI)

For information about using the CLI, see Command Line Interface (CLI). For a complete list of flags and options available for CLI commands, see CLI Help.

Tip

Each vault has a unique endpoint for create, update, and list operations for keys. This endpoint is referred to as the control plane URL or management endpoint. Each vault also has a unique endpoint for cryptographic operations. This endpoint is known as the data plane URL or the cryptographic endpoint. When using the CLI for key operations, you must provide the appropriate endpoint for the type of operation. To retrieve a vault's endpoints, see instructions in To view vault configuration details.

To create a new key

Open a command prompt and run `oci kms management key create` to create a new key:

```
oci kms management key create --compartment-id <target_compartment_id> --display-name <key_name> --
key-shape <key_encryption_information> --endpoint <control_plane_url>
```

For example, on a MacOS or Linux machine:

```
oci kms management key create --compartment-id
ocid1.compartment.oc1..example1example25qrlpo4agcmothkbgqgmuz2zzum45ibplooqtabwk3zz --display-name key-1
--key-shape '{"algorithm":"AES","length":"16"}' --endpoint https://exampleaaacu2-management.kms.us-
ashburn-1.oraclecloud.com
```

Or, for example, on a Windows machine:

```
oci kms management key create --compartment-id
ocid1.compartment.oc1..example1example25qrlpo4agcmothkbgqgmuz2zzum45ibplooqtabwk3zz --display-name key-1
--key-shape '{\"algorithm\":\"AES\",\"length\":\"16\"}' --endpoint https://exampleaaacu2-
management.kms.us-ashburn-1.oraclecloud.com
```

Warning

Avoid entering confidential information in the key name.

To create a new key with resource tags

Open a command prompt and run `oci kms management key create` with one or both of the `--defined-tags` and `--freeform-tags` options to create a new key with resource tags:

```
oci kms management key create --compartment-id <target_compartment_id> --display-name <key_name> --
key-shape <JSON_formatted_key_encryption_information> --defined-tags <JSON_formatted_defined_tag> --
freeform-tags <JSON_formatted_freeform_tag> --endpoint <control_plane_url>
```

For example, on a MacOS or Linux machine:

```
oci kms management key create --compartment-id
ocid1.compartment.oc1..example1example25qrlpo4agcmothkbgqgmuz2zzum45ibplooqtabwk3zz --display-name key-1
--key-shape '{"algorithm":"AES","length":"16"}' --defined-tags '{"Operations": {"CostCenter":"42"}}' --
```

```
freeform-tags '{"Department":"Finance"}' --endpoint https://exampleaaacu2-management.kms.us-ashburn-1.oraclecloud.com
```

Or, for example, on a Windows machine:

```
oci kms management key create --compartment-id ocid1.compartment.oc1..example1example25qrlpo4agcmothkbgqgmuz2zzum45ibplooqtabwk3zz --display-name key-1 --key-shape '{\"algorithm\":\"AES\",\"length\":\"16\"}' --defined-tags '{\"Operations\":{\"CostCenter\":\"42\"}}' --freeform-tags '{\"Department\":\"Finance\"}' --endpoint https://exampleaaacu2-management.kms.us-ashburn-1.oraclecloud.com
```

Warning

Avoid entering confidential information in the key name.

To view a key's details

Open a command prompt and run `oci kms management key get` to view a specific key's details:

```
oci kms management key get --key-id <key_OCID> --endpoint <control_plane_url>
```

For example:

```
oci kms management key get --key-id ocid1.key.region1.sea.exampleaaacu2.examplesmtpsuqmoy4m5cvblugmizcoeu2nfc6b3zfaux2lmqz245gezevsq --endpoint https://exampleaaacu2-management.kms.us-ashburn-1.oraclecloud.com
```

To view a list of keys

Open a command prompt and run `oci kms management key list` to list keys in a vault:

```
oci kms management key list --compartment-id <target_compartment_id> --endpoint <control_plane_url>
```

For example:

```
oci kms management key list --compartment-id
ocid1.compartment.oc1..example1example25qrlpo4agcmothkbgqgmuz2zzum45ibplooqtabwk3zz --endpoint
https://exampleaaacu2-management.kms.us-ashburn-1.oraclecloud.com
```

To view a list of key versions

Open a command prompt and run `oci kms management key-version list` to view a list of key versions for a specific key:

```
oci kms management key-version list --key-id <key_OCID> --endpoint <control_plane_url>
```

For example:

```
oci kms management key-version list --key-id
ocid1.key.region1.sea.exampleaaacu2.examplesmtpsuqmoy4m5cvblugmizcoeu2nfc6b3zfaux2lmqz245gezevsq --
endpoint https://exampleaaacu2-management.kms.us-ashburn-1.oraclecloud.com
```

To change the name of a key

Open a command prompt and run `oci kms management key update` to edit a key's name.

Warning

Avoid entering confidential information in the key name.

```
oci kms management key update --key-id <key_OCID> --display-name <new_key_name> --endpoint <control_
plane_url>
```

For example:

```
oci kms management key update --key-id
ocid1.key.region1.sea.exampleaaacu2.examplesmtpsuqmoy4m5cvblugmizcoeu2nfc6b3zfaux2lmqz245gezevsq --
display-name key-A --endpoint https://exampleaaacu2-management.kms.us-ashburn-1.oraclecloud.com
```

To enable a key

Open a command prompt and run `oci kms management key enable` to enable a key:

```
oci kms management key enable --key-id <target_key_id> --endpoint <control_plane_url>
```

For example:

```
oci kms management key enable --key-id
ocid1.key.region1.sea.exampleaaacu2.examplesmtpsuqmoy4m5cvblugmizcoeu2nfc6b3zfaux2lmqz245gezevsq --
endpoint https://exampleaaacu2-management.kms.us-ashburn-1.oraclecloud.com
```

To rotate a key

Open a command prompt and run `oci kms management key rotate` to rotate a key:

```
oci kms management key rotate --key-id <target_key_id> --endpoint <control_plane_url>
```

For example:

```
oci kms management key rotate --key-id
ocid1.key.region1.sea.exampleaaacu2.examplesmtpsuqmoy4m5cvblugmizcoeu2nfc6b3zfaux2lmqz245gezevsq --
endpoint https://exampleaaacu2-management.kms.us-ashburn-1.oraclecloud.com
```

To disable a key

Open a command prompt and run `oci kms management key disable` to disable a key:

```
oci kms management key disable --key-id <target_key_id> --endpoint <control_plane_url>
```

For example:

```
oci kms management key disable --key-id
ocid1.key.region1.sea.exampleaaacu2.examplesmtpsuqmoy4m5cvblugmizcoeu2nfc6b3zfaux2lmqz245gezevsq --
endpoint https://exampleaaacu2-management.kms.us-ashburn-1.oraclecloud.com
```

To delete a key

Warning

When you set a key to the Pending Deletion state,

anything encrypted by that key immediately becomes inaccessible. The key also cannot be assigned or unassigned to any resources or otherwise updated. When the key is deleted, all key material and metadata is irreversibly destroyed. Before you delete a key, either assign a new key to resources currently encrypted by the key or preserve your data another way. If you want to restore use of a key before it is permanently deleted, you can cancel its deletion.

Open a command prompt and run `oci kms management key schedule-deletion` to schedule a key's deletion:

```
oci kms management key schedule-deletion --key-id <target_key_id> --endpoint <control_plane_url>
```

For example:

```
oci kms management key schedule-deletion --key-id
ocid1.key.region1.sea.exampleaaacu2.examplesmtpsuqmoy4m5cvblugmizcoeu2nfc6b3zfaux2lmqz245gezevsq --
endpoint https://exampleaaacu2-management.kms.us-ashburn-1.oraclecloud.com
```

By default, the service schedules keys for deletion 30 days from the current date and time. You can set a range between 7 days and 30 days. For example:

```
oci kms management key schedule-deletion --key-id
ocid1.key.region1.sea.exampleaaacu2.examplesmtpsuqmoy4m5cvblugmizcoeu2nfc6b3zfaux2lmqz245gezevsq --time-
of-deletion 2019-06-30T10:00:00Z --endpoint https://exampleaaacu2-management.kms.us-ashburn-
1.oraclecloud.com
```

To cancel the deletion of a key

Tip

You can only cancel the deletion of a key that's in a

Pending Deletion state.

Open a command prompt and run `oci kms management key cancel-deletion` to cancel a key's scheduled deletion:

```
oci kms management key cancel-deletion --key-id <target_key_id> --endpoint <control_plane_url>
```

For example:

```
oci kms management key cancel-deletion --key-id
ocid1.key.region1.sea.exampleaaacu2.examplesmtpsuqmoy4m5cvblugmizcoeu2nfc6b3zfaux2lmqz245gezevsq --
endpoint https://exampleaaacu2-management.kms.us-ashburn-1.oraclecloud.com
```

To move a key to a different compartment

Open a command prompt and run `oci kms management key change-compartment` to move a master encryption key from one compartment to another within the same tenancy:

```
oci kms management key change-compartment --key-id <target_key_id> --compartment-id <new_compartment_
id>
```

For example:

```
oci kms management key change-compartment --key-id
ocid1.key.region1.sea.exampleaaacu2.examplesmtpsuqmoy4m5cvblugmizcoeu2nfc6b3zfaux2lmqz245gezevsq --
compartment-id ocid1.compartment.oc1..example1example25qrlpo4agcmothkbgqgmuz2zzum45ibplooqtabwk3zz
```

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the following operations to manage keys:

- CreateKey
- DisableKey

- EnableKey
- GetKey
- UpdateKey
- CreateKeyVersion
- GetKeyVersion
- ListKeys
- ListKeyVersions
- CancelKeyDeletion
- ScheduleKeyDeletion
- ChangeKeyCompartment

Managing Vaults

This topic describes what you can do with vaults. For information about what you can do with keys, see Managing Keys.

Key Management lets you create virtual private vaults in your tenancy. A virtual private vault provides you with a dedicated partition in a hardware security module (HSM), offering a level of storage isolation for encryption keys that's effectively equivalent to a virtual independent HSM. As such, virtual private vaults have dedicated administration and users. They also restrict other tenants from accessing your encryption keys.

Vault management tasks include the following:

- Creating a vault
- Viewing vault configuration details
- Updating the vault name
- Managing vault tags
- Deleting a vault
- Moving a vault to a new compartment

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: For typical policies that give access to keys and vaults, see Let security admins manage vaults and keys.

Also, be aware that a policy statement with `inspect vaults` gives the specified group the ability to see *all* information about the vaults. Likewise, a policy statement with `inspect keys` gives the specified group the ability to see *all* information about the keys. For more information, see Details for the Key Management Service.

If you're new to policies, see Getting Started with Policies and Common Policies.

Tagging Resources

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the desired tags. For general information about applying tags, see Resource Tags.

Moving Resources to a Different Compartment

You can move vaults from one compartment to another. After you move a vault to a new compartment, inherent policies apply immediately and affect access to the vault. Moving a vault doesn't affect access to any keys that the vault contains. You can move a key from one compartment to another independently of moving the vault it's associated with. For more information, see Managing Compartments.

Using the Console

To view vault configuration details

1. Open the navigation menu. Under the **Governance and Administration** group, go to **Security** and click **Key Management**.
2. Under **List Scope**, in the **Compartment** list, click the name of the compartment that contains the vault you want to view.
3. From the list of vaults in the compartment, click the name of the vault.
4. The console displays the following information:
    - **OCID:** The unique, Oracle-assigned ID of the vault.
    - **Created:** The date and time when you initially created the vault.
    - **Compartment:** The unique, Oracle-assigned ID of the compartment that contains the vault.
    - **Vault Type:** The type of vault. At this time, you can only have a virtual private vault (VIRTUAL_PRIVATE).
    - **Control Plane URL:** The service endpoint for CreateKey, CreateKeyVersion, EnableKey, DisableKey, UpdateKey, ListKeys, ListKeyVersions, GetKey, and GetKeyVersion operations.
    - **Data Plane URL:** The service endpoint for Encrypt, Decrypt, and GenerateDataEncryptionKey operations.

To create a new vault

1. Open the navigation menu. Under the **Governance and Administration** group, go to **Security** and click **Key Management**.
2. Under **List Scope**, in the **Compartment** list, click the name of the compartment where you want to create the vault.
3. Click **Create Vault**.

4. In the **Create Vault** dialog box, click **Name**, and then enter a display name for the vault. Avoid entering any confidential information in this field.
5. Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.
6. When you are finished, click **Create**.

To change a vault name

1. Open the navigation menu. Under the **Governance and Administration** group, go to **Security** and click **Key Management**.
2. Under **List Scope**, in the **Compartment** list, click the name of the compartment that contains the vault you want to rename.
3. From the list of vaults in the compartment, click the name of the vault.
4. On the **Vault Details** page, click **Edit Name**.
5. In the **Edit Vault Name** dialog box, click **Name**, and then enter a new display name for the vault. Avoid entering any confidential information in this field.
6. When you are finished, click **Save**.

To manage a vault's tags

1. Open the navigation menu. Under the **Governance and Administration** group, go to **Security** and click **Key Management**.
2. Under **List Scope**, in the **Compartment** list, click the name of the compartment that contains the vault for which you want to manage tags.
3. From the list of vaults in the compartment, click the name of the vault.

4. On the **Vault Details** page, click the **Tags** tab to view or editing existing tags. Or, click **Add Tag(s)** to add new ones.

To delete a vault

Note

When you delete a vault, the vault and all its associated keys go into a pending deletion state until the waiting period expires. By default, this is 30 days, but can be set from a minimum of 7 days up to a maximum of 30 days. When a vault is deleted, all its associated keys are also deleted.

1. Open the navigation menu. Under the **Governance and Administration** group, go to **Security** and click **Key Management**.
2. Under **List Scope**, in the **Compartment** list, click the name of the compartment that contains the vault you want to delete.
3. From the list of vaults in the compartment, click the name of the vault.
4. On the **Vault Details** page, click **Delete**.
5. To confirm that you want to delete the vault, type the name of the vault, and then choose the date and time you want the vault to be deleted.
6. When you are finished, click **Delete Vault**.

To cancel the deletion of a vault

1. Open the navigation menu. Under the **Governance and Administration** group, go to **Security** and click **Key Management**.

2. Under **List Scope**, in the **Compartment** list, click the name of the compartment that contains the vault that's in a pending deletion state.
3. From the list of vaults in the compartment, click the name of the vault.
4. On the **Vault Details** page, click **Cancel Deletion**.
5. To confirm that you want to cancel deletion of the vault, click **Cancel Deletion**.

To move a vault to a different compartment

1. Open the navigation menu. Under the **Governance and Administration** group, go to **Security** and click **Key Management**.
2. Under **Table Scope**, in the **Compartment** list, choose the compartment that contains the vault that you want to move.
3. Find the vault in the list, click the the Actions icon (three dots), and then click **Move Resource**.
4. Choose the destination compartment from the list.
5. Click **Move Resource**.

Using the Command Line Interface (CLI)

For information about using the CLI, see Command Line Interface (CLI). For a complete list of flags and options available for CLI commands, see CLI Help.

To view vault configuration details

Open a command prompt and run `oci kms management vault get` to view the configuration details for a vault:

```
oci kms management vault get --vault-id <target_vault_id>
```

For example:

```
oci kms management vault get --vault-id
ocid1.vault.region1.sea.exampleaaacu2.examplesrcvbtqe5wgrxn2jua3olmeausn5fauxseubwu5my5tf3w3j33edq
```

To create a new vault

Open a command prompt and run `oci kms management vault create` to create a new vault:

```
oci kms management vault create --compartment-id <target_compartment_id> --display-name <vault_name> --vault-type VIRTUAL_PRIVATE
```

For example:

```
oci kms management vault create --compartment-id
ocid1.compartment.oc1..example1example25qrlpo4agcmothkbgqgmuz2zzum45ibplooqtabwk3zz --display-name
vault-1 --vault-type VIRTUAL_PRIVATE
```

Warning

Avoid entering confidential information in the vault name.

To create a new vault with resource tags

Open a command prompt and run `oci kms management vault create` with one or both of the `--defined-tags` and `--freeform-tags` options to create a new vault with resource tags:

```
oci kms management vault create --compartment-id <target_compartment_id> --display-name <vault_name> --vault-type VIRTUAL_PRIVATE --defined-tags <JSON_formatted_defined_tag> --freeform-tags <JSON_formatted_freeform_tag>
```

For example, on a MacOS or Linux machine:

```
oci kms management vault create --compartment-id
ocid1.compartment.oc1..example1example25qrlpo4agcmothkbgqgmuz2zzum45ibplooqtabwk3zz --display-name
```

```
vault-1 --vault-type VIRTUAL_PRIVATE --defined-tags '{"Operations": {"CostCenter": "42"}}' --freeform-
tags '{"Department":"Finance"}'
```

Or, for example, on a Windows machine:

```
oci kms management vault create --compartment-id
ocid1.compartment.oc1..example1example25qrlpo4agcmothkbgqgmuz2zzum45ibplooqtabwk3zz --display-name
vault-1 --vault-type VIRTUAL_PRIVATE --defined-tags '{\"Operations\": {\"CostCenter\":\"42\"}}' --
freeform-tags '{\"Department\":\"Finance\"}'
```

Warning

Avoid entering confidential information in the vault name.

To change a vault name

Open a command prompt and run `oci kms management vault update` to change a vault's name:

```
oci kms management vault update --vault-id <target_vault_id>
```

For example:

```
oci kms management vault update --vault-id
ocid1.vault.region1.sea.exampleaaacu2.examplesrcvbtqe5wgrxn2jua3olmeausn5fauxseubwu5my5tf3w3j33edq --
display-name new-vault-name
```

To delete a vault

Open a command prompt and run `oci kms management vault schedule-deletion` to delete a vault:

```
oci kms management vault schedule-deletion --vault-id <target_vault_id>
```

For example:

```
oci kms management vault schedule-deletion --vault-id
ocid1.vault.region1.sea.exampleaaacu2.examplesrcvbtqe5wgrxn2jua3olmeausn5fauxseubwu5my5tf3w3
```

When you delete a vault, the vault and all its associated keys go into a pending deletion state until the waiting period expires. By default, this is 30 days, but can be set from a minimum of 7 days up to a maximum of 30 days. When a vault is deleted, all its associated keys are also deleted.

To cancel the deletion of a vault

Open a command prompt and run `oci kms management vault cancel-deletion` to cancel the pending deletion of a vault:

```
oci kms management vault cancel-deletion --vault-id <target_vault_id>
```

For example:

```
oci kms management vault cancel-deletion --vault-id
ocid1.vault.region1.sea.exampleaaacu2.examplesrcvbtqe5wgrxn2jua3olmeausn5fauxseubwu5my5tf3w3
```

To move a vault to a different compartment

Open a command prompt and run `oci kms management vault change-compartment` to move a vault from one compartment to another within the same tenancy:

```
oci kms management vault change-compartment --vault-id <target_vault_id> --compartment-id <new_
compartment_id>
```

For example:

```
oci kms management vault change-compartment --vault-id
ocid1.vault.region1.sea.exampleaaacu2.examplesrcvbtqe5wgrxn2jua3olmeausn5fauxseubwu5my5tf3w3 --
compartment-id ocid1.compartment.oc1..example1example25qrlpo4agcmothkbgqgmuz2zzum45ibplooqtabwk3zz
```

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the following operations to manage vaults:

- CancelVaultDeletion
- CreateVault
- GetVault
- ListVaults
- ScheduleVaultDeletion
- UpdateVault
- ChangeVaultCompartment

Using Keys

This topic describes what you can do with keys in terms of cryptographic operations. For information about managing keys, see Managing Keys. For information about managing the vaults in which you store keys, see Managing Vaults.

Cryptographic operations include the following:

- Encrypting data
- Decrypting data
- Generating data encryption keys

You can use either the command line interface (CLI) or API to perform cryptographic operations.

Required IAM Policy

Warning

Keys associated with volumes and buckets will not work unless you authorize Oracle Cloud Infrastructure Block Volume and Oracle Cloud Infrastructure Object Storage to use keys on your behalf. Additionally, you must also authorize users to delegate key usage to these services in the first place. For more information, see Let a user group delegate key usage in a compartment and Let Block Volume and Object Storage services encrypt and decrypt volumes and buckets in Common Policies.

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don't have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: For typical policies that give access to keys and vaults, see Let security admins manage vaults and keys.

Also, be aware that a policy statement with `inspect vaults` gives the specified group the ability to see *all* information about the vaults. Likewise, a policy statement with `inspect keys` gives the specified group the ability to see *all* information about the keys. For more information, see Details for the Key Management Service.

If you're new to policies, see Getting Started with Policies and Common Policies.

Monitoring Resources

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications. For more information, see Monitoring

Overview and Notifications Overview.

For information about monitoring the traffic associated with your master encryption keys, see Key Management Metrics.

Using the Command Line Interface (CLI)

For information about using the CLI, see Command Line Interface (CLI). For a complete list of flags and options available for CLI commands, see CLI Help.

Tip

Each vault has a unique endpoint for create, update, and list operations for keys. This endpoint is referred to as the control plane URL or management endpoint. Each vault also has a unique endpoint for cryptographic operations. This endpoint is known as the data plane URL or the cryptographic endpoint. When using the CLI for key operations, you must provide the appropriate endpoint for the type of operation. To retrieve a vault's endpoints, see instructions in To view vault configuration details.

To encrypt data by using your Key Management master encryption key

Open a command prompt and run `oci kms crypto encrypt` to encrypt data:

```
oci kms crypto encrypt --key-id <key_OCID> --plaintext <base64_string> --endpoint <data_plane_url>
```

For example:

```
oci kms crypto encrypt --key-id
ocid1.key.region1.sea.exampleaaacu2.examplesmtpsuqmoy4m5cvblugmizcoeu2nfc6b3zfaux2lmqz245gezevsq --
plaintext VGhlIHF1aWNrIGJyb3duIGZveCBqdW1wcyBvdmVyIHRoZSBsYXp5IGRvZy4= --endpoint https://exampleaaacu3-
crypto.kms.us-ashburn-1.oraclecloud.com
```

Optionally, you can include the `associated-data` option to provide an encryption context that might contain useful, but non-secret, information about the encrypted data. That information is associated with the encrypted data such that the data cannot be decrypted without it, providing an additional layer of protection. Associated data must be properly formatted JSON.

```
oci kms crypto encrypt --key-id
ocid1.key.region1.sea.exampleaaacu2.examplesmtpsuqmoy4m5cvblugmizcoeu2nfc6b3zfaux2lmqz245gezevsq --
plaintext VGhlIHF1aWNrIGJyb3duIGZveCBqdW1wcyBvdmVyIHRoZSBsYXp5IGRvZy4= --associated-data '
{"CustomerId":"12345", "Custom Data":"custom data"}' --endpoint https://exampleaaacu3-crypto.kms.us-
ashburn-1.oraclecloud.com
```

To decrypt data by using your Key Management master encryption key

Open a command prompt and run `oci kms crypto decrypt` to decrypt data:

```
oci kms crypto decrypt --key-id <key_OCID> --plaintext <base64_string> --endpoint <data_plane_url>
```

For example:

```
oci kms crypto decrypt --key-id
ocid1.key.region1.sea.exampleaaacu2.examplesmtpsuqmoy4m5cvblugmizcoeu2nfc6b3zfaux2lmqz245gezevsq --
plaintext VGhlIHF1aWNrIGJyb3duIGZveCBqdW1wcyBvdmVyIHRoZSBsYXp5IGRvZy4= --endpoint https://exampleaaacu3-
crypto.kms.us-ashburn-1.oraclecloud.com
```

If the data you want to decrypt had an encryption context associated with it at the time of encryption, the same encryption context is required to decrypt the data. For example, the `--associated-data` in the following sample matches what was provided in the preceding sample command for encrypting data.

```
oci kms crypto decrypt --key-id
ocid1.key.region1.sea.exampleaaacu2.examplesmtpsuqmoy4m5cvblugmizcoeu2nfc6b3zfaux2lmqz245gezevsq --
plaintext VGhlIHF1aWNrIGJyb3duIGZveCBqdW1wcyBvdmVyIHRoZSBsYXp5IGRvZy4= --associated-data '
{"CustomerId":"12345", "Custom Data":"custom data"}' --endpoint https://exampleaaacu3-crypto.kms.us-
ashburn-1.oraclecloud.com
```

To generate a data encryption key from your Key Management master encryption key

Open a command prompt and run `oci kms crypto generate-data-encryption-key` to

generate a data encryption key that you can then use to encrypt and decrypt data:

```
oci kms crypto generate-data-encryption-key --key-id <key_OCID> --key-shape <key_encryption_
information> --include-plaintext-key <Boolean_value> --endpoint <data_plane_url>
```

For example:

```
oci kms crypto generate-data-encryption-key --key-id
ocid1.key.region1.sea.exampleaaacu2.examplesmtpsuqmoy4m5cvblugmizcoeu2nfc6b3zfaux2lmqz245gezevsq --key-
shape file://path/to/json/file --include-plaintext-key true --endpoint https://exampleaaacu3-
crypto.kms.us-ashburn-1.oraclecloud.com
```

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the following operations to use keys in cryptographic operations:

- Decrypt
- Encrypt
- GenerateDataEncryptionKey

Key Management Metrics

You can monitor the usage of your Key Management service master encryption keys by using metrics, alarms, and notifications. For more information, see Monitoring Overview and Notifications Overview.

This topic describes the metrics emitted by the Key Management service in the `oci_kms_keys` namespace.

Resources: master encryption keys.

Overview of the Key Management Service Metrics

The Key Management service metrics help you measure the success and error count of cryptographic operations. You can use metrics data to diagnose and troubleshoot problems with keys.

To view a default set of metrics charts in the Console, navigate to the key that you're interested in, and then click **Metrics**. You also can use the Monitoring service to create custom queries.

Prerequisites

IAM policies: To monitor resources, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.

Available Metrics: oci_kms_keys

The metrics listed in the following table are automatically available for any master encryption keys that you create. You do not need to enable monitoring on the resource to get these metrics.

Key Management service metrics for keys include the following dimensions:

RESOURCEDISPLAYNAME

The friendly name of the resource to which the metrics apply.

RESOURCEID

The OCID of the resource to which the metrics apply.

RESPONSECODE

The HTTP response code to the cryptographic operation to which the metrics apply.

Metric	Metric Display Name	Unit	Description	Dimensions
`EncryptResponseCount`	**Encrypt Response Count**	count	HTTP responses received by the service for Encrypt calls.	`resourceDisplayName` `resourceId` `responseCode`
`DecryptResponseCount`	**Decrypt Response Count**	count	HTTP responses received by the service for Decrypt calls.	
`GenerateDataEncryptionKeyResponseCount`*	**GenerateDataEncryptionKey Response Count**	count	HTTP responses received by the service for GenerateDataEncryptionKey calls.	

Using the Console

To view default metric charts for a single master encryption key

1. Open the navigation menu. Under the **Governance and Administration** group, go to **Security** and click **Key Management**.
2. Click a key vault to view the master encryption keys it contains.
3. Click a key name to view its details.
4. Under **Resources**, click **Metrics**.

For more information about monitoring metrics and using alarms, see Monitoring Overview. For information about notifications for alarms, see Notifications Overview.

To view default metric charts for multiple master encryption keys

1. Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Service Metrics**.
2. For **Compartment**, select the compartment that contains the master encryption keys that you're interested in.
3. For **Metric Namespace**, select **oci_kms_keys**.
   The **Service Metrics** page dynamically updates the page to show charts for each metric that is emitted by the selected metric namespace.

Tip

If there are multiple master encryption keys in the compartment, the charts default to show a separate line for each master encryption key. You can instead show a single line aggregated across all master encryption keys in the compartment by selecting the **Aggregate Metric Streams** check box.

For more information about monitoring metrics and using alarms, see Monitoring Overview. For information about notifications for alarms, see Notifications Overview.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the following APIs for monitoring:

- Monitoring API for metrics and alarms
- Notifications API for notifications (used with alarms)

CHAPTER 20 Load Balancing

This chapter explains how to set up a load balancer.

Overview of Load Balancing

The Oracle Cloud Infrastructure Load Balancing service provides automated traffic distribution from one entry point to multiple servers reachable from your virtual cloud network (VCN). The service offers a load balancer with your choice of a public or private IP address, and provisioned bandwidth.

A load balancer improves resource utilization, facilitates scaling, and helps ensure high availability. You can configure multiple load balancing policies and application-specific health checks to ensure that the load balancer directs traffic only to healthy instances. The load balancer can reduce your maintenance window by draining traffic from an unhealthy application server before you remove it from service for maintenance.

How Load Balancing Works

The Load Balancing service enables you to create a public or private load balancer within your VCN. A public load balancer has a public IP address that is accessible from the internet. A private load balancer has an IP address from the hosting subnet, which is visible only within your VCN. You can configure multiple listeners for an IP address to load balance transport Layer 4 and Layer 7 (TCP and HTTP) traffic. Both public and private load balancers can route data traffic to any backend server that is reachable from the VCN.

Public Load Balancer

To accept traffic from the internet, you create a public load balancer. The service assigns it a public IP address that serves as the entry point for incoming traffic. You can associate the public IP address with a friendly DNS name through any DNS vendor.

A public load balancer is regional in scope. If your region includes multiple availability domains, a public load balancer requires either a regional subnet (recommended) or two availability domain-specific (AD-specific) subnets, each in a separate availability domain. With a regional subnet, the Load Balancing service creates a primary load balancer and a standby load balancer, each in a different availability domain, to ensure accessibility even during an availability domain outage. If you create a load balancer in two AD-specific subnets, one subnet hosts the primary load balancer and the other hosts a standby load balancer. If the primary load balancer fails, the public IP address switches to the secondary load balancer. The service treats the two load balancers as equivalent and you cannot specify which one is "primary".

Whether you use regional or AD-specific subnets, each load balancer requires one private IP address from its host subnet. The Load Balancing service supplies a floating public IP address to the primary load balancer. The floating public IP address does not come from your backend subnets.

If your region includes only one availability domain, the service requires just one subnet, either regional or AD-specific, to host both the primary and standby load balancers. The primary and standby load balancers each require a private IP address from the host subnet, in addition to the assigned floating public IP address. If there is an availability domain outage, the load balancer has no failover.

Warning

You cannot specify a private subnet for your public load balancer.

Private Load Balancer

To isolate your load balancer from the internet and simplify your security posture, you can create a private load balancer. The Load Balancing service assigns it a private IP address that serves as the entry point for incoming traffic.

When you create a private load balancer, the service requires only one subnet to host both the

primary and standby load balancers. The load balancer can be regional or AD-specific, depending on the scope of the host subnet. The load balancer is accessible only from within the VCN that contains the host subnet, or as further restricted by your security rules.

The assigned floating private IP address is local to the host subnet. The primary and standby load balancers each require an extra private IP address from the host subnet.

If there is an availability domain outage, a private load balancer created in a regional subnet within a multi-AD region provides failover capability. A private load balancer created in an AD-specific subnet, or in a regional subnet within a single availability domain region, has no failover capability in response to an availability domain outage.

All Load Balancers

Your load balancer has a backend set to route incoming traffic to your Compute instances. The backend set is a logical entity that includes:

- A list of backend servers.
- A load balancing policy.
- A health check policy.
- Optional SSL handling.
- Optional session persistence configuration.

The backend servers (Compute instances) associated with a backend set can exist anywhere, as long as the associated network security groups (NSGs), security lists, and route tables allow the intended traffic flow.

If your VCN uses network security groups (NSGs), you can associate your load balancer with an NSG. An NSG has a set of security rules that controls allowed types of inbound and outbound traffic. The rules apply only to the resources in the group. Contrast NSGs with a security list, where the rules apply to all the resources in any subnet that uses the list. For more information about NSGs, see Network Security Groups.

If you prefer to use security lists for your VCN, the Load Balancing service can suggest appropriate security list rules. You also can configure them yourself through the Networking service. See Security Lists for more information.

See Security Rules for detailed information comparing NSGs and security lists.

Oracle recommends that you create your load balancer in a regional subnet.

Oracle recommends that you distribute your backend servers across all availability domains within the region.

To create a minimal system with a functioning load balancer, you must:

- For a public load balancer, create a VCN with an internet gateway and a public regional subnet.

Warning

You cannot specify a private subnet for your public load balancer.

- For a private load balancer, create a VCN with at least one private subnet.
- Create at least two Compute instances, each in a separate availability domain.
- Create a load balancer.
- Create a backend set with a health check policy.
- Add backend servers (Compute instances) to the backend set.
- Create a listener, with optional SSL handling.
- Update the load balancer subnet security rules so they allow the intended traffic.

Note

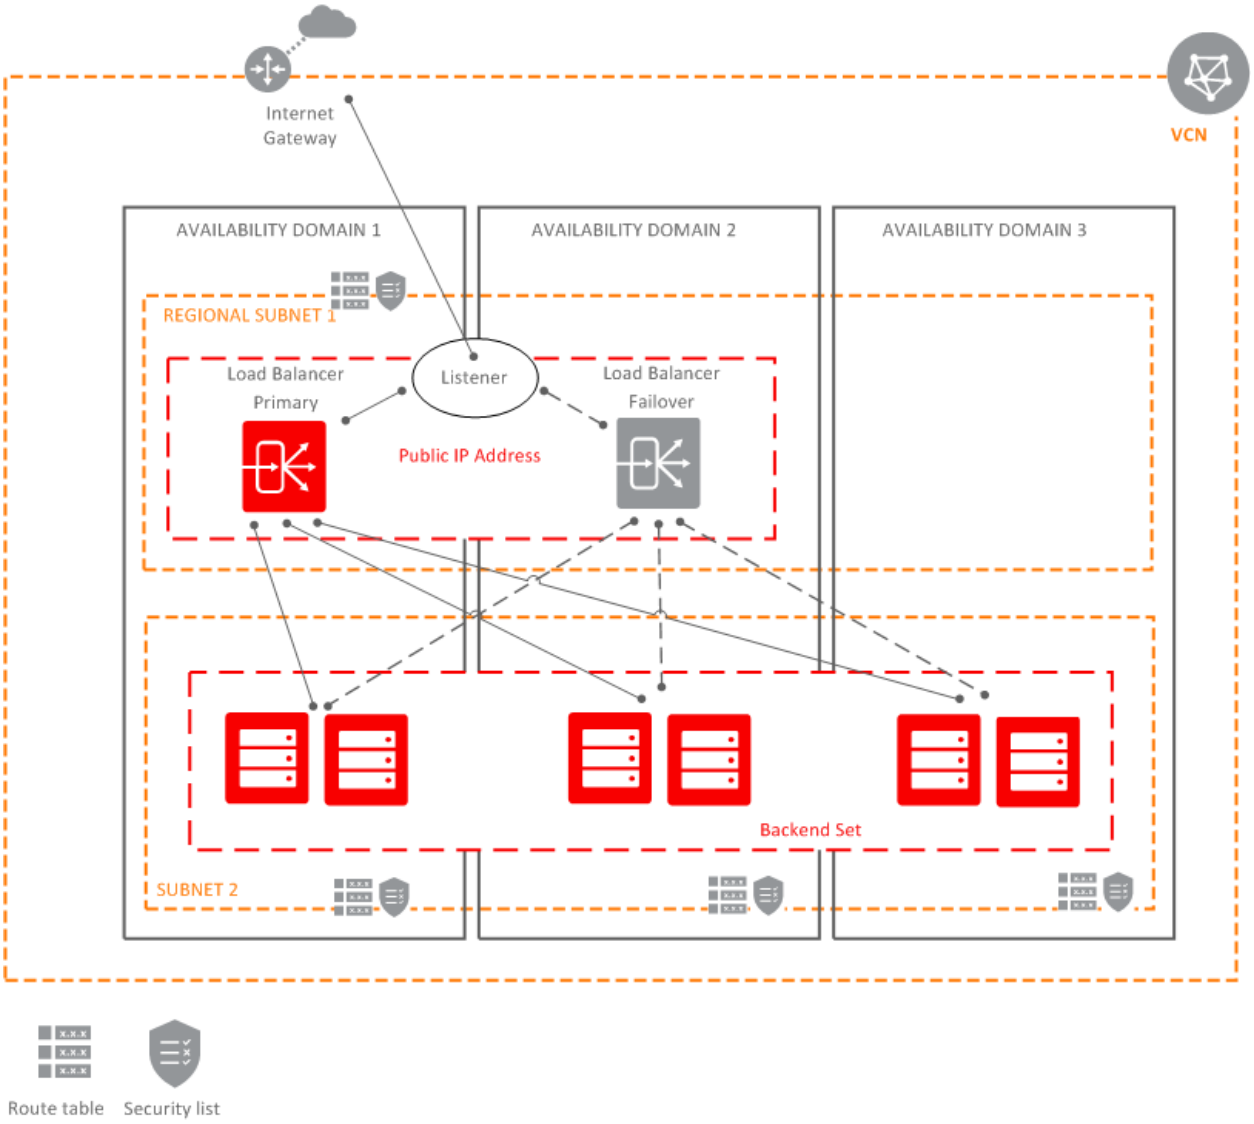
Private IP Address Consumption

A public load balancer created in one public subnet consumes two private IP addresses from the host subnet.

A public load balancer created in two public subnets consumes two private IP addresses, one from each host subnet.

A private load balancer created in a single subnet consumes three private IP addresses from the host subnet.

The following diagram provides a high-level view of a simple public load balancing system configuration. Far more sophisticated and complex configurations are common.



Load Balancing Concepts

The following concepts are essential to working with Load Balancing.

BACKEND SERVER

An application server responsible for generating content in reply to the incoming TCP or HTTP traffic. You typically identify application servers with a unique combination of overlay (private) IPv4 address and port, for example, 10.10.10.1:8080 and 10.10.10.2:8080.

For more information, see Managing Backend Servers.

BACKEND SET

A logical entity defined by a list of backend servers, a load balancing policy, and a health check policy. SSL configuration is optional. The backend set determines how the load balancer directs traffic to the collection of backend servers.

For more information, see Managing Backend Sets.

CERTIFICATES

If you use HTTPS or SSL for your listener, you must associate an SSL server certificate (X.509) with your load balancer. A certificate enables the load balancer to terminate the connection and decrypt incoming requests before passing them to the backend servers.

For more information, see Managing SSL Certificates.

HEALTH CHECK

A test to confirm the availability of backend servers. A health check can be a request or a connection attempt. Based on a time interval you specify, the load balancer applies the health check policy to continuously monitor backend servers. If a server fails the health check, the load balancer takes the server temporarily out of rotation. If the server subsequently passes the health check, the load balancer returns it to the rotation.

You configure your health check policy when you create a backend set. You can configure TCP-level or HTTP-level health checks for your backend servers.

- TCP-level health checks attempt to make a TCP connection with the backend servers and validate the response based on the connection status.
- HTTP-level health checks send requests to the backend servers at a specific URI and validate the response based on the status code or entity data (body) returned.

The service provides application-specific health check capabilities to help you increase availability and reduce your application maintenance window.

For more information on health check configuration, see Editing Health Check Policies.

HEALTH STATUS

An indicator that reports the general health of your load balancers and their components.

For more information, see the **Health Status** section of Editing Health Check Policies.

LISTENER

A logical entity that checks for incoming traffic on the load balancer's IP address. You configure a listener's protocol and port number, and the optional SSL settings. To handle TCP, HTTP, and HTTPS traffic, you must configure multiple listeners.

Supported protocols include:

- TCP
- HTTP/1.0

- HTTP/1.1

For more information, see Managing Load Balancer Listeners.

LOAD BALANCING POLICY

A load balancing policy tells the load balancer how to distribute incoming traffic to the backend servers. Common load balancer policies include:

- Round robin
- Least connections
- IP hash

For more information, see How Load Balancing Policies Work.

PATH ROUTE SET

A set of path route rules to route traffic to the correct backend set without using multiple listeners or load balancers.

For more information, see Managing Request Routing.

REGIONS AND AVAILABILITY DOMAINS

The Load Balancing service manages application traffic across availability domains within a region. A region is a localized geographic area, and an availability domain is one or more data centers located within a region. A region is composed of several availability domains.

For more information, see Regions and Availability Domains.

SESSION PERSISTENCE

A method to direct all requests originating from a single logical client to a single backend web server.

For more information, see Session Persistence.

SHAPE

A template that determines the load balancer's total pre-provisioned maximum capacity (bandwidth) for ingress plus egress traffic. Available shapes include 10Mbps, 100 Mbps, 400 Mbps, and 8000 Mbps.

The 10Mbps shape is Always Free eligible. For more information about Always Free resources, including additional capabilities and limitations, see Oracle Cloud Infrastructure's Free Tier.

Tip

Pre-provisioned maximum capacity applies to aggregated connections, not to a single client attempting to use the full bandwidth.

SSL

Secure Sockets Layer (SSL) is a security technology for establishing an encrypted link between a client and a server. You can apply the following SSL configurations to your load balancer:

SSL TERMINATION

The load balancer handles incoming SSL traffic and passes the unencrypted request to a backend server.

END TO END SSL

The load balancer terminates the SSL connection with an incoming traffic client, and then initiates an SSL connection to a backend server.

SSL TUNNELING

If you configure the load balancer's listener for TCP traffic, the load balancer tunnels incoming SSL connections to your application servers.

Load Balancing supports the TLS 1.2 protocol with a default setting of **strong** cipher strength. The default supported ciphers include:

- ECDHE-RSA-AES256-GCM-SHA384
- ECDHE-RSA-AES256-SHA384
- ECDHE-RSA-AES128-GCM-SHA256
- ECDHE-RSA-AES128-SHA256
- DHE-RSA-AES256-GCM-SHA384
- DHE-RSA-AES256-SHA256
- DHE-RSA-AES128-GCM-SHA256
- DHE-RSA-AES128-SHA256

For more information, see Managing SSL Certificates.

SUBNET

A subdivision you define in a VCN, such as 10.0.0.0/24 and 10.0.1.0/24. A subnet can span a region or exist within in a single availability domain. A subnet consists of a contiguous range of IP addresses that do not overlap with other subnets in the VCN. For each subnet, you specify the routing and security rules that apply to it.

For more information on subnets, see VCNs and Subnets and Public vs. Private Subnets.

TAGS

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the desired tags. For general information about applying tags, see Resource Tags.

VIRTUAL HOSTNAME

A virtual server name applied to a listener to enhance request routing.

For more information, see Managing Request Routing.

VIRTUAL CLOUD NETWORK (VCN)

A private network that you set up in the Oracle data centers, with firewall rules and specific types of communication gateways that you can choose to use. A VCN covers a single, contiguous IPv4 CIDR block of your choice in the allowed IP address ranges.

You need at least one virtual cloud network before you launch a load balancer.

For information about setting up virtual cloud networks, see Overview of Networking.

VISIBILITY

Specifies whether your load balancer is public or private.

PUBLIC

A public load balancer has a public IP address that clients can access from the internet.

PRIVATE

A private load balancer has a private IP address from a VCN local subnet. Clients can access the private load balancer using methods and technology that can provide access to a private IP, such as:

- Cross-VCN (via LPG peering)
- From another region (via RPC)
- From on-prem (via FC private peering)

For more information, see Managing a Load Balancer.

WORK REQUEST

An object that reports on the current state of a Load Balancing request.

The Load Balancing service handles requests asynchronously. Each request returns a work request ID (OCID) as the response. You can view the work request item to see the status of the request.

For more information, see Viewing the State of a Work Request.

Resource Identifiers

Most types of Oracle Cloud Infrastructure resources have a unique, Oracle-assigned identifier called an Oracle Cloud ID (OCID). For information about the OCID format and other ways to identify your resources, see Resource Identifiers.

Ways to Access Oracle Cloud Infrastructure

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. For a list of available SDKs, see Software Development Kits and Command Line Interface.

To access the Console, you must use a supported browser. Oracle Cloud Infrastructure supports the latest desktop versions of Google Chrome, Microsoft Edge, Internet Explorer 11, Safari, Firefox, and Firefox ESR. Note that private browsing mode is not supported for Firefox, Internet Explorer, or Edge. Mobile browsers are not supported.

For general information about using the API, see REST APIs.

Monitoring Resources

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications. For more information, see Monitoring Overview and Notifications Overview.

For information about monitoring the traffic passing through your load balancer, see Load Balancing Metrics.

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For

example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies. For specific details about writing policies for each of the different services, see Policy Reference.

If you're a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

Limits on Load Balancing Resources

See Service Limits for a list of applicable limits and instructions for requesting a limit increase.

Other limits include:

- You cannot dynamically change the load balancer shape to handle more incoming traffic. You can use the API or Console to create a load balancer with the new shape information.
- You cannot convert an AD-specific load balancer to a regional load balancer or the reverse.
- The Load Balancing services supports IPv6 addresses for load balancers in the US Government Cloud only. IPv6 support is only for the load balancer itself, and not the backend.
- The maximum number of concurrent connections is limited when you use stateful security rules for your load balancer subnets. In contrast, there is no theoretical limit on concurrent connections if you use stateless security rules. The practical limitations depend on various factors. The larger your load balancer shape, the greater the connection capacity. Other considerations include system memory, TCP timeout periods, TCP connection state, and so forth.

Tip

To accommodate high-volume traffic, Oracle strongly recommends that you use stateless security rules for your load balancer subnets.

- Each load balancer has the following configuration limits:
  - One IP address
  - 16 backend sets
  - 512 backend servers per backend set
  - 1024 backend servers total
  - 16 listeners

How Load Balancing Policies Work

After you create a load balancer, you can apply policies to control traffic distribution to your backend servers. The Load Balancing service supports three primary policy types:

- Round Robin
- Least Connections
- IP Hash

When processing load or capacity varies among backend servers, you can refine each of these policy types with backend server *weighting*. Weighting affects the proportion of requests directed to each server. For example, a server weighted '3' receives three times the number of connections as a server weighted '1'. You assign weights based on criteria of your choosing, such as each server's traffic-handling capacity.

Load balancer policy decisions apply differently to TCP load balancers, cookie-based session persistent HTTP requests (sticky requests), and non-sticky HTTP requests.

- A TCP load balancer considers policy and weight criteria to direct an initial incoming request to a backend server. All subsequent packets on this connection go to the same endpoint.
- An HTTP load balancer configured to handle cookie-based session persistence forwards requests to the backend server specified by the cookie's session information.
- For non-sticky HTTP requests, the load balancer applies policy and weight criteria to every incoming request and determines an appropriate backend server. Multiple requests from the same client could be directed to different servers.

Round Robin

Round Robin is the default load balancer policy. This policy distributes incoming traffic sequentially to each server in a backend set list. After each server has received a connection, the load balancer repeats the list in the same order.

Round Robin is a simple load balancing algorithm. It works best when all the backend servers have similar capacity and the processing load required by each request does not vary significantly.

Least Connections

The Least Connections policy routes incoming non-sticky request traffic to the backend server with the fewest active connections. This policy helps you maintain an equal distribution of active connections with backend servers. As with the round robin policy, you can assign a weight to each backend server and further control traffic distribution.

Tip

In TCP use cases, a connection can be active but have no current traffic. Such connections do not serve as a good load metric.

IP Hash

The IP Hash policy uses an incoming request's source IP address as a hashing key to route non-sticky traffic to the same backend server. The load balancer routes requests from the same client to the same backend server as long as that server is available. This policy honors server weight settings when establishing the initial connection.

IP Hash ensures that requests from a particular client are always directed to the same backend server, as long as it is available.

You cannot add a backend server marked as **Backup** to a backend set that uses the IP Hash policy.

Warning

Multiple clients that connect to the load balancer through a proxy or NAT router appear to have the same IP address. If you apply the IP Hash policy to your backend set, the load balancer routes traffic based on the incoming IP address and sends these proxied client requests to the same backend server. If the proxied client pool is large, the requests could flood a backend server.

Connection Management

Oracle Cloud Infrastructure load balancers support connection multiplexing. The load balancer can route many incoming requests from multiple clients to the destination backend server through a few (one or multiple) backend connections.

After your load balancer connects a client to a backend server, the connection can be closed due to inactivity. Also, you can configure load balancer listeners to control the maximum idle time allowed during each TCP connection or HTTP request and response pair. Oracle recommends that you do not allow your backend servers to close connections to the load balancer.

Highlights

Three different timeout settings affect your load balancer's behavior:

- Keep-alive **setting between the load balancer and backend server**
  The load balancer closes backend server connections that are idle for more than 300 seconds.
- **Keep-alive setting between the load balancer and the client**
  The Load Balancing service sets the keep-alive value to maintain the connection for 10,000 transactions or until it has been idle for 65 seconds, whichever limit occurs first. You cannot change the value of this setting.
- Idle timeout
  You can set the duration of the idle timeout when you create a listener. This setting applies to the time allowed between two successive receive or two successive send network input/output operations during the HTTP request-response phase.

Keep-Alive Settings

The load balancing service does not honor keep-alive settings from backend servers. The load balancer closes backend server connections that are idle for more than 300 seconds. Oracle recommends that you do not allow your backend servers to close connections to the load

balancer. To prevent possible 502 errors, ensure that your backend servers do not close idle connections in less than 310 seconds.

The Load Balancing service sets the keep-alive value to maintain the connection for 10,000 transactions or until it has been idle for 65 seconds, whichever limit occurs first. You cannot change the value of this setting.

Connection Configuration

When you create a TCP or HTTP listener, you can specify the maximum idle time in seconds. This setting applies to the time allowed between two successive receive or two successive send network input/output operations during the HTTP request-response phase. If the configured timeout has elapsed with no packets sent or received, the client's connection is closed. For HTTP and WebSocket connections, a send operation does not reset the timer for receive operations and a receive operation does not reset the timer for send operations.

Tip

This timeout setting does not apply to idle time between a completed response and a subsequent HTTP request.

The default timeout values are:

- 300 seconds for TCP listeners.
- 60 seconds for HTTP listeners.

Modify the timeout parameter if either the client or the backend server requires more time to transmit data. Some examples include:

- The client sends a database query to the backend server and the database takes over 300 seconds to execute. Therefore, the backend server does not transmit any data within 300 seconds.

- The client uploads data using the HTTP protocol. During the upload, the backend does not transmit any data to the client for more than 60 seconds.
- The client downloads data using the HTTP protocol. After the initial request, it stops transmitting data to the backend server for more than 60 seconds.
- The client starts transmitting data after establishing a WebSocket connection, but the backend server does not transmit data for more than 60 seconds.
- The backend server starts transmitting data after establishing a WebSocket connection, but the client does not transmit data for more than 60 seconds.

The maximum timeout value is 7200 seconds. Contact My Oracle Support to file a service request if you want to increase this limit for your tenancy. For more information, see Service Limits.

HTTP "X-" Headers

HTTP requests and responses often include header fields that provide contextual information about the message. RFC 2616 defines a standard set of HTTP header fields. Some non-standard header fields, which begin with `X-`, are common. The Load Balancing service adds or modifies the following `X-` headers when it passes requests to your servers.

X-Forwarded-For

Provides a list of connection IP addresses.

The load balancer appends the last remote peer address to the `X-Forwarded-For` field from the incoming request. A comma and space precede the appended address. If the client request header does not include an `X-Forwarded-For` field, this value is equal to the `X-Real-IP` value. The original requesting client is the first (left-most) IP address in the list, assuming that the incoming field content is trustworthy. The last address is the last (most recent) peer, that is, the machine from which the load balancer received the request. The format is:

```
X-Forwarded-For: <original_client>, <proxy1>, <proxy2>
```

Example incoming field:

```
X-Forwarded-For: 202.1.112.187
```

Example field with appended proxy IP address:

```
X-Forwarded-For: 202.1.112.187, 192.168.0.10
```

X-Forwarded-Host

Identifies the original host and port requested by the client in the `Host` HTTP request header. This header helps you determine the original host, since the hostname or port of the reverse proxy (load balancer) might differ from the original server handling the request.

```
X-Forwarded-Host: www.oracle.com:8080
```

X-Forwarded-Port

Identifies the listener port number that the client used to connect to the load balancer. For example:

```
X-Forwarded-Port: 443
```

X-Forwarded-Proto

Identifies the protocol that the client used to connect to the load balancer, either `http` or `https`. For example:

```
X-Forwarded-Proto: https
```

X-Real-IP

Identifies the client's IP address. For the Load Balancing service, the "client" is the last remote peer.

Your load balancer intercepts traffic between the client and your server. Your server's access logs, therefore, include only the load balancer's IP address. The `X-Real-IP` header provides the client's IP address. For example:

```
X-Real-IP: 192.168.0.10
```

Session Persistence

Session persistence is a method to direct all requests originating from a single logical client to a single backend web server. Backend servers that use caching to improve performance, or to enable log-in sessions or shopping carts, can benefit from session persistence.

You enable session persistence when you create a load balancer or when you create a backend set. You can also edit an existing backend set to enable, disable, or change the session persistence configuration.

Sticky Cookies

The Load Balancing service offers two mutually exclusive cookie-based configurations for enabling session persistence:

- Application cookie stickiness
- Load balancer cookie stickiness

Note

IP Address-driven Session Persistence

Some products offer session persistence support without cookies. These products depend on the IP address of the incoming request. ISP proxies and company exit gateways can issue many requests from a single IP address. In this case, a single backend server can be subject to high traffic volumes. Your backend fleet can become overwhelmed, one server at a time, even though effective load balancing is possible.

Another weakness of IP address-driven session persistence is that the originating IP address can change. In this case, session persistence can be lost or the request redirected to the wrong backend server.

Application Cookie Stickiness

To configure application cookie session persistence, you specify a cookie name and decide whether to disable fallback for unavailable servers.

The Load Balancing service activates application cookie session persistence (stickiness) when a backend server sends a `Set-Cookie` response header containing a recognized cookie name. The cookie name must match the name specified in the backend set configuration. If the configuration specifies a match-all pattern, '*', any cookie set by the server activates session persistence. Unless a backend server activates session persistence, the service follows the load balancing policy specified when you created the load balancer.

Requirements:

- Your load balancer must operate in HTTP mode to support server side, cookie-driven session persistence.

- The client computer must accept cookies for Load Balancing session persistence feature to work.

How It Works

The Load Balancing service calculates a hash of the configured cookie and other request parameters, and sends that value to the client in a cookie. The value stored in the cookie enables the service to route subsequent client requests to the correct backend server. If your backend servers change any of the defined cookies, the service recomputes the cookie's value and resends it to the client.

Warning

Oracle recommends that you treat cookie data as an opaque entity. Do not use it in your applications.

The backend server can stop application cookie persistence by deleting the session persistence cookie. If you used the match-all pattern, it must delete all cookies. You can delete cookies by sending a `Set-Cookie` response header with a past expiration date. The Load Balancing service routes subsequent requests using the configured load balancing policy.

Load Balancer Cookie Stickiness

When you configure load balancer cookie stickiness, the load balancer inserts a cookie into the response. The parameters configured within the cookie enable session stickiness. This method is useful when you have applications and web backend services that cannot generate their own cookies.

To configure load balancer cookie session persistence, you specify:

- *The cookie name.*
  If you do not specify a cookie name, the default name is `X-Oracle-BMC-LBS-Route`.

Note

Ensure that the cookie name used at the backend application servers is different from the cookie name used at the load balancer. To minimize the chance of name collision, Oracle recommends that you use a prefix such as `X-Oracle-OCI-`.

If a backend server and the load balancer both insert cookies with the same name, the client or browser behavior can vary depending on the domain value associated with the cookie. If the name and domain values of the `Set-cookie` header generated by a backend server and the `Set-cookie` header generated by the load balancer are the same, the client or browser treats them as one cookie. The client returns only one of the cookie values in subsequent requests. If both `Set-cookie` names are the same, but the domain names are different, the client or browser treats them as two different cookies.

- *The domain in which the cookie is valid.* The `Set-cookie` header inserted by the load balancer contains a domain attribute with the specified value.

  This attribute has no default value. If you do not specify a value, the load balancer does not insert the domain attribute into the `Set-cookie` header.

Note

- RFC 6265 - HTTP State Management Mechanism describes client and browser behavior when the domain attribute is present or not present in the `Set-cookie` header. If the value of the `Domain` attribute is `example.com` in the `Set-cookie` header, the client includes the same cookie in the `Cookie` header when making HTTP requests to `example.com`, `www.example.com`, and `www.abc.example.com`. If the `Domain` attribute is not present, the client returns the cookie only for the domain to which the original request was made.
- Ensure that this attribute specifies the correct domain value. If the `Domain` attribute in the `Set-cookie` header does not include the domain to which the original request was made, the client or browser might reject the cookie. As specified in RFC 6265, the client accepts a cookie with the `Domain` attribute value `example.com` or `www.example.com` sent from `www.example.com`. It does not accept a cookie with the `Domain` attribute `abc.example.com` or `www.abc.example.com` sent from `www.example.com`.

- *The URI path in which the cookie is valid.* The `Set-cookie` header inserted by the load balancer contains a `Path` attribute with the specified value.

Clients include the cookie in an HTTP request only if the path portion of the `request-uri` matches, or is a subdirectory of, the cookie's `Path` attribute.

The default value is `/`.

- *The amount of time the cookie remains valid.* The `Set-cookie` header inserted by the load balancer contains a `Max-Age` attribute with the specified value.

  The specified value must be at least one second. There is no default value for this attribute. If you do not specify a value, the load balancer does not include the `Max-Age` attribute in the `Set-cookie` header. Usually, the client or browser retains the cookie until the current session ends, as defined by the client.

- *Whether the `Set-cookie` header should contain the `Secure` attribute.* The `Secure` attribute directs the client or browser to send the cookie only using a secure protocol.

  Tip

  If you set this field to true, you cannot associate the corresponding backend set with an HTTP listener.

- *Whether the `Set-cookie` header should contain the `HttpOnly` attribute.* The `HttpOnly` attribute limits the scope of the cookie to HTTP requests. This attribute directs the client or browser to omit the cookie when providing access to cookies through non-HTTP APIs. For example, it restricts the cookie from JavaScript channels.
- *Whether to disable fallback for unavailable servers.*

  Note

  Path route rules take precedence to determine the target backend server. The load balancer verifies that session stickiness is enabled for the backend server and that the cookie configuration is valid for the target. The system ignores invalid cookies.

Fallback

By default, the Load Balancing service directs traffic from a persistent session client to a different backend server when the original server is unavailable. You can configure the backend set to disable this fallback behavior. When you disable fallback, the load balancer fails the request and returns an HTTP 502 code. The service continues to return an HTTP 502 until the client no longer presents a persistent session cookie.

Warning

If fallback is disabled, cookies with a distant future expiration date can cause a client outage.

The Load Balancing service considers a server marked `drain` available for existing persisted sessions. New requests that are not part of an existing persisted session are not sent to that server.

Managing a Load Balancer

This topic describes how to create or delete a load balancer on your system.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Prerequisites

To implement a working load balancer, you need:

- For a public load balancer in a region with multiple availability domains, you need a VCN with a public regional subnet or at least two public AD-specific subnets. In the latter case, each AD-specific subnet must reside in a separate availability domain. For more information on subnets, See VCNs and Subnets and Public vs. Private Subnets.

Warning

You cannot specify a private subnet for your public load balancer.

- For a public load balancer in a region with only one availability domain, you need a VCN with at least one public subnet.
- For a private load balancer in any region, you need a VCN with at least one private subnet.
- Two or more backend servers (Compute instances) running your applications. For more information on Compute instances, see Creating an Instance.

Note

Private IP Address Consumption

A public load balancer created in one public regional subnet consumes two private IP addresses from the host subnet. The primary and secondary load balancers reside within the same subnet. Each load balancer requires a private IP address from that subnet. The Load Balancing service assigns a floating public IP address, which does not come from the host subnet.

A public load balancer created in two public AD-specific subnets consumes two private IP addresses, one from each host subnet. The primary and secondary load balancers reside within different subnets. Each load balancer requires one private IP address from its host subnet. The Load Balancing service assigns a floating public IP address, which does not come from the host subnets.

A private load balancer created in a single subnet consumes three private IP addresses from the host subnet. The primary and secondary load balancers reside within the same subnet. Each load balancer requires a private IP address from that subnet. The floating private IP address also comes from the host subnet.

Working with Load Balancers

For background information on Oracle Cloud Infrastructure Load Balancing, see Overview of Load Balancing.

For the purposes of access control, you must specify the compartment where you want the load balancer to reside. Consult an administrator in your organization if you're not sure which compartment to use. For information about compartments and access control, see Managing Compartments.

When you create a load balancer within your VCN, you get a public or private IP address, and provisioned total bandwidth. If you need another IP address, you can create another load balancer.

A public load balancer in a region with multiple availability domains requires one public regional subnet or two public AD-specific subnets to host the primary load balancer and a standby. In the latter case, each AD-specific subnet must reside in a separate availability domain. A public load balancer in a region with only one availability domain requires a single public subnet to host the primary load balancer and a standby. For more information on VCNs and subnets, see Overview of Networking. You can associate the public IPv4 address with a DNS name from any vendor. You can use the public IP address as a front end for incoming traffic. The load balancer can route data traffic to any backend server that is reachable from the VCN.

A private load balancer requires only one subnet to host the primary load balancer and a standby. The private IP address is local to the subnet. The load balancer is accessible only from within the VCN that contains the associated subnet, or as further restricted by your security list rules. The load balancer can route data traffic to any backend server that is reachable from the VCN.

The essential components for load balancing include:

- A load balancer with pre-provisioned bandwidth.
- A backend set with a health check policy. See Managing Backend Sets.
- Backend servers for your backend set. See Managing Backend Servers.
- One or more listeners. See Managing Load Balancer Listeners.
- Load balancer subnet security rules to allow the intended traffic. To learn more about these rules, see Security Rules.

Tip

To accommodate high-volume traffic, Oracle strongly recommends that you use stateless security rules for your load balancer subnets.

Optionally, you can associate your listeners with SSL server certificate bundles to manage how your system handles SSL traffic. See Managing SSL Certificates.

For information about the number of load balancers you can have, see Service Limits.

Configuration Changes and Service Disruption

For a running load balancer, some configuration changes lead to service disruptions. The following guidelines help you understand the effect of changes to your load balancer.

- Operations that add, remove, or modify a backend server create no disruptions to the Load Balancing service.
- Operations that edit an existing health check policy create no disruptions to the Load Balancing service.
- Operations that trigger a load balancer reconfiguration can produce a brief service disruption with the possibility of some terminated connections.

Health Status

The Load Balancing service provides health status indicators that use your health check policies to report on the general health of your load balancers and their components. You can see health status indicators on the Console *List* and *Details* pages for load balancers, backend sets, and backend servers. You also can use the Load Balancing API to retrieve this information.

For general information about health status indicators, see Editing Health Check Policies.

Load Balancer Health Summary

The Console list of load balancers provides health status summaries that indicate the overall health of each load balancer. Health status indicators have four levels. The meaning of each level is:

The Console list of load balancers provides health status summaries that indicate the overall health of each load balancer. Health status indicators come in four levels. The meaning of each level is:

- **OK:** All backend sets associated with the load balancer return a status of OK.
- **WARNING:** All the following conditions are true:
  - At least one backend set associated with the load balancer returns a status of WARNING or UNKNOWN.
  - No backend sets return a status of CRITICAL.
  - The load balancer life-cycle state is ACTIVE.
- **CRITICAL:** At least one backend set associated with the load balancer returns a status of CRITICAL.
- **UNKNOWN:** Any one of the following conditions is true:
  - The load balancer life-cycle state is not ACTIVE.
  - No backend sets are defined for the load balancer.
  - All the following conditions are true:
    - More than half of the backend sets associated with the load balancer return a status of UNKNOWN.
    - None of the backend sets return a status of WARNING or CRITICAL.
    - The load balancer life-cycle state is ACTIVE.
  - The system could not retrieve metrics for any reason.

For guidance on detecting and correcting common issues, see Using Health Status.

Load Balancer Health Details

The load balancer *Details* page provides the same **Overall Health** status indicator found in the list of load balancers. It also includes counters for the **Backend Set Health** status values reported by the load balancer's child backend sets.

The health status counter badges indicate the following:

- The number of child entities reporting the indicated health status level.
- If a counter corresponds to the overall health, the badge has a fill color.
- If a counter has a zero value, the badge has a light gray outline and no fill color.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: For a typical policy that gives access to load balancers and their components, see Let network admins manage load balancers.

Also, be aware that a policy statement with `inspect load-balancers` gives the specified group the ability to see *all* information about the load balancers. For more information, see Details for Load Balancing.

If you're new to policies, see Getting Started with Policies and Common Policies.

Using the Console

To create a load balancer

1. Open the navigation menu. Under the **Core Infrastructure** group, go to **Networking**

and click **Load Balancers**.

2. Choose a **Compartment** you have permission to work in, and then click **Create Load Balancer**.
3. The workflow to create a load balancer includes three waypoints to configure your load balancer:

Step 1 - Add Details

Specify the attributes of the load balancer.

- **Load Balancer Name:** Required. Accept the default name or specify a friendly name for the load balancer. It does not have to be unique, but it cannot be changed in the Console. (You can, however, change it with the API.) Avoid entering confidential information.
- **Choose Visibility Type:** Specify whether your load balancer is public or private.
  - **Public:** Choose this option to create a public load balancer. You can use the assigned public IP address as a front end for incoming traffic and to balance that traffic across all backend servers.
  - **Private:** Choose this option to create a private load balancer. You can use the assigned private IP address as a front end for incoming internal VCN traffic and to balance that traffic across all backend servers.

- **Choose the Maximum Total Bandwidth:** Required. Specify a shape to provision the maximum total bandwidth (ingress plus egress) for your load balancer. Available shapes include:
  - Micro - 10 Mbps

    This load balancer shape is Always Free eligible.

    For more information about Always Free resources, including additional capabilities and limitations, see Oracle Cloud Infrastructure's Free Tier.
  - Small - 100 Mbps
  - Medium - 400 Mbps
  - Large - 8000 Mbps

Tip

After you create a load balancer, you cannot change the provisioned bandwidth. You can create another load balancer with a different maximum bandwidth.

- **Enable IPv6 Address Assignment:** Available only in the US Government Cloud. Specify whether the load balancer supports IPv6 addresses for incoming requests.

Note

- When you create a load balancer, you can optionally choose to have an IPv4/IPv6 dual-stack configuration. When you choose the IPv6 option, the Load Balancing service assigns both an IPv4 and an IPv6 address to the load balancer. The load balancer receives client traffic sent to the assigned IPv6 address. The load balancer uses only IPv4 addresses to communicate with backend servers. There is no IPv6 communication between the load balancer and the backend servers.
- IPv6 address assignment occurs only at load balancer creation. You cannot assign an IPv6 address to an existing load balancer.
- **Only VCNs in the US Government Cloud currently support IPv6 addressing.** For more information about Oracle Cloud Infrastructure's IPv6 implementation, see IPv6 Addresses.

- **Choose Networking**
  If the current compartment contains at least one VCN, the Console provides a drop-down list of VCNs for you to choose from.
  - **Virtual Cloud Network in <compartment>:** Required. Specify a VCN for the load balancer.
    By default, the Console shows a list of VCNs in the compartment you're currently working in. Click the **Change Compartment** link to select a VCN from a different compartment.
  - **Subnet in <compartment>:** Required. Select an available subnet. For a public load balancer, it must be a public subnet.
    By default, the Console shows a list of subnets in the compartment you're currently working in. Click the **Change Compartment** link to select a subnet from a different compartment.

    Tip

    In addition to *public* or *private*, subnets can be either *regional* or *AD-specific*. Oracle recommends using regional subnets. For more information, see About Regional Subnets.
  - **Subnet (2 of 2) in <compartment>:** Required for a public load balancer when you specify an AD-specific subnet for **Subnet**. Select a second public subnet. The second subnet must reside in a separate availability domain from the first subnet.

Tip

- If you chose to create a private load balancer under **Visibility Type**, the form prompts you to select only one subnet.
- If you're working in a region that includes only one availability domain, a second subnet is not required. The form prompts you to select only one subnet.

If the current compartment contains no virtual cloud networks, the Load Balancing service offers to create a VCN for you.

  - **Virtual Cloud Network in <compartment>:** When the current compartment contains no virtual cloud networks, the drop-down list is disabled. The system offers to create a VCN for you.

    If you want to use an existing VCN in another compartment, click the **Change Compartment** link and choose that compartment from the drop-down list.

    Virtual Cloud Network Name: Optional, when the system creates a VCN for you. Specify a friendly name for the new cloud network. It doesn't have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.

    If you do not specify a name for the new VCN, the system generates a name for you.

- **Use Network Security Groups to Control Traffic:** Check this box if you want to add your load balancer to a network security group (NSG). For more information about NSGs, see Network Security Groups.

- **Network Security Groups in <compartment>:** Choose an NSG to add your load balancer to.

  By default, the Console shows a list of NSGs in the compartment you're currently working in. Click the **Change Compartment** link to select an NSG from a different compartment.
- (Optional) Click **+ Another Network Security Group** to add your load balancer to another NSG.

Tip

You can change the NSGs that your load balancer belongs to after you create it. On the **Load Balancer Details** page, click the **Edit** link that appears beside the list of associated network security groups.

- **Show Advanced Options:** Click this link to change the host compartment or to create tags for the load balancer.
  - **Management:**
    - **Create in Compartment:** Optionally, you can select a different compartment to host the load balancer.
  - **Tagging:** Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.

Step 2 - Choose Backends

A load balancer distributes traffic to backend servers within a backend set. A backend set is a logical entity defined by a load balancing policy, a list of backend servers (Compute instances), and a health check policy.

The load balancer creation workflow creates one backend set for your load balancer. Optionally, you can add backend sets and backend servers after you create the load balancer.

- **Specify a Load Balancing Policy:** Required. Choose the load balancer policy for the backend set. The available options are:
  - **Weighted Round Robin:** This policy distributes incoming traffic sequentially to each server in a backend set list.
  - **IP Hash:** This policy ensures that requests from a particular client are always directed to the same backend server.
  - **Least Connections:** This policy routes incoming request traffic to the backend server with the fewest active connections.

  For more information on these policies, see How Load Balancing Policies Work.
- **Select Backend Servers:** Optional. Add backend servers to the backend set. Click **Add Backends** to select resources from a list of available Compute instances.

Important

When you add backend servers, the Load Balancing service automatically creates security list rules for you. If you prefer to create security list rules manually, click **Show Advanced Options** and choose the option to **Manually configure security list rules after the load balancer is created**.

- **Add Backends:** Select (check) the instances you want to include in the load balancer's backend set.

  To select instances from a different compartment, use the **Change Compartment** link and choose a compartment from the drop-down list.

  After you select the instances you want to add from the current compartment, click **Add Selected Backends**.

Tip

- You can choose instances from one compartment at a time. After you add instances from one compartment, you can choose **Add More Backends** to add instances from another compartment.
- You cannot add a backend server marked as **Backup** to a backend set that uses the IP Hash policy.

After you add instances to the backend set, they appear in the **Select Backend Servers** table. You can:

  - Specify the server **Port** to which the load balancer must direct traffic. The default is port 80.
  - Click the Actions icon (three dots) for a server and choose **Delete** to remove it from the backend set.

- **Specify Health Check Policy:** Required. Specify the test parameters that confirm the health of your backend servers.
  - **Protocol:** Required. Specify the protocol to use for health check queries, either HTTP or TCP.

Important

Configure your health check protocol to match your application or service.

- **Port:** Optional. Specify the backend server port against which to run the health check.

Tip

You can enter the value '0' to have the health check use the backend server's traffic port.

- **URL Path (URI):** (HTTP only) Required. Specify a URL endpoint against which to run the health check.
- **Interval in ms:** Optional. Specify how frequently to run the health check, in milliseconds. The default is 10000 (10 seconds).
- **Timeout in ms:** Optional. Specify the maximum time in milliseconds to wait for a reply to a health check. A health check is successful only if a reply returns within this timeout period. The default is 3000 (3 seconds).
- **Number of retries:** Optional. Specify the number of retries to attempt before a backend server is considered "unhealthy". This number also applies when recovering a server to the "healthy" state. The default is 3.
- **Status Code:** (HTTP only) Optional. Specify the status code a healthy backend server must return.
- **Response Body Regex:** (HTTP only) Optional. Provide a regular expression for parsing the response body from the backend server.

- **Show Advanced Options:** Click this link to access security list and session persistence options.
  - **Backend Set Name:** Specify a friendly name for the backend set. It must be unique within the load balancer, and it cannot be changed. If you do not specify a name, the Load Balancing service creates one for you.

Valid backend set names include only alphanumeric characters, dashes, and underscores. Backend set names cannot contain spaces. Avoid entering confidential information.

- **Security List:** Choose to manually configure subnet security list rules to allow the intended traffic or allow the system to create security list rules for you. To learn more about these rules, see Parts of a Security Rule.
  - **Manually configure security list rules after the load balancer is created:** When you choose this option, you must configure security list rules after load balancer creation.
  - **Automatically add security list rules:** Default. When you choose this option, the Load Balancing service creates security list rules for you.

    The system displays a table for egress rules and a table for ingress rules. Each table lets you choose the security list that applies to the relevant subnet.

    You can choose whether to apply the proposed rules for each affected subnet.
- **Session Persistence:** Optional. Specify how the load balancer manages session persistence.

  Important

  See Session Persistence for important information on configuring these settings.

  - **Disable Session Persistence:** Choose this option to disable cookie-based session persistence.
  - **Enable Application Cookie Persistence:** Choose this option to

enable persistent sessions from a single logical client when the backend application server response includes a `Set-cookie` header with the cookie name you specify.

- **Cookie Name:** The cookie name used to enable session persistence. Specify ***** to match any cookie name. Avoid entering confidential information.
- **Disable Fallback:** Check this box to disable fallback when the original server is unavailable.

- **Enable Load Balancer Cookie Persistence:** Choose this option to enable persistent sessions based on a cookie inserted by the load balancer.
  - **Cookie Name:** Specify the name of the cookie used to enable session persistence. If blank, the default cookie name is `X-Oracle-BMC-LBS-Route`.

    Ensure that any cookie names used at the backend application servers are different from the cookie name used at the load balancer. Avoid entering confidential information.
  - **Disable Fallback:** Check this box to disable fallback when the original server is unavailable.
  - **Domain Name:** Optional. Specify the domain in which the cookie is valid.

    This attribute has no default value. If you do not specify a value, the load balancer does not insert the domain attribute into the `Set-cookie` header.
  - **Path:** Optional. Specify the path in which the cookie is valid. The default value is `/`.

- **Expiration Period in Seconds:** Optional. Specify the amount of time the cookie remains valid. If blank, the cookie expires at the end of the client session.
- **Attributes**
  - **Secure:** Specify whether the `Set-cookie` header should contain the `Secure` attribute. If selected, the client sends the cookie only using a secure protocol.

    If you enable this setting, you cannot associate the corresponding backend set with an HTTP listener.
  - **HTTP Only:** Specify whether the `Set-cookie` header should contain the `HttpOnly` attribute. If selected, the cookie is limited to HTTP requests. The client omits the cookie when providing access to cookies through non-HTTP APIs such as JavaScript channels.

Step 3 - Configure Listener

- **Listener Name:** Required. Specify a friendly name for the listener. The name must be unique, and cannot be changed. Avoid entering confidential information.

  If you do not specify a name, the Load Balancing service creates one for you.
- **Specify the type of traffic your listener handles:** Required. Specify the protocol to use.
- **Specify the port your listener monitors for ingress traffic:** Required. Specify the port. Defaults are:
  - 443 for HTTPS
  - 80 for HTTP
  - 22 for TCP

- If you chose the HTTPS protocol, or if you chose the TCP protocol

and selected the Use SSL check box

- **Choose SSL Certificate File:** Required. Drag and drop the certificate file, in PEM format, into the **SSL Certificate** field.
  Alternatively, you can choose the **Paste SSL Certificate** option to paste a certificate directly into this field.

  Important

  If you submit a self-signed certificate for backend SSL, you must submit the same certificate in the corresponding CA Certificate field.

- **Specify CA Certificate:** Optional. (Recommended for backend SSL termination configurations.) Select (check) this box if you want to provide a CA certificate. See Working with SSL Certificates for more information.
  - **Choose CA Certificate File:** Drag and drop the CA certificate file, in PEM format, into the **CA Certificate** field.
    Alternatively, you can choose the **Paste CA Certificate** option to paste a certificate directly into this field.
- **Specify Private Key:** Optional. (Required for SSL termination.) Select (check) this box if you want to provide a private key for the certificate.
  - **Choose Private Key File:** Drag and drop the private key, in PEM format, into the **Private Key** field.
    Alternatively, you can choose the **Paste Private Key** option to paste a private key directly into this field.

        - **Enter Private Key Passphrase:** Optional. Specify the private key passphrase.

- **Show Advanced Options:** Click this link to set the idle timeout.
    - **Specify the maximum timeout in seconds:** Optional. Specify the maximum idle time in seconds. This setting applies to the time allowed between two successive receive or two successive send network input/output operations during the HTTP request-response phase.

      Tip

      The maximum value is 7200 seconds. For more information, see Connection Management.

4. Click **Create Load Balancer**.

After the system provisions the load balancer, details appear in the load balancer list. To view more details, click the load balancer name.

To delete a load balancer

1. Open the navigation menu. Under the **Core Infrastructure** group, go to **Networking** and click **Load Balancers**.
2. Choose the **Compartment** that contains the load balancer you want to delete.
3. For the load balancer you want to delete, click the Actions icon (three dots), and then click **Delete**.
4. Confirm when prompted.

Moving a Load Balancer to a Different Compartment

You can move your load balancer from its current compartment into a different compartment. For information about compartments and access control, see Managing Compartments.

To move a load balancer to a different compartment

1. Open the navigation menu. Under the **Core Infrastructure** group, go to **Networking** and click **Load Balancers**.
2. In the **List Scope** section, select a compartment.
3. Find the load balancer in the list, click the the Actions icon (three dots), and then click **Move Resource**.
4. In the **Move Resource** dialog box, choose the destination compartment from the list.
5. Click **Move Resource**.

Managing Tags for a Load Balancer

You can apply tags to your resources, such as load balancers, to help you organize them according to your business needs. You can apply tags at the time you create a load balancer, or you can update the load balancer later with the wanted tags. For general information about applying tags, see Resource Tags.

To manage tags for a load balancer

1. Open the navigation menu. Under the **Core Infrastructure** group, go to **Networking** and click **Load Balancers**.
2. Choose the **Compartment** that contains the load balancer you want to tag, and then click the load balancer's name.
3. Click the **Tags** tab to view or edit existing tags, or click **Apply Tag(s)** to add new ones.

For more information, see Resource Tags.

Monitoring Resources

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications. For more information, see Monitoring Overview and Notifications Overview.

For information about monitoring the traffic passing through your load balancer, see Load Balancing Metrics.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use these API operations to manage load balancers:

- ChangeLoadBalancerCompartment
- CreateLoadBalancer
- DeleteLoadBalancer
- GetLoadBalancer
- GetLoadBalancerHealth
- ListLoadBalancers
- ListLoadBalancerHealths
- UpdateLoadBalancer: You can update the load balancer's display name.
- UpdateNetworkSecurityGroups

Managing Backend Sets

This topic describes how to create and delete backend sets for use with a load balancer. For information about managing load balancers, see Managing a Load Balancer.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don't have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: For a typical policy that gives access to load balancers and their components, see Let network admins manage load balancers.

Also, be aware that a policy statement with `inspect load-balancers` gives the specified group the ability to see *all* information about the load balancers. For more information, see Details for Load Balancing.

If you're new to policies, see Getting Started with Policies and Common Policies.

Working with Backend Sets

A backend set is a logical entity defined by a load balancing policy, a health check policy, and a list of backend servers. To create a backend set, you must specify a load balancing policy and health check script, and then add a list of backend servers (Compute instances). SSL and session persistence configuration is optional. A backend set must be associated with one or more listeners for the load balancer to work.

You cannot delete a backend set used by an active listener.

Changing the load balancing policy of a backend set temporarily interrupts traffic and can drop active connections.

For background information on the Oracle Cloud Infrastructure Load Balancing, see Overview of Load Balancing.

Health Status

The Load Balancing service provides health status indicators that use your health check policies to report on the general health of your load balancers and their components. You can see health status indicators on the Console *List* and *Details* pages for load balancers, backend sets, and backend servers. You also can use the Load Balancing API to retrieve this information.

For general information about health status indicators, see Editing Health Check Policies.

Backend Set Health Summary

The Console list of a load balancer's backend sets provides health status summaries that indicate the overall health of each backend set. Health status indicators have four levels. The meaning of each level is:

- **OK:** All backend servers in the backend set return a status of OK.
- **WARNING:** Both of the following conditions are true:
  - Half or more of the backend set's backend servers return a status of OK.
  - At least one backend server returns a status of WARNING, CRITICAL, or UNKNOWN.
- **CRITICAL:** Fewer than half of the backend set's backend servers return a status of OK.
- **UNKNOWN:** At least one of the following conditions is true:
  - More than half of the backend set's backend servers return a status of UNKNOWN.
  - The system could not retrieve metrics for any reason.
  - The backend set does not have a listener attached.

For guidance on detecting and correcting common issues, see Using Health Status.

Backend Set Health Details

The backend set *Details* page provides the same **Overall Health** status indicator found in the load balancer's list of backend sets. It also includes counters for the **Backend Health** status values reported by the backend set's child backend servers.

The health status counter badges indicate the following:

- The number of child entities reporting the indicated health status level.
- If a counter corresponds to the overall health, the badge has a fill color.
- If a counter has a zero value, the badge has a light gray outline and no fill color.

Using the Console

To create a backend set

1. Open the navigation menu. Under the **Core Infrastructure** group, go to **Networking** and click **Load Balancers**.
2. Click the name of the **Compartment** that contains the load balancer you want to modify, and then click the load balancer's name.
3. In the **Resources** menu, click **Backend Sets** (if necessary), and then click **Create Backend Set**.
4. In the **Create Backend Set** dialog box, enter the following:
    - **Name:** Required. Specify a friendly name for the backend set. It must be unique within the load balancer, and it cannot be changed.
      Valid backend set names include only alphanumeric characters, dashes, and underscores. Backend set names cannot contain spaces. Avoid entering confidential information.

- **Traffic Distribution Policy:** Required. Choose the load balancer policy for the backend set. The available options are:
  - **IP Hash**
  - **Least Connections**
  - **Weighted Round Robin**

  For more information on these policies, see How Load Balancing Policies Work.

  Tip

  You cannot add a backend server marked as **Backup** to a backend set that uses the IP Hash policy.

- **Use SSL:** Optional. Check this box to associate an SSL certificate bundle with the backend set.

  If there are no certificate bundles attached to the load balancer, this option is disabled.
  - **Certificate Name:** Required. Select the certificate bundle to use. You can choose any certificate bundle that is attached to the current load balancer. See Managing SSL Certificates for more information.
  - **Verify Peer Certificate:** Optional. Select this option to enable peer certificate verification.
  - **Verify Depth:** Optional. Specify the maximum depth for certificate chain verification.
- **Session Persistence:** Optional. Specify how the load balancer manages session persistence.

> **Important**
>
> See Session Persistence for important information on configuring these settings.

- **Disable Session Persistence:** Choose this option to disable cookie-based session persistence.
- **Enable Application Cookie Persistence:** Choose this option to enable persistent sessions from a single logical client when the response from a backend application server includes a `Set-cookie` header with the cookie name you specify.
  - **Cookie Name:** The cookie name used to enable session persistence. Specify ***** to match any cookie name. Avoid entering confidential information.
  - **Disable Fallback:** Check this box to disable fallback when the original server is unavailable.
- **Enable Load Balancer Cookie Persistence:** Choose this option to enable persistent sessions based on a cookie inserted by the load balancer.
  - **Cookie Name:** Specify the name of the cookie used to enable session persistence. If blank, the default cookie name is `X-Oracle-BMC-LBS-Route`.

    Ensure that any cookie names used at the backend application servers are different from the cookie name used at the load balancer. Avoid entering confidential information.
  - **Disable Fallback:** Check this box to disable fallback when the original server is unavailable.
  - **Domain Name:** Optional. Specify the domain in which the cookie is valid.

This attribute has no default value. If you do not specify a value, the load balancer does not insert the domain attribute into the `Set-cookie` header.

- **Path:** Optional. Specify the path in which the cookie is valid. The default value is `/`.
- **Expiration Period in Seconds:** Optional. Specify the amount of time the cookie remains valid. If blank, the cookie expires at the end of the client session.
- **Attributes**
  - **Secure:** Specify whether the `Set-cookie` header should contain the `Secure` attribute. If selected, the client sends the cookie only using a secure protocol.

    If you enable this setting, you cannot associate the corresponding backend set with an HTTP listener.
  - **HTTP Only:** Specify whether the `Set-cookie` header should contain the `HttpOnly` attribute. If selected, the cookie is limited to HTTP requests. The client omits the cookie when providing access to cookies through non-HTTP APIs such as JavaScript channels.

- **Health Check:** Required. Specify the test parameters to confirm the health of backend servers.
  - **Protocol:** Required. Specify the protocol to use, either HTTP or TCP.

Important

Configure your health check protocol to match your application or service.

- **Port:** Optional. Specify the backend server port against which to run the health check.

Tip

You can enter the value '0' to have the health check use the backend server's traffic port.

- **URL Path (URI):** (HTTP only) Required. Specify a URL endpoint against which to run the health check.
- **Interval in ms:** Optional. Specify how frequently to run the health check, in milliseconds. The default is 10000 (10 seconds).
- **Timeout in ms:** Optional. Specify the maximum time in milliseconds to wait for a reply to a health check. A health check is successful only if a reply returns within this timeout period. The default is 3000 (3 seconds).
- **Number of retries:** Optional. Specify the number of retries to attempt before a backend server is considered "unhealthy". This number also applies when recovering a server to the "healthy" state. The default is '3'.
- **Status Code:** (HTTP only) Optional. Specify the status code a healthy backend server must return.
- **Response Body Regex:** (HTTP only) Optional. Provide a regular expression for parsing the response body from the backend server.

5. Click **Create**.

After your backend set is provisioned, you must specify backend servers for the set. See Managing Backend Servers for more information.

To edit a backend set

Warning

Updating the backend set temporarily interrupts traffic and can drop active connections.

When you edit a backed set, you can choose a new load balancing policy and modify the SSL configuration.

1. Open the navigation menu. Under the **Core Infrastructure** group, go to **Networking** and click **Load Balancers**.
2. Click the name of the **Compartment** that contains the load balancer you want to modify, and then click the load balancer's name.
3. In the **Resources** menu, click **Backend Sets**, and then click the name of the backend set you want to edit.
4. Click **Edit Backend Set**.
5. Make the configuration changes you need, and then click **Submit**.

If you want to modify the backend set's health check policy, see Editing Health Check Policies.

If you want to add or remove backend servers from the backend set, see Managing Backend Servers.

To delete a backend set

Tip

You cannot delete a backend set used by an active listener. First, remove any backend sets you want to

delete from the associated listeners.

1. Open the navigation menu. Under the **Core Infrastructure** group, go to **Networking** and click **Load Balancers**.
2. Click the name of the **Compartment** that contains the load balancer you want to modify, and then click the load balancer's name.
3. In the **Resources** menu, click **Backend Sets**.
4. For the backend set you want to delete, click the Actions icon (three dots), and then click **Delete**.
5. Confirm when prompted.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use these API operations to manage load balancer backend sets:

- CreateBackendSet
- DeleteBackendSet
- GetBackendSet
- GetBackendSetHealth
- ListBackendSets
- UpdateBackendSet

Managing Backend Servers

This topic describes how to manage backend servers for use with a load balancer. For information about managing load balancers, see Managing a Load Balancer.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: For a typical policy that gives access to load balancers and their components, see Let network admins manage load balancers.

Also, be aware that a policy statement with `inspect load-balancers` gives the specified group the ability to see *all* information about the load balancers. For more information, see Details for Load Balancing.

If you're new to policies, see Getting Started with Policies and Common Policies.

Working with Backend Servers

When you implement a load balancer, you must specify the backend servers (Compute instances) to include in each backend set. The load balancer routes incoming traffic to these backend servers based on the policies you specified for the backend set. You can use the Console to add and remove backend servers in a backend set.

To route traffic to a backend server, the Load Balancing service requires the IP address of the compute instance and the relevant application port. If the backend server resides within the same VCN as the load balancer, Oracle recommends that you specify the compute instance's private IP address. If the backend server resides within a different VCN, you must specify the public IP address of the compute instance. You also must ensure that the VCN's security rules allow Internet traffic.

Warning

When you add backend servers to a backend set, you specify either the instance OCID or an IP address for the server to add. An instance with multiple VNICs attached can have multiple IP addresses pointing to it.

- If you identify a backend server by OCID, Load Balancing uses the primary VNIC's primary private IP address.
- If you identify the backend servers to add to a backend set by their IP addresses, it is possible to point to the same instance more than once.

To enable backend traffic, your backend server subnets must have appropriate ingress and egress security rules. When you add backend servers to a backend set, you can specify the applicable network security groups (NSGs). If you prefer to use security lists for your VCN, the Load Balancing service Console can suggest security list rules for you. You also can configure them yourself through the Networking service. See Security Lists for more information.

Tip

To accommodate high-volume traffic, Oracle strongly recommends that you use stateless security rules for your load balancer subnets.

You can add and remove backend servers without disrupting traffic.

Health Status

The Load Balancing service provides health status indicators that use your health check policies to report on the general health of your load balancers and their components. You can see health status indicators on the Console *List* and *Details* pages for load balancers, backend sets, and backend servers. You also can use the Load Balancing API to retrieve this information.

For general information about health status indicators, see Editing Health Check Policies.

Backend Server Health Summary

The Console list of a backend set's backend servers provides health status summaries that indicate the overall health of each backend server. The primary and standby load balancers both provide health check results that contribute to the health status. Health status indicators have four levels. The meaning of each level is:

- **OK:** The primary and standby load balancer health checks both return a status of OK.
- **WARNING:** One health check returned a status of OK and one did not.
- **CRITICAL:** Neither health check returned a status of OK.
- **UNKNOWN:** One or both health checks returned a status of UNKNOWN or the system was unable to retrieve metrics.

To view the health status details for a specific backend server, click its **IP Address**.

For guidance on detecting and correcting common issues, see Using Health Status.

Backend Server Health Details

The *Details* page for a backend set provides the same **Overall Health** status indicator found in the backend set's list of backend servers. It also reports the following data for the two health checks performed against each backend server:

IP ADDRESS

The IP address of the health check status report provider, which is a Compute instance managed by the Load Balancing service. This identifier helps you differentiate same-subnet load balancers that report health check status.

The Load Balancing service ensures high availability by providing one primary and one standby load balancer. To diagnose a backend server issue, you must know the source of the health check report. For example, a misconfigured security rule might cause one load balancer instance to report that a backend server is healthy. The other load balancer instance might return an unhealthy status. In this case, one of the two load balancer instances cannot communicate with the backend server. Reconfigure the security rules to restore the backend server's health status.

STATUS

The status returned by the health check. Possible values include:

- OK
  The backend server's response satisfied the health check policy requirements.
- INVALID_STATUS_CODE
  The HTTP response status code did not match the expected status code specified by the health policy.
- TIMED_OUT
  The backend server did not respond within the timeout interval specified by the health policy.
- REGEX_MISMATCH
  The backend server response did not satisfy the regular expression specified by the health policy.
- CONNECT_FAILED
  The health check server could not connect to the backend server.

- IO_ERROR
  An input or output communication error occurred while reading or writing a response or request to the backend server.
- OFFLINE
  The backend server is set to **offline**, so health checks are not run.
- UNKNOWN
  Health check status is not available.

LAST CHECKED

The date and time of the most recent health check.

Health status is updated every three minutes. No finer granularity is available.

Using the Console

To add one or more servers to a backend set

1. Open the navigation menu. Under the **Core Infrastructure** group, go to **Networking** and click **Load Balancers**.
2. Click the name of the **Compartment** that contains the load balancer you want to modify, and then click the load balancer's name.
3. In the **Resources** menu, click **Backend Sets**, and then click the name of the backend set to which you want to add one or more backend servers.

Tip

If the load balancer has no backend sets, you must create one before you can specify a backend server.

4. In the **Resources** menu, click **Backends**, and then click **Add Backends**.

Tip

You cannot add a backend server marked as **Backup** to a backend set that uses the IP Hash policy.

5. **Choose how to add backend servers:** Specify how you want to add backend servers to the backend set:
   - **Compute Instances:** Choose this option to select from a list of available Compute instances.
     - **Instances in <compartment>:** Select (check) the instances you want to include in the backend set.

       To select instances from a different compartment, use the **Change Compartment** link and choose a compartment from the drop-down list.

       Tip

       You can choose instances from one compartment at a time. After you add instances from one compartment, you must repeat the **Add Backends** process to add instances from another compartment.

       Once you select an instance to add to the backend set, you can specify:
       - **Port:** Required. The backend server port to which the load balancer must direct traffic.
       - **Weight:** The load balancing weight assigned to the server. For more information, see How Load Balancing Policies Work.
     - Choose to manually configure subnet security list rules that allow the

intended traffic or let the Load Balancing service create security list rules for you. To learn more about these rules, see Parts of a Security Rule.

- **Manually configure security list rules after the load balancer is created:** When you choose this option, you must create your own rules after adding the backend servers.
- **Automatically add security list rules:** When you choose this option, the Load Balancing service creates security list rules for you. The system displays a table for egress rules and a table for ingress rules. Each table lets you choose the security list that applies to the relevant subnet. You can then choose whether to apply the proposed rules for each affected subnet.

- **IP Addresses:** Choose this option to enter the IP addresses of the backend servers (Compute instances) to add.
  - **IP Address:** Required. Specify the IP address of a backend server you want to add to the backend set.
  - **Port:** Required. Specify the server port to which the load balancer must direct traffic.
  - **Weight:** Required. Specify the load balancing weight to apply to this server. For more information, see How Load Balancing Policies Work.

  You can click the plus + icon to add another server to the list or click the X icon to remove a list item.

6. Click **Add**.

To edit backend server settings

1. Open the navigation menu. Under the **Core Infrastructure** group, go to **Networking** and click **Load Balancers**.
2. Click the name of the **Compartment** that contains the load balancer you want to modify, and then click the load balancer's name.

3. In the **Resources** menu, click **Backend Sets**, and then click the name of the backend set that includes the backend servers you want to edit.
4. In the **Resources** menu, click **Backends**. A list of servers in the backend set appears.
5. Select (check) the row corresponding to the backend server you want to edit.
6. Choose an action from the **Actions** button drop-down list. The available actions include:
    a. **Edit:** Opens a single dialog box in which you can edit the port, weight, drain, offline, and backup settings.
    b. **Edit Port:** Opens a dialog box in which you can change the application port setting.
    c. **Edit Weight:** Opens a dialog box in which you can change the load balancing weight.
    d. **Edit Drain State:** Opens a dialog box in which you can change the drain state.
    If you set the server's drain status to **true**, the load balancer stops forwarding new TCP connections and new non-sticky HTTP requests to this backend server. This setting allows an administrator to take the server out of rotation for maintenance purposes.
    e. **Edit Offline State:** Opens a dialog box in which you can change the offline status.
    If you set the server's offline status to **true**, the load balance forwards no ingress traffic to this backend server.
    f. **Edit Backup State:** Opens a dialog box in which you can change the backup status.
    If you set the server's backup status to **true**, the load balancer forwards ingress traffic to this backend server only when all other backend servers not marked as backup fail the health check policy. This configuration is useful for handling disaster recovery scenarios.

Warning

Backend servers marked as **Backup** are not compatible with a load balancer that uses the IP Hash policy.

g. **Delete:** Removes the server from the backend set.

Tip

You can select multiple servers to apply the same action to each one.

7. Click **Save Changes**.

To remove a server from a backend set

1. Open the navigation menu. Under the **Core Infrastructure** group, go to **Networking** and click **Load Balancers**.
2. Click the name of the **Compartment** that contains the load balancer you want to modify, and then click the load balancer's name.
3. In the **Resources** menu, click **Backend Sets**, and then click the name of the backend set from which you want to remove a server.
4. In the **Resources** menu, click **Backends**. A list of servers in the backend set appears.
5. Select (check) the row corresponding to the backend server you want to edit.
6. Choose the **Delete** action from the **Actions** button drop-down list.
7. Confirm when prompted.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use these API operations to manage the backend servers in a backend set:

- CreateBackend
- DeleteBackend
- GetBackend
- GetBackendHealth
- ListBackends
- UpdateBackend

Managing Load Balancer Listeners

This topic is part of the setup and maintenance of a load balancer. For more Load Balancing information about managing load balancers, see Managing a Load Balancer.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have

permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: For a typical policy that gives access to load balancers and their components, see Let network admins manage load balancers.

Also, be aware that a policy statement with `inspect load-balancers` gives the specified group the ability to see *all* information about the load balancers. For more information, see Details for Load Balancing.

If you're new to policies, see Getting Started with Policies and Common Policies.

Working with Listeners

A listener is a logical entity that checks for incoming traffic on the load balancer's IP address.

To handle TCP, HTTP, and HTTPS traffic, you must configure at least one listener per traffic type.

When you create a listener, you must ensure that your VCN's security rules allow the listener to accept traffic.

Tip

To accommodate high-volume traffic, Oracle strongly recommends that you use stateless security rules for your load balancer subnets.

You can have one SSL certificate bundle per listener. You can configure two listeners, one each for ports 443 and 8443, and associate SSL certificate bundles with each listener. For more information about SSL certificates for load balancers, see Managing SSL Certificates.

Using the Console

To create a listener

1. Open the navigation menu. Under the **Core Infrastructure** group, go to **Networking** and click **Load Balancers**.
2. Choose the **Compartment** that contains the load balancer you want to modify, and then click the load balancer's name.
3. In the **Resources** menu, click **Listeners**, and then click **Create Listener**.
4. In the **Create Listener** dialog box, enter the following:
    - **Name:** Required. Specify a friendly name for the listener. The name must be unique, and cannot be changed. Avoid entering confidential information.
    - **Hostname:** Optional. Select up to 16 virtual hostnames for this listener.

      Important

      To apply a virtual hostname to a listener, the name must be part of the load balancer's configuration. If the load balancer has no associated hostnames, you can create one on the **Hostnames** page.
    - **Protocol:** Required. Specify the protocol to use, either HTTP or TCP.
    - **Port:** Required. Specify the port on which to listen for incoming traffic.
    - **Use SSL:** Optional. Check this box to associate an SSL certificate bundle with the listener. The following settings are required to enable SSL handling. See Managing SSL Certificates for more information.
        - **Certificate Name:** Required. The friendly name of the SSL certificate bundle to use.

  - **Verify Peer Certificate:** Optional. Select this option to enable peer certificate verification.
  - **Verify Depth:** Optional. Specify the maximum depth for certificate chain verification.
- **Backend Set:** Required. Specify the default backend set to which the listener routes traffic.
- **Idle Timeout in Seconds:** Optional. Specify the maximum idle time in seconds. This setting applies to the time allowed between two successive receive or two successive send network input/output operations during the HTTP request-response phase.

Tip

The maximum value is 7200 seconds. For more information, see Connection Management.

- **Path Route Set:** Optional. Specify the name of the set of path-based routing rules that applies to this listener's traffic.

Important

- To apply a path route set to a listener, the set must be part of the load balancer's configuration.
- To remove a path route set from an existing listener, choose **None** as the **Path Route Set** option. The path route set remains available for use by other listeners on this load balancer.

5. Click **Create**.

When you create a listener, you must also update your VCN's security rules to allow traffic to that listener.

To edit a listener

1. Open the navigation menu. Under the **Core Infrastructure** group, go to **Networking** and click **Load Balancers**.
2. Choose the **Compartment** that contains the load balancer you want to modify, and then click the load balancer's name.
3. In the **Resources** menu, click **Listeners**.
4. For the listener you want to edit, click the Actions icon (three dots), and then click **Edit Listener**.
5. Make the configuration changes you need, and then click **Save Changes**.

To delete a listener

1. Open the navigation menu. Under the **Core Infrastructure** group, go to **Networking** and click **Load Balancers**.
2. Choose the **Compartment** that contains the load balancer you want to modify, and then click the load balancer's name.
3. In the **Resources** menu, click **Listeners**.
4. For the listener you want to delete, click **Delete**.
5. Confirm when prompted.

To enable a listener to accept traffic

To enable a listener to accept traffic, you must update your VCN's security rules:

1. Open the navigation menu. Under **Core Infrastructure**, go to **Networking** and click **Virtual Cloud Networks**.
   The list of VCNs in the current compartment appears.
2. Click the name of the VCN containing your load balancer, and then click **Security Groups** or **Security Lists**.
   A list of the security groups or lists in the cloud network appears.
3. Click the name of the NSG or security list that applies to your load balancer.
4. Add or edit the existing rules to allow access from the appropriate resources.
   An NSG's security rules appear on the **Network Security Group Details** page. From there you can add, edit, or remove rules.
   The **Security List Details** page provides access to separate tables in which you can add or edit **Ingress Rules** or **Egress Rules**.
   For details on rule configuration, see Security Rules.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use these API operations to manage listeners:

- CreateListener
- DeleteListener
- UpdateListener

Managing Request Routing

This topic describes how to manage your load balancer's request routing. For information about managing load balancers, see Managing a Load Balancer.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don't have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: For a typical policy that gives access to load balancers and their components, see Let network admins manage load balancers.

Also, be aware that a policy statement with `inspect load-balancers` gives the specified group the ability to see *all* information about the load balancers. For more information, see Details for Load Balancing.

If you're new to policies, see Getting Started with Policies and Common Policies.

Routing Incoming Requests

The Load Balancing service enables you to route incoming requests to various backend sets. You can:

- Assign virtual hostnames to a listener.
- Create path route rules.
- Combine these techniques.

Virtual Hostnames

You can assign virtual hostnames to any listener you create for your load balancer. Each hostname can correspond to an application served from your backend. Some advantages of virtual hostnames include:

- A single associated IP address. Multiple hostnames, backed by DNS entries, can point to the same load balancer IP address.
- A single load balancer. You do not need a separate load balancer for each application.
- A single load balancer shape. Running multiple applications behind a single load balancer helps you manage aggregate bandwidth demands and optimize utilization.
- Simpler backend set management. Managing a set of backend servers under a single resource simplifies network configuration and administration.

You can define exact virtual hostnames, such as "app.example.com", or you can use wildcard names. Wildcard names include an asterisk (*) in place of the first or last part of the name. When searching for a virtual hostname, the service chooses the first matching variant in the following priority order:

1. Exact name match (no asterisk), such as `app.example.com`.
2. Longest wildcard name that begins with an asterisk, such as `*.example.com`.

Tip

Prefix wildcard names might require a wildcard certificate for HTTPS sites.

3. Longest wildcard name that ends with an asterisk, such as `app.example.*`.

Tip

Suffix wildcard names might require a multi-domain Subject Alternative Name (SAN) certificate for HTTPS sites.

You do not need to specify the matching pattern to apply. The pattern is inherent in the asterisk position, that is, starting, ending, or none.

The following considerations apply to virtual hostnames:

- You cannot use regular expressions.
- To apply virtual hostnames to a listener, you first create one or more virtual hostnames associated with a load balancer.
- Virtual hostname selection priority is not related to the listener's configuration order.
- You can apply a maximum of 16 virtual hostnames to a listener.
- You can associate a maximum of 16 virtual hostnames with a load balancer.

Tip

The virtual hostnames feature supports HTTP and HTTPS listeners only, but does not support TCP listeners.

Note

Default Listener

If a listener has no virtual hostname specified, that listener is the default for the assigned port.

If all listeners on a port have virtual hostnames, the first virtual hostname configured for that port serves as the default listener.

Path Route Rules

Some applications have multiple endpoints or content types, each distinguished by a unique URI path. For example, `/admin/`, `/data/`, `/video/`, or `/cgi/`. You can use path route rules to route traffic to the correct backend set without using multiple listeners or load balancers.

A *path route* is a string that the Load Balancing service matches against an incoming URI to determine the appropriate destination backend set.

- You cannot use asterisks in path route strings.
- You cannot use regular expressions.
- Path route string matching is case-insensitive.

Important

Browsers often add an ending slash to the path in a request. If you specify a path such as `/admin`, you might want to configure the path both with and without the trailing slash. For example,`/admin` and `/admin/`.

A *path route rule* consists of a path route string and a pattern match type.

- Pattern match types include:
  - **EXACT_MATCH**
    Looks for a path string that exactly matches the incoming URI path.
    Applies case-insensitive regex:

    ```
    ^<path_string>$
    ```

  - **FORCE_LONGEST_PREFIX_MATCH**
    Looks for the path string with the best, longest match of the beginning portion of the incoming URI path.
    Applies case-insensitive regex:

    ```
    <path_string>.*
    ```

  - **PREFIX_MATCH**
    Looks for a path string that matches the beginning portion of the incoming URI path.
    Applies case-insensitive regex:

    ```
    ^<path_string>.*
    ```

  - **SUFFIX_MATCH**
    Looks for a path string that matches the ending portion of the incoming URI path.
    Applies case-insensitive regex:

    ```
    .*<path_string>$
    ```

- Path route rules apply only to HTTP and HTTPS requests and have no effect on TCP requests.

A *path route set* includes all path route rules that define the data routing for a particular listener.

- You can specify up to 20 path route rules per path route set.
- You can have one path route set per listener. The maximum number of listeners limits the number of path route sets you can specify for a load balancer.

Rule Priority

The system applies the following priorities, based on match type, to the path route rules within a set:

- For one path route rule that specifies the EXACT_MATCH type, there is no cascade of priorities. The listener looks for an exact match only.
- For two path route rules, one that specifies the EXACT_MATCH type and one that specifies any other match type, the exact match rule is evaluated first. If no match is found, then the system looks for the second match type.
- For multiple path route rules specifying various match types, the system applies the following priority cascade:
    1. EXACT_MATCH
    2. FORCE_LONGEST_PREFIX_MATCH
    3. PREFIX_MATCH or SUFFIX_MATCH
- The order of the rules within the path route set does not matter for EXACT_MATCH and FORCE_LONGEST_PREFIX_MATCH. The system applies the priority cascade no matter where these match types appear in the path route set.
- If matching cascades down to prefix or suffix matching, the order of the rules within the path route set DOES matter. The system chooses the first prefix or suffix rule that matches the incoming URI path.

Virtual Hostname and Path Route Rules Combinations

Virtual hostnames and path route rules route requests to backend sets. Listeners with a virtual hostname receive priority over the default (no hostname) listener. The following example shows the results of a simple routing interaction.

The example system includes three listeners and one path route set:

Listener 1

- Virtual hostname: *none*
- Default backend set: `A`

- Path route set: `PathRouteSet1`

Listener 2

- Virtual hostname: `captive.com`
- Default backend set: `B`
- Path route set: `PathRouteSet1`

Listener 3

- Virtual hostname: `wild.com`
- Default backend set: `C`
- Path route set: `PathRouteSet1`

Path Route Set

- Path route set name: `PathRouteSet1`
    - Exact match on path string `/tame/` routes to backend set `B`.
    - Exact match on path string `/feral/` routes to backend set `C`.

The example configuration routes incoming URLs as follows:

`http://animals.com/` is routed to backend set `A`

- Virtual hostname `animals.com` matches **Listener 1**.
- Path `/` is not an EXACT_MATCH for any path route string in `PathRouteSet1`.

`http://animals.com/tame/` is routed to backend set `B`

- Virtual hostname `animals.com` matches **Listener 1**.
- Path `/tame/` is an EXACT_MATCH for path route string `/tame/` in `PathRouteSet1`.

`http://animals.com/feral/` is routed to backend set `C`

- Virtual hostname `animals.com` matches **Listener 1**.
- Path `/feral/` is an EXACT_MATCH for path route string `/feral/` in `PathRouteSet1`.

`http://captive.com/` is routed to backend set `B`

- Virtual hostname `captive.com` matches **Listener 2**.
- Path `/` is not an EXACT_MATCH for any path route string in `PathRouteSet1`.

`http://captive.com/tame/` is routed to backend set `B`

- Virtual hostname `captive.com` matches **Listener 2**.
- Path `/tame/` is an EXACT_MATCH for path route string `/tame/` in `PathRouteSet1`.

`http://captive.com/feral/` is routed to backend set `C`

- Virtual hostname `captive.com` matches **Listener 2**.
- Path `/feral/` is an EXACT_MATCH for path route string `/feral/` in `PathRouteSet1`.

`http://wild.com/` is routed to backend set `C`

- Virtual hostname `wild.com` matches **Listener 3**.
- Path `/` is not an EXACT_MATCH for any path route string in `PathRouteSet1`.

`http://wild.com/tame/` is routed to backend set `B`

- Virtual hostname `wild.com` matches **Listener 3**.
- Path `/tame/` is an EXACT_MATCH for path route string `/tame/` in `PathRouteSet1`.

`http://wild.com/feral/` is routed to backend set `C`

- Virtual hostname `wild.com` matches **Listener 3**.
- Path `/feral/` is an EXACT_MATCH for path route string `/feral/` in `PathRouteSet1`.

Using the Console

You can specify virtual hostnames and path route sets when you create or update a listener.

Creating Virtual Hostnames

To apply virtual hostnames to a listener, you first create one or more virtual hostnames. The virtual hostnames become a part of the load balancer's configuration. You then specify one or more virtual hostnames to use when you create or update a listener for the load balancer.

To create a virtual hostname

1. Open the navigation menu. Under the **Core Infrastructure** group, go to **Networking** and click **Load Balancers**.
2. Choose the **Compartment** that contains the load balancer you want to modify, and then click the load balancer's name.
3. In the **Resources** menu, click **Hostnames**, and then click **Create Hostname**.
4. In the **Create Hostname** dialog box, enter the following:
    - **Name:** Required. Specify a friendly name for the hostname. The name must be unique, and cannot be changed. Avoid entering confidential information.
    - **Hostname:** Required. Specify the virtual hostname. See Virtual Hostnames for a description of valid hostname construction and behavior.
5. Click **Create**. The **Work Request Submitted** dialog box opens.
6. To close the dialog box, click **Close**. To open the **Work Requests** page and view the status of the work request, click **View All Work Requests**.

After you create a virtual hostname, the name becomes available for use with the associated load balance. To apply the hostname, create or update a listener.

To update a virtual hostname

1. Open the navigation menu. Under the **Core Infrastructure** group, go to **Networking** and click **Load Balancers**.
2. Choose the **Compartment** that contains the load balancer you want to modify, and then click the load balancer's name.
3. In the **Resources** menu, click **Hostnames**.
4. For the hostname you want to edit, click the Actions icon (three dots), and then click **Edit**.
5. In the **Edit Hostname** dialog box, enter your updates to the **Hostname** field.
   You cannot edit the **Name** field of an existing virtual hostname.
6. Click **Update**. The **Work Request Submitted** dialog box opens.
7. To close the dialog box, click **Close**. To open the **Work Requests** page and view the status of the work request, click **View All Work Requests**.

To delete a virtual hostname

1. Open the navigation menu. Under the **Core Infrastructure** group, go to **Networking** and click **Load Balancers**.
2. Choose the **Compartment** that contains the load balancer you want to modify, and then click the load balancer's name.
3. In the **Resources** menu, click **Hostnames**.
4. For the hostname you want to edit, click the Actions icon (three dots), and then click **Delete**. The **Work Request Submitted** dialog box opens.
5. To close the dialog box, click **Close**. To open the **Work Requests** page and view the status of the work request, click **View All Work Requests**.

Creating Path Route Sets

To apply path route rules to a listener, you first create a path route set that contains the rules. The path route set becomes a part of the load balancer's configuration. You then specify the path route set to use when you create or update a listener for the load balancer. To remove a path route set from a listener, edit the listener and choose **None** as the **Path Route Set** option.

To create a path route set

1. Open the navigation menu. Under the **Core Infrastructure** group, go to **Networking** and click **Load Balancers**.
2. Choose the **Compartment** that contains the load balancer you want to modify, and then click the load balancer's name.
3. In the **Resources** menu, click **Path Route Sets**, and then click **Create Path Route Set**.
4. In the **Create Path Route Set** dialog box, enter the following:
    - **Name:** Required. Specify a friendly name for the path route set. The name must be unique, and cannot be changed.

      The path route set name cannot begin with a period and cannot contain the characters **;**, **?**, **#**, **%**, **/**, ****, **[**, or **]**.

      Avoid entering confidential information.
    - **Path Route Rules**
        - **Order:** Optional. If you have multiple path route rules, you can click the up or down arrows to move the corresponding rule.

Tip

The order of the rules within the path route set does not matter in most cases. However, if matching cascades down to prefix or suffix matching, the system chooses the first prefix or suffix rule that matches the incoming URI path.

- **Match Style:** Required. The type of matching to apply to incoming URIs.
- **URL String:** Required. The path string to match against the incoming URI path, for example `/admin/`.
- **Backend Set Name:** Required. The name of the target backend set for requests where the incoming URI matches the specified path.

5. (Optional) Click **+ Additional Rule** to create another path route rule or click the red box to delete an existing rule. You can have up to 20 path route rules in a set.
6. Click **Create**.

After you create a path route set, the set becomes available for use with the associated load balance. Create or update a listener to apply the path route set.

To update a path route set

1. Open the navigation menu. Under the **Core Infrastructure** group, go to **Networking** and click **Load Balancers**.
2. Choose the **Compartment** that contains the load balancer you want to modify, and then click the load balancer's name.
3. In the **Resources** menu, click **Path Route Sets**.
4. Click the name of the path route set you want to update, and then click **Edit Path Route Rules**.

5. In the **Edit Path Route Rules** dialog box, edit the following as needed for each rule you want to change:
    - **Order:** Optional. If you have multiple path route rules, you can click the up or down arrows to move the corresponding rule.

      Tip

      The order of the rules within the path route set does not matter in most cases. However, if matching cascades down to prefix or suffix matching, the system chooses the first prefix or suffix rule that matches the incoming URI path.

    - **Match Style:** Required. The type of matching to apply to incoming URIs.
    - **URL String:** Required. The path string to match against the incoming URI path, for example `/admin/`.
    - **Backend Set Name:** Required. The name of the target backend set for requests where the incoming URI matches the specified path.
6. (Optional) Click **+ Additional Rule** to create another path route rule or click the red box to delete an existing rule. You can have up to 20 path route rules in a set.
7. Click **Save Changes**.

To update a single path route rule

1. Open the navigation menu. Under the **Core Infrastructure** group, go to **Networking** and click **Load Balancers**.
2. Choose the **Compartment** that contains the load balancer you want to modify, and then click the load balancer's name.
3. In the **Resources** menu, click **Path Route Sets**, and then click the name of the path route set you want to update.

4. For the path route rule you want to edit, click the Actions icon (three dots), and then click **Edit Path Route**.
5. In the **Edit Path Route Rule** dialog box, edit the following as needed for each rule you want to change:
    - **Order:** Optional. If you have multiple path route rules, you can click the up or down arrows to move the corresponding rule.

      Tip

      The order of the rules within the path route set does not matter in most cases. However, if matching cascades down to prefix or suffix matching, the system chooses the first prefix or suffix rule that matches the incoming URI path.

    - **Match Style:** Required. The type of matching to apply to incoming URIs.
    - **URL String:** Required. The path string to match against the incoming URI path, for example `/admin/`.
    - **Backend Set Name:** Required. The name of the target backend set for requests where the incoming URI matches the specified path.
6. Click **Save Changes**.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use these API operations to manage request routing:

- CreateListener
- CreatePathRouteSet

- DeleteListener
- DeletePathRouteSet
- GetPathRouteSet
- ListPathRouteSets
- UpdateListener
- UpdatePathRouteSet

Managing Rule Sets

This topic describes how you can create rule sets composed of actions to apply to traffic at an HTTP listener.

For more information about managing load balancer listeners, see Managing Load Balancer Listeners.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: For a typical policy that gives access to load balancers and their components, see Let network admins manage load balancers.

Also, be aware that a policy statement with `inspect load-balancers` gives the specified group the ability to see *all* information about the load balancers. For more information, see Details for Load Balancing.

If you're new to policies, see Getting Started with Policies and Common Policies.

Working with Rule Sets

A rule set is a named set of rules associated with a load balancer and applied to one or more listeners on that load balancer. Rules are objects that represent actions applied to traffic at a load balancer listener.

You can include the following types of rules in a rule set:

- Access control rules, which restrict access to application resources based on the source of the request.
- Access method rules, which specify the permitted HTTP methods.
- URL redirect rules, which route incoming HTTP requests to a different destination URL.
- Request and response header rules, which add, alter, or remove HTTP request or response headers.

Rule sets apply only to HTTP listeners.

You can apply an existing rule set when you edit a listener. You can apply the same rule set to multiple listeners on the same load balancer.

Rule sets are not shared between load balancers. To use the same set of rules on another load balancer, you must create a new, identical rule set under that load balancer.

You can have up to 20 rules in a rule set. You can associate a maximum of 50 rules with a load balancer.

Access Control Rules

Access control rules permit access to application resources based on user-specified IP address or address range match conditions. If you do not specify any access control rules, the

default rule is to allow all traffic. If you add access control rules, the load balancer denies any traffic that does not match the rules.

The service accepts only classless inter-domain routing (CIDR) format (`x.x.x.x/y or x:x::x/y`) strings for the match condition.

Specify `0.0.0.0/0` or `::/0` to match all incoming traffic.

Note

Only US Government Cloud regions currently permit IPv6 values.

Access Method Rules

Access method rules specify the HTTP methods allowed at the associated listener. The load balancer does not forward a disallowed request to the backend servers and returns a `405 Method Not Allowed` response with a list of the allowed methods. You can associate only one list of allowed methods with a given listener.

By default, you can specify only the standard HTTP methods defined in the HTTP Method Registry. The list of HTTP methods is extensible. If you need to configure custom HTTP methods, contact My Oracle Support to remove the restriction from your tenancy. Your backend application must be able to handle the specified methods.

URL Redirect rules

URL redirect rules specify how to route incoming HTTP requests to a different destination URL. URL redirect rules apply only to HTTP listeners. You configure each redirect rule for a particular listener and a designated path. A listener can have only one redirect rule for a given incoming URL path.

When you create a URL redirect rule, you specify the path string and match condition the service uses to evaluate an incoming URL for redirection. You also define the redirect URL and response code.

Incoming path string evaluation

You specify the path string, or pattern, to evaluate in the incoming URL. For example:

```
/video
```

You also specify the match condition to apply when evaluating the incoming URL for redirection. The available match types are:

- FORCE_LONGEST_PREFIX_MATCH
  The system looks for a redirect rule path string with the best, longest match of the beginning portion of the incoming URL path.
- EXACT_MATCH
  The incoming URL path must exactly and completely match the specified path string.
- PREFIX_MATCH
  The beginning portion of the incoming URL path must exactly match the specified path string.
- SUFFIX_MATCH
  The ending portion of the incoming URL path must exactly match the specified path string.

Redirection URL construction

You define the redirect URL applied to the original request. URL redirect rules recognize the following URL components:

```
<protocol>://<host>:<port>/<path>?<query>
```

You can specify a literal string or provide a token for any component. Tokens extract values from the incoming HTTP request URL. Tokens are case-sensitive. For example, `{host}` is a valid token, but `{HOST}` is not.

- **Protocol**
  The HTTP protocol to use in the redirect URL. Valid values are HTTP and HTTPS.
  The `{protocol}` token extracts the protocol from the incoming HTTP request URL. It is the only valid token for this property.
- **Host**
  The valid domain name or IP address to use in the redirect URL.

The `{host}` token extracts the host from the incoming HTTP request URL. All URL Redirect tokens are valid for this property. You can use any token more than once.

Curly braces **{}** are valid in this property only to surround tokens.

- **Port**

  The communication port to use in the redirect URL. Valid values include integers from 1 to 65535.

  The `{port}` token extracts the port from the incoming HTTP request URL. It is the only valid token for this property.

- **Path**

  The HTTP URL path to use in the redirect URL. To omit the path from the redirect URL, set this value to an empty string.

  The `{path}` token extracts the path string from the incoming HTTP request URL. All URL Redirect tokens are valid for this property. You can use any token more than once.

  If the path string does not begin with the `{path}` token, it must begin with a forward slash **/**.

- **Query**

  The query string to use in the redirect URL. To omit all incoming query parameters from the redirect URL, set this value to an empty string.

  The `{query}` token extracts the query string from the incoming HTTP request URL. All URL Redirect tokens are valid for this property. You can use any token more than once.

  If the query string does not begin with the `{query}` token, it must begin with a question mark **?**.

  You can specify multiple query parameters as a single string. Separate each query parameter with an ampersand **&**.

  If the specified query string results in a redirect URL ending with **?** or **&**, the last character is truncated. For example, if the incoming URL is `http://host.com:8080/documents` and the query property value is `?lang=en&{query}`, the redirect URL is `http://host.com:8080/documents?lang=en`. The system truncates the final ampersand **&** because the incoming URL included no value to replace the `{query}` token.

Warning

Failure to specify a value for at least one URL component field can result in a redirect loop.

Manual redirect URL construction

The Console provides text entry fields for each URL component. Alternatively, you can manually specify the full redirect URL.

You can retain the literal characters of a token when you specify values for the path and query properties of the redirect URL. Use a backslash **** as the escape character for the ****, **{**, and **}** characters. For example, if the incoming HTTP request URL is `/video`, the path property value `/example{path}123\{path\}` appears in the constructed redirect URL as `/example/video123{path}`.

Some path and query string examples:

- **/example/video/123** appears as `/example/video/123` in the redirect URL.
- **/example{path}** appears as `/example/video/123` in the redirect URL when `/video/123` is the path in the incoming HTTP request URL.
- **{path}/123** appears as `/example/video/123` in the redirect URL when `/example/video` is the path in the incoming HTTP request URL.
- **{path}123** appears as `/example/video123` in the redirect URL when `/example/video` is the path in the incoming HTTP request URL.
- **/{host}/123** appears as `/example.com/123` in the redirect URL when `example.com` is the hostname in the incoming HTTP request URL.
- **/{host}/{port}** appears as `/example.com/123` in the redirect URL when `example.com` is the hostname and `123` is the port in the incoming HTTP request URL.
- **/{query}** appears as `/lang=en` in the redirect URL when the query is `lang=en` in the incoming HTTP request URL.

- **lang=en&time_zone=PST** appears as `lang=en&time_zone=PST` in the redirect URL.
- **{query}** appears as `lang=en&time_zone=PST` in the redirect URL when `lang=en&time_zone=PST` is the query string in the incoming HTTP request. If the incoming HTTP request has no query parameters, the `{query}` token renders as an empty string.
- **lang=en&{query}&time_zone=PST** appears as `lang=en&country=us&time_zone=PST` in the redirect URL when `country=us` is the query string in the incoming HTTP request. If the incoming HTTP request has no query parameters, this value renders as `lang=en&time_zone=PST`.
- **protocol={protocol}&hostname={host}** appears as `protocol=http&hostname=example.com` in the redirect URL when the protocol is `http` and the hostname is `example.com` in the incoming HTTP request.
- **port={port}&hostname={host}** appears as `port=8080&hostname=example.com` in the redirect URL when the port is `8080` and the hostname is `example.com` in the incoming HTTP request URL.

Response code

You can specify the HTTP status code to return when the incoming request is redirected. Valid response codes for redirection from the standard HTTP specification are:

- `301 Moved Permanently`
- `302 Found`
- `303 See Other`
- `307 Temporary Redirect`
- `308 Permanent Redirect`

The default value is `302 Found`.

Request and Response Header Rules

Request and response header rules add, alter, or remove HTTP request or response headers. These rules can help you pass metadata to your backend servers to do things like:

- Identify which listener sent a request.
- Notify a backend server about SSL termination.

Examples of how rule sets can help you enhance site security include:

- Adding headers to prevent external domains from iframing your site.
- Removing debug headers, such as "Server", sent by backend servers. This action helps you hide the implementation details of your backend.
- Adding the "strict-transport-security" header, with a proper value, to responses. This header helps guarantee that access to your site is HTTPS only.
- Adding the "x-xss-protection" header with a proper value. This header helps you enforce the cross-site scripting (XSS) protection built into modern browsers.
- Adding the "x-content-type" header with a proper value. This header helps you prevent attacks based on content type shifting.

Example: Notify WebLogic that the load balancer terminated SSL

You can configure your load balancer to perform SSL termination. Often, your backend applications require notification of this action. For example, HTTPS WebLogic e-commerce online transaction processing looks for the `WL-Proxy-SSL` header to confirm that a request came in over SSL. You can use rule sets to add this header at the load balancer listener.

Tip

For security reasons, WebLogic ignores this header unless you select (check) the **WebLogic Plugin Enabled** check box in WebLogic's Administration Console.

1. Follow the instructions to create a rule set and:
    a. Choose the **Add Request Header** option from the **Action** drop-down list.
    b. Enter `WL-Proxy-SSL` as the **Header** name.
    c. Set the header **Value**:
        - If your load balancer is configured to perform SSL termination, set this value to "true".
        - If the SSL termination point is in the web server where the plug-in operates, set this value to "false".
2. Create a listener, or edit an existing listener, and add the new rule set.

Using the Console

To apply a rule set to a listener, you first create the rule set that contains the rules. The rule set becomes a part of the load balancer's configuration. You can specify the rule set to use when you create or update a listener for the load balancer.

To create a rule set

1. Open the navigation menu. Under the **Core Infrastructure** group, go to **Networking** and click **Load Balancers**.
2. Choose the **Compartment** that contains the load balancer you want to modify, and then click the load balancer's name.
3. In the **Resources** menu, click **Rule Sets**, and then click **Create Rule Set**.
4. In the **Create Rule Set** dialog box, enter the following:
    - **Name:** Required. Specify a friendly name for the rule set. The name must be unique, and cannot be changed. Avoid entering confidential information.
    - **Specify Access Control Rules:** Optional. Select (check) this box to add access control rules.

- **IP Address CIDR:** Enter the IP address CIDR block from which access is allowed.
- **+ Another Access Control Rule:** Optional. Click this button to enter another IP address CIDR or click the corresponding **X** to remove an existing entry.

- **Specify Access Method Rules:** Optional. Select (check) this box to add access method rules.
  - **Allowed Methods:** From the drop-down list, select the HTTP methods to allow. You can select multiple methods. Click the label's **X** to remove an existing method.
- **Specify URL Redirect Rules:** Optional. Select (check) this box to add URL redirect rules.
  - **Source Path:** Specify the incoming path string that triggers the redirect rule. For example, `/video`.
  - **Match Type:** Choose the match condition to apply when evaluating an incoming path string. The available match types are:
    - FORCE_LONGEST_PREFIX_MATCH
      The system looks for a redirect rule path string with the best, longest match of the beginning portion of the incoming URL path.
    - EXACT_MATCH
      The incoming URL path must exactly and completely match the specified path string.
    - PREFIX_MATCH
      The beginning portion of the incoming URL path must exactly match the specified path string.
    - SUFFIX_MATCH
      The ending portion of the incoming URL path must exactly match the specified path string.

- **Redirect to:** Specify a value for at least one URL component field. Component fields you do not modify retain the values of the incoming URL. Optionally, click the **Switch to full URL** link to enter the redirect URL manually.

  Warning

  Failure to specify a value for at least one URL component field can result in a redirect loop.

  - **Protocol:** Specify the HTTP protocol to use in the redirect URL. Valid values are:
    - {protocol}
    - HTTPS
    - HTTP
  - **Host:** Specify a valid domain name (hostname) or IP address for the redirect URL. All redirect URL tokens are valid for this property.
  - **Port:** Specify the communication port to use in the redirect URL. Valid values include integers from 1 to 65535.
  - **Path:** The HTTP URL path to use in the redirect URL. All redirect URL tokens are valid for this property.

Importa nt

If the path string does not begin with the `{path}` token, it must begin with the forward slash character `/`.

- **Query:** Specify the query string to use in the redirect URL. All redirect URL tokens are valid for this property.

Importa nt

If the query string does not begin with the `{query}` token, it must begin with the question mark `?` character.

- **Response Code:** Specify the HTTP status code to return when the incoming request is redirected. The default response code is **302 Found**.

  Valid response codes for redirection from the standard HTTP specification are:

  - `301 Moved Permanently`
  - `302 Found`
  - `303 See Other`
  - `307 Temporary Redirect`
  - `308 Permanent Redirect`

- **+ Another URL Redirect Rule** Optional. Click this button to create another rule or click the corresponding **X** to delete an existing rule.

- **Specify Request Header Rules:** Optional. Select (check) this box to add request header rules.
  - **Order:** Optional. If you have multiple rules, you can click the up or down arrows to move the corresponding rule.
  - **Action:** Select the action that the rule applies. Available actions include:
    - **Add Request Header**

      Adds the specified header and value to the incoming request.

      If the specified header is already present, the system replaces it.

      If more than one header with the same name is present, the system removes all of them and adds one header corresponding to the specified header and value.
    - **Extend Request Header**

      Adds the specified prefix or suffix to the incoming request.

      You must provide a prefix value, a suffix value, or both when you choose this action.

      The system does not support this rule for headers with multiple values.
    - **Remove Request Header**

      Removes the specified header.

      If the same header appears more than once in the request, the load balancer removes all occurrences of the specified header.

      Note

      These rules apply only to HTTP or HTTP2 headers.

- **Header:** A header name that conforms to RFC 7230.

Warning

The system does not distinguish between underscore and dash characters in headers. That is, it treats example_header_name and example-header-name as identical. Oracle recommends that you do not rely on underscore or dash characters to uniquely distinguish header names.

- **Value:** (Add rules only.) A header value that conforms to RFC 7230.
- **Prefix:** (Extend rules only.) A character string to add to the beginning of the existing header name. The resulting header must conform to RFC 7230.
- **Suffix:** (Extend rules only.) A character string to add to the end of the existing header name. The resulting header must conform to RFC 7230.
- **+ Another Request Header Rule** Optional. Click this button to create another rule or click the corresponding **X** to delete an existing rule.

- **Specify Response Header Rules:** Optional. Select (check) this box to add response header rules.
  - **Order:** Optional. If you have multiple rules, you can click the up or down arrows to move the corresponding rule.
  - **Action:** Select the action that the rule applies. Available actions include:
    - **Add Response Header**
      Adds the specified header and value to the outgoing response.
      If the specified header is already present, the system replaces it.

If more than one header with the same name is present, the system removes all of them and adds one header corresponding to the specified header and value.

- **Extend Response Header**

  Adds the specified prefix or suffix to the incoming request.

  You must provide a prefix value, a suffix value, or both when you choose this action.

  The system does not support this rule for headers with multiple values.

- **Remove Response Header**

  Removes the specified header.

  If the same header appears more than once in the response, the load balancer removes all occurrences of the specified header.

Note

These rules apply only to HTTP or HTTP2 headers.

- **Header:** A header name that conforms to RFC 7230.

Warning

The system does not distinguish between underscore and dash characters in headers. That is, it treats example_header_name and example-header-name as identical. Oracle recommends that you do not rely on underscore or dash characters to uniquely distinguish header names.

- **Value:** (Add rules only.) A header value that conforms to RFC 7230.
- **Prefix:** (Extend rules only.) A character string to add to the beginning of the existing header name. The resulting header must conform to RFC 7230.
- **Suffix:** (Extend rules only.) A character string to add to the end of the existing header name. The resulting header must conform to RFC 7230.
- **+ Another Response Header Rule** Optional. Click this button to create another rule or click the corresponding **X** to delete an existing rule.

5. Click **Create**.

After you create a rule set, the set becomes available for use with the associated load balancer. Update a listener to apply the rule set.

To update a rule set

1. Open the navigation menu. Under the **Core Infrastructure** group, go to **Networking** and click **Load Balancers**.
2. Choose the **Compartment** that contains the load balancer associated with the rule set you want to modify, and then click the load balancer's name.
3. In the **Resources** menu, click **Rule Sets**.
4. Click the name of the rule set you want to edit, and then click **Edit Rules**.

5. In the **Edit Rule Set** dialog box, add or remove rules as needed.
   You cannot edit the **Name** field of an existing rule set.
6. Click **Save Changes**.

To remove a rule set from a listener

1. Open the navigation menu. Under the **Core Infrastructure** group, go to **Networking** and click **Load Balancers**.
2. Choose the **Compartment** that contains the load balancer associated with the rule set you want to delete, and then click the load balancer's name.
3. In the **Resources** menu, click **Listeners**.
4. For the listener you want to edit, click the Actions icon (three dots), and then click **Edit Listener**.
5. In the **Rule Sets** section of the dialog box, click the corresponding **X** to remove an existing rule set.

Tip

This action removes the rule set from the current listener, but the rule set remains available for application to other listeners on the load balancer.

6. Click **Save Changes**.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use these API operations to manage rule sets:

- CreateRuleSet
- DeleteRuleSet
- GetRuleSet
- ListRuleSets
- UpdateRuleSet

Managing SSL Certificates

This topic is part of the setup and maintenance of a load balancer. For more information about managing load balancers, see Managing a Load Balancer.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: For a typical policy that gives access to load balancers and their components, see Let network admins manage load balancers.

Also, be aware that a policy statement with `inspect load-balancers` gives the specified group the ability to see *all* information about the load balancers. For more information, see Details for Load Balancing.

If you're new to policies, see Getting Started with Policies and Common Policies.

Working with SSL Certificates

To use SSL with your load balancer, you must add one or more certificate bundles to your system. The certificate bundle you upload includes the public certificate, the corresponding private key, and any associated Certificate Authority (CA) certificates. For the easiest workflow, upload the certificate bundles you want to use *before* you create the listeners or backend sets you want to associate them with.

Load balancers commonly use single domain certificates. However, load balancers with listeners that include request routing configuration might require a subject alternative name (SAN) certificate (also called multi-domain certificate) or a wildcard certificate. The Load Balancing service supports each of these certificate types.

Important

- The Load Balancing service does not generate SSL certificates. It can only import an existing certificate that you already own. The certificate can be one issued by a vendor, such as Verisign or GoDaddy. You can also use a self-signed certificate that you generate with an open source tool, such as OpenSSL or Let's Encrypt. Refer to the corresponding tool's documentation for instructions on how to generate a self-signed certificate.
- If you submit a self-signed certificate for backend SSL, you must submit the same certificate in the corresponding CA Certificate field.

Oracle Cloud Infrastructure accepts x.509 type certificates in PEM format only. The following is an example PEM encoded certificate:

```
-----BEGIN CERTIFICATE-----
<Base64_encoded_certificate>
-----END CERTIFICATE-----
```

Converting to PEM format

If you receive your certificates and keys in formats other than PEM, you must convert them before you can upload them to the system. You can use OpenSSL to convert certificates and keys to PEM format. The following example commands provide guidance.

CERTIFICATE OR CERTIFICATE CHAIN FROM DER TO PEM

```
openssl x509 -inform DER -in <certificate_name>.der -outform PEM -out <certificate_name>.pem
```

PRIVATE KEY FROM DER TO PEM

```
openssl rsa -inform DER -in <private_key_name>.der -outform PEM -out <private_key_name>.pem
```

CERTIFICATE BUNDLE FROM PKCS#12 (PFX) TO PEM

```
openssl pkcs12 -in <certificate_bundle_name>.p12 -out <certificate_bundle_name>.pem -nodes
```

CERTIFICATE BUNDLE FROM PKCS#7 TO PEM

```
openssl pkcs7 -in <certificate_bundle_name>.p7b -print_certs -out <certificate_bundle_name>.pem
```

Uploading Certificate Chains

If you have multiple certificates that form a single certification chain, you must include all relevant certificates in one file before you upload them to the system. The following example of a certificate chain file includes four certificates:

```
-----BEGIN CERTIFICATE-----
<Base64_encoded_certificate>
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
<Base64_encoded_certificate>
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
<Base64_encoded_certificate>
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
<Base64_encoded_certificate>
-----END CERTIFICATE-----
```

Submitting Private Keys

Tip

Oracle recommends a minimum length of 2048 bits for your RSA private key.

If your private key submission returns an error, the three most common reasons are:

- You provided an incorrect passphrase.
- Your private key is malformed.
- The system does not recognize the encryption method used for your key.

PRIVATE KEY CONSISTENCY

If you receive an error related to the private key, you can use OpenSSL to check its consistency:

```
openssl rsa -check -in <private_key>.pem
```

This command verifies that the key is intact, the passphrase is correct, and the file contains a valid RSA private key.

DECRYPTING A PRIVATE KEY

If the system does not recognize the encryption technology used for your private key, decrypt the key. Upload the unencrypted version of the key with your certificate bundle. You can use OpenSSL to decrypt a private key:

```
openssl rsa -in <private_key>.pem -out <decrypted_private_key>.pem
```

Updating an Expiring Certificate

To ensure consistent service, you must update (rotate) expiring certificates:

1. Update your client or backend server to work with a new certificate bundle.

Note

The steps to update your client or backend server are unique to your system.

2. Upload the new SSL certificate bundle to the load balancer

a. Open the navigation menu. Under the **Core Infrastructure** group, go to **Networking** and click **Load Balancers**.
b. Click the name of the **Compartment** that contains the load balancer you want to modify, and then click the load balancer's name.
c. Click the load balancer you want to configure.
d. In the **Resources** menu, click **Certificates**, and then click **Add Certificate**.
e. In the **Add Certificate** dialog box, enter the following:
    - **Certificate Name:** Required. Specify a friendly name for the certificate bundle. It must be unique within the load balancer, and it cannot be changed in the Console. (It can be changed using the API.) Avoid entering confidential information.
    - **Choose SSL Certificate File:** Required. Drag and drop the certificate file, in PEM format, into the **SSL Certificate** field.
      Alternatively, you can choose the **Paste SSL Certificate** option to paste a certificate directly into this field.

      Important

      If you submit a self-signed certificate for backend SSL, you must submit the same certificate in the corresponding CA Certificate field.

    - **Specify CA Certificate:** Optional. (Recommended for backend SSL termination configurations.) Select (check) this box if you want to provide a CA certificate.
        - **Choose CA Certificate File:** Drag and drop the CA certificate file, in PEM format, into the **CA Certificate** field.

Alternatively, you can choose the **Paste CA Certificate** option to paste a certificate directly into this field.

- **Specify Private Key:** Optional. (Required for SSL termination.) Select (check) this box if you want to provide a private key for the certificate.
  - **Choose Private Key File:** Drag and drop the private key, in PEM format, into the **Private Key** field.
    Alternatively, you can choose the **Paste Private Key** option to paste a private key directly into this field.
  - **Enter Private Key Passphrase:** Optional. Specify the private key passphrase.

f. Click **Add Certificate**.

3. Edit listeners or backend sets (as needed) so they use the new certificate bundle

EDITING A LISTENER:

a. Open the navigation menu. Under the **Core Infrastructure** group, go to **Networking** and click **Load Balancers**.

b. Choose the **Compartment** that contains the load balancer you want to modify, and then click the load balancer's name.

c. In the **Resources** menu, click **Listeners**.

d. For the listener you want to edit, click the Actions icon (three dots), and then click **Edit Listener**.

e. In the **Certificate Name** drop-down list, choose the new certificate bundle.

f. Click **Submit**.

EDITING A BACKEND SET:

Warning

Updating the backend set temporarily interrupts traffic and can drop active connections.

a. Open the navigation menu. Under the **Core Infrastructure** group, go to **Networking** and click **Load Balancers**.
b. Click the name of the **Compartment** that contains the load balancer you want to modify, and then click the load balancer's name.
c. In the **Resources** menu, click **Backend Sets**, and then click the name of the backend set you want to edit.
d. Click **Edit Backend Set**.
e. In the **Edit Backend Set** dialog box, select (check) **Use SSL**.
f. In the **Certificate Name** drop-down list, choose the new certificate bundle.
g. Click **Save Changes**.

4. (Optional) Remove the expiring SSL certificate bundle

Important

You cannot delete an SSL certificate bundle that is associated with a listener or backend set. Remove the bundle from any additional listeners or backend sets before deleting.

a. Open the navigation menu. Under the **Core Infrastructure** group, go to **Networking** and click **Load Balancers**.

b. Click the name of the **Compartment** that contains the load balancer you want to modify, and then click the load balancer's name.
c. Click the load balancer you want to configure.
d. In the **Resources** menu, click **Certificates**.
e. For the certificate you want to delete, click the Actions icon (three dots), and then click **Delete**.
f. Confirm when prompted.

Configuring SSL Handling

With Oracle Cloud Infrastructure Load Balancing, you can:

- Terminate SSL at the load balancer. This configuration is *frontend SSL*. Your load balancer can accept encrypted traffic from a client. There is no encryption of traffic between the load balancer and the backend servers.
- Implement SSL between the load balancer and your backend servers. This configuration is *backend SSL*. Your load balancer does not accept encrypted traffic from client servers. Traffic between the load balancer and the backend servers is encrypted.
- Implement end to end SSL. Your load balancer can accept SSL encrypted traffic from clients and encrypts traffic to the backend servers.

Terminating SSL at the Load Balancer

To terminate SSL at the load balancer, you must create a listener at a port such as 443, and then associate an uploaded certificate bundle with the listener.

Implementing Backend SSL

To implement SSL between the load balancer and your backend servers, you must associate an uploaded certificate bundle with the backend set.

Tip

- If you want to have more than one backend server in the backend set, sign your backend servers with an intermediate CA certificate. The intermediate CA certificate must be included as part of the certificate bundle.
- Your backend services must be able to accept and terminate SSL.

Implementing End to End SSL

To implement end to end SSL, you must associate uploaded certificate bundles with both the listener and the backend set.

Using the Console

To upload an SSL certificate bundle to your load balancing system

1. Open the navigation menu. Under the **Core Infrastructure** group, go to **Networking** and click **Load Balancers**.
2. Click the name of the **Compartment** that contains the load balancer you want to modify, and then click the load balancer's name.
3. Click the load balancer you want to configure.
4. In the **Resources** menu, click **Certificates**, and then click **Add Certificate**.
5. In the **Add Certificate** dialog box, enter the following:
    - **Certificate Name:** Required. Specify a friendly name for the certificate bundle. It must be unique within the load balancer, and it cannot be changed in the Console. (It can be changed using the API.) Avoid entering confidential

information.

- **Choose SSL Certificate File:** Required. Drag and drop the certificate file, in PEM format, into the **SSL Certificate** field.
  Alternatively, you can choose the **Paste SSL Certificate** option to paste a certificate directly into this field.

  Important

  If you submit a self-signed certificate for backend SSL, you must submit the same certificate in the corresponding CA Certificate field.

- **Specify CA Certificate:** Optional. (Recommended for backend SSL termination configurations.) Select (check) this box if you want to provide a CA certificate.
  - **Choose CA Certificate File:** Drag and drop the CA certificate file, in PEM format, into the **CA Certificate** field.
    Alternatively, you can choose the **Paste CA Certificate** option to paste a certificate directly into this field.
- **Specify Private Key:** Optional. (Required for SSL termination.) Select (check) this box if you want to provide a private key for the certificate.
  - **Choose Private Key File:** Drag and drop the private key, in PEM format, into the **Private Key** field.
    Alternatively, you can choose the **Paste Private Key** option to paste a private key directly into this field.
  - **Enter Private Key Passphrase:** Optional. Specify the private key passphrase.

6. Click **Add Certificate**.

To delete an SSL certificate bundle from your load balancing system

Important

You cannot delete an SSL certificate bundle that is associated with a listener or backend set. Remove the bundle from any listeners or backend sets before deleting.

1. Open the navigation menu. Under the **Core Infrastructure** group, go to **Networking** and click **Load Balancers**.
2. Click the name of the **Compartment** that contains the load balancer you want to modify, and then click the load balancer's name.
3. Click the load balancer you want to configure.
4. In the **Resources** menu, click **Certificates**.
5. For the certificate you want to delete, click the Actions icon (three dots), and then click **Delete**.
6. Confirm when prompted.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use these API operations to manage load balancer certificates:

- CreateCertificate
- DeleteCertificate
- ListCertificates

Editing Health Check Policies

This topic describes how to modify health check policies for a backend set.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: For a typical policy that gives access to load balancers and their components, see Let network admins manage load balancers.

Also, be aware that a policy statement with `inspect load-balancers` gives the specified group the ability to see *all* information about the load balancers. For more information, see Details for Load Balancing.

If you're new to policies, see Getting Started with Policies and Common Policies.

Working with Health Check Policies

A health check is a test to confirm the availability of backend servers. A health check can be a request or a connection attempt. Based on a time interval you specify, the load balancer applies the health check policy to continuously monitor backend servers. If a server fails the health check, the load balancer takes the server temporarily out of rotation. If the server subsequently passes the health check, the load balancer returns it to the rotation.

You configure your health check policy when you create a backend set. You can configure TCP-level or HTTP-level health checks for your backend servers.

- TCP-level health checks attempt to make a TCP connection with the backend servers and validate the response based on the connection status.
- HTTP-level health checks send requests to the backend servers at a specific URI and validate the response based on the status code or entity data (body) returned.

The service provides application-specific health check capabilities to help you increase availability and reduce your application maintenance window.

Important

Configure your health check protocol to match your application or service.

If you run an HTTP service, be sure to configure an HTTP-level health check. If you run a TCP-level health check against an HTTP service, you might not get an accurate response. The TCP handshake can succeed and indicate that the service is up even when the HTTP service is incorrectly configured or having other issues. Although the health check appears good, customers might experience transaction failures. For example:

- The backend HTTP service has issues and returns 5XX messages. An HTTP health check catches the message and marks the service as down. In this case, a TCP health check handshake succeeds and marks the service as healthy, even though the HTTP service is not usable.
- The backend HTTP service responds with 4XX messages because of authorization issues or no configured content. A TCP health check does not catch these errors.

Health Status

The Load Balancing service provides health status indicators that use your health check policies to report on the general health of your load balancers and their components. You can see health status indicators on the Console *List* and *Details* pages for load balancers, backend

sets, and backend servers. You also can use the Load Balancing API to retrieve this information.

Health status indicators have four levels. The general meaning of each level is:

OK (GREEN)

No attention required.

The resource is functioning as expected.

WARNING (YELLOW)

Some reporting entities require attention.

The resource is not functioning at peak efficiency or the resource is incomplete and requires further work.

CRITICAL (RED)

Some or all reporting entities require immediate attention.

The resource is not functioning or unexpected failure is imminent.

UNKNOWN (GRAY)

Health status cannot be determined.

The resource is not responding or is in transition and might resolve to another status over time.

The precise meaning of each level differs among the following components:

- Load balancers
- Backend sets
- Backend servers

Using Health Status

At the highest level, load balancer health reflects the health of its components. The health status indicators provide information you might need to drill down and investigate an existing

issue. Some common issues that the health status indicators can help you detect and correct include:

A HEALTH CHECK IS MISCONFIGURED.

In this case, all the backend servers for one or more of the affected listeners report as unhealthy. If your investigation finds that the backend servers do not have problems, then a backend set probably includes a misconfigured health check.

A LISTENER IS MISCONFIGURED.

All the backend server health status indicators report **OK**, but the load balancer does not pass traffic on a listener.

The listener might be configured to:

- Listen on the wrong port.
- Use the wrong protocol.
- Use the wrong policy.

If your investigation shows that the listener is not at fault, check the security list configuration.

A SECURITY RULE IS MISCONFIGURED.

Health status indicators help you diagnose two cases of misconfigured security rules:

- All entity health status indicators report **OK**, but traffic does not flow (as with misconfigured listeners). If the listener is not at fault, check the security rule configuration.
- All entity health statuses report as unhealthy. You have checked your health check configuration and your services run properly on your backend servers.
  In this case, your security rules might not include the IP range for the source of the health check requests. You can find the health check source IP on the *Details* page for each backend server. You can also use the API to find the IP in the `sourceIpAddress` field of the HealthCheckResult object.

Note

Source IP

The source IP for health check requests comes from a Compute instance managed by the Load Balancing service.

ONE OR MORE OF THE BACKEND SERVERS REPORTS AS UNHEALTHY.

A backend server might be unhealthy or the health check might be misconfigured. To see the corresponding error code, check the **status** field on the backend server's *Details* page. You can also use the API to find the error code in the `healthCheckStatus` field of the HealthCheckResult object.

OTHER CASES IN WHICH HEALTH STATUS MIGHT PROVE HELPFUL INCLUDE:

- VCN network security groups or security lists block traffic.
- Compute instances have misconfigured route tables.

Health Status Limitations

Health status is updated every three minutes. No finer granularity is available.

Health status does not provide historical health data.

Using the Console

You create your health check tests when you create a backend set.

To edit an existing health check policy

1. Open the navigation menu. Under the **Core Infrastructure** group, go to **Networking** and click **Load Balancers**.

2. Click the name of the **Compartment** that contains the load balancer you want to modify, and then click the load balancer's name.
3. In the **Resources** menu, click **Backend Sets**, and then click the name of the backend set you want to modify.
4. Click **Update Health Check**.
5. In the **Health Check** section, specify the test parameters to confirm the health of backend servers.

Tip

All parameters are required when updating an existing health check policy.

- **Protocol:** Required. Specify the protocol to use, either HTTP or TCP.

Important

Configure your health check protocol to match your application or service.

- **Port:** Required. Specify the backend server port against which to run the health check.

Tip

You can enter the value '0' to have the health check use the backend server's traffic port.

- **URL Path (URI):** (HTTP only) Required. Specify a URL endpoint against which to run the health check.
- **Interval in ms:** Required. Specify how frequently to run the health check, in milliseconds. Default is 10000 (10 seconds).
- **Timeout in ms:** Required. Specify the maximum time in milliseconds to wait for a reply to a health check. A health check is successful only if a reply returns within this timeout period. Default is 3000 (3 seconds).
- **Number of retries:** Required. Specify the number of retries to attempt before a backend server is considered "unhealthy". This number also applies when recovering a server to the "healthy" state. Default is 3.
- **Status Code:** (HTTP only) Required. Specify the status code a healthy backend server must return.
- **Response Body Regex:** (HTTP only) Optional. Provide a regular expression for parsing the response body from the backend server. The system treats a blank entry here as the value ".*".

Tip

Health checks require all fields to match. Your status code and response body both must match, as specified.

6. Click **Save**.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use this API operation to edit a backend set's health check policy:

UpdateBackendSet

Use these API operations to retrieve health status information:

- GetBackendHealth
- GetBackendSetHealth
- GetLoadBalancerHealth
- ListLoadBalancerHealths

Viewing the State of a Work Request

This topic describes how to view the state of work requests associated with a given load balancer.

Note

The Load Balancing service does not use the common Work Requests API to support work request operations. Instead, Load Balancing work requests are supported by the Load Balancing API. See Using the Console to View Work Requests for information on viewing work requests for other services.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators: For a typical policy that gives access to load balancers and their components, see Let network admins manage load balancers.

Also, be aware that a policy statement with `inspect load-balancers` gives the specified group the ability to see *all* information about the load balancers. For more information, see Details for Load Balancing.

If you're new to policies, see Getting Started with Policies and Common Policies.

Monitoring Work Requests

Many of the Oracle Cloud Infrastructure Load Balancing service requests do not take effect immediately. In these cases, the request spawns an asynchronous workflow for fulfillment. To provide visibility for in-progress workflows, the Load Balancing service creates a work request object. Because some operations depend on the completion of other operations, you must monitor each operation's work request and confirm it has succeeded before proceeding to the next operation. For example, if you want to create a backend set and add a backend server to the new set, you first must create the backend set. After that operation completes, you can add the backend server. If you try to add a backend server before the backend set creation completes, the system cannot ensure that the request to add the server succeeds. You can monitor the request to add a backend set to determine when that workflow is complete, and then add the backend server.

The work request states are:

ACCEPTED

The request is in the work request queue to be processed.

IN PROGRESS

A work request record exists for the specified request, but there is no associated WORK_COMPLETED record.

SUCCEEDED

A work request record exists for this request and an associated WORK_COMPLETED record has the state SUCCEEDED.

FAILED

A work request record exists for this request and an associated WORK_COMPLETED record has the state FAILED.

Using the Console

The Oracle Cloud Infrastructure Console consumes the REST API and is subject to the same considerations as any Oracle Cloud Infrastructure client. You can view the state of a load balancing work request in the Console:

1. Open the navigation menu. Under the **Core Infrastructure** group, go to **Networking** and click **Load Balancers**.
2. Click the name of the **Compartment** that contains the load balancer you want to review, and then click the load balancer's name.
3. In the **Resources** menu, click **Work Requests**. The status of all work requests appears on the page.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use these operations to monitor the state of work requests:

- ListWorkRequests
- GetWorkRequest

Load Balancing Metrics

You can monitor the health, capacity, and performance of your load balancers by using metrics, alarms, and notifications.

This topic describes the metrics emitted by the Load Balancing service in the `oci_lbaas` metric namespace.

Resources: Load balancers, listeners, and backend sets.

Overview of the Load Balancing Service Metrics

Your load balancer acts as an intermediary for data traffic between clients and your application servers. Clients send requests to your load balancer and the load balancer distributes the requests to your backend servers according to rules you establish. See the diagram in Overview of Load Balancing for a high-level view of a simple public load balancing system configuration.

The Load Balancing service metrics help you measure the number and type of connections, and quantity of data managed by your load balancer. You can use metrics data to diagnose and troubleshoot load balancer and client issues. The metrics also help you analyze the HTTP responses returned by the servers in your backend set.

To view a default set of metrics charts in the Console, navigate to the load balancer or backend set you're interested in, and then click **Metrics**. You also can use the Monitoring service to create custom queries.

Prerequisites

- IAM policies: To monitor resources, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.
- The metrics listed on this page are automatically available for any load balancer, listener, and backend set you create. You do not need to enable monitoring on the resource to get these metrics.

Available Metrics: oci_lbaas

Load Balancing service metrics include the following dimensions:

AVAILABILITYDOMAIN

The availability domain in which the load balancer resides.

BACKENDSETNAME

The name of the backend set to which the metrics apply.

LBCOMPONENT

The load balancer component to which the metrics apply.

Valid metrics for the Load Balancing service vary among the three **lbComponent** dimension values:

- **Backendset**
- **Listener**
- **Loadbalancer**

The tables on this page describe which data is valid for each of these dimension values. If you choose a metric that does not apply to the specified dimension value, the metric returns no data.

LBHOSTID

A unique ID that represents the current load balancer host. This ID is subject to change.

LISTENERNAME

The name of the listener to which the metrics apply.

REGION

The region in which the load balancer resides.

RESOURCEID

The OCID of the resource to which the metrics apply.

Metrics for the lbComponent Dimension Value "Backendset"

Metric	Metric Display Name	Unit	Description	Dimensions
ActiveConnections	**Active Connections**	count	The number of active connections from the load balancer to all backend servers.	availabilityDomain backendSetName lbComponent lbHostId region resourceId
BackendServers	**Backend Servers**	count	The number of backend servers in the backend set.	
BackendTimeouts	**Backend Timeouts**	count	The number of timeouts across all backend servers.	
BytesReceived	**Bytes Received**	bytes	The number of bytes received across all backend servers.	

Metric	Metric Display Name	Unit	Description	Dimensions
`BytesSent`	**Bytes Sent**	bytes	The number of bytes sent across all backend servers.	
`ClosedConnections`	**Closed Connections**	count	The number of connections closed between the load balancer and backend servers.	
`HttpRequests`	**Inbound Requests**	count	The number of incoming client requests to the backend set.	
`HttpResponses`	**Responses**	count	The number of HTTP responses across all backend servers.	

Metric	Metric Display Name	Unit	Description	Dimensions
HttpResponses200	**HTTP 200 Responses**	count	The number of HTTP 200 responses received from backend servers.	
HttpResponses2xx	**HTTP 2xx Responses**	count	The number of HTTP 2xx responses received from backend servers.	
HttpResponses3xx	**HTTP 3xx Responses**	count	The number of HTTP 3xx responses received from backend servers.	
HttpResponses4xx	**HTTP 4xx Responses**	count	The number of HTTP 4xx responses received from backend servers.	

Metric	Metric Display Name	Unit	Description	Dimensions
HttpResponses502	**HTTP 502 Responses**	count	The number of HTTP 502 responses received from backend servers.	
HttpResponses504	**HTTP 504 Responses**	count	The number of HTTP 504 responses received from backend servers.	
HttpResponses5xx	**HTTP 5xx Responses**	count	The number of HTTP 5xx responses received from backend servers.	
InvalidHeaderResponses	**Invalid Header Responses**	count	The number of invalid header responses across all backend servers.	

Metric	Metric Display Name	Unit	Description	Dimensions
KeepAliveConnections	**Keep-alive Connections**	count	The number of keep-alive connections.	
ResponseTimeFirstByte	**Average Response Time (TCP only)**	ms	Average time to the first byte of response from backend servers. TCP only.	
ResponseTimeHttpHeader	**Average Response Time (HTTP only)**	ms	Average response time of backend servers. HTTP only.	
UnhealthyBackendServers	**Unhealthy Backend Servers**	count	The number of unhealthy backend servers in the backend set.	

Metrics for the lbComponent Dimension Value"Loadbalancer"

Metric	Metric Display Name	Unit	Description	Dimensions
AcceptedConnections	**Accepted Connections**	count	The number of connections accepted by the load balancer.	availabilityDomain lbComponent lbHostId region resourceId
AcceptedSSLHandshake	**Accepted SSL Handshakes**	count	The number of accepted SSL handshakes.	
ActiveConnections	**Active Connections**	count	The number of active connections from clients to the load balancer.	
ActiveSSLConnections	**Active SSL Connections**	count	The number of active SSL connections.	
BytesReceived	**Bytes Received**	bytes	The number of bytes received by the load balancer.	

Metric	Metric Display Name	Unit	Description	Dimensions
BytesSent	**Bytes Sent**	bytes	The number of bytes sent by the load balancer.	
FailedSSLClientCertVerify	**Failed Client SSL Cert Verifications**	count	The number of failed client SSL certificate verifications.	
FailedSSLHandshake	**Failed SSL Handshakes**	count	The number of failed SSL handshakes.	
HandledConnections	**Handled Connections**	count	The number of connections handled by the load balancer.	
HttpRequests	**Inbound Requests**	count	The number of incoming client requests to the load balancer.	

Metrics for the lbComponent Dimension Value "Listener"

Metric	Metric Display Name	Unit	Description	Dimensions
HttpResponses200	**HTTP 200 Responses**	count	The number of HTTP 200 responses received from backend sets.	availabilityDomain lbComponent lbHostId listenerName region resourceId
HttpResponses2xx	**HTTP 2xx Responses**	count	The number of HTTP 2xx responses received from backend sets.	
HttpResponses3xx	**HTTP 3xx Responses**	count	The number of HTTP 3xx responses received from backend sets.	
HttpResponses4xx	**HTTP 4xx Responses**	count	The number of HTTP 4xx responses received from backend sets.	
HttpResponses502	**HTTP 502 Responses**	count	The number of HTTP 502 responses received from backend sets.	
HttpResponses504	**HTTP 504 Responses**	count	The number of HTTP 504 responses received from backend sets.	
HttpResponses5xx	**HTTP 5xx Responses**	count	The number of HTTP 5xx responses received from backend sets.	
HttpResponses	**Responses**	count	The number of incoming responses received from backend sets.	

Using the Console

To view default metric charts for a single load balancer

1. Open the navigation menu. Under the **Core Infrastructure** group, go to **Networking** and click **Load Balancers**.
2. Choose the **Compartment** that contains the load balancer you want to view, and then click the load balancer's name.
3. In the **Resources** menu, click **Metrics** (if necessary).
   The **Metrics** page displays a default set of charts for the current load balancer.

For more information about monitoring metrics and using alarms, see Monitoring Overview. For information about notifications for alarms, see Notifications Overview.

To view default metric charts for multiple load balancers

1. Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Service Metrics**.
2. For **Metric Namespace**, select **oci_lbaas**.
   The **Service Metrics** page displays a default set of charts for the selected metric namespace. For more information about the emitted metrics, see the foregoing table. You can also use the Monitoringservice to create custom queries.

For more information about monitoring metrics and using alarms, see Monitoring Overview. For information about notifications for alarms, see Notifications Overview.

Using the API

Use the following APIs for monitoring:

- Monitoring API for metrics and alarms
- Notifications API for notifications (used with alarms)

CHAPTER 21 Marketplace

This chapter explains how to work with listings in the Oracle Cloud Infrastructure Marketplace.

Overview of Marketplace

Oracle Cloud Infrastructure Marketplace is an online store that offers solutions specifically for customers of Oracle Cloud Infrastructure. In the Oracle Cloud Infrastructure Marketplace catalog, you can find listings for two types of solutions from Oracle and trusted partners: images and stacks. These listing types include different categories of applications. Also, some listings are free and others belong to certain pricing models.

Images are templates of virtual hard drives that determine the operating system and software to run on an instance. You can deploy image listings on an Oracle Cloud Infrastructure Compute instance. Marketplace also offers stack listings. Stacks represent definitions of groups of Oracle Cloud Infrastructure resources that you can act on as a group. Each stack has a configuration consisting of one or more declarative configuration files. With an image or a stack, you have a customized, more streamlined way of getting started with a publisher's software.

Note

Marketplace is not available in Oracle Cloud Infrastructure Government Cloudrealms.

Resource Identifiers

Most types of Oracle Cloud Infrastructure resources have a unique, Oracle-assigned identifier called an Oracle Cloud ID (OCID). For information about the OCID format and other ways to identify your resources, see Resource Identifiers.

Ways to Access Oracle Cloud Infrastructure

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. However, you cannot specifically access Marketplace using the Command Line Interface (CLI). Marketplace does not have CLI support. For a list of available SDKs, see Software Development Kits and Command Line Interface.

To access the Console, you must use a supported browser. Oracle Cloud Infrastructure supports the latest desktop versions of Google Chrome, Microsoft Edge, Internet Explorer 11, Safari, Firefox, and Firefox ESR. Note that private browsing mode is not supported for Firefox, Internet Explorer, or Edge. Mobile browsers are not supported.

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies. For specific details about writing policies for each of the different services, see Policy Reference.

If you're a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

Working with Listings

This topic describes how to work with listings in the Oracle Cloud Infrastructure Marketplace. You can do the following:

- Filter listings to find what you want
- View a listing to learn about the product that it offers
- Launch an instance from an image listing
- Launch stack resources from a stack listing

By default, Oracle Cloud Infrastructure Marketplace displays all listings in its catalog. Image listings have a **Launch Instance** button. Stack listings have a **Launch Stack** button.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators, the following policies provide access to Marketplace. These policies specify different target groups as examples, but you can specify the same target group (for example, MarketplaceUsers) when applying the policies in your own tenancy.

- The policy Let users list and subscribe to images from the Partner Image catalog gives the specified group the ability to list, read, and use Marketplace image listings.
- The policy Let users launch Compute instances gives the specified group general access to managing instances and images, along with the required level of access to attach existing block volumes to the instances. Use this policy in conjunction with the preceding policy for users who need to launch instances from image listings. Use this policy in conjunction with the following policy for users who need to launch stacks from stack listings.
- The policies described in Managing Stacks and Jobs grant access to stacks and jobs in the tenancy. Use the appropriate policy statements to give a group the ability to list, read, and use Marketplace stack listings. (Users do not need permission to run destroy jobs to launch a stack from a Marketplace listing, but they do need permissions to run plan jobs and apply jobs.)

- If you need to write more restrictive policies for Marketplace, see Details for the Core Services and Details for Resource Manager, as needed.

If you're new to policies, see Getting Started with Policies and Common Policies.

Using the Console

To filter listings

1. Open the navigation menu. Under the **Solutions and Platform** group, go to **Marketplace**.
2. Under **Filters**, do one or more of the following:
    - To display listings of a certain deployment type, click **Type**, and then click either **Image** or **Stack**.
    - To display listings from a specific publisher, click **Publisher**, and then click a publisher name.
    - To display listings from a particular product category, click **Category**, and then click a category name.
    - To display listings according to price, click **Price**, and then click a pricing model.

You can combine multiple filters to further narrow down listings. You can also clear filters to expand the list of listings that you see.

To view a listing's details

1. Open the navigation menu. Under the **Solutions and Platform** group, go to **Marketplace**.
2. Click the listing that you're interested in.
3. Marketplace displays the listing overview by default. To view other details, do the following:

- To view information about the publisher, click **Provider**.
- To view other listings from the same publisher, click **More Apps**.
- To view instructions for using the instance that you create from the listing, click **Usage Information**.

To launch an instance based on an image

Tip

When you create an instance, several other resources are involved (for example, an image, a cloud network, or a subnet). Those other resources can be in the same compartment with the instance or in other compartments. You must have the required level of access to each of the compartments involved in order to launch the instance. This is also true when you attach a volume to an instance; they don't have to be in the same compartment, but if they're not, you need the required level of access to each of the compartments.

1. Open the navigation menu. Under the **Solutions and Platform** group, go to **Marketplace**.
2. Click the listing that you're interested in.
3. Review the **Usage Instructions** tab to ensure you understand what you will need to deploy and to access the instance after you launch it. Both Linux and Windows instances require a cloud network to launch the instance into. For more information, see Overview of Networking. Depending on the type of instance, to access it, you might need an SSH key pair or a security list that enables Remote Desktop Protocol. For more information, see Managing Key Pairs on Linux Instances and To enable RDP access .

4. Under **Version**, click the package version of the image that you want to install. By default, the menu displays the latest version.
5. Under **Compartment**, click the name of the compartment where you want to launch the instance.
6. Select the check box to accept the terms of use, and then click **Launch Instance**.
7. To finish launching the instance, follow the instructions in Creating an Instance.

The information you need to connect to an instance after you create it might be in the **Usage Information** or the **Related Documents** sections of the listing.

To launch a stack

Tip

When you create a stack, potentially many other resources are involved (for example, an instance, a cloud network, or a subnet), aside from the stacks and jobs resources. You must have the required access to all involved resources to create a stack. Those other resources can be in the same compartment with the instance or in other compartments. You must have the required level of access to each of the compartments involved in order to launch the instance. This is also true when you attach a volume to an instance; they don't have to be in the same compartment, but if they're not, you need the required level of access to each of the compartments.

1. Open the navigation menu. Under the **Solutions and Platform** group, go to **Marketplace**.

2. Click the listing that you're interested in.
3. Review the **Usage Instructions** tab and ensure you understand what you will need to deploy and to access the instance after the stack finishes deployment.
4. Under **Version**, click the package version of the stack that you want to install. By default, the menu displays the latest version.
5. Under **Compartment**, click the name of the compartment where you want to launch the instance.
6. Select the check box to accept the terms of use, and then click **Launch Stack**.
7. On the **Stack Information** page, configure the following:
   - **Name**. Optionally, provide a name by which you can refer to the stack after it's deployed.
   - **Description**. Optionally, provide a description of the stack. For example, you can specify the name of the application that will run on the instance after the stack is deployed.
   - **Create in Compartment**. This is the compartment where the stack will be created in the tenancy. (Stacks are attached to a specific region. However, where necessary, the resources on a given stack can be deployed across multiple regions.)
   - **Tags**. Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.

   When you are ready, click **Next**.
8. On the **Configure Variables** page, verify that the values for variables extracted from the Terraform configuration file are as you want them. Some variables might be required, but don't have a default value and must be configured before you can proceed. These vary from listing to listing, but often include the following: availability domain

and compartment. Optionally, you can change default values, such as any display names automatically given to resources, to help differentiate them. For some stacks, you can customize additional variables by selecting the **Additional Customization** or **WLS Instance Advanced Configuration** check box. The variables in these sections otherwise use default values. When you are ready, click **Next**.

9. On the **Review** page, confirm that variables have been configured properly. (Marketplace does not display variables that have default values or variables that you didn't change.) Then, click **Create**.

Resource Manager runs the plan job and the apply job to create stack resources accordingly. The information you need to connect to the instance created as part of the stack can appear in the **Application Information** tab or in the **Usage Information** or **Related Documents** sections of the listing.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the following operations to work with listings:

- GetListing
- GetPackage
- ListCategories
- ListListings
- ListPackages
- ListPublishers

Viewing Terms of Use Agreements for Deployed Applications

Before you can launch an image or a stack from a Marketplace listing, you must first read and accept all terms of use agreements associated with the package version that you choose. This topic describes how to see what software terms of use agreements you have accepted through Oracle Cloud Infrastructure Marketplace. Your organization might need or want to review the specific terms of use associated with a particular package version after you deploy one or more Marketplace solutions.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in.

For administrators, the following policies provide access to Marketplace. These policies specify different target groups as examples, but you can specify the same target group (for example, MarketplaceUsers) when applying the policies in your own tenancy.

- The policy Let users list and subscribe to images from the Partner Image catalog gives the specified group the ability to list, read, and use Marketplace image listings.
- The policy Let users launch Compute instances gives the specified group general access to managing instances and images, along with the required level of access to attach existing block volumes to the instances. Use this policy in conjunction with the preceding policy for users who need to launch instances from image listings. Use this policy in conjunction with the following policy for users who need to launch stacks from stack listings.
- The policies described in Managing Stacks and Jobs grant access to stacks and jobs in the tenancy. Use the appropriate policy statements to give a group the ability to list, read, and use Marketplace stack listings. (Users do not need permission to run destroy

jobs to launch a stack from a Marketplace listing, but they do need permissions to run plan jobs and apply jobs.)

- If you need to write more restrictive policies for Marketplace, see Details for the Core Services and Details for Resource Manager, as needed.

If you're new to policies, see Getting Started with Policies and Common Policies.

Using the Console

To view the accepted terms of use agreements for a given compartment

1. Open the navigation menu. Under the **Solutions and Platform** group, go to **Marketplace**.
2. Click **Deployed Applications**.
3. Under **Scope**, click **Compartment**, and then click the name of the compartment where you deployed a solution you now want to view the terms of use agreements for.
4. In the list, find the listing that you're interested in, and then click the Actions menu (•••). (Marketplace independently lists package versions with their distinct terms of use agreements. Also, Marketplace tracks what agreements you accept regardless of whether you actually complete the software deployment. Therefore, the list might show the names of solutions that you didn't actually finish deploying in your tenancy.)
5. To review any of the terms of use agreements you accepted for the specified listing and package version, click its name.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the following operations to work with a listing's terms of use agreements:

- CreateAcceptedAgreement
- DeleteAcceptedAgreement
- GetAcceptedAgreement
- GetAgreement
- ListAcceptedAgreements
- ListAgreements
- UpdateAcceptedAgreement

CHAPTER 22 Monitoring

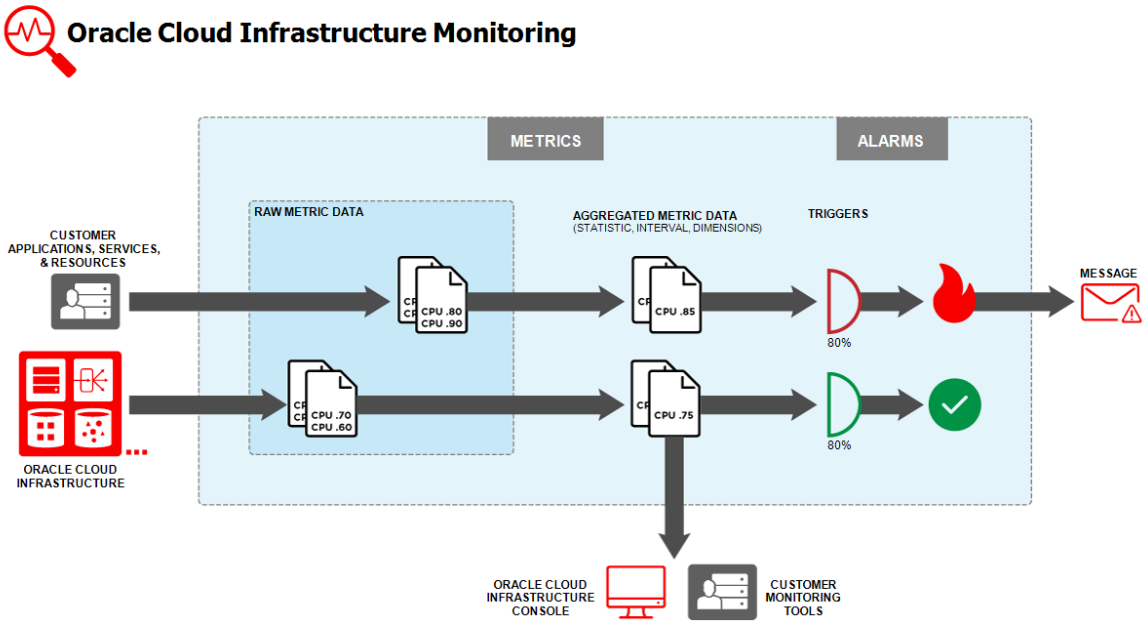
This chapter explains how to actively and passively monitor performance and usage metrics for your resources.

Monitoring Overview

The Oracle Cloud Infrastructure Monitoring service enables you to actively and passively monitor your cloud resources using the Metrics and Alarms features.

Note

Monitoring is not available in Oracle Cloud Infrastructure Government Cloudrealms.



How Monitoring Works

The Monitoring service uses metrics to monitor resources and alarms to notify you when these metrics meet alarm-specified triggers.

Metrics are emitted to the Monitoring service by resources as raw data points, or timestamp-value pairs, along with dimensions and metadata. For example, the Compute service (metric namespace "oci_computeagent") posts this data for monitoring-enabled Compute instances. The posted data includes all oci_computeagent metrics, such as CpuUtilization. Metric data posted to the Monitoring service is only presented to you or consumed by the Oracle Cloud Infrastructure features that you enable to use metric data.

When you query a metric, the Monitoring service returns aggregated data according to the specified parameters. You can specify a range (such as the last 24 hours), statistic, and interval. The Console displays one monitoring chart per metric for selected resources. The

aggregated data in each chart reflects your selected statistic and interval. API requests can optionally filter by dimension and specify a resolution. API responses include the metric name along with its source compartment and metric namespace. You can feed the aggregated data into a visualization or graphing library.

Metric and alarm data is accessible via the Console, CLI, and API. For retention periods, see Storage Limits.

The Alarms feature of the Monitoring service publishes alarm messages to configured destinations managed by the Notifications service. Each destination is a topic with a set of subscribers. For more information about the Notifications service, see Notifications Overview.

Message types

The message type indicates the reason that the message was sent.

- `OK_TO_FIRING`: The alarm changed from `OK` status to `FIRING` status.
- `FIRING_TO_OK`: The alarm changed from `FIRING` status to `OK` status.
- `REPEAT`: The alarm is maintaining a `FIRING` status and repeat notifications are configured.
- `RESET`: The alarm is not detecting the metric firing; the metric is no longer being emitted. The resource that was emitting the metric might have been moved or terminated.

Important

When a `RESET` status change occurs, determine the health of the resource.

Message format and examples

Alarm message format:

Parameter	Description
dedupekey Required	**string** Unique identifier that can be used for de-duplication.
title Required	**string** The alarm's configured display name.
body	**string** The alarm's configured message body.
type Required	**string** The reason for sending the notification message. Valid values: See Message types.
severity Required	**string** The highest severity level of the listed alarms. Valid values: `CRITICAL`, `ERROR`, `WARNING`, and `INFO`
timestampEpochMillis Required	**long** The time when the alarm was triggered, in milliseconds since epoch time.
alarmMetadata Required	**array of objects** List of alarms related to this notification message.
version Required	**int** The version of the alarm message format.

alarmMetadata format:

Parameter	Description
id Required	**string** The alarm OCID.
status Required	**string** The alarm state. Valid values: `OK`, `FIRING`
severity Required	**string** The alarm severity level. Valid values: `CRITICAL`, `ERROR`, `WARNING`, `INFO`
query Required	**string** The alarm's configured query. `CpuUtilization[1m]{availabilityDomain="cumS:PHX-AD-1"}.absent()`
totalMetricsFiring Required	**int** The number of metric streams represented in this notification message.
dimensions	**array of objects** List of dimension key-value pairs that identify each metric stream. The list is limited to a hundred entries. Empty for an alarm with a status of `OK`.

Example message "High CPU Utilization" for an alarm that is continuing to be in the FIRING state. In this example, the message includes two metric streams: one for "myinstance1" and another for "myinstance2."

```
{
  "dedupeKey": "exampleuniqueID",
```

```
  "title": "High CPU Utilization",

          "region": "us-ashburn-1"
        }
      ]
    }
  ],
  "version": 1.0
}
```

Metrics Feature Overview

The Metrics feature relays metric data about the health, capacity, and performance of your cloud resources. A metric is a measurement related to health, capacity, or performance of a given resource. Resources, services, and applications emit metrics to the Monitoring service. Common metrics reflect data related to:

- Availability and latency
- Application uptime and downtime
- Completed transactions
- Failed and successful operations
- Key performance indicators (KPIs), such as sales and engagement quantifiers

By querying Monitoring for this data, you can understand how well the systems and processes are working to achieve the service levels you commit to your customers. For example, you can monitor the CPU utilization and disk reads of your Compute instances. You can then use this data to determine when to launch more instances to handle increased load, troubleshoot issues with your instance, or better understand system behavior.

Example Metric: Failure Rate

For application health, one of the common KPIs is failure rate, for which a common definition is the number of failed transactions divided by total transactions. This KPI is usually delivered through application monitoring and management software.

As a developer, you can capture this KPI from your applications using custom metrics. Simply record observations every time an application transaction takes place and then post that data to the Monitoring service. In this case, set up metrics to capture failed transactions, successful transactions, and transaction latency (time spent per completed transaction).

Alarms Feature Overview

The Alarms feature of the Monitoring service works with the Notifications service to notify you when metrics meet alarm-specified triggers. When configured, repeat notifications remind

you of a continued firing state at the configured repeat interval. You are also notified when an alarm transitions back to the OK state, or when an alarm is reset.

You can search for alarms using Search-supported attributes. For more information about Search, see Overview of Search.

Search-Supported Attributes for Alarms

For attribute descriptions, see Alarm Reference.

- id
- displayName
- compartmentId
- metricCompartmentId
- namespace
- query
- severity
- destinations
- suppression
- isEnabled
- lifecycleState
- timeCreated
- timeUpdated
- tags

Monitoring Concepts

The following concepts are essential to working with Monitoring.

AGGREGATED DATA

The result of applying a *statistic* and *interval* to a selection of raw *data points* for a given *metric*. For example, you can apply the *statistic* `max` and *interval* `1h` (one hour) to the last 24 hours of raw *data points* for the *metric* `CpuUtilization`. Aggregated data is displayed in default metric charts in the Console. You can also build metric queries for specific sets of aggregated data. For instructions, see Viewing Default Metric Charts and Building Metric Queries.

ALARM

The *alarm query* to evaluate and the *notification destination* to use when the alarm is in the firing state, along with other alarm properties. For instructions on managing alarms, see Managing Alarms.

ALARM QUERY

The Monitoring Query Language (MQL) expression to evaluate for the *alarm*. An alarm query must specify a *metric*, *statistic*, *interval*, and a *trigger rule* (threshold or absence). The Alarms feature of the Monitoring service interprets results for each returned time series as a Boolean value, where zero represents false and a non-zero value represents true. A true value means that the *trigger rule* condition has been met. For more information, see Building Metric Queries and the query attribute description in the Alarm API reference.

DATA POINT

A timestamp-value pair for the specified *metric*. Example: 2018-05-10T22:19:00Z, 10.4

A data point is either raw or aggregated. Raw data points are posted by the *metric namespace* to the Monitoring service using the PostMetricData operation. The *frequency* of the data points posted varies by *metric namespace*. For example, your custom namespace might send data points for a given *metric* at a 20-second *frequency*.

Aggregated data points are the result of applying a *statistic* and *interval* to raw data points. The *interval* of the aggregated data points is determined by the SummarizeMetricsData request. For example, a request specifying the *statistic* `sum` and

interval `1h` (one hour) returns a `sum` value for each hour of available raw data points for the given *metric*.

DIMENSION

A qualifier provided in a *metric definition*. Example: Resource identifier (`resourceId`), provided in the definitions of oci_computeagent metrics. Use dimensions to filter or group metric data. Example dimension name-value pair for filtering by availability domain: `availabilityDomain = "VeBZ:PHX-AD-1"`

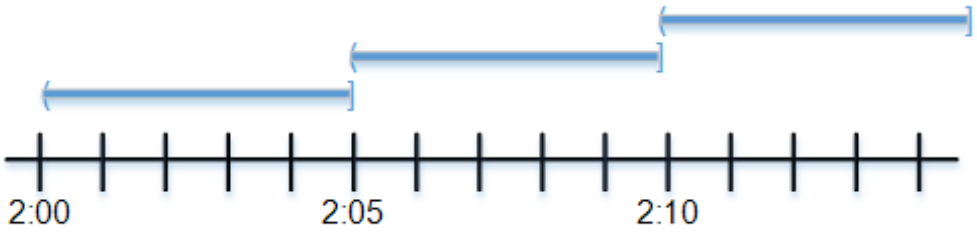
FREQUENCY

The time period between each posted raw *data point* for a given *metric*. (Raw data points are posted by the *metric namespace* to the Monitoring service.) While frequency varies by metric, default service metrics typically have a frequency of 60 seconds (that is, one data point posted per minute). See also *resolution*.

INTERVAL

The time window used to convert the given set of raw *data points*.

The timestamp of the aggregated data point corresponds to the end of the time window during which raw data points are assessed. For example, for a five-minute interval, the timestamp "2:05" corresponds to the five-minute time window from 2:00:*n* to 2:05:00.



The following example query specifies a 5-minute interval. `CpuUtilization[5m].max()` For supported values, see Monitoring Query Language (MQL) Reference.

See also *resolution*.

MESSAGE

The content that the Alarms feature of the Monitoring service publishes to topics in the *alarm's* configured *notification destinations*. A message is sent when the *alarm* transitions to another state, such as from "OK" to "FIRING." For more information about messages, see How Monitoring Works.

METADATA

A reference provided in a *metric definition*. Example: unit (bytes), provided in the definition of the oci_computeagent *metric* `DiskBytesRead`. Use metadata to determine additional information about a given metric. For metric definitions, see Supported Services.

METRIC

A measurement related to health, capacity, or performance of a given resource. Example: The oci_computeagent *metric* `CpuUtilization`, which measures usage of a Compute instance. For metric definitions, see Supported Services.

Note

Metric resources do not have OCIDs.

METRIC DEFINITION

A set of references, qualifiers, and other information provided by a *metric namespace* for a given *metric*. For example, the oci_computeagent *metric* `DiskBytesRead` is defined by *dimensions* (such as resource identifier) and *metadata* (specifying bytes for unit) as well as identification of its *metric namespace* (oci_computeagent). Each posted set of *data points* carries this information. Use the ListMetricData API operation to get metric definitions. For metric definitions, see Supported Services.

METRIC NAMESPACE

Indicator of the resource, service, or application that emits the *metric*. Provided in the *metric definition*. For example, the `CpuUtilization` *metric definition* emitted by the

OracleCloudAgent software on Compute instances lists the *metric namespace* `oci_computeagent` as the source of the `CpuUtilization` *metric*. For metric definitions, see Supported Services.

METRIC STREAM

An individual set of *aggregated data* for a *metric*. A stream can be either specific to a single resource or aggregated across all resources in the compartment. Within a metric chart in the Console, each metric stream is represented as a line. By default, metric streams are resource-specific, so the chart displays a line for each resource. If you choose to aggregate all metric streams, then the chart displays one line for all resources.

NOTIFICATION DESTINATION

Protocol and other details for sending *messages* when the *alarm* transitions to another state, such as from "OK" to "FIRING." The details and setup may vary by destination service. For the Notifications service, each destination includes a topic and subscription protocol (such as PagerDuty). For more information about messages, topics, and subscriptions, see Notifications Overview.

ORACLECLOUDAGENT SOFTWARE

Software that allows a Compute instance to post raw *data points* to the Monitoring service. Automatically installed with the latest versions of supported images. See Enabling Monitoring for Compute Instances.

QUERY

The Monitoring Query Language (MQL) expression to evaluate for returning *aggregated data*. The query must specify a *metric*, *statistic*, and *interval*. For more information, see Building Metric Queries.

RESOLUTION

The period between time windows, or the regularity at which time windows shift. For example, use a resolution of `1m` to retrieve aggregations every minute.

Note

For metric queries, the interval you select drives the default resolution of the request, which determines the maximum time range of data returned.

Maximum time range returned for a query

The maximum time range returned for a metric query depends on the resolution. By default, for metric queries, the resolution is the same as the query interval. The maximum time range is calculated using the current time, regardless of any specified end time. Following are the maximum time ranges returned for each interval selection available in the Console.

Interval	Default resolution (metric queries)	Maximum time range returned
1h	1 hour	90 days
5m	5 minutes	30 days
1m	1 minute	7 days

See examples of returned data

Example 1: One-minute interval and resolution up to the current time, sent at 10:00 on January 8th. No

resolution or end time is specified, so the resolution defaults to the interval value of `1m`, and the end time defaults to the current time (`2019-01-08T10:00:00.789Z`). This request returns a maximum of 7 days of metric data points. The earliest data point possible within this seven-day period would be 10:00 on January 1st (`2019-01-01T10:00:00.789Z`).

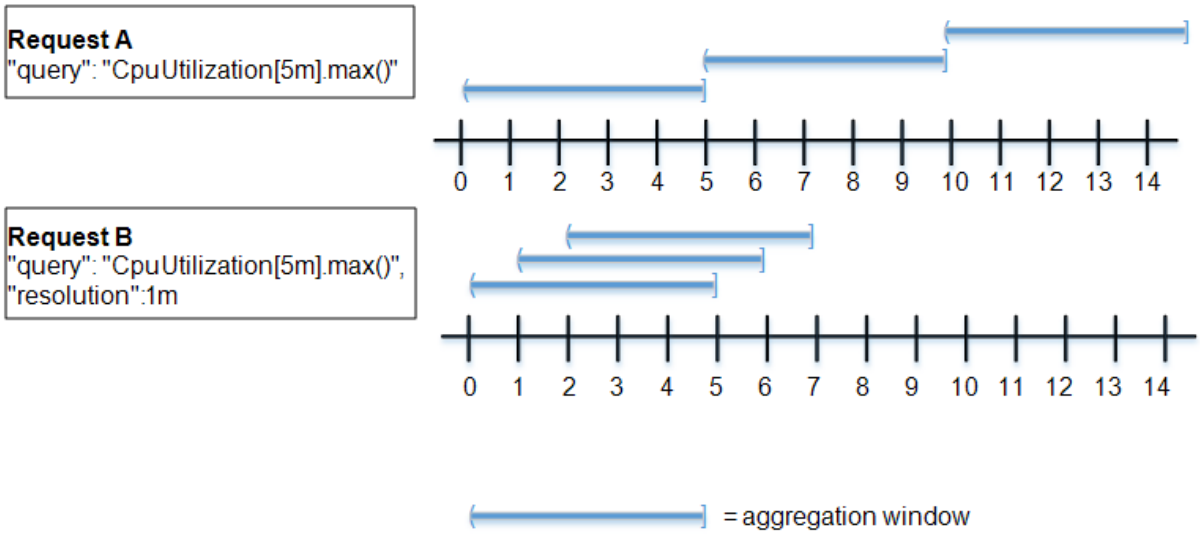
Example 2: Five-minute interval with one-minute resolution up to two days ago, sent at 10:00 on January 8th. Because the resolution drives the maximum time range, a maximum of 7 days of metric data points is returned. While the end time specified was 10:00 on January 6th (`2019-01-06T10:00:00.789Z`), the earliest data point possible within this seven-day period would be 10:00 on January 1st (`2019-01-01T10:00:00.789Z`). Therefore, only 5 days of metric data points can be returned in this example.

For more information about the resolution parameter as used in metric queries, see SummarizeMetricsData.

For alarm queries, the specified interval has no effect on the resolution of the request. The only valid value of the resolution for an alarm query request is `1m`. For more information about the resolution parameter as used in alarm queries, see Alarm.

As shown in the following illustration, *resolution* controls the start time of each aggregation window relative to the previous window while *interval* controls the length of the windows. Both requests apply the statistic `max` to the data within each five-minute

window (from the interval), resulting in a single aggregated *data point* representing the highest `CPUutilization` counter for that window. Only the resolution value differs. This resolution changes the regularity at which the aggregation windows shift, or the start times of successive aggregation windows. Request A does not specify a resolution and thus uses the default value equal to the interval (5 minutes). This request's five-minute aggregation windows are thus taken from the sets of data points emitted from 0:*n* to 5:00, 5:*n* to 10:00, and so forth. Request B specifies a 1-minute resolution, so its five-minute aggregation windows are taken from the set of data points emitted every minute from 0:*n* to 5:00, 1:*n* to 6:00, and so forth.



RESOURCE GROUP

A custom string provided with a custom metric that can be used as a filter or to aggregate results. The resource group must exist in the definition of the posted metric. Only one resource group can be applied per metric.

STATISTIC

The aggregation function applied to the given set of raw *data points*. For supported statistics, see Monitoring Query Language (MQL) Reference.

SUPPRESSION

A configuration to avoid publishing *messages* during the specified time range. Useful for suspending alarm notifications during system maintenance. Each suppression applies to a single alarm. In the Console, you can apply one definition of a suppression to multiple alarms. The result is an individual suppression for each alarm. For instructions on suppressing alarms, see To suppress alarms.

TRIGGER RULE

The condition that must be met for the alarm to be in the firing state. A trigger rule can be based on a threshold or absence of a metric.

Availability

Monitoring is currently available in the following regions:

Region Name	Region Location	Region Key
India West (Mumbai)	Asia-Pacific: Mumbai, India	BOM
South Korea Central (Seoul)	Asia-Pacific: Seoul, South Korea	ICN
Australia East (Sydney)	Asia-Pacific: Sydney, Australia	SYD
Japan East (Tokyo)	Asia-Pacific: Tokyo, Japan	NRT
Canada Southeast (Toronto)	Canada: Toronto	YYZ
Germany Central (Frankfurt)	Europe: Frankfurt, Germany	FRA
Switzerland North (Zurich)	Europe: Zurich, Switzerland	ZRH

Region Name	Region Location	Region Key
Brazil East (Sao Paulo)	South America: Sao Paulo	GRU
UK South (London)	United Kingdom: London	LHR
US East (Ashburn)	United States: Ashburn, VA	IAD
US West (Phoenix)	United States: Phoenix, AZ	PHX

Supported Services

The following services have resources or components that can emit metrics to Monitoring:

- Block Storage - see Block Volume Metrics
- Compute - see these topics:
  - Compute Instance Metrics
  - Infrastructure Health Metrics
- Database - see Database Metrics
- Events - see Events Metrics
- Health Checks - see Health Checks Metrics
- Load Balancing - see Load Balancing Metrics
- Key Management - see Key Management Metrics
- Networking - see these topics:
  - VNIC Metrics
  - FastConnect Metrics
  - VPN Connect Metrics
- Notifications - see Notifications Metrics
- Object Storage - see Object Storage Metrics
- Oracle Functions - see Function Metrics

- Streaming - see Streaming Metrics
- WAF - see WAF Metrics

Resource Identifiers

Most types of Oracle Cloud Infrastructure resources have a unique, Oracle-assigned identifier called an Oracle Cloud ID (OCID). For information about the OCID format and other ways to identify your resources, see Resource Identifiers.

Note

Metric resources do not have OCIDs.

Ways to Access Monitoring

You can access the Monitoring service using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. For a list of available SDKs, see Software Development Kits and Command Line Interface.

Console: To access Monitoring using the Console, you must use a supported browser. Oracle Cloud Infrastructure supports the latest desktop versions of Google Chrome, Microsoft Edge, Internet Explorer 11, Safari, Firefox, and Firefox ESR. Note that private browsing mode is not supported for Firefox, Internet Explorer, or Edge. Mobile browsers are not supported. Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring**.

API: To access Monitoring through APIs, use Monitoring API for metrics and alarms and Notifications API for notifications (used with alarms).

Moving Alarms to a Different Compartment

You can move alarms from one compartment to another. When you move an alarm to a new compartment, its associated metrics remain where they are. After you move the alarm to the new compartment, inherent policies apply immediately and affect access to the alarm through

the Console. For more information on moving resources to other compartments, see Moving Resources to a Different Compartment.

Important

To move resources between compartments, resource users must have sufficient access permissions on the compartment that the resource is being moved to, as well as the current compartment. For more information about permissions for Monitoring resources, see Details for Monitoring.

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies. For specific details about writing policies for each of the different services, see Policy Reference.

If you're a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

Administrators: For common policies that give groups access to metrics, see Let users view metric definitions in a compartment and Restrict user access to a specific metric namespace. For a common alarms policy, see Let users view alarms. To authorize resources, such as instances, to make API calls, add the resources to a dynamic group. Use the dynamic group's matching rules to add the resources, and then create a policy that allows that dynamic group

access to metrics. See Let instances make API calls to access monitoring metrics in the tenancy.

Limits on Monitoring

See Monitoring Limits for a list of applicable limits and instructions for requesting a limit increase.

Other limits include the following.

Storage Limits

Item	Time range stored
Metric definitions	14 days
Alarm history entries	90 days

Returned Data Limits (Metrics)

When you query metrics and view metric charts, the returned data is subject to certain limits. Limits information for returned data includes the 100,000 data point maximum and time range maximums (determined by resolution, which relates to interval). See MetricData Reference.

Troubleshooting Limits

If you see an error that the query has exceeded the maximum number of metric streams, then update the query to evaluate a number of metric streams that is within the limit. For example, you can reduce the metric streams by specifying dimensions. You can continue to evaluate all metric streams that were in the original query by spreading the metric streams across multiple queries (or alarms).

Viewing Default Metric Charts

This topic describes how to view metric charts for selected resources or a single resource and create alarms based on queries used for charts. Charts are available using the Console.

Warning

Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Prerequisites

- IAM policies: Viewing metric charts is part of monitoring. To monitor resources, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.
- Metrics exist in Monitoring: The resources that you want to monitor must emit metrics to the Monitoring service.
- Compute instances: To emit metrics, Compute instances must be monitoring-enabled. OracleCloudAgent software installation may also be required. For more information, see Enabling Monitoring for Compute Instances.

Working with Default Metric Charts

For background information on metrics in Oracle Cloud Infrastructure, see Metrics Feature Overview. For default metrics by service, see Supported Services.

Default metric charts use predefined service queries. You can select resources of interest and update the interval, statistic, and time range.

Note

Very small or large values are indicated by International System of Units (SI units), such as M for mega (10 to the sixth power). Units correspond to the selected metric and do not change by statistic.

Using the Console

To view default metric charts for all resources

Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Service Metrics**.

The **Service Metrics** page displays the default charts for all resources in the first accessible **Compartment** and **Metric Namespace**. Very small or large values are indicated by International System of Units (SI units), such as M for mega (10 to the sixth power).

Don't see all expected resources or metrics?

- Try a different time range.
- Make sure the correct **Compartment** is selected.

On the **Service Metrics** page, metric namespaces are shown only when associated resources exist in the selected compartment. For example, the `oci_autonomous_database` namespace is shown only when Autonomous Databases exist in the selected compartment.

- Confirm that the missing resources are emitting metrics. See Enabling Monitoring for Compute Instances.
- Review limits information. Limits information for returned data includes the 100,000 data point maximum and time range maximums (determined by resolution, which relates to interval). See MetricData Reference.

To investigate missing resources or metrics

- Try a different time range.
- Make sure the correct **Compartment** is selected.
  On the **Service Metrics** page, metric namespaces are shown only when associated resources exist in the selected compartment. For example, the `oci_autonomous_database` namespace is shown only when Autonomous Databases exist in the selected compartment.
- Confirm that the missing resources are emitting metrics. See Enabling Monitoring for Compute Instances.
- Review limits information. Limits information for returned data includes the 100,000 data point maximum and time range maximums (determined by resolution, which relates to interval). See MetricData Reference.

To filter results

Filter results to limit the data plotted on the metric chart. For example, filter results to a resource or region of interest.

Filtering of default metric charts is done through selected dimensions; available dimensions vary by metric.

1. View the default metric charts: Open the navigation menu. Under **Solutions and Platform**, go to **Monitoring** and click **Service Metrics**.
2. To the right of **Dimensions**, click **Add**.
3. In the **Edit dimensions** dialog box, select a **Dimension Name** and **Dimension Value**.

   ### Dimension fields
